EUROPEAN HEMATOLOGY ASSOCIATION (EHA)

EHA aims to promote excellence in clinical practice, research and education in European hematology.

Today, EHA – with over 3200 active members from 100 countries – is a consolidated organization that pursues a large and growing number of projects and programs. An Executive Board and Councilors elected by the membership form the governmental body and are responsible for the strategy and organization of the Association.

CORE VALUES OF THE EUROPEAN HEMATOLOGY ASSOCIATION

1. Promote scientific research in hematology
2. Promote education and training in hematology
3. Promote optimal clinical care in hematology
4. Advance the exchange and dissemination of knowledge and scientific information in hematology
5. Advance the position of hematology as a medical discipline in Europe

EHA'S MAIN ACTIVITIES

- Annual Congress
- Haematologica/The Hematology Journal
- Fellowships Program
- EHA Hematology Curriculum-Passport & H-NET
- Education:
  - Continuing Medical Education
  - EHA Training On-line
  - Scientific Workshops and Tutorials

EHA MEMBERSHIP

If you recognize the need for a strong European Hematology Association and would like to take advantage of the various activities of the Association, you may wish to become a member of the EHA and contribute to its objectives. Membership is open to all medical professionals with an active interest in the specialist field of hematology.

BENEFITS OF EHA MEMBERSHIP

- Subscription to Haematologica/The Hematology Journal, including on-line access (impact factor 5.516)
- Reduced registration fee for the Annual Congress
- Eligible for the EHA Research Fellowship Program
- Eligible to nominate candidates and vote for new councilors on the board
- EHA Newsletter
- Access to EHA membership database
- Access to webcast sessions of the EHA Annual Congress

All activities of EHA are displayed at the website www.ehaweb.org

European Hematology Association
E-mail: info@ehaweb.org,

14TH CONGRESS
JUNE 4 - 7, 2009
BERLIN

Word of welcome

On behalf of the EHA Board and the Scientific Program Committee we would like to welcome you to Berlin for the 14th Congress of the European Hematology Association.

This year, over 2000 abstracts have been submitted – a new record – showing the growing significance of the EHA Congress to hematologists in Europe and abroad. Moreover, the Scientific Program Committee is pleased with the steadily increasing quality of the data presented. From these abstracts, an exciting program has been composed including the Presidential Symposium (5 best abstracts), Simultaneous Oral Sessions and Poster Sessions with organized poster walks.

On behalf of the EHA Board, the committees and all people involved in this years' EHA congress, we thank you for coming to Berlin and hope that this Abstract Book will serve you as an important reference for recent advances in hematology research.

Radek Skoda
Chair Scientific Program Committee

Rüdiger Hehlmann
Congress President

EUROPEAN HEMATOLOGY ASSOCIATION

EHA FELLOWSHIP PROGRAM

One of EHA's goals is to promote the career development of young scientists involved in basic, clinical, and experimental research in hematology. EHA funds research fellowships, including the long-established EHA – José Carreras Young Investigator Fellowship, for researchers in the field of malignant and non-malignant hematology. Each grant is for a two-year period. The next call for applications will be announced on the EHA website in October 2009. Awards will be made at the 15th Congress of EHA in Barcelona and will be payable from January 2011.

EHA PARTNER FELLOWSHIP PROGRAM

A partner fellowship program was established last year to support training in centers of excellence in Western Europe for the career development of young scientists involved in basic and clinical research in hematology in new accession and EU candidate countries. The goal of this program is to build up and create inter-institutional networks of collaboration between hematology institutes in Western Europe focusing on research and clinical hematology and similar institutes in new accession and EU candidate countries. The call for applications is announced on the EHA website and the deadline for the letter of interest is June 30, 2009. Deadline for full application is August 15, 2009 and notification of the award will be November 1, 2009.

EHA – ASH RESEARCH EXCHANGE AWARD

The EHA-ASH International Research Fellowship Award was established in 2006. This award has been developed as a partnership between the European Hematology Association (EHA) and the American Society of Hematology (ASH) to provide hematologists in training or early in their careers the opportunity to conduct research in another country. The purpose of the program is to give both clinical and laboratory-based researchers an opportunity to establish new collaborations and experience research in a different environment. This program will benefit not only the individual participants, but also each host institution, as it will build stronger ties between the North American and European scientific community. The call for applications is announced on EHA and ASH websites and the deadline for the letter of intent was May 15, 2009. Deadline for full application is September 25, 2009. Awards will be made on July 1, 2010.

Submission: Detailed information on the EHA and EHA/ASH fellowship programs and submission is available in the Fellowships section at the EHA website: www.ehaweb.org or contact fellowships.grants@ehaweb.org

RESCUE OF HEMATOPOIETIC FAILURE INDUCED BY THE GATA 1(LOW) MUTATION IS MEDIATED BY A PERMISSIVE MICROENVIRONMENT IN THE SPLEEN THAT INDUCES DIFFERENTIATION OF GATA -1(LOW) PROGENITORS THROUGH THE ALTERNATIVE ENHANCER HS2

[1]Mount Sinai School of Medicine and myeloproliferative Disease Reser, Consortium, NEW YORK, NY, USA; [2]Istituto Superiore di Sanità, ROME, Italy; [3]University of Florence, FLORENCE, Italy; [4]University of Chieti G. D'Annunzio, CHIETI, Italy; [5]Leiden University Medical Center, LEIDEN, Netherlands

Background. Recently, progress has been made in understanding the relationship existing between stem cells and their marrow niches under steady state conditions. By contrast, little is known on the relationship between these cells and the niches in extramedullary sites under stress. Targeted deletion of the HS1 enhancer of Gata1 (Gata1low mutation) induces in C57BL/6 mice a lethal phenotype because of severe anemia and thrombocytopenia at birth. The mutation is not lethal in those backgrounds (CD1 and DBA2) that recover from anemia by developing hematopoiesis in the spleen (Martelli *et al.,* Blood 106:4102, 2006), suggesting the existence of a *unique* relationship between Gata1low stem cells and the niches present in extramedullary sites. *Aim.* To identify the relationship between Gata1low stem cells and the extramedullary niche in the spleen, that rescues the Gata1low mutation in the CD1 strain. *Methods.* The phenotype of Gata1low/0 males and heterozygous Gata1low/+ females (Gata1 is on the X chromosome) after splenectomy was determined. In addition, tracking experiments of cKitpos cells in Gata1low/0 males carrying a reporter gene under the control of an alternative Gata 1 enhancer (HS2) spared by the mutation (-2.7kbGata1GFP), and transplantation experiments with Gata1low/0 male bone marrow cells into NOD/SCID females were performed. *Results.* After splenectomy, hemizygous males died of severe anemia within 1 month while heterozygous females survived. Moreover, while in untreated heterozygous females hematopoiesis was driven by both stem cells expressing the wild-type allele and those expressing the Gata1low allele, hematopoiesis in spenectomized heterozygous females was wild type, suggesting that spleen and marrow drive maturation of wild-type and Gata1low stem cells, respectively. This hypothesis was confirmed by the localization of -2.7kbGata1GFPcKitpos cells within the architecture of the marrow and spleen of Gata1+/0 and Gata1low/0 males. Rare GFPnegcKitpos cells were detected along the endosteum of -2.7kbGata1GFPGata1+/0 males but numerous cKitpos cells were detected within their medulla. Rare cKitpos cells were also detected in the spleen of these males. By contrast, clusters of GFPposcKitpos cells were detected along the endosteum of -2.7kbGata1GFPGata1low/0 males while cKitpos cells detectable within their medulla were rare. Numerous cKitpos cells were in stead detected in the spleen of these mice. Therefore, Gata1low stem/progenitor cells are associated in greater numbers with the osteoblast niches than with the marrow vascular niche, consistently with the low levels of CXCR4, the receptor necessary for interaction with the vascular niche, expressed by these cells. -2.7kbGata1GFPGata1low/0 stem/progenitor cells from the spleen, but not those from the marrow expressed high GFP levels and were functional in colony assay. In addition, Gata1low bone marrow cells engrafted NOD/SCID females and donor-derived cells were mainly detected in blood, spleen and liver, but not in the marrow of the recipients two-four months after transplantation, indicating that Gata1low stem/progenitor cells contribute to hematopoiesis by engrafting preferentially the extramedullary sites of the hosts. *Summary and conclusions.* These data suggest that Gata1low hematopoiesis is supported by the splenic microenvironment that favors maturation of those stem/progenitor cells which activate Gata1 expression through the alternative HS2 enhancer.

0002

COMPARISON OF HEMATOPOIETIC STEM CELL ENGRAFTMENT ON SYNGENEIC AND ALLOGENEIC STROMAL TERRITORIES IN THE ABSENCE OF IMMUNE REACTION

I. Resnick, T. Prigozhina, G. Elkin, B. Avni, M. Shapira, R. Or, P. Stepensky, O. Gurevich

Hadassah Hebrew University Medical Center, JERUSALEM, Israel

Background. In clinical practice of bone marrow transplantation (BMT) there is a set of cases with compromised HSC engraftment which is apparently not a consequence of immunological rejection but most likely due to recipient stromal microenvironment which they encounter. We evaluate hypothesis that matching between stromal and hematopoietic cells is important for adequate support of hematopoietic development. Aim of this study was to demonstrate that hematopoietic stem cell (HSC) can discriminate between *self* and *non self* stromal territories. *Methods.* An animal model of two genetically different types of functioning stroma in the common recipient was worked out. Step 1: bone marrow plugs from C57Bl/6 and BALB/c donor mice were ectopically transplanted to F1(C57Bl/6xBALB/c) recipients. Within one month the newly formed ectopic osteo-hematopoietic complex displayed all properties of a skeletal hematopoietic area. Forty days later F1 recipients having additional stromal territories of C57Bl/6 and BALB/c genotypes got total body irradiated with 1150 cGr, a the lethal dose for the cells of hematopoietic but not mesenchymal stromal origin. Step 2: the first group of irradiated mice was injected with the mixture (1:1) of embryonic liver precursor cells from C57Bl/6 and BALB/c fetuses while second received hematopoietic cells from C57Bl/6 embryonic liver only. Step 3: histological examination and evaluation of competitive repopulation of C57Bl/6 and BALB/c stromal territories with C57Bl/6 and BALB/c HSC using FACS analysis of harvested hematopoietic cell populations on days +14 and +28 after transplantation of HSC were performed. *Clinical trial design.* A single pediatric patient with severe Wiscott-Aldrich syndrome who had neither sibling nor matched unrelated donor was admitted for haploidentical HSC transplantation. Treatment was approve by IRB. After myeloablative conditioning patient got intravenous transplantation of positively selected $CD34^+$ cells combined with intraosseous injection of pre-expanded mesenchymal stromal cells (MSC) from the same donor. *Results.* Histological analysis of ectopic ossicles developed from hematopoietic inoculum of C57Bl/6 embryonic cells on C57Bl/6 and BALB/c ectopic territories showed young, active and very dense hematopoietic tissue on syngeneic (C57Bl/6) stroma while on the allogeneic (BALB/c) stroma was observed aplastic hematopoiesis accompanied with numerous fat containing cells. Both 2 and 4 weeks after HSC transplantation proportion of C57Bl/6 and BALB/c HSC was 1.5 to 2.5 times higher on syngeneic compare to allogeneic compartment. The same effect was clearly seen in clinical setting. After engraftment, morphological findings in the bone marrow demonstrate 50% cellularity with 3 lineage hematopoiesis in the site of donor type MSC injection compare to aplastic bone marrow in different place. *Interpretation.* Taking into consideration that immunological conditions for inoculated HSC of C57Bl/6 and BALB/c genotypes present in the common F1 recipient are similar, different colonization of *self* and *non self* stroma is not mediated by immunocompetent cells. This effect can be due to discrepancy between hematopoietic tissue and misfitting stromal territories. Our pilot clinical data confirm that presence of genetically identical niche can significantly influence on HSC engraftment.

0003

THE EFFECT OF THE TEL-TRKC ONCOGENE ON THE HAEMATO-ENDOTHELIAL DIFFERENTIATION FROM HUMAN EMBRYONIC STEM CELLS

R. Malladi, J. Sloane-Stanley, R. Gupta, N. Rodrigues, W. Wood, T. Enver

Weatherall Institute of Molecular Medicine, OXFORD, UK

Background. A fusion between the pointed domain of TEL and the tyrosine kinase domain of TRKC (TEL-TRKC) causes tumours presenting in utero and in early childhood. We hypothesised that a cellular intermediate in the mesoderm-derived haemato-endothelial hierarchy is a potential target for the TEL-TRKC oncogene. The human ES cell system can generate haemato-endothelial cells from mesoderm precursors and may provide a suitable *in vitro* model for investigating the oncogenic properties of TEL-TRKC during ontogeny. *Aims.* We sought to identify a cellular target for TEL-TRKC during human embryonic stem (ES) cell differentiation into haemato-endothelial lineages as well as to understand the impact of TEL-TRKC on cell fate decisions within this hierarchy. *Methods.* Haemato-endothelial differentiation of human ES cells was achieved by co-culture with the murine OP9 stroma according to the protocol of Vodyanik *et al.* Blood 108, 2006. In this model, $CD34^+$, KDR^+, $CD43^-$ endothelial cells and $CD34^+$, $CD43^+$ haematopoietic cells were prospectively isolated for functional analysis. Enforced expression of TEL-TRKC in human ES cells was achieved by lentiviral gene delivery with a green fluorescent protein reporter. The equivalent lentiviral vector without the TEL-TRKC was used as a control. *Results.* Normal human ES cells co-cultured with OP9 give rise to a population of $CD34^+$ cells which can differentiate into either blood or endothelium. TEL-TRKC expression was compatible with the generation of normal numbers of these $CD34^+$ precursors derived from mesoderm. TEL-TRKC, however, promoted the expansion of $CD43^+$ haematopoietic cells from these $CD34^+$ precursor cells without affecting the capacity of this $CD34^+$ population to differentiate into endothelial cells. The function of these endothelial cells was normal, as judged by uptake of Dil-Ac-LDL and the matrigel tube formation assay. We next investigated the function of the expanded $CD43^+$ haematopoietic cells from TEL-TRKC transduced hES cells and found that this population acquired self-renewal properties as assessed by its ability to replate on OP9 stroma. Strikingly, these $CD43^+$ haematopoietic cells demonstrated an endothelial phenotype as evidenced by inappropriate co-expression of the endothelial marker, VE-Cadherin. This, together with the reduced ability of these $CD43^+$ cells to form colony forming units in methylcellulose assays, suggests a block or arrest in haematopoietic commitment or differentiation. *Summary and Conclusion.* TEL-TRKC expression in human ES cell derived haemato-endothelial cells is consistent with the trapping of a population of $CD43^+$ haematopoietic cells with acquired self-renewal properties and endothelial potential. We conclude that TEL-TRKC transforms mesoderm derivatives and speculate that these derivatives are a target for TEL-TRKC in the provenance of developmental cancers in children.

0004

INTERFERON-ALPHA ACTIVATES DORMANT HSCS *IN VIVO*

M.A.G. Essers,[1] S. Wurzer,[2] A. Trumpp[1]

[1]DKFZ, HI-STEM, HEIDELBERG; [2]DKFZ, HEIDELBERG, Germany

Maintenance of the blood system is dependent on dormant haematopoietic stem cells (HSCs) with long-term self-renewal capacity. Upon injury these cells are induced to proliferate in order to quickly re-establish homeostasis. The signalling molecules promoting the exit of HSCs out of the dormant stage remain largely unknown. We have recently uncovered that in response to treatment of mice with interferon-alpha (IFNα), HSCs efficiently exit G0 and enter an active cell cycle. HSCs respond to IFNα treatment by increased phosphorylation of STAT1 and PKB/Akt, expression of IFNα target genes and up-regulation of stem cell antigen-1 (Sca-1). HSCs lacking either the interferon-α/β receptor (IFNAR), STAT1 or Sca-1 are insensitive to IFNα stimulation, demonstrating that STAT1 and Sca-1 mediate IFNα induced HSC proliferation. We will present our newest data on the examination of the molecular basis of these striking effects of IFNa signalling on HSCs, both during homeostasis as well as during stress. Moreover, we are examining the change in HSC-niche interactions upon IFNα stimulation. Although dormant HSCs are resistant to the anti-proliferative chemotherapeutic agent 5-FU, HSCs pre-treated (primed) with IFNα and thus induced to proliferate are efficiently eliminated by 5-FU exposure *in vivo*. Conversely, HSCs chronically activated by IFNα are functionally compromised and are rapidly out competed by non-activatable $IFNAR^{-/-}$ cells in competitive repopulation assays. Data on a possible role for STAT1 and Sca-1 in this chronic IFNα treatment will be presented. In summary, while chronic activation of the IFNα pathway in HSCs impairs their function, acute IFNα treatment promotes the proliferation of dormant HSCs *in vivo*. These data may help to clarify the so far unexplained clinical effects of IFNα on leukemic cells, and raise the possibility for novel applications of type I interferons to target cancer stem cells.

0005

FURTHER CHARACTERIZATION OF COMMITTED NK PROGENITORS IN ADULT BONE MARROW

H. Nozad Charoudeh, M. Cheng, Y.J. Tang, S.E.W. Jacobsen, E. Sitnicka

Lund Stem Cell Center, LUND, Sweden

Natural killer cells, members of the innate immune system, represent a third lymphoid lineage distinct from T and B lymphocytes. Although significant progress has been made in understanding the regulation and the function of mature NK cells, the cellular and molecular pathways of the earliest stages of NK lineage commitment and development remain largely unknown. Committed NK progenitors (NKPs) have been recently identified in adult bone marrow (BM) as having the $Lin^-CD122^+NK1.1^-DX5^-$ phenotype; however NKPs lineage potential has not been studied at the single cell level. In adult mice, BM is the main site of NK cell production and it harbours both progenitors and mature NK cells. Recent studies demonstrated the existence of another and seemingly distinct, thymus dependent NK pathway and it remains to be established whether BM- and thymic- dependent NK cells can be generated from the same NK committed progenitor. In agreement with the previous studies, FACS phenotypic analysis revealed that NKP population is heterogeneous: small fraction of NKPs expressed tyrosine kinase receptor FLT3 (5-10%) or KIT (5-10%), while majority of NKPs were positive for B220 (40-50%) and Interleukin 7 (IL-7) receptor (IL-7R) (50-60%). In addition, analysis using Rag-1-GFP reporter mouse, confirmed that 50-60% of NKPs expressed Rag-1. Limiting dilution culture assay revealed that NKPs lack myeloid and B cell potentials, while 60% of single sorted NKPs cultured on OP9DL cell line for 14 days generated clones containing $CD3^-NK1.1^+DX5^+$ NK cells (72%), $TCR\beta^+NK1.1^+DX5^+$ NK T cells (21%) and $TCR\beta^+NK1.1$-DX5-$CD4^+CD8^+$ T cells (9%). In agreement with *in vitro* data, NKPs after transplantation into $Il2rg^{-/-}$ recipients showed NK cell ($CD3^-NK1.1^+DX5^+$), T cell ($CD3^+CD4^+CD8^+$) and NK T cell ($CD3^+NK1.1^+$) donor-derived lineage reconstitution, but failed to generate B, myeloid as well as thymic NK cells. Taken together these data suggest that NKPs maintains significant T cell potential that will be further addressed both *in vitro* as well as in intra-thymic transplantation assays.

0006

TYROSINE KINASE INHIBITION FAILS TO ERADICATE LEUKEMIC STEM/PROGENITOR CELLS IN FLT3-ITD+ ACUTE MYELOID LEUKEMIA: ROLE OF THE STEM CELL NICHE

S. Götze,[1] A. Parmar,[1] S. Rushton,[1] S.M. Marz,[1] K. Lind,[1] S. Kayser,[2] K. Döhner,[2] C. Peschel,[1] R. Oostendorp[1]

[1]Technische Universität München, MUNICH; [2]Internal Medicine III, University of Ulm, ULM, Germany

Background and Aims. Acute myeloid leukemia (AML) is a clonal disease originating from a leukemic stem/progenitor cell. Activating mutations of the FLT3 receptor by internal tandem duplication (FLT3-ITD) are present in 30% of all cases of AML and are associated with poor prognosis. Although inhibition of mutant FLT3 leads to clearance of leukemic blasts in the periphery, the bone marrow often remains unchanged and remissions are usually short-lived, suggesting a protective effect of the marrow niche on leukemic stem cells. We studied the effect of tyrosine kinase inhibition on $CD34^+$ leukemic stem/progenitor cells from patients with newly diagnosed normal karyotype AML with wild-type FLT3 or mutated FLT3-ITD receptor in the presence or absence of stromal support. *Methods.* $CD34^+$ cells were isolated from bone marrow of AML patients at diagnosis by density gradient centrifugation and magnetic bead isolation. Cells were cultured for four days in serum-free medium with growth factors in the presence or absence of the tyrosine kinase inhibitor SU5614 in suspension culture or stroma-contact cultures with the stromal cell line EL08-1D2. Cell division was measured by flow cytometry after labelling of cells with CFSE. Analysis of cell cycle and apoptosis was performed by flow cytometry after staining with propidium iodide (PI) and annexin V. Hematopoietic activity was assessed

in short-term and long-term colony-forming assays. PCR for FLT3 WT and ITD products was performed to determine colony origin. Results. CD34+ cells from FLT3-ITD samples divided at an intrinsically slower pace over four days *in vitro* than CD34+ cells from FLT3-WT samples. Treatment with SU5614 resulted in reduced cell division of both FLT3-WT and FLT3-ITD progenitor cells. However, FLT3 mutated progenitor cells differed from FLT3 WT cells in their behavior on stroma. Whereas stromal contact induced cell division of FLT3-WT progenitors in the presence of SU5614, no such effect was observed with FLT-ITD progenitors. Apoptosis induced by tyrosine kinase inhibition was more pronounced in FLT3-ITD than FLT3-WT progenitors. Stromal contact protected both FLT3-WT and FLT3-ITD CD34+ progenitor cells from apoptosis. Colony assays revealed that FLT3-ITD committed progenitors were effectively reduced by SU5614 treatment in suspension culture while stroma contact exerted a significant protective effect. In contrast, committed progenitors from FLT3-WT AML were less susceptible to tyrosine kinase inhibition but also protected by adhesion to stroma. More importantly, primitive LTC-IC from FLT3-ITD AML were selectively spared from tyrosine kinase inhibition. Additional stromal contact led to significant expansion of LTC-IC in the presence of SU5614. PCR from single hematopoietic colonies of long-term cultures revealed both WT and ITD FLT3 products, indicating LTC-IC were of leukemic origin. Cell signaling studies revealed independent activation of AKT in the presence of stroma in FLT-ITD cells treated with SU5614. Inhibition of downstream ERK and STAT5 by SU5614 in FLT3-ITD cells was not affected by stromal support. *Conclusions.* Our data demonstrate that tyrosine kinase inhibition fails to eradicate leukemic stem/progenitor cells in FLT3-ITD AML. Interaction with stromal cells additionally promotes selective survival of leukemic stem/progenitor cells in the presence of tyrosine kinase inhibitor, resulting in net expansion of malignant cells. Independent activation of AKT through alternate pathways mediated by stromal contact in FLT3-ITD cells allows escape from dependence on FLT3 signalling. This data highlights the fact that molecular therapy may have unpredicted effects on leukemic stem cells and underlines the importance of developing strategies to selectively eliminate the malignant stem cell clone.

ARYL HYDROCARBON RECEPTOR ACTIVATION PERTURBS MYELOID SUBLINEAGE DIFFERENTIATION BY INHIBITING PU.1 UPREGULATION

S. Richter,[1] P. Platzer,[2] M. Woisetschlager,[3] D. Waltenberger,[4] H. Strobl[4]

[1]Institut of Immunology, VIENNA, Austria; [2]Division of Gastroenterology and Nutrition, Harvard Medical School, BOSTON, USA; [3]Novartis Institutes for Biomedical Research (NIBR), VIENNA, Austria; [4]Institute of Immunology, VIENNA, Austria

The transcription factor aryl hydrocarbon receptor (AhR) is a ligand inducible transcription factor. AhR activation by different ligands has been been shown to influence lymphopoiesis as well as myelopoiesis and in line with this human hematopoietic stem cells express AhR and are affected by AhR ligands. Furthermore, dysregulated AhR function can be found in certain hematopoietic malignancies (e.g. high expression of AhR in adult T cell lymphomas). Besides its role in hematopoeisis, the AhR represents a promising therapeutic target in allergy and autoimmunity. AhR signalling induced by the newly described ligand VAF347 inhibits allergic lung inflammation as well as suppresses pancreatic isl*et al.*lograft rejection. These effects are mediated likely via alterations in dendritic cell (DC) function. Moreover, VAF347 induces tolerogenic DCs. The mechanisms underlying functional DC alteration by AhR remained undefined. Furthermore, data on human DCs were lacking. Langerhans cells (LCs) are immediate targets of exogenous AhR ligands at epithelial surfaces; how they respond to AhR ligands remained undefined. We studied AhR expression and function in human LCs and myelopoietic cell subsets using a lineage differentiation and gene transduction model of human CD34+ hematopoietic progenitors. We found that AhR is highly regulated during differentiation. LCs expressed highest AhR levels followed by monocytes. Conversely, granulocytes lacked AhR expression. AhR ligands including VAF347 arrested the differentiation of monocytes and LCs at an early precursor cell stage, whereas progenitor cell expansion or granulopoiesis remained unimpaired. AhR expression was co-regulated with the transcription factor PU.1 during myeloid subset differentiation. VAF347 inhibited PU.1 induction during initial monocytic differentiation, and ectopic PU.1 restored monocyte and LC generation in the presence of this compound. AhR ligands failed to interfere with cytokine receptor signalling (TGF-β1 or TNFα) during LC differentiation and failed to impair LC activation/maturation. In conclusion, activation of AhR signalling interferes with transcriptional processes leading to monocyte/DC lineage commitment of human myeloid progenitor cells.

ULTRACONSERVED GENOMIC REGIONS EXPRESSION IN HEMATOPOIESIS

R. Garzon, E. Heaphy, C. Croce

The Ohio State University, COLUMBUS, USA

Background. Ultraconserved genomic regions (UCRs) are a subset of conserved sequences (100% between orthologous regions of human, rat and mouse genomes) located in both intra- and intergenic regions. There are 481 UCRs described and more than 50% of all the UCRs have been classified as non exonic (with no evidence of coding protein), while the other 47% have been designated either exonic (overlap mRNAs of known genes), or possible exonic. *Aims*. Since hematopoiesis is regulated by signaling pathways and transcription factors that are highly conserved throughout phylogeny, we hypothesize that UCRs may be differentially expressed in hematopoietic tissues and may play a role in the regulation of this process. *Methods*. To explore the UCRs expression in normal hematopoiesis we performed microarray analysis of hematopoietic precursors (HPCs) obtained by culturing human bone marrow (non-mobilized) CD34+ selected cells with different cytokine combinations for 2-3 weeks to stimulate differentiation to the erythrocyte (E), megakaryocyte (MK), monocyte (M) and granulocyte lineages (G). The following cytokine combinations were used: E (TPO/SCF/IL-3); G (G-CSF, GM-CSF, SCF, IL-3, IL-3); MK (TPO, SCF, IL-3) and M (M-CSF, GM-CSF, IL-6, IL-3 and SCF). Differentiation to the selected lineages was monitored every 3 days after 1 week of culture, using morphology, special staining (benzidine) and flow cytometry analysis using appropriate lineage specific antibodies. Human bone marrow CD34+ and peripheral blood CD3+ (pan-T cells) and CD-19+ (B-lymphocytes) selected cells were obtained from 3 different donors. Total RNA was obtained from the E and M cultures at days 7, 9, 11 and 14; G (days 10 and 14) and MK at day 14 and was hybridized in duplicate to the UCRs/miRNA microarray chip. After normalization of the array data with quantiles and exclusion of genes with less than 20 % of expression data with at least a 1.5 -fold change in either direction from gene's median value, we proceeded with further analysis using the BRB tools. *Results.* Unsupervised analysis of the differentiated CD34+ HPCs and peripheral blood lymphocytes revealed that the samples cluster according to the hematopoietic lineage of origin. To detect the minimum number of UCRs that are able to distinguish differentiated HPCs from BM CD34+ cells with high accuracy we performed class prediction analysis. As expected, very few numbers of UCR were able to predict the lineage with no error (mean percentage of correct classification: 100%). These UCRs were overlapping with the ones identified later by using two class analysis where we compared the UCRs expression of CD34+ HPCs Vs. differentiated cells (E, G, MK, MO, T and B-lymphocytes) one at a time (i.e. CD34+ Vs. E; CD34+ Vs. MK) Table 1. We were able to validate the results for uc.283+, uc.285+, uc.73+ in a panel of CD34+ derived hematopoietic precursors using qRT-PCR. *Conclusions*. We characterized the UCRs expression at different stages of hematopoietic differentiation and identified distinctive signatures associated with particular lineages. This research has the potential to identify novel regulators of hematopoiesis and may give insights into basic biology of gene expression and cell fate determination.

THE ROLE OF CYCLIN A1 AND APOPTOSIS IN MURINE HEMATOPOIETIC STEM CELLS

E. Diffner, J. Liao Persson

Experimental Cancer Research, MALMÖ, Sweden

The cell cycle regulating protein cyclin A1 is found at elevated levels in several malignancies, including acute leukemia. In normal tissues cyclin A1 expression is restricted to meiotic cells, brain and hematopoietic progenitor cells. Several reports have suggested a potential role of cyclin A1 in the regulation of the apoptotic pathways. The studies indicate that cyclin A1 may either protect or promote cells for undergoing apoptosis independently of the origin of the tissue. Given that cyclin A1 is restricted to early hematopoietic cells it was of interest to define the physiological function of cyclin A1 in the regulation of apoptosis in hematopoietic stem (HSC) and progenitor cells. We used mice engineered with knockout alleles on the cyclin A1 gene, CCNA1, and characterized the effect of cyclin A1 deficiency on apoptosis in hematopoietic stem cells (HSC) and progenitor cells. This was determined by staining Lin^- cells with the cell surface markers, Sca-1 and c-kit, combined with the apoptotic markers, AnnexinV/7AAD. There was a significantly higher level of apoptosis in the HSC compartment of cyclin A1 deficient mice compared to wild type mice. However, the Lin^- cells from the different genotypes showed only a minor difference in the rate of apoptosis. These results suggest that the role of cyclin A1 in apoptosis may be more crucial for stem cells than for more developed hematopoietic cells. With these data, we are currently elucidating the pathways by which cyclin A1 is involved in modulating apoptosis in the hematopoietic compartments.

INTEGRIN ALPHA9 CONTRIBUTES TO ADHESION AND DIFFERENTIATION OF HUMAN HEMATOPOIETIC STEM/PROGENITOR CELLS IN THE HUMAN BONE MARROW

G. Klein,[1] C. Steinl,[1] C.A. Müller,[1] W.K. Aicher,[2] T.D. Schreiber[1]

[1]University Medical Clinic Tübingen, TUEBINGEN; [2]Department of Orthopedic Surgery, University of Tübingen, TÜBINGEN, Germany

Background. Hematopoietic stem cells can interact with their microenvironment via integrins which are adhesion receptors consisting of α and β subunits. Current knowledge suggests that the integrin subunits α4 and α6 expressed on hematopoietic stem and progenitor cells (HSPCs) have distinct roles in retaining stem cells in the bone marrow. *Aim*. The aim of our study was to gain insight into the expression and functions of the integrin subunits α7-α11, which have not been studied so far in the human bone marrow, within the endosteal stem cell niche. *Methods.* Human osteoblasts isolated from trabecular bone and HSPCs purified from umbilical cord blood or bone marrow aspirates were analyzed for the expression of integrin α7-α11 chains by RT-PCR. The involvement of the integrin α9β1 in HSPC cell adhesion, proliferation and differentiation was analyzed in functional assays. *Results*. Transcripts for all investigated integrin chains were found in primary osteoblasts. Highly purified $CD34^+$ HSPCs, however, expressed only transcripts encoding integrin subunits α7 and α9. Flow cytometric analysis verified extracellular expression of the integrin α9β1on HSPCs. Cell-cell adhesion assays with osteoblasts and dye-labeled $CD34^+$ HSPCs in the presence of function-blocking antibodies revealed a role for integrin α9 in HSPC adhesion to osteoblasts. Furthermore, the addition of anti-integrin α9 antibodies significantly inhibited proliferation and *in vitro* differentiation of $CD34^+$ HSPCs. *Summary*. The integrin α9β1 has been identified as a new member of the integrin β1-subfamily expressed on human hematopoietic stem cells. The functional studies strongly suggest that integrin α9β1 contributes to adhesion and differentiation of HSPCs in the endosteal stem cell niche.

DIFFERENTIAL LOCALIZATION OF P-SELECTIN AND VON WILLEBRAND FACTOR DURING MEGAKARYOCYTE MATURATION

M.K. Zetterberg,[1] R.A. Rana,[2] M. Zingariello,[2] M.E. Fabucci,[3] D. Bosco,[2] A.R. Migliaccio,[4] F. Martelli[3]

[1]Istitituto di sanità superiore, ROMA, Italy; [2]Department of Biomorphology, University of Chieti, CHIETI, Italy; [3]Istitituto di Sanità Superiore, ROMA, Italy; [4]Department of Oncology and Hematology, Mount Sinai School of Medicine, New York, NEW YORK, USA

Background. An important step in megakaryocyte maturation is the appropriate assembly of at least two distinct subsets of α-granules, containing either pro- or anti-angiogenic factors. In addition, the α-granules contain hemostatically active factors such as fibrinogen, von Willebrand factor (VWF) and P-selectin. Since P-selectin and VWF mediate different platelet functions during wound healing (VWF binds to exposed collagen and P-selectin mediates neuthrophil attachment), we hypothesized that these two proteins may be routed to different α-granule subsets. In apparent contrast with this hypothesis, the megakaryocytes from Gata1low mice, mice harboring a hypomorphic mutation that decreases Gata1 expression and blocks megakaryocyte maturation, are characterized by reduced expression of VWF and abnormal localization of P-selectin, suggesting that correct P-selectin transport is dependent on VWF and that the two proteins may be routed together to the α-granules. This Gata1low megakaryocyte phenotype is partially rescued by treatment with thrombopoietin. Whether thrombopoietin rescues P-selectin localization to the α-granules is not known. *Aims.* To investigate the localization of P-selectin and VWF during megakaryocyte maturation induced in wild-type and Gata1low mice by treatment with thrombopoietin. *Methods.* Gata1low and wild-type mice were injected with recombinant murine thrombopoietin (100 microgram thrombopoietin/Kg of body weight/daily for 5 days) and sacrificed at day 7 after the first injection. Their spleens were sterilely removed and analyzed by transmission electron microscopy and double immuno-electro microscopy using goat-anti-P-selectin and rabbit-anti-VWF as primary antibodies and either anti-goat or anti-rabbit secondary antibodies coupled with 20 or 15 nm gold-particles, as appropriate. *Results.* The megakaryocytes present in spleen sections from untreated wild-type mice were scarce (0.33 megakaryocytes/field) and mostly mature. By contrast, spleen sections of thrombopoietin-treated wild-type mice were hyper-cellular (6.3 megakaryocytes/field) and contained both immature and mature megakaryocytes. Sections from the spleen of untreated Gata1low mice were also hyper-cellular (5.1 megakaryocytes/field) but did not contain detectable mature megakaryocytes. However, after thrombopoietin-treatment, mature megakaryocytes became detectable in the spleen of Gata1low mice (3.2 mature vs. 1.2 immature megakaryocytes/field, p=0.003). Double gold-immuno-labelling for P-selectin (isolated dots) and VWF (punctuate pattern) in the α-granules (arrow heads) and cytoplasm/DMS (arrows) of megakaryocytes at different stages of maturation is presented in Figure 1. In mature (stage III) megakaryocytes from untreated wild-type mice, P-selectin and VWF gold-particles were not co-localized. By contrast, in thrombopoietin-treated wild-type mice, the two factors were frequently associated in immature (stage I) megakaryocytes, but became localized in separate α-granules in mature cells. Also in immature megakaryocytes from the spleen of untreated Gata1low mice, P-selectin and VWF were found in close proximity, while in mature megakaryocytes from thrombopoietin-treated Gata1low animals they were found in separate cellular compartments. *Summary and conclusions*. This study shows that VWF and P-selectin are associated in the cytoplasm at early stages of megakaryocyte maturation but that their localization diverges to separate α-granules with maturation. The separate localization of the two proteins supports the hypothesis that the two proteins, by binding sequentially to their respective ligand, may time the release of the content of different α-granule subtypes during the process of wound healing.

ASSESSMENT OF INDUCED BONE MARROW SUPPRESSION AND HEMATOPOIETIC GROWTH FACTORS ON HEPATIC REGENERATION AFTER PARTIAL HEPATECTOMY IN ALBINO RATS

E.D.S. Alaa Abd El Hamid

Faculty of Medicine, Sue Canal University, ISMAILIA, Egypt

Introduction. The remarkable capacity of hepatic regeneration after partial hepatectomy or hepatic injury had been frequently documented, however; the role of the hematopoietic stem cells and the hematopoietc growth factors is still controversal. Aim of the study: to evaluate the effect of bone marrow suppression & the hematopoietic growth factors (Erythropoietin and Granulocyte colony stimulating factor) on hepatic regeneration after partial hepatectomy in albino rats. Material & methods; 36 adult male albino rats were included & they were divided into six groups each group included 6 rats: the 1st group: the control group, the 2nd group: bone marrow suppression was induced by benzene subcutaneous injection for three weeks, the 3rd group: rats were subjected to 70% surgical partial hepatectomy, the 4th group: rats were subjected to bone marrow suppression by benzene followed by 70% surgical partial hepatectomy, the 5th group: rats were subjected to 70% surgical partial hepatectomy and injection of (Erythropoietin and Granulocyte colony stimulating factor) for five days starting after partial hepatectomy, The 6th group; rats were subjected to bone marrow suppression by benzene followed by 70% surgical partial hepatectomy with injection of (Erythropoietin and Granulocyte colony stimulating factor) daily for five days post hepatectomy. Cytological changes during regeneration were assessed in all groups by quantitative assessment of binucleated cells, the restored number of hepatocytes and mitotic index. Histological evaluation & immunohistochemical study for $CD34^+$ cells in the hepatic tissues were assessed. *Results.* There were no regenerative changes in both control & benzene treated groups, a statistically significant changes was detected regarding the regenerative changes in the partial hepatectomy group compared to bone marrow suppressed group, in the same time a statistically significant changes was detected regarding the regenerative changes in the partial hepatectomy group compared to bone marrow suppressed both groups were treated simalteously with hematopoietic growth factors, Immunostaining of CD34 expression as marker of HSCs in liver sections showed the following; the normal group, benzene treated group and partially hepatectomized group after benzene treatment showed no expression, but partially hepatectomized group show focally positive expression. Both groups treated with hematopoietic growth factors either after partial hepatectomy or after partial hepatectomy and bone marrow suppression by benzene show diffusely positive expression. *Conclusion.* the present study had shown that the hematopoietic growth facors (Erythropoietin and Granulocyte colony stimulating factors) stimulated the hepatic regenerative process after partial hepatectomy only, while a reduced effect was detected after partial hepatectomy with bone marrow suppression.

ISOLATION, DIFFERENTIATION AND NEUROPROTECTIVE PROPERTIES OF NEURONAL PROGENITORS FROM HUMAN UMBILICAL CORD BLOOD

H. Arien-Zakay,[1] P. Lazarovici,[2] H. Galski,[1] A. Nagler[1]

[1]*Chaim Sheba Medical Center, RAMAT-GAN;* [2]*The Hebrew University of Jerusalem, JERUSALEM, Israel*

Since the availability of human neuronal stem cells derived from early embryos is extremely limited, progenitors of other origins, such as human umbilical cord blood (HUCB), a novel source of hematopoietic stem cells for allogeneic transplantation in hematological disorders, are being considered for cell therapy of neurodegenerative disorders. For this purpose, populations of collagen-adherent, nestin-positive (94.8±2.9%) progenitors expressing $\alpha 1/2$ integrin receptors HUCB-derived neuronal progenitors (HUCBNP), were isolated from the mononuclear fraction. *In vitro* differentiation of the HUCBNP was achieved by treatment with 10% human SH-SY5Y neuroblastoma cell-conditioning media (CM) supplemented with 10 ng/mL nerve growth factor (NGF) and characterized by analysis of neurite outgrowths (83±8.2%), MAPK kinases activation (ERK2-36-fold vs control; p38α-nine-fold vs control; p38β-23-fold vs. control) and neuronal markers expression such as microtubule-associated protein 2 (MAP-2; 98.5±2%), neurotrophin receptor (TrkA; 98.5±0.06%), neurofillament-160 (NF-160; 94.2±1%), β-tubulin III (89.8±4.2%) and neuron specific enolase (NSE). Since the growth factors requirement for neuronal differentiation *in vitro* is poorly understood, we explored interferon-γ (IFN-γ) effects on HUCBNP and demonstrated IFN-γ-induced neuronal differentiation alone and in a cooperative manner with NGF. IFN-γ was detected in the CM and transcriptome analysis of CM-differentiated HUCBNP, identified 79 genes highly up-regulated, among them 26 genes interferon-induced. These findings propose IFN-γ and NGF use in future protocols of neuronal differentiation of HUCB-derived progenitors towards cell therapy. The neuroprotective potential of HUCBNP was evaluated using a neuronal ischemic *in vitro* model. In this model, HUCBNP conferred ~30% neuroprotection towards apoptotic and necrotic neuronal cell death. HUCBNP decreased by 95% the level of free radicals in the insulted-neuron, in correlation with the appearance of antioxidants in the medium. An increased level of NGF, VEGF and FGF-2 protein and mRNA modulation were temporally correlated with the neuroprotection effect. These findings indicate a "bystander" effect of HUCBNP-induced neuroprotection involving antioxidant(s) and neurotrophic factors, which, by paracrine and/or autocrine interactions between the insulted-neuron and the HUCBNP, conferred neuroprotection. Altogether, these studies contribute a novel understanding on human umbilical cord blood-derived progenitors for future cell therapy approaches.

Transcriptional control, epigenetics, cell cycle regulation and apoptosis

0014

MAINTENANCE OF NORMAL HEMATOPOIETIC PROGENITOR CELLS BY THE DEACETYLASE INHIBITOR LAQ824 IS ASSOCIATED WITH INDUCTION OF NOTCH TARGET GENES

G. Bug,[1] A. Romanski,[1] O.G. Ottmann,[1] J.W. Scott,[2] H. Serve,[1] K. Schwarz[1]

[1]Goethe University, Frankfurt, FRANKFURT, Germany; [2]Novartis Pharmaceuticals Corporation, FLORHAM PARK, NJ, USA

Background. Deacetylase inhibitors (DACi) are known to induce cell cycle arrest and apoptosis in AML blasts. However, we have recently demonstrated stimulation of leukemic hematopoietic progenitor cells (HPC) by the selective class I DACi valproic acid (VPA), which may contribute to its rapid clinical failure in spite of promising antileukemic activity in the bulk of AML blasts. Here, we describe the effect of the novel and more potent hydroxamic acid LAQ824 on phenotype and function of leukemic $CD34^+$ HPC in comparison to VPA. In addition, we show that LAQ824 enhances maintenance of normal HPC and evaluate the mechanisms involved by analysing LAQ824-induced gene expression in the most primitive $CD34^+CD38^-$ normal HPC population. *Methods*. Differentiation and proliferation of $CD34^+$ cells of bone marrow of healthy donors and peripheral blood samples of newly diagnosed AML patients were evaluated after one week of culture in presence of SCF, FLT3 ligand, TPO, IL-3 ± LAQ824. The effect of LAQ824 on gene expression profiles in normal $CD34^+CD38^-$ cells was assessed in three independent cell samples following incubation with cytokines ± LAQ824 for 48 hours using Affymetrix GeneChip Human Genome U133 Plus 2.0 and Gene Spring Software. Serial replating of murine Sca1+Lin- HPC was performed in the presence of SCF, G-CSF, GM-CSF, IL-3, IL-6 ± LAQ824. *Results*. Treatment of murine Sca1+Lin- HPC with LAQ824 (10 nM) significantly augmented colony numbers ($p<0.01$; n=3), and supported colony growth after four cycles of replating whereas no colonies developed in its absence beyond the second plating indicating preservation of functionally active multipotent progenitor cells. LAQ824 (10-20 nM) mediated acetylation of histone H3 in human normal and leukemic HPC. In normal HPC, LAQ824 (0-20 nM) lead to a dose-dependent increase in the proportion of $CD34^+$ cells (20% w/o LAQ824 vs. 36% with LAQ824 20nM, $p=0.07$) and a significant reduction of $CD14^+$ monocytes (18% vs. 3%, $p=0.02$; n=3). The total number of $CD34^+$ cells remained stable up to 10 nM and decreased at 20 nM. Gene expression analysis showed, that LAQ824 (20 nM) lead to an at least 3-fold up-regulation of 221 genes in all three HPC samples tested including HDAC11 and the cell cycle inhibitor p21waf1/cip1 known to be induced by most DACi in HPC. We identified several members of the notch pathway such as mastermind-like protein 2 (MAML2, a component of the active notch transcriptional complex) and notch target genes including the transcription factors HES1, HEY1 and HOXA10 and confirmed increase of protein levels by Western blotting. Reduced gene expression of mini-chromosome-maintenance (MCM) protein family members was observed which - in addition to up-regulation of p21 - has previously been associated with notch-mediated cell cycle arrest. To compare the effect of LAQ824 (20 nM) with VPA (150 ng/mL) on leukemic HPC, cells were cultured for one week with or w/o DACi. Of note, LAQ824 resulted in a 20% reduction of $CD34^+$ leukemic HPC, while VPA expanded this population to 220% compared with cytokine-treated controls ($p=0.03$; n=12). CFU numbers growing from $CD34^+$ leukemic HPC in presence of LAQ824 did not differ significantly from controls (n=9). *Conclusion*. LAQ824 seems to diminish, but not eliminate normal as well as leukemic HPC as determined by phenotypic and functional *in vitro* analyses. Our gene expression analysis suggested an association with coactivator and target genes of the notch pathway and cell cycle arrest-inducing genes. In contrast to VPA, LAQ824 does not seem to support growth of leukemic HPC which may contribute to its more potent antileukemic effect.

THE TUMOR SUPPRESSOR GENE DISABLED-2 IS EPIGENETICALLY DOWNREGULATED IN MULTIPLE MYELOMA

E. Jost,[1] C. Schubert,[1] S. Wilop,[1] Y. Akiyama,[2] R. Osieka,[1] O. Galm[1]

[1]UK Aachen, AACHEN, Germany; [2]Tokyo Medical and Dental University, TOKYO, Japan

Background. Multiple myeloma (MM) is a B-cell neoplasm characterized by the accumulation of malignant plasma cells in the bone marrow. Aberrant DNA methylation of CpG islands in the promoter region is the best studied epigenetic mechanism and is associated with dysregulation of cancer-related genes. Wnt signalling is a key factor in regulation of cell proliferation, hematopoietic stem cell maintenance and B-cell proliferation. Disabled-2 (DAB2) is a tumor suppressor gene and acts a negative regulator of Wnt signalling. *Aims.* In this study, we have analyzed the occurrence and the possible impact of epigenetic dysregulation of DAB2 in MM cell lines and samples from patients with malignant plasma cell disorders. Furthermore, correlations between epigenetic dysregulation of DAB2 and clinical parameters were investigated. Methods: The methylation status of the DAB2 promoter region was analyzed by methylation-specific PCR (MSP) and pyrosequencing. Furthermore, the expression of DAB2 in cell lines was examined by real-time RT-PCR before and after treatment with the demethylating agent 5-aza-2'-deoxycytidine (DAC) for 96 hours at a 1.0 µmol/L concentration. Additionally, correlations between the methylation status of the DAB2 promoter and clinical parameters were investigated. *Results.* By MSP, DAB2 promoter hypermethylation was observed in the MM cell line OPM-2, in the human Burkitt lymphoma cell line Raji, as well as in the lymphoma cell line L-540. Aberrant methylation of DAB2 was associated with low expression in these hematopoietic cell lines. Treatment of the cell lines with DAC induced higher DAB2 expression and partial promoter demethylation. By pyrosequencing, we confirmed the high methylation density in the promoter region of DAB2 in the hematopoietic cell lines OPM-2, Raji and L540, and we observed partial demethylation after treatment with DAC. We then analyzed the DAB2 methylation status in 95 samples from patients with plasma cell disorders by MSP. The frequency of hypermethylation among the patient cohort was 7.4 % (7/95). Patients with DAB2 hypermethylation showed significant shorter overall survival ($p=0.0045$). Median survival time of the seven patients with methylated DAB2 promoter was 18 months, whereas patients without methylation had an overall survival time of 57 months. In patient samples, we confirmed by pyrosequencing the hypermethylation of the DAB2 promoter region observed by MSP. *Summary.* We conclude that DAB2 downregulation is a novel epigenetic event in MM and may contribute to dysregulation of the Wnt pathway. The functional consequences of aberrant Wnt signalling in the pathogenesis of MM have to be elucidated. The prognostic impact of DAB2 hypermethylation needs to be confirmed in prospective trials. The increasing evidence for the important role of DNA methylation changes in MM may serve as a basis for epigenetically targeted approaches in MM.

0016

A DNASE I HYPERSENSITIVE SITE IN THE DISTAL PROMOTER REGION OF THE BCL-6 LOCUS BINDS ZEB1 AND IS RESPONSIBLE FOR TRANSCRIPTIONAL REPRESSION

V. Papadopoulou,[1] A.C.G. Porter,[1] A. Postigo,[2] S.D. Wagner[3]

[1]Imperial College London, LONDON, UK; [2]IDIBAPS, BARCELONA, Spain; [3]Department of Cancer Studies and Molecular Medicine, University of Leicester, LEICESTER, UK

Background. The B-cell transcription factor, BCL-6, is expressed at a high level in germinal centre B-cells and prevents terminal differentiation to plasma cells whilst allowing proliferation. BCL-6 is essential for high affinity antibody production. Translocation of the BCL-6 locus (especially with the IgH locus) is associated with diffuse large B-cell lymphoma, and expression from an undisrupted locus occurs in Burkitt lymphoma, follicular lymphoma and lymphocyte predominant Hodgkin's lymphoma. Understanding the regulation of BCL-6 transcription is, therefore, important for normal immunity and also some non-Hodgkin's and Hodgkin's lymphomas. *Aims.*We have taken a systematic approach to mapping possible cis-acting transcriptional control regions at the BCL-6 locus. *Methods.* We employed DNase I hypersensitive site mapping across 50kb of the locus. Transcription factor binding to the strongest sites were identified and further characterized by gel shift assays and reporter assays. *Results.* We identified strong DNase I hypersensitive sites at -4.4kb, +0.3kb, +0.5kb and +3.8kb (relative to the tran-

scription start site) at the BCL-6 locus in human tonsillar B cells and EBV(-) Burkitt cell lines. We noted that there was a site of human/mouse DNA sequence homology at HSS-4.4 and focused subsequent work on this site. Gel shift assays showed a strong shift with a probe containing an E-box sequence (CAGGTG). Anti-E2A and anti-ZEB1 antibodies both produced super-shifts suggesting specific binding of these proteins, which are known to compete for binding to the same sequence. We confirmed specific E2A and ZEB1 binding by chromatin immunoprecipitation, and also that of CtBP, a known ZEB1 co-repressor. Transient transfection of ZEB-1 cDNA downregulated levels of the BCL-6 mRNA and protein in two EBV(-) Burkitt lymphoma cell lines and reduced luciferase activity of a BCL-6 promoter construct when transfected into 293T cells. *Conclusions.* Our study revealed a novel DNase I hypersensitive site (HSS-4.4) containing binding elements for E2A and ZEB1. We implicate ZEB1 as a transcriptional repressor of BCL-6 acting in concert with CtBP, and competing with E2A. Future work will characterize the function of ZEB1 in normal immunity and lymphomagenesis.

GENOME-WIDE IDENTIFICATION OF BINDING SITES OF EVI1 IN HUMAN MYELOID CELL LINES

M. Maicas, I. Vazquez, M.A. García-Sánchez, N. Marcotegui, L. García-Ortí, O. Marín, N. Ortega, E. Guruceaga, A. Conchillo, M. Gómez-Benito, M.D. Odero

CIMA, University of Navarra, PAMPLONA, Spain

The ecotropic viral integration site-1 (EVI1) is an oncogenic transcription factor in murine and human acute myeloid leukemia (AML). Overexpression of EVI1 in AML is one of the worst prognostic factors in patients with or without 3q26 rearrangements. The effect of EVI1 involves several pathways through the interaction with proteins with important functions in transcriptional control; however, the role of EVI1 as a transcription factor is not well known. In mice, several EVI1 target genes have been identified, including Gadd45g, Gata2, Fog2, Skil, Klf5, and Map3k14; nevertheless, no EVI1 target genes have been described in human models. Our aim was to investigate the pathways and direct target genes of EVI1 by studying the differential expression profile of cell lines before and after the gene knockdown, by a bioinformatics approach to identify hypothetical EVI1 binding sites, and by chromatin immunoprecipitation (ChIP). Differential expression profiles after EVI1 knockdown allowed us to identify 125 genes involved in cell growth, differentiation and signal transduction that could be related to EVI1. Moreover, we looked for potential EVI1 binding sites within the region 1000pb upstream of the transcription start sites of all human genes, and selected the genes found in both the Transfac and Jaspar databases. We selected a total of 69 genes from the bioinformatics search, genes related to EVI1 by literature, and genes differentially expressed in the TF1 cell line expression array. We performed ChIP in the TF1 and HEL cell lines with two EVI1 antibodies, and demonstrate that EVI1 binds to the proximal promoter regions of 12 of these genes, confirming the important role of EVI1 in GATA2, and SKIL transcription. Interestingly, EVI1 seems to regulate its own transcription. To extend this study, we analyzed 3000pb upstream of the transcription start site of the reference form of EVI1, and we found 3 more EVI1 binding sites. Further functional studies are in progress. In conclusion, we have identified 12 EVI1 target genes, most of them involved in important differentiation and proliferation pathways. Interestingly, EVI1seems to have binding sites on its promoter, suggesting that it could be regulating its own transcription. These data provide a starting point for further studies aimed at uncovering the mechanism for EVI1-induced transformation.

MICRORNA EXPRESSION PROFILES IN UMBILICAL CORD BLOOD CELL LINEAGES

M. Merkerova, A. Vasikova, M. Belickova, H. Bruchova

Institute of Hematology and Blood Transfusion, PRAGUE, Czech Republic

Background. MicroRNAs (miRNAs) are a class of small non-coding RNAs that regulate gene expression either by inhibiting protein translation or by cleavage of mRNA targets. miRNAs are key regulators of many cellular processes such as differentiation, proliferation and apoptosis. It has been demonstrated that miRNAs show characteristic expression signatures in different cell lineages and stages of hematopoietic stem cell (HSC) differentiation, indicating their importance in hematopoiesis. Because neonatal blood displays various features of cellular immaturity compare to adult blood, we could expect differential miRNA expression in neonatal blood cells. *Aims.* To understand molecular basis of phenotypic differences between neonatal and adult blood, we studied variations in miRNA expression between umbilical cord blood (UCB), peripheral blood (PB) and bone marrow (BM) cells with emphasis on HSC. METHODS: Samples of UCB, PB and BM were collected from healthy adult donors (10 samples of PB and 3 samples of BM) or Cord Blood Bank of the Czech Republic (10 samples of UCB). All samples were obtained with donor's written informed consent. Using qRT-PCR low-density arrays, we determined miRNA expression profiles of UCB cell lineages (CD34+ progenitor/stem cells, $CD3^+$ T-lymphocytes, $CD14^+$ monocytes, and granulocytes) and compared them to those of BM and PB cell counterparts. Further, in the same samples we determined mRNA expression profiles using whole-genome microarrays. An approach combining bioinformatic prediction of miRNA targets with mRNA expression profiling was used to search for putative targets of miRNAs with potential functions in UCB. *Results.* We pointed out several differentially expressed miRNAs in particular cell lineages and associated their expression with their putative or previously verified target gene levels. miR-148a expression was suppressed in HSCs and its level inversely correlated with its previously verified target DNA methyltransferase 3B (DNMT3B), suggesting dependence of *de novo* DNA methylation in HSCs on miR-148a. Prolonged cell survival of HSCs may be associated with low expression of miR-143 and miR-145 and up-regulation of their down-stream targets (high expression of c-MYC and miR-17-92 oncogenes and following repression of tumour suppressor TGFBR2). In HSCs, we monitored significant up-regulation of 8 miRNAs (miR-10a miR-99 miR-126, miR-130a, miR-181d, miR-196b), which were previously verified as regulators of HOX genes. Further, miR-146b may be associated with immaturity of neonatal immune system because it is strongly up-regulated in UCB granulocytes and T-lymphocytes compared to PB cells. Comparative analysis revealed 13 miRNAs significantly altered between UCB and BM $CD34^+$ cells (up-regulation of miR-517c, miR-518a, miR-519d, and miR-520h and down-regulation of let-7b, miR-1, miR-34a, miR-195, miR-203, miR-214, miR-545, and miR-548d in UCB $CD34^+$ cells). As has been previously suggested, miR-520h might promote differentiation of HSCs into progenitor cells (possibly due to ID1 and ID3 suppression) and miR-214 expression might support survival of BM HSCs. *Conclusions.* UCB shows specific miRNA expression pattern, demonstrating different regulation in these cells compared to adult PB and BM.

RESTORATION OF RETINOIC ACID-TARGET GENE TRANSCRIPTION BY EPIGENETIC THERAPY IN ACUTE MYELOID LEUKEMIA CELL LINES

M. Victor,[1] A. Cras,[1] P.Y. Boelle,[2] B. Pollitis,[1] H. Dombret,[3] E. Raffoux,[4] C. Chomienne[1]

[1]Inserm UMR S 940, PARIS; [2]Inserm UMR S 707, PARIS; [3]Hematology, Hôpital Saint-Louis, PARIS; [4]Hematology, hôpital Saint-Louis, PARIS, France

Background. Retinoic acid (RA) plays a major role in control of cell growth, differentiation, and apoptosis via RA receptors (RARs), which act as transcription factors to regulate the expression of RA-target genes. All-trans RA (ATRA) is the first example of targeted therapy in PML-RAR+ acute myeloid leukemia (AML). Repression of RA signalling pathways through aberrant epigenetic mechanisms may explain ATRA resistance in others AMLs. Thus, combination of a DNA hypomethylating agent (5-azacytidine, AZA) with a histone deacetylase inhibitor (valproic acid, VPA) might sensitize RA-resistant AMLs to ATRA therapy. Promising results of clinical trial with the combination of these drugs confirm the rational of epigenetic therapy with ATRA in AML patients. AIM: The objective of this *in vitro* study was to define molecular and cellular parameters of epigenetic drug response in AMLs through a candidate gene approach on RA-target genes and a wider global methylome analysis. METHODS: All cellular analyses were performed in five AML cell lines (NB4, UF1, U937, KG1, Kasumi1). Epigenetic status of RARs promoters, as representative of RA-target genes, was studied by quantitative methylation specific PCR and chromatin immunoprecipitation experiments. Quantitative DNA methylation of 808 genes (1536 CpG sites) involved in cancer was realized using the GoldenGate Assay for Methylation with BeadArray® from Illumina. Gene expression was measured by quantitative PCR. *Results.* Unlike ATRA alone, AZA/VPA/ATRA induced apoptosis and inhibition of cell growth in all cell lines except KG1 ($p<0.05$). Differentiation was achieved only in ATRA-sensitive cell lines (NB4 and U937), with no significant improvement with AZA/VPA/ATRA compared to ATRA alone. On the other hand, increase of RARα, β and γ gene expression was more potent with AZA/VPA/ATRA than with ATRA alone in ATRA-sensitive cell lines

(p<0.05), as well as in ATRA-resistant cell lines (UF1, Kasumi1) except KG1. Expression was associated with a prolonged and stable DNA demethylation of RARs promoters while increased levels of acetylated H3 histones followed a more time-dependant pattern. Interestingly, increased levels of acetylation induced by AZA/VPA/ATRA occurred in the same time interval as with ATRA alone, suggesting a synergistic effect on ATRA-induced chromatin modification. Methylome analysis showed that median methylation level before treatment across all sites was different according to each cell line (UF1 76.6%, NB4 71.8%, U937 65.9%, KG1 53.2%; p<0.0001). In sites with methylation level >50% before treatment (n=806), AZA/VPA/ATRA led to significant decreases of methylation values of CpG sites in 542 sites (p<0.05), while no significant difference was found with ATRA alone. Overall, the mean decrease in methylation level with AZA/VPA/ATRA ranged between 3 and 33% (median 10%). The number of sites showing more than 20% reduction was different in each cell line (UF1: 133 sites; NB4: 48 sites; U937: 68 sites; KG1: 4 sites). *Conclusions.* Epigenetic modifications induced by AZA/VPA/ATRA combination, involve some RA-target gene promoters. These modifications might thus participate in restoring ATRA sensitivity in some ATRA-resistant AML cells.

SMALL MOLECULE XIAP INHIBITORS SENSITIZE CHILDHOOD ACUTE LEUKEMIA CELLS FOR DEATH RECEPTOR- OR CHEMOTHERAPY-INDUCED APOPTOSIS IN VITRO AND EXERT ANTI-LEUKEMIC ACTIVITY IN A NOD/SCID MOUSE MODEL *IN VIVO*

S. Fulda,[1] S. Löder,[1] M. Fakler,[1] K. Schneider,[2] I. Jeremias,[2] K.M. Debatin,[1] S. Fulda[1]

[1]Ulm University, ULM; [2]GSF, MUNICH, Germany

Children with high risk acute lymphoblastic leukemia (ALL) do not respond well to current treatments. This failure is, at least in part, due to defects in apoptosis programs. Therefore, new strategies are required that counter apoptosis resistance in order to improve the poor prognosis of high risk pediatric acute leukemia. Since XIAP, a member of *Inhibitor of Apoptosis Proteins* (IAPs), is expressed at high levels in acute leukemia and blocks apoptosis at a central point of the apoptotic machinery, XIAP may present a suitable molecular target for therapeutic intervention. Here, we report that neutralizing XIAP by small molecule inhibitors is a novel and effective approach to sensitize childhood acute leukemia cells for death receptor- or chemotherapy-induced apoptosis. XIAP inhibitors at subtoxic concentrations, but not a structurally related control compound, synergize with TRAIL, agonistic anti-CD95 antibodies or various anti-leukemic drugs, e.g. cytarabine, doxorubicin, etoposide and 6-mercaptopurine, to induce apoptosis in acute lymphoblastic leukemia cells. Further, XIAP inhibitors act in concert with TRAIL, anti-CD95 antibodies or chemotherapeutic drugs to reduce clonogenic growth of ALL cells demonstrating that they also suppress long-term survival. Analysis of signaling pathways reveals that XIAP inhibitors enhance death receptor- or chemotherapy-induced activation of caspases, loss of mitochondrial membrane potential and cytochrome c release in a caspase-dependent manner, indicating that they promote a caspase-dependent feedback mitochondrial amplification loop. Intriguingly, XIAP inhibitors promote TRAIL-mediated caspase activation, mitochondrial perturbations and apoptosis regardless of high Bcl-2 expression by enhancing Bcl-2 cleavage and Bak conformational change. Thus, XIAP inhibitors in combination with TRAIL even break Bcl-2-imposed resistance, a defect in the apoptotic pathway that is common in acute leukemia and associated with poor prognosis. In contrast to malignant cells, XIAP inhibitors at equimolar concentrations alone or in combination with TRAIL are non-toxic to normal peripheral blood lymphocytes despite surface expression of the apoptosis-inducing TRAIL receptors, pointing to a therapeutic index. Of note, XIAP inhibitors also kill primary leukemic blasts from children with ALL ex vivo and cooperate with TRAIL, anti-CD95 antibodies or chemotherapeutic drugs to induce apoptosis in primary leukemia cells. Most importantly, XIAP inhibitors significantly reduce leukemic burden *in vivo* in a mouse model of pediatric ALL engrafted in NOD/SCID mice. Thus, small molecule XIAP inhibitors present a promising novel approach for apoptosis-based therapy of childhood acute leukemia, which warrants further exploitation.

CASPASE INHIBITION BLOCKS APOPTOSIS CAUSED BY MLL-AF4 DEPLETION IN T(4;11)-POSITIVE ALL CELL LINES, BUT CANNOT ABROGATE SUBSEQUENT NECROPTOSIS-LIKE CELL DEATH

P. G. C. Garrido Castro,[1] A. Gessner,[1] J. Greil,[2] O. Heidenreich[1]

[1]Newcastle University, NEWCASTLE UPON TYNE, United Kingdom; [2]Department of Paediatric Haematology and Oncology,University Children's Hospital, HEIDELBERG, Germany

Chromosomal rearrangements involving the 11q23 locus are recurring cytogenetic aberrations in acute leukaemias. One of the common chromosomal abnormalities in acute lymphoblastic leukaemia (ALL) is the reciprocal translocation t(4;11)(q21;q23). This translocation generates the fusion oncogene MLL-AF4, and cell lines carrying this translocation show a remarkable resistance to chemotherapy-related stress and cell death. Accordingly, MLL-AF4-positive paediatric ALL is associated with poor prognosis. In order to further elucidate the role of MLL-AF4 in leukaemogenesis, we employ RNA interference (RNAi) to functionally analyse MLL-AF4. We have shown that RNAi-mediated depletion of the MLL-AF4 oncogene induces apoptosis in cell lines in a caspase-dependent manner. In this work we investigated whether apoptosis in response to MLL-AF4 down-regulation could be prevented by inhibiting caspase activity. The t(4;11)-positive pro-B ALL cell line SEM was transfected with siMLL-AF4, a siRNA specifically directed against the fusion breakpoint of the endogenous MLL-AF4 transcript and which has no off-target activity in t(4;11)-negative leukaemic cell lines. As control, SEM cells were transfected with an active siRNA targeting a fusion transcript absent in our cell line. In an attempt to block apoptosis, we cultured siRNA transfected cells simultaneously with the pancaspase inhibitor zVAD-FMK or with its solvent DMSO. Immunoblotting and a luciferase-based caspase-3 and caspase-7 activity assay demonstrate that, in contrast to the corresponding siMLL-AF4/DMSO control, the addition of zVAD to siMLL-AF4 transfected SEM cells blocks effector caspase activation and functional activity. Concomitantly, other apoptotic markers such as PARP1 cleavage, ANNEXIN V-single positive staining and DNA fragmentation are absent in siMLL-AF4/zVAD treated cells, and induced in siMLL-AF4/DMSO cells. The siRNA controls show no apoptotic activation and a viable, non-necrotic phenotype when cocultured with or without zVAD. However, zVAD-FMK does not abrogate siMLL-AF4-mediated cell death, as SEM cells transfected with siMLL-AF4 and zVAD-FMK show an increase in ANNEXIN V/PI double-positive population. This finding implies that caspase-inhibition directs SEM cells to an alternative non-canonical death pathway. Gene expression profiling revealed induction of RIPK1, PARP2, CYLD, JUN, TNF, LC3B in cells transfected with siMLL-AF4 and treated with zVAD-FMK, but not in siMLL-AF4/DMSO cells or appropriate controls. These genes have been recently described as key players in a novel programmed cell death pathway termed necroptosis. Necroptosis is phenotypically matched to necrosis, but opposed to the conventional view of the necrosis pathway, underlies tight regulation, sharing key modulators of the TNFR (tumour necrosis factor receptor) and TLR (Toll-like receptor) signalling pathways and involving autophagy. Our data suggests that in combination of caspase inhibition, MLL-AF4 knock-down results in activation of the necroptosis pathway. These findings illustrate the oncogene addiction of t(4;11)-positive cells to MLL-AF4, as RNAi-mediated oncogene ablation has the inevitable consequence of cell death.

INDUCTION OF APOPTOSIS BY SHORT-TERM, HIGH-DOSE KINASE-INHIBITOR EXPOSURE IS A COMMON MECHANISM IN CELLS TRANSFORMED BY ONCOGENIC KINASES

M.-C. Blum,[1] F. Heidel,[2] E. Ziesché,[1] T. Kindler,[1] T. Fischer,[2] D.B. Lipka[1]

[1]Universitätsmedizin Mainz, MAINZ;[2]Universitätsklinikum Magdeburg, MAGDEBURG, Germany

Small-molecule tyrosine kinase inhibtors (TKI) have become a valuable tool in the treatment of a number of malignant diseases. Chronic myeloid leukemia (CML) has pioneered the way for targeted therapy with TKIs. It is widely accepted that continuous target inhibition of oncogenic kinases *in vivo* is a prerequisite for successful TKI treatment. The clinical experience with Dasatinib, a TKI approved for the treatment of BCR-ABL positive CML questions this paradigm: Dasatinib has a serum half-life of about 4h. Thus, administration of Dasatinib once daily results in transient target inhibition only. Nevertheless, excellent clin-

ical responses are observed when using this schedule. Recently, published data suggested, that this results from a more pronounced target inhibition upon a single dose of Dasatinib (100 mg) as compared to a single dose of Imatinib (400 mg). However, if equipotent doses of Dasatinib and Imatinib are applied to BCR-ABL positive cells *in vitro*, one can observe that Imatinib also induces apoptosis upon short-term exposure. Our current study addresses the question whether induction of apoptosis by short-term, high-dose kinase-inhibitor exposure is a common mechanism in cells transformed by oncogenic kinases. BCR-ABL, JAK2V617F, and FLT3-ITD transformed Ba/F3-cells were treated with different doses of specific TKIs (IC_{50}, IC80, 10xIC_{50}) for various periods of time and the percentage of cells in sub-G1-phase was measured at 24, 48, and 72h. To determine the relation between inhibition of specific oncogene-dependent intracellular signaling pathways (pSTAT5, pERK) and induction of apoptosis (cleaved caspase 3), we measured these molecules simultaneously at the single-cell level by flow-cytometry. To confirm flow-cytometry results, Western blot experiments were performed. In all three cell-models, significant induction of apoptosis after 24, 48, and 72h with all tested dose levels was observed when cells were treated with the respective inhibitor continuously. When the inhibitor was washed out upon a short incubation time, no significant induction of apoptosis was observed when IC_{50} and IC80 were used. However, interestingly, the 10xIC_{50} dose-level nevertheless lead to significant induction of apoptosis in all three cell-models. Flow-cytometry analysis revealed a rapid decrease of pERK and pSTAT5 after 2h, followed by a pronounced increase of cleaved caspase 3 after 8-10h. Western Blot experiments revealed early caspase 3 cleavage even with standard dose inhibitor treatment: As soon as 4h after initiation of inhibitor treatment cleaved caspase 3 was detectable, reaching a maximum level after 10h of treatment. When looking at total caspase 3, the earliest time point one could recognize a decrease in total caspase 3 was after 10h, with almost no detectable total caspase 3 after 16h. The aim of our study was to provide data for the hypothesis, that induction of apoptosis by short-term, high-dose kinase-inhibitor exposure is a common mechanism in cells transformed by oncogenic kinases. Our current derived data from three clinically relevant tyrosine-kinase-mutant driven cell-models, strongly confirm this hypothesis. The exact mechanism is currently investigated in our laboratory but unknown at this point of time. However, the data presented provide a strong rationale to test modifications in dose and schedule of currently used TKIs in clinical trials.

0023

CHANGES OF NUCLEOLIN EXPRESSION IN PERIPHERAL BLOOD MONONUCLEAR CELLS IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA

E. Maloney, T. Ociepa, E. Kamienska, T. Urasinski, E. Urasinska

Pomeranian Medical University, SZCZECIN, Poland

Nucleolin (NL) is a nucleolar phosphoprotein involved in many essential biological processes which are often impaired in neoplastic cells. NL is associated with cell proliferation, cell cycle control, apoptosis, and it also regulates gene expression. Experimental data suggest that during apoptosis NL is involved in nucleolar-cytoplasmatic distribution of cleaved p89 fragment of poly(ADP-ribose) polymerase-1 (p89 PARP-1), this leads to NL accumulation in apoptotic bodies and its removal. The cytoplasmatic occurrence of p89 PARP is early and sure molecular evidence of apoptosis. According to literature data NL interacts with glucocorticoid receptor, is overexpressed in cancer cells and correlates with their proliferation activity. Cellular NL overexpression is associated with chemotherapy resistance. Steroids response is the one of the most significant prognostic factor in children with acute lymphoblastic leukemia (ALL). This study aims to evaluate changes of NL expression in peripheral blood mononuclear cells collected prior to and after 12 hours of prednisone administration, and their correlation with early treatment response in children with newly diagnosed ALL. *Patients.* This study comprised of 38 children (aged 15-206 months, median 51months) with ALL. All children were treated with prednisone in a dose 60 mg/m^2/day according to ALL IC 2002 protocol. The follow up time was 7-66 months (median 38 months). *Methods.* Peripheral blood mononuclear cells were collected prior to and after 12 hours of prednisone administration. Cytospin preparations of these cells were stained with Mouse Monoclonal IgG1 anti-Human Nucleolin (Santa Cruz Biotechnology) followed by Allophycocyanin, Crosslinked, Goat anti-Mouse IgG (Molecular Probes). In order to assess the rates of apoptotic cells respective slides were stained with Polyclonal Rabbit anti-PARP p85 fragment (Promega Corporation) followed by FITC conjugated Polyclonal Swine anti-rabbit antibody (DakoCytomation). Nuclear DNA was stained with propidium iodide (PI). Red fluorescence of DNA - bound PI was a contouring parameter. NL-associated long red fluorescence and p85 PARP green fluorescence were measured by laser scanning cytometer (LSC, CompuCyte, USA). Based on early treatment response patients were divided into 2 subgroups. Patients with absolute leukemic cell counts of less than 1000/µL of peripheral blood after 7 days of prednisone treatment and with bone marrow leukemic cells below 5% on day 15 were classified as early good responders (n=26). All remaining patients were classified as early poor responders (n=12). *Results.* After 12 hours from prednisone administration the percentage of apoptotic cells as well as p85 PARP expression were significantly higher in the group of early good responders (p=0.002 and p=0.04).Those alterations were not observed in the remaining group of patients. The mean pretreatment values of NL expression and after 12 hours from prednisone administration were significantly higher in the early poor responders group comparing to the the early good responders (p=0.003 and p=0.04). *Conclusions.* These data seems to indicate that NL overexpression may contribute to poor early treatment response, influencing the outcome for these patients.

0024

THE EFFECT OF P16 ON GLUCOCORTICOID RESPONSES IN A B-CELL LYMPHOBLAST CELL LINE

S.Y. Kim,[1] E.S. Park,[2] D.C. Jeong[3]

[1]Chungnam National University, DAEJEON; [2]Gyeong Sang National university, JIN JU; [3]Cathoilc University of Korea, INCHEON, South-Korea

Background. Glucocorticoid (GC) has been used as a major anticancer agent for the lymphoid malignancies and their effect appears via glucocorticoid receptor (GR). p16INK4 (p16) is a one of the cyclin-dependent kinase inhibitors acts as a negative cell cycle regulator. It has been suggested that p16 has some roles in GC related apoptosis in lymphoblsts, and the inactivation of p16 in B-cell acute lymphoblastic leukemia (ALL) may induce the lymphoblsts more resistant to GC. *Aims and Methods*. To evaluate the relationship between GC responses and p16 expression, we generated the p16-inactivated cells using a B-cell lymphoblast cell line, NC-37 through p16 siRNA transfection method. We evaluated the GR expression, apoptosis and cell viability between control cells (the p16+ cells) and the p16 siRNA transfected cells (the p16- cells) after a single dose of dexamethasone (DX) treatment. *Results.* There was a significant increase of the cytoplasmic GR expression after 6, 12 and 18 hours with proportional pattern, and followed by a sharp decrease at 24 hour in both cell groups. The GR expressions tended to be higher in the p16+ cells than in the p16- cells through 24 hours, and those at 18 hour was statistically significant(p<0.05). In apoptosis test assessed by flow cytometry using 2 monoclonal antibodies, we could observe a two-phase process of apoptosis in both cell groups; early apoptosis appeared along with GR changes through 24 hours, and late apoptosis appeared higher levels at 18 and 24 hours when the GR was already down-regulated. The latter phenomenon also tended to be more prominent in the p16+ cells than that of the p16- cells, and the result at 18 hour was statistically significant (p<0.05). In cell viability test assessed by Alamar blue staining, viable cells were decreased in both cell groups after DX treatment, but the degree of reduction was more prominent in the p16+ cells after 18 hours (p<0.05). *Conclusions*. These results suggest a relationship between GR expression and cell cycle inhibition, whereby, inactivation of p16 leads to reduced sensitivity to DX in lymphoblst cell line. This observation might have important implications for cancer therapy.

PERIPHERAL BLOOD LYMPHOCYTE SUBSETS, TREG CELLS AND FOXP3 EXPRESSION IN β-THALASSEMIA MAJOR AND β-THALASSEMIA TRAIT PATIENTS

E. Erdem,[1] G. Bozdogan,[1] G. Yanikkkaya Demirel,[2] Y. Yildirmak[1]

[1]Sisli Etfal Research and Training Hospital, ISTANBUL; [2]Centro Laboratories, ISTANBUL, Turkey

Background. Infectious complications constitute an important part of the clinical spectrum of β-thalassemia, being associated with significant morbidity and mortality. Other than the high risks of blood-born infections associated with multiple transfusions, coexistent immune abnormalities have also been held responsible for the increased susceptibility of these patients to infectious diseases. A wide spectrum of immune abnormalities including both quantitative and functional defects has been reported by numerous studies relevant to β-thalassemic patients with multiple transfusions. These defects have been attributed both to the β-thalassemia itself and/or the applied therapeutic interventions. Naturally occurring regulatory T cells (Tregs) play a crucial role in the maintenance of immunological self-tolerance and negative control of various immune responses to non-self antigens. Forkhead transcription factor, FoxP3, is specifically expressed on Tregs and is a master control gene for the development and function of natural Treg cells. Increased antigenic stimuli due to repeated blood transfusions might change the Tregs ratio and FoxP3 expression on T lymphocytes in β-thalassemia patients. *Methods.* Thirty patients with β-thalassemia major who are regularly transfused, 30 patients with β-thalassemia trait who had never been transfused and 20 healthy age-matched children for control group were included in the study. Total lymphocyte count, total neutrophil count, IgG, IgA, IgM, peripheral blood lymphocyte subsets including naive and memory T cell, Treg cells and FoxP3 expression on Tcells were evaluated in these patients and control group. *Results.* Moderate abnormalities were observed in peripheral blood subsets, whereas a signifiant difference was noted in Treg cells and FoxP3 expression on these T cells in β-thalassemia when compared wih β-Thalassemia trait patients and control group. *Conclusions.* Our findings suggest that ß-thalassemia itself, either major or trait, may directly lead to permanent immune stimulation. In β-thalassemia major, immune system seems to be balanced in spite of immune stimulation as a consequence of increased Tregs ratio whereas in thalassemia trait, immune system seems to be continuously activated, associated with high frequency of infectious antigens alone. This is the first study, which evaluated effect of Tregs in β-thalassemia. Additional studies are required to establish alterations of Tregs and immunosupression more clearly in other transfusion dependent diseases.

PERSONALISED MEDICINE - THE USE OF PROTEOMICS BIOMARKERS TO PREDICT RESPONSE TO THALIDOMIDE IN MULTIPLE MYELOMA

R. Rajpal,[1] P. Dowling,[1] J. Meiller,[1] W.G. Murphy,[2] R. O'Connor,[1] K.C. Anderson,[3] P. Murphy,[4] M. Clynes,[1] P. O'Gorman[5]

[1]National Institute for Cellular Biotechnology (NICB), DUBLIN 9, Ireland; [2]University College Dublin & National Blood Centre, DUBLIN, Ireland; [3]Dana-Farber Cancer Institute, BOSTON, USA; [4]Beaumont Hospital, DUBLIN, Ireland; [5]Mater Misericordiae Hospital, DUBLIN, Ireland

Background. Multiple Myeloma (MM) is a disease characterized by a proliferation of malignant plasma cells. The understandings of haematological malignancies at the protein level are important for the prediction of therapy response. *Proteomics* describes the analysis of the entire proteome of a cell or tissue and incorporates multiple technologies including 2D-DIGE. There are a limited number of studies to date in MM; those already performed highlight the potential impact of these technologies in the discovery of potential novel proteins biomarkers associated with the drug resistance. As such, this approach aims to minimize that one-size-fits-all approach by matching the patient to a specific treatment based on the proteomic characteristics of that person's malignancy. Thalidomide alone or in combination represents an effective treatment strategy for newly diagnosed, relapsed and refractory MM patients. The identification of novel biomarkers could lead to more effective, individualized therapeutic strategies with improved patient outcomes. *Patients, Method and Material.* Serum samples of 36 newly diagnosed and relapse MM patients, who had had initial treatment with thalidomide based regimens were analysed. Based on D100 re-staging, 20 responders and 16 non responders to thalidomide were identified. Samples were analysed using 2D-DIGE, a technique based on pre-electrophoretic labelling of samples with one of three spectrally resolvable Fluorescent CyDyes (Cy2, Cy3, and Cy5) allowing multiplexing of samples into the same gel. Initially serum samples were immunodepleted, this step is designed to specifically remove 14 high- abundant Proteins representing approximately 94% of total protein mass. This allowed for easier analysis of low abundance proteins, which are more likely to be a source of potential biomarkers. All 2D-DIGE images were scanned and collected on a Typhoon Fluorescent Imager. Pooled samples were used as an internal standard to quantify expression changes with statistical significance. Statistical analysis and quantitation of protein expression were carried using DeCyder Extended Data Analysis (EDA) software. This allowed us through multivariate analysis to uncover and cluster the protein expression pattern. (Data derived from 2-D DIGE experiments). *Results.* 12 proteins have been identified to be differentially expressed in non-responders compared to responders: 7 were up-regulated and 5 were down-regulated (t-test ≤0.02). All 12 proteins were >1.25-fold differentially expressed, with changes up to 6.62-fold. For example Figure 1 shows statistical analysis of protein 1 using DeCyder BVA software. These proteins were increased 2.45 fold respectively in the immuno-depleted serum from non-responders compared to responders, (t-test 0.0046).

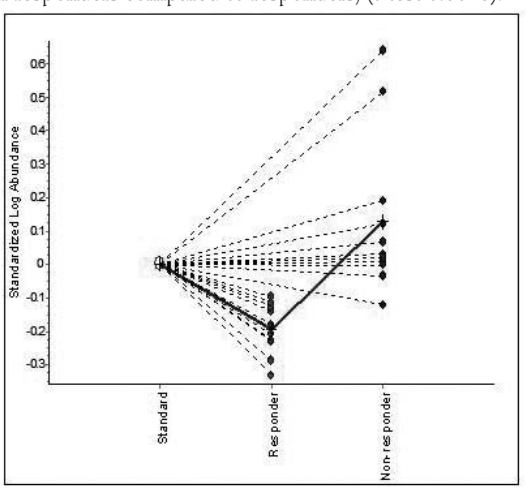

Figure 1.

Once the 12 panel proteins were established, further statistical analysis was performed using DeCyder EDA software. Principal Component Analysis (PCA) was used to separate the responders from the non-responders based on the panel of 12 statistically significant differentially expressed proteins (Figure 2). Each dot on this plot represents a clinical sample; clinical samples from the same experimental groups are located in the same distinct areas, i.e. contained in one half of the plot, confirming consistency of results. *Conclusions.* Accurate prediction of an individual patient's drug response is an important prerequisite of personalized medicine. Using a panel of proteomic biomarkers, we have demonstrated the feasibility of predicting sensitivity and response to thalidomide in previously untreated myeloma. We have so far identified 6 of these proteins and in the process of identification of remaining proteins and plan to confirm their predictive value in a larger group of patients.

DIFFERENT RESPONSES TO ADRIAMYCIN AND RADIATION ON RAJI CELLS: A COMPARATIVE MITOCHONDRIAL PROTEOMIC STUDY

Y.J.J. Jiang, X.W. Wang

Provincial Hospital Affiliated to Shandong University, JINAN, China

Chemotherapy including adriamycin (ADR) and radiotherapy are both popular used in the treatment of non-Hodgkin's lymphoma (NHL) alone or combined together, but many side effects induced by ADR or radiation (e.g. dose-related cardiotoxicity, bone marrow depression, and *second tumor*) represent most challenging problems in the successful treatment of NHL. Furthermore, chemoresistance and radioresistance are both obstacles to achieve a satisfied therapeutic outcome. Former studies confirmed that the anti-tumor mechanism of both ADR and radiation were thought to contribute to the induction of apoptosis and inefficiency of DNA repair, which were closely regulated by mitochondria. Mitochondrial proteome, the main executor of diverse functions in this important subcellular organelle, has received considerable attention with the development of proteomics. To our most knowledge, there have been no simultaneous, quantitative proteomic studies on comparative mitochondrial proteome of lymphoma and their cell lines. *Aims.* The purpose of this study was to investigate different responses of mitochondrial proteome of Raji cells exposed to ADR and radiation respectively, and also to shed new lights on identify mitochondrial associated biomarkers as promising targets for NHL treatment. *Methods.* Two-dimensional differential in-gel electrophoresis (2D-DIGE) in combination with linear ion trap quadrupole-electrospray ionization tandem mass spectrometry (LTQ-ESI-MS/MS) were conducted as a non-biased approach to assess changes in the mitochondrial proteome of Raji cells following exposure to ADR and radiation respectively. *Results.* Total 1485 protein spots were located, of which 41 were chosen to be analyzed further (differently expressed ≥1.5-fold) and resulted in 55 unique proteins or peptides in three groups of Raji cells (control, ADR-treated, and radiation-treated) as showed in Table 1. Differentially expressed mitochondrial proteins distributed their functions in OXPHOS, redox, protein synthesis and degradation, DNA repair, transporters and channels, etc (Figure 1A). Compared to the control and radiation-treated Raji, ADR-treated group were accompanied by down-regulated proteins involved in OXPHOS, DNA repair, cells cycle, and protein synthesis. Intriguingly, proteins involved in above four kinds of functions in radiation-treated Raji were even higher than the control (Figure 1B). Total 7 proteins were common in three conditions, distributing their functions in OXPHOS, DNA repair, transporters and channels, proteins synthesis and degradation (Figure 1C).

Table 1.

Function Group	*Potein Name (Gene Name)*	*Control/ADR Trend (Folds)*	*Control/ Radiation Trend (Folds)*	*ADR/ Radiation Trend (Folds)*
OXPHOS	ATP SYNTHASE D CHAIN (ATP5H)	±1.93		
	ATP synthase subunit O, mitochondrial precursor (ATP5O)			±3.52
	LOC644189 Similar to Acyl-coenzyme A thioesterase 2 (ACOT2)	±3.52		
	Glyceraldehyde-3-phosphate dehydrogenase (GAPDH)	±3.52	±2.72	±2.57
	Hydroxyacyl-coenzyme A dehydrogenase, mitochondrial [Precursor] (HADH)	±3.52		
Energy metabolism	Adipophilin (ADFP)		±2.72	
	Carnitine O-palmitoyltransferase 2, mitochondrial precursor (CPT2)		±1.94	
Cell cycle	Prohibitin (PHB)	±2.53		±1.96
	HRAS-like suppressor 2 (HRASLS2)	±2.26		±2.57
	Kinetochore protein Hec1 (NDC80)	±3.52		
	Isoform Long of Antigen KI-67 (MKI67)		±2.72	
	Isoform 1 of Neuron navigator 3 (NAV3)		±2.72	
	Isoform 1 of Forkhead box protein M1 (FOXM1)		±2.14	±2.69
	ATPase family AAA domain-containing protein 3B (ATAD3B)		±1.94	
Transporters and channel	Heat shock 70kDa protein 9 precursor (HSPA9)	±2.29		
	Isoform 4 of Mitochondrial ATP-binding cassette sub-family B member 6 (ABCB6)	±2.26		±2.57
	Geranylgeranyl transferase type-1 subunit beta (PGGT1B)	±3.05		±2.74
	Isoform 1 of Bifunctional heparan sulfate N-deacetylase/ N-sulfotransferase 2 (NDST2)	±3.05		±2.74
	Hemoglobin subunit epsilon (HBE1)	±3.52	±1.94	±2.74
	HBA1 Hemoglobin subunit alpha (HBA2)	±3.52	±1.94	
DNA repair	DNA repair protein RAD52 homolog (RAD52)	±3.05	±2.14	±2.74
	DNA mismatch repair protein Msh3 (MSH3)	±2.26		±2.57
	Similar to Fanconi anemia group F protein (FANCF)	±2.45		
	ATP-dependent DNA helicase Q4 (RECQL4)		±2.14	±2.69
Protein synthesis	Elongation factor Tu, mitochondrial [Precursor] (TUFM)	±3.05	±2.14	±2.74
	KIAA0415 gene product (KIAA0415)	±3.05	±2.14	±2.74
	Isoform 2 of Uncharacterized protein C19orf60 (C19orf60)	±3.05		±2.74
	Something about silencing protein 10 (UTP3)	±3.05		±2.74
	Isoform C1 of Heterogeneous nuclear ribonucleoproteins C1/C2 (HNRNPC)	±3.52		
	LOC344382 similar to Serine-threonine kinase receptor-associated protein?STRAP?	±3.52		
	Coiled-coil-helix-coiled-coil-helix domain-containing protein 3 (CHCHD3)	±4.71		
	Mediator complex subunit 29 (MED29)		±2.14	±2.69
	Elongation factor G 1, mitochondrial (mEF-G 1)		±1.61	
	Isoform 1 of NTPase KAP family P-loop domain-containing protein 1 (NKPD1)		±1.94	
REDOX	Superoxide dismutase [Mn], mitochondrial precursor (SOD2)	±3.12		±3.52
	Peroxiredoxin 3 (PRDX3)			±1.56
Cell structure and motility	Vimentin (VIM)	±3.53		±3.44
	Poliovirus receptor-related protein 1 [Precursor] (PVRL1)	±2.26		±2.57
	Bullous pemphigoid antigen 1, isoforms 6/9/10 (DST)	±3.05		±2.74
	Centrosomal protein of 170 kDa (CEP170)	±3.05		±2.74
	MYH9	±2.67		
	MYH11	±3.52		
	ACTB Actin	±4.44	±2.14	
	ACTA2 Actin	±3.52	±2.72	
Signaling	Probable G-protein coupled receptor 81 (GPR81)	±3.52		
	Receptor expression-enhancing protein 2 (REEP2)		±2.14	±2.69
	CDNA FLJ12595 fis, clone NT2RM4001344 (FLJ12595)			±3.52
Other	Embigin precursor (EMB)	±3.05	±2.14	±2.74
	B2M Beta-2-microglobulin (β2M)	±3.05	±2.14	±2.74
Unknown	Noelin-2 precursor (OLFM2)	±3.28		±3.44
	CDNA FLJ41134 fis, clone BRACE2 (Q6ZWG4)	±3.52		
	CDNA FLJ25713 fis, clone TST05089		±2.14	
	Homo sapiens cDNA clone IMAGE:4663196 5', mRNA sequence		±2.49	
	Eukaryotic translation initiation factor 4E family member 1B (EIF4E1B)			±3.52
	CDNA FLJ25713 fis, clone TST05089			±2.69

Additionally, several proteins which had been reported to be associated with chemo- or radio-resistance such as HSPA9, PHB, ABCB6, and ATAD3B have also showed significant alterations in their abundance. *Conclusions.* This study examined different responses of mitochondrial proteome exposed to ADR and radiation respectively. Raji cells treated by ADR seemed to be undergoing more intensive stress than radiation-treated group, which indicating more effective anti-tumor outcome. Our finding suggested that proteins such as HSPA9, PHB, ABCB6, and ATAD3B should be investigated in more details to reverse the chemo- or radio-resistance as promising biomarkers in NHL treatment.

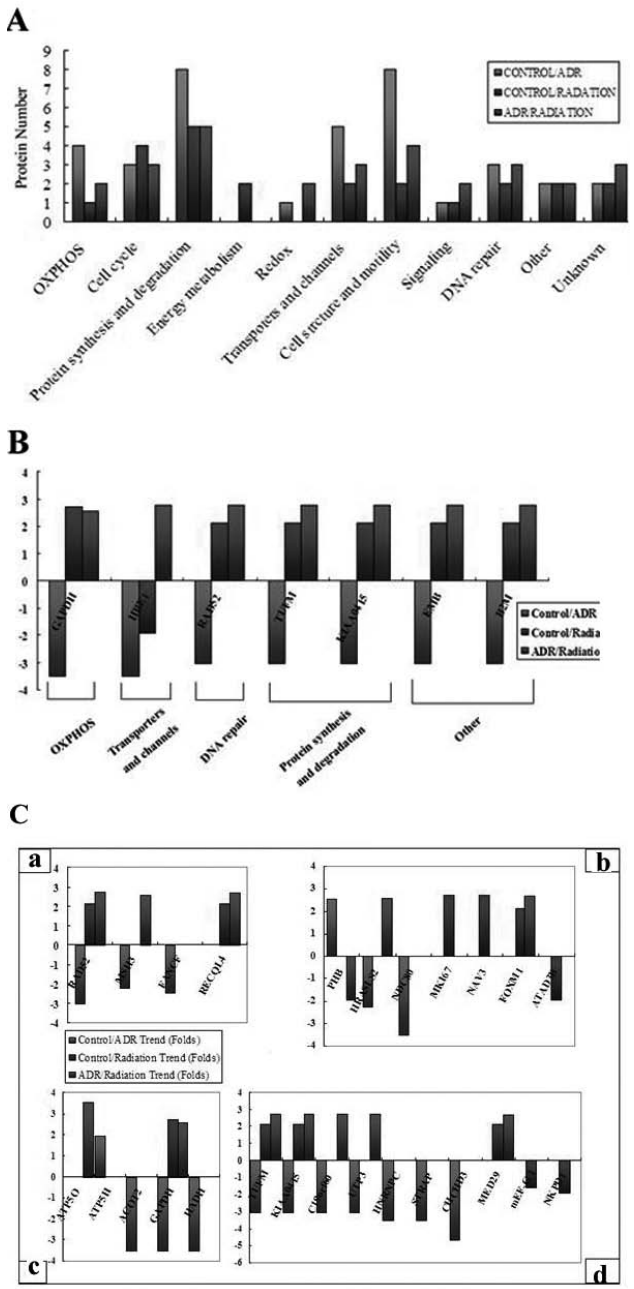

Figure 1. A. Identified proteins from three groups of Raji cells (control, ADR-treated, and radiation-treated) were categorized according to their functions. Differentially expressed mitochondrial proteins distributed their functions in OXPHOS, cell cycle, redox, protein synthesis and degradation, DNA repair, transporters and channels, ect. B. Seven proteins were common in three conditions, distributing their functions in OXPHOS, DNA repair, transporters and channels, proteins synthesis and degradation, etc. C. Mitochondrial proteins identified which involved in functions associated with apoptosis and DNA repair. a: proteins involved in DNA repair; b: proteins involved in cell cycle; c: proteins involved in OXPHOS; d: proteins involved in proteins synthesis and degradation.

0028

COMPARATIVE PROTEOMIC PROFILING OF SUBTYPE M1 AND M2 OF ACUTE MYELOID LEUKEMIA BY TWO-DIMENSIONAL ELECTROPHORESIS AND MASS SPECTROMETRY

M. Luczak,[1] M. Kazmierczak,[2] L. Handschuh,[3] K. Lewandowski,[2] M. Komarnicki,[2] M. Figlerowicz[3]

[1]Polish Academy of Sciences, POZNAN; [2]Department of Haematology, Poznan University of Medical Sciences, POZNAN; [3]Institute of Bioorganic Chemistry, Polish Academy of Sciences, POZNAN, Poland

Background. Proteomic analysis of blastic cells of acute myeloid leukemia (AML) may help to distinguish different morphological/cytogenetic/molecular forms of the disease. The results of this analysis may also give a valuable information concerning prognosis and potential therapeutic targets in AML patients. This problem has not been evaluated thoroughly so far. Therefore, in order to identify new biomarkers associated with AML, a method for comparative proteomic analysis of mononuclear cells was elaborated. *Aims*. The aim of the study was to create proteomic maps of bone marrow and peripheral blood mononuclear cells of M1 and M2 subtype of AML. *Methods.* Twelve patients with AML-M1 and eleven with M2 diagnosed according to FAB classification, after obtaining the informed consent, were included into this study. Mononuclear cells were obtained from bone marrow and peripheral blood in three time points: at diagnosis, after induction polychemotherapy (daunorubicin 3, Ara-C 7 days) when the complete remission was achieved or not, and at the time of possible relapse. A traditional proteomic approach based on two-dimensional electrophoresis (2DE) and MALDI-TOF mass spectrometry was used. *Results.* Until now, we have identified 185 proteins among around 653 protein spots on 2DE gels. All the identified proteins have been classified (based on their function or sub-cellular localization) into the following groups: enzymes, structural proteins, gene regulation proteins, signaling proteins, cellular defense and stress related proteins, extracellular proteins, heat-shock proteins and chaperones, protein involved in protein processing, membrane proteins, nuclear proteins and miscellaneous proteins. Among the identified proteins, 12 displayed qualitative or quantitative differences in the accumulation pattern between particular patients with AML. Only protein spots that showed at least 1,5-fold increase or reduction in abundance were selected. We found that the best markers are: annexin III, 6-phosphogluconate dehydrogenase and vesicle amine transport protein 1 (Vat1 protein), which were almost exclusively present in M2 samples. Concentration of these proteins was below 2DE detection level in almost all M1 patients. Annexin III was found in all M2 and in two M1 samples (but in the latter relative concentration of this protein was very low). L-plastin was detected in all M1 and M2 samples, but in seven M2 patients we also detected its second isoform. Peroxiredoxin 6 and catalase were also increased in the M2 in comparison to M1 samples but differences were not so obvious. Several other proteins, e.g. purine nucleoside phosphorylase, peroxiredoxin 2 and vimentin also exhibited various accumulation in particular samples, but the observed changes did not correlate with FAB AML subtypes. Independently form FAB subtype, a visibly higher accumulation of annexin I was noted in remission state in comparison to patients resistant to the treatment applied. Interestingly, a higher accumulation of actin-χ 1 in patients who relapsed was also observed. *Summary and conclusions.* The traditional proteomic approach allowed to find marker proteins which distinguish between AML-M1 and M2 subtype. In our opinion some of them also seem to be useful in prediction of polychemotherapy resistance.

0029

THE ROLE OF TNF MICROSATELLITE POLYMORPHISMS IN SURVIVAL OF PATIENTS AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION

K. Stingl, R. Zunec, B. Labar, R. Serventi-Seiwerth, Z. Grubic

University Hospital Centre Zagreb, ZAGREB, Croatia

Background. The conditioning regimens performed prior to the hematopoietic stem cell transplantation (HSCT) are responsible for the release of proinflammatory cytokines such as TNFα. A correlation between TNFα serum levels and occurrence of post-transplantation complications such as acute GvHD has been reported. Previous studies have found an association between TNFα production and TNF microsatellite polymorphisms. *Aims.* The purpose of the present study was to investigate a possible influence of TNFα, TNFβ and TNFδ microsatellites on the outcome of HSCT. *Methods.* One hundred patients who underwent HSCT were included in the analysis of TNFα, TNFβ and TNFδ microsatellites. All of them received transplant from a sibling identical for HLA-A, -B, and -DRB1 loci. The microsatellite analysis was performed using PCR amplification with fluorescently labeled primers followed by electrophoresis on a 6% polyacrylamide gel in an automated sequencer (ALFexpress, Amersham Pharmacia, Uppsala, Sweden). *Results.* The distribution of alleles at the tested TNF microsatellites among the patients did not differ from the results obtained for healthy individuals previously tested, with the exception of an increased frequency of TNFα8 and TNFδ3 alleles among patients. This difference was statistically significant only before correction. Patients were then analysed with respect to their survival and presence of an individual allele. The only significant difference in the survival rates was found for TNFα microsatelite alleles. The presence of TNFα8 allele was associated with worse survival (p<0.01) while TNFa10 allele showed a correlation with better prognosis (p=0.03). However, the difference observed for TNFα10 allele was significant only before correction. *Summary*. The results suggest an association of TNFα8 allele with a worse outcome of HSCT. However, since this is an allele which is found rarely both among healthy individuals and patients, the value of this finding should be confirmed with a study including a larger number of subjects.

SET-NUP214 EXPRESSION REQUIRES ALTERNATIVE SPLICING

H. Quentmeier, B. Schneider, S. Röhrs, J. Romani, M. Zaborski, R.A.F. MacLeod, H.G. Drexler

DSMZ - German Collection of Microorganisms and Cell Cultures, BRAUNSCHWEIG, Germany

Background. The SET-NUP214 (TAF-1/CAN) gene fusion has been described as result of a chromosomal translocation t(9;9)(q34;q34) in a case of acute undifferentiated leukemia and more recently as result of recurrent cryptic deletion del(9)(q34.11q34.13) in T-acute lymphoblastic leukemia (T-ALL). The fusion protein appears to be involved in high-level expression of HOXA cluster genes in T-ALL and may contribute to the pathogenesis of the disease. *Aims.* Immortalized cell lines have often been used to elucidate the function of aberrantly expressed or mutated genes. We screened a panel of 141 leukemia/lymphoma cell lines to find cellular systems for SET-NUP214 research. *Methods.* RT-PCR analysis was performed to find SET-NUP214 - positive cell lines. Deletion del(9)(q23.11q34.13) was confirmed by fluorescence in situ hybridization (FISH) analysis with tilepath BAC and fosmid clones, array-based copy number analyses and quantitative genomic PCR. Genomic PCR plus sequencing analysis allowed detecting genomic SET and NUP214 breakpoints. Western blot analyses were performed to verify SET-NUP214 protein expression. *Results.* The T-ALL cell line LOUCY and the megakaryocytic leukemia cell line MEGAL expressed the SET(TAF-I β)-NUP214 fusion gene transcript and the TAF-I α -NUP214 splice variant. Results of FISH, array-based copy number analysis and quantitative genomic PCR were consistent with del(9)(q34.11q34.13). Genomic sequencing localized the breakpoints of the SET gene to regions downstream of the stop codon and to NUP214 intron 17/18 in both LOUCY and MEGAL cells. Expression of a SET exon 7 / NUP214 exon 18 fusion mRNA and the 140 kDa SET-NUP214 fusion protein was found in both cell lines. *Summary and Conclusions.* Cell lines LOUCY and MEGAL express the recently described SET-NUP214 fusion gene. Formation of the SET exon 7 / NUP214 exon 18 gene transcript requires alternative splicing as the SET breakpoint is located downstream of the stop codon in exon 8.

0031

THE UNUSUAL MLL REARRANGEMENT IN ACUTE MYELOID LEUKEMIA

I. Sarova,[1] J. Brezinova,[1] L. Lizcova,[2] Z. Zemanova,[2] O. Fuchs,[1] A. Kostecka,[1] D. Provaznikova,[1] J. Filkukova,[1] J. Maaloufova,[1] K. Michalova[1]

[1]Institute of Hematology and Blood Transfusion, PRAGUE;[2] General Teaching Hospital and [1] st Faculty of Medicine of Charles University, PRAGUE, Czech Republic

Background. Aberrations of the MLL gene (myeloid/lymphoid leukemia) located on chromosome band 11q23 are of great interest because of their high variability and association with unfavorable prognosis. One mechanism of interrupting the MLL gene is a partial tandem duplication (PTD). The MLL PTD has been described in about 6 - 10 % of adult patients with acute myeloid leukemia (AML) with normal karyotype and in most cases with trisomy 11 as a sole cytogenetic abnormality. In rare cases, the duplication is nontandem (PNTD) due to insertion of DNA from another chromosome. The MLL PNTD is generated as a consequence of multiple recombination events and can simulate a simple translocation. *Aim.* Presentation of an unusual and rare MLL rearrangement identified by cytogenetic and molecular methods. *Methods.* Bone marrow cells of all patients with diagnosis of AML were examined by conventional cytogenetics and FISH with a commercially available MLL Break Apart Rearrangement probe. Further investigations of the karyotype changes were performed by FISH with commercially available probes and/or by multicolor FISH and/or mBAND. At the molecular level, the MLL PNTD was analysed by RT-PCR and DNA sequencing. *Results.* During the years 2003-2008, we examined 171 patients at the time of diagnosis of AML and MLL PNTD was found in four cases (2,3%). In patient 1, the translocation t(10;11)(p12;q23) and the MLL PNTD including exons 2 through 9 with the insertion of the MLLT10 exon 10 was proved. In patient 2, the reciprocal complex translocation t(9;12;11)(p22;p13;q23) and the MLL duplication of exons 2 through 8 with the insertion of the MLLT3 exon 9 and 10 was identified. In patient 3, the translocation t(11;19)(q23;p13) and the MLL PNTD including exons 2 through 8 with cryptic insertion of MLLT1 exons 2 and 3 was detected. Complex aberrations 46,XY,der(11)del(11)(q13q23.3) ins(10;11)(p12;q23.3q23.1) were identified in patient 4. The MLL PNTD included exons 2 through 9 and the insertion of the exon 10 of the MLLT10 gene. *Conclusions.* The formation of new fusion genes is an important event in leukemogenesis. Many different processes leading to a MLL fusion have been described, however mechanisms triggering the formation of MLL PNTD remain unclear. The systematic and careful detection of the MLL gene aberrations in patients with hematological malignancies are extremely important due to its correlation with poor prognosis and aggressive progression of the disease.

COMPLEX CHROMOSOMAL ABERRATIONS IN BONE MARROW CELLS OF 86 PATIENTS WITH MYELODYSPLASTIC SYNDROMES (MDS)

Z. Zemanova,[1] K. Michalova,[1] J. Brezinova,[2] L. Lizcova,[1] S. Izakova,[2] D. Bystricka,[1] I. Sarova,[2] M. Siskova,[3] R. Neuwirtova,[3] O. Cerna,[4] J. Cermak[2]

[1]General Teaching Hospital and First Faculty of Medicine, Charles University, PRAGUE [2];[2]Institute of Hematology and Blood Transfusion, PRAGUE;[3]1st Medical Department, General Teaching Hospital, PRAGUE;[4]Department of Clinical Hematology, Faculty Hospital Kralovske Vinohrady, PRAGUE, Czech Republic

Karyotype of bone marrow cells represents one of the most valuable prognostic marker for MDS patients with profound impact on diagnosis and therapeutic decisions. Specific and recurrent aberations are delineated for diagnostic subgroups. In 10-20% of MDS patients complex chromosomal aberrations (CCA) can be found and precise identifications of chromosomal regions involved in CCA could yield detection of cryptic, recurrent, prognostically relevant aberrations and identification of candidate genes involved specially in progression of the disease. The aim of this study was to evaluate significance of specific chromosomes and/or chromosomal regions involved in CCA and to establish the exact localization and frequency of chromosomal breakpoints. Various modifications of molecular cytogenetic techniques were used for detailed analysis of CCA: FISH, mFISH/mBAND, CGH and/or array CGH. During 2002-2008 we examined bone marrow samples of 680 adults with MDS and in 96 of them (14.1%) CCA were found (in 86 patients at dg and in 10 cases during the disease progression). Out of 86 patients with

CCA at dg primary MDS was diagnosed in 74 (86.0%) of them, in 12 cases therapy related MDS was ascertained. Dg according to the WHO classifications: MDS NS 6x, RA 2x, RA/RCMD 6x, RCMD 7x, RAEB I 22x, RAEB II 23x, MDS-AML 19x and RARS 1x. Deletion of 5q31 region was proved in 75 patients (87.2%). In 35 cases mFISH analyses showed that parts of deleted No.5 were translocated into other chromosomes. The most recurrent partners of deleted No.5 in unbalanced translocations were chromosomes 17 (11x), 3 (6x), 7 (5x) and 12 (5x). Monosomy of No.5 was confirmed in one case only, thus proving that monosomy 5 is not separated diagnostic entity in MDS patients with CCA. The most frequent breakpoints on chromosome 5 were 5q33 (31x), 5q13 (25x), 5q14 (7x) and 5q12 (5x). Except No. 5 the most frequently involved in CCA were chromosomes 7 (37x), 3 (33x), 12 (31x), 17 (31x) and 11 (24x), the most recurrent breakpoints were at regions 7p11 (6x), 7q11 (6x) and 12p11 (7x). Presence of CCA at diagnosis were connected with poor response to the therapy and short overall survival. For survival analysis patients were classified into three groups according to the molecular cytogenetic findings: (1) del(5)(q) and additional CCA - 39 cases, (2) deleted chromosome 5 involved in CCA - 35 cases, (3) CCA without deletion of 5q - 12 cases. The shortest overall survival was found in group 2 (median 3 months), followed by group 1 (median 5 months) and 3 (median 9 months). Patients with MDS and CCA should be considered as a unique entity with extremely poor prognosis. Exact molecular cytogenetic analysis of all chromosomal aberrations which are involved in CCA will lead to redistribution of the patients into new prognostic groups, could improve the therapeutic outcome and contribute to the development of a new targeted treatment strategy.

INTER-LABORATORY PERFORMANCE EVALUATION OF A NEW RQ-PCR ASSAY AIMED AT MEASURING RESPONSE TO TREATMENT IN CHRONIC PHASE CML PATIENTS

F. Hermitte,[1] J.R. Cook,[2] J. Howell,[3] K. Lyon,[2] S. Turcan,[1] V. Frayssinet,[1] N. Maroc,[1] R.R. Tubbs,[2] A. Ferreira-Gonzalez[3]

[1]Ipsogen, MARSEILLE, France; [2]CCF, CLEVELAND; [3]VCU, RICHMOND, USA

Background. Real-time quantitative PCR (RQ-PCR) measurement of BCR-ABL transcripts in blood has been proven to be a reliable alternative to bone marrow cytogenetics and is now used as in daily practice for monitoring of patients with Chronic Myeloid Leukemia (CML). Analysis of BCR-ABL transcript levels by RQ-PCR reflects the level of leukemic inhibition induced by therapy and provides a highly sensitive method to determine minimal residual disease (MRD). However, differences in RQ-PCR techniques (including choice of the control gene, calibration method and primers and probe design) lead to significant variability in BCR-ABL reported values (Zhang *et al.* JMD 2007, Branford *et al.* Leukemia 2006). Considering the influence BCR-ABL quantification can have on treatment decisions, a higher degree of standardization is required to allow consistent measures of drug response. *Aim.* This study aimed at evaluating inter-laboratory analytical performance of a new assay named *BCR-ABL Mbcr FusionQuant® Ez*. This assay was developed as an aid to evaluate major and complete cytogenetic responses in CML patients. The kit incorporates all reagents and enzymes required to run the RQ-PCR test, in an attempt to improve robustness of BCR-ABL quantification. *Methods.* Three study sites contributed to this evaluation, and analyzed the same 50 anonymous and blinded blood samples, containing different spiked levels of BCR-ABL positive cells. RNA extractions and BCR-ABL RQ-PCR measurements were performed according to the kit package insert on a Roche Light Cycler 1.2. BCR-ABL results were reported as Normalized Copy Number ratios (NCN=CNBCR-ABL/CNABLx100). *Results.* One hundred and thirty eight samples gave interpretable NCN values from the 150 samples (i.e. 92%). No statistically significant impact of the testing laboratory was found. Agreement between Cleveland and Ipsogen was calculated on 44 common interpretable samples, on 42 between Richmond and Ipsogen, and on 40 between Richmond and Cleveland. Taking Ipsogen NCN values as reference, 95.5% of Cleveland and 88.1% of Richmond NCN values were comprised in a 2-fold interval, and 100% within 5-fold. For Major Cytogenetic response (MCyR, threshold=8.89 NCN) all samples were found to be concordant between the 3 testing sites, corresponding to a Kappa coefficient of 1. Only one sample was found to be discordant between Ipsogen and Cleveland regarding Complete Cytogenetic response (CCyR, threshold=0.87 NCN). The same sample was also discordant between Ipsogen and Richmond. As a result, for CCyR, overall percent agreement between Cleveland and Ipsogen was found to be 97.7%, 97.6% between Richmond and Ipsogen and 100% between Richmond and Cleveland. Inter-laboratory agreement was equal to 0.962 (Kappa). *Summary and conclusions.* Overall, inter-laboratory agreement was perfect for MCyR (Kappa=1), and almost perfect for CCyR (Kappa=0.962). No discordant sample was identified between the 2 external laboratories. Therefore, our assumption that a significant proportion of inter-laboratory variability in BCR-ABL NCN reporting is related to the lack of standardization of test procedures is supported by this study using a kit including all reagents needed to run the experiment from patient's RNA. The increased robustness obtained with this kit should ultimately benefit the patients and allow for optimized treatment decisions.

0034

HIGH RESOLUTION MELTING ANALYSIS FOR THE RAPID DETECTION OF C-KIT MUTATIONS IN CORE BINDING FACTOR-ACUTE MYELOID LEUKEMIA

O. Fuster,[1] E. Barragan,[1] P. Bolufer,[1] J. Cervera,[1] M.J. Larrayoz,[2] A. Jimenez,[3] J. Martínez,[4] A. Valencia,[1] F. Moscardó,[1] M.A. Sanz[1]

[1]Hospital La Fe, VALENCIA; [2]Universidad de Navarra, PAMPLONA; [3]Hospital Carlos Haya, MÁLAGA; [4]Hospital 12 de Octubre, MADRID, Spain

Background. c-KIT gene encodes a transmembrane glycoprotein receptor that is member of the type III receptor tyrosine kinases family implicated in cell proliferation, differentiation and survival. Activation of c-KIT receptor may be achieved by gain-of-function mutations predominantly located within exon 8 and 17 and have been reported to occur preferentially in acute myeloid leukemias (AML) with CBF rearrangements [t(8;21) or inv(16)/t(16;16)]. *Aims.* We report the results obtained in a group of CBF AML patients by using a high resolution melting (HRM) method for simultaneous screening of exon 8 and 17 c-KIT mutations. *Methods.* The study included 69 CBF AML patients, 55 adults [30 with t(8;21) and 25 with inv(16)] and 14 children [8 with t(8;21) and 6 with inv(16)]. c-KIT mutations study was performed on genomic DNA extracted from bone marrow samples collected during active disease (diagnosis and relapse). The HRM assays were performed in duplicate using the LightCycler® 480 Instrument (Roche). Two DNA normal controls and one positive mutated DNA sample for each exon were included in each run. Thirty ng of DNA were amplified in 10 µL final volume containing 1x LightCycler®480 High Resolution Melting Master (Roche), 0.5 µmol/L of each primer-pair and 2.0 mM MgCl2 for exon 8 or 0.2 µmol/L of each primer-pair and 3 mM MgCl2 for exon 17. Results were analyzed as fluorescence versus temperature graphs using the Gene Scanning Software Version 1.5.0 (Roche). Differences in melting curve shape showed by the difference plot helps clustering the samples into groups. *Results.* Among 69 samples screened for the presence of c-KIT mutations, four samples in exon 8 and eight samples in exon 17 showed a clearly distinctive shape of the difference curve plot compared with those of the wild-type DNA. Direct sequencing confirmed presence of c-KIT mutations in 11 out of 69 (15.9%) AML patients (one infant and 10 adults). Mutations corresponded to insertion/deletions in exon 8 in three patients, point mutations in exon 17 in seven patients, and one who presented mutations in both exons (Table 1).

Table 1. Karyotype *c-KIT* mutations found exons 8 and 17.

Exon	Patient	Cytogenetics	Nucleotide change	Mutation description

	23530	t(8;21)	aat→aag	p.N822K

No false positive or negative results were found and the assay sensi-

tivity achieved for both exons detected mutations up to dilution 1:100 of a positive DNA sample for exon 8 and exon 17 in wild-type DNA. c-KIT mutations were statistically associated with high white blood cell count (WBC) (p=0.012) and prognostic value analyzed in adult patients showed a significantly reduced relapse free survival (p=0.04) for patients with c-KIT exon 17 mutations. *Conclusions.* HRM is a rapid, sensitive, specific and low cost method for the screening of exons 8 and 17 c-KIT mutations.The incidence of c-KIT mutations was 15.9% in CBF- AML patients (one infant and 10 adults). Exon 17 mutations seems to confer an unfavourable prognosis to these patients.

ANALYSIS OF ACTIVATION INDUCED CYTIDINE DEAMINASE MRNA AS PREDICTOR OF DISEASE PROGRESSION AND RESPONSE TO THERAPY IN B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA

H. ElAggan

Medical Research institute, ALEXANDRIA, Egypt

Background. B-cell chronic lymphocytic leukemia (CLL) is a clinically heterogeneous disease. Some patients exhibit a stable, indolent disease and survive for many years without requiring any therapy, while other show rapidly progressive disease and die within months. Recently, some new prognostic factors, such as IgVH mutational status, 2AP-70 and Activation Induced Cytidine Deaminase (AID) mRNA expression were introduced to identify indolent versus progressive types of CLL bearing the potential to facilitate risk-adapted treatment strategies. *Aims.*The study was performed to evaluate the clinical value of AID mRNA expression as predictor of disease progression in early stages and response to therapy in later stages of CLL. *Methods.* The study included 42 B-CLL patients. They were divided into 2 main groups; group 1 patients (N=15) did not exhibit an indication to start antileukemic therapy at presentation, while group 11 patients (N=27) were indicated to receive antileukemic therapy. Group 11 patient were further subdivided into 2 subgroups according to the treatment protocol they received. Group 11 A patients (N=13) received fludarabine and cyclophosphamide (FC protocol), while group 11B patients received chlorambucil with or without prednisolone.An informed consent was obtained from the patients. Investigations were done to all patients including complete blood count, bone marrow examination, ESR, LDH, B2M, liver and kidney function tests. Immunophenotyping of leukemic cells and assessment of AID mRNA expression by quantitative real time PCR (QRT-PCR). *Results.* Higher expression of AID was associated with need for treatment. A cut-off value of AID expression of 5 units was introduced using youden's index for prediction of need for treatment with 83% sensitivity and 67% specificity. A shorter treatment free survival was associated with high AID expression. In groups IIA and IIB patients, AID expression showed an association with the type of response to antileukemic treatment, being higher in those not achieving complete remission or non-responding to treatment. Moreover, a cut-off value of AID expression of 4000 units was introduced for prediction of treatment refractoriness in patients who received chlorambucil with 80% sensitivity and 89% specificity. *Summary and Conclusions.* AID could be used to predict early disease progression and its ability to predict responsiveness to anti-leukemic treatment in CLL cases. Real time-PCR is a rapid and sensitive method for evaluating AID expression.

CONSTITUTIONAL RUNX1 DELETION IN NON-SYNDROMIC THROMBOCYTOPENIA; 21Q22 ITSN1 AS A CANDICATE GENE IN MENTAL RETARDATION

A. Buijs

University Medical Center Utrecht, UTRECHT, Netherlands

We present a developmentally normal patient with isolated thrombocytopenia and myelodysplastic features associated with a constitutional submicroscopic 21q22 deletion (including RUNX1). In contrast, four cases were recently published of syndromic thrombocytopenia with 21q22 deletions and variable degrees of dysmorphic features and mental retardation (MR), suggesting a dosage-sensitive causative role of gene(s) on 21q22 in MR. One patient had developed myelodysplastic syndrome/acute myeloid leukemia (MDS/AML) at the age of six years. A 5-year-old boy was referred with a history of frequent haematoma caused by a relatively mild thrombocytopenia. Growth and psychomotor development was normal as well as dysmorphologic evaluation. Bone marrow (BM) revealed an active, atypical megakaryopoiesis with slight dysplastic features. G-banding on BM showed a 46,XY karyotype. FISH analyses demonstrated two constitutional microdeletions of one chromosome 21; a 21q22 interstitial deletion with loss of RUNX1 and a terminal 21q deletion. High-resolution oligo array-CGH (105K Agilent) showed a 1.60 Mb interstitional deletion 21q22.11-12, including RUNX1, and a 2.22 Mb terminal 21q22.3 deletion. Several genes at 21q22.12 have been proposed as candidate genes to contribute to MR in syndromic thrombocytopenia. We compared the genotypes and phenotypes of the published cases with our case. This approach pointed to an association with MR of a minimally deleted region of 0.4 Mb containing the ITSN1. ITSN1 is a scaffold protein and has a role in endocytic vesicle trafficking in neurons. It has been implicated in Alzheimer's disease and Down syndrome, and could play a role in MR in these patients as a dosage-sensitive gene. We hypothesize that haploinsuffiency of ITSN1 is implicated in MR in syndromic thrombocytopenia with 21q22 deletions. Our case emphasizes the necessity of cytogenetic and molecular analyses of 21q22 for RUNX1 status in diagnosing patients with isolated or syndromic thrombocytopenia and supports RUNX1 haploinsufficiency in FPD/AML.

DETECTION OF NUMERICAL CHROMOSOME ABERRATIONS IN RARE ACUTE MYELOID LEUKEMIA (AML) CELLS

H. Minderman,[1] J.C. Arcadi,[1] A. Wierzbicki,[1] E.S. Wang,[1] S.N.J. Sait,[1] A.W. Block,[1] L. Liang,[2] T. George,[2] P.K. Wallace[1]

[1]*Roswell Park Cancer Institute, BUFFALO;* [2]*Amnis Corporation, SEATTLE, USA*

Background. Chromosomal aberrations, detected by karyotyping and fluorescent in situ hybridization (FISH), have high clinical significance for the diagnosis and treatment of leukemias, but the detection limits of the cytogenetic techniques are strongly affected by the abundance of the abnormal cells in a sample. Structural aberrations can alternatively be detected with high sensitivity by PCR but this technique lacks the component of visual verification (specificity) and in rare event cases of numerical aberrations, it is not applicable. The ImageStream system is a flow cytometry-based image analysis platform that produces high resolution images of cells prepared in suspension at rates that can exceed 100 cells per second. In order to adapt this technology for chromosome analysis a method was established to perform FISH in suspension (FISH-IS) and an extended depth of focus (EDF) modification was designed to enable detection and enumeration of FISH signals that lie anywhere within a 16 µm range of depth within the cell. *Aims.*The present study aims to demonstrate applicability of FISH-IS for detecting numerical chromosome aberrations and to establish specificity and sensitivity of detection. Additionally, its clinical application is demonstrated in the analysis of samples of patients with +8 AML. *Methods.* Healthy donor peripheral blood samples hybridized with chromosome enumeration probes (CEP) served as model systems of disomy (♀, CEP-X), monosomy (♂, CEP-X) and trisomy (♂, CEP-8 + CEP-Y). FISH-IS analysis was also performed on cryopreserved samples procured at diagnosis and remission from 12 patients previously diagnosed by conventional cytogenetics with +8 AML. *Results.* By titrating healthy donor male cells into female cell populations before hybridization, the sensitivity of detection in these controlled models of monosomies and trisomies was determined to be at least 1% with 100% specificity (analyzing 10.000 cells/sample). For the diagnostic AML samples, +8 was detected in abun-

dance by both conventional FISH (c-FISH) and FISH-IS but the % trisomies detected by c-FISH was generally higher than detected by FISH-IS. For the AML remission samples, the opposite was true. Whereas the % +8 in all remission samples was below the detection limit of c-FISH, the % +8 detected by FISH-IS was generally higher. Of note, for 8/12 patients, relapse samples were available for which 2 were determined to have relapsed with +8 by c-FISH which correlated with the 2 highest +8 scores determined by FISH-IS in the corresponding remission samples. *Summary and Conclusions.* It is important to consider that some of the discrepancies between the c-FISH and FISH-IS results may be due to the analysis of samples obtained in parallel rather than analysis of the exact same sample. The pre-clinical data demonstrate that FISH-IS detects numerical chromosome aberrations with a higher sensitivity and specificity level than conventional cytogenetic analyses. The preliminary clinical data suggest that FISH-IS can be used to detect numerical chromosome aberration in minimal residual disease in AML. Further studies are underway to verify the suggested observed correlation between +8 detected at remission and relapse.

A RAPID, SENSITIVE AND SPECIFIC REAL-TIME POLYMERASE CHAIN REACTION ASSAY FOR QUANTIFICATION OF THE JAK2V617F ALLELE BURDEN

B. Denys,[1] H. El Housni,[2] F. Nollet,[3] B. Verhasselt,[1] J. Philippé[1]

[1]Ghent University Hospital, GENT; [2]Université Libre de Bruxelles, BRUSSELS; [3]AZ Sint-Jan Brugge-Oostende, BRUGES, Belgium

Background. The JAK2V617F mutation has emerged as an essential molecular determinant of chronic myeloproliferative disorders (CMPDs), occurring in >95% of polycythemia vera, and >50% of essential thrombocytosis or idiopathic myelofibrosis patients. A correlation between the proportion of mutant JAK2 allele and the propensity to a more symptomatic disease has been described. Moreover, JAK2V617F targeted therapy is expected to become available in the near future. Therefore, sensitive and specific quantification of the mutant allele is needed. However, most of the current assays are hampered by false positive results due to aspecific amplification. *Aim.* To evaluate the analytical and clinical performances of a real-time polymerase chain reaction (qPCR) assay using a combination of hydrolysis probes and a wild-type blocking oligonucleotide, all containing locked nucleic acids (LNA) for sensitive and specific detection of the JAK2V617F mutation. Moreover, we validated a procedure for precise quantification of the JAK2V617F allele burden. *Materials.* We used 116 DNA samples from patients suspected to suffer from a CMPD and dilutions of HEL cells known to carry the mutation to compare the LNA-based qPCR to those obtained by two previously published and well established methods: a qPCR[1] and an allele specific PCR.[2] In order to validate the accuracy of the LNA-based qPCR, 77 randomly selected samples were genotyped for the JAK2V617F mutation using conventional sequencing. In addition, 20 normal donor peripheral blood samples were analysed. *Results.* All assays detected the same 36 JAK2V617F positive patients out of 116 suspected CMPD diagnostic samples. In contrast to the other qPCR test[1], no amplification in normal donor DNA was observed in LNA-based qPCR, proving the specificity of the assay. Moreover, the latter was the sole assay able to detect as few as 0.1% of JAK2V617F allele drown into wild-type alleles. Low intra- and inter-assay variabilities with high efficiency of amplification ensure a good reproducibility of the LNA-based qPCR assay. Finally, quantification of the JAK2V617F allele burden showed similar levels among each of the different CMPD entities as described by other groups. *Conclusions.* The LNA-based qPCR is a rapid, robust, sensitive and highly specific assay for quantitative JAK2V617F determination. It can be easily implemented in clinical molecular diagnostic laboratories. Moreover, precise quantification allows determination of JAK2V617F burden at diagnosis as well as the evaluation of the response to novel JAK2 inhibitors.

Background. The myelodysplastic syndromes (MDS) are a heterogeneous group of hematopoietic malignancies, characterized by cytopenias in at least one lineage of peripheral blood cells, ineffective hematopoiesis and hypercellular bone marrow. Gene expression profiling in MDS using microarray technology has demonstrated that several genes are useful for subtype discrimination, assessment of prognosis and distinguish *de novo* AML with myelodysplasia from MDS-associated leukemia. *Objective*. Reproduce these results using low density arrays. *Patients and Methods*. Sixty-nine patients with MDS were studied (18 RCMD, 2 RA, 16 RAEB, 3 RARS, 3 MDS with hipoplasia, 14 AML with myelodysplasia, 8 CMML and 4 MDS associated with isolated del(5q)). Bone marrow samples were obtained by aspiration at the time of initial diagnosis. Cells were obtained after hypotonic lysis of erythrocytes, washed in PBS, labeled using MACS $CD34^+$ MicroBeads and selected with miniMACS magnetic cell separation columns according to the manufacturer's instructions. Purity of the selected $CD34^+$ cells was evaluated by flow citometry. Total RNA was extracted from these samples and one microgram was converted to cDNA by reverse-transcription using random primers. Sixty-one genes among those proposed in the different microarray studies and 3 endogenous genes were selected and a quantitative low density array (Micro fluidic card, MFC) was performed. Lineal models were used to detect differences in the expression profiles of genes in logarithmic scale from MFC (cytological and cytogenetic groups as categorical variables and prognosis score as an ordinal one). Observed p-values were then compared to their expected distribution assuming lack of association in a QQ-plot. Genes with a high deviation from the expected distribution were considered as significant. *Results.* Several genes were found to be significantly expressed according to: 1) Cytological subgroups: in MDS associated with isolated del(5q) PF4, DCK, MAP3K12, DYNLL1 and RB1CC1 genes were overexpressed. In AML with dysplasia PF4 was underexpressed and DCK was overexpressed. In RAEB RAC1 was underexpressed; 2) cytogenetic abnormalities: In patients with del(5q) PF4, MAP3K12 and DYNLL1 genes were overexpressed; 3) prognostic score (IPSS): PF4 expression decreased from better to poor prognosis. ITPR1 expression increased from better to poor prognosis; 4) any gene allowed us to differentiate MDS-associated leukaemia from *de novo* AML with myelodysplasia. *Conclusions.* In MDS a significant correlation between the expression of some genes and cytological subgroups, cytogenetics abnormalities and prognosis score was found. We could not reproduce exactly the gene expression profiles described in the literature due to the low number of patients in some MDS subtypes. Granted: PI-05-1409, FIJC-P-EF-08 and RD06/0020/1056 from RETICS.

MOLECULAR CHARACTERISATION OF TRANSLOCATION (7;8) IN A CASE OF T-CELL LYMPHOBLASTIC LYMPHOMA

J. Augustyniak,[1] G.K. Przybylski,[2] P. Grabarczyk,[1] K. Dittmann,[1] R. Siebert,[2] S. Gesk,[2] K. A,mus,[1] G. Dölken,[1] C.A. Schmidt[1]

[1]University of Greifswald, GREIFSWALD, Germany; [2]Institute of Human Genetics, POZNAN, Poland

Background. The number of cytogenetically identified chromosomal translocations increases rapidly. The consecutively deregulated expression of genes or expression of neogenes is important for pathogenesis and development of malignant tumours in many instances. Unravelling these translocations precisely down to the molecular level may give therefore new insights in tumorigenesis. *Aims.* Precise molecular characterisation of chromosomal breakpoints in tumor samples and characterisation of affected genes is our goal. *Methods.* We here describe clarification of a leukaemia sample derived from a patient with T-cell-lym-

phoblastic lymphoma. Cytogenetically a split in FISH analysis within TRB was found. To localize the precise breakpoints of the chromosomal alteration in this case, FT-CGH (fine tiling comparative genomic hybridisation) was used. Observed imbalances were further examined using LM-nested-PCR (ligation-mediated nested PCR). In brief: sample and reference DNA is separately digested with six restriction enzymes (DraI, PvuII, EcoRV, StuI, SmaI, HindII) and adaptors are ligated. A pair of gene specific primers is designed at the border of deletion spots observed upon FT-CGH analysis. After first round PCR a nested PCR is performed using a gene specific primer and an adaptor primer. The expected germline product can be predicted using database and restriction sites. PCR-product with aberrant size upon gel analysis can be distinguished from germline PCR-products, are gel extracted and sequenced. Sequencing results reveals presence of translocations comparing the data with genomic databases. Presence of these alterations is confirmed with gene specific primers analyzing undigested DNA. *Results.* The FT-CGH analysis showed small deletion (about 2 kb) in J1 region of TRB (TRBJ1). Using libraries of restricted and ligated DNA nested PCR was performed with pair of primers gene specific and pair of adaptor primers. Upon gel electrophoresis of PCR products of DraI digested sample two bands were observed: an expected germline band about 4 kb and an atypical band of 2.6 kb size. The atypical band was cut out, extracted and sequenced. Sequencing revealed a translocation (7;8) with the breakpoints: 142,196,004 on chr.7 (TRBJ1-4 region) and 128,824,471 on chr.8 (telomeric of the c-Myc gene). The second break was localized at position 142,194,034 on chr.7 and 128,824,487 on chr.8. This translocation was confirmed on genomic DNA with gene specific primers. *Summary and Conclusions.* Using combination of both methods (FT-CGH and LM-PCR) in the case of lymphoblastic-T-cell-lymphoma we characterized for the first time exact breakpoints of translocation (7;8). Here known protooncogene c-Myc is transposed upstream of TRBJ1 region. The c-Myc protooncogene is known to be a partner gene for a translocation in Burkitt lymphoma with the varying immunoglobuline sites (as a V(D)J recombination mediated translocation). In Burkitt lymphoma this type of translocation causes overexpression of c-Myc. In our work we showed for the first time, that in T-cell-lymphoblastic lymphoma c-Myc is rearranged to the TRB gene, resembling the c-Myc-Ig rearrangement observed in B cell lymphomas.

0041

A BRANCHED DNA-BASED TECHNIQUE FOR DETECTION OF BCR-ABL GENE PRODUCTS

M. Yakicier,[1] T. Acun,[1] S. Dizlek,[2] A. Timuragaoglu[2]

[1]Bilkent University, ANKARA; [2]Akdeniz University, School of Medicine, ANTALYA, Turkey

Background. Genetic abnormalities especially translocations are probably the critical pathogenetic events in acute leukemias which lead to development and progression of disease. The specific genetic abnormalities can be used not only for diagnosis but also to determine the prognosis, therapy protocols and therapy response. BCR/ABL test for CML is one of the mostly used tests in molecular hematology laboratories in recent years. There are different techniques to display translocations but, both FISH and Q-RT-PCR have been widely used. Both of them are expensive, need special equipments and skilled technicians. Other than higher contamination risk, false positive and negative results are important defects of these tests. Therefore it has been necessary to develop new technique which is easy to standardize, cheaper, easier and does not need skilled technicians. *Aim*. Herein we used branched DNA (bDNA) technology for detection and quantification of BCR-ABL gene product with specific probes which has been used for diagnosis and quantification of viral nucleic acids. *Methods.* K562 (b3-a2) and MEG-01 (b2-a2) cell lines were used as positive controls, HepG2 (hepatic carcinoma cell line) was used as a negative control in order to determine the test conditions and sensitivity assessment. We also evaluated the presence of BCR-ABL gene product in blood samples of 22 CML patients by bDNA assay. The sensitivity and specificity of this approach were compared to Q-RT-PCR (lightCycler- Roche diagnostic corporation) results. The cell lines and 10 µL of whole blood from CML patients were lysed with lysing mixture, the cell samples were incubated with capture probes which can hybridize with BCR-ABL gene products and recognize two different fusion gene mRNA (b3-a2 and b2-a2). Unbound probes were removed by washing and again hybridized with label probes. Two additional washes used to remove unbounded material and substrate added to make the signal visible using a luminometer. Spesific probes for β-glucuronidase (GUSB) gene were used as a control probe to detect GUSB mRNA expression in three cell lines. *Results.* GUSB gene was expressed in all three cell lines and the expression level correlated well with cell count. BCR-ABL gene mRNA was also expressed in K562 and MEG-01 cell lines and comparable with cell count but no expression was found in Hep G2 cell line even cell count increase. Detection of the BCR/ABL signal by bDNA assay was observed in 12 patients. These twelve patients were also showing a positive PCR signal. All patient samples giving a negative signal using bDNA assay were also negative by QRT-PCR. BCR/ABL signal values obtained with bDNA-based assay were comparable with those obtained with Q-RT-PCR. The bDNA-based assay was also able to detect transcript variants (b3-a2 and b2-a2). *Conclusions.* Our results suggest that branched DNA assay is a quantitative and reliable assay that can be employed in hematological malignancies, characterized by translocations leading to the formation of hybrid genes.

GENOMIC IMBALANCES IN HCV-RELATED CRYOGLOBULINEMIAS

C. Matteucci,[1] G. Barba,[2] D. Sansonno,[3] F.A. Tucci,[3] S. Romoli,[2] D. Beacci,[2] M.F. Martelli,[2] F. Dammacco,[3] C. Mecucci[2]

[1]University of Perugia, PERUGIA; [2]Hematology, University of Perugia, PERUGIA; [3]Section of Internal Medicine and Clinical Oncology, University of Bari, BARI, Italy

Background. Hepatitis C virus (HCV) is estimated to infect 130-170 million people worldwide. A cluster of endemic HCV is found in Southern Italy, with infection rates ranging from 4.6-10.4% and prevalence increasing to 34% in the elderly. HCV causes viral hepatitis, liver cirrhosis and hepatocellular carcinoma and is associated with B-cell lymphoproliferative disorders, including the cryoglobulinemic syndrome. Usually benign, mixed cryoglobulinemia (MC) evolves to overt lymphomas in 5-10 % of cases. Previous claims of IgH/BCL2 rearrangement in MC were not confirmed (Matteucci C *et al.*, Leukemia 2008;22:219-222; Sansonno D *et al.*, Hepatology 2006;43:1166-7). FISH screening detected a 3q trisomy in 1/19 MC cases, suggesting genomic imbalances may arise in this disease (Matteucci C *et al.*, Leukemia 2008;22:219-222). *Aim.* To trace the genomic profile of HCV-related MC in a new series of patients using Metaphase Comparative Genomic Hybridization (M-CGH). *Methods.* 27 patients with HCV-positive MC (21 females, 6 males, median age 61 years, range 44-80; type II MC in 25; type III MC in 2) were selected from patients referred to Internal Medicine and Clinical Oncology, University of Bari Medical School. HCV genotype was 1b in 15 cases and 2a2c in 12. Liver histology indicated chronic active hepatitis in 26 and cirrhosis in 1. Clinical symptoms in all matched a typical cryoglobulinemic syndrome, with 2 showing peripheral lymphoadenopathy, splenomegaly, and a oligo/monoclonal circulating B-cell population. DNA was extracted from peripheral blood mononuclear cells in 25 cases and from bone marrow cells in 2. M-CGH experiments were performed as previously described (Matteucci *et al.,* CGC 2002;135:28-34). Analysis was performed with a CytoVision system (Applied Imaging, Genetix Limited, New Milton, Hampshire, UK). Genomic gains and losses were defined by comparing the green-to-red ratio profiles with the 99.5% dynamic standard reference interval.

Table. Clinico-immunological data in 27 HCV-related MC.

N.	AGE/SEX	LIVER HISTOLOGY	GENOTYPE	ALT (U/L)	RF (U/L)	IgM (mg/dL)	CRYOCRIT (%)	IC	HCV VIRAL LOAD (U/mL)	BCR	FOLLOW UP (months)

CAH: chronic active hepatitis; RF: rheumatoid factor; IC: immunocomplexes; BCR: B-cell receptor

Results. Genomic imbalances were found in 2/27 cases (7.4%). Case n.1 had a chromosome 8 long arm gain and short arm loss. Case n. 16 had a 8q21-qter region gain and a 6q16-qter loss. M-CGH profiles were normal in 25 cases. *Conclusions.* For the first time we showed genomic imbalances occur in around 7% of MC in absence of NHL and found 8q21-qter duplication was a recurrent event underlying oligo/monoclon-

al B lymphocyte benign expansion. 8q duplication was previously found in 12% of HCV-related NHL (Matteucci C *et al.*, Leukemia 2008;22:219-222). Unlike all the other MC cases in this series, both cases with 8q duplication had clinical features mimicking B-cell NHL i.e. peripheral lymphoadenopathy and splenomegaly. Both remained stable over 44 and 94 months of follow up. These data suggest genetic analysis should be included in the work-up of HCV-related cryoglobulinemic syndromes in order to elucidate pathogenetic mechanisms of lymphomagenesis and to select candidates for antiviral and/or anti B-cell expansion treatment.

FRAGMENT LENGTH ANALYSIS SCREENING FOR CEBPA MUTATIONS DETECTION IN ACUTE MYELOID LEUKEMIA

O. Fuster, E. Barragan, P. Bolufer, J. Cervera, E. Such, P. Montesinos, M.A. Sanz

Hospital La Fe, VALENCIA, Spain

Background. CEBPa encodes a protein member of the basic region lucine zipper (bZIP) transcription family that is essential for myeloid differentiation. CEBPa gene consists of two N-terminal transactivating domains (TAD1 and TAD2) and a C-terminal basic and leucine zipper region (bZIP). Inactivating CEBPa mutations have been reported predominantly in normal karyotype acute myeloid leukaemia (AML) and have been related with a favourable outcome. *Aims.* Our objective was to set up a rapid fragment analysis method for the screening of CEBPa mutations and to validate this method in a group of AML patients. *Methods.* The study included 70 AML patients with normal or intermediate-risk karyotype. Twenty-nine patients (41%) showed FLT3-ITD, NPM1 mutations or both. CEBPa mutations study was performed on genomic DNA extracted from bone marrow samples collected at diagnosis. Three PCR were performed using three primer pairs to amplify TAD1, TAD2 (including region between the two domains) and bZIP domains with forward primers fluorescently labelled with FAM. Thirty nanograms of DNA were amplified in a 25 µL reaction containing 7% DMSO and 0.3U of Taq Expand High Fidelity for TAD1 and bZIP fragments and 10% DMSO, 1x Pfx Amp Buffer, 1x PCR Enhancer Solution and 2U Platinum Taq DNA Polimerase for TAD2 fragment. Initial denaturation at 95°C for 3 min was followed by 35 cycles of denaturation at 95°C 1 min, annealing at 55°C for 40 sec and extension at 60°C for 1 min. A final extension of 94°C 30 sec and 60°C 45 min was performed. The mixtures were electrophoresed on an ABI PRISM 3130 Genetic Analyzer and results were analysed using the GENEMAPPER software (Applied Biosystems). Results were confirmed by sequence analysis using ABI PRISM terminator cycle sequencing kit v1.1 (Applied Biosystems) on the ABI PRISM 3130 Genetic Analyzer. *Results.* Eleven out of 70 (16%) patients showed altered electropherograms. Sequence analysis confirmed nucleotide sequence variation in all the cases. These variations were the polymorphism P194_H195dup in two patients and CEBPa mutations in the remaining nine patients (13%) (Table 1).

Table 1. Characteristics of *CEBPa* mutations detected in AML patients.

	PATIENT	MUTATION	PROTEIN	COMMENTS
ONE MUTATION	8861	bZIP:c.1499_1518dup	A303_V308dup	In-frame duplication in BR
	14011	bZIP: c.1525_1527dup	Q312dup	In-frame duplication in LZ
	17210	bZIP: c.1532dup	L315fsX320	Frameshift duplication in LZ and STOP
TWO MUTATIONS	3889	TAD1:c.852_853dup and bZIP:c.1525_1527del	S21fsX160 and Q312fsX358	N-terminal stop and frameshift deletion in LZ
	7100	TAD1: c.779_782dup and bZIP:c.1520_1521ins	I68fsX108 and T310_Q311insL	N-terminal stop and in-frame insertion in LZ
	9147	TAD1:c.838del and bZIP:c.1518_1553dup	Q83fsX159 and E309_D320dup	N-terminal stop and in-frame insertion in LZ
	12816	TAD1:c.790_791dup and bZIP:c.1497_1538dup and c.1538_1539ins	I68fsX160 and A303_L315dup and L315_E316insDR	N-terminal stop
	13356	TAD1: c.858del and bZIP: c.1500_1501ins	K90fsX159 and A303_K304insF	N-terminal stop and in-frame insertion in BR
	15635	TAD1: c.899del and bZIP:c.1507_1530dup	G36fsX159 and R306_K313duo	N-terminal stop and in-frame duplication in LZ and BR

BR: basic region in bZIP domain, LZ: leucine zipper in bZIP domain

Six out of nine patients had two mutations and three patients had a single mutation. All patients were sequenced in parallel and no additional mutations were detected. When we consider FLT3 and NPM1 status we observed that 41 patients without FLT3 or NPM1 mutations showed 9 (22%) CEBPa mutations. By contrast no CEBPa mutations were detected in any of the 29 patients with FLT3 and/or NPM1 mutations. The subgroup of patients FLT3 and NPM1 negatives with CEBPa mutated showed a trend to a better relapse free survival than wild-type patients (75% vs. 23%, p=0.09) at 2 years. *Conclusions.* Fragment analysis is a rapid, specific and sensitive method for CEBPa mutation screening. The incidence of CEBPa mutations was 22% in the group of AML with normal or intermediate karyotype and without FLT3 or NPM1 mutations. In this group without molecular markers CEBPa mutations may establish a subgroup of patients with better prognosis.

MUTATIONS IN THE IRF ASSOCIATION DOMAIN OF THE TRANSCRIPTION FACTOR GENE ICSBP MAY BE ASSOCIATED WITH LEUKEMOGENESIS IN SHWACHMAN-DIAMOND SYNDROM

N. Otto, C. Zeidler, K. Welte, B. Schlegelberger, D. Steinemann

MHH, HANNOVER, Germany

Background. Patients with congenital bone marrow failure syndromes (CMBF) have an increased risk for developing MDS or AML. Yet it is not known which gene defects may induce the malignant transformation. ICSBP (interferon-consensus site binding protein), coding for a transcription factor of the IRF family controlling myeloid cell differentiation, is one putative candidate gene, since ICSBP has been identified as one of the genes most dramatically down-regulated in G-CSF-treated patients diagnosed as CN compared to G-CSF-treated healthy controls. *Aim.* The aim of our study was to investigate patients with congenital bone marrow failure syndromes for ICSBP mutations, deletions or methylation defects leading to a down-regulation of ICSBP. *Methods.* DNA was extracted from peripheral blood or bone marrow of 50 CBMF including Shwachman-Diamond syndrome (SDS, 21), Fanconi anemia (FA, 6), Diamond-Blackfan anemia (DBA, 10), and congenital neutropenia (CN, 13) patients. Screening for mutations in the DNA binding domain (DBD) and in the IRF association domain (IAD) of ICSBP was done by direct sequencing. Furthermore, the promoter region of ICSBP was analyzed for *de novo* methylation and for deletion in the chromosomal region 16q24.1 by fluorescence in situ hybridisation (FISH) using BAC. *Results.* The substitution c:827 G>A leading to Arg276His was found in 3 of 21 SDS patients. These point mutation was constitutional, since they were also present in the oral mucosa, but was not present in a control group (>150 patients). Another substitution c:602 C>T; p:Ala201Val was observed in one of ten DBA patients investigated. The known SNP (rs61995933) was found in one of six FA patients. No alterations were found in 13 CN patients. By means of methylation specific PCR we found no evidence for promoter methylation in the patients diagnosed with CBMF. Furthermore, no significant changes in this chromosomal region were observed by means of FISH analysis. *Conclusions.* Inactivation of the transcription factor ICSBP may disturb normal hematopoietic differentiation and may also play a role in triggering leukemogenesis in patients with congenital bone marrow failure syndromes. Interestingly, one SDS patient carrying an ICSBP point mutation developed leukemia with a complex karyotype supporting our hypothesis. Functional consequences of the mutation remain to be determined.

A NEW RELIABLE FISH METHOD FOR IDENTIFYING MULTIPLE SPECIFIC CYTOGENETIC ABNORMALITIES IN ACUTE MYELOID LEUKEMIA

A. Valencia, J. Cervera, E. Such, E. Gamero, E. Barragan, O. Fuster, P. Bolufer, F. Moscardo, M.A. Sanz

Hospital Universitario La Fe, VALENCIA, Spain

Background. Cytogenetics is considered the most important prognostic factors in acute myeloid leukaemia (AML). However, often it fails to completely resolve complex karyotypes and cryptic translocations. *Aim.* To analyze the capability of the Chromoprobe Multiprobe AML Panel for the detection of the most important chromosomal abnormalities in AML and cryptic rearrangements using eight non liquid probes attached to a glass device. *Methods.* We analyze 80 patients diagnosed with AML in parallel by chromosome banding analysis and interphase FISH using the panel which includes: -5/del(5q), -7/del(7q), TP53, del(20q), PML/RARα, AML1(RUNX1)/ETO, MLL, and CBFβ/MYH11 probes. Briefly, slides were prepared pipetting 4 µL of cell suspension onto all eight areas of the template slide. Before the hybridization, the probes were dissolved back into solution adding 2 µL of hybridization solution to each of the eight areas on the device. Then, the template slide was aligned with the probe device and both were replaced in a humid chamber in a 37 °C water bath overnight (Figure 1A). Fluorescent signals were analyzed using Metacyte v3.5.1 image analysis software (Metasystems Inc., Germany) (Figure 1B). *Results.* Using both cytogenetics and multiprobe FISH, we identified 7 patients (9%) with good risk cytogenetics: four patients with inv(16), two patients with t(8;21), and one t(15;17). Five rearrangements were detected by both methods, whereas one inv(16) and one t(15;17) were just detected by FISH. Regarding patients with intermediate risk cytogenetics, we found complete concordance between both methods in all the 33 patients (41%) with normal karyotype, except for the aforementioned cryptic t(15;17). Nineteen additional patients (24%) of the intermediate category had other miscellaneous structural or numerical defects. The multiprobe AML panel was useful in the characterization of chromosomal aberrations in 15 patients (19%) with adverse risk cytogenetics. It showed a good correlation with conventional karyotype in all cases except one, who had a cryptic deletion of the CBFβ allele and was detected only by FISH. However, FISH was ineffective to detect aberrations in 6 cases (7.5%) that involved chromosome regions not represented in the multiprobe panel. However, the panel helped to identify aberrations in 9 patients (11%) without metaphases (7 cases) or with non evaluable chromosomes (2 cases): 3 MLL rearrangements, 2 monosomy 7, one of them also with del(5q), and one inv(16). No alterations were found in the remaining 3 cases. *Conclusions.* We showed the panel is a step forward in the right direction to make FISH easier to handle. The panel identified several chromosomal abnormalities within all cytogenetic risk groups and helped us to clarify complex karyotypes. It also provided a valuable tool for cases without or not assessable metaphases. In conclusion, the panel can be a complementary technique for the identification of most common rearrangements in AML, particularly in cases with poor quality or not available metaphases. Given the importance of chromosome aberrations for prognostication in AML, this method helps in the diagnosis and treatment decision making.

ACUTE MYELOID LEUKEMIA WITH BIALLELIC CEBPA GENE MUTATIONS AND NORMAL KARYOTYPE REPRESENTS A DISTINCT GENETIC ENTITY ASSOCIATED WITH A FAVORABLE CLINICAL OUTCOME

A. Dufour,[1] A Dufour,[2] F. Schneider,[2] K.H. Metzeler,[2] E. Zellmeier,[2] T. Benthaus,[2] M.-C. Sauerland,[3] T. Büchner,[3] J. Braess,[2] W. Hiddemann,[2] S. Bohlander,[2] K. Spiekermann[2]

[1]Klinikum Grosshadern LMU, MUNICH; [2]Laboratory for Leukemia Diagnostics, Dept. of Medicine III, LMU- Grosshadern, MUNICH; [3]Department of Medicine A, Hematology and Oncology, University of Münster, MÜNSTER, Germany

Background. Acute myeloid leukemia (AML) without chromosome abnormalities (cytogenetically normal AML, CN-AML) represents a molecularly heterogeneous disease in which mutations in a small number of genes have shown to define subgroups with prognostic significance. Point mutations in the CEBPA gene occur at about 8-12% of CN-AML patients and confer a favorable prognosis with an increased overall survival. CEBPA mutations are found as either biallelic (biCEBPA) or monoallelic (moCEBPA). *Aims.*We set out to explore in a large number of CN-AML patients whether the number of mutated alleles in CEBPA is of prognostic relevance. *Methods.* We screened bone-marrow samples of 467 CN-AML patients within the AMLCG study for the presence of CEBPA gene mutations using a multiplex PCR-based fragment length analysis. We identified 58 CEBPA gene mutations in 38 patients of which 20 patients had biCEBPA mutations, 18 patients had moCEBPA mutations and 423 patients had wildtype (wt) CEBPA. These three subgroups were analyzed for clinical parameters and for additional mutations in the NPM1, FLT3 and MLL genes. Furthermore, we obtained gene expression profiles (GEP) using oligonucleotide microarrays. *Results.* Only biCEBPA patients had an improved median overall survival when compared to patients with wtCEBPA (not reached vs. 20.4 months; p=0.018) whereas moCEBPA and wtCEBPA patients had a similar intermediate outcome. Interestingly, biCEBPA patients were never associated with mutated NPM1 (0 vs. 43%; p=0.000) and rarely associated with FLT3-ITD (5 vs. 23%; p=0.059), whereas moCEBPA patients had a similar frequency of mutated NPM1 and a significantly higher association with FLT3-ITD (44 vs. 23%; p=0.037) compared to wtCEBPA. Furthermore, biCEBPA but not moCEBPA patients showed a high concordance to previously identified GEP signatures of CEBPA mutant AML patients. *Conclusions.* Biallelic disruption of the N and the C-terminus of CEBPA is required for the favorable clinical outcome of CEBPA mutated patients and represents a distinct molecular subtype with a different frequency of associated gene mutations and a distinct GEP. These findings have major prognostic impact for risk-adapted therapeutic strategies in AML.

0047

MENINGIOMA GENE 1 (MN1) EXPRESSION IS A SENSITIVE MARKER FOR MINIMAL RESIDUAL DISEASE DETECTION IN ACUTE MYELOID LEUKAEMIA

D. Cilloni,[1] F. Arruga,[1] S. Carturan,[1] F. Daraio,[1] G. Tramuta,[1] A. Coco,[1] M. Fava,[1] E. Gottardi,[1] F. Messa,[1] E. Bergatto,[2] F. Farinazzo,[2] G. Stefanuto,[2] E. Messa,[1] F. Lo Coco,[3] G. Saglio[1]

[1]University of Turin, TURIN; [2]Nanogen, Advanced Diagnostics, TURIN; [3]University Tor Vergata, ROME, Italy

Background. The assessment of minimal residual disease (MRD) has currently become a necessary strategy to better address treatment intensity in human leukemias. However, so far the applicability of this strategy has been limited to those leukaemia subsets characterized by genetic markers amenable to sensitive detection by PCR Meningioma 1 (MN1) gene overexpression has been reported in acute myeloid leukaemia (AML) patients. The aim of the study was to characterize the patients presenting MN1 overexpression and to establish the role of MN1 as a marker for MRD detection. *Methods.* 158 AML patients, 30 CML patients and 50 healthy donors were analyzed for MN1 expression by RQ-PCR. In 20 patients bearing a fusion gene transcript (FG), we analyzed MN1, WT1 and FG during follow-up and in 7 patients also NPM1 mutations has been quantified by RQ-PCR. *Results.* The MN1 levels were extremely low in normal samples: median value of 136 MN1/104ABL copies in PB (range 9-300) and 254 in BM (range 80-500) and 12,9 (range 11-19) in

CD34+ cells. By contrast, about 50% of the AML samples with normal karyotype (NK) showed high MN1expression with a median of 5136 copies/104 ABL copies (range 852-90230) and 6780, (range 1367-15900) in PB. All samples carrying the CBFβ-MYH11 FG expressed a significantly higher amount of MN1 transcript as compared to controls (p<0.0001 in both BM and PB): median 46950, (range 2149-98000) in BM and 34500, (range 1400-67999) in PB. About 50% of the samples with AML1-ETO FG abnormally expressed MN1: median 16950, (range 3500-34000) in BM and 3475, (range 1260-56000) in PB. Finally, the APL samples expressed MN1 values comparable to those of healthy subjects in both BM and PB (p=0.05 and 0.08). No association between FLT3 mutations and MN1 was demonstrated. In contrast, MN1 is typically overexpressed in patients with NPM mutations. 36 out of 47 NPMc+ patients were characterized by abnormal MN1expression. We were unable to confirm the correlation between EVI1 and MN1 expression (r= 0.06) reported in literature. Finally, MN1 is not expressed in CP CML (10 cases) but is overexpressed during AP (n=10) and BC (n=10) (median 49100 and 62741 respectively). Finally MRD has been detected by measuring MN1, FG, WT1 and in 7 cases also NPM. MN1 expression always paralleled that of the FG. Furthermore, MN1 strictly parallels WT1. In addition, MN1 is more sensitive than NPM1 in predicting relapse. In all the cases MN1 rose at least two months before relapse. *Conclusions.* These data show that 47% of patients with NK are characterized by abnormal MN1 expression. The overexpression is typical of AML with NPMc+ and inv(16) and CML in AP and BC. MN1 could therefore represent a marker for MRD in patients with normal karyotype and it seems to be more sensitive than NPM1. Increased MN1 expression in BM during follow up was always found to be predictive of an impending hematological relapse.

0048

MEASUREMENT OF MICRORNA EXPRESSION LEVELS BY QUANTITATIVE REAL-TIME POLYMERASE CHAIN REACTION IS A USEFUL TOOL TO PREDICT OUTCOME IN PATIENTS WITH B CELL CHRONIC LYMPHOCYTIC LEUKAEMIA

A.H. Schuh, E. Ballabio, S. Gooding, O. Dyar, M. Jones, C. Lawrie

University of Oxford, OXFORD, United Kingdom

Background. B-cell chronic lymphocytic leukaemia (B-CLL) is the most common form of adult leukaemia in the Western World. FISH abnormalities, differential expression of cell surface markers and IgH mutation status have been validated as useful prognostic markers. Besides, differences in microRNA (miR) expression patterns have been proposed as novel prognostic markers in B-CLL largely on the basis of miR expression arrays. *Aim.* However, arrays are not practical for routine diagnosis and therefore we tested these data by quantitative real-time polymerase chain reaction (qRT-PCR) and correlated it with clinical and biological outcome measures. *Methods.* We performed fluorescent in situ hybridization (FISH) and IgH mutation analysis on enriched B-CLL peripheral blood samples (>80% CD19+;CD5+) from 79 clinically annotated patients collected at our institution. FISH results were confirmed by comparative genomic hybridization (aCGH). Next, samples and normal CD19 positive B-cell controls were subjected to qRT-PCR for miRs-155, 223, 15a, 16, 29c, 150, 34a and 21. Results were correlated to clinical and biological features. *Results.* To date, the data show that miR-155, miR-150 and miR-29c are significantly over-expressed in samples from patients with B-CLL compared to normal controls. In contrast, miR-223 expression is down-regulated. Interestingly, miR-15a and 16 expression levels are not significantly different in del13q14.1 vs non-del 13q14.1 subsets. We are currently comparing miR-15a and 16 expression levels to CGH analysis of the 13q14.1 locus. In accordance to previous studies, MiR-223 under-expression is associated with unmutated IgH locus whereas miR-155 over-expression is predictive of advanced stage disease. *Conclusions.* Taken together, we demonstrate that miR expression levels measured by qRT-PCR correlate with biological and clinical features of the disease and warrant further validation as potetially useful prognostic markers within large clinical trials.

Background. The level of mininmal residual disease is increasingly being recognized as an important prognostic parameter in a number of hematologic diseases and is used to guide therapy in adult and childhood acute lymphoblastic leukaemia. Reverse-transcription real-time quantitative PCR (rtPCR) for quantification of BCR-ABL mRNA transcripts in peripheral blood and bone marrow is employed routinely during treatment of patients with Philadelphia chromosome positive chronic myeloid leukaemia (CML) or acute lymphoblastic leukaemia (Ph+ALL). However, laboratories may differ substantially in their methodology and analysis strategy, making interpretation and comparison of results difficult or impossible. As a consequence, recommendations for the harmonization of RQ-PCR for BCR-ABL have been established for the p210bcr-abl transcript characteristic of CML. In case of Ph+ ALL and the p190bcr-abl transcript, neither the interlaboratory variability nor the optimal approach for standardisation and/or harmonisation of RQ-PCR for m-BCR-ABL have been established. Therefore, it was the aim of this collaborative European study to assess the variability of m-BCR-ABL detection between numerous well established laboratories involved in diagnosis and MRD monitoring of adult and pediatric patients with Ph+ ALL. We here report the results of the first m-BCR-ABL laboratory control rounds involving 21 participating laboratories from the EWALL and the ESG-MRD-ALL. *Aims.*As a first step towards standardization of m-BCR-ABL detection, the first two laboratory control rounds focused on a comparative analysis of the variability of RNA-extraction and of real-time PCR, the sensitivity of real-time PCR, the proportion of false positive/negative results. *Methods.* Serial dilutions of the BCR-ABL positive cell line Sup B15 in the BCR-ABL negative cell line Nalm 6 were prepared to yield dilutions of 10%, 2 %, 1 %, 0.1 %, 0.01%, 0.001%. Nalm 6 cells alone served as a negative control. The total amount of cell preparation was 5×10E+06 cells stabilized in 2 mL of TRIZOL and frozen at -20°C until shipment. For lab round one, participants were asked to perform RNA-extraction, cDNA-synthesis, and BCR-ABL/ABL measurement in three different experiments. In lab round 2, cDNA was sent out centrally and only the quantitative PCR were to be performed. *Results.* The median measured RNA-amount ranged from 0,07-2,65 (median 0,5 µg/µL), resulting in abl copy numbers ranging from 1.03E+03 to 1.93E+06 (median 1.05 E+05). 20 of 21 participating laboratories detected BCR-ABL in the low-level sample 0.01%. 12 of 20 evaluable participating laboratories failed to detect the 0.001%. For lab round 2, only 4 of 14 evaluable laboratories to date failed to detect the 0.001%. 3 laboratories detected the negative control as positive in lab round 1, none of the 14 evaluable laboratories detected the negative control as positive in lab round 2. *Summary.* Initiation of laboratory control rounds and beginning implementation of standardized methodology resulted in improved variability and lower frequency of false-positive results in the second quality control round. Despite these improvements, further standardisation of methodology is needed to improve results of m-BCR-ABL quantification to ensure comparability of MRD analysis between laboratories and clinical trials at the European level.

JAK2 V617 ALLELE BURDEN AND THROMBOSIS IN PATIENTS WITH POLYCYTHEMIA VERA AND ESSENTIAL THROMBOCYTHEMIA

E. Kalagiakou,[1] I. Evmorfiadis,[2] M. Hatzouli,[2] E. Manioudaki,[2] M. Kotsopoulou,[3] S. Malegkou,[4] K. Vallianatou,[2] I.-D. Triantafyllopoulou,[3] E. Samaridis,[2] L. Dadiotis,[4] Ch. Mitsouli,[3] C. Belessi,[2] N. Laoutaris[2]

[1]Nikea General Hospital, ATHENS; [2]Nikea General Hospital, Haematology Department, ATHENS; [3]Metaxa Oncology Hospital, Haematology Clinic, ATHENS; [4]Tzanion General Hospital, Transfusion Center, PIREAUS, Greece

The V617F mutation of the JAK2 gene is frequently detected in patients with Myeloproliferative Neoplasms (MPN) and it seems to be directly implicated in the pathogenesis of these diseases. It is found in virtually all the patients with Polycythemia Vera (PV) and about half the patients with Essential Thrombocythemia (ET) or Idiopathic Myelofibrosis (IM). Given the increased incidence of thrombotic episodes in these patients, research has been made on the possible correlation of the V617F mutation to the development of thrombosis with contradicting results. In the present study we examined the possible correlation of the JAK2 V617F allele burden with the development of thrombosis in patients with PV and ET. Furthermore, patients were tested for the presence of the most common hereditary risk factors for thrombosis (HRFT): the G1691A mutation of Factor V (FV Leiden), the G20210A mutation of Factor II (FII) and the homozygosity C677T of the MTHFR gene, with the intention of investigating possible synergic action between the presence of V617F mutation and the HRFT in developing thrombosis in patients with MPN. We studied 58 patients with ET and 41 patients with PV. Diagnosis was based on the WHO criteria. We identified the JAK2 V617F mutation by using DNA PCR followed by digestion of PCR product with BsaXI restriction enzyme and quantified the JAK2 V617F mutational load with quantitative Real time DNA PCR. The result was expressed as a percentage of mutated to mutated plus non-mutated JAK2 copies. The patients that carried more than 50% copies were considered of being homozygous for the mutation. The mutations of FV, FII and MTHFR were determined using allele-specific PCR. Seventy patients were found positive for JAK2 V617F mutation [39/41 (95.1%) with PV and 31/58 (53.4%) with ET]. Quantitative real time PCR was performed in 67/70 JAK2 V617F$^+$ patients. Overall, 28/67 patients carried homozygous clones (26/38 with PV and 2/29 with ET). Three of 87 patients with available data carried the G1691A mutation of FV, 4/87 the G20210A mutation of FII and 11/87 were homozygous for the C677T mutation of the MTHFR gene. In 14/87 patients we observed coexistence of JAK2 V617F mutation with one HRFT. 24/99 patients developed a thrombotic episode. Correlation of the frequency of thrombotic episodes with presence of: (i) JAK2 V617F mutation (ii) homozygous JAK2V617F clones and (iii) HRFT, showed an important increase in thrombotic episodes only in the concomitant presence of JAK2 positivity and one HRFT (5/14, 36%). Adversely, the presence of V617F on its own does not seem to increase the chance of thrombotic episodes. Conclusively, this study indicates the synergic role of the V617F mutation of the JAK2 gene with the HRFT on the development of thrombosis, bringing up the need of determining HRFTs in JAK2$^+$ patients with MPNs. However, the increased frequency of thrombosis in patients with MPNs independent of the presence of JAK2 mutation, imposes the quest for additional predisposing factors that lead to the high frequency of thrombosis in these patients.

MONOCLONALITY TESTING USING PYROSEQUENCING

D.R. Robert, P. Makrythanasis, S. Mach-Pasqual, P. Beris, S. Antonarakis, S. Deutsch, T. Matthes

University Hospital Geneva, GENEVA, Switzerland

Background. In medicine, and in particular in hematology, clonality studies have been used to establish the single origin of tumors and to differentiate nonmalignant from malignant states. X-chromosome inactivation based assays exploit the fact that during female embryonic development most of the genes of one X-chromosme are inactivated in each cell. The subsequent progeny of each cell maintains the same inactivated genes, resulting in a mosaic of cells expressing genes from one X-chromosome or the other. On the contrary, in a malignant clonal population genes from the same X-chromosome are inactivated. Current assays are technically laborious and demanding, and not suited for high throughput analysis. *Aims.* In this study we describe a phenotypic clonality test based on pyrosequencing of single nucleotide polymorphisms (SNPs), present in mRNAs transcribed from the active X-chromosome. *Methods.* Eight single nucleotide polymorphisms (SNPs) from eight different X-chromosomal genes (MPP1, GK, CFP, EBP, PIGA, SPRY3, SUV39H1, CHST7) were chosen, localized in regions of the X-chromosome with a stable inactivation pattern and with detectable expression in hematopoietic cells. DNA and RNA were extracted from peripheral blood of 69 normal female blood donors (19 to 75 years old). Previous to RNA extraction blood cells were separated into mononuclear (lymphocytes and monocytes) and polynuclear (granulocytes) fractions, using dextran and Ficoll gradients. Purity of cell fractions was confirmed by flow cytometry. Pyrosequencing reactions for each SNP were set up in triplicates and analysed on a Pyrosequencer 96MA machine (Qiagen). For each blood donor, analyses were performed for DNA and the two RNA fractions, with primers specific for the eight chosen SNPs. Pathologic samples (peripheral blood or bone marrow) were also obtained from twelve patients with various suspected myeloproliferative and myelodysplastic syndromes, with histiocytosis, PNH or with AML. *Results.* Analysis of DNA samples allowed to establish for each SNP the frequency for informative heterozygosity, which varied from 34% (for SPRY3) to 60% (for PIGA), according to the SNP studied. For 67/69 blood donors ≥ 1 SNP gave informative results (mean: 3 to 4 SNPs). For MPP1, CFP, EBP, PIGA, SPRY3, and SUV39H1, levels of heterozygosity were distributed around 50 %, as expected for non-skewed X-inactivation. The SNPs GK and CHST7 showed a different distribution, with skewed as frequent as non-skewed samples. Interestingly, skewed expression of GK and CHST7 were found in 6 blood donors, in which the other SNPs showed a normal distribution. These results argue for extensive variability in X-linked gene expression or inactivation, depending on the gene studied. Using combinations of informative SNPs and comparing X-inactivation between different cell lineages, we were able to confirm clonality in some of the patients studied. Data on these patients is still under study and will be presented. *Conclusions.* Pyrosequencing of a combination of different SNPs is a highly precise method for the distinction between clonal and non-clonal cell populations. Comparisons between patterns of inactivation in different cell lineages of the same patient are needed to correctly interpret inactivation patterns in hematologic diseases.

0052

COOPERATING MUTATIONS OF RECEPTOR TYROSINE KINASES/JAK2/RAS SIGNALING PATHWAYS IN *DE NOVO* AML WITH MLL TRANSLOCATIONS AT DIAGNOSIS AND RELAPSE

L.-Y. Shih,[1] D.-C. Liang,[2] C.-F. Huang,[1] J.-F. Fu,[1] T.-L. Lin,[1] M.-C. Kuo,[1] C.-L. Lai,[1] T.-H. Lin[1]

[1]Chang Gung Memorial Hospital, TAIPEI; [2]Mackay Memorial Hospital, TAIPEI, Taiwan

Background. MLL gene located at 11q23 is fused to a variety of partner genes through chromosomal translocations in acute leukemia. Two-hit model of leukemogenesis has been proposed for acute myeloid leukemia (AML). MLL translocation (MLL-T) is considered a class II mutation. The occurrence of cooperation of class I mutations in AML with MLL-T is not clear. Aims. We sought (1) to determine the frequencies of collaboration of class I mutations involving receptor tyrosine kinases (RTK)/JAK2/Ras signaling pathways in *de novo* AML patients with MLL-T at diagnosis and to assess their prognostic impact, (2) to analyze the mutation status and pattern changes at relapse to determine the roles of cooperating mutations in relapse. *Patients and methods.* Sixty-five patients had *de novo* AML with MLL-T which was detected by cytogenetic, Southern blot or FISH analyses at initial diagnosis. RT-PCR was used to detect common MLL fusion transcripts. cDNA panhandle PCR was used to identify the rare MLL partner genes. MLL fusion partners included 19 AF9, 12 AF10, 11 AF6, 10 ELL, 3 ENL, 2 AF4 and one each for CBL, LARG, LCX, MSF, and SEPT. Mutational analyses were performed on bone marrow samples at diagnosis, complete remission, and relapse by DNA/cDNA PCR with GeneScan analysis for FLT3/ITD, PCR-RFLP followed by direct sequencing for FLT3/TKD, DNA/cDNA-PCR with direct sequencing for c-KIT, c-FMS, N-Ras, K-Ras or PTPN11, and allele-specific PCR for JAK2V617F. Results. At diagnosis, FLT3-ITD mutations were detected in 3 and FLT3-TKD in 8; c-KIT mutation in 1, c-FMS in 3, N-Ras in 8, K-Ras in 12, and PTPN11 mutations in 4; none had JAK2V617F. All the mutations detected at diagnosis were not present in the complete remission samples, indicating these mutations were leukemia-specific. Together, cooperating mutations involving RTK/ JAK2/ Ras pathways occurred in 55% (36/65) of *de novo* AML patients with MLL-T. Three patients had two class I mutations (2 FLT3-TKD plus N-Ras, 1 FLT3-TKD plus K-Ras muta-

tions). Twenty of 23 patients who relapsed had relapse samples available for comparative analysis. Three patients retained the same N-Ras mutations at relapse whereas one with Gly12Asp changed to Gly12Cys at relapse. Two relapsed with identical K-Ras mutations, one gained and another one lost K-Ras mutation. All 3 patients who harbored FLT3-TKD mutations at diagnosis lost the mutations at relapse. Another one lost PTPN11 mutation at relapse. All the 5 treated patients carrying FLT3-ITD, c-FMS or c-KIT mutations at diagnosis had an overall survival and event-free survival of less than 6 months. Conclusions. Our results showed that more than half of AML patients with MLL-T carried mutations involving RTK/JAK2/RAS pathways at diagnosis and FLT3-TKD, K-Ras or PTPN11 mutations might lose in relapse. AML patients with MLL-T harboring RTK mutations had a poor outcome.

PROGNOSTIC SIGNIFICANCE OF TELOMERE LENGTH, MOLECULAR CYTOGENETIC FINDINGS AND IMMUNOPHENOTYPIC FEATURES IN PATIENTS WITH B-CHRONIC LYMPHOCYTIC LEUKEMIA

J. Brezinova,[1] S. Vcelikova,[1] A. Berkova,[2] Z. Zemanova,[2] I. Izakova,[1] I. Sarova,[1] H. Cechova,[1] J. Tajtlova,[2] L. Grosova,[2] L. Lizcova,[2] E. Malinova,[2] M. Zemanova,[2] E. Cmunt,[2] J. Karban,[2] J. Schwarz,[1] K. Michalova[1]

[1]Institute of Hematology and Blood Transfusion, PRAGUE; [2]General Teaching Hospital and 1st Faculty of Medicine, Charles University, PRAGUE, Czech Republic

Background. The clinical course of patients with B-chronic lymphocytic leukemia (B-CLL) is highly variable. Therefore, several indicators related to the genetics and biology of B-CLL are increasingly used for prognosis and treatment response prediction. Recently, some evidences suggest that short telomeres are associated with poor outcome and telomere restriction fragment length (TRF-L) might be of predictive significance. *Aims.*The aim of this study was to evaluate telomere restriction fragment length in a cohort of patients with B-CLL and to correlate these findings with interphase FISH (I-FISH) analyses of chromosomal aberrations, telomerase activity, IgVH mutational status and ZAP-70 and CD38 expression. *Methods.* During years 2007-2008, peripheral blood samples of 77 patients with B-CLL (40 male, 37 female, mean age 67) were analyzed. 21 patients were studied at time of diagnosis and 66 patients were examined at follow-up (45 untreated, 11 after treatment). I-FISH analyses were performed using DNA probes: 1) CLL Probe panel for regions 17p13.1 (gene p53), 11q22.3 (gene ATM), 13q14.3, 13q34 and 12p11.1-q11; 2) LSI IGH (14q32) Break probe for detection of 14q32 aberrations. Telomere length - TRF index in kilobases (kbp) was determined by Terminal Repeat Fragment (TRF) method using Telo TAGGG Telomere Length Assay kit. The cases with TRF shorter than 6.7 kbp (mean TRF from 18 age matched healthy individuals, median=61 years) were considered as cases with reduced telomeres. Telomerase activity was detected using TeloTAGGG Telomerase PCR ELISAPLUS kit. ZAP-70 expression analysis was performed by flow cytometry, PCR "touch down" methodology was used for mutational analyses of IgVH genes. *Results.* Patients were grouped according to molecular cytogenetic findings as follows: good prognosis (del 13q14 as a sole aberration) - 32 patients; standard prognosis (normal findings, +12 and/or combination of monoalelic and bialelic deletion 13q14) - 40 patients; poor prognosis (deletion of ATM and/or p53 genes) - 5 patients. IgVH mutational status was analyzed in 74 patients - in 48 mutated, in 20 unmutated IgVH status was proved, in 6 patients the germline IgVH genes were not identified. 28 of 72 patients were ZAP-70 positive and CD38 positivity was detected in 18 out of 76 examined patients. High heterogeneity in telomere length was observed in a range of 3.50 kbp - 15.5 kbp (median 6.1 kbp), reduced telomeres were proved in 48 patients. A correlation between TRF-L and IgVH mutational status was confirmed whereas IgVH mutated patients showed long and IgVH unmutated short telomeres (p=0.001). Detailed results of TRF-L analyses in comparison with other prognostic features will be presented. *Conclusions.* Finding new prognostic markers in early stage of B-CLL is a subject of intensive research. We confirmed that TRF-L analyses have predictive value and can contribute to prognostication in B-CLL patients.

B-CELL LYMPHOPROLIFERATIVE DISORDERS WITH T(11;14)(Q13;Q32) OR T(14;18)(Q32;Q21) SHOW VARIATIONS IN THE PATTERN OF ADDITIONAL CYTOGENETIC ABERRATIONS, GENE EXPRESSION PROFILE AND ANTIGEN EXPRESSION

F. Dicker, L. Reindl, S. Schnittger, T. Haferlach, W. Kern, C. Haferlach

MLL Munich Leukemia Laboratory, MUNICH, Germany

Background. The t(11;14)(q13;q32) is considered a marker of mantle cell lymphoma (MCL), while the t(14;18)(q32,q21) is associated with follicular lymphoma. Both translocations have also been reported in other B-cell malignancies, including chronic lymphocytic leukemia (CLL). *Aims and Methods.* We evaluated immunophenotypic as well as genetic characteristics occurring in association with t(11;14) and t(14;18) in order to define specific entities. 51 B-cell lymphoproliferative cases with t(11;14) and 26 with t(14;18) were studied by chromosome banding, FISH, immunophenotyping and gene expression analyses (HG-U133+ 2.0, Affymetrix). *Results.* Based on immunophenotyping 13 of 26 t(14;18)+ cases were classified as NHL and 13 cases as CLL (9 CLL, 4 CLL/PL). The mean number of cytogenetic aberrations in addition to t(14;18) was 1.1 in CLL cases and 4.2 in NHL cases (p=0.016). A complex karyotype (≥3 aberrations in addition to t(14;18)) was identified in 9 of 13 B-NHL cases (69.2%), however, in none of the 13 CLL cases (p=0.0002). In CLL the only additional recurring aberrations were +12 (n=7) and -13q (n=5). Additional aberrations in B-NHL cases were +1q (n=3), -4q (n=2), -6q (n=5), +7 (n=3), +12 (n=4), -15q (n=2), +der(18)t(14;18) (n=2), +21 (n=2), +22 (n=2), and +X (n=2). Notably, deletion 13q was not detectable in t(14;18)+ B-NHL. Two antigens were significantly higher expressed in t(14;18)+ B-NHL: CD10 (mean positivity (mp) 34.9% vs. 1.7%, p=0.006), and CD38 (60.9% vs. 29.8%, p=0.014), whereas 3 antigens were significantly lower: CD11c (38.6% vs. 14.5%, p=0.005), CD23 (66.6% vs. 24.0%, p=0.001), and CD5 (80.8% vs. 29.5%, p<0.001). Gene expression analysis identified 28 significantly differentially expressed genes. In cases with t(11;14)+ 39 of 51 cases were classified as NHL and 12 were classified as CLL (3 CLL, 9 CLL/PL). The mean number of aberrations in addition to t(11;14) were 2.1 in CLL and 5.8 in NHL cases (p=0.011). Whereas 26 of 39 NHL cases (67%) revealed a complex karyotype, only 3 of the 12 CLL cases (25%) did (p=0.011). In CLL the only additional recurring aberrations were +3q (n=3), +12p (n=2), -13q (n=2), +15q (n=2), -17p (n=4) and in NHL (observed in at least 5 cases): -1p (n=8), +3q (n=20), -6q (n=5), -8p (n=11), +8q (n=12), -9p (n=8), -9q (n=8), +11q (n=8), -11q (n=9), -13q (n=11), +13q (n=8), +15q (n=5), and -17p (n=13). CD23 was significantly higher in t(11;14)+ CLL as compared to t(11;14)+ B-NHL: (mp 48.8% vs. 20.8%, p=0.0001). CD22 was significantly higher expressed in t(11;14)+ B-NHL (mp 72.3% vs. 56.9%, p=0.036). However, gene expression profiling did not identify significant statistical differences in gene expression. *Summary.* t(14;18)+ CLL were characterized by a low number of chromosome aberrations and a higher expression of CD11c, CD23, and CD5. In contrast, t(14;18)+ NHL frequently demonstrated a complex karyotype and a higher expression of CD10 and CD38. Differences in gene expression were observed. Although, t(11;14)+ CLL were characterized by a lower number of additional chromosome aberrations as compared to t(11;14)+ NHL and a higher expression of CD23 and a lower expression of CD22, no global differences in the gene expression profile were identified.

ASSOCIATION OF INTERPHASE FLUORESCENCE *IN SITU* HYBRIDIZATION RESPONSE CRITERIA WITH CONVENTIONAL METAPHASE CYTOGENETICS IN CML PATIENTS ON THERAPY

T. Schenk,[1] M.C. Müller,[1] A. Fabarius,[1] P. Erben,[1] H. Daikeler,[1] T. Ernst,[1] A. Hochhaus,[1] C. Haferlach[2]

[1]Universitaetsmedizin Mannheim, MANNHEIM; [2]MLL, Munich Leukemia Laboratory, MUNICH, Germany

Background. The Philadelphia (Ph) chromosome and its molecular equivalent, the BCR-ABL fusion gene, represent the pathogenetic cause and a useful target for detection and follow up monitoring of chronic myeloid leukemia (CML). Cytogenetic analysis of bone marrow metaphases (Cy) has been established as the standard method. In contrast, interphase fluorescence in situ hybridization (IP-FISH) has been increasingly applied in many studies due to recent optimization of the technique but is not represented in current treatment guidelines. The aim of our study was to define IP-FISH response criteria which correspond best with complete and major cytogenetic responses. *Methods.* In order to quantitatively compare results of both methods 1,750 bone marrow

samples from 748 CML patients at different stages of CML were analyzed in parallel with Cy and IP-FISH. 5 patients with known Ph negative/BCR-ABL positive CML were excluded and not considered for analysis. These patients can be monitored by BCR-ABL FISH on metaphases or interphase nuclei only as conventional cytogenetics is not informative. 643 patients in chronic phase were analyzed during treatment with an imatinib based therapy, ten patients received interferon α (IFN). 74 patients at different stages of the disease received a therapy with second generation tyrosine kinase inhibitors: nilotinib, n=18 (chronic phase n=13, accelerated phase n=2, blast crisis n=3); dasatinib, n=56 (chronic phase n=41, accelerated phase n=4, blast crisis n=11). 21 patients received no therapy or the therapy was not evaluable. The correlation between Ph positive metaphases and the proportion of FISH positive interphase cells was determined by using the Spearman´s rank correlation coefficient. The chi-square test was used to compare IP-FISH and Cy data. We calculated probability levels for different threshold values of IP-FISH response groups using the minimum p-value approach. The optimally separating threshold value was chosen as cut-off point. *Results.* Cy and IP-FISH data showed a good correlation (r=0.87; $p<0.0001$). The following cut-off values were defined: ≤30% interphase positive cells by FISH was found to correspond best with major cytogenetic response (MCyR; ≤35% Ph^+ metaphases by Cy); ≤6% interphase positive cells by FISH revealed to be concordant with complete cytogenetic response (CCyR; 0% Ph^+ metaphases; Table 1). 96.2% of samples with ≤30% IP-FISH positive cells had a major cytogenetic response. Of 1,163 samples in CCyR, 99.3% showed a percentage of ≤6% IP-FISH positive cells. 82 of 1,163 samples (7.0%) with 0% Ph^+ metaphases by Cy were IP-FISH positive (median 3%, range 1-21% positive interphases). IP-FISH showed false negative results in 10 of 1,090 samples (0.92%) with a median of 8% Ph^+ metaphases (range 4-40%). In conclusion, IP-FISH data are comparable with metaphase cytogenetics but the cut-off points differ. The prognostic value of IP-FISH data should be analyzed in prospective controlled studies.

Table 1.

	FISH positive interphases	
	0-30%	**>30%**
MCyR (0-35% Ph+ metaphases)	n=1,331	n=8
no MCyR (>35% Ph+ metaphases)	n=52	n=359
	FISH positive interphases	
	≤6%	**>6%**
CCyR (0% Ph+ metaphases)	n=1,155	n=8
no CCyR (>0% Ph+ metaphases)	n=88	n=499

FREQUENT MONITORING OF WILMS' TUMOR GENE EXPRESSION LEVELS IN PERIPHERAL BLOOD FOR EARLY DIAGNOSIS OF ACUTE LEUKEMIA RELAPSE AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

H. Tamaki,[1] R. Kato,[2] K. Ikegame,[2] T. Fujioka,[2] Y. Taniguchi,[2] S. Yoshihara,[2] K. Kaida,[1] T. Inoue,[1] H. Ogawa[1]

[1]Hyogo College of Medicine, NISHINOMIYA CITY; [2]Osaka University Graduate School of Medicine, SUITA CITY, Japan

Background. Wilms' tumor gene WT1 expression levels have been extensively studied using bone marrow (BM) as the most common source for assessment of minimal residual disease (MRD) in acute leukemia. Aims. We examine whether peripheral blood (PB) is available as an alternative source for MRD assessment or not. *Methods.* Between April 1994 and December 2001, 44 transplants for 41 patients with acute leukemia were performed with BM or peripheral blood stem cells at Osaka University Hospital. We obtained PB samples once every one to three weeks from day 20-400 after transplant. WT1 expression levels in PB were measured by real-time reverse-transcription polymerase chain reaction methods The WT1 expression level in K562 cells was defined as 1.0 and serial dilutions of K562 cDNA were used for construction of standard curves. Results. As a background level in PB, we defined WT1 levels of less than 2×10^{-4}, based on the expression in samples of 24 healthy volunteers and leukemia-specific chimeric-gene-negative samples from 4 patients who had the minor bcr-abl or AML1-MTG8 chimeric gene. If WT1 levels increased to 2.0×10^{-4} or more, we would obtain PB samples once or twice per week until WT1 levels decreased to less than 2.0×10^{-4} or patients relapsed. Of 33 patients who are in CR, 18 are alive at a median follow-up of 2117 days (range, 909-3709 days), 15 died of transplant-related mortality at a median follow-up of 332 days (range, 52-551 days). In 324 of 352 PB samples (92.0%) obtained from 33 patients who are in CR, WT1 levels distributed less than 2.0×10^{-4}. In only 28 of 352 PB samples (8.0%), WT1 levels ranged from 2.0×10^{-4} to 2.0×10^{-3}, but returned ultimately within the background level ($<2.0\times10^{-4}$). On the other hand, hematologic relapse ultimately occurred on 11 transplants at a median time to relapse of 157 days (range, 43-535). In PB samples within 120 days before relapse of 9 transplants, WT1 levels increased over the background level at a median of day -41 (range, -106 to -14), and then increased to more than 2.0×10^{-3} at least once before relapse. In the remaining 2 transplants, WT1 levels of more than 2.0×10^{-3} were observed only at the time of relapse, although WT1 levels showed 1.4×10^{-3} and 7.6×10^{-4} over the background level, on day -7 and -21 before relapse, respectively. Furthermore, based on kinetics of WT1 levels prior to relapse, we found the following two relapse patterns: a rapid increase in a doubling time of less than 7 days, and a slow increase in that of 7 days or more. *Conclusions.* WT1 levels in PB of more than 2.0×10^{-4} suggested the presence of MRD after transplants. Patients with WT1 levels in PB of more than 2.0×10^{-3} ultimately relapsed, and thus we need frequent monitoring of WT1 levels in PB until they decrease to the background level. In particular, for early detection of impending relapse with a rapid increase in a doubling time of less than 7 days, we need blood sampling for WT1 assessment once or twice weekly.

0057

DNA METHYLATION PROFILES OF DIFFERENT LYMPHOID MALIGNANCIES

C. Stanganelli, C. Chena, I. Slavutsky

Academia Nacional de Medicina de Buenos Aires, BUENOS AIRES, Argentina

Background. There is increasing evidence that, in addition to genetic aberrations, epigenetic processes play a major role in carcinogenesis. Particularly, aberrant methylation of promoter CpG islands is known to be a major inactivation mechanism of tumor-related genes. Studies in different tumor types suggest that specific tumors may have their own distinct patterns of methylation. *Aims.* To compare the methylation profile of tumor suppressor genes (TSG) in multiple myeloma (MM), chronic lymphocytic leukemia (CLL) and mantle cell lymphoma (MCL) patients. *Methods.* We have evaluated the methylation status of p15INK4b, p16INK4a, p14ARF, SOCS-1, p27KIP1, RASSF1A and p73 (TAp73 isoform) TSG genes in newly diagnosis patients with CLL, MM and MCL. Forty-four CLL patients (23 males; median age: 65 years); 44 MM (21 males; mean age: 67 years) and 6 MCL (2 males; median age: 61 years) were analyzed. All patients gave informed consent and the study was approved by the local Ethics Committee. Peripheral blood (PB) samples from 10 normal individuals and CpGenome Universal Methylated DNA (Chemicon International) were used as negative and positive controls, respectively. DNA was extracted from bone marrow cells (BM) of MM patients, PB of LLC patients and controls and BM or lymph nodes of MCL using phenol/chloroform method. Methylation status was performed using Methylation Specific PCR technique and DNA sequencing. The methylation index (MI; ratio between the number of genes methylated and the number of genes analyzed) was also calculated. *Results.* All pathologies showed TP73 and p15INK4bgenes methylated. TP73 showed similar percentages in both CLL and MCL (70% and 67%, respectively) and a lower frequency in MM (45%). The frequencies of p15INK4b were: 67% for MCL, 32% for MM and 16% for CLL. SOCS-1 and p14ARFgenes methylation were more frequent in MCL (83% and 100%) than MM (52% and 29% of cases, respectively) and, both genes lacked methylation in CLL patients. Low frequencies were observed for p16INK4a (4%, 7% and 0%) and RASSF1A genes (0%, 2% and 0%) for CLL, MM and MCL, respectively. All patients lacked methylation at p27KIP1 gene. None of the target genes were methylated in normal samples. Our MSP results were confirmed by sequencing analysis. In LLC the MI ranged from 0 to 0.29, with a median de 0.14, corresponding to one gene/sample. In MM the MI ranged from 0 to 0.71, with a median de 0.28, corresponding to two gene/sample while in MCL the median MI was 0.43 (range: 0.29-0.57), corresponding to three genes/sample. *Conclusions.* Highest frequencies of methylation for MCL and lowest levels for CLL were observed. CLL had a strong association with TP73 methylation. The perturbation of cytokine signalling via silencing of SOCS-1 gene seems to be important in both MCL and MM. The comparison of the profiles of this three tumor types showed important similarities and

differences, suggesting individual patterns of methylation. These results indicate that epigenetics would have a different value in the pathogenesis of these entities.

0058

TET2 DELETION IS A COMMON DENOMINATOR IN HAEMATOLOGICAL PATHOLOGIES WITH 4Q24 REARRANGEMENTS

R. La Starza,[1] E. Varasano,[2] B. Crescenzi,[2] G. Barba,[2] N. Testoni,[3] V. Gianfelici,[4] V. Pierini,[2] C. Baldazzi,[3] V. Nofrini,[2] A Pierini,[2] T. Zei,[2] M.F. Martelli,[2] C. Mecucci[2]

[1]University of Perugia, PERUGIA; [2]Hematology, University of Perugia, PERUGIA; [3]Istituto Seragnoli, BOLOGNA; [4]Hematology, University La Sapienza, ROME, Italy

Background. Chromosome deletions, the most frequent copy number changes in MDS and AML, produce diverse molecular events, such as gene fusion, loss of microRNA, and tumour suppressor gene inactivation or haploinsufficiency, most of which remain to be characterized. *Aims.* To characterise the 4q rearrangement in 9 patients with haematological diseases. *Methods.* G-banded metaphases were karyotyped according to ISCN (1995). To study del(4q), fluorescence in situ hybridization (FISH) was performed with 22 DNA clones mapping from 4q21 to 4q26. Patient materials included bone marrow, peripheral blood (PB) cultured with PHA, $CD3^+$ PB lymphocytes, and buccal mucosa cells at diagnosis and during disease evolution. FICTION studies (Fluorescence immunophenotyping and interphase cytogenetics as a tool for the investigation of neoplasms) used clone RP11-16G16 labelled in green (Spectrum green, Vysis) combined with anti-CD34, -CD133, -CD13, -CD33, -CD14, -CD19, -CD20, -CD7, and-CD3 antibodies labelled in red (CY3, Jackson-Immunoresearch/ListarFISH, Milano, Italy). Exon 6 TET2 mutations were analysed by DHPLC and direct sequencing using the following primers: TET2_EX6FOR 5'- CTTATCTGCTGCAAGTACC-3' and TET2_EX6REV 5'- CACGCTGAACTCTCTTCCTT-3'. *Results.* We collected 2 cases of CMML and 1 of AML with interstitial 4q deletions and 6 with translocations (1 severe transient pancytopenia; 1 persistent therapy-related leucopenia without bone marrow dysplasia; 1 CMML, 3 AML). FISH analysis identified a 4q deletion at the translocation breakpoint in all 6 cases and identified a common deleted region of about 75kb at band 4q24, corresponding to clone RP11-16G16, despite of varying deletion sizes. The common deleted region contains only TET2, a putative tumour suppressor gene. In the patient with severe transient pancytopenia constitutional karyotype suggested mosaicism, confirmed by FISH which detected del(4)(q24)/TET2 on PB, $CD3^+$ lymphocytes and cells from buccal mucosa. In 1 patient with AML FICTION demonstrated $CD34^+$ cells as well as myeloid, T- and B-cell lymphoid lineages carried del(4)(q24). Wild-type TET2 exon 6 was found in 7/9 cases. Additional karyotype or cryptic changes were found in 5/9 cases, del(5q) was present in four. *Summary and Conclusion.* In benign and malignant haematological pathologies we demonstrated for the first time that: del(4)(q24) involves TET2, a member of a well-conserved protein family with unknown functions, often at the 4q24 translocation breakpoint; no concomitant second allele mutations at TET2 exon 6 were present; del(4)(q24)/TET2 targets $CD34^+$ haematopoietic cells in AML. As it occurred as a germline event in the patient with transient pancytopenia who has not developed haematological malignancies it remains to be determined whether and how it plays a causative role in disease pathogenesis.

COMBINATION OF FT-CGH AND LM-PCR ALLOWS MOLECULAR CHARACTERIZATION OF CHROMOSOMAL ALTERATIONS IN T-ALL CASES

K. Dittmann,[1] G.K. Przybylski,[2] P. Grabarczyk,[1] S. Gesk,[2] G. Dölken,[1] R. Siebert,[2] C.A. Schmidt[1]

[1]University of Greifswald, GREIFSWALD, Germany; [2]Institute of Human Genetics, POZNAN, Poland

Background. Chromosomal abnormalities, like deletions, amplifications, inversions or translocations play a key role in malignant transformation. However, only a portion of these abnormalities has been clarified down to the molecular level so far. The precise clarification of such genomic alterations in leukaemia allows identification of genes involved in malignant transformation. Furthermore, this information can be useful for monitoring of the disease progression. *Aims.*In this study combination of fine tiling comparative genomic hybridization (FT-CGH) and ligation mediated PCR (LM-PCR) was used for cloning and molecular characterization of novel chromosomal breakpoint regions and gene rearrangements in T-cell acute lymphoblastic leukaemia (T-ALL). *Methods.* The TCRA/D split was shown previously by fluorescent in situ hybridization (FISH) in 68% of malignant cells suggesting an inv(14)(q11q32). Since chromosomal translocation involving the TCRA/D locus are usually accompanied by DNA losses due to V(D)J recombination, a custom fine-tiling oligonucleotide array of 385,000 oligonucleotides (NimbleGen) covering 24 Mb of different genomic areas, including the T-cell receptor α/δ locus (TCRA/D) on 14q11.2, was designed for comparative genomic hybridization (CGH). All DNA losses within TCRA/D were further analyzed by LM-PCR. *Results.* FT-CGH analysis revealed several mono- and biallelic deletions within the TCRA/D locus between positions 21,635 K, 21,976 K, 21,989 K and 22,093 K and were further analyzed by LM-PCR. Using a sets of nested primers located at the borders to the deleted regions amplification products differing from the germline control were obtained. Sequence analysis of these non-germline LM-PCR products revealed one physiological TCRD rearrangements between TRDV1 and TRDJ1 (position 21,635 K and 21,989 K). In addition sequencing of atypical fragments of the LM-PCR products obtained within the breakpoint at 21,976 K revealed the inversion of chromosome 14 with the breakpoint at sequence 21,977,838 of 14q11 together with the sequence of 105,948,661 of 14q32 in the IGH locus. LM-PCR analysis of the remaining breakpoint of the TCRA/D locus at position of 22,093 K with reverse gene specific primers revealed a translocation 14q11 at position 22,092,696 joined together with IGHV4-61 at 106,166,169 of 14q32.33. By this chromosomal aberration genomic regions of about 114,858 bp within the TCRA/D locus and 217,508 bp of the IGH locus (105,948,661-106,166,169) were deleted. The identification of this inv14(q11q32) confirmed the split observed with fluorescence in-situ hybridization (FISH) probes for the TCRA/D locus in 68% of cells. *Summary and Conclusions.* We show that the combination of FT-CGH and LM-PCR allows the amplification and molecular characterization of gene rearrangements and chromosomal translocation in patient samples with limited percentage of malignant cells. Furthermore, complex genomic alterations which are not visible using conventional cytogenetic procedures can be unraveled. This precise information can be used for minimal residual disease monitoring and most importantly may help to better understand the pathophysiology of T cell leukaemia.

AN ACCURATE MLPA SCREENING METHOD FOR MLL-PTD DETECTS A LOW FREQUENCY OF MLL-PTD IN PEDIATRIC ACUTE MYELOID LEUKEMIA

B.V. Balgobind,[1] I.H.I.M. Hollink,[1] D. Reinhardt,[2] E. van Wering,[3] S.S.N. de Graaf,[3] A. Baruchel,[4] J. Stary,[5] H.B. Beverloo,[6] G.E. de Greef,[7] R. Pieters,[1] C.M. Zwaan,[1] M.M. van den Heuvel-Eibrink[1]

[1]Erasmus MC - Sophia Children's Hospital, ROTTERDAM, Netherlands; [2]Medical School Hannover - Pediatric Hematology/Oncology, HANNOVER, Germany; 3DCOG, THE HAGUE, Netherlands; [4]St. Louis Hospital - Hematology, PARIS, France; [5]2nd Medical School, Charles University - Pediatric Oncology, PRAGUE, Czech Republic; [6]Erasmus MC - Clinical Genetics, ROTTERDAM, Netherlands; [7]Erasmus MC - Department of Hematology, ROTTERDAM, Netherlands

Background. Mixed-lineage leukemia (MLL)-partial tandem duplications (PTD) are found in 3-5% of adult acute myeloid leukemia (AML) samples, and are associated with a poor prognosis. In adult AML, MLL-PTD is either detected as sole abnormality or in conjunction with trisomy 11 or FLT3-ITD. Until now, studies in pediatric AML are scarce; reported large differences in frequency of MLL-PTD; and are often based on RT-PCR, which can give false-positive results. *Aim.* Retrospectively, a cohort of 286 children with AML was screened for MLL-PTD using multiplex ligation-dependent probe amplification (MLPA), which is a method to detect copy number differences of specific sequences. MLPA is less laborious as compared to genomic RT-PCR, and therefore suitable for screening a large number of samples. Moreover, this may resolve the problem of false positive cases when using RT-PCR. *Method.* We designed a reaction mix for MPLA-analysis containing probes for exon 2 to 13 of MLL for MLL-PTD detection and exon 17 of MLL as internal control. A probe in the serpinB2 gene was used as external control. If possible, screening was also performed for MLL-PTD transcripts with RT-PCR (n=226). The method is currently validated on an independent cohort of adult AML, for whom Southern Blot was performed to detect

MLL-PTD. *Results.* We detected MLL-PTD in 7/286 patients (2.4%), indicating a low frequency in pediatric AML. In these patients MLL-PTD transcripts were also present. Moreover, MLL-PTD transcripts were detected in 7 patients with an MLL-rearranged AML, but without evidence for MLL-PTD using MLPA, hence they were considered false-positive results. This was not encountered in the other 219 AML samples screened with RT-PCR without MLL-rearrangement. Three patients had normal cytogenetics; 1 patient had a trisomy 11, while for 3 patients no conventional cytogenetic data were available. Moreover, in 4 patients a FLT3-ITD was detected, in 1 other patient a FLT3 tyrosine kinase domain mutation, and in another patient a mutation in NRAS. MLL-PTD was not related to sex. The median age of patients with MLL-PTD was 7.5 (4.8-18) years and the median white blood cell count 95×10^9/L (44-170). Survival analysis was restricted to the subset of patients treated according to uniform DCOG and BFM treatment protocols (n=184). In this cohort, patients with MLL-PTD (n=5) had similar 3-years event-free survival rates (pEFS) compared to patients without MLL-PTD (40 vs. 44%, p=0.98). *Summary and Conclusions.* In conclusion, the frequency of MLL-PTD in pediatric AML has probably been overestimated in earlier studies. In this study we used MLPA as an accurate stand-alone screening method for MLL-PTD on the genomic level, which revealed a frequency of only 2.4% in pediatric AML.

Background. Pediatric acute leukemias with MLL gene rearrangements form a distinct group characterized by specific biology, high clinical aggressiveness and frequently serious prognosis. Split-signal fluorescent in situ hybridization (FISH) is currently gold standard for the detection of all rearrangements to breakpoint cluster region of MLL gene on chromosome 11q23. However, this investigation requires special laboratory settings and the results are usually obtained within several days. Data from the literature indicate that surface expression of NG2 antigen on leukemic cells as detected by flow cytometry might predict the presence of MLL gene rearrangements. Such flow cytometric results are readily available immediately at diagnosis. *Aims.* Evaluation of flow cytometric detection of NG2 antigen expression as a surrogate marker of the MLL gene rearrangements in pediatric acute leukemias. *Patients and Methods.* The study group consisted of 247 consecutive children with acute leukemias treated at the centers of Polish Pediatric Leukemia and Lymphoma Study Group (PPLLSG), including 207 pactients with acute lymphoblastic leukemias (ALL) and 40 patients with acute myeloid leukemias (AML). In all patients, bone marrow or peripheral blood slides obtained at initial diagnosis were analyzed with MLL split-signal FISH. In parallel, expression of NG2 antigen on blast cells was determined with multicolor flow cytometry using monoclonal antibody 7.1. *Results.* MLL gene rearrangements were found with split-signal FISH in 24 patients with *de novo* acute leukemias (9.7%). MLL was rearranged in 17 of 207 patients with ALL (8.2%). This incidence is comparable to data obtained in European and American studies. Interestingly, MLL aberrations were more frequent in AML patients occurring in 7 of 40 cases (17.5%). Such frequency is higher than usually described in literature (approximately 10%). NG2 antigen expression was found in 25 acute leukemia patients (10.1%), including 18 patients with ALL (8.6%) and 7 AML patients (17.5%). The results obtained with FISH and flow cytometry were largely overlapping. In ALL patients, the sensitivity of MLL gene rearrangement detection via flow cytometric NG2 expression assessment reached 82%; specificity of the test was very high (98%), with positive predictive value of 77% and negative predictive value of 98%. In AML patients, the sensitivity of NG2 test reached only 43%, with specificity of 88%, positive predictive value of 43% and negative predictive value of 88%. *Conclusions.* The flow ctometric assessment of NG2 antigen expression is highly specific and useful screening test for MLL gene rearrangements in pediatric ALL.

The study was supported by Polish Ministry of Science and Higher Education Grant 2 P054 095 30 "Biological and clinical characteristics of pediatric acute leukemias with MLL gene rearrangements".

DELETION OF 14Q INVOLVING IGH GENE IN PATIENTS WITH MULTIPLE MYELOMA

J. Balcarkova, T. Pika, H. Urbankova, M. Holzerova, V. Scudla, J. Bacovky, K. Indrak, M. Jarosova

University Hospital Olomouc, OLOMOUC, Czech Republic

Chromosomal translocations involving the IGH locus on 14q32 are one of the most frequent chromosomal abnormalities in patients with multiple myeloma (MM). Recent publications have shown that IGH in B-cell malignancies can be also involved in deletions affecting chromosome 14. Deletion involving IGH gene can be divided into 3 categories detected by FISH: whole IGH deletion, deletion of IGHV part (telomeric) of IGH and deletion of 3´IGH flanking (centromeric) sequences. Deletions including telomeric part of IGH gene are usually results of somatic VDJ recombination of IGH sequences. It has been suggested that deletions of 3´IGH flanking sequences can occur through deletions of whole der(14) soon after translocation affecting IGH gene, especially t(4;14) or as a results of interstitial del(14q). The aim of the present study was to determine frequency and type of IGH deletion using molecular cytogenetic methods and to correlate these findings with other cytogenetic abnormalities in our cohort of 200 MM patients. We detected deletions involving IGH gene in 42 (21%) patients using FICTION method with LSI IGH probe (Abbott-Vysis, Downers Grove, IL, USA). The deletions were grouped into 3 categories: 1. Deletion of whole IGH (15 cases); 2. IGHV deletion (14 cases); 3. Deletion of 3´IGH flanking sequence (13 cases). IGH deletions were found together with RB1 deletion in 29 out of 42 patients. Monosomy of chromosome 13 was confirmed in all patients with whole IGH deletion and RB1 deletion (12 patients). In 11 patients with whole IGH deletion the monosomy of chromosome 14 was proved by using 14qTEL specific Probe (Abbott-Vysis) and TCR A/D (14q11) (Dako, Stockholm, Sweden). Terminal deletion of (14q) not involving TCR A/D locus was confirmed in 4 patients. The translocation was proved in 7 out of 13 patients with 3´IGH deletion, in 5 patients t(4;14) and in another 2 patients t(11;14). Using CGH/arrayCGH deletion of 14q involving 3´IGH flanking sequence was proved in 2 patients. Finally, our data confirmed that deletions involving IGH were detected in 21 % patients in our cohort of 200 MM patients and should be considered as a marker of monosomy 14, translocation involving IGH gene or deletion of 14q. Deletions involving IGH most often coexist with monosomy 13 or RB1 deletion.

A NOVEL CHROMOSOMAL TRANSLOCATION T(11;14)(Q24.1;Q32) INVOLVING IGH IN CHILDHOOD B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKAEMIA

E. Tassano,[1] M. Acquila,[2] E. Tavella,[2] C. Rosanda,[2] C. Micalizzi,[2] C. Panarello,[2] C. Morerio[2]

[1]Istituto Giannina Gaslini, GENOA; [2]IRCCS Istituto Giannina Gaslini, GENOA, Italy

Rearrangements involving IGH gene on chromosome 14q32.3 are well known in mature B-cell malignancies and have been more recently described in B-cell precursor acute lymphoblastic leukaemia (BCP-ALL). IGH translocations are usually reciprocal and bring genes on other chromosomes into close apposition with the IGH locus, where their expression is deregulated due to the presence of potent B-cell-specific transcriptional enhancers. A two-year-old girl was diagnosed with an ALL common type and treated according to AIEOP-ALL-00 Protocol. Death occurred after four months due to haematological toxicity. Cytogenetic analysis of PB and BM blasts revealed a t(11;14)(q24-32;q32). FISH analy-

sis with IGH break-apart probe confirmed the rearrangement of the IGH locus between chromosomes 11 and 14. Cloning by LDI-PCR localized the breakpoint on chromosome 11q24.1 within the intronic region 1 of BC089451, a non coding gene. Quantitative real-time PCR showed over-expression of BLID mRNA, located 14Kb downstream the BC089451 gene. BLID codes for a protein containing a BH3-like domain essential for apoptosis. FISH studies performed with 11 close BACs to confirm the breakpoint junction identified a 585Kb deletion on der(11), with complete SORL1 loss. SORL1 controls intracellular trafficking of amyloid precursor protein and is causally linked to the pathogenesis of Alzheimer disease. Moreover SORL1 is down-regulated in high-grade astrocytoma. Deletion of SORL1 could play a role in leukemogenesis, like the IGH-ID4 association in the t(6;14)(p22;q32) with PAX5 and CDKN2A deletions. The functional consequence of BLID over-expression due to IGH enhancer juxtaposition is currently unknown. Mutational analysis of BLID BH-3 like domain is ongoing. The translocation to the Ig locus may result not only in deregulated expression of the incoming oncogene, but also in mutations due to the action of the Ig somatic hypermutation mechanism. In our case, a mutation of BLID in BH3 domain could result in a protein not inducing apoptosis.

K-RAS MUTATIONS IN CYTOGENETICALLY NORMAL AML PATIENTS

A. Morgan, J. Krauter, F. Onono, T. Bunke, F. Damm, G. Göhring, B. Schegelberger, A. Ganser, C.W.M. Reuter

Hannover Medical School, HANNOVER, Germany

RAS genes encode a family of membrane-associated G-proteins which are important for the transduction of receptor signalling into cellular processes such as proliferation, differentiation and apoptosis. Transforming mutations in the three functional RAS genes - H-RAS, K-RAS and N-RAS - cause constitutive activation of the RAS proteins, and have been identified in many types of human cancers, including hematologic malignancies such as acute myeloid leukemia (AML). AML is a genetically heterogeneous disease and karyotype analysis allows classification of clinically distinct leukemia subtypes. Almost half of AML patients are classified as cytogenetically normal (CN-AML), and prognostically significant mutations identified in this group of leukemias allow further sub-classification, which is important for risk-directed therapeutic intervention. The aims of this study were to investigate the incidence and influence of activating K-RAS mutations on clinical outcome in CN-AML patients. Following institutional guidelines in accordance with the Declaration of Helsinki, patient samples were collected upon informed consent. Primary leukemia cells were obtained from peripheral blood or bone marrow aspirates from patients (<60 years old), mononuclear cells were purified by Ficoll-Hypaque gradient centrifugation, and samples were evaluated by cytomorphology, cytochemistry, multiparameter flow cytometry, cytogenetics, fluorescence in situ hybridization, and molecular genetics in parallel. Cytogenetic R-banding analysis was accomplished and only patients with a normal karyotype upon chromosome-banding analysis were included in this study. K-RAS sequencing was accomplished by K-RAS-specific amplification of cDNA prepared from total RNA and mutations were confirmed by directly sequencing patient chromosomal DNA. Activating K-RAS mutations were detected in 3 of 143 (2.1%) CN-AML samples and occurred concomitantly with nucleophosmin-1 (NPM1) exon 12 mutations but did not overlap with N-RAS mutations, FLT3 internal tandem duplications (FLT3-ITD), or MLL partial tandem duplications (MLL-PTD). All K-RAS mutations were observed in codons 12 or 13, and no non-canonical mutations were identified. Interestingly, the one K-RAS$^+$/NPM1$^+$ patient who underwent autologous bone marrow transplantation had no relapse and is still alive after more than 2400 days from diagnosis. The two K-RAS$^+$/NPM1$^+$ patients who did not receive bone marrow transplantations following induction therapy both relapsed after 330 and 391 days, respectively. In CN-AML patients with NPM1 mutations, the benefit of bone marrow transplantation has been shown to be restricted to the subgroup of patients with the prognostically adverse genotype FLT3-ITD. Our findings suggest that CN-AML patients with activating K-RAS mutations may compose an additional sub-group of NPM1$^+$/FLT3-ITD- CN-AML patients who might benefit from bone marrow transplantation.

Cellular immunotherapy and vaccination

TARGETING LEWIS Y-EXPRESSING MULTIPLE MYELOMA AND ACUTE MYELOID LEUKEMIA WITH GENE-MODIFIED T CELLS DEMONSTRATING MEMORY PHENOTYPE

S. Peinert,[1] D. Hoenemann,[1] D. Ritchie,[1] P. Guru,[1] S. Harrison,[1] D. Westerman,[1] M. Kershaw,[1] M. Smyth,[1] J. Trapani,[1] P. Darcy,[1] A. Shin,[1] P. Gambell,[1] A. Scott,[2] P. Neeson,[1] H.M. Prince[1]

[1]Peter MacCallum Cancer Centre, MELBOURNE; [2]Ludwig Institute for Cancer Research, Austin Hospital, HEIDELBERG, VICTORIA, Australia

Background. AML and MM are sensitive to immune control as evidenced by T cell mediated allogeneic graft versus leukemia/myeloma effect. Adoptive immunotherapy with gene-modified T cells has shown clinical activity in some solid tumors and B cell non Hodgkin lymphomas. The carbohydrate antigen Lewis Y (LeY) is a tumor associated antigen expressed on numerous epithelial cancers. *Aim*. Our aim was to generate gene-modified clinical-grade T cells directed against LeY-positive hematological malignancies. Moreover, we aimed to produce cells that possessed T cell memory, essential for *in vivo* T cell persistence and long-term control of tumor cell targets. *Methods and Results*. MM and AML cell lines were found to express differing levels of the LeY antigen ranging from negative (median fluorescence intensity (MFI) equal to mature lymphocytes (lymph) as internal control) to strongly positive (up to10xMFI lymph). Furthermore, 25/46 (54%) and 15/29 (52)% of primary MM and AML bone marrow samples were LeY-positive (≥5xMFI lymph), respectively. LeY-expression did not correlate with patient age, gender, clinical risk status, cytogenetic abnormalities, extent of previous chemotherapy, degree of bone marrow infiltrate, disease subtype, cytopenias in peripheral blood (MM and AML), LDH, WBC > or ″ 30×10^9/L (AML), β2 microglobulin, albumin or pretreatment with bortezomib, thalidomide or lenalidomide (MM). We developed a novel retroviral vector construct enabling efficient transduction of PBMC-derived T cells with resultant high expression (up to 65%) of a single-chain anti-LeY chimeric T cell receptor comprising T cell activation via CD3zeta and CD28 signaling domains. Under GMP conditions, we achieved >100-fold expansion of T cells using a 12 day culture protocol. Anti-LeY T cells lysed LeY-positive tumor cells *in vitro* while sparing LeY-negative control tumor cells and moderately LeY-positive neutrophils (>3xMFI lymph). Similar transduction rates were achieved in CD4 and CD8 T cell subsets. End-of-culture T cells showed low expression levels of CD45RA and CCR7, moderate levels of the co-stimulatory molecules CD27 and CD28, and active proliferation in response to IL-2 and IL-15, suggesting an effector memory phenotype. On re-exposure to LeY expressing tumor cells, anti-LeY T cells displayed active proliferation and IFN-gamma production. *In vivo* efficacy was demonstrated in three independent experiments of a MM xenograft mouse model showing improved disease free survival of mice receiving anti LeY T cells compared to control mice treated with non-transduced T cells. Transplantation of syngeneic murine anti LeY T cells into sublethally irradiated Balb/C mice subsequently monitored for up to two years was found to be safe without generation of lymphoproliferative disorders arising from the anti-LeY T cells and no impact on OS compared to irradiated control mice not receiving adoptive T cell transfer. *Conclusions.* Consequently, we are about to undertake a first-in-human phase I trial of autologous anti-LeY T cells for patients with LeY-expressing MM or AML. LeY is a promising and immunologically relevant target for T cell immunotherapy and our anti-LeY T cells are likely to demonstrate persistence in patients, an outcome which will be specifically addressed in our upcoming study.

PEPTIDE VACCINATION ELICITS LEUKEMIA-ASSOCIATED ANTIGEN-SPECIFIC CYTOTOXIC CD8$^+$ T-CELL RESPONSES WITH POTENTIAL CLINICAL RELEVANCE IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

K. Giannopoulos,[1] A. Dmoszynska,[1] M. Kowal,[1] J. Rolinski,[1] E. Gostick,[2] D.A. Price,[2] J. Greiner,[3] M. Rojewski,[3] S. Stilgenbauer,[3] H. Doehner,[3] M. Schmitt[3]

[1]Medical University of Lublin, LUBLIN, Poland; [2]Cardiff University School of Medicine, CARDIFF, UK; [3]University of Ulm, ULM, Germany

Background. Results from bone-marrow transplantation, as well as remission phenomena after viral infection, suggest that CLL might be

targeted effectively by T-cell based immunotherapy. The receptor for hyaluronic acid mediated motility (RHAMM) is a tumor-associated antigen in chronic lymphocytic leukemia (CLL). $CD8^+$ T cells primed with the RHAMM-derived epitope R3, which is restricted by HLA-A2, effectively lyse $RHAMM^+$ CLL cells. *Aims.*We initiated a phase I clinical trial of R3 peptide vaccination and monitored immune responses against R3 epitope in patients with early stage CLL. *Methods.* Six HLA-A2+ CLL patients were vaccinated four times at biweekly intervals with the R3 peptide (ILSLELMKL; 300 μg/dose) emulsified in incomplete Freund's adjuvant; GM-CSF (100 μg/dose) was administered concomitantly. Detailed immunological analyses were conducted throughout the course of peptide vaccination including assessment of R3-specific T-cells by tetramer staining and ELISpot assays, evaluation of T-cell subsets which play a role in regulation of immune responses ($CD3^+CD4^+CD25^{hi}CD127^{lo}FOXP3^+$ Tregs, Th17, $CD8^+CD137^+$, $CD8^+CD103^+$ and IL-17 producing $CD8^+$ T cells ($CD8^+IL\text{-}17^+$)) as well as assessment of TNF, TGFβ, IL-10 and IL-2 serum levels. *Results.* No severe adverse events greater than CTC I° skin toxicity were observed. Four patients exhibited reduced white blood cell counts during vaccination. In 5/6 patients, R3-specific $CD8^+$ T cells were detected with the corresponding peptide/ HLA-A2 tetrameric complex; these populations were verified functionally in 4/5 patients using ELISpot assays. In patients with clinical responses, we found increased frequencies of R3-specific $CD8^+$ T cells that expressed high levels of CD107a and produced both IFN-γ and granzyme B in response to antigen challenge. Interestingly, vaccination was also associated with the induction of regulatory T cells in four patients. We could find a correlation between the frequency of Tregs and activated $CD8^+CD69^+$ T cells. Interestingly, $CD8^+CD137^+$ cells correlated with $CD8^+IL\text{-}17^+$ T cells. Further, we noted a correlation between IL-2 concentrations in the serum and Treg frequencies. *Conclusions.* This study provides a proof of concept that peptide vaccination is safe, feasible and able to mount immunological responses even in the immunosuppressive environment of CLL. The manipulation of therapeutic schema as well as the definition of a group of patients who will mostly profit from this treatment could help to translate immunological responses to significant clinical benefit.

0067

EPIGENETIC MANIPULATION OF TUMOUR ANTIGEN EXPRESSION: A STRATEGY FOR SELECTIVELY UP-REGULATING THE GRAFT-VERSUS LEUKAEMIA RESPONSE IN PATIENTS ALLOGRAFTED FOR HAEMATOLOGICAL MALIGNANCIES

A. Agathanggelou,[1] A. McLarnon,[2] O. Goodyear,[2] D. Sansom,[3] T. Stankovic,[2] C. Craddock,[4] P. Moss[2]

[1]University of Birmingham, BIRMINGHAM; [2]CRUK Institute for Cancer Studies, University of Birmingham, BIRMINGHAM; [3]Division of Immunity and Infection, IBR, University of Birmingham, BIRMINGHAM; [4]Centre for Clinical Haematology, Queen Elizabeth Hospital, BIRMINGHAM, UK

Background. There is compelling evidence to suggest the curative effect of reduced intensity allografts in acute myeloid leukaemia (AML) and other haematologic malignancies is mediated by a graft-versus-tumour (GVT) immune reaction. Cancer testis antigens (CTA) represent a family of immunodominant proteins that are variably expressed in haematological malignancies and represent a potential target of a GVT response. Importantly a number of CTA genes demonstrate promoter hypermethylation in solid tumours which can be reversed using demethylating agents such as azacytidine. *Aims.*To determine whether donor T cell responses to CTAs are present in patients allografted for AML and multiple myeloma (MM) and whether epigenetic therapies can be used to manipulate T cell mediated killing of haemopoietic targets. *Methods.* We first screened 37 patients with AML and 8 with MM, who had not received demethylating agent treatment, for T cell responses to 25 peptides derived from 10 CTA genes, including BAGE, LAGE, MAGE-A1, MAGE-A2, MAGE-A3, MAGE-A4, MAGE-C2, RAGE-1, by interferon-γ cytokine secretion assay (IFN-γ CSA). Subsequently, we studied the effect of epigenetic modifying reagents on the immunogenicity of tumour cell lines, primary tumours and normal primary fibroblast. We examined expression of 15 CTAs and costimulatory molecules important for T cell activation in AML, MM and Hodgkins' lymphoma cell lines before and after exposure to the demethylating agent azacytidine (Aza) and the histone deacetylase inhibitor sodium valproate (VPA), both as single agents and in combination. Finally we have used an interferon-γ ELISA assay to determine the effect of Aza and VPA on the recognition of target cells by CTA-specific T cells. *Results.* We found CTA specific T cells in 11.1% of patients (5 of 45) with frequencies ranging from 0.0005-0.2% (median 0.024%). We showed that expression of CTAs including HAGE, SACA3, SPANXB, PASD1 and SSX1 was induced in a dose dependent manner by Aza alone but not with VPA alone. We also observed that expression induced by Aza was further increased by combination treatment with VPA. Furthermore, we show increased expression of costimulatory molecules such as CD86 in AML and MM cell lines treated with either Aza or VPA. Induction of CTAs and costimulatory molecules was confirmed *in vitro* in primary AML cells and *in vivo* in AML patients on an Aza trial. The tumour-specific activity of Aza was confirmed in normal primary fibroblasts in which CTAs SPANXB, MAGEA4, HAGE and SSX1 were not induced. Finally we demonstrate that Aza-induced expression of the CTA MAGEA1 in MM cell lines was accompanied by increased recognition by MAGEA1-specific T cells. Consistent with the expression data, T cell recognition was increased further by combination treatment with VPA. *Conclusions.* These studies confirm the importance of members of the CTA family as targets of a T cell mediated immune response. Our data demonstrate that the expression of these putative immunodominant antigens in haematological malignancies in disease such as AML and myeloma, can be significantly and selectively up-regulated by epigenetic therapies with functional increases in target cell recognition. Our observations support the use of adjunctive epigenetic therapies after allogeneic transplantation with the aim of augmenting a GVL response.

HIGH-DOSE RHAMM-R3 PEPTIDE VACCINATION FOR PATIENTS WITH ACUTE MYELOID LEUKEMIA, MYELODYSPLASTIC SYNDROME AND MULTIPLE MYELOMA

J. Greiner,[1] A. Schmitt,[2] K. Giannopoulos,[1] M. Rojewski,[1] M. Götz,[1] G. Ritter,[3] S. Gnjatic,[3] P. Guillaume,[3] M. Ringhoffer,[1] M. Bommer,[1] R.F. Schlenk,[1] D. Bunjes,[1] H. Döhner,[1] M. Schmitt[2]

[1]University of Ulm, ULM, Germany; [2]University of Rostock, ROSTOCK, Germany; [3]Ludwig Institute of Cancer Research, NEW YORK, USA

Recently, we have demonstrated immunological responses and positive clinical effects of a peptide vaccination in ten patients with acute myeloid leukemia (AML), myelodysplastic syndrome (MDS) and multiple myeloma (MM) overexpressing RHAMM using 300 μg RHAMM-R3 peptide. Here, we report the second cohort of nine patients with AML, MDS and MM vaccinated with a higher peptide dose of 1000 μg RHAMM-R3 peptide. The vaccine was given four times at a biweekly interval and GM-CSF was added for five days each vaccination. Similar to the patients vaccinated with 300 μg peptide only mild drug-related adverse events were observed such as erythema and induration of the skin. Immunological analysis were performed using ELISpot assays for Interferon gamma and Granzyme B, tetramer staining and chromium release assays. Moreover, regulatory T cells were quantified during vaccination. In this second cohort of patients treated with 1000 μg peptide we detected specific immune responses in a lower frequency (33%) in contrast to patients in the 300μg cohort (70%). In these patients with immune responses we found an increase of $CD8^+$/HLA-A2/RHAMM-R3 $tetramer^+/CD45RA^+/CCR7^-/CD27^-/CD28^-$ effector T cells in flow cytometry and an increase of R3-specific $CD8^+$ T cells in ELISpot assays. Two patients with positive immune responses showed a significant decrease of regulatory T cells. One patient without positive immune and clinical effects showed an impressive increase of the frequency of regulatory T cells (5.03-15.9%). Three patients treated with 1000 μg showed positive clinical effects. One patient with MDS RAEB 2 showed a reduction of leukemic blasts in bone morrow to lower than 5%, one MDS patient an improve of peripheral blood counts and one patient with multiple myeloma a reduction of light chain in serum. However, the patients in the 300 μg cohort showed a higher frequency of positive clinical effects. Taken together, RHAMM-R3 peptide vaccination induced both immunological and clinical responses. Therefore, RHAMM constitutes a promising structure for further targeted immunotherapies in patients with different hematological malignancies. However, higher doses of peptide do not improve the frequency and intensity of immune responses in this clinical trial.

CLINICAL RESPONSES IN ALLOGRAFTED ACUTE LEUKEMIA PATIENTS WITH RESISTANT DISEASE USING A COMBINED CHEMO-IMMUNOTHERAPEUTIC TREATMENT STRATEGY

G.F. Torelli, W. Barberi, R. Maggio, M.S. De Propris, N. Peragine, A.P. Iori, F. Natalino, A. Guarini, R. Foà

Sapienza University of Rome, ROMA, Italy

Background. Chemotherapy manipulates the host milieu through different mechanisms including provision of lymphoid space, elimination of host anti-donor immune reactivity, suppression of regulatory T cells and induction of activating cytokines. Animal models have demonstrated that the serum peak concentration of activating cytokines is reached 48 hours after a chemotherapeutic treatment. We hypothesized that acute leukemia patients with resistant disease who have already undergone an allogeneic stem cells transplant (SCT) may benefit from donor lymphocyte infusions (DLI) performed closely after chemotherapy. *Aims.* Aim of this study was to analyze the immunologic and clinical effects of a chemo-immunotherapeutic treatment strategy consisting of chemotherapy followed 48 hours later by DLI in allografted acute leukemia patients. *Methods.* Four patients with acute myeloid leukemia evolved from a myelodisplastic syndrome and 1 with acute lymphoid leukemia, who had presented evidence of disease recurrence after an allogeneic SCT (1 from an haplo-identical donor, 2 from a matched unrelated donor [MUD] and 2 from a sibling), underwent 2 cycles of DLI (CD3=1×10^7/Kg of recipient body weight for haplo and MUD, and 1×10^8/Kg of recipient body weight for siblings) 2 days after a lymphodepleting chemotherapeutic treatment. These patients underwent cytofluorimetric analysis of the peripheral blood for CD3, CD3/CD4, CD3/CD8, CD3/CD4/CD25, CD16/CD56, CD20, CD7, CD38, HLA-DR and intracytoplasmic staining for γ IFN, α TNF, IL-2, IL-10 at days 0, 2, 5, 10, 20, 30 from DLI; two patients who underwent 2 cycles of standard DLI served as controls. *Results.* Analyses of the results demonstrated that from day 2 throughout the entire study period, patients who received DLI after chemotherapy showed a significant increase of activated elements, as documented by lymphocytes expressing the CD7/CD38/HLA-DR antigens, compared to controls (p=0.003); moreover, when considering the intracytoplasmic staining for specific cytokines, gamma IFN production was also superior for patients belonging to the study group (p=0.09). Four of the 5 patients who received DLI after chemotherapy presented for the first time a clinical picture of graft-versus-host disease (GVHD), although they had previously undergone many cycles of standard DLI; in these 4 patients, the onset of GVHD was associated to an hematologic complete remission (CR). The first three patients are now in persistent CR with a follow-up of 21, 7 and 2 months, respectively. The fourth patient obtained a CR, but died of pneumonia 2 months after the treatment. The fifth patient, who did not show any sign of GVHD, relapsed 4 weeks later. *Summary and Conclusions.* These observations suggest that donor lymphocytes may undergo a process of activation when infused into allografted patients who have received a chemotherapeutic protocol in the preceding 2 days; this seems to be associated with the onset of GVHD and with evidence of a clinical response. These results advocate a possible new chemo-immonotherapeutic strategy that can be taken into consideration for patients who have undergone an allogeneic SCT and have evidence of resistant/residual disease.

RNA-MODIFIED DENDRITIC CELLS AS THERAPEUTIC VACCINES

N. Berneman,[1] A. Van Driessche,[1] A. Van de Velde,[1] A. Schroyens,[1] P. Gadisseur,[1] I. Vrelust,[1] G. Nijs,[1] B. Stein,[1] K. Vermeulen,[1] K. Pieters,[1] N. Cools,[1] R. Van Gulck,[2] G. Vanham,[2] F. Van Tendeloo[1]

[1]*University of Antwerp, Vaccine and Infectious Disease Institute, EDEGEM;* [2]*Institute of Tropical Medicine, ANTWERP, Belgium*

Background. Messenger RNA (mRNA)-based gene transfer has gained an important interest over the last decade, especially in the field of immuno-gene therapy of cancer. *Aims.* The aim is to prepare and to use immunostimulatory autologous dendritic cells (DC), the most professional antigen-presenting cells, as an adjuvant treatment for malignant hematological disease and for chronic infectious disease in an antigen-specific manner. *Methods.* In this area, most researchers have exploited low voltage electrical pulses (electroporation) as a means to introduce coding RNA into the cells. mRNA electroporation has become a method of choice for transfecting DC, given its superior cytoplasmic expression efficiency, its simplicity over viral transduction protocols and its clinical safety profile because of a strictly transient expression profile and the inability to integrate into the host genome. Furthermore, it allows the simultaneous introduction of antigens and immunostimulatory proteins into DC through co-electroporation of multiple mRNA sequences. Recently, optimized strategies to produce highly translatable mRNA and more insights into the immunostimulatory properties of RNA structures further advocates the use of RNA for vaccination purposes. *Results.* We are currently performing several phase I/II clinical trials using antigen RNA-electroporated DC in several disease models such as acute myeloid leukemia (AML), human immunodeficiency virus (HIV) infection and cytomegalovirus (CMV) reactivation or infection following allogeneic stem cell transplantation (allo-SCT). Feasibility, safety, immunogenicity and clinical effects were investigated. We have shown successful GMP-grade DC generation and vaccine production in AML patients in remission, in stable HAART-treated HIV patients and in allo-SCT patients. No serious adverse events or toxicity were observed upon vaccination. For AML patients in remission, we observed a molecular anti-leukemic response by a reproducible decrease in tumor marker by molecular minimal residual disease monitoring as well as a significant increase in tumor antigen-specific $CD8^+$ T-cell responses following DC vaccination. Feasibility and immunomonitoring data will be presented for the HIV and CMV trials. *Conclusions.* In conclusion, we provide evidence that RNA loading by electroporation provides a versatile gene therapy tool for the design of DC-based therapeutic vaccines in cancer and infectious diseases.

IN VITRO GENERATION OF BOTH CONVENTIONAL AND UNCONVENTIONAL MATURE TCRAB CELLS FROM HUMAN HEMATOPOIETIC STEM AND PROGENITOR CELLS

S. Van Coppernolle, G. Verstichel, I. Velghe, J. Plum, B. Vandekerckhove, C.C. Kerre

UZ Gent, GENT, Belgium

Background. The *in vitro* generation of mature T cells from human hematopoietic stem and progenitor cells (HSPC) could fulfill two existing needs. First, it could enhance and quicken T cell immune reconstitution after stem cell transplantation (SCT). Second, by generation of tumour antigen specific T cells it could provide an efficient therapy for numerous malignancies and could enhance GVT effect in the context of allogeneic SCT, without aggravating GVHD. When human HSPC are cultured on the murine stromal cell line OP9-transduced with the Notch ligand Delta-like-1 (OP9-DL1), they differentiate to T cells which can proliferate and produce interferon-γ upon polyclonal stimulation. The nature of the mature cells generated in these cultures, however, has not been well studied so far. *Aims.* As thymic epithelial cells (TEC) are not present is this co-culture system, and as they are thought to be the main cell type mediating positive selection of conventional TCRαβ cells, we investigated whether the T cell populations generated in OP9-DL1 cultures contain mature conventional TCRαβ cells, illustrating their positive selection. *Methods.* $CD34^+$ HSPC from postnatal thymus (PNT) or cord blood were cultured on OP9-DL1, in the presence of the cytokines Flt-3L (5 ng/mL), SCF (2.5 ng/mL) and IL-7 (5 ng/mL), and in some experiments IL-15. At repetitive timepoints, an aliquot of the cells was analysed phenotypically. Mature T cells were transferred to feeder cells, consisting of irradiated JY cell line and PBMC, in the presence of PHA (1 mg/mL). After 7 days, IL-2 (50 IU/mL) was added to the culture. Every 14 days, cells were restimulated. Before functionality assays, cells were stimulated overnight with PMA and ionomycin. Results Phenotypically mature $CD27^+CD1^-$ TCRγδ as well as TCRαβ cells were generated in OP9-DL1 cultures. Few mature $CD4^+$ single positive (SP) TCRαβ cells were observed. Mature $CD8^+$ SP cells co-expressed variable ratios of CD8αβ and CD8αα dimers, suggesting that the $CD8^+$ SP T cells consisted of two different cell populations. TCRαβ CD8αα and TCRγδ cells both expressed the IL-2Rβ receptor consitutively and both proliferated on IL-15 without prior TCR stimulation, a characteristic of unconventional T cells. These latter cells produced IFN-γ but virtually no IL-2 upon activation. In contrast, CD8αβ and CD4 TCRαβ cells were unresponsive to IL-15, but could be expanded upon TCR stimulation. These T cells had the characteristics of conventional $CD4^+$ (ThPOK, CD40L, high levels of IL-2 and IL-4 production upon stimulation) and $CD8^+$ (granzyme, perforin and IFN-γ production upon stimulation) T cells. *Conclusions.* We can conclude from these data that OP9-DL1 supports the development of both unconventional T cells and T cells with the characteristics and functionality of post-selection T cells. This suggests that a process similar to positive selection on TEC may be operative, although less efficient than in the thymus. We are currently investigating the *in vitro* anti-tumor capacities of both populations.

IMMUNOSTIMULATORY LEUKEMIC DENDRITIC CELLS CAN EFFICIENTLY EXPAND LEUKAEMIA-REACTIVE T CELLS FROM HSCT DONORS

M. Casucci,[1] S.K. Perna,[2] A. Bondanza,[1] Z. Magnani,[1] M. Bernardi,[1] A. Crotta,[1] C. Tresoldi,[1] K. Fleischhauer,[1] F. Caligaris-Cappio,[1] F. Ciceri,[1] C. Bordignon,[3] A. Cignetti,[4] C. Bonini[1]

[1]San Raffaele Scientific Institute, MILANO; [2]Baylor College of Medicine, HUSTON, TEXAS, USA; [3]MolMed spa, MILANO; [4]Institute for Cancer Research and Treatment, CANDIOLO (TORINO), Italy

Allogeneic hematopoietic transplantation (allo-HSCT) is the only curative option for patients affected by high-risk acute myeloid leukemia (AML). This is possibly due to the ability of allogeneic immune system to eradicate leukemic stem cells. In order to improve the efficacy of the allogeneic immune system against leukemia, we exploited the unique ability of myeloid blasts to differentiate into leukemic dendritic cells (LDC). We observed that a short (48h) exposure to calcium ionophore A23187 and IL-4 is able to induce LDC differentiation in a large proportion (86%) of *de novo* and secondary high-risk AML. Compared to original blasts, LDC significantly up-regulate molecules of the immunological synapse (CD86, CD80, HLA-DR, CD54 and CD58) while maintaining an intact leukemic antigenic (c-kit, CD34, WT1) expression profile. This possibly suggested a direct access of leukemic stem cells to the process. This favourable phenotype correlates with a high T-cell stimulatory capacity, similar to that of healthy mature DC. Most importantly, LDC proved to be superior to the original blasts in promoting the expansion of leukemia-reactive T-lymphocytes from related and unrelated HLA-identical and haploidentical donors. The extent of T-cell expansion directly correlated with the sensitivity of AML blasts to LDC differentiation. T lymphocytes stimulated with LDC in the presence of IL-7 and IL-15 were of central memory phenotype and reacted against the original leukaemia *in vitro* and *in vivo*. When infused in NOD/Scid mice, transplanted with the original leukaemia, LDC-stimulated T lymphocytes induced long-term (>18 weeks) complete remissions in the majority of mice, suggesting that this approach may be active against leukemic stem cells. These results show that functionally competent LDC can be generated from the majority of high-risk AML and may be used for an integrated allogeneic immunotherapeutic approach.

IN VITRO ACTIVATION OF MYELOMA-SPECIFIC CYTOTOXIC T CELLS BY MUC1 PULSED DENDRITIC CELLS

F. Kryukov, L. Zahradová, D. Ocadlíková, L. Kovárová, E. Matejková, R. Hájek, J. Michálek

Masaryk University, BRNO, Czech Republic

Background. Multiple myeloma is a hematological malignancy with weak immunogenicity and defective function of the immune system. An important issue for immunotherapy of myeloma is the identification of appropriate tumor-associated antigens. Recently, MUC1 was detected on a majority of myeloma cell lines. *Aim.* We studied antigen-specific and HLA-A2-restricted cytotoxic activity against MUC1-positive ARH77 myeloma cell line *in vitro*. *Methods.* A HLA-A2 specific MUC1-derived nonapetide (TSAPDTRPA) was used as a tumor-associated antigen. Dendritic cells (DCs) were generated from HLA-A2 positive PBMCs using GM-CSF and IL-4 and were matured with TNFα. Myeloma-specific cytotoxic activity of MUC1-reactive CTL was established by repeated stimulation of CTL via dendritic cells loaded with MUC1-derived nonapeptide. MUC1-reactive IFN-γ$^+$ T cells were sorted with immunomagnetic beads (MACS) and further expanded *in vitro*. Specific cytotoxicity of MUC1-reactive T cells against ARH77 myeloma cell line was evaluated. *Results.* The IFN-γ subset of CD3$^+$CD4$^+$ and CD3$^+$CD8$^+$ T cells after repeated stimulation via DCs reached 1.31±0.15% and 1.05±0.12%, respectively and after MACS enrichment reached 66.94±7.19% of IFN-g$^+$ CD3$^+$CD4$^+$ and 64.59±6.03% IFN-γ$^+$ CD3$^+$CD8$^+$ T cells. At a ratio 20:1 (effector:target cells) cytotoxicity of IFN-γ$^+$ T lymphocytes vs. ARH77 reached 17.16±5.13% compared to non-specific killing of allogeneic PBMC (negative control) which was 0.79±0.39%. At a ratio 40:1 IFN-γ$^+$ T cells were able to kill 36.14±6.51% of ARH77 MUC1-positive target cells while the cytotoxicity against allogenic PBMC remained negligible 0.77±0.38%. The differences between experimental and control groups were significant (p<0.01). *Conclusions.* We were able to demonstrate that MUC1-reactive T cells can be identified and expanded using a relatively simple *in vitro* techniques consisting of antigen-specific stimulation, immunomagnetic sorting and rapid expansion. In summary, MUC1-pulsed DCs could be a good candidate for future clinical vaccination trials.

CYTOKINE INDUCED KILLER CELLS: *IN VITRO* DIFFERENTIATED T CELLS WITH ANTI-TUMORAL ACTIVITY

A. Pievani,[1] G. Borleri,[1] M. Franceschetti,[1] L. Vago,[2] K. Fleischhauer,[2] J. Golay,[1] M. Introna[1]

[1]Laboratory of Cellular Therapy G.Lanzani, BERGAMO; [2]Department of Immunohematology and Blood Transfusion, HSR, MILANO, Italy

Background. Cytokine-Induced Killer (CIK) cells are CD3$^+$/CD56$^+$ positive cells obtained *in vitro* by stimulation of mononuclear cells with IFN-γ, monoclonal antibody anti-CD3 and IL2.They show considerable cytotoxic activity against leukemic cell lines and fresh samples and potent anti-tumoral activity *in vivo* in mice with little GVHD. CIK cells represent then a promising tool for immunotherapy of haematological malignancies. *Aims.*We aim to obtain a full ontogenetic and functional characterization of *in vitro* generated CIK cells to better understand their therapeutical potentiality in cancer patients. *Methods.* CIK cells were generated *in vitro* by stimulation of mononuclear cells or sorted T cell subsets with INF-gamma, anti-CD3 and IL-2. They were fully characterized in terms of phenotype, cytotoxic activity and gene expression in comparison with CD56$^-$ T cells and NK cells also present during the culture and with circulating CD3$^+$/CD56$^+$ cells. *Results.* By culturing sorted subpopulations we demonstrate that CIK derive only from proliferating CD3$^+$/CD56$^-$/CD8$^+$ T cell subset and not from the few CD3$^+$/CD56$^+$ cells present in the peripheral blood of normal o seem to be terminally differentiated and don't divide further. Purified CIK cells express high donors. CFSE proliferation assay show that the same CD3$^+$/CD56$^+$ cells generated in vitr level of NK markers CD56 and NKG2D, but lack expression of other NK specific activating (NKp30, NKp44, NKp46, CD16) and inhibitory (KIR2DL1, KIR2DL2, KIR3DL1, NKG2A, CD94) receptors. Similarly to NK cells, they present a large granular lymphocyte morphology and can kill K562 target in a 4 hours calcein-release assay. CIK cells, similarly to T cells present in culture, are mostly CD8$^+$, TCR α-β and show a polyclonal usage of Vβ chains. They are CD45RA$^+$, CCR7$^-$, CD62L weakly positive, CD11a$^+$, CD27$^+$, CD28$^-$ and then they can be classified as effector memory T cells. Also gene expression analysis confirme that CIK are more related to CD56$^-$ T cells compared to NK cells. In fact, among 1076 immune-related genes analysed, only 50 are deregulated in CIK cells compared to T cells instead 115 compared to NK cells. A lot of genes up-regulated in CIK cells compared to CD56- T cells confirmed also by immunophenotyping (MIP1α, Perforin, FasL, TNFα) are consistent with a inflammatory phenotype. Circulating CD3$^+$/CD56$^+$, contrary to *in vitro* expanded CIK cells, are oligoclonal, poorly cytotoxic for K562 also upon IL-2 stimulation and express lower levels of CD56 and NKG2D. *Conclusions.* CD3$^+$/CD56$^+$ CIK cells derive from proliferating CD3$^+$/CD56$^-$/CD8$^+$ T cells present throughout the culture. Gene expression and phenotypic analysis demonstrate that CIK cells are more related to T cells than NK cells. Differentely for T cells, CIK cells show cytotoxic activity against the target K562.CIK cells, except for NKG2D and CD56, which are not specific NK cell markers, do not express to a significant extent the other activating or inhibitory NK receptors. By virtue of the CD45RA, CCR7, CD27 and CD28 expression, in addition to Perforin, FasL and MIP1α CIK cells can be considerated as fully differentiated memory CD8 T cells. They may represent an even more advanced stage of *in vitro* differentiation of CD56$^-$ T cells.

Acute lymphoblastic leukemia - Clinical

0075

A NOVEL DASATINIB-SENSITIVE RCSD1-ABL1 FUSION TRANSCRIPT IN CHEMOTHERAPY-REFRACTORY ADULT PRE-B LYMPHOBLASTIC LEUKEMIA WITH T(1;9)(Q24;Q34)

S. Mustjoki

Hematology Research Unit Helsinki, Biomedicum, HELSINKI, Finland

Background. Dasatinib is an oral broad-spectrum kinase inhibitor and predominantly targets BCR-ABL, SRC, C-KIT and PDGFR tyrosine kinases. It has been approved for clinical use for chronic myeloid leukemia (CML) and Philadelphia chromosome positive (Ph^+) acute lymphoblastic leukemia (ALL) patients carrying the 9;22 translocation and the resulting BCR-ABL1 fusion gene. In other subtypes of ALL, the clinical efficacy and putative molecular targets of dasatinib are unknown. *Aims.* The aim of this study was to characterize the molecular background of a clinical B-ALL entity characterized by a t(1;9) translocation and dasatinib sensitivity. *Methods.* Cytogenetic characterization of blood and bone marrow (BM) samples was done by G-banding and with FISH assay using 1p36 and 1q25 -specific probes, chromosome 9 painting and a BCR/ABL1 ES dual color extra signal translocation probe. Molecular characterization of the translocation was done with specific primers for RCSD1 and ABL1 using qualitative PCR. The PCR products were subsequently gel purified and sequenced in both directions. *Results.* The index patient is a 40-year old male patient with a chemotherapy-resistant pre-B ALL, who failed two consecutive induction therapies. G-banding indicated a balanced 1;9 translocation in leukemic blasts. FISH analysis suggested that the translocation occurs between ABL1 and an unknown gene located in chromosome 1q24-25. Based on the involvement of the ABL1 gene, the patient was started with dasatinib therapy (140 mg QD) and hematological remission was achieved 2 weeks later. After 4 weeks, patient was in complete cytogenetic remission which was maintained with dasatinib monotherapy until allogeneic BM transplantation was performed. A relapse occurred 1 year after transplantation, but was successfully re-treated with dasatinib. Molecular characterization of the translocation with specific primers covering the kinase domain of ABL1 gene (located in chromosome 9) and most of the exons of RCSD1 (located in the long arm of chromosome 1) yielded 2 positive PCR products with different molecular size. Sequencing revealed that the longer PCR product consisted of the 3 first exons of RCSD1 gene fused to ABL1 gene starting from exon 4. The shorter PCR product consisted of the first 2 exons of RCSD1 gene fused similarly to exon 4 of ABL1 gene. The predicted oncogenic product of the novel RCSD1-ABL1 fusion gene is in-frame and encodes the entire tyrosine kinase domain of ABL. *Conclusions.* In Ph^+ALL dasatinib is a novel promising treatment option. Results presented here suggest that dasatinib (and other tyrosine kinase inhibitors) may have clinical efficacy in other types of B-ALL as well. Although t(1;9)(q24;q34) translocation with RCSD1-ABL1 fusion gene is an uncommon subtype of acute leukemia, our results warrant the search for this novel fusion gene. It could be included in multiplex PCR panels commonly used in the routine diagnostic workup of acute leukemia enabling a rational and effective selection of optimal treatment modalities for each patient.

LONG-TERM FOLLOW-UP OF HIV-INFECTED ADULT PATIENTS WITH BURKITT'S LYMPHOMA OR LEUKEMIA TREATED WITH INTENSIVE SPECIFIC CHEMOTHERAPY AND RITUXIMAB

A. Oriol,[1] J.M. Ribera,[1] F. Vall-llobera,[2] J. Esteve,[2] C. Grande,[2] E. Giménez-Mesa,[2] S. Brunet,[2] J. Bergua,[2] L. Escoda,[2] D. Hoelzer[3]

[1]ICO-Hospital Germans Trias i Pujol, Badalona, Spain, BADALONA, Spain; [2]Pethema Group, BARCELONA, Spain; [3]Gmall Group, FRANKFURT, Germany

Background. A GMALL-derived PETHEMA trial (BURKIMAB) proved that rituximab could be associated with specific intensive chemotherapy to treat HIV-positive patients with Burkitt's lymphoma or leukemia (BL), with a survival similar to HIV-negative patients but significantly greater short-term toxicity (Cancer 2008;113:117-25). *Aims.* We aimed to study the impact of such immunochemotherapy on the clinical and immunologic status of HIV-positive long-term survivors. *Patients and Methods.* Twenty-four HIV-infected patients were included in the trial between July 2003 and December 2008. Treatment included a cyclophosphamide (Cy) and prednisone (PDN) five-day prephase, followed by six intensive 7-day cycles at 3-4 week intervals including rituximab in each cycle (plus two additional doses at the end of therapy), and several of the following: Cy, iphosphamide, vincristine, vindesine, dexamethasone, HD-MTX, HD-ARAC, teniposide, etoposide, and doxorubicin, together with intrathecal CNS prophylaxis with MTX+ARA-C+DXM. 14 patients (58%) achieved complete response and completed the scheduled treatment. All patients received HAART concomitantly to and after immunochemotherapy. *Results.* 14 patients, followed for more than one year (median 37 months, range 13-43), were selected for long-term evaluation of clinical and immunological status. 13 (93%) were males, with a median age of 37.5 (range 31-54). 3 (21%) were in immunologic and virologic response to HAART treatment at the time of diagnosis and all of them remained in the same situation after completing immunochemotherapy and during later follow-up. Four patients in immunologic response and with detectable viral load achieved and maintained a virological response after resuming treatment. Finally, 5/7 (71%) patients with uncontrolled HIV infection at diagnosis achieved and maintained both an immunologic and viral response after treatment. After a follow-up of 496 patient-years, no durable response losses have been reported, 4 HIV-associated infections were diagnosed including atypical mycobacterial infections (2), blastocystis enteritis and syphilis (one each) and one patient developed Kaposi's sarcoma. Up to date, no fatalities have occurred. *Conclusions.* Our results prove that specific immunochemotherapy for HIV-related BL/ALL3 has no significant long-term impact on the clinical and immunologic status, and is associated with a low incidence of HIV-associated events.

Background. The use of imatinib combined with chemotherapy has improved the short-term outcome of elderly patients with Ph^+ ALL. However, few data are available on the long-term impact of tyrosine kinase inhibitors on survival. Aims. In this presentation, we update the survival data of a cohort of 30 patients treated from January 2003 to November 2004, with a median follow-up of 64 months. *Methods.* Patients with Ph^+ ALL, aged 55 years or older were treated according to the AFR09 protocol developed by the GRAALL (Leukemia 20;1526, 2006) which included a pre-phase with steroids, an induction treatment with chemotherapy, a consolidation phase with imatinib and steroids, and 10 maintenance blocks, including two 2-month blocks of imatinib. Overall, imatinib was given for 6 months during this 2-year regimen. A group of 21 patients treated during the pre-imatinib era with a similar chemotherapy regimen is used as a control. Results. Out of 30 patients included in the study, 27 achieved a complete response. At last follow-up (November 2008), 7 patients were still alive (23%, 95% C.I.: 10-42%), including 4 patients who had experienced a molecular (n=3) or a hematological (n=1) relapse. Patients surviving after a molecular relapse had been salvaged with various regimens, including imatinib or dasatinib given alone or combined with chemotherapy. The single patient offered an allogeneic stem cell transplantation relapsed and died. No clinical or biological characteristics (age, blood counts, and steroid sensitivity) at diagnosis allowed for prediction of long-term survival. Compared with patients treated during the pre-imatinig era, the survival advantage con-

ferred by the use of imatinib could be confirmed with a longer follow-up (Figure). Summary/conclusions. In the imatinib era, approximately 20% of elderly patients are alive 3 years after a diagnosis of Ph+ ALL was made. In this study characterized by a relatively short exposure of patients to imatinib, molecular relapses could be successfully managed by additional treatment with tyrosine kinase inhibitors with or without chemotherapy.

THE HUMORAL IMMUNE RESPONSE DURING THE L-ASPARAGINASE THERAPY - THREE CLASSES OF ANTIBODIES

M. Zalewska-Szewczyk, L. Wyka, D. Adrianowska, A. Zubowska, M. Mlynarski

Medical University of Lodz, LODZ, Poland

The use of L-asparaginase - a crucial agent in the treatment of malignant blood disorders - is often associated with the appearance of hypersensitivity reactions. During the treatment anti-asparaginase antibodies may cause the clinical manifested allergy and/or decrease enzyme activity. The aim of the study was to assess the presence of anti-asparaginase antibodies during two consecutive therapy courses, containing L-asparaginase in three classes of immunoglobulin: IgG, IgM and IgE and to analyze a putative clinical importance of the anti-asparaginase antibodies. The study group includes 80 children and adolescents with newly diagnosed ALL, treated according BFM protocols. The real serum asparaginase activity during the treatment was established before a next administration of the drug, during the phase of induction and reinduction therapy. On the last day of the treatment with asparaginase, the blood samples were collected for the examination of anti-asparaginase antibodies in classes IgG, IgM and IgE. Both assays were based on ELISA method. At the end of induction phase, anti-asparaginase antibodies were found in 28% of children in class IgG, in 25% of children in class IgM and in 18% of children in class IgE. In 30% of children the antibodies in only one class were found, however in 5% the presence of all three of antibodies was noted. The median concentration of the antibodies amounted 39.56 µg/dL (33.0; 57.4) for IgG, 7.49 µg/dL (5.88; 8.87) for IgM and 1.47 (1.14; 2.33) for IgE. In the reinduction phase of treatment anti-asparaginase IgG antibodies were found in 45%, IgM antibodies in 51% and IgE antibodies in 18% of patients. The median concentration of anti-asparaginase antibodies amounted 79.3 µg/dL (41.4; 213.0) for IgG, 9.7 µg/dL (6.78; 12.4) for IgM and 2.0 µg/dL (1.3; 3.3) for IgE. Antibodies in class IgG and IgM, especially in the reinduction phase of treatment, were associated with the clinical manifested hypersensitivity/allergy against asparaginase (IgG p=0.0059, IgM p=0,009, IgE p=0.07) and asparaginase activity (IgG 55 vs. 297.6 AU, p<10-5, IgM 63.3 vs. 281 AU, p<10-5). The IgE antibodies did not show such an association (hipersensitivity reaction p=0.07, asparaginase activity 113 U/L vs. 161 U/l, p=0.39). *Summary.* The use of asparaginase leads to the development of several classes of anti-L-ASP antibodies. The frequency and the concentration of anti-asparaginase antibodies are significant higher in the second course of treatment. The most important of the clinical point of view seem to be IgG and IgM antibodies but not IgE antibodies.

0079

LIPOSOMAL CYTARABINE FOR THE PROPHYLAXIS OF CENTRAL NERVOUS SYSTEM RELAPSE IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA. INTERIM ANALYSIS OF THE PALG 5-2007 ALL STUDY

J. Piszcz,[1] B. Piatkowska-Jakubas,[2] S. Giebel,[3] A. Grzywacz,[4] M. Adamczyk-Cioch,[5] L. Bolkun,[1] M. Krawczyk-Kulis,[6] A. Holowiecka,[3] J. Holowiecki[3]

[1]Bialystok Medical Academy, BIALYSTOK; [2]Jagiellonian University, KRAKOW; [3]Comprehensive Cancer Center, M.Sklodowska-Curie Memorial Institute, GLIWICE; [4]J. Strus Hospital, POZNAN; [5]Medical University, LUBLIN; [6]Silesian Medical University, KATOWICE, Poland

Background. Prophylaxis of central nervous system (CNS) involvement is one of the principles of the treatment of adults with acute lymphoblastic leukemia (ALL) and includes cytostatics administered intrathecally by lumbar puncture. However, results of the preceding study by the Polish Adult Leukemia Group (PALG 4-2002) revealed poor compliance to the regimen with only 55% of patients receiving the planned 6 i.t. injections during induction-consolidation phase. We hypothesized that the introduction of the depot liposomal cytarabine formulation (DepoCyte, Mundipharma, Cambridge, UK) characterized by prolonged activity in the cerebro-spinal fluid may increase compliance, by reduction of the total number of i.t. injections. *Aim.* The goal of this prospective, multicentre PALG 5-2007 ALL study was to evaluate the feasibility and safety of intrathecal prophylaxis based on the use of liposomal AraC, instead of native cytostatics (AraC + Mtx + Dexamethasone). *Methods.* According to the protocol, during pre-treatment phase, all patients received the first 'triple' i.t. injection. However, those with symptoms of post puncture syndrome, previously identified as a risk factor for non-compliance, continued with liposomal AraC injections (3x during induction-consolidation), while the remaining patients were further treated with native cytostatics (6x). I.t. liposomal AraC (50 mg) was administered on strictly defined days in order to avoid toxicity when combined with i.v. cytostatics. In particular, during consolidation, the i.t. therapy was given 48h hours after high doses of i.v. AraC or Mtx and 14 days before the next i.v. AraC or Mtx. *Results.* Among 70 patients registered between Jan and Dec 2008, liposomal AraC was introduced in 12 cases (8 male, 4 female) with B-ALL (n=10) or T-ALL (n=2). One patient was Ph-positive. The median age equaled 30 (19-57) years. Among 11 patients who completed induction-consolidation treatment in CR, all but one received planned 3 i.t. liposomal AraC injections. The rate of compliance was 10/11 (91%). For the total number of 31 injections, adverse events were reported in 3 cases: 1 patients developed brain edema (during Mtx-containing consolidation), 2 patients experienced post puncture syndrome. With the median follow-up of 7 (5-12) months, none of the patients developed CNS relapse. *Conclusions.* For the first time we report results of a prospective study on the prophylactic use of liposomal AraC, within a uniform induction-consolidation protocol for adult ALL. This early evaluation suggests that the procedure is feasible and safe. Reduction of the total number of i.t. injections probably facilitates compliance to the protocol.

QUALITATIVE AND QUANTITATIVE CONCORDANCE IN MRD DATA, ASSESSED BY FLOW CYTOMETRY AND RT-PCR OF FUSION GENE TRANSCRIPTS IN INFANTS WITH MLL-REARRANGED ALL

A. Popov,[1] G. Tsaur,[2] A. Ivanova,[2] Y. Yakovleva,[3] T. Verzhbitskaya,[3] T. Riger,[3] E. Shorikov,[3] L. Saveliev,[1] L. Fechina[3]

[1]Ural State Medical Academy, EKATERINBURG; [2]Research Institute of Cell Technologies, EKATERINBURG; [3]Regional Children's Hospital, EKATERINBURG, Russian Federation

Background. Minimal residual disease (MRD) monitoring by flow cytometry (FC) or real-time quantitative polymerase chain reaction (RQ-PCR) is a strong tool for risk-adapted treatment in childhood acute lymphoblastic leukemia (ALL). ALL in infants is known to be very specific leukemia subset with frequent MLL-rearrangements and poor outcome. Prolonged MRD monitoring is essential during infants' ALL treatment. IgH/TCR rearrangements monitoring by RQ-PCR is well-standardized but very laborious and costly approach. Hence other methods - FC and RQ-PCR of fusion gene transcripts (FGt) - can be used for long-term MRD monitoring. *Aim.* To evaluate qualitative and quantitative concordance between MRD assessed by FC and FGt copy number (CN) measured by RQ-PCR in infants with primary and relapsed MLL-rearranged ALL during treatment. *Methods.* Tandem application of multicolor FC for MRD detection and RQ-PCR for FGt CN has been performed in 72

follow-up bone marrow samples from 15 infants with MLL-rearranged B-lineage ALL. 20 samples were obtained during remission-induction, 36 - during post-induction and 16 - during relapse treatment respectively. FGt CN was measured by RQ-PCR according to «Europe against cancer» recommendations. ABL has been used for normalization. MRD value was calculated as previously described. *Results and discussion*. Sensitivity of FC MRD detection varied from 10-4 to 10-5. RQ-PCR sensitivity ranged from 5-10-5 to 10-5. 7 of 72 samples (9.72%) were MRD-negative by both methods, 2 (2.78%) - were negative by FC but positive by RQ-PCR. Remaining 63 samples (87.50%) were MRD-positive by both methods. High qualitative concordance (97.22%) between FC and RQ-PCR was obtained. Samples with and without normal lymphoid regeneration were analyzed separately, because presence of normal B-cell precursors (BCP) in follow-up samples is known to be an obstacle for FC data analysis. Qualitative concordance in BCP-negative and BCP-positive samples was similar (96.43% and 97.73% respectively). In contrast, low quantitative concordance was found between FC and RQ-PCR (r=0.54). Low quantitative concordance was also observed in BCP-positive and BCP-negative samples (r=0.64 and r=0.59 respectively). Significant quantitative difference in FC and RQ-PCR data could be associated with variability of FG expression during treatment that does not correspond to the cell number. Moreover, percentage of tumor blasts among all nucleated cells is calculated during FC MRD detection, while MRD value in RQ-PCR of FGt is corresponded to the initial FGt and control gene levels. FC appears to be better for the quantitative MRD assessment; however FGt detection in RQ-PCR is more appropriate for MRD qualitative analysis because of its higher sensitivity. Hence, FC is more applicable for early treatment stratification and RQ-PCR of FGt - for later time-points. *Conclusion.* Tandem application of FC at early time-points and FGt detection by RQ-PCR at later time points seems to be a useful tool for MRD monitoring in infants with MLL-rearranged ALL.

0081

OUTCOME FOR ADOLESCENT AND YOUNG ADULTS UP TO AGE 35 YEARS (AYA) WITH ACUTE LYMPHOBLASTIC LEUKEMIA TREATED ON THE PEDIATRIC PROTOCOLS OF MOSCOW-BERLIN 91 AND 2002

S.V. Semochkin, S.S. Kulikova, L.A. Antipova, V.V. Lunin, A.G. Rumiantsev

Federal Scientific Clinical Center for Pediatric Hematology, Oncology and Immuno, MOSCOW, Russian Federation

Background. Over the past decades, several research groups have demonstrated improvement in survival for adolescents and young adults (AYA) up to age 35 years with acute lymphoblastic leukemia (ALL) using pediatric regimens compared to adult treatment regimens. Original national pediatric protocols ALL-MB 91 and 2002 have shown high efficiency of treatment of children in Russia. *Aims.* The purpose of the study was to assess the efficacy and toxicity pediatric protocols ALL-MB 91 and 2002 for adolescents and AYA with ALL. *Methods.* Enrollment on the study began in December 1997. Inclusion of patients (pts) in protocol ALL-BFM 90 (n=43) was completed in September 2005 and ALL-MB 91/2002 - March 2008 (n=34). In protocols ALL-MB 91/2002 the pts receive four drug induction with dexametasone 6 mg/m^2 daily for 36 days, daunorubicin 45 mg/m^2 for 2 doses, vincristine 2 mg weekly for 5 doses and and intrathecal (IT) cytarabine and IT methotrexate and IT prednisolone weekly for 6 doses. Consolidation therapy included L-asparaginase in a constant dose of 10000 ME/m^2 weekly for 18 doses and 6-merkaptopurine 50 mg/m^2 (100%) daily and methotrexate 30 mg/m^2 (100%) weekly with weekly doses adjusted according to white blood cell count. Central nervous system (CNS) irradiation is performed for pts with CNS involvement at diagnosis and for patients with T-cell ALL and a high presenting white blood cell count. Traditional maintenance was carried out up to 24 months. The protocol ALL-BFM 90 called for the purpose of comparison as an effective standard therapy. *Results.* 78 (m - 8, f - 30) pts have been enrolled. 77 pts are valuable (1 withdrew on day 1 of therapy). The median age is 19.3 years (range 15-35). 37 (86%) pts are in complete remission (CR) on the protocol ALL-BFM 90 vs. 29 (88%) pts - ALL-MB 91/2002. Respectively 3 (7%) and 3 (9%) pts died in the induction. 3 (7%) and 1 (3%) pts is refractory to therapy. 5 (12%) and 1 (3%) pts died in CR from significant toxicities. Respectively 9 (21%) and 3 (9%) pts relapsed. 4 (33%) pts have CNS relapse, and 6 (50%) have bone marrow relapse. 6-years event free survival (6y-EFS) has 54 vs.77% (median of observation 5.7 years, p>0.05), and 6-years overall survival (6y-OS) has 65 vs. 82% (p>0.05) respectively. Myelosuppression toxicities of ALL-MB 91/2002 protocols have less significant compared with the ALL-BFM 90. In postremission period the most frequent significant toxicities are neutropenia Grade 4 (21 vs. 66%, p<0.05), and thrombocytopenia Grade 4 (0 vs. 62%, p<0.05), and infectious Grade 3-4 (32 vs. 55%, p>0.05). *Conclusions.* Protocols ALL-MB 91/2002 is effective therapeutic regimes for ALL. Further studies with higher power are needed to determine if this treatment regimen offers an advantage to AYA patients with ALL.

0082

HUMORAL IMMUNITY TO DIPHTHERIA, TETANUS, MEASLES, AND HAEMOPHILUS INFLUENZAE TYPE B IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA AND RE-VACCINATION RESPONSES

E. Zengin, N. Sarper

Kocaeli University, KOCAELI, Turkey

Background. Loss of immunity to previous vaccinations and timing of re-vaccinations in children receiving chemotherapy remains controversial. *Aims.* To investigate the immunity to vaccine preventable diseases in children with acute lymphoblastic leukemia (ALL) before and after chemotherapy and to evaluate re-vaccination responses. *Methods.* Sixty-one patients with acute lymphoblastic leukemia and 13 healthy siblings were enrolled. Relapsed patients or patients undergoing stem cell transplantation were excluded. The study was approved by the local ethical committee and written informed consents of patients, parents and controls were obtained. Türk ALL-2000 protocol (TRALL-2000), a modified BFM-95 protocol was administered. Newly diagnosed patients (group 1), patients on maintenance chemotherapy (group 2) and patients that completed chemotherapy (group 3) were three study groups. Serum samples were stored at -80°C until analysis of the antibody titers was performed to minimize the inter-assay variation. Patients in group 2 were vaccinated with diphtheria, tetanus and Hib. Group 3 and controls were vaccinated also with measles. Post-vaccination antibody titers were also studied. All of the titer determinations were performed with the ELISA method. *Results.* Patients and controls had primary vaccination with diphtheria, tetanus and measles, but not with Hib. After chemotherapy median antibody levels against diphtheria, tetanus, measles and Hib were decreased but tetanus antibodies were still at the protective levels. Proportions of the patients with protective levels were 11.1%, 83.3%, 16.7% and 16.7% for diphtheria, tetanus, Hib and measles. Vaccination maintained protective antibody levels in 81%, 100%, 89.5% and 70% of the patients for diphtheria, tetanus, Hib and measles respectively. Vaccine responses during maintenance were also satisfying; 82.4%, 100% and 73.3% of the patients achieved protective antibodies for diphtheria, tetanus and Hib respectively (Table 1). *Summary and Conclusions.* Present study shows loss of immunity especially to diphtheria and measles after ALL chemotherapy. We recommend administration of Hib vaccine especially to children with no primary vaccination after the first three months of maintanence, followed by a second booster dose after cessation of the chemotherapy to increase immunity. Re-vaccination with tetanus, diphtheria and measles 3 months after cessation of chemotherapy seems more practical and economical instead of monitoring antibody levels.

Table 1. Proportions of patients and controls with complete protection.

groups	Diphtheria		Tetanus		Hib		Measles	
	Prevac	postvac	Prevac	postvac	Prevac	postvac	Prevac	postvac
At diagnosis n=20	80%	–	100%	–	35%	–	55%	–
During maintenance n=36	40%	82.4%	91.4%	100%	17.1%	73.3%	20%	–
After chemotherapy n=20	11.1%	85%	83.3%	100%	16.7%	89.5%	16.7%	70%
Controls n=13	46.2%	88.9%	100%	100%	15.4%	88.9%	38.5%	66.7%

0083

PROGNOSTIC SIGNIFICANCE OF ULTRASOUND-DETECTED BOWEL WALL THICKENING IN NEUTROPENIC ENTEROCOLITIS

T. Hassan, M. Atfy, M. El Tohamy

Zagazig University, ZAGAGZIG, Egypt

Background. Neutropenic enterocolitis is a life-threatening condition associated with severe neutropenia. It is most commonly seen in patients with acute leukemia but has also been described in patients with other malignancies. Ultrasonography and color Doppler of the bowel support the diagnosis by detecting the mural thickening and bowel perfusion. *Aim.* This study was designed to assess the prognostic value of bowel wall thickening detected by US and bowel wall perfusion in monitoring children with neutropenic enterocolitis with regard to the severity of the disease. *Results.* Our results revealed abnormal intestinal wall thickening of the ileoceacal region and ascending colon in 29 out of 42 patients treated from leukemia (69%), the mean wall thickness was (8.71±2.16; range 6-12.5 mm). Hypervascularity on color Doppler imaging was noted in the majority of patients whereas two out of eight deaths revealed absent flow within the bowel wall. Complete resolution of symptoms occurred in 21 (72.4%) of US-positive group with a mean duration of symptoms (9.83±2.78; range 7-15days) while it occurred to all patients without bowel wall thickening, mean duration of symptoms was (6.15±1.14; range 5-8 days). Serial sonographic studies documented a gradual decrease in bowel wall thickness in the surviving patients who eventually recovered (72.4% versus 100%, $p<0.05$). NE-related death was significantly higher in US-positive patients (8 vs. 0, $p=0.05$). Patients with bowel wall thickness >10 mm had significantly higher mortality rate than those with bowel wall thickness <10 mm (70% vs. 5.3%, $p<0.001$). *Conclusion.* In conclusion, neutropenic patients with sonographically detected bowel wall thickening have a poor prognosis. In addition, the degree of bowel wall thickening was significantly impact the outcome of those patients; so the US-detected mural thickness and bowel wall perfusion reflects the course of the disease and predictive for the clinical outcome.

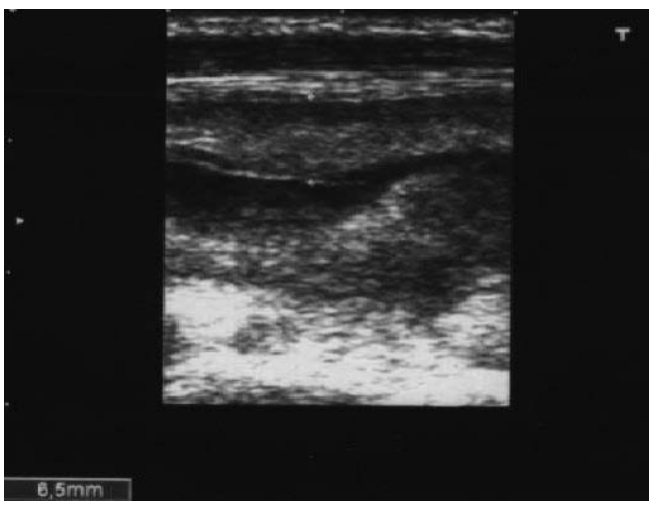

Figure 1. A case of NE in 10 yrs-old girl. (a&b) Ultrasound.

EARLY AND LATE RESPONSE ASSESSMENT WITH FDG-PET AFTER BEACOPP-BASED CHEMOTHERAPY IN ADVANCED-STAGE HODGKIN LYMPHOMA PATIENTS HAS A HIGH NEGATIVE PREDICTIVE VALUE

J. Markova,[1] C. Kobe,[2] M. Skopalova,[3] L. Zikavska,[1] Z. Vernerova,[1] K. Klaskova,[1] K. Dedeckova,[4] H.T. Eich,[5] M. Dietlein,[2] M. Fuchs,[6] A. Engert,[7] T. Kozak[1]

[1]University Hospital Kralovske Vinohrady, PRAGUE [1]0 - VINOHRADY, Czech Republic; [2]Department of Nuclear Medicine, University of Cologne, 50924 COLOGNE, Germany; [3]Department of Nuclear Medicine, PET Center, Na Homolce Hospital, PRAGUE, Czech Republic; [4]Institute of Radiation Oncology, University Hospital Na Bulovce, PRAGUE ,8 Czech Republic; [5]Department of Radiation Oncology, University of Cologne 50924 Cologne, 50924 COLOGNE, Germany; [6]German Hodgkin Study Group, University of Cologne, 50924 COLOGNE, Germany; [7]Department I of Internal Medicine, University of Cologne, 50924 COLOGNE, Germany

Background. Positron emission tomography (PET) is considered as a potential powerful prognostic factor in the treatment of Hodgkin lymphoma (HL) patients. *Aims.* To analyse the prognostic value of PET for early and late response to BEACOPP-based chemotherapy in patients with advanced-stage HL. *Methods.* Between January 2004 and April 2008, 69 patients with newly diagnosed HL in clinical stage IIB with large mediastinal mass or extranodal disease, in clinical stage III or IV with or without risk factors were treated according to the HD15 protocol of the German Hodgkin Study Group (GHSG). The treatment comprised of 6 - 8 cycles of BEACOPP-based chemotherapy and invoved-field radiotherapy in patients with PET positive rest-tumour after the end of chemotherapy. All patients received an early PET scan after 4 cycles of chemotherapy (early-PET) and a late PET scan after completion of chemotherapy (late-PET). For the calculation of the predictive value, death of any cause was counted as a treatment failure in addition to progression and relapse. *Results.* Of the overall group, 68 patients completed the scheduled chemotherapy and one patients died in the 8th cycle of chemotherapy due to bleomycin-induced pneumonitis. 18/69 patients had a positive early-PET (26%), while 51/69 had a negative early-PET (74%). The late-PET was positive in 9/68 patients (13%), and negative in 59/68 patients (87%). At a median observation time of 34 months, the negative predictive value for patients treated with BEACOPP only, was 96% for early-PET and 95% for late-PET. The positive predictive value for patients treated with BEACOPP with or without radiotherapy was 22% for both early- and late-PET. During the study-time 5 patients relapsed, 4 of them had a positive early-PET and 2 had a positive late-PET. Importantly, all patients who relapsed with negative late-PET had relapsed after 12 months follow-up. *Summary*. Advanced-stage HL patients with a negative PET in early and late response assessment have a very good prognosis, while PET positive patients have an increased risk for progression and relapse after BEACOPP-based chemotherapy. The sensitivity of a positive PET for treatment failure within the first year is very high, although later relapses can occur.

VEBEP REGIMEN AND HIGHLY ACTIVE ANTIRETROVIRAL THERAPY (HAART) IN PATIENTS (PTS) WITH HD AND HIV INFECTION (HD-HIV): FINAL RESULTS OF THE ITALIAN COOPERATIVE GROUP ON AIDS AND TUMORS (GICAT) STUDY

M. Spina,[1] A. Antinori,[2] V. Neri,[2] G. Rossi,[3] A. Re,[3] B. Allione,[4] A. Chimienti,[1] R. Talamini,[1] U. Tirelli[1]

[1]National Cancer Institute, AVIANO; [2]IRCCS Spallanzani, ROME; [3]Spedali Civili, BRESCIA; [4]Ospedale Civile, ALESSANDRIA, Italy

Background. The outcome of pts with HD-HIV is still poor, because the duration of complete remission (CR) is short. To improve the prognosis of HD-HIV, a feasibility study with the VEBEP regimen and HAART was started in previously untreated HD-HIV pts. *Methods.* CT included epirubicin 30 mg/m^2/day (days 1-3), cyclophosphamide 1000 mg/m^2 (day 1), vinorelbine 25 mg/m^2 (day 1), bleomycin 10 mg/m^2 (day 3) and prednisone 100 mg/m^2/day (days 1-3). *Results.* Since September 2001, 71 pts have been enrolled. The median age was 41 yrs. The median CD4$^+$ cell count was 248/mm^3 and 51% of pts had a detectable HIV viral load. Stage III-IV was present in 50/71 (70%) pts. Histologic subtypes were:

MC 70%, NS 20%, LD 4%, LP 2%, unknown 4%. Four toxic deaths were observed (septic shock, PCP, hepatic failure and pneumonia during neutropenia). An absolute neutrophil count <500 was noted in 60% of pts. Grade 3-4 anemia was observed in 38% of pts and severe thrombocytopenia in 22% of pts. Twenty-two per cent of pts had febrile neutropenia with 19 documented infections in 16 pts (4 varicella, 4 bacterial pneumonia, 3 bacterial sepsis, 2 PCP, 1 cerebral toxoplasmosis, 1 esophageal candidiasis, 1 HBV reactivation, 1 HCV reactivation, 1 prostatitis, 1 salmonellosis). CR was obtained in 47/71 pts (66%) and PR in 9/71 pts (13%). With a median follow up of 22 months, only 4 pts have relapsed. OS and TTF at 24 months are 69% and 59%, respectively. *Conclusions.* Our preliminary data demonstrate that VEBEP regimen in combination with HAART is feasible and active in pts with HD-HIV. This study was supported by ISS grants.

0086

18FDG-PET-NEGATIVE COMPLETE REMISSION PRIOR TO AUTOLOGOUS STEM CELL TRANSPLANTATION PREDICTS FOR SUPERIOR EVENT FREE SURVIVAL OF PATIENTS WITH RELAPSED OR REFRACTORY HODGKIN LYMPHOMA

S. Peinert,[1] R. Hoyt,[2] A. Grigg,[2] H.M. Prince,[1] J.F. Seymour,[1] L. Rigacci,[3] A. Roberts,[2] J. Szer,[2] D. Ritchie[1]

[1]Peter MacCallum Cancer Centre, MELBOURNE, Australia; [2]Royal Melbourne Hospital, PARKVILLE, Australia; [3]Careggi Hospital and University of Florence, FLORENCE, Italy

Background. In patients (pts) with Hodgkin lymphoma (HL) receiving first-line chemotherapy, interim restaging with 18F-FDG-PET scan (FDG-PET) after 1 or 2 cycles has been shown to predict event free survival (EFS) with high sensitivity and specificity overriding the clinical International Prognostic Score (IPS). The predictive value of FDG-PET in patients with relapsed or refractory HL undergoing high dose chemotherapy and autologous stem cell transplantation (ASCT) is less well established. *Aim.* We strived to determine the predictive value of FDG-PET in pts with HL planned to receive ASCT ± peri-transplant involved field radiotherapy (IFRT). *Methods*. A retrospective analysis was undertaken of 52 consecutive pts treated at three centres. Pts with primary refractory (n=25) or relapsed HL (n=27) underwent FDG-PET scanning after salvage chemotherapy and before ASCT. Remission status by FDG-PET post salvage, treatment details, including salvage type and peri-transplant IFRT, and clinical characteristics were recorded and EFS and overall survival (OS) post ASCT were evaluated. Survival analyses were performed using Kaplan-Meier estimates and cohorts were compared using the Log-rank (Mantel-Cox) and the Gehan-Breslow-Wilcoxon Test. The contingency of data between different groups was analysed using Fisher's exact test. *Results*. The median age of pts at the time of ASCT was 38 [18-61] years, 27/52 (52%) were male. The majority of pts received salvage chemotherapy with VIC (etoposide 100 mg/m^2 day (d)1-3, ifosfamide 5 g/m^2 d2, carboplatin AUC 5), n=24) or MADEC (methotrexate 400 mg/m^2 d1, cytosine arabinoside 75 mg/m^2 d1-5, dexamethasone 40 mg d1-4, etoposide 75 mg/m^2 d1-5, cyclophosphamide 750 mg/m^2 d2, n=13), other chemotherapy regimens used were BEACOPP, n=3, IGEV, n=3, FGIV, n=2, DHAC, n=2 or others, n=1 each. After salvage, 23/52 (44%) of pts were FDG-PET-negative and 29/52 (56%) were positive. With a median follow-up of 30 [4-115] months in surviving pts, the 6-year actuarial rates for EFS and OS for FDG-PET negative versus FDG-PET positive pts were 73% and 34% (p=0.03), and 95% and 64%, respectively (p=0.06). Overall, the addition of peri-transplant IFRT did not impact on EFS or OS. However, in 13 pts with post salvage FDG-PET-avid disease which was limited to an area entirely encompassed by IFRT, actuarial rates of 6-year EFS and OS were 51% and 66% which did not differ significantly from those obtained in FDG-PET-negative pts (p=0.47 and 0.39, respectively). Female gender was the only factor predictive for obtaining a complete FDG-PET-remission post salvage therapy (p=0.011). Female gender and duration of first remission of ≥12 months also independently predicted for superior EFS (p=0.017 and 0.039), respectively. Other characteristics including the presence of B-symptoms, extra-nodal disease prior to salvage, age ≥38 years, type of salvage or conditioning regimen used, or transplant centre did not influence EFS or OS. *Conclusions.* Our data show that FDG-PET-status after salvage chemotherapy for relapsed or refractory HL is a powerful predictor of EFS after ASCT demonstrating an excellent outcome for FDG-PET-negative pts. In pts with limited FDG-PET-avid disease following salvage chemotherapy, the addition of peri-transplant IFRT may reduce the poor prognostic impact of residual FDG-PET positivity in a subset of patients.

EARLY FDG-PET SCAN CONFIRMS ITS PROGNOSTIC IMPACT ALSO IN LOCALIZED STAGE, ABVD TREATED HODGKIN LYMPHOMA PATIENTS

L. Rigacci,[1] B. Puccini,[1] A. Gallamini,[2] F. Merli,[3] C. Stelitano,[4] M. Balzarotti,[5] P. Pregno,[6] C. Fraulini,[7] F. Salvi,[8] R. Emili,[9] S. Tavera,[2] I. Capodanno,[3] F. Morabito,[4] A. Santoro,[5] U. Vitolo,[6] T. Chisesi,[7] A. Levis,[8] A.M. Liberati,[9] A. Bosi[1]

[1]Azienda Ospedaliera Careggi, FLORENCE; [2]ASO S. Corce e Carle, CUNEO; [3]Ospedale S. Maria Nuova, REGGIO EMILIA; [4]Ematologia Ospedali Riuniti, REGGIO CALABRIA; [5]Ematologia Humanitas, MILANO; [6]Ematologia Ospedale S. Giovanni Battista, TORINO; [7]Ematologia Ospedali Riuniti SS. Giovanni e Paolo, VENEZIA; [8]Ematologia Ospedale S.S. Antonio e Biagio, ALESSANDRI; [9]Ematologia Ospedale, TERNI, Italy

Background. Hodgkin's lymphoma is one of the malignant diseases with the highest rate of cure particularly if diagnosed in early stage. Nevertheless a small proportion of patients with localized stage do not respond to therapy and become chemorefractory. We explored the predictive value on therapy outcome of an early evaluation of treatment response by 18F-fluorodeoxyglucose positron emission tomography (FDG-PET) scan performed after two corses of ABVD in patients with localized Hodgkin's disease. *Patients*. From 2002, 163 new localized stage Hodgkin's lymphoma patients were consecutively admitted to nine Italian hematological centers. Patients with stage I-IIA according to Ann Arbor stage were considered for the study. FDG-PET was mandatory at baseline, after two cycles and at the end of therapy. We evaluated the progression free survival of patients starting from the time of diagnosis to relapse or progression of disease or last follow-up. Patients were candidate to receive 3 or 4 course of ABVD followed by involved field radiotherapy at 30 Gy, except in the cases in which physician decided to omit radiotherapy. No treatment variation based only on PET-2 results was allowed. *Results.* The median age was 33 years (16-75), 85 patients were female and 78 male, 15 patients presented stage I and 148 stage II, bulky was reported in 45 patients. One-hundred and fourty-eight patients were treated with combined modality (CT+RT) and 15 patients were treated with chemotherapy alone (all with 6 cycles). One hundred and fourty-seven patients attained CR while 16 were chemoresistent: 9 showed disease progression during CT and 7 showed an early relapse. The FDG-PET performed after two cycles (PET2) was positive in 23 patients (14%): 12 (52%) progressed or relapsed and 11 remained in CR. By contrast 130/140 (93%) patients with a negative PET2 remained in CR. Thus the positive predictive value of a PET2 was 52% and the negative predictive value was 93%. The sensitivity and specificity of PET2 were 55% and 92%, respectively. Seventeen patients showed disease progression during therapy or within 12 months after having reached CR, 11/17 (65%) were PET2 positive. The FDG-PET performed at the end of therapy was positive in 15 patients. Six patients died due to the disease, four were PET2 positive and two were PET2 negative. In univariate analysis negative FDG-PET performed after two cycles (p=0.0000), absence of bulky disease at diagnosis (0.004) were statistically correlated with a better progression free survival. In multivariate analysis only PET2 was independently predictive of relapse/progression probability (p=0.000). With a median follow-up of 31 months (range 6-87) 154 patients are alive and 141 (92%) are free from progression. The 2-yr FFS probability for PET2 negative and for PET2 positive patients were 94% and 58% respectively. *Conclusions.* This prospective and multicentric study confirms that FDG-PET scan performed after two courses of conventional standard dose chemotherapy was able to predict treatment outcome in early stage Hodgkin disease. Due to the large number of false positive PET2 in localized lymphoma we suggest new evaluation methods in this subset of patients.

PHASE II STUDY OF ORAL PANOBINOSTAT IN PATIENTS WITH RELAPSED/REFRACTORY HODGKIN LYMPHOMA AFTER HIGH-DOSE CHEMOTHERAPY WITH AUTOLOGOUS STEM CELL TRANSPLANT

A. Younes,[1] A. Sureda,[2] D. Ben-Yehuda,[3] T.C. Ong,[4] D. Tan,[5] A. Engert,[6] C. Le Corre,[7] J. Gallagher,[7] S. Hirawat,[7] M. Prince[8]

[1]M. D. Anderson Cancer Center, HOUSTON, USA; [2]Hospital de la Santa Creu, BARCELON, Spain; [3]Hadassah Medical Organization, JERUSALEM, Israel; [4]Hospital Ampang, AMPANG, SELANGOR, Malaysia; [5]Singapore General Hospital, SINGAPORE, Singapore; [6]Klinikum der Universitat zu koln, KOLN, Germany; [7]Novartis Pharmaceuticals Corporation, FLORHAM PARK, NJ,USA; [8]Cabrini Institue, MALVERN, Australia

Background. Panobinostat (LBH589) is a pan-deacetylase inhibitor

(pan-DACi) targeting epigenetic and non-epigenetic oncogenic pathways. *In vitro*, panobinostat decreases proliferation and induces apoptosis in HL cell lines at low nanomolar concentrations. Encouraging clinical activity, with a CT scan-based response rate of 42% in patients with HL, has been demonstrated in an ongoing Phase I study in patients with hematologic malignancies (Ottmann OG *et al.* ASH 2008 Abstract #958). *Aims.* The aim of this open-label Phase II study is to confirm the efficacy of panobinostat in HL. *Methods.* Utilizing a Simon two-stage design, patients with hodgkin lymphoma (HL), whose disease is refractory to, or has progressed after ASCT are being enrolled in the study. The primary objective of the study is to determine the overall response rate using the modified Cheson criteria. Secondary objectives include time to and duration of response, progression-free survival (PFS) and overall survival; clinical and laboratory safety data will be collected. To be included in the study, patients must have adequate organ function, no other significant medical conditions, and ECOG PS ≤2. Panobinostat is administered orally at a dose of 40 mg three-times weekly in a 21-day cycle. Treatment is continued until disease progression or intolerance. Dose delay and modification for toxicity is allowed. CT/MRI scans are conducted at the end of every two cycles. The *in vivo* effect of panobinostat on the expression of programmed cell death protein 1 (PD-1) on peripheral blood T-lymphocytes was evaluated by multicolor FACS analysis. *Results.* As of Feb 20, 2009, 30 patients have been enrolled, of whom 14 have completed at least 2 months of therapy and for whom preliminary data are available (median age 27.5 years [range 18-51]; six male, eight female; median number of prior regimens five [range one to six]). The more common AEs have been thrombocytopenia (n=6/14, all Grade 3 or 4), diarrhea (n=6/14), and nausea (n=8/14). Among the 295 ECGs analyzed, there have been no ≥Grade 2 QTc abnormalities. Efficacy data are available for six of the 14 patients who had tumor reductions ranging between 18% and 68%, including two partial responses. All these patients continue on study. Serial blood samples were obtained from four patients, and in all cases panobinostat significantly decreased the expression of PD-1 on $CD8^+$ T cells after 7 and 15 days of therapy. *Summary*. Panobinostat has encouraging clinical activity in heavily pretreated patients with relapsed classical HL. In addition to its direct antitumor effect, our data suggest that panobinostat may enhance the antitumor immune response by downregulating PD-1 on patients' T lymphocytes. Panobinostat is generally well tolerated, and thrombocytopenia is managed by dose delay or dose reduction. Enrollment into the study is ongoing; efficacy and safety data available at the time of the meeting will be presented.

0089

QUALITY OF LIFE AND FERTILITY IN HODGKIN DISEASE PATIENTS TREATED WITH ESCALATED BEACOPP

W. Jurczak,[1] D. Krochmalczyk,[1] W. Pabian,[2] P. Chrapczynski,[3] A. Cwierz,[3] A. Giza,[1] M. Sobocinski,[1] D. Zimowska-Curylo,[1] A.B. Skotnicki[1]

[1]Dpt of Haematology, KRAKÓW; [2]CMUJ Ob/Gyn Clinic, CMUJ, KRAKÓW; [3]Stdent Scientific Association CMUJ, KRAKÓW, Poland

Aims and Background. Quality of life and fertility was assessed in 173 patients with advanced hodgkin disease (HD) IIBX - IV CS, treated in a single institution with a medium follow-up of 5.5 years (2-12 years). After initial therapy with ABV, ABVD or escalated BEACOPP regimens (3 cycles) they were all assessed by CT or PET-CT. Good responders (defined as over 50% tumor mass reduction) were treated by ABV or ABVD (3 cycles), while other patients were subjected to escalated BEACOP. Involved field radiotherapy was considered in IIB patients, while second line regimens with ASCT in relapsing/ refractory cases. Average 5 year OS and EFS was significantly longer in patients treated with upfront escalated BEACOPP regimen: 94 and 89% (n=78) versus 90% and 74% respectively (n=95, $p<0.01$, D. Krochmalczyk, W Jurczak *et al.*, ASCO 2008). Intensive upfront therapy reduced the number of relapsing/ refractory cases (4 and 22 pts were subjected to ASCT respectively). *Methods and Results.* Quality of life (QoL) assessment addressing social, physical and emotional functioning performed 6-60 months after completing chemotherapy in 113 patients (177 completed questionnaires) revealed no important differences. Results were also similar in a direct comparison of ABV/ABVD and escalated BEACOPP regimen by 64 patients who were treated by both of them. However dacarbasine makes a difference: while 24 of 39 (61%) of patients preferred escalated BEACOPP to ABVD, only 8 of 15 (32%) preferred escalated BEACOPP to ABV. Hormonal and reproductive function of gonads was assessed in 106 patients 6-60 months after completing chemotherapy (women elder than 50 years were not included in analysis, those on hormonal replacement therapy discontinued the drugs, 2 weeks prior to analysis). Hypogonadysm was defined by low estradiol and testosterone levels (<30 pg/mL an 10 ng/dL respectively). Reproductive function of gonads was indirectly assessed by FSH levels (patients with FSH > 15 m IU/mL were regarded unfertile). As expected gonad function was not impaired in patients treated with ABV or ABVD regimens. The risk of infertility after escalated BEACOPP regimen was greater for males than females (over 70%, even if only 3 cycles were given). In females, it increased with the number of chemotherapy cycles, and strongly depended on dacarbasine: 21,4% in those with 3 x escalated BEACOPP/3 x ABV compared to 53% after 3 x escalated BEACOPP / 3 x ABVD (p=0.04, see Table for details). Hypogonadism, was on the contrary observed only in females. *Summary and Conclusions.* An upfront escalated BEACOPP regimen improves the outcome of HD patients, as proven elegantly by GHSG. It is efficient and well tolerated, so it should be offered as a standard I line regimen to all high risk HD patients. De-escalation of therapy in good responders to ABV/ABVD regimens may reduce it's side effects, however it doesn't solve the infertility problem. Every male should be therefore offered a possibility of cryopreservation, while eliminating dacarbasine may be considered in young females

Table.

		6 x ABV	6 x ABVD	3 x esc. BEACOPP + 3 x ABV	3 x esc. BEACOPP + 3 x ABVD	6 x esc. BEACOPP	2-nd line regimens (including ASCT)	Chi square Pearson test

TANDEM AUTOLOGOUS/REDUCED-INTENSITY ALLOGRAFT FOR RELAPSED/REFRACTORY HODGKIN'S LYMPHOMA: EARLY ALLOTRANSPLANT AFTER INTENSIVE CYTOREDUCTION MAY MAXIMIZE GRAFT VS LYMPHOMA EFFECT?

E. Todisco,[1] A.G. Congiu,[2] L. Castagna,[3] S.T. Nati,[2] A. Santoro,[3] A.M. Carella[2]

[1]Istituto Clinico HumanitasI, ROZZANO MILANO; [2]Ospedale S.Martino, GENOVA; [3]Istituto Clinico Humanitas, ROZZANO, Italy

Background. Hodgkin's Lymphoma (HL) patients with disease at the time of autolgous transplantation (ASCT), have high probability of progression after ASCT. Reduced-intensity conditioning allotransplant (RICT) aims to exploit graft vs lymphoma (GvLy) effects while reducing conditioning-related toxicity. RICT is considered as the last therapeutic option and is usually offered to HL patients failing ASCT and in this contest GvLy responses might be insufficient. *Aims.* We pionered that offering RICT as an earlier option after intensive cytoreduction (ASCT) may allow GvLy reaction to be better exploited (Carella *et al.* JCO 2000; 18:3918). *Patients and Methods.* Twentyseven HL patients (14M/13F) underwent RICT preceeded by autografting (ASCT). Median age at diagnosis was 27 (range 15-44), median n° of chemotherapy lines was 2.5 (range 2-4). All but one patient had disease at ASCT. Twelve patients were chemosensitive and 15 chemorefractory at ASCT and high-dose therapy consisted of Melphalan 200 mg/mq (n=7) and BEAM (n=20). The time interval between ASCT and RIC was 3 months (range 1.3-6.7). RIC consisted of fludarabine-cyclophosphamide (n=12) or fludarabine-melphalan (n=15). *Results.* The median time to neutrophils and platelets recovery was 10 days and 16 days, respectively. Chimerism studies indicated 100% donor-derived engraftment. Seven patients developed aGVHD (grade II-IV) and 9 cGVHD (2 limited and 7 extensive). At the last follow up 17 patients (63%) were alive, 12 (70.6%) in RC and 5 (29.6%) with disease. Ten patients expired (37%), 7 of disease progression, 1 of aGVHD, 1 of cGVHD and 1 of infection. With a median follow-up of 46 months (6-117 months), median OS was 47 months. *Conclusions.* These encouraging results suggest that GvLy may have a role on residual disease after ASCT. A prospective study based on genetic randomization (ASCT vs ASCT followed by RICT) would help to answer this important issue.

0091

QUALITY OF LIFE IN A 2-YEAR FOLLOW-UP: SIGNS OF PNP PREDICTING FATIGUE IN SURVIVORS TREATED IN THE HD10-12 TRIALS OF THE GERMAN HODGKIN STUDY GROUP

T. Halbsguth,[1] H. Mueller,[1] H.-H. Flechtner,[2] C. Brillant,[1] K. Behringer,[1] Th. Schober,[1] H. Nisters-Backes,[1] A. Engert,[1] P. Borchmann[1]

[1]University of Cologne, COLOGNE; [2]Otto-von-Guericke-University Magdeburg, MAGDEBURG, Germany

Background. Hodgkin Lymphoma (HL) is one of the best curable cancers in adults. Thus, current research is focusing on the increasing proportion of HL survivors with respect to the long-term consequences of therapy. Especially health related quality of life (QoL) needs thorough investigation since its relevance for HL patients, complexity and limited knowledge up to now. QoL incorporates different aspects such as general QoL, fatigue, emotional, physical, role, social, sexual and cognitive functions. *Aims.* This analysis is focusing on QoL in the HD10-12 trials of the GHSG with special emphasis on fatigue and its predictors in a 2 year follow-up. *Methods.* Patients of the German hodgkin study group (GHSG) trials HD10-12 completed the QLQ-C30, the MFI20 and some additional items at the time of diagnosis, after chemotherapy, after radiotherapy and at follow-up examinations. We describe the courses of the QLQ-C30 scales with means and 95%-confidence intervals for each measurement point and in relation to the respective norm values. In multiple regressions we analyzed the role of the following predictors for fatigue 2 years after treatment: age, sex, disease stage, treatment modality, baseline score of fatigue and symptoms of peripheral neuropathy (PNP) before and after chemotherapy application. *Results.* In the sample of 3608 patients all scales showed abnormal values from the beginning, further deterioration to the end of chemotherapy and continuous recovery from the end of radiotherapy on. Most scales improved clearly beyond their pre-treatment values. Opposed to other scales, the scale for fatigue reached only a moderate improvement beyond the pre-treatment level. A first regression analysis showed a significant impact of sex, age, disease stage and symptoms of PNP before therapy on fatigue after 2 years. There was no effect of the treatment arms and the respective intensity of therapy within the 3 studies. When additionally fatigue baseline scores were included in the analysis, these baseline score were the best predictor of fatigue after 2 years and only PNP symptoms before chemotherapy (p<0.001) and age contributed additional significant information. *Conclusions.* In contrast to other QoL parameters, pathological values of fatigue occur frequently and show only a moderate improvement. The main finding from this large prospective study in a homogenous cohort of young cancer patients is that besides age and baseline values of fatigue, symptoms of PNP before therapy are specifically predictive of future fatigue complaints. Interestingly, we did neither find any significant effect of the type or intensity of therapy. With this knowledge, it is possible to define a patient cohort being at high risk for the development of chronic fatigue and to develop and test intervention strategies.

0092

EXPRESSION AND EPIGENETIC ANALYSIS OF KEY B-LINEAGE TRANSCRIPTIONAL PROGRAMMES IN HODGKIN / REED-STERNBERG CELLS

G.P. Collins,[1] J.C. Paterson,[1] L. Campbell,[1] D.Y. Mason,[1] T. Enver,[2] T. Marafioti[1]

[1]John Radcliffe Hospital, OXFORD; [2]Institute of Molecular Medicine, OXFORD, UK

Background. Classical Hodgkin Lymphoma (cHL) is characterised by the presence of Hodgkin / Reed-Sternberg (HRS) cells. Although derived from germinal centre B-cells, HRS cells have commonly down-regulated their B-cell phenotype due to mechanisms which are incompletely understood. *Aims.* 1. To determine the expression of the B-cell transcription factor Pax5 in cHL cell lines and primary tissue; 2. to investigate possible causes of Pax5 down-regulation: methylation of the Pax5 gene promoters and expression of proteins known to up-regulate Pax5 expression - EBF1, GABP and MTA1. *Methods.* Expression level of Pax5, EBF1, GABPα and MTA1 in cHL cell lines was determined using one or all of: - reverse transcriptase qPCR (Taqman primers and probes obtained from Applied Biosystems); - western Blotting of whole cell lysates; - immunocytochemistry of cytospin preparations. Expression of Pax5, EBF1 and GABPα in primary tissue from cHL cases was determined using immunohistochemistry on paraffin embedded samples subjected to antigen retrieval. Pax5 staining utilised the Envision kit (Dako) whereas EBF1 and GABPα staining was automated, using a Bond machine. Methylation analysis of the Pax5 α and β promoters was performed using bisulfite genome sequencing. DNA was bisulfite converted using the Epitect kit (Qiagen), amplified by PCR, cloned and sequenced. Demethylation was accomplished by culturing the cell lines in the presence of 5-aza-2-deoxycytidine +/- trichostatin A. *Results.* Pax5 protein expression was absent in L428 and KMH2 cell lines and weak in the L1236 cell line. 30 cHL cases were stained for Pax5 and staining of the HRS cells was compared with reactive B-cells: 3/30 cases were negative, 16/30 were weakly positive, 10/30 cases were moderately positive and only 1/30 of the cases was strongly positive. 10/21 Pax5α L428 cell line clones showed a high degree of CpG methylation. Only 4/21 L1236 α promoter clones showed a similar degree of methylation. The β promoters from both cell lines were largely unmethylated. Demethylation resulted in Pax5 mRNA upregulation in the L428 line. EBF1 protein in L1236 and KMH2 lines was not detected but it was strongly expressed in the L428 cell line. For primary tissue: 3/28 cases were negative for EBF1, 10/28 cases were weakly positive, 5/21 were moderately positive and 10/28 were strongly positive. GABPα was strongly expressed by L428, L1236 and KMH2 cell lines. 5/5 cases immunostained also showed strong HRS cell nuclear expression. MTA1 mRNA levels (relative to the control gene Abl1) in L428, L1236 and KMH2 were as high as those seen in B-cell non-Hodgkin Lymphoma lines. *Conclusions.* 1. Pax5 is down-regulated in cHL cell lines and HRS cells of primary tissue; 2. the Pax5α promoter is partly methylated in the L428 line and may be contributing to the down-regulation of Pax5 expression; 3. EBF1 is down-regulated in 2 of the cell lines tested and in the HRS cells of 13/28 cases tested suggesting this may underlie down-regulation of Pax5 expression in a proportion of cHL cases; 4. changes in GABP and MTA1 expression do not appear to be contributing to changes in Pax5 expression.

0093

PLASMA LEVELS OF CIRCULATING CELL-FREE DNA AND OF CYTOKINES AS POTENTIAL BIOMARKERS IN HODGKIN LYMPHOMA

S. Hohaus, G. Massini, M. Giachelia, B. Vannata, M. Criscuolo, M.C. Tisi, M. Martini, F. D'Alò, L.M. Larocca, M.T. Voso, G. Leone

Università Cattolica S. Cuore, ROME, Italy

Background. Hodgkin lymphoma (HL) is characterized by an abundant microenvironment surrounding the malignant Hodgkin and Reed-Sternberg (HRS) cells. Production of cytokines and chemokines contribute to create the favourable conditions for the growth and survival of HRS cells. In particular, interleukin-10 (IL-10) and the chemokine CCL17/TARC appear to play an important role in the recruitment of tolerant T cells to the HL lesions. Proliferation of the malignant and the immune cells results in release of free DNA into the circulation. Cytokine levels have been reported as useful biomarkers in Hodgkin lymphoma (Casanovas, J Clin Oncol 2007; 25; 1732). *Aim.* To assess the relation between levels of free circulating DNA in the plasma to levels of other biomarkers as cytokine levels of IL-10, IL-6 and TARC and patient characteristics and their role for failure-free survival in Hodgkin lymphoma. *Methods.* We studied 58 patients with Hodgkin lymphoma (median age 34 years, range 13-74 years; 31 females and 27 males). Fifty-five patients were treated with standard chemotherapy regimens: 29 patients received ABVD, and 26 pts with advanced stage disease BEACOPP. DNA was extracted from plasma collected at diagnosis using the QIAamp DNA Blood MiniKit (Qiagen, UK) and DNA levels were determined using a quantitative PCR for the β-globin gene. Plasma levls of IL-10, IL-6 and CCL17/TARC were determined using ELISAs. Associations with patient characteristics and event-free survival (EFS) were analyzed using standard statistics (STATA 10). *Results.* Plasma DNA concentrations correlated to several patient characteristics as age >45 years, male sex, and the presence of B-symptoms. HL cases of the nodular sclerosis type were graded according to the BNLI classification, and patients with grade 2 disease had significant higher levels than patients with grade 1 disease (p=0.005). There was a weak, but significant correlation between plasma DNA levels and IL-6 levels (r=0.33, p=0.01), while IL-10 and TARC levels did not correlate to DNA plasma levels. The probability of failure-free survival at 4 years for patients with normal DNA levels was 92%, while it was 64% for patients with elevated DNA levels (95% C.I.,72-98, and 36-82, respectively; p=0.009). Elevated IL-10 and IL-6 levels were associated with failure-free survival as well (p=0.006 and p=0.04). Including the circulating DNA and cytokine levels into a multivariate analysis, circulating DNA and IL-10 proved to be independent predictors of survival (both p=0.03), while IL-6 and TARC were not of prognostic significance. *Conclusions.* We describe levels of circulating DNA in the plasma as a potential new biomarker in Hodgkin lymphoma, independent of other biomarkers as IL-10 and IL-6.

0094

THE INFLUENCE OF POLYMORPHISMS OF GLUTATHIONE S-TRANSFERASE MU 1 (GSTM1), THETA 1 (GSTT1) AND PI 1 (GSTP1) GENES IN THE OUTCOME OF HODGKIN'S LYMPHOMA

I. Lorand-Metze, G.J. Lourenço, M.T. Delamain, E.C.M. Miranda, R.E. Kameo, C.S.P. Lima

State University of Campinas, CAMPINAS, Brazil

Background. Glutathione S-transferases (GST) are involved in the conjugation of several anticancer drugs, including alkylating agents, anthracyclines and cyclophosphamide. The presence of at least one deletion in two of these enzymes, GSTT1 and/or GSTM1 is associated with an improved disease-free survival for patients with Hodgkin's Lymphoma (HL). In Brazil many patients present with advanced disease at diagnosis. *Aim.* To study the influence of the GST polymorphisms on the stage, response to chemotherapy and survival in HL. *Patients and Methods.* Our retrospective analysis included 110 patients, diagnosed between May 1993 and September 2007. Median age: 27 years (17-63); 58 males, 52 females. HL was diagnosed according to the WHO classification and staged by Ann Arbor criteria. All patients were treated with either ABVD or BEACOPP. In 55 patients, radiotherapy was included for consolidation. At diagnosis 67 patients had stages I / II and 42 had stages III / IV. Genomic DNA from peripheral blood of all individuals was analysed by the multiplex-PCR for identification of the GSTM1 and GSTT1 genotypes and PCR-RFLP for identification of genotypes of the GSTP1. *Results.* GSTP1 wild genotype and GSTM1 null type were higher in patients with stages III / IV (p=0.03 and p=0.05 respectively). The same was obtained for the International Prognostic Score. However, presence of bulky disease and bone marrow involvement was equally distributed in all genotypes. GSTT1 undeleted and GSTM1 null genotypes were associated with a lower percentage of complete remission (p=0.03), primary resistance and recurrence (p=0.08). After a median time of observation of 54 months (9-155) the overall survival in 5 years was 74%. Only GSTM1 null genotype was associated with a longer disease free survival (p=0.02). None of the examined polymorphisms was associated with the progression-free interval. A better overall survival was observed in patients with the GSTT1 null genotype (p=0.006). In the multivariate analysis for overall survival, comparing stage and International Prognostic Score with the polymorphisms studied, only failure to achieve a complete remission and GSTT1 undeleted genotype were independent risk factors. *Conclusions.* Detoxification enzyme polymorphisms may influence the outcome of HL by modifying the metabolism of cytostatic agents. Their study may help to identify patients that need intensification of chemotherapy.

ANTHRACYCLINE CARDIOTOXITY OCCURS EARLY DURING THERAPY IN CHILDREN WITH HODGKIN'S DISEASE

A. Tantawy, O.A. Elmasry, D.N. Toaima, A.M. El Shahat

Faculty of Medicine, Ain Shams University, CAIRO, Egypt

The ABVD (doxorubicin, bleomycin, vinblastine, dacarbazine) regimen is the standard therapeutic regimen for treatment of Hodgkin's Disease (HD). However ,the therapeutic value of doxorubicin is limited by the cumulative dose-related cardiotoxicity. Echocardiography is used to serially assess left ventricular (LV) function in children, but the correlation between LV ejection fraction (EF) measured by echocardiography and cardiotoxicity assessed by endomyocardial biopsy grade is poor. *Objective*. We aimed to assess LV function in children with HD by radionuclide ventriculography (RVG) and compare it to simultaneous echocardiographic assessment of LV function. *Methods.* 39 children diagnosed with HD were included in the study, 10 patients early during the course of treatment (≤2 ABVD cycles) [Group I; mean age 8.9±3.4 years; 5 males, 5 females; doxorubicin cumulative dose: 75±27.3 mg/m^2; range: 50-100 mg/m^2] and 22 patients late during the course of treatment (≥6 ABVD cycles) [Group II; mean age 8.4±3.3 years; 17 males, 12 females; cumulative doxorubicin dose 328±64 mg/m^2; range: 210-485 mg/m^2].All patients were assessed prior to radiotherapy. Ten patients were stage II, 23 were stage III and 6 were stage IV HD. Following informed parental consent, all children underwent a full clinical assessment, 2D, M-mode and Dopper echocardiography and radionuclide ventriculography (RVG) for assessment of LV function. Seven of the children in Group I were reassessed after completion of 6 ABVD cycles and their data included in the analysis of group II (n=29).

Results. There was no significant difference between both groups as regards the stage of HD. The EF in Group I was 58.2±9.1% by echocardiography compared to 51.7±2.5% by RVG (p<0.05), and 7 patients had an EF<50% by RVG compared to only 1 patient by echocardiography. Group II had lower EF than group I by echocardiography (53±7.7%; p=0.09), but this was only significant when EF was assessed by RVG (44.2±4.5%; p=0.000). An EF<50% was present in 11 and 15 patients in group II by echocardiography and RVG, respectively. Paired analysis of the 7 children who were studied early and late during therapy showed a significant drop in EF by both echocardiography [58.7±7.3 vs. 52±52.44%; p=0.04] and RVG [51.4±2.6% vs. 47.2±3.1%; p=0.004]. There was a significant negative correlation between the cumulative dose of doxorubicin and EF measured by RVG (r=-0.531; p=0.001) but not with EF measured by echocardiography (r=-0.075; p=0.3). No correlation was found between EF measured by RVG and echocardiography EF(r=0.217; p=0.25). *Conclusions.* Doxorubicin cardiotoxicity occurs early and at relatively low cumulative doses in children with HD treated with the ABVD regimen. RVG is more sensitive than echocardiography in detecting early cardiotoxicity manifested as impaired LV EF in children receiving doxorubicin therapy. Baseline and serial assessment of LV function by RVG is recommended in children with HD receiving ABVD based protocols

COMPLETE RESPONSE TO IGEV (IFOSFAMIDE, GEMCITABINE AND VINORELBINE) AND OUTCOME IN RELAPSED/REFRACTORY HODGKIN'S LYMPHOMA PATIENTS

A. Anastasia,[1] R. Mazza,[1] L. Giordano,[1] M. Balzarotti,[1] M. Magagnoli,[1] L. Castagna,[1] M. Spina,[2] U. Tirelli,[2] A. Santoro[1]

[1]Istituto Clinico Humanitas, ROZZANO; [2]Centro di Riferimento Oncologico, AVIANO, Italy

Background. High dose chemotherapy with autologous stem cells transplant (ASCT) is the gold standard in patients with relapsed/refractory hodgkin's lymphoma (HL). Response to induction chemotherapy (chemosensitive patients) plays a major role in prognosis, however the role of complete response (CR) status after induction therapy has not been established. *Aim.* Primary endpoint was to evaluate the role of CR versus no-CR to IGEV induction therapy on the outcome in terms of progression free survival (PSF) and overall survival (OS). *Methods.* One hundred twenty one patients with relapsed/refractory HL received 4 courses of IGEV followed by single (N=59) or tandem (N=19) ASCT (Santoro *et al.,* Haematologica 92, 2007). Response to IGEV was evaluated by Cheson criteria (1999). Statistical analysis was performed by using the Kaplan-Meier method and Cox proportional hazard model. *Results.* IGEV induced an overall response rate of 75% with 46% of CR. In the univariate analysis favourable factors for outcome were CR vs no-CR to IGEV (PFS: p<0.001, OS: p 0.002), A vs B symptoms (PFS: p 0.003; OS: p=0.05), limited vs advanced stage (PFS: p 0.03; OS: p 0.03), and 1 vs.≥2 previous chemotherapy lines (PFS: p 0.03, OS: p 0.02); response to last therapy (relapsed vs refractory) influenced PFS (p 0.03) but not OS (p 0.70). The multivariate analysis confirmed the favourable prognostic role of CR to IGEV (PFS HR: 2.5, CI 95%:1.3; 4.6 - OS HR 2.3, CI 95%:1.1;4.8) and of the number of previous chemotherapy lines (PFS HR:1.8, CI 95%:1.0;3.2 - OS HR 2.1, CI 95%:1.1;3.9). *Conclusions.* According to our data, we conclude that: 1. CR to IGEV is the strongest indicator of outcome in relapsed/refractory HL. 2. Achievement of CR to IGEV overcomes the role of initial disease status. 3. Efforts are warranted to increase the CR rate by induction therapy.

0097

THE PROGNOSTIC SIGNIFICANCE OF PET SCAN IN PATIENTS WITH RELAPSED/REFRACTORY HODGKIN LYMPHOMA TREATED WITH HIGH DOSE THERAPY AND AUTOLOGOUS STEM CELL TRANSPLANTATION

M. Moschogiannis,[1] T.P. Vassilakopoulos,[1] G.A. Pangalis,[1] P. Tsirkinidis,[1] V. Pappi,[1] O. Tsopra,[1] S. Sachanas,[1] Z. Galanis,[1] M. Angelopoulos,[1] X. Yiakoumis,[1] C. Kalpadakis,[1] M.P. Siakantaris,[2] K. Konstantopoulos,[1] M.-C. Kyrtsonis,[1] P. Panayiotidis,[1] M.K. Angelopoulou[1]

[1]National and Kapodistrian University of Athens, ATHENS; [2]National & Kapodistrian University of Athens, ATHENS, Greece

Background. Approximately 50% of patients with relapsed/refractory hodgkin's lymphoma (HL) can be cured with high-dose therapy/autologous stem cell transplantation (HDT/ASCT). Response to salvage

chemotherapy, as assessed by clinical staging, prior to ASCT is one of the most powerful prognostic factors for outcome. On the other hand, the prognostic significance of interim PET scan in advanced HL patients treated with first-line ABVD chemotherapy is well established. However, its role in the ASCT setting for relapsed/refractory disease is not yet elucidated. *Aims.* To study the prognostic significance of PET scan before and after HDT/ASCT in patients with relapsed/refractory HL. *Methods.* Clinical staging with computed tomography and PET scan were performed after salvage chemotherapy just prior to ASCT and at 3 months post transplant and findings were correlated with failure free survival (FFS). PET scan was considered negative, when no uptake was present, positive, when any lesion was FDG avid with SUV equal to or greater than 4 and minimal residual uptake positive (MRUp), when any lesion showed abnormal uptake with SUV<4. *Results.* 33 patients were studied, 20 were males and 13 females, median age at ASCT was 26 years (18-53), 18 patients were treated for primary refractory disease, 12 at first relapse and 3 beyond first relapse. All patients received salvage chemotherapy and 22 had chemosensitive disease prior to ASCT. Among the 33 patients included in the study, 25 had a PET scan available pre ASCT, 29 post and 21 at both time points. Pre ASCT PET scan did not correlate with FFS. Five patients had a negative pre-ASCT scan and one of them relapsed, whereas 9 relapses were observed among 20 patients with a positive or MRUp pre-ASCT PET scan. One-year FFS was 100% and 48% respectively (p=non-significant). The figure of 48% remained unchanged for 3 years following ASCT. On the contrary, post-ASCT PET scan had a strong predictive value for outcome. Thus there were 2 relapses among 14 patients with a negative post-ASCT scan, vs 10 among 15 cases with a positive or MRUp post-ASCT PET scan. The corresponding 1-year FFS was 92% vs 34% (p=0.002). Pre-ASCT PET scan was positive or MRUp in 13/18 chemosensitive patients, vs 7/7 chemoresistant ones. Among the 21 patients who had a PET scan available at both time points, there were no relapses recorded for those who were pre-ASCT PET scan either positive or MRUp and became post-ASCT PETscan negative (0/10 patients), as shown in the Table. On the contrary, all patients with a pre-ASCT PET scan positive or MRUp, who remained or became post-ASCT PET scan positive, relapsed (7/7 patients), as shown in the Table. *Conclusions.* Pre-ASCT PET scan positivity does not preclude a positive outcome for patients with relapsed/refractory HL undergoing HDT/ASCT, since half of them remain relapse free for the three subsequent years. Patients who remain or become PET positive after ASCT have an extremely poor prognosis, whereas those who convert to negativity enjoy a favorable outcome.

Table. Relapses according to pre- and post-asct pet scan.

		PRE-ASCT PET SCAN		
		+	MRUp	-
POST-ASCT PET SCAN	+	5/5	2/2	-
	MRUp	0/2	-	0/1
	-	0/6	0/2	1/3

LOW INCIDENCE OF PREMATURE OVARIAN FAILURE IN FEMALE PATIENTS TREATED FOR HODGKIN LYMPHOMA DURING PREPUBERTAL OR POSTPUBERTAL PHASE

S. Falorio, G. La Barba, F. Fioritoni, G. Fioritoni, F. Angrilli

Civic Hospital, PESCARA, Italy

Background. Chemotherapy and radiotherapy may cause infertility in young women with Hodgkin Lymphoma (HL) because of the massive depletion of the ovarian follicle reserve resulting in premature ovarian failure (POF). Factors affecting the risk of POF include the age at the time of therapy, the types of drug used and the intensity of treatment. Without any ovarian protection, the expected rate of POF in postpubertal women is approximately 10-20%, 70% and 90-100% following the use of alkylating-free regimens (ABVD/ABVD-like), alkylating-containing regimens (MOPP/ABV, COPP/ABVD, BEACOPP) and ASCT, respectively. *Aims.* To evaluate the incidence of POF and infertility after chemoradiotherapy in prepubertal girls and in postpubertal women who received a Gonadotropin Releasing Hormone analogue (GnRHa) to prevent ovarian damage during treatment. *Methods.* From January 1991 to August 2008, 115 untreated female patients (pts) with HL aged 8-40 years (median 24) have been treated in our institution. Before HL treatment, 4 pts are prepubertal girls and 111 pts are postpubertal women. To protect ovarian function during chemo-radiotherapy, postpubertal pts received GnRHa monthly, while prepubertal girls not received ovarian protection. HL treatment included 4 to 6 courses of chemotherapy plus radiotherapy for CS I-IIA and 6 courses of chemotherapy plus radiotherapy to residual masses for CS IIB-IV. Overall, 90 pts received alkylating-free chemotherapy and 25 pts received alkylating-containing regimens (MOPPEBVCAD, COPPEBVCAD, COPP/ABV, BEACOPP) as first-line (20 pts) or salvage treatment (5 pts). Four of the 81 irradiated pts received subdiaphragmatic radiotherapy. Ten relapsed/refractory pts received salvage treatment including ASCT in 7 cases and allo-SCT in one case. *Results.* After a median follow-up of 144 months (range 5-204) 3 pts died of HL, 112 are alive and 103 are evaluable for treatment-related gonadotoxicity. All 3 evaluable pts treated during prepubertal phase have today normal menses. Only 7 pts (7%) developed POF, while 93 pts (93%) recovered a normal ovarian function in the group of postpubertal women treated with GnRHa. After treatment, 27 pts attempted pregnancy and conceived. Twenty-six healthy babies were delivered and 3 pregnancies are ongoing. We analyzed risk factors and found that the salvage treatment had a very significant impact on the incidence of POF (p<0.0001). The age (> 30 years) correlates with POF only in pts who received salvage treatment (p=0.05), while first-line treatment with alkylating drugs (p=0.2) and advanced stages of disease (p=0.18) were not significative. *Conclusions.* Our data confirm that prepubertal status may protect the ovaries from the toxicity of chemoradiotherapy. In agreement with this concept, we think that in postpubertal women who received GnRHa during HL treatment, the low incidence of POF following first-line therapy is due to the reversible induction of a prepubertal hormonal milieu during chemoradiotherapy. Unfortunately, in relapsed/refractory pts GnRHa does not seem to be very effective, and further experimental approaches are required for ovarian protection and fertility preservation. In this regard ovarian tissue cryopreservation represents a promising technology that may restore both complete ovarian function and fertility.

0099

COMPARATIVE STUDY OF TWO MOPP-DERIVED CHEMOTHERAPEUTIC PROTOCOLS FOR MANAGEMENT OF PEDIATRIC HODGKIN'S DISEASE: SINGLE CENTER 5-YEARS EXPERIENCE

Y. Al-Tonbary, M. Abul-Kheir, A. EL-Ashry, E.E. Salama, M. Sedky, E. Fouda

Mansoura University Children's Hospital, MANSOURA, Egypt

Background. In 1990s, countries with limited resources accounted for 86% of the world's children (<15 years), a figure projected to increase to more than 90% by 2030. These countries bear most of the global burden of childhood cancer (World Development Report, 1993). The inability to ensure most of the high-cost chemotherapeutic agents beside the world increment of drug cost with inability of local production of such high-technology medications obligate us among other underdeveloped countries to change the COPP-AV protocol to more available and less expensive COMP or OAP protocols. *Subjects and Methods.* A total of 119 newly diagnosed Hodgkin disease children were treated in the pediatric Hematology/Oncology Unit at Mansoura University Children's Hospital, in the period from January 2002 to December 2006. They were 74 males and 45 females with M/F ratio of 1.64:1 and median age of 8 years (range: 1-16 years). Median follow up was 587 days (19.5 months) with last follow up end at March 2008. Most of the patients were in stage I; 61 cases (51.3%), while stage II; 27 cases (22.7%), stage III; 24 cases (20.1%), and stage IV; 7 cases (5.9%). The histopathological type was mixed cellularity; in 67 cases (56.3%), Nodular sclerosis; in 26 cases (21.8%), Lymphocyte predominance; in 25 cases (21.0%), and lymphocyte depletion; in only 1 case (0.9%). The patients were randomized to receive either alkylating based COMP protocol (Cyclophosphamide 600 mg/m^2 IVI, Oncovin 1.4 mg/m^2 day 1,8 IV, methotrexate 40 mg/m^2 day 1,8 IVI and prednisone 40 mg/m^2 day days 1-14 PO for 8 cycles every 28 days) or anthracycline based OAP protocol (Oncovin 1.5 mg/m^2 day 1,8,15 IV, Adriamycin 60 mg/m^2 day 1,15 IVI and Prednisone 40 mg/m^2/day days 1-14 PO for 8 cycles every 28 days). Procarbazine was substituted in the 1st protocol and omitted in the 2nd one. Sixty patients received COMP protocol and 59 patients received OAP protocol. *Results.* Complete remission was achieved in a higher percentage of patients treated with COMP protocol 81.4% (48 cases), while only it was achieved in 50% of those received OAP treatment (32 cases) (p<0.001). Partial response was more

in those treated with OAP (23%) and less with COMP protocol treatment (5%). Relapse rate was almost equal in both treatment limbs but was earlier with OAP treated patients, as it occurred in 16 patients (27%) in COMP protocol at a duration of 106 days and in 18 patients (30%) in OAP protocol at a median duration of 60 days. The re-induction of remission after that relapse was successful in COMP limb in 7.5% vs. 3% in OAP limb. Acute drug toxicities were minor in both protocols of therapy. Chronic drug toxicities in the form of toxic hepatitis or liver cell failure were recorded in 3 cases only (5%) in COMP protocol patients. On the other hand, the complications were more prevalent in those treated with OAP protocol as 4 cases (6.8%) developed heart failure and 12 patients (20.3%) showed toxic hepatitis or liver cell failure. Five years survival was higher in those received COMP protocol (76.3%), versus 60% in those received OAP protocol ($p<0.01$). *Conclusions.* Patients treated with COMP protocol achieved better response, less relapse, higher survival and less toxicities when compared to those given OAP protocol .

INTERLEUKIN-12 GERMLINE POLYMORPHISM AND OUTCOME OF PATIENTS WITH HODGKIN LYMPHOMA: A PROSPECTIVE STUDY OF THE GROUPE D'ETUDE DES LYMPHOMES DE L'ADULTE

H. Ghesquieres,[1] O. Casasnovas,[2] M. Fournier,[3] D. Cox,[1] P. Brice,[4] F. Morschhauser,[5] A. Verney,[3] C. Sebban,[1] V. Ribrag,[6] C. Haioun,[7] P. Feugier,[8] H. Tilly,[9] C. Ferme,[6] G. Salles[3]

[1]Centre Leon Berard, LYON; [2]CHU Bocage, DIJON; [3]Centre Hospitalier Lyon Sud, LYON; [4]CHU Saint Louis, PARIS; [5]CHRU Lille, LILLE; [6]Institut Gustave Roussy, VILLEJUIF; [7]CHU Henri Mondor, CRETEIL; [8]CHU Brabois, NANCY; [9]Centre Henri Becquerel, ROUEN, France

Background. Although Hodgkin lymphoma (HL) is a highly curable malignancy, about 15% and 30% of patients with respectively localized or disseminated disease do not respond or relapse after initial treatment. Several scoring systems using conventional biological and clinical parameters have been developed for limited and advanced stages in order to adapt the therapeutic strategy. However, the identification of patients with adverse outcome needs to be improved. Cytokines have an important role in the pathogenesis of HL. Among them, interleukin-12 had an important role in stimulating cytotoxic lymphocyte and natural killer cells. A recent study (Cozen *et al.* Blood 2008) showed that IL-12 level of HL patients and their twins was lower than matched controls and a IL-12 polymorphim (rs3212227) that modulate IL-12 expression was associated with an increase risk of HL. *Aims.* In this context, we evaluated the influence of this IL-12 germline polymorphism on response to treatment and outcome in patients with HL. *Methods.* Between 1998 and 2002, we prospectively investigated the prognostic role of plasma cytokines and soluble receptors in Hodgkin lymphoma patients (Casasnovas *et al.* JCO 2007). A sample was collected at diagnosis specifically to investigate single nucleotide polymorphisms (SNPs) in cytokine genes. DNA was extracted from venous blood samples. Genotyping experiments of IL12 rs3212227 (3'UTR +1188A>C) were performed in duplicate using Taqman technology (ABI Prism 7000, Applied Biosystems) in 259 patients. We estimated the prognostic value of this SNP for response to treatment, relapse and overall survival (OS). *Results.* Among the 259 studied patients, 25% were older than 45 years and 56% were male. At diagnosis, 187 patients (72%) were in Ann Arbor stage I-II and 116 (45%) presented with B symptoms. Histology was nodular sclerosis in 208 patients (80%). Treatment consisted of 4 to 6 courses of anthracycline-based chemotherapy (CT) followed by involved-field radiotherapy for stages I-II and 8 courses of anthracycline-based CT for stages III-IV. Complete response (CR) and uncertain CR (uCR) were observed in 228 patients (88%), partial response in 11 (4%) and stable and progressive disease in 20 (8%). Relapse occurred in 46 patients (18%) and 25 patients (10%) died, 18 of whom of HL. After a median follow-up of 4.2 years months, the 4-year progression free survival (PFS) and OS were 81.7% and 92.2%, respectively. Genotypes of IL12 +1188A>C were AA, AC and CC in 166 (64%), 73 (28%) and 20 (8%) patients, respectively. These distributions appear significantly different from what observed in the general population ($p<0.005$). No correlation was observed between initial characteristics of HL patients and IL-12 genotyping. Regarding treatment response, no specific IL-12 genotype was associated with a better CR or influenced OS and PFS. *Conclusions.* Whether HL patients presented a specific IL12 genotype distribution as suggested by our study and Cozen series need to be confirmed. However, we didn't observe in this large series of HL patients with a particularly favorable outcome that this SNP predict response to initial treatment or outcome of patients. The role of host immunogenetics as prognostic factors in HL deserves others studies.

Bleeding disorders (congenital and acquired)

0101

RECURRENT MUTATIONS IDENTIFIED ON LMAN1 AND COAGULATION FACTORS VII, X, XIII GENES

A. Cairo,[1] M. Menegatti,[2] M. Spreafico,[2] I. Garagiola,[2] F. Peyvandi[1]

[1]IRCCS Maggiore Hospital, Mangiagalli and Regina Elena Foundation, MILAN; [2]Dpt of Internal Medicine, University of Milan, MILAN, Italy

Rare Bleeding Disorders (RBDs) as Factor (F)V, FV+FVIII, FVII, FX, FXI and FXIII deficiencies, afibrinogenemia and hypoprothrombinemia, are transmitted as autosomal recessive traits. RBDs are relatively rare in Europe (1:0.5-2 millions), but their frequency is increasing due to the high rate of immigration from the Middle East and North Africa where the incidence is significantly higher. In 2004 an International RBDs Database (RBDD: www.rbdd.org), structured to collect and to report phenotype, genotype, clinical and therapeutic information on each single disorder, was developed. This database contains data on 310 not related patients from all over of the world. Of them, 258 have been genetically characterized, with only 6% (16 patients) lacking a gene mutation in the coding region and 400bp of 5'-3'UTR. Out of 172 identified mutations, 52% (90) were missense, 12% (21) nonsense, 12% (21) splicing site, 21% (35) insertion/deletion and 3% (5) were located at the 5'UTR. A careful analysis of RBDD showed common mutations specific to some geographical areas: -p.Gln160Arg (originally reported as Gln100Arg) mutation on FVII gene was confirmed to be present only in Europeans, being found only in Italians (5 families out of 20, 25%) and in one Swedish although 62 families coming from different countries (Table 1) were characterized; -p.Arg40Thr (Arg-1Thr) mutation, on FX gene, was found only in Iranians (4 families out of 23, 17%), although 33 families coming from different countries (Table 1) were characterized; -p.Met1Thr mutation on LMAN1 gene was confirmed to be present only in Italians (4 families out of 8, 50%), although 26 families coming from different countries (Table 1) were characterized; p.Gly216Arg (Gly215Arg) and p.Arg78His (Arg77His) mutations on FXIII gene, were found respectively only in Serbians (100% of studied families) and in Iranians (6 families out of 20, 30%), although 30 families coming from different countries (Table 1) were characterized. The haplotype analysis in future will help to explain more on each genetic mutation distribution in different ethnic groups and eventual "founder" effect. Our results suggest the existence of recurrent mutations in specific geographic areas which could help for prevention of these disorders through prenatal diagnosis in families with already one severe affected child, particularly in those countries with low economic resources.

Table 1.

GENE	Recurrent mutations	N° characterized families	Countries	N° families in which the mutation was found and country of origin	% of families from the same geographical region with the same mutation
FVII	p.Gln160Arg (Gln100Arg)	20 25 4 1 1 3 3 1 1 1 1 1	Italy Iran Turkey Sweden Hong Kong India Serbia Greece Pakistan Romania Arabia USA	5 Italians 1 Swedish	25% -
FX	p.Arg40Thr (Arg-1Thr)	5 23 2 1 1 1	Italy Iran Turkey France India UK	4 Iranians	17%
LMAN1	p.Met1Thr	8 2 2 13 1	Italy Iran Turkey India Serbia	4 Italians	50%

MANAGEMENT OF ACUTE HAEMARTHROSIS IN HAEMOPHILIA: A EUROPEAN SURVEY

R.J.R. Hermans,[1] P. De Moerloose,[2] K. Fischer,[3] K. Holstein,[4] R. Klamroth,[5] T. Lambert,[6] G. Lavigne-Lissalde,[7] R. Perez,[8] M. Richards,[9] G. Dolan[10]

[1]Cliniques universitaires Saint-Luc, BRUSSELS, Belgium; [2]Hôpital cantonal, GENÈVE, Switzerland; [3]Van creveld Clinic, UTRECHT, Netherlands; [4]Onkologisches Zentrum, II. Medizinische Klinik und Poliklinik, Universitätsklini, HAMBURG, Germany; [5]Vivantes-Klinikum in Friedrichhain, BERLIN, Germany; [6]CHU Kremlin - Bicètre, PARIS, France; [7]Laboratoire d'Hématologie, Groupe Hospitalo-Universitaire Caremeau, NÎMES, France; [8]Hospital Virgen del Rocio, SEVILLE, Spain; [9]Paediatric Haematology Department, LEEDS, UK; [10]Queen's Medical Centre, NOTTINGHAM, UK

The treatment of haemarthrosis in a person with haemophilia may involve several different treatment modalities including factor replacement therapy, joint aspiration, ice, non-weight bearing interventions and/or immobilisation, analgesics including anti-inflammatory agents and rehabilitation. However, few data are available on the optimal management of acute haemarthrosis in practice. Such information may be critical in view of recent insights into the pathophysiology of haemophlilic arthropathy. Current management algorithms for acute haemarthrosis were surveyed among 23 haemophilia physicians representing 15 different European countries and responsible for the care of 3,633 patients. Three clinical scenarios of acute haemarthrosis in patients with haemophilia A were presented and management was recorded using 16 questions per scenario. For moderate haemarthrosis, a first dose of 30 U/kg FVIII was given by 75 % treaters once a day (88%) and repeated on day 2 (66%) and up to day 4 (22%). At presentation of a severe haemarthrosis, a first dose of 40-50 U/kg was given by 75 % treaters and repeated on day 1 (81 %). Replacement therapy was continued up to day 3 (77%) or 4 (54 %). Aspiration was considered by 19% of the physicians. Inhibitor screen was ordered by 27%, factor assays 70%, and imaging 57%. Active additional interventions in case of a severe bleed included immobilisation (splint or cast) (71%) and non-weight-bearing (85%). Analgesics were used in most cases, but steroids, NSAIDs and antifibrinolytic agents were used infrequently (<20%). In conclusion, this survey highlights potentially important variation in the management of acute haemarthrosis across the EU with respect to intensity and duration of replacement therapy as well as use of adjunctive therapies. Local practice and national guidelines may need to be revised in light of recent advances in the understanding of the pathogenesis of haemophilic arthropathy.

0103

CIRCULATING VERSUS PROGENITOR ENDOTHELIAL CELLS ARE ABNORMAL IN PATIENTS WITH DIFFERENT TYPES OF VON WILLEBRAND DISEASE AND CORRELATE WITH MARKERS OF ANGIOGENESIS: A COHORT STUDY OF 74 CASES

G. Gritti,[1] A.B. Federici,[1] A. Cortelezzi,[1] P. Bucciarelli,[2] M. Punzo,[2] S. Lonati,[1] F. Rezzonico,[2] I. Silvestris,[1] V. Rubini,[2] S. La Marca,[2] G. Lambertenghi-Deliliers,[1] P.M. Mannucci[2]

[1]Deapartment of Hematology, University of Milan, MILAN; [2]Dep. Internal Medicine, University of Milan, MILAN, Italy

Background. von Willebrand disease (VWD) is the most common inherited bleeding disorder and is caused by quantitative (VWD1 and VWD3) or qualitative (VWD2A, VWD2B, VWD2M, VWD2N) defects of von Willebrand factor (VWF). VWF, synthesized by endothelium and magakaryocytes, circulates in plasma and is present in sub-endothelium and platelets: therefore VWF is an ideal marker for endothelial formation/ damage and megakaryocytopoiesis. Circulating (CEC) and progenitor (CEP) endothelial cells have been also recently proposed as markers of peripheral and bone marrow-derived angiogenesis. *Aims of the study, Patients and Methods.* To evaluate the association of CEC/CEP with cellular and circulating VWF, we have measured the number of CEC/EPC together with VWF and cytokines involved in angiogenesis in a cohort of 74 patients with different VWD types. Seventy-four VWD patients were diagnosed according to the recommendations of the Scientific Standardization Committee on VWF of the ISTH. VWD cohort was composed by the following VWD types (number): VWD1 (22), VWD2A (9), VWD2B (19), VWD2M (17), VWD3 (7). Twenty healthy individuals were used as controls. CEC ($CD146^+$, $CD31^+$, $CD45^-$) and CEP ($CD34^+$, $CD133^+$, $CD45^-$) were evaluated by flow cytometry. Serum levels of VEGF, E-selectin, P-selectin, EPO and TPO were determined by ELISA. Both CEC/EPC and cytokines were analyzed by the same authors in blind, i.e. without knowing in advance VWD diagnosis. Continuous variables were expressed as median and range. CEC, EPC, VEGF, E-selectin, P-selectin, EPO, TPO were all left-skewed, so that a logarithmic transformation was performed before statistical analysis in order to approximate a normal distribution. Comparison between groups was made by Student's t-test or one-way ANOVA where needed. To evaluate the influence of VWF on CEC and EPC levels, a simple linear regression analysis was performed. Adjustment for age, sex and WBC levels was made by a multiple linear regression analysis. Correlation analysis was performed by using the Spearman's rank correlation test. $p<0.05$ was taken as a cut-off point for statistical significance. *Results.* CEC, E-selectin, VEGF and EPO tended to be higher in all VWD patients than in controls. TPO was particularly high in VWD3 patients but not in the other VWD types, while P-selectin serum levels were almost similar in VWD patients and in controls. Conversely, EPC were lower in all VWD patients than in controls. Considering VWD patients all together, there was a statistically significant difference between VWD patients and controls in mean levels of CEC, EPC, VEGF, E-Selectin and EPO ($p<0.01$ for all of them), while no statistically significant difference was found for P-Selectin and TPO. Dividing VWD patients into types (VWD1, VWD2A/2M, VWD2B, VWD3), a statistically significant difference was found for CEC (one-way ANOVA: $p=0.005$), EPC ($p=0.001$), E-Selectin ($p<0.0001$), EPO ($p=0.021$) and TPO ($p=0.004$). VEGF showed a trend towards significance ($p=0.061$), while for P-Selectin no significant difference was found ($p=0.952$). Considering only VWD1, we found a significant inverse relationship between CEC and VWF:Ag plasma levels ($p=0.048$; $R^2=0.19$). The relationship was still significant after adjustment for age, sex and WBC in a multiple linear regression analysis ($p=0.046$). *Discussion and Conclusions.* Based on these results, we can conclude that CEC are increased in VWD patients, especially in VWD2B and 3: high CEC are associated with increased levels of cytokines involved in angiogenesis (up-regulation). Conversely, CEP are always decreased in VWD patients, especially in VWD1 and VWD2A/2M, suggesting down-regulation of bone marrow-derived angiogenesis. This abnormal results on CEC/CEP in patients with inherited deficiencies of VWF might suggest a major role of VWF in peripheral and bone marrow-derived angiogenesis

0104

THE HEMOSTATIC POTENTIAL OF ACUTE PROMYELOCYTIC LEUKEMIA CELLS BY THE CALIBRATED AUTOMATED THROMBOGRAM ASSAY: MODULATION BY ARSENIC TRIOXIDE AND ALL-TRANS RETINOIC ACID

A. Falanga,[1] E. Diani,[2] L. Russo,[2] D. Balducci,[2] M. Marchetti[2]

[1]Ospedali Riuniti Bergamo, BERGAMO; [2]Hemostasis and Thrombosis Center, Ospedali Riuniti di Bergamo, BERGAMO, Italy

Background. Acute promyelocytic leukemia (APL) cells highly express both procoagulant and anticoagulant activities. Overall these activities contribute to the coagulopathy typical of APL patients. Differentiation therapy with all-trans retinoic acid (ATRA) or arsenic trioxide (ATO) induces the APL molecular remission and affects the cellular hemostatic properties. *Aims.*We wanted to characterize the APL cell hemostatic potential by the calibrated automated thrombogram (CAT) standardized global assay, which reflects the net results of pro- and anti-coagulant forces. The endogenous thrombin potential (ETP), measured as the area under the thrombin generation (TG) curve, is a good indicator of overall plasma prothrombotic and hemorrhagic tendency. We evaluated 1) the sensitivity of NB4 cell TG potential to treatment with ATRA or ATO; 2) the correlation of CAT parameters to the levels of two known procoagulants, i.e. tissue factor (TF) and cancer procoagulant (CP), and 3) the association of global TG to cell differentiation, proliferation, and apoptosis/necrosis. *Methods.* NB4 cells TG was measured before and after 24h incubation with either 0.1 μM ATO, 1 μM ATRA, the combination 0.1 μM ATO/1 μM ATRA or the vehicle (control). TG potential of NB4 was evaluated in normal pool plasma (NPP) by CAT assay; TF by chromogenic, immunological, cytofluorimetric assays; TFmRNA by RT-PCR; CP activity by chromogenic assay; cell differentiation by cytofluorimetric analysis of surface CD11b expression; and cell apoptosis/necrosis by annexin V/propidium iodide staining. *Results.* Before any treatment the TG potential of NB4 cells (=1350±70 nM*min) was significantly increased compared to normal granulocytes ($p<0.05$). When the CAT was performed in the absence of factor VII (FVII), a significant decrease of ETP was observed, confirming a major role to global TG for TF, but also suggesting a role for other procoagulants (i.e. CP, phospholipids) to the remaining FVII-independent activity. Both ATRA

and ATRA/ATO significantly reduced the NB4 TG (980±100 nM*min, and 1090±90 nM*min, respectively) compared to untreated cells, whereas ATO alone had a minor effect (1200±120 nM*min). Results of specific assays to identify TF and CP confirmed a greater effect of ATRA and the combination ATO+ATRA in reducing both procoagulants compared to ATO alone. The observed modulation of TG potential by the two drugs paralleled the reduction of cell proliferation due to induction of apoptosis and cell differentiation (ATRA and ATO+ATRA) or to cell necrosis (ATO). *Summary and Conclusions.* The CAT assay appears to be a reliable and sensitive method for characterizing the TG potential of APL cells. It can be a valuable tool to characterize the overall hemostatic phenotype (both procoagulant and anticoagulant) of APL cells and ultimately to understand the role of different TG phenotypes in predicting the outcome of the APL coagulopathy.

0105

SINGLE CENTRE EXPERIENCE OF DESMOPRESSIN RESPONSE IN CHILDREN WITH MILD FVIII DEFICIENCY, VON WILLEBRANDS DISEASE AND PLATELET FUNCTION DEFECTS

A. Breen, M. Kavanagh, I. Kelly, B. Nolan, I. Regan, P. Smith, C. McMahon

Our Lady's Children's Hospital, DUBLIN, Ireland

Background. Desmopressin(1-deamino-8-D-arginine-vasopressin) is a synthetic vasopressin analogue that increases factor VIII levels in mild Factor VIII deficiency, von Willebrand factor in von Willebrands disease(VWD), and improves bleeding time in some platelet function defects(PFD), thus avoiding the risk of acquiring blood-borne viral infections. Most clinical studies of Desmopressin (DDAVP) response have been in adults with only a few studies reviewing DDAVP efficacy in paediatric patients. It is suggested that response is lower and less predictable in children, particularly in younger children and those with lower baseline levels. *Aims.* We wished to evaluate the safety and efficacy of intravenous DDAVP in paediatric patients with mild factor VIII deficiency, VWD (type 1, type 2A and type 2M) and PFD, and determine if age and baseline values were predictors of response. *Methods.* A retrospective study was conducted of all children diagnosed with mild factor VIII deficiency (baseline FVIII:C <0.05iu/dL), VWD and PFD, who had a trial of treatment with intravenous DDAVP in an 11 year period between 1997-2008. Exclusion criteria included patients aged <2 years, history of heart disease or epilepsy, type 2B or type 3 VWD. Baseline diagnostic chromogenic factor VIII (FVIII:C) levels, von willebrand factor antigen(VWF:ag) and ristocetin co factor (VWF:RCo) and platelet function abnormalities were determined. All received 0.3 mcg/kg DDAVP over 30 minutes and further testing was performed on samples obtained prior to and one hour post DDAVP infusion. Response was defined as normalization of FVIII:C levels, VWF:ag, VWF:RCo levels or underlying platelet function defect. Adverse events associated with Desmopressin administration were recorded. *Results*. Two hundred and six children, aged 2-15 years (median 6.5yrs), were included. Fifty one (25%) had mild Factor VIII deficiency, 118 (57%) had VWD, {104 (88%) had type 1VWD, 5 (4%) had type 2A VWD and 9 (8%) had type 2M VWD}, and 37(18%) had a PFD. Thirty eight children (74%), aged 2-11 years (median 3.5yrs) with Factor VIII deficiency had a therapeutic response. Their baseline FVIII:C level was 0.18-0.47iu/dL (mean 0.33iu/dL). The age (2-11yrs, median 3yrs) of the non-responder group was similar but baseline levels were lower (mean 0.19iu/dL, range 0.09-0.47iu/dL). One hundred and one (85%) children, aged 2-15yrs median 5.5yrs, with VWD had a therapeutic response. Their mean baseline VW:ag level was 0.46iu/dL (range 0.18-0.46iu/dL) and VW:RCo level of 0.31iu/dL (range 0.09-0.47iu/dL). The non-responder group had a median age of 4.5 yrs (range 2-15 yrs), with mean baseline VW:ag levels of 0.28iu/dL (range 0.1-0.22iu/dL) and VW:RCo levels 0.22iu/dL (range 0.07-0.13iu/dL). VWD subtype did not influence response. Seventeen of thirty three (51%) children with a platelet function defect showed a therapeutic response. There was no age difference between the 2 groups. There were 6 adverse events, 4 children reported headaches and 2 developed hyponatraemia. *Conclusion.* Desmopressin is an effective and safe treatment modality for children with mild Factor VIII deficiency, VWD and PFDs but age, baseline FVIII:C, VW:ag or VW:RCo do not reliably predict response and a DDAVP trial should always be undertaken.

0106

GENZ-112638, AN INVESTIGATIONAL ORAL THERAPY FOR GAUCHER DISEASE TYPE 1: PHASE 2 CLINICAL TRIAL RESULTS AFTER ONE YEAR OF TREATMENT

E. Lukina,[1] N. Watman,[2] E. Arreguin,[3] M. Banikazemi,[4] G. Pastores,[5] M. Iastrebner,[6] M. Dragosky,[6] H. Rosenbaum,[7] A. Zimran,[8] M. Kaper,[9] S.E. Smith,[9] A.C. Puga,[9] J. Peterschmitt[9]

[1]Russian Academy of Medical Sciences, MOSCOW, Russian Federation; [2]Hospital Ramos Mejia, BUENOS AIRES, Argentina; [3]Instituto Mexicano del Seguro Social Hospital de Especialidades, COL. LA RAZA, Mexico; [4]Columbia University Medical Center, NEW YORK, NY, USA; [5]New York University, NEW YORK, NY, USA; [6]Instituto Argentino de Diagnostico y Tratamiento, BUENOS AIRES, Argentina; [7]Rambam Medical Center, HAIFA, Israel; [8]Sha'are Zedek Medical Center, JERUSALEM, Israel; [9]Genzyme Corporation, CAMBRIDGE, MA, USA

Background. Genz-112638 is a novel oral small molecule inhibitor of glucosylceramide synthase under development for the treatment of Gaucher disease type 1 (GD1). *Aim.* An open-label Phase 2 clinical study to evaluate efficacy, safety, and pharmacokinetics of Genz-112638 in patients with GD1 has recently completed 52 weeks of treatment. *Methods.* This clinical trial of Genz-112638, given 50 or 100 mg bid orally, treated 26 adults with GD1 (16F:10M; mean age 34 years, range 18-60; all Caucasian) at 7 sites in 5 countries. Eligible patients were required to have splenomegaly (volume≥10x normal) and either thrombocytopenia (platelets 45,000-100,000/mm^3) or anemia (hemoglobin 8-10 g/dL, female; 8-11 g/dL, male). None received enzyme replacement or substrate reduction therapy in the prior 12 months. The composite primary efficacy endpoint is based on improvements in ≥2 of the 3 main parameters: spleen volume (-15%), hemoglobin level (+0.5 g/dL) or platelet count (+15%) after 52 weeks of treatment. Liver volume, chitotriosidase, glucosylceramide are also assessed. Patients continue to be treated and monitored long-term. *Results.* Twenty-two patients completed the study to Week 52; 4 patients withdrew. The 52-week composite primary endpoint was met by 20/26 patients. Mean (±SD) changes from baseline to Week 52 were: hemoglobin +1.6 (±1.28) g/dL; platelet count +40.3% (±37.49%); spleen and liver volume (multiples of normal) 38.5% (±11.42%) and 17.0% (±10.48%), respectively; and chitotriosidase (median change) 51.3% (±17.16%). Plasma glucosylceramide levels normalized in all patients. Genz-112638 was well tolerated with an acceptable safety profile. In the first 52 weeks of treatment, the majority of AEs (91%) were reported as unrelated to study treatment. All of the AEs reported as treatment-related (7 AEs in 6 patients) were mild and transient. *Summary and Conclusions.* Results from this Phase 2 study indicate that Genz-112638 may be a safe, effective, and convenient oral therapy for patients with GD1. Clinical development of Genz-112638 is proceeding, and Phase 3 studies are planned.

0107

GAUCHER DISEASE DIAGNOSTIC AND DISEASE MANAGEMENT ALGORITHMS: A GUIDE FOR HEMATOLOGISTS

M.D. Cappellini,[1] P. K. Mistry,[2] E. Lukina,[3] H. Özsan,[4] S.M. Pascual,[5] H. Rosenbaum,[6] M.H. Solano,[7] Z. Spigelman,[8] J. Villarrubia,[9] N.P. Watman,[10] G. Massenkeil[11]

[1]University of Milan, MILAN, Italy; [2]Yale University, NEW HAVEN, CT, USA; [3]Russian Academy of Medical Sciences, MOSCOW, Russian Federation; [4]Dokuz Eylul University, IZMIR, Turkey; [5]Hôpital Cantonal, GENEVA, Switzerland; [6]Ramban Medical Centre, HAIFA, Israel; [7]San Jose Hospital, BOGOTÁ, Colombia; [8]Parker Hill Oncology & Hematology, BOSTON, MA, USA; [9]University Hospital Ramón y Cajal, MADRID, Spain; [10]Hospital J.M.Ramos Mejía, BUENOS AIRES, Argentina; [11]Städtisches Klinikum Gütersloh, GÜTERSLOH, Germany

Background. Gaucher disease (GD) is an inherited deficiency of acid β-glucocerebrosidase leading to abnormal glycolipid accumulation in macrophage lysosomes and consequent hematologic, visceral, and skeletal abnormalities. GD is rare (estimated prevalence 1:60,000, though more common in individuals of Ashkenazi Jewish descent) and clinically heterogeneous, and therefore can present a diagnostic challenge. *Aims.*GD patients often present to haematologists when unexplained haematologic abnormalities (thromobocytopenia, anemia) are identified, often in conjunction with enlarged spleen. Recent studies have found that GD does not have a high index of suspicion (Mistry *et al.* 2007) and is often only considered when other possibilities excluded;

hematologic malignancy is more often suspected. Prompt diagnosis is critical as diagnostic delay increases the risk of disease progression, inappropriate intervention (such as splenectomy) and sub-optimal treatment. *Methods.* In order to raise awareness about GD and facilitate diagnosis, an international group of GD experts was convened to review GD management guidelines and to determine under which circumstances GD should be given greater priority in differential diagnosis. *Results.* Algorithms for diagnosis specifically geared toward haematologists were created. Separate algorithms were developed for individuals of both Ashkenazi Jewish and non-Ashkenazi Jewish background. The algorithms include a review of the differential diagnosis and guidance on diagnostic procedure when GD is suspected. GD can be confirmed or eliminated through a simple enzyme activity assay performed on peripheral blood leucocytes. DNA analysis and bone marrow biopsy can provide additional information about disease burden but should not be considered diagnostic. Diagnostic algorithms are accompanied by disease management algorithms focusing on assessment and monitoring, which reflect published therapeutic goals and monitoring guidelines, to simplify decision making in the evaluation, treatment and ongoing monitoring of GD. *Summary and Conclusions.* The identification of symptoms highly suggestive of Gaucher disease and creation of diagnostic algorithms geared specifically toward haematologists may help decrease the time to diagnosis for patients affected by this rare, heterogeneous but treatable disorder. Associated guidelines for disease assessment and monitoring may simplify the development of patient-specific management plans.

0108

THE SEQUENTIAL COMBINED BYPASSING THERAPY IS EFFECTIVE AND SAFE IN THE TREATMENT OF UNRESPONSIVE BLEEDS IN HAEMOPHILIA PATIENTS WITH INHIBITORS

A. Gringeri,[1] K. Fischer,[2] A. Karafoulidou,[3] M.F. López-Fernández[4]

[1]University of Milan, MILAN, Italy; [2]Van Creveldkliniek, Department of Hematology, University Medical Center, UTRECHT, Netherlands; [32]nd Blood Transfusion Center and Hemophilia Center, Laikon General Hospital, ATHENS, Greece; [4]Servicio de Hematología y Hemoterapia, Complexo Hospitalario Juan Canalejo, A CORUÑA, Spain

Background. Development of inhibitors is today the most severe and challenging event in the treatment of patients with haemophilia. Replacement therapy with the missing coagulation factor is ineffective in high-responders and bypassing agents are required. Unfortunately, whatever by-passing agent is initially used, some bleeds (10-20%) cannot be controlled. When all treatments have failed the sequential administration of 2 bypassing agents (SCBT) has been recently reported to have a positive synergistic effect. *Aims.*To provide a deeper insight on efficacy and safety of SCBT. *Methods.* A survey on each course of SCBT given was conducted by the European Haemophilia Treatment Standardization Board by means of a web-based database. SCBT was defined as the administration of recombinant factor VIIa (rFVIIa) and activated prothrombin complex concentrate (APCC) within 12 hours from each other. *Results.* SCBT was used in 2 children (aged 8 and 14 year-old) and 4 adults (mean age: 34, range: 24-45 years) with haemophilia A (6 patients) and B (1 patient), all patients with high-responding inhibitors and unresponsive to APCC and rFVIIa. The children were suffering from joint bleeds refractory to high doses of rFVIIa (up to 270 µg/Kg/2h) and to high doses of APCC (up to 80 U/Kg/8h). Three adults had undergone major surgery (removal of knee prosthesis, knee arthrodesis, laparotomy for kidney rupture), initially treated with rFVIIa from 120 up to 270 µg/Kg/2h, followed by significant bleed. One of these patients was switched to APCC 80 U/Kg/8h without success. The fourth adult was suffering from lower limb compartmental syndrome and had no response after 5 administration of 180 µg/Kg every 3h and two infusions of FEIBA 75 U/Kg. SCBT was administered in children and adults alternating one APCC dose (range 50-80 U/Kg) to one or two rFVIIa doses (range 90-270 µg/Kg) every 4-12 hours. Complete bleeding control was achieved in 12-24 h in all patients. SCT was discontinued after 2-15 days. All patients underwent prophylaxis with FEIBA or rFVIIa thereafter. No clinical adverse event was observed, but a rise of D-dimer levels occurred in 3 of 6 patients, without a consumption of platelet and/or fibrinogen. *Conclusions.* SCBT might represent a valid salvage treatment of unresponsive bleeds. A much larger and prospective clinical trial is needed to confirm these findings.

0109

PREVALENCE OF VWD IN IRAN

M. Lak,[1] H. Mansouritorghabeh[2]

[1]Tehran University of Medical Sciences, TEHRAN; [2]Immunology Research Centre, Mashhad university of Medical Sciences, MASHHAD, Iran

Background. vWD described by Dr Erik von willebrand in 1962. It is the most frequent congenital bleeding disorder, Caused by the quantitative deficiency (type I&III) or dysfunction (type II) of vWF. The disease inherited in an autosomal dominant/ recessive pattern. The principle clinical symptoms of vWD are prolonging bleeding after surgeries and mucosal bleeding. Excessive bleeding at the time of menstruation and during childbirth is a frequent problem in women of childbearing age. vWD is classified into 3 different types; Type I, the most frequent type of vWD, (~ 80-85%) inherited in an autosomal dominant pattern. Type II vWD (Subtype: 2A, 2B, 2M, 2N) also transmitted in an autosomal dominant trait (~15%). Type 3 is rare (o.5-5%), but the most severe form of vWD, inherited in an autosomal recessive pattern. Clinically significant vWD is estimated 50-100 per million populations. *Aims.* To evaluate prevalence of vWD and distribution of different types, pattern of bleeding and type of complications associated with pregnancy and childbirth. *Methods.* Data collected from Tehran University, Imam Khomeini Hospital, Hemophilia Center retrospectively. *Results.* 900 patients with vWD are registered in our National Registry includes 426 females & 474 Males. Distribution of types of vWD in Iran: Type I: 118 Pts (13%), type II: 142 Pts (16%), type III: 460 Pts (71% of all cases). *Conclusions.* Menorrhagia is one of the most frequent complications in women with vWD and has a negative effect on their quality of life. Management of menorrhagia in women with vWD should be provided by a multidisciplinary team including a Haematologist and Gynacologist. There was no evidence of reduced fertility in married women. *Discussion.*Epistaxis and menorrhagia are the most frequent bleeding symptoms especially in typeIII vWD. Frequency of type 3 vWD and other bleeding disorders which inherited in an aoutosomal recessive trait increased by 5-10 times where consanguineous marriage is high, such as Iran and Soutern India. In Iran, prevalence of type III is 9 per million populations (Iran has 70 million population). The high prevalence of Type III and a low prevalence of type1 vWD in developing countries, suggests the low awareness of disease as also under-diagnosis of the mild cases.

Table 1. Types of (%) bleeding symptoms in 900 Iranian patients with vWD.

No	Bleeding symptoms	Type III (640 Pts)	Type II (142)	Type I
1	Epistaxis	77	63	61
2	Menorrhagia	69	36	32
3	Post dental extraction bleeding	70	39	31
4	Hematomas	35	14	13
5	Bleeding from wound	52	40	36
6	Gum bleeding	55	35	31
7	Post –surgical bleeding	41	23	20
8	Post partum bleeding	16	18	17
9	Gastrointestinal bleeding	20	8	5
1	Joint bleeding	37	4	3
1	Haematuria	1	5	2
1	Cerebral bleeding	5	2	0

0110

COMPARATIVE STUDY OF CLINICAL, X-RAY AND MRI SCORES IN THE FOLLOW-UP OF HAEMOPHILIC ARTHROPATHY

H. Pergantou,[1] H. Platokouki,[2] A. Papadopoulos,[3] G. Matsinos,[4] P. Xafaki,[2] S. Aronis[2]

[1]Agia Sophia Children's Hospital, ATHENS, Greece; [2]Haemophilia/haemostasis unit, Aghia Sophia Children's Hospital, ATHENS, Greece; [3]"Magnetic Resonance Imaging" Diagnostic Centre, ATHENS, Grenada; [4]2nd Orthopaedic Department, Aghia Sophia Children's Hospital, ATHENS, Greece

Arthropathy is the most frequent cause of morbidity in patients with severe haemophilia. Once established, arthropathy is considered as an irreversible or progressive complication, even in children on prophylaxis. To estimate the role of clinical, x-ray and MRI scores in the evaluation of progression of haemophilic arthropathy, 84 joints of 24 boys with severe (n=18) and moderate (n=6) haemophilia (A: 22, B: 2) were investigated with clinical examination, x-rays and MRI at two time periods (Time 0 and 1). Patients' age at Time 0 was 10.5±3.6 years and time elapsed to time 1 was 3.8±1.4 years. At Time 0: All investigated joints had a history of more than three bleeds. 16 boys were on secondary prophylaxis for 5.4±2.8 years. Clinical score: 2.0±3.6, Pettersson score: 2.1±2.8, Denver score: 4.5±3.8. After the first evaluation prophylaxis was intensified in 11 children and initiated in 4. At Time 1: Clinical score: 1.5±3.1, Pettersson score: 1.7±2.7, Denver score: 5.1±4.1. The analysis of results provided evidence that the information carried by the three scores could be divided into two parts: a) overlapping information given by one score that was explained by the information given by the other, b) information given by one score that was not explained by the other. At both examinations, the x-ray (Pettersson) score was acting as a mediator, correlating well both with the clinical and the MRI (Denver) score while the last two were more alienated from each other. The correlation of x-ray with the Denver score was significantly reduced at the second examination, while it was slightly improved with the clinical score. Comparing the findings, deterioration was found in 15.3%, 15.3% and 34.1% and improvement in 25.9%, 40% and 16.5% of the joints with clinical, x-ray and MRI scores, respectively. Besides, in 58.8%, 44.7% and 49.4% of the joints no progress of arthropathy was found with the three scores, respectively. Moreover, the number of haemarthroses per joint per year was reduced (0.7±1.76 vs. 2.0±1.8) (p<0.01). Initiation or intensification of prophylaxis resulted in three fold reduction of haemarthroses (p<0.01) and significant improvement of clinical and Pettersson scores (p<0.01). On the contrary, MRI findings were mostly progressive with the exception of 16.5% of joints with reversible elements (mild or moderate synovitis). *Conclusions.* Apart from the information shared by the clinical, x-ray and MRI scores, each of them provide different and additional information which should be estimated separately by the physician in the follow-up of evolution of haemophilic arthropathy.

0111

MUTATION SPECTRUM OF SEVERE VON WILLEBRAND DISEASE TYPE 3 IN INDIA

F. Ahmad,[1] R. Schneppenheim,[2] F. Oyen,[2] T. Obser,[2] U. Budde,[3] M. Kannan,[1] R. Saxena[1]

[1]All India Institute of Meical Sciences, NEW DELHI, India; [2]Department of Pediatric Haematology Oncology, University Medical Centre Hamburg, HAMBURG, Germany; [3]Coagulation Laboratory, HAMBURG, Germany

Background. von Willebrand disease (VWD) is the most common autosomal inherited bleeding disorder caused by defects of von Willebrand factor (VWF). Severe type 3 VWD is characterized by complete absence or presence of only trace amounts of non-functional VWF. Severe VWD is caused by small insertions and deletions, splice site, missense and nonsense mutations of the VWF gene respectively but large deletions are a rare cause of type 3 VWD. *Aims.* To evaluate the VWF gene mutation spectrum in severe type 3 VWD patients from India. *Methods.* This study includes 20 unrelated Indian patients previously diagnosed with severe VWD type 3 by conventional tests and multimer analysis. Mutation screening was done by PCR and direct sequencing of the coding region (exon 2-52) of VWF including intronic flanking regions. Characterization of breakpoints of two novel large deletions was done by using walking primer pairs. *Results.* Twenty-five different mutations were identified including 17 novel mutations. Ten patients were homozygous, six were compound heterozygous, one patient had a gene conversion with the VWF pseudogene on chromosome 22 comprising the mutations V1279I, Q1311X, A1317, I1343V, V1360A and F1369I. In one patient no candidate mutations were identified. In a second patient only one mutation was found. A third patient was homozygous for a silent mutation in exon 26 (N1138N) that might possibly affect splicing. Six different nonsense mutations were detected. Five patients had homozygous nonsense mutations, four patients were compound heterozygous including two patients with an additional third mutation. Six patients carried deletions including four small novel deletions (1bp or 2bp) while two carried large novel deletions of ≈81 kb and ≈2.3 kb, respectively. *Conclusions.* Our results reveal that VWD type 3 is caused by a broad spectrum of mutation located in the whole VWF gene. Large homozygous deletions were found in two unrelated patients. Nonsense mutations and deletions were found to be a common cause of severe type 3 VWD in India.

0112

INCIDENCE OF LUPUS ANTICOAGULANT IN HEMOPHILIA PATIENTS

V. Krasivska, O. Stasyshyn, V. Loginsky

State institution Institute of Blood Pathology and Transfusion Medicine of AMS, LVIV, Ukraine

Background. Two types of pathological inhibitors of coagulation have been developed in hemophilia patients: inhibitor against factors VIII(IX) and lupus anticoagulant. *Aims.* To investigate the incidence of lupus anticoagulant in hemophilia patients depending on severity of the disease, titers of inhibitors against factors VIII (IX) and type of responsiveness of patients' immune system (low-responder or high-responder). *Patients and methods.* 82 hemophilia patients were investigated (69 -hemophilia A, 11- hemophilia B, 1 - hemophilia C and 1 - hemophilia (A+B)). Their age ranged from 10-77 years. There were 46 hemophilia patients with inhibitors and 36 persons with suspicion of LA presence or clinical signs of resistance to substitution therapy. All patients underwent general clinical and laboratory tests, coagulological investigations necessary for diagnostics, as well as determination of coagulation factors and activity of inhibitor of the deficient procoagulant. Investigation of LA activity was performed using three-step complex of tests according to the international criteria. *Results.* In the investigated group of patients LA activity was detected in 24 (29.3%) patients with hemophilia, 20 of them (24.4%) had hemophilia A and other 4 (4.9%) - hemophilia B. Particularly, laboratory signs of anticoagulant were found in 39,1% of patients with specific inhibitors and in 16,7% of patients without inhibitors of coagulation factor VIII (IX). The proportion of LA-positive persons in the group of patients with immune inhibitors of coagulation factors was significantly larger than in patients without inhibitors (χ^2=3.897, p<0.05). There was no LA activity detected for patients with hemophilia C and hemophilia (A+B). No influence of age on the incidence of LA in hemophilia patients was found, as well as connection between the anticoagulant and the disease type and severity. The main clinical manifestations of LA presence were relapsing hemorrhagic complications and resistance to the substitution therapy with plasma products. The signs of thrombosis were detected in 1 patient during the substitution infusion therapy. *Conclusion.* Effects of the lupus anticoagulant were revealed in 29.3% of hemophilia patients, particularly - 24.4% with hemophilia A and in 4.9% with hemophilia B. In patients with inhibitor form of hemophilia the antiphospholipid activity was diagnosed significantly more frequently than in patients without specific inhibitors. Age of patients, disease type and severity had no influence on the incidence of lupus anticoagulant in patients with hemophilia. Clinical consequences of the occurrence of lupus anticoagulant activity in hemophilia patients may be represented by hemorrhage relapse as well as thrombotic complication.

0113

INDIVIDUALISED ORAL VITAMIN K FOR REVERSAL OF WARFARIN EXCESSIVE ANTICOAGULATION

M. Briz,[1] K. Talks,[2] J. Hanley,[2] P. Kesteven,[2] P. Avery,[3] A. Daly,[3] F. Kamali[3]

[1]Hospital Sierrallana, TORRELAVEGA, Spain; [2]Haemostasis and Thrombosis, NHS Foundation Trust, NEWCASTLE UPON TYNE, UK; [3]University of Newcastle, NEWCASTLE UPON TYNE, UK

Background. Warfarin over-anticoagulated patients present a wide range of international normalized ratio (INR) values and may respond differently to fixed doses of vitamin K. Consequently a high proportion of patients still remain outside their target INR 24 hours after vitamin K treatment, being prone to either hemorrhage (if the patient is still over-anticoagulated) or thromboembolism (if the INR is over-corrected). *Aims.* 1. To assess the effectiveness of a *tailored* vitamin K dosing regimen

based on individual patient INR, in the reversal of warfarin over-anticoagulation. 2. To determine the impact of patient age, gender, weight, height, body surface area, warfarin daily dose, target INR and CYP2C9 and VKORC1 polymorphism on the rate of INR reversal. *Methods.* Patients on warfarin, either asymptomatic or with minor hemorrhagic complications, and with a venous INR >6.0 were recruited into the study. Written informed consent was obtained. Oral vitamin K was administered to the patient and unless already taken the day's dose of warfarin was omitted. Vitamin K dose was calculated using a regression equation produced from a previous study and it is based on initial INR and target INR. Venous INR was determined again 24 hours after vitamin K administration. Regression analysis was used to evaluate the impact of patient characteristics and genetic polymorphisms on INR reversal. *Results.* Eighty seven events (38M/49F) were included in the study. Total number of patients was 69, with 14 of them having more than one episode requiring vitamin K (one event in 55 patients, two events in 11, three events in 2 and four events in 1). Initial INR ranged from 6 to 16 (median 7.4), median vitamin K administered dose was 1.7mg (range 1.1-3.4) and median INR after 24 hours was 2,4 (range 1.3-6.4). Out of the 87 analysed events, INR after 24 hours was in range in 33 (37.93%), above range in 17 (19.54%) and below range in 37 (42.53%). Change in INR (initial INR - INR after 24 hours) showed a statistically significant correlation with dose of vitamin K, body surface area, not omitting warfarin on day zero and target INR. Genetic variants for CYP2C9 and VKORC1, tested in a subgroup of 66 events, did not show any impact on INR reversal although, as previously described, they correlated with warfarin daily dose. *Conclusions.* The individualized vitamin K dose did not result in a significant improvement on the percentage of patients reaching their target INR after 24 hours compared to previously published results. Factors that influence INR reversal are vitamin K dose, body surface area, target INR and whether the patient takes warfarin on the same day that vitamin K is administered. Those factors should be used in subsequent studies for accurate vitamin K dose calculation. Genetic variants of CYP2C9 & VKORC1 do not seem to affect response to vitamin K, although due to the low number of patients it needs confirmation in larger studies.

NOVEL ASSOCIATION BETWEEN ACQUIRED TYPE 2 VON WILLEBRAND DISEASE AND GLYCOGEN STORAGE DISEASE IA: A REPORT OF 3 AFFECTED SIBLINGS

Y.S. Sorour,[1] M.J. Sharrard,[2] A. Vora,[1] G.T. Gillett,[3] J.H. Payne[1]

[1]Haematology Department, Sheffield Children's Hospital NHS Foundation Trust, SHEFFIELD; [2]Department of Paediatric Medicine, Sheffield Children's Hospital NHS Foundation, SHEFFIELD; [3]Clinical Biochemistry, Sheffield Teaching Hospitals NHS Foundation Trust, SHEFFIELD, UK

Background. Glycogen storage disease type Ia (GSD Ia) is an autosomal recessively inherited disorder of carbohydrate metabolism caused by defects of the glucose-6-phosphatase complex which results in inadequate glucose production. An associated bleeding diathesis has been recognized since the 1970s and was initially attributed to a platelet function defect but defects in von Willebrand function (VWF) have since been described. Defects have been found in 60% of screened patients with GSD Ia but published cases are almost exclusively mild type 1 von Willebrand disease (VWD). Correction of the glucose with continuous gastric feeding or intravenous glucose infusions for 24-48 hours has been shown to correct the coagulopathy and is often recommended prior to elective surgery. We describe three female siblings affected by GSD 1a who developed acquired type 2 VWD. VWF parameters were not corrected by glucose infusion. *Patients and Methods.* A 13 year old girl with GSD Ia presented with severe periorbital bruising following mild blunt trauma. She had previously undergone portacath insertion without significant bleeding or bruising. Investigations revealed a prolonged APTT 40 sec (26.7-37.6), FVIII:C 0.43U/mL (0.50-1.50), VWF:Ag 0.15U/mL (0.46-1.46), VWF:RCo 0.05U/mL (0.50-1.72), compatible with type 2 VWD. The mulitimer pattern was normal. A 48 hour trial of 10% glucose infusion resulted in an improvement in FVIIIC and APTT but there was no effect on VWF:Ag or VWF:RCo. Desmopressin (DDAVP) resulted in FVIII:C 1.18U/mL,VWF:RCo 0.6U/mL at 1 hour post infusion and has been used for minor bleeding. Intermediate purity factor concentrate (Haemate P) has provided adequate haemostasis for minor surgery. An 8 yr old sister, also with GSD Ia, was found to have similar results to her sister: APTT 40.7 sec VWF:Ag 0.18U/mL, VWF:RCo <0.05U/mL, FVIII:C 0.43U/mL with normal VWF multimers. She bruised easily but had previously undergone tonsillectomy and portacath insertion without complication. A 20 yr old sister, also affected with GSD Ia, was found on testing to have results consistent with type 2 VWD but with a less marked defect of VWF than her two sisters: FVIII:C 0.63U/mL, VWF:RCo 0.23U/mL. She had undergone dental extractions, a liver biopsy and multiple central venous catheterisations without abnormal bleeding. Both parents had normal coagulation profiles, FVIII:C, VWF:Ag, and VWF:RCo. We conclude that all three siblings have acquired type 2 (probably 2M) VWD in association with GSD Ia. We discuss the possible mechanism of this association. *Conclusions.* Although acquired type 1 VWD in association with GSD Ia is reported, this may not be widely recognised even amongst paediatric haematologists. This report is the first, to our knowledge, of affected siblings with acquired type 2 VWD associated with GSD Ia. Previous surgery without bleeding complications does not exclude a severe coagulopathy and we recommend that all patients with GSD should be investigated for VWD prior to surgical procedures. Acquired VWD in association with GSD Ia may require DDAVP or intermediate purity factor concentrate to manage haemostatic challenges since the haemostatic defect may not be corrected by glucose infusion alone.

0115

BONE STATUS OF CHILDREN WITH HEMOPHILIA A ASSESSED WITH DUAL ENERGY X-RAY ABSORPTIOMETRY AND QUANTITATIVE ULTRASONOGRAPHY: COMPARISONS AND CORRELATIONS

M. Economou, A. Christoforides, E. Papadopoulou, N. Gompakis, M. Athanassiou-Metaxa

Hippokration General Hospital of Thessaloniki, THESSALONIKI, Greece

Background. Adult patients with hemophilia A are known to be at risk for developing osteopenia or osteoporosis due to multiple factors, the main cause being recurrent hemarthrosis and subsequent reduced physical activity. Recent reports have demonstrated decreased bone mineral density (BMD) values even to younger hemophilic patients. *Aims.* To evaluate bone status of hemophilic children using two different *Methods.* Dual Energy X-ray Absorptiometry (DXA) and Quantitative Ultra-Sonography (QUS) and to determine the degree of correlation between these two techniques. *Methods.* Seventeen patients with hemophilia A, aged 11.87±4.91 years (range: 4.94-17.62 years) participated in the study. The majority of patients had a severe bleeding phenotype and were receiving either primary or secondary prophylaxis. Patients were HCV and HIV negative. With regards to study methods, weight and height were measured using standard techniques. Pubertal status was determined according to Tanner staging. Body Mass Index (BMI) was calculated as the ratio weight/height2 (kg/m^2). For every auxological parameter, Standard Deviation Scores (SDS's) were calculated according to sex- and age-matched normal greek population. BMD at lumbar spine (L2-L4 vertebrae) was determined by DXA technique using Cronos' bone densitometer (DMS, France). Results were expressed as grams per centimetre squared (g/cm^2), whereas Z-scores were calculated based on BMD measurements of normal sex- and age-matched Caucasian population, provided by the DXA device's manufacturer. QUS measurements (Speed Of Sound, SOS) were performed using Omnisense 7000 P (Sunlight Medical Ltd, Israel) at two peripheral sites: distal third of the radius (SOSR) and midshaft tibia (SOST), both at the patient's non-dominant and dominant side. Z-scores were calculated according to normative data derived from sex- and age-matched Greek population. Levels of intact parathormone (iPTH), fT4, fT3, TSH, calcium (Ca), phosphate (P) and alkaline phosphatase (ALP) were evaluated using commercial assays. Finally, joint evaluation was performed using the Hemophilia Joint Health Score (HJHS), a validated 11-item scoring tool scale assessing six index joints (elbows, knees and ankles).

Table 1.

	Weight SDS	BMI SDS	HJHS	BMD_L Z-score	QUS_R Z-score	QUS_T Z-score
Age	r=-0.264 p=0.153	r=0.165 p=0.264	r=0.402 p=0.077	r=0.408 p=0.052	r=-0.127 p=0.314	r=-0.304 p=0.118
Weight SDS		**r=0.832 p<0.001**	r=-0.053 p=0.428	r=0.349 p=0.085	r=0.188 p=0.235	r=0.287 p=0.132
BMI SDS			r=0.019 p=0.475	**r=0.448 p=0.036**	r=0.069 p=0.396	r=0.291 p=0.129
HJHS				**r=0.473 p=0.044**	r=0.048 p=0.435	**r=-0.541 p=0.023**
BMD_L Z-score					r=0.150 p=0.283	r=-0.197 p=0.224
QUS_R Z-score						r=-0.216 p=0.202

Results. All patients had normal pubertal development for age whereas biochemical profile, intact PTH concentrations and thyroid function tests were normal. Mean BMD Z-score was -0.12±1.08 g/cm^2, whereas 3 and 2 patients were classified as having osteopenia and osteoporosis respectively. Mean SOSR Z-score and mean SOST Z-score were -0.08±0.83 m/sec and -0.10±1.6 m/sec, respectively. No correlation was observed between DXA values and QUS-derived measurements. No agreement was recorded between the two methods in identifying hemophilic patients at risk for osteoporosis (kappa value = -0.25, p=0.17). SOS values at the dominant side were significantly correlated to SOS values at the non-dominant side both at radius (r=-0.541, p=0.01) and at tibia (r=0.45, p=0.04). Finally, the HJHS was negatively correlated with the SOST Z-scores (r=-0.541, p=0.023), whereas it was, surprisingly, positively correlated to BMD Z-scores (r=0.473, p=0.044). Correlations between studied parameters are demonstrated in Table 1. *Conclusions.* DXA detected a significant number of hemophilic children with impaired bone status; however, these findings were not confirmed by QUS measurements.

0116

FUNCTIONAL CHARACTERIZATION OF FIBRINOGEN POZNAN: A PREMATURE TRUNCATING MUTATION IN FGG ASSOCIATED WITH HYPOFIBRINOGENEMIA AND MILD BLEEDING TENDENCY

M. Zawilska,[1] A. Undas,[2] L. Malendowicz-Portala,[1] P. de Moerloose,[3] R. Fish,[4] M. Neerman-Arbez[3]

[1]J.Strus Hospital, POZNAN, Poland; [2]Institute of Cardiology, Jagiellonian University School of Medicine, KRAKOW, Poland; [3]Division of Angiology and Haemostasis, University Hospital, GENEVA, Switzerland; [4]Department of Genetic Medicine and Development, University Medical Centre, GENEVA, Switzerland

We report here a novel nonsense mutation in FGG exon 4 identified in heterozygosity in three members of a Polish family causing hypofibrinogenemia and mild bleeding tendency in two out of three individuals. A 25-year-old male was referred due to lifelong history of mild bleeding symptoms i.e. bleeding from minor skin wounds, epistaxis, easy bruising, and bleeding after tooth extraction. Fibrinogen antigen level (immunonephelometry) was 1.12 g/L and functional fibrinogen (von Clauss method) was 1.0 g/L. Thrombin time (TT) was prolonged (21.1 s [N10-17.5 s]). Liver function tests showed normal results. The patient's 18-year-old brother reported prolonged bleeding after tooth extraction. Fibrinogen level was reduced to 1.37 g/L, with functional fibrinogen 1.0 g/L and TT 23.6 s. Their parents and sister as well as her 2 children had no bleeding history and normal fibrinogen levels. All exons and intron-exon junctions of the FGA, FGB and FGG genes were analyzed by PCR amplification followed by sequencing. We identified a novel nonsense mutation in FGG exon 4 c.331A>T (AAG>TAG) p.Lys111X (Lys85X in the mature chain lacking the signal peptide) in heterozygosity in the two brothers with low fibrinogen levels (Fibrinogen Poznan). Interestingly, despite normal fibrinogen levels, the father was also heterozygous for the Lys111X (Lys85X) mutation, which might be due to differential allelic expression, a widespread phenomenon affecting the expression of around 20% of human genes. The Fibrinogen Poznan mutation is predicted to encode a severely truncated fibrinogen gamma chain, lacking part of the coiled coil domain necessary for fibrinogen intermediate formation and hexamer assembly and the conserved globular C-terminal domain, also important for fibrinogen assembly. Co-transfection of the mutant FGG cDNA with the wild-type FGB and FGA cDNAs in COS cells followed by Western blot analysis demonstrated that the mutant is incapable of assembling a functional hexamer, since no hexamer was detected in the cells nor in the media.

0117

DIFFERENT REGIMENS OF PROPHYLAXIS TREATMENT IN YOUNG SEVERE HEMOPHILIA A PATIENTS: COMPARISONS ON EFFICACY, FVIII CONSUMPTION AND THERAPY COMPLIANCE

C. Santoro,[1] F. Biondo,[2] A.P. Leporace,[2] R. Foà,[2] M.G. Mazzucconi[2]

[1]Hematology, ROME; [2]Hematology, Sapienza Univeristy, ROME, Italy

Background. Primary and secondary prophylaxis is the emerging standard treatment for severe hemophilia A patients. The routine administration of FVIII is effective in children as prophylaxis against hemophilic arthropathy. Nevertheless, the costs and the patient's compliance represent barriers to prophylaxis treatment and to date the most efficacious, cost-effective regimen has not yet been determined. *Aims.* We retrospectively evaluated our severe hemophilia A patients, aged ″18 years, treated with different prophylaxis regimens to compare efficacy, FVIII consumption and patient/family's compliance. *Methods.* Nineteen patients (median age 13 years, range 3.6-17.8) with severe hemophilia A) on prophylaxis treatment were evaluated. Three regimens of therapy were implemented: administration of FVIII once a week in 1 patient, twice a week in 12, three times a week in 6. Prophylaxis was initiated because of increasing hemorrhages and presence of target joint. Results are shown in the Table. Before prophylaxis, 4 patients presented a low titer inhibitor that disappeared during treatment. All patients are HCV, HIV, HBsAg seronegative and are treated with rFVIII. In patients on the "twice a week regimen" treated with rFVIII at a dosage of 50 IU/kg, the level of FVIII before the administration was always between 0.5-1.5%. *Conclusions.* When the two most used prophylaxis regimens (twice and three times a week) were evaluated in young patients with severe hemophilia A, an important reduction of hemorrhagic episodes on prophylaxis versus on demand treatment was observed; however, no significant differences were recorded between the two prophylaxis regimens. There is no difference in the total amount of concentrates administered between the two prophylaxis regimens, but there is a very important increase in the consumption of FVIII concentrate during prophylaxis. There is no difference in the orthopedic score before (median 0; 0-2) and during prophylaxis (median 0.5; 0-2), probably due to the young age of patients. The twice a week prophylaxis regimen should be a good alternative treatment to the classic one, and preferable especially for young children because of the reduction in the number of venipunctures. The consequences are a better compliance and a greater adherence to treatment by patients and their families.

Table.

	Once a week	Twice a week	Thrice a week
Duration of prophylaxis (months)	9.6	Median 60 (18-111)	Median 113.5 (35.7-141.6)
rFVIII Dosage (IU/kg)	50	Median 42.5 (35-50)	Median 29 (25-30)
Number of hemorrhages in the year before prophylaxis	4	Median 9 (4-30)	Median 4 (0-65)
Number of hemorrhages/year during prophylaxis	0	Median 0 (0-1)	Median 1 (0-2)
Number of hemarthroses in the year before prophylaxis	1	Median 7 (1-18)	Median 5.5 (2-26)
Number of hemarthroses/year during prophylaxis	2	Median 0 (0-2)	Median 0.25 (0-2)
rFVIII units/kg/year before prophylaxis	300	Median 1200 (200-5760)	Median 850 (200-900)
rFVIII units/kg/year during prophylaxis	1800	Median 4320 (2900-5200)	Median 4320 (4032-4800)

0118

PHYSICAL ACTIVITY AS PREVENTION OF OSTEOPOROSIS IN PATIENTS WITH SEVERE HAEMOPHILIA ON LONG TERM PROPHYLAXIS

M. Khawaji, J.E. Berntorp

Malmö University Hospital, MALMÖ, Sweden

Background. Physical activity is considered as an important factor for bone density and as prevention of osteoporosis. Physical activity confers the greatest benefit when initiated in prebubertal, promotes greater maintenance of bone density in adult. However, normal bone density during adulthood is an important protective factor against osteoporosis and related fractures in later life. *Aims.* The purpose of this study was to examine the relation between different aspects of physical activity and bone mineral density (BMD) in patients with severe haemophilia on long-term prophylaxis. *Methods.* The study group consisted of 39 patients with severe haemophilia (mean age 30.2 years). All patients with severe haemophilia receive prophylaxis to prevent bleeding (≥2 times per week). The median age at start of prophylaxis was 2 years. The bone density (BMD g/cm^2) of the total body, lumbar spine (vertebrae L1-L4), total hip, femoral neck and trochanter was measured by dual energy x-ray absorptiometry (DXA). Physical activity was assessed using the self-report Modifiable Activity Questionnaire (MAQ), an instrument which collects information about leisure and occupational activities for the prior 12 months. Physical activity was scored as duration in hours/week (h/wk) and as metabolic physical activity score by weighting the intensity (MET. h/wk). *Results.* There was only significant correlation between duration and intensity of vigorous physical activity (i.e.: activity with high intensity >6 MET) and bone density at lumber spine L1-L4; for

duration (R=0.429 and p=0.020) and for intensity (R=0.430 and p=0.019); whereas no significant correlation between vigorous physical activity and bone density at total hip, femoral neck, trochanter and total body. However, there was no significant correlation between other aspects of physical activity (i.e.: weight bearing activity, non weight bearing activity, walking activity, total leisure activity + walking, occupational activity and total activity + walking) and bone density at all measured sites. Moreover, there was no correlation between all aspects of physical activity and bone mineral content (BMC) at all measured sites. *Conclusions.* we could not find a significant correlation between all aspects of physical activity and BMD at different measured sites, except for vigorous activity and bone density at lumber spine. These result may support that the responsiveness to either an increase or a decrease in mechanical strain is probably greater in growing bones than in those of adults and also supports the importance of starting prophylaxis early in life so that the children can play and lead active life and normal bone density when they grow up.

0119

AN INVESTIGATION INTO THE EFFECT OF STORAGE TIME ON THE STABILITY OF SAMPLES FOR INR DETERMINATION AND THE RELIABILITY OF RESULTS THROUGH DELAYED INR DETERMINATION

C. Woods, G. McLoughlin, J. Bowers

South Eastern Trust, BELFAST, UK

Background. The distinct increase in samples for International Normalised Ratio (INR) determination being received from sites distant to the laboratory and the related delay in INR determination for up to 48 hours has raised uncertainty over the stability of these samples on which the quality of anticoagulant care rests. *Objectives*. To determine the effect of delayed INR determination on the stability of samples through repeated testing at timed intervals over a 48-hour period. In addition these results will be further substantiated by the monitoring Factor VII (FVII) activity. *Patients and Methods.* A total of 214 subjects were included in the study, 197 had a baseline INR result <4.0 and 17 had a baseline INR of ≥4.0. Samples were then analysed at 4, 12, 24, and 48-hours. FVII activity (n=20) was measured at baseline and at 24 hours. Statistical analysis included One-way repeated measures ANOVA, linear regression analysis. *Results.* The mean overall difference and % change after 48 hours for samples within the therapeutic range was -0.04 INR and -1.4% respectively. For over anticoagulated samples the mean difference and % change was -0.2 and -4.1% respectively. Any deviations outside the 10% limit set were not deemed clinically important in either group. There was a significant mean increase in levels of FVII activity over the 24-hour period, though this was not considered of any clinical significance to results obtained. *Conclusions.* Samples undergoing delayed INR determination show no clinically significant changes over 48 hours and produce accurate and dependable results.

0120

PREOPERATIVE EVALUATION OF PLATELET FUNCTION WITH THE PFA-100 IN ORTHOPEDIC PATIENTS RECEIVING ASPIRIN AND/OR CLOPIDOGREL

N. Tragomalos,[1] T. Assimakopoulou,[1] M. Stamouli,[2] A. Giotsidou,[1] I. Anagnosti,[1] P. Lianidou[1]

[1]KAT Hospital, KIFISSIA; [2]Metaxa Hospital, PIRAEUS, Greece

Background. Aspirin and clopidogrel are antiplatelet compounds that are widely used in patients suffering from coronary artery disease, stroke or peripheral artery disease and are likely to result in a higher risk of increased perioperative bleeding. Although these agents are often stopped 7 days before elective orthopedic surgery, little is known regarding management of patients undergoing emergency surgery. In such patients, the risk of bleeding has to be balanced against the risk of delaying emergency surgery. PFA-100 (platelet function analyzer) is a relatively simple tool for the investigation of primary hemostasis and its results could be useful in this setting. *Aims.*The objective of this study was to assess platelet function (using the PFA-100) in patients who were treated with aspirin and/or clopidogrel in whom the antiplatelet agent was discontinued in order to undergo major orthopedic surgical procedure. *Methods.* The study included 380 consecutive patients (146 men and 234 women; age range: 45-95 years, mean: 76 years) who were admitted in the orthopedic departments of our hospital from June 2007 to January 2009 on an emergency basis (mostly due to fractures). Among these patients, 261 were under treatment with aspirin, 99 were under clopidogrel and 20 patients were receiving both aspirin and clopidogrel. In all of them, platelet function was evaluated preoperatively using the PFA-100. *Results.* C/EPI and C/ADP closure times (CT) in patients under aspirin or clopidogrel are shown on Tables 1 and 2. The sample of patients receiving both aspirin and clopidogrel was too small (n=20) to draw any conclusions. Though, it must be mentioned that no patient had normal C/EPI-CT and C/ADP-CT 0-1 day after discontinuation of the drugs and only one patient had normal C/EPI-CT and C/ADP-CT 2-4 days after discontinuation. On the other hand, in patients receiving either aspirin or clopidogrel the following were noticed: a) only 2 patients in the aspirin group had normal C/EPI-CT and 1 patient in the clopidogrel group had normal C/EPI-CT and C/ADP-CT 0-1 day after the drug was stopped b) a significant proportion of patients under aspirin or clopidogrel (74% and 68.5% respectively) displayed normal closure times 2-4 days after cessation of antiplatelet treatment c) there were still 17 patients in the aspirin group and 7 patients in the clopidogrel group who had prolonged closure times more than 7 days after the treatment was stopped. *Conclusions.* Assessment of platelet function is very important in patients under antiplatelet treatment who need major orthopedic surgery on an emergency basis. According to the results of this study, there are a significant number of patients with normal PFA-100 values 2-4 days after discontinuation of aspirin or clopidogrel. Nevertheless, all PFA-100 results should be interpreted with caution, given the fact that this method certainly has its limitations when it comes to monitoring antiplatelet therapy. These results should probably be co evaluated with other parameters (e.g. severity of trauma), when a decision is made about the timing of surgery.

Table 1. Patients under treatment with apirin. *normal; **prolonged.

Day after cessation	0-1	2-4	5-7	>7
EPI-CT:(n*)	2 (10%)	82 (74%)	52 (73%)	42 (71%)
EPI-CT:(p**)/ADP-CT:(n)	13 (65%)	21 (19%)	10 (14%)	6 (10%)

0121

ACQUIRED HAEMOPHILIA; A COHORT OF 26 PATIENTS DIAGNOSED AND TREATED IN THE SOUTH EAST OF ENGLAND BETWEEN JAN 1996-2009

B. Chowdhury

St Thomas' Hospital, LONDON, UK

Background. Acquired haemophilia is a rare disorder caused by autoimmune destruction or inhibition of a coagulation factor, usually FVIII. It is seen most commonly in the elderly and is associated with other autoimmune disorders, pregnancy, and malignancy. Clinically life threatening bleeding into muscle, soft tissue, gastrointestinal & urological tracts is seen with mortality between 8-42% within weeks of presentation. Treatment is directed at eradicating the inhibitor using immunosuppressive agents and treating the bleeding with haemostatic agents. There is a lack of randomised studies; most reports in the literature are from findings of single centre cohorts. *Aims.*To review the treatments and outcome of all patients diagnosed with acquired haemophilia between Jan 1996-2009. *Methods.* All patients who presented with recent bleeding with a low FVIII caused by an inhibitor from South London and the South East were identified by retrospective analysis of medical notes, blood results and product usage between this period. Response to treatment was defined as FVIII level >50 iu/dL and undetectable inhibitor. Relapse was defined as re-emergence of inhibitor and / or a FVIII level <30 iu/dL. *Results.* 26 patients were identified of which 64% were female. At presentation the median age was 72yr, with FVIII level ranging from <1-14 iu/dl. The quantified inhibitor levels from presentation to peak ranged from 2 - 3800

Bu/mL. Two patients had a peak inhibitor above 400 Bu/mL. The majority of patients presented with subcutaneous bleeds, 3 had retroperitoneal bleeds. The 2 patients who presented with forearm bleeds developed compartment syndrome which required surgical decompression. One patient presented with a post partum bleed. Most patients (89%) received steroids alone, 68% had steroids + cyclophosphamide. One received Cyclosporine and another Azathioprine. 2 patients who failed to respond to steroids alone received Rituximab. 52% of patients also received intravenous immunoglobulin. The majority (52%) of patients received FEIBA as a bypassing agent, only 26% received rFVIIa, the rest (21%) did not need any treatment. One patient was switched from rFVIIa to FEIBA due to lack of response. The shortest duration of bypassing product usage was 1 day, the longest was 30 dys. Half of the patients needed >2 units of blood. Relapse was seen in 26%, 3/5 of these received Rituximab. In 3 patients the inhibitor was never eradicated. 4 patients had positive auto antibodies, 5 had raised malignancy markers, 2 had a paraprotein identified, and 2 were diagnosed with Pemphigus. 1 patient died from a sudden massive GI bleed soon after control of initial presenting bleed. *Summary and Conclusions.* Findings from this cohort are very similar to those previously reported. There is no improvement in outcome in patients treated with steroids in combination with Cyclophosphamide and ivIG. FEIBA was given preferentially for convenience of use. The majority of patients needed prolonged use of a low dose of steroids to sustain remission. Patients on combined immunosuppressive therapy did not show an increased rate of infections.

0122

COAGULATION SCREENING IN AN IRISH TEACHING HOSPITAL

J. McHugh, C. Holt, D. O'Keeffe

Mid Western Regional Hospital, LIMERICK, Ireland

Background. Coagulation screening using prothrombin time (PT) and activated partial thromboplastin time (APTT) is widely used. However these tests have significant limitations. They have not been shown to predict bleeding during surgery or invasive procedures. Furthermore mild prolongation of PT or APTT has not been shown to predict increased bleeding risk. They may miss some clinically significant bleeding disorders and they may be abnormal in conditions not associated with bleeding. *Aims.* To audit requests for coagulation screening in an Irish teaching hospital. *Methods.* We analysed prolonged PT and/or APTT during normal working hours during a one-week period in our hospital. Abnormal results due to anticoagulants were excluded from further study. In samples with PT longer than 15.5 seconds and/or APTT longer than 42 seconds we proceeded to 1:1 mixing studies if the PT was prolonged and 1:1 mixing studies, Factor XII assay and Lupus screen if the APTT was prolonged. We also obtained referral source for all samples and clinical details for abnormal samples. *Results.* 671 coagulation requests were received during the study period. 318/671 (47.4%) coagulation requests were for monitoring of anticoagulation. 353/671 (52.6%) requests were for coagulation screening rather than anticoagulant monitoring. 24/353 (6.8%) coagulation screens were abnormal. Of the coagulation screening requests 21 were from ICU/HDU and 8/21 (38.1%) were abnormal. 332 requests were received from outside ICU/HDU and 16/332 (4.8%) were abnormal. In the coagulation screens received PT was prolonged in 19/353 (5.4%), median 17secs, range 16-48 seconds. PT was longer than 20 seconds in 4/353 cases (1.1%). PT corrected using 1:1 mixing studies in 18/19 (94.7%) cases of prolonged PT. Referral sources for prolonged PT were: ICU/HDU-8; Medical-8; Surgical-3. APTT was prolonged in 19/353 (5.4%), median 46 seconds, range 43-59. APTT was longer than 50 seconds in 4/353 (1.1%). APTT corrected using 1:1 mixing studies in 16/19 (84.2%) cases of prolonged APTT. 3/19 (15.8%) cases of prolonged APTT had Factor XII levels less than 50%. 1/19 (5.3%) cases of prolonged APTT had lupus anticoagulant. Referral sources for prolonged APTT were: Medical-9; ICU/HDU-8; Surgical-2. The 24 abnormal coagulation screens were from 21 different patients. 5/21 (23.8%) patients had prolonged PT and normal APTT. 5/21 (23.8%) patients had prolonged APTT and normal PT. 11/21 (52.4%) patients had prolonged PT and APTT. *Conclusions.* Unregulated coagulation screening has a low yield of abnormal results and the majority of these abnormal results are mild prolongation of PT or APTT of uncertain clinical significance. Requests for coagulation screening outside the ICU setting have an even lower yield of abnormal results. We believe many of the coagulation requests received are not indicated. We plan to introduce evidence-based guidelines on indications for coagulation screening in our hospital. We will repeat this audit following the introduction of these guidelines to see if selected testing based on clinical criteria can reduce unnecessary coagulation screening.

Quality of life, palliative care and ethics

VALIDATION OF THE BRAZILIAN PORTUGUESE VERSION OF THE MEDICAL OUTCOMES STUDY - SOCIAL SUPPORT SURVEY IN HODGKIN LYMPHOMA SURVIVORS

A.S. Soares,[1] A. Scheliga,[2] R.L. Baptista,[1] W. Pulcheri,[1] I. Biasoli,[1] E. Brabo,[1] T. Vieites,[1] T. Hofmeister,[1] G. Werneck,[1] N. Spector[1]

[1]Rio de Janeiro Federal University, RIO DE JANEIRO; [2]Instituto Nacional de Câncer, RIO DE JANEIRO, Brazil

Background. Studies in the last three decades have documented the effects of social support on physical and psychological well-being, mainly in chronically ill patients or on the onset of a stressful event. There are few studies about social support in cancer survivors. *Aims.* To assess the psychometric properties of the "Medical Outcomes Study - Social Support Survey (MOS-SSS)" in Hodgkin Lymphoma (HL) survivors. *Methods.* The Brazilian Portuguese version of the MOS-SSS, already validated in a healthy population, was applied to a sample of 122 HL survivors treated in five institutions in Rio de Janeiro, Brazil. All the participants were contacted by telephone. The questionnaire was self-administered at the treatment center or at home, and sent by traditional or electronic mail, according to individual choice. An informed consent was obtained from each participant. *Results.* The median age of the patients at diagnosis was 32.5 years (16-77) and the median follow-up was 6.8 years (3.5-11.7) since diagnosis. Among the 122 individuals, 51% were female, 71% had a good International Prognostic Score (less than two factors), 61% had advanced HL, 35% had bulky disease, and 92% were treated with ABVD chemotherapy. Responses to the 19 social support items were skewed toward positive evaluations (item means of 3.27 to 3.8, in a 0-4 possible range of responses). Pearson correlation coefficients between items varied from 0.11-0.71, with most values higher than 0.3. Correlation coefficients between items and their dimensions varied from 0.44-0.71. The internal consistency was evaluated with Cronbach's alpha, and was 0.93 for the overall scale, ranging from 0.73 to 0.86 for the five subscales. The factor analysis yielded a 4 factor solution that explained 68% of the variance. These 4 functional support subscales measured affection, material aspects, emotional/informational aspects and positive social interaction. *Summary and Conclusions.* The psychometric properties of the Brazilian version were similar to those obtained with the original English version of the MOS-SSS. The Brazilian Portuguese version will now be used to evaluate social support and its association with structural support, long-term disease outcomes, socioeconomic status and the quality of life of Hodgkin lymphoma survivors.

0123a

QUALITY OF LIFE IN PATIENTS WITH VWD

S. von Mackensen,[1] C. Moorthi,[2] G. Auerswald[2]

[1]University Hamburg, HAMBURG, Germany; [2]Klinikum Bremen-Mitte, Prof.-Hess-Kinderklinik, Bremen, Germany, BREMEN, Germany

Background. Only few studies compared to haemophilia are published related to health-related quality of life (HRQoL) in patients with von Willebrand (VWD). In none of those studies a disease-specific HRQoL questionnaire was applied. The recently in Italy developed VWD-specific questionnaire (VWD-QoL) was administered to VWD patients during their annual patient meeting. *Methods*. During the annual meeting of the German VWD patients' association patients and parents of VWD children filled in the preliminary version of the German VWD-QoL questionnaire and were asked to evaluate the questionnaire concerning relevance and comprehensibility of items. *Results*. 22 adult patients (A) with VWD and 7 parents of children (C) with VWD filled in the questionnaire with a mean age of adult patients (M=55.86+13.4 years). All types of VWD patients were represented; children suffered mainly from Type 3 and were severely affected (71.4%), while the major part of adults had Type 1 (35%). Most patients were treated with factor concentrate (A: 59.1% vs. C: 85.7%). 66.7% reported often/always unpleasant sensations or strange sensation after injection (50%) due to treatment. 63.6% adults had bleeds in the last 4 weeks (C: 57.1%), mainly epistaxis (31.8% vs. 42.9%), followed by teeth bleeds (27.3% vs. 42.9%). Patients reported days lost at work/school in the past 12 months (A: 13.6%, Median No of days 52; C: 71.4%, Median No of days 27). Mean age of diagnosis in adults was 32.6+17.3 years (range 1-62), in children 2.4+3.41 years (range 0-10). When receiving the diagnosis 38.1% were frustrated and worried about their future while 28.6% felt calmer and more relaxed. 50% of adult patients worried about VWD and were afraid to hurt themselves (16.7% of children). More children reported about bruises (66.7% vs.

45.5%), while more adults stated that they could not walk as far as they wanted (50% vs. 16.7%). *Conclusions.* Time of diagnosis is quite different between children and adults which has an impact on their quality of life. Adult patients are more impaired in different aspects of their quality of life then children. Quality of life assessment is a new area in VWD which should be implemented in the routine care of those patients.

0124

PAIN RATE AND SOCIAL CIRCUMSTANCES RATHER THAN CUMULATIVE ORGAN DAMAGE DETERMINE THE QUALITY OF LIFE IN ADULTS WITH SICKLE CELL DISEASE

C.F.J. van Tuijn,[1] E.J. van Beers,[1] J.J. Schnog,[2] B.J. Biemond[1]

[1]Academic Medical Center, AMSTERDAM, Netherlands; [2]St. Elisabeth Hospital, WILLEMSTAD, CURACAO, Netherlands Antilles

Background. Sickle cell disease (SCD) is characterized by chronic haemolytic anemia and recurrent microvascular vaso-occlusion resulting in progressive organ damage and reduced life expectancy. Previous analyses have demonstrated a strongly reduced quality of life (QoL) in sickle cell patients which however could not be explained by the severity of pain only. Therefore, other factors like chronic organ damage and socioeconomic circumstances may play a role. Recently, we systematically screened consecutive patients with SCD for chronic organ damage and determined their social-economic circumstances. *Aim of the study.* In the present study, we analysed the specific contribution of chronic organ damage and social circumstances to the QoL in patients with SCD. *Methods.* Consecutive adult sickle cell patients in a teaching hospital were included. Genotype, pain rate, rate of acute complications (acute chest syndrome, stroke, priapism) in the last five years and cumulative organ damage (pulmonary hypertension, microalbuminuria, retinopathy, renal failure and osteonecrosis) were assessed during routine visits. Occupation and level of education were determined by interview. QoL was assessed with SF-36 forms and represented in a physical (PCS) and mental component (MCS) which was compared with the normative score of the general Dutch population and related to pain rate, organ damage, occupation and education level. Differences in continuous data were tested with the Mann-Whitney test and in categorical data with the Chi-square test. *Results.* QoL was analysed in 94 adult patients with SCD and was significantly reduced as compared to the Dutch population. Linear regression showed that pain rate was associated with MCS (p=0.021) demonstrating the lowest scores in patients most frequently admitted. The PCS of the QoL was not related to pain rate. With respect to social circumstances, 35% of the patients were unemployed as compared to 6% of the general population and 16% of immigrants without SCD. In contrast to pain rate, both occupation and the level of education were significantly related to PCS while no relation with MCS was found. Genotype and presence of chronic organ damage did not affect QoL. *Conclusion.* Patients with SCD have significantly reduced QoL-scores which are determined by the pain rate, occupation and education level. Frequent painful crises appear to have a major impact on the mental component of the QoL in patients with SCD while the physical component was related to occupation and the level of education. Chronic organ damage, although responsible for limited life expectancy, was not related to QoL. With respect to QoL, comprehensive care for patients with SCD should not only focus on reducing pain rate and organ damage but also on factors determining social wellbeing.

0125

HEALTH-RELATED QUALITY OF LIFE AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION: A MULTICENTRE PROSPECTIVE STUDY IN THE CZECH REPUBLIC (FINAL RESULTS)

V. Kajaba,[1] I. Rehorova,[2] M. Zitkova,[3] V. Pavlicova,[4] E. Bystricka,[5] E. Faber[6]

[1]Fakultni nemocnice Olomouc, OLOMOUC; [2]VFN, Hematooncology, PRAHA; [3]Fakultni nemocnice, IHOK, BRNO; [4]Fakultni nemocnice, OKH, HRADEC KRALOVE; [5]Fakultni nemocnice, HOO, PLZEN; [6]Fakultni nemocnice, HOK, OLOMOUC, Czech Republic

Quality of life is an important parameter evaluated not only as part of clinical studies but also as a routine indicator in the case of expensive and/or sophisticated therapeutic approaches. Since 2004, a prospective health-related quality of life (HR-QOL) assessment in patients with autologous stem cell transplantation (ASCT) has been in progress. Since July 2005, most Czech transplant centres (Olomouc, Pilsen, Prague, Brno and Hradec Kralove) have participated in the study. Inclusion criteria: A signed informed consent form, age 18 years and over, compliance, haematological malignancies, planned ASCT. *Methods.* Two questionnaires for assessing quality of life are used - the EORTC QL Q-C30 v. 3.0 (European Organisation for Research and Treatment of Cancer) and EQ-5D (EuroQol Group) - as well as other parameters (Hb, Plt, Leu, BMI, sex, age, duration of hospitalization etc.). As QOL assessment may change over time, the patients are followed at T0 (admission to the transplant unit), T1 (10 days after ASCT), T2 (100 days after ASCT) and T3 (1 year after ASCT). Group characteristics: A total of 148 patients (84 males, 64 females) who underwent ASCT. The patients were diagnosed with multiple myeloma, diffuse large B-cell lymphoma, follicular lymphoma, Hodgkin's disease and other non-Hodgkin's lymphomas. The median age was 54 years in both males and females (average ages 51.2 and 51.3 years, respectively). *Results.* It is obvious that at time T0, i.e. prior to transplantation, physical functioning, role functioning and social functioning of oncology patients is found to be impaired in comparison to the control group. Of the symptoms listed, the degree of financial independence is much lower than in the control group. The other studied symptoms and domains show no significant differences when compared with the healthy population. The most severe impact on quality of life (QOL) is observed at T1. In nearly all studied parameters (with the exception of dyspnoea and constipation), patients perceive their quality of life as decreased. At T2, however, the vast majority of the patients' parameters are comparable with those in the reference population (similar to T0). In physical functioning, role functioning and social functioning, the outcomes are significantly worse than in the reference population. The T3 assessment results show that in fact all studied QOL parameters remain at a level comparable with the reference population. Financial difficulties are constant throughout the studied period, confirming the fact that in formerly active population, oncological disease results in decreased financial independence. The overall QOL (1y after ASCT) is better than prior to transplantation (p=0.02). Other parameters are statistically significantly better as well. None of the quality-of-life parameters were found to be worse at one year after autologous transplantation than before it. According to the EQ-5D questionnaire, three-quarters of patients perceive their health status at 1 year post-transplant as better than a year earlier. Better overall global quality of life correlates with higher Karnofsky scores. *Conclusions.* ASCT and especially the preparatory regimen and previous intensive chemotherapy remain demanding and not always successful therapeutic regimens. The study results suggest that transplantations used to treat blood diseases do not imply prolonged decrease of health-related QOL. According to the patients, the most burdensome symptom is fatigue. Surprisingly, more than half of oncology patients are overweight or obese (BMI over 25 in nearly 60% of the studied patients). It seems crucial to prolong the time of monitoring the QOL parameters after transplantation (optimum time of 3-5 years) and to include the patients' occupational status.

The project was partly supported by the Czech Ministry of Education (MSM6198959205).

0126

INFLUENCE OF ANEMIA ON QOL, CLINICAL SYMPTOMS AND COGNITIVE FUNCTIONS IN NEWLY DIAGNOSED (NOT TREATED) HEMATOLOGIC PATIENTS

D. Petranovic,[1] R. Dobrila Dintinjana,[1] A. Duletic Nacinovic,[1] T. Valkovic,[1] I. Roncevic Grzeta,[1] K. Ruzic,[1] S. Janovic,[1] R. Rakun,[2] Z. Striskovic,[1] M. Petkovic,[1] I. Lovasic,[2] G. Golcic[1]

[1]Clinical Hospital Center Rijeka, RIJEKA; [2]Psychiatric Hospital Lopaca, RIJEKA, Croatia

Introduction. Anemia, bad Qol and cognitive disfunctions are commonly present in hematologic patients but often underreported by patients and underdiagnosed by health care professionals. Previous studies mainly evaluated these problems during chemotherapy or under influence of erythropoetic agents (Epo) which has been known to have various effects on QoL and cognition besides their influence on anemia. *Aim.* We evaluated influence of anaemia per se on QoL, clinical simptoms and especially on cognitive functions in hematologic patients before starting any chemotherapy and measured changes in short time period to see if correction of anemia by standard therapy could improve QoL and cognition. Pts on Epo has been excluded from this study. *Patients and Methods.* In Clinical Hospital Center of Rijeka, Croatia 137 pts in very early phase of diagnostic procedure which finally resulted in diagnosis of hematologic malignancies were evaluated by FactAn QoL Questionary and five point scale for subjective clinical symptoms. Cognitive functions have been measured by Complex Reactiometer Drenovac (CRD), a PC based psyhodiagnostic laboratory based on chronometric aproach which examine: perceptive abilities (detection, identification, visual orientation, spatial visualisation), memory (short term memory, maze learning, actualisation of memorized contents),thinking (operative thinking, problem solution, convergent thinking), psychomotor reactions (simple and complex), dynamic features of CNS function

(excitability, agility, stability, balance, endurance, reliability), attention (attention span, concentration, vigilance) and functional disturbances (rigidity, agitation, perseverance, regression). All parameters have been measured twice: T0 -basal measurement ,T1 -after one month (± 7 days). Among T0 and T1 patients received therapy for their anaemia according to anemia type and Hb level but no chemo, radio or immunotherapy for their disease or Epo agents. *Results.* Hemoglobin level significantly influence QoL and cognitive functions in all pts (so called anemic and non anemic).When statistically partialized , the effects of gender, age, education and Hb level showed the Hb level as the most effective variable on cognition analysed by β weights (anaemia has a 10,5% influence on IQ). Correction of anemia significantly improved QoL and cognitive functions but not in all categories (visual orientation and memory). Subjective feeling of cognitive disturbancies are not in correlation with real cognitive achivement measured by CRD. *Discussion.* Impairment of brain function caused by anaemia profoundly affects cognition, psychological well-being, the ability to perform the usual activities of daily living and in general affects their QoL esspecially in pts with malignant diseases. We concluded that changes in hemoglobin level during phase of diagnostic procedure before any treatment (immuno, chemo, irradiation therapy) in hematology patients greatly positively influence their QoL and esspecially their cognitive functions.

0127

HOME CARE FOR UNFIT ELDERLY PATIENTS WITH MYELODISPLASTIC SYNDROMES: AN ITALIAN SINGLE-CENTER EXPERIENCE

P. Alfieri,[1] L. Ferrara,[2] G. Leonardi,[3] M. Luppi,[3] R. Marasca,[3] G. Torelli,[3] E. Favale[1]

[1]AIL Hematology Home Care Service, MODENA; [2]Division of Oncology, Modena University Hospital, MODENA; [3]Division of Hematology, Modena University Hospital, MODENA, Italy

Background. Myelodisplastic syndromes (MDS) are an heterogeneous group of bone marrow disorders, with a higher incidence in old age. In the elderly setting main clinical needs are transfusion support and regular follow-up appointments, commonly provided on outpatient basis, often resulting in discomfort arising from driving distances and long waiting times. Hospital admissions, usually due to worsening of comorbities and infectious events, are also frequent. *Aims.* In our department a home care (HC) service sustained by the fundraising organization A.I.L. (Italian Association against Leukemia-Lymphoma-Myeloma) is active in order to manage fragile hematology patients outside the standard in-hospital assistance, to improve their quality of life and optimize healthcare resources. Here we describe our experience in 40 consecutive elderly patients with MDS referred to a domiciliary service of supportive care in the period 2000-2008. *Methods.* MDS diagnosis was formulated according to WHO classifications. The Severity of Illness Index was calculated to evaluate the impact of comorbidities. All 40 patients fulfilled inclusion criteria for HC (poor performance status, appropriate home logistics, caregiver availability, distance from hospital ″30 km). Home transfusions were requested on the basis of hemoglobin levels (Hb ″ 8 g/dL) and platelet count (PLT ″10.000/mcl) and/or in presence of symptoms related to anaemia and thrombocytopenia. HC duration, generally corresponding to the remaining lifetime, was compared among different patients' groups divided by age, MDS subtype and comorbidity burden. *Results.* Median age was 83 years (range 64-97), with 70% of patients aged ≥80 years. Gender was equally distributed (19 male, 21 female). 22 patients presented refractory anaemia (RA), 2 patients had refractory anaemia with ring sideroblasts (RARS); refractory anaemia with excess of blasts type 1 (RAEB-1) and type 2 (RAEB-2) were respectively diagnosed in 4 and 7 patients. 5 patients with chronic myelomonocytic leukemia (CMML) were also included in this report. 15 out of 40 patients (37.5%) developed leukemic transformation. The median number of severe non-hematologic comorbidities was 1.57, with prevalence of cardiac and pulmonary diseases. Median duration of HC was 309 days, with significant differences only according to the number of severe comorbidities (417 days if ″1, 146 days if ≥2). Home transfusion support was provided, without relevant adverse events, in 26 patients (65%), for a total of 385 units of packed red blood cells and 92 of platelet concentrates. 27 patients (67.5%) were admitted as inpatients for a total of 44 hospital admissions, mainly caused by cardiac failure, severe infections, caregivers' burn-out and end-of-life care. *Summary*. In our operating model HC for unfit elderly patients affected by myelodisplastic syndromes is feasible, sustainable and safe. Severe comorbidities are correlated with poorer survival, irrespective of MDS subtype and age distribution. HC represents a valid resource to implement the management of patients with blood malignancies, especially if there is a consultant hematologist fully dedicated to domiciliary patients, allowing an efficient integration among hospital division, general practitioners and community health services. Cost-effectiveness analysis and economic recognition in public health systems are some of the open issues to be shortly explored.

0128

PAIN MANAGEMENT OF BORTEZOMIB-INDUCED NEUROPATHY WITH ORAL CONTROLLED-RELEASE OXYCODONE

C. Cartoni,[1] G.A. Brunetti,[2] P. Niscola,[3] P.L. Alfieri,[4] G.M. Delia,[5] R. Foà[6]

[1]Hematology, University of Rome, ROME; [2]Division of Hematology, Department of Cellular Biotechnologies and Hematology, Policlinico Umberto I, University La Sapienza of Rome, ROME; [3]Hematology, Ospedale S Eugenio, ROMA; [4]Hematology, Policlinico, MODENA; [5]Hematology, Policlinico Umberto I, ROMA; [6]Hematology, University La Sapienza, ROME, Italy

Background. In nearly one third of patients treated with the proteasome-inhibitor bortezomib it has been reported the occurrence of an axonal sensitive neuropathy, which is responsible of severe neuropathic pain to the lower extremities, a very distressing symptom for patients. Strong opioids have been already employed for the treatment of neuropathic pain provoked by other causes. *Aims.* To evaluate in a group of patients with bortezomib-induced painful neuropathy: i) the effectiveness of controlled-release (CR) oral oxycodone to reduce the pain intensity and its interference with some daily activity functions; ii) the tolerability and the safety of this strong opioid. *Patients and methods.* Twenty-three patients with a Karnofsky performance status > 50 (median age 62 yrs.) affected by multiple myeloma (22), and non Hodgkin's lymphoma (1) with moderate-to-severe pain unresponsive to previous analgesic treatment for the bortezomib-related painful neuropathy were enrolled in the study. The continuous and breakthrough pain intensity was evaluated at baseline, on day 3, 7 and 14 with the Short-Form Brief Pain Inventory (SF-BPI), scored on an 11 point numerical rating scale (NRS), where 0 = *no pain* and 10 = *pain as bad as you can imagine*, along with the evaluation of pain interference with some functions such as quality of sleeping, appetite, walking ability, self care, daily activity, mood and concentration, the global patient evaluation of efficacy (GPE). Good pain relief was defined as >30% reduction of the previous NRS score. Side effects such as nausea and vomiting, constipation , drowsiness, confusion, and dry mouth were rated using a scale from 0 to 3 (not at all, slight, mild, severe). Patients received oral CR-oxycodone at the starting dose of 10 mg bid. During the study period, 14 days, no dose reduction of bortezomib has been carried out. *Results.* The daily average dose of CR-oxycodone administered was 28,46 mg (range 20-80 mg).CR-oxycodone reduced dramatically the pain intensity, from a mean NRS value of 7.6 at baseline, to 3.9 on day 3, 1.7 on day 7, and 1.3 on day 14. Similar trend to decreasing values was observed for all the daily life functions. Breakthrough pain events, observed at baseline in the 61% of patients, reduced their frequency and intensity: on day 14 the NRS value corresponded to 3,1 and these events occurred in the 47,% of patients. 11 patients used rescue drugs for breakthrough pain. Side effects occurred in 12 patients (51%), all of them of slight or mild intensity. *Summary*. CR-oxycodone was effective for pain relief caused by the bortezomib-related neuropathic pain and it was well tolerated. The pain control improved also the quality of the daily life functions, such as the walking ability, usually compromised in this clinical condition. A good pain control allowed the continuation of the cancer treatment.

0129

HOW HAEMOPHILIA IMPACTS THE QUALITY OF LIFE OF ELDERLY PATIENTS

S. von Mackensen,[1] A. Gringeri,[2] S.M. Siboni,[3] M. Ferretti,[4] F. Tradati,[5] M. Franchini,[6] A. Tagliaferri,[7] P.M. Mannucci[3]

[1]University Hamburg, HAMBURG, Germany; [2]Institute of Medical Psychology, University Medical Centre Hamburg-Eppendorf, HAMBURG, Germany; [3]Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Department of Medicine a, MILAN, Italy; [4]Geriatric Medical Office, MILAN, Italy; [5]Department of Internal Medicine, University of Milan, Geriatric Medicine Unit, I, MILAN, Italy; [6]Transfusion Center, University Hospital of Parma, PARMA, Italy; [7]Haemophilia Center, Department of Medicine, University Hospital of Parma, PARMA, Italy

Rationale. Due to improvements of haemophilia care over the last 3 decades the life expectancy of people with haemophilia (PWH) has increased enormously resulting in more PWHs reaching an old age. However, only few information are available on health status and health-related quality of life (HR-QoL) in elderly PWHs. Therefore a retrospective case-control study was carried out in Italy. *Methods.* Patients ≥65 years with severe haemophilia were enrolled matched to male controls without bleeding disorders for age, geography and social status. Emotional well-being was assessed with the Geriatric Depression Scale and various HR-QoL instruments, namely the generic EQ-5D, WHOQOL-BREF, WHOQOL-Old and

a disease-specific questionnaire (Haem-A-QoLElderly). *Results.* 84.6% of the in Italy registered elderly PWHs were enrolled (n=39) with a median age of 68 years (65-78). PWHs suffered significantly more from viral infections (chronic hepatitis C: 87% vs. 5%; HIV: 13% vs. 0%), hypertension, arthropathy (OJS: M=18.1 vs. M=1.19) and had more impairments in physical functioning and showed a trend to mild depression (M=9.9 vs. M=5.3). By contrast more controls suffered from hypercholesterolemia and cardiovascular diseases, but had similar cognitive functioning. PWHs showed significantly higher impairments in their generic HR-QoL compared to matched controls (WHOQOL-BREF: $p<0.0001$; WHOQOL-OLD:$p<0.041$; EQ-5D:$p<0.0001$). In regression models including infections, no of total bleeds, invalidity, OJS, marital status and depression the latter could explain up to 67% of the variance in HR-QoL. In turn depression correlated significantly with orthopaedic status, physical and mental functioning. *Conclusions.* Elderly PWHs show not only impairments in their health status and daily activities, but reveal to have as well significantly more emotional problems compared to controls. Since impairments in physical and mental functioning are correlated to depression and HR-QoL special care should be provided to this patient population.

0130

SINGLE DOSE PALONOSETRON IN PREVENTING CHEMOTHERAPY-INDUCED NAUSEA AND VOMITING IN PATIENTS WITH AGGRESSIVE NON HODGKIN'S LYMPHOMAS WHO UNDERWENT MODERATELY EMETOGENIC CHEMOTHERAPY

N. Di Renzo,[1] A. Montanini,[2] A. Dondi,[2] S. Muci,[3] E. Iannitto,[4] M.R. De Paolis,[1] C. Plati,[1] C. Stelitano,[5] C. Patti,[6] A. Olivieri,[7] E. Liardo,[4] G. Buda,[8] R. Cantaffa,[9] M. Federico[10]

[1]Vito Fazzi - Hospital, LECCE; [2]GISL Trial Office, MODENA; [3]Medicina Interna II ed Ematologia, P.O. San Salvatore, L'AQUILA; [4]Cattedra di Ematologia - Policlinico, PALERMO; [5]Ospedali Riuniti Bianchi, Melacrino, Morelli, REGGIO CALABRIA; [6]Ospedale Cervello, PALERMO; [7]Ospedale S. Carlo, POTENZA; [8]Divisione di Ematologia - Ospedale S. Chiara, PISA; [9]Divisione Ematologia, Osp. A. Pugliese Ciaccio, CATANZARO; [10]Cattedra di Oncologia - Policlinico, MODENA, Italy

Background. The standard approach in the antiemetic therapy in non hodgkin's lymphomas (NHL) is represented nowadays by antiserotoninergic drugs. Palonosetron is a selective and potent serotonin antagonist with a distinct pharmacological profile, different structure and enhanced binding affinity. Clinical studies in solid tumours have defined the improved efficacy of palonosetron compared to older 5-HT3 receptor antagonists. *Aims.* The objective of the study was to evaluate the efficacy and safety of a single dose of Palonosetron in preventing chemotherapy-induced nausea and vomiting (CINV) induced by moderately emetogenic chemotherapy (MEC) agents used for the treatment of aggressive NHL. *Methods.* This is an open-label, multicenter phase II study assessing the efficacy of a single i.v. dose of palonosetron (0.25 mg) prior to the administration of chemotherapy in the first day of treatment. The primary end point is the overall rate of patients achieving a complete response (CR-defined as no emetic episode and no use of rescue medication) during the whole study period (0-120 h). Drug activity was evaluated based upon a one-stage Fleming study design for determination of response rates based on a single treatment group. Relevant secondary endpoints included: CR in the acute (0-24h) and delayed (24-120) phases, no emesis and no nausea rates. Adverse events were also recorded. *Results.* In ten Italian centers eighty-six patients, affected by aggressive NHL, mostly undergoing CHOP±R (74.4%), were evaluated for the study. The primary endpoint was achieved with a CR rate of 86%. The CR in the acute and delayed phases was 90.7% and 88.4% respectively. No emesis rates were 91.9% (0-24h), 89.5% (24-120h) and 88.4% (0-120h). Similarly no nausea rates were 84.9%, 75.6% and 74.4% in the acute, delayed and overall period respectively. No serious drug related adverse events were reported. *Conclusions.* Palonosetron alone given as antiemetic treatment is effective and safe in preventing acute and delayed CINV in patients with aggressive NHL treated with moderately emetogenic chemotherapy.

0131

PHYSICIANS AND PATIENTS PERCEPTION OF A PROBLEM AS ETHICALLY RELEVANT IN ONCOHEMATOLOGY: ONLY A QUESTION OF PERSPECTIVE?

G. Giordano,[1] D. Sacchini,[2] S. Piano,[1] G. Farina,[1] I . Carrasco de Paula,[2] S. Storti[1]

[1]Research Center "J.Paul II" Catholic University Campobasso, CAMPOBASSO; [2]Catholic University, ROME, Italy

Background. Ethical problems are connatural to the medical activity. Ethical problems regarding some medical specialities as obstetrics or pre or perinatal medicine are well known. Nevertheless few is known about ethical problems perceived as remarkable from physicians and patients in oncohematology. *Aims.* Aim of this study is to recognize, in oncohematology, what are problems perceived as ethically relevant not only from physicians, but also from patients. It might consent to ameliorate medical practice and the quality of care perceived from patient. *Methods.* Ethical problems regarding oncohematologic patients were recognized consulting clinical diary of 200 patients treated in our institution. Patients have casually been selected in the temporal period from january 2004 to june of 2008. Ethical problems were listed in two groups: those perceived as remarkable for the physicians and those remarkable for the patients. This study is a retrospective monocentric descriptive study. *Results.* Median age was 58.5 years (R 33-86). M/F was 126/74. 123 patients were affected by chronic or indolent hemopaties. 143 patients received Ist line therapy, instead 67 IInd line or superior. 150 patients had licence of primary school, 40 of secondary, 10 degree. 150 patients were assisted from a relative. 60 patients perceived a problem as ethically relevant (9 compliance to treatments, 11 refusal of treatment, 15 intolerance to hospitalization, 17 scarce trust in caregivers, 8 difficulty to understand therapeutic plain). In 82 cases physicians perceived a problem as ethically relevant (19 over treatment, 14 type of treatment to adopt, 18 correct timing of therapy, 24 correct use of resources, 8 adequacy of treatment). Physicians perceived these problems mainly about patients requiring IInd line treatment or further (56 cases on 67). In 52 cases only patients perceived a problem, in 51 cases only physicians perceived a problem, while only in 39 cases a problem was perceived as ethically relevant from physicians and patiens simultaneously. *Summary andconclusion.* In our study, in oncohematology the main problem perceived from patients as ethically relevant is the scarce trust in caregivers, while for physicians is the correct use of resources. Physicians perceive a bioethic problem mainly considering patient candidate to IInd line treatment or further. In 25% of cases a problem perceived as ethically relevant from patients is underestimated from physicians. In this contest the possibility of bioethical counseling might create a convergence between physician and patient perspective.

0132

COST-EFFECTIVENESS OF RIVAROXABAN VERSUS ENOXAPARIN FOR PREVENTION OF VENOUS THROMBOEMBOLISM AFTER TOTAL HIP AND KNEE REPLACEMENT IN EUROPE

M. Monreal,[1] L. Ryttberg,[2] A. Diamantopoulos,[3] M. Lees,[4] C. Negrini[5]

[1]Hospital Universitari Germans Trias i Pujol of Badalona, BARCELONA, Spain; [2]Orebro Hospital, OREBRO, Sweden; [3]IMS Health, LONDON, UK; [4]Bayer HealthCare, UXBRIDGE, UK; [5]Pbe Consulting, MILAN, Italy

Background. Rivaroxaban, an oral direct Factor Xa inhibitor, was compared with enoxaparin after total hip replacement (THR) and total knee replacement (TKR) in four large randomized controlled trials. Two of these trials compared equal treatment durations of rivaroxaban (10 mg once daily [od]) and the most commonly used European regimen of enoxaparin (40 mg od). In RECORD1, patients undergoing THR received 35 days' prophylaxis with rivaroxaban or enoxaparin. Rivaroxaban reduced total venous thromboembolism (VTE; composite of any deep vein thrombosis, nonfatal pulmonary embolism and all-cause mortality) by 70% versus enoxaparin after 35 days' prophylaxis. In RECORD3, in patients undergoing TKR, 12 days' rivaroxaban reduced total VTE by 49% and symptomatic VTE by 66% versus 12 days' enoxaparin. Major bleeding was similar between rivaroxaban and enoxaparin regimens in both studies. *Aims.* To assess the cost-effectiveness of oral rivaroxaban versus subcutaneous enoxaparin for the prevention of VTE after THR and TKR in key European countries. *Methods.* An economic model was developed to assess the cost-effectiveness of rivaroxaban versus enoxaparin over equal durations of prophylaxis in several key European countries. RECORD1 and RECORD3 data were used to populate the model for THR and TKR, respectively. Risks of VTE and post-thrombotic syndrome (PTS) beyond the post-surgery trial period were estimated from published data and extrapolated out to 5 years. Costs to the healthcare sector were derived from published sources in Spain, Italy, Sweden and the UK. Weights of quality of life were also derived from published literature. The model estimated the cost-effectiveness of rivaroxaban versus enoxaparin over the 5-year time frame, which is sufficient for the long-term burden of venous thromboembolic events, such as PTS and recurrent VTE, to be incorporated. In the UK and Sweden, 8% and 10% of enoxaparin patients, respectively, require daily nurse visits to administer enoxaparin after hospital discharge; these costs were included in the analysis. Outcomes were expressed in quality-adjusted life years (QALYs). *Results.* Thirty-five days'

rivaroxaban was less expensive and improved health outcomes versus 35 days' enoxaparin after THR. Rivaroxaban was associated with a gain in QALYs (up to 0.004 QALYs) and per-patient cost savings over 5 years ranging from €4 to €46 in the UK. For TKR, 12 days' rivaroxaban is consistently less expensive than 12 days' enoxaparin and consistently improves health outcomes. Improved health outcomes were similar between countries (up to 0.0215 QALYs), whereas per-patient cost savings over the 5-year period ranged from €82 in Sweden to €145 in Spain. Extensive sensitivity analyses showed these findings to be robust. *Summary and Conclusions.* This analysis suggests that after both THR and TKR, rivaroxaban thromboprophylaxis consistently improves health outcomes and produces overall cost savings across a range of European settings. With more than 400,000 procedures being performed in Europe annually, rivaroxaban has the potential to produce substantial savings for European healthcare systems.

0133

ANALYSIS OF COSTS ASSOCIATED WITH REMOBILIZATION OF HEMATOPOIETIC STEM CELLS (HSC) USING CHEMOTHERAPY, IN PATIENTS WITH MULTIPLE MYELOMA FAILING ADEQUATE HSC COLLECTION FOR AUTOLOGOUS STEM CELL TRANSPLANTATION WITH G-CSF ALONE

C. Hosing,[1] V.R. Smith,[1] B. Rhodes,[2] R. Richmond,[1] K.H. Walters,[1] M.H. Qazilbash,[1] J.D. McMannis,[1] R. Champlin,[1] S. Giralt,[1] U.R. Popat[1]

[1]M. D. Anderson Cancer Center, HOUSTON; [2]Genzyme Corporation, BOSTON, USA

Background. Peripheral blood (PB) hematopoietic stem cells (HSC) can be mobilized with cytokines alone or chemotherapy plus cytokines. The HSC yield is higher and the failure rate is lower with chemo mobilization. Although a cell dose of 2 million CD34$^+$ cells/kg is considered adequate, some authors have shown that patients who receive <5 million CD34$^+$ cells /kg have higher resource utilization after transplant. *Aim.* the purpose of this study was to analyze the costs associated with remobilization of HSCs using chemotherapy in patients with multiple myeloma (MM) who collected <2 million CD34$^+$ cells/kg in 4 leukapheresis procedures in a prior mobilization attempt with G-SCF alone. *Methods.* This is an IRB approved retrospective chart review of 302 patients with MM who underwent HSC mobilization at our institution between 1/05 and 10/07. The estimated costs were divided into mobilization, pre apheresis, apheresis, and post apheresis costs. (Source: Cleverly and Associates; www.drugstore.com; Redbook'; Thompson PDR)

Table.

Procedure	National Average Hospital and Clinic Charges ($)	N, Median (Range)	Average Cost Per Patient ($)
Chemotherapy mobilization*			
Daily room charge	863.00	2.5 (0-36)	2158
Cyclophosphamide (350 mg/m^2 every 12 hours x 8 doses)	54.62/g	4.928 g	269
Mesna (400 mg/m^2 CIV over 24 hours daily x 4 days)	223.1/0.4 g	2.82 g	1570
Vincristine (0.4 mg/m^2 CIV over 24 hours daily x 4 days)	10/1 mg	2.81 mg	28
Doxorubicin (10 mg/m^2 CIV over 24 hours daily x 4 days)	44.4/10 mg	70.4 mg	313
Dexamethasone (40 mg IV daily x 4 days)	11.45/40 mg	160	45.8
Daily CBC, diff	93	2.5 (0-36)	233
Blood transfusions (n = 21)	494	1 (0-4)	494
Platelet transfusions (n = 12)	494	0 (0-3)	0
G-CSF	528	18.5 (11-32)	9768
Prophylactic oral antibiotics (valacyclovir/ fluconazole/ levofloxacin)		12.5 (5-29)	144/124/158
Readmission			
Daily room charge	863.00	6.5 (5-15)	5610
Daily CBC, diff	93	6.5 (5-15)	605
Apheresis			
Pre-apheresis			1800
Apheresis Procedure	1,917.73	3 (0-6)	5753
PB CD34 analysis	135	2 (estimated)	270
Post-Apheresis (Cryopreservation)	1246.42	3 (0-6)	3739
Average Total Cost of Remobilization/ Patient			**33,081**

**Chemotherapy dose based on median body surface area of 1.76 (range, 1.47-2.44); n=16*

Results. Twenty-six patients (9%) failed the first mobilization attempt. Of these, 21 patients were remobilized with chemotherapy. The most commonly-used chemotherapy regimen was modified hyper-CVAD (fractionated cyclophosphamide, mesna, vincristine, doxorubicin, and dexamethasone) in 16 of 21 patients. Two patients failed the second mobilization attempt also, and did not get an autologous transplant. Both received further salvage therapy for their MM. In patients who were successful remobilizers, the average number of apheresis procedures required to reach a target HSC dose of 6 million CD34$^+$ cells/kg was 3 (range, 0-6). The average in patient stay for chemotherapy administration during remobilization was 2.5 days (range, 0-36). The number of days on G-CSF was 18.5 days (range, 11-32). All patients received IV hydration while in the hospital and were discharged on prophylactic oral antibiotics (antibacterial, antiviral, and antifungal) to be continued till ANC > 500/mm^3. The median time on oral antibiotics was 12.5 days (range, 5-29). Platelet and RBC transfusions were administered in 7/16 and 10/16 patients, respectively. Six patients required readmission (for fever and/or infections) ranging from 5-15 days. The average charges per patient for chemotherapy administration, transfusions, prophylactic antibiotics and G-CSF were $15,304.Average pre-apheresis charge per patient was $1800 (clinic visit, laboratory evaluation, insertion of central venous catheter, and chest x-ray to check placement). The average cost of apheresis per patient was $6,023 (includes cost of apheresis and analysis of PB CD34$^+$ cells). This is an underestimation as it does not include the costs associated with supportive care, intravenous fluids, professional fees etc. The average post-apheresis charges were $3,739. The average cost of readmission per patient was $6,215. *Conclusions.* Although only a minority of patients with MM fail to collect adequate HSC with cytokines alone, for patients who do fail the costs of remobilization with chemotherapy are substantial. Accordingly, the financial implication for transplant centers where reimbursement charges are DRG (disease related group) or case rate based is also significant. Interventions that may reduce the failure rate or reduce the number of apheresis procedures required to reach the target cell dose without an increase in toxicity may ultimately result in cost savings.

0134

DEVOLOPMENT OF A TIME-DRIVEN ACTIVITY-BASED COSTING MODEL FOR ASSESSING THE SOCIETAL ACQUISITION COST OF ERYTHROCYTE CONCENTRATES IN EUROPE

D. Szucs,[1] J. Bauwens,[2] J. Alfonso,[2] N. Holtuis,[3] J. Von Knorring,[2] J. Demey[2]

[1]University Zurich, ZURICH, Switzerland; [2]HICT, BRUGES, Belgium; [3]Landstinget Kronoberg - Department of Clinical Chemistry & Transfusion Medicine, VÄXJÖ, Sweden

Background. The cost of blood products is regularly underestimated by public health decision makers, hospital administrators and clinicians since the acquisition cost does not represent the total cost for obtaining and producing blood components. Historical accounting attempts to assess the acquisition cost of erythrocyte concentrate have varied in scope, perspective and methodology, leading to incomparable and criticised conclusions. *Aims.* To assess the true acquisition cost of erythrocyte concentrate in different European health care systems. *Method.* We derived a time-driven activity-based costing model taking into consideration blood centre costs and donor costs. Input from 3 (Swedish) blood centres was consolidated to develop a country specific model. Together with transfusion specialists, the transfusion chain is described in main processes chronologically and further broken down into activities. A division is made between direct *production*, quality assurance and supporting processes. Hereafter, all necessary resources and outputs of the activities are identified and quantified. All cost information is collected from the blood centre's general ledger. A capacity cost rate, representing a monetary value for each minute of available practical capacity, is calculated for the resources actually performing the work. The consumption of each resource for all identified activities is quantified based on time estimates from transfusion professionals. To quantify donor costs, we obtained figures on transport method, time and moment of donation by questionnaires which were administered to donors. The national value of productivity is used to quantify donor time in monetary terms. All transport costs are obtained from national databases. *Results*. The main activity components and their relations are illustrated in Figure 1. Within each main process, between 5 and 24 activities are described. Outputs are represented by statistics on donors, blood collections and erythrocyte concentrate units. Practical capacity includes all direct labour functions and equipment performing automated work in the direct "producing" processes. Costs include expenditures for direct and indirect resources necessary to perform the activities. We were able to determine a simplified cost formula: Societal cost of erythrocyte concentrate = $\sum$(direct labour time x labour capacity cost rate) + $\sum$(direct equipment time x equipment capacity cost rate) + $\sum$donor time x national value of production + $\sum$cost donor transport. Dividing the obtained cost by the number of units erythrocyte concentrate obtained in the same period of time, shows the total societal cost of 1 unit erythrocyte concentrate. The model presents the respective costs, driven by time consumption, for each of the identified processes where costs are occurred. *Summary and Conclusions.* The detailed process description and analysis reveal many activities and a significant amount of resources that have been excluded in previous accounting attempts to assess the acquisition cost of erythro-

cyte concentrate. The described model provides a complete and documented scope with a straightforward and transparent cost allocation methodology, respecting the societal perspective. Reporting a detailed cost structure allows insights in how the total cost is occurred and comparisons of results from different health care systems. Assessing the total cost of erythrocyte concentrate is important for cost-effectiveness analyses. It will support public health decision makers in evaluating the effectiveness of alternative therapies. Furthermore, this true cost calculation should be beneficial for institutions seeking adequate financing of erythrocyte concentrate.

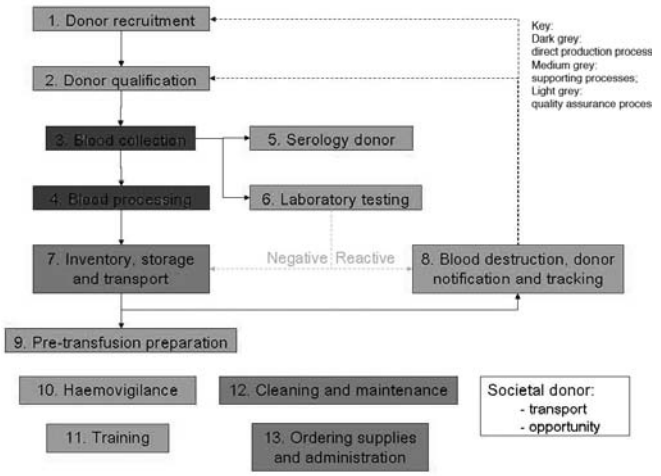

Figure 1. Main processes.

HEALTH ECONOMIC IMPACT OF INTRAVENOUS IRON SUPPLEMENTATION IN ANEMIA TREATMENT WITH ERYTHROPOIESIS-STIMULATING AGENTS

D. Szucs,[1] R. Blank,[1] M. Schwenkglenks[2]

[1]University Zurich, ZURICH; [2]European University of Basel, BASEL, Switzerland

Background. Currently, erythropoiesis stimulating agents (ESA) are widely used in the treatment of anemia, e.g due to chronic kidney disease (CKD) or due to chemotherapy induced anemia (CIA). Not only due to recent safety concerns but also due to their high acquisition price, the usage of ESAs has come under severe pressure from health care payers. By optimising iron stores and iron bioavailability, the initiation of ESA therapy can be delayed and their efficiency be maximized. The combination of ESA therapy with a systematic iv iron supplementation may hence lead to significant cost savings which are likely to be markedly higher than the expenditures for IV iron. *Aims.* This study aimed at establishing the economic benefit of using IV iron in anemia treatment. A cost neutral price for IV iron was determined by calculating cost savings due to increased ESA efficacy. In addition we tested whether simplified handling of intravenous administration of iron might yield additional cost-savings. *Methods.* We determined the cost neutral price of IV iron as the price of IV iron at which the intervention is cost neutral to the Swiss healthcare system. This price equals the costs of spared ESA per responding patient. Given this definition, any IV iron priced below cost neutrality would be cost saving to the system. Using a third party perspective, we analysed the economic benefits in the following areas: (1) hemodialysis-chronic kidney disease (HD-CKD), (2) non-dialysis-chronic kidney disease (ND-CKD) and (3) chemotherapy-induced anemia (CIA). *Results.* The cost-neutral price of IV iron per 1000 mg in different therapeutic areas was: €500 in HD-CKD, €420 in ND-CKD and €2090 in CIA. The total costs of administering 1000mg iron, including IV iron plus the ancillary costs of administration were €270 for ferric carboxymaltose, €370 for iron sucrose, €374 for iron dextran and €389 for iron gluconate. The corresponding costs of the iron preparations per 1000mg are €250, €137, €124, and €69 respectively. *Summary and Conclusions.* Even though ferric carboxymaltose is the most expensive IV iron product, the associated savings are that significant, to become the most economically viable option in three different treatment settings.

Stem cell transplantation – GvHD, graft rejection, infection

0136

PREVALENCE OF HUMAN HERPES VIRUS 6 CHROMOSOMAL INTEGRATION (CIHHV-6) IN ITALIAN ALLOGENEIC STEM CELL AND SOLID ORGAN TRANSPLANTATION PATIENTS

L. Potenza,[1] P. Barozzi,[1] P. Bresciani,[2] M. Pecorari,[1] G. Riva,[1] D. Vallerini,[1] C. Quadrelli,[1] E. Zanetti,[1] G. Rossi,[1] A.M.T. Sabbatini,[1] F. Di Benedetto,[1] M. Codeluppi,[1] E. Rivolti,[1] R. D'Amico,[1] M. Morselli,[1] F. Forghieri,[1] M. Maccaferri,[1] A. Donelli,[1] F. Rumpianesi,[1] F. Narni,[1] G. Torelli,[1] M. Luppi[1]

[1]University of Modena and Reggio Emilia, MODENA; [2]Department of Oncology, Hematology and Respiratory Diseases, MODENA, Italy

Background. Human herpes virus (HHV) 6, an ubiquitous β-herpesvirus, may reactivate and cause diseases upon immunosuppressive state. Half of stem cell (SC) and/or solid or-gan transplant (SOT) recipients experience HHV-6 viremia. Bone marrow (BM) suppression, encephalitis, pneumonitis and hepatitis are being increasingly associated clinical manifestations. A lesser recognized form of HHV-6 latency is the integration of the viral genome in a host chromosome (CIHHV-6). This phenomenon, characterized by a high viral copy number in blood or sera, may confound laboratory diagnosis of HHV-6 active infection, but apparently neither affects host health status nor requires clinical intervention. *Aims.* We have studied either SCT or SOT patients to identify cases of HHV-6 related-diseases and the prevalence of CIHHV-6. *Methods.* 78 allogeneic BMT and 345 SOT were evaluated. HHV-6 loads have been quantified by a commercially available quantitative real time polymerase chain reaction diagno-stic kit (Nanogen Advanced Diagnostics, Turin, Italy). *Results.* 70 out of 78 (90%) SCT and 135 out of 343 (39%) SOT patients were screened for HHV-6 either on body fluids or on tissue specimens. 16 out of 70 (23%) SCT patients and 52 out of 135 (39%) SOT patients presented at least one positive sample for HHV-6. 3 (18%) out of 16 SCT and 7 (13.4%) out of 52 SOT patients presented signs and symptoms consistent with HHV-6 related-diseases, namely four neutropenia and thrombocytopenia, two thrombocytopenia, two fever, one fever and lymphadenitis and one syncytial giant cell hepatitis. 2 (0,9%) out of 205 patients, one SCT and SOT respectively, demonstrated high value of HHV-6 DNAemia. The SOT patient presented a mean HHV-6 viral load >3.5 log10 copies/mL in plasma, and >6 log10/mL in blood during the entire clinical course. The alloSCT patient, presented high BM HHV-6 DNAemia (>5 log10 copies/mL) soon after transplantation, reducing to <4 log10 copies/mL with increasing chimerism, while presented fluctuating HHV-6 viremia, from 2 to >4 log10 copies/mL in plasma, unparalleled to white blood cell en-graftment and associated with graft versus host disease episodes. HHV-6 load in hair follicles in both patients revealed ≥1 HHV-6 copy/cell, indicating that the virus had been inherited in the germ line and is found in all cell of the body. Both patients had been heavily treated with antivirals without changes in HHV-6 loads. *Conclusions.* In Italian transplant patients, CIHHV-6 may occur at a frequency of 0.9%, while the frequency of HHV-6 related-diseases is approximately 5%. The results of molecular studies for HHV-6 should be critically evaluated and the distinction between HHV-6 active infection and CIHHV-6 should be pursued by the comparison of viral loads on different biological fluids. The search for HHV-6 on hair follicles, nails or other tissue specimens may confirm the occurrence of CIHH-6. The pretransplantation screening of donors and recipients could prevent misinterpretation of CIHHV-6 phenomenon in the recipients after transplantation, and preclude the administration of unnecessary and potentially toxic antiviral treatments.

0137

GENETIC VARIATIONS IN HEPARANASE GENE ARE ASSOCIATED WITH INCREASED RISK OF GRAFT VS. HOST DISEASE FOLLOWING ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

O. Ostrovsky,[1] A. Shimoni,[1] I. Vlodavsky,[2] A. Nagler[1]

[1]Chaim Sheba Medical Center, RAMAT GAN; [2]Rappaport Faculty of Medicine, Technion, HAIFA, Israel

Complications of allogeneic hematopoietic stem cell transplantation (HSCT) halt its wider application for a variety of diseases. Graft-versus-host disease (GVHD) is the most common cause of overall mortality and

morbidity after HSCT. Heparanase, endo-β-glucuronidase that specifically cleaves the saccharide chains of heparan sulfate proteoglycans, is involved in the process of inflammation and release of heparan sulfate-bound chemokines, cytokines and bioactive angiogenic factors that are main players in the development of GVHD. Therefore we investigated the possible association of HPSE gene SNPs with the risk of post HSCT GVHD and transplantation outcome. Assessment of heparanase gene SNPs among healthy individuals demonstrated a significant correlation between HPSE gene SNPs and the expression level of heparanase, SNP rs4693608 being the most prominent (p=0.00043). This approach allowed distribution of all possible HPSE genotype combinations into three groups (LR, MR and HR) correlating with low, intermediate and high heparanase mRNA and protein expression levels. In the group of HSCT patients we found a highly significant correlation between HPSE gene SNPs rs4693608 and rs4364254, their combinations and risk of acute GVHD. The cumulative incidence of acute GVHD, grade II-IV, was 54.5% (95% CI 43.2-68.6) in the recipient group HR, while in recipient groups MR and LR, the cumulative incidences were 34.7% (95% CI 26.1-46.2) and 20.5% (95%CI 12.4-34.0), respectively (p=0.0001). Moreover, mismatching between recipient and donor in these SNPs combinations significantly increased the risk of acute GVHD. This association was statistically significant when recipients possessed genotype combinations HR and MR correlating with high heparanase mRNA levels, while their donors possessed the MR or LR genotype combinations, respectively (mismatched I group: HR-MR, MR-LR, and HR-LR pairs) (p=0.0000). The cumulative incidence of acute GVHD was 72.9% (95% CI 59.3-89.5) in the group of mismatched I, while in groups of matched and mismatched II (LR-MR, LR-HR, and MR-HR pairs) the cumulative incidences were 33.7% (95% CI 24.6-46.1) and 29.6% (95% CI 17.1-51.2), respectively (Figure 1). In addition, HPSE gene SNPs correlated with incidence of extensive chronic GVHD, transplantation-related death, and overall survival. The study demonstrated significant correlation between HPSE gene SNPs and heparanase expression levels, resulting in increased risk of acute and extensive chronic GVHD. Our findings may imply the involvement of heparanase in the pathogenesis of GVHD. Differences in heparanase expression between recipient and donor may lead to aggressive phenotype of donor T lymphocytes followed by infiltration and destruction of patient tissues.

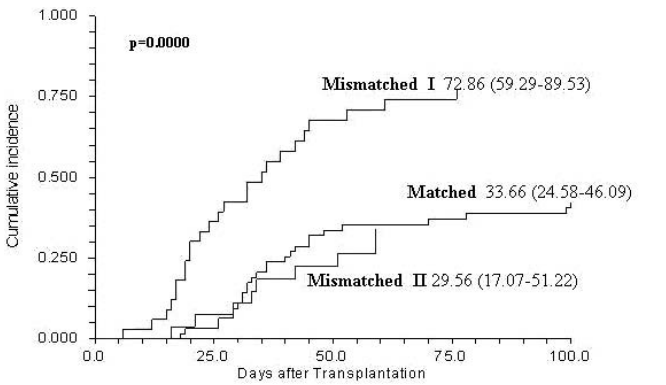

Figure 1. The cumulative incidence of acute GVHD, grade II-IV, following hematopoietic stemm cell transplantation according to matching or mismatching between HPSE gene SNPs combinations of recipient and donor.

0138

IMMUNE RECONSTITUTION AND RISK OF CYTOMEGALOVIRUS INFECTION IN PATIENTS AFTER ALLOGENEIC STEM CELL TRANSPLANTATION: IMPLICATIONS FOR PREEMPTIVE AND PROPHYLACTIC STRATEGIES

M. Schmidt-Hieber,[1] S. Schwarck,[2] A. Stroux,[3] E. Thiel,[2] H. Tillmann,[4] P. Reinke,[4] S. Ganepola,[2] L. Uharek,[2] I. Blau[2]

[1]*Charite Campus Benjamin Franklin, BERLIN;* [2]*Charite CBF, BERLIN;* [3]*Charite-CBF, BERLIN;* [4]*Charite CVK, BERLIN, Germany*

Background. Infection or disease by cytomegalovirus (CMV) is still a major cause of morbidity and mortality after allogeneic stem cell transplantation (allo-SCT). *Aims.*We prospectively analyzed immune reconstitution kinetics and risk factors for CMV infection in 89 patients after allo-SCT. *Methods.* The serum IgG concentration and counts of CD4$^+$ T cells, CD8+ T cells, CMV-specific (pp65) CD8$^+$ cytotoxic T cells (CTLs) and NK cells were monitored monthly, starting from day +30 and continued up to the maximum of one year after allo-SCT. CMV was monitored by the pp65 antigen assay or an real-time PCR. *Results.* The recipient/donor CMV serostatus and the type of *in vivo* T cell depletion (TCD) had a significant influence on the cumulative CMV infection incidence in univariate and multivariate analysis. The CMV infection incidence was 83% after *in vivo* TCD with alemtuzumab, but 43% and 36% in patients who received antithymocyte globulin (ATG) or no *in vivo* TCD (p=0.011 and 0.002). The conditioning type (non-myeloablative with 2 Gy total-body irradiation (TBI), fludarabine-based reduced intensity (RIC) or conventional) had no significant impact on the estimated cumulative CMV infection incidence (60%, 45% and 35%). Day +30 counts of CD4$^+$ T cells, CD8$^+$ T cells, CMV-specific CTLs, NK cells and the serum IgG concentration did not significantly influence the occurrence of CMV infection. However, the day +60 NK cell count was identified as the most important risk factor for CMV infections beside the recipient's CMV seropositivity, whereas patients who showed any CMV infection or disease prior to day +60 were excluded from this analysis (CMV infection incidence 6%, 17% and 38% for patients with a day +60 NK cell count of >200/μL, 100-200/μL and <100/μL). The mean percentage of CMV-specific CTLs was low at days +30 and +60 (0.09% and 0.92%), reached the maximum with 2.24% (range 0-7.1%) at day +90 and decreased again thereafter. At day +30, CMV-specific CTLs were detected in 4 of 7 patients (57%) allografted from a CMV seropositive donor, but in none of 10 patients who had a CMV seronegative donor (p=0.01). Alemtuzumab strongly depressed reconstitution of CD4$^+$ and CD8$^+$ T cells, whereas ATG only delayed CD4$^+$ T cell reconstitution. CD4$^+$ and CD8$^+$ T cell reconstitution was improved after non-myeloablative conditioning in comparison to fludarabine-based RIC and conventional conditioning. Neither the type of *in vivo* TCD nor the conditioning type had any significant influence on immune reconstitution profiles of NK cells. *Summary and Conclusions.* The type of *in vivo* TCD (alemtuzumab or ATG) influences differentially both the CMV infection risk and CD4$^+$ and CD8$^+$ T cell reconstitution kinetics in patients after allo-SCT. Therefore, preemptive strategies could be adequate for patients after *in vivo* TCD with ATG, but patients after *in vivo* TCD with alemtuzumab might require antiviral prophylaxis. Our data further suggest that NK cells play an important role in preventing CMV reactivation beyond day +60 in patients who underwent allo-SCT. This observation might be the basis for clinical trials evaluating the efficacy of adoptive NK cell transfer.

0139

EXPANSION AND SUPPRESSIVE FUNCTION OF UMBILICAL CORD BLOOD REGULATORY T CELLS

G.F. Torelli, R. Maggio, N. Peragine, M.S. De Propris, M. Screnci, F. Milano, M.G. Mascolo, E. Arleo, A. Guarini, R. Foà

Sapienza University of Rome, ROMA, Italy

Background. Cord blood (CB) stem cells are now broadly used in the unrelated stem cell transplant setting and comparative studies with different stem cell sources have shown that CB transplant is characterized by a lower risk of graft-versus-host disease (GVHD). The immaturity of CB T cells is considered the major contributing factor accounting for this phenomenon; the possible role played by CB regulatory T cells (Tregs) for the suppression of the allogeneic T-cell response is now under investigation, but very scarce data are so far available. *Aims.*Aim of this study was to analyze and compare the expansion and suppressive functions of Tregs obtained from CB units with those obtained from the peripheral blood (PB) of adult normal donors. *Methods.* Tregs were purified from mononuclear cells obtained from CB units or from the PB of normal donors using the CD4$^+$CD25$^+$ regulatory T-cell isolation kit (Miltenyi Biotec) and expanded for 6 days in 96-well U-Bottom plates coated with anti-CD3 (5 μg/mL) and anti-CD28 (5 μg/mL) MoAbs in the presence of IL-2 (100 U/mL). To assess their suppressive functions, expanded Tregs were seeded with autologous effector T cells stimulated with allogeneic dendritic cells (DC) pulsed with apoptotic leukemic blasts, then incubated with [3H]-thymidine and counted in a β-counter. Suppressor activity was measured as [3H]-thymidine incorporation in the presence or absence of Tregs. The IL-10 production capacity was also tested using an ELISA assay. *Results.* Tregs expanded from CB units (n=15) and from the PB of normal donors (n=8) presented similar immunophenotypic features in terms of expression of surface CD4, CD25, CD62L, CCR5 and CD45RO, and cytoplasmic CTLA-4 and Foxp3; also, they both were negative for the CD45RA antigen. On the contrary, Tregs obtained from CB units presented a more than double expansion capacity: [mean fold increase (range): CB 10.089 (1.76-24), normal donors 4.59 (1.5-10), p 0.05], and exerted a potent suppressive function on the proliferative reac-

tion of T cells stimulated by allogeneic DC (n=6) [mean fold reduction (range), CB units 7.8 (2.5-15.1)]. Tregs expanded from CB units also presented a high *in vitro* IL-10 production capacity. *Summary and Conclusions.* These results indicate that Tregs contained in CB units loose their naïve phenotype following expansion and may exert a potent suppressive function, possibly accounting for the reduced incidence of GVHD that characterizes CB transplants. Our data offer further insights into the understanding of the biology of CB transplant and suggest possible therapeutic options for the prevention and cure of GVHD based on the infusion of expanded CB Tregs.

0140

THE MODULATORY PROPERTIES OF REGULATORY T CELLS IN THE PERIPHERAL BLOOD OF PATIENTS WHO HAVE UNDERGONE AN ALLOGENEIC STEM CELL TRANSPLANT CORRELATE WITH THE PRESENCE OF GRAFT-VERSUS-HOST DISEASE

G.F. Torelli, R. Maggio, N. Peragine, M.S. De Propris, B. Lucarelli, M.G. Mascolo, A.P. Iori, V. Valle, E. Iannella, A. Guarini, R. Foà

Sapienza University of Rome, ROMA, Italy

Background. Graft-versus-host disease (GVHD) represents the major cause of morbidity and mortality after an allogeneic stem cell transplant (SCT). Studies in mouse models of SCT have shown that the infusion of culture-expanded regulatory T cells (Tregs) can be effective in preventing and suppressing GVHD, while apparently retaining the graft-versus-leukemia effect. *Aims.* Aim of this study was to verify whether the modulatory properties of Tregs expanded from the peripheral blood (PB) of patients who have undergone an allogeneic SCT correlate with the presence of acute and/or chronic GVHD. *Methods.* Tregs were purified from mononuclear cells obtained from PB using the $CD4^+CD25^+$ regulatory T-cell isolation kit (Miltenyi Biotec) and expanded for 6 days in 96-well U-Bottom plates coated with anti-CD3 (5 μg/mL) and anti-CD28 (5 μg/mL) MoAbs in the presence of IL-2 (100 U/mL). To assess their suppressive functions, expanded Tregs were seeded with autologous effector T cells stimulated with allogeneic dendritic cells (DC) pulsed with apoptotic leukemic blasts, then incubated with [3H]-thymidine and counted in a β-counter. Suppressor activity was measured as [3H]-thymidine incorporation in the presence or absence of Tregs. IL-10 production was also measured using an ELISA assay. *Results.* Tregs purified from the PB of patients with (n=7) or without (n=9) acute and/or chronic GVHD showed an equivalent expansion capacity and no immunophenotypic differences, in terms of expression of surface CD4, CD25, CD62L, cytoplasmic CTLA-4 and Foxp3. However, Tregs expanded from the PB of patients without signs of GVHD exerted a higher suppressive function on the proliferative reaction of T cells stimulated by allogeneic DCs compared to Tregs expanded from the PB of patients with GVHD: mean fold reduction (range), PB patients without GVHD 9.8 (5.28-21.82); PB patients with GVHD 3.9 (1.49-6.34), p 0.05. Moreover, Tregs expanded from patients without GVHD showed a significantly higher *in vitro* IL-10 production capacity: mean pg/mL (range), patients without GVHD 626 (461-731), patients with GVHD 245 (125-355), p 0.02. *Summary and Conclusions.* These observations indicate that the functional activity of Tregs in the PB of patients who have undergone an allogeneic SCT may protect from GVHD and support the design of therapeutic and/or preventive GMP protocols based on the *in vivo* infusion of ex vivo expanded and activated Tregs, aiming at modulating the activity of the immune system after an allogeneic SCT.

0141

DIVERSITY AND DIFFERENTIAL INVOLVEMENT OF HLA CLASS I AND II RESTRICTED MINOR HISTOCOMPATIBILITY ANTIGENS IN GRAFT-VERSUS-LEUKEMIA REACTIVITY

M. Griffioen, A.N. Stumpf, M.W. Honders, E.D. van der Meijden, S.A.P. van Luxemburg-Heijs, C.A.M. van Bergen, R. Willemze, J.H.F. Falkenburg

Leiden University Medical Center, LEIDEN, Netherlands

Background. Donor lymphocyte infusion (DLI) can be an effective cellular immunotherapy for patients with hematological malignancies after HLA-matched allogeneic stem cell transplantation (alloSCT). The effect of DLI is mediated by donor derived T-cells recognizing minor histocompatibility antigens (mHags) on malignant cells of the recipient. These T-cells may also induce Graft-versus-Host Disease (GvHD) when directed against mHags with broad expression on non-malignant tissues. *Aims.* The aim of the study was to investigate T-cell diversity and specificity in Graft-versus-Leukemia (GvL) reactivity. *Methods.* $CD8^+$ and $CD4^+$ T-cell clones were isolated from a patient successfully treated with DLI for relapsed chronic myeloid leukemia (CML) more than one year after HLA-matched alloSCT. GvL reactivity in this patient was accompanied with mild GvHD of the skin. Reactivity of the T-cell clones was analyzed in detail and HLA-class I and II restricted mHags were characterized by screening plasmid and bacteria cDNA libraries, respectively. *Results.* The isolated T-cell clones were shown to be directed against 13 different mHags. HLA-class I mHags included HA-1 and HA-2 in HLA-A2 and 5 unknown mHags in HLA-B8 and -B60. HLA-class II mHags were presented by HLA-DQ and -DR. By screening plasmid and bacteria cDNA libraries, we identified an HLA-B60 mHag encoded by the TRIP10 gene, an HLA-DQ mHag encoded by the PI4K2B gene and four HLA-DR mHags encoded by the PTK2B, MR1, LY75 and MTHFD1 genes. Analysis of public microarray databases revealed ubiquitous expression of TRIP10 and PI4K2B, whereas the other mHags were selectively (HA-1, HA-2, LY-75) or predominantly (PTK2B, MR1, MTHFD1) expressed in hematopoietic cells. The T-cell clones were analyzed in detail for reactivity against hematopoietic cells, including non-malignant peripheral blood cells (monocytes, B- and T-cells), malignant $CD34^+$ CML progenitor cells, professional antigen presenting cells (APC) and acute myeloid and lymphoblastic leukemias (AML and ALL). All $CD8^+$ and $CD4^+$ T-cell clones recognized (subsets of) peripheral blood cells, except for the T-cell clone for TRIP10. Moreover, all $CD8^+$ T-cell clones, except for the T-cell clone for TRIP10, recognized $CD34^+$ CML cells. Differential recognition of $CD34^+$ CML cells was observed for $CD4^+$ T-cell clones. The T-cell clone for MTHFD1 recognized $CD34^+$ CML cells, whereas no reactivity was observed for the T-cell clones recognizing LY-75, PTK2B and MR1. All T-cell clones strongly recognized professional APC, including monocyte-derived dendritic cells and *in vitro* differentiated $CD34^+$ CML cells with APC phenotype. Finally, all T-cell clones were capable of recognizing primary AML and ALL, except for the T-cell clone for TRIP10, which showed restricted recognition of AML-M4 and -M5 of monocytic origin. *Conclusions*. Our data show a detailed analysis and characterization of mHags recognized by T-cells induced in a patient successfully treated with DLI for relapsed CML and provide evidence for differential involvement of mHags in the onset and execution of GvL reactivity. All identified mHags were shown to be expressed on (subtypes of) primary leukemic cells, and may therefore be appropriate targets for T-cell based immunotherapy.

0142

CYCLOSPORINE, METHOTREXATE AND METHYLPREDNISOLONE FOR GRAFT-VERSUS-HOST DISEASE PROPHYLAXIS IN CHILDREN WITH HEMOGLOBINOPATHIES: A PROSPECTIVE STUDY

J. Gaziev,[1] G. Lucarelli,[1] A. Santucci,[2] C. Gallucci,[1] P. Sodani,[1] P. Polchi,[1] A. Isgrò,[1] M. Marziali,[1] K. Paciaroni,[1] M.D. Simone,[1] A. Roveda,[1] A. Montuoro,[1] C. Alfieri,[1] G. De Angelis[1]

[1]Mediterranean Institute of Hematology, ROME; [2]Dipartimento di Medicina Clinica e Sperimentale. Sezione di Ematologia ed Immuno, PERUGIA, Italy

Background. Although children are at less risk for GVHD than adults its incidence is still significant despite drug prophylaxis. Unlike hematological malignancies where the high rate of GVHD may be offset by lower relapse rates there is no benefit of GVHD for non malignant diseases. In a retrospective study we have previously demonstrated a decrease in the incidence of acute GVHD in class 3 patients who received cyclosporine (CSA), a modified short course of methotrexate (MTX) [Cyclophosphamide 7.5 mg/kg on day +1] and methylprednisolone (MP) [CSA/CY/MTX/MP)] as compared to class 1 and 2 patients treated with a CSA/MP combination. Therefore in an attempt to reduce the incidence of GVHD in this patient population we used CSA/MTX/MP prophylaxis in all patients apart from risk classes. This is the first study prospectively evaluating a three drug regimen in children with hemoglobinopathies to date. *Aims.* to evaluate the efficacy and safety of CSA/MTX/MP regimen for GVHD prophylaxis in children with hemoglobinopathies. *Methods.* 101 children with median age of 8 years (range, 1.6-17) affected by thalassemia (n=95) or sickle cell anemia (n=6) were given a bone marrow graft from HLA matched family donors between 2004 and 2008. The conditioning regimen for class 1 and class 2 patients (n=52) consisted of BUCY200 ± thiotepa, class 3 patients (n=43) of BU/CY160 ± thiotepa (preceded by hydroxyurea, azathioprine and fludarabine) and for SCA patients of BUCY200 and thymoglobulin. Forty six patients received CSA, a short course of MTX (10 mg/m^2 on days +1, +3, +6) and low-dose MP (0,5 mg/kg/d) [CSA/MTX/MP], while 55 patients were given CSA/CY/MTX/MP as GVHD prophylaxis. The median NC, CD34 and CD3 cell dose was 4.4×10^8/kg (range 1.3-10.8), 7.1×10^6/kg (range 0.78-34.7) and 54×10^6/kg (range 3.8-208) respectively.

Thirty male patients received stem cells from female donors. Thirty seven patients were transplanted with marrow from ABO major or minor mismatched donors. *Results.* Overall 33 out of 96 evaluable patients have developed grade II-IV acute GVHD with the probability of 33% (95% CI: 24-42). The probability of grade III-IV GVHD was low 4% (95% CI 1-9). The incidence of aGVHD was similar in patients who received CSA/MTX/MP or CSA/CY/MTX/MP (p=0.8). In logistic regression analysis female donor for male patients (OR 2.8; p=0.005), the number of $CD3^+$ cells >54×10^6/kg (OR 2.2; p=0.025) and ABO mismatch (OR 2.3; p=0.021) predicted grade II-IV aGVHD. The probability of chronic moderate or severe GVHD was 9% (95% CI 4-16) and 3% (95% CI 1-8) respectively. Previous acute GVHD (OR 2.4; p=0.002) and patient age >8.8 years (OR 6.9; p=0.005) predicted chronic GVHD. Eight patients have died 3 of them from GVHD o related complications. *Conclusion.* This study showed that the incidence of grade II-IV acute GVHD following CSA/MTX/MP prophylaxis is similar to those observed after CSA/MP prophylaxis (our previous study). These data suggest that the addition of MTX to CSA/MP was not associated with a low incidence of aGVHD in this patient population. The incidence of extensive chronic GVHD in patients with hemoglobinopathies is low.

ALLOANTIGEN-SPECIFIC *DE NOVO* INDUCED FOXP3⁺ REGULATORY T CELLS FAIL TO PREVENT GVHD DUE TO *IN VIVO* INSTABILITY

C. Koenecke,[1] N. Czeloth,[1] A. Bubke,[1] S. Schmitz,[1] A. Kissenpfennig,[2] B. Malissen,[2] J. Huehn,[3] A. Ganser,[1] R. Förster,[1] I. Prinz[1]

[1]Hannover Medical School, HANNOVER, Germany; [2]Centre d'Immunologie de Marseille-Luminy, MARSEILLE, France; [3]Helmholtz Centre for Infection Research, BRAUNSCHWEIG, Germany

Background. Thymus-derived, natural Tregs (nTregs) have been shown to protect mice from lethal GvHD. Induced antigen-specific FoxP3+ T cells (iTregs) are discussed as a promising alternative to polyclonal natural FoxP3+ T cells for cell-based therapies, particularly to achieve more specific transplantation tolerance. *Aims.* To establish a reliable protocol to induce *de novo* alloantigen-specific iTregs *in vitro* and to test their ability to prevent GvHD *in vivo*. *Methods.* Using FoxP3-reporter mice (C56BL/6), we established an efficient protocol to induce and expand alloantigen-specific iTregs from $FoxP3^-CD4^+$ T cells with allogeneic cluster-disrupted dendritic cells (BALB/c). Interestingly, syngeneic or LPS-matured dendritic cells fail to induce FoxP3 in allogeneic $CD4^+$ T cells. Functionality of iTregs was tested *in vitro* and in a C57BL/6 into BALB/c mouse model of acute GvHD. *Results.* After *in vitro* induction $FoxP3^+$ induced Tregs were mainly $CD62L^+$ and $CD25^+$ and their immunosuppressive capacity *in vitro* was similar to those of natural Tregs. Induced and natural Tregs were retrieved from recipient mice after transplantation at similar levels, but, in contrast to nTregs, iTregs failed to prevent lethal GvHD. Within irradiated recipients, the majority of adoptively transferred $FoxP3^+$ iTregs but not $FoxP3^+$ nTregs had quickly reverted to $FoxP3^-CD4^+$ T cells (70% after four days and 80% after 8 days). *Conclusions.* Our data suggest that therapeutic approaches to treat GvHD should rely on nTregs whereas the use of *de novo* induced alloantigen-specific iTregs must be handled with caution since the stability of the regulatory phenotype of the iTreg appears to be of major concern. Thus, when exposed to a lymphopenic, recently conditioned environment after irradiation or chemotherapy, the use of iTregs may turn out to set a fox to keep the geese.

RECOVERY OF SPECIFIC CMV CD8+ T LYMPHOCYTES AND T REG AFTER ALLOGENEIC PERIPHERAL STEM CELL TRANSPLANTATION: A SINGLE CENTRE EXPERIENCE

D. Pastore, M. Delia, P. Carluccio, A. Mestice, M. Leo, A. Ricco, F. Gaudio, A.M. Giordano, A. Russo Rossi, V. Liso, G. Specchia

Hematology-University of Bari, BARI, Italy

Background. Recovery of cytomegalovirus (CMV)-specific T-cells after allogeneic stem cell transplantation (alloSCT) is critical for protection against CMV disease; in humans the CMV-specific $CD8^+$ must be regenerated after SCT in order to obtain long-term protection against CMV infection and disease. Moreover the recovery $CD4^+CD25^+Foxp3^+$ regulatory T cells (T reg) are a major regulator of adaptive immunity. The aim of our study was to evaluate the recovery of CMV-specific $CD8^+$ and T reg in the peripheral blood after alloSCT. AIMS We used fluorochrome-conjugated tetrameric complexes of HLA-A101, HLA-A201, HLA-B702, HLA-B801, HLA B3501 to monitor recovery of CMV-specific $CD8^+$ (according to the patient's HLA) in 60 patients after alloSCT. *Patients and Methods.* Patients were transplanted with unmanipulated peripheral blood stem cells from an HLA identical related donor (n=53) or an HLA identical unrelated donor (n=7). Median age was 36 years (range 18-61); diagnoses were acute myeloid leukaemia (n=48), acute lymphoblastic leukaemia (n=8), chronic myeloid leukaemia (n=3), myelofibrosis (n=1). *Results.* Median CMV-specific CD8+ T lymphocytes were significantly higher in patients without than with CMV infection/disease at 1 (2 cells/mcL vs 0 mcL, p=0.05), 2 (5 cells/mcL vs. 1 mcL, p=0.05), 3 (12 cells/mcL vs 2, p=0.03) and 6 months (22 cells/mcL vs 3 , p=0.03), respectively. Tetramer analysis showed that 31/60 (51 %) patients reconstituted CMV-specific $CD8^+$ at 2 months after transplantation; CMV infection/disease was observed in 0/12 (0%) patients with CMV-specific $CD8^+$ recovery and without GvHD, in 3/28 (10%) patients with recovery of CMV-specific $CD8^+$ T-cells with GvHD and in 19/20 (95 %) patients without recovery of CMV-specific $CD8^+$ T-cells. In our experience no CMV infection/disease was observed in cases with recovery of CMV-specific $CD8^+$ T-recovery cells > 5 mcL. Moreover, we observed a good correlation between the recovery of CMV-specific $CD8^+$ lymphocytes and of $CD4^+/CD25^{high}$ regulatory T cells at 2 (p=0.05, r=0.8) and 3 (p=0.06, r=0.7) months after alloSCT. However, median T reg values were significantly higher in patients without than with CMV infection/disease at 2 (15 mcL vs 3mcL, p<0.03) and 3 months (22 mcL vs 6mcL, p=0.05). Acute GvHD grade II-IV was observed in 24/60 patients (40 %); at univariate analysis, T reg was significantly higher in patients without than with aGvHD (17 mcL vs 4 mcL, p=0.05). *Summary*. In conclusion we suggest a good correlation between the recovery of CMV-specific $CD8^+$ T-cells and the recovery of T regs; T regs mediate the protective effects toward the aGvHD and the maintenance of an optimal microenviroment for the reconstitution of functional immunity. This supports further consideration of T regs immunotherapy in clinical alloSCT.

PROTEOMIC PATTERNS AND GRAFT VERSUS HOST DISEASE AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

S. Bellesi, P. Chiusolo, C. Fanali, S. Giammarco, S. Sica, R. Inzitari, F. Iavarone, G. Leone, M. Castagnola

Università Cattolica S. Cuore, ROME, Italy

Background. The application of allogeneic hematopoietic stem cell transplantation (alloSCT) is limited due to severe life threatening complications such as severe acute GVHD (Graft Versus Host Disease). To date, diagnosis of GVHD is mainly based on clinical features. Recently the application of proteomic tools, allowing screening for differentially expressed or excreted proteins in body fluids, could allow detecting specific biomarkers, and, in this respect, whole saliva is highly attractive for the non-invasive specimen collection. Aims:in this aim, the application of proteomic analysis to salivary specimens of 14 patients (pts) submitted to alloHSCT in our Institution 2008 is here described. Pts characteristics' were: 7M/7F, median age 35 years (range 14-66). Underlying diseases were: 8 AML, 3 ALL, 2 MM, 1 HD. Nine pts were submitted to standard dose conditioning regimen while 5 to reduced intensity regimens. *Methods.* Samples of whole saliva were collected between 10.00 and 12.00 am by using a soft plastic aspirator. All specimens were mixed immediately in a 1:1 (v/v) ratio with aqueous 0.2% trifluoroacetic acid solution and centrifuged at 8,000 g at 4°C for 5 min. The obtained solutions were either immediately analyzed by High-Performance Liquid Chromatography (HPLC) coupled to ElectroSpray-Ionization Mass Spectrometry (ESI-MS) or stored at -80°C before analysis. *Results.* Seven out of 14 pts (50%) developed aGVHD involving oral mucosa. The chromatograms of the acidic soluble fraction of salivary proteins of pts with aGVHD were compared to the asymptomatic ones. Different expressions of calgranulin A, part of an etero-dimeric leukocyte-derived protein called calprotectin, over-expressed in oral mucosal inflammation were observed, as a preliminary result. Six pts out of 7 with GVHD showed in the chromatograms the presence of calgranulin A (M average 10834.6; elution time 38.5 min), while the protein was not detectable in the chromatograms of pts without GVHD (Fisher's exact test p=0.0047). *Conclusions.* Despite the small number of pts until now examined, highly significant statistic between the presence of calgranulin A and the development of aGVHD involving sequelae of oral mucosa was found. Further studies should clarify if this protein could be considered either a marker of GVHD or an index of mucosal inflammation. However, this protein is not detected in early phase after transplantation, when oral mucositis is present.

0146

CD8 DEPLETED DLI RECONSTITUTE FULL DONOR T-CELL CHIMERISM AND REPLENISH THE CD52-POSITIVE CD4 T CELL POOL AFTER ALEMTUZUMAB-BASED T-CELL DEPLETED ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

E.M. Wagner, A. Lay, T. Schmitt, J. Hemmerling, D. Wolff, K. Bender, C. Huber, W. Herr, R.G. Meyer

University Medical Center Mainz, MAINZ, Germany

Donor lymphocyte infusions (DLI) are frequently used preemptively for mixed hematopoietic chimerism after allogeneic hematopoietic stem cell transplantation (HSCT) although they carry a substantial risk of inducing graft-versus-host disease (GVHD). Removal of CD8 T cells from DLI has been shown to reduce this risk while preserving beneficial DLI effects. We investigated on the application of prophylactic DLI heavily depleted of CD8 T cells early after anti-CD52 (alemtuzumab) mediated T-cell depleted allo-HSCT with regard to T-cell chimerism (TCC) and immune-reconstitution. Peripheral blood mononuclear cells of patients following conditioning with fludarabine, melphalan and high-dose alemtuzumab (100mg) were monitored for TCC and phenotype in the course after HSCT. Monitoring TCC, we identified 20 individuals with mixed chimerism beyond day +60; 13 of them received DLI while 7 did not. The 13 DLI patients showed an increase of donor TCC, 12 converted to complete T-cell chimeras. In contrast, only 1 patient of the non-DLI group spontaneously converted to full donor TCC. Interestingly, we observed successful conversion by DLI even in cases with donor TCC less than 20%. When we analyzed the phenotype of reconstituting T cells, a substantial proportion of CD4 T cells did not express CD52, the target-antigen of the T-cell depleting antibody alemtuzumab. We followed the CD52-status on T cells of patients with and without CD8-depleted DLI and found significantly higher percentages of CD52+ CD4 T cells after DLI. After 1 year, CD4 T cells in DLI patients were mainly CD52 positive while without DLI, significant proportions of CD4 T cells remained negative for CD52. The CD52-expression of monocytes, B cells, and NK cells remained unaltered after transplantation and was not influenced by the application of CD8-depleted DLI. When we treated purified human CD4 T cells with Alemtuzumab *in vitro*, we observed down-regulation of CD52. But this loss of CD52-expression was transient with a minimum after 3-7 days of culture. In contrast, the CD52-expression remained negative over more than 6 weeks when we separated $CD52^-$ from $CD52^+$ CD4 T cell populations from the peripheral blood of our patients and expanded them *in vitro*. We did not find any evidence for a transcriptional regulation of CD52 by RT-PCR. Since CD52 is a glycosylphosphatidylinositol (GPI)-linked surface protein, we stained for other GPI-anchored proteins and found that $CD52^-$ CD4 T cells also had lost expression of CD55 and CD59 *in vivo* as well as in our *ex vivo* culture. In summary, we demonstrate that CD8-depleted DLI can be used to reliably convert mixed to full donor TCC after T-cell depleted allo-HSCT. Their impact on immune reconstitution is also verified by replenishment of the $CD52^+$ CD4 T-cell compartment. The *in vivo* CD52-downregulation after alemtuzumab-mediated T-cell depletion remains stable even if cells are transferred to cell culture and is associated with the loss of further GPI-anchored surface molecules.

0147

CYCLOSPORINE DOSE INTENSITY IS A CRITICAL DETERMINANT OF OUTCOME AFTER A REDUCED INTENSITY ALLOGENEIC STEM CELL TRANSPLANT

C. Craddock, S. Nagra, P. Moss, M. Cook

Queen Elizabeth Hospital, BIRMINGHAM, UK

Background. The ability of allogeneic transplants performed using a reduced intensity conditioning (RIC) regimen to deliver long term disease free survival is dependent on the genesis of an immunologically mediated graft-versus tumor (GVT) effect. Post-transplant immunosuppression plays an important role in limiting graft-versus-host disease (GVHD) but also modulates a GVT effect. Cyclosporine A (CsA) is the most commonly utilised form of GVHD prophylaxis after a RIC allograft but its impact on transplant outcome has not been studied. *Aim.* We wished to examine the impact of CsA dose intensity on disease relapse and overall survival (OS) in patients transplanted using an alemtuzumab based RIC regimen. *Methods.* CsA exposure in the first 21 days post-transplant was measured in 132 patients and correlated with overall survival, and relapse risk. 68 patients were transplanted for a myeloid malignancy (acute myeloid leukemia (n=41), myelodysplasia (n=17)) and 74 for a lymphoid malignancy (Non-Hodgkin's lymphoma (n=51) or Hodgkin's disease (n=23)). All patients with a myeloid malignancy were transplanted using a regimen consisting of fludarabine, melphalan and alemtuzumab (FMA). Patients with an underlying lymphoid disease were transplanted using FMA (n=31) or a regimen consisting of BCNU, etoposide, cytosine arabinoside, melphalan and alemtuzumab (BEAMA) (n=43). 39 patients had chemoresistant disease at the time of transplant. All patients received intravenous CsA at a loading dose of 5 mg/kg on day -1 followed by 2.5 mg/kg b.i.d. Patients were switched to oral CsA prior to discharge. Trough CsA levels were measured thrice weekly for the first three weeks after stem cell infusion and the dose of CsA adjusted to achieve levels in the region of 200-300 μg/L during this period. Trough levels obtained during the first 21 days post-transplant were used to calculate the CsA area under the curve (AUC) for each patient. *Results.* 71 patients were transplanted from HLA identical siblings and 61 from volunteer unrelated donors. The median age of the whole group was 48 years (range 17-68). The incidence of acute GVHD (Grades 2-4) was 34%. The median CsA AUC in the first 21 days post-transplant was 3682 microg.hr/l (range 2162-8084). In univariate analysis the presence of chemoresistant disease at the time of transplant and a high CsA AUC were both associated with a decreased OS. In multivariate analyses chemoresistant disease (HR=2.60, 95% CI 1.44-4.65, p=0.002) and linearly increasing CsA AUC were associated with an increased hazard of death (HR=1.1, 95%CI 1.02-1.24, p=0.02). The two year OS for patients with a CsA AUC less than 3682 microg.hr/l was 77% compared to 30% for patients with CsA greater than 3682 microg.hr/l (p<0.0001). Increased CsA AUC and the presence of chemorefractory disease at the time of transplant were associated with an increased risk of relapse in univariate analysis. In multivariate analyses only increased CsA AUC was significantly associated with a higher risk of relapse (OR=4.1, 95% CI 2.50-6.81, p<0.0001). Decreased CsA AUC and the use of an unrelated donor were associated with an increased risk of acute GVHD in univariate analysis. Multivariate analyses demonstrated that the use of an unrelated donor (HR=2.9, 9%% CI 1.36-6.36, p=0.006) and linearly decreasing CsA AUC were significantly associated with an increased risk of acute GVHD (HR=1.2, 95% CI 1.05-1.43, p=0.01). *Conclusions.* These data identify CsA exposure as a critical and manipulable determinant of outcome after a T depleted RIC allograft. They support a randomised trial aimed at identifying the optimal CsA dose schedule in this population of patients. It will be important to determine whether post-transplant CsA exposure plays a similar role in determining outcome after a T replete RIC allograft.

0148

IMPACT OF MINOR HISTOCOMPATIBILITY ANTIGEN MISMATCHES ON GRAFT-VERSUS-HOST DISEASE IN NON-MYELOABLATIVE OR REDUCED INTENSITY ALLOGENEIC STEM CELL TRANSPLANTATION

C. Carniti,[1] F. Spina,[1] L. Farina,[1] A. Raganato,[1] A. Vendramin,[1] S. Di Terlizzi,[1] A. Dodero,[1] N. Frungillo,[1] P. Corradini[2]

[1]Istituto Nazionale dei Tumori, MILANO; [2]Istituto Nazionale dei Tumori - Università degli Studi di Milano, MILANO, Italy

Background. In a fully molecular HLA-matched setting, mismatches in minor histocompatibility antigens (mHAs) between donor and recipient might impact the incidence of graft-versus-host disease (GVHD) and transplant survival after allogeneic stem cell transplantation (alloSCT). *Aims.* The aim of this study was to assess whether mHAs mismatches could affect GVHD incidence (acute and chronic, aGVHD and cGVHD), overall survival (OS) and progression free survival (PFS) in patients undergoing alloSCT for lymphoid malignancies. *Methods.* Fifty-two consecutive patients who underwent alloSCT were studied. Nine patients had chronic lymphocytic leukemia (17%), 13 had Hodgkin's lymphoma (25%) and 30 had multiple myeloma (58%). All the patients received peripheral blood stem-cell allograft after non-myeloablative (11 patients, 21%) or reduced intensity (RIC, 41 patients, 79%) conditioning. GVHD prophylaxis included cyclosporine plus methotrexate or micomofetil fenolate. Median age was 51 years (range 17-65). Twenty-nine patients were male (56%) and the median number of previous chemotherapies was 3 (0-7). Nineteen patients were in complete remission (CR, 37%), 27 in partial remission (PR, 52%) and 6 had progressive disease (PD, 11%). Karnofsky performance status (PS) at transplant was >80% in 41 patients (79%). Forty patients were allografted from HLA-matched siblings (77%), 12 from matched unrelated donors (23%): all were matched at allelic level for HLA-A, -B, -Cw, -DRB1 and -DQB1 loci. Allelic mHAs typing was performed by PCR with sequence-specific primers for 14 autosomic mHAs and H-Y. OS and PFS were analyzed with Kaplan-Meier method and log-rank test. aGVHD and cGVHD were analyzed with a multivariate logistic regression model including as covariates age,

sex, disease diagnosis, PS and mHAs mismatches. Grade >=2 aGVHD and extensive cGVHD were considered events. *Results.* Median follow-up was 42 months (range 2-83). One-year OS was 83%, 2- and 3-years OS were 79% and 74%. One-year PFS was 58%, 2- and 3-years PFS were 47% and 43%. OS and PFS were significantly affected by disease status (CR vs PR vs PD, $p<0.001$ and $p=0.003$) and PS (≤80 vs. >80, $p<0.001$ and $p=0.001$). Donor-vs-recipient (DR) mHAs mismatches did not have a significant impact on OS and PFS. The presence of at least one DR mHAs mismatch and the number of DR mHAs mismatches correlated with aGVHD ($p=0.02$ for both). Broad DR and H-Y mHAs mismatches did not influence aGVHD ($p=0.49$ and $p=0.27$, respectively). A correlation of DR hematopoietic-restricted mHAs mismatches with aGVHD was found ($p=0.01$). DR LB-ADIR mHAs mismatches had a significant influence on aGVHD ($p=0.04$) whereas DR HA-1, HA-2 and HA-8 mHAs mismatches did not ($p=0.42$, $p=0.31$ and $p=0.33$, respectively). Recipient-vs-donor (RD) mHAs mismatches, as well as the other factors considered in multivariate model did not significantly influence aGVHD. DR mHAs mismatches had no impact on cGVHD incidence whereas the presence of at least one RD mHAs mismatch correlated with cGVHD ($p=0.02$). *Conclusions.* This study showed that in non-myeloablative and RIC setting mHAs mismatches may have a significant role in determining aGVHD. Assessing mHAs mismatches may be a useful tool to choose patient-specific GVHD prophylaxis in conditioning regimens and in post transplant follow-up.

CHARACTERIZATION OF T CELL RECEPTOR BETA REPERTOIRE IN T CELL POPULATION ASSOCIATED WITH GRAFT-VERSUS-HOST AND GRAFT-VERSUS-LEUKEMIA EFFECT

V. Foltankova,[1] E. Matejkova,[1] M. Bartos,[2] M. Dendis,[2] J. Mayer,[3] R. Hajek,[3] J. Michalek[1]

[1]Masaryk University, Faculty of Medicine, BRNO; [2]Genex CZ, BRNO; [3]Department of Internal Medicine Hematooncology, Masaryk Univeristy Hospital, BRNO, Czech Republic

Background. Graft-verus-tumor (GVT) effect of the donor T cells in hematopoietic stem cell transplantation (HSCT) is usually complicated by the ineligible alloreactivity of these T cells which leads to acute graft-versus-host (GVH) disease. GVT and GVH reactions are proved to be mediated by different T cell clones and can be distinguished by virtue of their T cell receptore β sequence. *Aims.* The objective of this study was to identify and characterize T cells clones with specific antitumor activity without mediating GVHD in T cell populations activated by leukemia and myeloma antigens. *Methods*. We have performed primary mixed leukocyte reaction (MLR) *in vitro* using patient non-leukemic irradiated peripherial blood mononuclear cells (PBMC) as stimulators and donor PBMC as responders. To prepare GVT specific T cells, activated alloreactive T cells were first selectively depleted with an anti-CD25 immunotoxin. Allodepleted T cells were then stimulated in secondary MLR using irradiated leukemia or myeloma cells from the same patient. Activated tumor-reactive cells were purified by immunomagnetic selection or by FACS based on INF-γ or CD25 expression, respectively. Clonotypic assay was used for identification of individual tumor-specific T cell clones. This highly sensitive assay is based on detailed analysis of T cell receptor β VDJ unique sequence (TCRB-VDJ). mRNA was extracted from sortred activated cells and cDNA synthetized by anchored reverse transcription. Target TCRB-VDJ gene sequence was amplified by anchor PCR and used to transform bacteria. Bacterial colonies were picked for plasmid isolation and subsequent direct automated sequencing of the TCRB-VDJ sequences. We assume that the frequency of particular TCRB-VDJ sequences among bacterial clones after transformation is proportional to the frequency of those sequences in the original population of T cells activated by GVH or GVT reaction. *Results.* We investigated the presence of individual antileukemic T cell clones in T cell populations derived from MLR using tumor cells from patients with acute myeloid leukemia (AML), chronic lymphatic leukemia (CLL) a and multiple myeloma, and defined them by the TCRB VDJ unique sequence. The sequences that occured in more than 10% bacterial colonies are likely to represent the most immunodominant clones. The immune responses against tumor cells were oligoclonal, i.e. we observed limited number of individual immunodominat clones which plays important role in GVT reaction. In first CLL patient who had undergone HSCT, six antileukemic T cell clones were identified, four of them are considered to be immunodominant. In second CLL patient after HSCT, just one highly immunodominat autileukemic T cell clone was observed. *Conclusions*. Clonotypic assay is highly sensitive method for characterization of immunodominant tumor reactive T cells and can be used as a marker for evaluation of adoptive cell immunotherapy by potential further monitoring of individual T cell clones in patients peripherial blood or tissue.

RETROSPECTIVE SINGLE CENTER ANALYSIS OF PENTOSTATIN FOR THE TREATMENT OF STEROID-REFRACTORY ACUTE GRAFT-VERSUS-HOST DISEASE

T. Schmitt, S. Dietrich, T. Luft, U. Hegenbart, A.D. Ho, P. Dreger

Universitätsklinikum Heidelberg, HEIDELBERG, Germany

Background. Clinically significant acute graft-versus-host disease (aGVHD) remains a major cause of morbidity and mortality in patients undergoing allogeneic stem cell transplantation. In particular, the outcome of those patients who have failed first line therapy with glucocorticosteroids is still poor. Preliminary reports suggested that pentostatin, a purine analogue inhibiting T-cell numbers and function, might be clinically effective with a mild and manageable spectrum of side effects. *Patients and Methods.* Here we report on our single center experience using pentostatin for patients with acute GVHD or overlap syndrome after failure of first line therapy with glucocorticosteroids. From 2005 to 2008, a total number of n=25 patients (out of 301 at risk) who had been treated with pentostatin for GVHD were identified and retrospectively analyzed. Diagnoses included acute lymphoblastic leukemia (ALL, n=2), acute myeloid leukemia/myelodysplastic syndrome (AML/MDS, n=14) and lymphoma/myeloma (n=9). Gender was well balanced (male n=13, female n=12) with a median age of 47 (23-64). All transplants were peripheral blood stem cells from matched siblings (n=8), matched unrelated (n=4) or mismatched donors (n=13). Predominantly, aGVHD affected the gastrointestinal tract (24/25) with grades being III (n=11) or IV (n=13). Subjects received 1 (n=16) to 2 (n=9) cycles of pentostatin (1 mg/m^2, days 1-3). *Results.* Patients with resolved diarrhoea and patients discharged from inpatient care were classified as complete responders (CR). Using this definition, a CR rate of 46% (11/24) was observed with a median time to response of 7 days (3-29). Toxicity was assessed by comparing WBC, platelets, serum bilirubin, ALAT, creatinine and CRP values immediate prior pentostatin and 7 days after the first dose. Whereas significant changes in WBC (median -1.9 G/L), platelets (median -35 G/L), creatinine (median +0.03 mg/dL) and CRP (median +2.9 mg/dL) did not occur, moderate increases in total bilirubin (median +2 mg/dl, $p=0.083$) and ALAT (median +38 U/L, $p=0.016$) were observed. The toxicity data is summarized in Table 1.

Table 1. Toxicity data.

Parameter	d0	d7	p
Leukocytes (G/l)	7.1 (1 - 43.6)	5.2 (0.5 - 42.1)	ns
Platelets (G/l)	64 (11 - 210)	29 (18 - 203)	ns
ALAT (U/l)	*50 (5 - 402)*	*88 (14 - 936)*	*.016*
Bilirubin (mg/dl)	*1.4 (0.4 - 13.9)*	*3.4 (0.3 - 20.6)*	*.083*
Creatinine (mg/dl)	0.78 (0.52 - 4.3)	0.81 (0.31 - 3.7)	ns
CRP (mg/l)	5.3 (0 - 185)	8.2 (0 - 274)	ns

Cytomegalovirus (CMV) reactivation after pentostatin was observed in 44% of patients at risk (8/18) after a median time of 8 days (3-11). 22% of subjects (4/18) suffered from CMV reactivation before pentostatin administration within a median time of 4 days (2-6). Patients failing to respond to pentostatin also failed to respond to further salvage therapies including MSCs, tacrolimus, basiliximab, rituximab and infliximab, resulting in an overall non-relapse mortality of 64%. 16% of subjects (4/25) relapsed and died because of their underlying malignant hemato-

logical disease, translating in an overall survival rate of 18% at 2 years. 3 out of 4 long-term survivors living disease-free (with a median of 886 [820-959] days after transplantation) suffer from extensive chronic GVHD. *Conclusions.* Pentostatin is a safe and simple to use therapy for glucocorticosteroid-refractory aGVHD showing response and outcome rates similar to other clinically used aGVHD salvage regimens. Given the high rate of non-relapse mortality and failure to respond to further second line therapies, we conclude that new therapeutic strategies are still needed.

0151

GENETIC MISMATCH IN GSTT1 IS ASSOCIATED WITH HEPATIC ACUTE GRAFT VERSUS HOST DISEASE (GVHD) IN ALLOGENEIC STEM CELL TRANSPLANTATION (ALLO-SCT)

I. Tallon-Ruiz

Hospital Virgen del Rocio, SEVILLA, Spain

Background. Glutathione S-transferase T1 (GSTT1) is a hepatic enzyme involved in drug metabolic phase II pathway. Twenty percent of Caucasian population and 60% of Asiatic population has a genetic variant of GSTT1, by which GSTT1 is deleted, the so called "null genotype", resulting in the absence of the enzyme. Our group has previously found that a specific antibody-mediated alloimmune response is triggered when a null GSTT1 recipient receives a GSTT1 positive liver graft. The potential influence of GSTT1 genotype on immunobiologic reactions in the liver after allo-SCT has not been studied yet. *Aims.*We analyzed the association of GSTT1 genetic variants with the incidence of hepatic acute GVHD in 40 patients undergoing allo-SCT. *Methods and Results.* Transplants were performed in a single institution, donors were HLA identical siblings and all patients received myeloablative-conditioning regimen. All donor and recipient pairs were Caucasians. Median follow-up was of 75 months (range, 2-171 months). GSTT1 variants were analyzed, by PCR method, in 40 patients and donors. Of them, 3 pairs were null GSTT1 donor (donor -) and positive GSTT1 recipient (recipient +) (Group 1), 8 pairs were positive GSTT1 donor and null GSTT1 recipient (Group 2), 18 pairs were positive GSTT1 donor and positive GSTT1 recipient (Group 3), and 9 pairs were null GSTT1 donor and null GSTT1 recipient (Group 4). Results of the association of GSTT1 genotype and hepatic acute GVHD was as shown in Table 1 (attached). *Conclusions.* Genetic mismatch in GSTT1 between donors and recipients has a strong association with hepatic acute GVHD. This could help in the differential diagnosis of hepatic alterations after allo-SCT.

Table 1.

SECONDARY PROPHYLAXIS OF INVASIVE FUNGAL INFECTIONS IN ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANT RECIPIENTS: A RETROSPECTIVE STUDY OF 73 CASES AT A SINGLE INSTITUTION

F. Liu

Beijing Daopei Hospital, BEIJING, China

Background. Invasive fungal infections (IFI) remain a major cause of infection-related mortality following hematopoietic stem cell transplantation (HSCT). Transplanted recipients with a history of IFI are at a high risk for developing recurrent fungal infection. *Aims.*In the present retrospective clinical study, we evaluated the efficacy of secondary prophylaxis (SP) with different antifungal agents in allogeneic HSCT patients with a previous history of IFI. *Methods.* Seventy-three patients with hematological malignancies were enrolled in this study: the median age was 27(5-59) years. There were 50 males and 23 females. Many of them had high risk diseases, such as the second/third remission in 15 cases and refractory/relapse leukemia in 16 patients. Donor origins were from haploidentical (n=36), unrelated (n=19) or identical sibling (n=18). The previous diagnosis of IFI was made according to European Organization for Research and Treatment of Cancer/Mycoses Study Group (EORTC/MSG) criteria. Median time from diagnosis of IFI to HSCT was 85 (14-575) days. All patients received SP from the beginning of conditioning. Patients were divided into two groups according to different prophylaxis agents: In narrow-spectrum group, patients received fluconazole (n=24); in broad-spectrum group, patients received voriconazole/itraconazole/caspofungin or micafungin (n=49). Broad-spectrum agents were changed to fluconazole at a median 58 (14~120) days after stem cell transfusion when patients were without any signs of active fungal infections. Prophylaxis was continued until the withdrawal of immunosuppressants. Recurrent fungal infection was evaluated at 30 and 100 days after stem cell transfusion. *Results.* Log-rank analysis revealed that at day +30 the recurrent IFI rates were 25%, 12.4% in narrow-spectrum group and broad-spectrum group respectively, without significant difference (p=0.161). At day +100, however, patients in narrow-spectrum group developed much higher proportion of IFI recurrence compared with those in broad-spectrum group (41.7% versus 18.3%, p=0.035). In the broad-spectrum group, the day +100 recurrent IFI rates were 0/10 (0%) in voriconazole group, 6/24 (25%) in itraconazole group, 2/7 (28.5%) in caspofungin or micafungin group and 1/8 (12.5%) in the group who received caspofungin or micafungin during conditioning and then switched to voriconazole there after. Recurrent IFI developed in only one patient within 7 days after the change from broad-spectrum agents to fluconazole. At a median follow-up of 285 (18-1426) days, there were 53 patients alive with disease free, one alive with tumor and 19 died, but only 5 of them were died of severe fungal infection. The overall mortality rate was 26% and the fungus-related mortality was only 6.8%. Other reasons of death were relapse of original disease (n=8), severe GVHD (n=4), virus infection (n=1) and acute heart failure (n=1). Better overall survival rate (79.2%) was seen in broad-spectrum group compared with that in narrow-spectrum group (69.4%) without significant difference (p=0.285). *Conclusions.* History of IFI is not a contraindication to HSCT, SP by broad-spectrum antifungal agents can significantly reduce the incidence of recurrent IFI in allogeneic HSCT recipients.

0153

NATURAL KILLER CELL NUMBERS POST STEM CELL TRANSPLANT ARE STRONGLY ASSOCIATED WITH DONOR CHIMERISM AND ARE INCREASED FOLLOWING UMBILICAL CORD STEM CELL TRANSPLANT

U.A. Khan,[1] O. Najam,[1] A. Bastih1, R.W. Critchley,[1] N. Yonan,[2] J. Fildes,[1] R. Wynn[3]

[1]The Transplant Centre, MANCHESTER; [2]Wythenshawe Hospital, MANCHESTER; [3]Royal Manchester Children's Hospital, MANCHESTER, UK

Background. Full donor chimerism (FDC) with disease eradication is achieved following haemopoietic stem cell transplantation (HSCT). However the utility of HSCT is limited by loss of FDC with returning host haempoiesis - mixed donor chimerism (MDC) - and disease relapse. The use of umbilical cord blood (UCB) as a donor cell source in HSCT is associated with higher rates of FDC and potentially with improved disease control compared with bone marrow (BM) or peripheral blood (PB) as donor cell sources. *Aims.* We proposed that these differences in rates of FDC reflect natural killer (NK) activity of engrafting tissue. We compared NK cell numbers following SCT in patients with FDC and MDC transplant recipients and NK cell numbers in UCB recipients compared with BM and PB recipients. *Methods.* Peripheral blood from 50 paediatric HSCT patients was characterised via flow cytometric analysis of CD16 and CD56. Chimerism levels were assigned following short tandem repeat (STR) analysis of fluorescently labelled STR alleles; D3S1358, D5S818, THO1, D7S820, D12S391, FGA, D18S51 and Penta E. Analysis was of NK cell numbers in UCB vs. BM/PB recipients and FDC vs. MDC patients. *Results.* NK cells were significantly increased in the peripheral blood of patients with FDC compared to MDC (p=0.036). There was also a highly significant elevation of NK cells in patients transplanted with UCB in comparison to BM (p<0.001). *Conclusions.* The highly significant elevation of NK cells in patients with FDC and those transplanted with CB may indicate a role for them in successful donor engraftment. The use of NK cells to achieve FDC and eradication of pathological host cells may be an avenue for increasing the success of HSCT, without requiring intensity of conditioning or use of Graft versus Host Disease to eradicate host cells. The success of UCB in establishing FDC might reflect cord NK cell activity.

0154

ASSOCIATION BETWEEN PLASMA LEVEL CHANGES OF ENDOTHELIAL INJURY MARKERS AND GRAFT VERSUS HOST DISEASE IN PATIENTS TREATED WITH ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANTATION

A. Czyz, A. Anna, A. Blazejczak, E. Hanszke, D. Dytfeld, K. Zawilska, M. Komarnicki

University of Medical Sciences, POZNAN, Poland

Background. The endothelial injury caused by conditioning regimen is thought to play a central role in the activation of immune system and to precede non-infectious complications of vascular origin and graft versus host disease (GVHD). The aim of the study was to evaluate a possible correlation between the changes of plasma endothelial injury markers and the occurrence of GVHD after alloHSCT. Patients and mthods: Plasma levels of von Willebrand factor antigen (vWF Ag), trombomodulin (TM) and vascular endothelial growth factor (VEGF) were measured by immunoassay tests in 31 pts transplanted with allogeneic stem cells after myeloblative (18 pts) or reduced-toxicity (13 pts) conditioning regimen for AML (15 pts), ALL (9 pts), CML (6 pts) and AA (1 patient). Endothelial injury markers were measured before conditioning regimen (day -10), on the day of stem cells infusion (day 0) and on the day +10 and +30 after alloHSCT. *Results.* The concentration of vWF Ag increased significantly on the day +10 and +30 in comparison to the day -10 in all patients, whether or not GVHD occurred. The TM levels increased on the day +30 in comparison to the pretransplantation level (p=0.043) in the group with chronic GVHD (cGVHD), and no changes of TM levels were observed in the group of pts that did not develop cGVHD. The TM levels increased also on the day +30 in comparison to the pretransplantation level (p=0.016) in the group with acute GVHD (aGVHD) II-IV. No changes of TM levels were observed in the group of pts with aGVHD 0-I. VEGF level did not change significantly after transplantation in any group of pts. The concentration of plasma endothelial injury markers levels however did not differ significantly between group of pts with and without cGVHD, nor between group of pts with aGVHD II-IV and with aGVHD 0-I. *Conclusions.* vWF Ag is a sensitive endothelial injury marker, but not specific enough to assist in the early detection of GVHD. Our findings on a limited number of pts suggest that TM level increase may predict the occurrence of chronic GVHD after allogeneic HSCT, but it increases not early enough to precede aGVHD symptoms. Further studies with a larger group of patients and measurement of a broader panel of endothelial injury markers are necessary to evaluate the potential role of these markers as GVHD predictors after allogeneic HSCT.

0155

HUMAN MESENCHYMAL STROMAL CELLS EXPANDED WITH HUMAN PLATELET LYSATE ARE SAFE AND EFFECTIVE FOR THE TREATMENT OF STEROID-REFRACTORY GRAFT VERSUS HOST DISEASE

C. Capelli,[1] M. Introna,[1] C. Micò,[2] A. Algarotti,[2] A. Grassi,[2] A. Salvadè,[3] G. Gaipa,[3] D. Belotti,[3] P. Perseghin,[3] G. D'Amico,[3] A. Rovelli,[3] A. Balduzzi,[3] J. Golay,[1] A. Biondi,[3] A. Rambaldi,[2] E. Biagi[3]

[1]Lab.Cellular Therapy G.Lanzani, BERGAMO; [2]USC Hematology, Ospedali Riuniti di Bergamo, BERGAMO; [3]Division of Pediatrics, Ospedale San Gerardo, MONZA, Italy

Background. Very recently, encouraging results indicate that third party human Mesenchymal Stromal Cells (hMSCs) are a therapeutic tool for the treatment of severe steroid resistant acute graft versus host disease (aGVHD). We have established a highly efficient protocol for *in vitro* expansion, under strict GMP compliance, of bone marrow derived hMSCs using human platelet lysate (hPL) in place of FBS. In this study, upon Ethical Committee approval and patient's informed consent, hMSCs were administered on a compassionate basis for the treatment of refractory GVHD. *Methods.* hMSCs were prepared from third party HLA-mismatched healthy donors using washouts of bags and filters of normally discarded bone marrow collection sets left over at the end of the filtration of the bone marrow explants performed for hematopoietic stem cell (HSC) transplantation. Cells were grown in the presence of α-MEM with 5% hPL. In a short period of time (10-33 days), low density seeding of unmanipulated cells (100-200/cm^2), obtained from 7 bone marrow harvests, allowed to prepare large quantities of hMSCs, with only one *in vitro* passage. *Results.* 4 adults and 1 pediatric patients were treated for aGVHD (grade III-IV) and 1 adult and 2 pediatric patients for extensive chronic GVHD (cGVHD), using 18 hMSCs certified bags. Before hMSCs, second or third line treatments had been given to patients with aGVHD, including Etanercept (n= 4), Mycophenolate Mofetil (MMF, n= 3) and Extracorporeal Photopheresis (ECP, n= 2). Patients with cGVHD were previously treated with ECP (n=3), MMF (n=3), Imatinib (n=1), Rituximab (n=1) and Etanercept (n=2). Each infusion contained a median dose of 1x10^6/kg (range 0.7-1.2x10^6) hMSCs. As far as concerns patients with aGVHD, a single infusion was performed in the pediatric patient, while from 1 to 4 infusions were performed in 4 adult patients. The 3 patients with cGVHD received from 1 to 5 infusions. All infusions were very well tolerated with no immediate or late adverse events according to WHO common criteria. Among pediatric patients, 3/3 complete responses were registered. A complete response was observed in 1 adult with grade III cutaneous aGVHD, although the patient rapidly relapsed and died of leukemia progression. Three partial responses were observed in 3 adults, while only one adult showed no response and died of progressive grade IV gut and liver aGVHD. *Conclusions.* These data show that large numbers of third party hMSCs can be expanded *in vitro* with hPL-containing medium. Moreover, the clinical results and the toxicity profile confirm those reported with hMSCs expanded in FBS containing media.

HIGH CYTOMEGALOVIRUS -SPECIFIC CD8+ TEMRA CONTENT IN DONOR GRAFT PREDICTS A LOW RISK OF CMV REACTIVATION FOLLOWING UNMANIPULATED ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

H. Xiao-Jun, X.H. Luo

Peking University People's Hospital & Peking University Institute of Hematology, BEIJING, China

Background. Cytomegalovirus (CMV)-specific CD8$^+$ T cells (CTLCMV) are instrumental to protect against HCMV relapse and disease in human. *Aims.*To determine whether CTLCMV and its subsets in allogeneic stem cell transplantation (allo-HSCT) ameliorate CMV reactivation after transplantation. *Methods.* We phenotypically quantitated the absolute numbers of CTLCMV in 64 related donor unmanipulated allografts infused into HLA-matched/HLA-mismatched recipients and examined the incidence of CMV reactivation in respective recipients. High CTLCMV with TEMRA (CD45RO$^-$ CD62L$^-$) phenotype in the donor graft was associated with a reduced risk of CMV reactivation. We monitored CTLCMV during immune reconstitution in 44 patients with malignant hematologic disorders. *Results.* Early after SCT, there was a significant expansion in CTLCMV TCM (CD45RO$^+$ CD62L$^+$) compart-

ment when CMV reactivated. The frequency of CTLCMV TCM and CTLCMV TEMRA early post SCT (day 90, day 60, respectively) was higher in transplant recipients with more CTLCMV TEMRA infused, suggesting protective immunity transferred by infusion of CTLCMV within allografts. Our findings suggest that CTLCMV TEMRA content in donor graft may predict for risk of CMV reactivation early after SCT, which is closedly correlated with the immune reconstitution and differentiation of CTLCMV subsets. *Conclusions.* Our data suggest that determining the CTLCMV TEMRA levels in the donor and manipulating CTLCMV TEMRA cells at or early after transplantation may provide a new approach to controlling CMV reactivation. Address for Correspondence.

PROPHYLAXIS WITH MYCOPHENOLATE MOFETIL AND CYCLOSPORINE CAN DECREASE THE INCIDENCE OF SEVERE ACUTE GRAFT-VERSUS-HOST DISEASE FOLLOWING REDUCED INTENSITY CONDITIONING ALLOGENEIC STEM CELL TRANSPLANTATION (ALLO-SCT) FROM MATCHED UNRELATED DONORS

E. Brissot,[1] P. Chevallier,[2] J. Delaunay,[2] T. Guillaume,[2] S. Ayari,[2] V. Dubruille,[2] B. Mahe,[2] S. Le Gouill,[2] T. Gastinne,[2] N. Blin,[2] P. Moreau,[2] J.L. Harousseau,[2] M. Mohty[2]

[1]Department of Hematology-Hotel Dieu, NANTES; [2]Department of Hematology, NANTES, France

The use of reduced intensity conditioning (RIC) regimens for allo-SCT can result in a significant decrease in early procedure-related toxicity in patients not eligible for standard myeloablative regimens. However, acute graft-versus-host disease (GVHD) remains a matter of concern after RIC allo-SCT, especially in the context of matched unrelated donors (MUD). Indeed, the rapidly increasing use in elderly and high risk patients and evolving nature of RIC allo-SCT, emphasize the need for renewed clinical research of GVHD prophylaxis. This pilot report investigated mycophenolate mofetil (MMF) and cyclosporine (CsA) combination in comparison to CsA alone for GVHD prophylaxis in 35 consecutive patients with hematological malignancies receiving RIC allogeneic stem cell transplantation (allo-SCT) from a MUD, and treated within the same period in a single institution. In this series, the median age was 52 (range, 6-64; 20 males). The RIC regimen included fludarabine, busulfan and ATG in all patients (with minor adjustments in 3 patients). The first patients from this series (n=19; group I) received CsA alone for GVHD prophylaxis. The next patients (n=16; group II) received CsA and MMF. Mycophenolate mofetil (MMF) was given at a fixed oral dose of 1 g x 2/day without any treatment adjustment. The two groups had no significant differences as for demographic and disease features, GVHD risk factors, and allo-SCT procedure characteristics (except for GVHD prophylaxis). 31 patients (89%) received a 10/10 HLA matched graft at the allelic level. One allelic mismatch was observed in 4 cases, with this being comparable between both groups. 3 patients from this series did not engraft (early disease recurrence) and were not evaluable for acute GVHD. ANC >500/µL was achieved at a median of 19 (range, 0-27) days. The cumulative incidence of grade 2-4 acute GVHD at day 100 was 67% (95%CI, 45-89%) in patients receiving CsA alone as compared to 53% (95%CI, 28-78%) in those receiving the CsA and MMF combination (p=NS). However, the cumulative incidences of grade 3-4 acute GVHD was significantly lower in the "CsA+MMF" group (13%) as compared to 56% in the "CsA" group (p=0.03). After a median follow-up of 19.5 (range, 9-93) months for surviving patients, the one year overall survival was significantly higher in the "CsA+MMF" group (81% vs. 47%; p=0.03). Overall, 4 deaths were attributed to refractory acute GVHD in the "CsA" group versus none in the "CsA+MMF" group. Though a randomized trial is needed before drawing final conclusions, this pilot study suggests that adjunction of MMF to CsA can result in a significant reduction of the incidence of severe acute GVHD following ATG-based RIC allo-SCT using MUD, and this may have a significant impact on the probability of a favorable outcome.

Stem cell transplantation – autologous, DLI, miscellaneous

DONOR LYMPHOCYTE INFUSIONS FOR CHRONIC MYELOID LEUKAEMIA RELAPSING AFTER ALLOGENEIC STEM CELL TRANSPLANT: PROGNOSTIC FACTORS FOR A 'PURE' GVL EFFECT ARE DIFFERENT ACCORDING TO THE STAGE OF RELAPSE

C. Guglielmi,[1] S. Iacobelli,[2] J. Apperley,[3] D. Bunjes,[4] P. Jacobs,[5] H.-J. Kolb,[6] P. Ljungman,[7] E. Olavarria,[3] A. Schattenberg,[8] A. Van Biezen,[2] L. Verdonck,[9] T. de Witte[10]

[1]Università di Roma La Sapienza, ROMA, Italy; [2]Chronic Leukemia Working Party, LEIDEN, Netherlands; [3]Hammersmith Hospital, LONDON, UK; [4]Universitätsklinikum, ULM, Germany; [5]Constantiaberg Medi-Clinic, CAPE TOWN, South Africa; [6]Klinikum Grosshadern, MUNICH, Germany; [7]University Hospital, STOCKHOLM, Sweden; [8]Radboud University, NIJMEGEN, Netherlands; [9]Erasmus MC-Daniel den Hoed Cancer Centre, ROTTERDAM, Netherlands; [10]Radboud University - NMC, NIJMEGEN, Netherlands

Patients (pts) with chronic myelogenous leukemia (CML) relapsing after allogeneic stem cell transplant (SCT) may achieve a molecular remission (MR) with transfusions of donor lymphocytes (DLI), whenever relapse occurs in stable chimera. CML relapse may be diagnosed at molecular, cytogenetic and clinico-hematological level, bringing to an extreme heterogeneity of patient/disease status when treatment with DLI is applied. This is even more complex nowadays with the availability of TK inhibitors, capable to restore MR in some pts without the risk of secondary graft versus host disease (GvHD2), but with unknown effects on responsiveness to subsequent DLI. Infact CML response to DLI is frequently, but not always, accompanied by GvHD2. Thus physicians and/or pts may initially prefer to use pills rather than donor cells. We aim to provide information that may be used to select when treatment of CML relapse with DLI can be *optimal* (i.e. achievement of a prolonged survival and a durable MR without GvHD2). Five-hundred pts treated with DLI for CML relapse (not in blast crisis) before 2004 at 68 EBMT centres were retrospectively analyzed: 73% had an HLA-identical sibling donor, 27% unrelated. DLI was given at time of cytogenetic and/or molecular relapse (MoCyRel) (n=230), or at haematological relapse (HemRel) (n=270). DLI was given either in single (58%) or multiple (42%) infusions. Median initial cell dose (ICD)(T cells/Kg given at 1st DLI) was 1×10^7 for MoCyRel (range 0.001-31) and 4×10^7 for HemRel (range 0.01-36). 340 pts (68%) achieved a MR in a median of 7.5 months, 44% had GvHD2 in a median of 3 months, 16 pts recurred at a median of 19 months. Actuarial probability of being alive in MR without GvHD2 was 29% at 5 years: 40% in MoCyRel, 20% in HemRel ($p<0.001$). Thus prognostic factors for survival in MR without GvHD2 were analyzed separately according to the type of relapse. Factors into analysis (i.e. logrank test and logistic regression) were: patient age at DLI, donor type, donor sex, sex mismatch with the donor, phase at SCT, stem cell source, T-depletion, TBI in conditioning, GvHD prior to DLI, interval from SCT to DLI, ICD, and the stage of relapse at time of DLI (i.e. molecular, cytogenetic, chronic phase, accelerated phase). Results in MoCyRel: interval from SCT to DLI <1yr (HR 2.2, 95CI: 1.5-3.2, $p<0.001$) and a history of chronic GvHD prior to DLI (HR 1.8, 95CI: 1.3-2.5, $p=0.001$) were independent adverse prognostic factors; 48%, 41%, and 11% had 0, 1,and 2 adverse features, respectively. Survival in MR without GvHD2 at 5 years improved from 0%, 31%, to 65% in pts with 2, 1, and 0 adverse features, respectively. Results in HemRel: sex mismatch with the donor (HR 1.6, 95CI: 1.1-2.4, $p=0.01$), history of chronic GvHD prior to DLI (HR 1.7, 95CI 1.2-2.5, $p=0.006$), and ICD $>5\times10^7$/Kg (HR 1.8, 95CI: 1.2-2.7, $p=0.002$) were independent adverse prognostic factors; 17%, 40%, 33%, and 9% had 0, 1, 2, and 3 adverse features, respectively. Survival in MR without GvHD2 at 6 years improved from 0%, 17%, 33%, to 37% in pts with 3, 2, 1, and 0 adverse features, respectively. We conclude that: [a] the chance of durable remission without GvHD2 was higher when DLI is given at MoCyRel than at HemRel; [b] the chance of exploiting the *pure GvL effect* was as high as 65% when DLI were given beyond 1 year from SCT for a MoCyRel that was not preceded by cGvHD.

0159

EFFICACY OF RITUXIMAB AND DONOR LYMPHOCYTE INFUSIONS AS SALVAGE TREATMENT IN LYMPHOMA PATIENTS RELAPSED AFTER REDUCED INTENSITY ALLOGENEIC STEM CELL TRANSPLANTATION

F. Spina,[1] L. Farina,[1] V. Montefusco,[1] C. Carniti,[1] S. Piva,[1] M. Morelli,[1] P. Corradini[2]

[1]Istituto Nazionale dei Tumori, MILANO; [2]Istituto Nazionale dei Tumori - Università degli Studi di Milano, MILANO, Italy

Background. Patients with lymphoma who relapse after allogeneic stem cell transplantation (alloSCT) have a dismal prognosis. Salvage treatment is not standardized and the role of Rituximab and donor lymphocyte infusions (DLI) has not been clearly assessed yet. *Aims.* The aim of the study was to evaluate whether DLI may improve progression free survival (PFS) and overall survival (OS) compared to other salvage regimens in patients with non-Hodgkin's (NHL) and Hodgkin's (HL) lymphoma relapsed after alloSCT. We also aimed to assess whether Rituximab associated with DLI could further improve survival outcomes. *Methods.* Seventy-eight consecutive patients allografted between 2000 and 2007 were reviewed. Patients were affected by indolent NHL (23, 29%), aggressive NHL (38, 49%) or HL (17, 22%). All the patients were allografted after a reduced-intensity conditioning (RIC) from HLA-matched siblings (49, 63%) or matched unrelated donors (29, 37%). Thirty-five patients relapsed after allograft (45%). Median age of relapsed patients was 45 years (range 19-63). Eleven patients had indolent NHL (31%), 16 aggressive NHL (46%), 8 HL (23%). All relapsed patients underwent salvage treatment: 17 (49%) received chemotherapy and DLI (median of 2 DLI, range 1-4), 18 (51%) chemotherapy alone. Nine patients could not receive DLI because of GVHD. Fourteen patients (40%) received Rituximab as part of the salvage regimen, 11 (31%) were treated with Rituximab and DLI. Survival was calculated from relapse to death (OS) or to second relapse or death (PFS) with Kaplan-Meier method applying log-rank test. Cumulative incidence (CI) of relapse was estimated with CI method with competing risks and Gray's test. Multivariate analysis was done with Cox models. *Results.* Median follow-up from relapse after alloSCT was 15 months (range 1-104). One- and 2-year PFS was 34% and 31%, respectively. One- and 2-year OS was 54% and 45%, respectively. Patients who received DLI had a better PFS ($p=0.04$, HR=0.44 [CI95%=0.1-1.0]) compared to patients who did not. The combination of Rituximab and DLI improved both PFS ($p=0.007$, HR=0.25 [CI95%=0.08-0.75]) and OS ($p=0.001$, HR=0.07 [CI95%=0.01-0.5]). CI of relapse was 38% at 1 and 2 years. Rituximab and DLI significantly reduced CI of relapse ($p=0.03$) compared to all the other salvage treatments. Seven out of 17 patients (41%) who received DLI developed aGVHD (grade>=2 n=5), while 5 patients (29%) developed cGVHD (extensive n=1). GVHD after DLI did not affect PFS and OS ($p=0.9$ and $p=0.8$ respectively). In patients who received DLI, the association with Rituximab significantly improved both PFS ($p=0.008$, HR=0.20 [CI95%=0.05-0.74]) and OS ($p<0.001$, HR=0.06 [CI95%=0.01-0.52]) compared to DLI alone. Multivariate analysis, which included the salvage treatment (DLI+Rituximab vs other) and disease (HL vs aggressive NHL vs indolent NHL), confirmed that DLI and Rituximab significantly improve both PFS ($p=0.03$, HR=0.28 [CI95%=0.09-0.88]) and OS ($p=0.01$, HR=0.06 [CI95%=0.01-0.54]) regardless of lymphoma subtype. *Conclusions.* The results show that DLI can improve PFS of lymphoma patients relapsed after RIC alloSCT. The use of Rituximab prior to DLI can further improve PFS and OS, suggesting that this strategy may be the optimal salvage treatment in this setting.

ACUTE LUNG INJURY AFTER ALLOGENEIC HEMTOPOIETIC STEM CELL TRANSPLANTATION IS ASSOCIATED WITH INFERIOR SURVIVAL - A RANDOMIZED TRIAL ON THE EFFECTS OF EARLY NON-INVASIVE VENTILATION

M. Wermke,[1] G. Höffken,[2] G. Ehninger,[2] M. Bornhäuser,[2] T. Illmer[2]

[1]University Hospital Dresden, DRESDEN; [2]Medical Clinic I University Hospital Dresden, DRESDEN, Germany

Background and Aims. The prognosis of patients suffering from respiratory failure after allogeneic stem cell transplantation is still poor. Recent data suggested beneficial effects of non-invasive ventilation (NIV) in this setting. We therefore initiated a randomized trial to prove the impact of early NIV in patients in the early posttransplant period. *Patients and Methods.* 526 patients undergoing allogeneic hematopoietic stem cell transplantation in a single center were investigated for signs of acute lung injury (ALI) as defined by either an oxygenation index <300, a breath-

ing rate >25/min or a continuous decrease in oxygen saturation below 92%. Patients with the diagnosis were randomly assigned to either a conservative treatment arm A (oxygen supply only) or an intensified treatment arm B (oxygen + intermittent NIV). *Results.* ALI had to be diagnosed in 86 patients after transplantation (16%). Determination of oxygenation index using capillary blood gas analysis was found to be early predictor of ALI even in the absence of clinical signs of respiratory distress. In a multivariate analysis higher age at transplant and the use total-body-irradiation (TBI) of 8 Gy or more were indentified as risk factors for ALI. Irrespectively of randomization to a treatment arm in multivariate analyses ALI turned out to be an independent risk factor for both 100 day mortality (OR 2.76; $p<0.001$) and long term survival (OR 1.57; $p<0.01$). Although early NIV tended to be associated with a lower incidence of treatment failure (39% in arm A vs. 24% in arm B, $p=0.17$), neither ICU admission rate, nor need for intubation or survival parameters were affected by the treatment strategy. *Conclusions.* The occurence of ALI in the early postransplantation period is an important negative prognostic factor for patients undergoing hematopoietic stem cell transplantation. Oxygenation index is an early and sensitive indicator of respiratory distress. Early intervention by NIV failed to improve prognosis of the patients. The limited impact of NIV may be related to the design of the study allowing for switching of the treatment arm in case of unsatisfactory efficacy.

0161

THERAPEUTIC DRUG MONITORING IS AN IMPORTANT FACTOR DURING IV BUSULFAN TREATMENT

R. Malär,[1] M. Hassan,[2] T. Güngör[3]

[1]Childrens Hospital Zürich, ZÜRICH, Switzerland; [2]Karolinska University Hospital Huddinge, 141 86 STOCKHOLM, Sweden; [3]University children's hospital, ZÜRICH, Switzerland

Hematopoietic stem cell transplantation (HSCT) is increasing rapidly as a curative treatment for several malignant and non malignant disorders. More than 40% of patients undergoing HSCT are conditioned using chemotherapy including busulfan. Intravenous busulfan is a myeloablative chemotherapeutic drug which is increasingly used in numerous pediatric conditioning protocols for pediatric hematopoietic stem cell transplantation (HSCT). Between 2006 and 2008, we performed therapeutic drug monitoring of intravenous busulfan in 26 pediatric HSCT patients (age 5 mo - 23 yrs; medium 7 yrs), with n = 8/18 malignant/non-malignant diseases and n = 10/11/2/3 MSD/MUD-MMUD/MMRD/ autologous transplants. In order to optimize the targeted drug exposure and to minimize drug-related toxicity, a modified administration protocol was used. Intravenous busulfan was administered twice daily in a 4-hour infusion according to company-recommended weight-based doses and busulfan drug level measurements were performed after ‘O, ‘30, ‘60, ‘120, ‘240 and ‘360 minutes post infusion. Pharmacokinetic analysis was performed and the kinetic parameters were calculated for eventual dose adjustments. The targeted busulfan exposure was aimed to range between areas under the curve (AUC) of 9’000 - 14’000 ng/mLxh. In 18/26 patients (69%) the busulfan dose had to be adjusted at least once. In 13/18 patients (72%), the dose had to be increased in a range of +7 to +20% while in 5/18 patients (28%), the dose had to be lowered by -8 to -20%. The need of dose adjustment was not related to weight, age or underlying disease. Non-engraftment was observed after one CD34-positively selected haploidentical HSCT in an infant with T-,B-,NK+ SCID with no busulfan adjustment despite a low AUC of 6676 ng/mLxh. Hepatic veno-occlusive-disease (HVOD) was not observed in patients with >12 kg body weight, while 5/8 infants <12 kg developed mild to moderate VOD responding positively to defibrotide therapy. All HVOD patients had received a conditioning comprising cyclophosphamide. Two patients with Wiskott Aldrich syndrome (9 mo and 18 yrs) died before day +100 due to CMV infection/pulmonary hypertension and fulminant cryptosporidium-induced pancreatitis, respectively, with no signs for pulmonary or hepatic veno-occlusive disease or other busulfan-associated toxicity at autopsy. In 23/26 patients (88%) receiving our protocol, no events of transplant related mortality or transplant rejection were observed. Combined pharmacokinetic assessments and dose-adjustments of i.v. busulfan are essential for further improvement of efficacy and safety of busulfan-based myeloablative conditioning protocols in pediatric HSCT recipients.

0162

TOTAL BODY IRRADIATION AND THIOTEPA AS CONDITIONING TO AUTOLOGOUS STEM CELL TRANSPLANTATION IN PATIENTS WITH FOLLICULAR LYMPHOMA

M. Capponi, F. Falzetti, L. Flenghi, M. Di Ianni, P. Minga, F. Falcinelli

Istituto di Ematologia, PERUGIA, Italy

Background. Patients with follicular lymphoma can potentially be cured by supralethal chemo- radio- therapy followed by autologous stem cell transplantation (ASCT). This approach is however associated with an increased risk of transplant related mortality (TRM) and second neoplasms. *Aims.* To assess TRM and the incidence of late complications after a total body irradiation (TBI)-based conditioning regimen for ASCT in patients with follicular lymphoma. *Methods.* Between February 1992 and December 2005, 63 patients were recruited to the study (38 males, 25 females, age range 28-60 years; median age 47 years). Disease stage at diagnosis was advanced in 53 patients (clinical stage III in 12, clinical stage IV in 41); B symptoms were present in 15; 47 patients had undergone first-line therapy and 14 two lines of therapy before ASCT; 19 patients had received also rituximab. At the time of transplant 34 patients were in complete remission (CR), 20 were in partial remission (PR), 4 had achieved very good partial remission, 3 were refractory to chemotherapy and 2 were in relapse. Conditioning to ASCT included single fraction 8 Gy TBI at high dose rate with lung shielding followed by Thiotepa 5 mg/Kg/day for two days. Graft content was as follows: $CD34^+$ cells: 9.1×10^6/Kg (range 2.0 -23.5×10^6); $CD34^+$ cells were purged by positive selection in 23/63 patients. *Results.* All patients engrafted with good haematological reconstitution. Short term complications included 2 fatal cases of interstitial pneumonia, 1 case of VOD which quickly resolved, 1 case of renal failure which became chronic. TRM was 3.1%. Major long term complications included one bladder cancer after 2 years and one breast cancer after 6 years with both patients surviving after surgery and chemotherapy. At a median follow-up of 6.7 years (range 0.21-16.7 years) 52/63 patients survive and 44/63 were in complete remission. Three year overall survival (OS) and event free survival (EFS) rates were respectively 90% and 79%; projected 5-year OS and EFS rates were respectively 87% and 73%. Disease status at transplant was a significant prognostic factor for EFS ($p=0.007$ CR vs PR; Cox multivariate analysis: $p=0.047$), as was time from diagnosis to transplant. Patients who received rituximab before ASCT tended to have better EFS. *Summary and Conclusions.* Single fraction 8 Gy TBI at high dose rate plus thiotepa as conditioning to autologous transplantation for patients with follicular lymphoma is feasible with low TRM and low incidence of second neoplasms. OS and EFS rates were similar or even better in respect of other reportes of autologous transplantations.

In memory of Prof Antonio Tabilio, close friend and colleague, eminent physician and scientist.

0163

RECOMBINANT HUMAN GRANULOCYTE COLONY-STIMULATING FACTOR SIGNIFICANTLY DECREASES THE EXPRESSION OF CXCR3 AND CCR6 ON T CELLS AND PREFERENTIALLY INDUCES TH CELLS TO A TH17 PHENOTYPE IN PERIPHERAL BLOOD HARVESTS

L.X. Sun, H.Y. Ren

Peking University First Hospital, BEIJING, China

Backgroud. Neither the incidence nor the severity of acute graft-versus-host disease (GVHD) is higher than with marrow transplantations, although recombinant human granulocyte colony-stimulating factor (rhG-CSF)-mobilized peripheral blood harvests contain many more mature T cells. However, these mechanisms are not fully understood. *Aims.* The aim of this study was to investigate the expression of chemokine receptors on T cells and functional changes of T helper cells (Th cells) in peripheral blood stem cell harvests after treating healthy donors with rhG-CSF. *Methods.* Using multiparameter flow cytometry, we analyzed the expression of CXCR3 and CCR6 on T cells and the production of interferon-γ (IFN-γ), interleukin-4 (IL-4), and IL-17 by $CD4^+$ Th cells in peripheral blood stem cell (PBSC) grafts of healthy donors after *in vivo* rhG-CSF application. Alterations in the relative expression levels of TCRBV family members were determined using real-time PCR. All sample collections had the approval of the Peking University First Hospital Ethical Committee. *Results.* Our data demonstrated that rhG-CSF mobilization significantly decreased the expression of CXCR3 and CCR6 on T cells (Figure 1). The expression of CXCR3 on $CD4^+$ and $CD8^+$ T cells was significantly decreased after rhG-CSF mobilization ($p<0.001$). There were significant differences between PBSC grafts and steady-state peripheral blood (SS-PB) in the per-

centage of CCR6 expression on CD4+ and CD8+ T cells (p<0.001 and p=0.007, respectively). Treating donors with rhG-CSF resulted in decreased IFN-γ production and dramatically increased IL-4 and IL-17 secretion by CD4+ Th cells, leading to T cell polarization from the Th1 to the Th2 phenotype and a preferential increase in IL-17-producing CD4+ Th cells. We did not observe any differences in the relative expression levels of TCRBV family members before and after *in vivo* rhG-CSF application. *Conclusions.* Our results suggest that the expression of CXCR3 and CCR6 on donor T cells was dramatically downregulated and an IL-17 phenotype of CD4+ Th cells was preferentially induced in PBSC grafts after treating healthy donors with rhG-CSF. The observed effects of rhG-CSF on T cells may be independent of the relative expression levels of TCRBV family members. *Key Words.* recombinant human granulocyte colony-stimulating factor mobilization, chemokine receptors, IL-17, TCRBV.

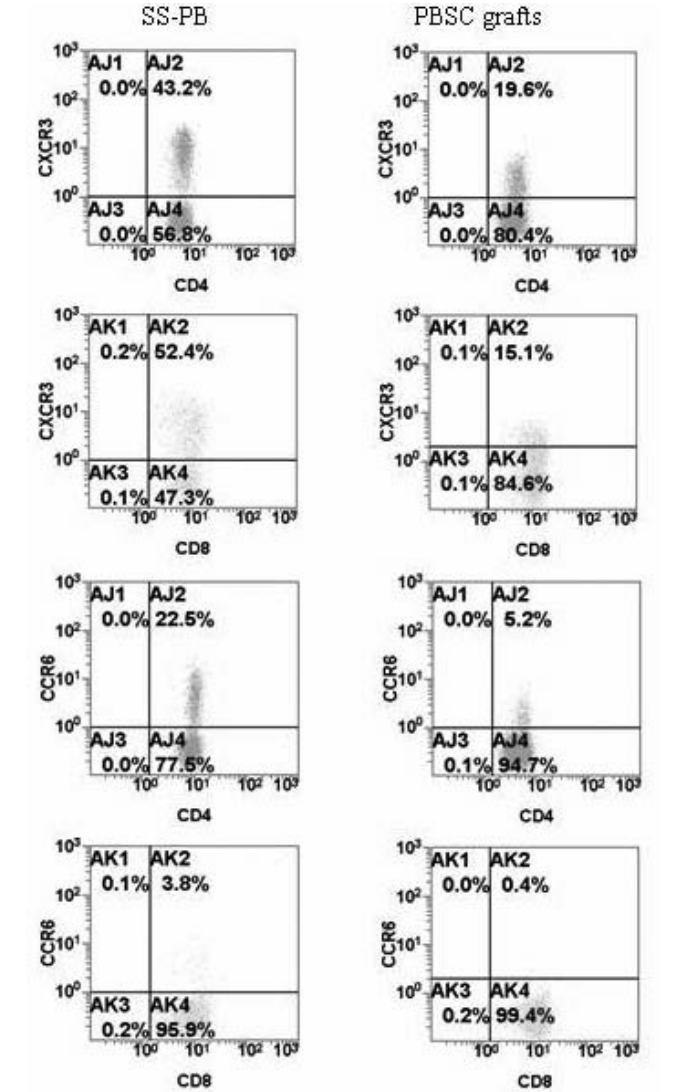

Figure 1. Representative example of CXCR3 and CCR6 expression on CD4+ and CD8+ T cells in SS-PB and PBSC grafts.

0164

REDUCED INTENSITY CONDITIONING UMBILICAL CORD BLOOD TRANSPLANTATION (RIC-UCBT) IN ADULTS: AGE, DISEASE STATUS AND INFECTIOUS COMPLICATIONS ARE IMPORTANT RISK FACTORS FOR OUTCOME

S. Fürst,[1] C. Faucher,[1] J. El Cheikh,[1] J.M. Boher,[1] P. Ladaique,[1] C. Lemarié,[1] N. Vey,[1] R. Bouabdallah,[1] A.M. Stoppa,[1] H. De Lavallade,[1] M. Mohty,[2] C. Chabannon,[1] D. Blaise[1]

[1]*Institut Paoli-Calmettes, MARSEILLE;* [2]*Centre Hospitalier Universitaire Hôtel Dieu, NANTES, France*

We report the outcome of 35 patients (pt) who received a RIC UCBT in a single centre between 2005 and 2008. All pt had high risk hematological malignancies (AML=19; ALL=9; NHL=5; CML=1; and Hodgkin disease=1). 27 pt (77%) were in CR (CR1=18; CR2=8; CR3=1), whereas 8 had a more advanced disease (PR=2; refractory=6) at time of UCBT. The median age was 44 (range, 17-62) years. For age we distinguished 2 groups: group 1 (n=13, age > 50 years) and group 2 (n=22, age ″ 50 years). 13 pt (37%) received a single CB unit, whereas 22 (63%) received 2 CB units in order to achieve a minimum required cryopreserved cell dose of 3.0×10^7 TNC/kg. For the entire group the median infused cell dose was 3.7×10^7/Kg (range, 1.9-5.5). Neutrophil engraftment occurred in 33 pt (94%) at a median of 20 (range, 6-45) days and a sustained platelet recovery was observed in 25 pt (71%) at a median of 36 (range, 23-136) days.The overall incidence of grade II-IV acute GVHD was 54% (95%CI=[37-71]; 7 grade II, 10 grade III and 2 grade IV) and 37% for chronic GVHD (95%CI=[21-55]; 8 limited and 5 extensive cases) with no difference between the 2 groups. 21 pt (60%; 95%CI=[37-71] experienced at least one episode of a severe infectious complication (SINC) (virus, n=11; bacteria, n=10; fungal, n=4), requiring long-term hospitalization. With a median follow-up of 468 (95%CI=[201-681]; range, 50-1170) days, 10 pt (28%) had relapsed or progressed with this being significantly lower in younger pt (p=0.045) and in those transplanted in CR (p=0.007). Regarding the 2 groups, 7 pt (54%) in group 1 died (infection=3; GVHD=2; disease=2; TRM=38%) whereas 7 (32%) in group 2 (infection=2; GVHD=1; disease=4; TRM=14%).The KM estimate of OS and DFS was 61% (95%CI=[42-75]) and 52% (95%CI=34-67) at 2 years respectively for the entire population with significant better outcome in pt in CR (OS, p=0.004; DFS, p=0.007) and pt in group1 (OS, p=0.052; DFS, p=0.041). The multivariate analysis showed a significant impact of 2 factors on DFS : age (group 1 vs group 2: HR 3.05, 95%CI=[1.07-8.73], p=0.037) and disease status at transplant (No CR vs CR: HR 6.33, 95%CI=[1.77-22.6], p=0.005). Age and disease status at transplant are crucial for patients outcome and further efforts are needed to define risk factor specific transplant procedures. Infectious complications and GVHD are still a matter of concern warranting better strategies to provide optimal prophylactic and therapeutic approaches.

CLINICAL IMPLICATIONS OF PULMONARY FUNCTION TESTS IN ALLOGENEIC STEM CELL RECIPIENTS

S.K. Sohn,[1] J.H. Moon,[1] J.H. Park[2]

[1]*Kyungpook National University Hospital, DAEGU;* [2]*Ulsan University Hospital, ULSAN, South-Korea*

Pulmonary dysfunction is one of major causes of morbidity and mortality in the allogeneic stem cell recipients. From Jun 2002 to Oct 2008, we retrospectively analyzed pulmonary functions (PF) in 116 consecutive patients who received allogeneic stem cell transplantation (SCT) and survived at least 3 months after transplantation. Pulmonary function test was performed at baseline, 3 months, 6 months, 1 year, and annually thereafter. Ventilatory capacity was measured by forced vital capacity (FVC), forced expiratory volume in the first second (FEV1), and FEV1/FVC ratio. Lung volume measurements included total lung capacity (TLC), residual volume (RV), and RV/TLC ratio. Diffusion capacity for carbon monoxide (DLCO) was determined with correction for hemoglobin concentration. Of the 116 patients, 63 patients were followed more than 1 year. The patients with acute graft-versus-host disease (GVHD; p=0.011), chronic GVHD (p=0.009), or CMV infection (p=0.410) showed a decline of FEV1 and FEV1/FVC after 1 year of transplantation. TLC and RV/TLC also showed an increasing tendency after 1 year of transplantation which reflected abnormal ventilatory pulmonary function. Conditioning intensity, unrelated donor type, stem cell dose did not adversely affect the pulmonary function. We calculated the lung function score (defined as FEV1 score plus DLCO score; NIH chronic GVHD consensus Project, 2003) at 1 year of transplant and compared it from that of baseline to identify the factors affecting late pulmonary dysfunction. In the multivariate analysis, extensive cGVHD (OR=3.692, 95% CI=1.154-11.818; p=0.028) and previous CMV infection (OR=5.356, 95% CI=1.311-21.882; p=0.019) negatively affected on late pulmonary function. In addition, the patients with early decline of FEV1 more than 10% at 3 months compared to baseline showed a higher incidence of cGVHD during follow-up (p=0.016). In conclusion, patients who had extensive cGVHD or CMV infection had a higher possibility of late pulmonary dysfunction and decline of FEV1 at 3 months of transplantation reflected the development of cGVHD.

HUMAN BONE MARROW AS SOURCE OF STEM CELLS FOR INTRAPANCREATIC TRANSPLANTATION IN IMMUNODEFICIENT MICE: EVIDENCE OF PANCREATIC-CELL LINEAGE COMMITMENT BY GENE EXPRESSION ANALYSIS

M.T. Arce-Franco,[1] J.M. Raya,[1] M. Barajas,[2] M.J. Dominguez-Luis,[1] A.M. Herrera,[1] A. Diaz-Martín,[1] T. Martín-Santos,[1] L. Morabito,[1] M.J. Rodriguez-Salazar,[1] J. Lopez-Fernandez[1]

[1]Hospital Universitario de Canarias, LA LAGUNA; [2]Clinica Universitaria de Navarra, PAMPLONA, Spain

Background. A major goal of diabetes therapy is to look for new sources of insulin-producing cells, preferably of autologous origin, and to explore other sites of implants different to liver (which provides a microenvironment that probably does not generate the correct signals to maintain the differentiation of such a fragile cellular system). The human bone marrow contains different types of stem cells, including mesenchymal stromal cell (MSC) and multipotent adult progenitor cell (MAPC), which have a large proliferative potential, the ability to differentiate into different cell types and to produce a variety of cytokines and growth factors. Pancreatic-cell differentiation follows a specific cascade or sequential pattern of gene expression that may help to recognize the cellular lineage. *Aims.* To analyze if human bone marrow-derived mononucleated cells are capable of nesting in the pancreas of immunodeficient mice, and to investigate the appearance of gene expression changes that indicate a commitment of the transplanted cells to pancreatic differentiation. *Methods.* Human bone marrow was obtained by aspiration from healthy voluntary donors. Mononucleated cells were separated by Ficoll gradient procedure, and then MSC and MAPC were isolated (the latter by negative immunoselection using magnetic cell sorting, MACS) and biologically characterized (by morphologic and immunophenotypic analysis). An intrapancreatic transplantation of this purified cellular fraction was performed in immunodeficient mice (SCID beige, a B and T deficient animals used for xenotransplantations). Among others, analyzed variables included the survival of mice, the development of pancreatitis by measurement of pancreatic enzymes in blood, the viability of the transplanted cells assessed by immunohistochemistry (presence or not of human vimentin and human ERV-3), and the expression of pancreatic genes (GATA4, HNF1β, PDX-1, Ngn3, Neuro D, Pax4, Nkx2.2, Nkx6.1, Isl-1, Glut-2, SUR1, insulin, glucagon, and somatostatin), by quantitative real-time PCR. Animals were sacrificed four and eight weeks after transplantation to perform all the above mentioned analysis. *Results.* The global survival of the mice was 94%, and the animals showed a healthy appearance along the whole experiment. An increment in serum levels of pancreatic enzymes, suggestive of pancreatitis, was never observed. Immunohistochemical studies demonstrated the presence of human vimentin and ERV-3 in the pancreas both at four and eight weeks after transplant. An increase in the expression of HNF1β (specific of endoderm-cell phase) and NKx6.1 (pancreatic) was detected; any other change in gene expression cascade of pancreatic differentiation was observed. *Conclusions.* Our results support that human bone marrow-derived stem cells may survive for a significant period of time after intrapancreatic transplantation in an animal experimentation model. Although further studies are certainly needed, MSC and MAPC might constitute a source of autologous stem cells for pancreatic regeneration. The constant and specific increase in the expression of some genes involved in pancreatic differentiation (HNF1β and NKx6.1), indicate that the microenvironment may be responsible, at least partially, of these cellular changes. Our group is currently carrying out a study with the same methodology but in diabetic mice, to analyze if the natural course of the disease may be influenced by this intrapancreatic transplantation.

RESULT OF DOUBLE UNITS CORD BLOOD TRANSPLANTATION IN CHILDREN AND ASSOCIATION OF CFU-GM WITH THE DETERMINATION OF DOMINANCY

H.J. Kang,[1] K.H. Yoo,[2] J.W. Lee,[1] H. Kim,[1] S.H. Lee,[2] K.W. Sung,[2] H.H. Koo,[2] H.Y. Shin,[1] H.S. Ahn[1]

[1]Seoul National University College of Medicine, SEOUL; [2]Department of Pediatrics, Sungkyunkwan University School of Medicine, SEOUL, South-Korea

Background. Cord blood transplantation (CBT) is an alternative means of allogeneic stem cell transplantation. To enhance engraftment and to improve transplantation results, CBT has been conducted using two units with promising results in adults but results in pediatric patients is not known yet. Our preliminary results showed the dominance of one unit which occurred early after CBT (Bone Marrow Transplant. 38:197). However, little is known about the mechanism of engraftment and factors influencing the dominancy. *Aims.* To improve the outcomes, CBT was performed with 2 units in pediatric patients with the analysis of factors that affect the determination of dominancy. *Methods.* In total 61 patients including 25 AML, 19 ALL, and 17 other hematologic diseases received double units CBT, the numbers of total nucleated cells, $CD34^+$ cells, $CD3^+$ cells, CFU-GM, order of infusion, and HLA disparities were viewed as factors that potentially influence dominancy. *Results.* The median age and body weight of patients (M:43, F:18) were 9 (1-18) years and 35 (9-72)kg, respectively. The median number of the infused nucleated cells and $CD34^+$ cells by the sum of 2 units were 5.4 (0.7-18.4)$\times10^7$/kg and 2.1 (0.6-7.2)$\times10^6$/kg, respectively. Donor type engraftment achieved in 50/61 patients (5 engraftment failure, 5 autologous recovery, and 1 early death). Engraftment failure rate in hematologic disease (35%) was significantly higher than in leukemia (9%) (p=0.02). Except one patient with persistent mixed chimerism of two units, other 49 patients showed dominancy of one unit. Among the factors influencing dominancy, only the CFU-GM was significant (p=0.02). The event free survival (EFS) of all 61 patients was 57.4%. The EFS of leukemia and other hematologic disease were 59% and 53%, respectively. The transplantation related mortality (TRM) rate of all patients was 28%. The EFS (22%) of 9 high risk leukemia with more than third complete remission (CR), second transplantation, or refractory disease was significantly worse than that (69%) of other patients received double units CBT in first or second CR (25%-should omit) (p=0.01). The relapse rate of high risk leukemia (40%) was significantly higher than others (13%) (p=0.02), but the TRM rate was not different. Among leukemia patients in first or second CR, the relapse rate was significantly lower (0%) in patients with higher $CD3^+$ cells (>0.25$\times4\times10^7$/kg) in winner unit than that (30.8%) of others (p=0.03), but the EFS was not different owing to high TRM rate in patient with higher $CD3^+$ cells. *Summary and Conclusions.* Double units CBT was a way to overcome the limitation of cell dose in single unit. However engraftment and TRM were not so satisfactory yet. Multiple factors associated with outcomes of CBT but optimal unit selection guidelines that take into account influencing factors are not available yet. CFU-GM was associated with the dominancy in our preliminary result but not associated with survival and $CD3^+$ cells seems to be associated with relapse. To improve the outcomes of double units CBT, development of new selection guideline and technology to enhance engraftment and reduce TRM were warranted.

0168

A PHASE I STUDY OF CLOFARABINE PLUS HIGH DOSE MELPHALAN AS A CONDITIONING REGIMEN FOR ALLOGENEIC TRANSPLANTATION

M. Kirschbaum, A.S. Stein, R. Nakamura, A. Nademanee, L. Popplewell, M. Delioukina, R. Chen, D. Snyder, J. Conrad, P. Frankel, S. Forman

City of Hope National Cancer Center, DUARTE, USA

Background. Allogeneic Stem Cell transplantation remains the only curative treatment modality for hematologic malignancies such as AML, ALL, and MDS. Reduced intensity regimens were designed which replaced the alkylating agent cyclophosphamide with the purine nucleoside antimetabolite, fludarabine, a potent immunosuppressive with a substantially milder toxicity profile. The success of these reduced intensity, less toxic regimens has allowed the benefits of transplantation to be extended to groups previously excluded from transplantation, such as the older population. Clofarabine is a purine nucleoside analogue designed to exploit a double halogen strategy which confers resistance to adenosine deaminase, increases stability and bioavailability and makes the drug more efficient than fludarabine at inhibiting Ribonucleotide Reductase (RR) and disrupting mitochondrial function, leading to apoptosis. This latter activity may explain the increased killing of non-dividing lymphocytes, an advantage which would theoretically reduce the likelihood of rejection in the allogeneic setting, and perhaps augment the potential graft versus tumor effect of the donor graft. *Aims.* To evaluate a novel clofarabine containing regimen as conditioning for allogeneic stem cell transplant. *Methods.* phase I dose escalation: clofarabine (dose level one= 30 mg/m^2, dose level two and three=40 mg/m^2) IV daily days -7 to day -3 infused over 30 minutes IV, plus Melphalan (dose level one and two, 100 mg/m^2 , dose level three, 140 mg/m^2) administered over 30 minutes IV on day -2. Related or unrelated allogeneic stem cells were infused on day 0. GVHD prophylaxis: initially CSP plus mycophenelate, then tacrolimus plus sirolimus was adopted

as per COH standard of care. Patients age ≥18 years with AML, ALL, MDS in either CR1, CR2 or in relapse (up to 50% marrow blasts), not deemed eligible for standard transplant regimens by the attending physician, or at high risk for relapse, are eligible. *Results.* We report on the first 2 dose levels. 8 eligible patients, all with AML, have been treated thus far, 4 Males, 4 Females, with a median age of 62.5 years (57-65). Four patients were in CR1, 2 patients were in CR2, and 2 patients were transplanted in relapse. Grade 3 non-hematologic toxicities included elevation of AST and LFT, diarrhea, and hyponatremia. No dose limiting toxicities (DLT) were seen in level one. One patient in dose level 2 died prior to engraftment due to hepatic, renal, and infectious toxicities; that dose level has been expanded thus far to five patients and no further DLT have been seen. One patient in relapse received an unrelated donor graft and had complete engraftment and obtained remission. Engraftment was rapid, full data is presented in the Table 1. Mild acute skin graft versus host disease (GvHD) was seen in one patient, mild chronic GvHD in one patient. No relapses have occurred with median followup of 366 days. *Conclusions.* The combination of clofarabine and melphalan is adequate as a conditioning regimen leading to rapid complete engraftment of related and unrelated allogeneic stem cells.

Table 1. Engraftment and survival data.

Dose Level	Pt	Days* to WBC≥1	Days* to PLT≥100	Follow-up**	Status
1	1	16	16	458	Remission
1	2	14	14	451	Remission
1	3	23	23	402	Remission
2	4***			23	Expired
2	5	11	13	330	Remission
2	6	15	12	413	Remission
2	7	10	13	94	Remission
2	8	12	13	44	Remission
	Median	14	13	366	

* - From Transplant
** - Days from transplant to relapse/death or last contact.
*** - Patient expired prior to engraftment.

PROGNOSTIC VALUE OF POSITRON EMISSION TOMOGRAPHY/ COMPUTED TOMOGRAPHY IN PATIENTS WITH LYMPHOMA TREATED WITH AUTOLOGOUS STEM CELL TRANSPLANTATION FOR RELAPSED/REFRACTORY OR HIGH RISK DISEASE

P.M. Stefani,[1] U. Salvadori,[1] M. Gottardi,[1] S. Bissoli,[2] F. Chierichetti,[2] F. Gherlinzoni[1]

[1]Struttura Complessa di Ematologia, TREVISO; [2]Nuclear Medicine Unit, Castelfranco Veneto Hospital, CASTELFRANCO VENETO, Italy

Background. Positron emission tomography/computed tomography (PET/CT) imaging has increasingly been used for management of malignant diseases including lymphoma. This emerging modality combines the advantages of both PET and CT imaging especially improving specificity. Few prospective studies addressed its prognostic value in the setting of high dose therapy with autologous stem cell transplantation (ASCT) so far. *Aim.*We evaluated the predictive role of PET/CT before ASCT (PET/CT1) and after ASCT (PET/CT2) in lymphoma patients in terms of overall survival (OS) and disease-free-survival (DFS). *Methods.* OS and PFS have been evaluated using Kaplan-Meier estimates; OS and DFS curves have been assessed using Log-rank test. *Results.* We conducted a prospective study including 12 patients with Hodgkin Lymphoma (6 in relapse, 6 refractory diseases at early PET/CT in induction), 38 patients with non Hodgkin Lymphoma (13 in relapse, 9 in PR after induction therapy, 10 high-risk patients while in CR and 6 patients with Mantle cell Lymphoma treated with R-HDS regimen). All patients presented a positive PET/CT before starting treatment. 35 patients underwent both PET/CT1 and PET/CT2. After ASCT 5 patients never achieved a CR and all died because of progressive disease; 41 patients after ASCT were in CR (including 30 patients in CR before ASCT); 4 were in PR and they obtained CR after radiotherapy. No patients died of treatment-related-mortality. Of note 3 patients presented a PET/CT positivity after ASCT with a decreasing uptake at subsequent controls and without a clear correlation with any lesion detectable by CT: none of them relapsed. Median follow up is 28 months (5-77); OS of whole cohort of patients was 85.7% and DFS 67.1%. On the basis of PET/CT1 we did not observe statistically significant differences in both OS (92.3% negative vs. 78% positive) and DFS (74% negative vs. 60% positive). Conversely, on the basis of PET/CT2, OS was 100% negative vs. 46.7% positive (p<0.01), while DFS was 81.8% negative vs. 54.1% positive (p<0.01) (Figure 1). All relapses have been documented in PET/CT2 positive group within 12 months from ASCT. In PET/CT2 negative group 3 patients died, one of TRM after allogeneic stem cell transplantation, one of secondary leukaemia after radioimmunotherapy and the last because of progressive disease. Seven PET/CT2 positive patients died: 6 because of progressive disease and one of TRM after allogeneic stem cell transplantation. *Conclusions.* In this cohort of lymphoma patients, the role of PET/CT1 in predicting relapse after ASCT is less clear compared to previous published studies, while the role of PET/CT2 seems to be more reliable, especially for early relapses.

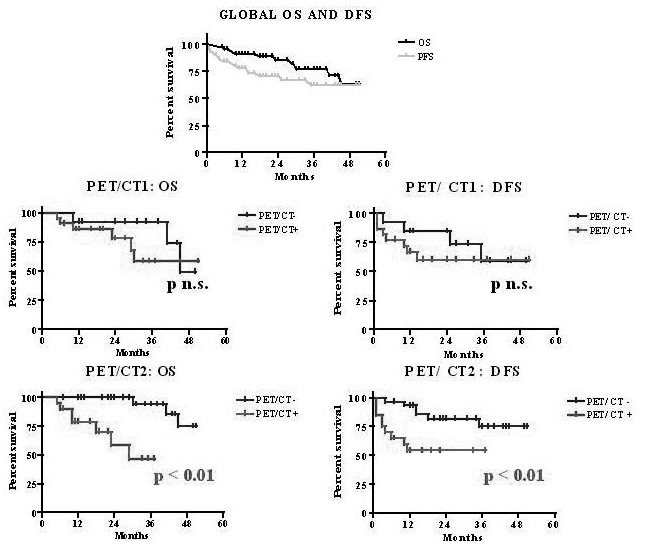

Figure 1.

0170

BOTH IL-3 AND IL-6 ARE NECESSARY FOR BETTER *EX VIVO* EXPANSION OF CD133+ CELLS FROM UMBILICAL CORD BLOOD

P. Bordeaux-Rego,[1] A. Luzo,[2] F.F. Costa,[3] S.T.O. Saad,[3] D.P. Crosara-Alberto[3]

[1]University of Campinas-Brazil, CAMPINAS; [2]Cord Blood Bank, University of Campinas - UNICAMP, CAMPINAS; [3]Haematology and Hemotherapy Centre, University of Campinas - UNICAMP, CAMPINAS, Brazil

Background. CD133$^+$ cells, a subpopulation of CD34$^+$ cells, constitute a group of earlier, less-differentiated hematopoietic stem cells (HSC) with a potentially higher capacity for engraftment. Umbilical cord blood (UCB) is the ideal source for HSC for transplantation; readily available, rich in progenitor cells with lower risk for severe acute graft-versus-host disease. However, UCB contains fewer transplantable cells, compared to bone marrow aspirate or mobilized from peripheral blood. The identification of conditions favoring UCB-HSC *ex vivo* expansion and their repopulating potential remains the major challenge of experimental and clinical hematology. SCF, FLT-3l and TPO have been proved crucial growth factors for promoting this expansion. However the role of IL-3 and IL-6 in CD133$^+$ and/or CD34$^+$ cells *ex vivo* expansion has not been clearly established. *Aim.* Investigate the influence of IL-3 and IL-6 or both on CD133$^+$ from UCB *ex vivo* expansion for 8 days and the effect of these cytokines upon cell phenotype. *Methods.* After mothers informed consent, UCB samples were collected from normal full-terms by standard procedures. CD133$^+$ cells were isolated by immunomagnetic method, and cultured as follows: basal medium (BM): IMDM with 10% FBS, SCF (25 ng/mL), TPO (10 ng/mL), FLT-3l (10 ng/mL); BM+IL-3: BM +IL-3 (10 ng/mL); BM+ IL-6: BM + IL-6 (10 ng/mL); BM+IL-3+IL-6: BM+ IL-3 (10 ng/mL) + IL-6 (10 ng/mL). Colony Formation Unit (CFU). Cells were seeded in methylcellulose medium with recombinant cytokines without EPO for 14 days. Real time PCR. RNA was extracted from CD133$^+$ cells to quantify relative SOX-2 and NANOG expression using ABL gene as endogenous control. *Results.* Flow cytometry analysis revealed 85% of purity of CD133$^+$ cells, immediatly after isolation, but this percentage diminished after 4 and 8 days of expansion as follows: BM alone (65.55% and 71.39%, respectively); BM+IL-3 (56.64%, p<0.01; and 50.50%, p<0.001); BM+IL-6 (66.53% and 70.22%) and BM+IL-3+IL-6 (61.67%, p<0.05; and 61.95% p<0.05) respectively. Fold-increase (calculated as

CD133+ number on days 4 or 8 divided by CD133+ number on day 0) of BM+IL-3 and BM+IL-3+IL-6 was higher on day 8 (13.83 and 17.47 fold increase, respectively, $p<0.001$). CD133+ cells cultured with BM+IL-6 for 4 and 8 days presented no significant difference compared with BM alone. CFU number (CFU-mix) doubled in BM+IL-3+IL-6 after 8 days of incubation compared with BM-group ($p<0.05$). Cell cycle analysis revealed a quiescent cell after isolation, 95.5% of CD133+ cells in the G0/G1-phase, 1.33% S-phase and 3.27% G2-M. Regardless culture period or cytokine incubation, approximately 70% of CD133+ cells remained in G0/G1-phase, 30% CD133+ cells in S-phase and 3% in G2-M phase ($p<0.001$). A higher relative gene expression of SOX-2 and NANOG on day 0 after isolation was detected. BM+IL-6 prevented decrease in NANOG and SOX-2 gene expression levels (no significant difference compared on day 0), when compared to cells incubated with BM, BM+IL-3 or BM+IL-3+IL-6 ($p<0.05$). *Conclusions.* CD133+ cells isolated from UCB are better ex vivo expanded in the presence of SCF, Flt3-L, TPO, IL-6 + IL-3. IL-3 probably promotes higher expansion of CD133+ cells and IL-6 maintains the immature phenotype.

0171

TRACKING OF DONOR TYPE GREN FLUORESCENT AND LUCIFERASE POSITIVE MARROW MONONUCLEAR OR MESENCHYMAL STEM CELLS IN POSTMORTEM SPINAL CORD HISTOPATHOLOGICAL SECTIONS FOR DETERMINATION OF REGENERATION IN A SPINAL CORD INJURY MODEL

M. Beksac,[1] I. Kuzu,[1] M. Ozdemir,[1] M. Ayten,[1] K. Dalva,[1] D. Uçkan,[2] E. Kiliç,[2] A. Attar,[1] M. Beksac,[3] Y. Kanpolat[4]

[1]Ankara University, ANKARA; [2]Hacettepe University Pediatric Transplantation U, ANKARA; [3]Ankara University Department of Hematology, ANKARA; [4]Turkish Academy of Sciences, TURKEY, Turkey

Background. Spinal cord trauma induces disability as a consequence of different mechanisms. Studies on reversal of injury are focused on two areas: 1. the use of neuroprotective agents 2. cellular therapy to induce axonal regeneration. *Aim.*In this experimental study, the effects of neuroglial tissue regeneration and functional recovery of intralesionally implanted bone marrow mononuclear (MNC) or mesenchymal stem cells (MSC) are examined by *in vivo* bioluminesence imaging and postmortem immunohistochemical techniques. *Method*. The study design included four groups: 1. non traumatized control group, 2. the cord were traumatized with 3 gram Tator klips but not followed by cellular implants , groups 3 and 4:Following similar trauma luciferase (+) bone marrow (BMMNC) (1×10^6/100 microliters) or MSC (1×10^5) obtained from CMV-Luc or β-Actin Luc transgenic mice were given intralesionally using fine needles. Following surgery, before the effects of seboflorein anesthesia ends, 150 mg/kg luciferine was enjected intraperitoneally to obtain *in vivo* bioluminescence imaging (Xenogen IVIS 50). All mice were neurologically examined weekly by oblique plane, BBB scores and *in vivo* imaging of the surgery area. On day 60, mice were decapitated and immunohistochemical evaluation was performed. Neural stem cells, neurons, myelin were detected by antibodies: nestin, MAPO and MOSP. *Results.*All mice of the groups 3 and 4 showed various degrees of improvement in the BBB scores. However there were no changes in groups 1 and 2. The improvement was significantly better in the group 4 compared to group 3 ($p=0.002$). The immunohistochemical staining demonstrated tracking of donor type gren fluorescent (GFP)+Luc+ neuronal cells that were also positive with any of these markers: nestin, MAG, MOP or MOPB which supplies evidence for the donor type neuronal regeneration. Neuronal cells expressing variable levels of neuronal differentiation and GFP/Luc were present in 13/25 mice(group3) and 17/25 mice(group 4). *Conclusions.* Current findings demonstrate, compared to a control group which did not receive cellular implants, that donor marrow cells contribute to neuronal regeneration and functional improvement.

0172

TEAM (THIOTEPA, ETOPOSIDE, CYTARABINE, MELPHALAN) AS CONDITIONING REGIMEN FOR LYMPHOMA TREATMENT WITH AUTOLOGOUS HAEMATOPOIETIC STEM CELL TRANSPLANTATION

A.M. Carella,[1] G. Palumbo,[2] E. Merla,[1] F. Ferrara,[3] M. Greco,[1] M. Dell'Olio,[1] P. Scalzulli,[1] G. Pisapia,[4] P. Mazza,[4] A. Guarini,[5] A. Iacobazzi,[5] P. Musto,[6] S. Capalbo,[2] N. Cascavilla[1]

[1]Casa Sollievo Della Sofferenza, SAN GIOVANNI ROTONDO; [2]Ospedali Riuniti, FOGGIA; [3]Ospedale Cardarelli, NAPOLI; [4]Ospedale G.Moscati, TARANTO; [5]IRCCS Istituto Tumori, BARI; [6]IRCCS CROB, RIONERO IN VULTURE (PZ), Italy

Background. Standard conditioning regimen before an autologous haematopoietic stem cell transplantation (AHSCT) for chemosensitive relapsed Hodgkin Lymphoma (HL) and Non Hodgkin Limphoma (NHL) patients (pts) is still represented by a scheduled combination of carmustine, etoposide, cytarabine and Melphalan (BEAM). Despite the efficacy of this regimen, it is disadvantaged by the presence of carmustine, which is responsible of a high pulmonar toxicity with fibrosis and progressive reduced diffusion capacity. In order to prevent pulmonar toxicity, we replaced carmustine with Thiotepa in 26 chemosensitive relapsed HL and NHL pts. We have also evaluated the efficacy and tolerability of this new regimen. *Patients*. At day -7 27 pts received 10 mg/kg thiotepa (5 mg twice every 12 hours) followed by cytarabine 200 mg/m^2 die (-5 to -3) etoposide 200 mg/m^2 die (-5 to -3) and melphalan 140 mg/m2 (day -2). Out of these pts, 16 were male and 11 female. Sixteen pts were affected by da NHL and 11 by HL. At the moment of transplant only 8 pts were in CR, 15 were in PR and 4 were in progression. All patients were in second or sebsequent line of therapy. The median time of neutrophil >500 and platelets >20000 recovery was of 10 (range 8-12) and 12 (range 10-20) days respectively. No severe infectious event has been observed. Eight pts maintain the CR, 13 have reached CR, 3 have a stable disease and 3 pts did not respond to the treatment. Three pts that were in CR have subsequently relapsed. *Conclusions.* Our experience with TEAM protocol has shown a significant efficacy not lower to our historical experience with BEAM protocol. The tollerability was significantly accetable and no serious adverse event has been documented during the treatment or during aplastic phase, therefore the TRM at 100 days has been equal to zero. In no case, oral mucositis was higher than grade 2, even if most of the pts underwent total parenteral nutrition. Finally no cases of serious organ toxicity was observed (pulmonar, hepatic, cardiac and renal). Hematopoietic recovery, stimulated with G-CSF, has been reached as scheduled and no cases of prolonged neutropenia were observed.

Novel therapeutics, targeted therapies and gene therapy - Preclinical and Clinical

0173

ACE-041, A SOLUBLE ACTIVIN RECEPTOR-LIKE KINASE FUSION PROTEIN, IS A NOVEL ANTI-ANGIOGENIC AGENT

A.V. Grinberg, D.C. Mitchell, E.G. Pobre, J.A. Ucran, A.W. Mulivor, N. Solban, K.W. Underwood, R. Kumar, R. Pearsall, J. Seehra

Acceleron Pharma, CAMBRIDGE, USA

Background. Activin receptor-like kinase 1 (ALK-1) is an endothelium-specific type I receptor of TGF-beta receptor family, which is believed to play an essential role in modulating angiogenesis. Mutations in ALK-1 result in hereditary hemorrhagic telangiectasia (HHT2). HHT2 patients have chronic hemorrhaging and arteriovenous malformation, indicating a key role of this receptor in the regulation of angiogenesis. The homozygous inactivation of the ALK-1 gene in mice leads to embryonic lethality resulting from severe vascular anomalies, while heterozygous (ALK-1 +/-) mice exhibit phenotypes that are reminiscent of HHT2. However, overexpression of ALK-1 has been associated with inhibition of angiogenesis, and ligands of ALK-1 (BMP-9 and BMP-10) appear to inhibit various angiogenic activities *in vitro*. Thus, while the available data demonstrate that ALK-1 participates in the regulation of blood vessel formation and maintenance, the data do not clarify whether an antagonist of the ALK-1 signaling pathway is likely to have a pro- or anti-angiogenic effect when administered to an adult animal in a therapeutic modality. *Aims.*Here we describe an ALK-1 pathway inhibitor, a soluble form of ALK-1 receptor fused to the Fc region of human IgG1 (ACE-041), and we demonstrate that ACE-041 inhibits angiogenesis *in vitro* as well in tumor models. *Methods.* ACE-041 was expressed in CHO cells and purified from conditioned medium by immunoaffinity, ion-exchange and hydrophobic interaction chromatography to greater than 95% purity. Biacore T100 was used to study selectivity and kinetics of ACE-041 binding to target ligands. Chick Chorioallantoic Membrane (CAM) Assay was used to assess anti-angiogenic potential of ACE-041 *in vivo*. *Results.* We demonstrate that ACE-041 binds to the circulating ligands BMP9 and BMP10 and prevents them from signaling through the endogenous ALK-1 receptor. By using Surface Plasmon Resonance (SPR) analysis we studied the selectivity of ACE-041, and demonstrated that ACE-041 binds with high affinity to its target ligands BMP9 and BMP10. We also showed that receptor binding to BMP9 and BMP10 is blocked by ALK-1 mutations found in HHT2. Treatment with ACE-041 reduced vessel formation and branching induced by multiple pro-angiogenic factors in chick CAM assays. Melanoma explant CAM assays showed similar anti-angiogenic effects after treatment, exhibiting reduced size, weight and vascularization of tumors. Anti-tumor activity was additionally evaluated in an orthotopic breast cancer tumor model using MDA-MB-231 cells. ACE-041 treatment decreased tumor volume, tumor weight and reduced blood vessel density. *Conclusions.* These data demonstrate the efficacy of ACE-041 in abrogating vessel formation in *in vitro* and *in vivo* assays, suggesting that it is a powerful anti-angiogenic agent with anti-tumor activity.

0174

PHARMACOLOGY OF CPX-351: A NANO-SCALE LIPOSOMAL FIXED MOLAR RATIO CYTARABINE-DAUNORUBICIN FOR PATIENTS WITH ADVANCED LEUKEMIA

E.J. Feldman,[1] J.E. Lancet,[2] J.E. Kolitz,[3] J.M. Trang,[4] L. Mayer,[5] A.C. Louie[5]

[1]Weill Cornell Medical College, NEW YORK; [2]H. Lee Moffitt Cancer Center and Reserach Institute, TAMPA; [3]North Shore University Hospital, MANHASSET; [4]PK/PD International, Inc., TUCSON; [5]Celator Pharmaceuticals, PRINCETON, USA

Background. Antitumor activity of cytarabine and daunorubicin chemotherapy exhibits maximum synergy at a 5:1 molar ratio *in vitro*, implying a drug-drug interaction that can be exploited to maximize clinical efficacy by maintaining this molar ratio *in vivo*. CPX-351, a nano-scale liposomal formulation of cytarabine and daunorubicin encapsulated at the 5:1 molar ratio has marked synergy in murine leukemia models, and has undergone Phase I clinical testing (see Blood (ASH Annual Meeting Abstracts), Nov 2008; 112: 2984.). That study demonstrated a high degree of clinical efficacy in relapsed/refractory acute leukemia, with complete responses observed at doses ranging from 32-134 u/m2 (1 unit represents 1 mg of cytarabine plus 0.44mg of daunorubicin). Analyses of plasma drug levels from that study are presented here to examine the pharmacokinetic (PK) features associated with this anti-leukemic activity. *Aims.*To characterize how encapsulation of cytarabine and daunorubicin within CPX-351 affects drug bioavailability, elimination kinetics, and delivery of the 5:1 molar ratio. *Methods.* Plasma specimens following CPX-351 administration by 90-minute infusion on Days 1, 3, and 5 were collected and assayed for the following dose levels: 24, 32, 43, 57, 76, 101, and 134 u/m^2. Validated LC/MS/MS assays were developed for measuring total cytarabine, daunorubicin, Ara-U, and daunorubicinol. WinNonlin (v5.2) was used for analysis of noncompartmental PK data. *Results.* Both Ara-U and daunorubicinol were present in the plasma indicating that encapsulation did not impair bioavailability. Cytarabine and daunorubicin exhibited linear multiple-dose PK with mono-exponential plasma elimination of both drugs and a very limited distribution phase. The Cmax and AUC(0-tau) of cytarabine and daunorubicin were linearly correlated with dose and there was evidence of accumulation observed between Day 1 and Day 5 for some dose groups. Mean cytarabine:daunorubicin molar ratios for 24 hours following Day 1 and Day 5 administration of CPX-351 were generally very close to the intended 5:1 ratio (3.33-5.85 after Day 1 and 5.38-6.89 after Day 5). The Table 1 presents PK data at the MTD (101 u/m^2). When compared to the literature, liposome encapsulation increased the daunorubicin exposure (~200 fold for Cmax and ~1200 fold for AUC) and multiplied the exposure to cytarabine (up to 900 fold for AUC). Inter-patient variability was low. *Summary and Conclusions.* Encapsulation of cytarabine and daunorubicin using this methodology markedly increases and prolongs the systemic exposure of the two drugs while maintaining their bioavailability. Plasma elimination kinetics for both cytarabine and daunorubicin were predictable and dose independent. The ability of CPX-351 to deliver synergistic cytarabine:daunorubicin ratios at high absolute concentrations for extended times may underlie clinical efficacy observed in the Phase 1 study and support further evaluation of CPX-351 in ongoing Phase II trials in untreated and relapsed acute myeloid leukemia.

Table 1.

Mean (SD) Cytarabine, Daunorubicin, Arabinofuranosyuracil, and Daunorubicinol Pharmacokinetic Parameters on Day 5 Following Intravenous Administration of 101u/m^2 CPX-351 over 90 minutes on Days 1, 3 and 5

Analyte	C_{max} (ng/mL)	T_{max} (hr)	$AUC_{(0\text{-}tau)}$ (ng*hr/mL)	$t_{1/2}$ (hr)	C_{max}/Dose [(ng/mL) /(u/m^2)]	$AUC_{(0\text{-}tau)}$/Dose [(ng*hr/mL) /(u/m^2)]
Cytarabine	64608 (23230)	3.02 (2.25)	1851089 (934523)	36.9 (24.5)	640 (230)	18328 (9253)

UTILIZING CELL-BASED SCREENING TO IDENTIFY NOVEL USES FOR EXISTING DRUGS: INDUCING SPECIFIC APOPTOSIS OF B-CELL LYMPHOCYTES

T. Bennett,[1] D. Primo,[1] L. Suarez,[1] S. Lago,[1] M. Matoses Osborne,[1] C. Tudela,[1] E. Arroyo,[1] A. Espinosa,[1] W. Jackson,[1] A. Okun,[2] A. Orfao,[3] J. Ballesteros[1]

[1]Vivia Biotech, MÁLAGA, Spain; [2]Etogen Scientific, SAN DIEGO, USA; [3]Universidad de Salamanca, SALAMANCA, Spain

Background. We have developed a cell-based screening platform that incorporates both automated sample preparation and automated evaluation by flow cytometry, in conjunction with proprietary analytical software and a database structure, that is geared for rapid data acquisition, analysis and reporting of results. This platform, we call ExviTech, has been used to screen a compound library comprised of 2,000 drugs already approved for human use. Vivia's research is based on this reprofiling type of screening, searching for new indications for existing drugs. Additionally, all screening is done directly on patient samples, either peripheral blood or bone marrow, extracted from persons diagnosed with haematological malignancies. The complete patient sample is diluted and plated, retaining the erythrocyte population and serum proteins,

screening targets in an approximation of their biological context. Using these patient samples, we have identified a series of related compounds that induce apoptosis specifically in B-cell lymphocytes through a mechanism that appears to be fully independent of the known primary mode of action for these drugs. *Methods.* Working in collaboration with four hospitals in Spain, samples are extracted from patients diagnosed with haematological malignancies, having first obtained informed consent. The experimental assay is setup within 2-6 hours of obtaining the sample. The sample is diluted to achieve a leukemic cell concentration of approximately 3,000 cells/µL, then 45 µL of the suspension is added to each well of 96-well plates that contain the pharmacological agents (final concentration of 30 µM). Sample extraction from the patients and the experimental setup are all done under sterile conditions. The compound plates are then incubated for 24 hours at 37°C with 5% CO2 for screening, and additionally for 48 and 72 hours in subsequent tests. After incubation, the erythrocytes are lysed and Annexin V-FITC, monoclonal antibodies anti-CD45-APC and anti-CD19-PE, are added to each well. The plates are then transferred to an automated flow cytometry system where the contents of each well is aspirated and analyzed by a CyAn flow cytometer. *Results and Conclusions.* Analyzing primary screens from over 60 patients, a series of three related compounds (Vivia007, Vivia008 and Vivia009) were consistently able induce apoptosis in patients with B-cell lymphoproliferative disease, at levels equal to or greater than known cytotoxic agents. Of these, Vivia007 is the most effective. Dose-response analysis was done on 20 additional patients diagnosed with B-cell chronic lymphocytic leukaemia (B-CLL) and Vivia007 displays an average EC50 of 6.8 µM. The effect is specific to B-cell lymphocyte populations, with only a minor level of apoptosis being induced in the T-cell lymphocytes. Additionally, these compounds do not appear to be effective in chronic myelomonocytic leukemia or in T-cell lymphoproliferative disease. The kinetics of the induction of apoptosis is faster for the Vivia compounds than it is for Fludarabine, Cyclophosphamide or Mitoxantrone, cytotoxics used in the treatment of B-CLL. These results demonstrate the potential of the ExviTech technology platform as a successful model for the systematic search of new uses for existing drugs, with testing being done directly on patient samples.

HUMAN MESENCHYMAL STROMAL CELLS DISPLAY SKEWED ADHESION RECEPTOR USAGE FOR ARREST ON ENDOTHELIAL CELLS AND TRANSENDOTHELIAL MIGRATION, FAVOURING E-SELECTIN, BETA1 INTEGRINS, AND A PLEIOTROPIC CHEMOKINE RESPONSE: IMPLICATIONS FOR CELLULAR THERAPY WITH MSC

D. Henschler,[1] E. Deak,[1] F. Ciuculescu,[1] M. Giesen,[1] N. Hartmann,[2] E. Seifried[1]

[1]*Institute of Transfusion Medicine, FRANKFURT, Germany;* [2]*Laboratory for Immunological and Molecular Cancer Research, LIMCR, SALZBURG, Austria*

Background. Mesenchymal Stromal Cells (MSCs) have been used in various preclinical and clinical studies. In proof-of-concept experiments, MSCs were found to suppress immune reactions such as Graft versus Host Disease in children, to target the tumor microenvironment, and to improve outcome in patients with severe sepsis. We have previously shown that these fibroblast-type cells can roll on endothelial cells and can co-ordinately extravasate into tissues (Blood 108:3938, 2006). However, the repertoire of adhesion receptors active on MSCs has not been fully characterized. *Aims.*We asked which of the known key receptors used by leukocytes to roll and arrest on endothelial cells, to polarize, and to transmigrate across endothelial cells can be activated on MSCs under conditions of shear stress. *Methods.* Human MSCs were isolated from normal healthy donors and characterized using differentiation assays, RT-PCR, flow cytometry, and in parallel plate flow chambers preloaded with endothelial cells or recombinant adhesion ligands. *Results.* Of the main selectin-type rolling receptors, MSCs did not or hardly express P-selectin glycoprotein ligand (PSGL)-1, L-selectin and CD24, whereas CD44 which encodes an E-selectin ligand was highly expressed. β1 integrins were expressed by MSCs and comprised Very Late Antigens (VLA)-4 and -5, whereas β2 integrins LFA-1 and Mac1 were present only in low amounts. Chemokine receptors of the CCR and the CXCR families were expressed both intracellularly and, at lower levels, on the cell surface of MSCs. In shear stress assays, MSCs showed comparable frequencies of rolling and arresting cells on activated endothelial cells as human $CD34^+$ cells or blood lymphocytes. Function-blocking antibody experiments and experiments on coated recombinant single ligands showed that E- and also P-selectin were the main mediators of MSC rolling. In addition, MSCs rolled on VLA-4. Arrest of MSCs was efficiently induced by co-coated chemokines, and was dependent on VLA-4 but not β2 integrins. Once arrested, MSCs could transmigrate through endothelial cells. Blockade of MSC arrest and of transmigration was seen after pretreatment of MSCs with pertussis toxin, an inhibitor of G α subunits, and NSC23766, a specific inhibitor of the small GTPase Rac, confirming involvement of chemokine initiated G protein coupled receptor signalling in this response. We next dissected potential chemokine responses and found that integrin-mediated MSC adhesion can be efficiently elucidated through an array of individual chemokine receptors including CCR 5 (used by neutrophils, monocytes), CCR6 and 7 (used by B- and T-lymphocytes as lymph node entry receptors), CXCR4 (used by many cell types) and CXCR5 (B cell lymph node entry receptor). *Summary and Conclusions.* MSCs show a unique profile of adhesion receptor usage when binding endothelial cells under shear stress. They roll and arrest very similarly as hematopoietic cells, but show little response to L-selectin and β 2 integrins. Moreover, they display a highly pleiotropic chemokine receptor usage. These data provide a basis for MSC graft engineering by modulating expression and activation of homing receptors.

A NOVEL RECOMBINANT BISPECIFIC ANTIBODY TARGETING HM1.24 ON MULTIPLE MYELOMA

M. Peipp,[1] C. Ehlert,[1] M. Staudinger,[1] A. Muskulus,[1] C. Kellner,[1] S. Mohseni Nodehi,[1] P. Glorius,[1] M. Dechant,[1] R. Burger,[1] J. Brünke,[2] G.H. Fey,[2] M. Gramatzki,[1] R. Repp[1]

[1]*Christian-Albrechts-University Kiel, KIEL;* [2]*Chair of Genetics, Friedrich Alexander University Erlangen, ERLANGEN, Germany*

Background. Multiple myeloma (MM) is a malignant plasma cell disorder that accounts for about 10% of all hematologic cancers. Although continuous progress has been made by adding novel treatment modalities (e.g. stem cell transplantation, proteasome inhibitors such as bortezomib, and IMiDs) to conventional chemotherapy regimes, for a substantial number of patients MM is still a fatal disease. Besides small molecule inhibitors that interfere with various signalling pathways, antibody-based therapeutic strategies are urgently needed. HM1.24 (CD317) has been identified as a type II transmembrane protein that is preferentially expressed on terminally differentiated B cells and its overexpression has been observed on malignant plasma cells. Although the HM1.24 antigen has been identified as a possible target for immunotherapy, this has not led to translation into the clinic yet. Besides target antigen selection, efficient recruitment of immune effector cells via activating Fc'gamma' receptors is important for the anti-tumor activity of therapeutic antibodies. Enhancing antibody-dependent cellular cytotoxicity (ADCC) - the major effector mechanism triggered by conventional monoclonal HM1.24-directed antibodies - may represent a promising strategy to enhance the cytolytic potency of HM1.24-directed antibody therapy. *Aims.* Here, we tested the hypothesis whether specific engagement of FcγRIII by HM1.24-directed bispecific antibodies could further enhance the major effector mechanism reported for HM1.24-directed IgG1 antibodies. *Methods.* A novel bispecific scFv targeting HM1.24 on multiple myeloma and Fc'gamma'RIII (CD16) on immune effector cells was generated. HM1.24xdsCD16 was expressed in 293T cells and purified by two-step purification. Specific binding to HM1.24 and CD16 was analyzed by flow cytometry with antigen positive and negative cells. The lytic capacity of the bispecific scFv was evaluated in ADCC experiments (chromium-release assay) with mononuclear cells as effector cells and different myeloma cell lines (RPMI8226; U266; JK6-L; INA-6) as well as primary tumor cells from a patient with plasma cell leukemia as target cells. *Results.* HM1.24xdsCD16 was successfully expressed and purified to homogeneity. The bispecific scFv specifically bound to HM1.24 expressing myeloma cell lines and CD16 positive effector cells. In ADCC experiments using human peripheral blood mononuclear cells as effectors, HM1.24xdsCD16 mediated specific lysis of both myeloma cell lines and primary patient-derived plasma cell leukemia cells. In these experiments HM1.24xdsCD16 demonstrated superior activity in comparison to a humanized HM1.24 IgG1 antibody. Summary / *Conclusions.* A single-chain bispecific antibody, HM1.24xdsCD16 was designed and produced for targeting human myeloma cells and recruitment of Fc'gamma'RIII-positive immune effector cells. In antibody-dependent cellular cytotoxicity experiments HM1.24xdsCD16 demonstrated superior activity in comparison to a humanized HM1.24 IgG1 antibody. Thus, HM1.24xdsCD16 bispecific molecules represent a novel tool for efficient effector-cell mediated tumor lysis in multiple myeloma.

D EPITOPE EVALUATION OF THE 25 RHESUS D SPECIFIC IGG1 ANTIBODIES IN ROZROLIMUPAB (SYM001), THE FIRST RECOMBINANT POLYCLONAL ANTIBODY PRODUCT

M. Wikén,[1] A.M. Valentin Jensen,[2] P.S. Andersen,[2] W.A. Flegel[3]

[1]Biovitrum, STOCKHOLM, Sweden; [2]Symphogen, LYNGBY, Denmark; [3]Institute for Transfusion Medicine University Hospital Ulm, ULM, Germany

Rozrolimupab is the first in class of recombinant polyclonal antibody products and is in clinical development for the prevention of hemolytic disease of the newborn by anti-D prophylaxis (ADP) and for the treatment of Immune Thrombocytopenic Purpura (ITP). Rozrolimupab is composed of 25 genetically unique IgG1 antibodies all specific for the Rhesus D erythrocyte protein. The 25 Sym001 anti-D antibodies are derived by phage display from the antibody repertoires of 8 female human anti-RhD plasma donors, with high antibody titers against RhD, enrolled in a Danish anti-RhD collection program. The antibodies of the rozrolimupab composition have been selected to ensure that the final product, apart from the complete RhD phenotype commonly expressed in the human population (>99%), also recognizes the rare Rhesus D variants DIII, DIV, DVI and DVII that account for <1% of the overall RhD+ population. The RhD epitope (epD) specificities of the individual rozrolimupab antibodies have been determined following the principle applied at the Paris 2001 workshop on epitope mapping of monoclonal anti-D antibodies. The reactivity of the individual rozrolimupab antibodies with an extensive panel (n=19) of genetically defined RhD erythrocyte variants, present in populations of different ethnic origin, was determined applying the low-ionic strength saline (LISS) indirect antiglobulin test (IAT). The results show that 7 of the currently defined D epitopes (epD1, epD2, epD3, epD4, epD5, epD6 and epD16, including several subspecificities thereof) were recognized by 22 of the 25 antibodies. Some of the epitopes were recognized by more than one of the antibodies. The epitope specificities of the remaining 3 antibodies could not be defined by this approach due to their broad reactivity profiles. The 7 epD recognized are found to constitute epitopes present, in different combinations, on all RhD variants of clinical importance in a situation of RhD incompatibility between mother and foetus that may lead to isoimmunisation of the mother. Thus, the selected polyclonal antibody composition of rozrolimupab would ensure adequate recognition of foetal erythrocytes with potential clinical impact, which is a basic requirement for use in anti-D prophylaxis.

0179

IBRITUMOMAB TIUXETAN IN LYMPHOMA- A SINGLE CENTRE EXPERIENCE FROM KUWAIT

P. Nair, A.l. Shemmari, H. Chokshi, S. Sajnani

Kuwait Cancer Control Centre, CALICUT, KERALA, India

Background. Ibritumomab is a murine monoclonal antibody, conjugated to tiuxetan that chelates yttrium or indium, and is directed against CD 20 molecules of B lymphocytes. Ibritumomab tiuxetan is FDA approved for treatment of low grade lymphomas that have failed prior therapy. Emerging trials show promising results in indolent as well as aggressive lymphomas, in both upfront and relapsed settings. *Aim.* To see the outcome of radio-immunotherapy (ibritumomab tiuxetan) in lymphoma patients. *Methods.* We treated 20 lymphoma patients from April 2005 until June 2008 with ibritumomab tiuxetan. Median age of the patients was 62yrs. 14 cases were indolent and 6 cases were aggressive lymphomas. 3 patients received ibritumomab tiuxetan as part of first line chemotherapy and the remaining 17, in relapsed setting. A bone marrow examination was done in all patients before administration of the drug, and those having bone marrow involvement of lymphoma or hypocellular marrow were excluded. During administration the patients were closely monitored for infusion related complications. Serial complete blood counts were done on follow up. All patients were reevaluated after 3 months by CT scan and gallium scan. They were periodically reviewed in the out-patient clinic to look for long term complications. *Results.* 12 patients achieved complete remission (60%) and 5 achieved partial remission (25%), constituting an ORR of 85%. 3 patients developed long standing myelosuppression (lasted more than 2 months), out of which, 1 patient died due to related complications. 3 patients (15%) developed treatment related acute leukemia. All the three patients who developed leukemia had received ibritumomab tiuxetan in relapsed setting and two of them had received radiotherapy to the pelvic area, as part of the first line treatment. Mean time of development of leukemia from the diagnosis of lymphoma was 6 years and from radio-immunotherapy was 2 years. Multiple cytogenetic aberrations were found in all the three patients but, interestingly, chromosome 5 or 7 anomalies were not found. *Conclusions.* Although ibritumomab tiuxetan produced high response rate in lymphomas, high incidence of fatal complications, especially secondary leukemias is worrisome and warrants long term follow up. Previous radiation exposure to pelvic area might be an additional risk factor for the development of radio-immunotherapy induced secondary leukemias.

0180

THE CXCR4 ANTAGONIST 4F-BENZOYL-TN14003 STIMULATES THE EXIT OF HEMATOPIETIC CELLS AND THE REGENERATION OF THE BONE MARROW FOLLOWING TRANSPLANTATION

A. Peled,[1] M. Abraham,[1] K. Beider,[1] A. Nagler,[2] Z. Zipori,[3] E. Eizenberg[4]

[1]Hadassah Hebrew University Hospital, JERUSALEM; [2]Sheba Medical Center, Tel-Hashomer, Ramt Gan Israel., RAMAT GAN; [3]Weizmann Institute of Science, Rehovot 76100, REHOVOT; [4]Biokine Therapeutics Ltd., Science Park, Ness Ziona, Israel., NESS ZIONA, Israel

Background. Cytopenia represents a significant complication following chemotherapy, irradiation prior to bone marrow (BM) transplantation or as a therapy for cancer. The mechanisms that determine the pace of BM recovery are not fully understood. *Aim.* Studying the role of CXCR4 in the regeneration of the BM following chemotherapy or irradiation. *Methods.* The role of CXCR4 in the recovery of the bone marrow following irradiation was tested using transplantation model and the role of CXCR4 in the recovery of the bone marrow following chemotherapy was done using Cyclophosphamide model of cytopenia. The role of CXCR4 in the proliferation and differentiation of hematopoietic progenitors and mature cells was tested *in vitro* using BM stromal culture. In all experimental models the CXCR4 antagonist 4F-benzoyl-TN14003 (T-140) and AMD3100 were used to modify CXCR4 activity. *Results.* During the recovery phase following chemotherapy or irradiation, the signals for retention of white blood cells (WBC) within the BM increase significantly. This leads to a delay in the release of WBC. The CXCR4 antagonist, known as T-140, can induce mobilization of hematopoietic stem cells and progenitors within a few hours post-treatment in a dose-dependent manner. Furthermore, T-140 can also increase the number of WBC in blood including monocytes, B and T cells. T-140 was found to efficiently synergize with G-CSF in its ability to mobilize WBC and progenitors including erythroblasts. We found that by targeting the CXCR4 axis with T-140 the delay in the release of WBC can be overcome. The delay in the WBC release of WBC is also accompanied by suppression in the production of progenitor cells and mature cells by the BM stroma. Interestingly, *in vivo* administration of T-140 to mice transplanted with BM cells stimulates the production of all types of progenitors and mature cells and increases the exit of mature cells to the periphery. Moreover, addition of T-140 to *in vitro* BM stromal cultures stimulates the production of mature cells and progenitors from all lineages. *Summary.* The unique ability of the CXCR4 antagonist, T-140 to stimulate the production and exit of WBC cells may be used as a novel therapeutic approach to overcome cytopenia associated with treatments for cancer and BM transplantation.

0181

DEXAMETHASONE AND DASATINIB INDUCE SYNERGISTIC INHIBITION OF MAJOR T CELL EFFECTOR FUNCTIONS

R. Seggewiss, C. Dix, H. Einsele

University of Würzburg, WÜRZBURG, Germany

Background. In addition to their antitumor activity tyrosine kinase inhibitors (TKIs) exert immuno-modulatory effects on T cells. We (Weichsel *et al.* 2008) and others (Blake *et al.* 2008; Fei *et al.* 2008; Schade *et al.* 2008) have shown that the multitargeting TKI dasatinib may lead to a complete inhibition of T cell effector functions via the SRC kinases LCK and FYN. *Aims.* We investigated the impact of combining clinically relevant doses of dasatinib [1-100nM] with the immunosuppressant dexamethasone [1-1000nM] on T cells. *Methods.* Purified human $CD3^+$ cells from healthy blood donors were studied *ex vivo.* Functional outcomes assessed included IL-2 production, CD69 upregulation, proliferation (CFSE dilution) and apoptosis/necrosis induction. EBV or CMV antigen specific $CD8^+$ T cell proliferation were evaluated applying tetramers. Results. Complete inhibition of proliferation and activation occurred with dasatinib at 50 nM, whereas application of dexamethasone did not lead to complete inhibition even at 1000 nM. Dose-dependent inhibition of OKT3-induced T cell activation and proliferation was observed with the combination of dasatinib and dexamethasone.

Strongest synergistic inhibitory effects of the drug combination were observed for OKT3-induced cytotoxic $CD8^+$ T cell proliferation (mean±SEM given: OKT3 induced 63±5% proliferating T cells after 4 days, OKT3 + 10nM dexamethasone 44±5%, OKT3 + 10nM dasatinib 39±10%, OKT3 + combination 16±4%; n=5; $p<0.05$). A significant inhibition of OKT3 induced CD69 up-regulation was demonstrated with the combination but not for dexamethasone alone (n=5). Our previously published data on dasatinib alone showed inhibition of OKT3-induced up-regulation of CD69 expression, and this was potentiated in combination with dexamethasone. The pre-treatment time did not influence the dexamethasone effect except for increased reduction of IL-2 production after 24h vs. 1h pre-incubation. Overall, helper $CD4^+$ T cells were more sensitive to the inhibitory effects of the drug combination regarding activation and proliferation than cytotoxic $CD8^+$ T cells. Of note, synergistic effects occurred primarily in the different memory CD4 and CD8 subsets but not in naïve T cells (e.g. for $CD8^+CD45RO^+CD27^+$ memory T cells mean±SEM given: OKT3 92±1%, OKT3 + 100nM dexamethasone 77±2%, OKT3 + 10nM dasatinib 69±15%, and OKT3 + combination 27±11%; n=5; $p<0.05$). IL-2 production in purified T cells was significantly reduced ($p<0.05$) in a dose dependent nature for both dasatinib and dexamethasone compared to the OKT3-stimulated condition, either alone or in combination (n=5). Similarly, activation induced cell death (AICD) was significant reduced when the two drugs were combined, whereas no synergistic effects were observed regarding necrosis inhibition (n=5; $p<0.05$). In contrast, initial results suggested that dexamethasone did not inhibit clinically relevant EBV or CMV antigen specific $CD8^+$ memory T cells proliferation when used alone and did not show synergistic effects with dasatinib (n=3). This may be due to a reduced sensitivity of the specific viral memory subset composition towards dexamethasone. *Summary and conclusion.* With an indication that each drug, when combined, could be used at reduced dose, this research may pave the way for synergistic uses of TKIs and glucocorticosteroids in graft versus host disease or autoimmune diseases potentially without increasing the risk of infections.

0182

EX VIVO ACTIVITY OF SGI-1776, A POTENT SMALL MOLECULE PIM KINASE INHIBITOR, IN PRIMARY HUMAN LEUKEMIA AND LYMPHOMA CELLS

P. Taverna,[1] G. Berk,[2] S. Kanekal,[2] D. Bearss[2]

[1]SuperGen, DUBLIN, CA; [2]SuperGen Inc., DUBLIN, CA, USA

Background. The serine-threonine kinases Pim-1, Pim-2 and Pim-3 are downstream effectors and potent inhibitors of apoptosis involved in various signaling pathways. Pim-1 and Pim-2 are commonly over-expressed in hematological malignancies, while Pim-3 is over-expressed in many tumors of epithelial origin. Pim-1 over-expression has been also associated with a poor prognosis in mantle cell lymphoma. SGI-1776 is a novel small molecule identified through our proprietary CLIMB' process and characterized to be a selective pan-Pim kinase inhibitor (6.7 nM, 69 nM and 363 nM biochemical IC50s for Pim-1, Pim-3 and Pim-2, respectively) with potent effects on cellular signaling pathways and cancer cell proliferation *in vitro* and *in vivo*. SGI-1776 is entering into phase 1 clinical studies in patients with relapsed and refractory non-Hodgkin's lymphoma, as well as patients with relapsed/refractory leukemias. *Aims.* Evaluate the sensitivity to different concentrations of SGI-1776 on fresh or viably preserved cancer cells from 3 Acute Lymphocytic Leukemia (ALL), 5 Acute Myeloid Leukemia (AML) , 5 Chronic Myeloid Leukemia (CML) and 5 non-Hodgkin's Lymphoma (NHL) patients. By Immunohistochemistry (IHC), the expression of Pim kinases in formalin-fixed, paraffin embedded (FFPE) human leukemia and lymphoma samples were evaluated. *Methods.* De-identified clinical specimens were obtained by Mosaic Laboratories (Lake Forest, CA) in accordance with an IRB-approved protocol. Drug sensitivity was evaluated by incubating cells for 96 hours at 37°C in the presence of different concentrations of SGI-1776 (range, 0.005-2 μM) and assessed by a differential staining cytotoxicity (DiSC) assay. ALL and AML cells were also incubated with vincristine (VCR), NHL cells with 4-hydroperoxycyclophosphamide (4HC) and CML cells with imatinib. *Results.* Viability of 14 specimens (out of 18 tested) was affected by SGI-1776. Overall, the IC50 for NHL samples was the most sensitive to SGI-1776 (0.43 μM), followed by CML (0.6 μM), AML (0.92 μM) and ALL (1.51 μM). Specifically, the effects of SGI-1776 was further characterized by a low or sub-μM IC50 in MDR-1 ALL (2.01 μM), FLT-3 mutated AML (4.15 μM) and 4 BCR-ABL t(9;22) CML (range, 0.39-0.66 μM) specimens. In NHL, 2 μM of SGI-1776 was significantly more active than 4HC at all concentrations tested (up to 50 μM); SGI-1776 also demonstrated a lower IC50 than Imatinib in 4 of the 5 CML specimens and this difference was significant at the equimolar concentration of 2 μM. The highest expression of Pim-1,-2 and -3 was observed in NHL cells consistently with their sensitivity to drug effects. CML cells displayed a relatively low expression of the 3 Pim kinases with the exception of Pim-3. *Conclusions*. The pan-Pim kinase inhibitor SGI-1776 potently reduces ex-vivo survival of primary human leukemia and lymphoma cells and retains its activity in cells otherwise resistant to standard chemotherapy. Pim kinases expression is evident in these primary cells and, in NHL, may correlate with sensitivity to SGI-1776.

0183

IN VITRO ANALYSIS OF NOVEL ANTI-CD20 ANTIBODY GA101 AND RITUXIMAB IN MANTLE CELL LYMPHOMA

D. Heinrich, K. Decheva, M. Weinkauf, G. Hutter, Y. Zimmermann, T. Weiglein, W. Hiddemann, M. Dreyling

Department of Medicine III, University Hospital Munich - Campus Großhadern, MUNICH, Germany

Background. Mantle cell lymphoma (MCL) is an aggressive B-cell non-Hodgkin-lymphoma characterized by a poor prognosis with a median survival of 3 years. The type I monoclonal antibody Rituximab has shown a marked anti-proliferative effect in MCL and achieves increased response rates in combination with chemotherapy. The new third generation, glycoengineered type II IgG1 anti-CD20 monoclonal antibody GA101 is considered having enhanced antibody dependent cellular cytotoxicity (ADCC) and superior caspase-independent cell death induction by targeting a type II epitope on CD20. *Aims.* In this study GA101 was analyzed for its anti-proliferative effects on a panel of MCL cell lines both as single agent and in combination therapies in direct comparison to Rituximab. *Methods.* Using an established panel of MCL cell lines (Rec-1, HBL-2, Jeko-1, Granta-519, JVM-2 and Z-138) we determined the effect of GA101 alone as well as in combination with Rituximab on cell proliferation and viability. MCL cells were treated with GA101 at concentrations of 1,25-20 mg/mL and Rituximab. Cell viability was analyzed by trypan-blue exclusion tests at 0h, 24h, 48h and 72h. The panel of MCL cell lines was treated with GA101 and Rituximab each at 10 mg/mL to determine potential synergism of antibody combinations. Accordingly, fractional product was calculated: synergism > 0.1; antagonism < -0,1. *Results.* After monotherapy with GA101 (1 mg/mL), Granta-519 and Rec-1 showed the highest sensitivity (65-75% cell reduction in Granta-519 and 25-30% in Rec-1). Intermediate results were achieved for Z-138, HBL-2, Jeko-1 and JVM-2 (15-20%). Rituximab mono-exposure at 12,5 mg/mL showed a 25% reduction of cell count in Granta-519, 20% in HBL-2 and < 5% in Rec-1, Jeko-1 and Z-138. Combination experiments suggested the competitive binding of the two antibodies. *Conclusions.* Even at a >10-fold lower concentration, GA101 demonstrates higher efficacy in MCL cell lines compared to Rituximab. Combination experiments suggested the competitive binding of the two antibodies. In addition, further experiments suggested an additive effect of GA101 in combination with various cytostatic compounds.

0184

EFFECTS OF THE PI3 KINASE/MTOR INHIBITOR NVP-BEZ235 ON GROWTH AND IGE-DEPENDENT MEDIATOR RELEASE IN HUMAN BASOPHILS AND MAST CELLS

K. Blatt

Medical University of Vienna, Austria, VIENNA, Austria

Growth and function of human basophils (BA) and mast cells (MC) are triggered by various cytokines and other ligands, and a complex network of signal transduction pathways. In allergic reactions, cross-linking of high affinity IgE-binding sites leads to activation and mediator secretion. In MC, the KIT ligand stem cell factor (SCF) promotes IgE-dependent mediator secretion. In mastocytosis, the SCF receptor KIT is mutated at codon 816 and expressed as a constitutively activated target in neoplastic MC. Recent data suggest that IgE-receptor downstream signalling molecules and KIT downstream signalling molecules represent potential therapeutic targets. The phosphoinositide 3-kinase (PI3 kinase) is a key signalling molecule in IgE receptor-dependent activation and KIT D816V-dependent activation in MC and has been implicated in growth and survival of normal and neoplastic cells. In the present study, we examined the effects of the dual PI3 kinase/mTOR inhibitor NVP-BEZ235 (Novartis, Basel, Switzerland) on IgE-dependent mediator release in human BA and cultured cord blood cell-derived MC as well as on growth of neoplastic BA (KU812) and neoplastic MC (HMC-1). We found that NVP-BEZ235 inhibits IgE-dependent histamine release in BA

in healthy individuals in a dose-dependent manner (IC_{50} 0.5-1 μM). In addition, NVB-BEZ235 inhibited anti-IgE-induced upregulation of CD63 and CD203c on the surface of BA, although responses were not seen with both CD molecules in all donors. In cultured MC, NVP-BEZ235 decreased IgE-dependent upregulation of surface CD63 as well as the release of β-hexosaminidase, but did not block upregulation of CD203c. Moreover, as assessed by 3H-thymidine uptake, NVP-BEZ235 was found to inhibit the growth of the BA leukemia cell line KU812 (IC_{50}: 0.01-0.05 μM) and the KIT D816V+ MC leukemia cell line HMC-1 (IC50: 0.005-0.01 μM). Apoptosis-inducing effects of NVP-BEZ235 were examined by light microscopy and AnnexinV-staining and were also observed in both cell lines, although the concentrations required to induce clear effects were substantially higher compared to effects on proliferation (effective range: >0.5 μM). In summary, NVP-BEZ235 inhibits spontaneous growth of neoplastic BA and MC as well as IgE-dependent activation and mediator secretion in normal mature BA and MC. Whether these effects of NVP-BEZ235 have clinical implications remains at present unknown.

0185

EFFECT OF THE NON-PEPTIDE THROMBOPOIETIN RECEPTOR AGONIST ELTROMBOPAG (PROMACTA® /REVOLADETM) ON BONE MARROW CELLS FROM PATIENTS WITH ACUTE MYELOID LEUKEMIA AND MYELODYSPLASTIC SYNDROMES

B. Will,[1] J.P. Luciano,[1] M. Kawahara,[1] C. Erickson-Miller,[2] A. Verma,[1] M. Aivado,[2] U. Steidl[1]

[1]Albert Einstein College of Medicine, NEW YORK; [2]Glaxo Smith Kline, COLLEGEVILLE, USA

Disease-related or chemotherapy-induced thrombocytopenia is a frequent symptom and clinical challenge in patients with myelodysplastic syndromes (MDS) or acute myeloid leukemia (AML). Recently, the novel non-peptide Thrombopoietin receptor agonist Eltrombopag (Promacta®/ Revolade™) was approved for treatment of patients with chronic idiopathic thrombocytopenic purpura (ITP) in the US. Eltrombopag has been shown to effectively elevate platelet numbers and to reduce thrombocytopenia-related complications. Therefore, Eltrombopag might be a new option to treat thrombocytopenia in patients with MDS or AML, provided that it does not stimulate malignant hematopoiesis in these diseases. We therefore studied the effects of Eltrombopag on bone marrow mononuclear cells (BM-MNC) of patients with AML and MDS. BM-MNC of 10 patients with AML/MDS (5 AML, 3 AML with previous history of MDS, 2 MDS (RAEB-II) and 5 healthy controls were exposed to different concentrations of Eltrombopag (0.1-30 ug/mL). We assessed cell growth, colony formation (suspension culture, colony-forming assays), proliferation (Bromodeoxyuridine (BrdU) incorporation assays), apoptosis (Annexin-V assays), and differentiation (cytomorphology, FACS analysis of differentiation markers). Long-term malignant self-renewal was tested *in vitro* by serial replating assays in semi-solid methylcellulose medium. Eltrombopag effectively stimulated megakaryocytic colony formation of BM-MNC in semisolid methylcellulose assays, resulting in 80% increased colony numbers (compared to 100 ng/mL TPO as a positive control [100%]) at concentrations of 1-3 ug/mL. A preferential effect on early megakaryocyte-erythrocyte progenitors (MEP) and immature megakaryocytic (Mk) progenitors was seen, while more mature MK progenitors were less affected. In contrast, malignant BM-MNC of patients with AML/MDS did not show increased proliferation, neither in suspension culture, nor in methylcellulose assays at any of the examined concentrations of Eltrombopag. In fact, while cell numbers of two patients were unchanged we observed a decrease of numbers of malignant cells in 8 of 10 patients after two weeks Eltrombopag treatment. However, due to interindividual variation, this inhibition (mean: 56%, SD: 28%, at 3 ug/mL Eltrombopag) was statistically not significant. In line with these observations we could not detect increased proliferation utilizing BrdU incorporation assays, nor significantly decreased apoptosis (Annexin-V assays) in the malignant cells of any of the patients upon Eltrombopag treatment. We neither found evidence for an increase of more immature cells or blasts when we examined cells morphologically and by FACS for surface marker expression (CD34, CD33). Utilizing serial replating assays at a concentration of 3 ug/mL Eltrombopag, we did not observe long-term malignant self-renewal of AML/MDS BM-MNC in any of the samples (4 replatings). *in vivo* studies of the effect of Eltrombopag on AML/MDS BM-MNC in a murine xenotransplantation model (NOD-SCID IL2Rgamma null) are currently ongoing. In conclusion, utilizing a variety of assays, we did not find any evidence that Eltrombopag stimulates malignant growth from BM-MNC from patients with AML/MDS. These results provide a preclinical rationale for the use of Eltrombopag in future clinical trials in AML/MDS.

FETAL HEMOGLOBIN MODULATION BY NOVEL ALKYLATING AGENTS IN HUMAN ERYTHROID CELLS; SYNERGISTIC EFFECTS WITH ESTABLISHED HBF-INDUCING AGENTS

I. Chiotoglou,[1] M. Samara,[1] G. Paterakis,[2] S. Likousi,[1] Z. Iakovidou,[3] E. Mioglou,[3] D. Mourelatos,[3] I. Marinou,[4] P. Liakos,[1] P. Kollia[4]

[1]University of Thessaly, LARISSA; [2]G. Gennimatas Hospital, ATHENS; [3]Aristotelion University, THESSALONIKI; [4]National and Kapodistrian University of Athens, ATHENS, Greece

Pharmacological induction of fetal hemoglobin (HbF) is beneficial for some patients with β-thalassemia and ameliorates the severity of pain episodes in sickle-cell anemia, mainly by hydroxyurea (HU). However, refractoriness or poor response of some patients treated with HU triggered research for other drugs. In the present study, we evaluated the effects of novel steroidal alkylating agents EA80(0.1-1 μM), XK4(0.1-30 μM) and CS-211(0.1-30 μM) alone or in combination with HU, hemin (HE) and butyric acid (BU) on HbF induction in $CD34^+$ cell cultures from normal donors. HbF cells were determined by Flow-cytometry. α/β/γ-globin mRNA transcripts were evaluated by Real-Time RT-PCR. Continuous exposure of $CD34^+$ to EA80 had a dose(up to 0.4 μM)- and time-dependent effect on cell number (measured by trypan blue) and on gamma-globin mRNA level; EA80(0.4 μM) caused a time-dependent increase in γ-globin mRNA (1-3 days:1.5 to 2.0-fold) as well as 1.5- and 2.4-fold increase in benzidine-positive and HbF-cells, respectively. The addition of HU, HE and BU combined with EA80 in $CD34^+$ cell cultures led to a 1.3, 3.0 and 2.0-fold increase in cell number at day 3, respectively. Furthermore, the combination of EA80 with either HU or HE was accompanied by an increase in γ-mRNA content (2.5 and 3.0-fold, respectively), whereas the addition of BU in combination with EA80 caused the predominant increase in γ-mRNA levels (5.0-fold at day 3); the addition of HE and BU increased HbF-cell number (3.0 and 2.0-fold, respectively). XK4 at any concentration and duration proved toxic. The third drug, CS-211, had a dose(up to 5 μM)- and time-dependent effect on cell number and γ-globin mRNA transcripts (highest effect at day 3, 3.8-fold at 5 μM). The addition of HU, HE and BU together with CS-211(5 μM) led to a 2.9, 3.7 and 2.9-fold increase in cell number at day 3, respectively. The combination of HU and CS-211 caused a 3.2-fold increase in γ-mRNA transcripts, whereas CS-211 combined with BU resulted in 3.0-fold decrease in the γ-mRNA levels. In the contrary, the combined effect of HE and CS-211 led to an extraordinary-(13.3-fold)-increase in γ-mRNA content and a 4.2-fold increase in HbF-cells. The level of both adult globin mRNAs was not affected by any of the tested drugs. The simultaneous addition of EA80 and CS-211(5 and 10 μM) in the $CD34^+$ cell cultures showed their synergistic effect in cell proliferation. As for their effect in γ-mRNA levels, it arises that CS-211(5 μM) enhances EA80 effect in increasing γ-mRNA transcription, whereas CS-211(10 μM) has a more synergistic effect with EA80 promoting γ-mRNA in quite higher levels; this is support by the high number of HbF-cells. Our findings suggest that the beneficial effect of EA80 and CS-211 might be threefold: i)increasing cell number and Hb-F cells ii)affecting preferentially the rate of transcription of γ-globin mRNA, iii)acting synergistically with HE, HU and BU, most likely through transcriptional and posttranscriptional mechanisms. These results indicate that novel alkylating agents EA80 and CS-211, either alone or in combination with other HbF-augmenting drugs, might provide a potentially useful treatment for patients with β-hemoglobinopathies with poor or no response to established Hb-F inducing agents.

0187

LENALIDOMIDE IN ELDERLY PATIENTS WITH MANTLE CELL LYMPHOMA

A. Tempescul, J.C. Ianotto, G. Guillerm, C. Berthou

University Hospital Brest, BREST, France

Background. Mantle cell lymphoma (MCL) is an aggressive non-Hodgkin's lymphoma characterized by a low response rate and a short progression-free survival (PFS) after conventional therapy. In refractory or relapsed MCL, and for elderly patients, non-eligible for intensive treatments, the prognosis is even worsen. Several novel therapeutic approaches have been proposed, including monoclonal antibodies, radioimmunotherapy, proteasome inhibitors, m-TOR inhibitors and immunomodulatory drugs (Thalidomide and Lenalidomide). It has been recognized that stromal cells provide important stimuli for the survival of malignant B-cells. Immunomodulatory drugs interact with the microenvironment, altering cytokines secretion and expression of adhe-

sion molecules, which can result in apoptosis of malignant B-cells. *Aims.* The aim of this study was to evaluate the efficacy and the adverse events of Lenalidomide, as treatment of mantle cell lymphoma within elderly patients, non-eligible for intensive treatments. *Methods.* Seven patients, with median age of 78 years (72-86 years), non-eligible for intensive chemotherapies, were treated with Lenalidomide. It was administrated, as single agent in 5 patients, associated with Dexamethasone or Rituximab in one patient each. Five of seven patients were in relapsed disease and two were in first line of treatment. We evaluated the response to Lenalidomide, the time to response and the presence of adverse events. *Results.* All seven patients presented a response to the treatment with Lenalidomide. We obtained one complete remission (CR), one unconfirmed complete remission (uCR) and five partial remissions (PR), with two minor responses. The median time to response was 5 months (1-12 months). The tolerance of the treatment was good. We noticed moderate hematological toxicity, essentially neutropenia and thrombopenia. Only two patients, with partial remission, presented an evolution of the lymphoma. *Conclusions.* MCL represents a distinct clinico-pathologic entity among the non-Hodgkin's lymphomas, characterized by a short PFS. For the elderly patients, non-eligible for intensive treatments, Lenalidomide as a single agent, or in combination with Rituximab or Dexamethasone, proves to be an important therapeutically agent. We obtained one complete remission, one uCR and 3 partial remissions and two minor responses. The tolerance of the treatment was good, with only moderate hematological toxicity.

0188

BINDING OF THE RECOMBINANT POLYCLONAL ANTI-D PRODUCT ROZROLIMUPAB (SYM001) AND PLASMA DERIVED ANTI-D TO RHD VARIANTS

M. Wikén,[1] A.M. Valentin Jensen,[2] P.S. Andersen,[2] W.A. Flegel[3]

[1]Biovitrum, STOCKHOLM, Sweden; [2]Symphogen, LYNGBY, Denmark; [3]Institute for Transfusion Medicine University Hospital Ulm, ULM, Germany

Rozrolimupab is the first in a new class of recombinant polyclonal antibody products and is under clinical development for the prevention of hemolytic disease of the newborn by anti-D prophylaxis (ADP) and for the treatment of Immune Thrombocytopenic Purpura (ITP). Rozrolimupab is composed of 25 genetically unique IgG1 antibodies all specific for the Rhesus D erythrocyte protein and derived by phage display from the antibody repertoires of 8 female human anti-RhD plasma donors enrolled in a Danish anti-RhD collection program. The 25 antibodies have been selected with the aim to obtain a recombinant anti-D product that mimics the D-specific polyclonal antibody repertoire of the plasma derived anti-D products but with the advantage of being devoid of antibodies irrelevant for the believed mechanism of action of anti-D products in ADP and ITP. Also, a recombinant product does not carry the risk of transmission of blood borne pathogens and can be produced independent of plasma donor availability. The individual antibodies in rozrolimupab have been shown to collectively recognize a broad panel of RhD variants present in populations of different ethnic origin and that may be of clinical importance in ADP. In order to confirm that this polyclonality has been adequately maintained in the final product, the binding of 7 batches of rozrolimupab to a similar panel of genetically defined RhD erythrocyte variants was analyzed and compared to that of two marketed plasma derived products. For this purpose the low-ionic strength saline (LISS) indirect antiglobulin test (IAT) was applied with the approach to give an estimate of titers of antibodies needed in order to induce agglutination with an exhaustive panel of D variants including 3 weak D types, DIV, DV, 3 DVI types, DVII, DFR, R0Har, DOL, DBT and DHMi. Also the binding under more physiological buffer conditions, mimicking the *in vivo* situation, to 4 RhD variants (DIII, DIV, DVI and DVII) was compared applying flow cytometry. The results show that polyclonality is maintained in rozrolimupab in a reproducible manner and that rozrolimupab and two commercially available plasma derived products are comparable in terms of binding to RhD variants when tested both at non-physiological and physiological buffer conditions. Thus, in regards to the anti-D antibody repertoire and coverage of RhD variants rozrolimupab constitutes a potential alternative to plasma derived anti-D in prevention of hemolytic disease of the newborn and treatment of ITP.

CD200, A CELL SURFACE PROTEIN WITH IMMUNOREGULATORY FUNCTION, IS A NEW POTENTIAL TARGET FOR HEMATOLOGIC MALIGNANCIES IMMUNOTHERAPY

L. Brunetti, E. Abate, M. Gorrese, M. Raia, C. Pascariello, A. Gravetti, G. Scalia, L. Del Vecchio

Ceinge Institute, NAPLES, Italy

Background. CD200 is a transmembrane glycoprotein with immunoregulatory function expressed on several tissues in rats and humans. Through its interaction with CD200 receptor, CD200 seems to switch cytokine production from a TH1 to a TH2 pattern, thus reducing T-cell mediated cytotoxic response and promoting tumor escape and growth. CD200 is also a target for a novel blocking humanized monoclonal antibody (Anti-CD200 MAb) and interesting results have been obtained in *in vivo* assays testing Anti-CD200 MAb with CD200 positive Burkitt lymphoma cell lines. Expression of CD200 has been already described in chronic lymphocytic leukemia/small lymphocyte lymphoma (CLL/SLL) and CD200 positivity is known as an unfavorable prognostic factor in multiple myeloma (MM) and in acute myeloid leukemia (AML). *Aim.* Starting from this data we performed a comprehensive cytometric study on a large number of hematologic neoplasms to identify specific diseases in witch Anti-CD200 MAb could be considered as a therapeutic option and to explore the possibility to use CD200 as a diagnostic tool in clinical cytometry. *Methods.* Between February 2007 and December 2008, using six-color flow cytometry, we analyzed CD200 expression in 269 samples: 185 bone marrow aspirates (BM), 58 peripheral blood specimens (PB) and 26 fine needle aspiration cytology samples (FNAC). 160 were lymphoproliferative disorders, 21 MM, 20 myelodysplastic syndromes (MDS) and 68 acute leukemias. CD200 expression was evaluated by using CD200-PE-conjugated antibody. CD200 positivity was assigned to every single case when CD200 mean fluorescence intensity (MFI) was higher then 256 arbitrary units, a channel close to the cut-off point between positive and negative cells, in our experience. *Results.* All results concerning our analysis are showed in the Table 1.

Table 1.

Disease	N	Positive N (%)	PPC (mean)	PPC (25°-75° percentile)	MFI (median)	MFI (25°-75° percentile)
AML	50	29 (58)	32.9	4-51	290	134-591
APL	4	0 (0)	1.7	1-3	35	11-126
MDS	20	13 (65)	28.3	2-44	458	140-1003
AHL	5	4 (80)	60.2	27-87	420	238-1194
ALL	9	8 (88)	64.2	57-84	1099	369-1532
CLL/SLL	73	73 (100)	98.4	98-99	3004	2051-3590
LPL	8	8 (100)	58.2	40-66	536	326-839
MCL	13	6 (46)	33.5	2-71	69	20-751
FL	15	1 (6)	8.3	2-8	46	30-83
DLBCL	19	7 (37)	19.7	1-15	68	30-279
MZL	14	9 (64)	39.4	2-74	344	35-1017
HCL	10	6 (100)	95.6	92-99	3016	1382-5430
MM	21	20 (95)	61.3	31-88	2491	1227-5764
T-NHL	8	3 (37)	26	1-63	39	23-964

CLL/SLL and hairy cell leukemia (HCL) displayed a constant positivity for CD200 with a high level of MFI. Lymphoplasmacytic lymphoma (LPL) was positive in 100% of cases but with lower MFI and lower percent of positive cells (PPC) as compared to CLL/SLL and HCL ($p<0.001$). MM/MGUS and B-cell acute lymphoblastic leukemia (B-ALL) showed CD200 positivity in, respectively, 96% and 86% of cases. CD200 was also expressed in cases of marginal zone lymphoma (MZL), mantle cell lymphoma (MCL), diffuse large B-cell lymphoma (DLBCL), T-non Hodgkin lymphoma (T-NHL), AML, acute hybrid leukemia (AHL) and T-cell acute lymphoblastic leukemia (T-ALL). Only one case of follicular lymphoma (FL) was found to be CD200 positive. In AML we also found a significant inverse correlation with myeloperoxidase (MPO-7) (Spearman's r=-0.5; $p<0.001$). No case of acute promyelocytic leukemia (APL) was positive for CD200. *Conclusions.* CD200 is candidate as a new specific target for immunotherapy with anti-CD200 in all cases of CLL/SLL, B-ALL and HCL as well as in selected cases of MZL, DLBCL, MCL, LPL, MM, T-NHL, AML, AHL and T-ALL.

0190

SUCCESSFUL TREATMENT WITH BEVACIZUMAB IN POEMS-SYNDROME

V. Buxhofer-Ausch,[1] B. Gisslinger,[2] G. Stangl,[3] H. Rauschka,[4] H. Gisslinger[2]

[1]Donauspital, WIEN; [2]Medical University of Vienna, Department of Hematology and Blood Coagulation, VIENNA; [3]Donauspital, Department of Nuclear Medicine, VIENNA; [4]Donauspital, Department of Neurology, VIENNA, Austria

Background. POEMS syndrome (acronym for polyneuropathy, organomegaly, endocrinopathy, M protein, skin changes) is a rare, paraneoplastic disorder associated with an underlying plasma cell disorder. In addition to other symptoms that are not included in the acronym, a markedly elevated level of vascular endothelial growth factor (VEGF) is usually confirmatory and might account for some of the symptoms (A Dispenzieri, Blood Reviews, 2007, 21:285-299). Since therapeutic VEGF targeting is available, 7 cases of bevacizumab treated patients have been reported describing controversial results (4 patients had a successful and 3 a fatal outcome). *Aim.* To assess response and tolerance of treatment with bevacizumab following radiotherapy and cyclophosphamide in 2 newly diagnosed patients with POEMS- syndrome. *Methods.* After local irradiation of the solitary bone lesions, high dose cyclophosphamide (5 g/m^2) prior to stem cell collection was administered, followed by 5 (patient 1) and 4 (patient 2) cycles respectively of bevacizumab (5 mg/kg BW). *Results.* Patient 1 is a 44 years old woman who was diagnosed with POEMS syndrome in May 2005. Beside other typical symptoms, she was affected by a rapid progressive, peripheral sensory-motor neuropathy on both legs and arms which rendered her wheelchair bound. VEGF level was 7 times the normal range at diagnosis. Patient 2 is a 57 year old man that first experienced symptoms of chronic progressive, distal, sensory-motor neuropathy in November 2007 making him unable to walk longer distances. In February 2008 diagnosis of POEMS syndrome was established upon other, charactersitic symptoms. VEGF level was 9 times the normal range at diagnosis. Treatment was tolerated very well in both patients without any severe side effects. In patient 1 physical condition improved dramatically after bevacizumab with fully recover of mobility 1 year after end of treatment. In patient 2, already after the first bevacizumab course, nerve conduction studies improved significantly. A few months after end of treatment, the patient reports less pain and better muscular strength with continuous improvement. *Summary and Conclusions.* According to a very limited experience with bevacizumab treatment in POEMS patients it seems that bevacizumab is poorly tolerated at a stage when VEGF levels are extremely high. Taking the published knowledge in account, we compiled a treatment sequence for both patients: after local irradiation, one cycle of high dose cyclophosphamide as conditioning therapy prior to prophylactic stem cell collection was administered. Subsequently the anti-VEGF antibody bevacizumab could be administered safely, since VEGF levels have dropped already significantly prior to anti-VEGF treatment initiation. Even if some, including ours, of the available experiences with bevacizumab in POEMS syndrome are encouraging, we need to learn more about the interactive role of VEGF in this uncommon syndrome in order to select the appropriate patients and to place it proper into sequence with other treatment options.

0191

SLUG AND ERK (P42-44): NEW TARGETS IN CHRONIC MYELOID LEUKEMIA THERAPY

M. Mancini,[1] S. Petta,[1] V. Corradi,[2] G. Martinelli,[1] E. Barbieri,[3] M.A. Santucci[1]

[1]Istituto di Ematologia e Oncologia Medica L. e A. Seràgnoli, BOLOGNA; [2]Dipartimento del Farmaco Chimico Tecnologico, SIENA; [3]Dipartimento di Scienze radiologiche e Istopatologiche L. Galvani, BOLOGNA, Italy

Background. SLUG (SNAI2) is a Snail-related zinc-finger transcription factor involved in the regulated functions of hematopoietic stem cells downstream of stem cell factor (SCF)/c-KIT ligand. Its aberrant expression has been found in t(17;19) leukemic cells, rhabdomyosarcoma expressing the PAX3-FKHR translocation and breast cancer (where it correlates with the loss of E-cadherin). Besides promoting the transition to a less differentiated phenotype, SLUG provides protection against apoptotic death in response to DNA damage and has been thereby involved in tumor progression towards drug resistance (Kajita M *et al.*, Mol Cell Biol 2004;24:7559-66). Notably, SLUG is required for BCR-ABL leukemogenesis *in vivo*, as it promotes leukemic cell survival and migration into different environments (Pérez_Mancera PA *et al.*, Oncogene 2005;24:3073-92). *Aim.* We investigated the role of SLUG in Imatinib (IM) resistance of BCR-ABL-expressing cells. *Methods.* The critical role of SLUG in BCR-ABL-induced transformation and drug resistance came from experiments with a specific silencing of SLUG through the following siRNA duplex oligoribonucleotides: 1) AUCAGAAUGGGUCUGCAGAUGAGCC; 2) GGCUCAUCUGCAGACCCAUUCUGAU. Fourty eight hrs exposure to this siRNA promoted, in fact, PUMA induction followed by massive apoptosis induction in BCR-ABL-transduced 32D and Ba/F3 cells either IM-sensitive and IM-resistant. Apoptotic cell death was measured by Annexin V and PI labelling of cells in control condition and after treatment with siRNA, IM and PD9805. SLUG overexpression in CML cells, investigated by semiquantitative PCR, may arise from the constitutive activation of mitogen-activated protein kinase (MAPK) pathway. Protein expression and post-translational modifications were investigated by western blotting. *Results.* We found that SLUG is over-expressed in Ba/F3 murine B cell progenitor and 32D cell lines stably transduced with a wild type (wt) p210 BCR-ABL construct. SLUG over-expression was revoked by anti-SLUG oligonucleotides, by PD9805, a specific inhibitor of ERK 1/2 (p42/44 MAPK) and by IM (1 microM for 24 h), supporting its dependence upon the constitutive activity of p210 BCR-ABL and MAPK pathway. SLUG reduction in response to IM had a significant impact on its downstream targets, the pro-apoptotic PUMA (which was reduced) and the anti-apoptotic BCL-xL (which was conversely reduced). Accordingly, it addressed BCR-ABL-expressing cells towards apoptotic death. Ba/F3 and 32D cells expressing BCR-ABL mutations T315I and E255K associated with IM resistance *in vivo* exhibited a further and significant increase of SLUG expression compared to cells expressing the wt BCR-ABL construct. Such further increase arises from transcriptional events. Notably, anti-SLUG oligonucleotides and PD9805 revoked SLUG over-expression and induced apoptotic death also in this drug-resistant context. *Conclusion*. Our results support a role of SLUG in the development of IM resistance in chronic myeloid leukemia (CML), likely contingent upon MAPK activation. SLUG induction might be prevented by dual SRC/ABL inhibitors, that efficiently target BCR-ABL downstream intracellular signals, including p42/44 MAPK (Konig H *et al.*, Cancer Res 2008;68:962433). MEK or MAPK inhibitors might further potentiate the cytotoxic effects of TK inhibitors and be considered for the therapy of drug-resistant CML (La Rosée P *et al.*, Clin Cancer Res 2006;12:6540-6; Nguyen TK *et al.*, Blood 2007;109:4006-15).

0192

CMC-544, AN ANTI-CD22 IMMUNO-CONJUGATE OF CALICHEAMICIN, DECREASES THE LEVEL OF COMPLEMENT INHIBITORY FACTORS ON MALIGNANT B-CELL LYMPHOMA CELLS

A. Takeshita,[1] N. Yamakage,[1] K. Shinjo,[1] I. Hirano,[1] T. Ono,[1] H. Fujihara,[1] H. Watanabe,[1] K. Iino,[1] D. Hashimoto,[1] M. Maekawa,[1] K. Ohnishi,[1] R. Ohno[2]

[1]Hamamatsu University School of Medicine, HAMAMATSU; [2]Aichi Syukutoku University, NAGOYA, Japan

Background. Investigation of complement inhibitory factors (CIF) demonstrated that they play an important role as a regulator of complement-dependent cytotoxicity (CDC) in the treatment of malignant B-cell lymphoma, and that their expression correlated with rituximab resistance. CMC-544, a conjugate of N-acetyl gamma-calicheamicin dimethyl hydrazide and a recombinant humanized antibody (IgG4) directed against the CD22 antigen, has been introduced as a promising agent to treat refractory or resistant B-cell lymphoma (BCL). The additive effects of the CMC-544 have been reported in combination with rituximab recently. However, the mechanism has not been well elucidated. We analyzed the quantitative alteration of CIFs in cell lines as well as on cells obtained from patients with BCL to clarify the underlying mechanisms of the positive concomitant effect of CMC-544 and rituximab. *Methods.* $CD22^+$ cell lines used were Daudi, Raji and Ramos cells, as well as malignant cells obtained from 15 patients with BCL after informed consents. Humanized IgG4 anti-CD22 mAb (G5/44) and NAc-gamma-calicheamicin DMH conjugated antibody (CMC-544) as well as unconjugated NAc-gamma-calicheamicin DMH were kindly provided by Wyeth Research (PA, USA). Rituximab was purchased from Zenyaku Co (Tokyo, Japan). To assess the effect of CMC-544 on CIF, cells were cultured for 2 hours in a medium containing CMC-544, switched to an antibody-free medium, and then examined at various time points thereafter. The levels of CD55 was analyzed by RT-PCR, laser microscopy and flow cytometry. The CDC effect of rituximab was studied in the presence or absence of CMC-544. To determine if CDC is enhanced by the sequential incubation of rituximab and CMC-544, cells were first incubated in a medium containing CMC-544 before the incubation for 12 hours in an antibody-free medium, and then CDC by rituximab was analyzed. *Results.* The level of CD55 significantly reduced ($p<0.001$) after incubation with CMC-544 in the three different methods. It did not change after the incubation with G5/44. The viable cell count significantly decreased after incubation with rituximab via CDC. However, significant effect on CDC was not observed with CMC-544 or G5/44 alone. Furthermore, the CDC caused by rituximab was not enhanced by simultaneous incubation with CMC-544. The CDC effect of rituximab was significantly increased within 12 hours following incubation with CMC-544 ($p<0.001$). The effect was not observed after the incubation with G5/44. *Conclusions.* CIFs are important regulators of CDC in the treatment of BCL. The increase of these molecules has been reportedly related to their resistance to rituximab, and the decrease to their susceptibility to rituximab. In our study, the reduction of CD55 and the enhancement of CDC were shown on BCL cells after incubation with CMC-544. These results support the rationale for the combined use of CMC-544 and rituximab.

Red blood cells and Iron I

Background. Despite the availability of iron chelation therapy, heart failure secondary to myocardial siderosis remains the main cause of death in regularly transfused patients with β-thalassaemia. Once-daily oral iron chelation therapy with deferasirox effectively reduces body iron burden in patients with transfusion-dependent anaemias, and the removal of myocardial iron has been demonstrated in preclinical and small clinical studies. A substudy of the EPIC trial has also allowed assessment of the efficacy of deferasirox in reducing cardiac iron. *Aim.* To evaluate the efficacy of deferasirox in removing myocardial iron in heavily transfused β-thalassaemia patients with myocardial siderosis. *Methods.* Patients aged ≥10 years with cardiovascular magnetic resonance (CMR) imaging of myocardial T2* >5-<20 ms, left ventricular ejection fraction (LVEF) ≥56%, serum ferritin (SF) >2500 ng/mL, MR (R2) liver iron concentration (LIC) >10 mg Fe/g dry weight (dw), and a lifetime minimum of 50 transfused blood units were included. Deferasirox was initiated at 30 mg/kg/day and subsequent dose adjustments of 5-10 mg/kg/day were based on changes in SF, month-6 cardiac T2* and safety parameters. The primary endpoint was change in myocardial T2* from baseline to 1 year. *Results.* 114 patients (54 male:60 female; mean age 20.9±7.3 years) were enrolled. Baseline myocardial T2* was <10ms (severe cardiac siderosis) in 47 patients (41%), and 10-20ms (mild-to-moderate cardiac siderosis) in 67 (59%). Patients had received a mean of 185 mL/kg of blood in the previous year, had a mean baseline LIC of 28.2±10.0 mg Fe/g dw and a median SF of 5235ng/mL. 68% had received deferoxamine and 32% deferoxamine/deferiprone combination therapy. Mean deferasirox dose over 1 year was 32.6 mg/kg/day. At 1 year, myocardial T2* improved significantly from baseline (Figure 1); improvement in T2* (>4% increase) was observed in 69.5%; no change in 14.3%; and worsening (>4% decrease) in 16.2%.

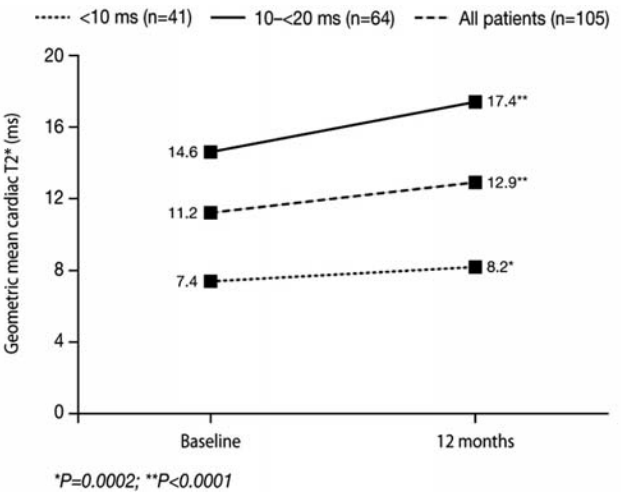

Figure 1. Geometric mean change in cardiac T2* over 12 mths.

LVEF remained stable. Both mean LIC and absolute change of median SF were reduced significantly from baseline by -6.6±9.9 mg Fe/g dw and -1257ng/mL, respectively (p<0.0001). Change from baseline in T2* was inversely correlated with change in LIC (r=-0.2, p=0.03). 105 patients (92.1%) completed treatment; four discontinuations (3.5%) were due to adverse events (AEs) and five (4.4%) for other reasons. No deaths were reported. Investigator-assessed drug-related AEs were reported in 56 patients (49.1%); rash was the most common (n=15; 13.2%). Most drug-related AEs (78.6%) were of mild-to-moderate severity. Two drug-related serious AEs (one nephritis leading to acute renal failure, one renal tubular disorder) were reported that resolved following drug discontinuation. Five patients (4.4%) had a non-progressive increase in serum creatinine >33% above baseline and upper limit of normal (ULN) on two consecutive visits. Two patients (1.8%) had an increase in alanine aminotransferase >10xULN on two consecutive visits; levels were already elevated at baseline in both patients. *Summary and Conclusions.* Deferasirox was effective in removing iron from the heart in β-thalassaemia patients with cardiac siderosis. The statistically significant improvement in myocardial T2* was associated with maintained normal cardiac function, and a concomitant significant decrease in hepatic and total body iron burden.

LABILE PLASMA IRON LEVELS IN HEAVILY IRON-OVERLOADED PATIENTS WITH TRANSFUSION-DEPENDENT ANAEMIAS IN RESPONSE TO DEFERASIROX THERAPY: RESULTS FROM THE LARGE-SCALE, PROSPECTIVE 1-YEAR EPIC TRIAL

A. Kattamis,[1] A. El-Beshlawy,[2] J.F. Seymour,[3] C.-K. Li,[4] H. Nick,[5] D. Habr,[6] G. Domokos,[5] B. Roubert,[5] M.D. Cappellini[7]

[1]University of Athens, ATHENS, Greece; [2]Cairo University, CAIRO, Egypt; [3]Peter MacCallum Cancer Center, MELBOURNE, Australia; [4]Prince of Wales Hospital, Chinese University of Hong Kong, HONG KONG, Hong Kong; 5Novartis Pharma AG, BASEL, Switzerland; 6Novartis Pharmaceuticals, EAST HANOVER, NJ, USA; 7Universitá di Milano, Policlinico Foundation IRCCS, MILAN, Italy

Background. Labile plasma iron (LPI) is a toxic, directly chelatable form of non-transferrin-bound iron produced in conditions of iron overload when levels surpass the binding capacity of transferrin. LPI is taken up in hepatocytes, myocardium and endocrine tissues leading to oxidative tissue damage. Continuous presence of adequate levels of an effective iron chelator in the plasma may bind LPI, ameliorating tissue damage and minimizing iron-related morbidity and mortality. *Aim.* To evaluate the effect of deferasirox on LPI levels in patients with a variety of transfusion-dependent anaemias enrolled in the prospective, 1-year EPIC trial. *Methods.* Patients aged ≥2 years with transfusion-dependent anaemia and serum ferritin (SF) ≥1000 ng/mL, or <1000 ng/mL with a history of multiple transfusions (>20 transfusion episodes or >100 mL/kg of red blood cells) and an R2 MRI-confirmed liver iron concentration >2 mg Fe/g dry weight were enrolled. Deferasirox starting dose was determined based on blood transfusion frequency (10-30 mg/kg/day). Dose adjustments in steps of 5-10 mg/kg/day (in the range 0-40 mg/kg/day) were based on SF trends and safety markers. Blood samples to measure LPI and assess the deferasirox pharmacokinetic profile were taken pre-administration and 2 hours post-administration at baseline, weeks 12, 28 and 52. *Results.* LPI data are available from 1602 patients (825 male, 777 female; mean age 30.4±23.0 years). Underlying anaemias were: β-thalassaemia (n=1029), myelodysplastic syndromes (MDS; n=305), aplastic anaemia (AA; n=104), sickle cell disease (SCD; n=79), rare anaemias (mostly hemolytic in nature) (RA; n=42), and other transfusion-dependent anaemias (n=43). Mean LPI, pre- and post-deferasirox administration, at baseline, weeks 12, 28 and 52 are shown in the Table. Overall mean deferasirox dose during the 1-year treatment period was 22.4±6.0 mg/kg/day (β-thalassaemia, MDS, AA, SCD and RA: 24.3±5.5, 19.3±5.7, 17.8±4.7, 20.2±3.8 and 18.6±5.6 mg/kg/day, respectively). At each time point, peak LPI levels observed just before deferasirox dosing were decreased compared with baseline and were mostly within the normal range from week 12 onwards in each underlying anaemia. A slight increase at 52 weeks was seen in the thalassaemia sub-group: this could be associated with decreased compliance or other reasons, to be investigated further. There was a significant correlation between change from baseline in pre-dose LPI and changes from baseline in SF (data previously presented) in patients with β-thalassaemia and SCD (p=0.03 for both).[1] In all patients, mean steady-state deferasirox plasma concentration (ie pre-administration value) at weeks 12, 28 and 52 was 32.9, 35.9 and 39.4 μmol/L, respectively. At each time point this was approximately half the concentration value observed at 2 hours post-administration (84.4, 89.3 and 97.0 μmmol/L, respectively). *Summary and Conclusions.* These results confirm the ability of once-daily deferasirox to achieve sustained reductions in toxic LPI levels to within the normal range across various transfusion-dependent anaemias, supporting previous data in β-thalassaemia and MDS patients.[2,3] This is likely due to trough levels of deferasirox being within the therapeutic range, thereby preventing LPI levels rebounding between doses. These data support the proposal that deferasirox therapy may prevent end-organ damage through ablation of toxic LPI in these patients.

Table 1. Mean LPI, pre and post deferasirox administration, at baseline and after repeat doses.

THE EFFICACY OF IRON CHELATOR REGIMES IN REDUCING CARDIAC AND HEPATIC IRON IN PATIENTS WITH THALASSAEMIA MAJOR: A CLINICAL OBSERVATIONAL STUDY

V.A. Berdoukas, G.I. Chouliaras, P. Moraitis, K. Zannikos, E. Berdoussi, A. Ladis

Thalassaemia Unit, ATHENS, Greece

Background. Available iron chelation regimes in thalassaemia may achieve different changes in cardiac and hepatic iron as assessed by MRI. *Aims.* To assess the four available iron chelator regimes with respect to their efficacy in reducing cardiac and hepatic iron. *Methods.* Patients attending the centre are transfused at approximately 2 weekly intervals and have access to iron chelation either with desferrioxamine (DFO), deferiprone (DFP) since the year 2000, combination of desferrioxamine and deferiprone (Comb) and since 2006 deferasirox (DFX). Since the start of 2001, patients have had MRI of the heart and liver to assess the degree of iron load in those organs. Patients who had at least two MRI were included in the study. The rate of change of cardiac and hepatic MRI were assessed according to the chelation regime that they received for the greatest period of time between each set of two MRI measurements. Only the first two MRIs that were at least 12 months apart while on each prescribed regime were included in the analysis. The MRI T2* results were converted to both Cardiac Iron Concentration (CIC) and Liver Iron Concentration (LIC), because of the lack of linearity between tissue iron and T2* (both with methods of Wood *et al.*). Compliance and dose of medications were not taken into account for the purposes of this study as the aim was to observe expected clinical outcomes according to prescription of the chelation regime. *Results.* 232 patients had more than one MRI with a total of 464 studies. Table 1 shows the mean estimated change in CIC mg/gdw (Δ CIC) according to severity of cardiac siderosis. Similarly, Table 2 shows the mean estimated change in LIC mg/gdw (Δ LIC). In summary, for the heart, Comb significantly reduced cardiac iron at all levels of iron loading while DFP did so in the mild and moderate groups. DFO and DFX did not show a significant reduction in cardiac iron in patients with cardiac iron load. In the liver, Comb resulted in the most rapid decline at all levels of iron load and DFX achieved

significant falls in the moderate and heavily loaded patients. DFO and DFP maintained hepatic iron levels. *Discussion and Conclusions.* The outcomes of this retrospective study conform to expected outcomes based on other studies but that were usually not comparative between regimes. The advantages of this study were that it was from a large clinic with homogeneous care and does compare outcomes of the different chelation regimes. With the knowledge of the efficacy of the different available regimes and the specific iron load in the heart and the liver, appropriate tailoring of chelation therapy should allow clearance of iron. These outcomes may be useful to physicians as to the chelation they should prescribe according to the levels of iron load found in the heart and liver by MRI and should contribute to the reduction in morbidity and mortality associated with iron load.

INCREASED PLASMA LEVELS OF NGAL AND IL-18 CORRELATE WITH REDUCED GFR PROVIDING EVIDENCE OF TUBULOGLOMERULAR DEFECT IN PATIENTS WITH HBS/BETA-THALASSEMIA

I. Papassotiriou,[1] A. Margeli,[2] E. Hantzi,[2] E. Terpos,[3] I. Voskaridou[4]

[1]Aghia Sophia Childen's Hospital, ATHENS; [2]Department of Clinical Biochemistry, "Aghia Sophia" Children's Hospital, ATHENS; [3]Department of Medical Research, [251] General Airforce Hospital, ATHENS; [4]Thalassemia Center, Laikon General Hospital, ATHENS, Greece

Background. Promising novel biomarkers for acute kidney injury (AKI) or chronic kidney injury (CKI) include a plasma levels of cystatin C, Neutrophil Gelatinase-associated Lipocalin (NGAL) and Interleukin-18 (IL-18) and urinary levels of NGAL, IL-18 and Kidney Injury Molecule-1 (KIM-1). These biochemical indices have been reported to be useful for evaluating the duration and severity of kidney disease and for predicting progression and adverse clinical outcomes. Furthermore, these biomarkers have given promising results in differentiating the various causes of AKI or CKI. Progressive renal failure is one of the main complications in HbS/β-thalassemia (HbS/β-thal). Early identification of patients at high risk of developing renal failure is of great importance as it may allow specific measures to delay the progression of renal damage and thus to reduce the incidence of end-stage renal failure and mortality. *Aims.*To explored the activation of tubuloglomerular feedback in patients with HbS/β-thal. *Methods.* Fifty-eight adult patients with HbS/beta-thal (age 42±17years, males/females 20/58) were included in the study. We determined the above mentioned parameters, along with the more classical ones such us β2-microglobulin and N-acetyl-β-D-glucosaminidase (NAG) in blood and urine using standard methodology. GFR values were calculated according to the recently proposed cystatin C-based prediction equation using only each concentration in mg/L: GFR [mL/min/1.73m(exp)2] = 76.7 x Cystatin C(exp)-1.18. *Results.* We found that: a) impairment of GFR in 21/58 patients (36%); b) increased plasma concentrations of NGAL and IL-18 in 34/58 (58%) and 58/58 (100%) patients, respectively; c) increased and/or detectable urine concentrations of NGAL and IL-18 in 54/58 (93%) and 46/58 (79%) patients, respectively; d) significant negative correlations between GFR and plasma NGAL and IL-18 (r=-0.735, $p<0.0001$ and r=-0.350, $p<0.007$, respectively) and e) significant positive correlations between cystatin C and urine NGAL and IL-18 (binomial, $p<0.005$ and r=0.412, $p<0.03$, respectively). *Conclusions.* These findings suggest that tubuloglomerular feedback is activated in almost all studied patients with HbS/β-thalassemia. Measurements of plasma and urine NGAL and IL-18 contribute significantly to the early detection and risk stratification of renal disease in these patients. However, prior to their clinical usefulness, these biomarkers must undergo through rigorous validation in multiple cohorts.

ANALYSIS OF IRON HOMEOSTASIS AND ERYTHROID ACTIVITY IN A COHORT OF LOW-RISK MYELODYSPLASTIC PATIENTS

E. Messa,[1] C. Maffè,[1] G. Volpe,[1] N. Campostrini,[2] D. Gioia,[3] A. Levis,[3] D. Cilloni,[1] D. Girelli,[2] C. Camaschella,[4] G. Saglio[1]

[1]University of Turin, ORBASSANO; [2]University of Verona, VERONA; [3]ASO Arrigo e Biagio, ALESSANDRIA; [4]San Raffaele Institute, MILAN, Italy

Background. The small liver peptide hepcidin is the principal regulator of iron homeostasis in humans through the binding and the subsequent degradation of ferroportin both in enterocytes and macrophages. A broad range of different molecules are known to influence hepcidin levels in different conditions. Inflammation, through Interleukin-6 production and iron overload through BMP activation increase hepcidin expression while iron deficiency and hypoxia have opposite effects. Growth differentiation factor 15 (GDF15), a member of the transforming growth factor-β family, has been described as a potential hepcidin inhibitor in clinical conditions characterized by ineffective erythropoiesis such as thalasssemia and congenital dyserythropoietic anemia type 1. Little is known about iron regulation in myelodysplastic syndromes (MDS) in which anemia is a common clinical feature and a high degree of ineffective erythropoiesis coexist with chronic inflammation or iron overload leading to opposite effects on hepcidin production. *Aims.*to evaluate iron parameters and markers of erythroid activity in a cohort of low-risk MDS patients at diagnosis or never transfused. *Methods.* 47 serum samples were collected from 40 low-risk MDS patients after written informed consent. WHO diagnosis was as follows: 17 refractory anaemia, 6 unclassifiable MDS, 10 refractory anaemia with blast excess, 2 refractory anaemia with ringed sideroblasts (RARS), 5 refractory cytopenia with multilineage dysplasia. In 7 out of 40 patients, samples were analyzed before and after 4 months of EPO treatment. Serum GFD15 evaluation was performed by ELISA. Serum hepcidin evalution was performed by SELDI-TOF-MS technique. The results were compared to 30 matched healthy controls and 30 transfusion-dependent thalassemic patients. *Results.* Median transferrin saturation was 28% (range 4-76) , median serum ferritin levels were 558,06 ng/mL (range 58-1959), median haemoglobin value was 11,7 g/dL (range 7.5-14.6). Serum GDF15 values in MDS patients with erythroid dysplasia were significantly increased compared to healthy controls (median value 2537 pg/mL versus 206, $p<0.001$ by Mann-Whitney test) and significantly lower than thalassemic patients. No difference was found between GDF15 values of MDS patients without erythroid dysplasia and healthy subjects. Hepcidin median value was 7,045 nM/L (range 0.55-41.54) compared to a range of 3-7 nM/L in controls. In patients with erythroid dysplasia hepcidin median value was 10.44 nM/L but was very low in RARS patients. Regression analysis showed a statistically significant correlation between sTFR and either GDF15 or hepcidin levels. We failed to found any significant correlation between GDF15 and hepcidin values and also between hepcidin and ferritin, haemoglobin and EPO values. In patients who reached a positive erythroid response after EPO treatment we detected a significant reduction in GDF15 values and a parallel increase in hepcidin levels. *Summary and Conclusions.* Serum GDF15 and hepcidin are both increased in a cohort of low-risk MDS patients with erythroid dysplasia but not in cases with only megakaryocytic or myeloid dysplasia. GDF15 is confirmed a marker of ineffective erythropoiesis also in MDS patients but in our series did not show significant correlation

with hepcidin levels probably due to the heterogeneity of the cohort. Furthermore both variables appear to be modulated by a successful EPO treatment.

0198

MYOCARDIAL LESIONS AND IRON DEPOSITS AFTER TREATMENT WITH ANTHRACYCLINES

A. Cascales,[1] F. Pastor,[2] B. Sanchez-Vega,[2] J. Corral,[1] V. Vicente,[1] F. Ayala[3]

[1]Centro Hemodonacion, MURCIA; [2]Hospital Reina Sofia, MURCIA; [3]Hospital Morales Meseguer, MURCIA, Spain

The involvement of iron in anthracycline-induced cardiotoxicity is suggested by several experimental models but there is no available data of iron role in clinical studies. Only a few postmortem series have attempted to characterize the cardiac injury induced by anthracyclines. However, these studies are previous to those supporting the involvement of iron in the pathogenesis of anthracycline cardiotoxicity, and therefore they did not evaluate the relationship between deposits of iron and myocardial damage. *Aim.* The aim of this work was to describe the myocardial lesions induced by anthracyclines in necropsies obtained from cancer patients and determine the relationship between myocardial lesions and cardiovascular risk factors, clinical cardiac events, and cardiac iron deposition. *Methods.* We retrospectively studied 97 clinical necropsies from patients with a solid or haematological tumour treated in the Hematology and Oncology Department between 1996 and 2005. Inclusion criteria were histologically confirmed diagnosis of cancer, availability of complete clinical record, and archived heart and liver histological tissue. Clinical, histopathology, and iron deposition studies were performed. All cardiac and liver samples were examined by light microscopy. Heart and liver iron concentration (iron mg/g of dry tissue) was determined in all cases in which formalin fixed tissue was available for atomic absorption spectroscopy. Statistical analysis was performed using SPSS program version 15.0 and SNPStats software. *Results.* 97 patients were included in the study. The median age for all patients was 56 years (range, 5-83 years). 48 (49%) patients had received treatment with anthracyclines, 24 (25%) with chemotherapy without anthracyclines, and the other 25 (26%) had not been treated with chemotherapy. The median dose of anthracycline was 281 mg/m^2 (range 36-639). We found a statistical association of anthracycline treatment with myocytolysis (29/48 vs. 10/49, p=0.001), with interstitial fibrosis (30/48 vs. 19/49, p=0.09), and with patches of necrosis (9/4 vs 0/49, p=0.001). Nuclear hypertrophy was associated with higher doses of anthracyclines (301 vs 90.8 mg/m^2, p=0.016). Conversely, myocardial lesions were not correlated either with cardiovascular risk factors (sex, age, hypertension, diabetes, dyslipemia, alcohol, tobacco, thoracic radiotherapy), or previous cardiac disease. Congestive heart failure was significantly more frequent in patients with anthracycline treatment (7/48 vs. 2/49, p=0.03), whereas no relationship was found between clinical cardiac events and histopathologic lesions. A cumulative anthracycline dose greater than 200 mg/m^2 was associated with a higher iron concentration in heart tissue (0.49 vs. 0.24 mg/gr; T-Student, p=0.01). Myocytolysis, interstitial fibrosis and patches of necrosis were associated with higher iron stores, but the differences were not significant. History of transfusions (p=0.32) and systemic iron deposits were not related to heart iron load. *Conclusions.* Our data shows that anthracycline treatment is associated with myocitolysis, interstitial fibrosis, and patches of necrosis. Also, anthracycline treatment induces a specific heart iron overload independent of systemic iron load which is in accordance with previously published experimental data

0199

ASSESSMENT OF SAFETY IN PATIENTS RECEIVING LONGER-TERM IRON CHELATION THERAPY WITH DEFERASIROX WHO HAD ACHIEVED SERUM FERRITIN LEVELS OF <1000 NG/ML DURING THE STUDY COURSE

J.B. Porter,[1] A. Piga,[2] A. Cohen,[3] J.M. Ford,[4] J. Bodner,[5] M.D. Cappellini[6]

[1]University College London, LONDON, UK; [2]Universitá di Torino, TURIN, Italy; [3]Children's Hospital, PHILADELPHIA, PA, USA; [4]Novartis Pharma AG, BASEL, Switzerland; [5]Novartis Pharmaceuticals, EAST HANOVER, NJ, USA; [6]Universitá di Milano, Policlinico Foundation IRCCS, MILAN, Italy

Background. A target serum ferritin (SF) value was not specified in study protocols in the deferasirox clinical trial program, but was determined by the individual investigators. A large proportion of patients achieved SF levels below 1000 ng/mL, a threshold that is known to be associated with improved survival and a reduced risk of iron-overload-related complications (eg heart failure) in patients with thalassaemia. As the use of deferoxamine (DFO) has been associated with increased toxicity at low SF, assessment of the adverse event (AE) profile of patients enrolled in deferasirox studies has been performed in the subgroup of patients that achieved low SF levels. *Aim.* To evaluate the safety of deferasirox in a cohort of adult and paediatric patients with transfusion-dependent anaemias and iron overload from two large clinical trials (0107 and 0108) whose SF levels fell to <1000 ng/mL during treatment with deferasirox. *Methods.* In the 1-year core studies, frequently-transfused patients ≥2 years of age with a range of chronic anaemias received deferasirox 5-30 mg/kg/day. Eligible patients were subsequently enrolled in 4-year extension trials, where dose was adjusted based on SF levels. Patients eligible for this analysis had baseline SF of ≥1000 ng/mL but achieved a SF level of <1000 ng/mL on ≥2 consecutive visits any time after starting deferasirox therapy. The number of days when SF was <1000 ng/mL was calculated for each patient. AEs in these patients were determined for the entire treatment period and for the period following the first SF measurement of <1000 ng/mL, irrespective of future SF levels. *Results.* 474 patients were included in this analysis: underlying anaemias were β-thalassaemia (n=379), myelodysplastic syndromes (n=43), Diamond-Blackfan anaemia (n=30) and other anaemias (n=22). The percentage of patients achieving a SF <1000 ng/mL by year of treatment were as follows: 13.5% in year 1, 18.6% in year 2, 25.7% in year 3, 32.5% in year 4 and 36.7% in year 5 to date. Overall 174 patients (36.7%) reached a SF level of <1000 ng/mL at ≥2 consecutive visits, while SF levels remained ≥1000 ng/mL in 300 patients. The median duration of SF levels <1000 ng/mL was 149 days (range 18-1726). Patient demographics, baseline characteristics and safety profiles are shown in the Table 1, demonstrating a comparable safety profile in the two groups. In addition, the incidence of drug-related AEs (gastrointestinal, renal and liver) did not appear to increase during the periods after SF levels first decreased below 1000 ng/mL. *Summary and Conclusions.* The safety profile of patients achieving low SF levels during the core and extension study phases was comparable to those who did not, suggesting that when appropriately dosed, iron-overloaded patients can be safely chelated to SF levels of <1000 ng/mL. The observed lack of increase in the proportion of patients with creatinine increases >33% above baseline and ULN or with ALTs >10xULN is of particular note.

Table 1. Demographics, baseline characteristics and safety profile of patients who achieved SF levels <1000 ng/mL and patients who did not.

	Patients who achieved SF <1000 ng/mL	Patients who did not achieve SF <1000 ng/mL
n	174	300

SAFETY AND EFFICACY OF IRON CHELATION THERAPY WITH DEFERASIROX IN PATIENTS WITH SICKLE CELL DISEASE: 3.5-YEAR FOLLOW-UP

E. Vichinsky,[1] T. Coates,[2] A.A. Thompson,[3] F. Bernaudin,[4] D. Lagrone,[5] V. Dong,[5] M.M. Heeney[6]

[1]Children's Hospital and Research Center Oakland, OAKLAND, CA, USA; [2]Children's Hospital Los Angeles, LOS ANGELES, CA, USA; [3]Children's Memorial Hospital, CHICAGO, IL, USA; [4]Centre Hospitalier Intercommunal, CRÉTEIL, France; [5]Novartis Pharmaceuticals, EAST HANOVER, NJ, USA; [6]Children's Hospital Boston, BOSTON, MA, USA

Background. Patients with sickle cell disease (SCD) require repeated blood transfusions to manage complications, inevitably resulting in the development of chronic iron overload and the need for lifelong iron chelation therapy. Controlled studies of the long-term effects of iron chelation therapy in patients with SCD are scarce, but an ongoing extension phase of a 1-year deferasirox Phase II study is designed to provide up to 5-years' treatment data. *Aim.* To evaluate the cumulative 3.5-year safety and efficacy of deferasirox in patients with SCD and transfusional iron overload enroled in a 4-year extension to a 1-year comparative study. *Methods.* A 1-year comparative study has demonstrated that once-daily oral therapy with deferasirox was well tolerated and produced similar (dose-dependent) reductions in liver iron concentration (LIC) to deferoxamine (DFO) in SCD patients with iron overload. Eligible patients subsequently entered a 4-year extension phase and received deferasirox only; dose adjustments were based on monthly serum ferritin (SF) levels and safety assessments (adverse events [AEs] and laboratory parameters). Patients with abnormal renal function were excluded. *Results.* Data from 132 patients (mean age 19.3±10.7 years) entered the extension phase. The median duration of exposure to deferasirox was 37.4 months (3.1 years) at a mean dose of 18.4±6.2 mg/kg/day. Mean daily dose of deferasirox increased from 15.4±6.9 mg/kg/day at month 1 to 22.3±7.3 mg/kg/day at month 42. Mean iron intake over this period was 0.3±0.1 mg/kg/day. 72 patients (54.5%) continue to receive deferasirox. Reasons for discontinuation include: consent withdrawal (n=24, 18.2%), AEs (n=11, 8.3%), lost to follow-up (n=9, 6.8%), unsatisfactory therapeutic effect (n=4, 3.0%), and other reasons (n=11, 8.3%). One death was reported (post-liver transplantation, unrelated to study drug). The most frequent drug-related (investigator-assessed) AEs were nausea (n=20; 15.2%), diarrhoea (n=14; 10.6%), vomiting (n=8; 6.1%) and abdominal pain (n=6; 4.5%). The annual frequency of drug-related AEs generally decreased from year to year (Table). Nine patients (6.8%) had two consecutive increases in serum creatinine that were both >33% above baseline and above the upper limit of normal (ULN); however, there were no progressive increases. Five patients (3.8%) had an increase in alanine aminotransferase >10xULN on at least one visit; baseline levels were already >ULN in two patients. Median SF levels decreased from a baseline level of 3439 ng/mL (n=132) by 651 ng/mL (p=0.0533, Wilcoxon signed rank test; n=49). SF decreases were dose-dependent. *Summary and Conclusions.* Over 3.5 years of deferasirox treatment showed no evidence of progressive increases in serum creatinine in patients with SCD, who have a tendency to develop progressive renal disease. The incidence of drug-related AEs decreased after the first year. Deferasirox provided continued reduction in SF over the course of the study.

Table. Most common (>4% overall) drug-related AEs, by year of deferasirox treatment.

AE	Frequency, n (%)	Incidence			
		Year 1	Year 2	Year 3	Year 3.5
Nausea	20 (15.2)	17 (12.9)	2 (1.6)	–	1 (0.8)
Diarrhoea	14 (10.6)	13 (9.9)	–	1 (0.8)	–
Vomiting	8 (6.1)	7 (5.3)	1 (0.8)		–
Abdominal pain	6 (4.5)	5 (3.8)	–	1 (0.8)	–

0201

DEFERASIROX IN PAEDIATRIC PATIENTS WITH THALASSAEMIA MAJOR: 1-YEAR RESULTS FROM A LARGE PAEDIATRIC COHORT ENROLLED IN THE PROSPECTIVE, MULTICENTRE EPIC STUDY

A. Filosa,[1] M. Elalfy,[2] C. Li,[3] Y. Lai,[4] L.L. Chan,[5] P. Sutcharitchan,[6] D. Habr,[7] G. Domokos,[8] B. Roubert,[8] A. El-Beshlawy[9]

[1]Cardarelli Hospital, NAPLES, Italy; [2]Ain Shams University, CAIRO, Egypt; [3]Guangzhou Nang Fang Hospital, GUANGZHOU, China; [4]The first hospital affiliated Guang Xi Medical University, NANNING, China; [5]University Malaya Medical Centre, KUALA LUMPUR, Malaysia; [6]Chulalongkorn University, BANGKOK, Thailand; [7]Novartis Pharmaceuticals, EAST HANOVER, NJ, USA; [8]Novartis Pharma AG, BASEL, Switzerland; [9]Cairo University, CAIRO, Egypt

Background. Chronic anaemias including thalassaemia major (TM) are often diagnosed during infancy, requiring long-term red blood cell (RBC) transfusions. Iron overload can therefore occur as early as 2 years of age, hence the need to initiate effective and safe iron chelation therapy early in life to avoid significant clinical sequelae. The multicenter deferasirox EPIC trial, the largest conducted for an iron chelator, enrolled the largest cohort of paediatric patients ≥2 years in a single prospective study. *Aims.* To investigate the efficacy and safety of fixed starting doses of deferasirox according to transfusional iron intake, with subsequent dose titration in paediatric patients with TM. *Methods.* Patients enrolled in EPIC were ≥2 years with transfusion-dependent anaemias and serum ferritin (SF) ≥1000 ng/mL, or <1000 ng/mL with a history of multiple transfusions (>20 transfusions or >100 mL/kg of RBCs), and R2 MRI-confirmed liver iron concentration of >2 mg Fe/g dry weight. Deferasirox starting dose was 20 mg/kg/day for patients receiving 2-4 blood units/month. An initial dose of 10 or 30 mg/kg/day was considered for patients receiving less or more frequent blood transfusions, respectively. Protocol-specified dose adjustments of 5-10 mg/kg/day (range 0-40 mg/kg/day) were performed every 3 months based on SF trends and safety markers. The primary efficacy endpoint was change in SF from baseline at 1 year. Data from paediatric patients (aged ≥2-<16 years) with TM are presented. *Results.* 421 patients (234 male:187 female; mean age 8.8 [range 2-15] years) aged 2-<6 (n=118), 6-<12 (n=164) and 12-<16 (n=139) years were enroled. A mean 15.8 transfusions were received in the previous year and patients had been receiving transfusions for a mean 7.7 years. 85.5% had received prior chelation therapy for a mean 5.3 years: deferoxamine (66.5%), deferiprone (1.2%), deferoxamine/deferiprone combination (17.8%). 385 patients (91.4%) started on deferasirox 20 mg/kg/day or less. 343 patients (81.5%) received dose adjustments during the study, most commonly due to insufficient response (50.8%). The average actual deferasirox dose received was 23.8±5.2 mg/kg/day, with a final dose ≥30 mg/kg/day in 55% of patients. 405 patients (96.2%) completed 1 year; main reasons (>2 patients) for discontinuation were adverse events (AEs, n=6; 1.4%), consent withdrawal (n=3; 0.7%) and abnormal laboratory values (n=4; 1.0%). Drug-related serious AEs were reported in four patients (1.0%; Fanconi syndrome [n=1], gastric haemorrhage [n=1], rash [n=2]) and no deaths occurred. The most common (>2%) drug-related (investigator-assessed) AEs were rash (n=34; 10.4%) and abdominal pain (n=10; 2.3%). Nine patients (2.1%) had serum creatinine values >33% above baseline and the upper limit of normal (ULN) on two consecutive visits; there were no progressive increases. Four patients (1.0%) had increases in alanine aminotransferase >10xULN on two consecutive visits; levels were already elevated in three patients.

Table 1. Reduction in SF by dose cohort.

	<20 mg/kg/day (n=85)	≥20–<30 mg/kg/day (n=299)	≥30 mg/kg/day (n=35)	All patients (n=419)
Median SF at baseline	2317	3197	5093	3122
Median SF at end of study	2385	3282	3945	3181
Absolute change in SF	101	36.5	-1036	19
P-value	0.6318	0.7849	0.0295	0.5604
Mean iron intake (mg/kg/day)	0.48	0.56	0.44	0.53

Summary and Conclusions. Data suggest that in heavily transfused TM

paediatric patients, a higher starting deferasirox dose and/or prompt dose escalation provides more optimal control of iron burden. Deferasirox was generally well tolerated with a very low discontinuation rate and a safety profile consistent with previously reported data in paediatric patients.

0202

DELETION IN THE LDLR1 & 2 DOMAINS IN THE TMPRSS6 GENE IN A CHILD CAUSES IRIDA WITH EXTREMELY HIGH HEPCIDIN LEVEL

I. Tchou,[1] M. Diepold,[2] M. Neerman-Arbez,[3] P. Beris[1]

[1]Geneva University Hospital, GENEVA; [2]Pediatric Clinic, Bern Univ. Hospital, BERN; [3]Medical Genetics, CMU, GENEVA, Switzerland

Background. Matriptase-2 (Tmprss6), a type II transmembrane serine protease, plays an essential role in iron homeostasis as an inhibitor of hepcidine. Cases with mutations in both Tmprss6 genes have already been described and lead to severe microcytic anemia with iron deficiency state refractory to iron treatment (IRIDA). Aims and case report: We describe the first case of IRIDA in Switzerland and report our studies concerning the identification of the mutations in matriptase-2 gene. The propositus is a male child born at Bern in 2005. At 12 months laboratory analyses showed: Hb 77 g/L; MCV 51 fl; iron 2 µmol/L, transferrin saturation 3% and ferritin 49 µg/L. WBC and PLT count were normal. He received oral and i.v. iron with Hb 85 g/L at day 35 post treatment. Bone marrow showed iron in macrophages but not in erythroblasts; karyotype analysis and search for infection were negative. Subsequent infusion of fresh frozen plasma and iron in a month period raised Hb to 101 g/L. This effect was transitory although ferritin increased to 310 µg/L. CBC as well as iron status of both parents was normal. On June 2008 we infused 5×4 hours 25 mg/day of Venofer®. Within 3 weeks, Hb and RBCs increased from 70-103 g/L and 4.7-6.0×10^{12}/L, respectively. *Methods.* Hepcidine was dosed by a combination of weak cation exchange chromatography and time-of-flight mass spectrometry; TMPRSS6 exons were screened by PCR amplification of genomic DNA and sequenced using ABI 3130XL; HLA typing was performed by PCR-SSO. *Results.* Serum hepcidine was 30.7, <1.4, <1.4 and 2.2 ng/mL (propositus, and three healthy controls matched for the age). Sequencing of TMPRSS6 exons revealed a novel missense mutation in exon 8 (Ser304Leu), in heterozygosity in the propositus and the mother but absent in 200 control chromosomes as verified by RFLP analysis. Interestingly, the father was apparently homozygous for SNPs in exon 12 which were not present in his son. Paternity was confirmed by HLA typing. A deletion contributed by the father was therefore suspected and confirmed by PCR amplification. The deletion breakpoints were identified in exons 12 and 13 eliminating 1054 nucleotides and resulting in an in-frame deletion of 30 residues in LDLR1 and LDLR2 domains. *Conclusions.* In children of the same age as the propositus, serum hepcidin is low (<5 ng/mL with our method) most probably reflecting increased iron needs in that period of development. The hepcidin level (30.7 ng/mL) found in the propositus suggested matriptase-2 dysfunction, confirmed by DNA analysis. In fact a 30 amino acid deletion, most likely abolishing matriptase-2 function, and a missense mutation, Ser304Leu, affecting a residue conserved in all species studied so far were found in the propositus. As very little iron is absorbed or released from macrophages in such a situation, iron was given as continuous i.v. infusions to saturate serum transferrine. Obtained Hb value support this new therapeutic approach.

0203

OUTCOMES OF PATIENTS WITH SICKLE CELL DISEASE ADMITTED TO THE INTENSIVE THERAPY UNIT – A SINGLE INSTITUTION EXPERIENCE

C.J. Gardner, C. Bell, M. Allman, M. Ervine, S.L. Thei, M. Awogbade

King's College Hospital, LONDON, UK

Background. King's College Hospital has a cohort of 500 adult patients with sickle cell disease. The commonest reason for hospitalisation is acute pain that can precipitate other more serious complications requiring intensive care. *Aims.* To examine the reasons for admission to the intensive therapy unit (ITU) in sickle patients, and to look at patients' outcome. *Methods.* The study includes adult patients (over 16 years old) over an eight year period, 1 January 2000 to 31 December 2007. We matched the King's database of general ITU admissions with the King's sickle database, to create a list of sickle-ITU admissions. Information on each patient was documented from the two databases, plus the hospital's electronic patient record system and each patient's medical notes. We collected information on the patient's past medical history, as well as specific information on that ITU admission (indication for admission, length of stay, organ failure, support required). *Results.* For the period studied, there were 46 admissions (19 male, 27 female) of 38 unique patients (14 male (12 HbSS and 2 HbSC), 24 female (20 HbSS and 4 HbSC)) to general ITU at King's. Out of the 46 admissions, 16 were to the high dependency unit, including all seven elective post-operative patients. The median age on admission to ITU was 31 years (range 17 to 59 years). The reasons for admission were categorised as "medical" (31.69%), "acute surgical" (4.9%), "trauma" (3.7%) or "planned post-operative" (7.15%). The "medical" reasons were further sub-classified as multi-organ failure (8), acute chest syndrome (14), renal (1), neurological (4) or other (4). The median stay in ITU was 3 days (range 1 to 68 days). Of 46 admissions, 37 survived to be discharged from ITU (i.e. 19.6% mortality), and 36 survived to hospital discharge. At one year post-ITU discharge, there were a further three deaths, bringing the total one year mortality to 28.2%, with none lost to follow up. Although a surprisingly high number of patients were genotypically HbSC (6 of 38), two of these admissions were for trauma, one was planned post-operatively, and only three were "medical" (two patients post cardiac arrest, one chest sepsis). Re-admission was common: during the 8 year period considered, for the 38 unique patients, six had re-admissions (one re-admitted four times and five twice), yielding a 16% risk of ITU re-admission. The organ support required by "medical" patients (typically with a reason for admission directly related to sickle cell disease) included: 48% receiving inotropes, 20% requiring ventilation, 16% requiring haemofiltration, 24% requiring transfusion and 76% requiring antibiotics. Many of the patients had pre-existing multi-organ damage, often sickle-related. *Conclusions*. Compared to a within-ITU mortality of 17.6% during the same period, in the same institution, sickle cell patients who are admitted to ITU have a similar mortality. Relatively more female patients (59% of total admissions) were admitted to ITU, contributing risk factors were gynaecological. Admission to ITU itself, is a significant risk factor for re-admission for sickle patients, possible causes are discussed.

0204

TREATMENT WITH DEFERASIROX EFFECTIVELY DECREASES IRON BURDEN IN PATIENTS WITH THALASSEMIA INTERMEDIA

E. Voskaridou,[1] M. Konstantinidou,[2] M. Douskou,[3] E. Plata,[1] M. Papadakis,[1] E.E. Delaki,[1] D. Christoulas,[4] E. Terpos[4]

[1]Thalassemia Center, Laikon General Hospital, ATHENS; [2]Novartis Hellas, ATHENS; [3]Bioiatriki Medical Center, ATHENS; [4]Department of Medical Research, [251] General Air-Force Hospital, ATHENS, Greece

Background. Thalassemia intermedia encompasses a wide clinical spectrum of β-thalassemia phenotypes. Iron overload is frequently present in patients with thalassemia intermedia, and becomes evident mainly after the second and third decades of life. A variable rate of iron loading, reaching toxic levels in some patients, was seen in a series of intermittently transfused patients with β-thalassemia intermedia. Some patients were at risk of the toxic effects of iron overload, necessitating adequate chelation therapy. *Aim.* The aim of this study was to investigate the efficacy and safety of the once-daily oral iron chelator, deferasirox, in iron-overloaded patients with thalassemia intermedia. *Methods.* We evaluated 11 adult patients with thalassemia intermedia (5M/6F; mean age 41.2±6.5 years) who had serum ferritin levels >1000 ng/mL and who were sporadically transfused with <20 units of red blood cells before starting deferasirox treatment for up to 12 months. Nine and two patients were initially treated with deferasirox at 10 and 20 mg/kg/day, respectively, (mean initial dose 11.8±4.1 mg/kg/day). After 3 months, dose adjustments (increases) were allowed in increments of 5 mg/kg/day every 3 months as required to reduce markers of iron overload. Total iron burden was monitored by measuring serum ferritin levels before and monthly after starting deferasirox, while liver iron concentration and cardiac iron burden were measured by magnetic resonance imaging (MRI) T2 and T2* parameters at baseline and 12 months after deferasirox treatment. Left ventricular ejection fraction (LVEF) by MRI, and 24-hour proteinurea (Prot 24h) before and after treatment, were also measured. Hemoglobin (Hb) levels, serum creatinine, cystatin C, alanine (ALT) and aspartate aminotransferase (AST) were measured before and every month during deferasirox treatment. *Results.* The mean serum ferritin level was significantly reduced after 12 months of deferasirox treatment, while the mean baseline liver T2 and T2* significantly increased following 12 months of therapy (Table 1). Mean cardiac T2* and LVEF were normal at baseline and did not significantly change after 12 months of treatment. There were also no significant changes in mean serum creatinine, cystatin C, Hb or Prot 24h levels after 12 months of deferasirox treatment, while mean ALT and AST levels significantly decreased over 12 months. *Summary and Conclusions.* These data indicate that over 12 months deferasirox significantly reduced liver iron burden and serum ferritin levels in these iron-

overloaded patients with thalassemia intermedia. The decreases in ALT and AST are suggestive of an improvement in liver function. This study indicates that deferasirox provides effective iron chelation therapy in these patients without any significant adverse effects.

Table 1.

ACUTE SPLENIC SEQUESTRATION IN SICKLE CELL DISEASE

V. Brousse,[1] E. Lesprit,[2] F. Bernaudin,[3] M.H. Odievre,[4] C. Guitton,[5] B. Quinet,[2] S. Dangiolo,[1] M. De Montalembert[1]

[1]Hopital Necker, PARIS; [2]Hopital Trousseau, PARIS; [3]Centre Hospitalier Intercommunal, CRETEIL; [4]Hopital Louis Mourier, COLOMBES; [5]Hopital Bicetre, BICETRE, France

Background. Acute splenic sequestration (ASS) is a life threatening event in sickle cell disease (SCD) during early childhood. Subsequent related mortality has been greatly reduced by neonatal screening enabling parents to be taught to recognize pallor and, if possible, to feel sudden enlargement of the spleen indicating splenic sequestration and consequently a need for immediate hospital attendance for blood transfusion. *Aims.* Our aim was to update spleen sequestration epidemiology in a French cohort followed after neonatal screening. *Methods.* We reviewed the medical files of SCD children born between 2000 and 2007, followed since birth in 5 pediatric centres. We included all SCD children who had presented acute splenic sequestration, defined as an acutely enlarging spleen with a fall in hemoglobin (Hb) level of at least 2 g/dL. *Results.* A total of 266 episodes of ASS occured in120 children, 69 boys and 51 girls. Genotypes were as follows: 9 S β° thalassemia, 2 SD-Punjab, 4 SC, 105 SS. In the SS subgroup, median age at first episode was 16 months [1-83] and 34.8% of these first episodes occurred before 12 months of age. Associated symptoms were found in 37 cases (isolated fever n=20, vasoocclusive crisis n=5, identified viral or bacterial infection n= 12) and did not influence the rate of recurrence. Mean Hb level during first ASS was 5.2 g/dL [3.3-7]. Fifty-nine % of SS patients had more than one episode. Mean ages at first episode of those who experienced only one episode (n=43) versus those who had more than one episode (n=62) were statistically different (28±22 months versus 18±10 months, p=0.002, Student test). Median interval between first and second episode was 3.5 months [1-31]; 31 patients had 3 or more episodes with a mean interval between the second and the third episode of 2 months [1-17]. There was no significant difference in the mean age at first episode in children who experienced 2, 3 or more than 3 episodes. There was only one fatal case due to acute anemia which occurred in a girl at first recurrence (Hb: 2.2 g/dL). After the second attack 14(22.5%) patients were splenectomized, 26 patients (41.9%) were started on a transfusion program (followed in 13 cases by splenectomy) and 21 remained in a standard care programme. Splenectomy was performed at a median age of 4.5 years. *Conclusions.* These results show that ASS remains a major concern in the management of SCD children and predictive factors need to be determined. We show a high rate of recurrence (59%) and that young age at the first episode favours this risk. This study confirms the efficacy of early diagnosis and parental education in the decrease of mortality. Prospective studies on spleen dysfunction are warranted.

IRON CHELATION THERAPY WITH DEFERASIROX FOR TRANSFUSIONAL IRON-OVERLOADED PATIENTS WITH APLASTIC ANAEMIA AND OTHER RARE ANAEMIAS

J.B. Porter,[1] S.-S. Yoon,[2] Z.X. Shen,[3] S.L. Thein,[4] K.-H. Lin,[5] D. Habr,[6] G. Domokos,[7] B. Roubert,[7] J.W. Lee[8]

[1]University College London, LONDON, UK; [2]Seoul National University College of Medicine, SEOUL, South-Korea; [3]Ruijin Hospital, Shanghai Second Medical University, SHANGHAI, China; [4]Kings College Hospital, LONDON, UK; [5]National Taiwan University Hospital, TAIPEI, Taiwan; [6]Novartis Pharmaceuticals, EAST HANOVER, NJ, USA; [7]Novartis Pharma AG, BASEL, Switzerland; [8]The Catholic University of Korea, SEOUL, South-Korea

Background. Few studies have reported the efficacy of iron chelation therapy in transfusion-dependent patients with aplastic anaemia (AA) and other rare anaemias (RA). The deferasirox EPIC study included subsets of anaemia patients rarely evaluated in iron chelation therapy-related trials. *Aim.* To assess the efficacy of deferasirox over 1 year in reducing body iron in patients with AA and other RAs. *Methods.* Patients aged ≥2 years with transfusional iron overload indicated by serum ferritin (SF) levels of ≥1000 ng/mL, or patients with SF of <1000 ng/mL but with a history of multiple transfusions (>20 transfusions or 100 mL/kg of blood), and liver iron concentration >2 mg Fe/g dry weight confirmed by R2 MRI were enrolled. Initial deferasirox dose was 10-30 mg/kg/day depending on transfusion requirements. Dose adjustments in steps of 5-10 mg/kg/day (range 0-40 mg/kg/day) were based on SF trends and safety markers. The primary efficacy endpoint was change in SF from baseline at 12 months. Safety assessments included adverse event (AE) monitoring and assessment of laboratory parameters. *Results.* Data from 116 AA and 43 RA patients (red cell aplasia [n=20], hemolytic anaemia [n=11], pyruvate kinase deficiency anaemia [n=5], autoimmune hemolytic anaemia [n=3], acute porphyria [n=2], congenital anaemia [n=1], hereditary hemolytic anaemia [n=1], and thrombocytopenic purpura [n=1]) are reported. Transfusion requirements in the year prior to enrolment were 115.8 and 153.0 mL/kg of blood for AA and RA patients, respectively. 68.1% of AA and 30.2% of RA patients were also chelation-naive. In AA patients, after 12 months, median SF decreased significantly by 964.0 ng/mL (p=0.0003) at an average actual deferasirox dose of 17.6±4.8 mg/kg/day. In RA patients, median SF significantly decreased (-832.0 ng/mL, p=0.0275) at an average actual deferasirox dose of 18.6±5.6 mg/kg/day. Reductions in SF were observed in both groups at an actual mean dose of deferasirox ≥20-<30 and <20 mg/kg/day (Table 1). Overall, 76% (n=88) of AA and 70% (n=30) of RA patients completed the study. Five AA patients (4%) died (pneumonia [n=1], sepsis [n=3] and hepatic adenoma rupture [n=1]). Two deaths were recorded in RA patients (acute respiratory insufficiency and bladder tumour). No death was suspected by investigators to be drug-related. The most common (>10%) investigator assessed drug-related AEs in AA patients were: nausea (n=26, 22%), diarrhoea (n=18, 16%) and rash (n=13, 11%); in RA patients: diarrhoea (n=13, 30%), nausea (n=9, 21%), and abdominal pain (n=6, 14%). AEs were generally mild to moderate. 29 AA patients (25.0%; n=10 receiving concomitant cyclosporine) and eight RA patients (18.6%) had an increase in serum creatinine >33% above baseline and the upper limit of normal (ULN) on two consecutive visits; there were no progressive increases. Increase in alanine aminotransferase >10xULN on two consecutive visits occurred in one AA (0.9%) and one RA patient (2.3%); both had elevated levels at baseline. *Summary and Conclusions.* Deferasirox significantly reduced iron burden in transfusional iron-overloaded patients with AA and other RAs. Despite high iron burden at baseline, many patients had no prior chelation therapy, indicating a need for treatment. Deferasirox was generally well tolerated.

Table 1. Median change from baseline in SF (ng/mL) by average actual dose.

			Baseline		End of study		
Aplastic anemia	Average actual dose categories (mg/kg/day)	Mean iron intake ± SD, mg/kg/day	n	Median SF	n	Median change from baseline in SF	*P*-value versus baseline
	<20	0.21 ± 0.18	75	3263.0	75	−970.0	<0.0001
	≥20–<30	0.31 ± 0.20	41	3238.0	40	−883.8	0.2777
	All patients	0.25 ± 0.19	116	3254.0	115	−964.0	0.0003
Rare anemias	Average actual dose categories (mg/kg/day)	Mean iron intake ± SD, mg/kg/day	n	Median SF	n	Median change from baseline in SF	*P*-value versus baseline
	<20	0.43 ± 0.55	25*	2571.7	25	−846.0	0.0174
	≥20–<30	0.56 ± 0.86	17	4247.7	17	−770.5	0.4452
	All patients	0.49 ± 0.70	42*	3161.0	42	−832.0	0.0275

A CLOSER LOOK AT CELLULAR IRON METABOLISM IN IRP2 DEFICIENT ERYTHROBLASTS

M. Schranzhofer,[1] B. Galy,[2] M. Schifrer,[3] M. Hentze,[2] E. Muellner,[3] P. Ponka[1]

[1]Jewish General Hospital, McGill University, MONTREAL, Canada; [2]European Molecular Biology Laboratories (EMBL), HEIDELBERG, Germany; [3]MFPL, Medical University of Vienna, VIENNA, Austria

Background. Developing red blood cells are the major consumers of body iron which is indispensable for the enormous production of heme for hemoglobin synthesis. The uptake of iron occurs via binding of iron-loaded transferrin to its cognate receptor (TfR). Thereafter the iron is shuttled to the mitochondria where it is incorporated into protoporphyrin IX to form heme. Excess iron is enclosed within the iron storage protein ferritin. Coordinated control between iron uptake and storage is mainly achieved by the post-transcriptional regulation of TfR1 and ferritin synthesis by the iron regulatory proteins IRP1 and IRP2. Recently, two groups independently created mice lacking either IRP1 or IRP2 and showed that only IRP2 deficient mice developed microcytic hypochromic anemia. Both groups observed a reduction in TfR1 protein expression levels in the developing red blood cells of IRP2 knockout animals and suggested that the decrease in receptor levels is responsible for the development of anemia. *Objective.* Aim of the study was a more detailed analysis of how the loss of IRP2 expression influences iron metabolism and hemoglobinization during terminal erythroid differentiation leading to microcytic hypochromic anemia. *Methods.* We isolated CFU-E-like erythroid cells from mouse fetal liver of wild type, IRP1 and IRP2 knock out animals. *in vitro* cultivation of these primary erythroid cells and their synchronous induction for differentiation allowed us to study their cellular iron metabolism at different time points. We analyzed the extent of hemoglobinization and cell size as well as the expression of ferritin and TfR1 during various stages of erythroid differentiation in IRP1, IRP2 and wild type cells. *Results.* In agreement with the published phenotype of microcytic hypochromic anemia, only erythroblasts lacking IRP2 exhibited a reduction in hemoglobinization and showed a significant increase in ferritin protein levels before and after induction of differentiation. In contrast, TfR1 protein expression levels on the cell surface were significantly decreased in IRP2 deficient cells until 24h of differentiation, but converged with those of wild type cells at 48h of differentiation at the time point at which hemoglobinization is fully in progress. Moreover, measurement of 59Fe uptake and its cellular distribution showed that there is significantly more 59Fe located in cytosolic ferritin of IRP2 knock out cells at all time points compared to their wild type counterpart. *Conclusion.* In summary, these results suggest that not only the reduced expression of TfR1, but also the up-regulation of ferritin, play important roles in the development of anemic phenotype in IRP2 knock out mice.

ASSESSMENT OF NON-TRANSFERRIN BOUND IRON IN THALASSEMIC SERA USING A NEW FLUORESCENCE BASED ASSAY

N.K. Gohil,[1] M. Sharma,[1] R. Saxena[2]

[1]Indian Institute of Technology Delhi, NEW DELHI; [2]All India Institute of Medical Sciences, NEW DELHI, India

Background. Transfusional iron overload associated with thalassemia leads to the appearance of non-transferrin bound iron (NTBI) in blood which is toxic and causes morbidity and mortality via tissue damage. A number of methods have already been described for quantification of NTBI based on chelation of iron. According to one method, NTBI is mobilized by a low affinity iron chelator, followed by its separation from serum proteins. The chelated fraction is then analyzed by HPLC1, or atomic absorption spectrometry. The second group of methods mobilizes and detects NTBI in the same reaction mixture without separation of the serum proteins from chelated iron using iron-sensitive fluorescence probes, such as fluorescence-labeled apotransferrin2. A limitation in these, is the interference from serum color and turbidity and thereby may not be discerning, particularly at low NTBI levels. In general large variations have been observed in measured values between different methods. *Aims.* Hence a highly sensitive and accurate assay of NTBI, with broad clinical application in both diagnosis and validation of treatment regimens for iron overload is important. Main focus of this study is on the application of bacterial siderophore as an analytical tool for assessing the free iron levels in biological fluids. *Methods.* The patient population consisted of 42 males and 21 females ranging between 2-25 years of age and suffering from β- thalassemia major. The protocol for the study included phlebotomy only and was approved by the Ethics Committee of All India Institute of Medical Sciences, New Delhi, India. Informed consent was obtained from all participating patients. Serum was separated within 1 hr of collection. Siderophore azotobactin with high affinity to Fe^{3+} has been used as the probe. The assay includes blocking of native apotransferrin iron binding sites, mobilization of NTBI, ultrafiltration of all serum proteins and finally addition of the probe molecule which also has a chromophore that fluoresces at 490 nm (Figure 1A). Binding of Fe^{3+} to azotobactin quenches the fluorescence in a concentration dependent manner (Figure 1B).

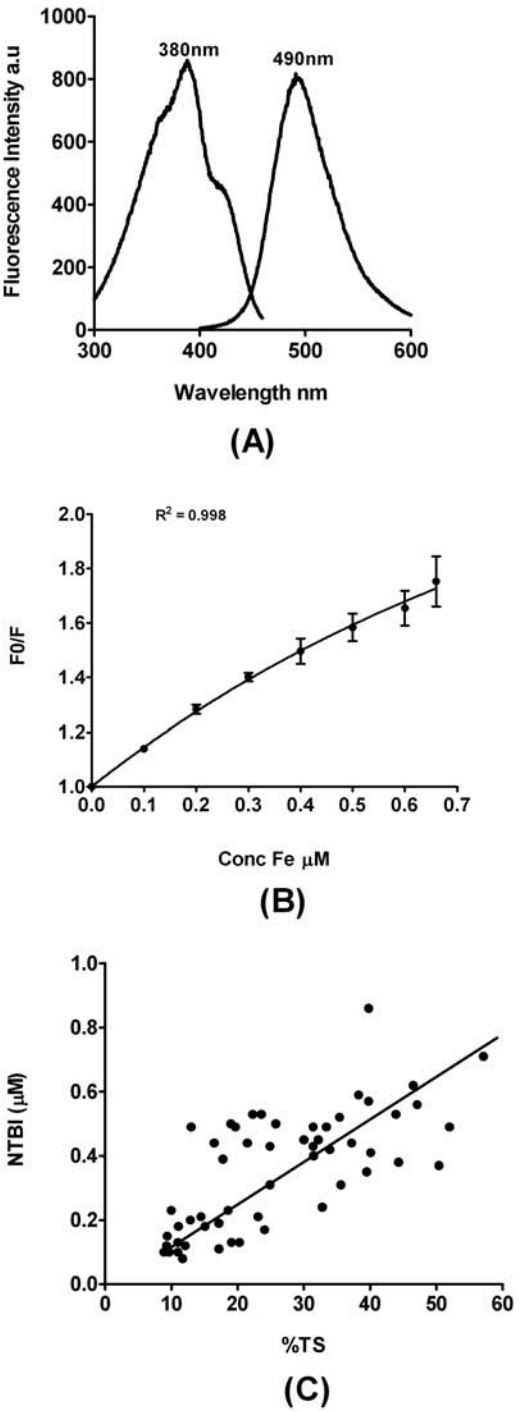

Figure 1. Measurement of NTBI and its correlations

Results. The present assay employs an intrinsically fluorescent bacterial siderophore, azotobactin, for sensing NTBI . The novelty lies in its being an iron chelator itself, along with the presence of the fluorescent chromophore as part of the molecule. Measured NTBI levels in 63 sera ranged from 0.07-3.24 µM (0.375±0.028 µM; mean ± SD). It correlates well with serum iron and percent transferrin saturation but not serum ferritin. Pearson's correlation coefficient was found to be 0.6074 (p<0.0001; Figure 1C) and 0.6102 (p<0.0001) for %TS and serum iron respectively. NTBI is reported to be present at concentrations varying between 1-10 µM3. The low values may be due to the patients being under regular chelation therapy even prior to sampling, indicating that the method is sensitive to very low levels of NTBI , allowing a detection limit much lower than the available methods. *Conclusions.* A simple, highly sensitive and elegant assay has been developed for accurate estimation of NTBI, not only in severe iron overload cases but also in cases where low to moderate levels of NTBI exist, when the patient is put on chelation therapy.

DEFERASIROX SIGNIFICANTLY REDUCES IRON BURDEN IN HEAVILY IRON-OVERLOADED PATIENTS WITH β-THALASSAEMIA: 2.7 YEAR RESULTS FROM THE ESCALATOR STUDY

A. Taher,[1] A. El-Beshlawy,[2] M. Elalfy,[3] K. Al Zir,[4] S. Daar,[5] D. Habr,[6] U. Kriemler-Krahn,[7] B. Roubert,[7] A. Al Jefri[8]

[1]American University of Beirut Medical Center, BEIRUT, Lebanon; [2]Cairo University, CAIRO, Egypt; [3]Ain Shams University, CAIRO, Egypt; [4]National Thalassemia Center, DAMASCUS, Syria; [5]Sultan Qaboos University, MUSCAT, Oman; [6]Novartis Pharmaceuticals, EAST HANOVER, NJ, USA; [7]Novartis Pharma AG, BASEL, Switzerland; [8]King Faisal Specialist Hospital and Research Centre, RIYADH, Saudi Arabia

Background. The ESCALATOR study, evaluating deferasirox in heavily iron-overloaded β-thalassaemia major patients previously unsuccessfully chelated, showed that 76% of patients required dose increases at a median of 24 weeks within the 1-year core phase, thus suggesting that the effect of deferasirox on iron burden at 52 weeks may have been suboptimal due to insufficient dosing. An extension phase, which has now been completed, assessed at least 1 additional year of treatment at more optimal dose levels. *Aim.* To evaluate deferasirox efficacy and safety in patients entering the extension phase of the ESCALATOR study. *Methods.* All patients initially received deferasirox 20mg/kg/day (except three receiving 10 mg/kg/day). Deferasirox dose at the start of extension depended on the last dose received in the core trial. Dose adjustments, performed in steps of 5-10 mg/kg/day were based on serum ferritin (SF) levels and safety markers; dose increases above 30 mg/kg were permitted due to a protocol amendment in the extension phase. *Results.* Data presented here are based on 233 patients (162 paediatric [≥2-<16 years] and 71 adult [≥16 years]) who entered the extension study, excluding patients from site 602. 94% of patients completed the 1.7-year extension phase; reasons for withdrawal were: lost to follow-up (n=8, 4%), adverse events (AEs) [n=3, 1%], death (n=3 [cerebral haemorrhage, subarachnoid haemorrhage, respiratory failure], 1%), protocol violation (n=2, 1%), and consent withdrawal (n=1, <1%). Patients received deferasirox for a median of 140 weeks (2.7 years). Dose increases were performed in 137/233 patients (59%) during the extension, with increases to above 30 mg/kg/day in 112. Dose decreases and temporary treatment interruptions due to achievement of target SF level (″500 ng/mL x2 consecutive occasions) occurred in 5 and 15 patients, respectively. Mean liver iron concentration (LIC) and median SF at baseline, 1 year and end of study are shown in the Figure 1. At core baseline, 23 patients (9.9%) had LIC <7 mg Fe/g dw (4.5±1.7) and 210 had LIC ≥7 mg Fe/g dw (21.2±8.2). After 1 year's treatment the proportion of patients with LIC <7mg Fe/g dw had risen to 26.2%, increasing further to 44.4% after a median of 2.7 years. Safety analysis is based on 231 patients who received at least 1 dose of deferasirox during the extension phase (two patients did not receive the drug as their SF remained below 500 ng/mL throughout the study). High doses of deferasirox were well tolerated; drug-related AEs were lower in the extension than core phase (24% vs. 44%). Dose was decreased in six patients due to AEs or abnormal lab values. No progressive changes in markers of renal or liver function markers were seen. At end of study, left ventricular ejection fraction increased from baseline (65.2±6.8%) by 2.3±8.6% (p<0.0007). *Summary and Conclusions.* With optimal dosing, deferasirox therapy for a median of 2.7 years resulted in a significant reduction in LIC and SF in heavily iron-overloaded β-thalassaemia patients. More patients were able to achieve LIC <7 mg Fe/g dw with a longer course of deferasirox treatment. Despite dose increases to ≥30mg/kg/day in many patients, the overall safety was maintained with a low discontinuation rate in the extension phase.

DEFERASIROX FOR THE TREATMENT OF TRANSFUSIONAL IRON OVERLOAD IN SICKLE CELL ANEMIA: A 1-YR PROSPECTIVE STUDY

R. Cancado, M.C.A. Olivato, P. Bruniera, C. Chiattone

Santa Casa Medical School, SAO PAULO, Brazil

Background. Majority of patients with sickle cell disease receive repeated blood transfusions by adulthood. Because the body has no physiological mechanism to actively excrete excess iron, chelation therapy is important for the management of iron overload and its complications, including iron deposition into the liver, heart and endocrine organs, eventual death. While studies are limited, progressive iron loading and subsequent tissue injury in SCD appears similar to other transfused populations. Deferasirox (Exjade, ICL670) is a once-daily, oral iron chelator that is approved as first-line treatment of chronic transfusional iron overload. Its safety, tolerability and efficacy in reducing body iron burden have been demonstrated in patients with β-thalassaemia major and in other chronic transfusion-dependent anaemias, including SCD. *Aims and Methods.* Objectives of this prospective, non-randomised, phase IV trial were to evaluate the iron overload status, before and after one year-treatment with deferasirox, using liver iron concentration [LIC, mg/d dry weight (dw)] by magnetic resonance imaging (MRI) hepatic, MRI cardiac (Cardiac T2*, ms), serum ferritin (SF, µg/L), and to evaluate the safety and tolerability of deferasirox. *Results.* A total of 31 paediatric (age >2y) and adult (age <65y) patients with SCD and iron overload, defined as the use of ≥20 units of RBC units and/or two SF levels ≥1000 µg/L during the 6 months preceding enrollment, received starting dose of 20 mg/kg/day of deferasirox. Efficacy was assessed monthly by measuring change from baseline in SF levels. Safety was evaluated on a monthly basis according to the incidence and type of adverse events and measurement of laboratory parameters, including serum creatinine and liver enzyme levels. Two patients discontinued treatment at 8 and 9 months, due to pregnancy and moving to other city, respectively. Mean ± SD and median (range) age 26.9±12.5y and 25.0y (9-49), respectively; 84% female, 90% afrodescendent, 61.3% on regular blood transfusion; mean ± SD and median (range) deferasirox dose (mg/kg/day) over 12 months were 19.7 ± 1.2 and 20 (15-20), respectively. Mean ± SD and median (range) SF levels (µg/L) did not significantly reduced at 12 months compared to baseline [from 2344.6±1077.09-2113.0 ± 1199.7 (p=0.052) and 2051.0 (1013.0-6074.0) to 2050.0 (407.0-6060.0), respectively]. The proportion of patients with SF levels <2000, 2000- <3000 and ≥3000 µg/L from baseline to 12 months by percentage of patients changed from 48.4% to 48.3%, 25.8% to 34.5% and 25.8% to 17.2%, respectively. Mean ± SD and median (range) MRI hepatic (LIC, mg/g dw) iron concentration significantly dropped at 12 months compared to baseline [from 14.0±7.4-10.5 ± 6.4 (p<0.001) and 14.0 (2.5-30.7) to 9.5 (2.0-19.5), respectively]. The proportion of patients with LIC levels (mg/g dw) ″7.0, >7.0-″14.0 and >14.0 from baseline to 12 months by percentage of patients changed from 13.6-36.4%, 40.9-27.3% and 45.5-36.4%, respectively. Mean ± SD and median (range) MRI cardiac (Cardiac T2*, ms) at baseline and 12 months varied from 40.5±6.0 to 39.0±5.8 (p=0.167) and 39.8 (27-51.2) to 39.0 (27.8-50.9), respectively. In all patients, Cardiac T2* was normal (> 20 ms) at baseline and 12 months of treatment. There was no significant difference between left ventricular ejection fraction values at baseline and after 12 months of treatment. The most common drug-related AEs were mild, transient diarrhea (7 patients), headache (7) and nausea (5). Maculopapular skin rash and serum creatinine increases upper limit of normal were observed in 2 (6.5%) patients. No patient experienced progressive increases in serum creatinine or renal failure. *Conclusions.* Our preliminary data confirms that deferasirox is effective in reducing body iron burden in transfused patients with SCD, well tolerated in pediatric and adult patients and with a clinically manageable safety profile. Although LIC significantly decreased over a 12-month-period of treatment, median SF did not. This aspect points to the fact that SF should not be the only laboratory parameter to be considered in the evaluation of iron chelation in SCD patients. The availability of deferasirox as a once-daily, oral iron chelator would potentially facilitate improved compliance, and thereby reduce morbidity and mortality from iron overload.

HPLC QUANTITATION OF ALPHA-GLOBIN HEMOGLOBINOPATHIES IS INFLUENCED BY CONCURRENT ALPHA-THALASSEMIA

M. Okon,[1] A. Braester,[2] D. Filon,[3] Y. Dickstein[4]

[1]Leumit Health Fundation, PETACH-TIQVA; [2]Western Galilee Hospital, NAHARIA; [3]Hadassah-Hebrew University Medical Center, JERUSALEM; [4]Leumit Health Fundation Laboratories, PETACH-TIQVA, Israel

Cation-exchange high performance liquid chromatography (HPLC) has been shown to be a sensitive , specific and reproducible alternative screening method for diagnosis of hemoglobinopathies to electrophoresis. HPLC is emerging as the method of choice for sensitive direct identification and quantification of major and minor, normal and pathological hemoglobin fractions. Retention time, percentage hemoglobin and peak characteristics measures lead to hemoglobin identification. In instances of combined hemoglobinopathies, the abnormal hemoglobins are represented on HPLC as separated peaks. When α-thalassemia is concomitant with another hemoglobinopathy, there is only one peak but α-thalassemia can be suspected because of the increased height of the abnormal segment. In this manuscript we document the HPLC elution patterns of a concurrent α-thalassemia/hemoglobinopathy: α -3.7/α Setif (α 94 (G1)Asp→Tyr (α 2), with retention time of 6.28 minutes and percentage peaks of 23.6-37.6. Hemoglobin Setif alone is characterized by time retention of 6.18 minutes and percentage peak of 15.8. Molecular analysis (PCR and sequencing of the α-2 gene) was performed in order to confirm these compound heterozygosities. The increased height of the peak representing hemoglobin Setif is explained by the concomitant presence of α-thalassemia. HLC-G7 HPLC was design to identify β-talassemia but we found it is capable to diagnose α-talassemia in compound heterozygosities.

GLUTATHIONE S TRANSFERASE GENE MUTATIONS AS THE CANDIDATE FACTOR RESPONSIBLE FOR THE OXIDATIVE STRESS BURDEN IN INDIAN HBE/B THALASSEMIA PATIENTS

V. Sharma, B. Kumar, R. Saxena

All India Institute of Medical Sciences, NEW DELHI, India

Background. Iron overload is the consequence in the HbE/ β thalassemia after repeated blood transfusions. Iron overload can generate the peroxidative status and the increase of superoxide dismutase (SOD) and glutathione peroxidase (GPx) activity. Severe oxidative damage is observed in erythrocytes due to the presence of excess α -globin chains. Thus, both the accumulation of excess α chains and iron overload causes oxidative stress in patients. The glutathione S-transferases (GST) are a family of enzymes that detoxify reactive electrophiles and products of oxidative stress. To our knowledge, there is no published study indicating role of GST deletions in HbE/β thalassemia patients. Indeed, there is supporting evidence that inheritance of GST deletions increases oxidative burden in anemia. Objective: Main objectives of the study were to compare the frequency of the null genotype for GSTM1, GSTT1, or both in HbE/βthalassemia patients to that in healthy controls, and to ascertain whether the oxidative burden increases due to coinheritance of specific genetic polymorphisms of GSTM1 and GSTT1. *Methods.* Subjects were 150 HbE/β thalassemia and 100 controls. The homozygous null polymorphisms GSTM1 and GSTT1 were determined using a modified multiplex PCR approach for simultaneous amplification of both genes and co-amplification of a housekeeping gene BCL2 as an internal control. Plasma MDA levels were determined by using the thiobarbituric acid reaction substance [TBARS] methods and Serum vitamin E levels were measured spec-throphotometrically. *Results.* The frequency of GSTM1/T1 null 11 (7.3%) and GSTT1 null 48 (32%) genotypes were significantly higher (p≤0.001, p=0.002 respectively) in patients when compared to controls (GSTM1/T1 0(0%), GSTT1 15(15%). Plasma Malandoaldehyde levels were significantly higher (p=0.01, p=0.01, p≤0.001) in patients positive for GSTM1 (2.7 nmol), GSTT1 (2.7 nmol) and GSTT1/M1 (5.6 nmol) null genotypes than patients negative (1.9nmol) for the same while Vitamin E levels were significantly lower for GSTM1 (4.5 mg/dL), GSTT1 (4.3 mg/dL) and GSTT1/M1 (0.89 mg/dL) (p=0.002, p≤0.001, p≤0.001) than those of negative for the same (5.9 mg/dL). *Conclusions.* GST deletions are more frequent in HbE/β thalassemia patients than normal individuals and its occurrence doubles the oxidative stress burden in these patients.

ALTERATIONS IN CONTRACTILE RESPONSE OF DETRUSOR SMOOTH MUSCLE OF SICKLE CELL DISEASE TRANSGENIC MICE

M.A. Claudino

UNICAMP, CAMPINAS, Brazil

Introduction. Berkeley mouse model is well-accepted animal model of severe anemia that displays several clinical manifestations similar to those seen in humans. These animals have showed changes in the vascular and non-vascular smooth muscle reactivity. However, there is no study that has assessed the effect of detrusor smooth muscle (DSM) reactivity in sickle cell disease (SCD) mice. Bladder filing occurs by ability of the bladder to increase in volume at low intravesical pressure to prevent exposure to the upper urinary tract. Bladder emptying is accompanied by a reversal of function in which predominates DSM contraction. These DSM regulatory actions are promoted mainly by enhanced cholinergic-mediated contractions and decreased β-adrenoceptor-mediated relaxations. Activation of DSM muscarinic receptors promoted stimulation of phospholipase C with increased formation of inositol trisphosphate and diacylglycerol to release calcium from intracellular stores induced DSM contraction and causing emptying of bladder. Alterations in the contraction or relaxation mechanism of the DSM during the filling and emptying phases may contribute to bladder dysfunction. Thus, the aim of this study was to evaluate the contractile mechanism of isolated DSM in SCD transgenic mice. *Methods.* SCD transgenic mice (SS mice) and C57BL/6 mice (control) DSM was removed and placed in Krebs solution. The DSM strips were mounted in 10mL organ baths containing with Krebs at 37°C continuously aerated with a mixture of 95% oxygen and 5% carbon dioxide (pH 7.4). The tissues were stretched to a resting tension of 10 mN and allowed to equilibrate for 60min. Changes in isometric force were recorded using a PowerLab 400 Data Acquisition System (Chart, 5.2, AD Instruments, Colorado-USA). After the equilibration period, viability of the muscles was confirmed following addition of solution potassium chloride (KCl; 80 mM). Cumulative concentration-response curves were constructed for a muscarinic agonist, charbacol (CCh; 0.01-100 μM) and hyperpolarizing solution, KCl (1-300mM). Frequency-response curves for electrical field stimulation (EFS; 1-32Hz; 80V) were constructed in DSM strips in the presence and in the absence of atropine (1 μM) or suramin (100 μM). EFS were applied in strips placed between two platinum ring electrodes connected to a Grass S88 stimulator (Astro-Med Industrial Park, RI-USA). *Results.* Cumulative addition of the CCh produced concentration-dependent contractile responses in DSM segments, and potency (pEC50) did not change in SS mice (5.80±0.02), when compared with control mice (5.69±0.05), whereas the maximal response (Emax) was significantly reduced in SS mice (4.20±0.42mN), compared with control mice (9.96±1.77mN). Cumulative addition of the KCl produced concentration-dependent contractile responses in DSM segments and both pEC50 (0.98±0.08) and Emax (7.63±1.03mN) were significantly reduced in SS mice, compared with control mice (1.24±0.07 and 11.24±0.84mN, respectively). EFS-induced contractions in DSM of SS mice were significantly decreased in the higher frequency than compared to control mice. In addition, EFS-induced contractions in DSM were significantly decreased in the presence of atropine and suramin in both SS mice and control mice. *Conclusions.* In summary, this study is the first to demonstrate that SS mice exhibit a moderate contraction response in DSM, and suggesting a possible hypoactive bladder in SCD.

DO WE HAVE TO RECONSIDER FERRITIN OPTIMAL LEVELS IN MULTI-TRANSFUSED THALASSAEMIA MAJOR PATIENTS?

K. Farmaki, I. Tzoumari, Ch. Pappa

Thalassaemia Unit, CORINTH, Greece

Background. Serum Ferritin levels are considered as the gold standard for monitoring chelation treatment in iron overloaded Thalassaemia major patients (TMps). Over the time different values were proposed as the goal of optimal chelation. Nowadays, the introduction of T2* MRI have given new insight in iron deposition suggesting that even with low Ferritin levels a TMp may develop complications. *Aim.* to determine a safe margin of Ferritin levels in our TMps *Methods.* 1. Ferritin was measured by immunoturbidimetric assay and calculated as the mean of monthly determinations in order to eliminate false positive results, since ferritin is an acute phase reactant. 2. Cardiac and hepatic iron loading were investigated by Signa-MRI, 1.5-Tesla, T2*-sequences. 3. LIC:liver iron concentration was calculated by Ferriscan. 4. Cardiac function was assessed annually by echo-Doppler. 5. Endocrine function by dynamic tests (OGTT, GnRH) and hormonal screening annually.6. Statistical analyses were performed using SPSS ($p<0.05$ was considered significant). *Patients.* 50 transfusion-dependent TMps, mean age 30.8±2.03, switched from Desferrioxamine monotherapy to an intensive combined chelation with Desferrioxamine (40-60 mg/kg/d) and Deferiprone (75-100 mg/kg/d), on an individually tailored regimen. *Results.* after 3-7 years of combined chelation. 1) A trend analysis, PROC MIXED in SAS, revealed a negative trend of Ferritin over time ($p<0.0001$) with a rate of decline=-75 ng/mL/month and a cumulative decrease. In 90% of compliant TMps, mean Ferritin decreased dramatically from 3.421±882 ng/mL to 87±25ng/mL 2) MRI measurements led to significant reduction ($p<0.0001$) of iron load to virtually iron free organs (T2*Heart from 13.6msec to 35.5msec & T2*Liver from 1.5msec to 33.2msec). 3) In 12/50 TMp with pre-existing cardiac dysfunction on medication, symptoms reversed and heart medications were stopped. Ventricular dimensions and function in echo-Doppler shifted to normal. 4) Statistical correlations were observed, in 9/14 Diabetic TMps and 17/19 with Impaired Glucose Tolerance who normalized their glucose metabolism. The decrease in Glucose secretion ($p<0.0001$) and the increase in Insulin secretion ($p<0.05$) were correlated with a decrease in ferritin to 113±19 ng/mL (r= -0.592 $p<0.02$, r=0.568 $p<0.02$ respectively) and the normalization of MRI T2*L and LIC (r=0.629, $p<0.01$ & r= -0.619, $p<0.01$ respectively). 5) Also statistical correlations were noted between the increase of FSH & LH during GnRH test in Hypogonadal TMps and the decrease in ferritin 114±12ng/mL and the normalization of MRI T2*L (r=-0.936 $p<0.01$, r=0.723 $p<0.04$ respectively). Additionally in 7/14 males with pre-existing Hypogonadism who reversed and stopped testosterone injections, correlations were established between the increase of testosterone and the decrease in ferritin (108±32ng/mL) & LIC (r=-0.634 $p<0.04$, r=-0.679 $p<0.03$ respectively). 6) No serious adverse events which led to permanent interruption of combined chelation were observed in our TMps even with ferritin levels <500 ng/mL. *Conclusions.* The use of combined chelation, by achieving a negative iron balance and a reduction of total body iron, induces the reversal of iron-load complications in the majority of TMps. This was correlated with the dramatic decrease of ferritin to normal levels. Additionally the fact that no serious adverse events have occurred might lead us to reconsider Ferritin optimal levels in TMps.

TREATMENT WITH DEFERASIROX EFFECTIVELY DECREASES IRON BURDEN IN PATIENTS WITH SICKLE CELL SYNDROMES

E. Voskaridou,[1] M. Douskou,[2] E. Plata,[1] C. Papanikolaou,[1] E.E. Delaki,[1] D. Christoulas,[3] E. Terpos[3]

[1]Thalassemia Center, Laikon General Hospital, ATHENS; [2]Bioiatriki Medical Center, ATHENS; [3]Department of Medical Research, [251] General Air-Force Hospital, ATHENS, Greece

Background. Iron overload was not thought to be an important issue in the past because of the short life-span of patients with sickle cell disease (SCD). However, the increase in longevity during the recent years has been associated with clinical evidence of iron overload in some SCD patients. The etiology of the latter is complex and comprises accumulation of transfusional iron, increased absorption associated with intensive erythopoiesis and iron deposition as a result of continuous hemolysis. Therefore, iron overload may play an important role in the severity of SCD and iron chelation has a definite indication in several SCD cases. *Aim.* The aim of this study was to investigate the efficacy and safety of the once-daily oral iron chelator, deferasirox, in iron-overloaded patients with sickle cell syndromes. *Methods.* We evaluated 18 adult patients with sickle cell syndromes (8M/10F; mean age 41.3±8.5 years) who had serum ferritin levels >1000 ng/mL and who were sporadically transfused with <20 units of red blood cells before starting deferasirox treatment for up to 12 months. Fifteen and three patients were initially treated with deferasirox at 10 and 20 mg/kg/day, respectively, based on the number of blood transfusions received before the initiation of treatment. After 3 months, dose adjustments (increases) were allowed in increments of 5 mg/kg/day every 3 months as required to reduce markers of iron overload. Total iron burden was monitored by measuring serum ferritin levels before and monthly after starting deferasirox, while liver iron concentration and cardiac iron burden were measured by magnetic resonance imaging (MRI) T2 and T2* parameters at baseline and 12 months after deferasirox treatment. Left ventricular ejection fraction (LVEF) by MRI, and 24-hour proteinurea (Prot 24h) before and after treat-

ment, were also measured. Hemoglobin (Hb) levels, serum creatinine, cystatin C, alanine (ALT) and aspartate aminotransferase (AST) were measured before and every month during deferasirox treatment. *Results.* The mean serum ferritin level was significantly reduced after 12 months of deferasirox treatment, while the mean baseline liver T2 and T2* significantly increased following 12 months of therapy (Table 1). Mean cardiac T2* and LVEF were normal at baseline and did not significantly change after 12 months of treatment. There were also no significant changes in mean serum creatinine, while cystatin C significantly increased after 12 months on treatment. However, cystatin C values between six and 12 months did not show any increased trend. Hb or Prot 24h levels did not change after 12 months of deferasirox treatment, while mean ALT and AST levels significantly decreased over 12 months. The side-effects of deferasirox were minimal and easily manageable, while the compliance was excellent. *Summary and Conclusions.* These data indicate that over 12 months deferasirox significantly reduced liver iron burden and serum ferritin levels in these iron-overloaded patients with sickle cell syndromes. The reductions in ALT and AST are suggestive of an improvement in liver function, if we take into consideration that liver is the target-organ of this disease. This study indicates that deferasirox provides effective iron chelation therapy in these patients and it was well tolerated without significant side effects.

Table 1.

	Baseline	6 months	12 months

RED BLOOD CELL SEPARATION IN PK ACTIVITY ASSAY: A CRITICAL STEP FOR PK DEFICIENCY DIAGNOSIS

D. Scribano, T. De Michele, A. Minucci, L. Colacicco, E. Capoluongo, B. Giardina, C. Zuppi

Institute of Biochemistry and Clinical Biochemistry, ROME, Italy

Background. Pyruvate kinase (PK) deficiency is the most frequent enzyme abnormality of the glycolysis pathway causing hereditary chronic non spherocytic haemolytic anaemia (HNSHA). Since the haematological feature of PK deficiency are not always distinctive, the diagnosis of PK deficiency depends on the red blood cells (RBC) residual enzyme activity determination. In fact, PK activity assay represents an important tool to diagnose the PK deficiency, but some technical issues such as compensatory M2 isoform, high reticulocyte count and especially the incomplete white blood cells (WBC) removal, make this test not always reliable. *Aim.* In order to obtain accurate PK enzyme activity measurement, avoiding the PK activity interferences from other cell sources, and to improve the reference interval to better correlate the phenotype with the genotype, we optimized the RBC separation method, using the Ficoll procedure instead of saline separation, as suggested by the in-use kit. *Methods.* We assayed PK activity on 30 healthy subjects and on a PK deficient subject, utilizing a manual commercial Kit (PKD: Greiner Diagnostic GmbH). For RBC separation, we used both Ficoll and saline separation as suggested by ICSH recommendations and we compared the PK activity obtained with two methods. *Results*. The Ficoll procedure yelded a better reduction of the number of leucocytes (>95%) and platelets (>85%), as confirmed by cell count, with little loss of RBC (<4%). The obtained PK values after Ficoll separation are about 10% lower than those obtained after saline separation, so it was mandatory to redefine our PK reference intervals on 30 healthy subjects. Using the new reference values (70-180 IU/GR) instead of precedent values (60-220 IU/GR) we identify a subject with low PK activity. This subject, studied for PK-LR gene mutations, showed two mutations: p.R486W (c.1456C>T) and p.M403I (c.1209G>A). The first is a common mutation in Southern Europe while the second one has been reported only once in compound heterozygosis with the other. Moreover, we studied the two daughters of this patient. One of these showed normal PK values, carrying the c.1456C>T mutation, the other showed low PK values, carrying the c.1209G>A mutation, suggesting an hypothetical dominant transmission of this mutation, as reported by Fermo *et al. Conclusions.* The clinical manifestations of PK deficiency are widely variable ranging from mild to severe haemolytic anemias. In the mild deficient forms it is important that the PK deficient diagnosis was performed as soon as possible. The suggested Ficoll RBC separation is easy, timesaver, reproducible technical work and since it eliminates false negative results due to leukocytes and platelets, allows a better identification of the PK mild deficient subjects. In addition, since the genotype-phenotype correlation is a very important field of investigation to understand the effect of the mutations on the functional role of each part of the enzyme, it is very important to utilize a sensitive PK activity assay method.

RELEVANCE OF ALPHA HEMOGLOBIN STABILIZING PROTEIN POLYMORPHISMS IN SICKLE CELL DISEASE PATIENTS FROM OMAN

V. Pathare,[1] A. Al Zadjali,[1] S. Alkindi,[1] N. Huneini,[1] S. Al Farsi,[1] L. Misquith,[1] J. Dennison,[1] R. Krishnamoorthy[2]

[1]Sultan Qaboos University, MUSCAT, Oman; [2]INSERM,763 Hopital Robert Debre, PARIS, France

Background. Interaction of the genetic modifying factors play a significant role in makeup of the phenotype and has important implications. α-Hemoglobin stabilizing protein (AHSP), a chaperone of α-globin, is a potential modifier of the genotype by virtue of its ability to detoxify excess free α-globin. *Aims.* To study the impact of AHSP polymorphisms on the hematological parameters in Sickle cell disease patients from Oman. *Methods.* Sickle cell disease (SCD) patients following in the outpatient clinic at the Sultan Qaboos University Hospital were prospectively enrolled after an informed consent. Genomic DNA was isolated using the semi-automated 6100 nucleic acid extractor. Sickle mutation was defined by direct sequencing of the β globin gene (ABI 3100 genetic analyzer). Sickle haplotypes were defined using previously described techniques by RFLP using specific restriction enzymes(HincII5'to ε, XmnI 5' to Gγ, Hind III within Gγ and Aγ, Hinc II within and 3'to β, Hinf I and RsaI5' to β, and Taq1 within Gγ and Aγ).

Table 1. Distribution of Hp and Red cell indices in SS-SCD with respect to the AHSP Haplotypes.

		RBC count [RR4.5-5.8]	Hb [RR11.5-15.5]	MCV [RR78-96]	MCH [RR26-33]	MCHC [RR31-35]	RDW [RR11.5-16.5]
AHSP - High	Mean ± SD	3.9 ± 0.77	9.6 ± 1.53	69.6±5.08	23.6±1.56	34.7±0.97	18.9±3.12

AHSP- Low N=7	Mean ± SD	2.74±0.37	7.75±0.75	74.1±6.1	25.6±3.4	35.2±0.73	22.03±3.8
	Range	2.33-3.25	7-8.6	65-79.8	22-29.7	34.3-36.4	18.3-29.3
AHSP - Intermediate N=32	Mean ± SD	3.87±0.9	9.6±1.52	70.98±5.3	24.1±2.46	34.2±1.3	19.9±3.56
	Range	2.49-5.98	7.1-13.2	60.8-80.5	19.9-29.4	31.6-36.9	13.6-28.4
p value	H v/s L	0.0007	0.0049	0.060	0.022	0.027	0.04
	H v/s I	0.733	0.879	0.296	0.337	0.810	0.265
	L v/s I	0.0051	0.0062	0.208	0.194	0.115	0.195

Direct sequencing of AHSP gene (coding exons & exon-intron junctions) was performed and three AHSP haplotypes were constructed as

High, intermediate, and low AHSP expression using six SNPs (rs4499252, rs5816533, rs8050390, rs4296275, rs17677 & rs10843). *Results.* 93 patients (50 males) aged between 5-42 years, mean age 20.9±8.6(SD) were consecutively enrolled. 19(20.5%) patients were genotyped as Sickle-Thal, whereas 74 (79.5%) were homozygous SS cases. βs haplotyping amongst the SS group revealed that 29,11, and 9 cases were homozygous Benin, Bantu and Arab-Indian haplotypes respectively, with the remaining 25 being mixed heterozygous. AHSP haplotyping with regards to AHSP protein expression amongst the SS group revealed that 35(47%), 32 (43%) and 7(10%) showed High, Intermediate and Low expressor haplotype. There was a significant difference in the hemoglobin and red cell indices amongst the High and Low AHSP expression haplotypes (Table 1). *Conclusions.* Apart from the number of α globin genes and an inherent capacity to produce Hb F, the proteolytic capacity of the erythroid precursors in catabolizing the excess α globin chains has been suggested as another factor in modifying the genotype. AHSP polymorphisms are common and represent a potential mechanism through which genetically determined variations in AHSP expression could influence the underlying genotype.

NON-TRANSFERRIN-BOUND IRON: A NOVEL INDICATOR OF IRON OVERLOAD IN PATIENTS WITH SICKLE CELL DISEASE

A. Inati,[1] K. Musallam,[2] M. Taha,[3] F. Ziade,[4] A. Taher[2]

[1]Rafik Hariri University Hospital, BEIRUT, Lebanon; [2]American University of Beirut Medical Center, BEIRUT, Lebanon; [3]Lebanese American University, BYBLOS, Lebanon; [4]Lebanese University, BEIRUT, Lebanon

Background. The use of serum ferritin and liver iron concentration (LIC) to detect iron overload in patients with sickle cell disease (SCD) has been established. However, ferritin levels alone are not fully acceptable because they may display considerable variations due to inflammation, infection, or other chronic disorders. Moreover, the discomfort and risk that a liver biopsy causes to patients can potentially limit its diagnostic value. Assessment by R2 magnetic resonance imaging has been proven reliable but its use remains limited due to cost and the need for specialized equipment. Several studies have demonstrated that non-transferrin-bound iron (NTBI) is a good indicator of iron overload in thalassemia patients; however, data in patients with SCD is limited. *Aims.* The current study evaluates whether NTBI is a useful indicator of iron overload in non-chelated patients with SCD by assessing the relationship between NTBI, serum ferritin, LIC, total number of lifetime transfusions, patient- and disease-related characteristics. *Methods.* This was a cross-sectional study of randomly selected patients with SCD treated at two comprehensive SCD centers: Nini hospital and Rafik Hariri University Hospital (RHUH), Lebanon. The sampling frame consisted of 200 non-chelated SCD patients >2 years of age and a simple random sample was obtained. Patient charts were reviewed and a medical history compiled, which included details of drug use, transfusional history, status of the spleen, and comorbid illnesses or infections. Blood samples were obtained for assessment of NTBI, steady state serum ferritin, and liver enzyme levels. Direct determination of LIC was performed using R2 magnetic resonance imaging. Written informed consent was provided by all patients. *Results.* Data from 52 SCD patients were included in the analysis (Table 1).

Table 1. Patient, disease and iron overload characteristics

Parameter	Value
Mean age ± SD, years (range)	18.54 ± 9.0 (4-49)
Male/Female	5/8
Splenectomized, (%)	16 (30.8)
Persistent splenomegaly[a], (%)	21 (42)
Mean transfusions[b] ± SD, n (range)	50.9 ± 61.4 (0-300)
Mean hemoglobin ± SD, g/dL (range)	8.6 ± 1.4 (5.6-11.9)
Mean SF ± SD, ng/mL (range)	987.5 ± 1230.3(16-6190)
Mean LIC ± SD, mg Fe/g dw (range)	5.9 ± 9.4 (0.3-50.0)

SF = serum ferritin at steady state; LIC = liver iron concentration; dw = dry weight. [a]For more than 6 years. [b]Total number of lifetime transfusions.

None of the patients had evidence of hepatitis C or B infection, or elevation in liver enzymes. A significant positive correlation was observed between NTBI and LIC (Pearson correlation 0.466; p=0.001). There was also a significant correlation between NTBI and serum ferritin (Pearson correlation 0.514; p<0.0001). Moreover, a significant positive correlation was noted between age and NTBI (p=0.028) but not with serum ferritin or LIC. The total number of transfusions was positively correlated to NTBI, serum ferritin and LIC (p=0.003, <0.0001, <0.0001; respectively). Although female gender, splenectomy, and persistent splenomegaly were associated with higher levels of NTBI, serum ferritin and LIC; the relationships did not reach statistical significance. *Summary and Conclusions.* Significant correlation was found between NTBI and both serum ferritin and LIC, confirming the value of this method for assessing iron overload in SCD patients. Neither splenectomy nor persistent splenomegaly seem to significantly affect NTBI levels, thus questioning the role of the spleen in scavenging iron free radicals, including NTBI, in SCD patients. Increasing age and total number of lifetime transfusions are associated with higher NTBI levels, thus, suggesting its accumulation over time. The value of NTBI in monitoring iron chelation therapy is to be evaluated.

0219

OUTCOME OF PREGNANCY IN SICKLE CELL SYNDROMES. A SINGLE CENTER STUDY

E. Plata

Laiko General Hospital, ATHENS, Greece

Background. Pregnancy has been associated with exacerbation of sickle cell disease and may place patients and their infants at an additional risk. However since 1980 many studies have reported a decline of maternal and fetal complications. Aims. The aim of this retrospective observational study is to examine maternal and fetal outcomes of pregnancy in women with sickle cell syndromes. *Methods.* During the period 1991 to 2009, 161 women with sickle cell syndromes are attended in our center. We present the gynecologic and obstetric history from 78 women with sickle cell syndromes (S/β 59, S/S 17,S/C 1, S/δβ 1), median age at time of study 49.5 years (range 25-72). Data were recruited from our hospital records and were all verified with interview of the patients. Results. In the group of our patients the median age of menopfania is 14 years (range 11-17), primitive amenorrhea referred two patients, irregular menstrual cycles 7 and menorrhalgia 6, under hormone therapy are 4 women. There were 120 pregnancies in 57 of the 78 patients, the others 21 never become pregnant. Median age of pregnancy is 27 years (range 17-41). The outcome of these pregnancies is: 32 (26.6%) elective and 27 (22.5%) spontaneous abortions (first trimester: 22, second trimester: 2, third trimester: 3), 61 (50.8%) labors and delivery of 63 alive infants (two twin pregnancies). Birth weight average is 2.791 (1.300 -4.800). Ten of the newborns needed intensive care, from one to thirty days and one received exchange transfusions because of jaundice. From these 63 infants one died at the age of ten months, because of a genetic cardiac problem and another at sixteen months of age because of neurological problems because of a preterm labor continuing a severe painful crisis of the mother. All the others are alive and healthy. During these pregnancies, increase in the frequency and severity of pain episodes documented in 6 women, while decrease in 33. From our group of patients, 33 were supported with transfusions during pregnancy, 3 of them received exchange transfusions. Three women were transfused only during labor. Severe maternal complications included: a gastric bleeding during 4th month, one pre-eclampsia during 8th month, an acute chest syndrome in one woman after delivery and a severe uterus bleeding after labor. Five patients receiving hydroxyurea, manage to become pregnant after discontinuation of the medicine. They were supported with transfusions, or exchange transfusions, carried out their pregnancies without problems and gave birth to five healthy infants. The mode of delivery was: vaginal in 27/61 (44.2%) and cesarean section in 34/61 (55.7%). Cesarean section was performed for medical and obstetric reasons in 6 cases, all the others were programmed. Gestational age at delivery was higher than 37 weeks in 51 (83.6%), while preterm labor was reported to occur in 10 (16,4%) deliveries, (8 between 32-36 weeks, 1 at 30 w and 1 at 27w). *Conclusions.* Our study suggests that women with sickle cell syndromes, with appropriate management, can carry their pregnancy to term, without serious maternal and fetal complications.

0220

INCREASED PLATELET AND NEUTROPHIL ADHESION IN SICKLE CELL DISEASE CORRELATES DIFFERENTLY TO VARIABLE LEVELS OF HEMOGLOBIN A

M.A.C. Bezerra,[1] C.F. Franco-Penteado,[1] C. Lanaro,[1] S. Gambero,[1] K.Y. Fertrin,[1] M.R.B. Mello,[1] D.M. Albuquerque,[1] S.T.O. Saad,[1] A.S. Araujo,[2] F.F. Costa[1]

[1]UNICAMP, CAMPINAS; [2]HEMOPE, RECIFE, Brazil

Sickle cell disease (SCD) is a group of disorders in which the inheritance of the gene codifying the abnormal hemoglobin S (HbS) occurs in homozygosity (SCA), or in heterozygosity with other abnormal β globin genes, such as HbC, HbD or β thalassemia, among others. SC disease and HbS-β thalassemia account for most of the compound heterozygote forms of SCD. These conditions may have a clinical phenotype similar to sickle cell anemia, as in HbS-β0 thalassemia, while SC disease and HbS-β+ thalassemia, depending on the β globin mutation, present with a milder form of the disease. Polymerization of HbS and vaso-occlusive events in SCD generate a chronic inflammatory state, but differences in the inflammatory markers among genotypes have not yet been determined. The aim of this study was to evaluate the expression of adhesion molecules, adhesion properties of platelets and neutrophils and neutrophil chemotaxis in SCD patients. Neutrophils and platelets were isolated from peripheral blood samples of healthy controls and patients with SCA, SC disease and three groups of HbS-β thalassemia (HbS/β0-CD39 C->T; HbS/β+-IVS1-nt5 G->C - severe phenotype - and HbS/β+-IVS1-nt6 T->C - mild phenotype), transfusion-independent patients and not on hydroxyurea treatment. Basal adhesions were compared using static adhesion assays and data are represented by % of cells adhered. Surface protein expression in neutrophils was evaluated by flow cytometry. Chemotaxis of control and patients neutrophils (4×10^6 cells/mL in RPMI medium) was assessed using static adhesion assays and a 96-well chemotaxis chamber assay (ChemoTX, Neuroprobe). Flow cytometry showed no differences in neutrophil positivity for CD11a, CD11b and CD49d adhesion molecules among SCD groups compared to control individuals. SC and SCA neutrophils had higher chemotactic activity than controls ($3.8\pm0.6\times10^5$mL; $4.1\pm0.5\times10^5$mL vs $1.98\pm0.2\times10^5$mL, p=0.0034; p=0.0027, respectively). No significant differences were observed in chemotaxis of the three groups of HbS-β thalassemia compared to control group. Mean hemoglobin A levels in HbS-β thalassemia groups were 5.2±1.3% and 26.3±1.4% for HbS/β+-IVS1-nt5 and HbS/β+-IVS1-nt6 groups, respectively. Our data suggest that platelet adhesion is increased in all forms of sickle cell disease, while lower neutrophil adhesion seems to correlate with higher levels of hemoglobin A production as occurs in HbS/β+-IVS1-nt6. This may explain why *in vitro* analysis of SC and SCA groups were similar despite being clinically different. Further studies may contribute to our understanding of the differences in the clinical presentation of these patients.

Table.

	N	Neutrophils (%)	P value	Platelets (%)	P value
Control	n≤21	7.9 ± 0.53		11.7 ± 1.2	
SS	n≤14	14.5 ± 1.1	<0.0001	29.4 ± 3.8	0.0005
SC	n≤29	14.4 ± 1.1	<0.0001	26.4 ± 3.0	0.0001

IMPLEMENTATION, EFFICACY AND SAFETY OF A BLOOD CONSERVATION PROTOCOL IN PATIENTS UNDERGOING SURGERY FOR HIP FRACTURE REPAIR. AN ANALYSIS OF 399 CONSECUTIVE PROCEDURES

J.A. García-Erce,[1] J. Cuenca,[1] S. Haman-Alcober,[2] B. Soria,[1] D. Rubio,[1] A. Herrera,[2] M. Muñoz[3]

[1]SALUD, ZARAGOZA; [2]Orthopaedic Surgery, HU Miguel Servet, ZARAGOZA; [3]GIEMSA. Medicina Transfusional. Universidad Málaga, MÁLAGA, Spain

Background. To restore hemoglobin levels and avoid deleterious effects of anemia, 30-70% of patients undergoing perthrochanteric (PHF) or subcapital hip fracture (SHF) repair receive allogeneic blood transfusion (ABT). *Aims.* We prospectively investigated the effect of a blood conservation protocol on ABT requirements in 384 consecutive patients. *Methods.* The conservation protocol consisted of the application of a restrictive transfusion trigger (Hb<8 g/dL) and the perioperative administration of IV iron sucrose (3×200 mg/48 h). Additionally, patients with Hb <13 g/dL may received recombinant human erythropoietin (EPO 40,000 IU sc) on admission to the orthopedic ward. Perioperative clinical data were collected. *Results.* Overall, 136 (35.4%) received at least one ABT unit (2.1 ± 0.9 U/patient). However, ABT rates were significantly lower in SHF than in PHF (29.5% vs. 40.3%, respectively; p=0.028), but not pre-transfusion Hb or transfused volume. In both groups, patients receiving EPO (n=96) presented with lower preoperative Hb than those who did not (n=288), but there were not significant differences in ABT rates or postoperative Hb between them. There was a higher incidence of postoperative complications and 30d mortality among transfused patients (n=136) than among non-transfused patients (n=248). Only 7 mild IV iron adverse effects were witnessed, but 50 patients received only 400 mg IV iron. *Conclusions.* Our blood conservation protocol seems to be safe and effective in reducing ABT in hip fracture patients. However, a persisting awareness among the medical staff and nurses is crucial to avoid protocol violations and to limit further limiting the exposure to ABT and ABT related risks.

OXIDANT-ANTIOXIDANT SYSTEM AND LYMPHOCYTE DNA DAMAGE IN BETA THALASSEMIA CHILDREN

M. Soker

Dicle University Faculty of Medicine, DIYARBAKIR, Turkey

Background. Thalassemia is an autosomal recessively inherited hemoglobinopathy which basicly characterised by ineffective eritropoesis, hemolysis and anemia. Metabolic disorders, iron overload, chronic hypoxia and cell damage are added to these findings. Oxidative stres is recently being investigated in β-Thalassemia major (TM) patients as well as in cardiovascular diseases, cancer, renal diseases, infection and neurological diseases. Oxidative stress develops as a result of imbalance between formation and neutralisation of pro-oxidants. Pro-oxidant / antioxidant equilibrium disorders may cause oxidative stress and DNA damage in cellular structures. *Aims.*The aim of this study was to detect and correlate iron overload with the oxidant / antioxidant status and DNA damage in transfusion dependent b-TM patients. *Methods.*The patient group was constituted from 83 patients with transfusion dependent b-TM whose mean age was 7,34±4,21 years. 40 sex and age-matched children with non-anemia, served as control group. The damage of mononuclear DNA were assessed with comet assay method and total oxidant status (TOS) and total antioxidant capacity (TAC) measurement by using Erel's methods. *Results.* In the b-TM patients, mean DNA damage level was 10,65±6,58 AU, mean TOS level was 15,98±9,44 (μmol H2O2 Eqv./L), mean TAK level was 1,62±0,27 (mmol Trolox Eqv./L), mean Oxidative Stres Index (OSI) level was 11,11±8,42 AU and mean lipid hydroperoxide (LOOH) level was 5,44±1,80 (μmol H2O2 Eqv./L) detected. In control group, mean DNA damage level was 1,45±2,02 AU, mean TOS level was 7,18±3,74 (μmol H2O2 Eqv./L), mean TAK level was 1.76±0.38 (mmol Trolox Eqv./L), mean OSI level was 4,66±3,46 AU and mean LOOH level was 2,44±0,86 (μmol H2O2 Eqv./L) detected. When compared to the controls, DNA damage was detected to be increased in b-TM patients (p<0.001). When oxidant-antioxidant system were evaluated, while TOS, OSI and LOOH levels were significantly increased, TAC levels were decreased in b-TM patients compared to controls (p<0.001; p<0.001; p<0.001 and p=0.018 respectively). There was a statistically significant positive correlation between serum ferritin levels and DNA damage, TOS, OSI and LOOH; however a negative correlation was observed between serum ferritin and TAC levels in the b-

TM patients. There was a statistically significant positive correlation between the serum iron and ferritin levels and AST, ALT and transfusion years in the β-TM patients. TOS and OSI levels were positively correlated with ALT, however a negative correlation was observed between TAC and ALT levels in the b-TM patients. Serum AST and ALT levels were detected to have a stastistically significant positive correlation with transfusion years in the b-TM patients. In the b-TM patients the DNA damage was detected to have a stastistically significant positive correlation with TOS, OSI, LOOH, AST and ALT respectively; however a negative correlation was observed between DNA damage and TAC levels. *Conclusions.* There were increased iron dependent oxidative stress and DNA damage present in patients with b-TM. The combination of effective iron-chelatory agents with natural or synthetic antioxidants can be very helpful in the clinical practice and in decrease of the oxidant stress and DNA damage of patients with β-TM.

DISORDERS OF GLUCOSE METABOLISM ARE A MAJOR ENDOCRINE COMPLICATION IN OMANI THALASSAEMICS

S. Daar,[1] N. Woodhouse,[1] K. Panjwani,[2] O. Elshafie,[2] A.V. Pathare[2]

[1]*Sultan Qaboos University, MUSCAT;* [2]*Sultan Qaboos University Hospital, MUSCAT, Oman*

Background. The thalassaemia centre at Sultan Qaboos University hospital (SQUH) opened in 1991 and is now the largest thalassaemia referral centre in Oman. Compared to european centres, iron chelation for the majority of our patients started relatively late in 1985 with regular chelation only since 1991. Although endocrine dysfunction secondary to iron overload is a major problem in thalassaemia major, there is very little data on the prevalence of endocrinopathies in Arab thalassaemics. *Aims.* To assess the overall prevalence of endocrine complications in Omani patients with thalassaemia major and compare two cohorts of patients; those born before 1990 and those born after, to assess if early access to iron chelation has reduced endocrinopathies in the latter group. *Methods.* Endocrine screening is performed yearly after the age of 11 years in all patients at the Day Care Thalassaemia unit in SQUH. MRI cardiac and liver T2* measurements are also part of routine management of all patients over the age of 10 years. We reviewed data of 104 thalassaemia major patients between the ages of 12 and 35 years, (55 females and 49 males). 66 patients were born before, (Group 1) and 38 after (Group2), 1990. *Results.* Delayed puberty, hypogonadotrophic hypogonadism, arrested puberty or secondary amenorrhoea were seen in 62 patients (59.6%) overall with 46 and 16 in groups 1 & 2 respectively (Chi Square 2.04; p=0.15). Amongst the 40 patients who developed pancreatic endocrine dysfunction, 17 (16.3%) patients were frankly diabetic and 23(22%) had impaired glucose tolerance [Total 40; 35 and 5 in groups 1 and 2 respectively(Chi Square 6.86; p=0.0088)]. 9 patients had hypoparathyroidism (8.6%) and 3 patients (2.8%) were hypothyroid. A further 5 patients had subclinical hypothyroidism and one had congenital hypothyroidism, unrelated to iron overload. Cardiac T2* was available for 102 patients. There were 24 patients with cardiac T2* <10ms, 30 in the range of 10-20ms and 48 were >21ms. We found a low correlation, (Pearson's r -0.3), between the degree of cardiac siderosis and presence of an endocrinopathy. *Conclusions.* The incidence of gonadal failure is similar to that noted in other thalassaemia centers around the world. However the prevalence of diabetes and deranged glucose tolerance (38%) is markedly higher. Optimizing chelation seems to have reduced this complication significantly [p=0.008] in the younger cohort who had the opportunity of better chelation facilities at an early age. In contrast to data from the Italian working group, few of our patients have developed hypothyroidism, but hypoparathyroidism is an increasing problem. Expectedly the younger cohort of patients had a significantly lower prevalence of endocrine complications. This was particularly true of gonadal and glucose dysfunction. However, longer follow up is needed to see if the improvement is sustained. Early intervention with diet, exercise and chelation is essential in Omani thalassaemics to prevent the endocrine complications, and in particular diabetes, as it has a high prevalence in the general population(diabetes 16.1%, impaired fasting glucose 7.1%).

OXYDATIVE STRESS AND ERYTHROPOIETIN REDUCTION DURING AND AFTER A FOURTEEN DAYS SCUBA DIVE

B.M. Ricerca,[1] L. Revelli,[2] A.M. D'Amore,[2] E. Di Stasio,[3] S. Persichilli,[3] G. Storti,[4] C.P. Lombardi,[2] J. Gervasoni,[3] S. Vagnoni[5]

[1]*Catholic University of Sacred Heart, ROME;* [2]*Surgery Department Catholic University of Sacred Heart, ROME;* [3]*Clinical Biochemistry Department Catholic University of Sacred Heart, ROME;* [4]*Hematology Department Catholic University of Sacred Heart, ROME;* [5]*Anestesiology Department Catholic University of Sacred Heart, ROME, Italy*

Background. Six scuba divers (three men and three females), lived for 14 days under the sea, controlled by a physician's team. The conditions applied in this experiment were different compared to those of others previously conducted. *Aims*. Since oxygen is the main regulator of Epo synthesis, we investigated the effects of a so long staying underwater, breathing Air in hyperbarism (HyperBaric Air-HBA), on s-Epo production. In addition, we evaluated some markers related to the oxidative stress to elucidate if the last could influence Epo production. *Methods.* During the entire length of the experiment, the six scuba divers stayed at a depth of 8-10 metres (22-28 feet), breathing air (oxygen 21%) at a pressure ranging between 1,8 and 2 ATA. Serum Erythropoietin (s-Epo) (Immulyte-Medical System), complete and differential blood count (CBC) (ADVIA 120 Bayer Diagnostics) as far as percentage and absolute reticulocyte count (Beckman Coulter LH 750) and the most important routine hemato-chemical parameters were assayed. Moreover, serum nitric oxide (NO) (Nitric Oxide Colorimetric Assay, Roche), glutathione, cysteine and homocysteine (HPLC with fluorimetric detection according Araki *et al.* 1987) were evaluated. All these exams were performed before immersion (TIME 0), 7 days (TIME 1) and 14 days (TIME 2) after the beginning of the dive, two hours (TIME 3) and 24 hours (TIME 4) after the resurfacing. *Results.* As shown in the Table Hgb, did not change whereas s-Epo and other data not shown such the ratio between s-Epo predicted and observed (O/P ratio), and reticulocyte (absolute and percentage) declined progressively from TIME 0 to TIME 3. At TIME 4, s-Epo increased again. All these changes were statistically significant (Fisher test for non parametric data). Among oxidative stress parameters, NO, glutathione and cysteine vary similarly to s-Epo, decreasing during the diving and then turning up at resurfacing. Homocysteine follows an opposite trend. However the statistical significance of these changes is reached only for NO (p=0.001), Cysteine (p=0.001) and Homocysteine (p<0.05). Only a trend of statistical significance is present for Glutathione (p=0.08). *Conclusions.* These observations suggest that during the dive, a progressive rise of oxidative stress occurs. In fact, the reduction of the antioxidants, probably as an effect of their consumption, and the homocysteine elevation support this conclusion. Moreover, the results obtained can give an explanation of the s-Epo reduction. Since Hgb does not vary during the dive, the prolonged hyperoxia could be a factor lowering the s-Epo production through the oxidative stress. In fact, our data show significant direct correlation between s-Epo and glutathione (r 0.41; p=0,04) and indirect correlation between s-Epo and homocysteine (r -0,61; p=0,002) (Spearman test).

ENDOSOMAL TRANSPORT OF TRANSFERRIN TO MITOCHONDRIA IS ESSENTIAL FOR EFFICIENT UTILIZATION OF IRON FOR HEME SYNTHESIS

P. Ponka,[1] A.-S. Zhang,[2] T. Kahawita,[1] O. Shirihai,[3] D. Sheftel[4]

[1]McGill University, MONTREAL, Canada; [2]OHSU, PORTLAND, USA; [3]Boston University School of Medicine, BOSTON, USA; [4]Philipps-Universität-Marburg, MARBURG, Germany

An exquisite relationship between iron and heme in hemoglobin (Hb)-synthesizing cells makes blood red. Erythroid cells are the most avid consumers of iron (Fe) in the organism and synthesize heme at a break-neck speed. Developing red blood cells (RBC) can take up Fe only from the plasma glycoprotein transferrin (Tf). Delivery of iron to these cells occurs following the binding of Tf to its cognate receptors on the cell membrane. The Tf-receptor complexes are then internalized via endocytosis, and iron is released from Tf by a process involving endosomal acidification. Iron, following its reduction to Fe^{2+} by Steap3, is then transported across the endosomal membrane by the divalent metal transporter, DMT1. However, the post-endosomal path of Fe in the developing RBC remains elusive or is, at best, controversial. It has been commonly accepted that a low molecular weight intermediate chaperones Fe in transit from endosomes to mitochondria and other sites of utilization; however, this much sought iron binding intermediate has never been identified. In erythroid cells, more than 90% of iron must enter mitochondria since ferrochelatase, the final enzyme in the heme biosynthetic pathway that inserts Fe^{2+} into protoporphyrin IX, resides in the inner part of the inner mitochondrial membrane. In fact, in erythroid cells, strong evidence does exist for specific targeting of Fe toward mitochondria. This targeting is demonstrated in Hb-synthesizing cells in which Fe acquired from Tf continues to flow into mitochondria even when the synthesis of protoporphyrin IX is suppressed. Based on this, we have formulated a hypothesis that in erythroid cells a transient mitochondrion-endosome interaction is involved in iron translocation to its final destination. Recently, we have collected strong experimental evidence supporting this hypothesis: we have shown that Fe, delivered to mitochondria via the Tf pathway, is unavailable to cytoplasmic chelators. Moreover, we have demonstrated that Tf-containing endosomes move and contact mitochondria in erythroid cells, that vesicular movement is required for iron delivery to mitochondria and that "free" cytoplasmic Fe is not efficiently used for heme biosynthesis. Additonally, performing flow cytometry on cell lysates from reticulocytes incubated with two different fluorescent markers for endosomes and mitochondria, we have identified three distinct populations: endosomes, mitochondria, and a population of particles labelled with both fluorescent markers. The size of the double-labelled population increases with the incubation time and plateaus in ~30 min. Reticulocyte re-incubation with unlabelled Fe^{2}-Tf leads to a time-dependent decrease, and ultimate disappearance, of the double-labelled population, indicating a reversible nature of mitochondria-endosome interactions As mentioned above, the substrate for the endosomal transporter DMT1 is Fe^{2+}, the redox form of iron which is also the substrate for ferrochelatase. These facts make the above hypothesis quite attractive, since the "chaperone"-like function of endosomes may be one of the mechanisms that keeps the concentrations of reactive Fe^{2+} at extremely low levels in oxygen-rich cytosol of erythroblasts, preventing ferrous ion's participation in a dangerous Fenton reaction.

REDUCED CORTICOSTEROID IN ADULTS WITH ITP RECEIVING ROMIPLOSTIM

M. Michel,[1] C. Desborough[2]

[1]CHU Henri Mondor, Service de Médecine Interne, CRÉTEIL, France; [2]Amgen International Biostatistics, CAMBRIDGE, UK

Background. Romiplostim, a novel thrombopoietin mimetic agent, was recently approved for the treatment of chronic immune thrombocytopenia (ITP) in adults. ITP is an autoimmune disease caused by increased platelet destruction and suboptimal platelet production. Patients are commonly given oral corticosteroids as first-line treatment. Although initial response rates with corticosteroids are high, their long term use can be associated with serious side effects and complications, including excessive weight gain and obesity, mood changes, diabetes, and osteoporosis. Furthermore, the therapeutic effects of corticosteroids often cease when treatment is stopped. *Aims.*To assess the proportion of patients with chronic ITP able to reduce or discontinue concurrent corticosteroid treatment while being treated with romiplostim in two randomised, double-blind, placebo-controlled phase 3 trials. *Methods.* Altogether 125 patients (63 splenectomised, 62 non-splenectomised) with chronic ITP and a mean of three platelet counts 30×10^9/L or less were enrolled and randomised in a 2:1 ratio to receive either romiplostim (n=42, splenectomised, n=41 non-splenectomised) or placebo (n=21 in both studies). Informed consent was obtained from all patients prior to performing any study specific procedures. Details of the treatment regimen used in the studies have been published previously (Kuter. D, J *et al.* 2008). Overall platelet response was defined as four or more weekly platelet counts above 50×10^9/L in the absence of rescue medication. Patients could enter the studies while receiving concurrent corticosteroids and reductions in these were permitted when platelet counts were above 100×10^9/L. In a post-hoc analysis, the proportion of patients able to reduce their corticosteroid dose by at least 25%, or discontinue corticosteroids permanently by the end of week 25 was investigated. Analyses were performed on the full analysis set. *Results.* With regards to efficacy, in both studies overall platelet response was higher for the romiplostim-treated patients compared with placebo (Table). The percentage of patients in the romiplostim group receiving corticosteroids at study entry was similar to that in the placebo group. By the end of week 25, all except two of the romiplostim-treated patients had reduced their corticosteroid dose by at least 25% or discontinued corticosteroids permanently, compared with approximately half of the placebo-treated patients. Furthermore, with the exception of two patients, the reductions in corticosteroids observed in the romiplostim-treated patients were sustained until the end of week 25 and subsequent dose increases were not required. *Conclusions.* Romiplostim, a new non-immunosuppressive therapy for adult ITP, allows the majority of patients to reduce or discontinue concurrent corticosteroid treatment while raising and sustaining platelet counts.

Table.

	Overall platelet response* n (%)	Corticosteroid use at study entry n (%)	Corticosteroid use by wk 25	
			Reduced by ≥ 25%† n (%)	Permanently discontinued† n (%)
Splenectomised				
Romiplostim (N=42)	33 (79%)	12 (29%)	5 (42%)	7 (58%)
Placebo (N=21)	0 (0%)	5 (24%)	1 (20%)	1 (20%)
Non-splenectomised				
Romiplostim (N=41)	36 (88%)	11 (27%)	5 (45%)	4 (36%)
Placebo (N=21)	3 (14%)	8 (38%)	2 (25%)	3 (38%)
Pooled data				
Romiplostim (N=83)	69 (83%)	23 (28%)	10 (43%)	11 (48%)
Placebo (N=42)	3 (7%)	13 (31%)	3 (23%)	4 (31%)

*p<0.0001 for all comparisons (romiplostim versus placebo); †categories mutually exclusive, percentages calculated from number receiving corticosteroids at study entry.

MULTICENTER STUDY OF LOW-DOSE ANTI-CD20 VELTUZUMAB FOR TREATMENT OF RELAPSED IMMUNE THROMBOCYTOPENIA

A. Wegener,[1] H.A. Liebman,[2] M.N. Saleh,[3] R. Abassi,[4] J. Bussel,[5] T.M. Cosgriff,[4] H. Horne,[1] T. Wolffgram,[6] D.M. Goldenberg[1]

[1]Immunomedics, Inc, MORRIS PLAINS, USA; [2]Keck School of Medicine, USC, LOS ANGELES, CA, USA; [3]Georgia Cancer Specialists, ATLANTA, GA, USA; [4]Hematology Oncology Specialists, DENVILLE, NJ, USA; [5]NY Presbyterian Hospital, NEW YORK, NY, USA; [6]Nycomed GmbH, KONSTANZ, Germany

Background. Veltuzumab, a 2nd-generation humanized anti-CD20 monoclonal antibody with structure-function differences from rituximab, is clinically active in non-Hodgkin's lymphoma, even at lower doses than used with rituximab. Since immunotherapy with rituximab has demonstrated activity in immune trombocytopenia (ITP), we hypothesized that low-dose veltuzumab would also be effective in this disorder. *Aims.* A multicenter, phase I/II study was undertaken to evaluate low-dose veltuzumab in adults who had ITP for at least 6 months, who failed >1 standard therapy, and presented with platelets <30 K/μL, but no major bleeding. *Methods.* Initially, veltuzumab was given by intravenous (IV) infusion, but after the development of a high-concentration formulation, is being administered by subcutaneous (SC) injection. All patients received 2 doses of veltuzumab 2 weeks apart (without steroids) and were evaluated for up to 12 weeks, with responding patients continuing in long-term follow-up. Efficacy was assessed by platelet level increases, with responses confirmed at least 1 week apart classified as complete (CR, >150K/μL), partial (PR, 50-150K/μL), or minor (MR, 30-50K/μL). Adverse events and safety laboratories were evaluated by NCI CTC v3 toxicity grades. Other evaluations included circulating B-cell levels (CD19), veltuzumab serum levels, and human anti-veltuzumab antibody (HAHA) titers. *Results.* The Phase I dose-escalation portion of this study has been completed with 17 patients (6M/11F, 21-67 years old, 5 post-splenectomy) receiving IV doses at 80 (N=3), 120 (N=3), or 200 mg (N=1), or SC doses at 80 (N=3), 160 (N=4), or 320 mg (N=3) veltuzumab. They had ITP for up to 18 years (median 1.9 yr) and previously were treated with steroids (N=17), IVIG/anti-D (N=11), azathioprine/danazol (N=6), rituximab (N=3), chemotherapy (N=2), and TPO-R agonists (N=1). One patient had a Grade 3 infusion reaction to veltuzumab after receiving ~100 mg at first IV dose, but otherwise veltuzumab was well tolerated with other infusion/injection reactions limited and transient Grade 1-2 events, and with no other safety issues. B cells were depleted rapidly with both IV and SC dosing and are continuing to be followed for recovery. Even at these low doses, IV veltuzumab achieved expected serum levels (mean Cmax, 20.3 and 46.0 μg/mL at 80 and 120 mg, respectively) without evidence of rapid clearance or sequestration (mean post-treatment half-life ~1 week), while SC veltuzumab had slower release over several days with lower serum levels, but comparable availability/exposure. Two patients developed low-level HAHA titers of uncertain clinical significance. Of 13 patients with post-treatment results currently available, 8 (62%) responded, including 4 (31%) CRs, 2 (15%) PRs, and 2 (15%) MRs. Responses, including CRs, occurred with both SC and IV administrations, and across all dose levels, even 80 mg. The PR and MRs were short lived (3-12 weeks), but all CRs are still continuing, now up to one year later. *Conclusions*. Low-dose veltuzumab (2 doses, 2 weeks apart), given IV or SC without steroids, demonstrates promising activity in relapsed ITP, including durable complete responses. Based on these findings, Phase II is proceeding, with patients being recruited to provide additional/confirmatory data for further clinical development.

0228

SAFETY AND EFFICACY OF LAPAROSCOPIC SPLENECTOMY IN PATIENTS WITH REFRACTORY IMMUNE THROMBOCYTOPENIC PURPURA. A LONG-TERM SURVEY

N. Cascavilla,[1] M. Scaramuzzi,[2] A. Ambrosio,[2] C. Bodenizza,[1] A. Falcone,[1] L. Melillo,[1] M. Nobile,[1] G. Sanpaolo,[1] P. Scalzulli,[1] P. Di Tonno,[3] P Di Sebastiano[2]

[1]Hematology, Casa Sollievo Della Sofferenza Hospital IRCCS, SAN GIOVANNI ROTONDO; [2]Surgery, Casa Sollievo Della Sofferenza Hospital IRCCS, SAN GIOVANNI ROTONDO; [3]Hematology, "Di Venere Hospital, BARI, Italy

Background. Despite the popularity of splenectomy has decreased dramatically in the past few years, the surgical approach remains the therapy of choice for patients with refractory Immune Thrombocytopenic Purpura (ITP) in terms of high and durable rate of response (Vesely *et al.*, Ann Intern Med 2004;140:112). The recent introduction of anti-CD20 antibodies and thrombopoietins of second generation such as AMG 531 and Eltrombopag may have a relevant role (Kuter *et al.*, Lancet 2008; 371: 362) but their long-term safety and efficacy have not been still established. In parallel with new drugs, there has been an evolution in the surgery of splenectomy as well (Dolan *et al.*, Am J Hematol 2008; 83: 93). Actually, the laparoscopic surgery is considered the standard approach ant the ITP represents the most common indication in 50-80% of all the laparoscopic splenectomies. *Methods.* The aim of this work is to evaluate the long-term complete and partial response (CR + PR), as well as the short and long-term complications, of 40 patients (30 females and 10 males; median age: 38 years - range 6-71) with unresponsive ITP after one or more medical approaches and underwent laparotomic splenectomy at our Institution from 1999 through 2006. The 40 patients accounted for 22.2% of 181 patients diagnosed in those years. An abdominal CT scan to evaluate the presence of accessory spleens was performed in all cases. All patients received meningococcal, pneumococcal and haemophilus influenzae vaccine one week before splenectomy. For 4 or 5 days before splenectomy the patients were treated with high doses of intravenous Immunoglobulins. Anti-thrombotic prophylaxis was performed with low molecular weight heparin (LMWH) for 10 days and afterwards with cardioaspirin (ASA) if the platelet count exceeded 500×10^9/L. *Results.* No cases required conversion to laparotomic splenectomy. An accessory spleen was found in 2 patients (5%). Immediate haematological response rate was of 100%. At date, after a median follow-up of 78 months (range 28-112 months), 36 patients (90%) remain in CR or PR with a platelet count more than 50×10^9/L and 2 patients are taking ASA. Four patients (10%) relapsed, out of which 2 patients have a platelet count less than 10×10^9/L. Short and long-term mortality rate was 0%. Immediate postoperative complications rate was 5%: we observed 2 cases of hemoperitoneum related to a trocar's tube and to an active bleeding respectively, both resolved with laparoscopic approach. The mean postoperative hospital stay was 4,5 days (range 4-8). Neither cases of bacterial sepsis in the postoperative or during the follow-up time, nor cases of splenic-portal vein thrombosis (SPVT) and no cases of neoplasms occurred. *Conclusions.* Our experience suggests that laparoscopic splenectomy is an excellent approach to patients with refractory ITP in terms of safety, efficacy and costs. With respect to laparotomic splenectomy, the use of laparoscopy is likely to make the splenectomy even safer and therefore suitable for a larger number of patients. Undoubtedly there is a great expectation for the new drugs (Rodeghiero *et al.*, Am J Hematol 2008;83:91) and we agree that only controlled comparative clinical trials (Vianelli *et al.*, Haematologica 2005; 90: 72) will be able or not to say a final word and to challenge the role of splenectomy.

0229

USE OF FONDAPARINUX IN PATIENTS WITH SUSPECTED HEPARIN-INDUCED THROMBOCYTOPENIA

E. Marti Saez,[1] S. Novelli Canales,[1] J. Mateo Arranz,[1] A. Oliver,[2] A. Santamaria Ortiz,[1] J.C. Souto Andres,[1] J. Fontcuberta Boj[1]

[1]Hospital de la Santa Creu i Sant Pau, BARCELONA; [2]Fundació Puigvert, BARCELONA, Spain

Background. Heparin-Induced thrombocytopenia (HIT) is a rare side effect of heparin therapy. Although the use of fondaparinux in this situation is not approved, it could be a good alternative in these patients. *Aims.* We studied a total of 21 patients that were treated with fondaparinux because of suspected heparin HIT. The primary endpoint was platelet recovery after fondaparinux initiation. Secondary endpoints were the appearance of thrombosis or bleeding. *Methods.* Retrospective observational study in one center. Twenty-one patients with suspected HIT, in which fondaparinux treatment was started, were included. Platelet counts were obtained daily until platelet recovery and fondaparinux dose was adjusted according to anti-factor Xa levels. We also registered hemorrhagic and thrombotic complications. *Results.* Eleven (52%) patients were men and 10 (48%) women. The median age at the moment of admission was 67 (range 41-83) years. Most patients were admitted in the cardiology (5, 21%) or cardiac surgery (6, 28%) wards. All patients presented a decrease in platelet count after heparin initiation. Nine (44%) patients received low molecular weight heparin (LMWH), 8 (39%) unfractionated heparin and 4 (17%) patients recieved both types were administered. All these patients presented a drop in platelet count after initiating heparin. HIT was suspected in all them. The grade of HIT suspicion was high in 9 (45%), intermediate in 7 (30%) and low in 5 (25%) patients. Heparin-dependent IgG antibodies were tested in all

patients. In 11 patients the test was positive. Heparin was replaced by fondaparinux at a dose between 1.5 and 7.5 mg daily. The dose depended on the indication of anticoagulant therapy and patient creatinine clearance and weight. After three days tratment an incresed of at least 30% occured in 17 (80%) patients. Treatment with fondaparinux was maintained a median of 39 days (range 1-180). Seven patiens (30%) were undergoing hemodyalisis. In six cases the procedure was hemodiafiltration and in one conventional hemodyalisis. In these patients fondaparinux dose was adjusted according to anti-factor Xa levels. A median of 5 (range 1-12) controls were made. Only one thrombotic complication was registered during fondaparinux treatment, a deep vein thrombosis of the leg seven days after discontinuation of heparin. No hemorrhagic complications were registered. *Conclusions*. This study suggests that fondaparinux may be an alternative to heparin therapy in patients in who HIT is suspected. Fondaparinux seems to be safe even in patients with renal failuire undergoing hemodialysis. The dose in these patients should be adjusted according to anti-Xa levels. Anyway, we should be aware of thrombotic complications during fondaparinux therapy in patient affected of HIT.

0230

THE HOSPITALIZATION NEED AND COST OF ADULT PRIMARY IMMUNE THROMBOCYTOPENIA TREATMENT: A MONOCENTRIC EVALUATION

M. Ruggeri, S.F. Fortuna, F.R. Rodeghiero

San Bortolo Hospital, VICENZA, Italy

Background. Primary immune thrombocytopenia (ITP) results in an increase of healthcare resource utilization and hospitalization rate, for diagnosis, medical therapy, surgery and treatment of bleeding complications. However, there are not accurate data about ITP related cost. Few studies on the burden of illness were carried out, with some unavoidable limitations, such as the patient selection bias, due to retrospective analysis. Aims. To overcome these difficulties, a prospective study of a consecutive cohort of ITP patients was carried out, focused on the hospital based costs, calculated as the reimbursements to the hospital by the Italian Health Service (HIS), using the Disease Related Group tariffs, for essential thrombocytopenia (ICD-9-CM, code 287.3). In addition, the cost of highly expensive drugs (intravenous immune-globulins, IVIg, and rituximab) prescribed for rescue therapy in ITP was considered. *Methods.* All patients with a consecutive diagnosis of primary ITP (ASH 1996 criteria), from January 1997 to May 2007, age above 18 years and platelet count <50×10^9/L were enrolled. Data on patients demographics characteristics, medical history and hospital admission were collected. *Results.* From the 170 patients diagnosed during the observation time at our Institution (male 61, 35%, median age 41, range 18-95 years), 18 were excluded from the evaluation because never treated or admitted. 152 patients (median platelet count at the start of therapy: 10×10^9/L, range 1-48) received at least one line of treatment; 80 patients required at least one hospital admission, for a total of 126 admissions (1.5/patient): 45 at the time of diagnosis, 37 for relapse or ITP-related complications, 44 at Surgery Department for splenectomy (ICD-9-CM code: 41.2). Patients with significant bleeding symptoms (WHO score 2 or 3) were more frequently admitted at diagnosis than non or mild-bleeders, WHO 0 or 1 (35/72, 48%, vs. 10/80, 12.5%, Fischer exact test <0.001). The total admission days was 775 (median 6 days/admission; 10 days/patient). The cycles of IVIg infusion were 198 (one cycle = 1 g/Kgw/day x 2 or 400 mg/Kw/day x 5); of rituximab infusion were 10 cycles (one cycle = 375 mg/m^2 weekly x 4). The cumulative reimbursement (at 2005 tariffs) by HIS was 227.000 euro and 418.000 euro for medical and surgical discharged, respectively. The cost of IVIg and rituximab at the hospital price purchased was 994.000 euro; the total cost was thus 1.639.000 euro (10.780/patient). At last follow-up visit, (after a median of 6 years) 101 patients were in remission and out of treatment (complete response, platelet count >100×10^9/L or response, platelet count >30×10^9/L). 40 (26%; 12 after splenectomy) were in non-response and required continuous medical therapy; limiting the analysis to this subgroup, the median cost for patients was 20.125 euro. 11 patients were deceased (one for hemorrhagic complications). Conclusions. Taking into account the limitations of this analysis (DRG reimbursement tariffs do not reliable the real cost of assistance; moreover, resource medical utilization for outpatients care were not considered) the median costs for the hospital assistance for ITP appear to be in the lower range of the most common chronic disease; however, major expenses were due to splenectomy interventions and recurrent admissions for high-cost drugs as rescue therapies. Our estimates offer a rough basis for the comparison of the treatment cost incorporating new drugs.

0231

DURABLE AND OVERALL PLATELET RESPONSES IN PATIENTS WITH CHRONIC IDIOPATHIC THROMBOCYTOPENIC PURPURA DURING LONG-TERM TREATMENT WITH ORAL ELTROMBOPAG BY SPLENECTOMY STATUS: THE RAISE STUDY

R. Stasi,[1] G. Cheng,[2] M.N. Saleh,[3] J. Bussel,[4] S. Vasey,[5] B. Mayer,[5] M. Aivado,[5] M. Arning,[5] N.L. Stone[5]

[1]Regina Apostolorum Hospital, ALBANO LAZIALE, Italy; [2]Chinese University of Hong Kong, SHATIN, Hong Kong; [3]Georgia Cancer Specialists, ATLANTA, USA; [4]Weill Cornell Medical College, NEW YORK, USA; [5] GlaxoSmithKline, COLLEGEVILLE, USA

Background. Eltrombopag is the first, oral, small molecule, non-peptide, thrombopoietin receptor agonist being studied for the treatment of thrombocytopenia related to a variety of conditions. *Aim.* To assess the efficacy of eltrombopag as measured by a durable platelet response in previously treated adults with chronic immune thrombocytopenia (ITP) and platelet counts <30 Gi/L, by splenectomy status. *Methods.* RAISE was the largest 6-month, randomized (2:1 [eltrombopag:placebo]) double-blind, placebo-controlled phase 3 study in patients with chronic ITP. The primary efficacy analysis has been previously presented (Cheng *et al.* Blood 2008;112:400). Additional post-hoc analyses have been performed to ascertain the effect of eltrombopag on durable and overall response by splenectomy status. Durable response was defined as having a platelet count elevation ≥50 and ″400 Gi/L for at least 6 of the last 8 weeks in the 6-month treatment period. Overall response was defined as having either a durable response or a transient response with platelet count elevations ≥50 and ″400 Gi/L for at least 4 consecutive weeks at any time during the 6-month treatment period. All patients who received a rescue medication (conservatively defined as any increased dose of baseline ITP medication, a new ITP medication, platelet transfusion, and/or splenectomy) during the 6-month treatment period were not considered to have a durable platelet response, irrespective of platelet counts. Platelet count elevations occurring during periods of rescue and up to the time platelet counts fell below 50 Gi/L were not included in the assessment of transient response. *Results.* Durable response was achieved by 60% of patients in the eltrombopag group versus 10% in the placebo group. Overall response was achieved in 81% of patients in the eltrombopag group versus 18% of patients in the placebo group, and similar overall responses were observed in both splenectomized (70%) and non-splenectomized (88%) cohorts treated with eltrombopag. Fifty-one percent (51%) of splenectomized and 66% of non-splenectomized patients treated with eltrombopag also achieved a durable platelet response. *Conclusions.* In this 6-month study, both splenectomized and non-splenectomized patients achieved more durable and overall platelet responses when treated with eltrombopag compared with placebo.

Table 1. Summary of Durable and Overall Response During the 6-Month On-Therapy Period – ITT Population

		Treatment Group	
		Placebo N=39	Eltrombopag N=95
All Patients	Durable Response, n (%)	4 (10)	57 (60)
	Overall Response, n (%)	7 (18)	77 (81)
Baseline Splenectomy Status			
Splenectomy	Splenectomized, n	12	37
	Durable Response, n (%)	1 (8)	19 (51)
	Overall Response, n (%)	2 (17)	26 (70)
No Splenectomy	Non-splenectomized, n	27	58
	Durable Response, n (%)	3 (11)	38 (66)
	Overall Response, n (%)	5 (18)	51 (88)

0232

STUDY OF THE *IN VITRO* EFFECT OF THE NONPEPTIDE THROMBOPOIETIN -RECEPTOR AGONIST SB-497115 (ELTROMBOPAG) ON MEGAKARYOPOIESIS OF PATIENTS WITH LOW/INTERMEDIATE-I RISK MYELODYSPLASTIC SYNDROME

I. Mavroudi, M. Psyllaki, K. Pyrovolaki, G. Gvazava, C. Kalpadakis, H.A. Papadaki

University of Crete School of Medicine, HERAKLION, Greece

Background. Thrombocytopenia remains a major problem in myelodysplastic syndromes (MDS) because an effective thrombopoiesis-stimulating agent has not been available so far for these patients. The aim of the present study is to evaluate the *in vitro* effect of the nonpeptide thrombopoietin-receptor agonist SB-497115 (Eltrombopag) on bone marrow (BM) megakaryopoiesis of patients with MDS. This agent has been

successfully given as an oral agent for the treatment of patients with Idiopathic Thrombocytopenic Purpura. *Methods.* BM aspiration was performed in 5 MDS patients with low/intermediate-1 risk according to the International Prognostic Scoring System (IPSS) and 3 haematologically normal controls and the BM mononuclear cells (BMMCs) were isolated after gradient centrifugation. We evaluated the growth of the megakaryocytic colony forming units (CFU-Meg) in the BMMC fraction using the commercially available Mega-Cult medium in the presence or absence of different concentrations of SB-497115 (0.1 μg/mL-30 μg/mL). CFU-Megs were scored after fixation and staining of culture slides with anti-CD41 monoclonal antibody using the alkaline phosphatase anti-alkaline phosphatase technique (APAAP). We also studied the effect of the above concentrations of SB-497115 on the survival characteristics of BMMCs, following overnight incubation, by means of flow-cytometry and 7-amino-actinomycin D (7AAD). *Results.* The number of CFU-Meg in MDS patients increased significantly following 14-day incubation of BMMCs with 0.1 μg/mL SB-497115 (97.80±23.93 CFU-Meg per 5×10^4 BMMCs) compared to baseline (73.60±34.20 CFU-Meg per 5×10^4 BMMCs; p=0.047, paired t-test). An increase was also obtained in the number of CFU-Meg obtained from healthy controls following incubation of BMMCs with 0.1μg/mL SB-497115 (239±37.32 CFU-Meg per 5×10^4 BMMCs) compared to baseline (176.33±53 CFU-Meg per 5×10^4 BMMCs; p=0.116, paired t-test). In the presence of higher concentrations (1.0 μg/mL-30μg/mL) of SB-497115, a dose-dependent decrease was obtained in the frequency of CFU-Meg in both patients and healthy controls in comparison to untreated cultures although not at a statistically significant level (p=0.4751 and p=0.290, respectively; one-way ANOVA). In accordance with the CFU-Meg data were the flow-cytometry results. In the presence of 0.1 μg/mL SB-497115 the proportion of apoptotic (7AADdim+bright) BMMCs remained unchanged in both patients and healthy controls (12.98±11.84% and 2.13±2.13%, respectively) compared to baseline (12.64±11.93% and 2.27±2.37%, respectively) suggesting a non-toxic effect of this concentration. However, in the presence of higher doses (1.0 μg/mL-30 μg/mL) of SB-497115, the proportion of apoptotic BMMCs increased at a dose-dependent manner in both patient and control groups although not at a statistically significant level (p=0.4018 and p=0.1377, respectively). A pooled analysis of patient and control data showed a statistically significant increase in the proportion of apoptotic BMMCs in the presence of SB-497115 at a dose ≥1 μg/mL (1.0μg/mL-30μg/mL), compared to baseline (p=0.0402, one-way ANOVA). *Summary and Conclusions.* These preliminary data suggest that SB-497115 at a dose of 0.1μg/mL displays a beneficial effect on megakaryopoiesis of MDS patients with low/intermediate-I IPSS without any adverse effect on BMMC survival. These encouraging *in vitro* data indicate a possible clinical beneficial effect of Eltrombopag in this group of patients. Studies investigating the *in vitro* effect of lower SB-497115 concentrations are in progress.

IMPROVEMENT IN FATIGUE AND HEALTH-RELATED QUALITY OF LIFE (HRQOL) WITH LONG-TERM ELTROMBOPAG THERAPY IN CHRONIC IDIOPATHIC THROMBOCYTOPENIC PURPURA: RESULTS OF PHASE 3, DOUBLE-BLIND STUDY(RAISE)

D. Provan,[1] J.B. Bussel,[2] G. Cheng,[3] K.M. Grotzinger,[4] M. Duh,[5] J. Signorovitch,[5] N.L. Stone,[4] M. Aivado[4]

[1]Bart's and the London Queen Mary's School of Medicine and Dentistry, LONDON, UK; [2]Weill Cornell Medical College, NEW YORK, USA; [3]Chinese University of Hong Kong, SHATIN, Hong Kong; [4]GlaxoSmithKline, COLLEGEVILLE, USA; [5]The Analysis Group, BOSTON, USA

Background. Eltrombopag is the first, oral, small molecule, non-peptide, thrombopoietin receptor agonist for the treatment of chronic idiopathic thrombocytopenic purpura (ITP). *Aim.* To assess the effects of long-term eltrombopag treatment on HRQoL in patients with chronic ITP. *Methods.* RAISE was a 6-month, randomized, double-blind, placebo-controlled, phase 3 study that evaluated the efficacy and safety of eltrombopag in previously treated adults with chronic ITP and platelet counts <30.000/μL. Patients were stratified by splenectomy status, use of baseline ITP medication, and platelets ″15.000/μL. Efficacy results (eg, platelet count, bleeding, reduction in ITP medications), and safety results were previously reported (Cheng *et al.* Blood 2008;112:400). HRQoL was self-reported at baseline, week 6, week 14, and upon completion or withdrawal from study using the SF-36v2, fatigue sub-scale of FACIT-Fatigue, and a 6-item subset of the FACT-thrombocytopenia (FACT-Th) that focuses on concern with bleeding and bruising, and limits to physical and social activities. Maintenance of eltrombopag therapy over time on mean outcomes was assessed using longitudinal generalized estimating equation models and exchangeable correlation structures. Minimally important differences in responses were defined as improvement from baseline of at least 1/2 the standard deviation of the baseline score. Further adjustment was made for stratification variables. *Results.* One hundred ninety-seven (197) patients (eltrombopag, 135; placebo, 62) were enrolled in RAISE; baseline characteristics were balanced: in both arms ~50% of patients had platelet counts ″15.000/μL, ~50% were receiving baseline concomitant ITP therapies, ~35% were splenectomized, and >15% had received at least 3 prior ITP medications. During 6 months of eltrombopag treatment, patients reported meaningful improvements in vitality, emotional and physical role domains, and in overall mental health. Patients consistently reported clinically and statistically significant benefits in physical and social activities and in concerns for bleeding and bruising symptoms. The odds of observing a minimal important difference during treatment with eltrombopag was significantly greater for the eltrombopag group compared with the placebo group, further supporting the reported results (data not shown). No decreases (relative to baseline) in mean HRQoL scores in any category were reported during eltrombopag treatment. *Conclusions.* This evidence suggests that long-term treatment with eltrombopag improves vitality/fatigue, physical role, and emotional role for patients with chronic ITP. With eltrombopag treatment, patients perceived a reduction in fatigue symptoms and an improved ability to participate in activities of daily living.

Table.

Patient-Reported Outcome: Instrument and Domain	Average Effect of Eltrombopag vs Placebo on Score Change From Baseline[a] (ITT population) Estimate of Score Change	95% CI	*P* value
SF-36v2			
Physical Function	2.8	-1.1, 6.7	0.154
Physical Role	5.4	0.5, 10.3	0.030[b]
Bodily Pain	5.1	-0.5, 10.6	0.074[c]
General Health	2.4	-1.6, 6.5	0.243
Vitality	3.9	0.1, 7.7	0.045[b]
Social Function	4.1	-0.6, 8.9	0.089[c]
Emotional Role	5.4	0.8, 10.1	0.023[b]
Mental Health	2.5	-0.9, 6.0	0.154
Physical Component Summary[d]	1.3	-0.2, 2.9	0.092[c]
Mental Component Summary[e]	2.1	0.2, 4.0	0.030[b]
FACIT-Fatigue	1.6	-0.2, 3.5	0.082[c]
FACT-Th (6 selected items)	1.5	0.5, 2.5	0.004[b]

CI, confidence interval; ITT, intent to treat

a. Estimated from a longitudinal regression model for the effect of eltrombopag vs placebo of on-therapy score changes from baseline.
b. Indicates significant at 5% level of significance.
c. Indicates significant at 10% level of significance.
d. Physical Component Summary includes all domains but Physical Function, Physical Role, Bodily Pain and General Health contribute proportionately the most to the aggregate scores.
e. Mental Component Summary includes all domains but Vitality, Social Function, Emotional Role and Mental Health contribute proportionately the most to the aggregate scores.

0234

USEFULNESS OF PRETEST CLINICAL SCORES ('4T'S) AND THEIR CORRELATION WITH THE RAPID ID-HEPARIN / PF4 ANTIBODY TESTING FOR THE DIAGNOSIS OF HEPARIN INDUCED THROMBOCYTOPENIA

K. Mathur,[1] L. Anderson,[2] R. Green,[1] R. Soutar[3]

[1]Scottish National Blood Transfusion Services, GLASGOW; [2]Dept of Anaesthesia, Western Infirmary, GLASGOW; [3]Dept of haemato-oncology, The Beatson, West of Scotland cancer centre, GLASGOW, UK

Background. Heparin-induced thrombocytopenia (HIT) is a serious thrombocytopenic and thrombotic condition. A prompt diagnosis and immediate replacement of heparin with an alternative anticoagulant is required to prevent life threatening thrombotic complications of HIT, however, differing operational characteristics of the laboratory assays and the common occurrence of thrombocytopenia makes diagnosis of HIT difficult. *Aim.* We evaluated the usefulness of a pretest clinical scoring system "the 4T's" (BCSH Guidelines 2006) in combination with a rapid Particle Gel Agglutination Assay (PAGIA) in diagnosing the probability of HIT in 111 patients at a single centre. *Materials and Methods.* The "4Ts" includes (i) the severity (ii) timing (iii) association with thrombosis and (iv) likely cause of the thrombocytopenia and scores patients into low (0-3), intermediate (4-5) and high (6-8) risk groups of having HIT. ID-PAGIA (Diamed, Dalkeith, Scotland) shows agglutination of polymer particles coated with Heparin/PF4 (HPF4) complexes in the presence of anti - heparin/PF4 complex antibodies. 4T score was calcu-

lated either retrospectively (58 unselected patients) or prospectively after a request form including the score and management advice had been devised to aid clinicians (53 patients). *Results.* None of the low "4Ts" were reported test positive for HIT (36/36). The risk of a positive HIT test increased with the increasing 4Ts scores (29% of intermediate (15/51) and 61% of high risk (14/23) respectively). PAGIA showed a false negative rate of 20% when judged against the clinical decision having HIT. Amongst the patients having clinical and serological diagnosis of HIT (29/111), 86% had a platelet fall of >50%, 24% had thrombosis and 63% had suspicion on another potential cause for thrombocytopenia. *Conclusions.* The pretest clinical scoring can be difficult due to involvement of other potential aetiologies for the thrombocytopenia. However, the "4Ts" appear very useful in ruling out HIT. Patients scored as low risk do not seem to need lab testing (32% avoidable requests in this audit). The risk of HIT is significant with intermediate and particularly with the high scores.

Table 1.

PROSPECTIVE STUDY OF ABBREVIATED COURSE RITUXIMAB FOR AUTOIMMUNE HAEMATOLOGICAL DISORDERS REFRACTORY TO STANDARD IMMUNOSUPPRESSIVE THERAPY

S.Z. He,[1] D.A. Ritchie,[1] B. Kuss,[2] P. Macardle,[2] K.E. Matoga,[1] A.P. Grigg[1]

[1]*The Royal Melbourne Hospital, MELBOURNE;* [2]*Flinders Medical Centre, ADELAIDE, Australia*

Background. Profound B cell depletion by rituximab (R) has led to its off-label use for antibody-mediated autoimmune haematological disorders (AHD) adopting standard anti-lymphoma dosing (375 mg/m^2 weekly x 4). There are limited data, however, on the efficacy of abbreviated schedules which may be more cost-effective. *Aim.* To investigate prospectively the efficacy of abbreviated dose R in a variety of AHD refractory to conventional immunosuppression (IS). *Methods.* Informed consent was obtained in all eligible adult patients (pts) who received one dose of R (375 mg/m^2) as part of salvage therapy. A repeat dose was indicated if no response (NR) was seen 4-8 weeks after first infusion, or relapse after achieving complete (CR) or partial response (PR). Planned follow-up was 36 months and disease-specific autoantibodies, lymphocyte subsets and serum R levels were obtained. Concomitant IS was tapered at physician's discretion after two weeks according to response using standard criteria. *Results.* 30 eligible patients with median age of 55 years (range 21-84) were enrolled from March 2007 to February 2009 with 13 pts receiving two doses. Haematological conditions included refractory or recurrent immune thrombocytopenia (ITP), thrombotic thrombocytopenic purpura (TTP), refractory autoimmune haemolysis (AIHA), and miscellaneous conditions. Table 1 describes the results in ITP and TTP. ITP: 11 pts were on prednisolone (median dose 25 mg/d) for a mean duration of 2 weeks and 4 pts received additional IVIG 1 week prior to R; 2 pts had prior splenectomy. The median platelet count immediate prior to R was 21 (range 4 to 54) $\times 10^9$/L. 2 pts treated at relapse by single dose of R alone have attained CR for 15+ and 31+ wks respectively; in 5 other complete responders, prednisolone was ceased after a median of 6 weeks post R. TTP: 4 pts were given single dose R as maintenance after achieving CR at completion of plasma exchanges (PE) during first episode. R was combined with PE as salvage therapy in 5 others with refractory or relapsed TTP. AIHA: 2 pts had unsustained PR (defined as transfusion-independence and positive haemolytic markers) requiring splenectomy and 1 pt remains in CR for 25+ wks. Responses in other disorders: cold agglutinin disease [n=1] - PR for 76+ wks; refractory Evans syndrome [n=1] - failed; acquired factor VIII inhibitor in first relapse [n=1] - CR for 12+ wks; combined autoimmune neutropenia and haemolysis [n=2] with one unsustained and one ongoing CR. In the whole study population, no grade 2-4 infusion toxicity was observed. 2 pts died from refractory TTP and stroke. Grade 3 infection was observed in 2 pts. In pts receiving a single infusion, peripheral blood B cells were detectable at or above the lower limit of normal (i.e. $\geq 0.05\times10^9$/L) earliest at week 24; the median B cell number in these patients at 12, 24, 48, and 72 weeks was 0.01, 0.03, 0.26 and 0.31×10^9/L; serum R levels peaked at week 2 at a median of 30 mcg/mL and became undetectable beyond week 8. *Conclusions.* The preliminary data suggest abbreviated R is safe and sustained response is achievable in refractory/relapsing AHD.

Table 1.

	N=	Response (number)	Median time to attain CR	Duration of CR (weeks)
ITP	13	CR# after 1 dose: 7 CR after 2 doses: 1 PR^:2 NR:3	3 weeks (range: 1-10)	7+, 10*, 11+, 15+, 31+, 34*, 40+, 43+
TTP: first episode Post PE	5	CR: 4 NR: 1 (death)	N/A	58+, 59+, 101+, 104+

CHRONIC IDIOPATHIC THROMBOCYTOPENIC PURPURA THERAPIES: THE PATIENTS' PERSPECTIVE ON BOTHERSOME EFFECTS

R. Horblyuk,[1] A. Matzdorff,[2] T.M. Brown,[3] K.M. Grotzinger,[1] A. Brainsky[1]

[1]*GlaxoSmithKline, COLLEGEVILLE, USA;* [2]*Onkologisches Zentrum Saarbrücken, Caritasklinik St. Theresia, SAARBRÜCKEN, Germany;* [3]*Abt BioPharma Solutions, Inc., LEXINGTON, USA*

Background. Multiple therapies are available for treatment of chronic idiopathic thrombocytopenic purpura (ITP); however, these treatments are associated with side effects that are poorly tolerated. Little information is currently documented on the impact of these side effects from the patients' perspective. *Aim.* The objective of this study was to quantify patient-perceived burden associated with frequently used chronic ITP therapies. *Methods.* Patients who were ≥18 years, had a self-reported history of chronic ITP (>6 months), had been exposed to corticosteroids, IVIg, anti-D, or rituximab, and belonged to a patient ITP support association in the United States were surveyed. Patients completed an online questionnaire that was developed from a literature review using clinician and patient input. Data on demographics, patient disease histories, ITP therapy-related side effects and associated levels of bother were collected in this IRB-approved study in September 2008. The level of bother for each of 26 potential side effects associated with treatment was measured using a 5-point Likert scale in which 1 = not bothered at all and 5 = extremely bothered. *Results.* Five hundred eighty-nine (589) patients completed the survey. Most were female (78%), Caucasian (89%), and diagnosed with ITP for ≥5 years (59%). Corticosteroids were the most frequently reported therapy (n=542, 92%), followed by IVIg (n=322, 56%), rituximab (n=213, 36%), and anti-D (n=209, 36%). Seventy-three percent (73%) and 98% of respondents reported ≥1 side effect associat-

ed with rituximab and corticosteroid treatments, respectively. Corticosteroid-treated patients reported significantly more side effects, compared with other therapies (mean[SD]): corticosteroids (10.7[5.7]); anti-D (2.4[2.2]); IVIg (2.3[2.2]); rituximab (2.1[2.2]) (p<0.0001 for all). The mean level of bother reported for corticosteroids side effects was substantially higher compared with other therapies (mean[SD]): corticosteroids (3.67[0.78]); anti-D (2.98[1.39]); IVIg (2.97[1.39]); rituximab (2.77[1.41]) (p<0.0001 for all). Between 22% (rituximab) and 39% (corticosteroids) of respondents reported the need to stop or reduce their dose of the medication due to side effects of treatment. *Conclusions.* ITP patients recognize, remember, and report multiple bothersome side effects that may lead to dose reduction or treatment discontinuation. Corticosteroid treatments are associated with the greatest number of bothersome and potentially serious side effects. Clinicians and patients may want to consider patient-perceived burden of ITP therapies when making treatment choices.

0237

THROMBOPOIETIN RECEPTOR EXPRESSION IN INHERITED AND ACQUIRED PLATELET DISORDERS

S. Vettore, R. Scandellari, M. Scapin, F. Tezza, M.L. Randi, F. Fabris

University of Padua Medical School, PADOVA, Italy

Background. The interaction between thrombopoietin (TPO) and thrombopoietin receptor (cMpl) appears to be critical in the initial phases of thrombopoiesis (platelet production) promoting $CD34^+$ differentiation, megakaryocytes (MK) proliferation and maturation via cytoplasmatic down-stream signalling. The second consequence of TPO/cMpl interaction is the regulation of TPO level. On platelet surface, there are about 100 high affinity cMpl binding sites that bind, internalize and degrade TPO by a time course process constituting the main regulation of TPO levels. This model explains the high amount of TPO observed in thrombocytopenia secondary to MK hypoplasia. However, TPO levels are unexpected low in immune thrombocytopenia as well in inherited macrothrombocytopenia, and unexpected variable in patients with primary thrombocythemia (ET) where cMpl is underexposed. These observations may be potentially explained by different expression of the receptor on platelets and/or MK in platelet disorders. *Aim of the study.* We aimed to investigate platelet cMpl expression in several familial and acquired platelet disorders in order to clarify their pathogenesis and to potentially better address the treatment of immune thrombocytopenia with the cMpl receptor agonists. *Material, methods and patients*. We studied 34 patients suffering from inherited and acquired platelet disorders: immune thrombocytopenic purpura (ITP),10 patients; megakaryocyte hypoplasia thrombocytopenia (MK-Hyp) 9 patients; inherited thrombocytopenia (FAM) 8 patients: MYH9 related disorder, 1 patient; Bernard-Soulier 1 patient; heterozygous Bernard-Soulier type N41H, 4 patients; heterozygous Bernard-Soulier Bolzano type 2 patients; essential thrombocythemia (ET), 7 patients. We studied 13 healthy subjects as control group. cMpl expression has been evaluated by Western-Blot on 2×10^7 platelet lysates using 1 μg/mL rabbit polyclonal anti-Human cMpl antibody. Anti CD41-clone SZ22 monoclonal antibody against platelet GPIb complex was used as control on the same membranes, after stripping anti-cMpl antibody. For each sample, expression of both cMpl and anti CD41 was quantitated by densitometry analysis of Western Blot. The results are given as mean cMpl/CD41 expression ratio for each group of patients, and as the percent of value of healthy controls set as 100%. *Results.* The results are shown in Table 1.

Table 1. cMpl expression in platelet disorders.

	N	Platelet count $x10^9$/L (mean ±SD)	cMpl/CD41 ratio ($2x10^7$ Plt) (mean ±SD)	cMpl, % of controls (mean)
Controls	13	254 ± 46	0.136 ± 0.103	----
ITP	10	30 ± 20	0.434 ± 0.291	320%
FAM	8	87 ± 25	0.276 ± 0.188	203%
MK-Hyp	9	54 ± 18	0.314 ± 0.243	231%
ET	7	865 ± 372	0.109 ± 0.094	80%

In all groups of patients we observed a heterogeneous pattern of cMpl expression. However, all thrombocytopenic patients showed a greater platelet cMpl expression than controls and ET patients where cMpl is lower. Among thrombocytopenic patients, the increase in cMpl was more pronounced in ITP patients than in those with inherited and MK-Hyp thrombocytopenia. *Conclusions.* Our data seem to confirm that cMpl expression might be inversely regulated by platelet count. Surprisingly, cMpl expression shows a similar pattern in ITP and MK-Hyp patients, despite opposite levels of TPO that have been described in these two types of thrombocytopenia. This observation may be potentially explained by a different cMpl expression on platelet surface in spite of the same total amount of cMpl.

0238

EFFICACY AND SAFETY OF INTRAVENOUS ANTI-D TREATMENT OF PATIENTS WITH REFRACTORY AUTOIMMUNE THROMBOCYTOPENIC PURPURA

M. Mantzourani,[1] S. Raptis,[1] L. Dimitrakopoulou,[2] T. Vassilakopoulos,[1] M. Moschogianni,[2] A. Katsandri,[2] G. Pangalis,[1] G. Vaiopoulos[1]

[1]National and Kapodistrian University of Athens, GOUDI, ATHENS; [2]Laikon Hospital, ATHENS, Greece

Background. Autoimmune thrombocytopenic purpura (AITP) is an autoantibody-mediated hematological disorder in which platelets are prematurely destroyed by the reticuloendothelial system. The initial treatment, according to the American Society of Hematology practice guidelines for ITP in 1996, is a steroid course but a significant percentage (20%-30%) of adult patients remain with PLT levels<20000/μL and need immediate therapeutic intervention to avoid severe bleeding. Intravenous Immunoglobulin treatment and intravenous (IV) Anti-D treatment, both with similar action mechanisms, have been used for this cause. *Aims.* In this study we investigate whether repeated infusions of intravenous anti-D globulin could allow adults with Autoimmune Thrombocytopenic Purpura (AITP) who had failed an initial steroid course to postpone and ultimately avoid splenectomy. *Methods.* Eleven Rhesus positive ITP patients, [9 under relapse and with resistant to previous treatments (steroids or IVIg) disease and 2 on diagnosis] received IV anti-D globulin in repeated doses of 25 μg/Kg every 21 days. Prior to treatment all the patients had PLT levels <30000/μL and had denied splenectomy. Attainment of PLT levels >50000/μL after 7 days was defined as response to treatment. The patients' median age was 36 years (extreme values: 18-82). *Results.* Eight patients (80%) completely responded to treatment with a PLT median value of 89000/μL (extreme values: 50000-150000/μL). 1/8 relapsed after interruption of treatment for 64 days and repeated it successfully with doses of 40 μg/Kg. 7/8 patients have completed 12 cycles of treatment. 1/8 patients completed 10 cycles and maintained normal PLT levels. 3/8 patients are to the present day healthy without any maintenance therapy. 1/11 responded partially, having received only one cycle of treatment, and remains with PLT levels around 50000/μL 12 months later. 2/11 patients did not respond at all. Headache was recorded on 3 patients and 1/7 suffered hemolysis (-b=9 gr/dL) after receiving the second treatment cycle in less than 21 days. *Conclusions.* Despite the small number of patients, it seems that repeated low-dose IV anti-D globulin treatment: 1) is a safe and effective treatment for patients with chronic ITP and 2) removes the need of splenectomy without, anyhow, offering a permanent solution. For safer conclusions, by all means, the necessity of a study of a larger number of patients for a longer period of time should be under imperative consideration.

0239

IMPROVEMENT IN FATIGUE AND HEALTH-RELATED QUALITY OF LIFE WITH LONG-TERM ELTROMBOPAG TREATMENT IN ADULTS WITH CHRONIC IDIOPATHIC THROMBOCYTOPENIC PURPURA: THE EXTEND STUDY

J. Bussel,[1] M. Saleh,[2] A. Salama,[3] K.M. Grotzinger,[4] M. Duh,[5] J. Signorovitch,[5] N.L. Stone,[4] M. Aivado[4]

[1]Weill Cornell Medical College, NEW YORK, USA; [2]Georgia Cancer Specialists, ATLANTA, USA; [3]Charité, Institute of Transfusion Medicine, BERLIN, Germany; [4]GlaxoSmithKline, COLLEGEVILLE, USA; [5]The Analysis Group, BOSTON, USA

Background. ITP is characterized by autoantibody-induced platelet destruction and reduced platelet production, leading to low platelet

counts(<150Gi/L). Eltrombopag treatment is aimed at elevating and maintaining platelets to ≥50Gi/L to minimize risk of bleeding, to reduce or discontinue concomitant medications including corticosteroids, and to improve health-related quality of life (HRQoL). *Aim.* To assess effects of eltrombopag on fatigue and other HRQoL measures among chronic immune thrombocytopenia (ITP) patients in the EXTEND study. *Methods.* EXTEND is an ongoing, open-label extension study in chronic ITP patients previously enrolled in an eltrombopag trial. Interim efficacy and safety analyses have been reported (Bussel *et al.* Blood 2008;112:3432); however, HRQoL data have not. In this study, both eltrombopag and concomitant ITP medications could be dose-adjusted to the minimal treatment necessary to maintain platelet counts in a safe range. HRQoL, self-reported at baseline and upon progression toward establishing an effective dose, was measured with: 1) SF-36v2 (comprises 8 domains, mental component summary [MCS], and physical component summary [PCS]); 2) FACIT-Fatigue subscale; and 3) 6 items from FACT-Thrombocytopenia (FACT-Th) focusing on bruising and bleeding concerns, and limits in daily physical and social activities.

Table.

HRQoL Measure	Baseline Score (95% CI)	Dosing Initiation (Stage 1)	Minimizing ITP Medications (Stage 2)	Optimizing Dosing (Stage 3)	Maintenance Dosing (Stage 4)
		Estimated Change From Baseline (95% CI)			
SF-36v2 Physical Component Summary (PCS)	46.1 (45.0–47.2)	NS	NS	2.2 (0.6–3.7) *P*=0.007	2.1 (0.4–3.8) *P*=0.015
Physical Functioning Domain	73.0 (69.8–76.1)	NS	NS	5.2 (1.1–9.2) *P*=0.013	NS
Physical Role Domain	68.8 (65.1–72.4)	4.6 (0.8–8.3) *P*=0.016	NS	6.1 (0.9–11.2) *P*=0.020	NS
Bodily Pain Domain	74.1 (70.7–77.5)	NS	NS	NS	NS
General Health Domain	52.1 (49.2–55.0)	NS	NS	6.0 (1.6–10.3) *P*=0.007	6.4 (1.4–11.4) *P*=0.012
SF-36v2 Mental Component Summary (MCS)	46.0 (44.4–47.5)	2.1 (0.5–3.7) *P*=0.009	3.9 (1.5–6.3) *P*=0.001	NS	NS
Vitality Domain	54.3 (51.1–57.4)	NS	6.3 (0.7–12.0) *P*=0.026	NS	NS
Social Functioning Domain	75.3 (72.1–78.6)	4.9 (1.6–8.2) *P*=0.003	NS	5.9 (1.1–10.7) *P*=0.016	NS
Emotional Role Domain	76.2 (72.9–79.5)	3.6 (0.1–7.2) *P*=0.042	4.4 (0.2–8.6) *P*=0.039	NS	NS
Mental Health Domain	68.7 (66.1–71.4)	3.2 (0.5–5.9) *P*=0.021	6.8 (2.4–11.1) *P*=0.002	NS	NS
FACIT-Fatigue	36.1 (34.5–37.7)	NS	NS	NS	NS
FACT-Th	14.3 (13.4–15.2)	2.0 (1.2–2.7) *P*<0.001	2.1 (0.8–3.4) *P*=0.002	2.9 (1.9–3.8) *P*<0.001	2.7 (1.2–4.3) *P*=0.001

CI, confidence interval; NS, not statistically significant.
Covariates included: time since baseline visit, stage, prior splenectomy, baseline platelet count ≤15 Gi/L, age, ethnicity, BMI, region, sex, country, prior exposure to eltrombopag, and treatment termination status.

Treatment effect was assessed using longitudinal models with generalized estimating equations methodology and an exchangeable correlation structure. *Results.* At time of this analysis, 144/207 patients in EXTEND had both baseline and on-therapy HRQoL assessments. At baseline, patients had a median age of 50 years, 67% were female, 33%(n=69) were receiving concomitant ITP medication, 40%(n=82) had been splenectomized; 57% had ≥3 prior therapies. Baseline SF-36 domain and summary scores were consistent with those reported in other eltrombopag studies (Bussel *et al.* New Engl J Med 2007) reflecting impaired HRQoL in chronic ITP patients compared with general US population (Ware *et al.*, 2000). Similarly, baseline FACIT-Fatigue scores were worse than observed for general US population (Cella, 2002). Improvements from baseline in HRQoL were observed throughout EXTEND. Statistically significant, clinically meaningful improvements from baseline were reported in SF-36v2 MCS during initiation of treatment with eltrombopag (p=0.009) and during reduction of concomitant ITP medications (p=0.001). Improvements from baseline in SF-36v2 PCS were reported during eltrombopag dose adjustment (p=0.007) and maintenance dosing (p=0.015). Improvements in vitality, social functioning, mental health, and emotional role were reported during initiation of eltrombopag dosing and minimization of concomitant ITP medication, whereas improvements in physical functioning, physical role, and general health domains of the SF-36v2 tended to be observed once a stable platelet count elevation was achieved and maintenance dosing of eltrombopag was initiated. Improvements from baseline in the FACT-Th were observed throughout therapy(p″0.002) evidenced as reductions in bleeding/bruising concerns and improved capacity for physical and social activities. *Conclusions.* In the EXTEND study, health status and fatigue among those with chronic ITP is worse than reported for the general US population. EXTEND study results also suggest improvement in HRQoL, across measures and domains. With eltrombopag treatment, patients initially report improvement in MCS and subsequent improvement in PCS; the difference in response time may reflect both increased confidence in activities from improvements in MCS and reduction in concomitant medications.

0240

MICOPHENOLAT MOPHETIL IN THE TREATMENT OF REFRACTORY ADULT CHRONIC IMMUNE THROMBOCYTOPENIC PURPURA

M. Colovic, A. Vidovic, D. Tomin, I. Elezovic, N. Colovic, V. Palibrk

Institute of Hematology, BELGRADE, Serbia

Aim. The authors evaluate the treatment with mycophenolate mophetil (MM) of refractory chronic immune thrombocytopenic purpura (ITP) and outcome over a period of 8 years in a single institution. *Patients and Methods.* data from 16 patients (pts) suffering from ITP followed in our Institution between 2001 and January 2009. refractory to more than two therapeutic modalities were collected. The diagnosis required a platelet count <50×10^9/L and exclusion of other haematological and non haematological disorders. There were 11 females and 5 males with median age of 51 years. In 11 pts (67%) the haemorrhagic syndrome (purpura and petechial bleeding) was present, 1 pts (6%) had gastrointestinal bleeding and 5 pts (24%) were asymptomatic. 9 pts (56%) had severe thrombocytopenia (<10^9/L) at diagnosis. Splenectomy was performed in 10 patients and all had relapsed after splenectomy. Ten pts showed untoward effects to danazol and prolonged corticosteroids administration. In 8 pts several treatment modalities were applied including azathioprin, ciklosporin, i.v. immunoglobulins and long infusion of vincristine without effect. Median platelet count before MM was 7×10^9/L .MM was administered per orally in doses 2000 mg daily. *Results.* MM therapy was tolerated exceptionally well without any clinically significant side effect. At a median of follow up of 10,3 months (range 2-32), 14 patients responded to treatment, 9 (56.2%) with complete remission and 5 (31.2) with partial response, 2 (12.5%)pts did not respond. Four patients maintain platelet count within normal range after withdrawal of MM, whereas 6 have platelet count between 50-100×10^9/L without reccurence of severe ITP. *Conclusion.* Micophenolat mophetil appears as a favorable immunomodulatory agent for the treatment of chronic autoimmune thrombocytopenia purpura or in the case of old patients with contraindication to splenectomy and/or unresposivness to other treatment modalities.

0241

RITUXIMAB IN THE TREATMENT OF PATIENTS WITH REFRACTORY IDIOPATHIC THROMBOCYTOPENIC PURPURA

C. Montes-Gaisan,[1] J. Nunez,[1] L. Yanez,[1] A. Bermudez,[1] M. Ruiz,[2] I. Olaya,[2] J. Baro,[1] E. Conde,[1] A. Iriondo[1]

[1]Hospital Universitario Marqués de Valdecilla, SANTANDER; [2]Hospital Sierrallana, TORRELAVEGA, Spain

Aims. To evaluate the efficacy and safety of Rituximab in patients with refractory idiopathic thrombocytopenic purpura as well as to analize potential factors in relation with the results. *Material and Methods.* A retrospective study has been performed at our medical centres involving the use of Rituximab in 17 patients who had been diagnosed of idiopathic thrombocytopenic purpura. All of them, who had been unresponsive to steroids and/or immunoglobulin, received Rituximab (375 mg/m^2 weekly for 4 doses) as rescue therapy between 1996 and 2007. It was used as second or third line therapy in 13 of 17 patients, and 3 of them had been previously splenectomized. The median time from the diagnosis was 13 months (range,0-314). There were 13 women and 4 men, with a median age of 48 years (range,5 to 82). The median platelet count at baseline was 5,5×10^9/L (range,1 to 54) and 15 of 17 had mucocutaneous hemorrhagic syndrome at the beginning. We found no etiology for 11 patients and we only detected platelet antibodies in 7 of them. *Results.* Complete Remission (>100-10^9/L) was achieved in 12 patients (71%) and Partial Remission (>50-10^9/L) in another 2 (11%), only 3 of them showed No Response. The median follow-up was 7 months (range 2-32) and the median time from the first Rituximab dose to any response was 4 weeks (range, 1-8). Only 4 patients (28%) experimented relapse beyond the twelveth month of follow-up (range, 7-32). There were no severe adverse events during drug administration, and increased number of infections

were not recorded either. We found some response related factors with different scientific evidence: age (remission in patients older than 18 years was 100% while it was only reached in 25% patients younger than 18 years: p=0.001), number of treatment regimens received before Rituximab (remission when Rituximab was used as second or third line therapy was 91% while it was 67% when Rituximab was used at least as fourth line: p=0.21) and detection of platelet antibodies (remission when platelet antibodies were not found was 90% while it was 67% when they were positive: p=0.24). *Conclusions.* The use of Rituximab in refractory idiopathic thrombocytopenic purpura showed a global response rate of 82%. Relapse 30 months after the use of Rituximab was found in 28% patients, and none of them have reached any kind of response with any other later treatment. The factors associated with no Rituximab response were paediatric age, higher number of previous treatment regimens and presence of platelet antibodies. No splenectomized patient was able to reach any kind of response.

0242

CORTICOSTEROIDS FOR THE TREATMENT OF CHRONIC IDIOPATHIC THROMBOCYTOPENIC PURPURA: PATIENT-PERCEIVED BURDEN

K. Grotzinger,[1] A. Matzdorff,[2] T.M. Brown,[3] R. Horblyuk,[1] A. Brainsky[1]

[1]GlaxoSmithKline, COLLEGEVILLE, USA; [2]Onkologisches Zentrum Saarbrücken, Caritasklinik St. Theresia, SAARBRÜCKEN, Germany; [3]Abt BioPharma Solutions, Inc., LEXINGTON, USA

Background. Pharmacologic management of chronic idiopathic thrombocytopenic purpura (ITP) relies heavily on corticosteroids as a first-line treatment. Until now, data on patient-perceived burden associated with corticosteroids have been anecdotal, assumed, or based on the product information. *Aims.* This study evaluated types and numbers of side effects associated with corticosteroids and their level of bother as reported by exposed patients with chronic ITP. *Methods.* Patients ≥18 years with self-reported history of chronic ITP (>6 months) and exposure to corticosteroids were recruited from a US ITP patient support association and surveyed online using a questionnaire developed using a literature review, and clinician and patient input. Demographics, patient and treatment history, and corticosteroid-related treatment side effects data were collected in this IRB-approved study in September 2008. The levels of bother for 26 potential side effects associated with treatment, generated with clinician and patient input, were measured using a 5-point Likert scale (1 = not bothered at all, 5 = extremely bothered). Bother responses were aggregated to express overall burden of reported side effects. Regression modeling predicted level of corticosteroid burden, controlling for factors in patient history, including demographics and clinical characteristics. *Results.* A total of 542 patients completed the survey. Most were female (77%) and Caucasian (90%), and the mean age was 47.5(±14.4). Fifty-nine percent (59%) had been diagnosed with ITP for ≥5 years. Thirty-one percent (31%) were taking corticosteroids at the time of the survey. Fifty-five percent (55%) reported having experienced ≥11 adverse effects or adverse experiences of treatment with corticosteroids, although the constellation of side effects for each patient was unique. Weight gain (83%), changes in personality/mood (77%), problems sleeping (75%) and moon face (67%) were experienced most frequently. More than 50% of patients were highly bothered (4 = bothered quite a bit or 5 = extremely bothered) by these 4 most frequent side effects. The mean level of bother was highest for weight gain (4.2) and moon face (4.2) and averaged 3.67 across all side effects. In a regression model, greater levels of corticosteroid bother were associated with female gender (p<0.001), number of perceived side effects (p<0.0001), and the need to reduce the dose due to side effects (p=0.0011). *Conclusions.* Corticosteroids are the most frequent first-line therapy for the treatment of chronic ITP; however, corticosteroids are associated with multiple side effects, which are substantially bothersome and burdensome to patients. These patient-reported data may make clinical discussions between patient and physician more informative regarding the selection and consequences of treatment with corticosteroids for chronic ITP.

0243

COMPARATIVE EVALUATION OF PLATELET COUNTING ON CELLAVISION DIFFMASTERTM OCTAVIA VERSUS OPTICAL FLUORESCENT PLATELET COUNTING ON SYSMEX XT-2000I AUTOMATED HEMATOLOGY ANALYZER

A. Agorasti, E. Nikolakopoulou, E. Mem*et al.*i, D. Konstantinidou

General Hospital of Xanthi, XANTHI, Greece

Background. CellaVision DiffMasterTM Octavia (DiffMaster) is an automated image analysis system for peripheral blood smears. One of the advantages of the system is the ability to review cases (slides) from a remote location (via internet). The system provides functionality for platelet morphologic features and for estimation of platelet count. The Sysmex XT-2000i incorporates two platelet methodologies, impedance and fluorescent optical (PLT-O). PLT-O is counted by flow cytometry in the reticulocyte channel using a semiconductor laser and nucleic acid fluorescent dye. The PLT-O measurement is an accurate platelet count in specimens where small red blood cells or large platelets are present, because overlapping of populations is avoided. *Aim.* The aim of this study is to evaluate the platelet count on DiffMaster in samples containing microcytic erythrocytes (mean corpuscular volume, MCV ″79fl). *Methods.* All samples included in this study [n=80, MCV 66.5±8.0fl, hemoglobin 11.4±1.5 gr/dL (mean±SD), platelet 58-573×10^3/μL (range)] had been analyzed on Sysmex XT-2000i in the reticulocyte channel. Blood smears were prepared in duplicate with a semiautomated method and stained with May-Grünwald - Giemsa stain. Two laboratory physicians (A, B) counted the platelets (on four images consisting of 36 patched areas of the slide). A calculated estimate of the platelet concentration is made based on the counts per image and a platelet estimate factor. We calculated the mean platelet count of the two observers (score A + score B/2) for each sample. Two comparisons were made: one between the counts of the two physicians and one between DiffMaster (score A + score B/2) and Sysmex XT-2000i PLT-O values. Statistical analysis: the data were analyzed with Pearson correlation and regression analysis. Statistical significance was set at p<0.05. *Results.* Neither fragmented erythrocytes, nor platelet clumping were reported. For each comparison the correlation coefficients (r), linear regression equations, slopes and P values are summarized in Table 1. The agreement between the two examiners A and B was very good (r=0.94, p=0.001). *Conclusions.* The evaluation has shown that the CellaVision DiffMasterTM Octavia and Sysmex XT-2000i PLT-O have excellent correlation on platelet count (r=0.92, p=0.001). Platelet count on CellaVision DiffMasterTM Octavia tended to be the same as the corresponding values reported by XT-2000i PLT-O as suggested by a slope of 0.9876. As digital images can be reviewed remotely, small laboratories could rely on laboratory physicians in remote locations by using the CellaVision DiffMasterTM Octavia system.

Table 1.

Platelet count	r	linear regression equation	slope	P
score A versus score B	0.94	y = 0.8609x + 26.153	0.8609	0.001
DiffMaster vs PLT-O	0.92	y = 0.9876x + 2.7413	0.9876	0.001

0244

MEDICAL CONTRAINDICATIONS FOR SPLENECTOMY AMONG ADULTS WITH IMMUNE THROMBOCYTOPENIC PURPURA: DATA FROM THE GENERAL PRACTICE RESEARCH DATABASE

W.M. Schoonen,[1] L. Li,[2] J.P. Fryzek,[3] J.A. Kaye[2]

[1]Amgen Ltd, UXBRIDGE, MIDDLESEX, UK; [2]Boston U School of Medicine & Boston Collaborative Drug Surveillance Program, LEXINGTON, MA, USA; [3]Amgen Inc, THOUSAND OAKS, CA, USA

Background. Splenectomy is a potential treatment for chronic immune thrombocytopenia purpura (ITP), generally recommended for patients with severe disease who have a risk of serious bleeding and fail to respond to first-line treatment. It is thought that a subgroup of ITP patients may not be able to undergo splenectomy due to medical con-

traindications. These contraindications have not been clearly described. *Aims.* To describe characteristics of unsplenectomised ITP patients and compare with characteristics of splenectomised ITP patients. *Methods.* We first performed a review of the literature to identify potential medical contraindications for splenectomy. We then assessed the prevalence of these contraindications among a group of splenectomised incident adult ITP patients. We compared this to the prevalence of contraindications among unsplenectomised adult ITP patients. ITP patients were identified from the UK General Practice Research Database (GPRD). Newly diagnosed patients aged between 18-100 years who had at least one medical code for ITP and received at least one prescription for prednisolone were included in the study. *Results.* Potential medical contraindications identified from the literature included diabetes mellitus, congestive heart failure, ischaemic heart disease, cerebrovascular disease, asthma and chronic obstructive pulmonary disease and older age (over 70 or 80 years). The prevalences of these conditions were examined among 342 incident adult ITP patients receiving prednisolone treatment, of whom 44 (13%) were splenectomised. None of the ITP patients who had coexistent diabetes mellitus, congestive heart failure and cerebrovascular disease were observed to have undergone splenectomy (Figure). Forty of the 44 splenectomies (91%) were performed on adults aged less than 75 years. The median age of splenectomised adult ITP patients (52 years, interquartile range (IQR): 36-65) was substantially younger compared to non-splenectomised individuals (median 68 years, IQR: 47-76; p=0.0001 (t-test)). The proportion of splenectomised ITP patients did not differ by gender or by calendar year of ITP diagnosis. *Summary and Conclusions.* Data from routine clinical practice support findings from the literature that certain subgroups of ITP patients may not be indicated to undergo splenectomy. However, it should be noted that some of the ITP patients included in our study may have responded to first-line treatment and/ or had less severe disease. Therefore, some of the patients in our non-splenectomised group may not have been indicated for splenectomy for reasons other than their coexisting medical conditions.

Figure. Comorbidities in adult ITP by splenectomy status.

Background. The appropriate prophylactic platelet transfusion threshold (TT) in haematologic patients was lowered in the last two decades from 20-10×10^9/L without significantly increasing the haemorrhage risk. Recently, a further reduction of TT to 5×10^9/L has been suggested, though the potential inaccuracy of standard routine haematology analysers for very low platelet count (PC) is a major concern. It has been showed that with PC below 20×10^9/L the failure to discriminate platelets from other cell fragments and debris of a similar size or the presence of giant platelets increases the PC variability. *Aims.* Our aim was to evaluate, in adult haematological thrombocytopenic patients, the PC accuracy of 4 different haematology analysers utilizing different technologies: i) optical ADVIA120 (Siemens); ii) impedancemetry-based PENTRA120DX (Horiba Medical) and LH750 (Coulter); iii) both technologies XE2100 (Siemens). The obtained results were compared to the immunological reference method validated by the International Society of Laboratory Haematology. *Methods.* 90 blood samples with PC less than 150×10^9/L were collected from 55 thrombocytopenic haematological patients, 66 samples (73%) showed PC less than 50×10^9/L. The samples were analyzed within 4 hours from phlebotomy, while the immunological PC was performed within 24 hours. Spearman correlation was used to analyze correlation between methods. Mean value was compared by t test. Comparison between methods were made through Bland Altman graph and Roc curve was used to evaluate sensibility, specificity and possible better cut off. *Results.* Data (Table 1) show a good correlation between immunological reference values and counts provided by automatic analysers: 0.946 for ADVIA120; 0.957 and 0.942 for XE2100 impedancemetry and optical method respectively; 0.938 for LH750; 0.954 for PENTRA120DX.

Table 1.

	Advia 120	XE 2100i	XE 2100o	LH 750	Pentra 120dx
N	87	90	72	89	90
Correlation (r)	0.9469	0.9572	0.9423	0.9389	0.9544
Mean differences	4.79	3.59	0.18	12.10	6.57
Regression coefficient (b)	0.84	0.86	1.04	0.67	0.80
Cut off 20x10^9/l					
Sensibility	93.33	90.32	76.92	80.65	74.19
Specificity	100.00	98.31	100.00	100.00	100.00
Correctelly classified	97.70	95.56	91.67	93.26	91.11
Recalculated best cut off	20	23	21	24	24
Sensibility	93.33	96.77	81.48	98.28	96.61
Specificity	100.00	98.31	92.87	90.32	87.10
Correctelly classified	97.70	96.81	91.89	95.51	93.33
Cut off 10x10^9/l					
Sensibility	61.11	77.78	73.33	55.56	66.67
Specificity	97.10	95.83	96.49	97.18	95.83
Correctelly Classified	89.66	92.22	91.67	88.76	90.00

All analysers over-estimated the PC compared with the immunological method by a mean of 4.79×10^9/L for ADVIA120, 12.10×10^9/L for LH750, 6.57×10^9/L for PENTRA120DX, 3,59 and 0.18×10^9/L for XE2100 impedancemetry and optical method respectively. Anyway there is a good sensitivity (range 74.19-93.33) and excellent specificity (range 98.31-100) at a cut-off set to 20×10^9/L platelets. The 10×10^9/L cut-off is critical for all the analyser due to the worsened sensitivity (range 55.56-77.78) and specificity (range 94.2-96.49). The best accuracy (higher number of patients correctly classified) is obtained with the following cut-off: 20×10^9/L for ADVIA120; 23 and 21×10^9/L for XE 2100 impedance and optical method respectively; 24×10^9/L for LH750 and Pentra120DX. *Summary and conclusions.* The analysers show a good correlation with the immunological reference method in thrombocytopenic hematological patients. Their best accuracy is obtained when PC is equal or higher 20, 23, 21 and 24×10^9/L depending on the utilized analyser (Table 1), However, the analyzer performances are poor when PC is very low (″10×10^9/L). Moreover, all analysers over-estimated the PC when compared to the immunological reference method. Therefore, despite dramatic advancements in automated blood count technology have been made, to reduce the current accepted platelet prophylactic TT from 10.0-5.0×10^9/L continues to be a challenge for the future.

LENALIDOMIDE ABROGATES THE CLONAL ADVANTAGE OF DEL(5Q) MDS STEM CELLS VIA ALTERATION OF NICHE INTERACTIONS

C. Scharenberg, M. Jädersten, J. Palmquist, L. Forsblom, M. Jansson, E. Hellström-Lindberg

Karolinska Institute, STOCKHOLM, Sweden

Background. The myelodysplastic syndromes (MDS) constitute a heterogenous group of clonal disorders of hematopoietic stem cells (HSC) leading to ineffective hematopoiesis in one or more lineages in the bone marrow. A range of cytogenetic abnormalities can be identified in around 50% of cases, with the most frequent cytogenetic entity being the 5q-syndrome, characterized by loss of the 5q31-33 region. Recently, the thalidomide analogue lenalidomide has been demonstrated to induce cytogenetic response and restored erythropoiesis in this group of patients. While inhibition of angiogenesis, cell adhesion, and proliferation, as well as modulation of pro-apoptotic cytokines, have all been put forward as putative modes of action of lenalidomide, the exact mechanism has remained unclear. Interestingly, the more primitive hematopoietic compartment seems to possess a clonal advantage where del(5q) HSC are able to outcompete non-5q HSC. Whether the molecular mechanism for clonal advantage is intrinsic to the stem cell clone or a result of a compromised niche is unclear. However, we have previously demonstrated that lenalidomide is able to abrogate this clonal advantage. *Aims.* Our previous results implicated the matri-cellular protein SPARC to be upregulated in CD34$^+$ del(5q) cells in response to lenalidomide. Thus, we sought to test the hypothesis that a putative decrease in SPARC expression of a clonal hematopoietic progenitor should give rise to a population of cellular descendants that exhibit an increased adhesion to the microenvironment and more active rates of proliferation, thus explaining the clonal advantage of del(5q) MDS stem cells. *Methods.* We therefore studied the basal adhesion of del(5q) CD34$^+$ progenitor cells to the murine stromal cell line MS-5 using a gravitational-force upon-inversion assay. Using multi-parameter flow cytometry, we studied proliferation and apoptosis in del(5q) and normal HSC and how these parameters are affected by lenalidomide and recombinant SPARC-protein. *Results.* Our data show that del(5q) CD34$^+$ progenitors exhibited increased adhesion to the murine stromal cell line MS-5 compared to normal CD34$^+$ cells. In short-term *in vitro* cultures, lenalidomide and recombinant SPARC were able to abrogate this increased adhesion. Multiparameter flow cytometry revealed a decreased rate of spontaneous apoptosis in del(5q) HSC compared to progenitors. Lenalidomide increased apoptosis in both compartments and this effect was specific to del(5q) cells. However, neither lenalidomide nor SPARC appeared to have any effect on the proliferation of CD34$^+$ progenitors from normal or del(5q) bone marrow. *Summary and Conclusions.* These studies suggest that decreased expression of SPARC leads to increased adhesion of del(5q) HSC/progenitor cells to their microenvironment and may explain why del(5q) HSC are able to outcompete the remaining healthy HSC. Our studies suggest that lenalidomide is able to abrogate this clonal advantage partly via its increase in SPARC expression with a consecutive decrease in adhesion and increase in apoptosis

EVALUATION OF COMORBIDITY AS PROGNOSTIC VARIABLE IN 419 PATIENTS WITH MYELODYSPLASTIC SYNDROMES: A STUDY OF THE AUSTRIAN MDS WORKING GROUP

W.R. Sperr,[1] F. Wimazal,[2] M. Kundi,[3] C. Baumgartner,[2] T. Nösslinger,[4] A. Makrai,[4] R. Stauder,[5] O. Krieger,[6] M. Pfeilstoecker,[4] P. Valent[2]

[1]Dept. of Int. Med I, VIENNA; [2]Dept of Int Med I, Div of Hematol & Hemostaseol, Med Univ of Vienna, VIENNA; [3]Institute of Environmental Hygiene, Medical University of Vienna, VIENNA; [4]3rd Medical Department for Hematology and Oncology, Hanusch Hospital, VIENNA; [5]Department of Int Med. V (Haematology and Oncology), Med.Univ. of Innsbruck, INNSBRUCK; [6]Department of Internal Medicine I, Hospital of the Elisabethinen, LINZ, Austria

Background. Myelodysplastic syndromes (MDS) are a group of clonal hematologic neoplasms characterized by ineffective erythropoiesis, peripheral cytopenia(s), and an increased risk to transform to secondary acute myeloid leukemia (AML). The prognosis in MDS is variable and depends on the disease variant, other disease-related features, and patient-related parameters. The evaluation of comorbidity is of increasing importance in patients with hematologic disorders. *Patients and Methods.* In the present study, the influence of comorbidity on survival and AML evolution was analysed retrospectively in 419 patients with *de novo* MDS (observation period: 1985-2007). The median age was 71 years (range 18-91 years). Two different scoring systems for comorbidity, the hematopoietic stem cell transplantation comorbidity index (HCT-CI) and the Charlson comorbidity index (CCI) were applied. *Results.* The HCT-CI was found to be a significant prognostic factor for survival (OS, $p<0.05$) as well as event-free survival (EFS, $p<0.05$) in our patients, whereas the CCI was of prognostic significance for OS ($p<0.05$) but not for EFS. For AML-free survival (AFS), neither the HCT-CI nor the CCI were of predictive value. In a next step, a multivariate analysis including age, LDH, serum ferritin, karyotype, number of cytopenias, FAB-groups, and comorbidity was performed. Analysing the entire group of patients neither the HCT-CI nor the CCI were independent prognostic parameters for OS or EFS after addition of ferritin to the multivariate cox model. However, chronic comorbidity was found to be an independent prognostic factor for both OS and EFS when good risk MDS patients (IPSS low or int-1) were analyzed separately. In particular, the HCT-CI was a prognostic variable for OS ($p<0.05$) and EFS ($p<0.05$) in this group of patients, independent of age, LDH, ferritin, FAB-subgroup, number of cytopenias, and karyotype. In contrast, the CCI was not of prognostic significance neither for OS nor EFS. With regard to int-2 or high risk MDS patients, both, HCT-CI and CCI were not of prognostic significance. *Conclusions.* Together, our data show that comorbidity as defined by the HCT-CI is an independent risk factors for OS and EFS in patients with low or int-1 MDS. The HCT-CI is a superior prognostic score system in MDS.

A NOVEL RECURRENT GENETIC ABNORMALITY IN MYELODYSPLASTIC SYNDROMES: REARRANGEMENTS AND AMPLIFICATIONS OF IER3

D.P. Steensma, J. Neiger, J.C. Porcher, J. Keats, P.L. Bergsagel, R.A. Knudson, R. Santana-Davila, R. Kumar, R.P. Ketterling

Mayo Clinic, ROCHESTER MINNESOTA, USA

Background. IER3 (Immediate Early Response 3; also known as IEX-1) has an important role in regulating death receptor-induced apoptosis, interaction with NF-kB pathways, and cellular response to genotoxic stresses such as ionizing irradiation. While murine models have suggested a role for IER3 in neoplasia (e.g., forced overexpression results in development of a lupus-like syndrome and lymphoproliferative disorders), and gene expression microarrays in various solid tumors and 2 independent CD34$^+$ microarray experiments in myelodysplastic syndromes (MDS) have identified IER3 as a striking expression outlier (Hofmann W-K *et al.* Blood 2002; Prall WC *et al.* Int J Hem 2009), definitive evidence for involvement of IER3 in a human disease has been lacking. During breakpoint cloning of an isolated tranlocation in a patient with MDS, we identified an IER3 rearrangement, and then detected IER3 abnormalities in other patients with MDS. *Methods and Results.* The propositus exhibited t(6;9)(p21.3;q34) as an isolated chromosomal abnormality in 18 of 20 metaphases; FISH assays for DEK/CAN fusion and ABL rearrangements were unrevealing. To clone the breakpoints efficiently without resorting to a large library of BAC clones, we generated somatic hybrid murine/human cell lines from a buffy coat; microdissected derivative chromosomes with laser capture microscopy; and hybridized to 6p/9q custom comparative genomic hybridization (CGH) arrays. The CGH results considerably narrowed the 6p and 9q breakpoints (within 800 bp for 6p), which were then amplified by long-range PCR and sequenced to define the rearrangement. The IER3 gene at 6p21.3 was found to be separated from all but 40 bp of its upstream regulatory elements in this rearrangement and translocated to a transcript-poor region of 9q, dramatically downregulating expression in the patient compared to healthy controls, as confirmed by RT-PCR and Western blotting. We then designed split-signal and locus-specific FISH probe sets for IER3. We examined archival bone marrow cell pellets from 204 additional patients with various clonal hematological disorders and chromosomal rearrangements involving 6p21 or 6p22 (i.e., translocations, inversions, deletions, or additions), and found IER3 abnormalities in 8 additional patients: 3 split signals and 6 amplifications (one patient had both abnormalities); all 8 patients had MDS. FISH studies in 157 additional MDS patients (90 higher-risk, 67 lower-risk) with normal karyotype were unrevealing. RT-PCR in 46 MDS patients without 6p rearrangements demonstrated down-regulation of IER3 by >4-fold in 16 patients (35%, mostly higher-risk) and down-regulation by >4 fold in 12 patients (26%, mostly lower-risk) when compared to the mean for 23 healthy controls. Direct sequencing of the IER3 coding region and the

promoter region in 74 patients without 6p rearrangements revealed no point mutations. Hematopoietic progenitor growth from IER3-/- mice was compared to wild-type controls, and we noted no differences in BFU-E, CFU-E, and CFU-GM growth under unstressed conditions. *Conclusions.* IER3 rearrangements and amplification represent a novel clonally-restricted recurrent genetic abnormality in MDS. This is the first time IER3 has been linked to human disease, and the combination of somatic hybridization + *array painting* may facilitate cloning of other breakpoints in hematological neoplasms. Dysregulation of IER3 expression is common in MDS (61% had either >4-fold increase or decrease in expression), even in patients without 6p rearrangements. In early MDS, lack of IER3 is expected to contribute to excessive apoptosis and hematopoietic failure; in later MDS, amplification or overexpression of IER3 would favor cell survival and progression to AML. Better understanding of the role of IER3 in MDS is likely to yield new insights into MDS pathobiology.

NEW INSIGHTS INTO THE BIOLOGY OF REFRACTORY ANEMIA WITH RING SIDEROBLASTS (RARS) AND IDENTIFICATION OF ERYTHROID G-CSF TARGETS BY GENE EXPRESSION PROFILING

M. Nikpour,[1] A. Pellagatti,[2] A. Liu,[3] M. Karimi,[3] L. Malcovati,[4] A. Forsblom,[3] V. Gogvadze,[5] J. Wainscoat,[2] M. Cazzola,[6] B. Zhivotovsky,[5] A. Grandien,[3] J. Boultwood,[2] E. Hellström-Lindberg[3]

[1]Karolinska Institute, HUDDINGE, STOCKHOLM, Sweden; [2]LRF Molecular Haematology Unit, NDCLS, John Radcliffe Hospital, OXFORD, UK; [3]Department of Medicine, Center of Experimental Hematology, Karolinska Institutet, STOCKHOLM, Sweden; [4]Dep.of Hematology, University of Pavia & Fondazione IRCCS Policlinico San Matteo, PAVIA, Italy; [5]Institute of Environmental Medicine, Div. of Toxicology, Karolinska Institute, STOCKHOLM, Sweden; [6]Dep. of Hematology, University of Pavia & Fondazione IRCCS Policlinico San Matte, PAVIA, Italy

RARS is characterized by severe ineffective erythropoesis and mitochondrial iron overload. Granulocyte-CSF inhibits erythroid apoptosis and mitochondrial leakage of cytochrome c *in vitro* as well as *in vivo*. The molecular mechanisms underlying the ineffective erythropoiesis in RARS and the effects of G-CSF were studied by gene expression profiling (GEP) of erythroblasts from normal (NBM) and RARS bone marrow after first confirming their clonal origin by HUMARA analysis. $CD34^+$ selected marrow cells were cultured for 7-14 days in Iscove´s medium with 15% BIT9500, and an aliquot of cells were treated with G-CSF at day 7. GEP was determined using Affymetrix, U133 Plus2.0 chips (Pellagatti *et al.*, 2006). The expression of several genes involved in cellular iron metabolism was significantly downregulated in the RARS samples: ABCB7, mutated in X-linked sideroblastic anemia with ataxia and involved in maturation of cytosolic Fe/S enzymes and Sfxn, mutated in mice with siderocytic anemia. Other downregulated genes included, FANCC, a key mutated gene in Fanconi anemia, and FOXO3A, a transcription factor regulating oxidative stress in erythropoiesis. None of these genes were, however, influenced by G-CSF, in spite of its anti-apoptotic effect. By contrast, the expression of another key down-regulated gene, MFN2, involved in mitochondrial membrane stability, was reverted back to the normal range by G-CSF, in line with previous findings of G-CSF inhibition of cytochrome c release (Tehranchi, 2003). Moreover, we studied methylation status by MCA-Methylation assay and confirmed that DNA methylation was not a significant cause of low mRNA expression. Importantly, both ABCB7 and MFN2 expression increased 2-3-fold during normal erythroid differentiation, while decreasing by 2-3-fold in the RARS cultures, as assessed by realtime-PCR. By comparing GEP between $CD34^+$ cells and erythroblasts, it was clear that a number of genes, including ALAS2, that were upregulated in $CD34^+$ was normalized or less dysregulated in the erythroblast fraction, indicating that the $CD34^+$ expression pattern may be strongly influences by the composition of that cell compartment. The expression level of HSPA1B and HSPA9B, two members of the HSP70 family, which were slightly up-regulated in RARS increased significantly after G-CSF treatment. HSPA1B regulates erythropoiesis by preventing caspase-3-mediated cleavage of GATA-1 during differentiation and HSPA9B acts as an anti-aopototic protein via inactivation of P53. Increased expressions of HSPA1B and HSPA9B are thus consistent with the observed *in vivo* response of RARS patients to G-CSF. In conclusion, our data supports the strength of assessing GEP in differentiating, cohorted cells. We have identified a number of key downregulated genes involved in mitochondrial function and iron transport, whose expression decreased during differentiation, while other genes involved in erythropoiesis and cell death / survival remained more or less normal in intermediate erythroblasts, in spite increased cytochrome c release and other apoptotic features in the cultures. G-CSF seems to act through upregulation of hsp 70 genes, but also has a very interesting direct effect of key mitochondrial function genes, such as MFN2.

[1]Institut Universitaire d'Hematologie, PARIS, France; [2]Department of Haematology, LONDON, UK; [3]King's College, LONDON, UK; [4]Médecine Nucléaire, Hôpital Bichat, PARIS, France; [5]Service d'Hématologie Clinique, Hôpital Avicenne, PARIS, France; [6]Institut Cochin, Department of Haematologie, Hôpital Cochin, PARIS, France; [7]MD Anderson, HOUSTON, TEXAS, USA; [8]University of Maryland, BALTIMORE, USA; [9]Queens University, BELFAST, UK; [10]Cell Biosciences, PALO ALTO, CA, USA

Background. Combinations of oncogenes that transform cells have been described; however, few studies have analyzed the progression of genetic events leading to the expansion of the leukemic clone. Animal models enable us to understand disease progression and provide us with reagents to test various therapeutic strategies. *Aims.*We have previously developed an animal model of myelodysplasia/acute myelogenous leukemia (MDS/SAML) progression using mutant NRAS, and overexpression of human hBCL-2. Here we plan to further characterize these models and compare them to the human disease. Using a mimetic inhibitor ABT 737, we aim to evaluate the effects of targeting BCL-2 in our preclinical models. *Methods.* Transgenic mice bearing the NRASD12 oncogene was crossed with mice bearing hBCL-2 driven by either the MMTVLTR or MRP8 promoters and were followed for disease my measuring their blood counts. The diseased mice were treated with 15x75mg/kg of the small molecule ABT 737 (Abbott) every other day. Cells were harvested and characterized. *Results.* Expanded leukemic stem cells (LSC) were identified as Lin-/Sca1+/KIT+ populations by flow cytometry, with increased myeloid colony growth and were transplantable. Increased hBCL-2 expression in the RAS-GTP complex are observed in both MDS/AML diseases using the RAS pulldown assay. Gene expression profiling studies indicate that the signatures of the AML-like disease resemble human AML with an underlying MDS. The MDS-like disease had increased apoptosis assayed by terminal deoxynucleotidyltransferase-mediated dUTP nick-end labeling (TUNEL) on liver sections, whilst the AML-like mice had liver apoptosis patterns similar to wild type. The single mutant NRAS line also had increased apoptosis. *in vivo* imaging by single-photon emission computed tomography (SPECT) using Tc-99m-labelled AnnexinV confirmed these findings. In the MDS mice the majority of the RAS and BCL-2 doubly stained cells localized to the plasma membrane, where active pro-apoptotic RAS is normally located, whereas in the AML disease RAS and BCL-2 co-localize in the mitochondria, where BCL-2 is normally found. This is concordant with the signalling profile measured by conventional western blotting and the nanoimmunoassay (NIA) (Firefly TM, Cell Bioscience) with phosphorylated ERK isoform expression patterns associated with disease progression. These patterns were also observed in patients with increased RAS/BCL-2 co-localizations correlating with clinical features. Increased genomic instability in the Sca1+ compartment provides a mechanism for disease progression. We have used these models to determine the efficacy of a BH3 mimetic inhibitor ABT 737. We have shown that treatment with this reagent targets primitive progenitors using flow cytometry and colony assays, induces apoptosis, measured by TUNEL and SPECT and clears the liver infiltrations in both MDS and AML mouse models with the disruption of the RAS/BCL-2 complex, measured by western blotting and confocal microscopy and increases in phosphorylated ERK isoforms by NIA. *Conclusions.* Emerging technologies of genomics, proteomics and imaging have been employed in the MDS/AML models to characterize disease progression and follow response to treatment in order to gain molecular insight in the evaluation of the efficacy. ABT 737 appears to target LSCs and induce apoptosis, regulating appropriate pathways.

0251

FISH PROBES DERIVED FROM ARRAY CGH (ACGH) REVEAL NOVEL CHROMOSOMAL LESIONS IN MDS PATIENTS WITH A NORMAL KARYOTYPE

P. Bernasconi, I. Dambruoso, M. Boni, P.M. Cavigliano, S. Calatroni, I. Giardini, B. Rocca, R. Zappatore, C. Calvello, M. Caresana, M. Lazzarino

Division of Hematology, Foundation IRCCS Policlinico S. Matteo, PAVIA, Italy

In MDS the cytogenetic pattern is one of the most important parameters to predict overall survival (OS) and the risk of MDS/AML evolution. However, in about 40-50% of patients, especially low-rish MDS, conventional cytogenetics (CC) fails to reveal clonal chromosomal defects. FISH with probes specific for chromosomal regions most commonly involved in MDS can improve CC results (Bernasconi *et al.*, 2003). Currently, aCGH revealed that MDS patients, independently of the cytogenetic pattern, harbour novel chromosomal lesions targeting unsuspected regions. Thus, our study was aimed at evaluating whether probes derived from a recent aCGH (Starczynowski *et al.*, 2008) were truly able to unmask cryptic lesions in chromosomally normal MDS patients, whether these defects consisted in either chromosomal gains/losses or balanced rearrangements and whether they influenced OS and disease evolution. The twenty-one patients entered the study were examined between January 2005 and May 2008. They were six females and fifteen males, their median age was 64 years (range 24-75). According to WHO classification, 3 patients were classified as RA, 8 as RAEB-1 and 10 as RAEB-2. Considering IPSS score, 4 patients were considered low-risk, 8 intermediate-1 risk and 9 intermediate-2 risk. Median follow-up was seven months (range 1-46). At the time of the study no patients have died, whereas 4 have evolved to RAEB-2 and 2 to AML. FISH probes were chosen based on the frequency of their involvement in MDS (Starczynowski *et al.*, 2008) and their Mb position determined using UCSC genome browser on Human Mar. 2003 assembly. They were obtained from BACPAC Resources Center at C.H.O.R.I. (Oakland, USA), labelled and applied as previously described. We used the following probes: RP11-912d8 (19q13.2); RP11-196p12 (17q11.2); RP11-269c4 (14q12); RP11-351o1 (10q21.3); RP11-144g6 (10q11.2); RP11-122a11 (7q34); RP11-951k18 (5q13.1); RP11-100m20 (4p14); RP11-544h14 (2q33). For i-FISH, cut-off values, obtained from the analysis of 300 nuclei from ten normal samples, were fixed at 10%. An abnormal FISH pattern was revealed in 10 patients (47.6%): 5 presented a 19q13.2 deletion, 2 an amplification of band 4p14, 2 a 14q12 deletion and one a potential rearrangement of band 10q11.2. One of these patients harboured two defects, namely a 19q13.2 deletion and an amplification of band 4p14. An abnormal FISH pattern was observed in 2/3 RA patients, in 3/8 RAEB-1 and in 5/10 RAEB-2 and in 2/4 IPSS low-risk, in 4/8 intermediate-1 risk and in 4/9 intermediate-2 risk MDS patients. Disease evolution occurred in the only 2 RA patients with an abnormal FISH pattern and in 2 of the 4 RAEB-1/RAEB-2 patients with an abnormal FISH pattern. Additional studies are warranted to assess the prognostic significance of cryptic chromosomal lesions. In conclusion our data suggest that FISH with probes derived from aCGH studies i) reveals novel unsuspected chromosomal lesions in about 47% of chromosomally normal MDS patients; ii) these chromosomal lesions mostly consist in gains/losses, whereas balanced rearrangements seem to be very rare; iii) an abnormal FISH pattern seems to correlate with disease progression even if this observation should be confirmed on additional patients.

Background. The only curative treatment known so far for myelodysplastic syndromes (MDS) is the allogenic stem cell transplantation (AlloSCT). Although pre-transplant characteristics which allow to predict the outcome after alloSCT remains to be clearly determined. *Aims.* Our objective is to describe the characteristics and outcome of the 190 MDS patients included in the Spanish Registry who have received an alloSCT. *Methods.* 190 patients who have received an alloSCT in 11 Spanish transplant centers between 1987 and 2008, have been included. The main characteristics of the patients are as follows: median age was 49 years (range 16-75); male / female ratio was 64.5 / 35.5; MDS diagnosis was established according to the WHO classification (1999): refractory anemia with/without ringed sideroblasts (RA+/-RS) 6.9%, refractory cytopenia with multilineage dysplasia (RCMD) 7,6%, refractory anemia with excess of blasts (RAEB)-1 15,2%, RAEB-2 23,4%, 5q- syndrome 1,4%, MDS unclassifiable 2,1%, myelodysplastic/myeloproliferative disease (MDS/MPD) 13,1%, secondary acute myeloid leukaemia (AML) 27%, and other MDS 2,8%. Patients with MDS/MPD such as cronic myelomonocytic leukaemia (CMML) (n=19) were also included in the analysis. *Results.* 42% of patients were treated with chemotherapy previous to the transplantation, and their disease status at transplant was: complete remission (CR) 25,7%, partial response (PR) 7,3% and relapse (Re) 8,3%. The rest of the patients received the alloSCT without previous chemotherapy (No-ch) 53,2% and 3,7% underwent alloSCT in progression (Pr) without previous chemotherapy. The mean of the percentage of blasts in the bone marrow, at transplantation, was 4.5 (0-10.7). Myeloablative conditioning (MC) treatment was used in 72,3% of patients while 27.7% received reduced intensity conditioning (RIC). Overall survival (OS) and event free survival (EFS) of the whole group were 51% and 48%, respectively (Figure 1) at ten years of follow up. WHO classification was predictive for both OS and EFS.

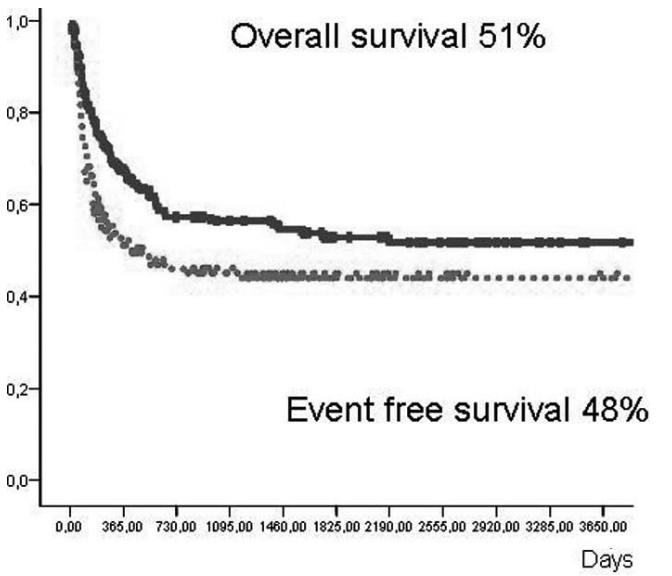

Figure 1.

None of the following variables significantly influenced OS or EFS: blast percentage and ferritin levels at the time of alloSCT, age, conditioning regimen (MC vs RIC) (50-48% for OS and 46-42% for EFS for MC vs RIC, respectively) although patients receiving RIC were significantly older (42 vs. 55 years). When only high risk patients (RAEB-1, RAEB-2, AML and MDS/MPD) were considered, disease status at transplant significantly influenced the outcome with better results being observed for patients in CR or No-ch. *Summary.* In summary, a significant percentage of patients with MDS, including high-risk patients, remain alive more than ten years after transplantation showing that this approach remains the only curative one for these patients. The WHO classification and the state of disease at transplantation in the high risk group are the most powerful predictors for survival.

0253

MICRORNA SIGNATURE OF CD34+ CELLS IN MYELODYSPLASTIC SYNDROME PATIENTS WITH DEL(5Q)

H. Bruchova, M. Merkerova, A. Vasikova, M. Belickova, J. Cermak

Institute of Hematology and Blood Transfusion, PRAGUE, Czech Republic

Background. An interstitial deletion of the long arm of chromosome 5, del(5q), is the most commonly reported deletion in *de novo* myelodysplastic syndrome (MDS). The del(5q) occurs as the sole karyotypic abnormality in 5q- syndrome, which is the most distinct of the MDS. The 5q- syndrome has a good prognosis and a low probability of transformation to acute myeloid leukemia. *Aims.* Pathophysiological basis of the 5q- syndrome is likely associated with haploinsufficiency for genes mapping to the deleted region at 5q; however, other mechanisms may contribute to the failure of normal bone marrow. Because microRNAs (miRNAs) have been shown to regulate hematopoiesis and their aberrant expression contributes to the pathogenesis of clonal hematopoietic disorders, we searched for differently expressed miRNAs in CD34+ progenitors of MDS patients. *Methods.* Bone marrow CD34+ cells from 5q- patients (n=8) and healthy donors (n=4) were sorted by magnetic columns. Gene expression profiling of miRNAs was performed by quantitative real time PCR based array platform with 365 miRNA probes. *Results.* Out of the miRNA panel, transcripts of ~202 miRNAs were expressed at the detectable level. Hierarchical clustering analysis defined miRNA signatures in 5q- patients distinct from those of controls. Comparative analysis revealed differential expression of 38 miRNAs in 5q- patients at $p<0.05$; up-regulation of 23 miRNAs and down-regulation of 15 mRNAs. For example, increased expression was observed in let-7b, miR-199a, miR-338, and miR-410. Especially, miR-34a showed abundant level of transcript in 5q- patients. This miRNA is a direct proapoptotic transcriptional target of p53 and may play a role in increased apoptosis of bone marrow progenitors seen in low-risk MDS. Down-regulation was found in miR-135b, miR-203, miR-369-5p, miR-429, and miR-589 etc. miR-203 is often hypermethylated in hematopoietic malignancies and targets ABL1 gene whose expression induces tumor cell proliferation. Three miRNA genes (miR-143, miR-145, miR-378) are mapped within the deleted region 5q31-q32. In the patients, miR-143 and miR-145 was expressed at the control level and only miR-378 showed 2fold decrease of expression. miR-146a is mapped close to the deletion and was down-regulated in the patients. Its target gene is TRAF6 whose induced expression in mouse bone marrow leads to the neutropenia, anemia, and thrombocytosis. In addition, mRNA profiles of CD34+ cells in the tested subjects were assayed using whole-genome microarrays with 24 500 probes and 245 significantly deregulated genes ($p<0.01$) in 5q- patients were found. An integrative analysis of microarray data with in silico target predictions (TargetScan and Miranda software) defined potential downstream targets of the deregulated miRNAs. We observed significant down-regulation of some putative targets of miR-299-5p (H3F3B, TP53INP2), miR-34a (KLF4, LEF1, NR4A2) and miR-223 (EBF3, PDE4B, PLEKHM1, RHOB). *Conclusions.* Our study demonstrates that the specific miRNA signature is associated with 5q- phenotype and that the aberrantly expressed miRNAs may be involved in the pathogenesis of MDS by a modulation of their target genes. MicroRNA profiles of other MDS patients (RAEB-2, RCMD) with del(5q) are being analyzed. Supported by IGA: NR/9236 MZ CR.

THE CAPACITY OF THE HYPOMETHYLATING AGENTS AZACYTIDINE AND DECITABINE TO INDUCE APOPTOSIS AND CELL CYCLE ARREST DEPENDS ON THE ACTIVATION OF THE DNA-DAMAGE RESPONSE PATHWAY

S. Boehrer,[1] L. Adès,[1] C. Gardin,[1] P. Fenaux,[1] G. Kroemer[2]

[1]Hôpital Avicenne, BOBIGNY; [2]Institut Gustave Roussy, VILLEJUIF, France

Background. The hypomethylating agents azacytidine (AZA) and decitabine (DEC) have shown clinical efficacy in patients (pts) with MDS. There is *in vitro* evidence that both agents, in addition to their hypomethylating effect, also function by inducing apoptosis, cell cycle arrest and/or the activation of a DNA damage response (DDR). However, the exact contributions of those mechanisms of action and their functional interdependence remain to be defined. Aims and *Methods.* A panel of MDS (P39, MDS-1)- and AML (HL-60, KG-1)-derived cell lines were incubated with increasing dosages of AZA (1-2 μM) and DEC (1-2 μM) and the drugs capacity to induce apoptosis (DiOC6(3)/PI), cell cycle arrest (PI) and/or a DDR (immunoflourescence staining of P-ATM, P-Chk-1, P-Chk-2, γ-H2AX) were assessed in absence and presence of the ATM-inhibitor KU-55933 and the Chk-1 inhibitor UCN-01. *Results.* We show that both drugs induced dose-dependent apoptosis in myeloid cell lines: whereas AZA increased apoptosis in KG-1 and HL-60 by about 10% (48h, 2 μM) the respective incubation with DEC augmented apoptosis by about 20% (HL-60) to 30% (KG-1). P39 cells were resistant to AZA and increased apoptosis by 15% after 48h of 2 μM DEC, and MDS-1 cells were resistant to both drugs. In addition, both drugs induced a G2/M-arrest in P39 (+15% after 48h with 2 μM of AZA or DEC) and HL-60 (+20% after 48h with 2 μM of AZA or DEC) cells, but not in KG-1 and MDS-1 cells. Noteworthy, both drugs induced a DDR in the apoptosis-sensitive KG-1 cells (but not P39 cells) as evidenced by the appearance of nuclear P-ATM and Á-H2AX foci. Surprisingly, this activation of P-ATM did not induce the nuclear translocation of P-Chk-1-Ser317 or P-Chk-2-Ser68. To more clearly define the importance of the DDR in AZA- and DEC-induced apoptosis and G2/M-arrest, experiments were recapitulated in the presence of the ATM-inhibitor KU-55933 and the Chk-1 inhibitor UCN-01. Inhibition of ATM abrogated the apoptosis-inducing activity of AZA and DEC in KG-1 cells (without influencing cell cycle progression), whereas inhibition of Chk-1 remained without effect. In contrast, in P39 and HL-60 cells, inhibition of ATM neither affected cell cycle progression, nor sensitivity towards the drugs. Nevertheless, inhibition of Chk-1 by UCN-01 completely abrogated the G2/M-arresting effect of AZA (and diminished that of DEC) in P39 and HL-60 cells. *Conclusions.* We provide novel evidence for the cell-type dependent capacity of the hypomethylating agents 5-azacytidine and decitabine to induce apoptosis, cell-cycle arrest and DDR in cell lines representing different subtypes of MDS and AML. Moreover, we show the crucial role of ATM and Chk-1 activation - as part of the DDR - in mediating apoptosis-inducing and cell cycle-arresting effects of AZA and DEC, respectively, providing evidence that hypomethylating agents confer their beneficial effects by employing different pathways of the DDR.

Background. The use of hypomethylating agents improved significantly the clinical outcome of myelodysplastic syndrome (MDS) patients. The stratification of patient group can help design risk adopted therapy or predicting the prognosis in the MDS patients receiving azacitidine. *Aims.* We analyzed the outcomes of the patients with MDS treated with azacitidine. *Methods.* From Aug. 2006 to Jun. 2008, a total of 129 patients with MDS who had anemia and/or thrombocytopenia were treated with azacitidine at a dose of 75 mg/m^2 per day SQ for 7 days, which was repeated every 28 days. The median age of the patients was 64 years (range, 20-82). Fifty-six patients had refractory anemia with excess blasts. Intermediate-2 and high risk in IPSS were in 43 patients (33.4%), and high and very high risk in WPSS were in 61 patients (47.3%). Of the 129 patients, 126 patients treated more than 2 cycles were analyzed. *Results.* Sixty patients (47.6%) had responses at median 3 cycles (range, 1-5). Seventeen patients showed response after 3rd cycles and 16 after 4th cycles. After 5th cycles, only 3 patients showed responses. Complete response (CR) including marrow CR was observed in 21 patients (16.7%), partial response (PR) in 6 patients (4.8%), and hematologic improvement (HI) in 33 patients (26.2%). The 3-year overall survival (OS) rate was 48.4±10.0% in young age group (<60) and 28.7±9.3% in old age group (≥60; $p=0.333$). The 3-year OS rate according to the IPSS risk group was 41.5±7.8% in low and intermediate-1 group and 29.3±12.7% in intermediate-2 and high group ($p=0.082$), and according to the WPSS risk group 71.6±10.4% in very low and low group, 31.6±8.9% in intermediate group, and 9.7±8.9% in high and very high group ($p<0.001$). Progression to acute leukemia was more common in advanced risk group; IPSS (22.0% vs. 8.2%, $p=0.030$) and WPSS (23.7% vs. 7.1%, $p=0.002$). But complete response to azacitidine did not prevent the progression to acute leukemia; 19.0% in CR and marrow CR vs. 11.4% in others ($p=0.338$). *Conclusions.* Pretreatment risk group was an important prognostic factor to predict the outcomes of the patients with azacitidine treatment. The response to 5-AZA did not prevent disease progression. Advanced risk group should consider more effective therapy.

RUNX1 MUTATIONS IN *DE NOVO* MDS AND CMML AT BOTH DIAGNOSIS AND AML TRANSFORMATION: A COMPARATIVE ANALYSIS ON 80 MATCHED PAIRED MARROW SAMPLES

M.-C. Kuo,[1] D.-C. Liang,[2] C.-F. Huang,[1] Y.-S. Shih,[2] T.-L. Lin,[1] J.-H. Wu,[1] L.-Y. Shih[1]

[1]*Chang Gung Memorial Hospital, TAIPEI;* [2]*Mackay Memorial Hospital, TAIPEI, Taiwan*

Background. Transcription factor RUNX1 is essential for normal hematopoiesis. Somatic mutations of RUNX1 have been described in *de novo* myelodysplastic syndrome (MDS). We also observed a high frequency (37%) of RUNX1 mutations in chronic myelomonocytic leukemia (CMML). The role of RUNX1 mutations in the progression of MDS and CMML to acute myeloid leukemia (AML) is not defined. Aims. We aimed to analyze RUNX1 mutations on paired samples of MDS and CMML at both diagnosis and AML transformation to determine their roles in AML progression and also to correlate with clinicohematologic features and outcome. *Materials and Methods.* Eighty matched paired bone marrow samples including 53 high risk MDS (17 RAEB1, 22 RAEB2 and 14 RCMD)/AML and 27 CMML (15 CMML1 and 12 CMML2)/AML were analyzed for RUNX1 mutations. Mutational analysis was performed by direct sequencing of all RT-PCR or DNA-PCR products amplified with different primer pairs covering the entire coding sequencies of RUNX1b gene. Results. Thirteen (7 RAEB1, 4 RAEB2 and 2 RCMD) of 53 patients with MDS had RUNX1 mutations at initial diagnosis: 6 missense mutations with two of them carrying additional silent mutations, 5 non-sense mutations, 1 silent mutation and 1 frameshift mutation. Six mutants were located in the runt homology domain. One patient with RAEB2 had homozygous mutation, the remainders had heterozygous mutations. At AML transformation, 12 patients retained the identical RUNX1 mutants and one had pattern change, from Met283X to Ser114Pro. Three patients did not have RUNX1 mutations at MDS phase acquired frameshift mutations during AML progression. Of the 27 patients with CMML, 14 had RUNX1 mutations at diagnosis, including 3 missense, 3 non-sense, 1 silent and 7 frameshift mutations; all but one had heterozygous mutations and 9 located in the N-terminal region. Twelve of the 14 CMML patients with RUNX1 mutations at diagnosis carried the same mutations at AML transformation. The remaining 2 had patterns changed, one from Ser268fsX578 to Arg177X and the other from Leu71fsX94 to Arg80Leu. None of the CMML patients acquired RUNX1 mutations during AML evolution. Genotyping analysis with 15 loci of short tandem repeats at 13 different chromosomes showed identities for the 3 paired samples carrying different mutants at two phases of disease. Missense mutations were associated with a higher percentage of bone marrow blasts in MDS. The mutation status, their locations and patterns did not influence outcome of MDS patients. There were no differences in the clinicohematologic features with respect to RUNX1 mutation status in CMML patients who subsequently had AML transformation. We found that CMML patients with C-terminal mutations had a shorter survival than those with N-terminal mutations (p=0.0315). Conclusions. RUNX1 mutations play a role in the development and progression of MDS or CMML in a subset of patients. Pattern changes or acquisition of RUNX1 mutations may occur during AML transformation.

EXPRESSION OF P53 OR CYTOPLASMIC NUCLEOPHOSMINE ASSOCIATED WITH INCREASED RISK OF DISEASE PROGRESSION IN MYELODYSPLASTIC SYNDROME WITH ISOLATED DEL(5Q)

M.S. Jädersten,[1] L. Saft,[1] H. Garelius,[2] R. Hast,[1] L. Nilsson,[3] J. Samuelsson,[4] A. Porwit,[1] E. Hellström-Lindberg[1]

[1]*Karolinska Institutet, STOCKHOLM;* [2]*Sahlgrenska University Hospital, GOTHENBURG;* [3]*Lund University Hospital, LUND;* [4]*South Hospital, STOCKHOLM, Sweden*

Background. Myelodysplastic syndrome (MDS) with isolated del(5q) and <5% marrow blasts has around 10% cumulative risk of leukemic transformation. Lenalidomide effectively improves hemoglobin levels in this category of MDS. However, due to concerns about the observed rate of disease progression the European Medicines Agency (EMEA) refrained from approval of the drug in 2008. It is unclear whether lenalidomide indeed increases the risk of AML or if progression merely reflects the natural course of the disease. A recent case report indicates that p53 and aberrant cytoplasmic nucleophosmine (NPMc) was present in small subpopulations of marrow progenitors at time of diagnosis, and that these clones evolved in conjunction with disease progression during lenalidomide treatment. Also, recent data demonstrated that 7 of 22 (32%) of 5q- patients treated with lenalidomide developed complex karyotypes and 6 of these 7 patients evolved to AML. *Aims.* To evaluate the association of p53 and NPMc expression with outcome in MDS with del(5q). *Methods.* We investigated 32 patients with MDS and del(5q) and less than 10% marrow blasts diagnosed at our department. Twenty-five had del(5q) as single abnormality, 5 had del(5q)+1, and 2 had del(5q) as part of a complex karyotype. Immunohistochemistry was used to detect expression of p53 and NPMc on sections of bone marrow biopsies or clots. The Kaplan-Meier estimate and the logrank test were used for analysis of survival and disease progression. *Results.* The median age was 79 years (range 38-94). The median follow-up was 47 months (interquartile range 25-63) and the median overall survival was 63 months (range 4-146+). Fourteen patients (44%) expressed p53 or NPMc in subpopulations of marrow cells at an early stage of the disease (5 only p53, 5 only NPMc, and 4 both). Nine patients (28%) progressed during the observation period, either by blast increase above 10% and/or by the acquisition of a complex karyotype, and 8 of these subsequently evolved to AML. Seven of 9 patients with disease progression expressed p53 or NPMc before transformation. Merely 2 of 9 patients with transformation had complex karyotypes at diagnosis, and none had del(5q)+1. The 5-year Kaplan-Meier estimate of survival was 63% and 45% (logrank test p=0.52) in patients with or without expression of p53 or NPMc before disease progression, respectively. The 5-year-risk of AML evolution was 12% and 52% (p=0.060), and of blast or cytogenetic progression 7% and 57% (p=0.019; Figure 1), respectively. The dataset was not powered to assess any potential influence of lenalidomide, however, this is currently being evaluated prospectively in a population-based trial within the Nordic MDS Group. *Summary and Conclusions.* The presence of p53 and/or NPMc expression in marrow progenitors at an early stage of MDS with del(5q) significantly correlates with subsequent disease progression in the study cohort.

Leonie Saft and Martin Jädersten contributed equally to this paper.

DIFFERENT PATTERNS OF TELOMERASE REVERSE TRANSCRIPTASE (HTERT) MRNA VARIANT EXPRESSION PROFILES IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES

E. Verrou,[1] V. Kaloutsi,[2] E. Katodritou,[1] V. Gastari,[1] A. Banti,[1] A. Nikitidou,[1] V. Garypidou,[3] K. Zervas,[1] V. Kotoula[2]

[1]*Theagenio Cancer Center, THESSALONIKI;* [2]*Department of Pathology, School of Medicine, Aristotle University, THESSALONIKI;* [3,2]*nd Prop Department of Internal Medicine, Aristotle University, THESSALONIKI, Greece*

Background. Alternative splicing of telomerase reverse transcriptase (hTERT) mRNA contributes to the regulation of telomerase activity in normal and neoplastic cells. The deleted variant A (Adel), lacking 36nts in the beginning of exon 6, blocks telomerase activity while the B delet-

ed variant (Bdel), lacking exons 7 and 8, exhibits no action in terms of telomerase activation. The expression of hTERT mRNA has been investigated in myeloid malignancies with controversial results. The expression of hTERT mRNA variants has not been explored in patients with myelodysplastic syndromes(MDS). *Aim.* To investigate the expression of hTERT mRNA variant transcripts A+B+ (contained in the full-length product), Adel and Bdel in the bone marrow of MDS patients. Seventeen patients with acute myelogenous leukemia(AML) were used as controls. *Methods.* Bone marrow aspirates from 27 patients with refractory anaemia (RA or RCMD defined as group A), 13 patients with refractory anaemia with excess of blasts (RAEB1 or RAEB2, defined as group B) and 17 AML patients (defined as group C) were studied. Relative expression of the above transcripts was assessed on total RNA with reverse transcription followed by real-time polymerase chain reaction (PCR). Specific primers and probes targeting exons 5-6, exons 8-9 and exons 10-11 were designed in order to distinguish between the different isoforms. The data obtained were analyzed by using Pearson chi-square and Kruskal Wallis statistics. *Results.* hTERT mRNA was detected in 10, 4 and 3 patients of groups A, B and C respectively. The full length product (A+B+) was detected in groups A,and C (2/27, 4/13, 3/17 respectively) (p0.05). Adel isoform was detected in groups A (7/27) and B (2/13) but not in group C (0/17) (pA/C=0.02). Bdel isoform was observed in group A (3/27), B (3/13) and C (2/17). Co-expression of isoforms was observed in 2 patients of A group (Adel/Bdel, Adel/A+B+), 4 patients of group B (1 Adel/A+B+, 1 Bdel/A+B+, 2 Adel/Bdel/A+B+) and two patients of group C (Bdel/A+B+). Relative expression levels of Adel, Bdel, and A+B+ transcripts were not significantly different between patient groups. *Conclusions.* Alternatively spliced hTERT variants either lack a critical reverse-transcriptase motif or produce a non-functional reverse-transcriptase therefore cells may control telomerase activity by switching their hTERT mRNA variant expression profile. Our results indicate that aberrations in hTERT variant profiles, especially regarding the Adel isoform, may be implicated in the pathogenesis and progression of MDS. The increased incidence of Adel positivity of RA or RCMD patients may be connected with a reduction of telomerase activity and thus, contribute to the establishment of chromosomal abnormalities. The presence of the full-length pruduct (A+B) in patients with RAE'-1 or RAEB-2 may be associated with the decreased apoptosis observed in these patients. Overall, our findings address the necessity of discriminating between the different hTERT mRNA variants when investigating hTERT expression in MDS patients.

INCREASED FREQUENCY OF REGULATORY T-CELLS IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES

C. Fozza, F. Longu, S. Contini, A. Galleu, P. Virdis, M.P. Simula, M. Longinotti

University of Sassari, SASSARI, Italy

Background. Regulatory T-cells (Treg) represents a small fraction of peripheral $CD4^+$ T-cells which plays a crucial role in the maintenance of immune tolerance. Moreover, they seem to modulate the susceptibility to and the evolution of several neoplastic and autoimmune diseases. Myelodysplastic syndromes (MDS) are a heterogeneous group of clonal haematologic diseases, characterised by a marked immune dysregulation. Indeed, beside the frequent occurrence of autoimmune manifestations, T-cell clones seem to be directly responsible of the functional inhibition of haematopoietic precursors. *Aims.* We analysed the frequencies of Treg and other T-cell subsets in a cohort of patients with MDS, especially focusing on their possible impact on the disease progression. *Methods.* The frequency of Treg was determined on the peripheral blood of 35 MDS patients (7 RA, 5 RARS, 18 RCMD, 4 RAEB and one 5q- syndrome) and 35 normal controls by flow-cytometry. We first determined the frequency of $CD3^+$, $CD4^+$, $CD8^+$ and $CD16^-56^+$ T-cells. Treg were then identified by considering the $CD4^+$ cell fraction characterised by a very high (>2 log) expression of CD25 and by a very low (<2 log) expression of CD127, as well as by determining the expression of FoxP3 and CD152. *Results.* We first showed in our patients a decreased frequency of both $CD3^+$ T-cells (mean 65% vs. 71%, $p<0.05$) and $CD4^+$ T-cells (35% vs. 40%, $p<0.05$) when compared to normal controls, while $CD8^+$ and CD16-56^+ cells were characterized by similar expression levels in patients and controls. We then showed that MDS patients had a higher frequency of Treg (1.51% vs. 1,14%, $p<0.05$) than normal controls. When we compared Treg frequencies in patients belonging to different WHO subclasses, we demonstrated a clear trend towards a higher frequency of Treg in high risk (RCMD and RAEB) than in low risk (RA, RARS and 5q- syndrome) patients (1.71% vs. 1.20%, $p=0.056$). When we stratified patients by IPSS, cytogenetics, blood counts and coexistence of autoimmune phenomena, we could not detect any statistically significant difference. Only transfusion dependence was associated to a reduced frequency of Treg (1.79% vs. 1,12%, $p<0.05$). *Summary and Conclusions.* Our data show that patients with MDS display an increased frequency of $CD4^+CD25^{high}$ $Foxp3^+$ Treg, which is even more pronounced in high risk patients. Such a difference between different patient subgroups may imply an involvement of Treg in modulating disease evolution, thus suggesting that their expansion could favour a progression of MDS towards more aggressive entities. Moreover we may speculate that the lower frequency of Treg in transfusion dependent patients may mirror a reduced control of possible autoreactive T-cells, which are known to be responsible of the inhibition of haematopoietic precursors and, therefore, of an increased need of transfusions.

PHOSPHOINOSITIDE-PHOSPHOLIPASE C BETA1 AS A TARGET OF EPIGENETIC THERAPY IN MDS PATIENTS

M. Follo,[1] C. Finelli,[2] S. Mongiorgi,[1] C. Clissa,[2] F. Chiarini,[1] C. Bosi,[3] M. Baccarani,[2] L. Manzoli,[1] G. Martinelli,[2] A. Martelli,[1] L. Cocco[1]

[1]University of Bologna, BOLOGNA; [2]Seragnoli Hematology Institute, BOLOGNA; [3]Hematology Unit, Piacenza Hospital, PIACENZA, Italy

Background. Myelodysplastic syndromes (MDS) are a heterogeneous group of hematological malignancies characterized by an increased although variable risk of evolution in acute myeloid leukemia (AML). Lipid signalling pathways are involved in many important processes, such as cell growth, differentiation and apoptosis. Namely, nuclear phosphoinositide-phospholipase C (PI-PLC) β1 appears as one of the main players of the signal transduction pathways. Our group demonstrated, by fluorescent in situ hybridization analyses, that in MDS patients PI-PLCβ1 can undergo an interstitial mono-allelic deletion, as 35/80 (43.75%) of the MDS patients analyzed showed this cytogenetic alteration. Interestingly, 23/35 (65.7%) of the MDS patients bearing the PI-PLCβ1 mono-allelic deletion evolved into AML, retaining a statistically higher significance as a prognostic factor of evolution into AML. On the other hand, the structure of PI-PLCβ1 promoter, displaying two CpG Islands, showed that also epigenetic mechanisms could be involved in the MDS progression. Azacitidine, an inhibitor of DNA methyltransferases, has proven effective in prolonging survival and delaying evolution into AML. *Aims.* The observation, in a single patient who favourably responded to azacitidine, (Follo *et al.*, Leukemia 2008) that treatment induced an increase in PI-PLCβ1 mRNAs accompanied by a down-regulation of activated Akt, prompted us to further investigate the relationship of this enzyme to demethylating treatment. *Methods.* We studied 14 patients with high risk MDS (IPSS risk: intermediate-2 or high) treated with azacitidine, 6 patients who only received best supportive care, as control group and 10 healthy subjects. 8/14 patients (57,1%) showed a favourable response to azacitidine (Complete Remission: 1 ; Partial Remission: 1; Hematologic Improvement: 6). We analyzed the structure of PI-PLCβ1 promoter and quantified the degree of PI-PLCβ1 methylation during azacitidine administration, and we also studied 6 patients only treated with supportive care, as control group. Results. We report for the first time that not only that PI-PLCβ1 is hyper-methylated in MDS as compared to healthy subjects, but also that the amount of PI-PLCβ1 is linked to azacitidine responsiveness in MDS patients. Following azacitidine treatment, and in correlation with the therapeutic response, PI-PLCβ1 expression increased, whereas PI-PLCβ1 promoter methylation was reduced in responder patients. Moreover, we observed that the decrease of promoter gene methylation may anticipate the hematologic response, given that the variations in PI-PLCβ1 gene expression may occur some cycles prior to the hematologic improvement. *Summary and Conclusions.* To our knowledge, this is the first time that PI-PLCβ1 has been demonstrated to be hyper-methylated in MDS patients. In addition, we showed that PI-PLCβ1 induction, and particularly the nuclear splicing variant PI-PLCβ1b, directly correlated with response to azacitidine. Our findings therefore suggest that PI-PLCβ1 promoter hypermethylation could represent an epigenetic mechanism involved in the pathogenesis of MDS so that PI-PLCβ1 could be a target for demethylating therapy.

HYPOMETHYLATING AGENTS IN MYELODYSPLASTIC SYNDROME - SYSTEMATIC REVIEW AND META-ANALYSIS

R. Gurion, L. Vidal, A. Gafter-Gvili, Y. Belnik, M. Yeshurun, P. Raanani, O. Shpilberg

Rabin Medical Center, PETACH TIKVA, Israel

Background. Supportive care for myelodysplastic syndrome (MDS) does not induce complete remission nor does it prevent progression to acute myelogenous leukemia (AML). Allogeneic stem cell transplantation has curative potential but is not applicable for most patients. Hypomethylating agents, e.g. 5-azacitidine and 5-aza 2' deoxyazacitidine (decitabine) have recently been shown to improve outcome of patients with MDS. *Aims.* We aimed to evaluate the effect of hypomethylating agents on overall survival for patients with MDS. *Methods.* Meta-analysis and systematic review of randomized controlled trials comparing treatment with hypomethylating agents to conventional care, e.g., best supportive care or chemotherapy, in patients with MDS. The Cochrane Library, MEDLINE, conference proceedings and references were searched until February 2009. Two reviewers appraised the quality of trials and extracted data. Outcomes assessed were: overall survival, time to AML transformation or death, overall (complete and partial) response and toxicity. Hazard ratios (HR) with 95% confidence intervals (CIs) were estimated and pooled for time to event data using methods described by Palmar *et al.* For dichotomous data, relative risks (RR) were estimated and pooled. *Results.* Our search yielded four trials including 952 patients, one of them as an abstract. These trials examined the effect of 5-azacitidine and decitabine. Most patients in the conventional care arm received best supportive care. Data of three trials counting 782 patients was available for analysis of overall survival. Treatment with hypomethylating agents improved overall survival (HR 0.68, 95% CI 0.57-0.83) (Figure 1). When 5-azacitidine was compared to conventional care, there was an advantage in overall survival in favor of 5-azacitidine (HR 0.56 95% CI 0.44-0.73, 2 trials, 549 patients). Conversely, this survival benefit could not be shown for decitabine (HR 0.88 95% CI 0.66-1.17, 1 trial, 233 patients). There was a significant advantage in favor of hypomethylating agents in time to AML or death (HR 0.69 95% CI 0.58-0.82) and in overall response (RR 4.01 95% CI 2.58-6.25). As expected, a higher rate of grade 3/4 adverse events was observed with the use of hypomethylating agents (RR 1.20 95% CI 1.09-1.32). *Conclusions.* Hypomethylating agents prolong overall survival as well as time to AML or death and improve response. Hypomethylating agents have an important role in the treatment of MDS patients.

CYTOGENETIC EVOLUTION IN MDS: IS IT PREDICTIVE OF OVERALL SURVIVAL AND RISK OF MDS/AML EVOLUTION?

P. Bernasconi,[1] C. Klersy,[2] M. Boni,[1] I. Dambruoso,[1] P.M. Cavigliano,[1] R. Zappatore,[1] I. Giardini,[1] S. Calatroni,[1] B. Rocca,[1] C. Calvello,[1] M. Caresana,[1] M. Lazzarino[1]

[1]Division of Hematology, Foundation IRCCS Policlinico S. Matteo, PAVIA; [2]Biometry Unit, Scientific Direction, Foundation IRCCS Policlinico S. Matteo, PAVIA, Italy

In every MDS patient the assessment of the cytogenetic pattern is a mandatory step for an accurate diagnosis and a precise prognostic stratification since it has been revealed that the cytogenetic defects present on clinical diagnosis (primary abnormalities) significantly influence overall survival (OS) and the risk of MDS/AML evolution (Progression-free interval, PFI). In contrast, very few studies have estimated how many patients develop chromosomal abnormalities during the course of the disease (secondary defects) and whether these karyotype defects have any prognostic relevance. These are the goals of the present study which is also aimed at correlating cytogenetic evolution (CE) with FAB/WHO classification and IPSS score, at testing whether the influence of CE on OS and PFI is independent of other prognostic parameters and at establishing which secondary defect is truly responsible of the course of the disease. Our study includes 153 *de novo* MDS patients who were diagnosed at the Division of Haematology, Foundation IRCCS Policlinico San Matteo, Pavia between January 1990 and December 2004. They were 80 males and 73 females; their median age was 60.5 years (range: 49.8-68.3). According to FAB, 27 were classified as RARS, 57 as RA, 58 as RAEB and 11 as RAEB-t; according to WHO classification, 17 were classified as RARS, 21 as RA, 11 as 5q- syndrome, 7 as RCMDS, 27 as RCMD, 27 as RAEB-1, 31 as RAEB-2 and one as unclassifiable MDS. Considering IPSS, 35 patients were low-risk, 58 intermediate-1 risk, 39 intermediate-2 risk and 21 high-risk. Median follow-up was 45.2 months (IQR=23.8-75.7) and median survival was not reached (IQR=34.3-not reached). At the time of the analysis 107 (69.9%) patients had survived and 46 (30%) had died. Disease progression (DP) occurred in a total of 65 (42.4%) patients and median progression-free interval (PFI) was 65.2 months (IQR 16.60-not reached). On clinical diagnosis 94 patients (61.4%) presented primary chromosomal defects. Cytogenetic evolution (CE) occurred in a total of 47 (30.7%) patients according to FAB classification and in 41 (28.9%) according to WHO classification. Since 7 patients according to FAB and 6 according to WHO experienced CE after disease progression they were considered karyotypically stable. CE had a significant influence on OS (p=0.0000) and PFI (p=0.0000) and its impact remained significant even when other variables, including FAB/WHO classification, IPSS score, primary defects, and IPSS cytogenetic categories, were considered. In early MDS the acquirement of a secondary defect significantly effected OS and PFI when patients were diagnosed according to FAB, but it lost its relevance when patients were diagnosed according to WHO classification. Among secondary defects, del(7)(q31q34) was the only one which significantly effected PFI.

ARHGAP21, A PARTNER OF ALPHA-CATENIN, MAY BE ALTERED EXPRESSED IN BONE MARROW CELLS FROM PATIENTS WITH MYELODYSPLATIC SYNDROMES LACKING 5Q DELETION

K.S. Barcellos,[1] S.M.B. Winnischofer,[2] M. Lazarini,[2] A.S.S. Duarte,[2] F. Traina,[2] F.F. Costa,[2] S.T.O. Saad[2]

[1]State University of Campinas, Campinas, CAMPINAS; [2]State University of Campinas, CAMPINAS, Brazil

Background. The gene encoding α-catenin (CTNNA1) is expressed at a much lower level in leukemia-initiating stem cells from individuals with Acute Myeloid Leukemia (AML) or Myelodysplastic syndrome (MDS) with del(5q). Thus, loss of expression of the α-catenin tumor suppressor in hematopoietic stem cells may provide a growth advantage that contributes to human MDS or AML with del(5q). ARHGAP21 is a partner of α-catenin and a negative regulator of RhoGTPase signaling pathways, which is upregulated during myeloid differentiation. *Aims.* The aim of this work was to evaluate the expression of ARHGAP21, α-catenin and β-catenin in bone marrow cells from MDS patients with del(5q), MDS patients lacking a 5q deletion and healthy donors. *Methods.* CD34$^+$ cells were isolated from bone marrow of 2 MDS patients del(5q), 4 MDS patients, including 3 refractory anemia (RA) and 1 refractory anemia with excess blasts (RAEB), and 4 healthy donors. Total bone marrow cells (BMC) were obtained from 3 MDS patients del(5q), 11 MDS patients, including 9 RA and 2 refractory anemia with ringed sideroblasts (RARS), and 10 control subjects. The National Ethical Committee Board approved the study and informed-written consent was obtained from all subjects. The mRNA expression of ARHGAP21, α-catenin and β-catenin was analyzed by Real-time PCR. Localization of proteins in CD34$^+$ cells was obtained using confocal microscopic analysis. *Results.* Regarding to α and β-catenin, mRNA expression was lower in CD34$^+$ cells from MDS patients del(5q), as compared to MDS and healthy controls (both p<0.05). ARHGAP21 mRNA was higher expressed in total bone marrow cells from MDS patients compared to healthy donors (12.91747±6.93183 vs. 1.185931± 0.341093, p=0.0012). Confocal analysis showed that ARHGAP21 and β-catenin are preferentially localized in the nucleus of CD34$^+$ cells from MDS patients in contrast to the preferential cytoplasmic and membrane localization in MDS del(5q) and healthy donors. α-catenin was mainly

observed in the membrane of the cells. In the patients del(5q) and healthy controls, ARHGAP21 and α-catenin preferentially co-localizated in the cell membrane. *Conclusions.* ARHGAP21 is overexpressed in differentiated cells but not in the progenitors cells of MDS patients. ARHGAP21 and α-catenin are co-localized in hematopoietic progenitor cells, suggesting that ARHGAP21 may be related with α-catenin regulation on those cells. The nuclear localization of ARHGAP21 and β-catenin in MDS patients may suggest an aberrant signalling in the Wnt pathway for β-catenin, or an abnormality of ARHGAP21 and β-catenin themselves, which may be implicated in the MDS pathogenesis. THALIDOMIDE FOR THE TREATMENT OF MYELODYSPLASTIC SYNDROMES: A SYSTEMATIC REVIEW AND META-ANALYSIS OF THE PUBLISHED STUDIES

P. Musto,[1] F. D'Auria,[1] V. Grieco,[1] A. Sparano,[1] A. Zonno,[1] R. Guariglia,[1] G. Pietrantuono,[1] O. Villani,[1] M.C. Martorelli,[1] G. Mansueto,[1] R. Lerose,[1] M. Marchetti[2]

[1]IRCCS, Centro di Riferimento Oncologico della Basilicata, RIONERO IN VULTURE; [2]IRCCS, Policlinico S. Matteo, PAVIA, Italy

Background. Thalidomide has been used to improve the cytopenia of myelodysplastic syndromes (MDS). However, due to the heterogeneity of patient populations treated and of doses/schedules adopted in the different studies so far performed, the efficacy of this drug in MDS remains controversial. Furthermore, some concerns also exist about its tolerability. Indeed, no individual clinical trial has been sufficiently extensive to provide a basis for a decision model to use thalidomide in MDS. *Methods.* In order to define better the role of thalidomide in MDS, we performed a systematic review of all published articles on this topic by using a Pub-Med web-site methodology. Ten phase I-II studies, including a total of 527 MDS patients who had received thalidomide as single agent, were identified and examined. Neither phase III trials, nor previous meta-analyses were found. *Results.* Thalidomide doses widely varied in the different studies, ranging from 50 to 1000 mg/d. The response criteria also were not uniform. Overall, average response rate was 32% (range 9-56%) and 43% (range 16-88%) on intention-to-treat analysis or considering only patients able to receive the drug for 12-16 weeks, respectively. The large majority of responses were erythroid in nature (mostly resulting in transfusion-independence) and were achieved within 2-3 months, without a clear evidence of a dose-response effect. Responses were more frequently observed in patients with lower IPSS risk score and with a recent diagnosis at treatment (<1 year). There was no evidence of a correlation between response to thalidomide and baseline levels of endogenous erythropoietin, transfusion support or prior treatment with epoetins. Cytogenetic response or changes in marrow morphology were only occasionally reported. The duration of response was highly variable, ranging from three months to more than six years. Side effects, mainly peripheral neuropathy, sedation, constipation, and skin rash, were frequent, determining a very high and often early dropout (mean 44%, range 15-67%), even in responders and especially in elderly patients where thalidomide doses >200 mg/d were employed. Despite the fact that no thrombotic prophylaxis was generally adopted, thrombotic events were very rare and exclusively associated with higher doses of the drug. Two studies suggested a possible survival benefit for MDS patients treated with thalidomide. *Conclusions.*Based on available evidences, thalidomide remains a possible therapeutic option for selected MDS patients, if appropriately employed and managed. An early use of individualized doses, starting with 100 mg/d and increasing the dose up to no more than 200 mg/d, if well tolerated, is recommended for at least 12 weeks. Lower doses may be enough in elderly subjects or for maintaining response. Preferable targets appear to be lower risk patients with transfusion-dependent anemia as single cytopenia, who are not candidates for alternative approaches, such as epoetins (high levels of endogenous erythropoietin or prior resistance), lenalidomide (no evidence of the 5q- cytogenetic abnormality) and high dose chemotherapy or hypomethylating agents (no blast excess). The detailed results of the meta-analysis will be presented at the Meeting

MESENCHYMAL STEM CELLS FROM 5Q- SYNDROME PATIENTS SHOW INCREASED EXPRESSION OF FGF4 AND IL32 IN COMPARISON TO OTHER MDS

C.M. Santamaria, O. Lopez-Villar, F.M. Sanchez-Guijo, P. Hernandez-Campo, M.C. Del Cañizo

University Hospital of Salamanca, SALAMANCA, Spain

Background. The 5q- syndrome is a particular form of myelodysplastic syndrome (MDS) with unique clinico-biological features. An altered microenvironment has been involved in the pathophysiology of MDS through the abnormal production of several cytokines and growth factors by mesenchymal stem cells (MSC). Recently, our group has shown that that MSC from MDS display several genomic aberrations, as assessed by array-CGH and FISH. (López-Villar *et al.*, Leukemia, 2009). In addition, we observed that 5q- syndrome samples displayed a singular genomic profile, including the gain of some genomic regions. Within these regions, there are some genes related to erythroid differentiation (GDF15 in 19p13.11), megakaryopoiesis (PDGFα in 7p22.1; FGF4 in 11q13.1) and TNFα-mediated apoptosis (IL-32 in 16p13.3). *Aim.* Our aim in the present work was to compare the expression profile of these molecular targets between MSC from 5q- syndrome and MSC from other MDS, which could be related with their differential characteristics. *Methods.* Twenty-one patients with untreated MDS were included. The median age was 74 years (range 54-92). The male/female ratio was 10/11.Diagnosis of MDS was established according to the WHO classification: 5q- syndrome (n=4), refractory anemia (n=2), refractory anemia with ringed sideroblasts (n=4), refractory cytopenia with multilineage dysplasia (RCMD;n=4), RCMD with ringed sideroblasts (n=1), refractory anemia with excess blasts type (RAEB) I (n=1), RAEB-II (n=3) and MDS unclassified (n=2). In addition, four normal bone marrow (BM) samples from healthy donors were assessed as expression control. MSC were isolated and *in vitro* expanded following standard procedures. After the third passage, total RNA was isolated using the phenol/chloroform protocol and subsequently retrotranscribed into cDNA using a commercial kit. The relative quantification of the different genes mentioned above was performed by quantitative PCR using the equation 2-ΔΔCt where ΔCt = Ctgen - CtGADPH and ΔΔCt= ΔCt Sample - ΔCt Control (mean). The Mann-Whitney non-parametric U-test was used to compare gene expressions between healthy donors, 5q- syndrome and other MDS. *Results.* MSC from MDS displayed increased RNA levels of TNFα (median 7.3, range 0.1-1231; p=0.014), PDGFα (median 2.6, range 0.8-5.2; p=0.018) and IL32 (median 2.3, range 0.1-39.2; p=0.05) than healthy MSC. Strikingly, MSC from 5q- syndrome showed higher gene expression of IL32 (median 5.3, range 2.4-39.2 vs. median 1.8, range 0.1-7.6; p=0.024) and FGF4 (median 7.1, range 0.4-14.4 vs. median 0.3, range 0.05-19.3; p=0.045) than MSC from other MDS, while a trend toward higher TNFα gene expression (median 27.8, range 1.1-1231 vs. median 7.2, range 0.1-170; p=0.09) was observed in the former group. A good correlation was found between IL32 and TNFα levels (Spearman correlation=0.592; p<0.001), which supports the fact that both markers may participate in an autoamplification loop that promotes apoptosis in MDS. *Summary.* We conclude that genotypic changes detected in MSC from 5q- syndrome by CGH-array and FISH, affect the expression of some relevant genes. Therefore, the differentiated expression of IL32 and FGF4 seems to promote a pro-apoptotic (TNFα-dependent) and thrombopoietic environment, which may explain the distinctive phenotype (increased anemia and normal/elevated platelet counts) of 5q- syndrome patients.

Background. The accumulation of monocytes in the peripheral blood is the main criterion that defines chronic myelomonocytic leukemia (CMML). In these disorders, a population of myeloid cells is hypersensitive to granulo-monocyte colony stimulating factor (GM-CSF) and a phosphorylation of STAT5 in CD14+ cells exposed to low doses of GM-CSF was recently proposed as their molecular signature. However, monocytes demonstrate important cellular heterogeneity. *Methods.* Clinical findings and laboratory findings were evaluated for 110 CMML patients. *Results.* In 94 of 110 CMML, blood cells usually identified as monocytes include a variable proportion of immature granulocytes (mean 22.8%; range 5-95%). A similar observation was made in juvenile myelomonocytic leukemias. The two cell populations belong to the leukemic clone, as demonstrated by comparative genomic hybridization or N-RAS or PTPN11 sequencing, respectively. They exhibit dramatically distinct immunophenotypes, gene expression patterns, functional properties and differentiation potential and are easily separated by simultaneous analysis of CD14 and CD24 at the surface of peripheral blood mononuclear cells. The phospho-STAT5 activation in response to low doses of GM-CSF is observed in CD14-positive CMML as well as normal monocytes, not in CD14-negative CMML cells. *Conclusions.* These results open new perspectives in the disease pathogenesis analysis and provide a new tool to follow the response to drugs currently developed to treat these diseases.

0267

ISOLATED DEL 20Q DEFINES A SUBGROUP OF MDS PATIENTS WITH LOWER BLAST COUNTS AND MORE FREQUENT THROMBOCYTOPENIA

T. Braun,[1] S. De Botton,[1] K. Guenda,[1] G. Leroux,[1] A.L. Taksin,[1] S. Park,[1] O. Beyne-Rauzy,[1] S. Chevret,[1] M. Fontenay,[1] B. Cassinat,[1] A. Lazareth,[2] C. Terré,[1] N. Vey,[1] A. Guerci,[1] F. Dreyfus,[1] D. Bordessoule,[1] A. Stamatoullas,[1] S. Castaigne,[1] V. Eclache,[1] P. Fenaux,[1] L. Adès[1]

[1]Groupe Francophone des Myelodysplasies (GFM), BOBIGNY; [2]Groupe Francophone des Myelodysplasies, BOBIGNY, France

Background. Isolated del 20q is common in MDS, and considered of good prognosis, but no large series of MDS with isolated del 20q have been reported. In addition, it has been suggested that MDS with isolated del 20q may be associated with only mild dysplastic features, sometimes causing difficulties to distinguish them from other causes of cytopenias (Br J Haematol. 2007, 139,265). Patients: 64 MDS pts with isolated del 20q diagnosed between 1990 and 2008 in 5 GFM centers were analyzed and compared with 1368 karyotyped MDS without del 20q included in the GFM registry. *Results.* Median age of the 64 MDS with isolated del 20q was 72 (48-92), 41 M, 23 F. They included 34 RA, 8 RARS, 16 RAEB, 4 CMML and 2 RAEB-T. Fifty two percent had <5% of marrow blasts vs 34% of non del 20q MDS (p=0.006). Despite a significantly higher proportion of low and int-1 IPSS risk (90% vs. 78%, p=0.021) pts with isolated del 20q had lower platelet count (mean 156 vs 212 G/l, p=0.014) and higher reticulocyte count (mean 84 vs 52 G/l, p=0.012) than non del 20q pts, but no significant differences in other parameters especially Hb level. When the analysis was restricted to pts with less than 5% marrow blasts, the same differences were seen between isolated del 20q and non del 20q pts. Nineteen percent of pts with isolated del 20q had Hb >12 g/dL and platelets < 100 G/L vs. 8% of non del 20q patients (p=0.007). In those purely thrombocytopenic del 20q pts, dysplastic features were present to the same extent as in non del 20q pts. *Conclusions.* MDS with isolated del 20q are characterized by lower percentage of marrow blasts and lower platelet counts. About 20% of them present with isolated thrombocytopenia and morphologic analysis may help to distinguish MDS from other causes of cytopenias (especially ITP) before cytogenetic results.

Acute myeloid leukemia - Biology I

MODULATION OF MIR-449A EXPRESSION DECREASES CELL VIABILITY, INCREASES APOPTOSIS AND INDUCES DIFFERENTIATION IN EVI1 DEREGULATED LEUKEMIA CELLS

A. De Weer,[1] B. Poppe,[1] P. Mestdagh,[1] K. De Preter,[1] P. Van Vlierberghe,[1] N. Van Roy,[1] M. Jeison,[2] B. Cauwelier,[3] B. Verhasselt,[1] J. Philippé,[1] L. Noens,[1] H.-A. Poirel,[4] P. Vandenberghe,[5] F. Lambert,[6] A. De Paepe,[1] N. Dastugue,[7] J. Vandesompele,[1] F. Speleman[1]

[1]Ghent University Hospital, GHENT, Belgium; [2]Schneider Children's Medical Center of Israel, PETACH TIKVA, Israel; [3]Hospital St-Jan, BRUGES, Belgium; [4]Cliniques universitaires UCL Saint-Luc, BRUSSELS, Belgium; [5]University of Leuven, LEUVEN, Belgium; [6]Centre Hospitalier Universitaire de Liège, LIÈGE, Belgium; [7]Hôpital Purpan, TOULOUSE, France

Background. Chromosomal rearrangements involving the EVI1 gene are a recurrent finding in malignant myeloid disorders. These translocations or inversions contribute to ectopic expression or to the formation of fusion genes involving the EVI1 gene. EVI1 transcriptional activation has been reported in up to 10% of acute myeloid leukemia (AML), and is a prognostic marker of poor outcome. *Aims.* As microRNA (miRNA) deregulation was recently identified as a major contributor to cancer initiation and progression, and since miRNA genes were shown to be directly regulated by activated proto-oncogenes, we aimed to identify miRNAs involved in EVI1 deregulated leukemia. *Methods.* In this study, miRNA profiling was performed on patient samples and on siRNA mediated EVI1 knockdown model systems of the EVI1 rearranged myeloid leukemia cell lines Kasumi-3, UCSD-AML1 and MUTZ-3. Our patient cohort consisted of 38 EVI1 rearranged and overexpressing samples as confirmed by FISH, karyotyping and RT-qPCR, 6 normal bone marrow samples and 2 CD34+ cord blood fractions. A total of 366 miRNAs and 18 small RNA controls were profiled using high-throughput megaplex stem-loop RT-PCR followed by PreAmp pre-amplification and RT-qPCR of individual miRNAs and controls. *Results.* MicroRNA profiling of patient samples allowed identification of a subset of significantly differentially expressed miRNAs (26 up and 27 down, p<0.05) in EVI1 rearranged samples compared to normal bone marrow. Among these, 2 upregulated and 6 downregulated miRNAs were also differentially expressed in the EVI1 knockdown model systems. The expression of three selected differentially expressed miRNAs, i.e. the downregulated miR-449a and upregulated miRs-213 and -107, was reconstituted by electroporation of a precursor miRNA or anti-miRNA molecules, respectively, in the Kasumi-3 and UCSD-AML1 cell lines. A decrease in cell viability and an increase in apoptosis were detected, as compared to the controls, with the strongest effects noticed for miR-449a. Furthermore, loss of *early* myeloid markers and an increase of megakaryocytic and monocytic markers were indicative for an effect on myeloid differentiation. To identify miR-449a target genes responsible for these effects we interrogated different prediction algorithms, and several candidate genes involved in apoptosis, differentiation or cell proliferation are currently under further investigation. *Conclusions.* This report is the first study that identifies miR-449a as an important miRNA involved in EVI1 pathogenesis. Given the poor prognosis of EVI1 rearranged leukemias and currently limited treatment options, the present findings together with the emerging possibilities of miRNA based therapeutics open new perspectives for treatment of this patient subgroup.

0269

RESTORING OF FOXO3 TRANSCRIPTION FACTOR ACTIVITY BY CHEMOTHERAPY INDUCES OF A QUIESCENT STATUS OF LEUKAEMIC PROGENITOR CELLS IN ACUTE MYELOID LEUKAEMIA

D. Cilloni,[1] C. Panuzzo,[1] E. Greco,[1] F. Arruga,[1] F. Messa,[1] M. Pradotto,[1] E. Bracco,[1] E. Messa,[1] I. Iacobucci,[2] C. Maffè,[1] S. Carturan,[1] M. Pautasso,[3] G. Martinelli,[2] G. Saglio[1]

[1]University of Turin, TURIN; [2]Seragnoli Institute, University of Bologna, BOLOGNA; [3]S. Luigi Hospital, ORBASSANO, Italy

Background. The FoxO transcription factor promotes apoptosis and triggers cell cycle inhibition through multiple mechanisms. It is inactivated by PI3K/Akt induced phosphorylation thus resulting in nuclear exclusion and degradation. Moreover, several data demonstrated an abnormal activation of PI3K/Akt pathway in acute myeloid leukemia (AML) with contrasting prognostic significance. The aim of this study

was to clarify the role of FoxO3 in AML and to investigate alternative pathways eventually responsible for FoxO3 inactivation. Importantly, we explore the effects of FoxO3 re-activation in CD34+ AML cells. *Methods.* Cell cycle was analyzed by FACS in CD34+ cell population as well as the levels of CD47, which has been demonstrated to increased during progression through the cell cycle and stem cell mobilization. Protein amount and localization were analyzed by Western blot and immunofluorescence, the DNA binding activity was measured by EMSA. 35 BM samples from AML patients at diagnosis and in 20 healthy donors were analyzed. Furthermore Spred1, known to be a FoxO3 target gene was quantified by RQ-PCR. We previously described the absence of Spred1 in AML patients and demonstrated that it promotes growth arrest and apoptosis in haematopoietic cells. Finally BM cells were incubated with a PI3K inhibitor LY294002 and the IKK inhibitor PS1145, alone and in combination. Moreover, the t(8;21) positive Kasumi cell line was transfected with pECE-FoxO3 to evaluate FoxO3 effects on cell growth and apoptosis. *Results.* We found that, while FoxO3 in control cells is localized in both nucleus (mean value of intensity of 21.4 2) and cytoplasm (14.6 1.7), it is completely cytoplasmatic in AML cells (18.1 4,6 in cytoplasm vs. 8,2 4 in the nucleus) and enters the nucleus after chemotherapy or *in vitro* incubation with LY29400. Moreover, FoxO3 DNA binding activity in AML patients is completely absent at diagnosis and restored after therapy. Also the mRNA of Spred1 is rather undetectable at diagnosis (2- Ct= 0,009 0,3) and shows normal levels during remission (2- Ct = 2 1,5) or after LY29400 incubation (2- Ct =0,8 0,3). In addition LY294002 and PS1145 treatment results in FoxO3 partial nuclear re-localization while their association induces a complete nuclear shuttle suggesting that both pathways could be implicated in FoxO3 inactivation. The restoring of FoxO3 function by LY29400 in CD34+ cells induces quiescence of this progenitor cell compartment as demonstrated by the comparison of cell cycle kinetics and the decreased expression of CD47 (p=0.01). Finally, FoxO3 overexpression in transfected cells results in a block of proliferation rate (66% of inhibition compared to empty vector transfected cells) and apoptosis induction (35% vs. 12%). *Conclusions.* Taken together these data suggest that FoxO3 inactivation may be crucial for the leukemic progression and demonstrate that also IKK pathway contributes to this effect, providing the rationale for a therapeutic strategy. On the other hand, the re-activation of FoxO3 induces quiescence of the stem cell compartment so providing a mechanism of escape from chemotherapy induced apoptosis.

PREVALENCE OF TET2 MUTATIONS IN *DE NOVO* ACUTE MYELOID LEUKAEMIA

O. Nibourel,[1] O. Kosmider,[2] M. Cheok,[3] A. Renneville,[4] N. Philippe,[4] H. Dombret,[5] F. Dreyfus,[2] B. Quesnel,[3] S. Geffroy,[4] S. Quentin,[6] C. Roumier,[4] W. Vainchenker,[7] O.A. Bernard,[8] J. Soulier,[9] M. Fontenay,[10] C. Preudhomme[4]

[1]Lille Hospital, LILLE; [2]Hôpital Cochin, PARIS; [3]INSERM U.[83],[7] LILLE; [4]Laboratoire d'hématologie, CHRU, LILLE; [5]Service d'hématologie, Hôpital Saint-Louis, PARIS; [6]Laboratoire d'hématologie, Hôpital Saint-Louis, PARIS; [7]Institut Gustave Roussy, VILLEJUIF; [8]Inserm, E02,10 PARIS; [9]Hôpital Saint-Louis, PARIS; [10]INSERM, U56,7 PARIS, France

Background. Recently, it was established that TET2, a member of Ten-eleven translocation family located on the 4q24 locus, is a gene frequently altered in myeloid malignancies (Delhommeau *et al.*, in press). *Methods.* To investigate the prevalence of TET2 mutations in *de novo* AML, we designed a retrospective study of 78 patients enrolled in two clinical centers (Lille and Cochin hospitals) for whom DNA was available at diagnosis and at first complete remission (CR). TET2 events were assessed by direct sequencing of exons 3 to 11. LOH and copy number variations were investigated by SNP arrays (Affymetrix® SNP array 6.0). All the patients are *de novo* AML (excluding APL), the median age was 43 years (14 to 69), the sex ratio M/F was 0.6, the cytological repartition was: 5 AML0, 14 AML1, 24 AML2, 20 AML4, 10AML5, 2AML6 FAB subtypes. Among these patients, 75 had an informative karyotype (14 favorable-risk, 60 intermediate-risk with 35 normal karyotypes, and 1 unfavorable-risk according to the British MRC classification). *Results.* We found a total of 16 anomalies of TET2 gene by direct sequencing: 7 nonsense and 5 missense mutations in conserved domains and 4 missense mutations in non conserved domains. For the latter 4 mutations, we confirmed that the mutations were absent in the CR sample in all 4 cases. Overall, 13/78 (17%) patients presented an acquired TET2 mutations at diagnosis. 3 patients had two anomalies of TET2 detected by direct sequencing, suggesting that the two copies are targeted in 4% of the patients. By SNP analysis, none of the 67 patients analyzed presented a deletion in the TET2 locus and only one presented a large UPD of 4q. The population with TET2 mutations had no difference in age, sex ratio, leukocytes, FAB subtypes, however, regarding the cytogenetic data, no mutation was detected in the MRC unfavorable-risk subgroup, and the majority of the TET2 mutated patients presented a normal karyotype *Conclusion*. In conclusion, in *de novo* AML patients, TET2 alterations are observed at a frequency of 17% in all FAB subtypes, but was preferentially associated with a normal karyotype. With the exception of a few cases, TET2 alterations are point mutations. The association with the others biological and clinical parameters will be presented.

Introduction. Acute myeloid leukemia (AML) is a heterogeneous disease with various chromosomal aberrations. The karyotype at diagnosis provides important prognostic information that influences therapy and outcome of this disease. However, using conventional chromosome banding techniques alone, karyotype abnormalities are detected in only half of all AML cases. Aims.We sought to identify novel genomic regions of interest in normal karyotype AML and to identify novel candidate regions and disease-related genes in patients with complex karyotypes using genome-wide high resolution SNP-array. Patients and Methods. Samples from 57 AML patients with FAB-M0, M1, M2, M3, M4, M5, miscellaneous cytogenetic abnormalities and normal karyotype were examined. Genomic DNA was isolated from mononuclear AML cells and applied to GeneChip® Human Mapping 250K NspI and Genome-Wide Human SNP 6.0 array microarrays (Affymetrix, Santa Clara, CA) following the manufacturer's instructions. Copy number aberrations were scored using the Hidden Markov Model and the segmentation approach available within the Partek software package as well as by visual inspection. All aberrations were calculated with respect to a set of 270 Hapmap normal individuals and a set of samples obtained from acute leukaemia cases in remission in order to reduce the noise of raw copy number data. When available, in order to exclude inherited copy number variants a comparison to paired constitutional DNA and to paired remission DNA was performed. Fluorescence in situ hybridization, quantitative PCR and nucleotide sequencing were used to confirm genomic alterations. Results. A wide spectrum of different genetic lesions (gains/losses) involving complete chromosome arms (del 16q, i(13q10), del 3p, del 7p, monosomy 9) or submicroscopic genomic intervals were identified in a substantial proportion of cases (55%) without differences in the frequency of losses or gains. Focal genetic alterations were detected at the breakpoints of previously cytogenetically identified chromosomal translocations, such as t(2;3)(p22-23)(q26-27) and t(1;11)(p32;q23). Hemizygous deletions were identified at 2q33.3-q34 involving ERBB4 (v-erb-a erythroblastic leukemia viral oncogene homolog 4 avian), at 9p21.3- p21.2 (CDKN2A-2B), at 12p13 (ETV6), at 17q12 (NF1) and 21q21.2 (RUNX1). Most frequent alterations affected the oncogene MYC at 8q24.13 - q24.21 (4.33 Mb), the ABC transporters genes ABCA8, ABCA9, ABCA6, ABCA5, ABCA10 at 17q24, PTPRM at 18p11.31-p11.23 and ERG at 21q22. Other recurring genetic lesions were uncommon and were identified only in single cases. Some lesions affected regions with a single gene, such as: ETAA1, FIGN, STK32B, PRAGMIN, PCM1, GLIS3, MRGPRX1, SESN3, BCL2L14 or lacking annotated genes. Marked differences in the combination of copy number anomalies were identified across the different genetic subtypes of AML. Patients with normal karyotype showed no relevant genetic alterations. Conclusions. These data demonstrated that, in contrast to adult acute lymphoblastic leukaemia (ALL), AML is characterized by relatively few recurring copy

number alterations, and that spectrum of genetic anomalies is significantly associated with AML disease subtype.

THE PROGNOSTIC ROLE OF C-FLIP IN AML

P. McLornan,[1] M.F. McMullin,[1] K.I. Mills,[1] R.K. Hills,[2] A. Gilkes,[2] A.K. Burnett,[2] P. Johnston,[1] D.B. Longley[1]

[1]*Centre for Cancer Research and Cell Biology, BELFAST, Northern Ireland;* [2]*Department of Haematology, Cardiff University, CARDIFF, UK*

Background. Defects in apoptosis contribute to the aggressive clinical phenotype of Acute Myeloid Leukaemia (AML). The anti-apoptotic protein c-FLIP (cellular FLICE-Inhibitory Protein) is a key inhibitor of processing and activation of Caspase 8 at the Death Inducing Signalling Complexes (DISCs). Differential splicing gives rise to long (c-FLIPL) and short (c-FLIPS) splice forms. Clinically relevant prognostic biomarkers are becoming increasingly important in risk stratifying the management of AML patients, particularly within the Cytogenetically-Normal (CN)-AML group. *Aims.* To investigate the prognostic role of c-FLIP gene expression in AML and determine the role of c-FLIP in chemosensitivity. *Methods and Results*. c-FLIP gene expression was assessed in 318 NCRI AML trial samples from the Cardiff and MILE studies which used standard U133 and U133Plus2 Affymetrix' chips. Overall, c-FLIP gene expression showed marked heterogeneity that was independent of WHO subclassification. However, c-FLIP gene expression had a convincing trend to display prognostic importance in the CN-AML subgroup (n=112), where those individuals with > median expression of c-FLIP had a marked trend to worse Overall Survival (OS) compared to those with < median expression levels (Log Rank; Chi Sq (df=1) p=0.08). Moreover, we found that within the NPM1 mutant group of the CN-AML subset (n=42), individuals with a c-FLIP gene expression score > median had a dramatically reduced OS compared to those individuals with scores < median (Log Rank; Chi Sq (df=1), p=0.009). There was also a marked increase in the risk of relapse within the first year in those with > median c-FLIP compared to those with < median c-FLIP expression in the NPM1 mutant group. Further analysis of c-FLIP gene expression via qRT-PCR in an independent cohort of AML samples (n=62) demonstrated that patients with FLIPL mRNA expression > median values had a significantly shorter OS and RFS compared to those with FLIPL mRNA expression < median values (p=0.03 in both cases). The role of c-FLIP in AML apoptosis has been investigated in the OCI, U937, NB-4 and K562 cell line models. c-FLIP gene silencing with a dual splice form targeted small interfering RNA (FT siRNA) alone resulted in enhanced apoptosis in the OCI, U937 and NB-4 cell lines in comparison to a control siRNA. In addition, FT siRNA sensitised all four cell lines to recombinant TRAIL with an increase in apoptotic cells detected by Flow Cytometry and enhanced Poly (ADP-ribose) polymerase (PARP) and Caspase 8 cleavage detected by Western Blot. *Conclusions.* In summary, gene expression profiling revealed a potential prognostic role for c-FLIP expression, which is highly statistically significant in the NPM1 mutant group. The prognostic significance may be related to the expression of the FLIP(L) splice form. Furthermore, as c-FLIP gene silencing modulates the apoptotic threshold and sensitises the cell lines to TRAIL, targeting c-FLIP may therefore be a therapeutic option.

SPECIFIC PATTERNS OF GLOBAL HDAC1 DYSLOCALIZATION IN ACUTE MYELOID LEUKEMIA

L. Tickenbrock,[1] H.U. Klein,[1] C. Trento,[1] A. Hascher,[1] S. Göllner,[1] N. Bäumer,[1] R. Kuss,[1] S. Agrawal-Singh,[1] G. Bug,[2] H.U. Serve,[2] C. Thiede,[3] G. Ehninger,[3] U. HDACs regulate transcriptional repression and are essential for fundamental cellular processes. HDACs are involved in tumorigenesis and in mediating the function of oncogenic translocation products in specific forms of leukemia and lymphoma. Furthermore, aberrant recruitment of HDAC activity has been reported in cell lines from patients with acute promyelocytic leukemia (PML). The oncogenic transcription factor produced by the fusion of the PML gene and the retinoic acid receptor alpha (RARα) represses gene transcription by association with a corepressor complex containing HDAC activity. The reversal of aberrant gene repression could benefit leukemia therapy and HDAC inhibitors (HDI) are currently in clinical trials for the treatment of leukemia and solid tumors. While these agents show promise, their mechanism(s) of action and selective toxicity against tumor cells have not yet been adequately defined. The altered expression of specific genes by HDAC1 is important for certain biological outcomes, but it is still unknown which genes are altered due to different HDAC1-promoter binding in patients with AML or whether altered chromosomal localization of HDAC1 is a general phenomenon in AML. Using ChIP-chip analyses we provide evidence that HDAC1 deposition patterns are specifically altered in human leukemias. The global HDAC1-chromatin binding patterns differed significantly between subtypes of AML (global test: p=0.04; Inv(16)=3; complex karyotype=5; t(15;17)=6; t(8;21)=4), implicating the importance of specific regulation of HDAC1 chromatin modifications modulated by different translocations. However, beyond the subtype specificity, we wanted to know if a general signature emerged that revealed an AML associated pattern of HDAC1 distribution to gene promoters. We therefore analyzed differences in HDAC1-binding patterns of specimens derived from AML (n=48), ALL (n=11) or $CD34^+$ progenitor cells (n=15) samples. The HDAC1 patterns differed significantly between these three groups (global test p=0.03). A class comparison analysis stringently corrected for multiple testing identified 196 genomic loci (FDR <0.05) that in HDAC1 binding differed between AML and CD34p specimen and 134 genomic loci between ALL and CD34p specimen. Interestingly, within the 196 identified genomic loci between AML and CD34p samples, HDAC1 binding was mainly increased in AML (130 genomic loci high HDAC1 binding vs 66 genomic loci high HDAC1 binding in CD34p). Gene ontology analysis revealed groups of genes to be altered, e.g. genes involved in biological processes as hematopoiesis or the involvement of MAPKK-pathway. Real-time RT-PCR analysis of two regulated genes also indicated higher mRNA levels in AML specimen that correlated with a decreased HDAC1 binding. Interestingly, based on specific HDAC1 binding differences, correct classification of AML, ALL or CD34p was achieved. Classification using leave-one-out cross validation was correct in overall 89% of cases (66/74), with highest sensitivity in AML (96%). Misclassification was low and occurred mainly in ALL samples. HDAC inhibitors have shown promising activity in AML and other diseases. In the current study, we provide evidence that disease specific alterations in HDAC1 localization exist in AML. These findings provide a rationale for the specific action of HDAC-inhibitors in malignant disease.

Background. Proteinase 3 (PR3) gene codes for a serine protease with a broad spectrum of proteolytic activity. PR3 is involved in the control of proliferation of myeloid leukemia cells. When abnormally expressed it confers factor-independent growth to hematopoietic cells. The Aim of this study was to investigate the role of PR3 gene in leukemic haematopoiesis. Mathods: We analyzed the expression levels of PR3 by RQ-PCR in 113 BM samples collected from AML patients at diagnosis. The FAB distribution was as follows: M0=5, M1=12, M2=38, M3=12, M4=37, M5=5, M6=4. 19 patients were characterized by t(8;21) and 16 by inv(16). PR3 expression level was also analyzed in 57 BM and 42 PB samples from 88 MDS patients (44 RA, 32 RAEB and 12 secondary-AML) and in 15 BM and 40 PB samples from healthy volunteers. PR3 protein was analyzed by western blot (WB) and its localization determined by immunofluorescence assay using specific antibodies. The transcription factor C/EBPa, which negatively regulates PR3 expression was studied in parallel at the RNA and protein level by RQ-PCR and WB. The DNA binding activity of C/EBPa was investigated by EMSA assay. Gain and loss of function experiments were performed by transfecting COS and 293T cell lines with a plasmid containing the full length PR3 sequence and HL60, Me-1, and Kasumi cell lines with specific shRNA. *Results.* We found that PR3 is significantly overexpressed in AML sam-

ples. The median value of 2-DDCt is 740, (range 15-5043). Interestingly, patients affected by Core Binding Factor leukemias showed significantly higher PR3 values compared to patients with normal karyotypes (NK) (p<0.0002 for t(8;21), p<0.001 for inv16) and lower C/EPBa levels. EMSA assay demonstrated the absence of C/EBPa DNA binding activity in CBF AML cells but not in NK AML. In addition, PR3 overexpression was detected in 60% of RA patients (mean value: 10, range 3-268), and in all the cases of RAEB (mean value 201: range:128-803) and secondary AML (mean value 589, range 207-7131). WB demonstrated the correlation between the mRNA and protein amount. Interestingly, immunofluorescence demonstrated the de-localization of the protein within the nucleous in CBF AML but it is completely cytoplasmatic in leukemic cells with normal karyotype and in MDS. Transfection experiments with PR3 plasmid demonstrated that PR3overexpression results into a significantly increased proliferation and reduced apoptosis. By contrast transfection with shRNA triggers apoptosis and cell growth inhibition. In addition, WB demonstrated that nuclear PR3 is able to cleavage the p65subunit of NF-kB into a p56 isoform which lacks any transcriptional activity as confirmed by EMSA. *Conclusions.* PR3 gene expression and protein are significantly increased in AML and MDS, particularly in CBF leukemias in which the protein is not only increased but also completely delocalized within the nucleous. PR3 overepression My be due to a significant downmodulation of C/EBPa. Ectopic expression of PR3 induces increased proliferation and apoptosis arrest. The abnormal nuclear localization of PR3 in CBF leukemias results into the loss of function of NF-kB thus representing one mechanism of chemo sensitivity in this group of patients.

PROGNOSTIC VALUE OF MINIMAL RESIDUAL DISEASE BY REAL-TIME QUANTITATIVE PCR IN AML WITH CBFB - MYH11 REARRANGEMENT: THE FRENCH EXPERIENCE

R. Guièze,[1] A. Renneville,[2] J.M. Cayuela,[3] R. Ben Abdelali,[4] N. Boissel,[5] S. De Botton,[6] M.T. Rubio,[7] F. Mazingue,[8] E.A. Macintyre,[4] F. Sigaux,[3] P. Fenaux,[9] H. Dombret,[5] C. Preudhomme[10]

[1]Service d'Hématologie Clinique Adulte et de Thérapie Cellulaire, CLERMONT-FERRAND; [2]Laboratoire d'hématologie CHU de Lille, LILLE; [3]Service d'Hématologie Biologique, Hôpital Saint-Louis, PARIS; [4]Service d'Hématologie Biologique, Hôpital Necker, PARIS; [5]Service des Maladies du Sang, Hôpital Saint-Louis, PARIS; [6]Service d'Hématologie Clinique, Institut Gustave Roussy, VILLEJUIF; [7]Service d'Hématologie Clinique Adulte, Hôpital Necker, PARIS; [8]Service de Pédiatrie, CHU de Lille, LILLE; [9]Service d'Hématologie Clinique, Hôpital Avicenne, BOBIGNY; [10]Laboratoire Hématologie du CHU de Lille, LILLE, France

Background. Despite the favorable prognosis of AML with inv(16)/t(16;16) leading to CBFB-MYH11 rearrangement, relapses still occur in 30 to 40% of the cases. With the possible exception of age and receptor tyrosine kinase mutations, no pretreatment-factor can strongly predict risk of relapse.

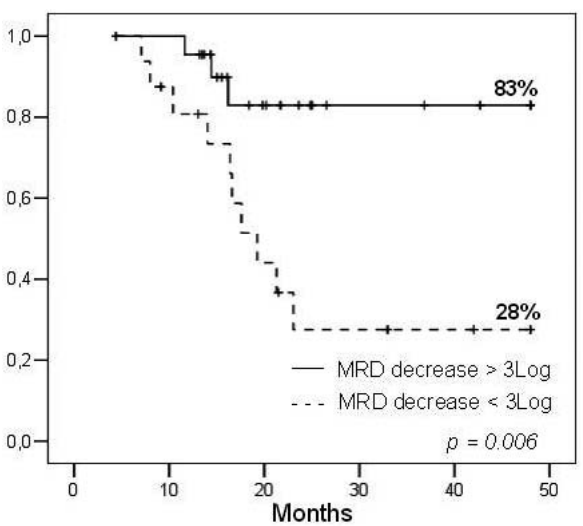

Figure. Kaplan-Meier plot of RFS according to MRD decrease after the first course of consolidation by comparison to the pretreatment level.

Aims and methods. To explore minimal residual disease (MRD) prognostic impact, we monitored CBFB-MYH11 transcript level by real-time quantitative PCR (RQ-PCR) in 59 inv(16)/t(16;16) AML patients included in French multicenter trials . *Results.* Median age was 36 years [4-76]. With a median follow-up of 26.5 months, 3 year-RFS was 63% and 3 year-OS 88%. No initial clinical or hematological characteristic including age, initial WBC or platelets count nor additional trisomy 22 was predictive of relapse. Pretreatment CBFB-MYH11 transcript level had no impact on RFS. After induction therapy, transcript levels >0.5% were significant predictors of poorer 3 year-RFS (35.7% vs. 75.5% if <0.5%, p=0.01). A reduction of transcript level by more than 3 log after first consolidation therapy course (compared to diagnosis) was also predictive of better RFS (83% vs. 28%, p=0.006) and better OS (100% vs. 67%, p=0.017). We did not observe any prognostic impact of mutational profile of the c-KIT, FLT-3 and RAS genes. Impact of the reduction of transcript level appears as an independent prognostic factor in a multivariate analysis. Conclusion. MRD monitoring by RQ-PCR appears to be a major prognostic factor of RFS in AML with CBFB-MYH11 rearrangement which may help therapeutic decisions for consolidation therapy.

0276

PROGNOSTIC VALUE OF MINIMAL RESIDUAL DISEASE MONITORING USING NPM1 MUTATION IN AML

R.I. Itzykson,[1] N. Boissel,[2] P. Fenaux,[3] B. Quesnel,[4] J. Fernandes,[5] S. Castaigne,[6] J.V. Malfuson,[7] S. Nguyen,[8] C. Curtillet,[9] M. Beaumont,[5] J.P. Marolleau,[10] Y. Perel,[10] D. Caillot,[10] Y. Bertrand,[11] S. Glaisner,[12] C. Pautas,[13] C. Preudhomme,[1] A. Renneville[1]

[1]CHRU Lille, LILLE; [2]Hôpital Saint-Louis, AP-HP, PARIS; [3]Hôpital Avicenne AP-HP, BOBIGNY; [4]CHRU, LILLE; [5]Centre Hospitalier, VALENCIENNES; [6]Hôpital Mignot, VERSAILLES; [7]HIA Percy, CLAMART; [8]Hôpital Pitié-Salpétrière AP-HP, PARIS; [9]Hôpital La Timone AP-HM, MARSEILLE; [10]CHU, AMIENS; [11]Hôpital Debrousse, Hospices Civils, LYON; [12]Centre René Huguenin, SAINT-CLOUD; [13]Hôpital Henri Mondor, AP-HP, CRÉTEIL, France

Background. Mutations of the NPM1 gene can be found in 35% of AML patients, mainly those with normal karyotype. They are mostly frameshift mutations (type A or B), that are usually stable at relapse, allowing their use to monitor minimal residual disease (MRD) during follow-up by real-time quantitative PCR (RQ-PCR). *Aims.*We retrospectively analyzed our AML patients with type A or B NPM1 mutation at diagnosis for whom blood or bone marrow (BM) MRD was assessed sequentially during follow-up, in order to identify the timing of MRD assessment with greatest prognostic value. *Patients and Methods.* 47 *de novo* AML with NPM1 mutation who had reached complete remission with intensive chemotherapy, M/F: 24/23; median age: 51y, median initial WBC 33.0G/L, karyotype normal, abnormal, and failure in 36, 5 and 6 pts resp. 42 and 5 pts had type A and type B NPM1 mutation. 17/45 pts (38%) had FLT3-ITD, and 8/45 (18%) a FLT3-D835 or I836 point mutations. Post-remission treatment (tx) included HD-araC in 23 pts, and allo-SCT in 8 pts. With a median follow-up of 12 months, 11 pts have relapsed. RQ-PCR was performed on cDNA from BM and/or blood samples. The MRD level (ratio of mutated NPM1/104 ABL copies), and log reductions were analysed as continuous variables, with stratification on NPM1 mutation type to account for differences in RQ-PCR sensitivities (10/104 and 100/104 for type A and B mutations, resp.). *Results.* 387 (197 BM and 190 blood) samples (median 4, range 2-13 per pt) were analysed. Median NPM1 MRD levels were 24.65 in blood, and 10.08 in BM samples at diagnosis, with no significant correlation to age, WBC, FAB, cytogenetics, NPM1 mutation type, or FLT3 status. MRD decreased by a median of 3.4 and 3.7 log10 after induction in BM and blood resp., and further decreased by a median of 1.0 and 0.6 log10 levels after post-remission tx, resp. During the follow-up, 78% and 87% pts reached undetectable MRD in BM and blood resp. In univariate Cox analysis, only FLT3-ITD status (p=0.02), WBC (p=0.053), MRD level at diagnosis in blood (p=0.03), but not in BM were associated with DFS. Post induction MRD levels in the blood (p=0.04) and BM (p=0.03) were correlated to DFS whereas at the end of tx, only the MRD level in BM (p=0.02) was correlated to DFS. In multivariate analysis, only post-induction BM MRD level retained a statistical significance independent of WBC and FLT3-ITD status (p=0.03). *Conclusions.* MRD monitoring in AML pts with type A or B NPM1 mutation is correlated to the relapse risk, but analysis seems more reliable on BM samples. The BM MRD level after induction therapy yields prognostic value independent of usual variables, including WBC and FLT3-ITD. Accrual to this cohort is continuing.

0277

THE AMP-KINASE AGONIST METFORMIN HAS TUMOR SUPPRESSOR ACTIVITY IN ACUTE MYELOID LEUKEMIA

A.S. Green,[1] L. Willems,[1] N. Chapuis,[1] V. Bardet,[1] S. Park,[1] M. Foretz,[1] B. Viollet,[1] N. Dedhin,[2] N. Azar,[2] N. Ifrah,[3] F. Dreyfus,[4] P. Mayeux,[1] C. Lacombe,[1] D. Bouscary,[1] J. Tamburini[1]

[1]Institut Cochin, PARIS; [2]Hôpital Pitié-Salpétrière, service d'hématologie, PARIS; [3]Hôpital d'Angers, service d'hématologie, ANGERS; [4]Hôpital Cochin, service d'hématologie, PARIS, France

Background. Acute myeloid leukemia (AML) is a clonal hematological disease characterized by the deregulation of multiple signaling pathways that contributes to cell proliferation and survival. The characterization of targets whose inhibition impairs AML growth advantage is therefore under active investigation. The mammalian Target Of Rapamycin Complex 1 (mTORC1) pathway is frequently activated in cancers including AML, and usually stimulates the expression of highly oncogenic proteins through the control of cap-dependent mRNA translation. However, we showed that allosteric mTORC1 inhibitors (rapamycin and derivate) fails to repress mRNA translation in AML, due to a rapamycin-resistant phosphorylation of the translation regulator 4E-BP1 on S65. Indeed, when phosphorylated on multiple residues, 4E-BP1 facilitates the assembly of active translation initiating complexes (eIF4F) and subsequent mRNA translation. It is noteworthy that the phosphorylation of 4E-BP1 on the N-terminal residues T37 and T46 is absolutely required for its phosphorylation on S65 residue, which is critical for translation activation. *Aims and Methods.* We studied the potential of AMPK as an inducible negative regulator of mTORC1 activity in AML biology. Experiments were done in 20 primary AML samples obtained from patients treated in varying studies of the GOELAMs French group after informed consent according to the declaration of Helsinki. MTORC1 and AMPK signaling were studied by immunoblot. Cap-dependent mRNA translation was studied by 7m-GTP pulldown assay, polysome analysis, [3H]leucine pulse assay and immunoblot. AML blast cells survival was assessed by methylcellulosis cultures and annexin V fixation in flow cytometry. *Results.* We show here in primary AML cells that mTOR inhibition by siRNA or by a catalytic inhibitor, PI-103, inhibited 4E-BP1 phosphorylation on T37/46, in contrast to rapamycin. Thus, a rapamycin-resistant activity of mTOR is involved in 4E-BP1 priming phosphorylation and represents a target to achieve inhibition of cap-dependent mRNA translation in AML. The AMP Kinase (AMPK) pathway is an inducible repressor of mTOR activity and constitutes a central regulator for mRNA translation process. AMPK is activated by metabolic stresses that either inhibit ATP production or stimulate ATP consumption and represents thereby the main cellular energy sensor. We tested 3 pharmacological AMPK agonists, metformin, AICAR and the A-769662 compound. Overall, only metformin specifically induced AMPK activity in AML. When tested in primary AML cells, metformin-induced AMPK activation led to a complete inhibition of all 4E-BP1 phosphorylation events that we reported to be rapamycin-resistant. Moreover, metformin markedly repressed cap-dependent mRNA translation in AML: this compound inhibited the assembly of the eIF4F translation initiating complex, impaired polysomes formation and decreased the amounts of polysome-bound c-Myc mRNA in AML cells. As a result, total protein synthesis was dramatically reduced in metformin-treated AML cells, as well as the expression of highly oncogenic proteins regulated at the translation-initiation level (c-Myc, Cyclin D1, Bcl-xL). Significantly, AMPK activation impaired the survival of primary AML cells, with a favourable therapeutic index when compared to the effects of metformin on normal $CD34^+$ hematopoietic progenitors. *Conclusions.* The activation of the AMPK tumor suppressor pathway represents a promising perspective in AML therapy and could be further explored in clinical trials.

SUPPRESSOR OF CYTOKINE SIGNALING 1 (SOCS1) IS INDUCED BY FLT3-ITD IN HEMATOPOIETIC STEM AND PROGENITOR CELLS AND COOPERATES IN LEUKEMOGENESIS

H. Brandts, P. Kumar Reddy Nagaruri Gonchi, B. August, H. Serve

Goethe-University Frankfurt, FRANKFURT, Germany

FLT3 (FMS-like tyrosine kinase 3) is a receptor tyrosine kinase expressed on early hematopoietic progenitors. Internal tandem duplications are frequently found mutations in the juxtamembrane domain of FLT3 (so called FLT3-ITD), lead to constitutive activation of the receptor and the STAT5 signaling pathway. Retroviral expression of FLT3-ITD in primary murine hematopoietic stem and progenitor cells leads to expression of SOCS (suppressor of cytokine signaling) genes, which are known STAT5 target genes. As SOCS proteins are known to inhibit growth of hematopoietic stem and progenitor cells, we investigated their role in FLT3-ITD-mediated transformation. In the presence of pro-proliferative cytokines and growth factors, colony growth was severely impaired in SOCS1-expressing primary bone marrow cells, while this inhibition was reversed by co-expression of FLT3-ITD, suggesting resistance of FLT3-ITD to SOCS1. Importantly, when colony assays were performed in the presence of anti-proliferative interferonγ (IFNγ), the SOCS1 co-expression protected FLT3-ITD from the IFNγ growth inhibitory effects when compared to FLT3-ITD alone. In a murine bone marrow transplantation model, the co-expression of SOCS1 and FLT3-ITD led to the rapid development of a myeloproliferative disease or acute lymphoblastic leukemia with significantly faster onset of disease and shorter median survival compared to FLT3-ITD. Together, these data demonstrate that in the context of the oncogene FLT3-ITD, SOCS1 promotes colony growth and leukemogenesis, while if SOCS1 is expressed alone it maintains its role as a negative regulator of cytokine signaling. Our data support the model that the expression of SOCS proteins in hematopoietic stem and progenitor cells may shield FLT3-ITD-expressing cells from cytokine control and that impaired cytokine signaling contributes to FLT3-ITD-mediated leukemogenesis.

Background. The development of standardized 8-color flow cytometry (FC) combined with bio-informatic merging of data from multiple tubes allows multiparameter evaluation of surface and intracellular proteins at the single cell level, while maintaining all the advantages of FC diagnostics (rapidity, evaluation of cellular heterogeneity, application to minimal residual disease, etc). *Aims.* Within the European EuroFlow program, we designed an 8-color acute leukemia screening tube (ALST) for fast and efficient evaluation of patients suspected of acute leukemia in order to choose more detailed immunophenotyping panels. *Methods.* 157 acute leukemia samples (105 BM, 45 PB, 7 others) were analyzed with the ALST tube by FC in 8 EuroFlow centers, using standard operating procedures which provided intercenter reproducibility. In parallel, conventional procedures for lineage assessment of blast cells were used at each centre. ALST data was collected and analysed centrally using the Infinicyt software (Cytognos®). The blast cell population was identified bio-informatically, extracted from each sample and virtually merged in a common database with the blast cell populations from all other samples. Within this database, each leukemic sample was represented by its median expression for each individual ALST antibody, and the results from all 157 samples underwent unsupervised discrimination by principal component analysis (PCA) using automated software tools. *Results.* Using a pair-wise PCA-based comparison, 152/157 AL could be clearly separated into 3 well defined clusters (89 B-Cell Precursor-ALL, 27 T-ALL and 36 AML), with no mis-classification compared to classical, more extensive FC panels. Five cases (3%) clustered together in between the typical T-ALL and AML clusters, in keeping with an undifferenciated T/Myeloid maturation arrest. These included 3 AML and 2 undifferen-

tiated AL. No intermediate Myeloid or clusters were observed. No center dependent effect on clustering was observed, in keeping with the use of highly standard operating flow cytometric procedures. *Summary and Conclusions.* This ALST FC strategy linked to Infinicyt analysis allows efficient, fast and accurate lineage orientation of acute leukemia samples and multicenter, multiparametric analysis of patient data. In addition, this approach allowed identification of a subgroup of T/Myeloid AL which should be further analysed in both T-ALL and AML panels. Multicenter identification of these relatively rare samples will allow analysis of their clinical and biological characteristics and, if appropriate, their individualization for specific therapy. In conclusion, we propose an easy, efficient and highly sensitive flow-based tool to screen for cell lineage in acute leukemias which contributes to optimise health resources for further FC panels, allow multicenter comparisons and may help in identifying new subgroups of patients.

EXPRESSION, FUNCTION AND REGULATION OF AUTOTAXIN, A RELEVANT MOTILITY AND SURVIVAL FACTOR, IN FLT3-ITD POSITIVE ACUTE MYELOID LEUKEMIA AND PRIMARY HEMATOPOIETIC STEM CELLS

C.O. Ortlepp, C. Steudel, S. Koch, A. Jacobi, M. Ryser, S. Brenner, M. Bornhäuser, G. Ehninger, C. Thiede

University Hospital Dresden, DRESDEN, Germany

Genetic aberrations of the FLT3 receptor gene are among the most common mutations of adult patients with acute myeloid leukemia (AML) and result in constitutive activation of several downstream pathways including the RAS/ERK, PI3K and STAT5-signaling pathway. With an incidence of approximately 25%, the internal tandem duplication (ITD) mutation of the juxtamembrane coding sequence represents the most frequent abnormality of the FLT3 receptor gene and is associated with inferior prognosis. We have recently demonstrated by microarray analysis that leukemic samples of patients with FLT3-ITD mutations have significantly upregulated expression levels of Autotaxin (ATX). The ATX protein acts as a secreted lysophospholipase D (lysoPLD) through generating lysophosphatidic acid (LPA) from lysophosphatidylcholine (LPC). LPA has several important functions in cell migration and proliferation and acts via G-protein coupled receptors. It has been shown that ATX represents an aberrantly expressed motility and growth factor in a variety of cancer cells. However data on ATX in myeloid leukemias and especially in AML are missing. To study more deeply the role of ATX in human leukemic cells, we stably expressed two alternatively spliced transcripts in several human leukemic cell lines without detectable levels of endogenous ATX. The expression of ATX transcripts was confirmed at both mRNA and protein levels by RT-PCR and Western blotting in several leukemic cell lines as well as in human primary progenitors. Transwell migration assays in the presence of LPC or LPA were performed to study effects of ATX on cell motility. Proliferation and clonogenic potential were investigated using MTT and colony forming assays. High ATX expression was found primarily in malignant cells. In normal cells, highest ATX mRNA expression was found in purified CD34+ cells. Stable overexpression of FLT3-ITD in OCI-AML3 cells induced an increased ATX expression (up to 6 fold). Vice versa, inhibition of FLT3-ITD by sublethal doses of PKC412 in MV4-11 cells resulted in a significant reduction of ATX expression down to 10% of the initial expression level. PKC412 treatment also resulted in a complete loss of LPC induced specific migratory capacity in MV4-11 cells. Moreover, we could show that the Jun N-terminal kinase (JNK) is an important mediator between FLT3 and ATX. Specific inhibition of JNK resulted in a reduction of ATX expression levels and subsequently in a complete loss of LPC mediated chemotaxis. The transduction of ATX increased the colony-forming capacity by 75% and significantly increased the short term proliferation. LPA increased chemotaxis in human leukemic cell lines and human $CD34^+$ progenitors in a dose dependent manner and induced significantly higher migratory rates by at least 50%. LPC induced chemotaxis by 80-200% only in cells with high expression of endogenous or exogenous ATX, demonstrating the autocrine activity of ATX. This LPC/LPA induced chemotaxis could be blocked by pertussis toxin (PTX) and Ki16425 demonstrating the involvement of PTX/Ki16425 sensitive LPA1 receptors in MV4-11 cells. Our data suggest that the production of bioactive LPA through ATX is involved in controlling proliferation and migration of haematopoietic stem cells and its deregulation may contribute to the pathogenesis of AML.

A MOLECUALR CIRCUITRY COMPRISING MICRORNA-223, C/EBPA AND E2F1 IN GRANULOPOIESIS AND IN ACUTE MYELOID LEUKEMIA

A. Pulikkan,[1] V. Dengler,[1] P.S. Peramangalam,[1] A. Peerzada,[1] C. Muller Tidow,[2] S.K. Bohlander,[3] D.G. Tenen,[4] G. Behre[1]

[1]Landeszentrum fur Zell und Genetherapie, HALLE, Germany; [2]University of Münster, MUNSTER, Germany; [3]HelmholtzZentrum 'German Research Center for Environmental Health', MUNICH, Germany; [4]Harvard Medical School, BOSTON, USA

MicroRNAs are novel regulators of gene expression and have shown to possess significant roles in various biological processes. Recent findings suggest deregulation of microRNAs as a hall mark of many cancers including leukemia. During granulopoiesis, microRNA-223 (miR-223) is upregulated by the transcription factor CCAAT enhancer binding protein α (C/EBPα). Mice deficient for miR-223 display defects in granulopoiesis pointing out the importance of miR-223 during granulopoiesis. Emerging studies suggest that deregulation of C/EBPα is a critical step in the development of acute myeloid leukemia (AML). Inhibition of E2F1, the master regulator of cell cycle progression by C/EBPα is pivotal for granulopoiesis. How ever, the mechanism with which C/EBPα inhibit E2F1 in granulopoiesis is poorly understood. Computational analysis suggests that E2F1 could be a putative target of miR-223. By luciferase assay using 3'UTR of E2F1, we show that E2F1 is a potential target of miR-223. Bone marrow cells isolated from miR-223 null mice shows accumulation of E2F1 protein as observed by Western blot analysis. Meanwhile, overexpression of miR-223 leads to downregulation of E2F1 protein levels. Proliferation assays as well as cell cycle analysis demonstrate that miR-223 blocks cell cycle progression in myeloid cells. We observed that miR-223 is downregulated in different subtypes of AML as analysed by quantitative Real-Time RT-PCR. It has been reported that E2F1 is able to block granulocytic differentiation. We demonstrate that E2F1 inhibits the microRNA-223 promoter activity through its transactivation domain as shown by promoter assays. Chromatin immunoprecipitation assays show that E2F1 binds to miR-223 promoter and this binding is reversed during granulocytic differentiation. Furthermore, overexpression of E2F1 down regulates the expression of miR-223, suggesting E2F1 as a transcriptional repressor of the miR-223 gene. Recent studies demonstrate that disruption of E2F1 inhibition by C/EBPα leads to leukemia, pointing out the significance of E2F1 inhibition in the development of AML. Our data support a circuitry comprising miR-223, C/EBPα and E2F1 as major components of the granulocyte differentiation programme, which is deregulated in AML. Manipulation of miR-223 could be therapeutically relevant in AML subtypes in which E2F1 inhibition is deregulated.

IMMUNOPHENOTYPIC CHARACTERIZATION OF $CD34^+/CD38^-$ AML PROGENITOR CELLS AND THEIR RESPONSE TO VARIOUS DRUGS

H. Herrmann,[1] C. Baumgartner,[1] W.R. Sperr,[1] S. Holmes,[2] P. Valent[1]

[1]Medical University of Vienna, VIENNA, Austria; [2]Domantis Ltd., CAMBRIDGE, UK

Background. In acute myeloid leukemia (AML), the malignant clone is organized hierarchically with i) more mature cells programmed to undergo apoptosis after a variable number of cell divisions and ii) immature cells that self-renew and repopulate NOD/SCID mice with leukemias. In most AML subtypes, leukemic stem cells supposedly reside within the $CD34^+/CD38^-$ fraction of the leukemic clone. Although AML stem cells are a logic target of therapy little is known so far about the regulation of growth and survival of these cells. *Aims.*We examined the expression of cytokine receptors (SCFR/KIT, IL-3Ra, GM-CSFRa, IL-3/GM-CSFRß, G-CSFR, M-CSFR, TGFßR/endoglin, EPOR, TPOR/MPL, FLT3, VEGFR/KDR) and of other molecular targets and markers (CD33, CD44, CD133) on $CD34^+/CD38^-$ cells in patients with AML (n=30), and determined responses to cytokines, conventional antileukemic drugs (ARA-C, fludarabine), and targeted drugs including Gemtuzumab/Ozogamicin (GO=Mylotarg®) in these cells. *Methods.* Apoptosis was analyzed by combined staining for surface markers and AnnexinV. In a group of patients, $CD34^+/CD38^-$ cells were purified to homogeneity by cell sorting and examined for 3H-thymidine uptake. *Results.* AML stem cells were found to display a variable pattern of cytokine receptors and other surface targets. In fact, only the IL-3R and CD44 were expressed consistently on AML stem cells in all donors. In most patients, at least a subset of AML stem cells also co-expressed the SCFR/KIT, G-CSFR, TGFßR, FLT3, CD33, and CD133. By contrast, AML stem cells in most donors were found to lack substantial amounts of the GM-CSFR, M-CSFR, EPOR, TPOR, and VEGFR/KDR. When cultured in RPMI-1640 medium and 10% FCS, about

5-15% of the CD34+/CD38- cells and about 10-40% of the more mature CD34+ AML cells were found to undergo spontaneous apoptosis within 48 hours. Spontaneous apoptosis was prevented by exposure to SCF, IL-3, or G-CSF, but not by EPO. In most donors, ARA-C (5 μM), fludarabine (5 μM), and clofarabine (5 μM) and GO/Mylotarg (1 μg/mL) were found to promote apoptosis in CD34+/CD38- cells and more mature AML cells. The effects of ARA-C, fludarabine, and clofarabine were dose-dependent. Moreover, we were able to show that ARA-C (2 μM) and fludarabine (2 μM) and also ARA-C (2 μM) and clofarabine (2 μM) cooperate with each other in producing apoptosis in CD34+/CD38- and CD34+/CD38+ AML cells. 3H-thymidine uptake experiments performed on purified CD34+/CD38- AML stem cells confirmed growth-inhibitory drug effects. In particular, ARA-C, fludarabine, and clofarabine were found to inhibit cytokine-induced 3H-thymidine incorporation into sorted AML stem cells in all samples analyzed. *Conclusions.* Together, our data show that multi-color flow cytometry and combined staining for surface markers and AnnexinV is a powerful approach to determine apoptosis-reverting effects of cytokines and apoptosis-inducing effects of anti-leukemic drugs in immature CD34+/CD38- AML cells. Using this assay, it should be possible to identify combinations of targeted and/or conventional drugs eliminating maximal numbers of leukemic stem cells in AML.

RETROVIRAL INTEGRATION MUTAGENESIS IN MICE AS A PLATFORM FOR IDENTIFICATION OF CRITICAL TUMOR SUPPRESSOR GENES IN HUMAN MYELOID DISORDERS

R. Beekman,[1] M. Valkhof,[2] E. Taskesen,[2] S.J. Erkeland,[2] I.P. Touw[2]

[1]ErasmusMC, ROTTERDAM; [2]Erasmus MC, ROTTERDAM, Netherlands

Background. Although a major improvement in diagnostic tools for AML and MDS has been established in the past few years, the exact genetic defects underlying these diseases are still unknown in many patients. New genome-wide methods (e.g. gene expression profiling, SNP/CGH analysis and methylation profiling) are currently being used to identify new genes that are deregulated in these diseases. However, because for instance multiple genes are located at regions affected by LOH and many genes have aberrant expression levels in AMLs, it is difficult to identify the key players that contribute to the pathogenesis of these disorders using these approaches. Other approaches, like retroviral integration mutagenesis in mice have been proven powerful to identify new genes relevant for human myeloid malignancies. *Aims.* We aimed to develop a new approach to retroviral integration mutagenesis, by using methylated DNA immunoprecipitation (MeDIP), inverse PCR and promoter array hybridisation, to specifically identify new candidate TSG in mice. These candidate TSG should serve as an important basis for detection of new TSG in human myeloid malignancies, by enabling a candidate gene approach for analysing large datasets. *Methods.* Tumor samples of a previous retroviral integration mutagenesis screen were used. Genomic DNA of 6 tumors, induced by Graffi 1.4 murine leukemia virus, was isolated and digested. Methylated fragments were immunoprecipitated using MeDIP, followed by inverse PCR to amplify fragments flanking methylated viral integrations (mVIS). Amplified fragments were labeled, fragmented and hybridized on murine promoter DNA arrays. We developed new algorithms to detect mVIS after promoter array hybridization, using strict criteria based on probe intensities and restriction sites employed in the inverse PCR procedure. CEAS (Cis-regulatory element annotation system) was used to identify the genes flanking the mVIS. *Results.* We identified a total of 891 mVIS in 6 different tumors. Within 10.000 base pairs downstream of these mVIS, 708 genes were found. Twenty-four genes were present in more than one tumor and are referred to as common mVIS (mCIS) genes. Using HomoloGene (NCBI) based approaches the human orthologues of 619 mVIS and 20 mCIS genes were identified. Interestingly, when looking into the AML expression data of 532 de novo AML patients, a highly significant downregulation of these 619 mVIS ($p<0.001$) and the 20 mCIS orthologues ($p<0.05$) was seen in comparison with genes not detected in our screen. The mCIS genes include SHIP1, a well known phosphatase with tumor suppressor activity in human AML. Other mCIS genes are involved in signalling, transcription, chromatin remodelling, apoptosis and DNA repair. Five genes show extensive promoter hypermethylation in more than 5% of AML patients and/or decreased expression levels in a subset of AML patient samples. *Conclusion.* By using a new approach to retroviral integration mutagenesis in mice, we are able to detect genes that interestingly show a highly significant downregulation of expression in a large AML cohort and/or hypermethylation in a subset of AML patient samples. These findings clearly show the high potential of this new method for detection of new TSG in human myeloid malignancies.

Acute myeloid leukemia - Biology II

0284

THE FAVORABLE IMPACT OF CEBPA MUTATIONS IN PATIENTS WITH ACUTE MYELOID LEUKEMIA IS ONLY OBSERVED IN THE ABSENCE OF ASSOCIATED CYTOGENETIC ABNORMALITIES AND FLT3 INTERNAL DUPLICATION (FLT3-ITD) (FOR THE ACUTE LEUKEMIA FRENCH ASSOCIATION ALFA GROUP)

O. Nibourel,[1] A. Renneville,[2] N. Boissel,[3] C. Roumier,[2] S. Geffroy,[2] J. De Vos,[4] S. Castaigne,[5] X. Thomas,[6] C. Preudhomme,[2] H. Dombret[7]

[1]Lille Hospital, LILLE; [2]Laboratoire d'hématologie, CHRU, LILLE; [3]Laboratoire d'hématologie, Hôpital Saint-Louis, PARIS; [4]Institute for Research in Biotherapy, Hôpital Saint-Eloi, MONTPELLIER; [5]Service d'hématologie, Hôpital Mignot, VERSAILLES; [6]Centre Hospitalier Universitaire, LYON; [7]Service d'hématologie, Hôpital Saint-Louis, PARIS, France

Background. CEBPA mutations are associated with a favorable outcome in younger patients with newly-diagnosed acute myeloid leukemia (AML). This was confirmed by other groups but mainly in patients with cytogenetically normal (CN) AML. The impact of cytogenetic abnormalities and bad-prognosis FLT3 internal tandem duplication (FLT3-ITD) on CEBPA mutated favorable outcome is not clear. Moreover, it has been recently reported that Double CEBPA mutations, but not single CEBPA mutations was associated with a favorable outcome. *Methods.* Here, we analyzed the impact of associated cytogenetic abnormalities, FLT3-ITD and CEBPa single or double mutation status in 53 patients with CEBPA+ *de novo* AML treated in the ALFA trials (26 CN-AML without FLT3-ITD, 10 CN-AML with FLT3-ITD, 17 abnormal karyotypes AML). CEBPa mutations screening was performed by direct sequencing. Gene expression profiling was performed on a subset of 15 of these CEBPA+ AML (8 AML with CEBPa double mutations and 7 with single mutation) using a CEBPA+ AML prediction model obtained from a previous AML cohort. *Results*. We found that only AML with a normal karyotype and no FLT3-ITD displayed the expected favorable outcome. In this context, relapse-free, disease-free, and overall survival were significantly longer than in corresponding patients without CEBPA mutation (p=0.035, 0.016, and 0.047 respectively). This was not observed in the context of an abnormal karyotype or associated FLT3-ITD. In univariate analysis, single CEBPa mutation compared to double mutation did not significantly influenced CR rate, RFS, or DFS, but a trend towards a shorter OS was observed compared to patients with double mutation (36 vs. 60% at 5 years, p=0.09). Furthermore, prediction model based on gene expression profiling detected CEBPA+ AML with a great specificity (no false positive) but a poor sensibility (8/15 false negative). Strikingly, 7/8 false negative were CEBPA+ AML with single mutations, suggesting a significative difference in gene expression profile between single or double mutations. This heterogeneity could explain the trend towards a shorter OS in single mutation CEBPA+ AML. *Conclusion.* These results suggest that CEBPA mutations are predictive of a favorable outcome mostly in patients with a normal karyotype and no FLT3-ITD. The difference between double or single CEBPA mutations has to be confirmed on a larger cohort.

0285

DIFFERENTIAL EXPRESSION OF NATURAL CYTOTOXICITY RECEPTORS (NCRS) IN CD56-POSITIVE ACUTE MYELOID LEUKEMIAS

S. Fuhrmann,[1] R. Schabath,[1] D. Schöndube,[1] C. Romagnani,[2] W.D. Ludwig,[1] L. Karawajew,[1] R. Ratei[1]

[1]Helios-Klinikum Berlin-Buch, BERLIN; [2]German Rheumatism Research Centre, BERLIN, Germany

Background. A subset of acute myeloid leukemias is characterized by the coexpression of CD56, a canonical natural killer (NK) cell marker. This raises the issue whether this is a random, leukemia associated phenomenon or whether it constitutes evidence for a NK cell origin of CD56 positive AML. *Aims.* Detailed immunophenotypic characterization of CD56 positive AMLs in order to detect a subgroup with enhanced expression of multiple NK- cell specific markers compatible with a NK-cell lineage derivation. *Methods.* We used multi-color flow-cytometry to analyse the expression of NK-cell specific markers on CD56 positive acute myeloid leukemic blasts and compared it with its respective expression on mature NK cells within the same sample. Bone marrow aspirates of 130 patients with newly diagnosed CD56 positive AML were characterized by their expression of the NCRs NKp30, NKp44 and

NKp46. These samples were also analyzed in detail for their expression of myeloid (CD13, CD33, CD65, CD15, MPO, LF), monocytic (CD14, CD64, CD4), B-lymphoid (CD19, CD20, CD22, CD79a), T-lymphoid (CD3, CD2, CD5, CD7, CD4, CD8) and progenitor (CD34, CD133, TdT, CD117) markers. Additionally, bone marrow samples of 52 patients were analyzed with nine color flow cytometry for the expression of the selected NK-cell markers CD94 and CD122. *Results.* Blast cells from all patients were negative for CD3 and positive for CD13 and/or CD33. The percentage of CD56-positive blasts varied between 21% and 98% with a mean of 59% for the whole group. Of the 50 female and 80 male patients with CD56-positive AML, 11.5% (n=15) were positive for at least one of the NCRs. The NCR-positive patients revealed a significantly lower expression (quantified as mean percentage of positive blast cells) than the NCR negative patients for the lymphoid/monocytic marker CD4 (23% vs. 42%), for the myelomonocytic markers CD14 (7% vs. 20%) and CD65 (23% vs. 43%), for the B-lineage marker CD79a (9% vs. 26%) and for the progenitor marker CD133 (3% vs. 33%). The investigation of additional NK-cell markers performed so far, revealed in 4 patients a strong expression of CD122 and in one patient a strong expression of CD94 on the blast cell population. *Conclusions.* These results indicate a subgroup of CD56-positive AML defined by the positivity of NCRs. The negativity for CD3 and the lower expression of other antigens related to the lymphoid and myelomonocytic lineage together with the strong positivity for NK cell specific markers are compatible with a NK-cell origin of this leukemia subgroup. Whether this represents a clinically relevant subset remains to be determined.

0286

COOPERATING MUTATIONS IN *DE NOVO* AML WITH MLL-PARTIAL TANDEM DUPLICATION AT DIAGNOSIS AND RELAPSE

T.-L. Lin,[1] D.-C. Liang,[2] C.-F. Huang,[1] M.-C. Kuo,[1] Y.-S. Shih,[2] C.-L. Lai,[1] L.-Y. Shih[1]

[1]Chang Gung Memorial Hospital, TAIPEI; [2]Mackay Memorial Hospital, TAIPEI, Taiwan

Background. Two-hit model of leukemogenesis has been proposed for AML. Cooperating mutations in *de novo* AML with MLL-partial tandem duplication (MLL-PTD) at diagnosis and relapse have not been systematically investigated. *Aims*. We analyzed cooperating mutations on diagnosis and relapse samples in *de novo* AML with MLL-PTD to determine the roles of class I mutations including receptor tyrosine kinases/JAK2/Ras signaling pathways and class II mutations including RUNX1 and CEBPa, as well as NPM1, P53 and WT1 mutations in the development and relapse of AML with MLL-PTD. *Patients and methods.* Eighty-eight patients were diagnosed with MLL-PTD which was screened by Southern blot analysis or RT-PCR then confirmed by real-time quantitative PCR. Mutational analyses were performed by DNA/cDNA PCR with GeneScan analysis for FLT3/ITD, PCR-RFLP followed by direct sequencing for FLT3/TKD, DNA/cDNA PCR and direct sequencing for c-KIT, c-FMS, N-Ras, K-Ras, PTPN11, RUNX1, CEBPa, NPM1, P53 and WT1 mutations, and allele-specific PCR for JAK2V617F. Results. In AML patients with MLL-PTD at diagnosis, 56 patients (64%) had class I mutations including 38 FLT3-ITD, 12 FLT3-TKD, 4 c-FMS (1 silent), 1 JAK2V617F, 2 N-Ras, and 7 PTPN11 (1 silent) mutations; 24 patients (27%) had class II mutations consisting of 23 RUNX1 and 3 CEBPa. In addition, P53 and WT1 mutations were detected in 1 and 4 patients, respectively. None had c-KIT, K-Ras or NPM1 mutations at diagnosis. Taken together, 63 patients (72%) with MLL-PTD AML had cooperating mutations. Eighteen patients had relapse samples available for comparative analysis. None of the 18 paired samples had c-KIT, c-FMS, JAK2V617F, N-Ras, NPM1, P53 or WT1 mutations. For class I mutations, 7 patients had FLT3-ITD mutations at both diagnosis and relapse, 1 lost and none gained the mutations at relapse; 2 retained FLT3-TKD, 2 lost and none acquired FLT3-TKD mutations at relapse; 1 gained K-Ras mutation at relapse; 1 retained the PTPN11 mutation and another 2 lost PTPN11 mutations at relapse. For class II mutations, of the 6 patients who harbored RUNX1 mutations at diagnosis, all relapsed with the identical mutants; another one patient acquired RUNX1 mutation at relapse. Additional 2 patients acquired CEBPa mutations at relapse. All the mutations detected at diagnosis were not present in the complete remission samples, indicating these mutations were leukemia-specific. There were no differences in overall survival or event-free survival between MLL-PTD AML patients with cooperating mutations and those without mutations of FLT3-ITD, FLT3-TKD, PTPN11 or RUNX1 genes. Conclusions. Cooperating mutations were detected in more than 70% of MLL-PTD AML at diagnosis. Most of those carrying FLT3-ITD or RUNX1 mutations retained the identical mutations at relapse; loss or gain of class I or class II mutations might occur in relapse.

NUP98 FUSION PROTEINS. NEW INSIGHTS INTO SUB-CELLULAR LOCALIZATION AND INTERACTION WITH NUCLEO-CYTOPLASMIC TRAFFIC ELEMENTS

P. Gorello,[1] R. Mannucci,[2] L. Brandimarte,[3] R. La Starza,[3] D. Jankovic,[4] D. Beacci,[3] M.F. Martelli,[3] M. Fornerod,[5] J. Schwaller,[4] I. Nicoletti,[2] C. Mecucci[3]

[1]Hematology, PERUGIA, Italy; [2]Institute of Internal Medicine ,University Hospital Perugia, PERUGIA, Italy; [3]Hematology, University of Perugia, PERUGIA, Italy; [4]Department of Biomedicine, University Hospital Basel, BASEL, Switzerland; [5]Department of Tumor Biology, The Netherlands Cancer Institute, AMSTERDAM, Netherlands

Background. Translocations involving 11p15/NUP98 were reported in myeloid leukaemia, myelodysplasias, chronic myeloid leukemia in blast crisis and acute T-cell lymphoblastic leukemia. A *promiscuous* gene with 24 fusion partners cloned to date, NUP98 belongs to the nucleoporin family, a class of proteins constituting the nuclear pore complex (NPC) which regulate nuclear-cytoplasmic traffic. Since abnormal nucleo-cytoplasmic traffic results in oncoprotein mislocation which may contribute to neoplastic transformation, we explored NUP98 fusion protein cellular localization in patients with hematological malignancies. *Aim.* To elucidate mechanisms underlying NUP98 fusions by investigating sublocalization of NUP98 and its fusions to HEX, LOC348801, HOXA9 and PMX1 and interactions with proteins involved in Nuclear Cytoplasmic Trafficking. *Methods.* Plasmids: pEGFP-NUP98, pEGFP-HHEX, pEGFP-NUP98/HHEX, pEGFP-LOC348801, pEGFP-NUP98/HHEX (ΔGLFG/GLEBS), pEGFP-NUP98/HHEX(ΔHD), pEGFP-NUP98/LOC348801(iso1), pEGFP-NUP98/LOC348801(iso2), pDsRed-NPM1wt, pEGFP-HOXA9, pEGFP-PMX1. *Cell transfection*. Hela cell lines were cultured in MEM medium supplemented with 10% FBS and 1% glutamine, seeded on glass coverslips, transfected using Lipofectamine 2000 (Invitrogen) and treated with Leptomycin (LMB) (5ng/mL for 6 hours). Immunofluorescence: Glass coverslips were fixed in 4% paraformaldehyde pH=7.4 and flipped on to standard glass slides with Mowiol mounting medium. Confocal microscopy (Zeiss LSM 510) analyzed protein sub-cellular localization, after deconvolution and 3D confocal image reconstruction. *Results and Comments*. EGFP-NUP98 was found in the nuclear rim and as small dots in nucleoplasm and nucleoli. Co-transfection experiments with DsRed-NPM1 showed NUP98 localized in the nucleolar fibrillar compartment. NUP98 and hCRM1 colocalized strongly in nucleoplasmic and nucleolar dots. LMB treatment, which impairs hCRM1 binding with nuclear export sequences, resulted in a diffused nucleoplasmic staining pattern and disappearance of dots, confirming the NUP98-karyopherin interaction played a functional role in nucleo-cytoplasmic traffic. EGFP-HHEX diffusely stained nucleoplasm excluding nucleoli. EGFP-LOC348801 diffusely stained nucleoplasm and cytoplasm. NUP98 fusions: EGFP-NUP98/HHEX , containing GLEBS domain and 9 GLFG repeats of NUP98 fused to the HEX homeodomain, gave a microspeckled pattern in nucleoplasm, sparing nucleoli. EGFP-NUP98/HHEX(ΔGLFG/GLEBS), lacking 4 GLFG repeats and GLEBS domain, provided a speckle-free nucleus diffuse distribution pattern like EGFP-HHEX. EGFP-NUP98/HHEX(ΔHD), lacking the homeodomain, gave a dot pattern in nucleoplasm and nucleoli like EGFP-NUP98. LMB treatment of EGFP-NUP98/HHEX(ΔHD), like EGFP-NUP98, dissolved nucleolar dots, suggesting the NUP98 N-terminal maintains its interaction with hCRM1 when fused to HHEX. NUP98/HOXA9 and NUP98/PMX1, yielded speckles like NUP98/HHEX. EGFP-NUP98/LOC348801(iso1) and EGFP-NUP98/LOC348801(iso2) showed speckles in nucleus, sparing nucleoli. Both isoforms were found in nucleoli when co-transfected with pDsRed-NPM1wt, a CRM1-binding protein. NPM1 co-transfection did not localize NUP98-HEX, NUP98-HOXA9, NUP98-PMX1 in nucleolus. *Conclusions.* NUP98 and partner determine the fusion protein subcellular localization. NUP98 interacts with the hCRM1 system through its N-terminal portion which is maintained in all fusions. In NUP98-Homeobox fusions, the homeodomain prevents the NUP98 localization in the nucleolus.

FLOW CYTOMETRIC PROTEIN EXPRESSION PROFILING AS A POTENTIAL APPROACH FOR DEVELOPING AN ALTERNATIVE CLASSIFICATION OF ACUTE MYELOID LEUKAEMIA

A.R. Hussein,[1] S.J. Richards[2]

[1]Universiti sains Malaysia, KUBANG KERIAN, Malaysia; [2]Haematological Malignancy Diagnostic Service, St James's University, LEEDS, UK

Background. In patients with acute myeloid leukaemia (AML), a multidisciplinary approach needs to be employed in order to make a complete assessment of the disease, which includes the diagnosis, classification, prognosis and stratification of the treatment. However, these complimentary efforts provide substantial prognostic and therapeutic information in about half of the patients and the current classification system does not fully reflect the molecular heterogeneity of the disease. Thus, treatment stratification is difficult, especially, for patients with a normal karyotype. *Aim.* To determine the association between antigen expression and cytogenetics in patients with AML. *Methods.* Antigen fluorescence intensity of 12 cellular antigens from samples of peripheral blood or bone marrow in 246 patients was determined. The determination of positive antigen expression of the blast cell populations was carried out qualitatively by visual approach and the measurement of the fluorescence intensity of 12 cellular antigens by geometric mean then was obtained. The geometric mean of the fluorescence intensity of the 12 cellular antigens exhibited by the positive blast cell populations and 10 selected of cytogenetic abnormalities of the patients were computational analysed using *DNA-Chip Analyzer* (dChip) software to determine the significant hierarchical clusters of the fluorescence intensity in relation to cytogenetic findings. *Results.* Unsupervised hierarchical clustering analysis identified 6 significant (p<0.001) clusters or groups of patients with AML on the basis of antigen fluorescence intensity using geometric mean associated with 6 chromosomal abnormalities; t(8;21), t(15;17), inv(16), normal karyotype, complex karyotype and +8. *Conclusions.* Hierarchical clustering of geometric mean of antigen fluorescence intensity might have the potential to allow a robust, comprehensive, clinically significance and cost-effective classification of AML that includes previously identified genetically defined subgroups and a novel cluster with an intermediate prognosis of normal karyotype.

GENOME PROFILING OF NORMAL KARYOTYPE AML WITH HIGH DENSITY ARRAY COMPARATIVE GENOME HYBRIDISATION

A. Chanalaris,[1] C. Grace,[1] R. Gale,[2] D. Linch,[2] E.P. Nacheva[1]

[1]UCL Medical School, LONDON; [2]UCL Cancer Institute, LONDON, UK

Introduction. AML is the most common myeloid leukemia affecting 3.8 people per 100000. Slightly more than half of the AML patients (55%), harbour at least one chromosomal abnormality, which is detectable by cytogenetics. There is a clear correlation between cytogenetic findings and survival and, or response to therapy. However, for the 45% of the AML patients with no cytogenetic findings (Normal Karyotype, NK), there is a need for discovering the molecular triggers that lead to leukemiogenesis. *Aims.*To screen the genome of AML NK patients with aCGH to identify common aberrations that might have a role in disease onset and/or progression. *Methods.* We analysed the genomes of 26 NK AML and the genomes of 10 healthy individuals with a customised Agilent 244k high density array. The custom aCGH chip that we constructed has been enriched with probes for 236 genomic loci that were previously shown to be implicated in leukemias. These include all the known tyrosine kinases and other signalling genes and transcription factors. *Results.* We have been able to identify a set of 147 probes that differentiate normal individuals from NK AML and in addition this probe set has shown to have a high predictive value in distinguishing between the two groups (Figure 1). We have failed to identify such a probe set that can distinguish between the different NK AML subgroups according to their mutation status, but we were able to detect a total of 47 loci with an aberrant copy number in more than 2 AML patients and that has not been detected in any of the normal neutrophil samples. These loci include genes that after Gene Ontology EASE analysis reveal their involvement in pathways previously shown to be involved in AML, 10 protein kinases and 28 genes involved in cell differentiation. Among these are deletions of hsa-mir-1233 in 5 patients, deletion of EPHA3 in 4 patients and deletions of PIAS4 in 3 patients. *Conclusions.* Normal karyotype AML is a heterogeneous group according to genomic copy number changes. However, we are able to identify *hits* in pathways that are involved in cell differentiation and cell signalling.

BOTH SEPT2 AND MLL ARE DOWN-REGULATED IN MLL-SEPT2 THERAPY-RELATED MYELOID NEOPLASIA

N. Cerveira,[1] J. Santos,[1] S. Bizarro,[1] V. Costa,[1] F. Ribeiro,[1] S. Lisboa,[1] C. Correia,[1] L. Torres,[1] J. Vieira,[1] S. Snidjer,[2] J. Mariz,[1] L. Norton,[1] C. Mellink,[2] A. Buijs,[3] M. Teixeira[1]

[1]Portuguese Oncology Institute, PORTO, Portugal; [2]Academic Medical Center, AMSTERDAM, Netherlands; [3]University Medical Center, UTRECHT, Netherlands

Background. A relevant role of septins in leukemogenesis has been uncovered by their involvement as fusion partners in MLL-related leukemia. Recently, we have established the MLL-SEPT2 gene fusion as the molecular abnormality subjacent to the translocation t(2;11)(q37;q23) in therapy-related acute myeloid leukemia. *Aims.*In this work we quantified MLL and SEPT2 gene expression in 58 acute myeloid leukemia patients selected to represent the major AML genetic subgroups, as well as in all three cases of MLL-SEPT2-associated myeloid neoplasms so far described in the literature. *Methods.* Cytogenetics, fluorescence in situ hybridization (FISH) and molecular studies (RT-PCR, qRT-PCR and qMSP) were used to characterize 58 acute myeloid leukemia patients (AML) at diagnosis selected to represent the major AML genetic subgroups: CBFB-MYH11 (n=13), PML-RARA (n=12); RUNX1-RUNX1T1 (n=12), normal karyotype (n=11), and MLL gene fusions other than MLL-SEPT2 (n=10). We also studied all three MLL-SEPT2 myeloid neoplasia cases reported in the literature, namely two AML patients and a t-MDS patient. *Results.* When compared with normal controls, we found a 12.8-fold reduction of wild-type SEPT2 and MLL-SEPT2 combined expression in cases with the MLL-SEPT2 gene fusion (p=0.007), which is accompanied by a 12.4-fold down-regulation of wild-type MLL and MLL-SEPT2 combined expression (p=0.028). The down-regulation of SEPT2 in MLL-SEPT2 myeloid neoplasias was statistically significant when compared with all other leukemia genetic subgroups (including those with other MLL gene fusions). In addition, MLL expression was also down-regulat-

ed in the group of MLL fusions other than MLL-SEPT2, when compared with the normal control group (p=0.023). *Conclusions.* We found a significant down-regulation of both SEPT2 and MLL in MLL-SEPT2 myeloid neoplasias. In addition, we also found that MLL is under-expressed in AML patients with MLL fusions other than MLL-SEPT2.

0291

METHYLATION ANALYSIS OF THE SNRPN AND MEG3 IMPRINTED GENES IN ACUTE MYELOID LEUKEMIA PATIENTS

L. Benetatos,[1] A. Dasoula,[1] E. Hatzimichael,[1] G. Dranitsaris,[2] M. Voukelatou,[1] S. Tsiara,[1] I. Georgiou,[2] K. Bourantas[1]

[1]University Hospital of Ioannina, IOANNINA, Greece; [2]Department of Medical Oncology, Princess Margaret Hospital, TORONTO, Canada

Background. MEG3 and SNRPN represent imprinted genes, maternally and paternally expressed respectively. MEG3 is involved in the pathogenesis of chromosome 14 uniparental disomy and SNRPN in Prader-Will syndrome. *Aim.* As both genes have been demonstrated to possess tumor suppressor activity, we investigated whether promoter hypermethylation of the differentially methylated region (DMR) of the specific genes occurs in acute myeloid leukemia (AML) patients. *Methods.* We studied 42 patients, 26 males and 16 females, with newly diagnosed AML. Median age was 62.85 years (range 35-91). Cytogenetic analysis was not performed in 12 cases and 30 patients were classified according to the SWOG cytogenetic prognostic system in good, intermediate, and poor prognosis karyotypes. DNA methylation pattern was determined by methylation-specific PCR of bone marrow samples previously subjected to bisulphite modification, according to preestablished protocols. Twelve subjects, who had undergone bone marrow aspiration for investigation of thrombocytopenia, and were proven to have no hematological or solid tumour malignancy, uniparental disomy 14 or Prader-Willi syndrome, served as controls. *Results.* The normal pattern of the MEG3 gene consists of 2 alleles, namely one corresponding to the methylated paternal allele, and one corresponding to the unmethylated maternal allele, while the normal pattern of the SNRPN gene consists of a methylated maternal chromosome and an unmethylated paternal chromosome. No abnormal methylation pattern was observed in any of the control group subjects. We found that alterations of the DMR (presence of the methylated allele only) of the MEG3 and SNRPN genes were present in 20 (47.62%) and 21 (50%) patients respectively, while 14 (33.33%) patients presented abnormal methylation of both genes. Aberrant methylation of the MEG3 gene was associated with a poorer overall survival (HR=1.98; p=0.047), while methylation of the SNRPN gene was not (HR=0.94; p=0.87). When both genes were hypermethylated there was a trend for reduced overall survival (HR=1.76; p=0.18). No significant association between WHO subtype or SWOG risk system with either gene was observed. *Summary and Conclusions.* MEG3 and SNRPN aberrant methylation has been observed in various types of solid tumors. Our findings suggest that these genes are abnormally methylated in AML patients, and methylation of MEG3 confers worse overall prognosis. The role of these imprinted genes in the pathogenesis of AML merits further investigation.

0292

GENE EXPRESSION PROFILE MIGHT PREDICT PROGNOSIS IN PATIENTS WITH INTERMEDIATE-RISK ACUTE MYELOID LEUKEMIA LACKING NPM1 AND FLT3 MUTATIONS

M. Camos,[1] S.G. Kalko,[2] M. Torrebadell,[3] M. Pratcorona,[4] M. Rozman,[3] M. Díaz-Beyá,[4] D. Costa,[3] A. Carrió,[3] E. Campo,[3] E. Montserrat,[4] J. Esteve[4]

[1]Hospital Clinic. Hematology Lab, Hospital Sant Joan de Deu., BARCELONA; [2]Bioinformatics Unit. Hospital Clínic, BARCELONA; [3]Hematopathology Unit. Hospital Clinic, BARCELONA; [4]Hematology Department. Hospital Clínic, BARCELONA, Spain

Background. In the heterogeneous category of acute myeloid leukemia (AML) patients with intermediate-risk cytogenetics (IR-AML), mutations of NPM1 gene (NPM1mut) and FLT3 internal tandem duplication (FLT3-ITD) segregate subgroups with different prognosis. Nonetheless, approximately 40% of IR-AML cases lack both mutations and their biological and prognostic background is mostly unknown. *Aim.* To elucidate if gene expression profiling (GEP) might contribute to undercover biological subtypes and prognostic markers within the subgroup of patients with IR-AML. *Methods.* Forty patients (age: 52, 17-68; gender: 27 M/13F) diagnosed with IR-AML (normal karyotype 73%) during interval 1996-2008 who achieved complete remission (CR) after intensive chemotherapy were included in the study, excluding those patients who underwent allogeneic hematopoietic stem-cell transplantation in first CR. Global gene expression was examined with oligonucleotide HGU133 Plus 2.0 arrays (Affymetrix), and gene expression measures were normalized using RMA methodology from the Affy package (Bioconductor project). Unsupervised and supervised comparisons were performed using TM4 Microarrays Software Suite (Saeed AI *et al.*, 2003) and Limma software (Bioconductor). Supervised analysis was based on patients outcome, comparing the gene signature of long-term responders (i.e. CR>2 years, n=25; FAV) with that of patients presenting with early relapse (n=15; UNFAV). Those genes with a significance value <0.005 and log fold change >0.5 were selected. NPM1mut and FLT3-ITD were screened as previously described. *Results.* Fourteen patients harbored a favorable genotype (i.e., NPM1mut/FLT3-ITDneg, 35%), 7 patients had FLT3-ITD (4 of them with concomitant NPM1mut), and the remaining 19 patients (48%) lacked both mutations. The molecular category (NPM1wt/FLT3-ITDneg vs. other) predicted outcome, with a 5-year LFS of 92% vs. 49.5% (p=0.01). On unsupervised GEP analysis, patients grouped in two major arms, which differed according to the presence of NPM1 mutations (77% vs. 31%, p=0.02) but not in terms of prognosis. Under supervised condition, 53 probe sets corresponding to 47 genes were differentially expressed in prognostic subgroups of patients; among these, homeobox genes HOXA4 and HOXB2, and LMNA were found to be overexpressed in the FAV subgroup, and genes such as ENG, PLSCR1, CSF3R, and RETN were overexpressed in the UNFAV subset. Moreover, when the analysis was restricted to patients lacking both NPM1mut and FLT3-ITD, 258 genes were differentially expressed according to outcome. Thus, several genes involved in apoptosis (CFLAR, FAS, DAPP1, BRCA1) and cell cycle control (CDC7, CDC2, CDC5) were highly expressed in the UNFAV subset. Of note, 19 genes correlated with patient outcome in both the overall series and the NPM1wt/FLT3-ITDneg subgroup. In contrast to the characteristic signature of NPM1mut patients, expression of HOX genes was low in the NPM1wt/FLT3-ITDneg population and did not show significant variation depending on prognosis. *Conclusions.* NPM1 and FLT3-ITD mutations are major determinants of prognosis in AML with intermediate cytogenetics. Nonetheless, the analysis of underlying gene signature might add relevant information for predicting the outcome of patients lacking both molecular markers.

0293

SURVIVIN GENE EXPRESSION SIGNIFICANTLY CORRELATES WITH CLINICAL OUTCOME IN PATIENTS WITH ACUTE MYELOID LEUKEMIA IN ASSOCIATION WITH MDR1/P-GLYCOPROTEIN OVEREXPRESSION AND FLT3-ITD

G. Balatzenko,[1] A. Stoimenov,[1] B. Spassov,[1] V. Nikolova,[1] M. Guenova,[1] S. Konstantinov[2]

[1]National Haematological Hospital, SOFIA; [2]Medical University of Bulgaria, SOFIA, Bulgaria

Background. Adult acute myeloid leukemia (AML) remains a very heterogeneous group with highly variable individual prognosis. It is generally accepted that some molecular markers could help to refine stratification. In AML, FLT3 is the most frequently mutated gene, with internal tandem duplications of the juxtamembrane (Flt3/ITD) accounting for up to 30%, and demonstrated to play a crucial role in driving proliferation and survival of the leukemic clone. Besides, one of the major reasons of induction chemotherapy failure is attributed to the expression of genes and proteins responsible for multidrug resistance and apoptosis. The aim of the study was to evaluate the influence of biomarkers with reported individual prognostic value and a potential to lead to targeted therapy on results of chemotherapy in patients with AML. We focused on the IAP-family gene survivin expression, MDR1/P-glycoprotein (P-gp) ATP-binding cassette transporter, as well as on Flt3/ITD. *Materials and Methods.* The study was performed in 56 patients (mean 53 years, ranged 19-79) with newly diagnosed AML according to the WHO criteria, as follows: AML with recurrent cytogenetic abnormalities - 10; AML with myelodysplasia related changes - 6; therapy-related AML - 2; AML not otherwise specified - 39. The expression of survivin gene and Flt3-ITD in leukemic cells was detected by RT-PCR. MDR1-Pgp expression was evaluated by flow cytometry. *Results.* Our studies showed lack of survivin gene expression in 24 patients (42.8%), intermediate - in 16 pts (28.6%), and high - in 16 pts (28.6%). No correlation was found with the main demographic and laboratory parameters. However, survivin overexpression was observed in only 1 out of 9 patients (11.1%) with cytogenetic/molecular markers associated with favorable prognosis as defined by WHO (AML1-ETO, CBFb-MYH11, PML-RARA), compared

to 31/47 (66%) in the remaining cases [p=0.009]. Complete remission was achieved in as few as 6/31 (19.4%) patients with high levels of survivin mRNA compared to 12/21 (57%) negative cases [p=0.008]. In addition, overexpression was significantly associated with shorter overall survival (OS) - mean 69 weeks, compared to negative cases - mean 224 weeks [log rank test, p=0.009]. The analysis failed to reveal any correlation between survivin gene expression and the presence of Flt3-ITD or high levels of Pgp. However, there was a significant difference in the OS of patients with lack of both survivin and P-gp - 2-years relative survival of 100% with a mean not reached after a follow up of 77 weeks [range 25-198]; expression of one of the biomarkers - 2-years survival of 56% with a mean of 103 weeks; or both - 1-year survival of 23%, mean of 44 weeks [log rank test, p=0.01]. Similarly, patients that had neither survivin nor Flt3-ITD showed best OS - 2-years survival of 73%, mean of 224 weeks. OS was the shortest in the double positive group with a mean of 26 weeks only [log rank test, p=0.002]. *Conclusions.* Our data showed that the apoptosis-related gene survivin is significantly associated with poor therapy outcome in AML. However, the simultaneous involvement of multiple molecular mechanisms is common in AML and has a progressively worse adverse effect on prognosis. After confirmation on larger group of patients our findings may have important significance in defining of prognosis in AML and individualization of therapy, eventually with molecularly targeted modulators.

Studies were funded by the National Research Fund, Bulgarian Ministry of Education and Science.

GENE TARGETS OF ETV6-NTRK3 FUSION

A.F. MacLeod, S. Chen, B. Schneider, S. Nagel, M. Kaufmann, H.G. Drexler

DSMZ, BRAUNSCHWEIG, Germany

Background. A recurrent chromosome abnormality, t(12;15)(p13;q25) which fuses ETV6 with NTRK3 uniquely occurs in both solid and hematologic tumors and, though of singular interest, has yet to be characterized in any detail. *Aims.*We describe the characterization of t(12;15) in a cell line (AP-1060) recently established from a patient with acute promyelocytic leukemia. In particular, we set out to identify potential downstream targets of this unique rearrangement. *Methods.* FISH using tilepath clones; rapid amplification of c-DNA ends (RACE); microarray transcriptional profiling; reverse transcriptase quantitative (RQ)-PCR; sequencing technology. *Results.* FISH revealed t(12;15)(p13;q25) with ETV6 rearrangement. 3´-RACE revealed NTRK3 involvement which was supported by FISH using fosmid clones. RT-PCR confirmed ETV6-NTRK3 fusion transcripts. Sequencing revealed the presence of both ETV6 exon-4 / NTKR3 exon-14, and ETV6 exon-2 / exon-18 of NTKR3 transcripts - the former dominating. Comparative transcriptional profiling of AP-1060 and control leukemia myeloid leukemia cells showed upregulation of RAS-MAPK and PI3K-AKT related genes, highlighting the involvement of both signaling pathways via ETV6-NTRK3. Several additional genes were conspicuously expressed by AP-1060 cells to serve as candidate ETV6-NTRK3 targets. Since growth and proliferation of AP-1060 cells was maximally sensitive to protein tyrosine kinase inhibitor (PTKi) treatment when compared to other hematopoietic cell lines, pharmacologic modulation of conspicuously expressed genes by PTKi was used to identify potential targets. Three candidates target genes thus emerged: CTHRC1 and IL32 (upregulated), and the MDS-EVI1 fusion transcript (downregulated). *Conclusions.* We identified CTHRC1, IL32 and MDS-EVI1 as potential targets of leukemogenic ETV6-NTRK3 growth signaling. Pharmacologically unmodulated but conspicuously expressed genes were preferentially stem cell in character highlighting this setting for t(12;15) formation in AP-1060 cells.

A HYPOTHETICAL-MATHEMATICAL MODEL OF ACUTE MYELOID LEUKEMIA PATHOGENESIS

A.M. Cucuianu,[1] R. Precup[2]

[1]Ion Chiricuta Cancer Institute, CLUJ-NAPOCA; [2]Babes-Bolyai University, Department of Applied Mathematics, CLUJ-NAPOCA, Romania

Background. Acute myeloid leukemia (AML) is defined by the expansion of a mutated stem cell clone, with the inhibition of surrounding normal clones. AML is in fact a very heterogeneous disease, suggesting various pathogenetic pathways for the different subtypes. *Aim.* To devise a simple theoretical model resembling hematopoiesis, to identify the possible general pathways through which the robustness of the hematopoiesis system can fail, leading to leukemia, and to give mathematical interpretation in term of dynamic systems. *Methods.* We used mathematical modeling with the help of a dynamic system inspired by Mackey--Grass and Dingli--Michor and basic results of stability of nonlinear systems. Numerical simulations with Maple 11 are made for clarifying the dynamic behavior of the system.

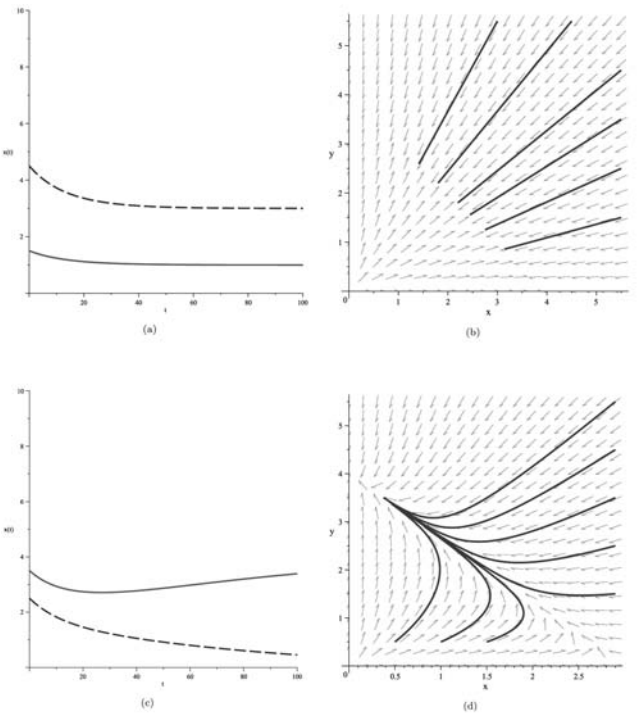

Figure 1.

Results. Theoretically, hematopoiesis can be seen as an evolutionary tree, starting with one cell that undergoes divisions during the expansion phase, afterwards losing cells during the contraction phase. During divisions, offspring cells acquire *variations*, which can be normal or abnormal. We postulate that if an abnormal variation exists in >25% of the cells, a leukemic pattern occurs. This may develop if: (A1) The abnormal variation occurs early, during the first divisions; (A2) The variation confers exceptional proliferative capacity; (B) A sizable proportion of the normal clones are destroyed and a previously non-significant abnormal clone gains relative dominance over a depleted environment; (C) The abnormal, variation confers relative immortality, rendering it significant during the contraction phase. Combinations of these pathways enhance the leukemic risk. A simple mathematical model expressed by a competitive differential system is used in order to descibe the dynamic of normal and leukemic cells populations, to characterize normal and leukemic states and to explain the above basic cellular processes generating leukemic patterns. The model parameters are growth, death and microenvironment sensibility rates of cells, and basic perturbations of the hematopoiesis system appear as alterations of one of the normal kinetic parameters. Estimations of the *aggressivity* and *immortality* of abnormal clones are also given. The Figure 1 presents in (a) the transitory situation from normal to leukemic hematopoiesis which is characterized by the coexistence of the two cells populations, x (normal cells - broken line) and y (leukemic cells - solid line) under a constant proportion depending on the initial concentrations. As a result, in (b), the orbits [x,y] of the dynamic system are semi-lines (rays) and there exist infinitely many stable equilibria of the biological motion. In (c), the time series plots of x and y and their behavior as time increases, is presented in case of leukemic hematopoiesis. Normal cell population x approaches zero, while leukemic population y tends to a saturation value D. Correspondingly, it is shown in (d), that in the xy-phase plane, the orbits are moving to the unique asymptotically stable equilibrium [0,D] (no normal cells, leukemic cells only). *Conclusions.* Our model shows that there are a finite number of pathways in which a hematopoiesis-like system can become leukemic. Such a model may have applicability in plotting therapeutic strategies in individual AML patients.

PROGNOSTIC VALUE OF IMMUNOPHENOTYPE IN AML PATIENTS WITH NPM1 MUTATION

M.T. Gomez Casares,[1] A. Lemes,[1] N. Navarro,[1] J.D. González San Miguel,[2] S. Fumero,[1] J.M. Bosch,[2] P. Martín,[1] M.D. Fiuza,[1] C.E. López,[1] H. Luzardo,[1] S. De la Iglesia,[1] T. Molero[1]

[1]Hospital U. de GC Dr. Negrín, LAS PALMAS DE GC; [2]Hospital U. Insular, LAS PALMAS DE GC, Spain

Background. Nucleophosmin (NMP1) gene mutations are fundamentally detected on AML with normal karyotype, and it is considered a good prognostic factor when not associated to FLT3-ITD mutations. Some studies have already tried to find an association between NMP1 mutations and the presence of several antigenic surface markers. In this way, a low incidence of CD34 has been reported and recent studies have also found specific immunophenotype patterns (positive CD34/CD7/DR) that could identify subgroups of NMP1 patients with a worse outcome. *Aim.* To analyse the incidence and prognostic relevance of CD34/CD7//DR surface markers in a group of NMP1 positive patients and relate it to FLT3-ITD mutations. *Methods.* Forty two non promyelocytic AML patients (24 men and 18 women), all positive for the NMP1 mutation, were retrospectively analysed. According to FAB criteria, there were 1 M0, 6 M1, 7 M2, 6 M4, 10 M5, 9 RAEB and 3 non labelled cases. Ages ranged from 20 to 88 years, with an average of 60. Thirty of them were treated according to a conventional induction to remission chemotherapy protocol (7+3) and subsequent consolidation therapy either with chemotherapy or autologous/ allogenic SCT depending on the different prognostic groups. The remaining patients did not receive any treatment at all. The risk estimation of the different groups as established according to their immunophenotype and the presence of mutations in FLT3-ITD was calculated using Pearson's chi-squared. *Results.* Forty one percent of the patients belonged in the M4/M5 subtypes, and 33.3% in the M1/M2. 84% of the NMP1 positive patients had normal karyotypes. Mutations in FLT3-ITD were detected in 23.8% of the cases. Analyzable patients according to data from their immunophenotypes were, 11 CD34 positive (34.3%), 19 DR positive (59.4%) and 8 CD7 (25%) positive. When time to complete remission and/or relapse were analysed together with each specific surface marker, no significant findings were obtained. Patients FLT3-ITD positive had a higher chance of being CD7 positive and carried a higher risk of relapse when compared to the group as a whole ($p<0.0001$), but not to the FLT3-ITD positive CD7 negative group. *Conclusions.* 1. A low incidence of CD34 and CD7 was found among the NMP1 positive patients as described previously in the literature. The incidence of DR was higher when compared to other reports, and was most frequently associated to FAB M4/M5 subtypes. 2. In contrast to what has been published, no significant differences were found as to response to treatment, and risk of relapse depending on the presence of CD34, CD7 and DR. 3. Patients that had NMP1 and FLT3-ITD mutations had a significantly higher risk of relapse and a higher chance of being CD7 positive when compared to those that only portrayed NMP1 as a sole genetic finding. This higher risk of relapse cannot be linked to CD7, since this risk was similar on both groups: FLT3-ITD/CD7 positive and FLT3-ITD/CD7 negative. 4. In the group studied, the presence of CD7 by itself, which has been suggested as a poor prognostic factor, can not be considered as such.

0297

FLT3 ANTIGEN EXPRESSION IN ACUTE LEUKAEMIA USING FLOW CYTOMETRY

S. Hassan,[1] M. Leung,[2] C. Ridler,[1] C. Stephens,[2] M. Macey,[2] M. Jenner,[1] S. Agrawal[1]

[1]St Bartholomew's Hospital, LONDON; [2]The Royal London Hospital, LONDON, UK

Background. The FMS-like tyrosine kinase (FLT3) is expressed in normal early myeloid and lymphoid progenitors and in many types of leukaemia. FLT3 mutations are expressed in a smaller percentage of acute leukaemias and correlate with worse outcomes. Traditionally FLT3 expression and mutation has been detected using PCR techniques followed by gel electrophoresis. To our knowledge, we are the first centre to routinely use flow cytometry (FC) analysis to measure FLT3 expression for the diagnosis of acute leukaemia. *Aims.* 1) To investigate the patterns of FLT3 expression in all acute leukaemias by FC and compare this to data with standard methods. 2) To identify whether any specific trends of FLT3 expression can aid diagnosis and classification of acute leukaemia. *Methods.* A retrospective analysis was carried out on peripheral blood or bone marrow samples on 414 patients (300 AML, 90 ALL, 25 bi/triphenotypic according to EGIL scoring) who were diagnosed with acute leukaemia between January 2003 and October 2008. Surface expression of FLT3 was measured on a Coulter Epics XL flow cytometer until spring 2006 and then on a BD Canto II flow cytometer using an IgG1 monoclonal antibody (4G8 clone; BD Pharmingen). *Results.* Using a threshold of ≥20%, 84.4% of AML and 77.8% of ALL patients were positive for FLT 3. However, a cut-off of ≥30% was found to be more discriminatory: analysis of the AML FAB groups revealed 72.5% of patients with M0-M6 subtypes were FLT3$^+$ in contrast to 0% of patients with M7 (0/3 cases); ALL subtypes showed 89.3% of B-ALL (Pro B-ALL, common B- ALL & pre B- ALL) were FLT3$^+$ compared to 6.3% of T-ALL (1/16 cases); 60% of all ambiguous lineage leukaemias were FLT3$^+$ whereas only 12.5% ofT lymphoid leukaemias were FLT3$^+$. This compares to 100%, 75% and 66% FLT3 positivity for Myeloi trilineage and myeloid/T respectively. The fluorescence intensity (FI) of FLT3 expression did not aid separation of different leukaemia subtypes, with a range from weak to moderate FI and the majority of cases showing weak expression. *Summary and Conclusions.* This data supports the use of flow cytometry for detecting FLT3 antigen expression in acute leukaemia. The distribution of FLT3 positivity in the acute leukaemias by FC correlates closely with that reported using molecular techniques. The observed trends indicate the utility of FLT3 detection in the immunophenotyping panel for acute leukaemia. In particular, FLT3 negativity provides supportive data in the diagnosis of M7 AML and T lineage diseases using a cut-off of 30%.

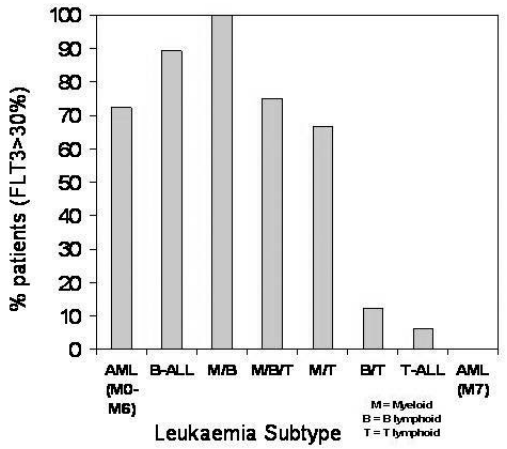

Figure. FLT3 positivity by leukaemia subtype.

QUANTITATIVE ASSESSMENT OF WT1 EXPRESSION: A USEFUL TOOL FOR MONITORING MINIMAL RESIDUAL DISEASE IN ACUTE LEUKEMIA PATIENTS

F. Salmi,[1] E. Ottaviani,[1] C. Papayannidis,[1] S. Paolini,[1] B. Lama,[1] D. Cilloni,[2] F. Messa,[2] N. Testoni,[1] N. Vianelli,[1] C. Finelli,[1] I. Iacobucci,[1] M. Baccarani,[1] G. Martinelli,[1] A. Curti[1]

[1]Department of Hematology/Oncology Seràgnoli, University of Bologna, BOLOGNA; [2]Department of Clinical and Biological Science, University of Turin at Orbassano, TURIN, Italy

Introduction. Wilms' tumor 1 (WT1) gene encodes a transcriptional factor important for normal cellular development and cell survival. Recently, the study of WT1's involvement in malignant cells, including haematological neoplasias, has revealed a potential role as an oncogene. Moreover, its overexpression in leukemias has been used as a molecular marker for the detection of minimal residual disease (MRD). *Aims.*Our study aims to verify if quantitative assessment of the WT1 transcript amount can be used as a marker for monitoring MRD and whether WT1 levels may be predictable of clinical outcome. *Patients and Methods.* WT1 amount was determined in BM and PBL samples of patients with AML lacking a molecular marker for MRD detection, and in normal control. We also analyzed WT1 levels at sequential time intervals during follow-up. Samples from 45 AML patients with miscellaneous cytogenetic abnormalities and normal karyotype at diagnosis (36 BM, 9 PBL) and 16 healthy control (4 BM, 12 PBL) were examined for WT1 expression. A total of 201 specimens of AML patients at diagnosis and during follow-up (181 BM, 20 PBL) were analyzed for quantitative assessment of the WT1 transcript amount. RQ-PCR reaction and fluorescence measurements were made on the ABI PRISM 7900 HT Sequence Detection System (PE Applied Byosystems). *Results.* In healthy controls, the median value of WT1 levels in BM

and PBL was 23,08 (range 0-176.70) and 0 (range 0-8,50), respectively. Among all the samples of AML patients at diagnosis and during follow-up, BM and PBL specimens showed a median of 276 (range 0-42.553,33) and 540,47 (range 2.18-25.696) respectively. At diagnosis BM and PBL samples had a median value of 3816,50 (range 7.97-23.094,10) and 7397 (range 6.00-25.696), respectively and overexpression of WT1 was observed in 92% of the cases. In 4 patients bearing an additional molecular marker, like AML1-ETO, PML-RARα or CBFβ-MYH11, we found a complete parallelism between the behaviour of WT1 transcript and the fusion genes. Clinically, the haematological relapse was correlated with the increase of WT1 expression. Moreover, we observed that the persistence of high level of WT1 transcript after induction chemotherapy was associated with imminent relapse. *Conclusions.* 1) WT1 expression may be useful for detection of MRD in AML patients lacking additional molecular markers; 2) there is a good correlation to other follow-up markers; 3) normal and abnormal WT1 transcript level may be able to detect patients at high risk of treatment failure after induction therapy, and quantitative analysis during follow-up can predict imminent relapse.

THE DELETION OF THE PROLINE-RICH REGION OF HOXB4 IS ASSOCIATED WITH MYELOID LEUKEMIA IN A MOUSE MODEL

M. Cusan,[1] A.J. Deshpande,[1] V. Vijay,[1] W. Wolfgang,[1] L. Quintanilla-Martinez,[2] K. Keith,[3] C. Christian,[1] M. Michaela[1]

[1]Klinikum Grosshadern, MUNICH, Germany; [2]Helmholtzzentrum, MUNICH, Germany; [3]Terry Fox Laboratory, BC Cancer Agency, VANCOUVER, Canada

Background. HOXB4 belongs to the family of homeobox transcription factors, which play a key role in hematopoietic development. The expression of HOXB4 induces a significant increase of long-term repopulating stem cells (SC) in human and mouse models, without inducing malignant transformation. So far the underlying mechanisms of the SC amplificatory impact of HOXB4 are poorly understood. *Aim.* In an attempt to understand the unique characteristics of HOXB4, we performed a mutational study by deleting its proline-rich region, which has been described to act as a transcriptional activation domain in many other proteins, like non-homeobox genes (e.g. p53, AP2) and other homeobox genes (e.g. HOXD4 and HOXA13). *Methods.* We performed *in vitro* and *in vivo* experiments transducing murine 5-FU enriched HSCs with the pMSCV-IRES-GFP based retroviral vector harbouring the HOXB4 wild-type (wt) and several mutants, including a Δproline HOXB4 mutant (ΔP), where the proline-rich sequence (50% P) between the amino acidic positions 71-120 in the exon 1 is deleted. *Results.* In previous experiments, when HOXB4-ΔPro (n=14) was over expressed in 5-FU enriched progenitor cells from BM, we reported a significant decrease (75fold, $p<0.05$) of the 12 days Δ-CFU-S frequency, in comparison to the HOXB4-wt (n=5), while it still generated significantly more Δ-CFU-S in comparison to the GFP control (n=11) (35fold, $p<0.0003$). Furthermore, we performed the CRU assay by transplanting lethally irradiated C3HxC57Bl/PeB mice with serial dilutions of 5-FU isolated bone marrow progenitor cells, in order to evaluate the effect of the HOXB4-ΔPro on the competitive repopulating unit frequency. At the 16th week post transplantation we reported no significant difference in the CRU frequency between the mice receiving HOXB4wt (CRU 1/834, n=18) and the mice receiving HOXB4-Δpro (CRU 1/413, n=18) expressing transplants. However, in mice transplanted with HOXB4wt (n=12) 45.3% of the circulating cells belonged to the transduced compartment compared to 19.2% in the HOXB4-Δpro group (n=13) ($p<0.006$), whereas the lineage distribution within the transduced compartment did not differ between both experimental arms 16 wks post transplant. Of note and in contrast to HOXB4wt, mice engrafted with HOXB4-ΔPro BM cells (n=9) developed myeloproliferation with a significant increase of Mac-1 and Gr-1 positive cells over time in the PB (29% Gr1 and 43% Mac1 wk 4-16 compared to 71.2% Gr1 and 86.6% Mac1 week 36-56 wk, $p<0.004$). The HOXB4-ΔPro mice developed acute myeloid leukemia without maturation, as confirmed by immunohistochemical analysis after a median latency time of 279 days (n=9), while the mice transplanted with HOXB4wt expressing BM cells did not develop disease after an observation for more than 466 days (n=5, $p<0.05$). The AML in HOXB4-ΔPro mice was readily transplantable (66.5 days for 2nd Tx, n=6; 43 days for 3rd Tx, n=4) ($p<0.05$ compared to 1st recipients). In order to investigate the proviral integration pattern in the transplanted mice, we performed LM-PCR. In more than five HOXB4-Δpro mice we did not find recurrent integration sites. *Conclusions.* Taken together our results demonstrate that the N-terminal proline-rich region of HOXB4 has an important function for the stem cell amplifying function of HOXB4 and that loss of this domain converts HOXB4 in a leukemogenic gene.

Acute myeloid leukemia - Clinical I

0300

CONTINUOUS SEQUENTIAL INFUSION OF FLUDARABINE AND CYTARABINE FOR ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA SECONDARY TO MYELODYSPLASTIC SYNDROME

F. Ferrara,[1] S. Palmieri,[2] G. Mele,[2] T. Izzo,[2] C. Criscuolo,[2] M. Pedata,[2] C. Riccardi,[2] B. Pocali,[2] C. Califano,[3] A.M. D'Arco[3]

[1]Division of Hematology and Stem Cell Transplantation Unit, Cardarelli Hospital, NAPLES; [2]Cardarelli Hospital, NAPLES; [3]Umberto I Hospital, NOCERA INFERIORE, Italy

Background. Acute myeloid leukemia (AML) secondary to myelodysplastic sydrome (MDS) is characterized by poor prognosis, namely in older patients. The combination of fludarabine (F) with cytarabine (ARA-C) +/- G-CSF was proven as effective in patients with poor risk AML. *Aims.* To investigate in a phase II trial the efficacy and toxicity of a regimen including F + ARA-C administered as sequential continuous infusion (CI-FLA) in a series of 57 untreated patients aged more than 60 years, in whom AML arose after a previously diagnosed MDS (5 RA, 20 RAEB1 and 32 RAEB2. *Methods.* F at loading dose of 10 mg/sqm over 15 min at day 0, and after three hours and half ARA-C at a loading dose of 390 mg/sqm over 3 hours were given; at the end, F at 20 mg/sqm/ci/24 hours for a total of 72 hours and ARA-C at 1440 mg/sqm/ci/24 hours for a total of 96 hours were started. G-CSF was added at day +15 at a dose of 5 microg/kg. Patients achieving CR were programmed to receive an additional reduced course of CI-FLA, followed by G-CSF given at 10 microg/kg from day 15 in order to mobilize $CD34^+$ cells and perform autologous stem cell transplantation (ASCT). Between June 2001 and October 2008, 57 patients underwent the therapeutic program. Median age was 67 years (range 61-81). Cytogenetic analysis was successful in 50 patients out of 57 (87%) and showed normal karyotype (classified as intermediate) in 33 patients (66%), while 17 patients (34%) had different chromosomal abnormalities and were classified as unfavourable according to MRC criteria. Finally, 18 patients (31%) were affected by one or more concomitant diseases requiring specific treatment. *Results.* Overall, 40 patients (70%) achieved CR, all but one following one course of CI-FLA. There were 8 induction deaths (14%), while 9 patients (15%) were refractory to induction treatment. The median number of days to neutrophil $>0.5\times10^9$/L and platelet $>20\times10^9$/L was 19 (7-34) and 20 (9-38), respectively. Documented infections occurred in 7 cases (12%). Thirty-two patients (80% of remitters) were eligible for the programmed consolidation course. Twenty-nine patients were monitorized for the mobilization of $CD34^+$ cells, collection being successful in 19 of them (66%). Median number of $CD34^+$ cells/kg collected was 6.8×10^6 (2.5-40.3), median number of apheresis being 2 (1-2). Eleven patients (20% of the whole population) received autologous stem cell transplantation (ASCT). Median disease free survival (DFS) and overall survival were 9 and 10 months, respectively. Survival at 5 years is projected to 15%. The only parameter significantly related to DFS duration was the presence of unfavorable cytogenetics (i.e. complex karyotype or chromosome 5 and or 7 aberrations). In particular, DFS was 15 months for patients with diploid karyotype as opposed to 7 months for those with adverse one (p:0.01). *Summary and conclusions*. CI-FLA is effective and well-tolerated in elderly patients with AML secondary to previously diagnosed MDS. Therapeutic results are encouraging as to CR achievement and ASCT feasibility and compare favorably with conventional anthracycline/ARA-C based therapy. Best results are achievable in the subgroup of patients with diploid karyotype.

INFLUENCE OF HIGH EXPRESSION OF SMAC/DIABLO PROTEIN ON CLINICAL OUTCOME IN ACUTE MYELOID LEUKEMIA PATIENTS

A. Pluta, A. Wrzesien-Kus, B. Cebula, A. Wolska, A. Szmigielska-Kaplon, T. Robak, P. Smolewski, A. Wierzbowska

Medical University of Lodz, LODZ, Poland

Background. Smac/DIABLO (second mitochondrial derived activator of caspase/direct IAP binding protein with low pI) is the best known antagonist of inhibitor of apoptosis proteins (IAPs) family. Smac/DIABLO was shown to trigger both external and internal apoptosis pathways in acute leukemia cell lines. The role and prognostic significance of Smac/DIABLO protein is not clearly determined in acute myeloid leukemia (AML) patients. *Aims.* The main objective of this study was to verify whether expression of Smac/DIABLO protein has a prognos-

tic impact on response to induction chemotherapy and overall survival (OS) of adult patients with AML. *Material and Methods.* Intracellular expression of Smac/DIABLO protein using multi-color flow cytometry was examined in leukemic blasts isolated from bone marrow or peripheral blood of 71 *de novo* AML patients (median age 54 years, range 28-81). The isotype controls were performed for all measurements. Protein expression was assessed by percentage of Smac/DIABLO positive cells. In parallel, immunocytochemistry was preformed to confirm the Smac/DIABLO expression. *Results.* Fifty six out of 71 AML patients received standard induction chemotherapy with daunorubicine and cytarabine (Ara-C) (3+7) and 15/71 were treated with low dose Ara-C. Fifty nine (47%) of all patients achieved complete remission (CR). The intracellular expression of Smac/DIABLO protein ranged from 0 to 99,8% of leukemic blasts. A cut-off point of the upper quartile was used to divide patients into *high-expressers* and l*ow-expressers* of investigated protein. It was found that CR rate in the *high-expressers* group was significantly higher than in the *low-expressers* (76% vs. 28% respectively; $p<0.01$). The median time of the follow up reached 7.2 months (range 0.2-63.4). The high expression of Smac/DIABLO was associated with significantly better (OS) in AML patients ($p<0.01$; Figure 1).

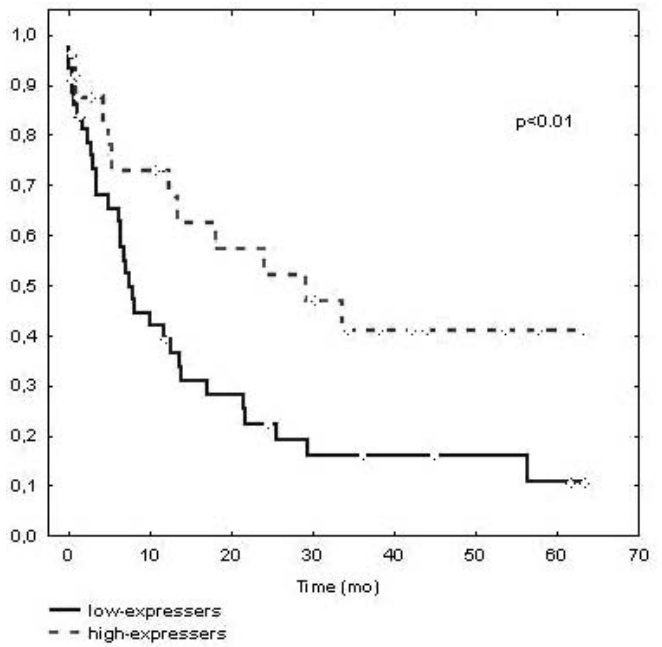

Figure 1.

Additionally, we observed that patients with good and intermediate karyotype according to SWOG classification showed significantly higher expression of Smac/DIABLO protein compare to poor risk group (median 74.7% vs. 37.7% respectively; $p<0.01$). *Conclusions.* These data, for the first time indicate that Smac/DIABLO protein expression is associated with higher sensitivity to standard chemotherapy, favorable karyotype and longer OS in AML patients. Further investigations evaluating the relationship between Smac/DIABLO as well as the other pro- and anti-apoptotic proteins should be undertaken to better demonstrate its prognostic and potentially therapeutic value.

0302

A PHASE 2 STUDY OF VORELOXIN AS SINGLE AGENT THERAPY FOR ELDERLY PATIENTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA (AML)

F. Ravandi,[1] R. Stuart,[2] M. Maris,[3] R. Stone,[4] L. Cripe,[5] M. Cooper,[6] F. Turturro,[7] W. Stock,[8] S. Strickland,[9] K. Mahadocon,[10] J. Fox,[10] G. Michelson,[10] C. Berman[10]

[1]MD Anderson Cancer Center, HOUSTON; [2]Medical University of South Carolina, CHARLESTON; [3]Rocky Mountain Bone Marrow Transplant Program, DENVER; [4]Dana-Farber Cancer Center, BOSTON; [5]Indiana University, INDIANAPOLIS; [6]St. Francis Hospital, INDIANAPOLIS; [7]LSU Health Sciences Center, SHREVEPORT; [8]University of Chicago, CHICAGO; [9]Vanderbilt University, NASHVILLE; [10]Sunesis Pharmaceuticals Inc, SOUTH SAN FRANCISCO, USA

Background. Voreloxin is a naphthyridine analog that intercalates DNA and inhibits topoisomerase II, inducing apoptosis. Interim results of REVEAL-1, a Phase 2 study of single agent voreloxin in newly diagnosed elderly AML patients, are reported. *Aims.*Overall remission rate (CR + CRp), duration of remission, overall and leukemia-free survival, 30-day all-cause mortality. *Methods.* Phase 2 study of 3 voreloxin schedules (approximately 30 patients/schedule): A, 72 mg/m^{2}qw x 3 or B, 72 mg/m^{2}qw x 2 or C, 72 mg/m^2/dose on D1 and D4. Eligibility: newly diagnosed AML (*de novo* or secondary AML), patients age ≥60 and ≥1 additional adverse risk factor (age ≥70, secondary AML, intermediate or unfavorable cytogenetics, or PS 2). PK were evaluated in a patient subset in cycle 1. Ex vivo sensitivity of patient BMA to voreloxin was evaluated by CellTiter-Glo® proliferation assay. *Results.* A (29) and B (35) are fully enrolled. A. Demographics: 66% male, 35% female; median age 75 (range: 61-89); ECOG PS: 28% PS 0, 62% PS 1; 10% PS 2. 28% had AHD and cytogenetics were intermediate in 48%, unfavorable in 45%, and unknown in 7%. Eleven patients achieved a CR (9) or CRp (2) for an overall remission rate of 38%. The 30-day all-cause mortality rate was 17%. Infection was the most common cause of early mortality. Most frequent common Grade 3 or higher non-hematologic AEs (≥10%) included mucosal inflammation, and pneumonia. B. Preliminary data: Demographics: 63% male, 37% female; median age 76 (range: 61-87); ECOG PS: 21% PS 0, 65% PS 1; 14% PS 2. 22% had AHD and cytogenetics were favorable in 3%, intermediate in 22%, unfavorable in 44%, and unknown in 31%. Nine patients have achieved a CR (7) or CRp (2) thus far; and 3 patients are too early to evaluate. All CR and CRp patients remain in remission and so median duration cannot be estimated. The 30-day all-cause mortality rate is now 9% (3 of 34). Tolerability has improved over Schedule A. Grade 3 or higher non-hematologic AEs (≥10%) reported in Schedule B vs Schedule A: mucosal inflammation (7% vs 24%), and pneumonia (19% vs. 24%). The change in dosing schedule and the addition of recommendations for infection prophylaxis has resulted in a reduction in early mortality while preserving clinical activity. C is enrolling to explore the more dose intense schedule. Voreloxin PK were similar in this frontline population and in a Phase 1 in relapsed/refractory AML. Ex-vivo sensitivity did not predict clinical response. *Conclusions.* In REVEAL-1, voreloxin demonstrates clinical activity with 2 dosing schedules in previously untreated elderly (age ≥ 60) patients with AML who are unlikely to benefit from standard chemotherapy. CR + CRp rate was 38% (11 of 29 patients) for 3 weekly voreloxin doses (A). Early results from 2 weekly voreloxin doses (B) show 9 CR + CRp, with 3 patients pending, and improved tolerability. Enrollment to C, voreloxin dosed D1 and D4, is ongoing.

0303

LONG-TERM MOLECULAR COMPLETE REMISSION WITH PULSED ATRA AS SINGLE AGENT IN PML-RAR-ALPHA-POSITIVE ACUTE PROMYELOCYTIC LEUKEMIA

E. Vigna,[1] P. Piccaluga,[2] E. Ottaviani,[2] C. Laterza,[2] M. Malagola,[3] M. Rondoni,[4] S. Paolini,[2] R. Morelli,[5] C. Finelli,[2] F. Morabito,[1] G. Visani,[6] M. Baccarani,[2] G. Martinelli[2]

[1]U.O. Ematologia Ospedale Civile dell'Annunziata di Cosenza, COSENZA; [2]University of Bologna, BOLOGNA; [3]University of Brescia, BRESCIA; [4]University of Pisa, PISA; [5]U.O. Ematologia Ospedale civile dell'Annunziata di Cosenza; COSENZA; [6]Ospedale San Salvatore, Pesaro, PESARO, Italy

Background. All-trans retinoic acid (ATRA), alone or combined with chemotherapy (CHT) is widely used in the treatment of acute promyelocytic leukemia (APL). If used alone, ATRA results in a substantial pro-

portion of complete remissions (CR). However, the continuous administration of ATRA as single therapy almost invariably leads to relapse in a short period of time (months). Current state-of-the-art treatments for molecular relapses include simultaneous administration of ATRA either with anthracycline-based chemotherapy or with arsenic trioxide (ATO). In addition, intensification with autologous or allogeneic stem cell transplantation (SCT) is often recommended in patients with persistent or recurrent disease. *Aims.* Basing on the pharmacokinetic evidence that acquired resistance to ATRA is frequently suppressed by the intermittent use of the drug, we designed the so called "pulsed" ATRA regimen for APL patients who were either molecularly refractory after combined ATRA/CHT treatment, or relapsed, or untreated, but not eligible for the combination treatment. *Methods.* Herein, we report on the long term follow up results of a cohort of pilot study. Eight patients were treated with ATRA (45 mg/m^2/day) for 15 days. After 2 weeks of rest, the treatment was then prolonged continuously for 1 week every 2 weeks. Molecular analysis was performed by qualitative and quantitative reverse transcription-polymerase chain reaction (RT-PCR). *Results*. All patients achieved a molecular CR after pulsed ATRA administration. Notably, none of the four patients treated at diagnosis relapsed. Conversely, 3/5 relapsed/refractory ones did present with further relapses (after 5, 20 and 24 months, respectively); two of them died, while one achieved a third molecular CR after allo-SCT. The remaining two are still CR after 8 and 11 months follow-up, respectively. Overall, 6/8 patients are alive and in continuous molecular CR, being the median relapse free survival 76 months (range, 11-111) and the median overall survival 78 months (range, 11-113). The toxicity was indeed mild; two cases of mucositis (grade II and III respectively) were recorded. *Summary and Conclusions.*In conclusion, though the relatively low number of cases, pulsed ATRA appeared to be particularly effective in previously untreated frail APL patients, who achieved long term remission and possibly cure. Indeed, to the best of our knowledge, this is the first evidence of persistent molecular CR in APL patients treated with ATRA alone. Interestingly, also relapsed/refractory cases did have some benefit; however, it was temporary, suggesting that this approach could be eventually used only as a possible *bridge* to allo-SCT. Certainly, confirmation in a larger cohort of patients is now warranted.

0304

A LUMINESCENT WHOLE CELL BACTERIAL BIOSENSOR FOR RAPID PRE-SCREENING OF CHEMOTHERAPY EFFICACY

E. Anderson,[1] H.M. Alloush,[1] M.A. Smith,[2] J.G. Smith,[3] V. Salisbury[1]

[1]University of the West of England, BRISTOL; [2]Royal Marsden NHS Foundation Trust, SUTTON; [3]Frimley Park NHS Foundation Trust, FRIMLEY, UK

Background. Patients with Acute Myeloid Leukaemia (AML) are routinely given cytosine arabinoside (Ara-C) chemotherapy, without any pre-screening, although up to 70-percent of patients fail to respond. This is mainly due to non-uptake of Ara-C or lack of conversion to the active form (Ara-CTP). Current methods to determine drug sensitivity of AML are time-consuming and unsuitable for routine screening. *Aims.*We have constructed a bioluminescent reporter strain of Escherichia coli that determines patient sensitivity to Ara-C within hours, which could allow screening of patient blood or bone marrow before administering chemotherapy. *Methods.* Ara-C has no effect on E. coli, which lacks deoxycytidine kinase (dCK) and deaminates Ara-C into Ara-U using cytidine deaminase (cdd). A cdd-deficient strain of E. coli was constructed and transformed with the human dCK gene under the control of the lac promoter. Expression of dCK, inducible with IPTG, rendered E. coli sensitive to Ara-C. The bacterial biosensor was made self-bioluminescent by introduction of a plasmid carrying the lux CDABE operon. *Results.* Following incubation with Ara-C (25 μM), significant increases in bacterial light output were detected from the lysate of an AML cell line known to be sensitive to Ara-C (KG-1a), compared to untreated controls. Lysate from a cell line (THP-1) known to deaminate Ara-C through over production of cytidine deaminase showed no significant increase in light production in the presence of Ara-C. Peak light output could be detected 5 hours after the start of the assay. This biosensor is currently under evaluation using clinical samples obtained with informed consent, to evaluate the uptake and metabolism of Ara-C by leukaemic blast cells, and shows 100-percent correlation with patient outcomes in over thirty blood samples examined to date. *Conclusions.* This technology could indicate the sensitivity of AML cells to Ara-C as well as other chemotherapeutic agents used in combination with Ara-C, such as anthracyclines, giving a chemosensitivity profile to clinicians and customising treatment for individual patients.

0305

INDUCTION INTENSIFIED REGIMENS INCLUDING FLUDARABINE OR GEMTUZUMAB-OZOGAMICIN FOR ACUTE MYELOID LEUKEMIA PATIENTS: COMPARISON BY RESPONSE AND FOLLOW-UP

C. Papayannidis,[1] C. Candoni,[2] P. Paolini,[1] E. Ottaviani,[1] I. Iacobucci,[1] M. Rondoni,[3] M. Malagola,[4] P.P. Piccaluga,[1] R. Fanin,[2] G. Visani,[5] M. Baccarani,[1] D. Russo,[4] G. Martinelli[1]

[1]Department of Hematology/Oncology "Seràgnoli", University of Bologna, BOLOGNA; [2]Hematology, University of Udine, UDINE; [3]Haematology Department, University of Siena, SIENA; [4]Hematology, University of Brescia, BRESCIA; [5]Department of Hematology, S. Salvatore Hospital, PESARO, Italy

Background. Conventional induction treatment in young Acute Myeloid Leukemia (AML) patients (≤60 years old) is still represented by the association of antracycline and cytarabine, which offers a complete remission (CR) rate not inferior to 63%. Since many non-randomized trials have recently demonstrated the superiority of intensified regimens, the present gold standard therapy includes the addition of at least a third drug to the classic 3/7 schedule. *Aim of the study*. We evaluated the safety profile and the efficacy of two four-drugs induction schedules, adding either fludarabine (25 mg/sqm days 1-5) or mylotarg (3 mg/sqm day 6) to idarubicin (6 mg/sqm days 1, 3, 5), cytarabine (1 g/sqm days 1-5), etoposide (100 mg/sqm days 1-5) (FLAIE and MyAIE, respectively). *Methods.* Sixty-six consecutive AML patients were enrolled either in the FLAIE (N=44, from 2002 to 2005) or in the MyAIE (N=22, from 2005 to April 2007) schedule, with similar clinical and biological characteristics. The median age was 45 and 48 years, respectively. According to kariotype, WBC count and FLT3 status, seventy and sixty-four percent of cases, respectively, were considered at high risk. Consolidation therapy consisted of 2 cycles of ID-AraC and da. *Results*. The complete remission rate was 75% and 59% for FLAIE and MyAIE, respectively (p=NS). Death during treatment rates were 5% and 0. After 1 consolidation course the overall CR rate was 80% and 73%. After a similar median follow up, 27 months (1-62) and 21 months (5-42) respectively, 41% of patients are alive in CR in the FLAIE group (12 SCT and 3 ASCT) and 64% in the MyAIE group (7 SCT and 4 ASCT) (p=n.s.; Chi-square, Fisher's exact test). Toxicity was comparable in the two regimens. The median time to ANC recovery (>1.0×10^9/L) was 31 and 23 days for FLAIE and MyAIE, respectively. The median time to PLT recovery (>100×10^9/L) was 28 and 24 days, respectively. The median time of neutropenic fever episodes for patients was 1 and 1.4 in the 2 groups, respectively. Grade III/IV GI toxicities occurred in 11% and 22% of cases, respectively. *Conclusions*. These data showed that four-drugs intensified induction therapy is a feasible approach in young AML patients. Because of the limited number of patients involved in this study, we showed no differences between these new therapeutic approaches, including fludarabine or mylotarg in addition to conventional chemotherapy. Nevertheless, when compared with previously tested ICE and FLAI regimens, these schedules seemed to be not more effective and with similar toxicities profiles. Future analyses and randomized trials will define their possible and definite role in AML treatment.

0306

PROGNOSTIC SIGNIFICANCE OF FLT3/ITD MUTATION AND ABCB1 GENE POLYMORPHISMS IN CORE BINDING FACTOR (CBF)-ACUTE MYELOID LEUKEMIA (AML)

Y.K. Kim,[1] H.N. Kim,[2] I.K. Lee,[2] S.M. Bang,[3] H.J. Kim,[4] D.Y. Jo,[5] J.H. Won,[6] J.Y. Kwak,[7] M.R. Park,[8] J.S. Ahn,[1] D.H. Yang,[1] J.J. Lee,[1] H.J. Kim[1]

Univ.Hwasun Hospital, JEOLLANAM-DO; [3]Seoul National University College of Medicine, SEOUL; [4]The Catholic University of Korea College of Medicine, SEOUL; [5]Chungnam National University College of Medicine, CHUNG-JU; [6]Soonchunhyang University College of Medicine, SEOUL; [7]Chonbuk National University Medical School, JEONJU; [8]Wonkwang University School of Medicine, IKSAN, South-Korea

Background. Although CBF-AML is associated with a relatively favorable prognosis, only approximately half of these patients are cured with standard therapy. Flt3/ITDs and NPM1 mutations are generally well known to be associated with clinical outcomes in AML patients. However, these mutations are reported to be rarely found in cases with CBF-

AML and it remains a matter of debate as to whether these mutations play an independent role in the prognosis of CBF-AML. MDR1/Pgp, the gene product of MDR1, is recognized as an important class of proteins for regulating pharmacokinetics. Several reports showed the effects of ABCB1 (mutidrug resistance 1 gene, MDR1, PgP) genotypes on pharmacotherapy in various malignancies including AML. *Aims.* To assess the prevalence and the prognostic role of Flt3/ITDs and ABCB1 gene polymorphisms in CBF-AML. *Methods.* Flt3/ITD, NPM1 mutation status and ABCB1 gene polymorphisms (SNP numbers: rs1055302, rs1002205, rs4148750, rs7779562, rs6980101, rs1922242, rs2235013, rs4728702, rs1922240, rs1922241, rs4148734, rs6950978, rs10256836, rs1202172, rs17327442, rs7802773, rs13229143, rs4148732, rs1978095, rs10264856) were evaluated by performing DNA polymerase chain reaction assays on BM samples obtained at initial diagnosis from the CBF-AML patients. DNA sequencing and GeneScan analysis was performed to confirm genotyping results. *Results.* Seventy-five CBF non-transplant AML patients who received intensive induction and consolidation chemotherapy including cytarabine were evaluated. Fifty-five (73.3%) were AML with t(8;21)(q22;q22) and twenty (26.7%) were AML with inv(16)(p13q22). The median age of patients was 38 years (range, 17-69 years). Twelve patients (16.0%) demonstrated the aberrant Flt3/ITD mutations. There was no statistically significant difference in age, gender, leukocyte count, hemoglobin level, platelet count and percentage of peripheral or bone marrow blasts, cytogenetics between the patients with or without Flt3/ITD. No NPM1 mutation was found in these patients. In univariate analysis, there was no significant difference in complete response (CR) rate (Flt3/ITD+: 100% vs. Flt3/ITD-: 98.4%, p=0.658). However, the presence of Flt3/ITD was associated with higher relapse rate in these patients (Flt3/ITD+: 75.0% vs. Flt3/ITD-: 13.3%, p=0.000). There was a significant shorter leukemic-free survival (LFS) in patients with Flt3/ITD compared to those without Flt3/ITD (1yr LFS; 13.9±11.9% vs. 57.7%±12.7%, p=0.024). On the other hands, there was significant difference in CR rate with ABCB1 gene polymorphisms types such as rs6980101 (genotype C/C: 65.0% vs. C/T: 100%, p=0.026), rs10256836 (G/G: 86.4% vs. G/C: 50.0%, p=0.037), rs17327442 (T/T : 84.6% vs. T/A: :40.0%, p=0.029) and rs4148732 (A/A: 91.3% vs. A/G: 50.0%, p=0.017). Whereas, there was no significant difference in relapse rate, LFS and overall survival between homo- and heterozygote groups in these polymorphsims. *Conclusions.* This study revealed that ABCB1 SNPs can affect CR rate of CBF-AML patients. Therefore, a stratified treatment plan in remission induction chemotherapy such as augmentation or addition of other chemotherapeutic agents may be warranted for the CBF-AML harvoring such ABCB1 polymophrisms. We also demonstrates that the presence of Flt3/ITD mutation is associated with significantly higher relapse rate and shorter LFS in CBF-AML, indicating the need for improved therapeutic approaches including stem cell transplantation as a post-remission therapy in CBF-AML with Flt3/ITD mutations.

LAROMUSTINE INDUCES REMISSIONS IN ELDERLY POOR RISK AML PATIENTS WITH ADVERSE CYTOGENETICS AND DEMONSTRATES SIGNIFICANTLY IMPROVED SURVIVAL IN A HISTORICAL COMPARISON WITH PATIENTS TREATED IN THE UK NCRI AML14 TRIAL

K. Hills,[1] S. O'Brien,[2] G. Schiller,[3] V. Karsten,[4] F. Giles,[5] A. Burnett[1]

[1]Cardiff University School of Medicine, CARDIFF; [2]University of Texas MD Anderson Cancer Center, HOUSTON TX; [3]UCLA School of Medicine, LOS ANGELES CA; [4]Vion Pharmaceuticals Inc, NEW HAVEN CT; [5]University of Texas Health Science Cetner, SAN ANTONIO TX, USA

Background. Among older patients with AML a considerable number are unlikely to benefit from intensive chemotherapy due to known poor risk factors. These patients have typically been treated with either best supportive care (BSC) typically involving hydroxyurea, or low dose Ara-C (LDAC). It has been shown that LDAC is superior to BSC in such patients;[1] however no remissions were induced in patients with adverse cytogenetics as defined by Grimwade (1998). Laromustine (Onrigin') is a novel sulfonylhydrazine alkylating agent which preferentially targets the O6 position of guanine resulting in DNA cross-links. Laromustine has shown clinical activity in patients with *de novo* AML and high risk MDS.[3] A confirmatory phase II study of single agent laromustine was conducted in previously untreated patients ≥60 years old with *de novo* AML, prospectively considered likely to be unfit for intensive chemotherapy. Patients had at least one poor risk factor, defined by age ≥70, performance status 2, unfavorable cytogenetics, or cardiac, pulmonary or hepatic dysfunction. Eighty-five patients received induction therapy with 600 mg/m^2 laromustine. *Aims.* To investigate outcomes for laromustine patients compared with a matched cohort from the NCRI AML14 trial. *Methods.* The 85 patients treated as part of this phase II study were combined with 55 patients fulfilling the same eligibility criteria from an earlier study of laromustine to form a cohort of 140 patients. A retrospective non-randomised comparison was performed between this cohort and 121 patients satisfying the same entry criteria treated in the UK NCRI AML 14 trial with either BSC or LDAC. Outcomes for patients with intermediate and adverse risk cytogenetics, according to the refined MRC criteria were performed.[4] *Results.* Patients in AML14 were slightly older than those treated with laromustine (median age 75 vs. 73), and tended to have higher white blood cell counts. Other important risk factors such as performance status and cytogenetics were similar between the groups. Overall 51/140 (36%) laromustine patients exhibited a response (CR/CRp) compared to 14/61 (23%) LDAC and 1/60 (2%) BSC patients. Importantly, 8/34 (24%) patients with adverse cytogenetics according to the refined criteria exhibited a response. LDAC or BSC did not result in remissions in patients with adverse cytogenetics. In the group of patients with adverse cytogenetics, laromustine also demonstrated significantly longer survival than LDAC (1 year OS 12% vs. 0%, HR 0.44, 95% CI 0.20-0.95), with borderline significant interaction between treatment effect and cytogenetics (p=0.05). There was significant benefit compared to BSC in all cytogenetic groups. *Conclusions.* Despite the well-known limitations of retrospective comparisons, laromustine induces more remissions in patients with adverse cytogenetics than LDAC or BSC. The achievement of remissions after laromustine therapy translates into significantly improved overall survival in patients that are unlikely to benefit from intensive chemotherapy.

RASGRP1/APTX RATIO IS A STRONG BIOMARKER WHICH PREDICTS RESPONSE TO THERAPY WITH TIPIFARNIB PLUS BORTEZOMIB IN ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA

C. Papayannidis,[1] P. Paolini,[1] E. Ottaviani,[1] I. Iacobucci,[1] F. Salmi,[1] B. Lama,[1] A. Curti,[1] S. Parisi,[1] D. Cilloni,[2] G. Saglio,[2] C. Candoni,[3] F. Morabito,[4] M. Raponi,[5] M. Baccarani,[1] G. Martinelli[1]

Background. Acute myeloid leukemia (AML) is characterized by a wide genetic heterogeneity, for which the identification of targeted-treatments for specific subset of patients is strongly required. A recent study based on microarray profiling identified RASGRP1/APTX gene expression ratio a selection criteria for predict responders to Tipifarnib (Zarnestra, Z), a farnesyltransferase inhibitor with demonstrated activity in AML patients. Interestingly, Z and Bortezomib (Velcade, V) appeared synergistic in AML cell lines; therefore, we designed a phase I/II study with Z and V in newly diagnosed, resistant or refractory AML elderly patients, unfit for conventional chemotherapy approach. *Aim.* In order to identify biomarkers to predict clinical response to each drugs, we performed a gene dosage analysis of candidate biomarkers, to assess the correlation between RASGRP1/APTX ratio and treatment response. *Methods.* We analyzed gene expression profile of several suggested genes predictive of response to Z (RASGRP1, APTX, SCAP2, AKAP13, AHR1, GAPDH-control gene) either on bone marrow (173 samples) or on peripheral blood (76 samples) of 126 patients with AML. *Results.* By quantitative RT-PCR assay of analyzed genes, we confirmed two candidates biomarkers RASGRP1 and APTX, identified by genes expression profile (Raponi *et al.*, Blood 2008). Their ratio was evaluated using the following formula: 2-DDCt(RASGRP1) / 2-DDCt(APTX) . Median value of RASGRP1 expression on BM was 2.70 (range 0.01-209.8) evaluated on 126 samples and 6.60 (range 0.18-444.16) on PBL, analyzed on 68 specimens. Median value of APTX expression on BM was 1.38 (range 0.01-80.6) evaluated on 126 samples and 1.24 (range 0.04-85.32) on PBL, evaluated on 68 samples. Median value of RASGRP1/APTX ratio was 2.02 (range 0.01-120.60) and 4.98 (range 0.12-102.4) on BM and PBL, respectively. Fifty one patients out of 68 were enrolled, treated and evaluable for treatment response (median age 72, 33 male/35 female). It is noteworthy

that the 7 patients who obtained a CR have a median RASGRP1/APTX ratio at screening of 15.29 (range 2.83-19.8) on BM samples and 29.03 (range 25.65-35.45) on PBL. On the contrary, among patients (40 pts) who were non responsive to therapy the median value of RASGRP1/APTX ratio at screening was 2.19 (range 0.46-32.7) on 31 BM samples and 4.90 (range 0.99-27.1) on 19 PBL specimens (p=0.002). *Conclusion.* RASGRP1/APTX ratio may be suggested to be performed for screening and selection to target clinical trial with Tipifarnib in AML.

BODY MASS INDEX IS AN INDEPENDENT PREDICTOR OF DIFFERENTIATION SYNDROME IN PATIENTS WITH ACUTE PROMYELOCYTIC LEUKEMIA

R. Jeddi,[1] H. Ghédira,[1] S. Mnif,[2] R. Ben Amor,[1] L. Aissaoui,[1] K. Kacem,[1] W. Bouteraâ,[1] R. Ben Lakhal,[1] A. Saad,[3] H. Ben Abid,[1] Z. Belhadjali,[1] B. Meddeb,[1] Z. Belhadjali,[1] Z. Belhadjali[1]

Differentiation syndrome (DS) can be a life-threatening complication in patients with acute promyelocytic leukemia (APL) undergoing induction therapy with all-trans retinoic acid (ATRA).Several factors have been associated with an increased risk of developing DS. The observation of several obese patients who developed DS led us to investigate this possible association in APL patients treated with an AIDA regimen. Between August 2004 and December 2008, 39 patients with APL genetically confirmed by t (15,17) and/or PML/RARA were treated with the PETHEMA LPA 99 protocol. Obese patients received adjusted doses of chemotherapy and ATRA on the basis of an adjusted Ideal Body Weight [IBW] (IBW+0.25 x [actual weight-IBW]). Seventeen patients were male and 22 female with a median age of 26 yrs (range,4-64).The median WBC 6.4×10^9/L (range,0.6-123.3). According to PETHEMA/GIMEMA risk stratification, 41% of patients were intermediate risk and 59% high risk. DS was observed in 11 patients with a median onset time of 12 days (range,3-23) and median WBC of 29×10^9/L (range,1.2-82.7). Five patients of 11 with DS had a BMI ≥35. All patients presenting WBC count $>10\times10^9$/L were on prednisone prophylaxis (1mg/kg from d1 to d15). In univariate analysis and then confirmed in multivariate analysis, we identified BMI ≥35 as an independent factor associated with both DS (p<0.0001, p=0.001) and ATRA-related complications (p=0.023, p=0.038) in addition to age >40 yrs and WBC $\geq20\times10^9$/L. As far as we know, this the first study that identifies high BMI as independent predictor of DS. Potential mechanisms implicated in the association between obesity and risk of developing DS should be investigated further.

A PHASE I STUDY WITH CP-4055 AND IDARUBICIN IN PATIENTS WITH REFRACTORY/RELAPSED AML

S. O'Brien,[1] D. Rizzieri,[2] S. Padmanabhan,[3] F. Ravandi,[1] T.F. Jacobsen,[4] K. Staudacher,[4] B.I. Nilsson,[4] F.J. Giles[3]

[1]*University of Texas, M. D. Anderson Cancer Center, HOUSTON;* [2]*Duke University Medical Center, DURHAM;* [3]*CTRC at the University of Texas Health Science Center, SAN ANTONIO, TEXAS;* [4]*Clavis Pharma ASA, OSLO, Norway*

Background. CP-4055 (elacytarabine [pINN]) is a novel cytotoxic nucleoside analogue. While CP-4055 has similar mechanisms of action to cytarabine, it is, unlike cytarabine, independent of nucleoside transporters for cellular uptake. *Aims.*Determination of safety, MTD, and recommended phase II dose (RP2D) of CP-4055 in patients with refractory/relapsed AML receiving CP-4055 in combination with idarubicin. *Methods.* Adult pts from whom informed consent was obtained received CP-4055 as continuous infusion over 24 h (CIV) in a d1-5 q3w schedule. The CP-4055 starting dose was 1150 mg/m^2/d in combination with a fixed dose idarubicin 12 mg/m^2/d in a d2-4 q3w schedule. *Results.* 15 pts (9 male and 6 female) with a median age of 51 years (range 21-76) were enrolled. All patients presented with refractory/relapsed AML. Six pts had received one and nine pts two or more previous chemotherapeutic regimens. Four pts (2 male, 2 female) were enrolled at the first dose level, 1150 mg/m^2/d and this was determined the MTD. Dose limiting toxicities (DLTs) were typhilitis and hand-foot syndrome. Eleven pts were enrolled at the dose level below MTD, 1000 mg/m^2/d. RP2D was determined at 1000 mg/m^2/d. One patient died on d19 due to sepsis. Related adverse events of CTCAE grade 3-4 (preliminary data) were typhilitis, hand-foot syndrome, tumour lysis syndrome, nausea, thrombocytopenia, leukopenia, neutropenia (ANC), klebsiella infection, all events reported only once. Clinical activity, 3 CR and 1 CRp, was recorded at the RP2D. All patients recorded with CR had previous therapy regimen(s) including ara-C. Two patients moved on to transplant. *Summary and Conclusions.* Toxicity was manageable when CP-4055 was administered CIV d1-5 q3w in combination with idarubicin. The recommended dose for CP-4055 was determined to be 1000 mg/m^2/d. Clinical activity, 3 CR and 1 CRp, was recorded. Efficacy and safety of this novel combination will be further elucidated in Phase II studies.

CNS MANIFESTION IN PATIENTS WITH ACUTE MYELOID LEUKEMIA SCHEDULED FOR ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

M. Bommer,[1] S. Von Harsdorf,[2] D. Bunjes,[2] H. Doehner,[2] M. Ringhoffer[2]

[1]*University of Ulm, ULM;* [2]*Department of Internal Medicine III, University of Ulm, ULM, Germany*

Background. Transplantation centres in Europe use heterogenic strategies concerning intrathecal (IT) prophylaxis as part of the conditioning regimen before allogeneic stem cell transplantation. An EBMT survey in 2005 (Ruutu *et al.*, BMT, 35: p.121) argued, that total body irradiation and busulfan both treat effectively the central nervous system (CNS) and did not recommend on IT prophylaxis due to lack of prospective data, neither pre- nor posttransplant. However, it remained unclear whether regular evaluations of the cerebospinal fluid (CSF) are performed in patients with acute myeloid leukaemia, who are scheduled for allogeneic transplantation at all and how the incidence of CNS involvement prior to allo-HSCT can be rated. This might be particularly important, because nowadays more AML patients suffering from refractory disease are treated and the more frequent use of fludarabine based reduced-intensity conditioning regimens leads to a reduced penetration of active cytotoxic drugs into the CNS. Here, we report on our prospective analysis evaluating the CSFs of 199 AML patients receiving an allogeneic HSCT at our centre in the years from 1997 to 2008. *Patients and Methods.* Between 1997 and 2008, 240 adult patients with AML received an allo-HSCT at our institution. The median age was 49 years at the time of transplant. Within this group, cerebrospinal fluids of 199 adult AML patients were examined for cell counts and if abnormal results were seen cytologically thereafter. A small fraction of patients did not get a CNS evaluation due to a high number of blasts in the peripheral blood, acquired coagulation disorders or technical problems. We did not use a routine flow-cytometry. All patients gave written informed consent. *Results.* In total, we identified 16/199 (8%) patients with cytologically proven CSF involvement with the half of the patients CNS expressing an AML FAB M4 or AML FABM5 phenotype. The cell counts at the timepoint of diagnosis ranged from normal to 1497/3 cells per µL CSF. Normal cell counts did not exclude CNS disease. In 8/16 of the patients the CNS disease was not expected, since they were clinically asymptomatic, and CNS involvement would not have been detected without a routinely scheduled examination. In a subgroup analysis, patients with refractory disease (11/52) had a significant higher risk for CNS disease when compared to patients responding to prior systemic therapy (21% versus 3.4%; p=0.0008, two sided Fisher's exact test). All patients received a prophylactic dose of 12 mg methotrexate during the diagnostic lumbar puncture. Patients with CNS involvement underwent a compartment directed approach with repeated courses of intrathecal chemotherapy or radiation of the neuro-axis after engraftment. *Conclusions.* In refractory AML patients scheduled for allogeneic hematopoietic stem cell transplantation, we found an unexpected high proportion of CNS involvement (21%). Since there were patients with CNS disease who were asymptomatic and had normal CSF cell counts, we emphasize on routine morphological CSF evaluations before starting conditioning in order to optimize posttransplant treatment strategies.

0312

FLAIE (FLUDARABINE, CYTARABINE, IDARUBICIN AND ETOPOSIDE) AS INDUCTION CHEMOTHERAPY OF ADULT ACUTE MYELOID LEUKEMIA. A PILOT STUDY REPORT

A. Candoni,[1] E. Simeone,[1] A. Michelutti,[1] D. Damiani,[1] D. Russo,[2] R. Fanin[1]

[1]Division of Hematology, UDINE; [2]Chair of Hematology and BMT, UNIVERSITY OF BRESCIA, Italy

The primary goal of this prospective phase II was to evaluate the efficacy and the safety profile of FLAIE as induction chemotherapy regimen in previously untreated AML. Fifty consecutive AML patients were included between 2003 and 2005. All patients were younger than 65 with a median age of 51 years (range 21-63). The M/F ratio was 19/31, and 37/50 (74%) of patients were poor-risk at diagnosis. The induction regimen (FLAIE) included Fludarabine (25 mg/sqm), Ara-C (2 g/sqm), Etoposide 100 mg/sqm on days 1-5, Idarubicin (6 mg/sqm) on days 1, 3, and 5. Patients were evaluated for response rate and treatment-related adverse events; Overall Survival and Relapse Free Survival were also reported. After induction with FLAIE, Complete Remission (CR) occurred in 63% of patients (31 of 49 evaluable cases); three patients (6%) achieved Partial Remission and 15 patients (31%) were resistant. There were two cases of death during induction (DDI 4%). The hematological and extra-hematological toxicity of FLAIE was acceptable. Infections occurred in 29/50 (58%) of patients including 18 episodes of bacteremia and 15 cases of pneumonia. Oral mucositis grade II-III WHO was reported in 11/50 (22%) of patients. Median time to neutrophil (> 1×10^9/L) and platelet (>50×10^9/L) recovery was 24 (range 18-42) and 26 days (range 20-45), respectively. Supportive treatment: 13 RBC units (range 10-28) and 9 PLT units (range 5-15). G-CSF was required in 22/50 (44%) of cases. After a median follow-up of 22 months (range 1-68), 19/50 (38%) patients are alive (19/19 in CR). The probability of 4-year OS and RFS were 36 and 30%. Allogeneic and autologus HSCT was performed in 36 (72%) and 4 (8%) of patients, respectively. These results suggest that the addition of Etoposide to FLAI scheme does not improve efficacy of FLAI alone in AML patients younger than 65 years. The FLAIE regimen appeared to have acceptable toxicity, but its efficacy was comparable with that of standard induction regimens.

0313

INDUCTION THERAPY WITH '3+7' CHEMOTHERAPY PLUS ATRA FOLLOWED BY CONSOLIDATIONS WITH THREE COURSES OF IDARUBICIN ALONE AND MAINTENANCE THERAPY WITH ATRA IN NEWLY DIAGNOSED ACUTE PROMYELOCYTIC LEUKEMIA HAS AN EXCELLENT LEUKEMIA-FREE SURVIVAL BUT MINIMAL TOXICITY IN LOW AND INTERMEDIATE RISK GROU

Y.C. Mun,[1] M.Y. Choi,[2] E.K. Cho,[3] J.H. Lee,[3] D.Y. Jo,[4] I.H. Kim,[5] S.M. Bang,[5] S.S. Yoon,[5] S.Y. Park,[5] B.K. Kim,[5] H. Kim,[6] Y.J. Min,[6] J.H. Park,[6] J.J. Seo,[6] H.N. Backgrounds. Currently, there are many efforts to design risk-adapted strategies according to predicted risk of relapse by modulating treatment intensity in newly diagnosed acute promyelocytic leukemia (APL) and this seems to be an efficient approach to minimize treatment-related morbidity and mortality (TRM) while maintain the potential in cure for each relapse-risk group. *Aims*. We performed a prospective multicenter trial in patients with newly diagnosed APL to examine the efficacy of our treatment protocol (induction therapy with "3+7" chemotherapy plus all-trans retinoic acid (ATRA) followed by consolidations with three courses of idarubicin alone and maintenance therapy with ATRA) and to compare this between the different risk groups. *Methods.* Eighty six patients with previously untreated *de novo* APL were enrolled in the multicenter AML-2000 trial after informed consent was obtained from January 2000 to July 2007. For remission induction therapy, patients received oral ATRA (45 mg/m^2/d, maintained until CR) combined with idarubicin (12 mg/m^2/d, D1-D3) plus cytarabine (Ara-C, 100 mg/m^2/d, D1-D7). After CR achievement, they received 3 monthly consolidation courses consisting of idarubicin (12 mg/m^2/d, D1-D3) alone and maintenance therapy with ATRA (45 mg/m^2/d, D1-D15, every 2 month) alone was continued for 2 years. Total patients was divided to low-risk, intermediate-risk and high-risk groups according to a predictive model for relapse risk (Sanz score) based on pretreatment WBC and platelet count and the treatment outcomes were compared in the different risk groups. *Results.* The median age of total patients was 40 years old (range; 6-80) and median follow-up was 27 months (range; 1-90). The distribution of patients in the 3 risk groups was as follows ; 28 (32.6%) patients in low-risk, 40 (46.5%) in intermediate-risk and 18 (20.9%) in high-risk. Overall, CR was achieved in 78 (90.7%) of 86 patients. The CR rate according risk groups was 96.4% in low-risk, 87.5% in intermediate-risk, and 88.9% in high-risk group and there was no significant difference between the different risk groups. During induction therapy, 48 (55.8%) patients experienced grade 3-4 treatment-related toxicity (TRT), mostly fever and infection (38.8% of all patients) and 6 (7.0%) patients died of treatment-related complications. During 3 consolidation courses, 25 (29.1%) of 78 patients experienced grade 3-4 TRT in 1st course, 27 (36.0%) of 75 patients in 2nd course, and 14 (28.0%) of 50 patients in 3rd course. Overall, 3 (3.5%) patients died of treatment-related complications in CR. The incidence of TRT and treatment-reated mortality (TRM) during induction or consolidation therapy showed no significant difference between the different risk groups. The relapse occurred in 6 (7.0%) patients; 2 cases in intermediate-risk and 4 cases in high-risk. 5 patients among them relapsed during consolidation courses and the other patient relapsed during maintenance therapy. The overall survival (OS) and leukemia-free survival (LFS) rate at 7 years in all of patients was 76.7% and 83.5%, respectively. The OS rate at 7 years was 92.9% in low-risk, 78.6% in intermediate-risk and 53.6% in high-risk group and the LFS rate at 7 years was 96.4%, 83.4% and 62.2% respectively, showing the significant difference between 3 different risk groups. *Conclusions.* This study indicates that our protocol composed of induction therapy with "3+7" chemotherapy plus ATRA followed by consolidations with three courses of idarubicin alone and maintenance therapy with ATRA yields a high CR rate and low relapse rate but minimal acceptable toxicity despite of adding Ara-C in induction therapy, leading to excellent outcome in LFS and OS, in low and intermediate risk group. Meanwhile, considering that in high-risk group, the relapse rate was significantly higher than other risk groups and most of the relapses occurred in the middle of consolidation courses. This study suggests that our consolidation therapy composed of anthracycline alone is not enough to minimize risk of relapse in high-risk group in contrast with the low- and intermediate-risk groups. More intensive consolidation therapy combined with Ara-C or ATRA or hematopoietic stem cell transplantation in first CR or the combination of arsenic trioxide in front-line therapy may be considered in the patients with high-risk of relapse.

MORPHOLOGIC AND MOLECULAR CHARACTERIZATION OF LEUKEMIC TUMORS IN THE BREAST: IMPLICATIONS FOR RESISTANCE TO CHEMOTHERAPY

I. Cunningham,[1] Cordon-Cardo's[2]

[1]Columbia University, NEW YORK; [2]Department of Pathology, Columbia University, NEW YORK, USA

Background. We have previously demonstrated in a review of 153 cases that leukemic tumors in the breast, occurring in both AML and ALL, are mainly reported in women under 50, before, during, or up to 8 years after chemotherapy or transplant (Leuk Lymphoma 12/06). The occurrence of leukemic localization in the breast constitutes a poor prognostic factor independent of FAB classification, white blood cell count, and karyotype. Treatment with conventional anti-leukemic drugs rarely eradicates the disease, which was noted to subsequently follow a path of extramedullary soft-tissue progression, in many cases in ipsi- and contralateral breasts and pelvic organs, regardless of marrow remission status. Moreover, only 8% of cases of marrow leukemia with breast involvement at any time remain disease-free at 3 years. Evidence suggests that proliferation of leukemia in the premenopausal breast responsible for relapse may occur more frequently than is reported and it appears to be resistant to standard chemotherapy protocols. Thus, elucidation of the biologic behavior of these leukemic cells is critical to understand their intrinsic resistance to chemotherapy. Such an understanding holds the potential for the development of novel and effective therapeutic strategies. *Aim.* The aim of the present study was to characterize morphologic and molecular features of a series of leukemic breast tumors. *Methods.* Immunohistochemical studies were performed on formalin-fixed, paraffin-embedded, tissue sections of 14 cases contributed by authors of case reports, on an IRB-approved protocol. Sections of 5-µm thickness were deparaffinized, dehydrated and stained with H&E for an evaluation of the morphologic characteristics of the leukemic and epithelial cell populations. To evaluate the presence of aberrant signaling pathways, selected sections were subjected to immunohistochemistry using standard techniques. Primary antibodies consisted of anti-pERK, anti-pAKT, anti-p53, anti-pEGFR, estrogen and progesterone receptors, and cytokeratin 18. For negative controls, the primary antibodies were replaced by a non-specific IgG. Visualization of antigen-antibody complexes, after incubation with the appropriate secondary antibodies, was performed with a streptavidin-peroxidase staining kit following manufacturer's instructions. Slides were counterstained with H&E prior to microscopic evaluation. *Results.* The lesions were characterized by dense infiltration by leukemic blasts with marked fibrosis and distortion of normal breast architecture. Leukemic cells were negative for estrogen and progesterone receptors, pEGFR, and cytokeratin 18, confirming the tumors were not of epithelial origin. Leukemic cells showed a strong immunoreactivity for phosphorylated ERK in 77% of cases. There was strong immunoreactivity to phosphorylated AKT in 62%. Importantly, the adjacent normal tissues were negative. p53 was wild-type in all cases. *Conclusions.* Our results show that leukemic breast tumors are characterized by increased immunoreactivity for activated ERK and AKT compared to adjacent normal tissue. These results suggest that resistance of leukemia growing as extramedullary tumors, often in a pattern of hormonally-active sites, is associated with activation of the PI3K/AKT and ERK pathways, known to be correlated with cell proliferation, resistance to apoptosis, and resistance to chemotherapy. Thus, targeting the ERK/AKT pathways could provide, in combination with marrow-directed therapies, a novel approach to overcome the chemoresistance of these tumors.

FINAL RESULTS. RESPONSE PREDICTION IN IMATINIB-TREATED CML BY EXPRESSION PROFILING

S. Schmidt

Medical University Innsbruck, INNSBRUCK, Austria

Background. CML treatment in era of 1st and 2nd generation TKIs is guided by monitoring cytogenetic and molecular therapy response. The next step ahead towards a further personalized medicine would be response prediction prior to treatment. Although, expression profiling was proven to allow this for other entities, data from previous studies in CML are conflicting, mostly because of the different technical platforms and rather small patient populations used. *Aims.*This profiling study aimed to establish a robust gene set for imatinib response prediction. Ideally, the resulting gene set should consist of few enough genes to be cost effectively and routinely used with inexpensive technologies like real time PCR. *Methods.* Blood samples from at total of 135 pretreated CML patients with early or late chronic phase disease were collected prior to and six weeks after treatment with either 400 mg/day for 12 months or 800 mg/day for 6 months followed by 6 months of 400 mg imatinib therapy. Cytogenetic response and molecular response were monitored. Whole blood samples preserved by PAX gene technology were further processed and evaluated centrally at the expression profiling core facility at Innsbruck Medical University. For expression profiling samples were subjected to hemoglobin mRNA reduction before target preparation for hybridization to Affymetrix hGU133 Plus 2 genechips detecting ~47000 transcripts thereby allowing a whole genome profiling approach. Genes expressed differentially between responders and non-responders prior to and after 6 weeks of treatment were determined. For response prediction we used linear discriminatory analysis (LDA) provided in Bioconductor software packages for the open source statistical language *R*. A 1000- or 100-fold crossvalidation was performed using a robust leave-10-out setting. Additionally imatinib response was analyzed according to molecular response at 12 months and where available based on intra-patient comparisons of samples prior to and after 6 weeks of treatment. For condensing the resulting gene sets we applied recursive feature elimination (RFE). *Results.* Preliminary results presented at EHA 2008 revealed a set of 40 genes which allowed a mean correct prediction of 84.2% corresponding to positive and negative predictive values of 0.89 and 0.78, respectively. Here we present the final analysis of all evaluable patients and subgroups and additional Gene Set Enrichment Analyses based on candidate genes sets from the literature. *Conclusions.* Intra-patient comparisons and subgroup analysis allowed to refine candidate selection and resulted in a imatinib response predicting gene set based on this -so far largest- prospective multicenter gene expression profiling study.

0316

CD34+ OBTAINED FROM HIGH SOKAL RISK CHRONIC MYELOID LEUKEMIA PATIENTS EXPRESSES GENE PROFILES SIGNIFICANTLY DIFFERENT FROM CD34+ OBTAINED FROM LOW AND INTERMEDIATE SOKAL RISK PATIENTS

S. Durante,[1] C. Terragna,[2] A. Astolfi,[3] F. Palandri,[2] F. Castagnetti,[2] G. Rosti,[4] N. Testoni,[2] S. Luatti,[2] I. Iacobucci,[2] T. Kalebic,[5] S. Soverini,[2] M. Amabile,[2] A. Poerio,[2] M. Baccarani,[2] G. Martinelli[2]

[1]Inst. of Hemat. Med. Oncol. Seràgnoli, BOLOGNA; [2]Inst. of Hemat.Med Oncol Seràgnoli, BOLOGNA; [3]Ped.Onc.and Hemat., BOLOGNA; [4]Insitute of Hematology Seragnoli, BOLOGNA; [5]Novartis Oncology, NEW JERSEY, USA

Background. CML is a clonal myeloproliferative disease which typically presents in chronic phase (CP), in which malignant progenitor cells proliferate rapidly, still retaining their ability to differentiate, with the disease later evolving to accelerated phase/blast crisis. Even after the introduction of imatinib, the calculation of the Sokal and the Euro prognostic scores has remained essential in clinical practice, since allow to stratify chronic myeloid leukemia (CML) pts at different evolutive risk at diagnosis, guiding therapeutic decisions. More recently, numerous research efforts, (which use high-throughput molecular approaches) are ongoing to gain a better understanding about the intrinsic heterogeneity of CML. *Aim.* Here we present data obtained from expresses gene profiles (GEP) experiments aimed at the identification of genes and pathways able to predict and/or to elucidate the disease course of CP-CML pts at the onset of the disease. *Patients and Methods.* The study was per-

formed on highly enriched CD34+ cells from peripheral blood obtained from pts with untreated CML in CP. Overall, 27 pts were included in the present analysis. GEP was performed using the Affymetrix HG-U133 Plus 2.0 platform. Raw data was normalized using the RMA algorithm and filtered. Genes associated with Sokal risk score were selected by a moderated t-statistic (Limma package, p-value threshold = 0.01). Hierarchical clustering was performed with TIGR MeV. *Results.* In the initial part of the study, the first 14 CML pts (the *training set*) were successfully assayed for global GEP and microarray data were used to define genes differentially expressed in high (6 pts) vs. low (8 pts) Sokal risk pts, thus identifying 89 probes set; clustering of their GEP showed an homogeneous pattern in high Sokal risk pts, where up-regulated genes are mainly related to the positive regulation of immune response (CR1, UBASH3A, EREG, C4B) and to the induction of apoptosis (CD38, TNFRSF25, Apoe, TIMP3) , whereas down-regulated genes are mainly involved in the negative regulation of metabolic processes. Of note, among the most significantly up-regulated genes are ABCC4, an ATP-binding cassette (ABC) transporter and LAT, which is phosphorylated by ZAP-70/Syk protein tyrosine kinases following activation of the T-cell antigen receptor (TCR) signal transduction pathway. Among the most significantly down-regulated genes is PLCB1, which we recently described as being deleted in myelodysplastic syndromes and in myeloid acute leukemia. In the second part of the study, the 89 probes set differentially expressed in the training set were tested on an independent test set of 13 CML pts, including 4 high, 4 intermediate and 5 low Sokal risk pts. The test set GEP clustering displayed the same trend observed in the training set and, while low and intermediate risk pts resulted quite scattered, high risk pts clustered together. *Conclusions.* Overall, our data suggests that the expression at diagnosis of a particular array of genes might drive the evolutive risk of CML pts.

EVALUATION OF THE PROTEASOMAL EFFECTS OF TYROSINE KINASE INHIBITORS AND BORTEZOMIB IN CHRONIC MYELOID LEUKAEMIA

M. McCloskey, M.F. McMullin, B. Walker, A.E. Irvine

Queen's University of Belfast, BELFAST, Northern Ireland

Background. Chronic myeloid leukaemia (CML) harbours cells which are resistant to the tyrosine kinase inhibitors imatinib and dasatinib irrespective of treatment duration. Proteasomes degrade intracellular protein through their catalytic β 1 (chymotrypsin-like activity), β 2 (trypsin-like activity), and β 5 (caspase-like activity) subunits. We have previously shown that BCR-ABL inhibition reduces proteasome proteolytic activity. The proteasome inhibitor bortezomib induces apoptosis in leukaemic cells by inhibiting the chymotrypsin-like activity of the β 5 subunit, and is a potential therapy in CML. *Aims.* The first aim of this study was to determine how therapeutically achievable concentrations of bortezomib affect proteasome expression and function in BCR-ABL positive cells. The second aim was to elucidate the mechanism by which imatinib or dasatinib reduce proteasome activity in BCR-ABL positive cells. *Methods.* Bone marrow aspirates were performed on patients with newly diagnosed CML. Mononuclear cells were obtained by Ficoll separation and were incubated for 24 hours with 0, 5, 10, and 20 nM bortezomib to examine the effect of proteasome inhibition on proteasome expression and activity. BCR-ABL is maximally inhibited by 1 μM imatinib or 1nM dasatinib, and cells were incubated for 24 hours with these concentrations to investigate the effect of tyrosine kinase inhibition on proteasome expression and activity. Three specific fluorogenic substrates, Suc-Leu-Leu-Val-Tyr-AMC, Z-Ala-Ala-Arg-AMC, and Z-Leu-Leu-Glu-AMC were used to measure the chymotrypsin-like, trypsin-like and caspase-like activities of the proteasome respectively. Proteasome subunit expression was measured by real-time PCR and Western blotting. *Results.* There was a concentration dependent reduction in each of the proteasome activities with increasing concentrations of bortezomib. All three proteolytic activities were significantly reduced after 24 hours incubation with 20nM bortezomib ($p<0.05$; n=4). At 10nM and 20nM bortezomib there was a significant increase in the RNA expression of the β 1 and β 5 subunits and increased expression of the β 2 subunit at 20 nM bortezomib ($p<0.02$; n=3). Western Blotting demonstrated that all three concentrations of bortezomib increased proteasome subunit levels ($p>0.05$; n=3). Incubation with imatinib or dasatinib for 24 hours did not alter proteasome proteolytic activity significantly ($p>0.05$; n=4). RNA expression of the β 5 subunit was significantly reduced by imatinib or dasatinib, and β 1 subunit expression was reduced by dasatinib alone ($p<0.05$; n=4). Using Western Blotting, proteasome subunit levels were reduced by both imatinib and dasatinib ($p>0.05$; n=3). *Conclusion*. Bortezomib reduced proteasome proteolytic activity in BCR-ABL positive cells. These cells compensated for proteasome inhibition by increasing proteasome expression. Imatinib and dasatinib reduced proteasome expression, but this did not affect proteasome proteolytic activity at 24 hours. These novel findings suggest that by reducing proteasome expression and ultimately proteolytic activity, tyrosine kinase inhibitors may target the toxic effects of bortezomib to BCR-ABL positive cells.

Background. Deletions adjacent to the breakpoint on derivative chromosome 9 [der(9)] have been reported in a subset of Chronic Myeloyd Leukemia (CML) patients and have been associated with an adverse outcome with conventional drugs and α-interferon. Huntly *et al.* (Blood 2003) suggest that der(9) deletions are associated with lower response rates and shorter time to progression. Quintas-Cardama *et al.* (Blood 2005) did not find any difference related with der(9) deletions. In these 2 studies, some patients received imatinib in early CP (51 and 152, respectively) while many patients (224 and 168, respectively) were treated in late CP. European LeukemiaNet (ELN) recommendations include der(9) deletions among the *warnings*, requiring a careful monitoring of the patient. *Aim.* To investigate the prognostic value of der(9) deletions, we performed an analysis by age groups of 3 concurrent clinical trials of the GIMEMA CML Working Party (Clin Trials Gov. NCT00514488, NCT00510926 and the observational trial CML/023). *Methods.* 559 consecutive CML patients in early CP have been enrolled from January, 2004 to January, 2007. The presence of a der(9) deletion has been investigated by FISH in 521/559 at enrollment: 60 (12%) showed a der(9) deletion and 461 (88%) did not. The 2 groups, with/without deletions, were comparable (no significant difference in age, Sokal risk, imatinib dose). Median observation time is currently 42 (1-64) months. FISH analysis of bone marrow cells at diagnosis was performed using BCR/ABL extra-signal, D-FISH or dual-color dual-fusion probes. Response monitoring was based on conventional cytogenetic examination every 6 months and quantitative molecular (Q-PCR) evaluations (PB) after 3, 6 and 12 months on imatinib (every 6 months thereafter). Definitions: Complete Cytogenetic Response (CCgR): 0% Ph+. Major Molecular Response (MMR): BCR-ABL/ABL ratio <0.1%IS . Events (ELN criteria for *failure*): no CHR at 6 months, no CgR at 6 months, no PCgR at 1 year, no CCgR at 18 months, loss of CHR, loss of CCgR, progression and death. *Results.* Overall, the cumulative incidence of CCgR and MMR was 92%/91% and 88%/87% in patients with/without der(9) deletions. The probability of Event Free Survival, Progression Free Survival and Overall Survival was 82%/80%, 89%/90 and 93%/91 respectively. No difference was statistically significant. *Conclusions.* When investigated by FISH, the presence of der(9) deletions do not constitute a poor prognostic factor in early CP CML patients treated with imatinib: the cytogenetic and molecular response rates in the 2 groups, with and without der(9) deletions, are superimposable. No differences in outcome have been observed. This long-term outcome evaluation suggests that a redefinition of ELN *warnings* would be advisable.

PRESENCE OF BCR-ABL POSITIVE CELLS AND DIAGNOSIS OF CHRONIC MYELOID LEUKEMIA IN IMMUNE SUPPRESSED ORGAN TRANSPLANT RECIPIENTS

P. le Coutre,[1] P. Reinke,[1] R. Neuhaus,[2] R. Trappe,[3] F. Ringel,[3] M. Lalancette,[4] P. Hemmati,[3] B. Dörken,[5] P. Daniel[3]

[1]Charité Universitätsmedizin Berlin, BERLIN; [2]Charite, BERLIN, Germany; [3]Charité, BERLIN, Germany; [4]Centre Hospitalier Universitaire de Quebec, QUEBEC, Canada; [5]Charitè, BERLIN, Germany

Background. Spatial proximity of specific chromosomes during the cell cycle may predispose to leukemogenic translocations, including t(9;22), t(15;17) and t(8;21). In patients with an impaired immune surveillance, cells carrying any of these alterations may become phenotypically relevant. *Aims.*Therefore, immunosuppressed solid organ recipients represent an optimal population to address the frequency of mRNA products (BCR-ABL, PML-RARα or AML1-ETO) of these translocations. *Methods.* Blood leukocytes were studied in 201 individuals (100 organ recipients and 101 control individuals) for the presence of BCR-ABL, PML-RARα and AML1-ETO transcripts by a nested reverse transcriptase-polymerase chain reaction assay, routinely used in our institution. *Results.* In 5/100 immunosuppressed patients (5%), at least one out of two rt-PCR products was BCR-ABL positive while all controls were negative. In two of these five patients a 12-month follow-up sample was available and was tested BCR-ABL negative. These findings are extended by three cases of solid organ transplant recipients who developed chronic myeloid leukemia (CML) in a total of 2088 transplantations in nine years suggesting a higher incidence of CML in these patients. A fourth case of CML in an immunosuppressed solid organ recipient occured in another centre. No individual was positive for PML-RARα or AML1-ETO transcripts. Aside from immunosuppression, DNA damage caused by immunosuppressant drugs such as azathioprine or 6-mercaptopurine may be an additional factor in the occurrence of bcr-abl transcripts in non-leukemic patients. However, *in vitro* exposure of BCR-ABL negative leukemic cell lines to azathioprine or 6-mercaptopurine did not generate BCR-ABL transcripts. *Conclusions.* This suggests that immune suppression, but not treatment-associated DNA damage may contribute to the presence of BCR-ABL transcripts or CML in suppressed organ transplant (SOT) recipients.

0320

THE ROLE OF THE FANCONI ANEMIA D2 (FANCD2) PROTEIN IN BCR/ABL-MEDIATED LEUKEMOGENESIS

T. Stoklosa,[1] M. Koptyra,[2] G. Hoser,[3] E. Glodkowska,[1] I. Seferynska,[4] T. Skorski[2]

[1]The Medical University of Warsaw, WARSAW, Poland; [2]Temple University School of Medicine, PHILADELPHIA, USA; [3]Medical Center for Postgraduate Education, WARSAW, Poland; [4]Institute of Hematology and Blood Transfusion, WARSAW, Poland

Background. BCR/ABL oncogenic tyrosine kinase transforms hematopoietic stem cells, also can increase DNA damage and compromise the fidelity of DNA repair causing genomic instability. We have shown that BCR/ABL-mediated leukemogenesis is associated with the elevation of reactive oxygen species (ROS), which may increase the number of oxidative DNA lesions including DNA double-strand breaks (DSBs). BCR/ABL-positive leukemia cells appear to accumulate an excess of ROS-induced DSBs, which may cause apoptosis if not repaired. We reported before that homologous recombination repair (HRR), involving RAD51 protein, plays a pivotal role in the response of BCR/ABL-positive leukemia cells to numerous DSBs induced by ROS. Fanconi D2 protein (FANCD2), a member of the Fanconi protein family, is monoubiquitinated on K561 by FANCL ubiquitinase and phosphorylated by ATM on S222 in response to DSBs. The K561 monoubiquitinated form of FANCD2 (FANCD2-Ub) interacts with RAD51 to facilitate HRR, and phosphorylation of FANCD2 on S222 is important for activation of S phase checkpoint. *Aims.* Determining the role of Fanconi D2 protein in genetic instability of chronic myeloid leukemia (CML) cells. *Methods.* Mo7e human myeloid GM-CSF-dependent and PD20 lymphoblast cells were used (wt and BCR/ABL-transformed). CD34$^+$ CML stem/progenitor cells from chronic phase (CML-CP) blast crisis (CML-BC) and CD34$^+$ cells from healthy donors were used after receiving informed consent. FANCD2$^{-/-}$ and wild type cells were from murine bone marrow. Vitamin E (VE) or N-acetylcysteine (NAC) were used as antioxidants. *Results.* We detected an increased amount of FANCD2-Ub in BCR/ABL-positive leukemia cell line and CD34$^+$ CML-CP and CML-BC cells in comparison to normal counterparts. This effect was not associated with up-regulation of FANCD2 ubiquitinase FANCL or down-regulation of FANCD2 deubiquitinase USP1, but was reversed after inhibition of BCR/ABL kinase with imatinib and reduction of ROS with antioxidants. Therefore we postulate that BCR/ABL kinase-dependent ROS-induced FANCD2-Ub may play a role in leukemic transformation. This hypothesis is supported by impaired transformation potential of BCR/ABL kinase in FANCD2$^{-/-}$ cells in comparison to wild-type counterparts. Restoration of the expression of FANCD2 protein in FANCD2$^{-/-}$ cells rescued the transforming potential of BCR/ABL kinase. In addition, expression of BCR/ABL kinase, but not the kinase-deficient K1172R mutant, inhibited the proliferation rate of FANCD2$^{-/-}$. The growth defect of BCR/ABL-positive FANCD2$^{-/-}$ cells was accompanied by delayed leukemogenesis in SCID mice. Growth potential of BCR/ABL-positive FANCD2$^{-/-}$ could be rescued by co-expression of FANCD2 wild-type and S222A mutant, but not the K561R mutant. This observation supports our hypothesis that K561 monoubiquitination, but not S222 phosphorylation of FANCD2 might play an important role in BCR/ABL-mediated transformation. Elevated levels of ROS-mediated DSBs in BCR/ABL-positive FANCD2$^{-/-}$ cells did not cause any significant changes in cell cycle distribution, but resulted in discrete but persistent apoptosis. Scavenging ROS by antioxidants reduced the number of DSBs and eliminated the growth defect in BCR/ABL-positive FANCD2$^{-/-}$ cells (Figure 1) without affecting their wild-type counterparts . *Summary and conclusions* We hypothesize that FANCD2-Ub, but not FANCD2-phosphoS222 may play an important role in BCR/ABL-dependent leukemogenesis and transition from chronic phase to the fatal blast crisis in CML, probably due to its ability to interact with RAD51 and facilitate HRR of the numerous ROS-induced DSBs.

Background. Chronic myeloid leukemia (CML) is a myeloproliferative disease characterized by the presence of the Philadelphia (Ph) chromosome and Bcr-Abl oncoprotein. Bcr-Abl is a tyrosine kinase (TK) which presents a deregulated activity associated with proliferation and accumulation of myeloid cells and their precursors. Much attention has been focused on the development of novel therapies based on mechanistic understanding of Bcr-Abl signaling in CML cells. Imatinib (IM), a tyro-

sine-kinase inhibitor (TKI), became the first choice drug in chronic phase CML. Despite of a promising IM clinical response, approximately 20-25% presents resistance caused by the appearance of clones expressing mutant forms of Bcr-Abl. Second-generation TKIs like Dasatinib and Nilotinib have provided new therapeutic option for the patients resistant to IM. These observations emphasize the importance of better elucidate the CML physiopathology. *Aims.*To determine miRNA global expression in HL60.Bcr-Abl and to associate them with apoptosis resistance. *Methods.* A concentration of 107 of the promyelocytic leukemia cell line (HL-60) and HL-60 transfected with the plasmid pSRαMSVp185bcr-abl tkneo which contains bcr-abl was submitted to RNA extraction by TrizolTM method and reverse transcription was performed with specified primers RT stem loop (Applied ByosistemsTM) for each miRNA. TaqManTM MicroRNA Assays Human Panel Early Access Kit (Applied ByosistemsTM) was used to miRNA global expression assay at ABIPRISM 7500 Real Time PCR (Applied BiosystemsTM). The miRNAs differentially expressed in HL60 and HL60.Bcr-Abl was analyzed by the fold change and was considered those genes with a fold change above 2.5. miRanda method was used to identify the miRNAs targets genes, the biological processes and the pathways which miRNAs are involved were determined by Gene Ontology and Kegg or Biocarta, respectively. *Results.* HL-60.Bcr-Abl in comparison to HL-60 presented fourteen up-regulated miRNA (miR-145, miR-96, let-7e, miR-16, miR-21, miR-26a, miR-130b, miR-132, miR-324-5p, miR-130a, miR-15b, miR-30e, miR-26b and miR-326) and twenty-three down-regulated (miR-15a, miR-29c, miR-152, miR-103, miR-23a, miR-198, miR-214, miR-133a, miR-106, miR-181c, miR-141, miR-150, miR-98, miR-125b, miR-142-3p, miR-200a, miR-155, let-7d, miR-302d, miR-204, miR-99a, miR-203 and miR-221). miR-145 was the more expressed miRNA with a fold change of 325.96 and some miR expression was absent in HL-60.Bcr-Abl. The majority of these miRNAs have as targets genes important for cell toxicity, apoptosis regulation, JAK-STAT, AKT, mitochondrial and caspases signaling pathways. *Conclusions.* Bcr-Abl may modulate several miRNAs which is responsible for cell apoptosis resistance phenotype. The results obtained could contribute for the description of the new molecules which could help to elucidate the resistance by TKI, CML progression and apoptosis resistance.

BOSUTINIB (SKI-606) COOPERATES WITH DASATINIB IN COUNTERACTING GROWTH AND VIABILITY OF CML CELLS CARRYING THE T315I MUTANT OF BCR/ABL

K.V. Gleixner,[1] L.L. Remsing Rix,[2] U. Rix,[2] R.A. Meyer,[1] H. Herrmann,[1] K. Schuch,[1] W.F. Pickl,[1] C. Sillaber,[1] M. Augustin,[3] J.H. Till,[3] G. Superti-Furga,[2] P. Valent[1]

[1]Medical University of Vienna, VIENNA, Austria; [2]Center for Molecular Medicine, VIENNA, Austria; [3]Millipore UK Ltd., DUNDEE, UK

Chronic myeloid leukemia (CML) is a stem cell disease defined by the Philadelphia chromosome and the related chromosome translocation, t(9;22). The ABL tyrosine kinase inhibitor (TKI) imatinib is effective in most patients and considered standard first line therapy. However, not all patients show a long-lasting response. Treatment failure is usually associated with the occurrence of imatinib-resistant BCR/ABL mutations. For these patients, novel TKI such as dasatinib represent alternative treatment options. Still, however, not all patients respond to these drugs, especially when leukemic cells bear the BCR/ABL mutant T315I that confers resistance against most TKI. Bosutinib is a novel multi-kinase inhibitor that has been described to act growth-inhibitory in BCR/ABL-transformed leukemic cells. In the present study, we examined the effects of bosutinib alone or in combination with dasatinib on growth and survival of primary CML cells (chronic phase CML, n=5, accelerated phase, n=1) and various CML cell lines. Bosutinib was found to inhibit 3H-thymidine uptake and thus proliferation in imatinib-sensitive and imatinib-resistant K562 cells in a dose-dependent manner, with comparable IC_{50} values (10-100 nM). Moreover, bosutinib was found to inhibit the growth of primary CML cells and Ba/F3 cells bearing various imatinib-resistant mutants of BCR/ABL, except T315I (IC50>1 μM). The growth-inhibitory effects of bosutinib were found to be associated with cell cycle arrest and signs of apoptosis. Dasatinib showed similar effects, but again did not block the growth of leukemic cells bearing BCR/ABL T315I. Unexpectedly, however, we found that bosutinib and dasatinib synergize with each other in producing growth inhibition in primary CML cells exhibiting BCR/ABL T315I at pharmacologic concentrations (0.01-1 μM). Clear synergistic effects were also observed in imatinib-sensitive and imatinib-resistant K562 cells as well as in Ba/F3 cells bearing BCR/ABL T315I. We also performed multiplexed kinase assays as well as chemical proteomics analysis and mass spectrometry using K562 cells and primary CML cells and coupleable dasatinib and bosutinib analogues. In these experiments, dasatinib and bosutinib were found to express an overlapping but non-identical profile of target kinases. As expected, both drugs were found to bind to wt ABL, SRC kinases, and TEC-family kinases including BTK. Targets preferentially bound and inhibited by bosutinib were STE20s, the FES/FER family, CAMKIIG, PYK2 and TBK1. We were also able to confirm that the dasatinib-targets KIT and PDGFRA are not recognized by bosutinib. Interestingly, whereas wt ABL (IC_{50}<0.5 nM) and most of the ABL mutants tested (H396P, M351T, Q252H, and Y253F) were all completely inhibited by both drugs at 1 μM in the kinase assay, the ABL T315I mutant was inhibited by bosutinib (IC_{50}=26 nM) almost 70 times more potently than by dasatinib. Together, these data show that bosutinib and dasatinib synergize with each other in producing antileukemic effects on CML cells including leukemic cells expressing BCR/ABL T315I. These synergistic effects may be explained by differential target kinase profiles and by the fact that bosutinib retains some activity against the T315I mutant.

EFFECT OF IMATINIB MESYLATE ON SERUM SOLUBLE VASCULAR ENDOTHELIAL GROWTH RECEPTOR-R2 AND MICROVESSEL DENSITY IN BCR-ABL POSITIVE CHRONIC MYELOID LEUKEMIA

S.U. Mogalluru,[1] P. Pati,[2] S. Saxena[2]

[1]Kokilaben Dhirubhai Ambani Hospital, MUMBAI; [2]All India Institute of Medical Sciences, NEW DELHI, India

Background and Purpose of the study. Angiogenic markers like serum vascular endothelial growth factor/receptors (sVEGF/sVEGF-R1 and R2) and Micro vessel density (MVD), as prognostic factors have been studied in chronic myeloid leukemia (CML). The degree of angiogenesis adversely affects the clinical and hematological prognostic indicators. VEGF mediates its role in angiogenesis through interaction of cellular and soluble receptors namely VEGF-R1 and R-2. Studies have shown that bone marrow cells in CML patients express very high levels of VEGF-R1 and R2 on their surface 1. Though the effect of Imatinib mesylate on VEGF and MVD in CML has been studied, such an effect on both cellular and serum soluble VEGF-R2 (sVEGF-R2) has not been studied so far. *Aim.* Our study aims at evaluating the effect of Imatinib mesylate on angiogenic parameters viz; sVEGF-R2 and MVD after a minimum of three months of imatinib therapy and to correlate the clinico-hematological and molecular parameters in BCR-ABL positive CML patients prospectively. *Patients and Methods.* Thirty-two newly diagnosed CML patients, comprising of 21,8,3 patients in chronic phase (CP), accelerated phase (AP) and blastic phases (BP) respectively, were included in the study. BCR-ABL by RT-PCR, base line serum sVEGF-R2 and a bone marrow biopsy for MVD estimation were done and the patients were put on imatinib mesylate at a dosage of 400, 600, and 800 mg/d for CP, AP and BP respectively. These were repeated after a minimum of 3 months of imatinib therapy. MVD was determined by mean micro vessel counts per 10 high power fields on bone marrow biopsies subjected to immunohistochemistry with CD34 monoclonal antibody (Dako) by immunoperoxidase technique in all cases and in 16 chronic ITP cases which served as controls. Serum soluble VEGF-R2 was done by ELISA (Bender Med systems) in 32 patients and 16 normal healthy controls. *Results.* Fourteen of 21 (67%) patients in CML-CP achieved hematological remission (HR) only and 7/21(33%) achieved both HR and BCR-ABL negativity by RT-PCR. Only one patient in AP and none of the BP patients achieved HR and BCR-ABL negativity. Both angiogenic parameters before the therapy were higher in all phases of CML than the normal controls. They were highest in the BP followed by AP and CP. Seven of 21(33%) CP patients who had achieved both HR and BCR-ABL negativity were found to have a statistically significant (p<0.001) reduction in the levels of both angiogenic parameters after a minimum of 3 months of imatinib therapy. However, no significant reduction in these parameters was found in all AP, BP patients and in 14/21(67%) CP patients who achieved only HR. *Conclusions.* Imatinib mesylate therapy has a significant anti-angiogenic effect in CML- CP patients who achieved both HR and BCR-ABL negativity. No significant effect was seen in all AP, BP patients and CP patients who achieved only HR.

EXPRESSION LEVELS OF MIR-150 AND TRANSCRIPTION FACTORS PU.1, EGR2 INVERSELY CORRELATE WITH MYB AND MYCN IN CHRONIC MYELOID LEUKEMIA

T. Lopotova,[1] K. Vlcanova,[1] T. Stopka,[2] J. Moravcova,[1] H. Klamova,[1] K. Machova Polakova[1]

[1]Institute of Hematology and Blood Transfusion, PRAGUE; [2]First Faculty of Medicine, Charles University, PRAGUE, Czech Republic

Background. Previously we found miR-150 downregulated in total leukocytes from peripheral blood of patients with chronic myeloid leukemia at diagnosis (n=5), hematological relapse (with no blasts in peripheral blood; n=5) and blast crisis (n=4). Normal levels were found in patients with major molecular response to imatinib (n=5) and imatinib suboptimal response/therapy failure (without relapse; n=5) (Machova Polakova *et al.*, ASH 2008, abstract 1082). Interestingly, miR-150 significant downregulation was found in native polycytemia vera reticulocytes (Bruchova *et al.* 2008, Haematologica, 93:1009). In contrast, upregulation was reported in chronic lymphocytic leukemia (Fulci *et al.* 2007, Blood, 109:4944). At the same time, the important role of miR-150 in hematopoiesis has been proved (Xiao *et al.* 2007, Cell, 131:146; Zhou *et al.* 2007, PNAS 104: 7080, Bruchova *et al.* 2007, Exp Hematol 35:1657). Aims.To further investigate the role of miR-150 in the pathogenesis of CML, we focused on the expression of its predicted targets PU.1 and Egr2, which are transcription factors regulating myelo-lymphoid lineage development. We also investigated expression of Myb as known target of miR-150, and miR-150 putative target MycN, both regulating cell proliferation. We aimed to correlate expression patterns of those genes with expression of miR-150. *Methods.* Real-time PCR was applied for quantification using the same samples from the previous study (see above). Relative fold changes of gene expression to normal control (expression average of 11 healthy donors) were assessed by Pfaffl *et al.* (2001, Nucleic Acid Res 29:e45). *Results.* Similarly as for miR-150, we found downregulation of PU.1 in blast crisis, diagnosis and most of hematological relapses. Downregulation of Egr2 was observed in blast crisis and hematological relapses. Significant PU.1 downregulation in CML at diagnosis (n=43) was described by Albajar *et al.* (2008, Cancer Lett, 270:328). Pospisil *et al.* (ASH 2008, abstract 473) reported downregulation of PU.1 and Egr2 in AML mononuclear cells. Authors described that PU.1 regulated transcription of the miR-17~92 cluster by inducing Egr2. Interestingly, we found upregulation of an oncogene miR-17~92 cluster in the CML blast crisis (Machova Polakova *et al.*, ASH 2008, abstract 1082) that inversely correlated to downregulated expression of PU.1 and Egr2. The expression of the known miR-150 target Myb was upregulated in the samples with downregulated expression of miR-150. Similarly, significant upregulation of MycN was found in blast crisis and diagnosis. *Conclusions.* At diagnosis and advanced phases of CML, expression of PU.1 and Egr2 genes encoding proteins that are necessary for differentiation during hemopoiesis is downregulated, while genes encoding proteins regulating cell proliferation Myb and MycN are overexpressed. Whether Myb and MycN overexpression may be the result of miR-150 downregulation in CML is for further investigation.

PREDICTED COMBINATORIAL APPROACHES FOR OVERCOMING INTRINSIC IMATINIB RESISTANCE IN CHRONIC MYELOID LEUKEMIA IDENTIFY POTENTIAL TARGETS FOR INTERVENTION

S. Brems,[1] W. Seifarth,[1] D.B. Jackson,[2] M. Giehl,[1] A. Fabarius,[1] M.A. Stein,[2] R. Hehlmann,[1] A. Hochhaus,[1] O. Frank[1]

[1]Universitätsmedizin Mannheim, MANNHEIM; [2]LIFE Biosystems GmbH, HEIDELBERG, Germany

Background. Imatinib (Glivec, Novartis) has revolutionized therapy of chronic myeloid leukemia (CML). However, a subset of patients displays intrinsic imatinib resistance. Microarray gene profiling led to the identification of potentially useful genes in predicting cytogenetic responses of CML patients to imatinib (Frank *et al.*, 2006, Leukemia). Imatinib-treated patients were evaluated for hematologic, cytogenetic and molecular responses for a minimal observation time of 12 months. Patients who remain in a major cytogenetic remission (MCR; <=35% Philadelphia chromosome-positive [Ph^+] metaphases) after initial response were defined as responders (n=23), whereas those with a continuous minor cytogenetic remission (lack of MCR; >35% Ph^+ metaphases) were considered non-responders (n=11). Patients were included into the retrospective gene profiling study if they met the following criteria: (i) CML in chronic phase, (ii) failure of interferon-α treatment before imatinib therapy and (iii) definite clinical outcome based on cytogenetics measured within the first 12 months of treatment to discriminate responders from non-responders. Diagnostic groups were matched according to demographic and hematologic parameters. *Aims.*Since the identified gene expression signature (128 genes) points to involvement of BCR-ABL-independent resistance mechanisms, microarray data were further analyzed using an innovative in silico discovery approach capable of predicting rational combination therapies. *Methods.* The PIPE-line technology firstly enabled us to define those pharmaceutically tractable components contained within this resistance associated gene set (n=43). Further analysis of this subset using a text-mining approach allowed us to establish a *proteo-anatomical* model of clinically relevant proteins specifically associated with the resistance phenotype. *Results.* This model comprised a set of six chemically tractable proteins, which served as blueprint for the rational prioritization of commercial and pre-clinical compounds for combination testing with imatinib *in vivo*. Compounds targeting two of these components, a G protein-coupled receptor (GPCR), and farnesyl pyrophosphate synthetase (FPPS), were analyzed in more detail. Previously, the predicted efficacy of bisphosphonates for targeting FPPS in imatinib-resistant CML has been verified by others (Chuah *et al.*, 2005, Leukemia) demonstrating proof of principle of PIPE-line technology. For the GPCR, downregulation observed in imatinib non-responders as evidenced by microarray analysis might contribute to the oncogenicity of BCR-ABL since it is capable of attenuating the proliferative effects of this chimeric tyrosine kinase. Subsequently, Western Blot analysis detected differential expression of this GPCR in four human CML cell lines (K562, LAMA84, AR230, KCL22) of which imatinib-sensitive and -resistant clones were investigated. Treatment with two different putative GPCR-interacting agents alone or in combination with imatinib resulted in inhibition of leukemic cell proliferation as measured by MTS colorimetric assay, but not of normal fibroblast cells. Apoptosis was induced by a FDA-approved component as evidenced by various apoptosis assays, whereas an experimental agent did not modulate the apoptotic pathway. Currently, the underlying antileukemic mechanism is further investigated. *Conclusions.* Based on the predictive power of the PIPE-line technology, we suggest the existence of promising new target molecules for novel combinatorial treatments of CML.

CCN3, A NOVEL PRO-APOPTOTIC FACTOR FOR CHRONIC MYELOID LEUKAEMIA

M.R. McCallum,[1] W Lu,[1] S Price,[1] N Planque,[2] B Perbal,[2] N Lazar,[2] A.E Irvine[1]

[1]Queen's University Belfast, BELFAST, UK; 2Laboratoire D'Oncologie Virale et Moleculaire,Universite Paris, PARIS, France

Background. Chronic Myeloid Leukaemia (CML) is characterized by expression of the constitutively active BCR-ABL tyrosine kinase. Previously, we identified down-regulation of the negative growth regulator, CCN3, as a result of BCR-ABL kinase activity in both primary human CML cells and cell lines. We now show that CCN3 is a growth inhibitory factor and expression enhances imatinib induced growth inhibition. *Aim.* To investigate the role of CCN3 expression in CML cells. *Materials and Methods.* K562 cells were stably transfected with a construct containing CCN3 (pCMV82-23) and compared to cells transfected with vector alone (control) using Amaxa nucleofection; stable expression was selected using ampicillin resistance. Real-time PCR was performed for CCN3 expression in comparison with known standards for gene copy number. Colony formation assays were performed in methyl cellulose over a period of 5 days; cell growth was assessed using the CyQuant' assay (Invitrogen, UK). Western blot analysis was performed on cell lysates using antibodies for phosphorylated and total levels of levels of ERK, Akt, STAT5 (Cell Signalling Technology, USA) and for CCN3 using an anti-NH5 antibody. Flow cytometry was used to determine cell cycle status. *Results.* CCN3 expression was undetected by Real-time PCR in control cells whilst pCMV82-23 cells expressed 2.25×10^6 copies per 50ng of cDNA and this was reflected in CCN3 protein levels using Western blot analysis. pCMV82-23 cells showed reduced colony formation capacity (p=0.003) and reduced cell growth over a period of five days (p=0.005) compared to control. CCN3 expression resulted in significant downregulation of three major signaling pathways and demonstrated reduced phosphorylation of ERK (p=0.002), pAKT (p=0.017) and pSTAT5 (p=0.005) compared to control cells; protein levels for total ERK, AKT and STAT5 were unaffected by CCN3 expression. Sustained CCN3 expression resulted in an accumulation of cells within the subG0 stage

of the cell cycle (p=0.040). To determine if CCN3 expression could influence sensitivity to the BCR-ABL kinase inhibitor, imatinib, pCMV82-23 cells and control cells were treated with imatinib (5 uM) for 48h. Control cells treated with imatinib showed moderate growth inhibition (19.6%±2.5). pCMV82-23 cells showed a significant increase in the magnitude of imatinib induced growth inhibition (63.3%±10.5 (p=0.043)). This was associated with an increased accumulation of cells in the subG0 area of the cell cycle (pCMV82-23 cells 34.6%±5; control cells 21.7%±8; p=0.006). To determine if these effects could be reproduced using recombinant CCN3 (rCCN3), K562 cells were treated with imatinib (5 µM) alone or in combination with rCCN3 (10 nM) for 48h. K562 cells treated with rCCN3 and imatinib showed enhanced growth inhibition (71.8%±7.9) compared to cells treated with imatinib alone (81.1%±9.2 (p=0.008)). Loss of CCN3 expression is consistent with properties associated with the CML phenotype. Sustained expression of CCN3 in K562 cells restores growth control and re-establishes induction of apoptosis. Increased expression of CCN3 provides an additional benefit for imatinib induced growth inhibition thus providing a novel avenue for therapeutic intervention.

3-DEAZANEPLANOCIN A (DZNEP) ACTIVITY AGAINST CD34+ LEUKAEMIA STEM CELLS

S. Myssina,[1] G. Jørgensen,[2] Y. Yu,[3] T. Holyoake[1]

[1]University of Gasgow, GLASGOW, UK; [2]University of Glasgow, GLASGOW, UK; [3]Genome Institute of Singapore, SINGAPORE, Singapore

Polycomb-repressive complex 2 (PRC2)-mediated histone methylation plays an important role in aberrant cancer gene silencing and is a potential target for cancer therapy. Recently it was shown that the S-adenosylhomocysteine hydrolase inhibitor 3-Deazaneplanocin A (DZNep) effectively depleted cellular levels of PRC2 and induced efficient apoptotic cell death in cancer cells but not in normal cells. Chronic Myeloid leukaemia (CML) stem cells, which express high levels of BCR-ABL, cannot be completely inhibited by ABL tyrosine kinase inhibitors (TKI) such as imatinib (Glivec) or dasatinib (Sprycel) and up to 20% of patients develop drug resistance. Therefore it is important to search for other pathways to inhibit leukaemia stem cell growth, thus we investigated DZNep for activity against primary CML stem cells.We aimed firstly to test DZNep for an ability to kill CD34$^+$ stem cells harvested from leucapheresis from CML patients at diagnosis in chronic phase and from non-CML leucapheresis as controls. We investigated cell proliferation and apoptotic cell death in CD34$^+$ stem cells. Cell counts and viability were determined by trypan blue dye exclusion to establish IC50. Annexin-V binding and caspase-3 activation were measured by flow cytometry as proof of induction of apoptosis. Carboxyfluorescein succinimidyl ester (CFSE) staining was performed to investigate the effect of DZNep on cell division, the surviving CFSEmax (undivided) cells were enumerated. DZNep was toxic to BAF3Bcrabl but not BAF3 parental cells at concentrations up to 1 micromolar. The IC50 for DZNep in CML stem cells was 100 nanomolar at 72h. Despite the selectivity against Bcrabl$^+$ versus Bcrabl- BAF3 cell line, Philadelphia negative CD34$^+$ cells were equally inhibited by DZNep. Moreover, the anti-proliferative effect first seen with imatinib, was also observed after 72 hours of DZNep treatment whereby 0.11% of input CML CD34$^+$ cells were arrested undivided in untreated wells as compared to 23.9% with 100 nanomolar DZNep. Nevertheless, we observed 29.9% apoptosis (Annexin-V / Viaprobe positive) in CML CD34$^+$ cells versus 17.2% in non-CML stem cells at 100 nM at the same time point. Further, caspase-3 activation in CML cells at 72h was twice the incidence seen in non-CML. Having confirmed that DZNep kills CD34$^+$ cells, we now plan to investigate the effect of DZNep on the most primitive, quiescent CD34$^+$38$^-$ CML stem cell populations.

A SET OF NEW GENES THAT MAY BE INVOLVED WITH THE PROCESS OF MODIFICATION OF GRANULOCYTIC CELLS IN CHRONIC MYELOID LEUKEMIA

C. Couto Mascarenhas

University of Campinas, CAMPINAS, Brazil

Background. Although the exact action mechanism of the protein BCR-ABL is unknown, studies *in vitro* and in animal models showed that the activity of protein tyrosine kinase (TK), by itself, is sufficient to cause the development of chronic myeloid leukemia (CML). This process occurs through the activation of several pathways of signal transduction, leading to: dysregulated cell proliferation, reduced adhesion of leukemic cells in bone marrow stromal and reduction of the apoptotic response to mutagenic stimuli. Thus, the progression of the disease to accelerated phase or blast crisis may be associated with genomic instability. The use of methods to detect the difference in gene expression between CML and normal granulocytes could bring new insights in the understanding of these complex mechanisms, highlighting new therapeutic targets for the CML treatment. *Aims.* Evaluation of the differential gene expression between CML and normal granulocytes using the Subtractive Suppression Hybridization (SSH) and investigation of the involvement of a set of differentially expressed genes in modulating the development of CML. *Methods and Patients*. The SSH libraries were constructed using a pool of RNA of granulocytes extracted from CML patients and from healthy blood donors. The study was approved by the Ethics Committee of the University of Campinas and prior to the study, in all cases, informed consent was obtained. *Results.* The comparison between granulocytes of CML patients and control granulocytes showed 39 genes exclusively expressed in CML and 169 genes in controls. These genes were related to different metabolic pathways like protein ligation (DCN1, KPNA6, SETDB1, FAM63A, KMT1E), transcription factors, (SETDB1, SIM1, IPOA7), apoptosis (PNUTL1, CDC42SE1, SRGN), lipid metabolism (TIMM23), ATP ligation (MTND4L), DNA repair (TOB1) and differentiation/cellular proliferation (PNUTL1, GP1B, SNAG1, ANXA9, MIER). Among these genes, some may play important roles in the CML development, as MIER, TOB1 and SRGN. The Mier protein is part of a complex responsible for the proliferation of T lymphocytes linked to the progression of CML; the TOB1 gene is a transcription factor related to cell proliferation and is involved in the control of cell cycle and hematopoiesis; and the gene SRGN, which is a regulator of apoptosis and acts in the neutralization of hydrolytic enzymes. Some of these genes were described as the first time in CML and represent new target for functional studies. *Conclusions.* Some important genes expressed exclusively in the library of CML may be related to the development and progression of this disease. The results showed in this study amplify the data published previously and may present new clues about gene regulation and the dynamic organization of genes and chromosomes in cells, improving the comprehension of the CML disease and the identification of new target genes for therapeutic purposes.

HETEROGENEOUS MECHANISMS AT THE BASIS OF 5'BCR/3'ABL FUSION GENE GENERATION IN CHRONIC MYELOID LEUKEMIA

F. Albano,[1] L. Anelli,[1] A. Zagaria,[1] N. Coccaro,[1] A. Pannunzio,[1] A. Russo Rossi,[1] L. Vicari,[2] F. Manodoro,[1] V. Liso,[1] M. Rocchi,[3] G. Specchia[1]

[1]Department of Hematology, BARI; [2]Azienda Ospedaliera A. Cardarelli, NAPOLI; [3]Dip. di Genetica e Microbiologia - DI.GE.MI., BARI, Italy

Background. The t(9;22)(q34;q11), generating the Philadelphia chromosome, is found in more than 90% of patients with chronic myelocytic leukemia (CML). About 5%-10% of CML patients show variant translocations, involving one or more chromosomes in addition to 9 and 22. In a subset of CML patients the 5'BCR/3'ABL fusion gene is generated by cryptic rearrangements such as nonreciprocal insertions between chromosomes 9 and 22. Moreover, microdeletions on the der(9) chromosome next to the t(9;22) breakpoint or on the third derivative chromosome involved in variant t(9;22) have been recently described and appeared to be a valuable prognostic factor. *Aims.* To our knowledge, an accurate frequency assessment of different mechanisms at the basis of fusion gene generation or of concomitant chromosomal rearrangements other than the t(9;22) has never been performed. The aim of this study was to perform a detailed molecular cytogenetic characterization of a large series of CML patients to unveil the biological heterogeneity of CML. *Methods.* 404 CML patients in chronic phase were analyzed by conventional cytogenetic analysis and by FISH experiments with *home-brew* probes specific for ABL and BCR genes. Breakpoints characterization and deletions size definition were carried out with additional bacterial artificial chromosome (BAC) and Phage P1-derived artificial chromosome (PAC) probes selected according to the University of California Santa Cruz (UCSC http://genome.ucsc.edu/index.html; March 2006 release) database. *Results*. This molecular cytogenetic study identified 43 (10.6%) out of 404 CML cases showing heterogeneous chromosomal mechanisms accountable for generation of the 5'BCR/3'ABL fusion gene. These cases could be classified in three main groups: i) cases with variant chromosomal rearrangements other than the classic t(9;22)(q34;q11) (8.9%), showing a *masked der(9)* (7.4%) or a *masked Ph* chromosome (1.5%); ii) CML cases with cryptic insertions of ABL into BCR, or vice

versa (1.5%); iii) CML cases bearing additional concomitant chromosomal rearrangements, apart from the generation of the 5'BCR/3'ABL fusion gene (1.2%). *Conclusions.* This study provides an outline of the frequency and molecular features of the most relevant cytogenetic groups identified in a very large series of CML patients at diagnosis. A clear division has been made between cases with variant t(9;22) rearrangements, cases with cryptic insertions generating the 5'BCR/3'ABL fusion gene, and patients with additional concomitant chromosomal rearrangement other than the presence of 5'BCR/3'ABL. However, the biological significance and the prognostic impact of the cytogenetic molecular heterogeneity occurring in the generation of the 5'BCR/3'ABL fusion gene remain to be clarified.

0330

EVALUATION OF DSBS REPAIR IN IMATINIB RESISTANT CELL LINES

R. Dinis, L. Gromicho, S. Martins, L. Laires, A. Rueff, S. Rodrigues

Centro de Investigação em Genética Molecular Humana (CIGMH) - FCM/UNL, LISBOA, Portugal

Background. Chronic myeloid leukemia (CML) is characterized by having a fusion gene, BCR-ABL, with constitutive tyrosine kinase activity. Standard treatment is the tyrosine kinase inhibitor Imatinib (IM). Several studies report that BCR-ABL expression decreases cytotoxicity associated with DNA damage, while others suggest it enhances cytotoxicity and may induce chromosomal instability/mutation accumulation. BCR-ABL increases reactive oxygen species production and also DNA double-strand breaks (DSBs), upon treatment with DNA-damaging agents. It has also been reported that treatment of CML cells with IM can modify DSBs repair as well. *Aim.* Since altered DNA repair may affect resistance to therapeutic agents, the aim was to evaluate DSB repair ability and apoptosis in IM resistant cell lines after exposure to the oxidant H_2O_2. *Methods.* The K562 cell line (CML cell line expressing BCR-ABL) was incubated with increasing concentrations of IM in order to create resistant cell lines, and 3 cell lines were isolated showing resistance to 0.5 μM, 1.0 μM and 5.0 μM. Simultaneously, control cultures were maintained. Detection of DSBs was carried out using FITC-antibodies for phosphorylated histone H2AX (gamma-H2AX). We incubated cells (control cells and IM-resistant cells) with H_2O_2 (100, 250 and 500 μM) for 1 hour. For each sample group a negative control was also prepared. Images from immunofluorescence analysis were captured using a fluorescence microscope and analysis was performed with the freeware Cellprofiler. Apoptosis was evaluated by the TUNEL assay. Cells were incubated with 250 μM of H_2O_2, for 1 hour, and cultured for an additional 6 hours before evaluating apoptosis. For this assay we used the four cell lines referred previously, as well as the corresponding controls. BCR-ABL expression was evaluated by RT PCR.

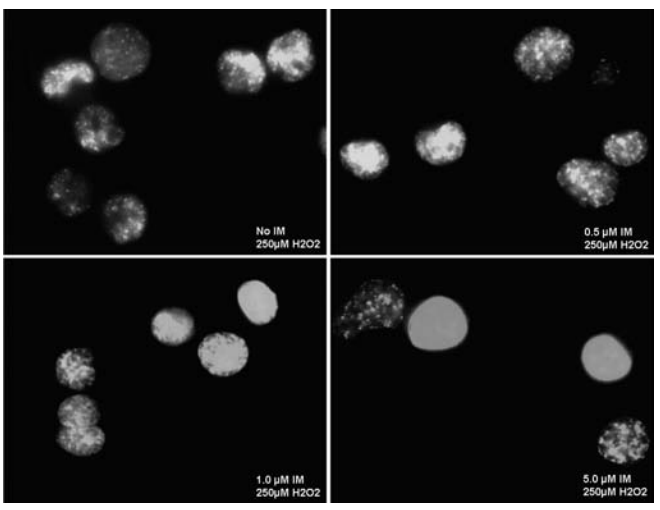

Figure 1

Results. Results suggest that IM-resistant cells are more sensitive to H_2O_2 damage. Comparing K562 negative controls vs. resistant negative controls we observed a slight increase in the basal level of gamma-H2AX foci with IM concentration. Additionally, the dose response curves showed a higher induction of gamma-H2AX foci in IM resistant cell lines compared to the K562 control cell line. Saturation of the gamma-foci was apparent at 250 μM H_2O_2. TUNEL assay did not show a significant variation on apoptosis in control and resistant cells incubated with H_2O_2. We did not find a significant variation in BCR-ABL expression in the different cell lines. *Summary and Conclusions.* IM-resistant cells showed higher levels of gamma-H2AX foci, indicating higher susceptibility to DNA damage upon exposure to H_2O_2 than non-resistant cells. In resistant cells, saturation of the gamma-H2AX signal was observed with lower concentrations of the oxidant, indicating either that these cells have a lower DNA repair capacity, or altered signaling in response to DNA damage. The increased number of DSBs with IM resistance does not seem to be associated with BCR-ABL expression, since its variation is not significant. We are evaluating other mechanisms of resistance in order to understand the increase of DSBs in IM-resistant cells.

E T315I MUTATION CONFERS RESISTANCE AGAINST SMALL MOLECULES BY RESTORING THE ABL-KINASE ACTIVITY ACCOMPANIED BY TRANSPHOSPHORYLATION OF ENDOGENOUS BCR, EVEN IN LOSS-OF-FUNCTION MUTANTS OF BCR/ABL

M. Ruthardt,[1] M. Mian,[2] M. Schüll,[2] Z. Zhao,[2] C. Oancea,[2] T. Beissert,[2] H. Serve,[2] O.G. Ottmann,[2] M. Ruthardt[2]

[1]Goethe University, FRANKFURT; [2]Department of Hematology/Oncology, Goethe University, FRANKFURT, Germany

Philadelphia Chromosome (Ph) positive ALL and CML the fusion between BCR and ABL leads to the BCR/ABL fusion proteins, which induces the leukemic phenotype because of the constitutive activation of multiple signaling pathways down-stream to the aberrant BCR/ABL fusion tyrosine kinase. Targeted inhibition of BCR/ABL by ABL-kinase inhibitors induces apoptosis in BCR/ABL transformed cells and leads to complete remission in Ph-positive leukemia patients. However, a large portion of patients with advanced Ph^+ leukemia relapse and acquire resistance. Kinase domain (KD) mutations interfering with inhibitor binding represent the major mechanism of acquired resistance in patients with Ph^+ leukemia. The T315I mutations confers resistance against all actually approved ABL-kinase inhibitors. It seems not only to decrease affinity for kinase inhibitors but to confer additional features to the leukemogenic potential of BCR/ABL. To determine the role of T315I in resistance to the inhibition of oligomerization and in the leukemogenic potential of BCR/ABL, we investigated its influence on loss-of-function mutants with regard to the capacity to mediate factor-independence. Thus we studied the effects of T315I on BCR/ABL mutants lacking functional domains in the BCR portion indispensable for the oncogenic activity of BCR/ABL such as the N-terminal coiled coil (CC), the tyrosine phosphorylation site Y177 and the serine/threonine kinase domain (ST), as well as on the ABL-portion of BCR/ABL (#ABL-T315I) with or without the inhibitory SH3 (ΔSH3-ABL) domain. Here we report that i.) T315I restored the capacity to mediate factor independence of oligomerization-deficient p185BCR/ABL; ii.) resistance of p185-T315I against inhibition of the oligomerization depends on the phosphorylation at Y177; iii.) autophosphorylation at Y177 is not affected by the oligomerization inhibition, but phosphorylation at Y177 of endogenous BCR parallels the effects of T315I; iv.) the effects of T315I are associated with an intact ABL-kinase activity; v.) the presence of T315I is associated with an increased ABL-kinase activity also in mutants unable to induce Y177 phosphorylation of endogenous BCR; vi.) there is no direct relationship between the ABL-kinase activity and the capacity to mediate factor-independence induced by T315I as revealed by the #ABL-T315I mutant, which was unable to induce Y177 phosphorylation of BCR only in the presence of the SH3 domain. In summary our here presented data provide evidence that the T315I requires autophosphorylation at tyrosine 177 in the BCR-portion to mediate resistance against the inhibition of oligomerization and restores the capacity to mediate factor-independent growth of loss-of-function mutants due to an increase in or activation of ABL-kinase which is accompanied by phosphorylation of endogenous BCR, suggesting aberrant substrate activation by BCR/ABL harboring the T315I mutation. These data show that T315I confers additional leukemogenic activity to BCR/ABL, which might explain the clinical behavior of patients with BCR/ABL -T315I-positive blasts.

SURVIVIN EXPRESSION IN CHRONIC MYELOGENOUS LEUKEMIA PATIENTS WITH IMATINIBE MESYLATE TREATMENT

M. Mantzourani, D. Georgopoulou, M. Gravia, A. Polonyfi, G. Pangalis, G. Vaiopoulos

National and Kapodistrian University of Athens, GOUDI, ATHENS, Greece

Background. Survivin protein is a member of the inhibitors of apoptosis protein (IAP) family that also regulates cell division. Present during fetal development and prominently expressed in cancer, survivin is undetectable in terminally differentiated adult tissues. Over 95% of patients with chronic myelogenous leukemia (CML) are Philadelphia chromosome positive [Ph^+] due to the translocation t(9;22)(q34;q11) resulting in the formation of BCR-ABL gene which codes for Bcr-Abl protein, a constitutively active tyrosine kinase. CML patients are treated with imatinib mesylate, an inhibitor of Bcr-Abl tyrosine kinase. Survivin was also found to be highly expressed in accelerated/blast phase (AP/BP) of CML but low in chronic phase (CP) and is regulated through Bcr-Abl/MAPK signaling at both transcriptional and posttranslational levels.[1] Aim of this study was to investigate SURVIVIN (SVV) and BCR-ABL expression in CML patients with imatinibe mesylate treatment in different phases of the disease. *Materials and Methods.* Twenty Ph^+ CML patients with fifty-seven blood samples (Twelve women and eight men, median diagnosis age 52, cytogenetic response: 63,2% complete, 6,2% partial, 2% minor, 12,3% minimal, 16,3% none) in different phases of the disease and twenty healthy control samples were investigated. Of these samples fifty were in CP and seven, in AP/BP. Total RNA was isolated from the blood cells. Then cDNA synthesis and quantitative real-time PCR with primers and hydrolysis probes for SVV, BCR-ABL and c-ABL (endogenous gene) sequences were performed. The quantification was relative with external standards and the SVV/c-ABL, BCR-ABL/c-ABL ratios were calculated. Results were statistically analyzed with T-test. *Results.* I. SVV expression is low-detected in healthy control samples (median ratio: 0,071) where BCR-ABL expression is absent. II. SVV expression is significantly higher (p<0,05) in CML patients in CP (median ratio: 0,17) in comparison with those in AP/BP (median ratio: 1,095) and follows BCR-ABL expression as it increases from CP (median ratio: 0) to AP/BP (median ratio: 0,66) (p<0,05). III. SVV expression is significantly higher (p<0,05) in CML patients in CP with complete cytogenetic response to treatment (median ratio: 0,178), where BCR-ABL expression (median ratio: 0) is undetected, in comparison with healthy controls. IV SVV and BCR-ABL expression are shown to be significantly higher (p<0,05) in CML patients in chronic phase with cytogenetic response less than complete to treatment (median ratios: 0,171 and 0,075) in comparison with healthy controls. But the comparison with the patients in complete cytogenetic response showed no significant difference. *Conclusions.* Survivin and Bcr-Abl expression follow the clinical expansion of CML with the first to be significantly higher in patients in CP with complete cytogenetic response to treatment.

AN APPROACH TO OVERCOME BCR-ABL INDEPENDENT STI571 RESISTANCE IN CML

E. Rabizadeh,[1] A. Aviram,[1] I. Belyaeva,[1] V. Merkin,[1] N. Avissar,[2] M. Shaklai,[1] Y. Zimra[1]

[1]Beilinson, PETAH TIKVA, Israel; [2]Department of Surgery University of Rochester, ROCHESTER, USA

Background. Chronic- myelogenous leukemia (CML) is associated with high tyrosine kinase (TK) activity of the chimeric protein BCR-ABL. CML is treated with the TK inhibitor Imatinib (STI571), but in some cases STI571 resistance appears. BCR-ABL over expression, amplification or mutation in the kinase domain was shown. However, CML cells can evade the inhibitory effect of STI571 by different mechanisms, such as enhanced efflux by Multidrug Resistance P-glycoprotein (MRD-Pgp) or mutations in genes other than BCR-ABL. One possible approach to overcome STI571 resistance involves combination with Histone Deacetylase Inhibitors (HDACI). We have shown that Pivaloyloxymethyl butyrate (Pivanex), a HDACI, alone and combined with STI571, induced apoptosis, differentiation and reduced BCR-ABL protein levels in CML cell line (K562). *Aims.*Herein we study the mechanism of STI571 resistance in a CML STI571 resistant cell line and the effect of HDACI on these cells. *Methods.* We developed a STI571 K562 resistant cell line (K562-R) by gradually exposing the cells to elevated levels of STI571. The K562-R cells had an IC50 33 times greater than that of K562 wild type (K562-S) cells. The following assays were conducted: viability loss using Alamar blue test, cell cycle parameters by PI and Anexin V staining analyzed, respectively, on Flow-cytometer, erythroid differentiation by glycophorin-A and Tetramethyl Benzidine staining, BCR-ABL and signal transduction proteins by western blot analysis, bcr-abl and WT1 expression by RQ-PCR and mutation analysis, by chip-based matrix-assisted laser desorption-time-of-flight mass spectrometer (MALDI-TOF) for 45 previously reported different mutations that confer STI571 resistance. *Results.* K562-R cells had very low MDR-Pgp levels, high BCR-ABL protein and transcript levels same as K562-S. No mutations were found in the catalytic TK domain. However, K562-R cells demonstrated higher spontaneous apoptosis, G2M arrest and P21, a cell cycle regulatory protein, but lower S phase and WT1 levels. Glycophorin A expression was higher in K562-R cells although spontaneous hemoglobin synthesis was lower. A preliminary study of the signal transduction pathway showed elevated phosphorylated p38 in K562-R cells but no differences in p70S6, STAT3, Erk 1/2, CREB, Ikβ-α and JNK proteins levels (total and phosphorylated). Pivanex did not change BCR-ABL levels; p21 and differentiation were raised to a lesser extent. However, it induced viability loss, apoptosis and caspase activity enhancement in K562-R cells. *Summary*. We suggest that STI571 resistance mechanism in K562-R cells does not involve BCR-ABL but other regulatory mechanisms in cell cycle, differentiation and signal transduction pathways. The higher spontaneous G2M arrest, apoptosis and differentiation could be related to changes in p21 and p38 signaling pathways. Reduced WT1 levels in K562-R cells may also facilitate apoptosis induction in these cells and may explain both the relatively higher spontaneous apoptosis and the higher Pivanex induced apoptosis. K562-R with no change in BCR-ABL present a model for STI571 resistance in CML that does not involve BCR-ABL and a possible benefit of HDACI treatment in CML STI571 resistant patient with no mutation or changes in BCR-ABL protein.

TARGETING CERAMIDE METABOLISM INCREASED SENSITIVITY OF PHILADELPHIA POSITIF CHRONIC MEGACARYOBLASTIC LEUKEMIA CELLS TO DASATINIB

E.B. Gencer,[1] A.U. Ural,[2] F. Avcu,[2] Y. Baran[1]

[1]Izmir Institute of Technolology, IZMIR; [2]Gulhane Medical School, ANKARA, Turkey

Background. Ceramide metabolizing genes have important functions in regulation of apoptosis, cell growth, proliferation, differentiation and senescent. While ceramide is a strong apoptotic molecule, conversion of apoptotic ceramide to antiapoptotic glucosylceramide by glucosyl ceramide synthase (GCS) results in resistance to anticancer agents. It was shown by different studies that GCS levels were increased in resistant cells and in patients resistant to different chemotherapeutic agents. Thus, inhibition of GCS or increasing intracellular concentrations of ceramides may sensitize cancer cells to anticancer agents. Dasatinib is a novel anticancer agent used for the treatment of Philadelphia chromosome positive chronic leukemias. *Aims.*In this study, we examined the possible outcomes of increased intracellular concentrations of ceramide through induction of *de novo* ceramide synthesis and inhibition of conversion of ceramide to glucosyl ceramide by a strong GCS inhibitor, PDMP, in human Meg-01 CML cells. *Methods.* The Ph^+ human Meg-01 cells were exposed to increasing concentrations of dasatinib, a ceramide analog (C8:ceramide) or PDMP. Then, we applied combinations of dasatinib and C8:ceramide or PDMP and cytotoxicity analyses were determined by XTT cell proliferation assay. Changes in caspase-3 enzyme activity were determined using the caspase-3 colorimetric assay. The mitochondrial membrane potential (MMP) was measured using JC-1 MMP detection kit. *Results.* IC50 values of dasatinib and C8:ceramide or IC90 value for PDMP were found to be 4 nM and 70 μM or 50 μM, respectively. Combination of dasatinib with 70 μM C8:ceramide or 50 μM PDMP increased sensitivity of Meg-01 cells to dasatinib as compared to only dasatinib applied cells. There were 0-, 8-, 17-, 24-, and 46% decreases in cell proliferation in 1-, 5-, 10-, 20-, and 50 nM dasatinib applied Meg-01 cells, respectively, while the combination of these doses with 70 μM C8:ceramide resulted in 72-, 76-, 78-, 81-, and 82% decreases cell proliferation, respectively, as compared to untreated controls. In parallel experiments, we have shown that, application of the same doses of dasatinib with IC90 value of PDMP (50 μM) caused 67-, 76-, 77-, 78-, and 80% decreases in cell proliferation. There were 1,3- and 1,52 times increases in caspase-3 enzyme activity in 1- and 10 nM dasatinib treated Meg-01 cells while 70 μM C8:ceramide and 50 μM PDMP increased the loss of MMP 1.24 and 1.4 times, respectively. Combination of 1- and 10 nM dasatinib with 70 μM C8:ceramide or 50 μM PDMP increased caspase-3 enzyme activity 1.94-, and 3.58-, or 1.81-, and 4.38 times which is significant. Similar results were obtained for the changes in mitochondrial membrane potential. *Summary and Conclusions.* It was shown for the first time that manipulating ceramide metabolism to provide accumulation of intracellular ceramides increased cytotoxic effects of dasatinib on human Meg-01 chronic megacaryoblastic cells.

DELTA EX6, THE NOVEL TRANSACTIVATION-DEFECTIVE SPLICING VARIANT OF TP53, IS DIFFERENTIALLY EXPRESSED IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA AND CONFERS ACCENTED PROLIFERATIVE PHENOTYPE *IN VITRO*

S. Pekova,[1] O. Mazal,[2] R. Cmejla,[3] T. Kozak,[2] L. Smolej,[4] M. Spacek,[2] S. Pekova[1]

[1]Na Homolce Hospital, PRAGUE; [2]University Hospital Kralovske Vinohrady, PRAGUE; [3]Institute of Hematology and Blood Transfusion, PRAGUE; [4]University Hospital and Medical School, HRADEC KRALOVE, Czech Republic

Background. The regulation of TP53 is substantially controlled at the transcriptional level. Nine different splicing variants of TP53 have been described so far, with distinct biological characteristics, resulting from combinations of an alternative splicing of intron 2, 9 and/or aberrant transcription, starting at so-far unrecognized cryptic promoter in intron 4. We have recently identified a novel splicing variant of TP53 gene, termed delta ex6, lacking the whole coding sequence of exon 6 and harboring an insertion at the exon9/10 boundary. The delta ex6 variant is differentially expressed in patients with chronic lymphocytic leukemia (CLL) as compared to healthy donors. Delta ex6 variant is devoid of transactivational activity as determined *in vitro* by FASAY (Functional Analysis of Separated Alleles in Yeast). *Aims.*The goal of the work was to test the biological properties of the novel TP53 transcript variant delta ex6 *in vitro*, using a TP53 double-knock-out model cell line H1299 with a stable integrated Tetracycline repressor (H1299TetR). *Methods.* We have cloned the whole delta ex6 coding sequence into a Tet-ON pcDNA4/TO vector and transfected the H1299TetR cell line to produce stable integrants. Four stable delta ex6 producing H1299TetR cell lines, as well as control cell lines in doublets (parental H1299TetR harboring the pcDNA4/TO cloning vector, and H1299TetR stably transfected with wild type TP53) were subjected to the Affymetrix GeneChip Human Exon 1.0 ST whole genome expression analysis. *Results.* Stable H1299TetR cell lines expressing the delta ex6 variant were distinguished by a remarkable loss of intercellular contacts and semi-suspension growth properties, in contrast to the strictly adherent growth of the parental cells and mock-transfected cells. The microarray data corroborated the accented and proliferative phenotype as observed *in vitro* in the tissue culture: overexpression of a number of cyclins (A1, G1, G2, F, I, B2, A2, T2), matrix metalloproteinases, hyaluronidases and caspase inhibitors; and downregulation of adhesion molecules and molecules of the intercellular matrix. *Summary*. Our data on the presence of the delta ex6 TP53 variant in CLL patients supports the recent evidence on dysregulation of TP53 splicing pattern in malignancies. Moreover, as assessed *in vitro*, overexpression of the delta ex6 variant leads to an accented and proliferative phenotype, a finding further supporting the biological role of the novel delta ex6 TP53 variant *in vivo*.

THE TUMOR SUPPRESSOR MECHANISM IN 13Q14.3 INVOLVES MONOALLELIC EXPRESSION, NON-CODING RNA GENES AND EPIMUTATIONS AFFECTING THE MAJORITY OF CLL PATIENTS

D. Mertens

University Ulm, ULM, Germany

Background. Deletions in chromosomal band 13q14.3 occur in a variety of human neoplasms like chronic lymphocytic leukaemia (CLL), indicating a tumor suppressor mechanism (TSM) in this region. Intriguingly, several characteristics of the region of interest point to an epigenetic pathomechanism: a) candidate protein-coding genes and non-coding RNA genes including miR15a and miR16-1 lack point mutations in the majority of patients, yet b) these genes are significantly downregulated in almost all CLL patients, c) the presence of large non-coding RNA genes in 13q14.3 is reminiscent of imprinted regions where only one gene copy is active. We have recently shown that already in healthy tissue only one gene copy of 13q14.3 is active while one gene copy is randomly chosen for silencing. *Aims.*To identify an epimutation in the critical region in 13q14.3 in CLL patients. *Methods.* In order to elucidate the epigenetic regulatory mechanism, we analysed DNA- and histone-methylation of all CpG islands in the region in non-malignant B-cells and CLL cells. To this end, we used aPRIMES and ChIP-qPCR as screening

tools, BioCOBRA as a quantitative high-throughput method and bisulfite sequencing for validation. *Results.* We could identify two candidate regulatory elements with abnormal chromatin in CLL patients (n=80, median 57% DNA-methylation, range 0-100%) as compared to healthy probands (n=20, median 88% DNA-methylation, range 74-100%, $p<0.003$). Interestingly, this epimutation can be found in all cytogenetic subgroups of CLL patients and is independent of IgV(H) mutation status, making it a prime candidate for an underlying epigenetic defect in CLL. Pilot studies suggest that this epimutation regulates gene expression of the critical region via large non-coding RNA genes. *Conclusions.* We propose a model for the TSM in 13q14.3 where i) in healthy B-cells, only one gene copy is active while the second is epigenetically silenced, ii) 13q14.3 harbors an epimutation that is present in all cytogenetic subgroups of CLL patients and that iii) deregulates expression of long ncRNA genes directly and protein-coding and miRNA candidate tumor suppressor genes indirectly.

INTEGRATIVE HIGH-RESOLUTION MICROARRAYS APPROACH IN B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA REVEALS THE PRESENCE OF MOLECULARLY DISTINCT SUBGROUPS IN PATIENTS WITH 13Q DELETION

L. Mosca,[1] L. Agnelli,[1] S. Fabris,[1] G. Cutrona,[2] S. Matis,[2] M. Lionetti,[1] K. Todoerti,[1] A. Andronache,[1] M. Gentile,[3] M. Spriano,[4] V. Callea,[3] G. Festini,[5] S. Molica,[6] G. Lambertenghi Deliliers,[1] F. Morabito,[3] M. Ferrarini,[2] A. Neri[1]

[1]Università di Milano e Fondazione IRCCS Policlinico di Milano, MILANO; [2]Istituto Nazionale per la Ricerca sul Cancro, IST, GENOVA; [3]Azienda Ospedaliera, COSENZA; [4]Azienda Ospedaliera S. Martino, GENOVA; [5]Azienda Ospedaliero-Universitaria, Ospedali Riuniti, TRIESTE; [6]Azienda Ospedaliera Pugliese- Ciaccio, CATANZARO, Italy

Background. B-cell chronic lymphocytic leukemia (B-CLL) is the most recurrent leukemia in the western world, with a highly variable clinical course that reflects its heterogeneous genomic pattern. Aims. To define clusters of patients based on their genomic profiles and identify gene expression patterns specifically associated to them. *Methods.* We applied SNP array technology (Affymetrix GeneChip® Human Mapping 250K Nsp) to characterize allelic imbalances in a panel of 100 newly diagnosed, untreated B-CLL patients in early stage disease (Binet stage A). We performed an integrative approach between whole genome and gene expression profiling data (Affymetrix GeneChip® HG-U133A) for 60 patients for whom RNA material was available. Results. The non-negative matrix factorization (NMF) algorithm allowed the identification of four significant clusters (correlation coefficient = 0.95), mainly driven by the major chromosomal alterations. Groups I and II, containing respectively 27 and 13 cases, were characterized by the presence of 13q14 deletion, stratified into the two groups based on the deletion size and the presence of biallelic deletion; group III consisted of all the 21 patients with trisomy 12; the remaining 39 patients, among which patients showing 11q (8 pts) and 17p (4 pts) deletions without other well known aberrations, were placed in group IV. A SAM multi-class analysis between the four groups identified sixty well-characterized differentially expressed genes, with a prevalent deregulation of genes located at 13q14 (8%) and on chromosome 12 (60%) (group I, II and III, respectively), whereas no specifically modulated genes were recognized in group IV. As regard the putative functional features of the deregulated genes, we found a significant involvement in transcription regulation (9/60 = 15%); regulation of apoptosis (6/60 = 10%), among which 3 genes mapping at chromosome 12 (DYRK2, TEGT and BTG1) and 1 at 13q14 (TPT1); glycolysis (3/60 = 5%) and negative regulation of cell cycle (3/60 = 5%), all located on chromosome 13 (TRIM13, RB1 and DLEU1) and already described by others as involved in B-CLL pathogenesis. Conclusions. The natural grouping of genome profiles reveals that the complex scenario of copy number alterations affecting B-CLL is mainly driven by the presence of deletion at 13q14 (groups I and II) and trisomy of chromosome 12 (group III). The prevalent deregulation of genes located in these regions suggests that the modulation of gene expression observed in the comparison of the 4 groups could be mostly due to a gene dosage effect. These data further suggest that the deregulation of genes involved in fundamental biological functions, as a result of genomic alterations, may play an important role in the molecular pathogenesis of B-CLL.

0338

PROTEIN KINASE C INHIBITION WITH ENZASTAURIN PRIMES CHRONIC LYMPHOCYTIC LEUKEMIA CELLS FOR DEATH THROUGH DOWN-REGULATION OF MCL-1

L. Ysebaert,[1] C. Liffraud,[1] S. Kheiralah,[1] A. Blanc,[1] E. Gross,[1] K. Benhadji,[2] A. Quillet-Mary,[1] G. Laurent[1]

[1]INSERM U[5],[63] TOULOUSE; [2]Eli-Lilly Company, PARIS, France

Background. Chronic Lymphocytic Leukemia (CLL) cells have many defects in the apoptotic machinery, among whom Mcl-1 plays a critical role, leading to drug resistance and, subsequently, poor clinical outcome. Aims We assessed the influence of Enzastaurin (an orally available PKC inhibitor) on CLL survival, based on emerging evidences that PKCβ does play a critical role in the establishment and maintenance of leukemic cells in transgenic mice models of CLL. *Methods.* Enzastaurin dose-effect (range 1-20 μM) was measured in 20 CLL samples, and correlated to Binet's stage, IgVH mutational status, caryotype/FISH and CD38 expression. Results Mean IC50 of 16/20 responding CLL patients was 6.9 μM (95% CI 3.6-10.4 μM), while sparing normal Peripheral Blood Lymphocytes. These data are reminiscent with published IC50 in Waldenstrom's macroglobulinemia cell lines, but lower than IC50 observed in CLL cell lines JVM3 and MEC2 (respectively 15 and 10 μM). Inhibition of phospho-serine 9-Glycogene Synthase Kinase 3β phosphorylation (see below as GSK3β activation), was also used as a surrogate marker for Enzastaurin activity. Enzastaurin induce significant GSK3 activation, except in the 20% resistant samples (including two 6q- and two 11q-deleted patients). A specific phosphatise assay demonstrated that Protein Phosphatase 2A (PP2A)-induced dephosphorylation of GSK3 was triggered by Enzastaurin in a dose-dependent manner, and its inhibition by 5 nM Okadaic Acid prevented totally GSK3 activation and partially cell death induced by Enzastaurin. As GSK3 regulates Mcl-1 expression through regulation of proteasome-mediated degradation, the influence of Enzastaurin on Mcl-1 expression was investigated. Pre-treatment with 5 μM Enzastaurin for 24 hours induced a decrease in Mcl-1 expression level in enzastaurin-sensitive samples. In these samples, Mcl-1 downregulation preceded apoptotic features, including cytochrome c release as well as caspase 3 and PARP cleavage. Finally, in 4/5 cases tested, we observed that Enzastaurin (E 5 μM) sensitized Rituximab (RTX 10 microgram/ml)-induced B-cell apoptosis (as measured at 24h by Annexin V binding : RTX alone 2-5% vs. RTX+E 15-55%, $p<0.05$) in peripheral mononuclear cells from gradient density-purified CLL blood samples, this effect being correlated with both GSK3 activation and, most importantly, Mcl-1 down-regulation. As Mcl-1 controls fludarabine resistance, combination of 5 μM Enzastaurin (E) and 1 μg/mL Fludarabine (F) for 4 days were assessed in 5 patients for synergistic activity. Yet, an additive but not synergistic effect was found, as evaluated by cell counting and PARP cleavage (living cells : F alone 74.4±20% vs. F+E 48.8±12.8%, two-sided student $p=0.016$). *Conclusion*. Our study shows for the first time that CLL cells are generally sensitive to enzastaurin, and that this drug should be tested alone or in combination with Rituximab. Effects of Enzastaurin are largely p53-independent, as 4/5 patients with 17p deletion were found to be good responders.

0339

ROLE OF CD38 IN HOMING OF CHRONIC LYMPHOCYTIC LEUKEMIA CELLS

T. Vaisitti,[1] S. Aydin,[2] D. Rossi,[3] L. Bergui,[4] G. D'Arena,[5] L. Bonello,[6] G. Chiorino,[7] G. Gaidano,[3] F. Malavasi,[2] S. Deaglio[2]

[1]Lab of Immunogenetics, TORINO; [2]Department of Genetics, Biology and Biochemistry, University of Torino, TORINO; [3]Division of Hematology, Department of Clinical and Experimental Medicine, Amedeo, NOVARA; [4]Department of Medicine and Experimental Oncology, University of Torino, TORINO; [5]IRCCS Casa Sollievo della Sofferenza Hospital, SAN GIOVANNI ROTONDO; [6]Research Center for Experimental Medicine (CeRMS), University of Torino, TORINO; [7]Fondo Edo Tempia, BIELLA, Italy

Chronic lymphocytic leukemia (CLL) is clinically heterogeneous, with the presence of two distinct subsets of patients characterized by different survival, propensity to grow according to microenvironmental signals and overall response to treatment. A limited number of molecular markers have been identified so far to distinguish these two extremes. Aggressive CLL is defined by the absence of mutations in the IgVh genes, expression of the surface molecule CD38 and of the cytoplasmic kinase Zap70. Human CD38 is a glycoprotein, simultaneously acting as an ectoenzyme and a receptor. The products of the enzymatic activity are

involved in the regulation of cytoplasmic Ca^{2+} levels, while the receptorial functions lead to activation/proliferation and migratory signals in T, B, NK and dendritic cells. Further more, the interaction with CD31, the only non-substrate ligand for CD38, controls an active signaling pathway in circulating and residential lymphocytes. We reported that CD38 acts as a receptor on CLL cells mediating proliferation and survival and modulating the expression of a set of genes involved in migration and signaling pathways. Furthermore, the simultaneous expression of CD38 and Zap70 in neoplastic B cells identify a subset of cells functionally and genetically distinct from all other subsets and characterized by a higher migration and signalling ability in response to CXCL12, a critical chemokine in CLL homing from blood to lymphoid organs. The aim of this work is to explore the role of CD38 in CXCL12-mediated homing of CLL cells. The ultimate goal is to define the mechanisms regulating CLL re-circulation from blood to lymphoid organs, an essential step in the maintenance and progression of the disease. The results obtained analysing a large cohort of clinically and molecularly characterized patients indicate that i) the concurrent expression of CD38 and Zap70 defines a subgroup of patients endowed with the highest migratory potential in response to CXCL12; further, ii) the $CD38^+$/$Zap70^+$ clones are able to induce a significantly phosphorylation of Erk1/2, compared to the negative counterpart, after exposure to the chemokine, and iii) the interactions CD31/CD38 activate genetic pathways involved in proliferation and migration. Further confirmation of the functional link between CD38 and CXCR4 has been obtained evaluating the response of CLL cells to CXCL12 in presence of blocking monoclonal antibodies (mAbs). Pre-treatment with anti-CD38 mAbs resulted in a decreased response to the chemokine in terms of Erk1/2 phosphorylation and chemotaxis. Similar results have been obtained also in an *in vivo* model, using NOD/SCID mice: pre-treatment of CLL cells with anti-CD38 mAbs resulted in a reduced homing to spleen and bone marrow. Taken together, the results so far obtained indicate that CD38 play a crucial role in modulating CXCR4 signalling pathway, exerted also through a physical association on CLL cells, and represent a novel mechanism in the regulation of lymphocyte chemotaxis and homing. Furthermore, they represent preliminary data supporting the hypothesis that CD38 may be used in CLL as a target for human specific mAbs.

THE FREQUENCY OF CIRCULATING CLL-LIKE B-CELL CLONES IN OTHERWISE HEALTHY INDIVIDUALS SIGNIFICANTLY INCREASES USING A HIGH-SENSITIVE MULTICOLOR FLOW CYTOMETRY APPROACH

W. Nieto,[1] M. Almeida,[1] A. Romero,[2] C. Teodosio,[1] A. Lopez,[1] A. Henriques,[1] M.L. Sanchez,[1] M. Jara,[1] A. Rasillo,[1] P. Fernandez-Navarro,[3] T. Vega,[4] A. Orfao[1]

[1]University of Salamanca, SALAMANCA; [2]Gerencia de Atención Primaria de Salud de Salamanca, Sanidad de Castilla y León, SALAMANCA; [3]Centro de Atención Primaria de Salud de Ledesma Salamanca, SACYL, SALAMANCA; [4]Junta de Castilla y León, SALAMANCA, Spain

Background. Monoclonal B-cell lymphocytosis (MBL) is the international consensus term proposed to indicate the presence of low numbers of circulating monoclonal B cells (<5×10^9/L) in otherwise healthy individuals. Whether MBL represent an early stage of a chronic B-cell malignancy particularly chronic lymphoid leukemia (CLL), as in a large proportion of MBL cases, cells have a CLL-like phenotype is still unknown. Recently, it has been reported that circulating CLL-like B cells can be detected using 4- or 5-multicolor flow cytometry in 5%-7% of adults with normal lymphocyte counts. *Aim.* to investigate the frequency of circulating monoclonal B cells in a series of healthy adults who belong to a population living in Salamanca (Western Spain), by using a high-sensitive multicolor flow cytometry approach. *Methods.* A total of 608 healthy individuals (47% m / 53% f) older than 40 years (62±13 years) with normal lymphocyte counts ($2.2\pm0.7\times10^9$/L) were randomly recruited from the Primary Health Care system region of Salamanca. EDTA-anticoagulated peripheral blood (PB) samples were immunophenotyped using a high-sensitive flow cytometry approach, based on 8-color staining panels and the systematic screening for >5x106 total PB leucocytes. Analyses of genetic abnormalities and IgH gene rearrangements were performed on FACSorted clonal B cells (purity ≥98%) by conventional iFISH and PCR amplification/sequencing, respectively. *Results.* the frequency of PB monoclonal B cells was markedly higher than previously reported (12% for CLL-like B cells, found at frequencies of $0.17\pm0.13\times10^9$ cells/L); interestingly, the incidence progressively increased with age (5%, 5%, 14%, 19%, 23% and 50% of individuals aged 40-49, 50-59, 60-69, 70-79, 80-89 and >90 years, respectively), while no association ($p>0.05$) was found between age and the size of the clone, or between the presence of circulating clonal B-cells and gender (11% of females versus 13.8% of males). In 62% of cases the infiltration was below the maximum sensitivity of the techniques described by others (<0.01%), at median frequencies of 0.38% of all PB B cells (interquartile range: 0.14%-4.2%). Clonal origin of these B-cell expansions was confirmed (n=15) by the presence of either clonal IgH gene rearrangements or the presence of genetic abnormalities. *Summary and Conclusions.* We show that the frequency of PB monoclonal B cells in healthy adults individuals >40y with normal blood counts is markedly higher than that previously reported (12% for CLL-like B cells), due to the higher sensitivity of the flow cytometry approach here applied. As it has been suggested that the fundamental biologic issue is the presence of a clonal population, and no cutoff point ensures 100% efficient discrimination of individuals at risk of progression, the precise identification of cases having circulating clonal B cells becomes a key question.

0341

THE LOCAL MICROENVIRONMENT PLAYS A DIFFERENT ROLE IN THE SURVIVAL OF TUMOR CELLS IN CHRONIC LYMPHOCYTIC LEUKEMIA WITH MUTATED AND UNMUTATED IMMUNOGLOBULIN (IG) VH GENES

M. Coscia,[1] F. Pantaleoni,[1] C. Riganti,[2] M. Rigoni,[1] S. Peola,[1] C. Vitale,[1] D. Drandi,[1] M. Ladetto,[1] A. Bosia,[1] M. Boccadoro,[1] M. Massaia[1]

[1]Divisione di Ematologia dell'Università di Torino, TORINO; [2]Department of Genetics, Biology and Biochemistry, Università di torino, TORINO, Italy

Background. Chronic lymphocytic leukemia (CLL) is a clinically heterogenous disease. The mutational status of the tumor immunoglobulin heavy chain variable region (IgVH) is a well established prognostic marker: patients with unmutated (UM) IgVH have a bad prognosis, whereas patients with mutated (M) IgVH have a good prognosis. It has already been reported that soluble factors (i.e. IL-4 and CD40L) and cellular components of the local microenvironment [i.e. bone marrow stromal cells (BMSC) and peripheral blood T cells (PBT)] are important survival factors for CLL B cells. It is currently unknown to what extent tumor cells from UM and M CLL patients depend on the local microenvironment for their survival. *Aims.* The aim of this work was to evaluate the different level of dependency of UM and M CLL cells from survival factors of the tumor microenvironment. *Methods.* M and UM CLL cells negatively selected by magnetic beads isolation were cultured in standard medium in the presence or in the absence of IL-4, CD40L, murine stromal cells (M2-10B4), CLL-derived BMSC and autologous T lymphocytes. Apoptotic and necrotic cells were quantified by annexin V and propidium iodide (PI) staining. The intracellular expression of Bcl2 and the nuclear translocation of NFkB were evaluated by flowcytometry and by EMSA, respectively. *Results.* Leukemic cells purified from the peripheral blood of UM CLL patients showed a significantly higher apoptotic rate than leukemic cells of M patients. Both M and UM CLL cells showed high level of expression of Bcl-2 and NF-kB soon after purification. *in vitro* spontaneous apoptosis of UM B-CLL cells was associated with a progressive time-dependent downregulation of the intracellular expression of Bcl2 and with a complete loss of the active nuclear form of NF-kB. On the contrary, the higher long term viability of M CLL cells was paralleled by the maintenance of Bcl2 and NF-kB expression. We next investigated whether the enhanced pro-apoptotic tendency of UM CLL cells could be reverted by extrinsic survival factors. We found that IL-4 and CD40L, used alone or in combination, as well as murine and human BMSC were capable of rescuing UM tumor cells from apoptosis. The pro-survival effect of these stimuli was exerted through the upregulation of Bcl-2 and was totally independent from the recovery of NF-kB expression. A pro-survival effect on UM CLL cells was also exerted by autologous T cells. Indeed, the cocolture of B and T cells at different ratios showed that the presence of sufficient numbers of viable T cells could prevent UM CLL cells apoptotic death by restoring the expression of the nuclear form of NF-kB and of Bcl2. *Conclusions.* These data indicate that the survival of tumor cells from UM CLL patients is dependent on the local microenvironment. On the contrary, tumor cells from M CLL patients are intrinsically more resistant to apoptosis and minimally influenced by the local microenviroment. This higher dependency of UM CLL cells from extrinsic signals might be exploited to develop new therapies targeting the tumor microenvironment to potentially improve patient outcome in more aggressive CLL.

GENOME-WIDE DNA COPY NUMBER ANALYSIS BY SNP ARRAYS OF B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA REVEALS THE PRESENCE OF NOVEL MOLECULAR LESIONS

L. Mosca,[1] L. Agnelli,[1] S. Fabris,[1] G. Cutrona,[2] S. Matis,[2] M. Lionetti,[1] K. Todoerti,[1] A. Andronache,[1] M. Gentile,[3] M. Spriano,[4] V. Callea,[3] G. Festini,[5] S. Molica,[6] G. Lambertenghi Deliliers,[1] F. Morabito,[3] M. Ferrarini,[2] A. Neri[1]

[1]Università di Milano e Fondazione IRCCS Policlinico di Milano, MILANO; [2]Istituto Nazionale per la Ricerca sul Cancro, IST, GENOVA; [3]Azienda Ospedaliera, COSENZA; [4]Azienda Ospedaliera S. Martino, GENOVA; [5]Azienda Ospedaliero-Universitaria, Ospedali Riuniti, TRIESTE; [6]Azienda Ospedaliera Pugliese- Ciaccio, CATANZARO, Italy

Background. B-cell chronic lymphocytic leukemia (B-CLL) is a genetically heterogeneous disease with a variable clinical course. Chromosomal changes have been identified by FISH in approximately 80% of patients, and the presence of specific lesions, such as trisomy 12 and 13q14, 11q23 and 17p deletions have been proven to be prognostic markers for disease progression and survival. Aims. To provide insights into the genomic complexity of B-CLL. *Methods.* A panel of highly purified neoplastic cells (>92%) from 100 untreated, newly diagnosed patients in Binet A was investigated. This series was characterized by fluorescence in situ hybridization (FISH) for the most recurrent genomic aberrations (trysomy 12, 13q14, 11q23 and 17p13 deletions) and for the major prognostic markers. Genome-wide profiling data were generated by means of Affymetrix GeneChip® Human Mapping 250K Nsp single nucleotide polymorphism (SNP) arrays. Copy number alterations (CNA) were calculated using the DNA copy Bioconductor package, which looks for optimal breakpoints using circular binary segmentation (CBS) (Olshen *et al.*, 2004). Results. FISH identified the presence of trisomy 12 in 21 cases; 13q14 deletion in 44 cases, 34 as the sole abnormality; 11q23, 17p13.1 and 6q23.3 in 15, 7 and 2 patients, respectively. In addition, ZAP-70 and CD38 expression resulted positive in 42 and 46 patients, whereas IgVH genes were mutated in 45 patients. The genome-wide analysis allowed the identification of CNAs in all cases. A total of 782 aberrations (from 1 to 31 per sample, mean and median values 7.82 and 7, respectively) were detected; losses (365/782=46.7% loss; 194/782=24.8% biallelic deletion) were found to be more frequent than gains (148/782=18.9% gain; 75/782= 9.6% amplification). The most recurrent alterations detected by FISH were all confirmed by SNP array analysis, strengthening further the good reliability of such high-resolution technology. We identified a total of 16 minimally altered regions (MARs) larger than 100 kb with a frequency higher than 5%. Among well known alterations, the largest was represented by chromosome 12 trisomy, followed by 6q, 17p and 11q23 deletions (32.87, 19.09 and 10.43 Mb, respectively) and 13q14 deletion (635 kb). Gain of 2p extended to almost the whole short arm of chromosome 2 in 6 cases, with smaller regions of gain encompassing cytobands 2p25.3-p25.2, 2p16.3-p16.2, 2p16.1-p15 and 2p12 in 5 additional patients. Among those alterations previously described in B-CLL, we found losses at 14q32.33 (12 pts) and 22q11.2 (5 pts) involving the IGH and IGLĬ loci, respectively. With regard to novel regions, we identified losses at 4q35.2 (5 pts), 8q24.23 (6 pts) and 11q25 (6 pts). In addition we found a high frequency of losses/gains at 14q11.2 (42 pts) and 15q11.2 (33 pts), two genomic regions reported to be affected by DNA copy number variations. Conclusions. Our data indicate that genetic abnormalities involving chromosomal gains and losses are very common in early-stage B-CLL and further support the application of high resolution SNP array platforms in the characterization of genetic changes in the disease. In addition we detected novel altered chromosomal regions that warrant future investigations to better define their pathogenetic role in B-CLL.

THE SYK INHIBITOR R406 BLOCKS BCR SIGNALING, CELL ADHESION AND MIGRATION, AND INDUCES APOPTOSIS IN CLL CELLS: AN EXPLANATION FOR THE CLINICAL ACTIVITY OF R406 IN CHRONIC LYMPHOCYTIC LEUKEMIA

J.A. Burger, M.P. Quiroga, K. Balakrishnan, V. Gandhi, A. Kurtova, W.G. Wierda, M.J. Keating

The University of Texas MD Anderson Cancer Center, HOUSTON, USA

Background. B cell receptor- (BCR-) signaling is increasingly recognized as factor promoting the expansion of Chronic Lymphocytic Leukemia (CLL) cells in tissue microenvironments. The spleen tyrosine kinase (Syk) is a key element of BCR signaling, and therefore represents a novel therapeutic target. R406, an ATP-competitive Syk inhibitor, displays clinical activity in CLL, characterized by transient increases in circulating CLL cells, and subsequent remissions in a significant number of patients (Friedberg J. *et al.* Ann Oncol. 2008 Jun; 19 Suppl 4). These findings suggest that R406 induces CLL cell mobilization form tissue compartments to the blood, and then induces CLL cell death. *Aims.* Because the effects of Syk on CLL cell migration, and BCR-dependent activation and survival are largely unknown, we examined the effects of R406 on CLL cell chemotaxis, expression of adhesion- and co-stimulatory-molecules, and survival. *Results.* Activation of BCR with polyclonal goat F(ab')2 fragments to human IgM significantly increased chemotaxis towards CXCL12 to 135.4±5.2% of controls and towards CXCL13 to 170.5± 31.5% of controls (Mean ± SEM, n=15). Engagement of BCR also significantly increased expression of CD40, CD44, CD54, and CD62L. Pretreatment with R406 abrogated the increased chemotaxis, and adhesion- and co-stimulatory molecule expression. BCR triggering also increased the viability of CLL cells in the majority of cases, preferably in ZAP-70$^+$ samples, and this pro-survival response was completely abrogated by R406. Co-culture with nurselike cells (NLC) represents an *in vitro* model for CLL cell interactions with their microenvironment, in which various pathways, including the BCR, become activated. We found that NLC-dependent CLL cell survival and anti-IgM- and NLC-dependent induction of the chemokines CCL3 and CCL4 in CLL cells was blocked by R406. Furthermore, R406 blocked BCR-induces phosphorylation of Syk, AKT and p44/42 MAP. *Conclusions.* Collectively, this study demonstrates that BCR engagement increases CLL cell migration, adhesion- and co-stimulatory-molecule expression, and survival. R406 effectively antagonizes these responses and induces CLL cells apoptosis in suspension and co-culture with NLC. The inhibitory effect of R406 on adhesion molecule expression and chemotaxis could be the reason for the transient mobilization of CLL cells into the blood of patients treated with R406, suggesting that our findings provide an explanation for the clinical activity of R406 in CLL patients.

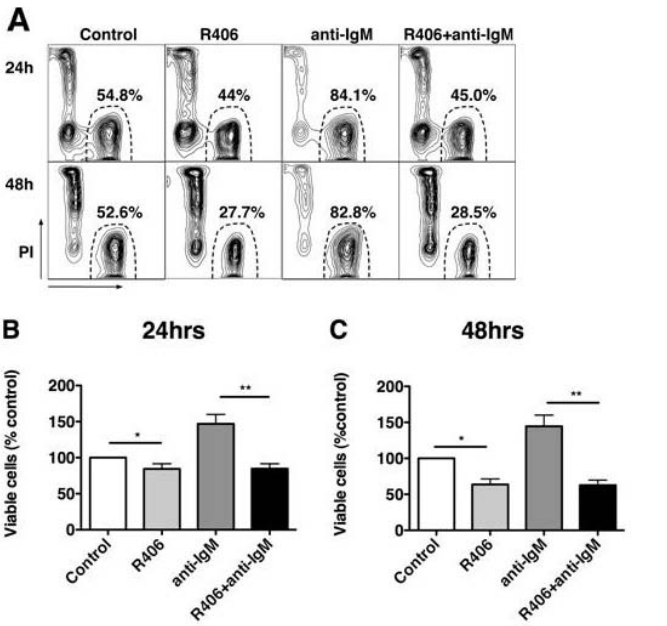

Figure 1. Effect of R406 on CLL cell viability.

MICRORNAS EXPRESSION PATTERN IN AGGRESSIVE SUBTYPE OF CHRONIC LYMPHOCYTIC LEUKEMIA

M. Mraz, K. Malinova, J. Kotaskova, S. Pavlova, B. Tichy, J. Malcikova, J. Lochmanova, Y. Brychtova, M. Trbusek, J. Mayer, S. Pospisilova

Center of Molecular Biology and Gene Therapy,Dept.of Internal Med-Hematooncology, BRNO, Czech Republic

Background. MicroRNAs (miRNAs) are small RNA molecules involved in the regulation of cell differentiation, proliferation and apoptosis. miRNAs expression was shown to be associated with known prognostic markers in CLL (deletion of 13q14, expression of ZAP70, unmutated IgVH, mutated IgVH). *Aims.* Although, recent publications demonstrat-

ed the involvement of miRNAs in the pathogenesis of CLL, the role of miRNAs in prognostically unfavourable disease has not been clearly defined. Thus, we examined miRNA expression patterns in aggressive CLL subtype harboring a deletion and/or mutation of the p53 gene (TP53) compared to wild-type p53 samples (mutated and unmutated IgVH). *Methods.* Micro-arrays (LNA oligos-Exiqon, EMBL) and Real Time-PCR (TaqMan MiRNA Assays, ABI) were used to define the miR expression pattern in CLL cells. MicroArrays (470 miRNAs) were performed for 11 CLL samples (del./mut. TP53 n=6, wt TP53 n=5) and Real Time-PCR for 30 CLL samples (35 miRNAs; del./mut. TP53 n=12, wt TP53 n=18). MicroRNAs expression was also studied in 6 control $CD19^+$ B cell samples from tonsils (after tonsillectomy). All control tonsillar and peripheral blood samples from patients were separated by RosetteSep Human B Cell Enrichment (purity ≥95% of $CD5^+19^+$ CLL cells; ≥95% of $CD19^+$ control B cells) *Results*. Using micro-arrays we identified 14 microRNAs down-regulated in CLL cells harboring deletion and/or mutation of p53 gene. Interestingly, no miRNAs were up-regulated in these samples compared to wild-type p53 cells. Real-time PCR was performed for miRNAs identified by microArrays and miRNAs added based on literature data and target prediction. By RT-PCR we observed a statistically significant down-regulation of three microRNAs, miR-34a, miR-29c and miR-17-5p, in the TP53-abnormal samples ($p<0.05$). Interestingly, these miRNAs target genes which were previously proposed to be involved in CLL pathogenesis or cell cycle regulation. miR-34a has been reported to regulate Bcl2 and to be directly regulated by p53 protein in response to genotoxic stress. Furthermore, miR-29 regulates the expression of TCL1 and MCL1 (anti-apoptotic Bcl2 family member) in the CLL cells. On the basis of animal models, deregulation of the TCL1 and MCL1 oncogenes was suggested to be important in the CLL pathogenesis. The third differently expressed miRNA, miR-17-5p, is a part of the c-myc regulated cluster (miR-17-92) and targets E2F1, p21 and Cyclin D1. MiR-17-5p also acts at the G1/S-phase cell cycle checkpoint by targeting genes involved in this transition. Moreover, miR-17-92 is included in the c-myc-mediated repression of hypoxia-inducible factor-1a (HIF-1a). HIF-1a plays a role in cell proliferation during hypoxia, and its upregulation in CLL bone marrow biopsies was linked with microvessel proliferation. Interestingly, for other hypoxia-associated miRNA family miR-23 we observed a higher expression in the unmutated IgVH samples. *Conclusions.* We describe a complex miR expression pattern in patients with deleted and/or mutated p53 gene compared to other CLL subtypes. MicroRNAs deregulated in aggressive CLL subtype target genes, which were previously proposed to be involved in CLL pathogenesis or cell cycle regulation suggesting their possible role in disease progression/pathogenesis.

IDENTIFICATION OF NOVEL RECURRENT COPY NUMBER VARIATIONS BY HIGH RESOLUTION COMPARATIVE GENOME HYBRIDISATION

A.H. Schuh, S.J.L. Knight, E. SadighiAkha, T. Enver, J. Taylor

University of Oxford, OXFORD, UK

Background. B-cell chronic lymphocytic leukaemia (B-CLL) is the most common form of adult leukaemia in the Western World. It is a heterogeneous disease and important biological and clinical differences have been identified. However, many questions remain about the molecular abnormalities underlying the genomic complexity of the disease. The technique of array based comparative genomic hybridization (aCGH) has revolutionized our ability to perform genome wide analyses of copy number variation (CNV) within cancer genomes. Most abnormalities noted previously have been very large, making it difficult to pinpoint specific candidate genes[3DOTS] By contrast, very small CNVs involving fewer genes are likely to have passed undetected due to insufficient array resolution. *Aim.* We therefore wanted to test a high resolution CGH array platform for its ability to detect small copy number variations (CNV). Method. To investigate this in more detail, we used a high resolution 244K aCGH platform to test and characterize enriched B-CLL peripheral blood samples (>80% $CD19^+$; $CD5^+$) from 40 clinically annotated patients collected at our institution. To distinguish CNVs seen commonly in the general population the results were compared with 'in house' control data sets and the Database of Genomic Variants (http://projects.tcag.ca/variation/. *Results.* Our results show that large abnormalities, already noted by FISH, were reliably identified and the boundaries of abnormalities at 11q22.3, 13q14.2 and 17p could be defined more precisely. In addition, novel and recurrent CNVs within the sample set were identified (1p33; 3p24.3; 3p14.2; 4q12; 4q13.3; 6q21; 6q27; 8p22; 10q24; 11p15.4; 11q12; 11q13.4; 11q14.1; 11q22.1; 11q23.3; 13q14.11; 14q21.1; 15q15.1; 15q25.3; 17p13.3; 17q22; 18p11.32; 18p23; 19p13.13; 19p13.12; 19p13.32; 22q11.21; 22q11.22). Interestingly, some of these abnormalities contain single gene alterations involving oncogenes, chemokine receptors, kinases and transcription factors important in B cell development and differentiation such as ETS-1. Assessment of smaller CNVs (less then 10 consecutive oligonucleotides), also revealed recurrent CNVs involving single genes, including gains of MAP2K5 (15q23) and NFKB activator (18q21.33) in the majority of samples. We are currently in the process of clustering single gene abnormalities into different groups according to gene function and pathways, ie oncogenes and tumour suppressors, receptors, signaling molecules, B-cell transcription factors, genes encoding for microRNAs and others. *Conclusions.* To date, the results suggest that genes belonging to pathways important for B cell development and differentiation are severely affected by the genomic instability observed in B-CLL samples. This work was supported by the Oxford Partnership Comprehensive Biomedical Research Centre with funding from the Department of Health's NIHR Biomedical Research Centres funding scheme. VASCULAR ENDOTHELIAL GROWTH FACTOR ACTS VIA AUTO- AND PARACRINE MECHANISMS AS A CRITICAL MICROENVIRONMENTAL FACTOR FOR THE SURVIVAL OF CHRONIC LYMPHOCYTIC LEUKEMIA CELLS

I. Gehrke, J. Paesler, R.K. Gandhirajan, R. Razavi, M. Hallek, K.-A. Kreuzer

University Hospital Cologne, COLOGNE, Germany

Background. Over the last years studies giving attention to the vascular endothelial growth factor (VEGF) status in chronic lymphocytic leukemia (CLL) have been published frequently and clearly indicated a role of VEGF in CLL. Whereas most of those studies were solely descriptive by focusing on the correlation of the VEGF status to patients´ characteristics and clinical features, actual functional data are missing. *Aims*. To describe the effect and functional background of VEGF on CLL cells and to further identify a potential involvement of the bone marrow microenvironment. *Methods*. Primary cells from either CLL patients or healthy individuals were used. Gene transcription status was analysed by real time PCR and protein expression levels by immunoblotting. Secreted VEGF was measured by ELISA. Phosphorylation of the VEGFreceptor2 was analysed using intracellular phospho flow cytometry. Cell survival was assessed by annexin V/PI negativity. VEGF-specific siRNAs were used to knock down VEGF in HS5 cells. *Results*. CLL and healthy B-cells produce VEGF, but only CLL cells seem to secrete it. Moreover, we found the VEGFreceptor2 to be phosphorylated to a higher extent in CLL than in healthy B-cells. Stimulation of CLL cells with rhVEGF enhanced the VEGF expression in an autocrine fashion. VEGF stimulation went along with increased expression of the antiapoptotic proteins Mcl1 and XIAP. We used the bone marrow stromal cell line HS5 to partly mimic the *in vivo* microenvironment of the CLL cell. HS5 themselves produce and secrete VEGF to a high extent. HS5/CLL coculture lead to an increase of VEGF expression in CLL cells. Furthermore, coculturing enhanced CLL cell survival an average of 28% after 72h of *in vitro* culture over monoculture, clearly indicating a prosurvival effect. Neutralization of VEGF using an anti-VEGF antibody resulted in a reduction of the coculture-mediated survival advantage in CLL cells by about two/thirds. Additionally, a coculture of CLL cells with siRNA-mediated VEGF-depleted HS5 did not support survival, explicitly displaying the significance of VEGF in CLL cell survival promotion by the coculture system. Additionally, we found STAT3, which is constitutively Ser727-phosphorylated, to become phosphorylated on Tyr705 in CLL cells upon rhVEGF stimulation and under coculture with HS5. This lead to STAT3 activation as seen by induction of expression of the target genes antiapoptotic Bclxl and CyclinD1. Blockage of the VEGFreceptor2 using small molecules reduced Tyr705-phosphorylation, STAT3 target gene expression and induced apoptosis. *Conclusions.* CLL cells, but not healthy B-cells, exhibit positive auto- and paracrine VEGF feedback loops. Furthermore, a coculture with HS5 prevents CLL cell death *in vitro*. VEGF plays an essential role in this regard, since the depletion of VEGF in this coculture setting reduced or even completely abrogated CLL cell survival. A potential mechanism for VEGF mediated CLL cell survival support is the activation of the potent oncogene STAT3. Hence, VEGF at least participates in the prolonged survival of the CLL cell *in vivo*, which characterizes the major pathophysiological problem of the disease. Therefore,

VEGF and downstream effectors, such as STAT3 have to be considered promising targets for CLL therapy aiming on induction of CLL cell apoptosis and subsequent reduction of the malignant clone.

LUMILIXIMAB INDUCES APOPTOSIS IN DRUG RESISTANT LYMPHOMA AND LEUKEMIA CELLS

N. Pathan,[1] S. Harris,[1] S. Tangri,[1] S. Hughes[2]

[1]*Biogen Idec Inc, SAN DIEGO, USA;* [2]*Biogen Idec Inc., LONDON, UK*

Background. Chronic lymphocytic leukemia (CLL) is the most prevalent leukemia in the western hemisphere. Although much progress has been made in CLL treatment, patients can develop resistance to currently available therapies, with CLL cells exhibiting an apoptosis-resistant phenotype via enhanced survival signaling due to the over-expression of anti-apoptotic proteins such as Bcl-2, Mcl-1 and XIAP, and activation of pro-survival kinases such as Akt. Lumiliximab, an anti-CD23 monoclonal antibody currently being evaluated in a registrational trial in CLL, differentially induces apoptosis in CLL cells via activation of capsases -9 and -3. In addition, lumiliximab downregulates anti-apoptotic proteins such as Bcl-2, Mcl-1, and XIAP, and reduces activation of pro-survival kinases such as Akt, enhancing the apoptotic effects of other therapeutic agents such as fludarabine and rituximab on CLL cells. *Aims.* To investigate the ability of lumiliximab to induce apoptosis in drug resistant cells *in vitro*. *Methods.* A preclinical, *in vitro* chemo-resistance model was generated by incubating SKW cells which over-express CD23 on the cell surface, with increasing concentrations of the chemotherapeutic drug adriamycin. *Results.* In the preclinical model, the drug-resistant cells (SKW-R) upregulated multi-drug resistance protein, MRP-2 and exhibited resistance to adriamycin and fludarabine as compared with parental cells (SKW-P). In addition, accompanying loss of CD20 expression rendered them insensitive to rituximab. Despite these changes, lumiliximab remained effective in inducing apoptosis in the drug-resistant cells. These results are consistent with findings in clinical trials of lumiliximab monotherapy and combination therapy: *in vitro* results from pre- and post-treatment patient samples obtained from a Phase 1 lumiliximab monotherapy trial in relapsed CLL (Study 152-20) showed activation activation of caspase-3, along with downregulation of Bcl-2 and Mcl-1, and a reduction in Akt activation. Lumiliximab induced apoptosis in samples from patients who did not respond well to prior fludarabine or rituximab treatment and apoptosis induction was independent of ZAP70 status. In addition, cytogenetic analysis of the available samples from this trial indicated that two of the three patients with a 17p deletion had decreases in CD5/CD19 counts. Furthermore all of the fludarabine-refractory subjects showed a reduction in ALC following treatment with lumiliximab and 50% had a reduction in lymph node bulk, as determined by SPD reduction. In a Phase 1/2 study of lumiliximab in combination with FCR, clinical response (including complete response) appeared to be unaffected by the presence at baseline of markers of poor prognosis (β2M levels greater than 2000 ng/mL; absence of IgVH mutation; $CD38^+$ CLL cells greater than 30% or $ZAP\text{-}70^+$ CLL cells greater than 30%) or by the presence of markers of rituximab resistance (CD55 or CD59). *Conclusions.* These data indicate that lumiliximab induces apoptosis in CLL cells and may be beneficial in the treatment of CLL, especially in those patients that have developed resistance to rituximab or fludarabine.

Background. Hemizygous and/or homozygous loss at 13q14 has been identified as the most frequent genomic alteration in B-cell chronic lymphocytic leukemia (B-CLL). Two microRNAs genes, *mir-15a* and *mir-16-1*, are located at 13q14 within a 30-kb region of loss in B-CLL and have been found to be deleted and down-regulated in the majority of cases with respect to normal B-cells. Aims. To narrow down the extent of the 13q14 deletion, to validate the genomic status of *mir-15a/16-1* cluster and to correlate the copy number (CN) and expression levels of the two miRNAs. *Methods.* The whole genome profile was investigated by means of single nucleotide polymorphism (SNP) arrays (Affymetrix GeneChip® Human Mapping 250K Nsp) in a panel of 100 untreated B-CLL patients in early stage disease (Binet stage A). The *mir-15a/16-1* cluster DNA CN and transcription levels of mature *miR-15a* and *miR-16* have been detected by quantitative Real Time RT-PCR (Q-RT-PCR) using a custom TaqMan® assay and TaqMan® microRNAs assays (Applied Biosystems), respectively. *Results.* Del(13)(q14) was present in 44 of our patients, in 34 as a single aberration. Biallelic deletions encompassing the 13q14.2-q14.3 region were found in 14/44 cases (32%). SNP arrays showed that the deletions varied considerably in size, ranging from 291 kb to 56 Mb. The minimal monoallelic deletion was 635 kb long, extending from physical position 49,635,024 bp to 50,270,550 bp. Notably, the *mir-15a/16-1* cluster is located approximately 87 kb upstream to this region, and thus apparently not affected by the deletion. Overall, in our series we found that 4 cases retained one or two copies of the *mir-15a/16-1* cluster. We evaluated the miRNA genes DNA CN by means of Q-RT-PCR in the four patients and in a selected panel of 28 cases (10 biallelic deleted, 7 monoallelic deleted, 11 non-deleted patients); the estimated gene CN values showed a very good correlation with SNP array data (p=1.37×E-06, Kruskal-Wallis test). As regards the miRNAs expression, we found a significant difference between biallelic and monoallelic deleted B-CLLs (p=0.009 and 0.006 for *miR-15a* and *miR-16*, respectively), whereas expression levels associated with the retention of 1 or 2 alleles were not statistically different. Conclusions. Our data confirmed the previous evidence of a short common deleted region at 13q14, narrowing it down to 635 kb of extent. Furthermore we demonstrated that one or two copies of *mir-15a/16-1* cluster can be maintained at DNA level in patients with 13q14 deletion. As regards *miR-15a* and miR-16 expression levels, we found that they are significantly down-regulated only in patients with biallelic deletion.

Chronic lymphocytic leukemia and related disorders - Clinical I

MICRORNA-29C AND 223 AND THEIR PROGNOSTIC VALUE IN CHRONIC LYMPHOCYTIC LEUKEMIA

B. Stamatopoulos,[1] N. Meuleman,[1] B. Haibe-Kains,[1] P. Saussoy,[2] E. Van Den Neste,[2] L. Michaux,[2] P. Heimann,[1] P. Martiat,[1] D. Bron,[1] L. Lagneaux[1]

[1]Institut Jules Bordet, BRUSSELS; [2]Cliniques Universitaires Saint Luc, BRUSSELS, Belgium

Background. MicroRNAs (or miR) are a novel class of small noncoding RNA involved in gene regulation. Aberrant microRNA expression has been recently associated with chronic lymphocytic leukemia (CLL) outcome. Currently, the heterogeneous evolution of this disease can be predicted by several prognostic factors. Nevertheless, a better individualization of the outcome in a given patient is still of utmost interest. *Aims and Methods.* In the current study, we investigated the expression of two microRNAs, miR-29c and miR-223, compared them to other biologic or clinical markers and proposed a real-time quantitative PCR (qPCR) score to better assess CLL outcome. *Results.* miR-29c and miR-223 expression decreased significantly with progression along Binet Stage A to C (p=0.0010 and p=0.0183, respectively), and were significantly lower in poor prognosis subgroup defined by cytogenetic abnormalities, IgVH mutational status, lymphocyte doubling time, solubleCD23, β2-microglobulin, ζ-associated protein 70 (ZAP70), lipoprotein lipase (LPL) and CD38 expression. Furthermore, miR-29c and miR-223 could predict TFS (n=110, p=0.0015 and p<0.0001, respectively) and OS (n=110, p=0.0234 and p=0.0008, respectively). Regarding all these results, we developed a qPCR score (from 0 to 4 poor prognostic markers) combining miR-29c, miR-223, ZAP70 and LPL in order to stratify treatment and death risk in a 110 patient cohort with a median follow-up of 72 months (range, 2-312). Patients with a score of 0/4, 1/4, 2/4, 3/4, and 4/4 had a median TFS of >312, 129, 80, 36 and 19 months, respectively (HR=17.00, p<0.0001). Patient with a score of 0-1/4, 2-3/4 and 4/4 had a median OS of >310, 183 and 106 months, respectively (HR=13.69, p=0.0001). Interestingly, during the first 50 months after diagnosis, only 10% of patients with a 0/4 score required a treatment, when compared to 100% of the 4/4. Furthermore, during the total follow-up (312 months), patients with a 4/4 score had a 27-fold higher risk to be treated and a 31-fold more risk to die comparing to patients with a 0/4 score. This score was validated by a 10-fold cross-validation (concordance of 82%) and a pre-validation study. Finally, in Binet stage A patients (n=77), this score remained relevant and significant for TFS and OS (HR=18.56, p<0.0001 and HR=12.5, p=0.0068, respectively). We also showed that miR-29c negative patients expressed higher level of Tcl1 oncogene (n=20, p=0.0068) making by this way a molecular connection of this our prognosis study. *Conclusions.* we showed that (i) miR-29c and miR-223 levels were decreased in poor prognosis patients regarding several well-known prognostic factors; (ii) a low level of these two microRNAs is thus associated to disease aggressiveness, high tumor burden and poor clinical evolution; (iii) we also showed that these two microRNAs could predict TFS and OS; (iv) we proposed a qPCR score to better individualized evolution of a particular CLL patient. This score will help to identify patients who will need early therapy and require thus a closer follow-up.

PHARMACOKINETICS, SAFETY AND ANTI-TUMOR ACTIVITY OF ABT-263 IN PATIENTS WITH RELAPSED OR REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA/SMALL LYMPHOCYTIC LYMPHOMA

G. Wierda,[1] P. Roberts,[2] R. Brown,[3] H. Wilson,[4] A. O'Connor,[5] S. Czuczman,[6] A. Busman,[7] H. Xiong,[7] P. Krivoshik,[7] H. Enschede[7]

[1]The University of Texas M. D. Anderson Cancer Center, HOUSTON, TX, USA; [2]The Royal Melbourne Hospital, PARKVILLE, Australia; [3]Dana-Farber Cancer Institute, BOSTON, USA; [4]National Cancer Institute, NIH, BETHESDA, USA; [5]Columbia University Medical Center, NEW YORK, USA; [6]Roswell Park Cancer Institute, BUFFALO, USA; [7]Abbott Laboratories, ABBOTT PARK, USA

Background. ABT-263 is an orally bioavailable BH3 mimetic that binds with high affinity (Ki ″1nM) and inhibits multiple antiapoptotic Bcl-2 family proteins. ABT-263 displays potent activity (EC50 ″ 1 μM) against human lymphoid and small cell lung cancer cell lines. Mechanism-based preclinical effects include apoptosis of circulating lymphocytes and apoptosis of circulating platelets mediated by inhibition of Bcl-2 and Bcl-XL, respectively. *Methods.* Two phase I monotherapy studies with continuous reassessment method (CRM) and 3+3 Fibonacci (3+3) designs are being conducted internationally to determine the pharmacokinetics, safety/tolerability and efficacy of ABT-263 in relapsed/refractory lymphoid malignancies (M06-814; 3+3) and CLL (M06-873; CRM). Patients (pts) were dosed on Days 1-14 of a 21-day dosing cycle with 10-440 mg (M06-814) or 10-250 mg (M06-873) ABT-263. Currently, continuous 21/21-day dosing (21d cycle) following a lead-in dose is being explored in the 275 mg (M06-814) and 300 mg (M06-873) cohorts from both studies. Tumor responses were evaluated by the NCI-WG criteria. *Results.* 72 pts have enrolled in these ongoing studies (n=53, 14/21-day dosing; n=19, 21/21-day dosing). Of these, 43 CLL/SLL pts were treated with ABT-263 (n=27, 14/21 day dosing; n=16, 21/21 day dosing). ABT-263 exposure increased proportional to dose from 10-440 mg with a terminal half-life of 18 h, supporting a QD schedule. Pts were heavily pretreated with a median of 4 prior treatments (range 1-12).The median progression-free survival has not yet been reached; the median time on study is 260 days [95% CI: 87, 364]. Among the 43 CLL/SLL pts, 4 had radiographically confirmed partial responses (PR) (99, 92, 72, and 64% reduction in lymphadenopathy) and 5 had unconfirmed regression in lymph node size at 72, 67, 55, 53 and 51%. 9 pts maintained a ≥50% decrease in circulating absolute lymphocyte count for ≥2 months (n=8, 14/21-day dosing; n=1, 21/21-day dosing). Stable disease (SD) was noted in 9 pts; 5 experienced minor radiographic responses (range from 15-49% reduction). Of these 43 patients, 10 were fludarabine and/or alemtuzumab refractory. Of the 6 fludarabine refractory pts, 2 had a 50% decrease in circulating lymphocytes, 1 a PR with a 92% reduction in lymphadenopathy, and 1 pt had a 49% reduction in lymphadenopathy. Of the 4 fludarabine and alemtuzumab refractory pts, 1 achieved a 46% reduction in lymphadenopathy and 1 had SD. Dose-dependent thrombocytopenia (TCP) resulting from on-target activity against Bcl-XL was observed. 27 pts on the 14/21-day schedule, had dose-limiting toxicities (DLT) occurring at 160mg (bronchitis), 315 mg (elevated ALT and Grade 4 TCP) and 440 mg (worsening pleural effusion in a pt with underlying afib) in M06-814, and at 110 mg (tumor lysis and Grade 4 TCP) and 250 mg (Grade 4 TCP) in M06-873. Among the 15 pts on the 21/21-day schedule, 3 experienced DLT; 2 Grade 4 TCP, 1 at 275 mg (M06-814) and 1 at 200 mg (M06-873), and 1Grade 2 nausea at 250 mg (M06-873). *Conclusions.* ABT-263 exhibited favorable pharmacokinetics and safety profiles with anti-tumor activity in relapsed/refractory CLL/SLL. Toxicities were predictable and manageable. Identification of optimal dose and schedule for phase II trials continues.

0351

RESULTS OF THE PHASE II NCRI CLL206 TRIAL OF ALEMTUZUMAB IN COMBINATION WITH HIGH-DOSE METHYLPREDNISOLONE FOR HIGH-RISK (17P-) CLL

R. Pettitt,[1] E. Matutes,[2] C. Dearden,[3] D. Oscier,[4] S. Carruthers,[1] J. Dodd,[1] S. Dodd,[1] R. Jones,[5] A. Rawstrom,[5] S. Agrawal,[6] D. Allsup,[7] A. Bloor,[8] J. Blundell,[9] S. Devereux,[10] G. Follows,[11] E. Heartin,[12] S. Proctor,[13] J. Radford,[8] T. Hamblin,[14] D. Catovsky,[2] P. Hillmen[5]

[1]University of Liverpool, LIVERPOOL; [2]Institute of Cancer Research, SUTTON; [3]Royal Marsden Hospital NHS Trust, SUTTON; [4]Royal Bournemouth Hospital, BOURNEMOUTH; [5]Leeds Teaching Hospitals NHS Trust, LEEDS; [6]St Bartholomew's Hospital NHS Trust, LONDON; [7]Hull and East Yorkshire Hospitals NHS Trust, HULL; [8]Christie Hospital NHS Trust, MANCHESTER; [9]Royal Cornwall Hospital, TRURO; [10]King's College Hospital NHS Trust, LONDON; [11]Addenbrookes Hospital NHS Trust, CAMBRIDGE; [12]North Wales NHS Trust, GLAN CLWYD; [13]Newcastle-upon-Tyne Hospitals NHS Trust, NEWCASTLE; [14]King's College Hospital, LONDON, UK

Background. Deletion of TP53 on chromosome 17p13 is the most ominous predictor of adverse outcome in CLL and is strongly associated with resistance to chemotherapy. Alemtuzumab and methylprednisolone are unusual in having established activity in 17p- CLL. However, these agents are of limited value when used alone. A combination regimen was therefore developed. Following a small pilot study that showed the *Cam-Pred* regimen to have promising activity in cases of CLL with TP53 defects [Leukemia 2006;20:1441-5], a multicentre phase II trial was developed to evaluate the regimen in more detail. *Aims.*To investigate the efficacy and toxicity of alemtuzumab in combination with high-dose methylprednisolone (HDMP) in high-risk (17p) CLL. *Methods.* Patients were eligible for the NCRI CLL206 trial if they had CLL requiring therapy and a 17p deletion in at least 20% of their malignant cells. The study treatment consisted of alemtuzumab 30 mg thrice week-

ly for up to 16 weeks (intravenous for the first 4 weeks and subcutaneous thereafter) plus methylprednisolone 1.0 g/m^2 for 5 consecutive days on weeks 1, 5, 9 and 13. Mandatory supportive care included antimicrobial prophylaxis with co-trimoxazole, aciclovir and itraconazole, G-CSF for neutropenia of <1.0×10^9/L and weekly CMV-PCR surveillance with pre-emptive (val)ganciclovir for CMV reactivation. Responses were assessed according to the criteria set out in the 2008 IWCLL guidelines. *Results.* 41 patients were recruited into the study between May 2006 and February 2008. Two patients died after registration but before receiving any treatment. Among the 39 remaining patients 56% were male and the median age was 61.5 (range 34-82). 46% were Binet stage C, 43% stage B, and 11% progressive stage A. 22 patients had received prior therapy whereas 17 were previously untreated. Data obtained up to October 2008 have been analysed. Response data were obtained for 37 patients and toxicity data for all 39 (Figure 1). 27 patients had CT scans performed, while reliable MRD data were available from 21 patients. The CR/CRi rate was 24% overall and 37% in previously untreated patients, with 3 patients achieving a confirmed MRD-negative CR/CRi. Grade 3-4 haematological toxicity and CMV reactivation rates were no greater than would be expected following alemtuzumab alone (67% and 23% respectively). However, there was a high rate of grade 3-4 non-CMV infection (41%) and glucocorticoid-related toxicity (38%). Rates of grade 3-4 infection were higher in previously treated patients (64% versus 41%). 12 of the 39 patients who received treatment died, 5 from disease progression, 2 from post-transplant complications, 1 from intracranial haemorrhage and 4 from infection including one case of suspected invasive aspergillosis and one of suspected viral encephalitis. Nine of the 12 deaths occurred among the 22 previously treated patients. Upated information on progression-free and overall survival will be presented. *Summary and Conclusions.* The Cam-Pred regimen appears to be the most active remission induction treatment for 17p- CLL hitherto reported, although it is also associated with a significant risk of infection and glucocorticoid-related toxicity.

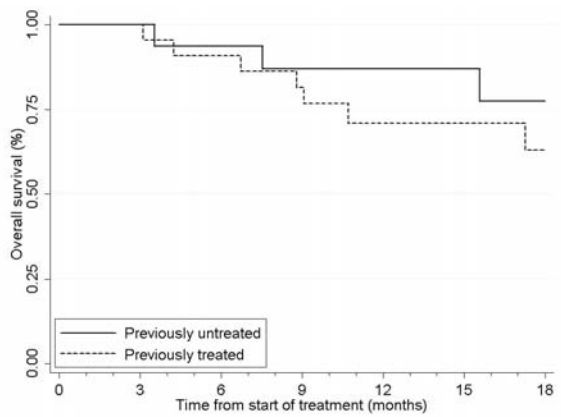

Figure 1. Summary of response and toxicity data.

Background. Richter's syndrome (RS) represents the transformation of CLL to aggressive lymphoma. Despite the abundance of biological markers available for predicting CLL progression, only few have been shown to be useful for RS prediction. *Aim.* To test the role of stereotyped HCDR3 in RS transformation. *Methods.* The first step of the study consisted of a case-control analysis comparing IGHV gene usage and prevalence of stereotyped HCDR3 in RS (n=69; all DLBCL) versus a control group (n=715) of CLL not transformed to RS. The second step consisted of an actuarial assessment of the impact of IGHV gene usage and stereotyped HCDR3 at CLL diagnosis, on the risk of subsequent transformation to RS in a cohort of 754 CLL, of which 39 had transformed to RS. Cluster analysis was performed by aligning HCDR3 of RS and non-transformed CLL into a database of 2421 HCDR3 of CLL. Results. Case-control comparison of IGHV usage documented that IGHV4-39 was the sole gene preferentially utilized in RS compared to non-transformed CLL (p=0.002). Cluster analysis revealed a significantly higher prevalence of stereotyped HCDR3 in RS compared to non-transformed CLL when considering all cases (RS: 34/69, 49.3% vs non-transformed CLL: 152/714, 21.3%; p<0.001), unmutated cases only (RS: 28/48, 58.3% vs non-transformed CLL: 95/276, 34.4%; p=0.002), and mutated cases only (RS: 6/21, 28.6% vs non-transformed CLL: 57/438, 13.0%; p=0.043). Subset 8 utilizing unmutated IGHV4-39/IGHD6-13/IGHJ5 genes was the sole HCDR3 subset preferentially utilized by RS (5/34, 14.7%) compared to non-transformed CLL (2/152, 1.3%) (p=0.002). Actuarial univariate analysis revealed higher risk of RS: i) in CLL utilizing stereotyped HCDR3 (5-year risk: 14.2%) compared to CLL without stereotyped HCDR3 (5-year risk: 3.9%) (p<0.00001); and ii) in CLL utilizing IGHV4-39 (5-year risk: 35.4%) compared to CLL utilizing other IGHV genes (5-year risk: 5.6%) (p<0.000001). Bivariate analysis combining stereotyped HCDR3 and IGHV mutation status indicated that stereotyped HCDR3 was not a surrogate of IGHV homology for RS prediction. Multivariate analysis selected IGHV4-39 usage (HR:4.25; p=0.002) and stereotyped HCDR3 (HR:3.08; p=0.002) as independent predictors of RS transformation. The observation that all RS utilizing IGHV4-39 carried stereotyped HCDR3 prompted investigation of the interaction between IGHV4-39 usage and stereotyped HCDR3 in the model. Multivariate analysis selected the interaction between IGHV4-39 usage and stereotyped HCDR3 at CLL diagnosis as the strongest independent predictor of RS transformation (HR:5.13; p=0.001). The relevance of the interaction between IGHV4-39 and stereotyped HCDR3 was confirmed by bivariate analysis. Accordingly, CLL utilizing both IGHV4-39 and stereotyped HCDR3 were identified as the disease category with highest risk of transformation (5-year risk: 68.7%) (Figure 1). Neither IGHV4-39 usage nor stereotyped HCDR3 affected the risk of CLL progression occurring without transformation to RS. Conclusions. The implications of our results are fourfold: i) RS carry stereotype HCDR3 at a very high frequency; ii) RS display biased usage of IGHV4-39 with stereotyped HCDR3; iii) stereotyped HCDR3 at CLL diagnosis is an independent risk factor of RS transformation; iv) the combination of stereotyped HCDR3 and IGHV4-39 usage in the same patient identifies CLL with a very high risk of RS transformation.

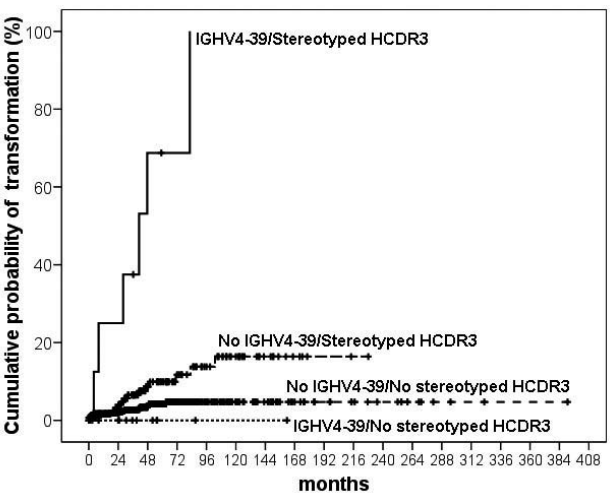

Figure 1. Cumulative risk of trasnformation to RS.

0353

FINAL RESULTS OF ORAL FLUDARABINE WITH CONCOMITANT SUBCUTANEOUS ALEMTUZUMAB IN RELAPSED/REFRACTORY B-CHRONIC LYMPHOCYTIC LEUKAEMIA (B-CLL): THE FLUSALEM STUDY

A. Egle,[1] T Melchardt,[1] L Pleyer,[1] I Tinhofer,[2] A. Lang,[3] F. Keil,[4] J. Thaler,[5] E. Gunsilius,[6] M. Fridrik,[7] R. Greil[1]

[1]University Hospital Salzburg, SALZBURG, Austria; [2]Charite, BERLIN, Germany; [3]Feldkirch General Hospital, FELDKIRCH, Austria; [4]Leoben General Hospital, LEOBEN, Austria; [5]Hospital Wels-Grieskirchen, WELS, Austria; [6]University Hospital Innsbruck, INNSBRUCK, Austria; [7]Linz General Hospital, LINZ, Austria

Background. Relapse of B-CLL presents a crucial problem to the patient and clinician. Combination of alemtuzumab and fludarabine was effective in heavily pre-treated patients in a very small pilot trial (Kennedy, Blood, 2002). The German CLL study group presented data on 36 relapsed or refractory CLL patients using intravenous fludarabine combined with a greatly reduced dose of 3 times 30 mg of intravenous alemtuzumab per cycle (FluCam regimen; Elter, JCO 2005). They showed a high 83% ORR, but did not report risk factors or MRD analysis. *Aims.* The FLUSALEM protocol combines 4 cycles of oral fludarabine (40 mg/m^2 3d) with continuous alemtuzumab therapy (30 mg s.c. 3 x weekly for 16 weeks), thereby increasing the cumulative alemtuzumab dose, while allowing a continous outpatient mangement. The study followed a 2-step Gehan design evaluating efficacy and safety of the therapy, with a previously reported interim analysis (Egle, ASH, 2006). *Methods.* In addition to the primary response endpoint, progression-free survival, risk factor profiles and MRD measurements after therapy were analysed. *Results.* Sixteen patients were evaluable for response and PFS. Median age was 60 years, 50% of patients had stageRai III/IV and median follow up was 18 months. Overall response was 87.5% (CR rate 56%, as compared to 30% in the FluCam Study), median time to reaching clinical CR was 59 days. Considering that 50% of included patients had Rai III/IV, bone marrow clearance by this regimen occurred very rapidly. Median PFS was 486 days or 16 months (as compared to 12 months in the dose-reduced FluCam) and 5 of 16 patients are in continued remission after 500-1300 days of follow-up. Therefore, 20% of our patients have a longer PFS than the longest reported from the FluCam study. Grade III infection was observed in 4 patients (25%, 3 CMV reactivations and 1 pneumocystis pneumonia in a trimethoprim-intolerant patient on pentamidine inhalation prophylaxis). No fatal infections were observed. One spontaneously resolving pulmonary grade 3 toxicity was observed after the end of therapy. CD4 depletion was profound (median 69/µL after 3 cycles) and prolonged (3/4 of patients did not reach CD4 counts >200/µL withinin 6 months). CD38 risk groups as well as mutation status are available for 14 and 11 patients with PFS follow up, respectively. Neither was predictive of PFS or response quality. MRD analysis by 4 colour flow cytometry was performed according to Rawstron (Blood 2001). MRD data at 2 months after treatment are available for 10 patients with 6 patients achieving an MRD negative state. MRD negativity at 2 months after end of therapy predicted a trend in PFS (p=0.09) and identified all but one patient with a PFS above the median. The exceptional case displayed a close to negative MRD measurement. *Summary and Conclusions.* Oral fludarabine combined with 16 weeks of subcutaneous alemtuzumab was feasible in an out-patient setting. Infectious complications were surprisingly low, and all were manageable. Response rates are high for previously treated patients and show high remission qualities, irrespective of risk factors. Long term progression-free survival is observed in MRD negative patients.

0354

LARGE BUT NOT SMALL COPY-NUMBER ALTERATIONS CORRELATE TO HIGH-RISK GENOMIC ABERRATIONS AND SURVIVAL IN CHRONIC LYMPHOCYTIC LEUKEMIA: A HIGH-RESOLUTION GENOMIC SCREENING IN NEWLY DIAGNOSED PATIENTS

R. Gunnarsson,[1] A. Isaksson,[2] M. Mansouri,[3] H. Göransson,[2] M. Jansson,[3] N. Cahill,[3] M. Rasmussen,[2] J. Staaf,[4] J. Lundin,[5] S. Norin,[6] A.M. Buhl,[7] K. Ekström Smedby,[8] H. Hjalgrim,[9] K. Karlsson,[1] J. Jurlander,[7] G. Juliusson,[1] R. Rosenquist[3]

[1]Stem Cell Center, LUND, Sweden; [2]Dept.of Medical Sciences, Cancer Pharmacology & Informatics, Uppsala University, UPPSALA, Sweden; [3]Dept.of Genetics and Pathology, Uppsala University, UPPSALA, Sweden; [4]Dept.of Oncology, Clinical Sciences, Lund University, LUND, Sweden; [5]Dept.of Hematology & Oncology, Karolinska University Hospital, STOCKHOLM, Sweden; [6]Dept.of Hematology, Karolinska University Hospital, STOCKHOLM, Sweden; [7]Dept.of Hematology, Leukemia Laboratory, Rigshospitalet, COPENHAGEN, Denmark; [8]Department of Medicine, Clinical Epidemiology Unit, Karolinska Institutet, STOCKHOLM, Sweden; [9]Dept.of Epidemiology Research, Statens Serum Institut, COPENHAGEN, Denmark

Background. Recurrent genomic aberrations (i.e. deletions of 11q, 13q, 17p and trisomy 12) are of great prognostic value in chronic lymphocytic leukemia (CLL). Identification of these alterations is routinely performed by fluorescence in-situ hybridization (FISH). However, less is known about the overall genetic complexity such as small copy number alterations (CNAs) and loss of heterozygosity (LOH) in CLL, and their contribution to prognosis. Moreover, the fact that no common genetic aberration has been described in the pathogenesis of CLL suggests that application of genome-wide techniques with high resolution would be valuable for identification of yet unidentified genetic lesions. *Aims.* To investigate genomic CNAs and CNN-LOH in newly diagnosed chronic lymphocytic leukemia (CLL) patients by applying high resolution SNP-arrays. *Methods.* 203 CLL patients were selected for inclusion in the present study from the Swedish part of a population-based Scandinavian cohort Array experiments were performed according to the standard protocols for Affymetrix GeneChip® Mapping 250K arrays. Copy-number analysis was performed by applying the BioDiscovery Nexus Copy Number 3.0 software. The evaluation of CNN-LOH was performed by applying a newly developed method, detecting tumor-specific CNN-LOH. *Results.* CNAs were identified in 90% of samples where deletions were more commonly detected than gains (70% vs. 30%, respectively). The known recurrent alterations were found in 75% of patients; del(13q) 52%, del(11q) 13%, trisomy 12 11% and del(17p) 4.4%. Interestingly, 5 samples (2.5%), which all carried del(11q), displayed a gain of chromosome 2p. Furthermore, 8 samples with homozygous del(13q) showed CNN-LOH of large parts of 13q, suggesting that a chromosomal duplication occurred after mono-allelic deletion. The prognostic impact of known recurrent aberrations was verified, although 11q-deleted and trisomy 12 patients displayed a similar poor-risk profile and patients with homozygous del(13q) had superior survival. Large aberrations (>5Mb) were strongly associated with poor-prognostic markers, i.e. 11q-/17p- and unmutated IGHV genes, and predicted poor survival. In contrast, small aberrations (<1Mb) were commonly detected in all samples, but were most often non-overlapping, and did not predict outcome. *Summary*. Whole-genome screening with SNP-arrays revealed a high frequency of known recurrent alterations in newly diagnosed CLL patients. Moreover, the SNP-technique allowed detection of additional large and small CNAs, which gave the opportunity to evaluate the overall complexity in CLL patients. As a result, we identified genomic complexity as a poor prognostic marker, but noted that this feature was strongly linked to established poor-risk molecular markers. Finally, this technique allowed identification of CNN-LOH in CLL, which were recurrently detected on chromosome 13. In conclusion, high resolution genomic arrays are applicable for the evaluation of recurrent aberrations and genomic complexity in newly diagnosed CLL samples.

Ematologia, Universita La Sapienza, ROMA, Italy; [12]Trial Consult Inc, MIESBACH, Germany; [13]Ematologia, Ospedale Niguarda Ca'Granda, MILANO, Italy

Background. Bendamustine (BEN) is a purine analogue / alkylator hybrid agent that provides effective treatment for a number of haematological and non-haematological malignancies. In Germany, it is used since more than three decades in first line therapy and pretreated CLL as well as for other types of non-Hodgkin's lymphomas. *Aims.* To compare the efficacy and safety of BEN versus chlorambucil (CLB) in treatment-naïve patients (pts) with CLL Binet stage B/C. This study was designed as pivotal trial for the approval of BEN in a number of European countries. *Patients and Methods.* Within this prospectively randomised phase III trial, pts received either BEN (100 mg/m^2 on days 1+2) or CLB (0.8 mg/kg on days 1+15) for up to 6 cycles. Primary endpoints were overall remission rate (ORR) and progression-free survival (PFS). Secondary endpoints were duration of remission, overall survival (OS), and safety, Also, type of remission (CR, nodular PR, PR) was analysed. Follow-up was for ≥12 months after completion of treatment of the last patient, or until progression for patients with CR, nPR or PR and stable disease, or until death or lost to follow-up. A 5-stage, adaptive-group, sequential procedure was used with planned interim analyses to adjust the number of patients. In addition to external data monitoring, efficacy was evaluated according to the NCI working group criteria by an independent committee in a blinded fashion. *Results.* 45 centres recruited 319 pts who were randomised to receive BEN (n=162) or CLB (n=157). All these pts were subject to the efficacy analysis (intention-to-treat population). As 7 pts did not receive any study medication, 312 pts were included in the safety analysis. Median age was 64 years; 71% had Binet stage B and 29% Binet stage C disease; median number of treatment cycles/patient was 6. ORR was significantly higher with BEN than with CLB (68% vs 31%; p<0.0001), with CR of 31% vs. 2%, respectively. Median PFS was 21.6 months with BEN and 8.3 months with CLB (p<0.0001), and median duration of remission (Kaplan-Meier estimate) was 21.8 months with BEN and 8.0 months with CLB (p<0.0001). No significant difference in OS is seen so far. Infection rates (CTC grades III+IV) were low in both treatment groups (7% BEN; 4% CLB). *Conclusions.* BEN was significantly more effective than CLB in treatment-naïve pts with CLL Binet stage B/C with respect to remission induction, PFS and duration of remission. Furthermore, safety data indicate that BEN toxicities are manageable and the drug is well tolerated. On the basis of these results, BEN should be considered as first-line chemotherapy for patients with CLL Binet stage B or C.

Buzzati-Traverso, ROME, Italy

Background. In the last years, the B cell receptor (BCR) has become a key molecule in chronic lymphocytic leukemia (CLL), given the correlation between mutational status of immunoglobulin heavy chain variable (IGHV) genes and disease prognosis. Recently, a fraction of CLL has been shown to preferentially express specific IGHV genes, often in a non-random combination with homologous heavy chain complementarity-determining region-3 (HCDR3) and peculiar light chains. Some of these stereotyped BCR mark CLL subsets with peculiar clinical behaviours regardless of IGHV mutations. These data suggest a role for BCR in defining the clinical and biological features of CLL, also beyond the mutational status of IGHV genes. *Aim.* To discover novel associations between specific IGHV gene usage and prognosis in CLL. *Methods.* A HCDR3-driven clustering of 1,426 IG sequences (1,398 patients) was performed using ClustalX(1.83). Time to treatment intervals (TTT), Rai staging, IGHV mutational status, CD38, ZAP-70, and karyotype abnormalities evaluated by FISH were available for 644 patients. Gene expression profiling (GEP) was performed on purified CLL cells, using a dual labelling strategy. Validation experiments were performed utilizing real-time quantitative PCR (QRT-PCR). *Results.* Taking into account the distribution of IGHV genes in 71 identified stereotyped BCR clusters, IGHV3-23 was totally absent in clusters despite being the second most frequently used IGHV gene (134/1,426). Although 109/134 IGHV3-23 CLL were mutated (M), alignment of IGHV sequences revealed a high degree of conservation in the context of the 13 AA positions involved in superantigen binding by IGHV3 subgroup genes, suggesting that the majority of M IGHV3-23 cases maintained the capacity to mediate superantigen recognition and binding. Median TTT (73 months) of M IGHV3-23 CLL (46 cases) was shorter than median TTT (153 months, p=0.0201) of the whole series of M CLL (350 cases), as well as of a series (342 cases) of M CLL in which 8 cases belonging to the bad prognosis IGHV3-21/IGLV3-21 cluster were excluded (median TTT=253 months, p=0.0115). The independent prognostic value of IGHV3-23 expression was tested in 396 M CLL. All the prognosticators and IGHV3-23 usage correlated with an increased risk of progressive disease by univariate analysis. Multivariate Cox proportional hazard analyses selected IGHV3-23 usage (p<0.05), Rai stage (p<0.0001) and FISH group (p<0.0001) as independent markers of disease progression for the whole cohort of M CLL, and in a cohort in which 8 M CLL from the IGHV3-21/IGLV3-21 cluster were excluded. By comparing 5 M IGHV3-23 and 22 M non-IGHV3-23 CLL for their differential GEP, 212 genes were selected, 108 up-regulated and 104 down-regulated in M IGHV3-23 CLL. Using the "Gene-Ontology Tree Machine" platform, a set of growth/tumor suppressor genes (PDCD4, DIDO1, TIA1, RASSF5), all down-regulated in M IGHV3-23 CLL, were significantly enriched in several gene-ontology categories related to apoptosis. The down-regulated expression of these genes was confirmed by QRT-PCR experiments. *Conclusions.* Expression of IGHV3-23 marks a subset of M CLL with a worse prognosis; such a peculiar clinical behaviour may be related to superantigen stimulation combined with down-regulation of specific growth/tumor suppressor genes.

0357

5-YEAR FOLLOW-UP OF HEAVILY PRETREATED PATIENTS WITH RELAPSED/REFRACTORY CLL IN PHASE 3 STUDY: SIGNIFICANT SURVIVAL BENEFIT WITH OBLIMERSEN PLUS FLUDARABINE/CYCLOPHOSPHAMIDE IN RESPONDING PATIENTS

M. O'Brien,[1] J. Gribben,[2] T. Cousin,[3] K. Rai[4]

[1]The University of Texas M.D. Anderson Cancer Center, HOUSTON, TX, USA; [2]Institute of Cancer, Barts and The London, LONDON, UK; [3]Genta Incorporated, BERKELEY HEIGHTS, NJ, USA; [4]Long Island Jewish Medical Center, NEW HYDE PARK, NY, USA

Background. Oblimersen (OBL) decreases the antiapototic protein, Bcl-2, and enhances cytotoxic activity of agents used to treat CLL. A randomized Phase 3 study of fludarabine/cyclophosphamide (FC) with/without OBL was conducted in patients who had relapsed/refractory CLL and at least 2 prior cycles of fludarabine. Informed consent was obtained; patients were stratified according to prior response to fludarabine (relapsed or refractory). The distribution of patients between groups was generally well balanced with respect to demographic and disease-related characteristics at baseline. In both groups, more than 80% of patients had disease-related symptoms, the median number of prior regimens was 3, and the median number of prior fludarabine cycles was 6. The primary endpoint -the relative proportion of patients who achieved a complete response (CR; defined as complete or nodular partial response)- was met: the CR rate was significantly greater among patients treated with OBL-FC than among those treated with FC (17% versus 7%; p=0.025; O'Brien *et al.*, J Clin Oncol 2007). With at least 2 years of follow-up, duration of CR also significantly favored OBL-FC (median not

reached [36+ months] versus 22 months; p=0.03; Moore *et al.*, ASH 2006). *Aim.* We evaluated whether the OBL-FC regimen would provide a long-term survival benefit. *Methods.* Patients received up to six 28-day cycles of FC (25 mg/m^2/d and 250 mg/m^2/d x 3d, respectively) with or without OBL (3 mg/kg/d x 7d by continuous IV infusion beginning 4 days before FC). Response and progression were determined according to NCI-WG criteria by a clinical expert blinded to treatment. An independent hematopathologist blinded to treatment and clinical information assessed bone marrow specimens. CT was required to confirm CR in patients with baseline abnormalities. Patients were followed for up to 5 years after randomization. *Results.* Five-year follow-up data were obtained for 97% of the 241 patients randomized (OBL-FC, 120 patients; FC, 121). Post-study CLL treatment was balanced between groups. In the intent-to-treat population, the 5-year survival rate was improved (25% versus 15%) with OBL-FC, but not significantly different. Among responding patients (ie, those with complete or partial response), survival was significantly increased in the OBL-FC group (hazard ratio=0.60; p=0.038). Patients with fludarabine-sensitive disease (as defined at baseline) had the greatest benefit from the addition of OBL: a four-fold increase in the CR rate (p=0.016) and a 50% reduction in the risk of death were observed (Figure). No between-treatment survival difference was apparent in nonresponding patients (hazard ratio=1.0; p=0.9). *Summary and Conclusions.* In heavily pretreated patients with relapsed/refractory CLL, adding OBL to FC significantly increases the rate of CR and durable CR and provides a significant survival benefit in patients who achieve a complete or partial remission. Greatest benefit was noted in the prespecified group of patients who retained sensitivity to chemotherapy.

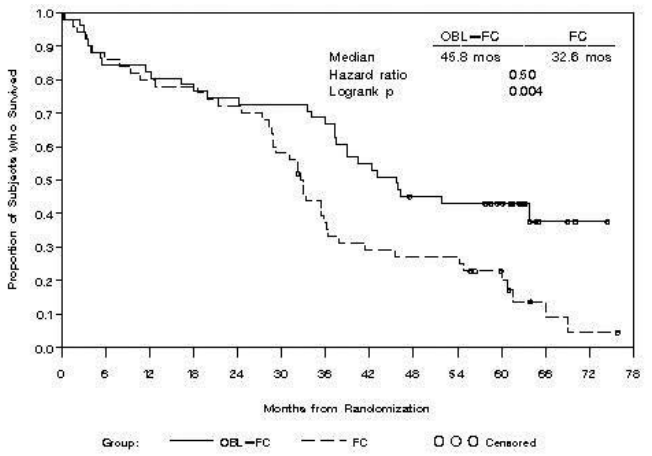

Figure. 5-year survival in fludarabine-sensitive subjects

CD49D EXPRESSION AND SHORT TELOMERE LENGTH INTERACT IN CHRONIC LYMPHOCYTIC LEUKEMIA AND IDENTIFY PATIENTS AT RISK OF PROGRESSION AND SHORT SURVIVAL

D. Rossi,[1] M. Ladetto,[2] C. Lobetti Bodoni,[2] A. Zucchetto,[3] F.M. Rossi,[3] V. Gattei,[3] G. Gaidano[1]

[1]Division of Hematology, Amedeo Avogadro University, NOVARA; [2]University of Turin, TURIN; [3]Centro di Riferimento Oncologico, AVIANO, Italy

Background. The rationale of the study stems from two considerations: i) CD49d expression and short telomere length (TL) represent novel prognostic markers for chronic lymphocytic leukemia (CLL); ii) both CD49d expression and short TL associate with clinico-biological features of highly proliferating CLL. *Aim.* To test the impact of the interaction between CD49d expression and short TL on CLL prognostication. *Methods.* The study was based on a consecutive series of 180 previously untreated CLL. CD49d expression was analyzed by flow cytometry. Peak TL was determined by Southern blot. Best CD49d and TL cut off points for CLL prognostication have been previously identified (Gattei *et al.*, Blood 2008; Rossi *et al.*, Leukemia 2009). *Results.* Figure 1A represents the relationship between CD49d expression and TL in a consecutive series of 180 CLL. When treated as categorical variables, CD49d>30% and TL<5000 bp were not associated (p=0.097). Clinico-biological variables at diagnosis and outcome were stratified according to CD49d and TL status. For this purpose, CLL were grouped into 3 categories: i) CD49d-low/TL-long (CD49d<30%/TL>5000bp); ii) CD49d-high/TL-short (CD49d>30%/TL<5000bp); iii) discordant cases (CD49d<30%/TL<5000bp and CD49d>30%/TL>5000bp). The prevalence of unfavorable variables at diagnosis progressively increased from CD49d-low/TL-long CLL to discordant cases and to CD49d-high/TL-short CLL (Rai stage III-IV: 3.8% vs. 15.5% vs. 24.1%, respectively, p=0.006; IGHV homology >98%: 19.0% vs. 41.4% vs 69.4%, respectively, p<0.001; CD38 >30%: 8.8% vs. 39.4% vs. 62.1%, respectively, p<0.001; unfavorable karyotype: 21.3% vs. 46.5% vs. 65.5%, respectively, p<0.001).

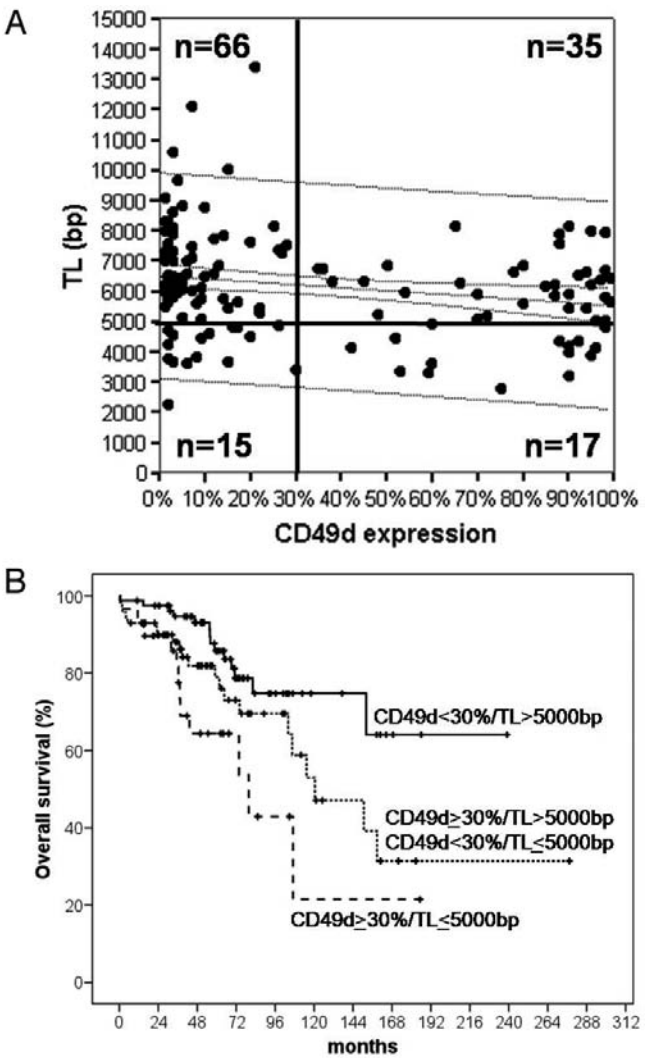

Figure 1. A: CD49d and TL correlation. B: survival.

Occurrence of markers of rapid cell turnover also progressively increased from CD49d-low/TL-long CLL to discordant cases, and to CD49d-high/TL-short CLL (median β-2-microglobulin: 2.1 mg/L vs 2.7 mg/L vs. 3.3 mg/L, respectively, p<0.001; median LDH: 323 U/L vs 370 U/L vs. 399 U/L, respectively, p<0.001). Time to lymphocyte doubling progressively decreased from CD49d-low/TL-long CLL to discordant cases, and to CD49d-high/TL-short CLL (54.2 months vs 28.6 months vs. 18.3 months, respectively, p<0.001). Time to progression to a more advanced stage progressively decreased from CD49d-low/TL-long CLL to discordant cases, and to CD49d-high/TL-short CLL (68.9 months vs 34.6 months vs. 23.0 months, respectively, p<0.001). Treatment free survival progressively decreased from CD49d-low/TL-long CLL to discordant cases, and to CD49d-high/TL-short CLL (130.8 months vs. 37.2 months vs. 21.5 months, respectively, p<0.001). Survival progressively decreased from CD49d-low/TL-long CLL to discordant cases, and to CD49d-high/TL-short CLL (not reached vs. 120.5 months vs. 79.8 months, respectively, p=0.006) (Figure 1B). Other variables associated with short survival were IGHV homology >98%, presence of del17p13 or 11q22-q23, Rai stage III-IV, and β-2-microglobulin >2.5 mg/L (p<0.05). Multivariate analysis selected the interaction between CD49d expression and TL as independent predictor of survival (HR:2.17; p=0.023)

after adjusting for IGHV homology, unfavorable FISH karyotype, Rai stage and β-2-microglobulin. Conclusions. The implications of our results are twofold: i) CD49d expression and short TL interaction identifies CLL with rapid tumor kinetics, high risk of progression, and short survival; ii) the interaction between CD49d expression and short TL is an independent predictor of short survival in CLL.

UPDATE OF THE FRENCH LGL PROLIFERATION REGISTRY: REPORT OF 229 CASES

T. Lamy,[1] B. Bareau,[1] J. Rey,[2] M. Hamidou,[3] J. Donadieu,[4] O. Reman,[5] N. Schleinitz,[6] O. Tournilhac[7]

[1]University Hospital, RENNES; [2]Institut PaoliCalmettes, MARSEILLE; [3]CHU de Nantes, NANTES; [4]Hopital Trousseau, PARIS; [5]CHU de Caen, CAEN; [6]CHU de Marseille, MARSEILLE; [7]CHU de Clermont-Ferrand, CLERMONT-FERRAND, France

Background. Large granular lymphocytes (LGL) leukemia is a rare lymphoproliferative disorder associated with autoimmune diseases and impaired hematopoiesis. Only few series have reported on a large number of patients. Clinico-biological presentation and therapeutic options need to be clarified. *Aims.* This study describes the largest series of clinical and biological characteristics of 229 patients with LGL leukemia. *Methods.* The French national LGL proliferations registry has included clinico-biological data from 250 patients suspected of LGL leukemia and coming from 35 medical centres. Using the updated criteria, the diagnosis was based on a LGL expansion (>0.5×10^9/L) lasting more than 6 months (excluding transient or reactive LGL proliferations). Monoclonal TCR γ gene rearrangement was detected in all T LGL leukemia. The term chronic NK lymphocytosis was used for patients with pauci or asymptomatic disease while patients with tissue LGL infiltration of spleen, liver or bone marrow with aggressive clinical behaviour were considered as having NK LGL leukaemia. Response to therapy was determined by monthly clinical and blood count assessments. The primary response criterion was defined based on results of blood count at 3 months.

Table 1.

T or NK subtype	T	NK	T or NK subtype	T	NK
Nb of patients	201	28	hyperlymphocytosis	51%	58%
Median age	59	58	LGL > 4 x 10.9/L	14%	21 %
Sex ratio (M/F)	90/111	14/14	LGL<1.10.9/L	55%	59 %
Non symptomatic	18%	25%	Neutropenia Severe neutropenia	61% 26%	48% 16%
Splenomegaly Hepatomegaly Adenopathy	24% 10% 6 %	25% 14% 7%	Anemia Anemia Hb < 8 g/dl Thrombocytopenia	24% 7% 19%	28% 4% 8%
B Symptoms	7%	10%	LGL Marrow infiltration	71%	61%
Infections	23 %	18%	Polyclonal gammapathy	35%	56%
RA	17%	11%	Monoclonal gammapathy	10%	6%
Autoimmune cytopenia	7%	11%	RF AAN	40% 48%	43% 63%
LGL related deaths	14/201	1/28	Need for treatment	44%	39%

Results. The diagnosis of T-LGL leukemia was confirmed in 201 cases, chronic NK lymphocytosis in 27 cases and NK LGL leukemia in one case. The main clinico-biological characteristics are summarized in Table 1 as follows. We did not observe any significant difference between T and chronic NK lymphocytosis. The classical phenotype of T-LGL leukemias was TCRαβ/CD3$^+$/CD4$^-$/CD8$^+$/CD16$^+$/CD57$^+$. γδ+ T cell LGL leukemia was uncommon (18%). Their common phenotype was similar (CD3$^+$/CD4$^-$/CD8$^+$/CD57$^+$) but 35% of those patients had a double negatif CD4$^-$/CD8$^-$ phenotype. NK LGL leukemia mainly expressed a CD3$^-$/CD16$^+$/CD56$^+$ phenotype. Vβ repertoire was analysed in 43 T LGL cases and showed a monoclonal V β expression in 39 cases (ie most frequently observed; Vβ14: n= 7, Vβ 8: n= 5, Vβ 7.1: n= 4), a potential defective repertoire in 2 cases and 3 patients showed two monoclonal clones. We did not observe any specific restricted Vβ subset. Associated auto-immune diseases or other neoplasms were associated in 70 and 34 cases, respectively. With a median follow-up of 58 months, 100 patients (44%) required a treatment, mainly for infections due to severe neutropenia (n=48), symptomatic auto-immune disease (n =28), transfusion-dependant anemia (n=15), and other causes (n=9). The onset of therapy was at diagnosis (n=43), within (n=31) or after (n=26) the 12 months following diagnosis. Patients were treated using steroids (n= 33), methotrexate (n=62), cytoxan (n=32), cyclosporine (n=24) either at first, second, third or fourth line therapy. The complete response rate (CR) and overall response rate (ORR) were as follows: steroids (12% and 3%), methotrexate (55% and 21%), cytoxan (66% and 45%), cyclosporine (21% and 5%), respectively. Four out of 13 patients responded to splenectomy. The mean number of treatment was 3.4 (1-7). There were 15 LGL leukemia related deaths. Estimated overall survival at 5 years was 75%. *Conclusions*. T LGL leukemia and chronic NK lymphocytosis dysplay similar clinico-biological features and response to treatment. Cytoxan induced a better response rate than methotrexate does.

0360

MONOCLONAL B-CELL LYMPHOCYTOSIS (MBL) IN FIRST-DEGREE RELATIVES OF PATIENTS WITH SPORADIC (NON-FAMILIAL) CHRONIC LYMPHOCYTIC LEUKEMIA

D. Matos, S.J. Ismael, C.A. Scrideli, F.O. Morato, R.P. Falcão

University Hospital of Ribeirão Preto (USP), RIBEIRÃO PRETO-SP, Brazil

Backgrounds. Although biological similarities have been described among MBL and CLL, the relationships between these two conditions are not fully understood, and new epidemiological studies in different populations and different countries continue to be reported. *Aims.* The goal of the study was to determine the prevalence, biological characteristics and evolution of MBL in first-degree relatives of families with just one case of CLL (sporadic CLL). *Methods.* We investigated 167 individuals from 42 families by 4-color flow cytometry assay as recommended by Rawstron *et al.* (Blood 2001;98:29-35). All subjects gave their written informed consent prior to entering the study. Purified B-lymphocytes CD19$^+$ of peripheral blood were selected by magnetic sorting and used for PCR (IgH/T-cell receptor) and FISH experiments (del 17p, del 13q, del 11q and trissomy of 12) in MBL cases. *Results.* MBL was found in seven individuals, from five families, of a total of 167 subjects (4,1%). The prevalence according to the age was 0 (0/54) in individuals with less than 40 years, 2,5% (2/81) between 40 and 60 years and 15,6% (5/32) in individuals over than 60 years. The Table shows the characteristics of MBL cases. With a median follow-up of 23 months, none individual has progressed to CLL.

Table. Age, sex and laboratorial characteristics of MBL cases.

Name	Family	Age/Sex	Ly#	MBL type	κ:λ ratio	PCR IgH
LPA	MPA	46/F	1,8	CD5$^+$/CD20$^{+bright}$/CD79b^{+dim}	0,08:1	Monoclonal
DRK	JRK	75/M	1,7	CD5$^+$/CD20^{+dim}/CD79b^{+dim}	0,25:1	Negative
AAJ	TAO	72/M	1,3	CD5$^+$/CD20^{+dim}/CD79b^{+dim}	1,28:1	Monoclonal*
BFR	LARB	53/M	1,2	CD5$^+$/CD20^{+dim}/CD79b^{+dim}	1,12:1	Monoclonal
ARP	LARB	62/M	1,8	CD5$^+$/CD20^{+dim}/CD79b^{+dim}	1,35:1	Monoclonal*
JGZ	MJZC	75/M	1,1	CD5$^+$/CD20^{+dim}/CD79b^{+dim}	4,35:1	NP
PCZ	MJZC	61/F	4,0	CD5$^+$/CD20^{+dim}/CD79b^{+dim}	4,94:1	Negative

#Lymphocytes (x 10^6/mL)
*Also monoclonal for T-cell receptor.
NP: Not Performed.

From the 7 individuals that have been detected with MBL, 6 were analyzed by PCR and FISH. Clonal gene rearrangements of IgH were detected in 4 subjects. In two, we also found a clonal rearrangement of the gene TCRG of T-cell receptor in the MBL population. FISH experiments did not show any abnormality. *Summary and Conclusions.* This is the first study of MBL in first-degree relatives of patients with sporadic CLL. Monoclonality was detected in all cases either by an abnormal κ:λ ratio, or by PCR, or by both. Although chromosomal lesions associated with poor prognosis are rare in MBL, 13q deletion and trissomy 12 have been found in similar proportion in MBL to that seen in CLL. Our not significant FISH results are probably related to the small number of MBL individuals studied. The overall prevalence of 4.1% found in our population is similar to that of MBL in individuals of general population,

which varies between 3.5% and 5.5%. However, with regard to the prevalence in age groups, we have found a value of 15.6% (5/32) in individuals over 60 years, which is higher than values found for the same age group in general population, but very similar to the prevalence of 16.7% (3/18) found by de Tute *et al.* (Leukemia 2006;20:728-729) in familial CLL subjects over 60 years. Provided that the higher risk of emergence of clinical CLL in relatives of CLL families is probably related to the high prevalence of MBL in these subjects, our data strongly suggests that in old first-degree relatives of patients with sporadic CLL, the risk of MBL detection is as high as in old first-degree relatives from CLL families, which could render these individuals belonging to *sporadic CLL families* as susceptible as individuals belonging to *familial CLL* to the development of clinical CLL.

0361

NCRN CLL207 STUDY OF ALEMTUZUMAB CONSOLIDATION IN CHRONIC LYMPHOCYTIC LEUKAEMIA: REPORT OF THE PLANNED INTERIM ANALYSIS

P. Hillmen,[1] D.R. Cohen,[2] C. Dearden,[3] G. Follows,[4] W.M. Gregory,[2] A.F. Smith,[2] E.J. Skinner,[2] A. Critchley,[1] A.C. Rawstron,[1] C.D. Fegan,[5] H. McCarthy,[6] C.F. Pocock[7]

[1]Leeds Teaching Hospitals NHS Trust, LEEDS; [2]Clinical Trials Research Unit, LEEDS; [3]Royal Marsden Hospital, LONDON; [4]Addenbrookes Hospital, CAMBRIDGE; [5]University Hospital of Wales, CARDIFF; [6]Royal Bournemouth Hospital, BOURNEMOUTH; [7]East Kent Hospitals NHS Trust, CANTERBURY, UK

Backgrounds. The duration of remission in patients with chronic lymphocytic leukaemia (CLL) is highly dependent on the level of minimal residual disease (MRD) that remains at the end of therapy, regardless of the therapy used to achieve remission. The conversion of remissions from MRD positive to negative should prolong remissions and survival. Several small studies have used alemtuzumab as consolidation therapy following conventional chemotherapy with good efficacy but concerns over toxicity; primarily due to immune suppression and infections. The dose and timing (i.e. interval between prior chemotherapy and alemtuzumab) seem to be critical. *Aims.* The NCRN CLL207 Trial is designed to assess alemtuzumab consolidation post-chemotherapy in a phase II setting. Herein are the results from a planned interim analysis on the primary endpoints: eradication of MRD and assessment of safety. 25 patients have completed treatment, with a maximum of 54 patients planned to be recruited. *Methods.* The alemtuzumab dose of 30 mg was administered subcutaneously 3 times a week for 6 weeks, at which time patients had a bone marrow to assess response. MRD negative patients and non-responders stopped therapy; MRD positive patients with a significant response compared to pre-alemtuzumab continued therapy for a further 6 weeks. MRD was assessed in peripheral blood and marrow using 6-colour flow cytometry with a 0.01% detection limit. All patients received prophylaxis with co-trimoxazole (or equivalent) and aciclovir as well as weekly CMV monitoring by PCR. *Results.* Of the 25 patients who have completed alemtuzumab therapy, 23 had received fludarabine combinations as the latest therapy and 4 had received rituximab combined with fludarabine-based treatment. Alemtuzumab was stopped in 2 patients before week 6 due to toxicity, 19 patients received 6-8 weeks of treatment and 4 patients received a 12-week course. 8 (32%) patients required G-CSF during alemtuzumab. There were 12 reported SAE's in 10 (40%) patients, most of which were infections. 3 patients have died: one as a direct result of a treatment-related SAE (parainfluenza); one due to treatment-related MDS presumed to be related to prior therapy; and one due to progressive CLL. Positive CMV PCRs were detected in 12 (48%) patients, all of whom were successfully treated with pre-emptive antiviral therapy. After alemtuzumab, of 24 patients with known results, 18 (75%) became MRD negative, 4 (16.7%) remained MRD positive and 2 (8.3%) were not evaluable. 8 out of 9 (89%) patients who were MRD positive CR's at initiation of alemtuzumab became MRD negative. 10 out of 15 (67%) patients who were MRD positive PR's at initiation of alemtuzumab became MRD negative. *Conclusions.* 18 of 24 patients (75%) treated with alemtuzumab as consolidation therapy achieved MRD negative responses in their marrows. Such an approach is associated with mainly infective toxicities, which are largely manageable with recommended prophylaxis and close monitoring. These results support the continued investigation of alemtuzumab consolidation in CLL but primarily within a clinical trial setting and with appropriate monitoring of patients.

NEW PROGNOSTIC MARKERS OF CHRONIC LYMPHOCYTIC LEUKEMIA IN THE EVERYDAY HEMATOLOGICAL PRACTICE. A MULTICENTER ANALYSIS

M. Doubek,[1] E. Cmunt,[2] J. Schwarz,[3] M. Brejcha,[4] Z. Pospisil,[5] P. Kozmon,[1] Y. Brychtova,[1] S. Pospisilova,[1] P. Cetkovsky,[3] M. Trneny,[2] J. Mayer[1]

[1]University Hospital, BRNO; [2]General Faculty Hospital, PRAGUE; [3]Institute of Hematology and Blood Transfusion, PRAGUE; [4]Mendel Oncologic Centre, NOVY JICIN; [5]Department of Mathematics and Statistics, BRNO, Czech Republic

Background. The opinions about the pathogenesis and prognostic factors of chronic lymphocytic leukaemia (CLL) have undergone significant changes over the past decade and a variety of new prognostic factors have been discovered. On the other hand, however, indication for the start of therapy continues to be based on the conventional hematological and clinical findings, while a range of new and effective therapeutic procedures is now used in the CLL therapy. Additionally, the methods used to detect new prognostic factors are not standardized, and it is also not clearly defined when these factors should be examined in CLL patients. The exact current role of the new prognostic markers of CLL therefore remains undefined. *Aims and methods.* The goal of the study was an analysis of the influence of conventional as well as new prognostic factors on overall survival (OS) of CLL patients. We retrospectively analyzed data of all patients entered into the databases of four big and independent hematological centers. The analysis of individual influence of each factor on OS, as well as multiparametric analysis of prognostic factors were performed. *Results.* The total of 1146 patients (median age 61 years, 32-90; sex: 707 male, 439 female) underwent the analysis. The median follow-up was 53 months (1-362). The median OS of all patients was 180 months; after excluding the patients who died from a cause different from CLL, the median OS was 233 months. In 353 patients (31%), the treatment of CLL was indicated. Through the use of uniparametric analysis, it was determined that advanced stage of CLL (Rai II-IV) ($p<0.001$), unmutated IgVH status ($p<0.001$), del/mut p53 ($p<0.001$), whether the cut-off is 5% or 20%, and increased expression of CD38 ($p=0.01$) have significant negative influence on OS. By contrast, uniparametric analysis did not prove either an unfavourable or a favourable influence on OS of these markers: +12, del ATM, del RB1 and cZAP70. The patients with unmutated IgVH, del/mut p53, del ATM, +12, cZAP70$^+$ or CD38$^+$ were treated significantly more frequently than patients without these changes. Multiparametric analysis revealed that OS is significantly influenced by sex (men with CLL have approximately three times higher risk of death than women; $p=0.02$), age ($p=0.04$), IgVH status ($p=0.03$) and del/mut p53 ($p=0.007$). When the patients who died from other causes than CLL were excluded from the analysis, a statistically significant influence on OS could only be found in one single factor: del/mut p53 ($p=0.004$). *Conclusion.* According to our analysis, the condition of p53 is the only prognostic factor that really and under all circumstances significantly influences the OS. Our analysis showed that this marker has the strongest predictive value even in an unselected large group of patients from a *real hematological practice*. For a non-selected patient group, the role of other factors is much less significant, and is likely diminished as well by the influence of new and more effective curative procedures.

LENALIDOMIDE INDUCED UPREGULATION OF CD80 ON LEUKEMIC CELLS CORRELATES WITH T-CELL ACTIVATION, THE RAPID ONSET OF A CYTOKINE RELEASE SYNDROME AND CLEARANCE OF TUMOR CELLS IN CHRONIC LYMPHOCYTIC LEUKEMIA

A. Wiestner,[1] N Njuguna,[1] B Vire,[1] P McCoy Jr,[2] W Wilson,[3] S Pittaluga,[4] G Aue[1]

[1]HB, NHLBI, NIH, BETHESDA; [2]Flow Cytometry Core Facility, NHLBI, BETHESDA; [3]CCR, NCI, BETHESDA; [4]Laboratory of Pathology, NCI, BETHESDA, USA

Background. The immunomodulatory drug lenalidomide demonstrated encouraging activity in several lymphoid malignancies including chronic lymphocytic leukemia (CLL) and mantle cell lymphoma (MCL). The mechanism of action has been hypothesized to include clearance of tumor cells through immune effector mechanisms. Despite the

absence of a pro-apoptotic effect on CLL cells *in vitro* patients typically have a rapid decrease in leukemic cell count with the start of treatment. Unique to CLL, lenalidomide causes a tumor flare syndrome that appears to be immune mediated and that has resulted in fatal complications. Whether immune activation correlates with anti leukemic activity has been controversial. Also, the basis for the particular side effect profile of lenalidomide in CLL is unclear. *Aims.*1) to describe and quantify the immune mediated effects in CLL patients treated with lenalidomide; 2) to test for correlations between immune activation and treatment response; 3) to derive predictors of immune activation, side effects, and treatment response. *Methods.* we conducted correlative analyses on clinical samples from patients with relapsed CLL enrolled on an investigator initiated, IRB approved, phase II study (registered under clinicaltrials.gov NCT00465127) of lenalidomide 20 mg (n=10) or 10 mg (n=8) daily for 3 weeks on 6 week cycles. We determined expression of costimulatory molecules on tumor cells and the activation marker CD69 on T-cells in PBMCs exposed to lenalidomide *in vitro*. We quantified cytokine levels in patient's serum, changes in lymphocyte subsets (CD4, CD8, NK, B) and effects on the lymph node environment during treatment (pretreatment vs day 8 biopsies). For comparison we included samples from patients with leukemic MCL in the *in vitro* analyses. *Results.* lenalidomide upregulated the costimulatory molecule CD80 on CLL and MCL cells but not on normal peripheral blood B cells *in vitro*. T-cell activation was apparent in CLL, weak in MCL, and absent in normal PBMCs and correlated with the upregulation of CD80 but not CD86 on B-cells. Strong CD80 upregulation and T-cell activation in the *in vitro* assay predicted more severe side effects (r=0.71, p=0.001), manifesting in 83% of patients as a cytokine release syndrome within 8-72 hours after the first dose. Within days, lenalidomide increased the inflammation marker CRP and caused a spike in inflammatory cytokines including TNFa, and IL-6. In most patients, lenalidomide rapidly reduced the number of circulating tumor cells but equally also the counts of T- and NK cells. In the matched lymph node biopsies we found no increase in T- or NK cells, even in patients with prominent lymph node swelling. CD80 upregulation on tumor cells correlated with clearance of leukemic cells from the peripheral blood (r=-0.79, p=0.006). In contrast, neither the clinical severity of the cytokine release syndrome, nor the degree of T-cell activation correlated with clinical response. *Conclusions.* upregulation of CD80 on tumor cells and T-cell activation correlates with unique toxicities of lenalidomide in CLL. T-cell activation appears to be dispensable for anti-tumor effects. This provides a rationale for combinations of lenalidomide with fludarabine or alemtuzumab.

STANDARD AND REDUCED INTENSITY ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATIONS FROM RELATED AND UNRELATED DONORS FOR CHRONIC LYMPHOCYTIC LEUKEMIA. A LONG-TERM FOLLOW-UP (10 YEARS) STUDY FROM THE EBMT REGISTRY

M. Michallet,[1] Q.-H. Le,[1] P. Dreger,[2] M. Sobh,[1] D. Niederwieser,[2] V. Koza,[2] T. Ruutu,[2] N. Russell,[2] L. Verdonck,[2] D. Milligan,[2] N. Dhedin,[2] T. Kozak,[2] M. Boogaerts,[2] J. Finke,[2] A. van Biezen,[2] R. Brand,[2] T. de Witte[2]

[1]Edouard Herriot Hospital, LYON, France; [2]CLL Sub-Committee, EBMT, Netherlands

This retrospective analysis concerned 374 patients (pts) who underwent an allo-HSCT for chronic lymphocytic leukaemia (CLL) reported to the EBMT registry. There were 282 males (75%) and 92 females, median age of 53 years (24-69). The median interval diagnosis-transplantation was 53 months (3-308). Forty-five pts (12%) have received a previous hematopoietic stem cell transplantation (HSCT). At transplant, 302 among 323 evaluated patients had a good performance status (PS) (93%), 51 pts were in CR (14%), 163 in PR (45.5%), 39 in SD (11.5%) and 105 in PD (29%) among 353 evaluated patients. Two hundred and ninety-two pts received a standard (Std) and 82 a RIC; 314 pts received PBSC, 55 BM and 5 cord blood cells from 202 HLA siblings (Sib), 2 mismatched related donors and 170 unrelated donors (UD). There were 136 (36%) sex-mismatched (90 F/M and 46 M/F), 150 pairs (40%) had an ABO incompatibility (61 minor, 99 major) and for CMV: 80 pairs were +, 148 - and 112 mixed. 359 pts engrafted, 201 pts developed an AGVHD (gr I: 76, gr II : 79 , gr III: 30 and gr IV:16) and 153 presented a cGVHD (75 limited and 78 extensive). At day 100 after transplant, the cumulative incidence of AGVHD for the total population was 17% (13-22) for gr I, 31% (26-36) for gr ≥II. [Sib: 19% (13-25) gr I and 27% (21-34) gr ≥II; UD: 16% (9-22) gr I and 38% (29-47) gr ≥II] (Table 1). At 1 year after transplant for the total population, the cumulative incidence of limited and extensive cGVHD were 15% (6-24) and 29.5% (18-41) for Std; 18.6 (13-24) and 18% (13-23) for RIC respectively. With a median follow up of 38 months, the probability of 3-year and 5-year OS and DFS for the total group were 56% (51-62) and 47.4% (42-53); 49% (43-56) and 42% (36-48.5) respectively. We observed a significant difference concerning 5-year OS according to the pretransplant disease status [CR: 73% (60-89), PR: 57% (48-68) and PD: 35% (26-46)] (p<0.00001).There was no significant difference between standard and RIC HSCT in term of OS with 52.4% (42-66) and 47% (40-55.5) respectively (p=0.44) (Figure 1) [Std and RIC Sib: 51% (37-70) and 56% (47-67); Std and RIC UD: 60% (44-83) and 40% (29-55) respectively]. The multivariate analysis showed a significant impact of 3 factors on OS: age: HR=1.061 (1.02-1.10) p<0.0001, gender: HR=2.29 (1.02-5.11) p=0.04 and PS: HR=3.15 (1.40-7.10) p=0.005.The cumulative incidence of non-relapse and relapse mortality (NRM and RM) at 3 months and 1 year after transplant were: 10% (7-13), 5% (3-7) and 24% (19-28), 15% (12-19) respectively [Std:23% (11-35.6), 6% (0-14) 1 year; RIC: 22.5% (17.5-27), 18% (13-22) at 1 year]. This large retrospective analysis showed a high percentage of long-term OS after HSCT for CLL either after Std or RIC conditioning without any difference between the 2 groups except for the AGVHD (gr I, III and IV) where we had an higher incidence in the Std group, and for the RM with a higher level in the RIC group. Moreover, we demonstrated the important impact of disease status pretransplant (univariate); age, PS and sex-matching (multivariate) on the global OS.

Table 1. Cumulative incidence of AGVHD, NRM and RM according to HLA typing and kind of conditioning.

		RIC	Std
HLA siblings			
AGVHD (D100)	gr I	15% [9 - 20,5]	34% [19 - 48]
	gr II	15% [9 - 21,4]	13,5% [7 - 48]
	gr III -IV	11% [6 - 16]	12% [2 - 22]
NRM at 1 year		18,4% [12 - 25]	23% [11-35,6]
RM at 1 year		13% [8 - 18]	6% [0-14]
Unrelated Donors			
AGVHD (D100)	gr I	13% [6 - 20]	22% [4 - 39]
	gr II	22% [13 - 30]	26% [7,5 - 45]
	gr III -IV	14% [7 - 21]	22% [4 - 39]
NRM at 1 year		24% [16 - 32]	38% [17-65]
RM at 1 year		16% [9 - 23]	4% [0-12]

INCREASED EXPRESSION OF MACROPHAGE INFLAMMATORY PROTEIN-1 ALPHA ON TREPHINE BIOPSIES CORRELATES WITH ADVANCED MYELOMA, EXTENSIVE BONE DISEASE AND ELEVATED MICROVESSEL DENSITY IN NEWLY DIAGNOSED PATIENTS WITH MULTIPLE MYELOMA

E. Terpos,[1] A. Tasidou,[2] M. Roussou,[1] E. Kastritis,[1] M. Migkou,[1] D. Christoulas,[1] M. Gavriatopoulou,[1] F. Zagouri,[1] C. Matsouka,[1] T. Papadaki,[2] M.A. Dimopoulos[1]

[1]University of Athens School of Medicine, ATHENS; [2]Department of Hematopathology, Evangelismos General Hospital, ATHENS, Greece

*Background/Aims.*Macrophage inflammatory protein-1 alpha (MIP-1α) is a potent osteoclast stimulator and a chemoattractant for monocytes. Recent studies showed that monocytes may give rise to vascular endothelium in the myeloma microenvironment. The aim of our study was to evaluate, for the first time, the expression of MIP-1α in marrow biopsies of MM patients and explore possible correlations with clinical data, including angiogenesis. *Methods.* We evaluated MIP-1α and microvessel density (MVD) in formalin fixed paraffin-embedded bone marrow sections of 130 newly-diagnosed MM patients (66M/64F, median age 68 years) before any kind of therapy and in 10 MGUS patients. Immunohistochemical staining was performed using an anti-MIP-1α monoclonal antibody (Santa Cruz, CA, USA), while identification of microvascular endothelial cells was performed using an anti-CD34 monoclonal antibody (DAKO, Glostrup, Denmark). MVD was measured according to standard methodology. The MIP-1α immunoreactivity was examined on the basis of positive plasma cells (PCs) with the following cut-off values: <20% positive PCs (negative expression), 20-50% positive PCs (intermediate expression) and >50% positive PCs (high expression). Serum MIP-1α was measured in MM patients and 20 controls using ELISA (R&D, Minneapolis, MN, USA). *Results.* Fifteen patients (11.5%) had asymptomatic myeloma and 45 (35%) ISS3 disease. Plain radiography of the skeleton showed that 43 (33%) patients had no lytic lesions or osteoporosis only (grade A bone disease), while 24 (18%) had 1-3 lytic lesions (grade B), and 63 (48%) >3 lytic lesions and/or a pathological fracture (grade C). Thirty-seven (28%) patients had negative MIP-1α expression, 17 (13%) intermediate expression and 79 (59%) high expression of MIP-1α in the trephine biopsies, while low- (MVD 1-2), intermediate- (MVD 3-6) and high-grade (MVD >6) angiogenesis was observed in 42%, 28% and 30% of the patients, respectively. All MGUS patients had negative MIP-1α expression and low-grade angiogenesis. There was a significant correlation between MIP-1α expression on marrow PCs and MVD measurement (ANOVA p=0.015). MM patients had elevated median values of serum MIP-1α compared with controls [22 pg/mL (2.1-135 pg/mL) vs. 14 pg/mL (0.02-54 pg/mL); p<0.0001]. There was a strong correlation between serum MIP-1α ≥and MIP-1α expression on PCs (r=0.32, p<0.001). MIP-1α expression significantly correlated with the extent of bone disease. The median values (range) of MIP-1α positive PCs in biopsies was 10% (5-35%), 40% (18-60%) and 90% (70-100%), for patients with grade A, B and C bone disease, respectively (ANOVA p<0.0001). Serum MIP-1α also correlated with the extent of osteolytic disease (ANOVA p<0.0001). ISS3 patients had increased MIP-1α (+) PCs (median 60%, range: 20%-100%) compared with ISS1 (35%, 5%-100%; p=0.03) and ISS2 (45%, 5%-100%; p=0.04). Similar results were observed with serum MIP-1α (p<0.04). Increased immunoexpression of MIP-1α correlated with low platelet count, hypercalcemia, elevated serum creatinine, and PC infiltration. *Summary and Conclusions.* Our findings underline the high incidence of MIP-1α positive PCs in the biopsies of MM patients. The correlation between high MIP-1α expression with advanced myeloma, extensive lytic bone disease and increased angiogenesis confirms the role of MIP-1α in the biology of MM and reveals MIP-1α as a rational therapeutic target for the development of novel anti-myeloma agents.

SECRETOME ANALYSES OF PRIMARY BONE MARROW FIBROBLASTS ISOLATED FROM MGUS AND MULTIPLE MYELOMA PATIENTS SUPPORT THE ROLE OF THE MICROENVIRONMENT FOR MYELOMA PATHOGENESIS

J. Drach, A. Slany, T. Mohr, J. Griss, J. Ackermann, C. Zielinski, C. Gerner

Medical University of Vienna, VIENNA, Austria

Background. The microenvironment of tumor cells in the bone marrow may be actively involved in the progression of malignant diseases. In multiple myeloma (MM), interactions of bone marrow stromal cells with the malignant plasma cells have gained significant importance as targets for novel therapeutic agents. *Aims.*Based upon these observations, we aimed at analyzing in detail the secretory capacity of bone marrow (BM) fibroblasts obtained from patients with MGUS and MM in order to better understand their contribution to disease progression. *Methods.* We analyzed the secretome of primary bone marrow fibroblasts of patients with MGUS and MM by proteome profiling based on highly sensitive mass spectrometry. Results were compared to those obtained with normal BM fibroblasts. *Results.* The secretome profile of normal BM fibroblasts included various extracellular matrix (ECM) proteins including fibronectin, collagens and laminins, in addition to some chemokines and cytokines including CXCL12, follistatin-like 1, insulin-like growth factor binding proteins 4, 5 and 7; and SPARC. In contrast, the secretion profile of BM-derived fibroblasts from MGUS patients was altered: This included secretion of CSF-1, chitinase-3-like protein 1, insulin-like growth factor II (IGF-II), and insulin-like growth factor binding protein 6. All proteins specific for the MGUS background were also found in BM fibroblasts from MM patients. In addition to those we found specific secretion of stem cell growth factor, stanniocalcin-1, hamartin, and matrix metalloproteinase 28 as well as increased amounts of α-fetoprotein. Co-culture of primary MM cells with these fibroblasts further stimulated the secretion of ECM proteins. *Conclusions.* BM fibroblasts from MGUS and MM background display a specifically altered secretion profile, and BM fibroblasts from MGUS background already show tumor-promoting activities as indicated by the expression of IGF-II. Proteome profiling of secreted proteins may thus help to identify relevant tumor-associated proteins, to increase our understanding of cell cooperativity and thereby increase our understanding of progression events in monoclonal gammopathies.

MICRORNAS AS KEY REGULATORS OF MULTIPLE MYELOMA CELL GROWTH

M. Roccaro,[1] A. Sacco,[1] A.K. Azab,[1] X. Leleu,[1] B.D. Thompson,[2] F. Azab,[1] X. Jia,[1] H.T. Ngo,[1] J. Runnels,[2] M.R. Melhem,[1] K.C. Anderson,[1] T. Witzig,[3] I.M. Ghobrial[1]

[1]Dana-Farber Cancer Institute, BOSTON; [2]Wellman Center for Photomedicine, Massachusetts General Hospital, BOSTON; [3]Hematology, Mayo Clinic, ROCHESTER, MN, USA

Background. Detailed genomic studies have shown that cytogenetic abnormalities contribute to multiple myeloma (MM) pathogenesis and disease progression. Nevertheless, little is known about the characteristics of MM at the epigenetic level, and specifically how microRNAs (miRNAs) regulate MM progression in the context of the bone marrow milieu. Therefore, multi-level genetic characterization of MM is required to improve our understanding of the underlying molecular changes that lead to the initiation and progression of this disease; as well as to develop novel therapeutic agents that specifically target epigenetic abnormalities of clonal plasma cells. *Aims.* 1) To identify miRNA signature in MM. 2) To identify and validate the functional role of deregulated miRNAs in MM pathogeneis. 3) To provide the basis for the development of miRNA-based targeted therapies in this disease. *Methods.* We performed miRNA-expression-profiling of bone marrow-derived $CD138^+$ cells isolated from patients with MM, compared to their normal cellular counterparts and validated data by qRT-PCR. MM cell lines (MM.1S/RPMI8226/U266) were also studied. *In vitro* and *in vivo* functional studies were performed on miRNA-15a- and -16-1-precursors-transfected MM cells. Effect of miRNA-15a and -16 on signaling cascades have been evaluated by western blot and immunofluorescence. NF-kB activity has been investigated using a DNA-binding-enzyme-linked-immunosorbent-assay-based-assay. *In vivo* MM cell growth has been evaluated by either using an *in vivo* imaging model or bioluminescence. Angiogenesis

has been studied both *in vitro* and *in vivo* using the chorioallantoic membrane model. *Results.* We identified a MM-specific miRNA signature characterized by decreased expression of miRNA-15a, -16 and increased expression of miRNA-222/-221/-382/-181a/-181b ($p<0.01$). MM cell lines showed similar miRNA expression pattern to primary MM tumor cells. qRT-PCR was performed on matched samples and showed expression patterns similar to those observed in miRNA analysis. Using algorithms commonly used to predict human miRNA gene targets (miRanda/TargetScan/PicTar), predicted targets of the decreased miRNAs in MM patients included pro-angiogenic cytokines, oncogenes, cell cycle regulators, NFκB activators. Conversely, predicted target genes for the increased miRNAs in MM included cell cycle inhibitors, suppressors of cytokine signaling, and pro-apoptotic factors. Functional studies revealed that miRNA-15a and -16 regulate proliferation and growth of MM cells. Indeed, transfected cells showed decreased DNA synthesis; decreased cyclinD1/cyclinD3/cdc25a/pRb protein expression; phase G1 cell cycle arrest; as compared to either scramble probe-transfected or not transfected MM cells. Moreover, transfected cells showed inhibition of NFkB pathway as shown by reduced p65-/p50-/p52-NFκB activities; downregulation of p-p65/p50/p52 nuclear protein level; upregulation of phospho-IkB in the cytoplasm; and inhibited translocation of p-p65 from the cytolplasm to the nucleus. Similarly, inhibition of MM cell growth was confirmed *in vivo*; and anti-angiogenic properties of miRNA-15a and -16 were validated both *in vitro* and *in vivo*. *Summary.* These data indicate that miRNAs play a pivotal role in the biology of MM; providing the basis for the development of new miRNA-based targeted therapies in this disease.

LENALIDOMIDE INDUCED P27 KIP1-ASSOCIATED GROWTH ARREST IN MYELOMA CELLS THROUGH DOWN-REGULATION OF BOTH C-MYC AND SCFSKP2 UBIQUITIN LIGASE

M. Amiot, S. Bonnaud, S. Maiga, G. Descamps, C. Pellat-Deceunynck, R. Bataille

Inserm U,892 NANTES, France

Background. Multiple Myeloma (MM) is a plasma-cell malignancy characterized by the accumulation of malignant plasma cells within the bone marrow. Lenalidomide is a new effective treatment of relapsed and/or refractory MM. Both the immuno-modulatory and anti-angiogenic effects of Lenalidomide emerge as potentially important mechanisms of its action. Furthermore, Lenanidomide counteracts the proliferation and survival pathways of MM cells but its mechanisms of action are still poorly understood. *Aim.* In the present study, we have investigated the molecular mechanisms responsible of the anti-proliferative effects of Lenalidomide on a large panel of human MM cell lines representative of MM molecular heterogeneity (n=14). *Methods.* Expression and regulation of key cell cycle and signal transduction pathway proteins were assessed by immunoblot analysis and quantitative PCR. *Results.* Lenalidomide significantly inhibits the proliferation of 10 of 14 MM cell lines (with IC50 values ranging from 0.2 μM to 8 μM). The sensitivity to Lenalidomide is independent of the genetic background of MM (types of 14q32 translocations). Four cell lines (JIM-3, Karpas 620, XG-6 and XG-7) of different molecular subtypes are resistant to Lenalidomide. Lenalidomide suppress the Erk/Mapkinase signaling pathway, either by inhibiting Erk1/2 or Erk5 whereas it has no effect on STAT-3 and PI3-kinase signaling pathway. Analysis of cell cycle distribution indicates that Lenalidomide provokes a marked decrease of the S phase and an accumulation of MM cells into the G1 phase. Cell cycle arrest was accompanied by a decrease of both PCNA and survivin expression and an up-regulation of p27. Kinetics study demonstrates that p27 expression increases during the first 72 hrs of stimulation, reaching a maximum at 72hrs. It is known that p27 expression is controlled both at the transcriptional level by c-myc and by multiple post - translational mechanisms. Indeed, p27 was thought to be regulated through the ubiquitin-proteasome pathway. In fact, p27 is recruited by SCFSkp-2 to be poly - ubiquitinated and the level of Skp-2 was found to be the rate-limiting regulator for the degradation of p27. For these reasons, we examined the level of c-myc and Skp-2 into MM cells exposed to Lenalidomide. We demonstrate that, parallel to p27 upregulation, both c-myc and Skp-2 protein expression were down-regulated in Lenalidomide sensitive cell lines. By performing kinetics study, we show an early down-regulation of c-myc which coincides with the increase of p27 followed by a decrease of Skp-2 and a stronger p27 up-regulation. Finally, we demonstrate by quantitative RT-PCR that p27 up-regulation is due in part to an increase of its transcription probably through c-myc down-regulation.

THE MTOR PATHWAY ACTIVATION PREDICTS A SHORT TIME TO PROGRESSION AND OVERALL SURVIVAL IN RELAPSED MULTIPLE MYELOMA PATIENTS

T. Guglielmelli,[1] R. Merlini,[1] E. Giugliano,[1] G. Saglio,[1] V. Brunetto,[1] S. Cappia,[1] E. Bacillo,[1] A. Berruti,[1] F. Gay,[2] M. Papotti,[1] A. Palumbo[2]

[1]AUO San Luigi Gonzaga, ORBASSANO; [2]ASO S Giovanni Battista Osp Molinette, TORINO, Italy

Background. The mammalian target of rapamycin (mTOR) is a serine/threonine-specific protein kinase, downstream of the phoshatidylinositol 3-kinase (P13-K/AKT) pathway. Recent findings highlight on the involvement of the mTOR signaling pathway in cancer cell proliferation, survival and in multiple drug resistance mechanisms. Previous studies demonstrated that rapamycin has preclinical potential as therapy for multiple myeloma (MM), especially when associated with other drugs. *Aims.* To evaluate the phoshporylation status of the mTor pathway (AKT, mTOR, P70S6K and 4E-BP1) and to correlate mTor positive status with clinical parameters, cytogenetic data and clinical outcome separately in newly diagnosed and relapsed MM patients. *Methods.* Immunohistochemical analysis with p-AKT (Ser 473), p-mTOR (Ser2448), p-P70S6K (Thr389) and p-4E-BP1 (Thr37,Trh46) was performed on bone marrow sections of 92 symptomatic MM patients (64 newly diagnosed and 28 relapsed). For each case, a value designed HSCORE was obtained multiplying the semi-quantitative intensity (0, no staining ; 1,weak staining; 2, moderate staining; and 3, strong staining) with the corresponding percentage of positive cells [HSCORE =Σ(1XPC), where 1 and PC represent intensity and percentage of cells, respectively]. The median value for each antibody was calculated and considered as the cut-off value. Fisher exact or chi square tests were used to correlate p-mTOR positivity to clinical data (age, isotype, β2-microglobulin, albumin, hemoglobin, creatinine and LDH serum levels) and molecular cytogenetic performed by FISH analysis. Curves for time to progression (TTP) and overall survival (OS) were plotted according to the method of Kaplan and Meier. *Results.* 27 out 64 (42.1%) newly diagnosed (group A) and 14 of 28 (50%) relapsed (group B) MM patients stained positive p-mTOR, respectively. In group A, 30 (46.8%), 30 (46.8%) and 28 (43.7%) cases also stained positive for p-AKT , p-P706SK and p-4E-BP1, respectively and a similar pattern was found in group B with 14 (50%), 13 (46.4%) and 15 (53.5%) p-AKT, p-P706SK and p-4E-BP1 positive, respectively. Overall, p-mTOR expression significantly correlated with p-AKT (r=0.4), p-P70S6K (r=0.5), and p-4E-BP1 (r=0.55) positive staining consistent with the hypothesis that the mTOR pathway is activated in a subset of myeloma cases. No difference was found between m-Tor positive and m-Tor negative patients in both group A and group B with respect to presenting clinical and cytogenetic characteristic. In group B, relapsed patients who expressed mTOR positivity (14 out 28) had a significantly shorter TTP (median time 6 vs 14 months $p=0.002$) and OS (median time 9 vs 16.5 months $p=0.03$) when compared with patients who did not. Multivariate Cox regression analysis adjusted for β2-microglobulin, del 13, del 17 and t(4;14) confirmed that mTOR positivity independently predicted short TTP in group B both as dicotomic (median value) and continuous variable. *Conclusions* In relapsed myeloma patients , mTOR positivity is closely associated with a short TTP that may be related to chemo-resistance. The mTOR pathway activation may be considered as a novel therapeutic molecular targets in relapsed myeloma patients to overcame chemo-resistance and in newly diagnosed myeloma patients to enhance chemo efficacy.

ANTIBODY RESPONSES TO CANCER-TESTIS ANTIGENS IN MULTIPLE MYELOMA PATIENTS

M.D. Kobold, Y. Cao, S. Tams, B.M. Bartels, C. Eberhardt, M. Ristic, T. Lütkens, C. Pabst, C. Bokemeyer, N. Kröger, D. Atanackovic

University medical center Hamburg-Eppendorf, HAMBURG, Germany

Background. Cancer-testis (CT) antigens show an expression restricted to malignancies and the human germline among healthy tissues and, therefore, represent attractive targets for immunotherapies. We and others have recently shown that CT antigens, such as MAGE-C1/CT7 and MAGE-A3, are frequently and specifically expressed in malignant plasma cells of patients with multiple myeloma. Furthermore, expression of CT antigens in myeloma represents an independent prognostic factor associated with higher rates of recurrence and reduced survival. Importantly, CT antigens are known to be capable of inducing spontaneous antibody and T cell-mediated immune responses. However, little is

known regarding spontaneous and therapy-induced immune responses against CT antigens in multiple myeloma. *Aim.* We set out to perform the first longitudinal analysis of antibody responses against a variety of CT antigens in multiple myeloma patients. This study was conducted to answer the question if and under which conditions humoral responses against CT antigens would occur in myeloma patients and if the existence of such immune responses had an influence on the patient's clinical outcome. *Methods.* Antibodies directed against CT-antigens (MAGE-C2/CT10, MAGE-A1, MAGE-A3, MAGE-A4, MAGE-A8, MAGE-A11, SSX-2, SSX-4, NY-ESO-1, PRAME) were analyzed by an ELISA using full-length recombinant proteins. The specificity of those antibodies was confirmed by Western blot analysis. *Results.* We screened 1100 sera of 194 patients with multiple myeloma at different time points for antibody responses against the 10 CT-antigens. The sera of 100 healthy volunteers were used as controls. Importantly, we identified a number of patients with significant titers against CT antigens, some of them consistently showing high-tittered responses. 51% of all myeloma patients were at least at one point of time antibody positive for MAGE C2 and MAGE A11, 33% for MAGE A8, 26,8% for MAGE A1, 26,8% for PRAME, 16,5% for SSX-2, 15,5% for MAGE A3, 15,5% for SSX-4 and 8.2% for NYESO-1. The control samples were all negative for antibodies directed against those antigens. Remarkably, in many cases titers were only induced by allogenic stem cell transplantation. Interestingly, patients with this transplantation-induced immune response seemed to have a longer overall survival compared to antibody-negative myeloma patients. *Conclusions.* We show in this first comprehensive and longitudinal analyses of humoral responses against CT antigens in myeloma that spontaneous occur and often persist over the course of the disease. Furthermore, allogenic stem cell transplantation can induce high titer humoral responses targeting CT antigens in multiple myeloma patients. This antigen-specific immune effect seems to improve the prognosis of these patients. We plan to further investigate these responses on the T cell level and we will analyse if the stimulation of the adaptive immune system is able to reverse the negative effect of CT antigen expression on the patients' prognosis.

RARA2 PLAYS A CRUCIAL ROLE IN RETINOID-BASED THERAPY OF MYELOMA STEM CELLS

G. Tricot, S. Wang, X. Xu, Z. Zangari, Z. Zhan

University of Utah, SALT LAKE CITY, USA

Despite major advances in treatment by combining autotransplantation with the newer drugs such as thalidomide, bortezomib and lenalidomide, multiple myeloma (MM) remains largely incurable because of the existence of a drug-resistant population, which may be the myeloma stem cell compartment. Previous investigation showed that the $CD138^-$ myeloma cell fraction contains the MM stem cells. However, little is known about the molecular characteristics of MM stem cells, which makes it difficult to specifically target such cells. In this study, comparing gene expression profiling (GEP) analysis of $CD138^+$ and $CD138^-$ cells isolated from MM cell lines, we discovered that RARα is the top one up-regulated gene in CD138- MM stem cells. RARα has two major isoforms, RARα1 and RARα2. Real-time PCR detected significantly higher expression of RARα2 but not RARα1 in $CD138^-$ MM stem cells than $CD138^+$ cells. Using RT-PCR, we also found that RARα1 was ubiquitously expressed in myeloma cells, but RARα2 was expressed in myeloma cells from about 30% of newly diagnosed patients and MM cell lines. Furthermore, patients with RARα2 expression had shorter overall-survival. These results strongly suggest that RARα2 may be critical for *stemness* properties and drug-resistance of MM stem cells. Both RARα1 and RARα2 are specific receptors for ATRA; interestingly, we found that ATRA selectively killed RARα2-overexpressing CD138- MM stem cells while spare the $CD138^+$ MM tumor cells and over-expressing RARα2 in RARα2-deficient myeloma cells restored the sensitivity of MM cells to ATRA-induced myeloma cell death and growth inhibition, demonstrating a crucial role of RARα2 in ATRA-induced cytotoxicity in MM stem cells. Wnt signaling pathway is activated in $CD138^-$ MM stem cells and ATRA down-regulates Wnt signaling in RARα2-overexpressing MM cells. Interestingly, previous investigation showed that down-regulation of COX-2 is required for ATRA-mediated inhibition of Wnt signaling pathway. In line with this investigation we found that a combination treatment of ATRA and a COX2 inhibitor induced synergistic effects on the inhibition of Wnt signaling pathway, as assessed by β-catenin levels, cell death and growth inhibition of RARα2-overexpressing MM cells. Altogether, our study suggests a crucial role of RARα2 in maintaining the *stemness* of myeloma stem cells and provides new approaches for targeting MM stem cells in MM therapy.

A NOVEL FISH-BASED NORMALIZATION PROCEDURE FOR WHOLE GENOME MICROARRAYS DETECTING ACCURATE LOCAL COPY NUMBERS: APPLICATION TO MULTIPLE MYELOMA

L. Agnelli,[1] L. Mosca,[1] A. Andronache,[1] S. Fabris,[1] M. Lionetti,[1] I. Kwee,[2] K. Todoerti,[1] D. Verdelli,[1] L. Nobili,[1] V. Polli,[1] C. Battaglia,[3] F. Bertoni,[2] G. Lambertenghi Deliliers,[1] A. Neri[1]

[1]University of Milan and Fondazione IRCCS Ospedale Maggiore Policlinico, MILAN, Italy; [2]Laboratory of Experimental Oncology, Oncology Institute of Southern Switzerland, BELLINZONA, Switzerland; [3]Department of Biomedical Sciences and Technologies and CISI, University of Milan, MILAN, Italy

Background. The introduction of Mapping arrays have significantly contributed to understanding of genomic disorders, providing high-resolution profiles of DNA copy number (CN) aberrations. However, CN inference using available conventional analysis procedures shows limitations in identifying the correct ploidy whenever the median CN value of the analyzed profile differs from normal ploidy; this is the case of marked aneuploidy characterizing most of human myeloma cell lines (HMCLs) and a significant fraction of primary myeloma tumors (MM). Aims. To correlate the local ploidy information given by FISH and Mapping arrays data, in order to robustly normalize genomic profiles and correctly infer local CNs. *Methods.* We developed a FISH-based normalization (FBN) algorithm, based on the evidence that Mapping arrays values of a genome profile tend to cluster as they represent different CNs. For each sample, at least one FISH probe information derived from highly purified populations was collected showing the same number of signals in >90% of cells. Using a k-means based algorithm, we determined all the clusters appearing on the frequency distribution of the array values, and linked them to exact inferred local CNs based on ploidy assessed by FISH. This allowed to estimate the scaling factor used to normalize the raw CNs of the entire array to their corresponding nominal multiplicity values. *Results.* We generated the FBN-corrected profiles of a subset of 25 HMCLs (profiled on GeneChip® Human Mapping 250K NspI arrays); we collected FISH data of 12 chromosomal loci critically involved in MM, and found complete and unambiguous information in the whole dataset for 4 probes (mapping to 1p31.3, 4p16.3, 13q14.3 and 16q23.1-23.2). We obtained a set of clusters of CN values for each sample, and correlated the ploidy as assessed by FISH with the cluster containing those values corresponding to the associated FISH probe, in order to infer the exact local CN values and subsequently the entire normalized CN profiles. Finally, we determined thresholds corresponding to different CN values. To validate the obtained profiles, the entire normalization procedure was repeated four times using each of the mentioned probes. After each of the four normalization processes, the most part of the available FISH data were correctly recognized using FBN procedure (93.3% accuracy of the estimated profiles). The FBN procedure was further applied and validated on a dataset of 45 MM samples profiled on GeneChip® Human Mapping 50K XbaI arrays. After normalization and generation of accurate thresholds, the obtained CNs were validated with additional FISH data, showing a concordance of 93.2% and thus indicating the correctness of FBN procedure. Moreover, the normalization allowed to identify a large part of MM samples (15%) showing marked aneuploidy, which conventional normalization procedures failed to identify. Conclusion. We propose a novel normalization procedure to detect the real multiplicity of local CN alterations combining FISH and mapping arrays; the method was robustly validated on MM and HMCLs datasets, providing an important contribution to define the genetic of myeloma tumors and, overall, to mapping arrays analysis procedures in the presence of complex aneuploid karyotypes.

0373

CARFILZOMIB: A SELECTIVE INHIBITOR OF THE CHYMOTRYPSIN-LIKE ACTIVITY OF THE CONSTITUTIVE PROTESOME AND IMMUNOPROTEASOME HAS ANTI-TUMOR ACTIVITY ON MULTIPLE MYELOMA, LYMPHOMA AND LEUKEMIA CELLS WITH MINIMAL EFFECTS ON NORMAL CELLS

F. Parlati,[1] S. Lee,[1] M. Aujay,[1] K. Levitsky,[1] J. Lorens,[2] Y. Lu,[1] D. Micklem,[2] P. Rurrs,[2] K. Shenk,[1] C. Sun,[1] E. Suzuki,[1] C. Sylvain,[1] M.K. Bennett[1]

[1]Proteolix, SOUTH SAN FRANCISCO, USA; [2]University of Bergen, BERGEN, Norway

Background. Carfilzomib, the first in a new class of specific and selective proteasome inhibitors, induces apoptosis in multiple myeloma cells

with minimal off-target effects. Carfilzomib primarily targets the chymotrypsin-like (CT-L) active site in both of the broadly expressed constitutive proteasome (subunit β5) and the hematopoietically-restricted immunoproteasome (subunit LMP7) with less pronounced effects on non-CT-L proteasome active sites (β1 and β2 of the constitutive proteasome and LMP2 and MECL1 of the immunoproteasome). We and others have proposed that inhibition of the CT-L activity of the constitutive proteasome and the immunoproteasome is sufficient for anti-tumor efficacy while inhibition on non-CT-L activities may reduce the therapeutic window (Cancer Res 67:6383-91; J Biol Chem 281:8582-90). *Aims.* To quantitate constitutive proteasome and immunoproteasome levels in normal and transformed hematopoietic cells and evaluate the relative contribution of CT-L and non-CT-L activities to proteasome substrate accumulation, apoptotic signaling and cell viability. *Methods.* Immunoproteasome and constitutive proteasome levels in non-transformed peripheral blood mononuclear cells (PBMCs) and hematopoietically-derived malignant cells were determined using an ELISA that accurately quantitates proteasome active site subunits. The relative impact of CT-L and non-CT-L activities on proteasome substrate accumulation (transfected GFPu), apoptotic induction (caspase-3 activation) and cell viability was evaluated in myeloma (MM1.S, RPMI-8226), lymphoma (Arh77, HS-Sultan) and leukemia (Molt4) tumor cell lines or PBMCs with the following reagents: carfilzomib, novel proteasome inhibitors that selectively target β5 or LMP7 and a shRNA targeting β5. *Results.* Immunoproteasome expression was high in both primary patient samples and hematopoietic tumor cell lines. Based on LMP7 expression levels, the immunoproteasome constitutes >97% and 85-88% of the total proteasome in PBMC and CD138+ cells from healthy volunteers, respectively, and 61-80% of the total proteasome in CD138$^+$ cells from multiple myeloma patients. For hematopoietic tumor cell lines, the immunoproteasome expression accounts for 39-45%, 48-68%, and 49% of the total proteasome levels in myeloma, lymphoma and leukemia cells, respectively. Inhibition of a single CT-L subunit activity using LMP7- or β5-selective inhibitors, was insufficient to induce protein accumulation in HS-Sultan and had no impact on the viability of either hematopoietic tumor cell lines or PBMCs. However, inhibition of both β5 and LMP7, using a combination of a LMP7- and a β5-selective inhibitors or a β5/LMP7-selective concentration of carfilzomib, initiates a cascade of cellular events that starts with proteasome substrate accumulation followed by caspase-3 activation and finally cell death in tumor cells without causing cell death in PBMCs. Knockdown of β5 expression in HS-Sultan cells with an shRNA resulted in enhanced anti-tumor activity with the LMP7-selective inhibitor. Lastly, we noted that inhibition of all proteasome catalytic activities resulted in maximal induction of proteasome substrate accumulation, caspase-3 activation and cell death in both tumor cell lines and PBMCs. *Conclusions.* The immunproteasome is a major form of the proteasome expressed in hematopoietically-derived cells, including primary CD138+ myeloma cells. Inhibition of proteasome CT-L active sites, either by a combination of β5- and LMP7- selective inhibitors or carfilzomib is sufficient to produce an anti-tumor effect with minimal toxicity in non-transformed cells.

CORRELATIONS BETWEEN ANGIOGENESIS, MIP-1 ALPHA EXPRESSION BY MALIGNANT CELLS AND MACROPHAGE COUNTS IN WALDENSTROM'S MACROGLOBULINEMIA: IMPLICATIONS INTO THE BIOLOGY OF THE DISEASE

E. Terpos,[1] A. Tasidou,[2] E. Eleutherakis-Papaiakovou,[1] D. Christoulas,[1] M. Gavriatopoulou,[1] M. Migkou,[1] E. Kastritis,[1] T. Papadaki,[2] M.A. Dimopoulos[1]

[1]University of Athens School of Medicine, ATHENS; [2]Department of Hematopathology, Evangelismos General Hospital, ATHENS, Greece

Background. Angiogenesis represents an essential step of disease progression in several hematological malignancies. A Mayo Clinic study reported that microvessel density (MVD) was increased (intermediate- or high- grade angiogenesis) in 30% of patients with Waldenstrom's Macroglobulinemia (WM), showed only weak correlation with marrow infiltration and had no impact on patients' survival [Rajkumar *et al.*, Semin Oncol 2003]. Macrophage inflammatory protein-1 alpha (MIP-1α) is a potent chemoattractant for macrophages and we have shown that serum levels of MIP-1α are elevated in WM [Terpos *et al.*, BJH 2006]. *Aim.* The aim of the present study was to evaluate the role of MIP-1α and macrophages in angiogenesis of WM. *Methods.* We investigated the association between MVD, MIP-1α expression by WM cells and the macrophage counts in trephine biopsies of 34 untreated patients with newly-diagnosed WM (3 with asymptomatic disease), and 11 with IgM-MGUS. Identification of microvascular endothelial cells was performed using an anti-CD34 monoclonal antibody (DAKO, Glostrup, Denmark) and MVD was measured according to standard methodology. When the microvessel count was 1-2, angiogenesis was characterized of low grade, while intermediate grade angiogenesis was defined by the presence of a microvessel count of 3-6 and high grade angiogenesis by the presence of microvessel count of ≥7. Bone marrow biopsies were also studied using double immunohistochemical staining for CD34 (endothelial cells) and CD68 (macrophages/mast cells) using respective antibodies from DAKO & Santa Cruz (CA, USA). We have also used double immunohistochemical staining for CD20/MIP-1α and for CD138/MIP-1α using an anti-MIP-1α human monoclonal antibody (Santa Cruz, CA, USA) to evaluate the MIP-1α expression by both CD20$^+$ and CD138$^+$ WM cells. *Results.* Thirteen patients out of 31 with symptomatic WM (41%) showed intermediate-grade and 4 (12%) high-grade angiogenesis. All patients with IgM-MGUS and asymptomatic WM had low microvessel count (median: 1, range: 1-3), while the median microvessel count for symptomatic WM was 4 (range: 1-8, p<0.01). There was a strong correlation between MVD and the number of macrophages into the *hot-spots* (r=0.823, p<0.0001). Furthermore, significant correlations were observed between the percentage of lymphoplasmacytoid cell's marrow infiltration with MVD (r=0.554, p=0.002) and macrophage counts into the *hot spots* (r=0.457, p=0.011). WM patients with intermediate or high grade angiogenesis had increased IgM levels (p=0.007), lower hemoglobin levels (p=0.024), and reduced platelet counts (p=0.043), while patients with high-grade angiogenesis had a tendency to higher incidence of lymphadenopathy compared with all others (3/4, 75% vs. 9/30, 30%; p=0.054). There was no correlation between angiogenesis and survival. We also observed that both CD20$^+$ and CD138$^+$ WM cells of all patients produced MIP-1α. Patients with increased counts of CD68$^+$ macrophages had also increased numbers of MIP-1α positive WM cells in their trephine biopsies (r=0.732, p<0.001). *Summary and Conclusions.* The results of this ongoing study suggest that intermediate to high-grade angiogenesis is present in a substantial number of WM patients. WM cells produce MIP-1α which possibly contributes to the chemoattraction of macrophages in the WM marrow microenvironment. These macrophages correlate with MVD and are possibly implicated into the biology of WM.

ABNORMAL SERUM FREE-LIGHT CHAIN RATIO IN PATIENTS WITH MULTIPLE MYELOMA IN LONG-LASTING COMPLETE REMISSION: STRONG ASSOCIATION WITH OLIGOCLONAL BANDS

C. Fernández de Larrea,[1] M.T. Cibeira,[2] M. Elena,[3] L. Rosiñol,[2] M. Rovira,[2] J.J. Arostegui,[4] X. Filella,[3] J. Yagüe,[4] J. Bladé[5]

[1]Hospital Clínic de Barcelona, BARCELONA; [2]Department of Hematology, Hospital Clínic, BARCELONA; [3]Department of Biochemistry, Hospital Clínic, BARCELONA; [4]Department of Immunology, Hospital Clínic, BARCELONA; [5]Department of Hematology. Hospital Clínic de Barcelona, BARCELONA, Spain

Background. Complete remission (CR) in multiple myeloma (MM) is defined by negative immunofixation. The serum free light chain (FLC) assay can potentially allow the detection of free kappa and lambda levels below the threshold of immunofixation. The International Myeloma Working Group (IMWC) has recently proposed the so-called Uniform Response Criteria for Multiple Myeloma, incorporating the FLC kappa/lambda assay in serum to define stringent complete response (sCR). A normal FLC ratio (0.26-1.65) in addition to negative immunofixation in serum and urine plus less than 5% bone marrow plasma cells is required to fulfill the sCR criteria. However, there is limited data on the prognostic significance of sCR. *Aims.* To investigate the incidence of abnormal serum FLC kappa/lambda ratio in patients with MM in long-lasting complete response (CR) seen at a single institution. *Methods.* 29 patients (12M/17F, median age 51 years) with MM who reached a CR were studied. All patients had a negative serum and urine immunofixation for the original monoclonal myeloma protein. The serum FLC measurement (FREELITE' assay, The Binding Site Ltd., Birmingham, U.K.) was performed by immunonephelometry. *Results.* CR was achieved after autologous (20) or allogenic (6) stem cell transplantation or after chemotherapy alone (3). The median follow up in CR was 7.4 years (range 1.5-23 years). Sixteen of the 23 patients (55.2%) had an oligoclonal band in serum and/or urine. Nine of the 29 patients (31%) had an abnormal serum FLC ratio. All of them had a ratio above the upper normal limit, indicating a kappa excess production. Seven of the patients with abnormal FLC ratio (77.8%) had an oligoclonal immunoglobulin. In contrast, among the 20 patients (69%) with normal serum FLC ratio, only 6 (30%) had an oligoclonal spike (p=0.04, Fisher's exact test). More-

over, the median value of FLC ratio was 2.09 in patients with an oligoclonal band versus 0.83 for those with no oligoclonal immunoglobulines (p=0.003, T-test for independent samples). No statistical significance was found between abnormal FLC ratio and time from CR achievement and FLC assay. The 4 relapsed patients who have relapsed all had a normal FLC ratio. Updated results will be presented at the meeting. *Summary and Conclusions.* 1) 55% of patients with MM in prolonged CR had oligoclonal bands, 2) 31% of patients with MM in CR had an abnormal FLC ratio and almost 80% of these had an oligoclonal band, 3) Since the presence of oligoclonal bands is associated with good outcome, our results question the value of sCR.

0376

DASATINIB ENHANCED APOPTOSIS OF RAPAMYCIN IN MULTIPLE MYELOMA CELLS THROUGH DOWN-REGULATION OF THE MTOR PATHWAY BY ABROGATING SIGNALING VIA AKT AND ERK

T. Guglielmelli, E. Giugliano, R. Merlini, M. Pautasso, I. Defilippi, S. Mussino, V. Brunetto, E. Bracco, G. Saglio

AUO San Luigi Gonzaga, ORBASSANO, Italy

Background. Multiple myeloma (MM) is a malignant plasma cells disorder and as far as now remains an incurable disease. Previous studies have shown the *in vitro* and *in vivo* activity of the mTor inhibitor rapamycin and of the tyrosine kinase inhibitor dasatinib in MM. *Aims.* We evaluated the anti-myeloma activity of dasatinib in combination with rapamycin in MM cell lines and in primary human MM cells and investigated the critical role of the Src activity in the deregulation of mTor signalling pathway. *Methods.* MM cell lines KMS18 and RPMI8226 were used. Bone marrow samples of 10 MM patients were subjected to CD138 immunomagnetic purification. Rapamycin was used at the dose of 100 nM in combination with increasing doses of dasatinib (50, 250 and 500 nM) and fixed dose of 250 nM dasatinib was combined with increasing doses of rapamycin (10, 100 and 500 nM). Apoptosis was assayed at 24 and 48h after treatment by flow cytometry evaluating annexin V marker. Inhibition of cell proliferation was evaluated with tripan blu exclusion assay. Src expression was reduced in cell lines by stable expression of a plasmid encoding small interfering RNA (siRNA) to Src. Pharmacological down-regulation of Src expression was obtained with the selective Src inhibitor PP2 (10 μM). Western blot analysis was performed to evaluate the anti-myeloma activity of the compounds and to assess the effects of the disruption of Src kinase activity on the phosphorylation status of AKT, mTOR, P706SK, Src and Erk. *Results.* Single agents rapamycin and dasatinib resulted in 20% and 32% (p<0.05) annexin V staining in KMS18 cells at 24 and 48h, respectively. The combination of rapamycin 100 nM and dasatinib 250 nM resulted in the highest level of apoptosis (47% at 48h, p<0.05). The RPMI8226 cells were less sensitive, values ranging between 15-25% for annexin V staining to the drug combination treatment. Rapamycin/dasatinib combination also enhanced apoptosis at 48h in MM cells of four out five mTor positive patients (38-75% annexin staining, p<0.05) while were ineffective in all MM cells of the five mTor negative patients. In KMS18 cells rapamycin determined a significant down-regulation at 24 and 48h of p-mTor (60%) and p-P706SK (55%) and a slight decrease of p-Erk (30%) while was ineffective on p-Akt. The rapamycin/dasatinib combination resulted in a more robust dephosphorylation of AKT (90%), mTor (88%), P706SK (85%) and Erk (70%). Pharmacological (PP2) and molecular (siRNA) down-regulation of Src and Dasatinib treatment strongly dephosphorylate mTor, P706SK, Src, AKT and Erk (24 and 48h). These data consistent with the hypothesis that dasatinib enhanced rapamycin activity and down-regulated the mTor pathway by dephoshporylating Src, Akt and Erk. A similar, but less evident pattern was expressed by the RPMI8226 cells studied in the same conditions. *Conclusions.* The dasatinib/rapamycin combination appears to induce significant cell death in MM cell lines and in a subset of MM patients with complete down-regulation of p-AKT. The synergism of the combination resulted in the down-regulation of the mTor signalling mediated by Src by abrogating signalling via Akt and Erk.

0377

PTEN IS DOWN REGULATED IN MULTIPLE MYELOMA

G. Piras, M. Monne, L. Pilo, A. Calvisi, A. Uras, M. Murineddu, L. Arca, L. Arru, L. Curreli, G.C. Latte, A. Murgia, A. Gabbas

U.O. Hematology, NUORO, Italy

Background. PTEN (phosphatase and tensin homologue deleted on chromosome 10) is a tumor suppressor gene that degrades the product of phosphatidylinositol 3-kinase (PI3K). The loss of function of PTEN causes accumulation of critical messenger lipids, which in turn increase AKT phosphorylation and activity, leading to decreased apoptosis and/or increased mitogen signaling. PTEN has essential roles in restricting the activation of the hematopoietic stem cells, in lineage fate determination, and in the prevention of leukemogenesis. It is frequently deficient in human cancer such as breast, brain and prostate cancer, due to mutations or through an epigenetic gene silencing mechanism. PTEN has a pivotal role in affecting myeloma cell apoptosis and growth thus linking the PI3-kinase-AKT pathway to myeloma leukemogenesis, where mutation and deletion have been observed as the major mechanism of PTEN inactivation. The present study aimed to investigate the expression of PTEN in primary bone marrow samples from multiple myeloma (MM) patients. Methylation analysis of PTEN gene promoter was performed in a subset of samples. *Patients and Methods.* Thirthy MM patients (male 15; female 15; 68.8 median age. ISS stage: 47% stage I, 8% stage II and 45% stage III.), and 11 MGUS patients were retrospectively examined for PTEN expression. Diagnosis was established on the bases of standard clinical and laboratory parameters and the disease stage was graded according to the International Prognostic Staging System (ISS). Relative quantification in real-time RT-PCR of PTEN gene transcript in comparison to ABL as reference gene was done on an ABI Prism 7500 (PE Applied Biosystems, Foster City, CA). Relative quantitative determination of target gene levels was done by comparing Ct and presented as *fold change* of matched tumor samples vs normal cells.Ten patients with monoclonal gammopathy of undetermined significance (MGUS) and 4 peripheral blood from controls were also evaluated. The methylation pattern of PTEN were determined using the methylation-specific polymerase chain reaction after bisulphite modification of genomic DNA from bone marrows. For statistical analysis Student t and Fisher exact tests were used. *Results.* PTEN was found to be differentially expressed in MM, MGUS and controls. The mRNA levels of PTEN were significantly decreased in MM compared with MGUS with a 5,1-fold difference, (p=0.0013). PTEN expression resulted down-regulated (> 5 fold reduction) in the 54% of MM examined. Three out of 30 (10%) MM showed a down regulated PTEN expression with a differences ranging from 7- to 48-fold. Clinical and laboratory parameters showed that MM showing the lowest expression of PTEN evolved from MGUS after 7-11 years, had IgG K isotype and methylation of the p16 gene. When PTEN promoter hypermethylation was examined, aberrant methylation pattern was found in 5/30 (16%) MM but none of MGUS or control samples were methylated. Of these, 5 patients had IgG ∫ isotype, 4 had abnormal cariotype with 13q deletion, one hyperdiploidia, one IgH rearrangements. Two patients were simultaneously hypermethylated in p16 gene promoter. Aberrant PTEN methylation correlates with the lowest levels of mRNA suggesting gene promoter methylation as mechanism of PTEN inactivation in a subset of MM patients. No statistically significant correlation between loss of PTEN expression and clinical parameters: gender, age, isotype of M component, type of light chain, haemoglobin, serum albumin level, calcium, β2 microglobulin, serum creatinine level, LDH, lytic bone lesions were found. *Conclusions.* Our results, eventhough on small number, demonstrate PTEN down regulation as a result of promoter hypermethylation in a subset of MM patients. Since talidomide seems to have a role in the PTEN/PI3K/AKT pathway, the PTEN function is worthy to be further investigated in multiple myeloma patients.

0378

DIFFUSE MRI PATTERN CORRELATES WITH INCREASED ANGIOGENESIS, EXTENSIVE BONE DISEASE AND POOR PROGNOSIS IN NEWLY-DIAGNOSED, PRIOR-UNTREATED, PATIENTS WITH MULTIPLE MYELOMA

E. Terpos,[1] M.A. Dimopoulos,[1] D. Christoulas,[1] E. Kastritis,[1] A. Koureas,[1] M. Roussou,[1] M. Gavriatopoulou,[1] M. Migkou,[1] M. Iakovaki,[1] M. Gotzamanidou,[1] A. Tasidou,[2] L.A. Moulopoulos[1]

[1]University of Athens School of Medicine, ATHENS; [2]Department of Hematopathology, Evangelismos General Hospital, ATHENS, Greece

Background and Aims. Magnetic resonance imaging (MRI) has been a useful technique for the assessment of patients with multiple myeloma (MM). Bone lytic disease is a major feature of MM, while increased angiogenesis is implicated in the myeloma cell growth and survival. The aim of this study was to evaluate the MRI pattern of marrow infiltration in newly-diagnosed myeloma and explore possible correlations with clinical and laboratory data, including myeloma bone disease, angiogenesis and survival. *Methods.* Eighty-two patients with newly diagnosed MM before the administration of any kind of treatment were studied. MRI of the thoracic and lumbar spine was performed and MR images were analyzed for patterns of myelomatous involvement. Four MRI patterns were identified: the normal, the focal, the diffuse and the variegated. Microvessel density (MVD) was evaluated in formalin fixed paraffin-embedded bone marrow sections of all patients using an anti-CD34 monoclonal antibody for identification of microvascular endothelial cells, while immunohistochemical staining for VEGF expression was also evaluated in all biopsies. Evidence of bone involvement at the time of diagnosis was documented using plain radiography. The following biochemical indices were measured in the serum of the patients on the day of MRI performance using ELISA methodology: i) osteoclast regulators (sRANKL, osteoprotegerin, osteopontin and MIP-1α), ii) osteoblast inhibitor dickkopf-1 (Dkk-1), iii) bone resorption markers (CTX, NTX, and TRACP-5b), iv) bone formation markers [bone alkaline phosphatase (bALP), and osteocalcin], and v) angiogenic cytokines [(VEGF, VEGF-A, angiogenin, angiopoietin-1, angiopoietin-2, and bFGF). *Results.* In MRI, 34 (41.5%) patients had focal pattern of marrow involvement, 26 (31.7%) diffuse, 18 (22%) normal, and 4 (4.9%) had a variegated pattern. In terms of MVD, 39% had low- (MVD 1-2), 41% intermediate- (MVD 3-6) and 20% high-grade (MVD >6) angiogenesis. Myeloma patients had increased values of sRANKL, osteoprotegerin, sRANKL/osteoprotegerin ratio, MIP-1alpa, NTX, CTX, TRACP-5b, Dkk-1, VEGF, VEGF-A, angiogenin, angiopoietin-2 and bFGF and reduced values of angiopoietin-1/angiopoietin-2 ratio compared to 36 healthy controls ($p<0.001$ for all comparisons). Patients with normal MRI pattern had normal values of Dkk-1, bone formation markers, angiogenin, and bFGF and only 39% of them had osteolysis in skeletal survey in comparison with 84% of patients with other MRI patterns who had osteolytic lesions ($p<0.001$). Patients with diffuse pattern of marrow involvement had reduced values of bone formation markers (OC and bALP, $p<0.01$), while patients with focal pattern had only a borderline reduction ($p=0.09$), although both diffuse and focal MRI patterns had increased Dkk-1 levels. MVD and VEGF expression in trephine biopsies was increased in patients with diffuse pattern compared to patients with focal ($p=0.037$) or normal pattern ($p=0.01$). Diffuse and variegated patterns of infiltration correlated with advanced disease stage ($p=0.018$), extensive bone disease ($p=0.033$) and poorer survival ($p=0.009$). *Summary and Conclusions.* These results suggest that patients with diffuse MRI pattern have suppressed bone formation compared to patients with focal or normal MRI patterns and subsequent extensive bone lytic disease. Diffuse MRI pattern correlates also with increased angiogenesis, advanced stage and poor survival suggesting a possible role of more aggressive therapies for these patients.

0379

CORRELATION BETWEEN LOSSES OF THE IGH OR ITS SEGMENTS AND DELETIONS OF 13Q14 IN MULTIPLE MYELOMA WITH TRANSLOCATION T(11;14) (Q13;Q32) DETECTED BY COMBINED ANALYSIS OF MORPHOLOGY AND FISH

L. Trakhtenbrot, I. Hardan, M. Koren-Michowitz, Sh. Oren, G. Yeshoev, G. Rechavi, A. Nagler, N. Amariglio

Institute of Hematology, RAMAT GAN, Israel

Background. Multiple myeloma (MM) is a malignancy of the plasma cells (PCs) characterized by a wide variety of genetic and chromosomal abnormalities. In recent years, major attention was drawn to the significance of chromosomal aberrations as a prognostic indicator in MM. The prognostic contribution of translocation t(11;14)(q13;q32) is ambiguous. Initially this translocation was reported by several groups as associated with a poor prognosis. Recently larger studies have demonstrated the improved outcome of MM patients with t(11;14) (q13;q32). Knowledge of the association between the translocation t(11;14) (11q13;q32) and established prognostic factors, such as Δ 13 and ploidy level, is important for evaluating the prognostic significance of this translocation and can give insight into the biology of MM. However, no correlation was found yet between deletions of the long arm of chromosome 13 [Δ13] and t(11;14)(q13;q32). The aim of this study was to analyze the correlation of the translocation t(11;14)(11q13;q32) with Δ13 on the level of single plasma cell (PCs). *Methods.* In this study we applied a combined cell morphology and FISH method for the analysis of coexistence of Δ13 and t (11; 14) (q13; q32) in PCs of 51 MM patients using several probes for the 13q14, 11q13 and IgH regions. *Results.* We found 15 different variants of the translocation t (11; 14) (q13; q32). These variants are the result of deletions of Variable or Constant IgH segments and also duplications and losses of the IgH gene on the normal non-translocated chromosome 14 as well as into IGH/ Cyclin D1 (CCND1) fusion on der 14 and CCND1/IGH fusion on der (11). A strong association between Δ13 and specific variants of t(11;14)(q13;q32) was found: variants with deletion of the IgH gene or its segments were found only in MM cases with deleted chromosome 13, while the common translocation t(11;14)(q13;q32) was found only in the MM cases with normal chromosome 13q. *Conclusions.* We were able to demonstrate a high heterogeneity of translocation t(11;14) in BM samples from MM patients using a combination of morphology and FISH analyses , that was overlooked in previous investigations. Moreover, we have shown the strong association between two chromosome alterations, Δ13 and deletions of the IgH gene or its segments in the group of MM patients with translocation t(11;14)(11q13;q32). Therefore we suggest that the prognostic impact of the deletions of the IgH gene or its segments should be studied in this group.

Introduction. Autologous stem cell transplant (ASCT) has become the standard of care in young newly diagnosed MM patients. Few studies have been prospectively conducted in order to evaluate different conditioning regimens, and in fact Melphalan 200 mg/m^2 is universally used as a standard.

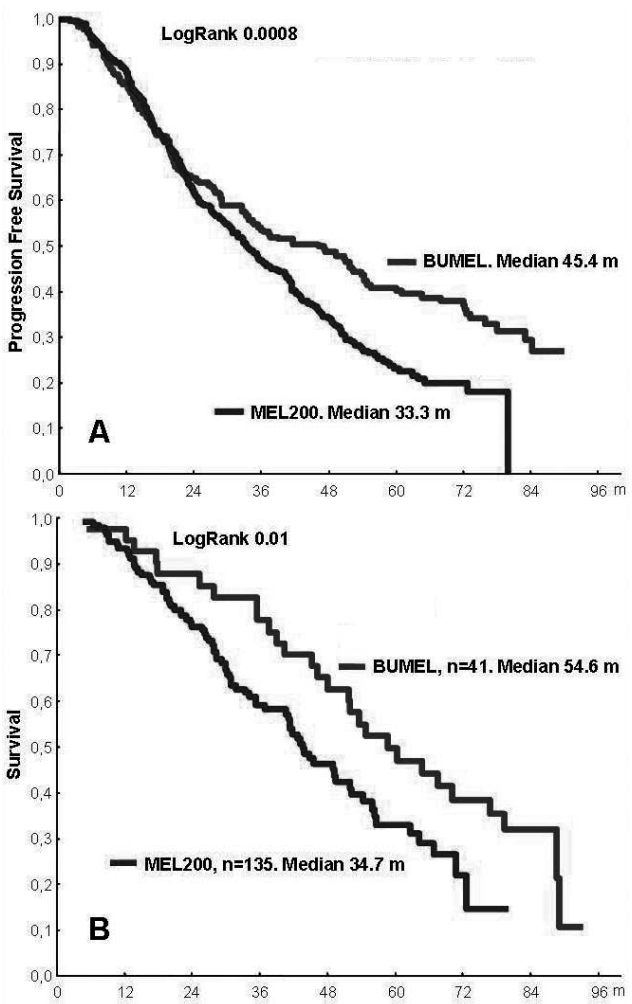

Figure.

Material and Methods. We have evaluated the efficacy and toxicity of two conditioning regimens in newly diagnosed MM patients included in the Spanish Pethema/GEM 2000 trial. 248 patients were conditioned with oral Busulphan at dose of 12 mg/Kg in combination with MEL 140 mg/m^2 and 554 with MEL 200 mg/m^2. All patients had previously received six cycles of alternating vincristine, BCNU, melphalan, cyclophosphamide, prednisone/vincristine, BCNU, Adriamycin, dexamethasone (VBMCP/VBAD). *Results.* Baseline characteristics were similar in both cohorts of patients, as well as the response rate to induction VBMCP/VBAD chemotherapy. Time to engraftment after transplant was also similar in both groups. Overall non-hematologic toxicities were higher in the BuMel arm (64% vs. 52%; *p*:0.002), as well as BuMel-related mortality (7,4% vs. 3,2%; *p*=0.009); hepatic toxicity, reported as sinusoidal obstruction syndrome (SOS) was the most relevant non-hematologic toxicity (observed in 8% of patients in the BuMel arm as compared to 0,4% in MEL arm; *p*:0.0001). Mortality directly associated to SOS was 2% and 0,2% in BuMel and MEL arms, respectively (*p*:0.026). There were not differences in the response rate (≥ partial response) at 100 days after ASCT: 92% in the MEL arm (36% CR with negative Immunofixation) vs. 91% for BuMel (38% CR IF-). With a median follow-up of 51 m, the median progression free survival (PFS) was significantly longer for BuMel (46,4 vs. 33.4m; *p*=0.002); however, not differences were observed in median overall survival (OS) between both arms (BuMel 79.3 vs MEL 70m; *p*=0.4). Nevertheless, the rescue therapy administered at the moment of first relapse clearly influenced the final outcome: patients who received bortezomib-based combinations had a significantly longer OS as compared with thalidomide-based combinations (41,3 vs. 34.3m; *p*=0.0008) vs. chemotherapy or steroids (25,8 m; *p*<10-5). Nevertheless, patients receiving BuMel were treated at an earlier time period (1999-2002) and the availability of IMiD's and bortezomib-based combinations as rescue therapies was more limited for these patients as compared to those subsequently treated with MEL. If we select the group of patients who received novel agents at the moment of relapse, median OS from diagnosis was significantly better for patients receiving BuMel as compared with pts treated with MEL and rescued with novel agents (54.6 vs. 34.7m; *p*=0.01). *Conclusions.* Conditioning with BuMel is associated with longer PFS but equivalent OS as compared with MEL. The absence of differences on OS could be due to the limited availability to novel rescue therapies in patients conditioned with BuMEL. Since we have used oral Busulphan without monitorization of serum levels and appropriate dose adjustment, it could be argued that the use of intravenous Busulphan would reduce the toxicity and eventually lead to a higher efficacy in MM patients.

0381

TANESPIMYCIN AND BORTEZOMIB IN PATIENTS WITH RELAPSED AND RELAPSED AND REFRACTORY MULTIPLE MYELOMA: FINAL RESULTS OF A PHASE 1/2 STUDY

P.G. Richardson,[1] A. Chanan-Khan,[2] S. Lonial,[3] A. Krishnan,[4] M. Carroll,[5] M. Alsina,[6] M. Albitar,[7] D. Berman,[8] T. Szatrowski,[8] S. Kaplita,[8] K.C. Anderson[1]

[1]Dana-Farber Cancer Institute, BOSTON; [2]Roswell Park Cancer Institute, BUFFALO; [3]Emory Winship Cancer Institute, ATLANTA; [4]City of Hope, DUARTE; [5]Sutter Regional Cancer Institute, SACRAMENTO; [6]H. Lee Moffitt Cancer Center, TAMPA; [7]Quest Hematopathology, SAN JUAN CAPISTRANO; 8Bristol-Myers Squibb, PRINCETON, USA

Background. Tanespimycin disrupts HSP90, a key molecular chaperone for signal transduction proteins critical to myeloma (MM) growth, survival, and drug resistance. Preclinical data show antitumor synergy between tanespimycin and bortezomib and suggest tanespimycin may be neuroprotective, including reversibility of bortezomib-induced peripheral neuropathy. A phase 1 study of single agent tanespimycin in advanced MM showed favorable tolerability and modest clinical activity. *Aim.* To assess the efficacy and safety of the combination of tanespimycin and bortezomib in patients with relapsed/refractory MM. *Methods.* Seventy-two (72) patients with relapsed/refractory MM received 0.7-1.3mg/m^2 bortezomib IV bolus followed by a 1-hr infusion of 100-340 mg/m^2 tanespimycin on days 1, 4, 8, and 11 in each 21-day cycle, with 42 patients receiving the highest dose of both drugs as part of a phase 2 expansion. Toxicities were assessed by CTCAE v3 and response rates were measured using modified EBMT criteria. *Results.* Of 72 patients, 72% had IgG subtype with a median age of 60 years. Median time since MM diagnosis was 50 months with median of 5 (range 1-15) prior regimens. Prior treatments included stem cell transplant (69%), thalidomide (74%), bortezomib (69%), lenalidomide (28%) and Hsp90

inhibitors (13%). Fifty-eight (58) patients with measurable disease were treated at 1 or 1.3 mg/m^2 bortezomib. Response rates (≥ MR) were 41%, 20%, and 14% in the bortezomib-naive, pretreated, and refractory patients, respectively. In the subgroup of patients with 1 to 3 prior therapies and who were bortezomib-naive, response rate was 56%. Median duration of response was 10.7 months (n=14 patients), including 3 bortezomib-refractory patients each with durable partial responses (PRs) through months 12, 22, and 28, respectively. Three additional patients remain in response through 24 months. The most frequent adverse events (AEs) were diarrhea (60%), nausea (49%), fatigue (49%), thrombocytopenia (40%), and AST elevation (28%), which proved manageable with dose reduction and supportive care. Most frequent Grade ≥3 AEs included: thrombocytopenia (25%); diarrhea, anemia and fatigue (7% each); back pain and AST elevation (4% each). Only 21% of patients had Grade 1 or 2 peripheral neuropathy; no Grade ≥3 peripheral neuropathy was observed. Only 4.2% of patients had any Grade neutropenia and 2.8% of patients had Grade ≥3 neutropenia. *Summary and Conclusions.* The combination of tanespimycin and bortezomib is active and well tolerated in relapsed/refractory MM, with durable responses in bortezomib-naive, pretreated, and refractory patients. Median duration of response for the combination compares favorably with historical bortezomib monotherapy. Final PFS data will be presented. No severe peripheral neuropathy has been observed, consistent with tanespimycin's neuroprotective effect in preclinical models. The incidence and severity of neutropenia compares favorably with historical bortezomib monotherapy. A phase 3 study of the combination of tanespimycin and bortezomib versus bortezomib monotherapy is ongoing.

0382

COMBINATION OF THALIDOMIDE, PEGYLATED LIPOSOMAL DOXORUBICIN, DEXAMETHASONE AND BORTEZOMIB (THADD-V) IN RELAPSED/REFRACTORY MULTIPLE MYELOMA: RESULTS OF A PHASE II STUDY

M. Offidani

Clinica di Ematologia Ospedali Riuniti Ancona, ANCONA, Italy

Background. ThaDD combination has been found to be an effective treatment for patients both with newly diagnosed and relapsed/refractory multiple myeloma (MM) (Offidani *et al.*, Blood 2006, Haematologica 2007). *Aim.* In an attempt to enhance the efficacy of ThaDD regimen we added bortezomib in a phase II study. *Methods.* ThaDD-V regimen consisted of thalidomide 100 mg/d continously, dexamethasone 20 mg days 1-2, 4-5, 8-9, 11-12, pegylated liposomal doxorubicin 30 mg/m^2 on day 4 and bortezomib 1.3 mg/sm days 1, 4, 8, 11. Due to a high incidence of > grade 2 peripheral neuropathy in the first 20 patients, the regimen was subsequently amended (thalidomide 50 mg/day, bortezomib 1.3 mg/sm days 1, 4, 11). Each course was repeated every 28 days for a total of 6 courses followed by 3 cycles consolidation with bortezomib 1 mg/sm days 1, 8 and dexamethasone 20 mg days 1-2, 8-9 alternated with 3 courses including thalidomide 50 mg/day for 28 days and dexamethasone 20 mg on days 1-4 and by maintenance with Thalidomide 50 mg/day until relapsed or toxicity. Patients received anti-bacterial (ciprofloxacin 250 mg bid), anti-viral (valaciclovir) and anti-thrombotic (ASA 100 mg/d or enoxaparin 40 mg/d) prophylaxis. Responses were assessed as per the International Response Criteria. *Results*. Forthy patients, median age 62 years (range 31-83) with relapsed or refractory MM were enrolled. ISS at least II in 73% and 14% of patients presented impaired renal function. Twenty-eight patients received ThaDD-V as second line of therapy, 12 as third or subsequent lines. Twenty-one (52%) had undergone previous ASCT whereas 21 (53%) and 6 patients (15%) had received prior thalidomide or bortezomib, respectively. Among 28 patients with FISH cytogenetics available, 12 (43%) showed unfavourable abnormalities. After at least 4 courses of therapy, 85% of patients achieved at least a PR, 67.5% at least a VGPR and 35% at least a CR with a 15% of patients obtaining a sCR. After a median follow-up of 25 months, median TTP, PFS and OS were 28 months, 23 months and not reached, respectively. Response to ThaDD-V was the only significant factor affected TTP and PFS whereas ISS, β2m, cytogenetics and previous thalidomide did not. Patients achieving at least a VGPR had a significantly higher TTP if compared with those obtaining a lower response (median 30 vs 8 months; p<0.001). Moreover, all 6 patients achieving sCR are still in remission and alive. Grade 3-4 thrombocytopenia and neutropenia occurred in 17% and 5% of patients. Main non-hematologic toxicities included grade 3 peripheral neuropathy (12%), fatigue (7%), diarrhoea (5%) and skin rash (2%). Four patients developed grade 3-4 infections (one fatal) and 2 DVT. Only one patient was withdrawn from the protocol because of toxicity, but 10 patients interrupted bortezomib because of neuropathy (5 patients) and thrombocytopenia (5 patients). Four patients discontinued thalidomide because of neuropathy (2) and thrombotic events (2). *Conclusions.* ThaDD-V is a very active and well tolerated regimen in patients with relapsed/refractory MM; it seems to induce durable responses besides adverse prognostic factors provided at least VGPR is achieved.

0383

A MULTICENTER PHASE II CLINICAL TRIAL OF LENALIDOMIDE, MELPHALAN, PREDNISONE AND THALIDOMIDE (RMPT) IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA

A. Palumbo,[1] A. Larocca,[1] G. Sanpaolo,[2] A.P. Falcone,[2] V. Federico,[3] L. Canepa,[4] M. Crugnola,[5] V. Magarotto,[1] F. Cavallo,[1] M.T. Petrucci,[3] M. Boccadoro[1]

[1]A.O.U. San Giovanni Battista, TORINO; [2]Ematologia e Trapianto, IRCCS Casa Sollievo della Sofferenza, SAN GIOVANNI ROTONDO; [3]Dipartimento di Biotecnologie Cellulari ed Ematologia, Università La Sapienza, ROMA; [4]Clinica Ematologica, Ospedale S. Martino, Università di Genova, GENOVA; [5]Cattedra e UO Ematologia e Trapianti midollo, Università degli Studi di Parma, PARMA, Italy

Background. Lenalidomide has shown significant antimyeloma activity in different clinical studies. In newly diagnosed multiple myeloma (MM) patients the addition of new drugs, lenalidomide or thalidomide or bortezomib, to the standard oral melphalan and prednisone (MP) combination significantly increased response rate and event-free survival. In advanced MM, the 4 drug combination VMPT further improves response rate. *Aims.*We conducted a multicenter open label phase I/II trial combining lenalidomide, melphalan, prednisone and thalidomide (RMPT) to determine safety and efficacy of this novel regimen in patients with relapsed/refractory multiple myeloma. *Methods.* Oral lenalidomide was administered at 10 mg/day on days 1-21, oral melphalan at 0.18 mg/kg on days 1-4 and oral prednisone at 2 mg/kg on days 1-4. Thalidomide was given at 50 mg/day (Arm A) or 100 mg/day (Arm B) on days 1-28. Each course was repeated every 28 days for a total of 6 courses. Maintenance therapy included lenalidomide alone at 10 mg/day on days 1-21, until progression. Aspirin 100 mg/day was given as a prophylaxis for thrombosis. *Results.* Forthy-four patients with relapsed or refractory MM were enrolled. Median age was 69 years (range 47-80). All patients had been already treated with a median of 2 previous lines of treatment: 26 patients received RMPT as second line of therapy and 18 as third line. Twenty patients received prior autologous transplant, 3 allogeneic stem cell transplant, 8 patients received conventional chemotherapy, 10 patients received thalidomide-based regimen and 9 bortezomib-based regimen. After a median of 5 courses, 75% of patients achieved at least a partial response (PR), including 20% very good partial response (VGPR) and 14% of patients achieving near or complete response (CR or nCR). Among 26 pts who received RMPT as second line therapy the PR rate was 73%, including VGPR 23% and CR/nCR 19%. Among patients who received thalidomide 100 mg, the PR rate was 82% (including VGPR 23% and CR/nCR 23%) compared to 68% of thalidomide 50 mg. The 1-year-progression-free survival was 51,5% and the 1-year survival from study entry was 72%. Grade 3-4 hematologic adverse events included: neutropenia (63%), thrombocytopenia (33,8%) and anemia (34,1%). Grade 3-4 non hematologic adverse events included: infections (22,3%), neurological toxicity (6,6%) and fatigue (6,8%). No thromboembolic events grade 3-4 were reported. *Conclusions.* RMPT is an effective salvage therapy with a high proportion of responses. Side effects were predictable and manageable. No thromboembolic complications were reported. An update of these data will be presented at the meeting.

0384

THALIDOMIDE-INTERFERON VS. INTERFERON MAINTENANCE THERAPY AFTER INDUCTION WITH THAL-DEX OR MP IN ELDERLY PATIENTS WITH MULTIPLE MYELOMA

H. Ludwig,[1] Z. Adam,[2] E. Tóthová,[3] R. Hajek,[2] B. Labar,[4] M. Egyed,[5] I. Spicka,[6] J. Drach,[7] H. Gisslinger,[7] I. Kuhn,[8] N. Zojer,[1] A. Hinke[9]

[1]Wilhelminenspital, VIENNA, Austria; [2]University Hospital Brno, BRNO, Slovakia; [3]Faculty Hospital with Policlinic, KOSICE, Slovakia; [4]Clinical Hospital "Rebro, ZAGREB, Croatia; [5]Kasposi Mór Teaching Hospital, KAPOSVAR, Hungary; [6]Charles University Prague, PRAGUE, Czech Republic; [7]Medical University of Vienna, VIENNA, Austria; [8]AESCA, Schering-Plough Austria, VIENNA, Austria; [9]WISP Research Institute, LANGENFELD, Germany

Background and Aims. Thalidomide maintenance therapy has been studied in a limited number of trials mainly after high dose therapy.

Here, we evaluated the efficacy of Thalidomide in combination with Interferon-α2b (Thal-IFN) in comparison to Interferon-α2b (IFN) maintenance treatment after first line treatment with either Thalidomide-Dexamethasone (Thal-Dex) or Melphalan-Prednisolone (MP). *Methods.* 289 patients (median age 72 years) had been randomized to either Thal-Dex or MP induction therapy. 249 of those received ≥2 cycles and 135 achieved stable disease or better. 128 of the 135 patients with ≥ stable disease after either Thal-Dex or MP induction therapy had finally been randomized to either Thal-IFN or IFN maintenance treatment. The starting dose for Thal maintenance was 100mg/day, and that for IFN maintenance 3 Mega U, TIW. Progression-free and overall survival have been estimated by the product limit method. *Results*. The outcome of the induction therapy has already been presented (BLOOD 2009). In short, Thal-Dex achieved a higher response rate compared to MP (69% vs. 50%, $p<0.0023$), but overall survival with Thal-Dex was shorter (41.5 vs. 49.4 months, $p=0.024$) mainly due to increased toxicity in elderly (age >75 years) patients with poor PS. The median follow up of after randomization to maintenance therapy was 32.3 months. The median duration of maintenance therapy was longer with Thal-IFN compared to maintenance with IFN only (10.2 months vs. 7.7 months, $p<0.02$). The cumulative dose of Thal was 27.200 mg (median) and the average daily dose was 75 mg. Maintenance with Thal-IFN resulted in significantly longer progression-free survival compared to IFN (24 vs. 12.6 months, $p<0.024$). Overall survival from start of maintenance treatment, however, did not differ between the Thal-IFN (52.6 months) and the IFN group (52.2 months, $p=0.68$) and was remarkably long. Likewise, no difference was observed when survival after start of maintenance was analyzed by first line therapy (Thal-Dex or MP). Progression free survival tended to be shorter in patients with unfavourable cytogenetics (t(4;14), t(14;16), del 17p, gain of 1q21) compared with standard risk patients (15.4 vs. 29.8 months, $p=0.088$). Median survival was 51.4 months in the former group while the median of survival has not yet been reached in the standard risk patients ($p=0.42$). Thal-Dex maintenance was associated with more grade 1-3 neuropathy (51% vs. 38%, $p=0027$), grade 1-2 constipation (44% vs. 18%, $p<0.0007$), and grade 1-2 skin toxicity (29% vs. 115, $p<0.009$). Maintenance IFN alone was initially relatively well tolerated but was discontinued earlier. *Summary and Conclusions.* Maintenance therapy with Thal-IFN resulted in significantly longer progression-free survival but overall survival did not differ between both groups

0385

REVERSAL OF ACUTE RENAL IMPAIRMENT BY BORTEZOMIB-DOXORUBICIN-DEXAMETHASONE IN MULTIPLE MYELOMA. RESULTS FROM AN PHASE II STUDY

H. Ludwig,[1] Z. Adam,[2] R. Greil,[3] E. Tóthová,[4] F. Keil,[5] N. Zojer,[1] J. Thaler,[6] H. Gisslinger,[7] M. Egyed,[8] A. Lang[9]

[1]Wilhelminenspital, VIENNA, Austria; [2]University Hospital Brno, BRNO, Slovakia; [3]Salzburg General Hospital and the Paracelsus Private Medical University, SALZBURG, Austria; [4]Faculty Hospital with Policlinic, KOSICE, Slovakia; [5]LKH Leoben, LEOBEN, Austria; [6]Hospital Wels-Grieskirchen, WELS, Austria; [7]Medical University of Vienna, VIENNA, Austria; [8]Kasposi Mór Teaching Hospital, KAPOSVAR, Hungary; [9]LKH Feldkirch, FELDKIRCH, Austria

Background. Acute light chain induced renal failure (ARF) is a severe complication of progressive multiple myeloma (MM), often leading to permanent renal dysfunction and dependence on chronic hemodialysis in a substantial proportion of patients. Reversal of kidney failure can only be achieved by fast and substantial suppression of pathogenic light-chains with effective anti-MM therapy. *Aims.* To evaluate prospectively the efficacy of the bortezomib-doxorubicin-dexamethasone (BDD) regimen in restoring renal function and in achieving tumour control in patients with light chain induced acute renal failure. *Patients and Methods.* 72 patients have been enrolled (age: median 66 years, range 40.7-82 years, DS stage I: 4%, II: 10%, III: 76%. 81% of patients presented with *de novo* MM, and 19% with progressive disease. ARF was defined in newly diagnosed patients as reduction of GFR to <50 mL/min and in previously treated patients as an acute reduction of GFR by >25% to <60 miL/min in patients who had a GFR of >60ml/min within 4 weeks before deterioration of renal function and documented progressive disease. Light-chain induced nephropathy had to be established as cause of ARF either by clinical findings or by renal biopsy. Treatment regimen: Bortezomib (1.3 mg/m^2, d 1, 4, 8, 11 until the first safety analysis and thereafter of 1.0 mg/m^2 d 1, 4, 8, 11), doxorubicin (9 mg/m^2, d 1, 4, 8, 11 until first safety analysis and thereafter of 9 mg/m^2, d 1, and 4) and dexamethasone 40 mg (d 1, 4, 8, 11). Mandatory antibiotic and antibacterial prophylaxis was instituted after the safety analysis. Cycles were repeated every 21 days. *Results*. 58 patients have completed at least 2 cycles and are evaluable for response as yet. Twenty seven patients (46.5%) achieved CR/nCR, 7 VGPR, 5 PR and 5 MR (CR-PR: 67%, CR-MR: 75.8%): Median GFR at baseline was 16.8 ml/min (range: 4-48 mL/min) and improved to 58 ml/min (range: 6.7 - 134 ml/min). Improvement of GFR correlated weakly with tumour response. GFR increased to a median of 64.6 ml/min (20.2-134 mL/min) in 34 patients with CR/nCR or VGPR, to 30.7 mL/min (14.7-55.3 mL/min) in 10 patients with PR or MR, and remained rather stable at 19.6 mL/min (6.7-57.9 mL/min) in 10 patients without anti-myeloma response (SD or PD). 62% of patients achieved a renal response and 31% a complete renal response (GFR>60 mL/min). Median time to best renal response was 4.4 months. Patients with severe renal impairment (anuria/oliguria and/or very low GFR (<15 mL/min) were less likely to achieve reversal of their renal failure even if they responded to anti-myeloma therapy. Overall Survival @ 2 years was 64% (CI: 50-82) in the ITT and 73% (CI: 59-92) in the evaluable patient population. A tendency towards better OS was seen in patients with renal response. Toxicity data are available in 49 patients as yet: The following G3-4 toxicities were observed: infections (16%), neutropenia (16%), cardiovascular (10%), weakness (10%), and thrombopenia and acute hearing loss in 5%. Grade 1-2 toxicities: infections 21%, neutropenia 16% and weakness, diarrhoea, GI bleeding in 5%. Of note, 4 of the 7 infectious complications were due to herpes virus infections/reactivations. *Summary and Conclusions.* The BDD regimen resulted in an overall renal response rate (improvement in stage of renal impairment by 2 stages-or better) of 62% and in a complete renal response rate (GFR>60 mL/min) of 31%. Significant anti-myeloma activity (CR/nCR/VGPR) was seen in 58% and CR-PR in 67% of patients. The increase in GFR correlated weakly with major anti-myeloma activity. The BDD regimen was well tolerated after dose adjustment. Updated results will be presented at the meeting.

0386

THE PRESENCE OF RESIDUAL NORMAL PLASMA CELLS BY MULTIPARAMETER FLOW CYTOMETRY IN THE BONE MARROW OF SYMPTOMATIC MULTIPLE MYELOMA PATIENTS AT DIAGNOSIS IDENTIFIES A GOOD PROGNOSTIC SUBGROUP

[1]University Hospital of Salamanca, SALAMANCA; [2]Hospital Universitario de Salamanca, Centro de Investigación del Cáncer (CIC, IB, SALAMANCA; [3]Hospital [12] de Octubre, MADRID; [4]Hospital Santa Creu I Sant Pau, BARCELONA; [5]Hospital Clínico Universitario de Valladolid, VALLADOLID; [6]Complejo Hospitalario de León, LEÓN; [7]Hospital General de Castellón, CASTELLÓN; [8]Hospital Comarcal del Bierzo, PONFERRADA; [9]Hospital General de Segovia, SEGOVIA; [10]Hospital Lozano Blesa, ZARAGOZA; [11]Hospital Central de Asturias, OVIEDO; [12]Clínico San Carlos, MADRID; [13]Hospital La Fe, VALENCIA; [14]Hospital Virgen de la Concha, ZAMORA; [15]Clínic Universitari, BARCELONA; [16]Centro de Investigación del Cáncer (CIC, IBMCC USAL-CSIC), Servicio General de C, SALAMANCA, Spain

Background. Multiparameter flow cytometry (MFC) immunophenotyping allows the discrimination between normal (N-PC) and myelomatous plasma cells (PC) within the bone marrow plasma cell compartment (BMPC). While in most MGUS and smoldering MM the BMPC contains N- PC, in symptomatic MM patients usually only clonal PC are identified. *Aims.*The aim of the present study is to investigate the frequency, characteristics and outcome of MM patients showing at diagnosis >5% N-PC among the BMPC. *Methods.* A total of 811 untreated symptomatic MM patients were included in the present study, all of them uniformly treated following the Spanish GEM2000 protocol. For the correlation with cytogenetics, we selected patients at diagnosis (N=501) in which cytogenetic/FISH was performed on enriched plasma cells using immunomagnetic separation. For MFC analysis, BM samples were stained using a four-color direct immunofluorescence technique that allowed the identification and characterization of the BMPC compartment. *Results.* We found that 88 cases (11%) had >5% N-PC/BMPC. Interestingly, patients with >5% N-PC/BMPC show a favourable profile at diagnosis compared with cases with ″5% N-PC/BMPC, with lower age (median of 58 vs. 60 years; $p=0.05$), lower frequency of IgA myeloma subtype (23% vs. 28% of patients; $p=0.04$), lower levels of serum

β2M (>3.5 mg/L: 33% vs. 46%; p= .01) and Monoclonal Component (≥3 g/dL: in 44% vs. 75%; p<0.001), lower BMPC infiltration by optical microscopy (>30% PC: in 17% vs. 45%; p<0.001) and by MFC (>5% PC: in 17% vs. 75%; p<0.001) and absence of immunoparesis (58% vs. 16%; p=.003). Also, they have higher levels of hemoglobin (>100 g/L: 80% vs. 56%; p<0.001), albumin (>3.5 g/dL: 62% vs. 50%; p=0.05), and platelet count (>200: 72% vs. 52%; p<0.001), and higher frequency of ISS stage I (48% vs. 33%; p=0.02). Interestingly, cases with >5% N-PC/BMPC showed lower frequency of IgH translocations (13% vs. 43%; p<0.001), del(13q) (5% vs. 41%; p<0.001) and del(17p) (3% vs. 8%; NS), and considering together high risk cytogenetics [t(4;14), t(4;16) or del(17p)] differences were highly significant (3% vs. 26%; p=0.006). Finally, patients with >5% N-PC/BMPC had better prognostic outcome than patients with ″5% N-PC/BMPC, with significantly longer progression-free survival (PFS; median 51 vs 39 months, p<0.001; Figure, Panel A) and overall survival (OS; median not reached vs 73 months, p=0.004; Panel B), and PFS and OS rates at 5 years of 40% vs. 30% (p<0.001), and 70% vs. 58% (p=0.004), respectively. *Conclusions.* Our findings uncover the existence of a particular good prognostic group of symptomatic MM patients defined by the presence of >5% of N-PC/BMPC assessed by MFC at diagnosis, stressing the clinical relevance of baseline routine BM evaluation by MFC in MM patients.

COMBINED VORINOSTAT, LENALIDOMIDE AND DEXAMETHASONE THERAPY IN PATIENTS WITH RELAPSED OR REFRACTORY MULTIPLE MYELOMA: A PHASE I STUDY

D. Siegel,[1] D. Weber,[2] C. Mitsiades,[3] M. Dimopoulos,[4] J. Harousseau,[5] S. Rizvi,[6] J. Howe,[6] D. Reiser,[6] K. Anderson,[3] P. Richardson[3]

[1]Hackensack University Medical Center, HACKENSACK, USA; [2]MD Anderson Cancer Center, HOUSTON, USA; [3]Dana-Farber Cancer Institute, BOSTON, USA; [4]University of Athens School of Medicine, ATHENS, Greece; [5]Centre René Gauducheau, SAINT HERBLAIN, France; [6]Merck & Co Inc., UPPER GWYNEDD, USA

Background. Multiple myeloma (MM), the second most common hematologic malignancy, remains incurable despite recent therapeutic advances. Treatment of patients with relapsed and refractory MM is extremely challenging and represents a specific unmet medical need. However, novel treatment combinations have the potential to improve patient outcomes. Vorinostat, an oral inhibitor of Class I and II histone deacetylase enzymes, enhances the anti-MM activity of other pro-apoptotic agents, providing potential synergy in combination with lenalidomide and dexamethasone. This Phase I, multicenter, open-label, non-randomized, dose-escalation study evaluated vorinostat plus lenalidomide and dexamethasone in patients with relapsed or refractory MM. *Aims.* The primary objective was to determine the maximum tolerated dose (MTD); secondary objectives included overall safety and tolerability, and evaluation of clinical activity. *Methods.* Patients aged ≥18 years with relapsed or refractory MM were enrolled sequentially into 1 of 5 escalating dosing levels (Table) using a standard 3+3 design for ″8 cycles. In the absence of dose-limiting toxicities (DLTs) in the first cycle, dose escalation continued until the MTD was established. Response to treatment was assessed using modified European Group for Blood and Marrow Transplantation (EBMT) criteria with the overall response rate (ORR) defined as minimal response or greater, and all adverse events (AEs) recorded. *Results.* Of 18 patients assessed for safety to date, 16 (89%) experienced ≥1 AE, with 13 (72%) patients experiencing a total of 32 drug-related AEs, the majority of which were mild or moderate in severity. The most common drug-related AEs were diarrhea (n=8, 44%), fatigue (n=6, 33%), neutropenia (n=6, 33%) and thrombocytopenia (n=5, 28%). A total of 4 serious AEs (SAEs) were reported in 3 (17%) patients: pneumonia (n=1, 6%) and septic shock (n=1, 6%) in the same patient; syncope (n=1, 6%), and diarrhea (n=1, 6%). One SAE (diarrhea) was considered related to study treatment. No patients discontinued due to AEs or SAEs. The MTD has not yet been reached and to date no DLTs have been observed in patients enrolled in the study. DLT evaluation is ongoing at dose level 5. Of 15 patients evaluable for efficacy, 11 (73%) experienced clinical benefit while on treatment. Best responses to vorinostat combined with lenalidomide and dexamethasone, defined by EBMT criteria, include: 1 complete response, 4 partial responses (PR), 1 minimal response, 5 stable disease (SD) and 4 progressive disease (PD), for an ORR of 40%. Nine of the ten patients who have received prior lenalidomide therapy were evaluable for response; best responses in these patients included PR (n=2), and SD (n=3); while 4 of these patients progressed. Of the 12 patients who remain on study, 6 out of 9 evaluable patients have responded (67%). To date, 6 out of 18 patients have discontinued therapy due to PD. *Conclusions.* These preliminary data suggest that vorinostat combined with lenalidomide and dexamethasone may represent a convenient oral combination therapy that is active and generally well tolerated in the treatment of relapsed or refractory MM. Dose escalation continues for determination of the MTD.

Table.

Dose level	Dosing escalation: Vorinostat dose (mg qd) 7 days on 7 days off (Days 1-7 and Days 15-21)	Lenalidomide dose (mg qd) x 21 days (Days 1-21)	Dexamethasone dose (mg qd) on Days 1, 8, 15, and 22	Number of patients evaluable for DLTs	Number of treatment cycles to date
1	300	10	40	4	≤8
2	400	10	40	4	≤7
3	400	15	40	3	≤4
4	400	20	40	3	≤2
5	400	25	40	4	≤1

Cycles were repeated every 28 days and use of concomitant aspirin was recommended

SURVIVAL AND YEARS OF LIFE LOST IN DIFFERENT AGE CATEGORIES OF PTS WITH MM

H. Ludwig,[1] Z. Adam,[2] E. Tóthová,[3] R. Hajek,[2] B. Labar,[4] M. Egyed,[5] I. Spicka,[6] J. Drach,[7] H. Gisslinger,[7] I. Kuhn,[8] N. Zojer,[1] A. Hinke[9]

[1]Wilhelminenspital, VIENNA, Austria; [2]University Hospital Brno, BRNO, Slovakia; [3]Faculty Hospital with Policlinic, KOSICE, Slovakia; [4]Clinical Hospital ″Rebro″, ZAGREB, Croatia; [5]Kasposi Mór Teaching Hospital, KAPOSVAR, Hungary; [6]Charles University Prague, PRAGUE, Czech Republic; [7]Medical University of Vienna, VIENNA, Austria; [8]AESCA, Schering-Plough Austria, VIENNA, Austria; [9]WISP Research Institute, LANGENFELD, Germany

Background and Aims. A systematic analysis of survival in different age cohorts (<40 to ≥80 years) by conventional or high dose therapy and information about the years of life lost of patients of different age categories is not available as yet. Here, we report results compiled in a large patient cohort. *Methods.* 10.549 patients (conventional therapy: 7.765, autologous transplantation: 2.784, median age: 60 years) were analysed. Estimates of relative overall survival were produced using to adjust for life expectancy depending on age, sex, and year of diagnosis. Years of life lost were calculated by subtracting the actual survival of individual patients since diagnosis from the patient's life expectancy at the time of diagnosis based on life tables from the country of the treating institution.

Results. Median relative survival decreased steadily from 5.2 years in patients <50 years by 10-year age categories to 2.6 years in those aged >80. Relative excess risk of death (RER) differed significantly between most 10 year age categories in the total cohort of patients, in males and females and those on conventional therapy. In patients with autologous transplantation, RER was only significantly increased in the age category 60-69 compared those aged 50-59 (1.263, p=0.0058). Average years of life lost years increased steadily over the various age categories from 4.6, 8.1, 13.7, 19.9, 26.9, to 36.1 years. *Conclusions*. Median relative survival decreased 2 fold (5.2 vs. 2.6 years) from patients <50 years to those ≥80 years of age, but the average years of life lost was almost 8 fold greater (36.1 vs. 4.6 years) in the youngest compared to the oldest cohort.

BORTEZOMIB , PEGYLATED LIPOSOMAL DOXORUBICIN AND DEXAMETHASONE (B-D-D) AS THERAPY FOR ELDERLY PATIENTS WITH RELAPSED REFRACTORY MULTIPLE MYELOMA: A WEEKLY BORTEZOMIB SCHEDULE REDUCES TOXICITIES MANTAINING THE SAME EFFICACY

A. Gozzetti,[1] A. Fabbri,[1] E. Marchini,[1] S. Oliva,[1] M. Defina,[1] M. Bocchia,[1] F. Lauria[2]

[1]*University of Siena, SIENA;* [2]*Hematology and Transplants, SIENA, Italy*

Background. There is a synergism between the proteasome inhibitor bortezomib and anthracyclines. In addition, several *in vivo* data show synergic-additive effect of bortezomib and pegylated liposomal doxorubicin (Peg LD). Recently these findings were confirmed by the results of a large phase III study. However the majority of patients treated in this study were younger then 65 years old. Nobody so far described the results of this combination regimen in an oldest group of patients. *Methods.* Patients. 40 patients (F:M 20:20), median age 68 years, (range 45-81) with a disease resistant to or relapsing after high or conventional dose chemotherapy have been treated. 24 of the 40 patients treated were elderly patients with a median of 75 years (71-81). 30 pts had IgG k/l (20/10); 3 pt had IgA/k, 1 IgA/l, 6pts had a Bence Jones k/l (3/3). β2-microglobulin was 3.1 (range 1.4-17.2). Treatment was started at a median of 31 months from diagnosis (range 2-108). Patient distribution according to disease status and previous therapy was as follows: 6 patients were refractory to the first regimen (primary refractory ,PR); 15 patients had an untreated relapse (UR); and 19 a refractory relapse (RR). A median of 3 lines of chemotherapy were received (range 1-6), with 9 patients with more then 5 lines of CHT. 15 patients were relapsing after autologous stem cell transplantation (ASCT) . Interestingly 5 patients had a disease previously refractory to antracyclines (VAD therapy), and 13 patients had an extramedullary localization of myeloma. *Therapy*. Bortezomib was given 1.3 mg/m^2 as a bolus IV injection on days 1,4,8 and 11 every 3 weeks PegLD was given IV at a dose of 30 mg/m^2 on day 4 every 3 weeks, desamethasone was given IV 40 mg on days 1-4 every 3 weeks, until a plateau phase was reached. After the age of 70 years bortezomib was given with the same schedule as previously described for the first two cycles and then weekly on days 1,7, 14,21 with a 10 days rest period until a plateau phase was reached. PegLD was given on day 4 every 3 weeks for the first two cycles and then was given on day 7 every 31 days cycle. Desamethasone was given with same schedule as previously reported for the first two cycles and then 20 mg IV on days 1,7,14,21 every 31 days. *Statistical analysis*. Overall survival (OS) and progression free survival (PFS) were calculated using the Kaplan -Meier method. Statistical analysis were performed using chi square or Fisher's exact tests. Logrank test comparison of survival curves was done. *Results*. Patients received a median of 4 cycles (range 2-6). B-PeghLD-D therapy resulted in 29/40 objective responses for an overall response rate (ORR) of 70% according to EBMT criteria. In particular we observed 8CRs and 2 nCRs (25%); 11 VGPRs (27%) and 5 PRs (12%), 3 MR (1%). Seven patients received less then 4 cycles (4NR, 3 for toxicity). Height patients had bortezomib dose reduction to 1mg/m^2. Median duration of response (PFS) was 6 months (range 1-36) and all 13 patients with less then PR relapsed. By contrary 17/26 (65%) patients with ≥VGPR still maintain a response at median of 8 months (range 1-36) (p=0.001). 20 patients that received more then 3 lines of previous chemotherapy had a median survival of 6 months compared to 13 months of patients that received less then 3 cycles (p=0.12). PFS in the same group was 3 vs. 10 months (p=0.5). 4/5 VAD refractory obtained a response. 5/13 patients with extramedullary disease responded. Toxicities were mild to moderate in most of the patients and maneageble. Grade 3-4 thrombocytopenia occurred in 7/40 (17%) patients and grade 3-4 neutropenia occurred in 7/40 patients (17%), but only 2 developed febrile neutropenia. 13 patients (32%) complained grade 1-2 paresthesias, 4 patients had grade 3-4 paresthesias. 6 pts (15%) had HSV reactivation, 1 hand-foot syndrome. Response in elderly patients. Interestingly in the oldest group we observed an ORR of 75% [7/24 CR/nCR (30%), 7 VGPR (30%), 1 PR, 3 MR and 6 NR]. Median OS was 15 months and PFS was 8 months. 10/24 patients with ≥ VGPR still maintain a response at 8 months vs 2 months of pts with ″ VGPR (PFS, OS p=0.0001). Toxicities were comparable to the youngest group. *Conclusion*. Bortezomib-PegLD-D combination is highly effective in resistant-relapsing MM with an ORR of 70% and 25% CR,nCRs, also in antracyclines refractory patients. Best and more durable responses are seen in patients treated with less then 3 lines of previous chemotherapy and in patients achieving at least a VGPR. Oldest patients with more then 70 years have fast and durable responses with acceptables and maneagebles toxicities . This regimen can be used also in the elderly MM patients.

BETA-2 MICROGLOBULIN IS AN INDEPENDENT PREDICTOR OF PROGRESSION IN ASYMPTOMATIC MULTIPLE MYELOMA

D. Rossi,[1] M. Fangzio,[1] L. De Paoli,[1] V. Pinto,[1] P. Riccomagno,[1] A. Puma,[1] A. Ramponi,[2] G. Gaidano[1]

[1]*Division of Hematology, Amedeo Avogadro University, NOVARA;* [2]*Division of Pathology, Amedeo Avogadro University, NOVARA, Italy*

Background. The rationale of the study stems from three considerations: i) to date, few clinical predictors of asymptomatic multiple myeloma (MM) progression are available; ii) no study has assessed the role of β-2-microglobulin (B2M) on risk of asymptomatic-MM progression; iii) β2M is a serum marker of tumor burden/disease kinetics and represents

a key variable of the ISS staging system for symptomatic-MM. *Aim.* To assess the impact of B2M on risk of asymptomatic-MM progression. *Methods.* The study was based on a consecutive series of 148 asymptomatic-MM diagnosed according to the IMWG. Cumulative probability of progression to symptomatic-MM was calculated from diagnosis of asymptomatic-MM to progression to symptomatic-MM according to IMWG. The best cut-off for β2M, percentage of bone marrow plasma cells (BMPC%), serum monoclonal component (sMC) and urinary monoclonal component (uMC) were selected according to Youden's index using progression as state variable. Survival analysis was performed by Kaplan-Meier method using log-rank to test for associations. Cox proportional hazard regression was used to build a multivariate model. *Results.* Clinical features at asymptomatic-MM diagnosis were as follows: median age 67 years, male:female ratio 1.02, previous MGUS 32/148 (21.6%), IgG MC 113/148 (76.4%), IgA MC 32/148 (21.6%), light chain MC 3/148 (2.0%), median sMC 1.1 g/dL, positive urinary immunofixation 27/148 (18.2%), median uMC 98 mg/24h, median BMPC% 15%, median B2M 2.0 mg/L, median albumin 4.3 g/dL, median C reactive protein 0.3 mg/L. After a median follow-up of 36 months, 24/148 asymptomatic-MM progressed to symptomatic-MM, accounting for a 30.5% 5-year probability of progression. According to Youden's index, best cut-off values were 2.5 mg/l for B2M, 1.5 g/dl for sMC, 500 mg/24h for uMC, and 20% for BMPC%. Univariate analysis identified B2M>2.5 mg/L(5-year risk: 64.5%; HR=3.85; $p<0.001$), sMC>1.5 g/dL (5-year risk: 49.1%; HR=5.76; $p<0.001$), uMC>500 mg/24h (5-year risk: 68.7%; HR=6.60; $p<0.001$) and BMPC%>20% (5-year risk: 50.2%; HR=5.77; $p<0.001$) as predictors of progression to symptomatic-MM. Clinical variables not associated with progression to symptomatic-MM ($p>0.01$ in all cases) were age, sex, sMC type, polyclonal Ig reduction, albumin, C reactive protein, Hb, calcium, creatinine, and previous MGUS. Multivariate analysis identified B2M>2.5 mg/L (HR=3.57; $p=0.001$) as an independent predictor of progression to symptomatic-MM, along with sMC>1.5 g/dL (HR=4.07; $p=0.003$), uMC>500 mg/24h (HR=3.66; $p=0.015$) and BMPC%>20% (HR=3.20; $p=0.007$). We next combined B2M, sMC, uMC, and BMPC% into a model for predicting progression to symptomatic-MM. This model stratified patients into four risk groups: very low risk (0 risk factors: 5-year risk 0%), low-intermediate risk (1 risk factor: 5-year risk 19.6%), high-intermediate risk (2 risk factors: 5-year risk: 60.7%), and high risk (3 or 4 risk factors: 5-year risk 80.7%) (Figure 1). *Conclusions.* The implications of our results are twofold: i) B2M predicts progression of asymptomatic-MM to symptomatic-MM independent of conventional risk factors (sMC, BMPC%, light chain burden); ii) B2M refines the conventional model for predicting progression of asymptomatic-MM by allowing the identification of a very low risk group of patients who never progress to symptomatic-MM and a high risk group of patients who are virtually all projected to progress.

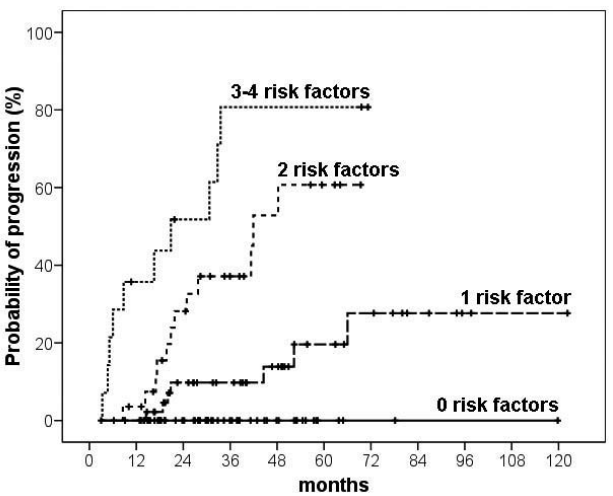

Figure 1. Risk of asymtomatic MM progression.

PATTERNS OF SURVIVAL AND CAUSES OF DEATH FOLLOWING A DIAGNOSIS OF MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE: A POPULATION-BASED STUDY

S.Y. Kristinsson,[1] M. Björkholm,[1] T.M.L. Andersson,[2] S. Eloranta,[2] P.W. Dickman,[2] L.R. Goldin,[3] C. Blimark,[4] U.H. Mellqvist,[4] A. Wahlin,[5] I. Turesson,[6] O. Landgren3

[1]Karolinska University Hospital and Karolinska Institutet, STOCKHOLM, Sweden; [2]Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, STOCKHOLM, Sweden; [3]National Cancer Institute, National Institutes of Health, Bethesda, MARYLAND, USA; [4]Dep of Med, Section of Hematology and Coagulation, Sahlgrenska University Hospit, GOTHENBURG, Sweden; [5]Cancer Centre, Section of Hematology, Umea University Hospital, UMEA, Sweden; [6]Department of Medicine, Section of Hematology, Malmö University Hospital, MALMO, Sweden

Background. Patients with monoclonal gammopathy of undetermined significance (MGUS) have an increased risk of lymphoproliferative malignancies. However, there are limited data on survival patterns among MGUS patients. *Aims.* To assess pattern of survival among MGUS patients diagnosed in clinical practice compared to the general population, and to classify causes of death in MGUS patients compared to matched controls. *Methods*. We included, from all major hematology outpatient units in Sweden, 4,259 MGUS patients (diagnosed 1986-2005) and compared survival to the general population by computing relative survival ratios (RSRs). We also compared causes of death with 16,151 matched controls using Cox's proportional hazards regression models. *Results*. One-year, 5-year, 10-year, and 15-year RSR were 0.98 (95% CI 0.97-0.99), 0.93 (0.91-0.95), 0.82 (0.79-0.84), and 0.70 (0.64-0.76), respectively (Figure). Younger age at MGUS diagnosis was associated with a significantly lower excess mortality compared to older ($p<0.001$). The excess mortality among MGUS patients increased with longer follow-up ($p<0.0001$). We found IgM (versus IgG/A) MGUS to be associated with a superior survival ($p=0.038$). MGUS patients had an increased risk of dying from MM (hazards ratio (HR)=553; 95% CI 77-3946), WM (HR= °), other lymphoproliferative malignancies (6.5; 2.8-15.1), other hematological malignancies (22.9; 8.9-58.7), amyloidosis (HR= °), bacterial infections (3.4; 1.7-6.7), ischemic heart disease (1.3; 1.1-1.4), other heart disorders (1.5; 1.2-1.8), liver diseases (2.1; 1.1-4.2), benign hematological disorders (6.9; 2.7-18), and renal diseases (3.2; 2.0-4.9). *Summary and conclusions.* Our findings of a decreased life expectancy in MGUS patients, most pronounced in the elderly population, explained by both malignant transformation and non-malignant causes are of importance in the clinical management of MGUS patients.

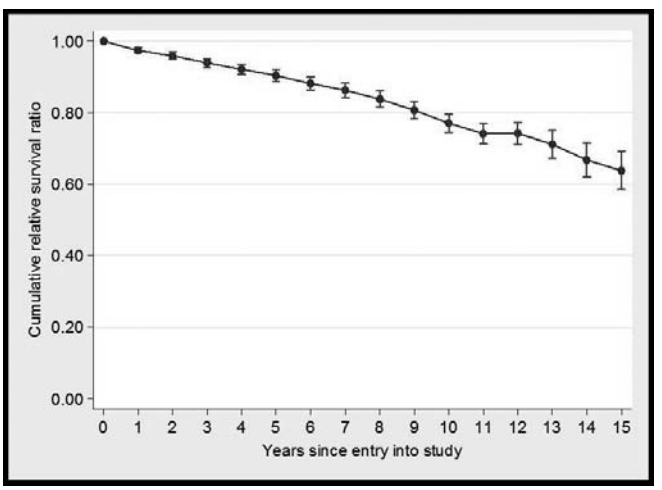

Figure. Relative survival ratios for MGUS patients.

0392

BORTEZOMIB IN COMBINATION WITH DEXAMETHASONE OVERCOMES THE NEED FOR ADDITIONAL CHEMOTHERAPY PRIOR TO HIGH-DOSE THERAPY WITH AUTOTRANSPLANT IN PATIENTS WITH MULTIPLE MYELOMA

A. Corso,[1] L. Barbarano,[2] S. Mangiacavalli,[1] L. Montalbetti,[3] A.M. Cafro,[2] A.M. Carella,[4] M. Spriano,[4] P.E. Alessandrino,[1] G. Grillo,[2] M. Varettoni,[1] P. Bernasconi,[1] M. Lazzarino,[1] E. Morra[2]

[1]Fondazione IRCCS Policlinico San Matteo, University of Pavia, PAVIA; [2]Ospedale Niguarda Ca' Granda, MILANO; [3]Divisione di Medicina-Oncologia Ospedale di Busto Arsizio, BUSTO ARSIZIO; [4]Division of Hematology, Ospedale san martino, GENOVA, Italy

Background. The introduction of high-dose therapy (HDT) followed by stem cell rescue has significantly changed the approach of multiple myeloma (MM) patients, becoming the gold standard as initial therapy in patients younger than 65 years. Patients who most benefit from HDT are those achieving a complete response (CR) or a very good partial response (VGPR) after transplant. Velcade in combination with dexamethasone (Vel-Dex) has proven to be effective in inducing high rate of good quality response (CR, VGPR). *Aims.*To evaluate the role of DCEP chemotherapy after induction with Vel-Dex in untreated younger MM patients candidate to a HDT program. *Methods.* We conducted a phase II multicenter trial including four Vel-Dex courses as induction, followed by 2 courses of DCEP (Dexamethasone, Cyclophosphamide, Etoposide, cysPlatinum) as intensification and stem cell mobilization, and single autologous transplant (Tx) with melphalan 200 mg/m^2 as conditioning regimen. Fifty-seven patients were studied. Patient characteristics were: male/female 35/22 (60%/40%), median age 58 years (37-65), IgG/IgA/light chain 33/12/12 (56%/22%/22%), D&S stage I in progression/II/III 3(5%)/5(9%)/49(84%), ISS I/II/III 24(43%)/13(22%)/20(35%), cytogenetic abnormalities absent/present 48%/52% (del 13 21%, t (4;14) 23%, t (11;14) 7%) *Results.* Forty-three patients completed the program (75%). Fourteen patients (25%) went off-study: 7 after Vel-Dex (3 for progression, 3 for toxicity, 1 patient withdrew consent), and 7 after DCEP (5 for progression, 1 for toxicity, 1 withdrew consent). All patients collected an adequate number of peripheral stem cells after DCEP. Table 1 reports response after Vel-Dex and after DCEP. After 2 cycles of DCEP, 5 patients (10%) improved, 35 (70%) remained unchanged, and 15 (20%) worsened. High-dose melphalan further improved response. In fact, after transplant, ORR reached 96% (with 80% ≥VGPR). On an intention to treat basis, the 86% ORR achieved after Vel-Dex, decreased to 76% after DCEP, and to 73% after transplant. After a median follow-up of 15.3 months from Tx, of 43 responding patients 16 (37%) progressed. The median duration of response after Tx was 13 months (1.4-24 months). Patients achieving CR had lower progression rate (p=0.02) and longer duration of response (p=0.04) compared to patients with VGPR or PR (progression rate 12%/42%/60% and median duration of response 18/13/9 months for patients with CR/VGPR/PR). *Conclusions.* Bortezomib in combination with dexamethasone is a safe and effective induction program for MM patients candidates to high-dose therapy. Consolidation with DCEP is unable to improve response to Vel-Dex, while high-dose melphalan further increases the ORR. Shortening the interval between induction and high-dose melphalan may help in maintaining the level of response, preventing progressions that may be observed during the post-induction/consolidation phase.

Table 1. Breakdown of response after Vel-Dex and a.

Response after vel-dex	Response after DCEP					
	CR	VGPR	PR	SD	PD	Total
CR	12	2	-	-	1	15
VGPR	5	14	2	-	2	23

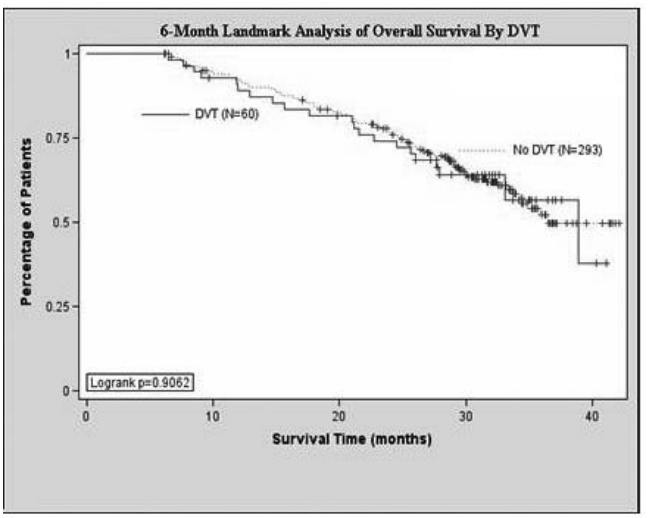
SURVIVAL EFFECT OF ERYTHOPOIETIC AGENTS AND VENOUS THROMBOEMBOLISM (VTE) IN MULTIPLE MYELOMA PATIENTS TREATED WITH LENALIDOMIDE AND HIGH-DOSE DEXAMETHASONE

M. Zangari,[1] G. Tricot,[1] L. Polavaram,[1] A. Finlayson,[1] F. Zhan,[1] R. Knight,[2] T. Fu,[2] D. Weber,[3] M. Dimopoulos,[4] R. Niesvizky,[5] L. Fink[6]

[1]University of Utah, SALT LAKE CITY, USA; [2]Celgene Corporation, SUMMIT, USA; [3]University of Texas, HOUSTON, USA; [4]University of Athens, ATHENS, Greece; [5]Cornell University, ITHACA, USA; [6]Nevada Cancer Institute, LAS VEGAS, USA

Background. Thromboembolism in cancer patients at diagnosis or during treatment has been associated with a shorter survival. Long-term follow-up studies in patients with thrombosis have shown that those with cancer have a 4- to 8-fold higher risk of dying after an acute cardiovascular event than patients without cancer. Concern has also been raised with regard to cancer-associated VTE during treatment with erythropoietin, either epoetin alfa or darbepoetin. Head and neck cancer patients treated with chemoradiotherapy and epoetin alfa experienced a 10-fold higher risk of VTE compared with patients treated only with chemotherapy. *Aims and Methods.* Retrospective analysis of the effect of erythropoietic agents and VTE development on patient survival. Two identically designed, multi-center, double-blind, Phase III clinical trials were conducted in Europe and the US to assess the effect of lenalidomide in combination with dexamethasone versus dexamethasone plus placebo in patients with relapsed or refractory multiple myeloma (MM), after failing at least one prior line of treatment. 353 patients were randomized to receive 25 mg of lenalidomide on days 1-21 of a 28-day cycle, plus 40 mg of oral dexamethasone on days 1-4, 9-12 and 17-20 for the first four cycles; after the fourth cycle, 40 mg of dexamethasone was administered on days 1-4 only.



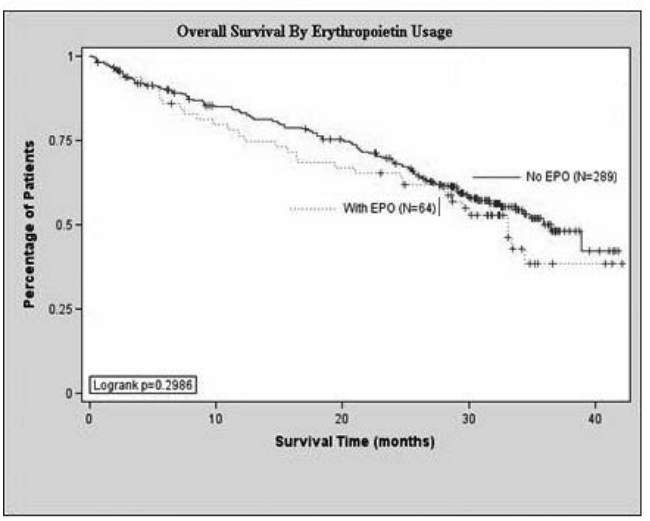


Figure 1 and 2.

Results. A total of 353 patients treated with lenalidomide and dexamethasone were included in this analysis; the median age was 63 years, 59.5% were male, 20.4% were IgA myeloma. With a median follow-up of 17.5 months, a total of 60 (17.0%) patients experienced a DVT during treatment. A total of 64 patients received erythropoietic agents during the treatment course (18.3% received EPO among DVT and 18.1% among non-DVT patients, p=0.96). Erythropoietin treated patients have been more exposed to thalidomide, had a significantly lower albumin, and higher β2 microglobulin. Figure 1, 2 show overall survival of patients by erythopoietic use and DVT development. The development of VTE did not significantly affect overall survival (p=0.40) or time to progression (p=0.43). No significant impact was observed in the subgroup of patients who received erythropoietic agents (overall survival p=0.85, time to progression p=0.26). *Conclusions.* Patients with relapsed or refractory MM treated with the combination of lenalidomide plus high-dose dexamethasone that developed a VTE, or received erythopoietic agent, did not experience shorter overall survival or time to progression.

SERUM DKK1 IN MULTIPLE MYELOMA PATIENTS

U. Heider,[1] M. Kaiser,[1] M. Mieth,[1] J. Rademacher,[1] B. Lamottke,[1] C. Jakob,[1] E. Braendle,[2] D. Stover,[2] O. Sezer[1]

[1]*Charite Campus Mitte, BERLIN, Germany;* [2]*Novartis Institutes for Biomedical Research, CAMBRIDGE, USA*

Introduction. Lytic bone destruction is a hallmark of multiple myeloma, caused by enhanced osteoclast activity and decreased bone formation. The Wnt-signaling antagonist Dickkopf (DKK) 1 has been identified as an important factor involved in osteoblast inhibition by myeloma cells. We therefore evaluated serum DKK1 in 184 untreated myeloma patients and correlated the results with disease stage and the extent of bone disease. In a second step, DKK1 was quantified in 101 patients undergoing anti-myeloma therapy for symptomatic disease, and correlated the results with disease activity, the kind of therapy and the response to treatment. *Results.* Mean serum DKK-1 significantly correlated with myeloma stage according to Durie and Salmon (2223 pg/mL vs. 15,209 pg/mL in stage I and II/III, p=0.005), with the presence of lytic bone disease (mean 3114 pg/mL vs. 17,915 pg/mL in patients with or without lesions, p=0.003), and the number of bone lesions (0 vs. 1-3 vs. >3 lesions: 3114 pg/mL vs. 3559 pg/mL vs. 24,068pg/mL; p=0.002). Pretreatment DKK1 levels in symptomatic MM patients were increased compared to individuals with MGUS (mean 3768 pg/mL vs. 1993 pg/mL). A significant decrease of DKK1 during therapy was seen in the following treatment groups: adriamycin/ dexamethasone (1668 pg/mL vs. 1241 pg/mL, p=0.016), HDCT + ASCT (2446 pg/mL vs. 1082 pg/mL, p=0.001), bortezomib (4059 pg/mL vs. 1862 pg/mL, p=0.016) and lenalidomide (11837 pg/mL vs. 4374/mL, p=0.039), whereas treatment with thalidomide led to a nonsignificant decrease in DKK1 (1705 pg/mL vs. 1269 pg/mL, p=0.081). Within all groups, a significant decrease of DKK1 was only seen in responders (i.e. patients achieving a complete or partial remission). Pretreatment serum levels of DKK1 were not predictive for response, and there was no significant difference in pretreatment DKK1 levels in responders and nonresponders (p=0.696). Furthermore, DKK1 did not correlate with the number of prior therapies given, and there was no difference between previously untreated patients with symptomatic multiple myeloma and patients at relapse regarding serum DKK1. These data suggest that myeloma cells are the main source of circulating DKK1 protein and provide a framework for clinical trials on anti-DKK1 treatment in multiple myeloma.

LENALIDOMIDE-BASED THERAPY LEADS TO IMPROVEMENT OF HUMORAL IMMUNE SYSTEM IN RELAPSED OR REFRACTORY MULTIPLE MYELOMA PATIENTS WHO RESPOND TO THE THERAPY

R. Baz,[1] M. Dimopoulos,[2] P. Richardson,[3] Z. Yu,[4] M. Hussein,[4] A. Chanan-Khan[5]

[1]*Moffitt Cancer Center, TAMPA, USA;* [2]*University of Athens School of Medicine, ATHENS, Greece;* [3]*Dana-Farber Cancer Institute, BOSTON, USA;* [4]*Celgene Corporation, SUMMIT, USA;* [5]*Roswell Park Cancer Institute, BUFFALO, USA*

Background. Recurrent bacterial infection is the most frequent cause of death in patients with advanced multiple myeloma (MM). Infections result primarily from the marked depression of normal immunoglobulins production that occurs in more than 75% of patients. Pneumococcal vaccination has been suggested as an option, however most MM patients respond poorly to bacterial antigenic stimulation. All MM patients including those with plateau-phase have an increased risk of life-threatening bacterial infections and polyclonal humoral immune suppression. Preliminary results from Borrello *et al.* demonstrated that the use of lenalidomide prior to pneumococcal vaccination significantly augments its efficacy, suggesting lenalidomide improves the humoral immune system. *Aim.* We evaluated the effect of lenalidomide plus dexamethasone (Len/Dex) therapy on IgA levels in relapsed or refractory MM patients from two large randomized pivotal phase III registration studies (MM009/010) comparing Len/Dex to placebo/Dex, as well as the large phase 2 study evaluating single agent lenalidomide (30 mg x 21 days in each 28-day cycle) in relapsed or refractory MM patients MM-014). These studies have shown that lenalidomide based therapy significantly improved response rate and progression free survival in patients with MM. *Methods.* The baseline level of residual polycolonal IgA, IgG and IgM levels for the different myeloma subtypes were evaluated and monitored monthly. Comparisons were made between responders and non-responders per the Blade criteria. Humoral improvement was defined as an increase from the baseline level of residual polycolonal immunoglobulin to at least the lower limit of normal and a 25% increase in value. *Results.* Of the 353 patients randomized to receive Len/Dex in MM009/MM010 (median age 63 years; median of 2 prior therapies) and 222 patients enrolled in MM014 who received Len (median age 63 years; median of 5 prior therapies), residual IgA was the only residual polyclonal protein to show recovery during the monitoring period of the studies. Patients with non-IgA MM type were included in this analysis (159 responders, 115 non-responders from MM009/MM010; 36 responders, 60 nonresponders from MM014). At baseline, residual IgA level was normal in (30% and 17%) in responders and (17% and 42%) in non-responders for patients on MM009/010 and MM014, respectively. Only patients responding to therapy showed significant improvement and normalization of residual IgA levels. 56% and 50% of patients on MM009/010 and 014 respectively normalized their IgA by cycle 7 and 5 of therapy. Baseline patient characteristics were similar in both groups. As expected patients showing normalization of the residual IgA levels experienced a longer progression free survival (PFS; 29-77 weeks; p=0.0001) and overall survival (OS; 121-220 weeks; p=0.0001). *Conclusions.* Lenalidomide-based therapy leads to normalization of the residual polyclonal IgA levels in a significantly number of relapsed/refractory MM patients who responded to the therapy. These patients also achieved longer PFS and OS.

0396

UP-FRONT SALVAGE TREATMENT WITH MELPHALAN 100 MG/M² IN FULMINANT PROGRESSION OF MULTIPLE MYELOMA AND CONSOLIDATION WITH NOVEL DRUGS

M. Krejci, Z. Adam, A. Krivanova, L. Pour, M. Holanek, V. Sandecka, J. Mayer, J. Vorlicek, R. Hajek

University Hospital Brno, BRNO, Czech Republic

Background. Patients (pts) with a fulminant progression (FPG) of multiple myeloma (MM) after autologous transplantation have poor prognosis. The treatment options are limited, pancytopenia and/or extramedullary disease and/or renal impairment are often presented. The treatment with melphalan 100 mg/m^2 (MEL 100) as a up-front salvage therapy with support of autologous peripheral blood stem cells (PBSC) can stop progression of MM and provides a opportunity for the application of novel drugs as a consolidation treatment. *Methods.* We have retrospectively evaluated 31 pts with FPG of MM after autologous transplantation (AT) treated with MEL 100 mg/m^2 with PBSC support and consolidation chemotherapy with novel drugs (thalidomide+dexamethasone+cyclophosphamide in 16 cases, bortezomib+dexamethasone+cyclophosphamide in 15 cases). Fulminant progression of MM was specified as a rapid progression during 4-8 weeks with one of these features: peripheral pancytopenia due to bone marrow myeloma infiltration, new presence of extramedullary disease, new renal impairment. Clinical stages according to ISS were the following: stage 1 in 22% of pts (7/31), stage 2 in 39% of pts (12/31), stage 3 in 39% of pts (12/31). Pancytopenia was presented at 52% of cases (16/31), renal impairment at 22% of cases (7/31), extramedullary disease at 32% of pts (10/31). Median time from diagnosis of MM to FPG was 18 months, median time from AT to FPG was 12 months, median number of previous therapy lines was 1 (range 1-3). The median age at MEL 100 was 58 years. *Results.* There was no treatment-related mortality. Mucositis grade 3-4 developed in 29% of pts (9/31), febrile neutropenia occurred in 39% of pts (12/31) after MEL 100. Overall response rate (ORR) was 58% (18/31). After MEL

100, one patient (3%) achieved complete remission, 29% of pts (9/31) were in partial remission, 26% of pts (8/31) had very good partial remission, and 42% of pts (13/31) had stable disease. Median number of consolidation chemotherapy cycles with novel drugs was 4 (range: 1-6); 40% of pts (12/31) interrupted therapy earlier for progression of MM, 6% of pts (2/31) ended therapy earlier for neurological toxicity grade 3, no other significant toxicity grade 3 or 4 was observed. Rapid progression within 3 months after MEL 100 occurred in 35% of pts (11/31). The median follow-up from MEL 100 was 8 months (range 3-23). The median TTP was 5.0 months (range: 2-15) and the median OS was 8.0 months (range: 3-23). *Conclusions.* MEL 100 is a safe salvage up-front regimen for fulminant progression of MM with good response rate (ORR 58%) and acceptable toxicity. This treatment strategy with combination of novel drugs can prolong survival over 12 months in 33% of pts with this fatal form of MM.

This work was supported by grants IGA NR9317-3 and NR9225-3.

SPEED OF RESPONSE WITH LENALIDOMIDE AND DEXAMETHASONE IN PATIENTS WITH RELAPSED OR REFRACTORY MULTIPLE MYELOMA: FIRST RESULTS OF THE MM-019 GERMAN COMPASSIONATE USE PROTOCOL

K.C. . Weisel,[1] M. Hänel,[2] D. Niederwieser,[3] R. Naumann,[4] N. Kröger,[5] M. Engelhardt,[6] H. Goldschmidt,[7] N. Lang,[8] C. Scheid,[9] H.G. Sayer,[10] A. Glasmacher[1,1] U. Dührsen[12]

[1]University of Tuebingen, TUEBINGEN; [2]Klinik für Innere Medizin III, CHEMNITZ; [3]University of Leipzig, LEIPZIG; [4]University of Dresden, DRESDEN; [5]University of Hamburg, HAMBURG; [6]University of Freiburg, FREIBURG; [7]University of Heidelberg, HEIDELBERG; [8]University of München (LMU), MÜNCHEN; [9]University of Cologne, KÖLN; [10]University of Jena, JENA; [11]University of Bonn, BONN; [12]University of Essen, ESSEN, Germany

Background. The combination of lenalidomide and dexamethasone has been well established as therapy for patients with relapsed or refractory multiple myeloma. However, the speed of obtaining response has not yet been sufficiently described. *Patients and Methods.* Before marketing approval patients could be recruited into this phase IIIb, open-label, non-comparative clinical trial if suffering from multiple myeloma with at least one previous therapy. All patients received lenalidomide, 25 mg/d, d1-21, and dexamethasone 40 mg/d, d1-4 (and for the first four courses d 9-12, 17-20). Courses were repeated every 28 days and continued until progression, toxicity or withdrawal from physician or patient. Dose reductions were made according to renal function or toxicity following standard guidelines. The EBMT response criteria were used and assessed every 28 days. However, confirmatory bone marrow aspirations required for CR are not available for all patients with respective M protein reductions. In addition, M protein and serum free light chains (sFLC) were analysed every 14 days for the first two courses. *Results.* Of 150 included patients, validated data are available for 122 at this time, the median age was 65 years (interquartile range: 58-71). ECOG performance scale was 0 in 32%, 1 in 55% and 2 in 13%. Previous transplantation therapy was noted in 61%, previous bortezomib in 57% and thalidomide in 40% of patients. Fifteen patients (12%) had all three regimens, 43 (35%) had two, 42 (34%) had one of these regimens. Best response information was available in 113 patients: CR in 4 (4%; 95% confidence interval: 1-9%), PR in 80 (71%; 62-78%), SD in 28 (25%; 18-33%) and PD in 1 patient (1%; 0-5%). Previous transplantation, bortezomib or thalidomide (≥ PR: no thalidomide 73% vs. previous thalidomide 77%) did not influence the remission rate. Time to a 50% reduction of M-protein or sFLC (in the absence of progression at other sites) was analysed in 77 patients (missing values in 3): Median time was 28 days (interquartile range 14-42, range 12-84 days). Thirty-two (39%) patients demonstrated this reduction in 12-15 days, 27 (33%) patients in 20-32 days, 14 (17%) in 40-49 days and 10 (12%) in 56-84 days. *Conclusions.* Despite considerable previous treatment at least a partial response was reached by 74% of patients; previous thalidomide, bortezomib or transplant did not influence the response rate. A 50% M protein/sFLC reduction was reached by half of the patients within 28 days and by 72% of the patients within 32 days.

0398

USE OF MAINTENANCE THERAPY WITH BORTEZOMIB AND DEXAMETHASONE (VD) IN ADVANCED MULTIPLE MYELOMA

G. Benevolo,[1] A. Larocca,[2] P. Pregno,[1] F. Gay,[2] B. Botto,[3] C. Gentile,[4] C. Frairia,[1] A. Evangelista,[3] F. Morabito,[4] A. Palumbo,[2] U. Vitolo,[3] M. Boccadoro[2]

[1]Hematology ,[2] TURIN; [2]Hematology Division, University, TURIN; [3]On the behalf of Intergruppo Italiano Linfomi, Hematology [2] ASO San G. Battista, TURIN; [4]U.O. Ematologia Ospedale Civile dell'Annunziata di Cosenza, COSENZA, Italy

Background. The efficacy and safety of bortezomid therapy ± dexamethasone in patients with relapsed or refractory multiple myeloma (MM) was confirmed by several studies but no data are available regarding the maintenance therapy (MT) after salvage treatment. *Aims.* In this trial we tested safety and efficacy of bortezomib/dexamethasone MT in patients with refractory/relapse MM who responded to salvage therapy. We also assessed the impact of MT on progression-free survival (PFS) and overall survival (OS). *Methods.* We included 49 MM patients with advanced MM who responded to salvage therapy. As MT, bortezomib was administered by intravenous bolus on days 1 and 15 at 1.3 mg/mq; dexamethasone was given orally at the dose of 20 mg/d on days 1-2 and 15-16 every 28-day cycle for a total of 6-8 cycles. PFS was defined as the time from start of MT to progression or death from any cause. The cumulative incidence of death for PD was calculated accounting for competitive death or other causes. *Results.* From October 2004 until April 2008, 49 MM patients have been enrolled. The characteristics of the patients were the follows: 28 males and 21 females, median age was 71 years (IQR:66-75). Median haemoglobin value was 11.3 (IQR:10.4-18.8) and 8 (16,3%) patients had a renal failure. The median number of prior therapies was 2 (2-3). All patients were in PR after salvage therapy that included bortezomib as single agent or in combination with steroids and/or thalidomide in 39 patients (79.6%). Median time from diagnosis to the first dose of MT was 39 months (IQR:26-56). The median number of bortezomib infusion was 8 (7-12). After a median follow up of 19 months (IQR:13-22), 12 patients died for PD, 1 for IMA and 6 patients for infections. The MT improved the quality of response after salvage therapy as follows: 4 CR, 3 VGPR, 10 PR, 19 SD whereas 13 patients experienced PD. The median time to progression was 17 months (95%CI: 7-38) with a progression free-survival at 1 year of 63% (95%CI: 48-75) (Figure 1). The overall survival at 1 years was 79% (95%IC: 75-88) and the cumulative incidence of death due to PD adjusted for competitive risk event was 12% (95%IC:2-19). In a univariate analysis the response rate to MT was not significantly affected by age, sex, number or type of previous therapy and haemoglobin concentration. Non-dose-limiting toxicities included neuropathy grade 1 (15 pts), herpes zoster reactivation (2 pts), pulmonary infections (2 pts), and gastrointestinal affections (3 pts). Three patients developed a neuropathy grade 2 which required a dose reduction (1.0 mg/mq) of bortezomib. *Conclusions.* The combination bortezomib/dexamethasone as a maintenance therapy in relapse/refractory MM is effective and well tolerated. These preliminary data suggest that bortezomib/dexametasone MT can improve remission duration and also quality of response with an acceptable toxicity.

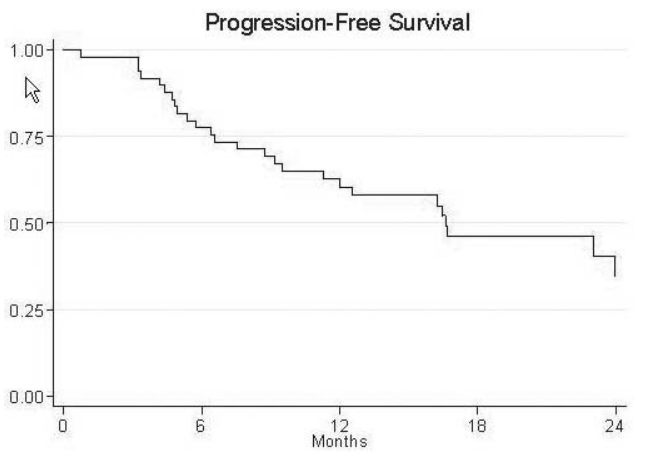

Figure 1.

HALOFUGINONE, AN ORALLY-BIOAVAILABLE AGENT, HAS *IN VITRO* AND *IN VIVO* ANTIMYELOMA ACTIVITY, ASSOCIATED WITH UP REGULATION OF C-JUN, JNK, AND P-53, PROAPOPTOTIC PROTEINS

M. Leiba,[1] J. Jakubikova,[1] S. Klippel,[1] C. Mitsiades,[1] T. Hideshima,[1] Y.T. Tai,[1] P. Richardson,[1] A. Nagler,[2] K. Anderson[3]

[1]Dana Farber Cancer Institute, BOSTON, MA, USA; [2]Sheba Tel Hashomer, RAMAT GAN, Israel; [3]Dana Farber cancer Institute, BOSTON, MA, USA

Halofuginone, a synthetic derivative of quinazolinone alkaloid, previously has been shown to have anti-cancer effects in various solid and hematological malignancies. Halofuginone inhibits mainly collagen type I synthesis, and extracellular matrix formation, via the inhibition of TGFβ signaling, matrix metalloproteinase 2(MMP2), and angiogenesis. Last year, we first reported, that Halofuginone in a low doses (IC50 of 50-100 nM) induces cytotoxicity in multiple MM cell lines, including cells resistant to conventional (e.g., dexamethasone, alkylating agents, and anthracyclines) or novel (e.g. thalidomide and bortezomib) anti-MM agents and overcomes the survival and growth advantages conferred by interleukin-6, insulin-like growth factor-1 and by bone marrow stroma cells. Halofuginone induced apoptosis in a caspase 3, 8, and 9 dependent mechanisms, reduced mitochondrial membrane potential, and down regulated MCL1 protein. We now assessed the cytotoxic effect of Halofuginone in primary MM patient cells *in vitro* and, its effect on tumor growth and survival in *in vivo* models. We found that Halofuginone also induces growth inhibition and cell death in primary MM cells (n=4, IC_{50}: 100-200nM). Importantly, Chou-Talalay analysis of the effects of combinations of Halofuginone with anti-MM drugs (dexamethasone, melphalan and Lenalidomide) revealed that all combinations have synergistic or additive MM cytotoxicity. In addition, Halofuginone inhibits IL6 production in the supernatant of a co-culture of MM.1S cells with HS-5 stromal cell line. Mechanistically, Halofuginone induces MM cell death, which involves the up-regulation of c-jun NH2-terminal kinase signaling (JNK), c-Jun, as well as the p-53 proapoptotic proteins, as shown by Multiplex analysis of phoshorylation signaling pathways, using the Luminex system. Additionally, the *in vivo* anti-MM activity of Halofuginone was evaluated in 2 separate *in vivo* models, a xenograft model in SCID mice (subcutaneous injection of MM1S cells), and a model of diffuse MM lesions in SCID-beige mice (generated by i.v. injections of OPM-2 cells). In both models, mice were first sublethally irradiated (200 rads), injected s.c or i.v., respectively, with 1x106 MM cells and then randomly assigned to receive, either treatment with 0.75 mg/kg halofuginone (IP or by oral gavage, respectively; n=10) or vehicle only (n=10) on a cyclical schedule of 5 days-on/2 days-off. In a very low dose(0.75/mg/kg), Halofuginone inhibited MM tumor growth and improved survival, 70% vs 40% at 220 days (p=0.07) in the treated vs control group respectively (Figure), longer follow up are needed. Clinical evidence of adverse events (weight loss, vomiting) were not observed. Halofuginone may, thus represents a promising novel orally bioavailable anti-MM agent that needs further evaluation for possible clinical trials in MM.

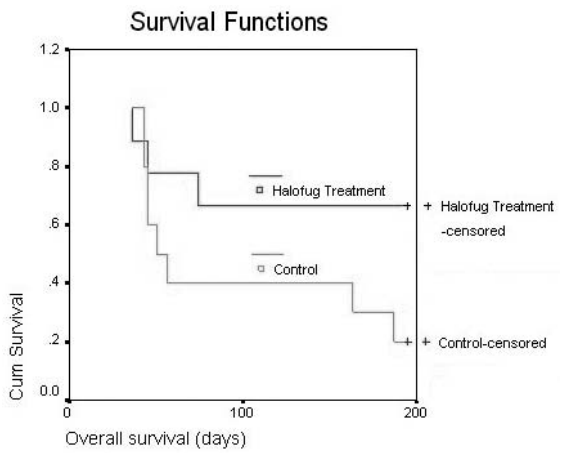

Figure. Diffuse MM lesions in SCID-beige mice.

SERUM LEVELS OF TOTAL-RANKL IN MULTIPLE MYELOMA

A. Goerke,[1] C. Jakob,[1] J. Sterz,[1] U. Heider,[1] M. Kaiser,[1] M. Mieth,[1] C. Müller,[1] E. Terpos,[2] O. Sezer[1]

[1]Charité, Universitätsmedizin Berlin, BERLIN, Germany; [2]Department of Haematology and Medical Research, General Airforce Hospital, ATHENS, Greece

Background. Receptor activator of nuclear factor-κB ligand (RANKL) plays a key role in osteoclast activation in myeloma bone disease. RANKL is a member of the tumor necrosis factor (TNF) superfamily and is produced mainly by osteoblastic lineage cells and stromal cells as a membrane-bound protein. It also exists in a soluble form, which is cleaved from the cellular protein or released as a primary secreted isoform. The increased expression of RANKL in the bone marrow microenvironment was demonstrated in several studies, but there are only rare data on circulating RANKL levels in multiple myeloma (MM) patients. *Aims.* In the present study we investigated the clinical significance of serum RANKL levels in patients with newly diagnosed MM, in individuals with monoclonal gammopathy of undetermined significance (MGUS) and in a control group of healthy donors. *Methods.* Circulating RANKL concentrations were measured by a commercially available ELISA-test (Immundiagnostik, Bensheim, Germany), which detects both free and osteoprotegerin (OPG)-bound RANKL (total-RANKL, tRANKL). The two-site sandwich assay is constructed by a monoclonal human anti-RANKL capture antibody to bind OPG-bound RANKL combined with a recombinant human OPG for capturing free RANKL and a polyclonal anti-OPG detection antibody. Serum samples were collected from 93 patients with newly diagnosed MM, 20 individuals with MGUS and 20 healthy donors.

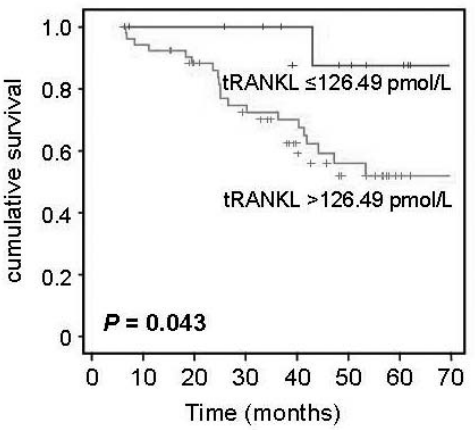

Figure 1. Prognostic value of tRANKL for OS in symptomatic MM.

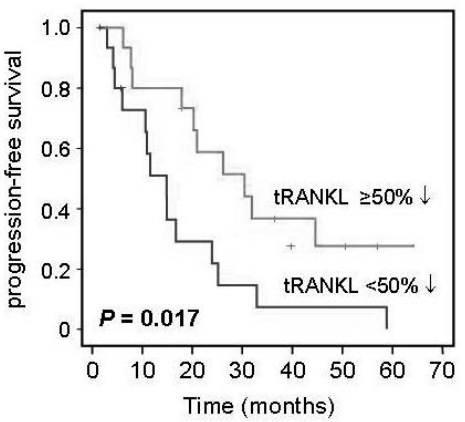

Figure 2. Improved progression-free survival in patients with post-treatment tRANKL decrease >50%.

Results. Circulating serum tRANKL was significantly elevated in MM patients compared to controls (p<0.001) or MGUS (p<0.001). Furthermore, tRANKL levels were higher in smoldering MM versus MGUS

(p=0.031) and in symptomatic versus smoldering MM (p 0.001). Serum tRANKL increased parallel to ISS stages I to III (p=0.031) and correlated with the presence of lytic bone lesions (p<0.001). Total-RANKL was a prognostic factor for overall survival in symptomatic MM (p=0.043, Figure 1) with a 5-fold elevated risk in patients with high (>126.49 pmol/L) tRANKL values. In the subgroup of symptomatic MM patients with elevated tRANKL, there was a significant survival benefit (p=0.018) of high-dose therapy (HDT), while this was not seen in the group with low tRANKL levels (p=0.431). A significantly longer progression-free survival was observed in patients with a greater than 50% decrease in tRANKL levels after 3 months of combined chemotherapy and bisphosphonate treatment (Figure 2). *Summary and Conclusions.* Our study shows for the first time, that serum tRANKL reflects advanced disease, lytic bone destruction and poor prognosis in MM.

Non-Hodgkin lymphoma - Clinical I

0401

QUALITATIVE AND QUANTITATIVE ASSESSMENT OF BONE MARROW INVOLVEMENT IN THE ENTIRE SPECTRUM OF NON-HODGKIN'S LYMPHOMAS: COMPARISON BETWEEN HISTOLOGY AND FLOW CYTOMETRY IN 572 PATIENTS

M. Merli,[1] L. Arcaini,[1] E. Boveri,[2] S. Rattotti,[3] C. Picone,[1] F. Passamonti,[1] L. Vanelli,[1] A. Tenore,[1] M. Varettoni,[1] S. Rizzi,[1] E. Brusamolino,[1] E. Rumi,[1] B. Burroni,[2] C. Pascutto,[1] M. Paulli,[2] M. Lazzarino[1]

[1]Division of Hematology, Fondazione IRCCS Polliclinico San Matteo, Pavia, Italy, PAVIA; [2]Department of Pathology, Fondazione IRCCS Policlinico San Matteo, PAVIA; [3]Fondazione IRCCS Polliclinico San Matteo - Università degli Studi, PAVIA, Italy

Background. Bone marrow (BM) examination is essential in the staging of non-Hodgkin's lymphoma (NHL) pts. Few studies have compared BM histologic findings with results of flow cytometric (FC) analysis. Overall, rates of concordance between the two techniques are usually good. However, detailed data about correlation of the results of these two methods in large series comprising different NHLs are lacking. *Aim.* To correlate histologic features of staging BM biopsies with corresponding FC data in a large series of consecutive NHL pts. *Methods.* We analysed the incidence and patterns of histologic BM involvement in a series of 822 pts with NHL diagnosed at Division of Hematology of Pavia from 1998 to 2008. BM specimens were plastic- or paraffin-embedded and both staining with hematoxylin-eosin and Giemsa and immunohistochemistry were carried out. For 572 pts a concurrent FC analysis on BM was available. FC analysis was performed accordingly to Bethesda International Consensus guidelines (2006). *Results.* We studied BM biopsies of 253 pts with follicular lymphoma (FL), 220 diffuse large B-cell lymphoma (DLBCL), 82 splenic MZL (SMZL), 69 extranodal marginal zone lymphoma of MALT (EMZL), 23 primary nodal MZL (NMZL), 30 lymphoplasmacytic lymphoma (LPL), 33 mantle cell lymphoma (MCL), 29 small lymphocytic lymphoma (SLL), 11 primary cutaneous follicle center lymphoma (PCFCL), 11 peripheral T-cell lymphoma (PTCL) and 16 cutaneous T-cell lymphoma (CTCL); 72 cases showed a isolated leukemic picture and were classified as B-cell chronic lymphoproliferative disorders (B-CLPD). Overall, histologic BM involvement was detected at diagnosis in 373/801 (44%) pts. In 21 pts a lymphoid infiltrate was detected without reaching minimal criteria for histologic involvement. By FC analysis, BM involvement was detected in 207/572 (36%) available samples. In the group with suspected histologic infiltrate, FC analysis was positive in 7 out of 16 pts. Detailed results are summarized in Table 1.

Table 1. Comparison betweem histological and flow citometry findings.

BM bone marrow, FC flow cytometry, DLBCL diffuse large B-cell lymphoma, FL follicular lymphoma, LPL lymphoplasmacytic lymphoma, EMZL extranodal marginal zone lymphoma of MALT, SMZL splenic marginal zone lymphoma, MCL mantle cell lymphoma, SLL small lymphocytic lymphoma, NMZL nodal marginal zone lymphoma, PCFCL primary cutaneous follicle center lymphoma, B-CLPD B-cell chronic lymphoproliferative disorder, PTCL peripheral T-cell lymphoma, CTCL cutaneous T-cell lymphoma

A concordance between 2 methods (Spearman's R=0.7, p<0.001) was detected in 459 (85%) cases (33% BM+/FC+; 52% BM-FC-) and a discordance was present in 82 (15%); 64 cases (12%) were BM+/FC- and 18 (3%) BM-/FC+ (with a small clonal population at FC; median 9%). Discordance was more frequent in FL (19% BM+/FC- and 3% BM-/FC+) and in LPL (18% BM+/FC- and 6% BM-/FC+). The rate of false negative FC exams resulted inversely related to the extent of histologic infiltrate for the whole series (p<0.001) and, specifically, for FL (p=0.01), LPL

(p=0.04) and B-CLPD (p=0.03). Patterns were analyzed in 316 BM biopsies. Nodular paratrabecular pattern was associated with FL (p<0.001), sinusoidal with SMZL (p<0.001), interstitial with SLL (p<0.001), diffuse with DLBCL (p<0.001) and with LPL (p=0.02). FC better overlapped with histology in case of interstitial (p<0.001), sinusoidal (p=0.03) and nodular centrolacunar pattern (p=0.01). False negative FC results correlated inversely with% of CD19+ cells (p=0.04). The quantitative assessment of infiltrate detected by the 2 methods resulted significantly overlapping (p<0.001). *Conclusions.* Our data demonstrate that FC is comparable with histology in qualitative and quantitative assessment of BM involvement for the entire spectrum of NHL, with the exception of FL and LPL.

0402

CLIPI: A NEW PROGNOSTIC INDEX FOR INDOLENT CUTANEOUS B-CELL LYMPHOMA PROPOSED BY THE INTERNATIONAL EXTRANODAL LYMPHOMA STUDY GROUP (IELSG 11)

M. Mian,[1] S. Cortelazzo,[1] M. Federico,[2] S. Luminari,[2] L. Marcheselli,[2] M. Cantonetti,[3] A.H. Sarris,[4] A. Rossi,[4] A. Rambaldi,[4] G. Lombardo,[5] M. Frontoni,[5] F. Pasini,[2] L. Devizzi,[6] O. Bairey,[7] M. Busetto,[8] E. Berti,[9] G. Martinelli,[10] R. Tsang,[11] S. Rudoy,[4] R. Blum,[1] A. Ferreri,[12] G. Pinotti,[13] E. Pogliani,[3] E. Zucca[14]

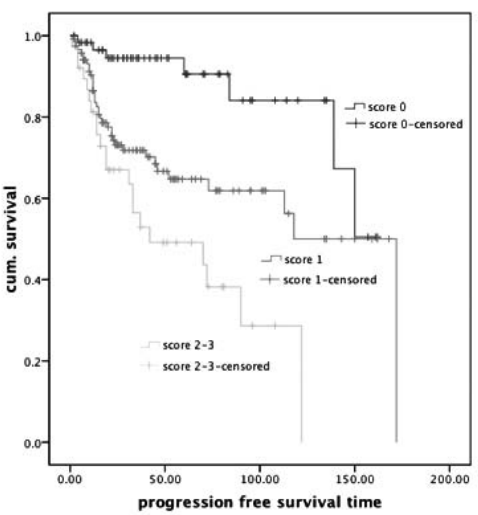
Low grade primary cutaneous B-cell lymphomas (PCBCL) are a distinct group of NHLs, which are generally associated with a good prognosis. However, they frequently relapse and in some cases disseminate, leading to a short survival. The aim of this study was to develop a model for predicting their clinical outcome. From 1980 to 2006, 19 cancer centres in 7 countries recruited 463 PCBCL patients. The median age was 55 years (range, 16-92 years) with a M/F ratio of 1.5. According to the WHO-EORTC classification the main histological subtype was FCL (n=341), followed by MZL (n=122). The sites of presentation were: trunk/arms (56%), head/neck (31%) and legs (7%). Seven percent had a generalized disease (>1 site) with a maximal lesion diameter of >4 cm in 27% of cases, while >2 lesions in one site occurred in 27%. Nodules prevail (75%), followed by plaques (17%), ulcers or 2 distinct coexisting lesion types. Few patients had Ann Arbour Stage II (11%), poor ECOG-PS (9%) and/or elevated LDH (5%).

Table 1. Impact of the CLIPI on treatment outcome.



10 - years	OS (P=0.309)	PFS (P<0.001)	DFS (P<0.001)
Low risk	92%	84	85
Intermediate risk	86%	54	53
High risk	66%	29	30
Total	83%	57	58

The majority of patients (50%) underwent local treatment, mainly consisting in radiotherapy and/or surgery, while 40% were given chemotherapy + local treatment, 7% received rituximab + other treatments, whereas 3% remained untreated. CR rate was 89%, PR 10% and SD 1%. Among 398 responders, 122 (33%) eventually relapsed, 65% in the skin, 26% in extracutaneous sites and 9% in both. After a median follow-up of 56 months (range, 2-333 months), 10-year estimate of OS was 87%, PFS 56% and DFS 59%, respectively. Disease caused 27/48 deaths (56%) and disease specific survival at 10 years was 91%. Taking account of the possible risk factors identified by univariate log-rank test we developed a prognostic model by bootstrap resampling of the original group of patients and applying Cox's proportional hazard model with backward elimination procedure on survival. A complete dataset was available in 240/463 patients. Elevated LDH, nodular lesion, and > 2 lesions proved to have a significant and independent impact on survival. Based on these four factors, weighting every factor with one point, the following prognostic index has been developed: 0 points, low risk (LR); 1 point, intermediate risk (IR) and 2 or 3 points, high risk (HR). We showed that this score significantly influences PFS (Figure 1) and DFS, while showed a trend in OS (Table 1). This retrospective multicenter study confirmed that PCBCLs have an high relapse rate and half of deaths depends on disease progression. The CLIPI proves an important impact on the clinical course of this disease, independently on treatment. Therefore, it could provide a risk adapted treatment strategy to be assessed in prospective clinical studies.

0403

RITUXIMAB-CHOP (R-CHOP) IN THE TREATMENT OF 441 DIFFUSE LARGE B-CELL LYMPHOMA PATIENTS: OUTCOME AND PROGNOSTIC FACTORS FOCUSING TO THE REVISED INTERNATIONAL PROGNOSTIC INDEX (R-IPI)

T.P. Vassilakopoulos,[1] G.A. Pangalis,[1] A. Anastasopoulou,[1] M.K. Angelopoulou,[1] M. Dimou,[1] E. Stavroulaki,[2] S. Karakatsanis,[3] C. Kalpadakis,[2] S. Sachanas,[1] M.C. Kyrtsonis,[1] S.I. Kokoris,[1] M.P. Siakantaris,[1] X. Yiakoumis,[1] P. Roussou,[3] P. Panayiotidis,[1] H. Papadaki,[2] N. Constantinou[4]

[1]Department of Haematology, University of Athens, ATHENS; [2]Department of Haematology, University of Crete, HERAKLION; [33]rd Internal Medicine Department, University of Athens, ATHENS; [4]Haematology Clinic, Theageneion Hospital, THESSALONIKI, Greece

Background. The improved outcome of iffuse large B-cell lymphoma (DLBCL) patients with R-CHOP and the biological mechanism of action of rituximab may overcome the adverse prognostic significance of various prognostic factors, identified prior to the introduction of rituximab. Although IPI is still applicable under R-CHOP, a minor modification may enhance its discriminative ability (Rituximab-IPI; R-IPI, Sehn LH, Blood 109: 1857-61, 2007). Furthermore, it is not clear whether a high-risk group of young DLBCL patients, suitable for front-line stem cell transplant, still exists under R-CHOP. *Aim.* The determination of the outcome of patients with DLBCL under treatment with immunochemotherapy in a multicenter retrospective study and the analysis of the corresponding prognostic factors. *Patients and Methods.* We analyzed 441 patients with DLBCL treated with R-CHOP or similar anthracycline-based combinations. The 5 components of the IPI, gender, B-symptoms, serum albumin levels and hemoglobin levels were evaluated as potential prognostic factors. The value of IPI, age-adjusted IPI (aaIPI) and R-IPI was determined. The analyzed endpoints were failure free survival (FFS) (including early toxic deaths as events) and overall survival (OS). *Results.* The median age of the patients was 65 years (18-88), 59% were older than 60 years, and 57% were males. The distribution of patients according to the IPI was as follows: Low Risk (L) 47%, Low-Intermediate (LI) 21%, High-Intermediate (HI) 19% and High Risk (H) 12%. According to the R-IPI, 21% were classified as Low Risk (L), 47% as Intermediate Risk (INT), and 32% as High Risk (H). The 3-year FFS and 5-year OS for all patients were 77% and 80% respectively. According to the IPI, the 3-year FFS was 91%, 84%, 53% and 54% for L, LI, HI and H risk patients respectively (p<0.0001). The corresponding 5-year OS rates were 93%, 77%, 59% ÎαÈ 62% (p<0.0001). According to the R-IPI, the 3-year FFS was 97%, 85% and 53% for L, INT and H Risk patients respectively (p<0.0001). The corresponding 5-year OS rates were 100%, 83%, and 60% (p<0.0001). All 5 IPI components, B-symptoms, low albumin and haemoglobin levels were predictive of FFS in univariate analysis. In multivariate analysis, serum albumin <3.5 g/dL and R-IPI were independent prognostic factors (p=0.01 and <0.001 respectively). In the group of 43 patients ≥60 years with aaIPI 2-3, the 3-year FFS and 5-year OS were

67% and 84%. Only the 12 patients with aaIPI=3 (7% of all younger patients) had indeed a poor 3-year FFS of 38%, with 5-year OS of 59%. *Conclusions.* Our data fully confirm the British Columbia study, which introduced the R-IPI as a better prognostic tool in R-CHOP-treated DLBCL. R-IPI may be further improved by the addition of other conventional prognostic factors, such as serum albumin levels. The role of intensified therapy in younger patients with aaIPI 2-3 is questionable in the era of R-CHOP, since only the minor subgroup of patients with aaIPI=3 appears to carry an indeed poor FFS. The concomitant evaluation of more conventional and biological prognostic factors in even larger series of patients treated with R-CHOP may improve the prognostic stratification.

0404

FINAL RESULTS OF THE PHASE II MULTICENTER ITALIAN STUDY OF IMMUNOCHEMOTHERAPY WITH FLUDARABINE, CYCLOPHOSPHAMIDE AND RITUXIMAB (FCR) FOR SYMPTOMATIC WALDENSTROM'S MACROGLOBULINEMIA

A. Tedeschi,[1] G. Benevolo,[2] M. Varettoni,[3] M. Battista,[4] C. Visco,[5] S. Miqueleiz,[6] F. Ricci,[6] P.L. Zinzani,[7] V. Meneghini,[8] P. Pioltelli,[9] F. Zaja,[4] M. Nichelatti,[6] M. Lazzarino,[3] U. Vitolo,[2] E. Morra[6]

[1]Niguarda Ca' Granda Hospital, MILANO; [2]Department of Hematology Ospedale San Giovanni Battista, TORINO; [3]Department of Hematology, IRCCS Policlinico San Matteo, PAVIA; [4]Department of Hematology DIRM University of Udine, UDINE; [5]Depatment of Hematology Ospedale San Bortolo, VICENZA; [6]Depatment of Hematology Ospedale Niguarda Ca' Granda, MILANO; [7]Department of Hematology L. A. Seragnoli University of Bologna, BOLOGNA; [8]Department of Hematology University of Verona, VERONA; [9]Department of Hematology University of Monza, MONZA, Italy

Background. Rituximab is an active and well tolerated agent in the treatment of Waldenstrom's Macroglobulinemia (WM), furthermore, there is evidence that the association of Rituximab (R) with chemotherapy may improve the quality of responses. In WM the combination of Fludarabine (F) + Cyclophosphamide (C) induces response rates of 85% and 55-89% in previously untreated and relapsed/refractory pts, respectively. Aims In February 2005 we started a multicenter phase II study on the effectiveness, tolerability and safety of FCR in symptomatic WM pts previously untreated or relapsed/refractory to one line of chemotherapy. *Methods.* Treatment consisted of: R 375 mg/sqm d1, F 25 mg/sqm and C 250 mg/sqm iv d 2-4 every 4 weeks. The first assessment of the disease, including bone marrow evaluation, was performed after the third FCR course. Pts with progressive disease (PD) were considered as failure, responding pts or those with SD went on to receive up to 3 further courses. *Results.* Accrual of the planned 43 pts, median age 65 years, ended on March 2008. Median time from diagnosis to FCR was 25.5 mos; 65% of pts were in first line treatment, 7% and 28% in relapsed and refractory disease, respectively. According to the International Scoring System for WM (ISSWM) 33% of pts were low risk, 38% intermediate and 29% high risk. Median number of courses administered was 6 (range 2-6), 65% pts received the planned 6 courses. Thirty-nine pts (91%) received ≥4 courses of therapy and have been considered valuable for response. The overall response rate was of 87% and categorized as follows: 13% CR, 69% PR, 5% MR. Nine of the 27 pts in PR could be considered as in *near CR* as they fulfilled criteria for CR except for the persistence of a positive immunofixation. None of the patient and disease variables (age, sex, light chain, disease status, Hb, PLT and Ig level,% BM infiltration, β2m, albumin, creatinine, ISSWM) was significant for the achievement of a response. A comparison was performed between responses achieved after the third course and after the end of treatment. A significant improvement in the achievement of a major response has been observed (49% vs. 62%) in the group of pts receiving the planned 6 courses. Extrahematological toxicity was manageable and mostly limited to grade 1-2 . Neutropenia occurred in 63% of courses and was the main cause for not completing the planned 6 courses of treatment (23%). A late improvement of responses was observed during follow-up: 3 PR converted to CR and 1 SD to PR. Median DFS and OS have not been reached after a median follow-up of 14 and 20.2 mos, respectively. *Conclusions.* FCR produced a high ORR with good quality of responses, which improved over time. However we observed a high incidence of neutropenia with long lasting neutropenic episodes limiting the administration of the planned therapeutic program. According to the analysis of our population it seems reasonable in order to avoid myelotoxicity to reduce the number of planned FCR courses, administering, Rituximab as consolidation/maintenance to.

0405

LNH-PRO-05 STUDY: EXCELLENT CLINICAL AND MOLECULAR RESPONSES IN FLIPI=2 FOLLICULAR LYMPHOMA PATIENTS WITH RITUXIMAB PLUS CVP (BAGLEY) AND 12 WEEKS OF INTERFERON ALFA

J. Cannata-Ortiz,[1] C. Nicolás,[2] A. Garcia-Noblejas,[1] S. Montes-Moreno,[3] J. López,[4] M.J. Requena,[5] M.A. Piris,[3] R. Arranz[1]

[1]Hospital de la Princesa, MADRID; [2]H. Central de Asturias, OVIEDO; [3]Cnio, MADRID; [4]H. Ramón y Cajal, MADRID; [5]H. Severo Ochoa, LEGANÉS, Spain

Background. The use of immunomodulator agents, such as Rituximab (R) and Interferon (IFN) in Follicular Lymphoma (FL), has improved progression free survival (PFS) and overall survival (OS). Since 1990, our FL patients receive CVP (Bagley, 1972) with IFN-α tiw for 12 weeks. In intermediate-high risk FLIPI patients overall response rate (ORR) was 90% (75% CR) with a median PFS of 6 years. Published data have shown that R and IFN have synergistic antitumor activity, so we designed a trial to test this treatment in association with R. *Aims.*Evaluate the efficacy (ORR, CR, PFS and MRD response) and toxicity of R +CVP+ IFN in newly diagnosed FL patients with FLIPI ≥2. *Methods.* Treatment was R 375 mg/m^2 + CY 400 mg/m^2 D1-5 (po) + VCR 1.4 mg/m^2 D1 + PRD 100 mg/m^2 D1-5 + IFN (3MU/m^2 tiw x 12 wks) x 8 cycles, with G-CSF support. Doses of CY and IFN were adjusted according to grade 3-4 toxicity. Patients were re-evaluated after the 4th cycle and at the end of treatment. Follow-up studies were performed every 4 months thereafter. Patients were removed from the study if no response after cycle 4. Molecular studies to detect MRD (classic and real-time PCR for Bcl-2/IgH and rearrangements of IgH, FR2-FR3) were performed at diagnosis, after 4th and 8th cycle, and during the follow-up period. *Results.* Since November 2006, 26 patients have been enrolled. Herein we communicate the results of 21 monitorized patients. Median age is 51 years old (range 33-74), FLIPI 3-5: 43%, ≥2 extranodal involvement: 57% and bulky disease: 29%. No molecular marker was detected in 4 patients in spite of bone marrow infiltration. Seventeen patients had molecular marker, 15 (88%) with Bcl-2/IgH and 4 (22%) IgH rearrangements. Clinical Response at the end of treatment, is available from 17 patients. At 4th cycle 82% were in CR and at 8th cycle all patients achieved CR/CRi. Molecular response data was available in 12 patients, with 87% response after the 4th and 100% at the end of treatment. Toxicity was evaluated over 124 cycles. Grade 3-4 neutropenia was observed in 33% cycles. Lymphopenia <400/mm^3 was present in 58% patients during treatment. Non-hematologic toxicity was low, 8% (3 cases with flu-like syndrome, 3 peripheral neuropathy, 2 diabetes, 1 diarrhea, 1 osseous pain). Dose intensity for CY was 77% (range 60%-86%) and 59% for IFN (range 31%-85%). Ten SAEs (7% of all cycles) were reported due to febrile neutropenia or infection, although in 6 patients were associated with protocol deviation. None of the patients experienced SUSAR. *Conclusions.* In patients with FLIPI ≥2 follicular lymphoma, R + CVP + IFN schema achieves excellent clinical and molecular responses with a very good toxicity profile.

0406

POSTTRANSPLANT LYMPHOPROLIFERATIVE DISORDER (PTLD): CHARACTERISTICS AND OUTCOME IN A BELGIAN UNIVERSITY HOSPITAL

D. Dierickx,[1] T. Tousseyn,[2] C. De Wolf-Peeters,[2] M. Delforge,[2] T. Devos,[2] A. Janssens,[2] J. Maertens,[2] S. Meers,[2] G. Verhoef[2]

[1]University Hospitals Gatshuisberg, LEUVEN; [2]University Hospital Gasthuisberg, LEUVEN, Belgium

Background. PTLD is a life-threatening complication of both solid organ transplantation (SOT) and hematopoietic stem cell transplantation (HSCT). Data regarding incidence, treatment and outcome are mainly retrospective and are derived from smaller single center studies and larger registration databases. *Aims.* We undertook a retrospective analysis of all patients diagnosed with PTLD between January 1989 and December 2008 at the University Hospitals of Leuven, aiming to obtain information about incidence, pretreatment characteristics, treatment and outcome. *Methods.* Medical records of all patients were used for this retrospective observational study. Information was obtained with regard to baseline patients characteristics, transplant related characteristics, PTLD characteristics, treatment administered and response to treatment. Histological subtyping was based on the medical records, but we still plan a revision of all samples. *Results.* 112 patients were included in this study. PTLD was biopsy proven in 107 patients, whereas in 5 patients, all following HSCT, diagnosis was made based on rapid increase of EBV viral

load combined with a positive PET/CT scan. Overall incidence for all transplant types was 1.96%. Highest incidence was reported in heart-lung transplantation (7.5%), followed by heart (4.9%), lung (2.9%), liver (2.67%), stem cell (1.45%) and kidney transplantation (1.34%), whereas no PTLD was seen in intestinal transplantation so far. Most PTLD were monomorphic (78.6%), with DLBCL being the most frequent subtype. The majority of cases occurred later than 1 year post-transplantation (67%). Recognized lymphoma and PTLD specific prognostic scores were calculated for all patients. At the moment of PTLD diagnosis immunosuppressive therapy included calcineurin inhibitors (93.8%), antimetabolites (67.9%), low dose steroids (68.5%) and proliferation signaling inhibitors (<1%). RIS was performed in 91% of the cases. Other first line treatment modalities included rituximab (49.1%), chemotherapy (26.8%), surgery (11.6%), radiotherapy (6.3%), antiviral therapy (4.7%) and high dose steroids (3.6%). Following first line therapy overall response rate was 69% (60% CR, 9% PR). At last follow up 54.5% of the patients were alive whereas 12.8% of the patients lost their graft during follow up. In univariate analysis complete response was associated with male gender (p=0.04), normal LDH (p=0.0003), use of high dose steroids (p=0.019), lower ECOG performance state (p=0.015), lower Ann Arbor stage (p<0.0001) and lower number of involved extranodal sites (p=0.019) , whereas overall response rate was associated with male gender (p=0.009), normal LDH (p<0.0001), absence of bone marrow involvement (p=0.04), lower ECOG performance state (p=0.003) and lower Ann Arbor stage (p=0.0063). Overall survival Kaplan Meier curves with regard to all prognostic scores are shown in Figure 1. Conclusions. We report a retrospective analysis of 112 cases of PTLD following SOT or HSCT. Overall incidence was 1.96%, with the highest incidence reported in heart-lung recipients. Interestingly, no PTLD was observed following intestinal transplantation, which might be related to the use of a specific tolerance promoting regimen. Rituximab therapy was not associated with a higher response rate. Although the prognostic role of the IPI score in PTLD has been questioned, we were able to confirm its value in our analysis.

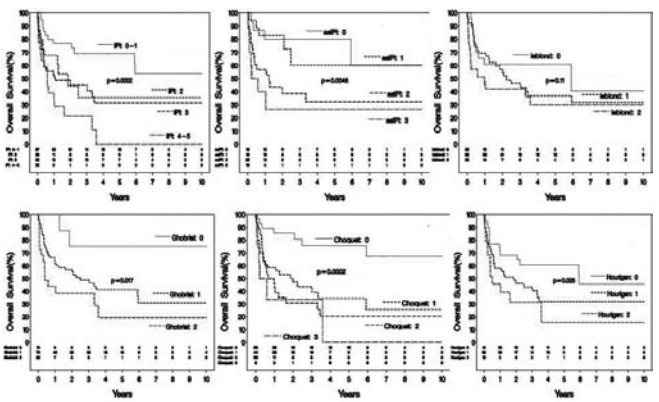


Figure 1. Kaplan Meier overall survival curves.

SAFETY AND CLINICAL ACTIVITY OF THE ANTI-CD22 IMMUNOCONJUGATE INOTUZUMAB OZOGAMICIN (CMC-544) IN COMBINATION WITH RITUXIMAB IN RECURRENT/REFRACTORY FOLLICULAR LYMPHOMA OR DIFFUSE LARGE B-CELL LYMPHOMA

W.M. Johnson,[1] L.E. Fayad,[2] B. Coiffier,[3] M.D. Smith,[4] A. Rohatiner,[5] G. Hess,[6] J.L. Kaufman,[7] G. Verhoef,[8] F. Offner,[9] S. Hua,[10] H. Patel,[10] E.R. Vandendries,[10] N.H. Dang[11]

[1]CR UK Centre, SOUTHAMPTON, UK; [2]M.D. Anderson Cancer Center, HOUSTON, TX, USA; [3]Hospices Civils de Lyon, LYON, France; [4]Fox Chase Cancer Center, PHILADELPHIA, PA, USA; [5]St Bartholomew's Hospital, LONDON, ENGLAND, UK; [6]Johannes Gutenberg University, MAINZ, Germany; [7]Winship Cancer Institute, ATLANTA, GEORGIA, USA; [8]University Hospital Leuven, LEUVEN, Belgium; [9]Ghent University, GENT, Belgium; [10]Wyeth Research, CAMBRIDGE, MA, USA; [11]Nevada Cancer Institute, LAS VEGAS, NEVADA, USA

Background. CMC-544 is a humanized anti-CD22 antibody conjugated to calicheamicin, a potent cytotoxic agent. CMC-544 targets CD22 which is expressed in the majority of B cell non-Hodgkin's lymphomas (NHL). In a phase 1 study of patients (pts) with CD22+ B-cell NHL, the maximum tolerated dose (MTD) for single agent CMC-544 was determined to be 1.8 mg/m^2 administered IV every 28 days. CMC-544 showed clinical activity in pts with follicular lymphoma (FL) and diffuse large B-cell lymphoma (DLBCL). *Aims.* A short dose-escalation study was performed to determine the MTD of CMC-544 in combination with rituximab. An expanded cohort at the MTD assessed the safety and efficacy of the drug combination in recurrent/refractory FL or DLBCL. *Patients and Methods.* Pts were eligible if they had CD20$^+$/CD22$^+$ FL or DLBCL, which had not responded to, or progressed after, 1 or 2 therapies of probable clinical benefit including at least 1 regimen containing rituximab, but could not be refractory to rituximab (arm 1 for FL and arm 2 for DLBCL). A third arm for rituximab-refractory aggressive lymphoma is currently enrolling with no upper limit on the number of prior therapies. Pts received 375 mg/m^2 of rituximab IV on day 1 followed by CMC-544 on day 2 of each 28-day cycle for up to 8 cycles, provide that there was no evidence of progression. *Results.* The MTD of CMC-544 given with rituximab was confirmed as 1.8 mg/m^2. The study is currently enrolling, and as of Feb 2009, 96 pts were entered at CMC-544 doses of 0.8 mg/m^2 (n=5), 1.3 mg/m^2 (n=3) and 1.8 mg/m^2 (n=88). Median number of doses received was four. Among the pts treated at the MTD, the median age was 66 y (range: 20-85), and 60% were male; 38% had 1 prior chemo/immunotherapy regimen, 49% had 2 regimens and 9% had ≥3 regimens; 69% had stage 3/4 disease, 35% elevated LDH, and 15% bulky disease (>7.5 cm). Pts in the relapsed DLBCL arm were generally older with a median age of 72 y. All 96 pts were evaluable for safety. The most common drug-related adverse events (AEs), all grades, were nausea (40%), fatigue (37%), increased AST (31%) and thrombocytopenia (37%). Grade 3/4 drug-related AEs occuring in ≥5% of pts were thrombocytopenia (22%), neutropenia/neutrophil decreased (13%/8%) and lymphopenia (6%). A total of 26 (27%) pts discontinued treatment due to an adverse event, most commonly hematologic AEs (14 pts) or elevation of ≥1 liver function test (10 pts). Table 1 shows the tumor response for patients in arms 1 and 2 treated at the MTD. Both groups had an objective response rate of 81%. The 6-month progression-free survival rate was 95% for FL pts and 66% for DLBCL pts. *Conclusions.* The safety profile of CMC-544 plus rituximab is similar to that previously reported for CMC-544 monotherapy. The main toxicity was manageable, self-limiting thrombocytopenia. The response rates indicate promising efficacy in pts with recurrent/refractory FL and DLBCL. These data warrant continued development of CMC-544 in combination with rituximab for the treatment of NHL.

Table. Best overall response for patients treated at MTD.

Response, n (%)	FL (N=37)	DLBCL (N=31)
Complete response (CR)	15 (41)	13 (42)
Complete response unconfirmed (CRu)	4 (11)	3 (10)
Partial response (PR)	11 (30)	9 (29)
Objective response (OR)	30 (81)	25 (81)
Stable disease	5 (14)	5 (16)
Progressive disease	2 (5)	1 (3)

Note: OR = CR + CRu + PR

CLINICAL SIGNIFICANCE OF THE PRESENCE OF OCCULT CNS INVOLVEMENT ASSESSED BY FLOW CYTOMETRY IN PATIENTS WITH NON HODGKIN'S LYMPHOMA AT HIGH RISK OF CNS RELAPSE

J.M. Sancho,[1] A. Orfao,[2] S. Quijano,[2] O. Garcia,[1] C. Panizo,[2] E. Pérez-Ceballos,[2] G. Deben,[2] A. Salar,[2] E. González-Barca,[2] N. Alonso,[2] J.A. García-Vela,[2] J. Capote,[2] F.J. Peñalver,[2] M. Provencio,[2] J. Arias,[2] J. Plaza,[2] D. Caballero,[2] M. Morado,[2] M. Cruz,[2] A. Palacios,[2] A. Carmona,[2] E. Conde,[2] T. Molero,[2] E. Romero,[2] M.C. Mateos,[2] M.J. Peñarrubia,[2] J.M. Ribera[1]

[1]ICO-Hospital Universitari Germans Trias i Pujol, BADALONA; [2]Spanish Group for the Study of CNS Disease in NHL, SALAMANCA, Spain

Background and Aim. Several studies have demonstrated that flow cytometry (FCM) improves the sensitivity of conventional cytology (CC)

in cerebrospinal fluid (CSF) for the identification of leptomeningeal disease in aggressive lymphomas with high risk of central nervous system (CNS) involvement. A previous report from our group showed infiltration assessed by FCM study in 27 out of 123 (22%) newly diagnosed aggressive B-cell lymphomas, while CC was positive in only 7 (6%) cases (Quijano *et al.*, J Clin Oncol 2009, in press). However, the clinical significance of occult disease in CNS (FCM positive and CC negative) remains unknown. *Patients and Methods.* At the time of the analysis, 105 out of 123 (85%) patients of the previous study had adequate follow-up (median follow-up for patients remaining alive [n=67] of 20 months). In this cohort of patients the presence of CNS involvement during follow-up was correlated with the CC and FCM results in CSF at diagnosis. *Results.* Three groups were defined according to the results of CC and FCM: Group 1, patients without CNS involvement (CC and FCM negative, n=83); Group 2, patients with occult CNS disease (FCM positive and CC negative, n=15); Group 3, patients with CNS disease (CC and FCM positive, n=7). The groups were comparable for the main clinical and biological characteristics, except for histological subtypes of NHL (23% of Burkitt's lymphoma in Group 1 vs 71% in Group 3, p=0.01). In Group 1, 58 patients received intrathecal (IT) prophylaxis, 2 received CNS therapy due to presence of neurological symptoms and 23 did not receive any prophylaxis. In Group 2, CNS prophylaxis was administered to 7 patients, 7 received active CNS therapy, whereas the remaining patient did not receive any prophylaxis. All 7 Group 3 patients received active CNS therapy. Overall, 6 patients showed CNS relapse/progression, 2 in Group 1 (2.4%) (both with diffuse large B cell lymphoma [DLBCL]), 2 in Group 2 (13%) (one with DLBCL and the other with Burkitt's lymphoma) and 2 in Group 3 (29%) (both with Burkitt´s lymphoma). Patients from Groups 2 and 3 showed a significantly increase in CNS relapses compared to those from Group 1 (Group 2 vs. 1, p=0.04; Group 3 vs. 1, p<0.001). However, the incidence of CNS relapse in patients from Groups 2 vs. 3 was not significantly different. In addition, patients with FCM+/CC+ showed a significant worse survival compared to those with FCM-/CC- (p=0.02), while no differences were observed for survival in patients with FCM+/CC+ vs FCM+/CC- (p=0.23) and FCM+/CC- vs FCM-/CC- (p=0.40). *Conclusions.* The presence of occult CNS disease in our cohort of patients with NHL at high risk of CNS disease was associated with a higher risk of CNS relapse. In addition to classical clinical and biological risk-factors, FCM could be an useful diagnostic tool to identify those NHL patients at higher risk of CNS relapse and to improve the CNS prophylaxis/therapy.

A PHASE 2 STUDY OF VORINOSTAT (SUBEROYLANILIDE HYDROXAMIC ACID, SAHA) IN RELAPSED OR REFRACTORY INDOLENT NON-HODGKIN'S LYMPHOMA. A CALIFORNIA CANCER CONSORTIUM STUDY

M. Kirschbaum,[1] L. Popplewell,[1] A. Nademanee,[1] V. Pullarkat,[1] M. Delioukina,[1] J. Zain,[1] D. Matsuoka,[1] B. Pulone,[1] P. Frankel,[1] S. Forman,[1] I. Espinoza-Delgado,[2] E. Newman[1]

[1]City of Hope National Cancer Center, DUARTE; [2]CTEP, National Cancer Institute, BETHESDA, USA

Background. The indolent (follicular, marginal zone and mantle cell) lymphomas tend to recur with decreasing intervals of remission after standard chemotherapy. New modalities of treatment are necessary. Vorinostat (SAHA) is an orally administered hydroxamic acid histone deacetylase inhibitor with activity against class I and II deacetylases with preclinical and clinical activity against various forms of lymphoma. *Methods.* We report the results of a phase II study of oral vorinostat in patients with relapsed or refractory (to chemotherapy and/or rituximab) follicular, marginal zone, or mantle cell lymphoma. Vorinostat is given at 200 mg PO twice daily for 14 consecutive days on a 21 day cycle. CT scanning and/or FDG-PET are performed after every three cycles, as is marrow biopsy for those with marrow involvement at time of entry into study. Patients may have received up to four prior chemotherapy regimens including tositumomab or ibritumomab; previous transplant is allowed. 37 patients (14 female, 23 male) were accrued (2 ineligible patient due to wrong histology are excluded from the analysis). The median age at treatment was 65 (32-79) years. Histologies represented: mantle cell (MC)-8, marginal zone (MZL)-7, and follicular lymphoma (FL)-20. Treatment was well tolerated. Grade 3-4 toxicities possibly attributable to study drug were thrombocytopenia, neutropenia, anemia, diarrhea, anorexia, myalgia (1 patient), hypokalemia, hypophosphatemia, hyponatremia, thrombus (1 patient), febrile neutropenia (1 patient), INR (1 patient), mucositis (1 patient) and fatigue. *Results.* The overall response rate is 29%, for patients with FL and MZL the response rate is 37%, with no responses seen in mantle cell. 19 patients were taken off study due to progression. Three pts came off study due to toxicities (fatigue and diarrhea after 10 cycles, diarrhea and dizziness after 2 cycles, DVT after 5 cycles), 1 stopped therapy due to intercurrent illness, 1 came off for alternate therapy and 1 due to patient refusal. Eight remain on therapy, and two completed therapy per protocol. By the current Cheson criteria, 5 patients achieved complete remission (CR), and 5 patients achieved partial remission (PR). Three patients with PR as best response subsequently progressed (at 6, 15 and 16 months), the other two remain on therapy (25+, and 32+ months). One CR was achieved after 2 years of stable disease on therapy. By histology, 10 formal responses were seen in patients with follicular (8) or marginal zone lymphoma (2) whereas no responses were seen in mantle cell lymphoma. The median progression-free survival for the 35 patients is 11 months; the median follow-up of alive patients is 11 months; 5 patients are progression-free for more than 18 months. *Conclusions.* The histone deacetylase inhibitor vorinostat is well tolerated over long durations of therapy, and shows promising activity (10 CR+PR out of 27 patients) against relapsed/refractory follicular and marginal zone lymphoma.

Support: NCI U01-CA062505 and N01-CM-62209.

EARLY EVALUATION OF 18-FDG-POSITRON EMISSION TOMOGRAPHY/COMPUTED TOMOGRAPHY (PET) DOES NOT PREDICT THE OUTCOME IN DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) PATIENTS TREATED WITH R-CHOP

P. Pregno,[1] A. Chiappella,[1] M. Bellò,[2] S. Ferrero,[3] R. Passera,[2] C. Boccomini,[1] B. Botto,[1] G. Castellano,[2] C. Frairia,[1] S. Franceschetti,[4] R. Freilone,[1] M. Menga,[2] F. Salvi,[5] M. Ladetto,[3] U. Vitolo[1]

[1]Hematology ,[2] AOU San Giovanni Battista, TURIN; [2]Nuclear Medicine, AOU San Giovanni Battista, University of Turin, TURIN; [3]Hematology ,[1] AOU San Giovanni Battista, University of Turin, TURIN; [4]Hematology, University of Piemonte Orientale Amedeo Avogadro, NOVARA; [5]Hematology, ASO SS. Antonio e Biagio e Cesare Arrigo, ALESSANDRIA, Italy

Background. Unlike Hodgkin Disease, the predictive value of early PET in DLBCL patients is controversial. Published data are often based on retrospective studies, including miscellanea of subtypes and therapies. Moreover, the dichotomous interpretation of PET findings as positive or negative is often difficult to apply in clinical evaluation. Aim of the study. To determine the predictive value of the early PET (PET-2) during treatment of DLBCL pts and of the final PET (PET -3) on Progression Free Survival (PSF). *Patients and Methods.* From April 2004 to December 2008, 81 newly diagnosed DLBCL or follicular grade IIIb pts were included into the study. Clinical characteristics were as follows: 49 males and 32 females; median age 56 years (22-82); 18 pts stage I-II and 63 stage III-IV; according to IPI 52 pts were at low/low-intermediate risk, 28 at intermediate-high/high risk. All pts were treated according to the planned treatment, not modified according on PET-2 *Results.* 55 with 6-8 R-CHOP and 26 with 4 R-CHOP courses followed by high-dose chemotherapy with autologous stem cell transplantation (HDC+ASCT). All pts had PET scan performed at the diagnosis, after 2-4 courses of therapy (PET-2) and at the completion of treatment (PET-3): all PET results were defined as positive or negative with visual dichotomous consensus response criteria. Results. 70 pts completed planned treatment and were evaluable for response. PET-2 was perfomed after 2 R-CHOP in 41 pts, after 3 courses in 15 and after 4 in 22. At the end of treament 64 pts (91%) achieved a CR and 6 (9%) were non responders. Forty-nine pts (62%) were negative and 30 (38%) positive at the PET-2 and 64 pts(91%) were negative and 6 (9%) positive at the PET-3. The concordance between clinical evaluation of CR and PET-3 negativity was 98.6%: one CR pt was false PET-3 positive due to parothid carcinoma. Correlation between PET results and outcome was evaluated. No correlation between PET-2 results and CR rate was found: CR 95% in PET-2 negative pts vs 81% in PET-2 positive (p=ns). With a median FU of 17 months, PFS was 76%. PET-2 did not correlate with PFS (p=.88), conversely PET-3 strongly predicted PFS (p<0.0001). (Figure 1). In univariate analysis IPI, time of PET-2 evaluation, plan of therapy had not a statistically significative influence. Mainly, the lack of predictive value of PET-2 was observed both in the subgroup of pts treated with/without HDC+ASCT. 2y-PFS rates PET-2 negative vs PET-2 positive pts were: HDC+ASCT group 77% vs. 91%; no HDC+ASCT group 81% vs. 79%. 2y-PFS rates PET-3 negative vs PET-3 positive pts were: HDC+ASCT group 86% vs. 0%; no HDC+ASCT group 88% vs. 33%. Conclusions.

In contrast to prior studies regarding prognostic value of interim PET in DLBCL untreated pts, our results indicate that in R-CHOP treated pts early PET does not predict outcome. Conversely PET results at the end of treatment strongly correlate with PFS. Future prospective larger studies will be need to establish the real role of interim PET to predicting outcome in this subset of patients.

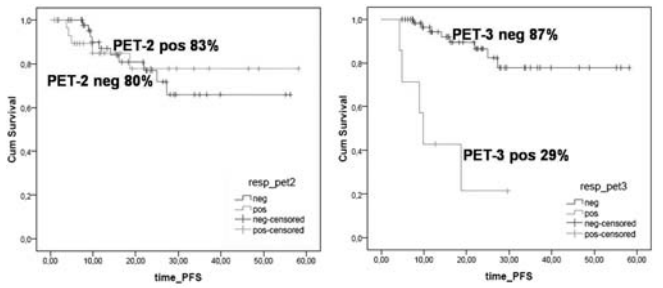

Figure 1. PFS at 17 months by PET-2 and PET-3 evaluation.

0411

ACTIVITY AND SAFETY OF BORTEZOMIB AND RITUXIMAB IN RELAPSED/REFRACTORY INDOLENT NON FOLLICULAR AND MANTLE-CELL NON HODGKIN LYMPHOMA: A PHASE II MULTICENTER STUDY BY INTERGRUPPO ITALIANO LINFOMI

P. Pregno, A. Chiappella, P.L. Zinzani, L. Orsucci, V. Stefoni, E. Russo, A. Tucci, S. Franceschetti, R. Freilone, A. Fabbri, A. Ferreri, L. Gargantini, A.M. Liberati, L. Rigacci, A. Evangelista, U. Vitolo

On behalf of Intergruppo Italiano Linfomi, Hematology ,[2] AOU S.Giovanni Battista, TURIN, Italy

Background. Combination of Bortezomib (B) and Rituximab (R) has been shown *in vitro* synergistic apoptosis and enhanced NFkB depletion in Mantle Cell Lymphoma (MCL) and Marginal Zone Lymphoma (MZL) cells. Aim of the study. To evaluate safety and efficacy of the association of R+B in relapsed/refractory indolent non follicular and mantle cell lymphoma patients not eligible to high dose chemotherapy and ASCT. The primary endpoint was Overall Response Rate (ORR) >40%. *Patients and methods.* From September 2006 to March 2008, 54 patients were enrolled into the study. Clinical characteristics were as follows: 29 males and 25 females; median age was 68 years (range 50-74); 20 lymphocytic/lymphoplasmacytic (LL), 10 MZL and 24 MCL; 45 stage III-IVdisease; according to IPI 36 patient were at low-intermediate risk and 18 at intermediate-high/high risk; 10 patients had 1 and 44 >2 prior lines of therapy; 17 were R-naïve patients and 37 R-pretreated, 23 patients had refractory disease (<1 yr from the last therapy) and 31 were in relapse (>1 yr). The treatment plan was: one course of 4 weekly doses of R (375 mg/mq) and B (1.6 mg/mq IV bolus) followed by 2 courses of 4 weekly IV bolus of B (1.6 mg/mq) as single agent. Responding (CR+ PR) and stable disease patients were planned to be given further 3 courses at the same schedule. Histological diagnosis was centrally reviewed. *Results.* ORR was 25/54 (46%, 95%CI: 34-59). Overall responses were: 14 CR+ CRu (26%) and 11 PR (20%). ORR by histology was: 7/20 (35%) in LL, 5/10 (50%) in MZL and 14/24 (58%) in MCL respectively. Pretreatment with Rituximab did not adversely influence the ORR: 18/36 (50%) in R-pretreated patients and 6/17 (35%) in R-naïve patients. ORR was better in relapsed patients compared with refractory ones: 19/30 (63%) and 5/23 (22%) (p=0.002). Data regarding PFS and OS are on course. A total of 251 courses were delivered with a median of 4.6 courses per patient. Thirty-two patients completed the treatment plan and 22 withdrawn from the study because of: 15 PD during treatment and 7 AE (1 pleural effusion, 1 neurotoxicity grade II, 2 pneumonia, 1 MOF, 1 concomitant gastrointestinal adenocarcinoma and 1 toxic death due to interstitial pneumonitis). Grade III-IV CTC haematological toxicity was rare with neutropenia in 4% of the courses and thrombocytopenia in <2%. The most frequent extra-haematological toxicity was: neurotoxicity grade II in 13 pts and grade III in 5 with recover or return to grade I in all of them but one; infections were detected in 3 patients (pneumonitis), constipation grade III in 2 and diarrhea grade >III in 5. *Conclusions.* This study suggests that the combination of R plus B is feasible and effective in relapsed/refractory indolent non follicular lymphoma and MCL. This combination treatment based on *in vitro* data of synergistic effect of R and B may be a good therapeutic option without chemotherapy mainly in MCL and MZL. The combination of R plus B should be explored in further and larger studies.

0412

LYMPHOMA - EMERGING REALITIES IN SUB-SAHARA AFRICA

P. Jacobs,[1] G. Sissolak,[1] J. Juritz,[2] D. Sissolak,[1] L. Wood[1]

[1]Stellenbosch University, CAPE TOWN; [2]University of Cape Town, CAPE TOWN, South Africa

Background. Substantial geographical differences exist for Hodgkin and other lymphoproliferative disorders with these having previously been documented in a report from the lymphoma reclassification project. *Aims.* In the light of rampant human immunodeficiency syndrome, largely centred in sub-Sahara, this experience is updated in a further 512 consecutive individuals treated over an eight-year period in a privately based academic centre. *Methods.* Consecutive registered cases were clinically evaluated. Diagnosis based on nodal histopathology and classification according to World Health Organisation criteria. Staging on traditional CT imaging and bone marrow trephine biopsy: performance status defined by international prognostic indices. Treatment was risk-stratified to standardized protocols with informed consent and outcome statistically analyzed using conventional methods. *Results.* Median age was 55.2 years 61% were males, 10% in Hodgkin lymphoma and, overall, constitutional symptoms were present in 20%. Prior to referral 19% had received chemotherapy and a further 20% some form of irradiation. Median survival in hairy cell leukaemia (n=14), chronic lymphocytic leukaemia-small lymphocytic lymphoma (n=103), Hodgkin (n=41) and follicular lymphoma (n=59) was not reached at the time of analysis and exceeded 36 months. This was followed by 32 months for those with mantle cell (n=7), splenic (n=2) and extranodal marginal cell (n=11), 24 months for T-cell lymphomas (n=24), 20 months for diffuse large B-cell variants (n=88) but only 12 months for the aggressive tumours exemplified by Burkitt (n=7) and lymphoblastic subtypes (n=6). The remaining 36 patients had to be excluded because numbers were too small for statistical analysis or unreliable staging. Adverse factors were constitutional symptoms, prior treatment with chemotherapy, intermediate or high-risk scores as defined by the International Prognostic Index, histologic grading and certain anatomical sites of primary tumour. In contrast gender, staging by Rye or Rai classification, prior treatment with radiotherapy and, notably, retroviral infection were without effect. Overall survival at three years in each category was compared to the curve for the entire cohort and was 100% in hairy cell leukaemia receiving two chlorodeoxyadenosine and greater than 88% in Hodgkin lymphoma treated according to the German study group protocols (p=0.0004). Corresponding figures for chronic lymphocytic leukaemia - small lymphocytic lymphoma were 82% (p=0.0006), follicular lymphoma 71% (p=0.060), peripheral T-cell lymphoma 43% (p=0.0156), diffuse large B-cell lymphoma 39% (p<0.0001), aggressive tumours 25% (p=o.0002) and for the indolent categories including mantle cell, splenic and extra nodal marginal cell lymphomas 22% (p=0.2023). *Summary and conclusions.* Outcome argues in favour of patient management by a multidisciplinary team implicit in which is use of standardised protocols for diagnosis, staging and treatment. Under these circumstances the well recognized centre effect applies and here results approximate those from first world reference centres. Conversely any deviation from such a disciplined approach is unlikely to achieve comparable benefit and therefore to be strongly discouraged. Relevantly effective antiretroviral has blunted the impact of this infection on outcome thereby significantly changing older practices in under resourced areas of the world.

0413

FIRST RESULTS OF LONG TERM RITUXIMAB MAINTENANCE TREATMENT IN FOLLICULAR LYMPHOMA: SAFETY ANALYSIS OF THE RANDOMIZED PHASE III TRIAL SAKK 35/03

F. Hitz,[1] S. Bassi,[2] C. Taverna,[3] W. Mingrone,[4] T. Pabst,[5] L. Cevreska,[6] A. Del Giglio,[7] D.A. Vorobiof,[8] M. Simcock,[9] M. Ghielmini[10]

[1]Kantonsspital St. Gallen, ST. GALLEN, Switzerland; [2]Istituto Europeo di Oncologia, MILANO, Italy; [3]Kantonsspital Münsterlingen, MÜNSTERLINGEN, Switzerland; [4]Kantonsspital Aarau/Olten, AARAU/OLTEN, Switzerland; [5]Inselspital Bern, BERN, Switzerland; [6]Department of Hematology, SKOPJE, Macedonia; [7]Hematology and Oncology, SAO PAULO, Brazil; [8]Sandton Oncology Center, JOHANNESBURG, South Africa; [9]Swiss Group for Clinical Cancer Research (SAKK), BERN, Switzerland; [10]Oncology Institute of Southern Switzerland, BELLINZONA, Switzerland

Background. Rituximab maintenance has been shown to be effective in patients with follicular lymphoma. *Aims.* To ascertain a more optimal duration of Rituximab maintenance in this indication. *Methods.* We

prospectively registered 270 patients with untreated, chemotherapy resistant or relapsed follicular lymphoma. All patients received rituximab induction consisting of 4 weekly doses (375 mg/m^2). Responding patients (PR and CR) were randomized to a short maintenance consisting of four doses of rituximab (375 mg/m^2) every two months (arm A) or prolonged maintenance consisting of rituximab every two months for a maximum of five years or until progression or unacceptable toxicity (arm B). The primary endpoint was event-free survival. All patients gave informed consent. Here we present the safety analysis results. *Results.* From October 2004 to November 2007 165 patients were randomized; 82 in arm A [25 (30%) previously relapsed/progressed, 57 (70%) untreated] and 83 in arm B [24 (29%) previously relapsed/progressed, 58 (70%) untreated and one stable]. Of the non-randomized patients, 49% (51 patients) were previously untreated and 50% (52 patients) were previously relapsed/progressed, the remaining 2 patients were previously resistant or stable. The median follow up is 22.7 months. A total of 442 hematological and non-hematological adverse events were observed, 27 of grade 3 and 6 of grade 4. Five subsequent cancers and 9 grade 3 and 4 infections were reported. Grade 3 and 4 neutropenia occurred in 5 patients of which the grade 4 neutropenia occurred in a previously untreated patient. Decreased levels of IgG were observed in 19 patients, 60% of who were previously untreated. Four grade 3 infections occurred after 2 years of maintenance. In arm B, maintenance was stopped due to unacceptable toxicity (fever) in 1 patient after 18 months and due to subsequent breast cancer in 1 patient after 20 months. One patient died 4 months after randomization because of ileus and consecutive peritonitis; considered to be unrelated to therapy. All three of these mentioned patients that stopped therapy were previously untreated. Twenty-nine patients are on maintenance for two or more years of which 6 patients are on for three or more years. In this analysis, median duration of the prolonged maintenance is 23.7 months. The trial has been closed for accrual but there are still patients on treatment. *Conclusions.* Rituximab maintenance beyond two years is feasible. Previous treatment seems not to influence occurrence of adverse events. However, close follow up of patients under prolonged rituximab maintenance is necessary.

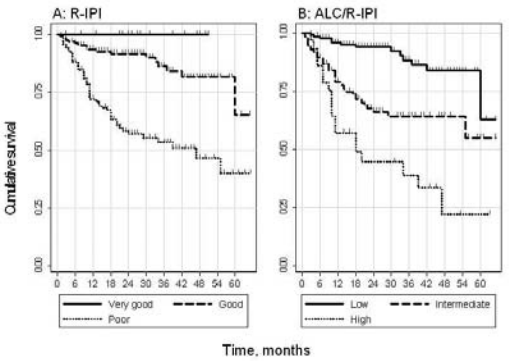
0414

VALIDATION OF ABSOLUTE LYMPHOCYTE COUNT / REVISED IPI (ALC/R-IPI) SCORE MODEL, AS A PROGNOSTIC INDEX FOR DIFFUSE LARGE-B-CELL LYMPHOMA IN RITUXIMAB ERA

F. Mendicino,[1] L. Marcheselli,[2] A . Bari,[2] R. Marcheselli,[2] S. Falorio,[3] G. Polimeno,[4] M.C. Cox[1]

[1]A.O. Sant'Andrea - [2]nd Faculty of Medicine - La Sapienza University, ROME; [2]Department of Oncology and Hematology - Oncology center - University of Modena, MODENA; [3]Unità Operativa di Ematologia - Ospedale di Pescara, PESCARA; [4]Unità Operativa di Ematologia - Ospedale di Acquaviva delle Fonti, BARI, Italy

Background. The International prognostic index (IPI), since its publication in 1993, became the primary prognostic tool for patients with DIFFUSE LARGE B-CELL LTMPHOMA (DLBCL). However, the introduction of rituximab (R) has improved patients outcomes and has partially changed the predictive capacity of IPI. In 2007, in the R era, a most accurate prognostic index, termed revised IPI (R-IPI) was proposed by Sehn *et al.* More recently, Cox *et al.* showed that absolute lymphocyte count (ALC), at diagnosis has a prognostic impact and it is independent from R-IPI. Thus, they have built-up a score, termed ALC/R-IPI, incorporating both parameters (low risk=ALC≥0.84 109/L and R-IPI very good or good, intermediate risk= ALC<0.84 109/L or R-IPI poor; high risk= ALC<0.84 109/L and R-IPI poor). Aim of our research, utilizing Gruppo Italiano Studio Linfomi (GISL) database is to validate the ALC/R-IPI model on a second larger independent patients data set like the GISL database. *Methods and Results.* From GISL database we collected data of 831 DLBCL patients, of which 560 treated with chemotherapy alone (1988-2003) and 271 treated with R-containing chemotherapy regimens (2003-2007). We have used the Kaplan-Meier curves, c-Harrell concordance index and the Cox proportional hazard regression to evaluate the ability of ALC/R-IPI to discern patients having good or poor survival. The median age of the 271 cases treated with R was 69 years and 51% were male. At diagnosis, 62% were in stage III/IV, 49% had LDH>UNL, 16% a PS>1, 26% had extranodal sites>1 and 26% presented with ALC<0.84 109/L. The distribution of patients in R-IPI was 7%, 48% and 45% in very good (VG), good (G) and poor (P) groups, respectively. The distribution in ALC/R-IPI was 47%, 42% and 11% in low (L), intermediate (I) and high (H) risk groups, respectively. The OS at 3-years was 88%, 64% and 39% in L, I and H risk groups, with significative differences (p<0.001). The HR were: I vs L = 3.7 (p<0.001); H vs I = 2.1 (p=0.012), while the c-Harrell was = 0.71 (CI95% 0.65-0.76). *Conclusions.* The ALC/R-IPI showed a good ability to discriminate the prognosis of patients in term of OS in our data base. ALC was confirmed as a specific prognostic factor for DLBCL in R era.



R-IPI: Very Good = IPI 0, Good = IPI 1-2 and Poor = IPI 3/5.
ALC/R-IPI: 1, Low risk = R-IPI VG AND ALC ?0.84·10^9/L ; 2, Intermediate risk = R-IPI Poor OR ALC<0.84·10^9/L; 3, High risk = R-IPI Poor AND ALC<0.84·10^9/L.

Figure. Overall survival stratified by revised prognostic models of our 271 patients. A) R-IPI; B) ALC/R-IPI.

0415

SPLENECTOMY VERSUS RITUXIMAB IN THE TREATMENT OF SPLENIC MARGINAL ZONE LYMPHOMA

C. Kalpadakis,[1] G.A. Pangalis,[2] T.P. Vassilakopoulos,[2] S. Sachanas,[2] M.C. Kyrtsonis,[2] M. Dimopoulou,[2] P. Korkolopoulou,[2] F.N. Kontopidou,[2] X. Yiakoumis,[2] M.P. Siakantaris,[2] E.M. Dimitriadou,[2] P. Panayiotidis,[2] H. Papadaki,[1] M.K. Angelopoulou[2]

[1]Department of Haematology, University of Crete, ATHENS; [2]Department of Haematology, University of Athens, ATHENS, Greece

Background. Splenic marginal zone lymphoma (SMZL) treatment is not standardized. Splenectomy has traditionally been considered as the treatment of choice. Recent data however suggests that Rituximab is a promising agent for the treatment of SMZL. *Aims.* To evaluate the activity of splenectomy as well as Rituximab monotherapy in the treatment of SMZL and to compare these two treatment modalities regarding response rate, progression free survival, overall survival and toxicity. *Methods.* 64 SMZL patients, diagnosed and followed in our Departments, were retrospectively analyzed. Among them, 36 (56%) received rituximab monotherapy (induction therapy at a dose of 375 mg/m^2/week for 6 weeks and maintenance therapy every 2 months for one year), while 28 patients underwent splenectomy. Treatment was administered to patients with symptomatic splenomegaly, cytopenias and/or autoimmune phenomena. *Results.* Clinical and laboratory characteristics between the two treatment groups are presented on Table 1.

Table 1. Characteristics of 64 SMZL patients.

Parameters	Splenectomized Patients		Rituximab treated Patients	
	#	(%)	#	(%)
Patients	28	44	36	56
Median age (years)	63		58	
Male gender	13	46	13	36
Median spleen size (range)	10 (0-18)		10 (0-20)	
B-symptoms	8	28	3	8
Lymphadenopathy	0		2	5
Anaemia (Hb<12gr/dl)	16	57	19	53
Median Lymphocyte count (10^9/L)	4.8		2.8	
Thrombocytopenia (<100 X10^9/L)	6	21	7	19
IPI				
Low Intermediate	21	75	27	75
High Intermediate	7	25	9	25
Median follow up (months)	57		30	

All splenectomized patients except one (96%) achieved complete resolution of splenomegaly-related symptoms along with restoration of cytopenias to normal, although lymphocytosis persisted. One toxic death was recorded one month after splenectomy. Moreover, 7 patients underwent bone marrow (BM) evaluation a year after splenectomy which revealed an increase in lymphocytic infiltration along with a change in the pattern of BM involvement in 5 of them. The overall response rate of rituximab treated patients was 92% (CR 45%, PR 25%, unconfirmed CR 22%) after induction therapy. Maintenance therapy further improved the response in 4 patients. Among the complete responders 38% achieved a molecular response. Rituximab treatment was well tolerated with no grade 3 or 4 toxicities. No differences were observed in 3-year overall survival and progression free survival between splenectomized and rituximab treated patients (84% vs. 94% and 79% vs. 90% respectively. *Conclusions.* The present study demonstrates that splenectomy and rituximab are among the most effective treatment strategies in SMZL. The limited toxicity of Rituximab along with a high complete response rate clearly indicate that it can replace splenectomy, especially in patients with advanced age, comorbidities, or an underlying autoimmune disorders.

0416

PHASE II STUDY OF INTRATHECAL LONG ACTING LIPOSOMAL CYTARABINE (DEPOCYTE®) IN THE PROPHYLAXIS OF LYMPHOMATOUS MENINGITIS IN HIV-RELATED NON-HODGKIN'S LYMPHOMA

M. Spina,[1] E. Chimienti,[1] F. Martellotta,[1] M. Berretta,[1] E. Zanet,[1] P.K. Nigri,[1] V. Canzonieri,[1] P. Bulian,[2] U. Tirelli[1]

[1]National Cancer Institute, AVIANO; [2]Centro di Riferimento Oncologico, Istituto di Ricovero e Cura a Carattere Scien, AVIANO, Italy

Around 5% of patients with aggressive non-Hodgkin's lymphoma (NHL) develop central nervous system (CNS) progression or relapse during the course of their disease. Patients with human immunodeficiency (HIV)-related NHL often develop CNS progression despite the use of adequate prophylaxis. Liposomal cytarabine has show a significant activity in lymphomatous meningitis but there are limited data in the prophylactic setting. Between May 2006 and December 2008, we performed a prospective phase II study of intrathecal liposomal cytarabine (Depocyte®) at the dose of 50 mg in 28 patients with HIV-NHL with the aim to evaluate the feasibility and activity of this drug in the prevention of lymphomatous meningitis. Twenty-three patients were males and the median age was 42 years (range 18-64 yrs). As far as the histological subtype of NHL, 64% of patients had a diffuse large B-cell (DLBC) NHL and 36% Burkitt NHL. Stage III-IV was diagnosed in 75% of patients and 79% of DLBC were age-adjusted IPI 2 or more. An extranodal involvement was diagnosed in 64% of patients (gastrointestinal 29%, bone marrow 18%, spleen 18%, bone 14%). Liposomal cytarabine was well tolerated with headache grade I to III being the most frequent side effect in 46% of patients. Less common toxicity (all grade I) included cortical changes (7%), fever (4%), vomiting (4%), hypertension (4%), chills (4%). With a median follow up of 10 months only one patient (4%) with Burkitt lymphoma developed a combined systemic and meningeal relapse. Moreover, in our experience previously the present study, we used methotrexate as practical use in 267 HIV-NHL with a meningeal progression or relapse of 10% (p=0.32). The use of a liposomal formulation allowed to significantly reduce the number of lumbar injections in comparison to the standard schedules (approximately of 50%) with an improvement of quality of life of patients and with a reduction of professional exposure risk for health care staff. In conclusion, in this first prospective study on prophylaxis of lymphomatous meningitis in HIV-NHL reported in the literature, liposomal cytarabine seems safe and active and it reduces of approximately 50% the number of lumbar punctures and exposure risk for health staff as well.

0417

INTEREST OF 18-FLUORO-DEOXYGLUCOSE POSITRON EMISSION TOMOGRAPHY (FDG-PET) IN INITIAL STAGING, RESPONSE ASSESSMENT AND PROGNOSTIC VALUE OF MANTLE CELL LYMPHOMA

C. Touzeau,[1] C. Bodet-Milin,[1] C. Leux,[1] S. Mehmet,[1] A. Moreau,[1] H. Maisonneuve,[2] N. Morineau,[3] H. Jardel,[2] P. Moreau,[2] R. Gressin,[1] J.L. Harousseau,[4] P. Moreau,[1] F. Kraeber-Bodere,[1] S. Le Gouill[1]

[1]University Hospital, NANTES; [2]Hospital, LA ROCHE SUR YON; [3]Centre Catherine de Sienne, NANTES; [4]CRLCC, NANTES, France

Background. FDG-PET is a non-aggressive imaging modality commonly used in the management of patients with malignant lymphoma. FDG-PET is recommended for initial staging and response assessment of diffuse large B-cell lymphoma and Hodgkin lymphoma. There are few published data on the interest of FDG-PET in the initial staging, response assessment and prognostic value in MCL. *Aims.* This multicentric retrospective study investigate FDG-PET imaging at initial staging, response assessment and its prognostic value in the setting of MCL patients. *Methods.* From 2003 to 2008, 44 previously untreated MCL patients were recruited in six GOELAMS centers and evaluated by both conventional method and FDG-PET for initial staging. After completion of therapy, response was assessed according to IWC and IWC-PET criteria. *Results.* FDG-PET uptakes at diagnosis were abnormal in all cases. Compared to conventional evaluation, some additional nodal and extra-nodal sites were only detected by FDG-PET, especially splenic involvement. FDG-PET was not able to detect bone marrow (BM), central nervous system and gastro-intestinal (GI) involvement. Due to frequent visceral involvement in MCL (BM and GI), initial staging was not modified by FDG-PET. At end-treatment assessment, response according to IWC and IWC-PET shown discrepancies in six cases. Statistical analysis demonstrated that response assessment according to IWC-PET was not associated with others prognostic variables (IPI, MIPI, treatment, blastoid variant, SUV, Ki67). The 2-year event-free survival rate was influenced by IWC response (p=0.01), IWC-PET response (p=0.002), maximal SUV (p=0.005) and the 2-year overall survival was influenced by IWC response (p=0.03), IWC-PET response (p<0.001), maximal SUV (p=0.04) and blastoïd morphology (p=0.002). *Conclusions.* FDG-PET is a relevant tool at initial staging, complementary to conventionnal evaluation BM and GI biopsies remains mandatory in MCL. Concerning final assessment, the IWC-PET system identifies patients at high risk of relapse and could be more effective than standard IWC system. However, prospective studies with a longer follow-up are warranted before to draw final conclusions about the clinical impact of FDG-PET in MCL.

0418

LONG-TERM FOLLOW-UP OF RITUXIMAB AND INFUSIONAL CYCLOPHOSPHAMIDE, DOXORUBICIN, AND ETOPOSIDE IN COMBINATION WITH HAART IN HIV-RELATED NON-HODGKIN'S LYMPHOMAS

M. Spina,[1] E. Chimienti,[1] E. Vaccher,[1] U. Jaeger,[2] J.A. Sparano,[3] R. Talamini,[1] U. Tirelli[1]

[1]National Cancer Institute, AVIANO, Italy; [2]Dept. Internal Medicine - University of Wien, WIEN, Austria; [3]Montefiore Medical Center, NEW YORK, USA

Background. The combination of Rituximab plus chemotherapy (CT) is more effective than CT alone in the treatment of high grade NHL. *Objective.* To report the long-term follow-up of etoposide (CDE) plus Rituximab in HIV-NHL. *Methods.* In June 1998, we started a phase II study using infusional CDE (Cyclophosphamide 187.5 mg/m^2/day, Doxorubicin 12.5 mg/m^2/day and Etoposide 60 mg/m^2/day) administered by continuous intravenous infusion for 4 days every 4 weeks and Rituximab 375 mg/m^2 i.v. on day 1. HAART was given concomitantly with CT. *Results.* Seventy-four patients (pts) have been enrolled. The median CD4$^+$ cell count was 161 (range 3-691) and the median Performance Status was 1 (range 0-3). Diffuse large B-cell NHL was diagnosed in 72% of pts and Burkitt in 28%. Seventy per cent of pts had advanced stage (III-IV) disease and 57% of pts had an age-adjusted international prognostic index >2. Fifty-two out of 74 pts (70%) achieved a complete remission (CR), 4/74 (5%) had a partial remission and 18 pts progressed. With a median follow-up of 61 months, only 17% of CRs have relapsed and 41/74 pts are alive. The overall survival, disease free survival and time to treatment failure (TTF) at 5 years were 56%, 81% and 52%, respectively. Only one secondary tumor (acute leukemia) has been observed. No case of late pulmonary or cardiac toxicity has been reported. *Conclusions.* The combination of Rituximab and CDE in HIV-NHL treated concomitantly with HAART is very active. CR rate (70%) and TTF at 5 years (52%) are comparable to those observed in high grade NHL of the general population. Our data confirm that in HAART era a high proportion of HIV-NHL can be cured.

Non-Hodgkin lymphoma - Clinical II

HISTOLOGIC TRANSFORMATION OF FOLLICULAR LYMPHOMA INTO DIFFUSE LARGE B-CELL LYMPHOMA IN THE IOSI EXPERIENCE

A. Conconi,[1] M. Motta,[2] L. Wannesson,[2] C. Piona,[2] A. Stathis,[2] P. Froesch,[2] E. Gracia,[2] W. Belisario Filho,[2] D. Rodriguez Abreu,[2] M. Ghielmini,[2] F. Cavalli,[2] E. Zucca[2]

[1]Hematology-AOU Maggiore della Carità/Oncology Institute of Southern Switzerland, NOVARA, Italy; [2]Oncology Institute of Southern Switzerland, BELLINZONA, Switzerland

Background. Follicular lymphoma displays an indolent clinical course characterized by a continuous pattern of relapses, with no clear evidence of cure. A proportion of patients ultimately experiences a histological transformation into aggressive large cell lymphoma. Patients and *Methods.* We retrospectively analyzed the outcome of 281 patients with FL treated at the Oncology Institute of Southern Switzerland (IOSI) since 1979 to 2007, with respect to clinical features at diagnosis, therapeutic approaches, survival patterns, with special reference to the impact of histologic transformation on disease course. Median survival times, Kaplan-Meier survival curves and relative survival rates were calculated. *Results.* The median age of the entire group at time of diagnosis was 58 years (range 21-92 years). Median overall survival was 11 years (95% CI, 8.8-14 years). After a median follow-up from diagnosis of 10 years, histologic transformation into aggressive lymphoma was observed in 39 patients (14%, 95%CI:10-18%). The median time to transformation was 5 years from diagnosis. Risk of transformation at 5, 10 and 15 years was 13% (95%CI, 9-18%), 16% (95%CI, 12-22%), 27% (95%CI, 19-38%), respectively. The histologic transformation adversely impacts cause specific survival (CSS) (p=0.0003): in the population who did not experience histologic transformation the 10-years CSS was 74% (95%CI:66-80), in the group of patients who had histologic transformation, the 10-years CSS was 44% (95%CI:26-61). The median survival after transformation was 3 years. The risk of histologic transformation was higher in the group of patients diagnosed before 1989 compared to the subsequent period (p=0.03). An initial watchful waiting approach was associated to a lower risk of subsequent histologic transformation (p<0.05). No other therapeutic approach seems to impact the risk of histologic transformation. Among the clinical variables at diagnosis evaluated, a trend toward a significant association has been observed for an hemoglobin level lower than 12,0 gr/dL (p=0.06) and for the presence of at least a single bulky site of disease at diagnosis (p=0.07). *Conclusions.* Our findings are in keeping with other reports showing a negative impact of histologic transformation on the clinical outcome but we were not able to confirm the recently reported increased risk of transformation in follicular lymphoma patients initially followed with a watchful waiting policy. The impact of specific therapeutic strategies on histologic transformation needs to be further explored.

0420

FOLLICULAR LYMPHOMA IN LEUKEMIC PHASE AT DIAGNOSIS: CLINICAL AND BIOLOGICAL FEATURES IN A SERIES OF 24 PATIENTS AND COMPARATIVE ANALYSIS WITH NON-LEUKEMIC PATIENTS

L. Morabito,[1] J.M. Raya,[1] S. Guedes,[2] P. Martin,[3] T. Martin,[1] J.M. Bosch,[2] A. Lemes,[3] T. Molero,[3] M.T. Hernandez-Garcia,[1] M.L. Brito,[1] L. Hernández-Nieto[1]

[1]Hospital Universitario de Canarias, LA LAGUNA; [2]Hospital Insular, LAS PALMAS DE GRAN CANARIA; [3]Hospital Doctor Negrín, LAS PALMAS DE GRAN CANARIA, Spain

Background. According to the WHO classification of tumours of lymphoid tissues, apart from common nodal presentation, bone marrow, spleen, Waldeyer´s ring and peripheral blood (PB) are possible sites of involvement, among others. However, presentation of follicular lymphoma (FL) with morphologically evident leukemic phase at diagnosis is rare. It is well known that prognosis of this type of lymphoma is closely related to the extent of the disease. As pointed out by other authors, if leukemic expression is considered as an extranodal involvement, it might serve as prognosis factor in FL. However, differential characteristics of patients with this specific form of presentation are poorly studied. *Aims.* To analyze the main clinical and biological features of patients with FL in morphological leukemic-phase at diagnosis, and to compare them with those of patients without peripheral expression. *Methods.* We retrospectively analyzed the records of 24 patients with FL in leukemic phase at onset, collected from three third-level hospitals in our community. Optical microscopic evidence of lymphoma cells in blood smear was the primary condition to recruit our cases. Among others, studied variables included: sex, age, constitutional B symptoms, FL grade, Ann Arbor stage, Follicular Lymphoma International Prognostic Index (FLIPI), spleen and liver involvement, hemogram, serum LDH and β 2-microglobulin, bone marrow biopsy findings, therapeutic approaches (specifically if rituximab and/or autologous stem cell transplantation were included), best achieved response, time to obtain a complete remission (CR), and survival. Immunophenotypic analysis of lymphomatous cells from blood samples was performed in the group of patients with peripheral expression. Randomly chosen from our database, a group of 30 patients with FL without peripheral blood involvement was used as control-group for comparisons. *Results.* There were not differences in sex, age, histological grade, and serum LDH, between both groups. Of interest, patients with leukemic phase at diagnosis, presented more frequently with B symptoms (p=0.024), and also with a higher incidence of splenomegaly (p=0.009), a higher serum level of β 2-microglobulin (p=0.007), and a lower haemoglobin level and platelet count (p=0.0004 and p=0.006, respectively). All the patients with peripheral expression had bone marrow involvement, while only 63.3% in the other group (p=0.001). According to the FLIPI, 50% of the patients in leukemic phase were classified as high risk, and 33% in the control group (trend to statistical significance, p=0.08). In the group of patients in leukemic phase at diagnosis, lymphocytosis was found in 71% of cases, peripheral lymphocyte count ranging widely from 6.7 to 365×10^9/L. Percentage of FL cells oscillates from 6% to 96% of lymphoid cells in blood (mean 59%). Lymphomatous cells in blood expressed CD19, CD20 and CD79b (100% of analyzed cases), CD10 (91%), CD22 (73%), FMC7 (65%), CD11c (43%), CD38 (42%), and CD23 (30%), and they were consistently negative for CD5 and CD103. Both groups of patients were therapeutically equivalent concerning the use of rituximab and autologous stem cell transplantation. Percentage of cases that reach CR and average time to achieve this CR were similar. Finally, patients with peripheral expression at onset showed a trend to a worse prognosis in terms of survival. *Conclusions.* In our study, patients with FL in leukemic phase at diagnosis presented with features of a greater tumor burden, bone marrow involvement in all cases included. In accordance with other authors, our results suggest that leukemic status may be associated with a worse prognosis in patients with FL. Thus, as indicator of tumour burden, the role of peripheral expression might be reconsidered as prognostic factor, although further studies are needed to confirm these findings.

0421

ORAL VORINOSTAT COMBINED WITH BEXAROTENE IN ADVANCED CUTANEOUS T-CELL LYMPHOMA: A PHASE I STUDY

R. Dummer,[1] K. Hymes,[2] W. Sterry,[3] M. Steinhoff,[3] C. Assaf,[3] H. Kerl,[4] J. Ahern,[5] S. Rizvi,[5] J. Ricker,[5] S. Whittaker[6]

[1]Universitätsspital Zürich - Dermatologische Klinik, ZÜRICH, Switzerland; [2]New York University Medical Center, NEW YORK, USA; [3]Universitätsklinikums Charité, BERLIN, Germany; [4]University Clinic of Dermatology, GRAZ, Austria; [5]Merck Research Laboratories, UPPER GWYNEDD, USA; [6]St John's Institute of Dermatology, LONDON, UK

Background. Vorinostat, an oral inhibitor of Class I and II histone deacetylase (HDAC) enzymes, is registered in the US for treatment of cutaneous manifestations of T-cell lymphoma (CTCL) in patients with progressive, persistent or recurrent disease on or following two systemic therapies. Preclinical studies suggest that vorinostat may synergistically enhance the activity of chemotherapeutic or biological anticancer agents in a variety of solid and haematologic malignancies. This Phase I, multicentre, open-label, non-randomised, dose-escalation study evaluated the combination of vorinostat and the retinoid bexarotene in patients with advanced CTCL. *Aims.* The primary objective was to determine the maximum tolerated dose (MTD) of this combination; secondary objectives included assessment of overall safety and tolerability, and estimation of clinical activity. *Methods.* Eligible patients were aged ≥18 years with stage ≥IB progressive, persistent or recurrent CTCL refractory to ≥1 systemic therapy. There were two parts to the Phase Ia portion of the study. In Part I, patients were enrolled sequentially to receive escalating doses of vorinostat (200-400 mg/day) and bexarotene (150-300 mg/m^2/day). In Part II, the dose of vorinostat was fixed at 400 mg/day and the dose of bexarotene was escalated (150-450 mg/day). Cycles were repeated every 28 days for a maximum of ″6 cycles. A continuation phase of the study was available for patients who experienced

potential clinical benefit after completing six cycles of treatment. *Results.* To date, all 23 patients who received ≥1 dose of study medication have been evaluated for safety. Three patients experienced dose-limiting toxicities (DLTs) at dose level (DL) 2 (Table). No DLTs were observed in the first cycle of DL 2a and 2b. The MTD for Part I was established at vorinostat 200 mg/day plus bexarotene 300 mg/m^2/day. The MTD for bexarotene dose escalation (Part II) was not reached as the study was discontinued early due to low enrolment. One DLT was observed at DL 7; DL 7 was the highest level tested. The most common drug-related adverse events (DRAEs) were hypothyroidism (35%), fatigue (30%), and hypertriglyceridaemia (30%). No Grade 4 or 5 DRAEs were reported and four patients had serious DRAEs (Grade <3). Eighteen patients have discontinued: five due to AEs, six due to progressive disease, and seven withdrew consent. Of 23 patients evaluated for efficacy (prior to the continuation phase), four patients (17%) had an objective response and seven patients (30%) derived clinical benefit (pruritus relief). *Conclusions.* These preliminary data suggest that vorinostat in combination with bexarotene is feasible and requires further investigation in patients with advanced CTCL; however, the dosage of either drug must be reduced to avoid unacceptable side effects.

Table.

Dose level (n=23)	Vorinostat (mg/day)	Bexarotene (mg/m^2/day)	Dose-limiting toxicity No. of patients	Objective response[a,b] n (%)	Pruritus relief[c] n (%)	Best response by individual physician's assessment[a] n (%) Confirmed response	Unconfirmed response	Stable disease	Progressive disease

0422

CLINICAL IMPACT OF SIX-COLOR FLOW CYTOMETRY IN LYMPHOPROLIFERATIVE DISORDERS: IDENTIFICATION AND EXTENDED CHARACTERIZATION OF COMPOSITE LYMPHOMAS

L. Brunetti,[1] A. De Renzo,[2] M. Picardi,[2] F. Chiurazzi,[2] E. Abate,[1] M. Gorrese,[1] M. Raia,[1] A. Gravetti,[1] C. Pascariello,[1] G. Scalia,[1] L. Del Vecchio[1]

[1]Ceinge Institute, NAPLES; [2]Division of Hematology, Federico II University, NAPLES, Italy

Background. Composite lymphomas (CLs) are relatively frequent neoplasms among B-cell chronic lymphoproliferative disorders (CLPDs). Sanchez *et al.* (Blood, 2003) validated the role of three-color flow cytometry for detection of biclonality in single specimens. *Aim.* In this study we used, for first time, six-color flow cytometry for the diagnosis of composite lymphomas with the aim to demonstrate the reliability of this technique in indentification and extended characterization of different clonal populations. *Methods.* In our clinico-diagnostic activity, we studied, form November 2006 to September 2008, 250 samples including peripheral blood (PB), bone marrow asiprates (BM) and fine needle aspiration cytology (FNAC) collected from patients with B-CLPDs. The specimens analyzed for the diagnosis of CLs were 4 PB, 2 BM, and 2 FNAC samples. A total of fifteen antigens were studied (see the Table) in every specimens, introducing in our antibody panel some less used antibodies such as anti-CD43, anti-CD25, anti-CD81 and anti-CD200. The two clones detected in every specimen were named as clone A and clone B. Analysis was performed using FACSCanto II cytometer (Beckton Dickinson, BD, San Jose, USA) and the FACSDiva software (BD). *Results.* Among 250 lympoproliferative disorders, six cases (4,8%) were classified as CLs. Two cases were composed by a marginal zone lymphoma (MZL) clone plus a chronic lymphocytic leukemia (CLL) clone, two cases showed the simultaneous presence of a mantle cell lymphoma (MCL) clone plus a MZL clone, one case was characterized by the presence of a MCL clone plus a follicular lymphoma (FL) clone and one was composed by two different clones of FL. Detection of biclonality was univocal and easy, as well as the extended characterization of clones. Complete immunophenotypes are shown in the Table. The two clonal population found in every specimen are reported as Clone A and Clone B. *Discussion.* In this study two or three flurochromes were exploited to apply high-quality gates and remaining fluorochromes were used to define other cytometrical specificities in each clone, making sure the cytometrical diagnosis of CLs. In four cases cytometrical and histopathological reports did not overlap. Complex architectural patterns in histological and immunohistochemical slides may not enable microscopical identification of different clones. On the other hand, six-color flow cytometry seems to overcome this obstacle capitalizing on analysis of several parameters that cannot be studied with less sophisticated flow cytometry techniques as well as light microscopy. Introduction of CD43 in our panel played a fundamental role in one case. Indeed, in one specimen we were able to completely split two clones only on a CD43-CD10 dot plot. All other investigated antigens gave us no chances to clearly separate two distinct populations. Multicolor techniques are becoming more diffuse day after day and 6-color flow cytometry is already present in a large number of laboratories of hematology. In this study we demonstrated feasibility and simplicity of 6-color flow cytometry in composite lymphomas diagnosis. We also emphasized advantages of this more sophisticated approach that can overcome problems related to a 3-color approach and can allow a cytometrical diagnosis of composite lymphoma even through a single tube analysis.

LONG-TERM FOLLOW-UP OF TANDEM HIGH-DOSE THERAPY WITH AUTOLOGOUS STEM CELL SUPPORT FOR ADULTS WITH HIGH-RISK AGE-ADJUSTED INTERNATIONAL PROGNOSTIC INDEX AGGRESSIVE NON-HODGKIN'S LYMPHOMAS: A GOELAMS PILOT STUDY

H. Monjanel,[1] E. Deconinck,[2] E. Perrodeau,[3] B. Mahé,[4] V. Delwail,[5] A. Moreau,[6] S. François,[7] C. Berthou,[8] E. Gyan,[9] N. Milpied[10]

[1]CHU de Tours, Hopital Bretonneau, TOURS; [2]Service d'Hématologie, CHU Jean Minjoz, BESANÇON; [3]Centre d'Investigation Clinique, CHU de Tours, TOURS; [4]Hématologie Clinique, CHU de Nantes, NANTES; [5]Service d'Onco-Hématologie et Thérapie Cellulaire, Hopital Jean Bernard, POITIERS; [6]Laboratoire d'Anatomie et Cytologie Pathologiques, CHU de Nantes, NANTES; [7]Service des Maladies du Sang, CHU d'Angers, ANGERS; [8]Service d'Onco-Hématologie, Hopital Augustin Morvan, BREST; [9]Service d'Hématologie et Thérapie Cellulaire, CHU de Tours, Hopital Bretonneau, TOURS; [10]Service des Maladies du Sang, Hopital Haut-Léveque, BORDEAUX, France

Background. Single high-dose therapy followed by autologous peripheral blood stem cell support improves the complete response and overall survival in untreated aggressive non-Hodgkin's lymphoma. However, patients with a high age-adjusted international prognostic index retain a poor prognosis with a complete response and 5-year overall survival rates at 46% and 32%, respectively. *Aims.* In an attempt to improve complete response in these patients, the GOELAMS conducted the phase II 073 pilot trial to evaluate upfront tandem high-dose therapy with peripheral blood stem cell support in aggressive non-Hodgkin's lymphoma with high-risk age-adjusted international prognostic index. This study was planned before the era of monoclonal antibodies. *Methods.* All patients aged from 15 to 60 years with previously untreated histologically proven aggressive non-Hodgkin's lymphoma (F, G, H according to the Working Formulation), a high age-adjusted international prognostic

index (equal to 3) provided written informed consent. Two courses of the CEEP regimen (cyclophosphamide, epirubicin, vindesine, prednisone) with two weeks intervals, were planned. Responders underwent tandem high-dose therapy conditioned by high-dose mitoxantrone plus cytarabine for the first high-dose therapy and total body irradiation, carmustine, etoposide and cyclophosphamide for the second. Patients were eligible for the second high-dose therapy if they reached at least a partial response after the first. *Results.* Thirty-one patients out of forty-one evaluable patients completed the program. A total of four toxic deaths occurred during treatment: one after the first CEEP, three after the second high-dose therapy. The intensity of the TBI-containing regimen was subsequently reduced to total body irradiation + cyclophosphamide, resulting in the absence of additional lethal toxicity. The complete response and overall response rates were 49% and 61% respectively. With a median follow-up time of 114 months, 10-year overall survival and progression-free survival are estimated by 51% [38-69%] and 53% [38-73%], respectively. On multivariate analysis, overall survival was significantly affected by serous effusion (p=0.043) and by histology, with a favorable prognosis of the G and H histologies (p=0.026) while progression-free survival was affected by histology (p=0.0064) only. All patients, except one, who survived after ten months were relapse-free. The patient who relapsed with a non aggressive histology (follicular) was successfully treated using rituximab alone. To date, two non-fatal secondary malignancies have been observed (54 and 113 months after inclusion). Of note, no myelodysplastic syndrome or secondary acute myeloblastic leukemia have occurred. *Summary and Conclusions.* With a complete response rate of 49% and a 10-year overall survival estimate of 51%, the 073 compares favorably with other studies. Moreover, the occurrence of a plateau after ten months suggests that a subgroup of patients with aggressive non Hodgkin's lymphoma and with high age-adjusted international prognostic index might be cured by tandem autologous high-dose therapy.

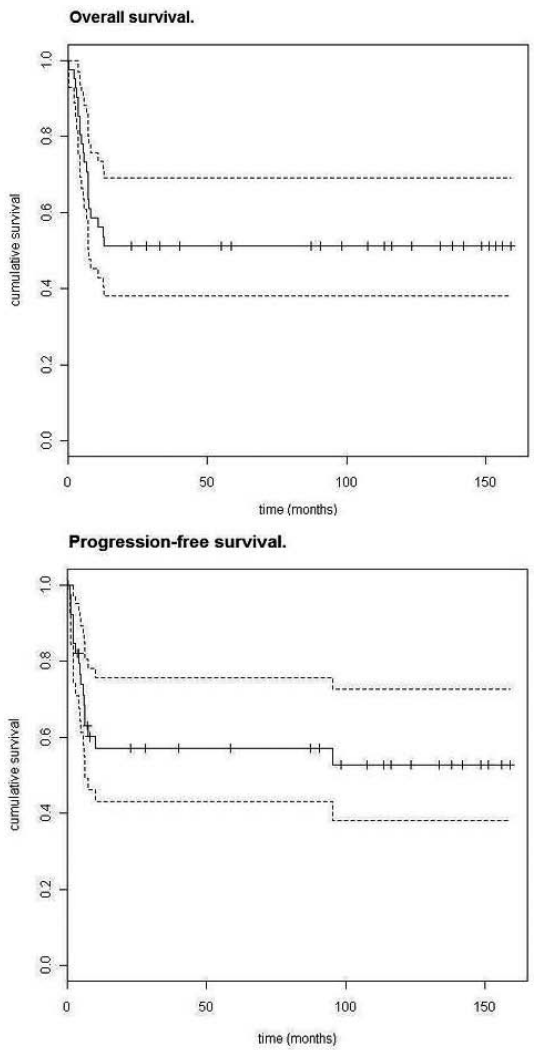

Figure. OS and PFS.

0424

RAPID INFUSION OF RITUXIMAB IS WELL TOLERATED AND ENABLES MORE EFFICIENT USE OF HAEMATOLOGY DAY WARD RESOURCES

S. Peinert, M. Moloney, H.M. Prince, M. Wolf, D. Ritchie, D. Westerman, D. Carney, H. Januszewicz, K. Herbert, S. Harrison, J.F. Seymour

Peter MacCallum Cancer Centre, MELBOURNE, Australia

Background. Rituximab is the only currently approved monoclonal antibody for the treatment of CD20 expressing B-cell malignancies with indications and usage continuously extending. Rituximab is generally well tolerated, however, infusion related toxicity remains a concern. Therefore, the recommended infusion rate is slow, resulting in infusion times of 4-6 hours. This has major implications on the resources of a chemotherapy day ward where a treatment chair usually remains occupied for the whole day by a patient receiving rituximab at the approved infusion rate. *Aim.* We sought to establish a simple, easy to follow schedule as previously described for infusion of rituximab at an increased infusion rate (Rapid Mabthera®) at our institution and in a second step quantify the benefits achieved in resource utilisation. *Methods.* We prospectively collected data from two patient cohorts, the first consisting of patients with B-cell NHL only, without circulating malignant cells, the second cohort included other diseases as well. All pts received their second or subsequent rituximab infusion after having tolerated previous rituximab without grade 3 or 4 adverse events (AEs). All patients received standard premedication including corticosteroids. Pts received 20% of the infusion over 30 mins and the remaining 80% over 60 minutes. All pts were monitored during the rituximab infusion and 30 min thereafter, AEs were recorded and graded according to NCI CTCAE version 2. For the 2nd cohort, the number of patients additionally treated as a result of liberated treatment space was determined. *Results.* Over a period of 14 months, 102 pts (58M, 44F), median age 59 years (range; 16-88) received a total of 284 Rapid Mabthera® infusions. The underlying diseases treated were DLBCL (51%), FL (24%), CLL (13%), other indolent B-cell NHL (10%), and autoimmune diseases (2%). The majority of pts (82/102, 80%) received Rapid Mabthera® in conjunction with chemotherapy (209/284 infusions, 74%). The rapid infusion of rituximab was very well tolerated with no AEs grade 3 or 4 observed. Only 2/284 (0.7%) of Rapid Mabthera® administrations were associated with infusion-related toxicities grade 1 (pruritus and chest pain), both resolved with interruption of the rituximab infusion for 30 min and additional anti-histamine and corticosteroid administration. The infusion was completed at conventional rates without further toxicities. The first patient cohort of 32 pts received a total of 83 Rapid Mabthera® infusions resulting in 208 hrs nursing time saved over a period of 7 months. A total of 201 Rapid Mabthera® infusions were given to the 76 pts of the 2nd patient cohort, resulting in an estimated 503 hrs of additional time the respective treatment spots became available. These liberated resources were used for 15 additional treatments. *Conclusions*. Our data confirm that Rapid Mabthera® administered over 90 min is well tolerated when given as second or subsequent administration and results in considerable saving of nursing time. However, this translated into modest additional patient treatment opportunities, most likely due to conventional allocation of treatment slots. Greater confidence in the ability to deliver rapid infusions will allow more efficient resource utilisation.

A NOVEL GERMLINE MUTATION IN MSH6 - IMPLICATIONS FOR THE CLINICAL CARE OF CHILDHOOD LEUKAEMIA/LYMPHOMA PATIENTS

T. Ripperger,[1] C. Beger,[1] N. Rahner,[2] K.W. Sykora,[1] C. Bockmeyer,[1] U. Lehmann,[1] H.H. Kreipe,[1] B. Schlegelberger[1]

[1]Hannover Medical School, HANNOVER; [2]University of Bonn, BONN, Germany

Background. Constitutional mismatch repair deficiency is caused by homozygous or compound heterozygous germline mutations in mismatch repair (MMR) genes, e. g. MLH1, MSH2 and MSH6, leading to a severe cancer susceptibility syndrome designated as mismatch repair cancer syndrome (MMRCS, MIM). Compared to Lynch syndrome (LS) caused by heterozygous germline mutations in the same genes, MMRCS is characterized by a more severe clinical phenotype with childhood onset of leukaemias / lymphomas or brain tumours, early onset of Lynch syndrome-associated malignancies, and phenotypic features of neurofibromatosis type 1. To illustrate the clinical implication of this syndrome for the management of childhood leukaemia/ lymphoma patients, we report here on a female index patient with MMRCS caused by a novel homozygous germline mutation in MSH6. *Subjects*. The female index

patient, having several café-au-lait spots, developed a mediastinal T-cell lymphoblastic lymphoma at age 6. Following chemotherapy, she relapsed and underwent haematopoietic stem cell transplantation from a matched sibling donor. By the age of 13, she was referred for genetic counselling due to the diagnosis of colorectal cancer. Her consanguineous parents reported on colorectal cancer at age 42 in a paternal uncle married to the sister of the index patient's mother, but LS or MMRCS was not yet considered. *Results.* The index patient's colon cancer showed high-grade microsatellite instability (MSI). Immunohistochemistry demonstrated a loss of MSH6 both in normal and cancer cells. Sequence analysis of MSH6 detected the homozygous germline mutation c.691delG (p.Val231TyrfsX15). Subsequently, the parents of the index patient and the affected paternal uncle, whose synchronous colorectal carcinomas also displayed MSI and loss of MSH6, were shown to be heterozygous carriers of the frame shift mutation. *Conclusions.* We report here on a novel MSH6 mutation and provide clinical information on a further family with LS and MMRCS. Although LS is well known, up to now there are only few reports on MMRCS. This report further emphasizes how important it is to be aware of MMRCS in pedigrees with Lynch syndrome-associated cancer, e.g. early-onset colon cancer, and childhood leukaemia / lymphoma and / or brain tumour. The synchronous colorectal carcinomas of the affected uncle, retrospectively the first evidence of a mismatch repair defect in the reported family, were diagnosed one year before the lymphoma relapse of the index patient and six years before she was diagnosed with colorectal cancer. Up to now, no evidence-based screening recommendation exists for patients with constitutional mismatch repair deficiency. Nevertheless, early diagnosis of this severe cancer susceptibility syndrome may improve the clinical management of affected individuals and their relatives at risk.

DOSE-DENSE THERAPY WITH NON-PEGYLATED LIPOSOMAL DOXORUBICIN, CYCLOPHOSPHAMIDE, VINCRISTINE, PREDNISONE AND RITUXIMAB (R-COMP) IS FEASIBLE AND EFFECTIVE IN ELDERLY PATIENTS WITH NEWLY DIAGNOSED AGGRESSIVE B-CELL NON-HODGKIN LYMPHOMA: R-COMP 14 VS R-COMP 21. INTERIM ANALYSIS FROM AN ITALIAN MULTICENTE

G. Visani,[1] F. Ferrara,[1] F. Merli,[1] F. Angrilli,[1] F. Ilariucci,[1] S. Falorio,[1] G. Fioritoni,[1] F. Alesiani,[2] M. Brunori,[1] F. Pollio,[1] M. Celentano,[1] D. Cangini,[3] S. Ronconi,[3] M. Catarini,[4] G. Giglio,[1] D. Vallisa,[1] A. Arcari,[1] D. Bernardi,[5] B. Guiducci,[1] S. Barulli,[1] F. Loscocco,[1] A. Isidori[1]

[1]Department of Hematology, PESARO; [2]Department of Oncohematology, SAN SEVERINO MARCHE; [3]Department of Oncology, FORLI; [4]Department of Internal Medicine, MACERATA; [5]Department of, SAN DONÀ DI PIAVE, Italy

The toxicity and efficacy of nonpegylated liposomal doxorubicin (MyocetTM) when substituted for conventional doxorubicin in the CHOP 14 or 21 regimen (Doxorubicin, Cyclophosphamide, Vincristine, Prednisone given every 2 or 3 weeks) were evaluated in the treatment of elderly patients with newly diagnosed aggressive B-cell non-Hodgkin's lymphoma. Forty-eight patients with aggressive B cell non-Hodgkin lymphoma at diagnosis were enrolled so far in the study. Patients were split in 2 groups according to the Multidimensional Geriatric Assessment (MDGA). Patients with an Activities of Daily Living (ADL) = 6 were addressed to receive dose-dense R-COMP every 2 weeks (14), whereas patients with an ADL > 7 were addressed to receive R-COMP every 3 weeks (21). Starting from this background, 30 patients were enrolled in the R-COMP 21 arm and 18 in the R-COMP 14 arm. The study was planned as a double phase II according to a single-step Fleming design using 3 years event-free survival as primary endpoint. The characteristics of patients enrolled in the study were as follows: the median age was 72 years (range: 67-80) in the R-COMP 14 group and 75 years (range: 66-89) in the R-COMP 21. At baseline 13/18 (72%) patients had stage IV disease in the R-COMP 14 group, whereas 13/30 (43%)in the R-COMP 21. Median performance status and median number of comorbities were comparable between the 2 groups. Thirteen out of 18 (72%) patients had an intermediate or high risk International Prognostic Index score in the R-COMP 14 group, compared to 12/30 (40%) in the R-COMP 21. The median left ventricular ejection fraction (LVEF) before starting chemotherapy was comparable between the two groups (59% vs 60%). A total of 261 cycles of chemotherapy were administered (96 R-COMP 14 and 165 R-COMP 21). Of the cycles administered, 9 (9%) were delayed by haematological toxicity in the R-COMP 14 group and 11 (7%) in the R-COMP 21 group, with a relative dose intensity for the regimens of 91% and 93%, respectively. Toxicity was mainly haematological in both groups. Grade 3/4 neutropenia occurred in 10% and 24% of cycles in the R-COMP 14 and 21 groups respectively, with an incidence of febrile neutropenia of 3% and 5% respectively. It is of note that patients addressed to receive dose-dense chemotherapy were treated with pegfilgrastim on day +2 during the entire study treatment, with a notable reduction in the incidence of both severe and febrile neutropenia. Regarding cardiotoxicity, only 1/18 patients presented a grade II-IV WHO toxicity (atrial fibrillation) in the R-COMP 14 group, whereas 4/30 in the R-COMP 21 group (one congestive heart failure, two ischemic heart failure, one reduction of 20% in the LVEF). All patients were evaluable for response between the two groups. In the R-COMP 14 group, 15/18 patients (83%) obtained a CR, 2/18 (11%) achieved a PR, and 1/18 (6%) did not respond to therapy and rapidly died due to progressive disease. In the R-COMP 21 group, 20/30 patients (67%) obtained a CR, 7/30 (23%) achieved a PR, and 3/30 (10%) did not respond to therapy and rapidly died due to progressive disease. With a median follow-up of 7 months (range 2-12) and 10 (range 4-24) as of January 2009, 15/18 patients (83%) and 25/30 (83%) are alive and disease free in the R-COMP 14 and in the R-COMP 21 group, respectively. In conclusion, the stratification of patients according to the MDGA allows elderly and fit patients with aggressive B-cell NHL with poor prognosis (high IPI score) to receive dose dense chemotherapy which might favorably impact on response rate and survival. The increased response rate obtained with dose-dense R-COMP 14 might impact on long-term event-free survival. A longer follow-up is warranted to better define the impact of dose-dense R-COMP regimen on overall survival of patients with high-intermediate or high IPI score.

ALLOGENEIC STEM CELL TRANSPLANTATION IN NON-HODGKIN'S LYMPHOMA PATIENTS WHO PROGRESSED AFTER HIGH DOSE CHEMOTHERAPY WITH AUTOLOGOUS STEM CELL TRANSPLANTATION: A RETROSPECTIVE STUDY BASED ON DONOR AVAILABILITY

J.W. Kim,[1] B.S. Kim,[2] S.M. Bang,[3] I. Kim,[1] S.S. Yoon,[1] J.S. Lee,[3] K.S. Han,[1] S. Park,[1] B.K. Kim[1]

[1]Seoul National University Hospital, SEOUL; [2]Seoul Municipal Boramae Hospital, SEOUL; [3]Seoul National University Bundang Hospital, SEONGNAM, South-Korea

Background. There are few treatment options in non-Hodgkin's lymphoma (NHL) patients who progressed after high dose chemotherapy (HDC) with autologous stem cell transplantation (auto-SCT). The role of allogeneic stem cell transplantation (allo-SCT) in these patients has not yet been clarified. *Aims.* The objective of this study was to investigate the role of allo-SCT in NHL patients who progressed after HDC with auto-SCT. *Methods.* Retrospective analyses were performed on NHL patients who underwent human leukocyte antigen (HLA) typing after failure of HDC with auto-SCT between February 1998 and November 2008. We compared patients who received salvage allo-SCT (allo-SCT group) with those who did not have a suitable donor and received salvage chemotherapy only (chemotherapy group). Analyses of clinical outcomes of allo-SCT were also performed. *Results.* A total of 30 patients (male, 20) were included. Median age was 38 years (range, 17-61). During a median follow-up of 43.3 months (range, 3.9-103.4), 20 patients (allo-SCT group) received allo-SCT from a suitable donor: 15 HLA-identical siblings (75.0%) and 5 matched unrelated donors (25%). The other 10 patients (chemotherapy group) did not have a donor and received salvage chemotherapy only. In allo-SCT group, 11 patients received conventional conditioning (CC) and 9 patients received reduced intensity conditioning (RIC). Median overall survival (OS) from the time of failure after HDC with auto-SCT was 11.9 months (95% confidence interval (CI), 3.2-20.6). Allo-SCT group (21.5 months (95% CI, 7.9-35.1)) had significantly longer OS than chemotherapy group (3.4 months (95% CI, 0.5-6.3); p=0.002). In allo-SCT group, median event-free survival (EFS) and OS from allo-SCT were 2.8 (95% CI, 0.0-6.5) and 19.0 months (95% CI, 4.0-34.0), respectively. Estimated 5-year survival rate of allo-SCT group was 33.8%. There was no significant difference in EFS and OS between CC group and RIC group. Median number of $CD34^+$ cells infused was 4.36×10^6/kg (range, 1.26×10^6-10.37×10^6). Median time to recovery of neutrophil (>500/microliter) and platelet (>20,000/microliter) was 17 and 27 days, respectively. Median duration of hospitalization after allo-SCT was 26 days (range, 2-54). Acute graft-versus-host disease developed in 4 patients (20.0%). There were 5 transplant-related deaths (25.0%). Incidence of transplant-related mortality (TRM) in CC group tended to be higher than that in RIC group (36.4% vs. 11.1%; p=0.319). Patients with low baseline serum albumin level (<3.0 g/dL) had significantly higher TRM (75.0% vs. 12.5%; relative risk 21.0 (95%

CI, 1.4-314.0); *p*=0.027) as well as shorter EFS (0.3 months (95% CI, 0.0-1.4) vs. 4.9 months (95% CI, 2.0-7.8); hazard ratio (HR) 7.4 (95% CI, 1.4-38.0); *p*=0.017) and OS (0.3 months (95% CI, 0.0-1.4) vs. 22.1 months (95% CI, 14.6-29.6); HR 11.9 (95% CI, 1.9-74.9); *p*=0.008) after allo-SCT. *Summary and Conclusions.* Despite high TRM, allo-SCT is a viable option in NHL patients who progressed after HDC with auto-SCT. Low baseline serum albumin level (<3.0g/dL) was related to higher TRM and shorter EFS and OS in this group.

0428

IFOSFAMIDE, EPIRRUBICIN, AND ETOPOSIDE (IEV) AS MOBILIZATION-THERAPY REGIMEN FOR PATIENTS WITH NON-HODGKIN LYMPHOMA AND HODGKIN DISEASE: COMPARISON WITH OTHER CHEMOTHERAPY REGIMENS

L. Quintana-Paris,[1] J.M. Bergua,[2] J. Sanchez-Garcia,[1] J. Serrano,[1] H. Bañas,[2] M.A. Alvarez,[1] J. Prieto-Fernandez,[2] G. Rodriguez-Garcia,[1] M. Bengochea-Casado,[2] A. Torres-Gomez[1]

[1]University Hospital Reina Sofia, CORDOBA; [2]Hospital San Pedro de Alcantara, CACERES, Spain

*Background and Aims.*High dose chemotherapy and autologous peripheral blood stem cell (PBSC) rescue is a treatment modality for lymphoma patients presenting with high risk features or relapse/refractory disease. PBSC can be obtained using growth factors alone or in combination with chemotherapy. The latter approach could be more effective to mobilize stem cells with an additional anti-lymphoma effect. Among these regimens, Ifosfamide, epirrubicin and etoposide (IEV) has been described as effective providing a high response rate in refractory/relapse patients and excellent mobilizing characteristics, but comparison with other chemotherapy regimens is lacking. In this study, we analyze the efficacy of IEV to mobilize stem cells and the impact on outcome after transplant compared with other chemotherapy regimens. *Patients and-Methods.* We included 74 patients who underwent autologous PBSC transplant for Non-Hodgkin lymphoma (NHL) and Hodgkin Disease (HD) in two institutions. 35 patients (19 HD and 16 NHL) in first complete remission (n=7), relapse (n=25) or refractory (n=3) disease received IEV regimen (Ifosfamide 2.500 mg/m^2, days 1-3, epirrubicin 100mg/m^2 day 1, etoposide 150 mg/m^2 days 1-3). 39 patients matched for diagnosis and status at transplant who received other chemotherapy schedules (OCS) (Cyclophosphamide 23.1%. ESHAP 20.5%, Etoposide 12.8%, ABVD/MOPP 7.7%, DexaBEAM 5.1% and Hiper-CVAD 5.1%), were used as cohort-control. Conditioning regimen was mostly BEAM (83.8%) and Total body irradiation + Cyclophosphamide (16.2%). *Results.* Number of CD34 positive cells obtained was higher with IEV regimen (8.2±1.5 vs. 5.4±0.7×10^{6}7Kg, *p*=0.08) compared to other regimens. The median of leukapheresis procedures was 1.5 (range 1-5) for IEV group and 2 (range 1-8) for OCS group (*p*=0.01). Meaningfully, we observed a earlier neutrophil (>500) engraftment day (10.5±1.4 vs. 12±4.5, *p*=0.08) and platelet (>20.000) engraftment day (11.2±3vs. 13. 6± 3.9, *p*=0.01) in IEV group. Disease free survival (DFS) for IEV group was 57.7±9.9% and 43.2 ±9.1% for OCS group (*p*=0.4). Overall survival (OS) was also higher in IEV group (55.8±10.7 vs. 36.1±12.1%) but these figures did not reach statistical differences. *Conclusions.* IEV regimen is highly effective in mobilizing PBSC for autologous transplant in patients with HD and NHL comparing to standard chemotherapy regimens, resulting in a faster hematopoiesis recovery. OS and DFS after transplant were also higher, although we did not find statistical differences.

0429

SMALL LYMPHOCYTIC LYMPHOMA: RETROSPECTIVE ANALYSIS FROM THE REGISTRY OF CZECH LYMPHOMA STUDY GROUP

L. Smolej,[1] I. Vasova,[2] J. Salkova,[3] D. Belada,[1] A. Sykorova,[1] M. Jankovska,[4] V. Campr,[5] H. Krejcova,[3] M. Trneny[3]

[1]University Hospital and Medical School, HRADEC KRALOVE; [2]Internal Department of Hematooncology, University Hospital, BRNO; [3]First Department of Medicine, Charles University General Hospital, PRAGUE; [4]Department of Clinical Hematology, University Hospital Kralovske Vinohrady, PRAGUE; [5]Institute of Pathology and Molecular Medicine, University Hospital Motol, PRAGUE, Czech Republic

Background. Small lymphocytic lymphoma (SLL) accounts for 3-10% of Non-Hodgkin´s lymphomas (NHL). According to World Health Organisation classification of lymphoid neoplasms, SLL forms a common entity with chronic lymphocytic leukemia (CLL). SLL differs from CLL only by arbitrary cut-off of circulating malignant lymphocytes below 5000/mm^3. SLL is still a relatively poor-defined entity with few published data, partly because clinical studies in CLL usually exclude patients with SLL. This results in marked variability in diagnostic and especially therapeutic strategies; uniform guidelines for SLL do not exist. *Aims.*to perform a retrospective analysis of patients (pts) with SLL focused on diagnostic and therapeutic approach in real practice. Patients and *Methods.* As of April 2008, the Czech Lymphoma Study Group (CLSG) registry contained data from 161 patients (63% males, median age 65 years [range, 29-87]) who fulfilled diagnostic criteria for SLL, i.e. coexpression of CD5/C19/23 by flow cytometry or immunohistochemistry and peripheral blood lymphocytes <5000/mm^3. Cases of SLL comprised 3.4% of all NHL in CLSG registry. *Results.* Ann Arbor stage I/II/III/IV was present in 6/2/8/84%. Splenomegaly was detected in 18%, elevated lactate dehydrogenase (LDH) in 30% and bone marrow involvement in 79% of pts. Of note, 91% pts underwent computer tomography (CT) of thorax and abdomen as part of initial staging. Mediastinal and retroperitoneal lymphadenopathy was discovered in 42% and 68%. Generalized lymphadenopathy (more than 4 involved regions) was found in 49%. Bulky lymphadenopathy (>5 cm) was present in 38%. Thirty percent of pts had B-symptoms. Age-adjusted International Prognostic Index (aa-IPI) score 0/1/2/3 was present in 7/49/38/6%. Treatment was initiated in 156 pts: chemotherapy in 94 and chemoimmunotherapy in 56 pts (rituximab, 55 pts; alemtuzumab, 1 case). Four patients were treated by radiotherapy and two by surgery. The most frequent regimens used in first line were CVP (18%), CHOP (17%), R-CVP (15%), chlorambucil (15%), FCR (11%), FC (10%) and R-CHOP (10%). Median follow-up was 37.7 months (mo). Median progression-free-survival (PFS) and overall survival (OS) were 35.3 and 63.3 mo. None of the prognostic factors (Ann Arbor stage, aa-IPI, elevated LDH, bulky lymphadenopathy) had significant influence on OS. Similarly, OS was not affected by the type of treatment (fludarabine-based vs. anthracycline-based vs. other; addition of rituximab to chemotherapy). *Conclusions.* Results from CLSG registry confirm previously published demographic data on SLL. In contrast to CLL (where routine radiological assessment is not recommended by NCI-WG criteria), nearly all SLL patients underwent CT for staging. Bulky lymphadenopathy was detected in more than a third of pts. No prognostic factors influencing overall survival were identified. Therapeutic strategies varied greatly; two thirds of pts were treated by regimens commonly used in other indolent lymphomas. Our study underscores the need for standardized diagnostic and therapeutic approach to SLL. Supported by grant NR/ 9453-3 and research project MZO 00179906 from Ministry of Health, Czech Republic.

PHARMACODYNAMIC ANALYSES OF PERIPHERAL BLOOD FROM RELAPSED B-NHL PATIENTS TREATED WITH ANTI-CD19/-CD3 BISPECIFIC BITE≥ ANTIBODY BLINATUMOMAB

M. Klinger,[1] D. Nagorsen,[1] C. Brandl,[1] S. Wissing,[1] P. Meier,[1] P.A. Baeuerle,[2] P. Kufer[1]

[1]Micromet AG, MÜNCHEN, Germany; [2]Micromet Inc., BETHESDA, MD, USA

Introduction. Blinatumomab (MT103/MEDI-538), a BiTE® antibody bispecific for CD19 and CD3, redirects and activates T cells resulting in the lysis of B lymphoma and normal B cells. An ongoing phase 1 single-agent dose escalation study in patients with advanced B-NHL has shown sustained complete and partial objective responses for up to and exceeding 12 months. *Methods.* Peripheral blood of patients with relapsed B-NHL undergoing treatment with blinatumomab was analyzed for counts of B cells, T cells and T cell subsets as well as T cell activation markers and cytokine levels at defined time points during the course of continuous i.v. treatment. *Results.* Blinatumomab caused a rapid reduction of B cell counts, which was amplified and accelerated with increasing dose levels. This reduction was caused by B cell depletion mediated by apoptosis. Specific fluctuations of T cell counts with a high inter-patient variability were seen. After onset of continuous infusion of blinatumomab, a fast disappearance of CD4$^+$ and CD8$^+$ T cells in peripheral blood within hours was followed by reappearance within few days. The majority of reappearing T cells expressed activation marker CD69 and to a lesser extent CD25 and HLA-DR. In most cases, peripheral T cell counts exceeded after several weeks of treatment those at baseline. Analysis of T cell subpopulations indicated that the expansion of peripheral T cell counts was limited to the subset of CD8$^+$ and CD4$^+$ effector memory T cells as defined by the absence of CD45RA and CCR7 markers. Counts of other T cell subsets remained more or less constant during treatment with blinatumomab, including those of naïve T cells defined as CD45RA$^+$/CD28$^+$. No clinical signs of cytokine release syndrome have

been observed. Nevertheless, cytokines IL-2, IL-6, IL-10, TNF-α, and IFN-gamma were detected in serum samples of patients treated with blinatumomab doses of 0.030 mg/m²/24 h and higher. All cytokine signals showed maximum levels within less than 24 h after onset of infusion and mostly returned to baseline within 24 h for the remaining treatment period. Of note, no IL-4 levels were detected. *Conclusions.* Blinatumomab dose-dependently depleted B cells from peripheral blood for the entire treatment period. Both $CD4^+$ and $CD8^+$ T cells of patients undergoing treatment with blinatumomab showed a specific pattern of activation, rapid redistribution and a subsequent expansion of effector memory cells with high inter-patient variability. Dose-dependent cytokine signals were transient and occurred early during treatment.

0431

SAFETY AND EFFICACY OF BENDAMUSTINE WITH OR WITHOUT RITUXIMAB IN THE TREATMENT OF HEAVILY PRETREATED PATIENTS WITH LYMPHOMA OR CLL. A MULTICENTER RETROSPECTIVE STUDY

L. Rigacci,[1] B. Puccini,[1] A. D'Arco,[2] E. Orciuolo,[3] S. Cortelazzo,[4] G. Gaidano,[5] C. Patti,[6] P. Musto,[7] P.L. Zinzani,[8] S. Storti,[9] A. Carpaneto,[10] N. Di Renzo[1],[1] N. Seràgnoli, BOLOGNA; [9]UOC di Onco-Ematologia Università Cattolica del Sacro Cuore, CAMPOBASSO; [10]Ematologia Ospedale di Ronciglione, VITERBO; [11]Ematologia Ospedale V. Fazzi, LECCE; [12]Ematologia Casa Sollievo della Sofferenza, S. GIOVANNI ROTONDO, Italy

Background. Bendamustine is an alkylating agent with a nitrogen mustard group and a purine like benzimidazol group. It was developed in 1960s but was never systematically studied in patients until 1990s. Recently this drug was introduced in Italy and it was used in pretreated patients to test its efficacy and safety. *Aims.* The aim of this study was to collect nationwide cases treated with bendamustin in order to evaluate response to therapy and haematological and extra-hematological toxicities. We analized all patients treated in eleven haematological Italian centers with Bendamustine alone or in combination with anti-CD20 antibody. *Methods.* Patients who have received at least one complete cycle were evaluated for response and toxicity, patients with ongoing therapy were not evaluated for response but were evaluated for toxicity. Treatment consisted of: Bendamustine 60-90 mg/m² days 2,3 alone or in combination with Rituximab 375 mg/m² day 1, every 21 or 28 days. *Results.* One hundred and twenty-two patients were analized, median age was 65 (range 31-87), 83 were male and 39 female, the diagnosis were: 40 chronic lymphatic leukaemia 28 indolent non-follicular lymphoma (small lymphocitic, marginal, lymphoplasmocitic), 20 diffuse large B cell lymphoma, 19 follicular lymphoma, 13 mantle cell lymphoma, 2 Peripheral T cell lymphoma. Patients were heavily pretreated and the median number of previous treatments was 3 (range 1-8). Fifthy patients have experienced more than three chemotherapy schemes. Ninety-six patients were previously treated with Rituximab and 21 had performed an autologous stem cell transplantation. The Bendamustine pre-treatment condition was: 53 relapsed patients, 28 with refractory disease and 41 with a progressive disease after partial response. The median number of Bendamustine cycles was 4 (range 1-11), 23 patients were on treatment. Ninety-seven patients were evaluable for response: 25 (26%) complete remission, 52 (54%) partial response or stable disease with an overall response rate of 81%. Nineteen patients were judged as non responders. No differences were observed according to Bendamustine dosage or scheduling. Interestingly, we observed that all evaluable patients with mantle cell lymphoma obtained a response (5 CR and 4 PR). Also, 22/23 (4 CR and 18 PR) indolent non follicular lymphoma and 13/15 (6 CR and 7 PR) follicular lymphoma obtained a response, 26/31 CLL obtained a response and 7/18 (3 CR and 4 PR) DLBCL obtained a response to therapy. With a median period of observation of 7 months (1-36), 78% of patients are alive. In this group of heavily pretreated patients, 498 cycles were performed: the extrahematological toxicity was acceptable in a subset of heavily pretreated patients (2 fatal sepis) and the hematological toxicity was trombocytopenia grade 3-4 in 7 patients and neutropenia grade 3-4 in 14 patients. *Conclusions.* In conclusion this retrospective study shows that treatment with Bendamustine alone or in combination with Rituximab is a safe and effective regimen in a subset of pluriresistent patients with lymphoma and CLL. These data show also that the best results could be obtained in indolent lymphoma and that data in mantle cell lymphoma are encouraging.

0432

CONTINUOUS, ORAL CYCLOPHOSPHAMIDE AND PREDNISOLONE AS A VALID TREATMENT OPTION FOR PERIPHERAL T CELL LYMPHOMA

A. Tucci,[1] E. Cerqui,[1] M. Ungari,[1] S. Ferrari,[1] A. Bacigalupo,[2] F. Facchetti,[1] G. Rossi[1]

[1]Spedali Civili, BRESCIA; [2]Ospedale S. Martino, GENOVA, Italy

Background. Peripheral T cell lymphomas (PTCL) are associated with a poor clinical outcome, regardless of the different treatments employed. Although anthracycline-containing regimens like CHOP are still the most frequent treatment used, there is no evidence that anthracyclines are of benefit in PTCL and alternative options are needed. Since patients often showed recurrence of symptoms, particularly fever, during the intervals between CHOP cycles, we decided to use long term administration of low dose oral cyclophosphamide and corticosteroids to try to continuously keep the lymphoma under control. *Aim.* to retrospectively compare the outcome of the series of patients with PTCL treated either with aggressive anthracycline-containing therapy, or with a therapeutic plan consisting in chronic oral cyclophosphamide and prednisolone administration. *Patients and Methods.* Fifty-five patients with a diagnosis of unspecified PTCL (PTCL-U) or angioimmunoblastic T cell lymphoma (AILD-T), consecutively seen at our Institute from January 1993 to December 2008, were considered. Treatment included: polychemotherapy, particularly CHOP or CHOP-like regimens, or oral cyclophosphamide 2.5 mg/Kg for 4 months and 1.5 mg/Kg for the subsequent 2 months and prednisolone starting at the dose of 1 mg/Kg and tapering it slowly over one year. Cyclophosphamide dose was adjusted based on WBC count. Eleven patients were excluded: two for early death, two lost of follow up, 3 with stage I treated with radiation only, 4 receiving corticosteroids only. Twenty patients received polichemotherapy (group PKT) and 24 cyclophosphamide and prednisolone (group CyPD). *Results.* The overall RR was 60% vs 46% (p=0.38) in group PKT and CyPD respectively; 5 ys PFS and OS were 13% (+ 12) and 29% (+ 13) in group PKT vs 26% (+15) and 31% (+ 11) in group CyPD respectively with no difference between the two groups (p=0.73 and p = 0.9). PKT and CyPD groups did not differ for main clinical characteristics including Ann Arbor stage (stage III/IV: 75% vs 91.6%), IPI score (intermediate-high/high score: 60% vs 70.8%). However mean age was significantly higher in CyPD group (64.7 vs 55.2; p = 0.038) which also had a significantly higher number of patients with the PIT high risk score (42% vs 10%; p=0.039). Median follow up was 16 months for group PKT (range 1-111) and 17 months for group CyPD (range 1-111). Toxicity was acceptable in both groups; cause of death was lymphoma in all patients except in two patients in group PKT (pneumonia and pulmonary thromboembolism) and in three patients in group CyPD (one pneumonia and two CMV infection). *Conclusions.* Overall survival data confirm the bad prognosis of patients with PTCL; however our analysis shows that the same results obtained with CHOP/CHOP-like regimens can be also obtained using less intensive, chronic, outpatient treatment with oral cyclophosphamide and prednisolone even in older patients and in patients with bad prognostic characteristics.

0433

LONG TERM OUTCOME OF HIGH DOSE ARACYTINE, RITUXIMAB, AND DEXAMETHASONE CHEMOTHERAPY FOR AGGRESSIVE MANTLE CELL LYMPHOMA IN ELDERLY PATIENTS

R. KOTB, J.A. Boisjoly, P. Beauregard, M. Lepine-Martin

CHU de Sherbrooke, SHERBROOKE, Canada

Mantle cell lymphoma (MCL) mainly affects elderly, and response to standard therapy is deceiving. High dose chemotherapy could ameliorate these results, but this is too toxic for elderly and fragile patients. We evaluate the safety and efficacy of chemotherapy associating High dose Aracytine, Rituximab and Dexamethasone (HARD) for the treatment of elderly patient with aggressive MCL. Patients & *Methods.* From November 2005, patients with aggressive MCL were eligible to receive HARD chemotherapy. All patients received Rituximab 375 mg/m²/cycle and Dexamethasone 40 mg/d x3 /cycle. The dose of Aracytine was modulated according to the general condition and accompanying comorbidities. Data were revised for all patients, and comorbidities were assessed according to medical records. *Results.* Eight consecutive patients, 5 males

and 3 females, median age 72.6 years (65-77) with aggressive MCL were treated by HARD based chemotherapy. All presented with an aggressive histological pattern, stage III or IV disease according to Ann Arbor classification. The majority had performance score >2 (6/8), high LDL (6/8), high β2-microglobulin (5/5), Hemoglobin level <12 g/dL (5/8). The FLIPI score was high-intermediate / high in most patients (7/8). The Charlson comorbidity score was >5 in most patients (7/8) and principal documented comorbidities were coronary heart disease (3/8), cardiac systolic dysfunction (3/8 with LVEF <55%), cerebrovascular diseases (3/8), chronic renal insufficiency (creatinine clearance <60 cc/min) (4/8)), and chronic respiratory disorders (3/8). A total number of 43 HARD based chemotherapy cycles were given. All patients received planned doses of Rituximab and dexamethasone. The median initial dose of Aracytine was 2.5 g/m2 (1.12 - 4 g/m^2), which was subsequently modified according to patient's tolerance. There were five episodes of thrombocytopenia and five episodes of anemia requiring transfusion. One patient developed acute transfusion reaction complicated by myocardial infarction with pulmonary edema and acute renal insufficiency that responded well to medical treatment. Only one cycle of chemotherapy was complicated by febrile neutropenia. There was no treatment associated mortality. Six patients responded favourably, 4 in complete remission (CR) that is still maintained for three, with a follow-up of 36, 26 and 17 months; while the forth patient relapsed 19 months later, and is currently in second CR after re-treatment with HARD, with 9 months of follow-up. Two patients had a partial remission that persisted for 15 and 6 months before disease progression to leukemic phase MCL and they died at 19 and 11 months. Two other patients were refractory and died rapidly from progressive disease. Of note that both patients had leukemic phase MCL at the time of treatment. *Conclusions.* HARD based chemotherapy is safe and effective in geriatric patients with MCL, providing that the dose is modulated according to patient comorbidities. Despite the modulation of the dose of Aracytine, the response rate is interesting and compares favourably with regimens adapted for young and physically fit patients.

0434

DOSE INTENSITY IN HODGKIN AND NON-HODGKIN'S LYMPHOMA

J.M. Mariz,[1] A. Teixeira,[2] A. Marques Pereira,[3] J. Espírito Santo,[4] M. Marques,[1] E. Magalhães,[2] C. Portela,[5] M.C. Trindade,[3] R. Costa,[4] I. Oliveira,[1] R. Vieira,[6] H. Marques[5]

[1]Instituto Português de Oncologia do Porto Francisco Gentil, E.P.E., PORTO; [2]Hospitais da Universidade de Coimbra, COIMBRA; [3]Hospital Garcia de Orta, E.P.E., ALMADA; [4]Hospital Nossa Senhora do Rosário, E.P.E., BARREIRO; [5]Hospital de São Marcos, BRAGA; [6]Eurotrials, Scientific Consultants, LISBOA, Portugal

Background. The major dose-limiting toxicity of anti-cancer chemotherapy (CT) is myelosuppression. The risk of neutropenic complications, frequency of dose reductions, and treatment delays in patients (pts) with Hodgkin (HL) and Non-Hodgkin's lymphoma (NHL) compromise Relative Dose Intensity (RDI) and consequently long-term outcome. *Aims.* Primarily to assess the risk factors for reduced RDI in pts treated with CT for HL and NHL in first line treatment regimens. Secondarily, to assess the incidence of grade 3 and 4 neutropenia and evaluate patterns of Granulocyte-Colony Stimulating Factors (G-CSF) use. *Methods.* Multicentre retrospective survey was conducted in 5 Portuguese oncology centres to evaluate CT treatments in 370 pts with HL and NHL that started CT between 2005-2007. Data from pts treated with ABVD (doxorubicin, bleomycin, vinblastine, dacarbazine), R-CHOP 21 like (R-CHOP) (rituximab, cyclophosphamide, vincristine, doxorubicin/mitoxantrone, prednisolone) and CHOP 21 like (CHOP) regimens was analysed using Dose Intensity Evaluation Programme (DIEP®) software, developed to allow calculation of RDI and registry of demographic and clinical data. Univariate and multivariate analyses were performed to identify factors related to RDI ″90% of standard. *Results.* One hundred and six pts (29%) were diagnosed with HL (median age: 31 years) and 99% of them were treated with ABVD. R-CHOP (49.2%, median age: 62 years) and CHOP (26.1%, median age: 72 years) were the most common CT regimens for the 264 pts diagnosed with NHL (median age: 62 years). Although overall median RDI was 97%, 19% of pts had a RDI ″90%. Univariate analysis revealed that reduced RDI was predominant in pts older than 65 years, with secondary extranodal involvement, higher levels of creatinine, and lower levels of haemoglobin. Within CT regimens groups differences in proportion of pts with reduced RDI was also statistically significant (ABVD: 20%, CHOP: 33%, R-CHOP: 20%). Primary prophylaxis with G-CSF was associated to RDI > 90%. Incidence of hospitalization were also significantly different in RDI ″ 90% (21%) and RDI >90% (9%) groups, as well the duration of hospitalization (median: 18 days and 6 days, respectively) being febrile neutropenia the major reason (54%) for hospitalization. Multivariate analysis identified several independent predictors for reduced RDI, including age ≥65 years (OR=4.02, CI95%:2.1-8.1), presence of secondary extranodal involvement (OR=2.2, CI95%:1.2-4.2), hospitalization (OR=2.66, CI95%: 1.3-5.9) and CT regimen CHOP (OR=3.7, CI95%:1.6-9.1) when compared to R-CHOP. Grade 3 and 4 neutropenia incidence as well as description of patterns of G-CSF use are presented on Table 1. Highest frequencies of grade 3 and 4 neutropenia episodes occur during cycle 1 of CT. *Conclusions.* A considerable number of our HL and NHL pts, receiving first line treatments continue to experience RDI reductions. Presence of age ≥65 years, secondary extranodal involvement, NHL chemotherapy regimens, and hospitalizations were identified as independent risk factors for reduced RDI. Primary G-CSF prophylaxis could be an appropriate supportive care in these subgroups of patients allowing the delivery of full chemotherapy doses on schedule.

Table 1. Incidence of neutropenia grade 3 and 4 and patterns of G-CSF use.

	Type of lymphoma		p-value
	Hodgkin	Non Hodgkin	
Total no. cycles	595	1493	
Total no. patients	106	264	
Incidence of neutropenia n (%)			
Total of cycles with Grade 3/4 episodes	117(20%)	116(8%)	p < 0.001
Cycle 1	38 (33%)	37 (32%)	-
Total of pts with Grade 3/4 episodes	36 (34%)	71 (27%)	p = 0.22
Patterns of G-CSF use n (%)			
Total no. patients with G-CSF administration	81 (76%)	173 (66%)	-
Primary Prophylaxis	10 (12%)	43 (25%)	p = 0.02
Secondary Prophylaxis	65 (80%)	125 (72%)	p = 0.17
Febrile Neutropenia	4 (5%)	25 (14%)	p = 0.03
Neutropenia	73 (90%)	133 (77%)	p = 0.01

T- AND B-CELL LYMPHOMAS IN CHILDREN: CLINICAL AND IMMUNOLOGICAL FEATURES, RESULTS OF TREATMENT

T. Valiev, O.V. Morozova, G.L. Mentkevich, A.I. Slugin, V. Popa

Paediatric Oncology and Hematology Research Institute, MOSCOW, Russian Federation

We reviewed all cases of primary pediatric T- and B-cell lymphomas diagnosed and treated over a 10-year period. In this study 186 cases of newly diagnosed childhood T- and B-cell lymphomas were included. The patients ranged in age from 9 months to 16 years at the time of diagnosis, with a mean age of 10 years. There were 138(74.6%) boys and 48(25,8%) girls, boys/girls ratio - 2,8:1. Diagnosis was based on cytomorphologic analyses, histopathological evaluation, imaging methods (CT scan of chest, abdomen and pelvis, clinical ultrasound, MRI), flow cytometry and/or immunohistochemistry of tumor species. B-cell lymphomas were diagnosed in 104(56%) cases, T-cell in 81 (43.5%) and NK-cell in 1(0,5%) case. According to WHO Classification of Hematological Malignances(2001) B-cell lymphoblastic leukemia/lymphoma was diagnosed in 28(15%) cases. Pre-pre-B-variant was in 19(68%), pre-B in 3(11%) and pro-B in 6(21%) cases. Diffuse large B-cell lymphoma (DLBCL) was found in 26(14%), Burkitt lymphoma/leukemia (BL) in 49(26%). Precursor T-cell lymphoblastic leukemia/lymphoma was diagnosed in 44 patients (24%), anaplastic large-cell lymphoma (ALCL) in 34(18%). The rate of a quite rare types of lymphomas (blastic NK-cell lymphoma - 1 case, follicular lymphoma - 1 case, angioimmunoblastic T-cell lymphoma-1 case) was 3%. At the time of diagnosis 13 patients (7%) had Stage I disease (by S.Murphy), 19(10%) Stage II, 63(34%) Stage III and 91(49%) Stage IV. Patients with BL were treated with the B-NHL-mBFM-90 protocol, relapse-free survival (RFS) during 2 years was 88.2±5.6%. Patients with DLBCL were treated with NHL-BFM-90 protocol and we achieved RFS in 58±13% cases. RFS in patients with ALCL treated according to NHL-mBFM-90/95 protocol was 86±9%. Lymphoblastic leukemias/lymphomas were treated with ALL-mBFM-90/95 protocol and 5-year RFS was registrated in up to 66.7% cases. T- and B-cell lymphomas are the third most common cancer in children. Our data show that it comprises a heterogeneous group of tumors with distinct pathologic and clinical characteristics. Over the past three decades, significant advancements have been made in the immunologic characterization of these disorders. With the use of intensive multiagent chemotherapy, T- and B-cell lymphomas are now among the most successfully treated cancers in the pediatric population.

THE NEW ALC/R-IPI SCORE HAS A GOOD ABILITY TO DISCRIMINATE PROGNOSIS IN DLBCL TREATED WITH IMMUNO-CHEMOTHERAPY

M. Cox,[1] I. Nofroni,[2] L. Ruco,[1] R. Amodeo,[1] B. Veggia,[1] A. Ferrari,[1] G. La Verde,[1] P. Cardelli,[1] E. Montefusco,[1] E. Conte,[1] G. Antolino,[1] M.P. Bianchi,[1] B. Monarca,[1] M.A. Aloe spirit[1]

[1]A.O. Sant'Andrea, ROME; [2]Department of Experimental Medicine, ROME, Italy

Background. The advent of immuno-chemotherapy for the treatment of Diffuse-Large-B-Cell-Lymphoma (DLBCL) has resulted in a marked improvement in survival outcome, but has altered the paradigm of risk assessment and the IPI factors can no longer identify a group of patients with a less than 50% chance of survival. Absolute-Lymphocytic-Count (ALC), has been recently identified as an independent prognostic factor in DLBCL. We built up a new score ALC/R-IPI incorporating both ALC and Revised-IPI (R-IPI) that, in a preliminary work, was the most powerful predictor of EFS, PFS and OS. *Aims.* Up-dating our preliminary work and confirm the prognostic value of ALC and of the new ALC/R-IPI score in a prospective series of DLBCL treated with R-CHOP-like chemotherapy. *Materials and Methods.* We assessed prospectively the value of ALC at diagnosis and also after the completion of immuno-chemotherapy in 131 Diffuse-Large-B-Cell-Lymphoma(DLBCL). Analysis of prognostic factors with respect to Overall Survival(OS), Event Free Survival(EFS) and Progression Free Survival(PFS) was done by two-tailed log-rank test. The ALC cut-off value was calculated as $<0.84\times10^9$/L at diagnosis: this was a strong negative prognostic factor for OS(p=0.0003), EFS(p<0.00001) and PFS(p<0.00001) and in multivariate analysis was independent from the Revised-International-Prognostic-Index(R-IPI). ALC after chemo-immunotherapy was not of prognostic value. As R-IPI and ALC$<0.84\times10^9$/L, were the factors better discriminating poor prognosis, a new trichotomous score(ALC/R-IPI) was built up: 1] low risk: R-IPI=Very Good or Good and ALC$\geq0.84\times10^9$/L; 2] intermediate risk: patients with at least one risk factor (R-IPI=Poor or ALC$<0.84\times10^9$/L). 3]high risk: patients with both risk factors. This new prognostic score was highly significant in univariate analysis for OS(p=0.0002), EFS(p<0.00001) and PFS(p<0.00001). In multivariate analysis ALC/R-IPI was the most predictive factor for OS(OR=2.32; p=0.002) and EFS(OR=2.431; p<0.0001) and the only predictive factor for PFS(OR=4.252; p<0.00001). *Conclusions.* Our data, show that ALC at diagnosis has a strong prognostic relevance and is independent from the R-IPI. The new score including both values proved the most powerful predictor at multivariate analysis.

PATIENTS REQUIRING INTERRUPTION OF LONG-TERM ORAL ANTICOAGULANT THERAPY: THE ADVANTAGE OF FIXED SUB-THERAPEUTIC DOSES OF LOW-MOLECULAR WEIGHT HEPARIN

A. Malato, G. Saccullo, L. Lo Coco, D. Caramazza, I. Abbene, G. Giuseppina, S. Siragusa

University of Palermo, PALERMO, Italy

Introduction. The interruption of long-term Vitamin-K antagonist (VKA) therapy for surgery or other invasive procedures puts patients at increased risk of thromboembolic events. We conducted a study testing the hypothesis that fixed doses of Low-Molecular Weight Heparin (LMWH) is a safe and efficacious perioperative bridging therapy in patients on long-term VKAs. *Methods.* This prospective, cohort study included patients requiring bridging therapy due to major surgery (defined as surgery lasting at least 1 hour) or invasive procedures at increased risk for bleeding that require interruption of VKA. Patients were considered to be at low or at high-risk for thrombosis. In all patients, Warfarin was discontinued 5 + 1days prior to the procedure. In patients considered at low-risk for thrombosis, LMWH at prophylactic dosage (4.000 UI anti-FXa once daily) was commenced the night before the procedure. In patients considered at high-risk for thrombosis LMWH at fixed sub-theraputic doses (4.000 UI anti-FXa twice daily).) was started pre-operatively when INR was below 1.5 and continued until the night before the procedure. In the post-operative period, LMWH was reinitiated 12 hours post-procedure while Warfarin was restarted the day after procedure in case of adequate haemostasis. LMWH was given accordingly to patients' thrombotic risk: those at high-risk received fixed sub-therapeutic dosage (4.000 UI anti-FXa twice daily) while those at low-risk received prophylactic doses (4.000 UI anti-FXa once daily). Heparin was continued until a therapeutic INR value. The primary efficacy endpoint was the incidence of thromboembolism from warfarin cessation to 30+2 days post-procedure. The primary safety endpoint was the incidence of major haemorrhage from first dose of LMWH until 24 hours after the last dose. *Results.* Over a period of 4 years (2003-2008), a total of 328 patients were included in the study; among them, 182 (55.4%) belonged to low-risk group and 146 (44.6%) to high-risk group. In total, 103 (31.4%) patients underwent major surgery and 225 (68.6%) other invasive procedures requiring VKAs suspension. Thromboembolic events occurred in 5 patients (1.5%); 4 belonging to high-risk and 1 to low-risk group. Major bleeding occurred in 7 patients (2.1%); among them, 5 patients belonged to high-risk and 2 to low-risk group. Five out of 7 major haemorrhage occurred in patients undergoing major surgery; none was fatal, intracranial, retroperitoneal, intraocular or required re-surgery. *Conclusion.* Use of LMWH given at fixed sub-therapeutic doses is a feasible and safe approach for bridging therapy in chronic anticoagulated patients.

RESISTANCE TO CLOPIDOGREL DETECTED BY REAL TIME EVALUATION OF PLATELET THROMBUS FORMATION

G.L. Mendolicchio,[1] D. Zavalloni,[1] E. Corrada,[1] M. Bacci,[1] M.L. Rossi,[1] L. Rota,[1] Z.M. Ruggeri[2]

[1]Istituto Clinico Humanitas, ROZZANO, Italy; [2]The Research Scripps Institute, LA JOLLA, SAN DIEGO, USA

Background. Platelet adhesion, activation and aggregation play a key pathogenetic role in acute coronary syndromes (ACS), thus antiplatelet therapy with aspirin and clopidogrel is a mainstay of treatment. Individual response is variable, however, and patients with lesser platelet inhibition are at increased risk of adverse cardiovascular events. *Aims.* Assess the phenotype of clopidogrel *resistance*. *Methods.* we studied 36 ACS patients treated with antiplatelet therapy by perfusing heparinized blood over collagen fibrils under controlled flow conditions and measuring thrombus volume by real time confocal videomicroscopy. Measurements were obtained within 24 h from admission, when therapy was initiated, and at 5 days, 1 and 6 months. Antiplatelet treatment consisted of aspirin, 100 mg, and clopidogrel administered with a 300 mg loading dose followed by 75 mg daily. *Results.* in 30 patients, thrombus volume was inhibited >50% relative to control in all samples tested. In contrast, 6 patients (16.7%) exhibited no significant decrease of thrombus volume in spite of antiplatelet treatment. In 4 patients the lack of response was evident in the first samples tested, while in two patients thrombus volume was decreased >50% at day 5 but not at 1 month. Three of the 6 patients (50%) showing no inhibition of thrombus volume developed stent thrombosis; in two of them the 'resistance' to treatment was detected after the onset of symptoms. After switching to ticlopidine, 5 patients showed >50% inhibition of thrombus volume. In selected cases, we measured the platelet VASP phosphorylation index as a direct test of P2Y12 inhibition by clopidogrel, and found agreement with the results of thrombus volume measurement. Patients with <50% thrombus volume inhibition had a VASP index >50%. In one case, however, the VASP index was 21% but thrombus volume was not significantly decreased and the patient developed stent thrombosis. In one patient the VASP Index remained 71% after switching to ticlopidine in spite of >50% thrombus volume inhibition. *Conlclusions*. Our findings indicate that thrombus volume measurement in flowing blood exposed to collagen may provide a clinically relevant correlate of the effect of antiplatelet therapy.

0439

EFFECT OF THE NOVEL, ORAL, DIRECT FACTOR XA INHIBITOR RIVAROXABAN ON COAGULATION ASSAYS

M.M. Samama,[1] L. Le Flem,[2] C. Guinet,[2] E. Perzborn,[3] J.-L. Martinoli,[4] F. Depasse[2]

[1]Hotel Dieu Hospital, PARIS, France; [2]Biomnis Laboratories R&D, IVRY-SUR-SEINE, France; [3]Bayer HealthCare AG, WUPPERTAL, Germany; [4]Stago, ASNIÈRES, France

Background. Rivaroxaban is an oral, direct Factor Xa (FXa) inhibitor that is approved in the EU and several other countries for the prevention of venous thromboembolism after elective hip and knee replacement, and is in advanced clinical development for other thromboembolic disorders. There is no need for routine laboratory monitoring with rivaroxaban. However, a haemostasis assay may be valuable to provide physicians with a means to measure the pharmacodynamics of rivaroxaban. *Aims.* The aim of this study was to identify a widely available assay (clotting assay or colorimetric assay) that could be used in clinical practice. *Methods.* Increasing concentrations of rivaroxaban were spiked into citrated pooled human platelet-poor plasma. The global clotting assays prothrombin time (PT), dilute PT (dPT) and activated partial thromboplastin time (aPTT) were assessed, as well as the specific clotting assays HepTest® (heparin test), prothrombinase-induced clotting time (PiCT), dilute Russell's viper venom time (dRVVT) and the thrombin generation test (TGT). In addition, inhibition of FXa activity was measured using the FXa coagulometric assay Staclot®. *Results.* A concentration-dependent prolongation of PT, dPT and aPTT was observed with rivaroxaban, although the results varied depending on the reagents used. When testing PT over time using frozen plasma spiked with defined concentrations of rivaroxaban, PT values did not change during storage. Using a standard calibration curve, the results of the PT test can be expressed in rivaroxaban (µg/mL) rather than as PT ratio or international normalized ratio. A concentration-dependent prolongation of the clotting time was also observed with dPT, a test that may be clinically more significant than conventional PT because it is closer to *in vivo* conditions (i.e. it uses lower tissue factor concentrations). However, the increase in clotting time varied depending on the reagents used. Conventional methods for the HepTest and two-step PiCT (incubation times of 120 seconds and 180 seconds, respectively) resulted in a paradoxical response, with low concentrations of rivaroxaban reducing clotting times. This paradoxical response was not observed with shorter incubation times (0 or 30 seconds for one-step PiCT and 30 seconds for HepTest) or when antithrombin-immunodepleted plasma was used. Modification of these tests by shortening the incubation period is now recommended by the manufacturer. Rivaroxaban also increased the dRVVT in a concentration-dependent manner; however, this test is not specific. Rivaroxaban influenced the various parameters of the TGT in a concentration-dependent manner; peak effect was the most informative parameter. Rivaroxaban inhibited FXa activity in a concentration-dependent manner in the Staclot FXa coagulometric assay, with results expressed in clotting times; this assay, however, is not specific for FXa inhibitors. *Summary and Conclusions.* PT assays calibrated to rivaroxaban concentrations appear to be valuable assays for monitoring the pharmacodynamic effects of rivaroxaban. Encouraging results were also obtained with the Staclot FXa coagulometric assay, although further studies are required before this assay can be recommended for monitoring the pharmacodynamic effects of rivaroxaban.

0440

THE HEMOSTATIC PROFILE OF ESSENTIAL THROMBOCYTHEMIA AND POLYCYTHEMIA VERA (PV) PATIENTS IS INFLUENCED BY THE JAK2V617F ALLELE BURDEN

M. Marchetti,[1] E. Castoldi,[2] L. Russo,[3] A. Vignoli,[3] J. Rosing,[2] H. Ten Cate,[4] A. Falanga[3]

[1]Ospedali Riuniti Bergamo, BERGAMO, Italy; [2]Biochemistry Dept, CARIM, Maastricht University, MAASTRICHT, Netherlands; [3]Hemostasis and Thrombosis Center, Ospedali Riuniti di Bergamo, BERGAMO, Italy; [4]Internal Medicine Dept, CARIM, Maastricht University, MAASTRICHT, Netherlands

Background. Thrombosis is a leading cause of morbidity and mortality in patients with Thrombocythemia (ET) and PV. Several mechanisms have been proposed to cause or to contribute to the acquired thrombophilic state of these patients. We recently described the occurrence of an acquired resistance to activated protein C (APC) in ET and PV patients, particularly in those carrying the somatic JAK2V617F mutation, due to a decrease in Protein S (PS) levels (Marchetti *et al.*, Blood 2008). *Aims*. This study investigated whether the JAK2V617F allele burden, quantified by real time PCR, may differently affect the APC resistance phenotype in a group of JAK2V617F-positive patients. *Methods.* APC resistance was evaluated in 27 ET and 26 PV patients by the endogenous thrombin potential (ETP) assay and expressed as normalized APC sensitivity ratio (nAPCsr). JAK2V617F allele burden was correlated to the plasma levels of procoagulant (FII, FV) and anticoagulant proteins (free PS, TFPI), known to be the major determinants of the nAPCsr, and to markers of neutrophil activation (plasma elastase, cell surface CD11b and CD14). *Results.* In our study subjects, the JAK2V617F allele burden ranged from 0.5-82% (mean: 25%) in ET and from 4.1-98.5% (mean: 51%) in PV patients. A significant positive correlation was found between the JAK2V617F allele burden and nAPCsr (R=0.359; p=0.009), plasma elastase (R=0.73, p<0.001), and surface expression of neutrophil CD14 (R=0.515; p=.005). An inverse and significant correlation was found between JAK2V617F allele burden and plasma levels of FII (R=-0.380; p=0.006), FV (R=-0.365; p=0.008) and free PS (R=-0.416; p=0.004). After correction for sex, age and hydroxyurea (HU) therapy, JAK2V617F allele burden was an independent predictor of the nAPCsr (B=0.396; p=0.004), while HU therapy was associated with a lower nAPCsr (B=-0.335; p=0.016). *Summary and Conclusions.* These data demonstrate that higher JAK2V617F mutational load is associated with a more profound increase in APCsr and neutrophil activation and dowregulation of anticoagulant PS, thus contributing to a prothrombotic phenotype of ET and PV patients. Further studies are warranted to clarify the molecular mechanisms underlying the relationship between this oncogenic mutation and the dysregulation of the hemostatic system in these diseases.

0441

SOLUBLE ENDOGLIN AND ITS INTERACTION WITH ADHESION MOLECULES IN PATIENTS WITH THALASSEMIA INTERMEDIA

I. Papassotiriou,[1] M. Siopi,[2] C. Lazaropoulou,[2] I. Kanavaki,[2] V. Ladis,[3] A. Kattamis[3]

[1]Aghia Sophia Childen's Hospital, ATHENS; [2]Department of Clinical Biochemistry, Aghia Sophia Children's Hospital, ATHENS; [3]First Department of Pediatrics, Athens University Medical School, ATHENS, Greece

Background. Endoglin (CD105) is an accessory protein of the transforming growth factor-β receptor system expressed on vascular endothelial cells. Mutations on the endoglin gene are associated with hereditary hemorrhagic telangiectasias (Osler-Weber-Rendu syndrome) and, thus, endoglin has been extensively studied in the context of this disease. Endoglin is highly expressed on endothelial cells in healing wounds, developing embryos, inflammatory tissues and solid tumors. It is a marker of activated endothelium, while its vascular expression is limited to proliferating cells. Previous studies have shown that the endothelial function is impaired in patients with Thalassemia Intermedia (TI). Oxidative damage resulting from hemolysis and iron load, leads to increased expression of the intercellular and vascular adhesion molecules-1 (ICAM-1 and VCAM-1) and impaired nitric oxide (NO) bioavailability. *Aims.* As endoglin plays a critical role in angiogenesis and dysregulation of its expression and/or activity has been implicated in multiple vascular diseases, we aimed to investigate the expression of endoglin and its correlation with factors of endothelial dysfunction in patients with TI. *Methods.* Thirty adult patients with TI were included in the study, while 20 healthy individuals served as controls. Soluble endoglin, soluble forms of adhesion molecules ICAM-1, VCAM-1, E and P-Selectins, thrombomodulin, von Willebrand factor, as well as NO and vascular endothelial growth factor (VEGF), were measured in patients and controls, by immunoenzymatic methods. *Results.* The main results of the study are: a) levels of endoglin, E-selectin, thrombomodulin, VCAM-1, ICAM-1 and VEGF in patients with TI (5.5±0.4 ng/mL, 91.4±20.0 ng/mL, 48.8±16.5 ng/mL, 1413.7±176.1 ng/mL, 658.8±34.6 ng/mL and 619.1±227.8 pg/mL, respectively) were higher compared to controls (4.9±0.3 ng/mL, 10.3±2.2 ng/mL, 4.0±0.6 ng/mL, 328.3±43.8 ng/mL, 107.6±26.5 ng/mL, 81.3±58.1 pg/mL), (p<0.01), b) endoglin levels in patients with TI correlated positively with concentrations of ICAM-1 (r=0.760, p<0.003), VCAM-1 (r=0.520, p<0.05), E-Selectin (r=0.790, p<0.0020, P-Selectin (r=0.530, p<0.04), while these correlations were absent in normal individuals. *Conclusions.* Angiogenesis is a highly coordinated process in which VEGF, endoglin and hypoxia inducible factor 1 (HIF-1) play a pivotal role by coordinating interaction between endothelial cells, extracellular matrix and the surrounding cells. Taking into assumption that endoglin is a protective-repair tissue protein, our findings support the hypothesis that patients with TI exhibit increased degree of angiogenesis and endothelial regeneration, which are probably compensatory mechanisms in response to tissue hypoxia and damage.

0442

ORAL PREVENTION OF VENOUS THROMBOEMBOLISM AFTER TOTAL KNEE OR HIP REPLACEMENT SURGERY IN THE ELDERLY AND THOSE WITH MODERATE RENAL IMPAIRMENT: EFFICACY AND SAFETY PROFILE OF DABIGATRAN ETEXILATE

O.E. Dahl,[1] A.A. Kurth,[2] N. Rosencher,[3] A. Clemens,[4] M. Feuring,[4] H. Noack,[5] B.I. Eriksson[6]

[1]Thrombosis Research Institute, London, UK and Elverum Central Hospital, ELVERUM, Norway; [2]University Hospital Frankfurt/Main, FRANKFURT, Germany; [3]Paris Descartes University, PARIS, France; [4]Boehringer Ingelheim GmbH, INGELHEIM AM RHEIN, Germany; [5]Boehringer Ingelheim Pharma GmbH & Co. KG, INGELHEIM AM RHEIN, Germany; [6]University Hospital Sahlgrenska/Östra, GOTHENBURG, Sweden

Background. Oral dabigatran etexilate (Pradaxa®) is approved for preventing venous thromboembolism (VTE) after knee or hip replacement surgery in Europe, Canada and other countries. *Aims.* We aimed to determine the efficacy and safety of dabigatran etexilate in the combined sub-group of patients with moderate renal impairment and those older than 75 years (as renal function naturally declines with age) compared with subcutaneous (sc) enoxaparin. *Methods*. The RE-MODEL' and RE-NOVATE' trials studied the efficacy and safety of 220 mg and 150 mg dabigatran etexilate once daily (qd) compared with 40 mg sc enoxaparin qd and statistically demonstrated non-inferiority for the primary endpoint, total VTE and all-cause mortality. A post hoc pooled analysis was performed in patients older than 75 years or those with moderately reduced renal function (creatinine clearance 30-50 mL/min). The secondary, clinically relevant efficacy endpoint was major VTE and VTE-related mortality; the safety outcomes were major bleeding events (MBE; including peri-operative surgical-site bleeds) and major or clinically relevant bleeding events (CRBE/MBE). *Results*. Of 5371 treated patients, 841 (15.7%) were over 75 years and 337 (6.3%) had moderate renal impairment; the combined group comprised 953 patients (17.7%). Event rates and relative risks (RR; with 95% confidence intervals) compared with enoxaparin are shown in the Table. A RR <1 indicates a lower risk and a RR >1 a higher risk with dabigatran etexilate compared with enoxaparin. *Summary and Conclusions.* Dabigatran etexilate 150 mg qd showed less VTE and VTE-related mortality and bleeding compared with the enoxaparin regimen. The 220 mg dose showed a lower thromboembolic event rate with a higher bleeding rate. This analysis supports the use of the 150 mg dose of dabigatran etexilate in patients over 75 years or with moderate renal impairment.

Table. Comparison of dabigatran etexilate with enoxaparin.

Event	Dabigatran etexilate 220 mg qd	Dabigatran etexilate 150 mg qd	Enoxaparin 40 mg qd
Major VTE and VTE-related mortality	2.2% (5/230) RR: 0.34 (0.13–0.92)	4.3% (10/230) RR: 0.68 (0.31–1.48)	6.4% (15/235)
MBE	3.7% (12/321) RR: 1.13 (0.51–2.52)	1.3% (4/300) RR: 0.40 (0.13–1.25)	3.3% (11/332)
CRBE/MBE	10.6% (34/321) RR: 1.13 (0.71–1.80)	8.0% (24/300) RR: 0.86 (0.51–1.43)	9.3% (31/332)

0443

EFFICACY AND SAFETY PROFILE OF 220 MG DABIGATRAN ETEXILATE IN PATIENTS UNDERGOING TOTAL HIP OR KNEE REPLACEMENT SURGERY WITH A HISTORY OF STROKE, TRANSIENT ISCHAEMIC ATTACK OR VENOUS THROMBOEMBOLISM

O.E. Dahl,[1] C. Francis,[2] A.A. Kurth,[3] N. Rosencher,[4] M. Feuring,[5] H. Noack,[6] A. Clemens,[5] B.I. Eriksson,[7] J.A. Caprini[8]

[1]Thrombosis Research Institute, London, UK and Elverum Central Hospital, ELVERUM, Norway; [2]University of Rochester, NEW YORK, USA; [3]University Hospital Frankfurt/Main, FRANKFURT, Germany; [4]Paris Descartes University, PARIS, France; [5]Boehringer Ingelheim GmbH, INGELHEIM AM RHEIN, Germany; [6]Boehringer Ingelheim Pharma GmbH & Co. KG, INGELHEIM AM RHEIN, Germany; [7]University Hospital Sahlgrenska/Östra, GOTHENBURG, Sweden; [8]NorthShore University Health System, EVANSTON, USA

Background. The oral direct thrombin inhibitor dabigatran etexilate is approved for the prevention of venous thromboembolism (VTE) after knee or hip replacement surgery in multiple countries, including the European Union and Canada. *Aims.* In this post hoc analysis we investigated the efficacy and safety of dabigatran etexilate in the sub-group of patients with a history of VTE, non-haemorrhagic stroke or transient ischaemic attack (TIA). *Methods.* The RE-MODEL' and RE-MOBILIZE' trials studied patients undergoing knee replacement surgery and compared 220 mg and 150 mg dabigatran etexilate once daily (qd) with 40 mg subcutaneous (sc) enoxaparin qd (RE-MODEL') or 30 mg sc enoxaparin twice daily (bid; RE-MOBILIZE'). RE-NOVATE' compared 220 mg and 150 mg dabigatran etexilate qd with 40 mg sc enoxaparin qd after hip replacement. The endpoints studied in these pooled analyses were major VTE and VTE-related mortality and major bleeding events (MBE), including surgical-site bleeds, plus clinically relevant bleeding events (CRB). This analysis is focused on the group which received 220 mg qd dabigatran etexilate as this group is representative of a population without renal impairment. *Results.* A history of VTE, non-haemorrhagic stroke or TIA was present in nearly 4% of the total pooled population of 8135 patients. The incidence of major VTE and VTE-related mortality was 6.3% in the 220 mg dabigatran etexilate group and 6.7% in the

enoxaparin group, which translates into a risk ratio (RR) for the comparison of dabigatran etexilate 220 mg with enoxaparin of 0.95 (95% confidence interval [CI]: 0.29-3.15). The combination of MBE and/or CRB occurred in 8.8% and 7.9% in the two groups, respectively. The RR for the bleeding events was 1.11 (95% CI: 0.45-2.77). *Summary and Conclusions.* For the prevention of VTE after total knee or hip replacement surgery in patients at risk due to a history of VTE, stroke or TIA, the 220 mg dose of oral dabigatran etexilate showed good efficacy and a good safety profile compared with subcutaneously administered enoxaparin.

0444

LOW PLATELET GLYCOPROTEIN IB-POSITIVE MICROPARTICLES IN PATIENTS WITH CORONARY STENT THROMBOSIS

G.L. Mendolicchio,[1] C. Godino,[2] D. Zavalloni,[1] A. Colombo,[3] Z.M. Ruggeri[4]

[1]Istituto Clinico Humanitas, ROZZANO, Italy; [2]San Raffeale, MILANO, Italy; [3]San Raffaele, MILANO, Italy; [4]The Research Scripps Institute, LA JOLLA, SAN DIEGO, USA

Background and Aim. Heightened platelet reactivity and/or resistance to anti-platelet therapy may cause thrombosis in patients with coronary stents. We hypothesized that this event might involve adhesion mediated by glycoprotein Ib (GPIb)/von Willebrand factor, possibly resulting in the generation of GPIb-positive platelet-derived microparticles (GPIb+P-MP). Methods and Results. We measured by flow cytometry GPIb+P-MP in the blood of patients with coronary stents as potential markers of a prothrombotic tendency, and membrane expression of P-selectin along with binding of the antibody PAC-1 as markers of the inhibitory effect of anti-platelet drugs. We studied 51 patients with stable angina (SA) who had received coronary stents without complications; 16 patients with a history of stent thrombosis (S-TH); and 29 normal individuals. All patients were treated with aspirin and a thienopyridine at the time of study. The number of GPIb+P-MP was similar in normal individuals and SA patients, indicating that anti-platelet therapy has no effect on the generation of these microparticles, but was unexpectedly lower in S-TH patients. Thus, GPIb+P-MP levels allowed discriminating SA from S-TH patients with significant sensitivity and specificity. P-selectin expression and PAC-1 binding were lower in patients than normal subjects but with no difference between SA and S-TH patients, evidence that platelet inhibition was similar in the two groups. Conclusions. Enhanced GPIb/von Willebrand factor interactions may alter generation and/or adhesion of GPIb+P-MP at sites of vascular lesion through mechanisms not inhibited by current anti-platelet therapy. A decrease of GPIb+P-MP in blood may indicate a prothrombotic tendency in patients with coronary stents.

0445

YOUNG PATIENTS WITH STROKE, PFO (PATENT FORAMEN OVALE) AND THROMBOPHILIA

C. Lodigiani,[1] P. Ferrazzi,[1] L. Librè,[1] E. Morenghi,[1] M. Minaudo,[1] L.L. Rota,[1] D. Mari[2]

[1]Ist Clinico Humanitas, ROZZANO/MILANO; [2]Ist Auxologico Italiano, MILANO, Italy

In young stroke patients PFO is present in about 50%: but the risk for cryptogenic stroke in healthy people with PFO is only 0.1%. Unbalanced haemostasis (thrombophilia) could enhance the risk. *Aim of the study.* To evaluate the prevalence of trombophilia in patients with PFO (PFO^+) and cryptogenic stroke ($stroke^+$). *Materials and Methods.* In 330 consecutive subjects with cryptogenic stroke 149 (45.15%) were PFO^+ and 181 (54.9%) were PFO^-. We performed neurological examination, brain CT and /or MRI scan, extracranial Doppler ultrasonography, ECG, trans thoracic and/or transesophageal echocardiography, standard blood tests and PT, aPTT, fibrinogen, protein C, protein S, antithrombin, APC resistance, homocysteine, LAC, anticardiolipin antibodies, F VIII , test for thrombofilia mutations G1691A Factor V, G20210A Factor II, C677T MTHFR; 433 healthy subjects,matched for age and gender,were control population: 98 were investigated for PFO (43 PFO^+, 55 PFO^-). *Results.* Stroke is more prevalent in women than in men (F 54.3%, M 42.1%, p=0.002).Fibrinogen (14.8 vs. 8.9%, p=0.023), homocysteine (fasting:15.5% vs. 6.0%, p<0.001, post load: 25.7vs. 5.6%, p< 0.001), factor VIII (57.0 vs. 43.0%, p=0.002), LAC (2.7 vs. 0.0%, p=0.002)and anticardiolipin AbIgG (5.6 vs. 0.0%, p<0.001) were higher in patients $stroke^+$ vs $stroke^-$. The multivariate analysis confirm female gender (OR: 2.38, 95%IC:1.53-3.68, p<0.001), homocysteine (OR 3.49, 95%IC:1.92-6.34), FVIII (OR 1.93, 95%IC:14-3.26) as risk factors.In patients $stroke^+$ and PFO^+, APC resistance, homocysteine, MTHFR mutation and LAC have p<0.05. PFO seems to be a risk factor for stroke when right-to-left shunt is >10 microbubbles (34 vs 45%, p=0.071) In multivariate analysis PFO, age, female gender and APC resistance are significant. *Conclusions.* An hypercoagulable state in association with concomitant risk factors as PFO could contribute to provoke an intracardiac thrombosis with subsequent embolism.

0446

HIGHER CIRCULATING ACTIVATED PROTEIN C /PC AND APC/FACTOR II RATIOS DURING ORAL ANTICOAGULANT THERAPY. INFLUENCE OF THE HAPLOTYPE 1 OF THE ENDOTHELIAL PROTEIN C RECEPTOR GENE

F. España, S. Navarro, P. Medina, F. Ferrando, A. Vayá, Y. Mira, A. Estellés, F. España

Hospital Universitario La Fe, VALENCIA, Spain

Background. Oral anticoagulation (OAC) therapy reduces levels of activated protein C (APC) remarkably less than levels of protein C (PC) and factor II (F II) in patients with systemic lupus erythematosus and in cardiac patients (Simmerlink MJA *et al.*, Blood 2002; 100: 4232). In addition, we have reported that carriers of the H1 haplotype in the endothelial PC receptor (EPCR) gene have higher APC levels than non carriers (Medina P *et al.*, Thromb Haemost 2004; 91: 905). *Aims.*To assess whether patients with venous thromboembolism under OAC therapy also show less decrease in APC levels, and whether this effect is associated with the presence of EPCR H1 haplotype. *Methods.* Blood was collected from 470 VTE patients, 143 (mean 44 years) with and 327 (mean 42 years) without OAC therapy. Levels of APC (España *et al.*, Thromb Haemost 2001; 86: 1368), PC (chromogenic) and F II (coagulometric) are expressed as the percentage of the level in pooled normal plasma from 30 healthy subjects. *Results.* The mean values for APC, PC and F II in patients under OAC therapy were 66%, 51% and 37%, whereas the values for patients without OAC therapy were 84%, 106% and 101%, respectively. For patients under OAC therapy the F II/PC ratio did not significantly vary for all PC values observed, whereas APC/F II and APC/PC ratios significantly increased as the F II and PC levels decreased, but only in patients under OAC therapy, showing a strong and inverse correlation between both ratios and its zymogen, reaching ratio values up to 3.5 for PC (Figure) and 5.0 for F II levels below 30%. Because the H1 haplotype in the EPCR gene is associated with higher plasma APC levels, we studied the influence of this haplotype on the analyzed ratios. Of the 18 patients under OAC therapy carrying the H1H1genotype, 8 (44%) showed APC/PC and 10 (56%) APC/F II ratios higher than 2, whereas of the 41 patients under OAC therapy not carrying the H1 haplotype only 5 (12%) and 4 (10%), respectively, had ratios higher than 2.0 (p<0.001). *Conclusions.* Our data confirm previous results showing that there is a disproportionately higher APC level in patients under OAC therapy and show that this effect is much more pronounced in homozygous carriers of the EPCR H1 haplotype. (Conselleria de Sanitat AP-151/08; RECAVA RD06/0014/004).

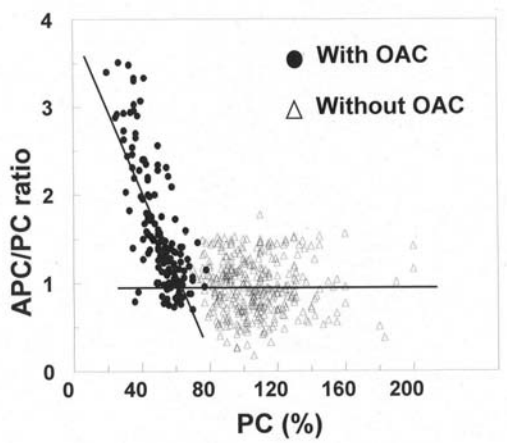

Figure.

0447

LAC TESTING IN PATIENTS WITH INFLAMMATORY STATUS

M.E. Schouwers, J. Delanghe, K. Devreese

Ghent University Hospital, GHENT, Belgium

Introduction. The presence of lupus anticoagulant (LAC) is one of the laboratory criteria for diagnosis of the antiphospholipid syndrome (APS). To exclude the transient nature of antiphospholipid antibodies, the International Society on Thrombosis and Haemostasis (ISTH) guidelines require a positive laboratory test on at least 2 occasions at least 12 weeks apart. In daily practice we observe transient LAC frequently in the course of infectious diseases. On the other hand we also observe unexplained prolonged aPTT in preoperative screening and intensive care patients. C-reactive protein (CRP) is an acute phase protein with a known affinity for phospholipids (PL). Hence, we investigated whether CRP interferes with LAC test results. *Materials and Methods.* CRP was measured in both the LAC positive and LAC negative sample of patients with transient presence of LAC. Patient plasma was qualified as LAC positive, by considering all ISTH criteria using a three step procedure in two test systems: an activated partial thromboplastin time (aPTT) (PTT-LA and Staclot-LA, Diagnostica Stago) and a diluted Russell's viper venom test (dRVVT) (LA-Screen and LA-confirm, Life Diagnostics). CRP was measured through a particle-enhanced immunoturbidimetric assay (CRPLX, Roche Diagnostica). Normal pooled plasma (NPP) was spiked with human CRP (Sigma-Aldrich) in a concentration range of 0.1 to 28.8 mg/dL to measure the effect on aPTT and dRVVT. A thrombin generation (TG) assay, measured via calibrated automated thrombinography (CAT), was performed with different types of PL at 1 µM and 5 pM tissue factor (TF). *Results.* Testing of 39 patients with transient LAC showed that CRP was significantly higher on the first occasion of LAC testing compared to the parallel testing on the second occasion (>12 weeks later), p=0.0001 (Wilcoxon test for paired samples). The aPTT test system was more sensitive to interference of CRP on LAC testing than the dRVVT test system. PTT-LA of CRP-spiked NPP showed an elevated normalised ratio from 2.4 mg/dL CRP onwards. Staclot-LA was strongly positive starting from CRP 5.3 mg/dL. dRVVT showed no elevated normalised ratio at any CRP concentration. TG using Staclot-LA hexagonal PL showed a decreased normalised peak/lagtime ratio starting from 2.4 mg/dL CRP. All other PL tested showed no decrease in normalised peak/lagtime ratio at any CRP concentration. *Conclusions.* Binding of CRP to negatively charged PL influences coagulation test results for LAC. The interaction strongly depends on the type of PL used in the reagent mixture. LAC testing should be interpreted with care in patients with inflammatory reactions.

0448

SILENT BRAIN ABNORMALITIES IN THALASSEMIA INTERMEDIA: DIAGNOSTIC CONTRIBUTION OF POSITRON EMISSION TOMOGRAPHY

A. Taher,[1] K. Musallam,[1] W. Nasreddine,[2] A. Beydoun[1]

[1]*American University of Beirut Medical Center, BEIRUT;* [2]*Rafic Hariri University Hospital, BEIRUT, Lebanon*

Background. Asymptomatic brain pathology has been described as a highly common phenomenon in patients with thalassemia intermedia (TI) and sickle cell disease (SCD). Current data in TI patients relied on the use of magnetic resonance imaging (MRI). However, in patients with SCD, the addition of position emission tomography (PET) to MRI identified a much greater proportion of patients with neuroimaging abnormalities, particularly in those who had no history of overt neurologic events. The utility of PET in detection of silent brain abnormalities in TI patients has not been evaluated. *Aims.* The present study examines the extent to which adding PET to MRI can improve the detection of silent brain abnormalities in adult patients with TI. *Methods.* Thirty patients (13 males and 17 females; with a mean age of 31.9 ± 11 years) carrying the diagnosis of TI - attending to the chronic Care Center, Hazmieh, Lebanon - were included in this study. Patients were randomly selected from a high-risk population of splenectomized, non-regularly transfused, non-anticoagulated TI patients. Patients were initially screened to confirm absence of neurological signs or symptoms and other associated stroke related disease. All patients underwent both MRI and 18F-FDG PET scan in the same day, after signing the informed consent. The criterion for abnormality on PET was the decrease in neuronal function (glucose utilization). MRIs were performed using T1 and T2 weighted spin-echo techniques. Abnormality was defined as an area of abnormally increased signal intensity on the T2 weighted pulse sequences. *Results.* Among the entire group of 30 subjects, 18 (60%) had abnormal MRI findings, 19 (63.3%) had abnormal PET findings, and 26 (86.7%) had either an abnormal MRI or abnormal PET or both. In patients with abnormality, 14 (53.8%) had multiple lesions on MRI, 14 (53.8%) had multiple findings on PET, and 19 (73.1%) had multiple findings on MRI, PET or both. Moreover, 13 (50%) had bilateral lesions on MRI, 3 (11.5%) had bilateral findings on PET, and 14 (53.8%) had bilateral findings on MRI, PET or both. Frontal lobe abnormalities were evident in 17 (65.4%), 3 (11.5%), and 18 (69.2%) patients by means of MRI, PET, or either; respectively. Parietal lobe abnormalities were evident in 9 (34.6%), 16 (61.5%), and 20 (76.9%) patients by means of MRI, PET, or either; respectively. Temporal lobe abnormalities were evident in 1 (3.8%), 13 (50%), and 14 (53.8%) patients by means of MRI, PET, or either; respectively. Occipital lobe abnormalities were evident in 3 (11.5%), 1 (3.8%), and 4 (15.3%) patients by means of MRI, PET, or either; respectively. Hence, concordance rates were 36.7% for detection of abnormality; 30.8% for detection of multiple lesions; 7.7% for detection of bilateral lesions; 7%, 19.2%, 0% and 0% for detection of frontal, parietal, temporal and occipital lesions, respectively. *Summary and Conclusions.* The addition of PET to MRI identified a much greater proportion of high-risk TI patients with silent neuroimaging abnormalities. PET lesions are equally extensive, less bihemispheric, and predominated in parietal and temporal lobes as compared to frontal lobes as with MRI.

0449

REVERSAL OF THE ANTIHAEMOSTATIC EFFECTS OF RIVAROXABAN BY ACTIVATED FACTOR VII AND ACTIVATED PROTHROMBIN COMPLEX IN PRIMATES

A. Gruber,[1] U.M. Marzec,[1] U. Buetehorn,[2] S. Hanson,[1] E. Perzborn[2]

[1]*Oregon Health and Science University School of Medicine, PORTLAND, OREGON, USA;* [2]*Bayer HealthCare AG, WUPPERTAL, Germany*

Background. Rivaroxaban is a novel, oral, direct factor Xa inhibitor approved in the EU and several other countries for the prevention of venous thromboembolism in adult patients undergoing elective hip or knee replacement surgery. The drug is in advanced clinical development for other thromboembolic disorders. *Aims.* We determined whether recombinant activated factor VII (rFVIIa; NovoSeven®) and activated prothrombin complex concentrate (APCC; FEIBA®) can reduce the antihaemostatic effect of high-dose rivaroxaban in baboons. *Methods.* In baboons, levels of rivaroxaban higher than therapeutic concentrations were achieved by administering an intravenous (i.v.) bolus (0.6 mg/kg) followed by continuous infusion (0.6 mg/kg/h) for 60 minutes. This caused progressive pharmacological impairment of haemostasis, resulting in a three- to fourfold increase in prothrombin time (PT) from baseline and at least a twofold increase in template bleeding time (BT). Thirty minutes after the bolus injection, one group of baboons (n=7) received an infusion of APCC (50 U/kg over 25 minutes) and another group (n=7) received an i.v. bolus of rFVIIa (210 µg/kg). BTs and clotting times were measured to assess the APCC- and rFVIIa-mediated reversal of the antihaemostatic effect of high-dose rivaroxaban.

Table. The effect of activated prothrombin complex (APCC) and recombinant activated factor VII (rFVIIa) on markers of haemostasis impairment in baboons anticoagulated with high-dose rivaroxaban.

Time	BT (x-fold change from baseline) n=7	PT (x-fold change from baseline) n=7	TAT concentration (µg/l) n=7
APCC			
Baseline	1.00	1.00	3.51±0.08
30 minutes after rivaroxaban	2.02±0.56	3.04±0.43	3.01±1.37
At end of APCC infusion	1.02±0.33	2.20±0.29	10.35±1.41
20 minutes after end of APCC infusion	1.65±0.94	2.28±0.29	–
rFVIIa			
Baseline	1.00	1.00	7.35±4.17
30 minutes after rivaroxaban	2.54±0.79	3.17±0.42	2.95±0.79
5 minutes after rFVIIa	1.68±0.80	2.38±0.41	2.58±0.52
30 minutes after rFVIIa	1.96±1.26	2.48±0.49	4.00±1.12

Values are given as mean ± standard deviation.
BT, bleeding time; PT, prothrombin time; TAT, thrombin–antithrombin complex.

Results. In APCC-treated baboons, high-dose rivaroxaban prolonged

BT to 202±21% (mean ± standard deviation) of baseline, and PT was prolonged to 304±43%, 30 minutes after dosing. After the completion of APCC infusion, PT was reduced by 28±29% and BT returned to baseline. In rFVIIa-treated baboons, rivaroxaban prolonged BT to 254±79% and PT to 317±42% of baseline, 30 minutes after dosing. rFVIIa infusion decreased BT by 34±80% and shortened PT by 25±41%, 30 minutes after dosing. Rivaroxaban infusion decreased circulating thrombin-antithrombin complex (TAT) levels; this decreased level did not change significantly after administration of the rFVIIa bolus. However, APCC increased plasma TAT above baseline, suggesting systemic hypercoagulation (Table). *Summary and Conclusions.* We conclude that, in baboons, APCC or rFVIIa administration can rapidly attenuate haemostasis impairment caused by levels of rivaroxaban at higher than therapeutic concentrations, potentially providing antidotes for use during emergencies.

0450

THE RISK OF RECURRENT VENOUS THROMBOEMBOLISM IN PATIENTS WITH MULTIPLE GENETIC THROMBOPHILIC DEFECTS: A COMPARATIVE STUDY

G. De Asis,[1] L. Tse,[2] J. Chan,[2] K. Ramadan[1]

[1]Providence Health Care and UBC, VANCOUVER; [2]University of British Columbia, VANCOUVER, Canada

Thrombophilias are genetic defects that have been associated with an increased risk of venous thromboembolisms (VTE) occurrence and recurrence. The objective of the study was to compare the risk of VTE recurrence in patients with multiple thrombophilias (including homozygous mutations) to patients that only have one. This was a retrospective, population-based, comparative study that involved 824 patients, out of which 292 had thrombophilia. 32 of the thrombophilia affected patients had multiple genetic defects and were compared to a randomly selected control group of 50 patients with single thrombophilia. These two groups were compared with regards to various aspects such as VTE occurrence, VTE recurrence, type of anticoagulant (IV Heparin, LMW Heparin, Warfarin), anticoagulant therapy duration (short-term <=6mo, long-term >6mo), acquired risks (e.g. malignancy, surgery or trauma, oral contraceptive pill or hormone replacement therapy, pregnancy, immobilization, hypertension, morbid obesity), family history of VTE, and type of thrombophilia (Antithrombin, Factor V Leiden, Homocysteine, Lupus Anticoagulant, Protein C Deficiency, Protein S Deficiency, Prothrombin). Overall, it was found that there were more patients with multiple thrombophilic defects than patients with a single defect among the aforementioned categories. The difference was particularly significant between the two patient groups in the rate of recurrence ($p<0.01$), the rate of having associated acquired risk(s) ($p<0.005$), and the rate of receiving anticoagulation therapy for initial thrombotic event ($p<0.05$). There was no statistically significant difference in the duration of anticoagulation therapy for both initial thrombotic event and recurrent episodes. This study provided additional evidence for the increase in risk of VTE recurrence in patients with thrombophilic defects, and an even greater risk in patients with multiple defects. Further study is required in order to appropriately assess the duration of anticoagulant therapy for thrombophilic patients.

Table. Comparison of patients: multiple vs single defects.

Percentage of Patients	Patients with Multiple Thrombophilia (n=32)	Patients with Single Thrombophlia (n=50)
VTE Occurrence	100%	92%
VTE Recurrence	59.4%	32%
Anticoagulation for 1st Occurrence	96.9%	82%
Anticoagulation for Recurrence	53.1%	42%
Acquired Risks	96.9%	74%
Family History	75%	70%

0451

ADAMTS13 LEVELS IN HIV INFECTED PATIENTS WITH AND WITHOUT THROMBOTIC THROMBOCYTOPENIC PURPURA

P.N. Badenhorst,[1] M. Meiring,[1] B. van Staden,[1] W.J. Janse van Rensburg,[1] H. Deckmyn[2]

[1]University of the Free State, BLOEMFONTEIN, South Africa; [2]University of Leuven, Campus Kortrijk, KORTRIJK, Belgium

Background. Thrombotic thrombocytopenic purpura (TTP) is a life-threatening disease characterised by microvascular platelet deposition and thrombus formation in selected organs with resulting microangiopathic haemolytic anaemia, thrombocytopenia, neurological symptoms, and renal failure. Typically a very rare disorder, TTP is being seen with increased frequency in patients infected with the human immunodeficiency virus (HIV). Deficiency of the Von Willebrand factor cleavage protease, also known as ADAMTS13, has been implicated as a major aetiological factor in TTP. However, before studying the role of ADAMTS13 in HIV related TTP, it is necessary to know the normal values of ADAMTS13 levels in the population group in question because lower ADAMTS13 levels had been reported in some populations such as the Chinese. It is also necessary to know whether HIV infection in the absence of TTP has any effect on ADAMTS13 levels. *Aim.* The aim of the study was threefold: a) to compare the ADAMTS13 levels in the local Caucasian and African populations; b) to study the effect of HIV infection on ADAMTS13 levels by correlating CD4 counts and viral loads with ADAMTS13 levels in HIV positive patients without TTP; and c) to measure ADAMTS13 levels in HIV infected patients with TTP. *Methods.* Ethics approval was obtained from the Ethics Committee of the Faculty of Health Sciences, University of the Free State. An ELISA for ADAMTS13-antigen levels was standardised and optimised for routine use in our laboratory. ADAMTS13 levels (mean ± 1SD) were measured in both local Caucasian (n=19) and African (n=21) populations. Thirty six HIV-positive patients without TTP and with CD4 counts varying from 4 to 681 and viral loads varying from 3 400 to 700 000, were tested. The CD4 counts were determined with a Beckman Coulter flow cytometer (Epics XL.MCL) and viral loads with a Roche Amplicor HIV-1 (RT-PCR) kit according to the manufacturer's instructions. ADAMTS13 levels were also measured in 20 patients with HIV associated TTP. *Results.* No statistically difference in ADAMTS13 antigen levels could be found in the local Caucasian and African populations (739±77 ng/mL vs. 714±47 ng/ml; $p<0.5$). The ADAMTS13 levels were normal in the HIV patients without TTP (750±89 ng/mL) and the severity of HIV infection as reflected by either CD4 count or viral load had no effect on the levels. The ADAMTS13 levels in all 20 HIV associated TTP patients were low (244±121 ng/mL). *Conclusion*. Neither population group nor severity of HIV infection as reflected by CD4 count and viral load had any effect on ADAMTS13-antigen levels, making it a useful diagnostic tool in the setting of HIV positive patients with TTP.

HIGH AVIDITY ANTICARDIOLIPIN ANTIBODIES ASSOCIATE WITH THROMBOSIS IN PATIENTS WITH ANTHIPHOSPHOLIPID SYNDROME

G. Lobreglio, G.C. Giancarlo

A.O. Card G Panico, TRICASE, Italy

Background. Anticardiolipin antibodies (ACA) are immunoglobulins that occur in the Antiphospholipid Syndrome (APS) and in a variety of disorders, including connective tissue diseases (secondary APS), syphilis and other infectious diseases. APS is an important cause of acquired thrombophilia and recurrent miscarriage; however not all ACA are associated with thrombotic events or pregnancy failure. Affinity/avidity of these autoantibodies and their association with thrombosis has not been sufficiently studied. *Aims.* The aims of our study were to evaluate if avidity of IgG ACA in sera from patients with primary or secondary APS or infectious disorders is associated with thrombosis or pregnancy loss. *Methods.* We studied sera from 60 patients: 22 with primary APS, 18 with APS secondary to SLE and 20 with syphilis. Avidity of IgG ACA was determined by enzyme-linked immunosorbent assay and modified buffer solution containing K-thiocyanate and Triton X-100 as dissociating agents. *Results.* High avidity IgG ACA (more than 70% of the initial binding) were detected in 18 primary and 10 secondary APS and were associated with thrombosis and/or pregnancy loss in 15 and 7 patients, respectively. In the other patients with APS and in those with syphilis ACA avidity was heterogeneous-low (<25%) and associated with venous thrombosis in 2 patients with SLE ($p<0.01$). *Summary and Conclusions.* IgG ACA with higher avidity appear to be significantly associ-

ated with thrombosis and/or obstetric complication in APS. Avidity of ACA may be a better predictor of predisposition to thrombosis and pregnancy loss than ACA levels , which may fluctuate over time owing to several factors. Thus, implementation of strategies for the characterization of ACA's avidity may have relevant clinical utility in the management of antiphospholipid syndrome.

THE USE OF INFERIOR VENA CAVAL FILTERS AT A DISTRICT GENERAL HOSPITAL IN THE UK

N.B. Bhatnagar, J. Blundell

Royal Cornwall Hospital NHS Trust, TRURO, UK

Background. Venous thromboemoblism (VTE) is a significant cause of morbidity and mortality worldwide. Anticoagulation remains the preferred treatment for deep vein thrombosis (DVT) and pulmonary embolism (PE), however, in recent years the use of inferior vena cava (IVC) filters has increased significantly as a preventative measure again PE. This has raised concerns about the indications for IVC filter placement and the management of IVC filters. In 2006 the British Committee for Standards in Haematology (BCSH) produced guidelines on the use of IVC filters. *Aims*. The aims were to establish which patients in the Royal Cornwall hospital were having IVC filters placed and if our practice was consistent with the current BCSH guidelines. *Methods*. Patients who had IVC filter inserted over a four year period (2004-2008) were identified using the Picture Archiving and Communication System. An audit proforma was designed to address each aspect of the current BCSH guideline. Clinical information was obtained retrospectively from the hospital notes. *Results*. 60 patients were identified over the four year period. 49 case notes were retrieved of which 23 were males and 26 females- 75% of the patients were aged above 60 years of age. All patients had IVC filters placed for appropriate reasons; 27 had a contraindication to anticoagulation, 14 were pre-operative patients with recent PE (within one month), 7 had VTE despite appropriate anticoagulation and 1 patient had VTE in pregnancy shortly before delivery (<2 weeks). Removal of IVC filter was delayed (>4 weeks) in 73% patients. A low rate of complications was observed after filter insertion with only 2 patients having IVC thrombosis, both of whom did not receive long-term anticoagulation and 1 patient with recurrent DVTs despite receiving anticoagulation. All 3 patients had underlying malignancy. There was no routine follow up in 76% of the cases. Survival was poor with death in 34/49 patients, of which 76% were secondary to malignancy. *Conclusions*. In our patient population IVC filters have been inserted for guideline appropriate indications. They appear to have had a useful role in the management of patients with VTE, in particular those who have contraindication to anticoagulation. In the majority of patients they were safe to use with low complication rates even without long-term anticoagulation and with prolonged placement. Routine radiological follow up may not be necessary in all patients as many have limited life expectancy due to underlying malignancy.

IDENTIFICATION OF MUTATIONS IN THE PROTEIN C GENE ASSOCIATED WITH THE RISK OF VENOUS TROMBOSIS

F. España, P. Medina, S. Navarro, A. Vayá, F. Ferrando, M.T. Contreras, A. Estellés, F. España

Hospital Universitario La Fe, VALENCIA, Spain

Background. During the diagnosis of protein C (PC) deficiencies in families with a history of venous thromboembolism (VTE), frequently occurs that some relatives of the investigated families show a PC level near the lower normal limit (60-70%), which makes clinicians difficult to reach a definitive diagnosis. *Aims.* To identify mutations in the PC gene responsible for the PC deficiency in 9 proposita with VTE and in their relatives. *Methods.* We sequenced the 9 exons (E) and their flanking intron (I) regions of the PC gene in the proposita and in two of their relatives, one with reduced and the other with normal plasma PC levels. Following identification of the mutation associated with the plasma PC deficiency, we genotyped the mutation in the remaining relatives by direct sequencing of the corresponding PC DNA fragment. *Results.* In total, we found 7 PC mutations, 2 of them in two different families. Three were mutations already described in the literature: Pro168Leu, Val297Met and Thr298Met. The first two mutations have been reported to induce an abnormal folding or thermodynamic instability in the PC molecule and the third would destabilize the structure of the hydrophobic pocket, blocking its function. We found 4 novel PC mutations. The Gly179Arg mutation, identified in two families, would induce an abnormal folding of the protein. The G3222T mutation modifies the consensus sequence of the E5-I5 splicing site, whereas the A3318G mutation modifies the consensus sequence of the I5-E6 splicing site, which could alter the sequence or the PC level. Finally, the Glu16Lys modifies the Glu16 residue in the Gla domain of the PC molecule, which is essential for the correct folding of the domain and for the PC anticoagulant function. *Conclusions.* Our study allowed us to identify the mutations responsible for the PC deficiency in all 9 families studied, and to provide genetic counselling to all family members (Conselleria de Sanitat AP-151/08; RECAVA RD06/0014/004).

ARE THROMBIN-ACTIVATABLE FIBRINOLYSIS INHIBITOR POLYMORPHISMS DETERMINANTS OF THE TYPE OF ACUTE CORONARY SYNDROME?

D. Tassies,[1] M. Roque,[2] J. Monteagudo,[2] T. Martorell,[2] A. Sionis,[2] D. Arzamendi,[2] M. Heras,[2] J.C. Reverter[2]

[1]Hospital Clinic Barcelona, BARCELONA; [2]Hospital Clinic, BARCELONA, Spain

Background. In patients with coronary disease at risk of acute coronary events it is unclear which biological factors could predict the type of acute coronary syndrome (ACS) clinical presentation. *Aim.* The aim of the study was to investigate the role of genetic polymorphisms in key proteins in fibrinolysis in the type of ACS. *Methods.* 248 patients with ACS (unstable angina or myocardial infarction) (77% male, mean age 60.75 SD 13.30 years) were prospectively recruited. PAI-1 (type-1 plasminogen activator inhibitor) 4G/5G and thrombin-activatable fibrinolysis inhibitor (TAFI) Ala147Thr, C+1542G, and Thr325Ile polymorphisms were determined by PCR. *Results.* 147 (59.3%) patients presented with ST-segment elevation (STE) ACS (all Q-wave myocardial infarction), and 101 (40.7%) with non-STE ACS (52 non-Q wave myocardial infarction, and 49 unstable angina). Homozygous TAFI +1542G and TAFI 325Ile genotypes were less prevalent in patients with STE ACS (p<0.001, OR: 0.22, 95% CI 0.10-0.50 and p<0.001, OR: 0.25, 95% CI 0.11-0.55, respectively). There were no differences in TAFI Ala147Thr or PAI genotype distribution between STE and non-STE ACS. In the multivariate analysis including clinical variables, the best model for STE ACS included TAFI +1542GG (p<0.001, OR: 0.17, 95% CI 0.07-0.30), age (in years, p<0.005, OR: 0.97, 95% CI 0.94-0.98) and dyslipidemia (p<0.005, OR: 2.33, 95% CI 1.42-3.80). *Conclusions.* TAFI polymorphism C+1542G and Thr325/Ile are related to the type of ACS. Patients with coronary disease would benefit from individualized cardiovascular prophylaxis based on genetic risk. Supported in part by grant FIS 02/0711 and FIS 05/0204 from the Fondo de Investigaciones Sanitarias, and HERACLES network RD06/0009, Ministerio de Ciencia e Innovacion, Instituto de Salud Carlos III, Spain.

ORAL VALGANCICLOVIR AS EARLY PRE-EMPTIVE TREATMENT FOR CMV REACTIVATION AFTER ALLOGENEIC STEM CELL TRANSPLANTATION: A SINGLE CENTER EXPERIENCE IN 45 PATIENTS

M.T. Lupo Stanghellini, R. Greco, T. Generali, D. Clerici, S. Malato, C. Corti, M.G. Carrabba, F. Lunghi, E. Biral, J. Peccatori, M. Bernardi, M. Marcatti, L. Fumagalli, F. Crippa, F. Ciceri

San Raffaele Scientific Institute, MILAN, Italy

Background. Cytomegalovirus (CMV) reactivation remains an important complication after allogeneic stem cell transplantation (allo-SCT), accounting for significant morbidity and mortality, despite recent advances in prevention and treatment. Preventive measures are both primary prophylaxis and preemptive therapy. According to the EMBT Infectious Disease Working Party and the European Conference on Infections in Leukemia both intravenous ganciclovir or foscarnet can be used as first line preemptive therapy; oral valganciclovir (VGCV) still remain an investigational option. *Aims.* We report the retrospective analysis of CMV treatment with valganciclovir and outcome in patients (pts) experiencing CMV reactivation after allo-SCT at our Institution in the last 4 years. *Materials and methods.* Between November-2004 and January-2009, 117 pts were evaluated for CMV reactivation within the first 3 months after allo-SCT. Pts were monitored for CMV quantitative pp65 antigenemia and quantitative DNA PCR twice weekly; response to treatment was defined as negativization of pp65 antigenemia for at least 2 consecutive determination under treatment. Preemptive therapies were: ganciclovir, foscarnet and VGCV. Toxicities were defined according to the Common Terminology Criteria for Adverse Events v3.0. *Results*. One-hundred-seventeen pts (median age 48 years, range 19-67; 71 males) received transplant for high risk haematological malignancies; 6/117 received a second transplant. Totally 123 allo-SCT were performed: 44 from HLA identical sibling, 36 from unrelated volunteer donor, 42 from family haploidentical donor (17 with *ex vivo* T-cell depletion, 25 without), 1 cord blood. Host/donor serostatus was: -/-7, +/+68, -/+6, +/-42. One-hundred-eleven pts received acyclovir as viral prophylaxis. Sixty-two pts out of 117 experienced CMV reactivation. Median time of CMV reactivation was 43 days (range 7-168). Median number of CMV Ag nuclei was 3 (range 1-35), median CMV DNA PCR was 2090 (range 131-66000). Forty-five out of 117 received oral VCGV as first line preemptive therapy; median time of treatment was 16 days (range 6-44). Thirty-one out of 45 (69%) completely resolved CMV reactivation, while 14 required drug crossover to ganciclovir or foscarnet iv for persistence of CMV positivity after a median time of 16 treatment-days. Thirty-one out of 45 patients (68%) developed haematological toxicities. Globally we observed: 16 grade IV neutropenia and 1 grade IV thrombocytopenia; 13 grade III neutropenia, 7 grade III anemia and 13 grade III thrombocytopenia. Six out of 29 pts with grade III-IV neutropenia experienced severe infectious adverse events (SAE), requiring hospitalisation. Twenty-one pts, out of the 31 who completely resolved CMV reactivation with VGCV did not present further reactivation. In 9/10 pts the recurrence of CMV reactivation within the first 3 months after transplant was successfully treated with VGCV. *Conclusions.* Oral valganciclovir treatment is effective as first line therapy early after allo-SCT. A prospective randomised study comparing oral VGCV and gancyclovit i.v. is planned in our Institution to assess the oral VGCV efficacy as standard treatment in allo-SCT.

INCIDENCE AND RISK FACTORS OF PROVEN OR PROBABLE INVASIVE FUNGAL INFECTIONS IN 286 PATIENTS UNDERGOING RELATED OR UNRELATED ALLOGENEIC BONE MARROW TRANSPLANTATION

A. Candoni,[1] E. Simeone,[1] M. Tiribelli,[1] M. Cerno,[1] A. Geromin,[1] A. Sperotto,[1] L. Pagano,[2] R. Fanin[1]

[1]Division of Hematology, UDINE; [2]Department of Hematology, Università Cattolica S. Cuore, ROME, Italy

Introduction. Allogeneic bone marrow transplantation (BMT) is increasingly used to treat hematologic diseases. Invasive fungal infections (IFI) remain an important cause of morbidity and mortality in this setting. Recent reports have indicate that the incidence of IFI (expecially aspergillosis) has increased in BMT recipients, particulary after engraftment. *Patients and Results.* To evaluate the epidemiology, outcome and risk factors of proven or probable IFI in allogeneic BMT recipients, we retrospectively reviewed the medical records of 286 consecutive adult patients (pts) who underwent allogeneic BMT (170 from related and 116 from unrelated donor) at our Department between 1992 and 2005; 213/286 (74%) pts received a myeloablative conditioning regimen and 73/286 (26%) a nonmyeloablative one. The median age of patients was 43 years (range 19-68). We identified 36 cases of proven or probable IFI (Aspergillus sp. 25, Candida sp. 5, Fusarium 2, Mucor 5) with an overall incidence of 13%. The incidence after related BMT (RD-BMT) was 9% while it was 16% after unrelated BMT (UD-BMT) (p<0,05). The incidence was the same in the myeloablative and non myeloablative setting. IFI occurred after a median of 38 days from BMT (range 5-1440); 16/36 (44%) cases occurred during pre-engraftment phase while 20/36 (56%) occurred after engraftment (with 12/20 cases after day 100). The sites of infection were: lung only 22/36 (61%), CNS 6/36 (17%), multiple sites 8/36 (22%). Advanced hematologic disease (relapsed or refractory) at time of transplant, history of pre-transplant IFI, presence of acute or chronic graft-versus-host-disease (GVHD), but not neutropenia, were significant risk factors (p<0.05). In the UD-BMT setting the incidence of IFI was significantly higher in patients who received a combination of immunosuppressive agents in the conditioning regimens (ATG +/- Fludarabine +/- Campath). Overall Survival after 100 days from diagnosis of IFI was only 20% and in these cases 64% of deaths were directly IFI related. *Conclusions.* 1) IFI is a significant cause of non-relapse mortality following RD and UD- BMT. 2) Aspergillus sp. remain the most important aetiologic agent. 3) Incidence of IFI in UD-BMT is significantly higher than in RD-BMT probably as a result of more intensive immunosuppressive conditioning regimen in this setting. 4) IFI can develop late after engraftment (after day 100 from transplant) and without neutropenia. 5) Status of hematologic disease (relapsed or refractory) at transplant, history of pre-transplant IFI and presence of GVHD, are important predisposing factors. 6) Retrospective studies, like this one, can be useful in order to identify high-risk BMT patients for which targeted and more effective diagnostic and therapeutic strategies should be used to prevent and treat IFI.

0458

ONCE-WEEKLY LIPOSOMAL AMPHOTERICIN B FOR PROPHYLAXIS OF INVASIVE FUNGAL INFECTION AFTER GRAFT VERSUS HOST DISEASE ì IN ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANTATION (ALLO-SCT): A COMPARATIVE RETROSPECTIVE MONOCENTER STUDY

J. El-Cheikh, L. Wang, C. Faucher, S. Furst, L. Castagna, B. Esterni, S. Duran, P. Berger, P. Viens, D. Blaise

Institut Paoli Calmettes, MARSEILLE, France

Invasive pulmonary aspergillosis (IPA) is a significant risk in patients with graft versus host disease (GvHD) after allo-transplantation. A comparative retrospective single centre study was conducted to investigate the efficacy and safety of liposomal amphotericin B (L-AmB, Ambisome®) prophylaxis of fungal infections in allo-transplanted patients with GvHD. A total of 125 patients receiving high-dose prednisone (2 mg/kg/day) therapy for acute and/or chronic GvHD after allo-SCT were identified. 118 pateints (94%) had a RIC regimen and 7 (6%) a myeloablative conditioning; 95 patients (76%) had a family donor and 30 patients (24%) had an unrelated donor. Median age at transplant was 48 years (range 18-70). Forty-two patients received once-weekly high-dose (7.5 mg/kg/week) L-AmB as prophylactic treatment. Eighty-three patients of the control group received possibly other prophylactic antifungal drugs such as fluconazole, voriconazole, itraconazole, posaconazole. The prophylactic median dose of L-AmB was 500 mg/week (range 300-650) and the median duration of treatment was 7 weeks (range 2-15). The incidence of IPA disease was 8% in the prophylactic group at both one year and two years vs 36% and 44%, respectively, in the control group (p=0.008). No fungal infection-related deaths were observed post-transplantation in the prophylactic group vs 12 (14%) at one year, 14 (17%) at two years and 16 (19%) at three years post-transplantation in the control group (p=0.005). The OS rate at one year was 69% for the prophylactic group vs 75% for the control group; at two years the OS was 55% in the prophylactic group vs. 64% in the control group (p= 0.60). There were no differences in the TRM rates between the two groups at two years (18% vs. 19%) and at three years (18% vs. 21%) (p=0.99). Prophylactic treatment with L-AmB was well tolerated. Renal toxicity leading to treatment discontinuation was observed in only five patients (12%) who were concomitantly treated with other nephrotoxic drugs; nephrotoxicity was reversible in all five patients. These data suggest L-AmB prophylaxis is an effective and well tolerated treatment for the prevention of invasive fungal infection and can reduce the fungal infection related mortality in RIC allo-SCT patients presenting a severe

GvHD; further prospective clinical studies are required to confirm these single center data.

Background and Aims. To evaluate epidemiological characteristics, and outcome of invasive aspergillosis (IA) in acute myeloid leukemia patients (AMLs), and to analyse efficacy of different therapeutic approaches. *Methods.* A multicenter survey conducted over 2004-2007 in 21 Italian Hematology Divisions. All proven/probable IA were reported. AMLs submitted to transplant were excluded. Principal demographic and clinical data, as well as antifungal therapies and outcome were analyzed. All available variables were investigated as predictors of death. Follow-up was assessed at 90th day from IA diagnosis. Response rate to 1st line antifungal therapy were thus analyzed. Our attention mainly focused on the three most frequently emploied drugs: voriconazole, liposomal amphotericin B (L-AmB), caspofungin.

Table. Therapuetic approaches employed in 140 patients and results of univariate analysis.

	N° cases (%)	N° exitus (AMR %)	*p-value*
Antifungal prophylaxis	20 (14%)	4 (20%)	
➢Topical	20 (14%)	6 (30%)

AMR: aspergillosis-attributable mortality rate; d-AmB: deoxycolate amphotericin B; L-AmB: liposomal amphotericin B; G-CSF: granulocyte colony stimulating factor, AF: antifungal

Results. 140 cases were collected, most of which were probable IA (66%). Infection mostly occurred after the 1st course of chemotherapy (61%). The majority of AMLs experienced a deep neutropenia before the onset of symptoms (90%). Overall attributable mortality rate (AMR) was 27% (38/140), and it remained stable over years. Outcome was significantly influenced by AML phase ($p<0.001$), duration of ($p=0.05$) and recovery from neutropenia ($p<0.001$). Role of neutropenia duration was confirmed at multivariate analysis ($p<0.005$). Antifungal approaches are reported in Table 1. No differences emerged between empirical and pre-emptive therapy and none of the drugs employed resulted to significantly influence outcome. In 66% of pts initial empirical/pre-emptive drug remained unchanged after IA diagnosis, while in 16% clinicians shifted to a combined treatment. When we compared the 3 most frequently emplojed drugs as 1st line target therapy (Table), the overall response rate was 71%, ranging from 61% with caspofungin to 84% with voriconazole. Ninety-three pts received subsequent oral antifungal therapy, and voriconazole was the most frequently employed drug. *Summary and Conclusions.* Because of availability of complete information about pts, this study allows as to analyzed multiple factors, as potentially influencing outcome. Frontline therapy choice is a crucial point, influencing patients' outcome. Our series confirmed the good result obtained in other recent series and perception that the application of a correct and timely diagnostic work-up and the availability of more efficacious and less toxic antifungal drugs (i.e. voriconazole, liposomal amphotericin B [L-AmB], caspofungin) have modified the course of IA. However all newer drugs resulted comparable in terms of survival and response rate. Even combined antifungal treatment did not confer any advantage in survival analysis. Despite of recent progresses, management of hematological malignancy and recovery from neutropenia continue to be the most crucial prognostic factors.

RAPID DETECTION AND IDENTIFICATION OF PATHOGENS IN HEMATOONCOLOGICAL PATIENTS USING MOLECULAR TECHNIQUES

S. Pekova,[1] O. Mazal,[2] J. Vydra,[2] H. Kabickova,[3] T. Kozak,[2] S. Pekova[1]

[1]Na Homolce Hospital, PRAGUE; [2]University Hospital Kralovske Vinohrady, PRAGUE; [3]Central Military Hospital, PRAGUE, Czech Republic

Background. Infectious complications in immunocompromised hosts (hematooncological patients) represent a serious clinical issue. In these individuals, not only common nosocomial agents, but also very unusual pathogens, zoonoses, pathogens with specific cultivation demands or fastidious pathogens can be identified. Moreover, in these patients, the disease course might be rapid, complicated and serious. *Aims.* The goal of the work was to improve the speed and precision of the laboratory diagnostics of infectious agents, as a supplement to the standard microbiological techniques. *Methods.* We have developed a system employing pathogen-specific probes and Real-Time PCR technology to detect 25 most frequent human pathogens causing severe nosocomial infections and 5 fastidious pathogens causing pulmonary infections. Each sample has also been tested using pan bacterial and pan fungal broad-range 16S and 18S rDNA PCR system coupled with direct sequencing of PCR products for precise identification of the causative agents. *Results.* We have investigated 1,248 clinical samples including peripheral blood, BAL, cerebrospinal fluid, sputum, aspirates from thorax cavity, drainage fluids, abscesses, tissue biopsies, urine, and stool. In addition to common pathogens we have identified a set of unusual and fastidious pathogens: Chlamydiophilla pneumoniae (BAL), Mycoplasma pneumoniae (BAL), Legionella pneumoniae (BAL, peripheral blood), Bordetella parapertussis (BAL), Peptostreptococcus micros (thorax cavity), Fusobacterium nucleatum, Listeria monocytogenes and Porphyromonas endodontalis (cerebrospinal fluid), Moraxella nonliquefaciens (urine), Mycobacterium tuberculosis (tissue, cerebrospinal fluid), Aspergillus flavus (tissue, sputum), Malassezia pachydermatis (tissue), Cryptococcus carnescens (BAL). Moreover, for the first time, we have identified a zoonosis caused by the tick-borne agent Candidatus Neoehrlichia mikurensis (CNM), in peripheral blood of a patient with relapsing mantle cell lymphoma. The CNM finding was corroborated by 16S rDNA sequencing and electron microscopy. *Conclusions.* Pathogen-specific Real-Time PCR technique coupled with direct pan bacterial and pan fungal sequencing represent a very fast and useful tool to accelerate and refine the diagnostics of infections in immunocompromised and critically ill patients. Timely information on the causative agents is highly important for rapid and accurate clinical decision making and targeted pharmacotherapy.

COMBINED QUANTITATIVE CMV PCR MONITORING WITH PRE-EMPTIVE ORAL VALGANCLOVIR IS EFFECTIVE IN PREVENTING SYMPTOMATIC CMV INFECTION IN ALLOGENEIC HAEMOPOIETIC TRANSPLANT RECIPIENTS

S. Hewamana, B. Austen, K. Karunanithi, U. Mohite, N. Price, K. Wilson

UHW, CARDIFF, UK

Background. Human cytomegalovirus (CMV) infection is a major cause of morbidity and mortality in haemopoietic transplant recipients prompting universal prophylaxis or treatment during the asymptomatic phase (pre-emptive treatment). Monitoring for CMV reactivation can be done by viral isolation, quantification of pp65 antigen or quantification of viral genome in the peripheral blood. Quantification of viral genome by a PCR based method is highly sensitive and allows rapid diagnosis and treatment. However the threshold for initiating (pre-emptive) treatment and the optimal therapeutic approach is not well defined. *Aims.* The aim of our study was to evaluate the use of a quantitative PCR CMV genome screening approach combined with standardised criteria for initiation of treatment with oral Valganciclovir in the control of the development of CMV disease in an allogeneic haematopoietic transplant (BMT) population. *Methods*. The study cohort included all allogeneic BMT patients treated in a single centre from January 2006 to December 2008. Peripheral blood samples were analysed for CMV reactivation at least weekly from day 0 of transplant until immunosuppressive drugs had been discontinued using a real time PCR method (Qiagen, Hamburg). The results were reported according to the manufacturers' instructions: copy number <650 was reported as not detected; copy number > 650 but <10000 was reported as detected; copy number > 10000 was reported as a numerical positive result. Patients were initiated on treatment, firstly, if they had CMV related symptoms and a positive result of any copy number and, secondly, if they were asymptomatic but either had two consecutive readings of a copy number of more than 10000 or two consecutive detectable readings with a rising titre. Treatment was discontinued when there were two negative results. Clinical data was collected by prospective follow up from case notes. *Results.* A total of 77 transplants (27 sibling and 50 unrelated donor) were performed. Thirty-five patients (45%) showed CMV reactivation amounting to 88 episodes. Twenty-three episodes (26%) did not fulfil the criteria for treatment initiation and resolved spontaneously. Fifty episodes (57%) were successfully treated with oral Valganciclovir and did not need hospitalisation. Twelve episodes were treated with Valganciclovir and then moved to IV Ganciclovir due to clinical deterioration / treatment failure or started on IV Ganciclovir initially and therapy continued on oral Valganciclovir. The remaining 3 episodes were treated with Ganciclovir as it was felt IV is preferable to oral therapy. There were two incidences of CMV retinitis while the peripheral blood CMV PCR was reported as not detectable and both these patients have previous incidence of positive CMV PCR that had required treatment. *Summary and Conclusions.* RT-PCR based method is a sensitive way of quantification of CMV viral genome. Oral Valganciclovir is effective in controlling CMV reactivation with minimal toxicity and avoiding patient hospitalisation. Two episodes of CMV retinitis while having low level of copy numbers (reported as not detectable by the present reporting method) raise the value for regular ophthalmology review for high risk patients.

0462

CANDIDEMIA IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES: THE ROLE OF PROPHYLAXIS AND THE IMPORTANCE OF LOCAL EPIDEMIOLOGY IN TREATMENT

M. Bastos Oreiro, M. Canales, R. De Paz Arias, A. Lopez de la Guia, P. Baltazar, M.J. Garcia Rodriguez, J. Garcia Rodriguez, F. Hernandez Navarro

Hospital La Paz, MADRID, Spain

Background. Candidemia is a serious condition with a high mortality rate in patients with hematologic malignancies. It is thus important to understand the associated risk factors, as well as the need to establish adequate prophylaxis and early, effective therapy. *Aims.*To determine the incidence of candidemia in hospital patients with hematologic malignancies; to describe its clinical features and the risk factors associated with infection and with a poor outcome. *Methods.* An electronic database was used to identify cases between January 2000 to March 2008, of a positive blood culture for Candida spp in hemato-oncologic patients admitted to the Hematology Ward of Hospital Universitario La Paz. Clinical history of each identified case was reviewed. *Results.* 47 patients were identified, with an annual incidence of 1%. Species identified were: Candida parapsilopsis in 46% of cases (n=22) and Candida albicans in 21.3% (n=10); the remainder was distributed amongst C. guillermondi, C. tropicalis and C. krusei. Underlying hemalogic malignancies were: non-Hodgkin lymphoma (34%, n=16), multiple myeloma (19%, n=9) and acute myeloid leukemia (17%, n=8). 48.9% of patients underwent stem cell transplantation (45.3% allogeneic and 54.7% autologous). No significant association was found between the underlying hematologic malignancy and the species of Candida that was isolated. The antifungals used in treatment were: liposomal amphotericin 48.9%, fluconazole 12.7%, caspofungin 4.2%, voriconazole 4.2% and combined therapy in 30% of patients. MIC50 and MIC90 for fluconazole against C. parapsilopsis were 4 and 32, respectively, and 0.03 and 8, respectively against C. albicans. MIC90 against the other species was 0.03. MIC50 and MIC90 for amphotericin were 0.03 and 1, respectively, against C. albicans, C. parapsilopsis and C. krusei. Voriconazole, itraconazole and caspofungin were found to have an MIC90 of 0.03 against all species of Candida. 37.8% of patients were already receiving antifungal prophylaxis at the time of diagnosis of candidemia, although 90% of cases of C. albicans candidemia were not on prophylaxis (p<0.05). In terms of risk factors, 76.6% of patients had a central venous catheter, 78.8% were undergoing chemotherapy, 95.6% were receiving concomitant, broad-spectrum antibiotics, 21.7% were diabetic, 46.8% were receiving parenteral nutrition of which more than half (59.1%) were associated with C. parapsilopsis, 26.7% had a serious associated mucositis, 60.5% had less than 0.2×10^9/L neutrophils, 37% had kidney failure. Eight patients (17%) died as a result of candidemia: 4 from C. albicans, 2 from C. parapsilopsis, 1 from C. glabrata and 1 from C. krusei. Of the patients with C. albicans, 33% died, compared to 11.8% of those with other species of Candida (p<0.05). *Conclusions.* Candida parapsilopsis was found to be the the main causative species of candedemia in our centre, with a markedly high MIC50 and MIC90 for fluconazole, probably related to fluconazole prophylaxis. These findings highlight the importance of understanding the epidemiology of each centre when planning treatment and establishing an effective scheme of prophylaxis in high-risk patients to avoid the mortality associated with this type of infectious complication.

0463

MANAGEMENT OF FEBRILE NEUTROPENIA EPISODES IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES BY USING THE MULTINATIONAL ASSOCIATION FOR SUPPORTIVE CARE IN CANCER RISK INDEX

A. Argyrou, M. Pergaminou, A. Galanopoulos, T. Marinakis, E. Michalis, G. Gkortzolidis, N.I. Anagnostopoulos

G.N.A. G.Gennimatas General Hospital of Athens, ATHENS, Greece

Background. Febrile neutropenia (FN) is a common and potentially life threatening problem for patients with hematological malignancies. That is why it is very important to define which of these patients could be considered as low or high risk, in order to manage the episodes of FN by the best way possible. *Aims.* In this study, we try to determine whether the Multinational Association for Supportive Care in Cancer (MASCC) Risk Index is able to predict the outcome of the FN episodes in patients with hematologial malignancies, by separating them in risk groups. *Methods.* This is a retrospective study of 100 episodes of FN in patients with hematological malignancies, which were hospitalized in our Clinic from January 2007 to May 2008. MASCC Risk Index Score was calculated for every FN episode. This Score is based on seven independent factors present at the onset of the FN. These factors are: 1) burden of illness: absent or mild symptoms (5 points), moderate symptoms (3 points), 2) absence of hypotention (5 points), 3) absence of chronic obstructive pulmonary disease (4 points), 4) presence of solid tumor or absence of previous fungal infection (4 points), 5) outpatient status (3 points), 6) absence of dehydration (3 points), 7) age <60 years (2 points). MASCC Risk Index- Score ≥21 indicates low-risk patients. MASCC Risk Index-Score <21 indicates high-risk patients which were candidates for developing serious medical complications. In our study, MASCC Risk Index- Score was compared to the outcome of each episode of FN. The results were statistically analysed with Chi-Square, Fisher Exact Test and Logistic retrogression. *Results.* 46/100 (46%) episodes of FN were scored with MASCC Risk Index- Score ≥21. 40 of them (40/46, 86.95%), had a favourable outcome with immediate response to their therapy. 6/46 (13.04%), had unfavourable outcome, such as no response to the initial therapy, worsening of the patient's status and death. 54/100 (54%) episodes of FN were scored with MASCC Risk Index- Score <21. 4 of

them (4/54, 7.4%), had a favourable outcome. 50/54 (92.59%) had unfavourable outcome. Conclusively, MASCC Risk Index- Score could predict the outcome of the FN episodes, with worthy predictive value (87%), sensitivity (90.9%) and specificity (89.3%). *Summary and Conclusions.* MASCC Risk Index- Score is both safe and feasible way to predict the outcome of the FN episodes in patients with hematological malignancies, as it accurately identifies patients at low or high risk for medical complications. This Index could possibly be used for evaluation of the patients at the time of their admission to the Hospital. Low risk patients could be managed safely with early hospital discharge and oral antibiotics, always under the recommendations of the attendant physician.

0464

SERUM N-TERMINAL PRO-BRAIN NATRIURETIC PEPTIDE IN HAEMATOLOGICAL PATIENTS WITH NEUTROPENIC FEVER: A PROSPECTIVE COMPARISON WITH C-REACTIVE PROTEIN

E. Jantunen,[1] S. Hämäläinen,[2] T. Kuittinen,[3] I. Koivula,[2] I. Matinlauri,[4] T. Nousiainen,[2] K. Pulkki,[5] A. Juutilainen[2]

[1]Kuopio University Hospital, KUOPIO; [2]Department of Medicine, Kuopio University Hospital, KUOPIO; [3]Biomedicum, HELSINKI; [4]Department of Clinical Chemistry, Turku University Central Hospital, TURKU; [5]Department of Clinical Chemistry, Kuopio University Hospital, KUOPIO, Finland

Serum amino-terminal pro-brain natriuretic peptide (NT-proBNP) is considered to be of importance in patients with severe sepsis. However, no data is available on NT-proBNP kinetics in haematological patients with neutropenic fever and severe sepsis. Seventy haematological patients were included into this prospective study. The median age was 56 years (range 18-70). Ten patients (14%) had previous cardiovascular disease. Nineteen patients received intensive chemotherapy for acute myeloid leukaemia and fifty-one patients were autologous stem cell transplant recipients. Laboratory samples for the determination of NT-proBNP and C-reactive protein (CRP) were collected at the beginning of the neutropenic fever (d0) and then daily up to 3-4 days. There were altogether 94 periods of neutropenic fever, of which 13 (14%) were complicated by severe sepsis. Two patients (15% of those with severe sepsis) died from septic shock. The median time after the onset of fever to the point when the criteria for severe sepsis were fulfilled was 1 day (range 1-7). The median pro-BNP (interquartile ranges) increased from 127 ng/l (57-393) on d0 to 542 ng/L (194-385) on d4. In patients with previous cardiovascular disease the NT-proBNP values were significantly higher than in patients without cardiac diseases throughout the whole study period. The median CRP increased from 35 mg/L on d0 to 109 mg/L on d2. Medians for NT-pro-BNP or CRP did not differ between periods with severe sepsis than those without on days 0-2. There was no correlation between CRP and pro-BNP measured on the same day. Neither serial NT-proBNP nor CRP showed any early predictive value in periods with severe sepsis. We conclude that NT-pro-BNP may not reflect inflammatory response in this patient group, rather it seems to be a marker of previous cardiovascular disease and a marker of cardiovascular stress during sepsis in these patients. It may thus serve as a useful adjunct to optimize management of patients with previous cardiovascular disease during sepsis.

0465

PALONOSETRON (ALOXI): A SINGLE-CENTER EXPERIENCE IN THE PREVENTION OF EMESIS IN PATIENTS AFFECTED BY HAEMATOLOGICAL MALIGNANCIES

A.A. Assanelli, S. Agazzi, C. Soliman, F. Ciceri, V. Matozzo

San Raffaele Hospital, MILANO, Italy

Chemotherapy (CT)-induced nausea and vomiting (CINV) still represents a concern for cancer patients care. Aloxi is the newest 5-HT3 receptor antagonist, with a higher receptor-binding affinity and a longer half-life (40 hours). It has demonstrated an improved antiemetic activity for delayed (>24 hours after the initial dose of CT) CINV. Limited data are available regarding its activity in a high-dose (HD) setting, in multiple-day CTs and in an allogeneic setting for haematological malignancies. Since January 2008, we are conducting a prospective monocenter study evaluating efficacy of Aloxi after administration of multiple-day and/or high-dose chemotherapy regimens and/or myeloablative conditioning treosulfan-based regimens for allogeneic bone marrow transplantation for different hematological malignancies. 100 consecutive patients received a double intravenous (IV) administration of Aloxi 0.25 mg over 30 seconds, approximately 30 minutes before the administration of chemotherapy on day 1 and on day 4 of each cycle plus dexamethasone 4 mg IV twice a day. No dosage adjustment has been performed in elderly patients (>65 years) and in patients with renal or hepatic impairment. No relevant adverse reactions occurred. Diagnosis was acute myeloid leukemia (65 patients), acute lymphoblastic leukemia (11 pts), non-Hodgkin's and Hodgkin's lymphomas (12 pts/4 pts), multiple myeloma (4 pts), chronic myelod and lymphocytic leukemia (1 pt/1 pt), severe aplastic anaemia (2 pts). 51 patients received an allogeneic myeloablative conditioning treatment with a treosulfan-based regimen; 12 patients received an autologous bone marrow transplantation after a myeloablative regimen with HD-melphalan alone or plus mitoxantrone; 24 patients received HD-aracytin alone or plus HD-methotrexate and 13 patients received multiple-day standard-dose treatments, as induction or consolidation therapies for acute leukemias. Major endpoints included complete response (CR) established as the proportion of patients with no nausea and/or emesis and no rescue medication during acute phase (<24 hours after initial dose of chemotherapy) and during delayed phase (>24 hours but <120 hours after initial dose of chemotherapy). Each patient was investigated by the assistant nurse with a specific tool of registration, in order to estimate the real CINV, otherwise just self-reported by the patients. As to acute-CINV evaluation, almost all 100 patients (93%) achieved a CR (no emesis, no need for rescue therapy) with only 7 patients (7%) experiencing nausea, followed by a minimum of one to a maximum of five episodes of emesis, treated with other 5-HT3RAs or metoclopramide as need. As to delayed-CINV evaluation, 13 patients (13%) suffered nausea, with up to 4 episodes of emesis, with a CR rate of 87%. Rescue therapies have been performed as above. The total amount of emesis events that have been registered during the whole observation time (0-120 hours) has been 32 events, corresponding to an overall response rate of 68%. Our experience with the combination of Aloxi (double injection) plus corticosteroid seems to be an effective therapy in the prevention of both acute and delayed CINV, confirming also its rational use in an allogeneic setting for patients affected by haematological malingnancies.

0466

PROLONGED FOLLOW-UP OF PATIENTS WITH HEMATOLOGICAL MALIGNANCIES INFECTED BY HBV AND HCV

S. Kulikov, T.S. Garmaeva, E. Mihailova, B. Sudarikov, P. Filatov, G. Savchenko

National Center for Hematology, MOSCOW, Russian Federation

Introduction. Patients with hematological malignancies are the group of high risk of infection by HBV and HCV due to large transfusion load and large number of invasive procedures. The aim of the study was to evaluate the presentation rate of clinical hepatitis, patient's survival and how the fact of hepatitis infection influenced on their survival. *Results.* The studied group comprised all pts of a hematology department admitted since February 2004 till June 2006. The pts were monitored till June 2008. All pts were monitored by testing of HBsAg, aHCV, DNA-HBV, RNA-HCV, HBeAg, aHBs, aHBc, aHbe in scheduled timing by near 3 weeks. Liver biopsy was held for 64 pts, for 23 pts - with HBV and HCV immunohistology. Total 7800 biological samples were collected for HBV and HCV testing, 4000 of them was tested by PSR methods. Acute leukemias (AL) and aplastic anemias (AA) constituted 77% (205) of 265 investigated pts. Median age was 38 years (ranged from 15 to 79), male - 47% (125), female - 53% (140). Median transfusion load (the number of donors per 1 pt for investigation period) was 45 (ranged from 0 to 418). At first admittance to hematological department viral markers were found: for HBV in 15% (39/265) pts and for HCV in 7% (19/265) pts. It was postulated that the rate of infection process is extremely high in the hematology clinic. After total staying in the clinic 51% (135/265) pts had HBV markers, 19% (51/265) pts had HCV markers, 14% (37/265) pts had markers of both types (HBV+HCV). We have shown that up to 95% of HCV-positive pts and up to 60% of HBV-positive pts developed clinical-biochemical symptoms of viral hepatitis at the end of 3 years observation from the time of the first appearance of HBV and HCV markers. 154 (58%) pts survived, 111 (42%) pts died, death reason in 2 pts of them was fulminate liver dysfunction due to severe hepatitis B. The analysis of survival risk factors demonstrates that expected life duration decreases statistically significant after HBV infection. For AL pts HR=1.8 (p=0.034), for AA pts HR=4,3 (p=0.022). Statistical significant association the expected life duration and HCV infection was not proved. Proportional hazard regression model with time dependent covariates (PHREG SAS) was used for the analysis. *Conclusions.* The majority of pts infected by HBV and HCV developed the clinical recognizable viral hepatitis within 3 year from first appearance of viral markers. Pts with severe

immunosupression often do not demonstrate evident features of acute viral hepatitis. So pts with hematological malignances should be monitored regularly (at least once in a month) and carefully on HBV and HCV markers during all period of treatment and after treatment cessation for 1-2 years. Viral hepatitis B is proved to be survival risk factor for pts with AL and AA.

0467

COMPARISON BETWEEN FILGASTRIM AND PEG-FILGASTRIM IN REDUCING FEBRILE NEUTROPENIA AND MOBILIZING PBSC IN LYMPHOMA PATIENTS TREATED WITH DHAP OR R-DHAP

M. Riva, A. Molteni, A. Nosari, G. Nador, L. Marbello, L. Gargantini, E. Morra

Niguarda Cà Granda Hospital, MILAN, Italy

Background. DHAP regimen is effective in relapsed/refractory Hodgkin and non Hodgkin lymphoma. This scheme is also effective in peripheral blood stem cell (PBSC) mobilization. In pre-growth factor era, after DHAP administration, 48% severe neutropenia and 28% documented sepsis were observed (Velasquez, Blood 1988). *Aims.* To compare usual employment of filgastrim (G-CSF) with PEG-filagastrim (PEG-G) in terms of 1) preventing febrile neutropenia, 2) mobilizing PBSC in patients undergone DHAP or R-DHAP schedules. *Methods.* Data regarding 69 DHAP or R-DHAP administrations in 67 patients (female 35, male 32) were retrospectively collected. In every case G-CSF or PEG-G were administered and PBSC harvest was planned. Incidence of neutropenia and infective complications were recorded. Data regarding efficiency of PBSC harvest were also collected. *Results.* Patients' median age was 41 years (range17-67). Forty-eight patients were treated with PEG-G on the second day (median, range 1-4) after the end of chemotherapy cycle. G-CSF was employed in 21 cases; a mean of 7.4 vials were administered for each cycle starting on day 8 (median, range 5-10) from the end of chemotherapy. Grade II neutropenia had a median duration of 2 days th with G-CSF (range 0-7) and with PEG-G (range 0-8). Grade IV neutropenia was observed for 1 day (median) both with G-CSF (range 0-5) and with PEG-G (range 0-6). Grade IV neutropenia lasting for at least 3 days was seen in 16 (23%) cases (4 with G-CSF, 12 with PEG-G) and lasting for at least 5 days only in 3 (4%) cases (all with PEG-G). Febrile events were observed in 7 (10%) cases (3 with G-GSF; 4 with PEG-G): 5 cases of fever of unknown origin, 1 case of pharyngitis and 1 case of bacterial pneumonia. No mortality due to infection was seen. PBSC mobilization was effective in 67/69 cases (both failures, i.e. harvest < 2 $\times 10^6$/kg with PEG-G, in previously over-treated patients). Mean harvest was 17.26×10^6/CD34/kg with G-CSF and 13.33×10^6/CD34/kg with PEG-G. In only 8 cases harvest was suboptimal (<5×10^6/kg): 4 after G-CSF and 4 after PEG-G. Cases where just a single harvest procedure was enough to reach PBSC target were 12/19 (63%) after G-CSF and 34/44 (77%) after PEG-G. This difference was not statistically significant (Mann - Whitney test V; p=0.3744). Median number of days to harvest from end of chemotherapy was 12 with G-CSF (range 7-15, mean 12, standard deviation 2.0) and 11 after PEG-G (range 9-16, mean 11.3, standard deviation 1.2). Variance is significantly different (test F; p=0.001 after logarithmic conversion), showing a better predictability of timing of harvest in PEG-G treated patients. *Conclusions.* Also in our experience the prophylactic use of neutrophil growth factors was able to reduce impact of infections in DHAP treated patients up to 10%. PEG-G seems more effective in reaching the PBSC target (>5×10^6/kg) with a single leukapheresis than G-CSF (77% vs. 63%), but this difference was not significant in this series. A higher predictability of harvest timing was shown in PEG-G treated patients.

0468

NATURAL HISTORY OF HEPATITIS E DURING THE COURSE OF HAEMATOLOGICAL MALIGNANCIES

S. Tavitian,[1] J.M. Peron,[2] A. Huynh,[3] J.M. Mansuy,[4] F. Huguet,[3] L. Ysebaert,[3] M. Roussel,[3] M. Attal,[3] C. Recher[3]

[1]CHU Toulouse, TOULOUSE; [2]CHU Toulouse, Service d'Hépatogastroentérologie, TOULOUSE; [3]CHU Toulouse, Service d'Hématologie, TOULOUSE; [4]CHU Toulouse, Laboratoire de Virologie, TOULOUSE, France

Background. Hepatitis E virus (HEV) is an RNA virus, endemic in developing countries and an emerging disease in industrialized countries. It was considered as an agent only responsible for acuting resolving hepatitis. However chronic hepatitis complicated by severe cirrhosis have recently been described in European solid organ transplantation recipients. Natural history of hepatitis E in haematological malignancies-related immunosuppressed patients remains largely unknown. *Aims.* To describe the clinical course of hepatitis E in patients with haematological malignancies. *Methods.* We retrospectively reviewed the clinical charts of patients followed in the hematology unit of the university hospital of Toulouse (France). Diagnosis of hepatitis E was based on abnormal liver tests of unknown origin and at least one concomitant positive blood PCR. In all patients, autoimmune hepatitis or viral hepatitis of other cause (CMV, HAV, HBV, HCV) were ruled out. *Results.* From 11/2003 to 11/2008, hepatitis E was diagnosed in six patients (5 males, 1 female; median age 46 years, range 32-65) followed for acute myeloid leukemia (N=2), mantle cell lymphoma (N=2), multiple myeloma (MM, N=1) and anaplastic large cell lymphoma (ALCL) (N=1). Delay between onset of hematological diagnosis and HEV diagnosis was 6 months (0-72). All patients but one were under specific treatment at the time of HEV diagnosis. Four patients were in complete response and 1 relapsing from AML. At the onset of HEV, AST and ALT were increased to 3-70N and 5-80N, respectively whereas prothrombine time was normal in all patients. Positive HEV viremia was detected for less than 6 months (acute hepatitis) in 4 patients and more than 6 months (chronic hepatitis) in 2. After HEV diagnosis, allogeneic (n=1), syngenic (n=1) and autologous (n=1) stem cell transplantation were succesfully performed. In one patient who had a syngenic allograft, transient recurrence (one month) of HEV viremia was observed. In one patient with MM-related hypogammaglobulinemia, chronic hepatitis occured despite IgIV supplementation and led to severe fibrosis (metavir score A2F3) at one year of follow-up. Chronic hepatitis (nine months) was also observed in a patient who received 4 cycles of ACBVD chemotherapy regimen for ALCL followed by autologous-SCT. Syngenic SCT graft was delayed in one patient and auto-SCT was challenged in one patient because of concomitant acute HEV. There was no evidence of liver failure in any patients regardless of HEV course and specific therapies. Of note, molecular evidence of patient-to-patient transmission of HEV in the hematology unit was demonstrated in 2 patients. Individual case reports, sequencing of HEV isolates and phylogenetic analysis will be presented at the meeting. *Conclusion*. Both acute and chronic hepatitis E may complicate the clinical course of patients with haematological malignancies. Evolution to cirrhosis seems improbable but patient to patient transmission is a concern. Whether management of malignancy, especially SCT, should be adapted to the HEV status remains to be determined.

0469

FILGRASTIM DOSE HAS AN IMPACT ON INFECTIOUS COMPLICATIONS IN PATIENTS WITH LYMPHOMA FOLLOWING AUTOLOGOUS STEM CELL TRANSPLANTATION

Z. Peric,[1] M. Kalac,[1] S. Jurenec,[1] V. Kovacevic,[2] S. Bukovski-Simonoski,[2] A. Tambic-Andrasevic,[2] H. Minigo,[1] B. Jaksic,[1] R. Vrhovac[1]

[1]Clinical Hospital Merkur, ZAGREB; [2]University Hospital for Infectious Diseases, ZAGREB, Croatia

Background. Infections represent the leading cause of morbidity and mortality in patients with lymphoma treated with autologous stem cell transplantation. Duration and depth of neutropenia following transplantation correlates with incidence and severity of infections in the post-transplant period. Filgrastim shortens the duration of neutropenia but its impact on the course and outcome of infections as well as the preferred dose remain somewhat controversial. *Aims.*to evaluate infectious complications in patients with lymphoma treated with autologous peripheral blood stem cell transplantation (PBSCT) and investigate possible influence of different filgrastim doses on incidence, severity and outcome of these infections. Patients and *Methods.* 120 consecutive patients (median age 42, range 19-71 yrs, 63M/57F) with relapsed or refractory Non-Hodgkin's Lymphoma (NHL, n=92) and Hodgkin's Disease (HD, n=28) treated with PBSCT in a single center have been evaluated for infectious complications following transplantation. In the post-transplant period, all patients received filgrastim subcutaneously, starting from the day of WBC<1×10^6/L until the second consecutive day of WBC>1×10^6/L. Two different dose levels of filgrastim were used, *Low*: 300 mcg/day, administered in 58 patients; and *Standard*: median dose 600 mcg (SD 94, average 628 mcg), administered in 61 patients. *Results.* Febrile neutropenia occurred in 79 (65.8%) patients at a mean of 6 days after transplantation (range 1-9, SD 1.65), more often in patients with longer duration of neutropenia post transplant (p=0.0003). In these patients, microbiological work-up was done and empirical antibiotic therapy was initiated; piperacillin-tazobactam was administered to all patients not having a history of penicillin allergy. Empirical therapy was modified according to recommended guidelines in 19 (24.1%) patients:

vancomycin was added in 32 patients (40.5%), a systemic antifungal in 10 (12.7%) and both in 6 (7.6%) patients. Twenty-eight patients (35.4%) had proven bacteremias while 29 (36.7%) had other microbiologically documented infections (MDIs). Gram-positive microorganisms were responsible for the majority (64.3%) of all bacteremias. Patients receiving standard doses of filgrastim had significantly shorter duration of neutropenia (average of 9.06 vs. 9.82 days, p=0.02) and developed febrile neutropenia less often than the group receiving lower doses of filgrastim (57.4% vs. 75.9%, p=0.03). They also responded better to empirical therapy - addition of vancomycin was not needed as often as in the group receiving lower filgrastim doses (28.6% vs. 50%, p=0.05) and had shorter duration of antimicrobial treatment (average of 9.71 vs. 10.9 days, p=0.11). *Conclusions.* Infections are serious but manageable complications of PBSCT. Gram-positive microorganisms remain the major cause of documented infections. In our patients treated with two dose levels of filgrastim, standard filgrastim doses were more efficacious in both shortening the duration of neutropenia and reducing the incidence of fever during neutropenia. Also, compared to the lower filgrastim doses, patients receiving standard filgrastim doses needed shorter antimicrobial treatment and fewer modifications of empirical antimicrobial regimen.

0470

THE CONTRIBUTION OF NUTRITIONAL STATUS OF CHILDREN WITH MALIGNANCY TO MORBIDITY, MORTALITY AND THERAPY OUTCOMES

T. Hassan

Zagazig University, ZAGAZIG, Egypt

Background. Children with malignancy frequently have associated cachexia with significant weight loss and malnutrition. Malnutrition has a deleterious effect on the results of therapy for malignant diseases in childhood. The impact of cytotoxic drugs on nutritional status is controversial. *Aims.*We aimed to evaluate the nutritional status of children with malignancy to determine whether the type of the tumor and aggressiveness of chemotherapy have any influence on nutritional status and to assess its relationship with survival and other outcomes of therapy.*Methods.* The study was carried out on 40 newly diagnosed cases of pediatric malignancies (23 males+17 females) at Pediatric Hematology and Oncology Unit in Zagazig University Hospital from December 2006 to January 2008. All patients were subjected to full medical history and examination with special emphasis on anthropometric parameters (WFA, HFA, WFH, BMI, MUAC, TSFT and MAMC). Laboratory investigations including hematological parameters [Hemoglobin level (Hb) and serum iron(S.Fe)] and biochemical parameters [Total protein (TP) and serum albumin (S.alb)] were done. The anthropometric, hematological, and biochemical parameters were measured at time of diagnosis and repeated after 1, 3, 5 and 7 months from start of chemotherapy.

Table. Comparison in outcomes of treatment of children with malignancy between well nourished and malnourished groups according to anthropometric parameters at diagnosis.

Parameter	Group	No of patients	Remission	Delay in therapy	Mortality	X^2			P value

wn= well nourished mn= malnourished A= Remission B =Delay in therapy C = Mortality * =significant relation

Results. Our study showed that the prevalence of malnutrition (based on WFA, HFA, and Hb level) was high among the studied cases at the time of diagnosis (>50%). As regard the effect of chemotherapy on different parameters along the whole period of the study, there was a highly significant increase in TSFT (p<0.001), significant increase in HFA and WFH (p<0.002) and a non significant increase in Hb level and WFA. Also there was a highly significant decrease in TP (p<0.001) and non significant decrease in BMI, MUAC, MAMC, S.alb and S.Fe. Except for malnutrition based on arm anthropometry (MUAC and TSFT) which was obviously higher (but non significant) among cases with solid tumors than in hematological tumors; there was no significant difference of prevalence of malnutrition based on other parameters between different types of tumors (p>0.05). Also, there was a significant increase of prevalence of malnutrition among non survivors than survivors of children with malignancy based on WFA, MUAC, TSFT, and S.alb.(p<0.05). As regard the outcome of therapy , there was a highly significant increase in remission response rates in well nourished children than in malnourished children (based on TP and S.alb) (p<0.001) ,meanwhile there was a significant increase in mortality rate in malnourished children than in well nourished children (based on the same two biochemical parameters) (p<0.003 and<0.04). *Summary and Conclusions.* Malnutrition is highly prevalent in children with malignancy at diagnosis. Malnourished children with malignancy have lower rate of achievement of remission, higher rate of delay in treatment and higher prevalence of mortality rates. Visceral proteins measurements (TP and S.alb), height and arm anthropometry are more reliable, easy, and economic parameters in diagnosis of malnutrition among children with malignancy than weight anthropometry especially for those with solid tumors.

Introduction. MP has been the standard of care for elderly MM pts in the past 40 years. However, bortezomib and thalidomide-based combinations have demonstrated to improve the efficacy in terms of response rate and time to events as compared to MP. VMP has demonstrated to be highly effective in the VISTA trial in elderly untreated MM patients. *Aims*. Spanish Myeloma Group (PETHEMA/GEM) wanted to try to optimize the treatment for this pts population and to answer the question which agent is the optimal partner for bortezomib: an alkylating or an immunomodulatory drug. *Methods*. In order to answer this question, PETHEMA/GEM activated a phase III trial comparing VMP versus VTP in elderly untreated MM pts. Patients in VMP received bortezomib 1.3 mg/m^2 twice weekly (days 1, 4, 8, 11; 22, 25, 29 and 32) for one 6-week cycle, followed by once weekly (days 1, 8, 15 y 22) for five 5-week cycles plus melphalan 9 mg/m^2 and prednisone 60 mg/m^2 on days 1-4. Patients in VTP received the same bortezomib and prednisone regimen, but instead of melphalan they received continuous thalidomide at dose of 100 mg daily. The primary endpoint was overall response rate (ORR) after induction therapy and secondary endpoints included time to events, time to and duration of response, and safety. *Results*. As of October 30, 2008, 260 planned patients have been included in the study and 205 are evaluable for response to induction therapy. 98 patients were randomly assigned to receive VMP and 107 to VTP. Regarding baseline characteristics, both arms were well balanced. No significant differences were observed in response rate: ≥ PR in 81% of patients in both groups, with a CR rate of 22% vs 27% (p=NS) and CR/nCR of 41% vs 37% (P= NS). Median time to first response was similar in both arms (1,6 months) and there were not differences in the median time to achieve CR (4,4 vs 4,9 months). Both regimens were effective in patients with poor prognostic characteristics. Regarding haematological toxicity, VMP resulted in higher incidence of ≥G3 neutropenia (37% vs 21%; p=0,003) resulting in a higher incidence of ≥G3 infections (7% vs <1%; p=0,01); by contrast, VTP resulted in a higher frequency of ≥G3 cardiac events (8,5% vs 0%; p=0,001). The incidence of ≥G3 thromboembolic events was 4% in VTP arm and <1% in VMP; finally, 9% of patients in VTP developed ≥G3 peripheral neuropathy and 5% in VMP. 38% of patients in VTP arm developed related-serious adverse events and 15% in VMP (p<0,001). Six patients died in VMP, five of them because of severe infections; by contrast, six patient also died in VTP and five because of cardiologic events. *Summary*. This analysis indicates there are no significant differences in terms of efficacy between VMP and VTP, while the incidence of non-hematological AEs, especially cardiac events, was higher in VTP, resulting in more serious AEs. These data suggest that thalidomide may not be the partner of choice for combination with bortezomib and other IMIDs such as lenalidomide should be explored.

BORTEZOMIB, MELPHALAN, PREDNISONE AND THALIDOMIDE (VMPT) VERSUS BORTEZOMIB, MELPHALAN AND PREDNISONE (VMP) IN ELDERLY NEWLY DIAGNOSED MYELOMA PATIENTS: A PROSPECTIVE, RANDOMIZED, PHASE III STUDY

[1]A.O.U. San Giovanni Battista, TORINO; [2]Italian Multiple Myeloma Network, GIMEMA, Italy

Background. In newly diagnosed myeloma patients the combination of bortezomib with melphalan-prednisone (VMP) was superior to MP. In relapsed-refractory patients the 4 drug combination of bortezomib-melphalan-prednisone-thalidomide (VMPT) induced a high proportion of complete responses (CR). *Aims*. In this prospective, randomized, phase III trial, we compared VMPT and VMP. The primary end point was progression-free survival (PFS). *Methods*. Patients (N=511) older than 65 years were randomly assigned to receive VMPT or VMP. Initially, patients were treated with nine 6-week cycles of VMPT (bortezomib 1.3 mg/m^2 days 1,4,8,11,22,25,29,32 in cycles 1-4 and days 1,8,22,29 in cycles 5-9; melphalan 9 mg/m^2 days 1-4; prednisone 60 mg/m^2 days 1-4 and thalidomide 50 mg days 1-42, followed by bortezomib 1.3 mg/m^2 every 15 days and thalidomide 50 mg/day as maintenance) or VMP (bortezomib, melphalan and prednisone at the same doses and schedules previously described without maintenance). In March 2007, the protocol was amended: both VMPT and VMP schedules were changed to nine 5-week cycles and bortezomib schedule was modified to weekly administration (1.3 mg/m^2 days 1,8,15,22 in cycles 1-9). *Results*. Patient characteristics were similar in both groups, median age was 71 years. Patients who received at least 1 cycle were evaluated: 221 patients for VMPT and 229 patients for VMP. Data were analyzed in intention-to-treat. The very good partial response (VGPR) rate was higher in the VMPT group (51% versus 42%, p=0.06), including a CR rate of 35% in the VMPT group and 21% in the VMP group (p<0.0001).

Table 1. Outcome according to bortezomib schedule.

	VMPT group (n=221)		VMP group (n=229)	
	All patients (n=221)	Subgroup with bortezomib weekly infusion (n=150)	All patients (n=229)	Subgroup with bortezomib weekly infusion (n=165)
CR rate (%)	35	32	21	20
2-year PFS (%)	76	77	70	75
Grade 3-4 peripheral neuropathy (%)	12	5	10	4

In the subgroup treated with weekly infusion of bortezomib, VGPR was 50% for VMPT and 39% for VMP (p=0.06), including 32% CR for VMPT and 20% for VMP (p=0.01). Subgroup analyses did not show any statistical difference between responses and either ISS or chromosomal abnormalities (such as del13, t(4;14), t(14;16) and del17). After a median follow-up of 14.8 months, the 2-year PFS was 76.1% in the VMPT group and 70.0% in the VMP group (HR=0.70, 95% CI 0.44-1.11, p=0.13). In patients who received weekly infusion of bortezomib, the 2-year PFS was 76.8% in the VMPT group and 75.5% in the VMP group (HR=0.81, 95% CI 0.44-1.49, p=0.50). Factors predictive of longer PFS were age ≤ 75 years (p=0.006) in VMPT but not in VMP and the achievement of VGPR in both groups (p=0.02 and p=0.004). The 3-year overall survival (OS) was 89.6% in the VMPT group and 88.6% in the VMP group (HR=0.92, 95% CI 0.46-1.84, p=0.81). The incidence of grade 3-4 adverse events was similar in the VMPT group and in the VMP group: neutropenia (28% vs 28%), thrombocytopenia (19% vs 16%), peripheral neuropathy (12% vs 10%), infections (12% vs 7%), and gastrointestinal complications (5% vs 7%), respectively. The weekly infusion of bortezomib significantly decreased the incidence of grade 3-4 peripheral neuropathy to 5% and 4%. *Conclusions*. VMPT is superior to VMP in

terms of response rates. Longer follow-up is needed to assess their effects on PFS and OS. The weekly infusion of bortezomib significantly reduced the incidence of peripheral neuropathy without influencing outcome.

FIRST ANALYSIS OF HOVON-65/GMMG-HD4 RANDOMIZED PHASE III TRIAL COMPARING BORTEZOMIB, ADRIAMYCINE, DEXAMETHASONE (PAD) VS VAD AS INDUCTION TREATMENT PRIOR TO HIGH DOSE MELPHALAN (HDM) IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA (MM)

P. Sonneveld,[1] B. van der Holt,[2] I.G.H. Schmidt-Wolf,[3] U. Bertsch,[3] L. El Jarari,[2] H. Salwender,[3] S. Zweegman,[4] E. Vellenga,[4] J. Schubert,[3] I.W. Blau,[3] G.S.K. Jie,[4] B. Beverloo,[1] A. Jauch,[3] D. Hose,[5] R. Schaafsma,[4] M.J. Kersten,[4] M. Delforge,[6] R.A. Raymakers,[4] O. De Weerdt,[4] R. Van der Griend,[4] P.W. Weijermans,[4] H. Martin,[3] H. Van der Velde,[7] H.M. Lokhorst,[4] H. Goldschmidt[5]

[1]Erasmus MC, ROTTERDAM, Netherlands; [2]HOVON, ROTTERDAM, Netherlands; [3]German Multiple Myeloma Group, GMMG, Germany; [4]Dutch-Belgium Hematology Oncology Group, HOVON, Netherlands; [5]GMMG, HEIDELBERG, Germany; [6]Durch Belgium Hematology Oncology Group, HOVON, Netherlands; [7]Johnson & Johnson, BEERSE, Belgium

The randomized, open-label, phase III trial HOVON-65/GMMG-HD4 was designed to evaluate the efficacy of bortezomib prior to HDM for response and progression-free survival (PFS) in patients with newly diagnosed MM. The trial was performed in 75 referral centers in the Netherlands and Belgium (HOVON group) and Germany (GMMG group). Patients with Salmon & Durie (SD) stage II or III, age 18-65 years inclusive, were randomly assigned to 3 cycles of VAD (vincristine 0.4 mg, adriamycine 9 mg/m^2 days 1-4, dexamethasone 40 mg days 1-4, 9-12, and 17-20) or PAD (bortezomib 1.3 mg/m^2 days 1,4,8,11, adriamycine 9 mg/m^2 days 1-4, dexamethasone 40 mg days 1-4, 9-12, and 17-20). No thrombosis prophylaxis was given. Stem cells were mobilized using the CAD regimen, including cyclophosphamide 1000 mg/m^2 iv day 1, and G-CSF. After induction therapy, all patients were to receive 1 or 2 cycles of high-dose melphalan (HDM) 200 mg/m^2 with autologous stem cell rescue followed by maintenance with thalidomide 50 mg daily (VAD arm) or bortezomib, 1.3 mg/m^2 once every 2 weeks (PAD arm) for 2 years. Between May 4, 2005 and May 16, 2008, 833 patients were randomized. After the trial was closed, we here report the planned interim analysis data on response after induction and HDM-1 of the initial 300 (150 per arm) randomized patients. The 2 randomization arms were equal for SD stage of disease, ISS stage, and distribution of chromosomal abnormalities. 137 patients (91%) completed PAD or 136 (91%) completed VAD and 132 patients (88%) in each arm completed HDM-1. Full dose bortezomib could be administered in 95% (PAD1), 89% (PAD2) and 85% (PAD3) of patients. Successful stem cell apheresis was achieved in all 137 PAD treated patients who received CAD mobilization . Peripheral polyneuropathy CTC grade 3-4 during PAD vs VAD was 16% vs 6%, while DVT/pulmonary embolism was diagnosed in 3% during VAD and 4% during PAD. Responses were assessed according to EBMT criteria including VGPR and nCR after PAD/VAD, after HDM-1 and best response on protocol treatment. Complete Response (CR/nCR), Very Good Partial Response (VGPR) and Partial Response (PR) in both arms were compared by logistic regression (table 1). Deletion of chromosome 13q or presence of t(4;14) did not have a significant impact on VGPR or (n)CR. We conclude that PAD induces significantly more PR+VGPR+(n)CR as compared with VAD, and that this effect is sustained after HDM-1.

This trial was supported by the Dutch Cancer Foundation (EudraCT nr 2004-000944-26), the German Federal Ministry of Education and Research and a grant from Johnson and Johnson

Background. Carfilzomib (CFZ) is a selective proteasome inhibitor with single-agent activity in relapsed myeloma (MM). In preclinical studies, CFZ overcomes bortezomib (BTZ)-resistance (Kuhn, 2007) and lacks off-target activities associated with BTZ (Kapur, ASH 2008). *Aims*. PX-171-004 is an ongoing, multicenter Phase II trial to evaluate the safety and efficacy of CFZ in 155 patients (pts) with relapsed MM after 1-3 prior therapies. We previously reported an Overall Response Rate (ORR) of 35.5% for the first 31 pts (Vij, ASH 2008). Updated data are now available. *Methods*. The study enrolled two pt cohorts: BTZ-naïve and BTZ-exposed. CFZ 20 mg/m^2 was administered Days 1, 2, 8, 9, 15 and 16 in a 28-day cycle, for up to 12 cycles. Dexamethasone 4 mg po was administered prior to each dose in Cycle 1. The primary endpoint was ORR [Partial Response (PR) + Very Good Partial Response (VGPR) + Complete Response (CR)]. Secondary endpoints included Duration of Response (DOR), Time To Progression (TTP) and safety. *Results*. 31 pts were enrolled; 14 (45%) BTZ-naïve and 17 (55%) BTZ-exposed. The extent of BTZ exposure included single agent (2 pts), BTZ + chemotherapy (6 pts) and BTZ-transplant induction (9 pts). Additionally, 16 (94%) of BTZ-exposed pts had relapsed following > 1 IMID regimen. Overall, 23 (74%) pts had > 1 prior therapy and 27 (87%) relapsed after stem cell transplant. CFZ achieved an ORR of 57%, with a median DOR of 8.55 months (range >1.94 to >9.67 months), in BTZ-naïve pts. The median TTP has not yet been reached in this group. In BTZ-exposed pts, CFZ achieved an ORR of 18%. The median DOR has not yet been reached (>8.52 months) and the median TTP was 8.9 months. To date, 7 pts from each cohort (50% BTZ-naïve; 41% BTZ-exposed) are progression free. Overall, pts received an average of 6.6 treatment cycles and 9 pts (29%) completed 12 full cycles. 22 pts (71%) did not complete 12 cycles. Reasons for early discontinuation were progressive disease (11 pts), voluntary withdrawal (1 pt) and adverse events (AEs) (10 pts). AEs leading to study termination included rash (1 pt), multi-organ failure (1 pt), tumor lysis syndrome (1 pt), edema/dyspnea (1 pt), congestive heart failure (1 pt) and Grade 1 elevated creatinine/Grade 2 hypertension (1 pt). One pt was withdrawn due to hyperthyroidism, unrelated to CFZ. One pt with a history of thalidomide-associated Grade 1 peripheral neuropathy (PN), was discontinued for Grade 3 PN despite resolution to baseline prior to receiving the final CFZ dose. 2 pts discontinued due to AEs (abdominal pain and pneumonia) during Cycle 12; neither was considered unrelated to CFZ. *Conclusions*. These preliminary results demonstrate that CFZ monotherapy achieves durable responses in relapsed MM, even in patients previously treated with BTZ. A significant number of pts remain progression free after 12 cycles. These results are notable for an anthracycline and steroid-sparing regimen. CFZ is well tolerated for up to a year and the incidence of treatment-limiting PN is significantly lower than that reported for BTZ (Argyriou, 2008).

Table 1.

	ORR	CR	VGPR	PR	TTP	DOR
BTZ-Naïve (n=14)	8 (57%)	1 (7%)	2 (14%)	5 (36%)	Not Reached	8.55 months
BTZ-Exposed (n=17)	3 (18%)	0 (0%)	0 (0%)	3 (18%)	8.9 months	Not Reached

LONG TERM FOLLOW UP OF A COMPARISON OF NONMYELOABLATIVE ALLOGRAFTING WITH AUTOGRAFTING FOR NEWLY DIAGNOSED MULTIPLE MYELOMA

B. Bruno,[1] R. Sorasio,[1] F. Patriarca,[2] N. Mordini,[1] B. Allione,[1] F. Carnevale-Schianca,[3] L. Giaccone,[1] M. Festuccia,[1] M. Aglietta,[3] A. Levis,[1] A. Gallamini,[1] R. Fanin,[2] A. Palumbo,[1] G. Ciccone,[4] M. Boccadoro[1]

[1]Division of Hematology, TORINO; [2]University of Udine, UDINE; [3]Division of Oncology, CANDIOLO; [4]CPO Piemonte, TORINO, Italy

Background. We previously reported on a study where the treatment assignment of 162 newly diagnosed myeloma patients younger than 65 years was based only on the presence/absence of an HLA-identical sibling donor (Bruno et al, N Engl J Med, 2007). *Aims*. To report an update analysis. *Methods*. As mentioned in the original study, up-front treatment plans consisted of induction with VAD-based regimens, a cytoreductive autograft followed by a nonmyeloablative allograft (Auto-Allo) or a second melphalan-based autograft (Double-Auto). Primary endpoints were overall (OS) and event-free (EFS) survivals by intention-to-treat analysis. The 80 patients with a sibling donor were offered a Auto-Allo and the 82 without a Double-Auto after high (140-200 mg/m^2) or intermediate dose melphalan (100 mg/m^2). No maintenance and/or consolidation therapy was allowed by protocol after nonmyeloablative allografting. *Results*. After a median follow up of 6 years, OS and EFS were significantly longer in patients with donors: not reached versus 52 months (p=0.003) and 35 versus 29 months (p=0.008). Median OS was not reached in the 58 (out of 60 enrolled, 97%) patients who completed Auto-Allo and was 64 months in the 46 (out of 59 enrolled, 78%) who completed high-dose Double-Auto (p=0.03). Moreover, an extended experience consisting of 100 newly diagnosed myeloma patients treated with Auto-Allo in a prospective clinical trial by the Gruppo Italiano Trapianti di Midollo Osseo confirmed these encouraging findings. After a median follow up of 5 years, OS was not reached and EFS was 37 months. Incidences of acute and chronic GVHD were 38% and 50%, respectively. Complete remission (including molecular remission) was achieved in 53% of patients. Profound cytoreduction (at least very good partial remission) prior to allografting was associated with achievement of post-transplant remission (HR 2.20, p=0.03) and longer EFS (HR 0.33, p<0.01). Interestingly, development of chronic GVHD was not correlated with response duration. *Summary*. Overall, the Auto-Allo approach allows prolonged disease free survival especially in patients with reduced tumor burden at the time of allografting. We are currently investigating the role of "new drugs" in intensifying pre-transplant cytoreduction and post-transplant graft-vs.-myeloma effects to further improve clinical outcomes in patients with poor prognosis.

Chronic myeloid leukemia - Clinical I

0476

SUBCUTANEOUS OMACETAXINE MEPESUCCINATE IN IMATINIB-RESISTANT CHRONIC MYELOID LEUKEMIA PATIENTS (PTS) WITH THE T315I MUTATION - DATA FROM AN ONGOING PHASE 2/3 TRIAL

J. Cortes,[1] H.J. Khoury,[2] F.E. Nicolini,[3] S. Corm,[4] T. Schenk,[5] A. Hochhaus,[5] D. Jones,[1] H. Kantarjian,[1] A.R. Craig6, A.C. Benichou,[6] E. Humphriss,[6] M. Michallet[3]

[1]MD Anderson Cancer Center, HOUSTON, USA; [2]Emory University School of Medicine, ATLANTA, USA; [3]Hopital Edouard Herriot, LYON, France; [4]CHU Lille, LILLE, France; [5]University of Heidelberg, MANNHEIM, Germany; [6]ChemGenex Pharmaceuticals, MENLO PARK, USA

Background. Omacetaxine (formally homoharringtonine, HHT), a first-in-class cetaxine, shows clinical activity against Ph$^+$ Chronic myeloid leukemia (CML) with a mechanism independent of tyrosine kinase inhibition. Currently available tyrosine kinase inhibitors (TKIs) have no activity against T315I. *Aims*. To evaluate the safety and efficacy of omacetaxine in Ph$^+$ CML Pts with chronic (CP), accelerated (AP), or blast phase (BP) disease who have failed imatinib and have the T315I mutation. *Methods*. Adult CML Pts who have failed imatinib and harbor the T315I kinase domain mutation are enrolled. All patients receive informed consent and then omacetaxine induction at 1.25 mg/m^2 subcutaneous (SC) twice daily (BID) for 14 days every 28 days followed by maintenance at 1.25 mg/m^2 SC BID for 7 days every 28 days. Maintenance therapy begins after at least one induction cycle and achievement of initial haematologic response. *Results*. 69 Pts (40 CP, 16 AP and 13 BP) have been enrolled. All had failed prior imatinib and 80% failed ≥2 prior TKIs. Median age is 58 years. Median disease duration is 58 months. Omacetaxine is well tolerated with transient myelosuppression as the primary toxicity. Treatment-related grade 3/4 events occurring in ≥10% of patients are: thrombocytopenia (48%), anaemia (30%), neutropenia (28%), and neutropenic fever (12%). Non-haematologic grade 3/4 events are rare with diarrhea (2%) and fatigue (3%) as the most frequently reported. Injection site reactions are mild with only grade 1/2 events reported and erythema the only event reported in > 10% of Pts (13.1%). Efficacy data are available for 47 Pts (28 CP, 11 AP, and 8 BP). In CP Pts, the median number of cycles is 4 (1-25) with 39% having received ≥6 cycles of therapy. The overall CP Pt complete haematologic response (CHR) rate is 82% with a median duration of response of 8.7 months (2.1 to 28.7+) and an overall cytogenetic response (CyR) rate of 25% (4 complete, 1 partial, 2 minimal). Six CP patients entered the study in CHR and maintained their response for at least 8 weeks to be considered responders. In AP Pts, the overall haematologic response rate is 45% (2 CHR, 1 haematologic improvement, 1 return to chronic phase [RCP]) with a median duration of response of 9.7 months (8.3-10.9+) and an overall CyR rate of 9% (1 minimal response). In BP Pts, the overall haematologic response rate is 13% (1 RCP) with no cytogenetic responses observed. For progression free survival (PFS), progression is defined as the development of advanced disease or death and in CP Pts, the loss of CHR or major CyR. In CP Pts, PFS is 80% at 1 year and 70% at 2 years; in AP Pts, PFS is 25% at 1 year and 18 months; In BP Pts, PFS is 44% at 6 months. In 64% of Pts, the T315I clone is reduced to below detection limits. *Conclusions*. Omacetaxine in CML patients who have the T315I mutation results in de-selection of the T315I clone, induces durable haematologic and cytogenetic responses, and results in meaningful progression free survival.

MULTICENTER OPEN LABEL STUDY OF SUBCUTANEOUS (SC) OMACETAXINE MEPESUCCINATE IN CHRONIC MYELOID LEUKEMIA (CML) PATIENTS THAT ARE RESISTANT OR INTOLERANT TO TWO OR MORE TYROSINE KINASE INHIBITORS (TKIS)

M. Wetzler,[1] P.M. Parikh,[2] D. Raghunadharao,[3] D. Jones,[4] A. Leitner,[5] A. Hochhaus,[5] A.-C. Benichou,[6] A.R. Craig,[6] E. Humphriss,[6] H. Kantarjian,[4] J. Cortes[4]

[1]Roswell Park Cancer Institute, BUFFALO, USA; [2]Cooperative Oncology Network, MUMBAI, India; [3]Nizam's Institute of Medical Sciences, HYDERABAD, India; [4]MD Anderson Cancer Center, HOUSTON, USA; [5]University of Heidelberg, MANNHEIM, Germany; [6]ChemGenex Pharmaceuticals, MENLO PARK, USA

Background. Omacetaxine (formally homoharringtonine, HHT), a first-

in-class cetaxine, shows clinical activity against Ph+ CML with a mechanism independent of tyrosine kinase inhibition. Omacetaxine has shown activity in multi drug-resistant CML patients. *Aims*. To evaluate the safety and efficacy of omacetaxine in Pts with imatinib-resistant CML with chronic (CP), accelerated (AP), or blast phase (BP) disease who have failed or are intolerant to at least 2 prior TKIs. *Methods*. Adult CML Pts who have failed multiple TKIs are enrolled. All patients receive informed consent and then omacetaxine induction at 1.25 mg/m^2 subcutaneous (SC) twice daily (BID) for 14 days every 28 days followed by maintenance therapy at 1.25 mg/m^2 SC BID for 7 days every 28 days. Maintenance therapy begins after at least one induction cycle and achievement of initial haematologic response. *Results*. 71 Pts have been enrolled (37 CP, 18 AP, and 16 BP). All have failed prior imatinib and at least one other TKI and 51% have failed ≥3 prior TKIs. Patients enrolled in India (N=8, recently enrolled and not included in efficacy evaluation) are accepted for enrollment after imatinib failure and at least one additional treatment. Median age is 58 yrs and 50% are male. Median disease duration is 74 months. At study entry, 39% of patients had Bcr-Abl mutations including 10% with compound mutations. Patients with the T315I mutation are enrolled into a separate clinical trial. In this study, the most frequently identified mutations are F317L (12%) and V299L (6%). Omacetaxine is well tolerated with transient myelosuppression as the primary toxicity. Treatment-related grade 3/4 adverse events occurring in ≥10% of patients are: thrombocytopenia (28%), neutropenia, (23%), and anaemia (13%). Non-haematologic grade 3/4 adverse events are rare, with fatigue (2%) as the most frequently observed. Injection site reactions are mild with only grade 1/2 events reported and erythema (8%) as the most common. Efficacy data are available for 30 Pts (12 CP, 9 AP, and 9 BP). The overall haematologic response (HR) rate in CP Pts is 75%, all of whom achieved complete haematologic response (CHR). Current median duration of response is 6.1 months. The overall HR rate in AP Pts is 44% with 22% achieving CHR with median duration of response of 3.5 months. In BP patients, the overall HR rate is 67% all of whom achieved return to chronic phase with a median duration of response of 5.0 months. Overall cytogenetic response (CyR) in CP patients is 17% (1 partial and 1 minor CyR). In AP patients, the overall CyR rate is 33% with 1 each, complete, partial and minimal CyR. No cytogenetic response is observed in BP patients. *Conclusions*. Omacetaxine therapy in heavily pre-treated CML Pts induces haematologic and cytogenetic responses and may provide an alternative therapy for patients resistant to multiple TKIs.

Background. In a substantial minority of CML patients imatinib fails or shows suboptimal responses. *Aims and Methods*. A 5-arm treatment optimization study was therefore designed to optimize responses and improve survival by randomized comparison of standard imatinib vs. imatinib + interferon alpha (IFN) vs. imatinib + low dose araC vs. imatinib after IFN failure (for low- and intermediate-risk patients) vs. imatinib 800 mg (for high-risk patients). Inclusion criteria were newly diagnosed BCR/ABL positive CML in chronic phase. In July 2005, randomization to the arms imatinib + araC and imatinib after IFN was discontinued and recruitment for imatinib 800 mg was expanded to low- and intermediate-risk patients. This arm therefore is not yet evaluable. Primary aims are: prolongation of survival and of duration of chronic phase, and determination of rates of hematologic, cytogenetic and molecular remissions, adverse events and role of allografting. Results. Since its activation in 7/2002, 1242 patients have been randomized. The current evaluation represents the first of three prospective, statistically adjusted interim analyses of 710 patients randomized by the end of 2005 to allow a follow-up of at least 3 years. Analysis was according to intention to treat. 687 patients (566 with primary imatinib, 121 with primary IFN) were evaluable for hematologic, 659 for cytogenetic, and 633 for molecular responses. Median age was 53 years, 60% were male, median values were for Hb 12.8 g/dL, WBC 71.2/nl and platelets 384/nl, 35% had low, 53% intermediate and 12% high risk (Euro score). Median observation time was 45 months. 5-year-survival probability of all patients currently is 92% (Figure 1). There are no significant survival differences recognizable yet. At 5 years, the rates of major cytogenetic remission (MCR) are 95%, of complete cytogenetic remission (CCR) 94% and of major molecular remission (MMR) 88% as determined by competing risk. There are no significant differences between the 4 evaluable treatment arms for CCR and MMR, except that the primary IFN group reaches CCR and MMR later. After five years, progression free survival (no death, patient still in first chronic phase) was 89%. 36 patients died, 56 patients were transplanted in first chronic phase, and 80 patients progressed, 43 of which were switched to alternative treatments (16 to new drugs, 18 to transplantation, 9 received both). Type and severity of adverse events (AE) did not significantly differ from those reported previously. Hematologic AEs (leukopenia, thrombocytopenia) were most frequent in the imatinib 800 mg arm. Nonhematologic AEs (gastrointestinal) were most frequent in the combination arms and with imatinib 800 mg. In no case recruitment had to be changed due to superiority or inferiority of any arm. Conclusion. This first interim analysis shows excellent survival and favorable long term response rates. Currently, survival in all treatment arms is better than in IRIS. Imatinib in combination with, or after, IFN or with low dose araC are feasible and safe treatment modalities. We expect that the final results of CML Study IV will optimize and improve therapy outcome in the future.

Background. HSCT remains an important option for patients with chronic myeloid leukemia (CML) who failed imatinib. Studies published so far have focused on a potential unfavourable effect of imatinib on the outcome after HSCT. Further, there are hints that pre-transplantation imatinib therapy might even improve outcome in line with observations that reduction of leukemia load prior to transplantation is associated with better transplantation outcome. *Aim and Methods*. The German CML-Study IV (five-arm randomized controlled trial to optimize imatinib therapy by combination, dose-escalation and transplantation) is designed to determine the role of transplantation in the imatinib era. *Results*. By November 2008, 1242 pts were randomized, 84 (6.8%) pts transplanted. 55 pts were male (65%), median age at diagnosis was 37 years (yrs, range 16-62), median time to HSCT was 12.9 months (mo, range 3.5-55). Based on the indications for HSCT three groups were defined: i) elective HSCT (n= 20, 24%); ii) HSCT after imatinib failure or intolerance in first CP (n=36, 43%) and iii) HSCT in advanced disease (n=28, 33%) including 25 in blast crisis. All randomized therapies were evenly represented as treatments prior to HSCT.

Table 1.

		HSCT in 1. CP	HSCT in advanced phases
n		56	28
Euro score	high	15 (27%)	9 (32%)
	intermediate	17 (30%)	8 (29%)
	low	24 (43%)	11 (39%)
Male		33 (59%)	22 (79%)
Median age (range)		37(16-56)	38 (18-62)
Median time to HSCT (months) (range)		13,0 (4,8 – 32,3)	12,8 (3,5-55,1)
EBMT score	0-1	9 (16%)	0
	2	9 (16%)	1 (4%)
	3-4	36 (64%)	9 (32%)
	>=5	2 (4%)	18 (64%)
Best response prior to HSCT	CHR	41 (73%)	15 (54%)
	CyR	36/52 (69%)	10/24 (42%)
	minor CyR	30/52 (58%)	10/24 (42%)
	MCyR	25/52 (48%)	8/24 (33%)
	CCyR	14/52 (27%)	5/24 (21%)
	MMR	5/48 (10%)	2/19 (10%)
Response after HSCT	MMR	41/44 (93%)	14/15 (93%)
	CMR	38/44 (86%)	14/15 (93%)
Transplant source	Sibling	21 (38%)	9 (32%)
	Unrelated	35 (63%)	19 (68%)
	PB	41 (73%)	23 (82%)
	BM	14 (27%)	5 (18%)
Conditioning therapy	standard	39 (70%)	18 (64%)
	reduced	6 (11%)	3 (11%)
	Other/n.a.	7/3 (13%)	6/1 (25%)
Probability of survival at 2/3 years after HSCT		91,4%	58,8%

Median follow-up in the 56 CP patients was 30 mo. 3-year survival probability after HSCT in first CP was 91%. Incidence of transplant-related mortality was 7%. Median follow-up in 28 advanced disease pts was 24 mo (0-50). Survival probability at 2 years was 59%. To compare survival of transplanted with that of non-transplanted pts on imatinib therapy in first CP, a matched pair analysis was performed. For 53 transplanted pts two non-transplanted pts in first CP at the time of transplantation of the partner were identified. Survival estimates at five years (92% vs 93%) did not show any significant difference. After HSCT, molecular data for 59 of 70 living patients demonstrated major molecular remission (MMR) in 55 pts (93%) being complete (CMR) in 52 pts (88%) at most recent follow-up analysis. *Conclusions*. We conclude that reduction of tumor load by initial imatinib therapy and improvements in transplantation procedures translate into improved outcome of pts after HSCT. In view of the curative potential of transplantation and the survival results that are equally good as with drug treatment, we propose HSCT as preferred second line option after failure or intolerability of first line TKI-therapy for eligible pts.

PHASE II MULTICENTRIC EXPLORATIVE STUDY OF INTERMITTENT IMATINIB (IM) TREATMENT (INTERIM) IN ELDERLY PATIENTS WITH PH+ CHRONIC MYELOID LEUKEMIA (CML) WHO ACHIEVED A STABLE COMPLETE CYTOGENETIC RESPONSE (CCGR) WITH STANDARD IM THERAPY

D. Russo,[1] G. Rosti,[2] G. Martinelli,[3] M. Malagola,[4] S. Mirto,[5] D. Turri,[5] U. Vitolo,[4] P. Pregno,[4] M. Gobbi,[4] I. Pierri,[4] F. Di Raimondo,[4] F. Stagno,[4] R. Foà,[6] G. Rambaldi,[5] T. Intermesoli,[5] F. Lauria,[4] M. Bocchia,[4] G. Quarta,[5] M. Girasoli[5]

[1]Chair of Haematology, Brescia, BRESCIA; [2]Insitute of Hematology Seragnoli", BOLOGNA; [3]Institute of Haematology Seràgnoli, BOLOGNA; [4]Chair of Haematology, BRESCIA; [5]Division of Haematology, PALERMO; [6]Chair of Haematology - La Sapienza, ROMA; [7]University of Torino, ORBASSANO; [8]Chair of Haematology - Sant'Eugenio Hospital, ROMA, Italy

Background. Standard therapy with Imatinib (IM) significantly prolongs the survival of Ph+ CML patients who obtain a complete cytogenetic response (CCgR). Elderly patients (i.e. > 65 yrs) have similar cytogenetic responses and survival, but they usually show a low compliance. *Aims*. The aim of the study is to investigate if CCgR that has been achieved with standard (daily administration) IM therapy can be maintained with the same dose of IM given intermittently (INTERIM). The study population is represented by elderly patients (at least 65 years) with Ph+ CML and with stable CCgR after at least 2 years of standard IM therapy (daily administration). *Methods*. IM is given at the same dose that was given at the time of enrollment by the following intermittent schedule: 1 week on / 1 week off for the 1st month; 2 weeks on / 2 weeks off for the 2nd and 3rd month; 1 month on / 1 month off from the 4th month thereafter. The CgR status will be evaluated at baseline (by conventional cytogenetics on bone marrow and FISH on peripheral-blood) and every 3 months during the study (only by FISH on peripheral-blood). Quantitative molecular assessment of BCR-ABL transcript by RQ-PCR on peripheral blood is due at baseline and every 3 months during the study and mutational analysis of ABL will be performed in case of loss of CCgR. If FISH documents a variation of the baseline value of more than 1% in two consecutive examinations, evaluation of marrow cells metaphases will be performed to confirm the loss of CCgR and to check for additional cytogenetic abnormalities. In case of loss of CCgR INTERIM will be stopped and standard therapy (daily administration) will be resumed. After 12 months, the patients who are in continuous CCgR are advised to continue the intermittent study schedule and to be followed indefinitely. *Results*. One-hundred and nine patients have been considered eligible, but 17 (16%) refused to enter into the protocol. Out of 92 enrolled patients, 61 started INTERIM, 4 patients (4%) went off the study for major protocol violation before the 3rd month and, at present, 57 patients are ongoing. Of these 57 patients, 25 and 10 completed the 3rd and 6th month, respectively. At the 3rd month, all the 25 evaluable patients maintained the CCgR. As detected by RQ-PCR, 19/25 (76%) maintained a major molecular response (MMR) and 6/25 (24%) showed at least 1 log increase of BCR-ABL ratio. At the 6th month, all the patients maintained the CCgR; 9/10 (90%) maintained a MMR and 1/10 (10%) showed a 1 log increase of BCR-ABL ratio. *Conclusions*. These preliminary data suggest that IM given intermittently can be sufficient to maintain the CCgR in those patients who have a stable CCgR, previously achieved with standard IM therapy.

IMMUNOCHEMOTHERAPY WITH RITUXIMAB IN ADULT CD20+ B-PRECURSOR ALL IMPROVES MOLECULAR CR RATE AND OUTCOME IN STANDARD RISK (SR) AS WELL AS IN HIGH RISK (HR) PATIENTS WITH SCT

D.H. Hoelzer,[1] A.M. Huettmann,[2] F.K. Kaul,[3] S.I. Irmer,[4] N.J. Jaeckel,[5] M. Mohren,[6] T. Lipp,[7] K. Wendelin,[8] F. del Valle,[9] M. Schmid,[10] E. Thiel,[11] M. Brueggemann,[4] M. Kneba,[4] N. Goekbuget[12]

[1]Onkologikum Frankfurt am Museumufer, FRANKFURT; [2]University Hospital Essen, ESSEN; [3]University Hospital Freiburg, FREIBURG; [4]University Hospital Kiel, KIEL; [5]University Hospital Leipzig, LEIPZIG; [6]University Hospital Magdeburg, MAGDEBURG; [7]Krankenhaus München-Schwabing, MÜNCHEN; [8]Klinikum Nuernberg Nord, NUERNBERG; [9]Klinikum Oldenburg, OLDENBURG; [10]University Hospital Ulm, ULM; [11]Charité Berlin, BERLIN; [12]University Hospital Frankfurt, FRANKFURT, Germany

Background. The effect of Rituximab with a chemo induction and consolidation therapy was studied in CD20+ and Ph/Bcr-abl negative B-precursor ALL (Pre-B/Common) ALL in GMALL Study 07/2003, since improvement of adult B-precursor ALL with chemotherapy was limited and also based on the encouraging results with combined intensive chemotherapy and Rituximab in adult Burkitt lymphoma / leukemia studies. *Methods*. Adult ALL patients (15 - 55 years) with standard risk B-precursor ALL being CD20 pos. (41% antigen expression of >20%) received Rituximab 375 mg/m^2 at day -1 before each induction course (phase I and II), the reinduction course and before each of the six consolidations for a total of 8 doses. Aim was to reduce MRD load and thereby the relapse rate. High Risk patients, candidates for a stem cell transplantation (SCT) in CR 1, received Rituximab three times (d -1 ind. I/II and Cons I) before SCT. *Results*. A total of 185 CD20 pos. patients were analyzed in the GMALL study 07/2003; 133 were SR and 52 HR patients. 117 received Rituximab (R+ arm) and were compared to 70 patients early recruited without Rituximab (R- arm), but identical chemo- and supportive therapy. In the SR there was no difference in the CR rate of 94% and 93% in the R+ vs. R- patients, neither in ED rate 5% vs. 4% or failure/PR 1% vs. 2%. However, MRD course differed substantially. Decrease in MRD load in the R+ vs. R- arm was faster with a Mol CR (MRD <10-4) at day 21 of 60% vs 19% and at wk 16 of 89% vs. 57%. Probability for continuous complete remission (CCR) at 3 years was 0.64 vs. 0.48 for R+ vs. R- pts. (p=0.009) and for overall survival (OS) 0.75 vs. 0.54. For HR pts OS at 3 yrs was 0.54 vs. 0.32 in the R+ vs. R- group. In the 66% HR pts receiving a SCT in CR1 OS was superior for the R+ vs. R- with 0.75 vs. 0.40, due to fewer relapses. OS was no excess toxicity in the R+ vs. R- patients, death in CR 1 was 4% in R+ vs. 3% in R. *Conclusions.* Intensive chemo- plus immunotherapy with Rituximab is feasible in adult SR and HR B-precursor ALL pts. There is a faster and higher Mol CR rate in the Rituximab arm with an improvement of CCR and OS. Thus, Rituximab + chemotherapy can improve outcome of adults with B-precursor ALL.

Background. Blinatumomab (MT103/MEDI-538) is targeting the CD19 and CD3 antigens, and is a member of a novel class of bispecific BiTE antibodies that redirect T cells for lysis of target cells. In patients with B-precursor ALL, MRD positivity after induction therapy or at any time point later predicts a hematological relapse, despite undergoing further intense chemotherapy. A phase II study is being conducted by the German Multicenter Study Group on Adult Lymphoblastic Leukemia (GMALL) in patients with MRD-positive B precursor ALL. *Methods*. B-precursor ALL patients in complete hematological remission with molecular failure or molecular relapse (defined as MRD >10-4) starting at any time after consolidation I of front-line therapy were included. MRD is assessed by quantitative PCR of either individual rearrangements of immunoglobulin/TCR-genes or specific genetic aberrations such as bcr/abl or ALL1-AF4, defined as < 10-4. One treatment cycle of blinatumomab is a 4-week continuous i.v. infusion, which can be followed by allogeneic SCT or repeated cycles of blinatumomab with 2-week treatment-free intervals. The dose level is 15 microgram/m^2/24 hr. Based on clinical activity and lack of safety concerns, the dose may be increased in this trial. *Results*. At the date of submission, 10 patients have been enrolled and 7 patients are evaluable for response. Most common adverse events included pyrexia, chills, hypoimmunoglobulinemia, and lymphopenia. Except for 1 lymphopenia grade 4, 1 hypoimmunoglobulinaemia grade 3, and 1 port infection grade 3 (unrelated), these AEs had an intensity of grade 1 or 2. Most AEs resolved during treatment. Overall, treatment demonstrated no unexpected safety concerns and no permanent treatment discontinuation was required. Five of seven evaluable patients went into molecular remission (mCR) after one cycle of blinatumomab treatment. One of these responding patients became negative for both individual rearrangements and bcr/abl. Another patient with bcr-abl positive B-ALL, who has been treated with 4 cycles of blinatumomab (first three cycles in combination with dasatinib) remained at stable MRD level as did one patient with ALL1-AF4 after one cycle. Of the 5 responding patients one patient had an extramedullar testicular relapse followed by hematological relapse one month after discontinuation of treatment. *Conclusions*. Blinatumomab as a single agent has induced molecular remissions in 5 out of 7 patients with MRD-positive ALL. Treatment has exhibited a safety profile that supports further study and recruitment is ongoing.

Background. Dasatinib (Sprycel®) is a potent multi-targeted kinase inhibitor (TKI) of BCR-ABL and SRC family kinases. Despite a 33% complete hematological response (CHR) rate in a Phase 2 study in patients with Philadelphia positive (Ph+) acute lymphoblastic leukaemia (ALL), the median duration of progression-free survival (PFS) was 3.3 months. A consensus has been reached by the EWALL (European Working group for adult ALL) to adopt a common first-line chemotherapeutic schedule for elderly ALL patients (aged 55 years or more). *Aims*. This schedule was adapted to test the addition of dasatinib in case of Ph+ ALL. *Methods*. After a prephase with dexamethasone 10 mg/m^2 d-7 to d-3, Dasatinib was administered at 140 mg QD (100 mg over 70y) during the induction period in combination with IV injections of vincristine 1 mg and dexamethasone 40 mg 2 days (20 mg over 70y) repeated weekly for 4 weeks. Consolidation cycles consisted in Dasatinib 100 mg/d sequentially with methotrexate 1000 mg/m^2 IV d1 (500 mg/m^2 over 70y) and asparaginase 10,000 UI/m^2 IM d2 (5,000 UI/m^2 over 70y) for cycles 1, 3 and 5 and cytarabine 1,000 mg/m^2/12h IV d1, d3, d5 (500 mg/m^2 over 70y) for cycles 2, 4 and 6. Maintenance phase consisted in Dasatinib sequentially with 6-MP and methotrexate orally 1 month every other

month and dexamethasone/vincristine in 2 months intervals up to 24 months of treatment. *Results*. A total of 30 patients were included from August 2007 to January 2009. Median age was 71 years (range, 61 to 83). The Ph+ chromosome was associated with complex abnormalities in 88% of cases. The CHR rate was 96.6% (29 out of 30 evaluable patients). The only case of induction failure was due to death during induction. The rate of complete molecular remission (CMR) after induction was 33% and MRD level continued to decrease with time. Eight relapses were observed after 2, 6, 6, 6 7, 9, 10 and 11 months of therapy. Seven relapses were associated with the detection of the T315I mutation and one with the F317L. We were able to describe the kinetic of the T315I mutation before haematological relapses using a specific T315I real time PCR. Four patients died while being on study, 1 during induction from invasive aspergillosis, 2 in CHR before consolidation from pulmonary embolism and physical deterioration and one during maintenance from pneumonia. Four other patients died from relapse. Events were defined as relapses, deaths, SAEs or study treatment discontinuations and median EFS was 212 days. However, median relapse free survival and overall survival were not reached with a median follow-up of 12.4 months. *Conclusions*. The EWALL-PH-01 protocol is highly effective with a 96.6% RCH rate in elderly patients with Ph-positive ALL. All relapsing patients except one harboured a T315I mutation and we were able to detect the kinetic of appearance of the mutation before haematological relapse. Of importance MRD level for responding patients was decreasing with time and median OS was not reached.

IMATINIB AFTER ALLOGENEIC STEM CELL TRANSPLANTATION (SCT) FOR PHILADELPHIA CHROMOSOME POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA (PH+ALL): INTERIM ANALYSIS OF A RANDOMIZED PHASE III STUDY

G. Ottmann,[1] B. Wassmann,[1] H. Pfeifer,[1] M. Bornhäuser,[2] W. Bethge,[3] J. Dengler,[4] M. Stadler,[5] D.W. Beelen,[6] N. Basara,[7] R. Schwerdtfeger,[8] K. Schäfer-Eckhart,[9] L. Uharek,[10] M. Stelljes,[11] H. Serve,[1] D. Hoelzer[1]

[1]University of Frankfurt, FRANKFURT; [2]Universitätsklinik Dresden, DRESDEN; [3]Universitätsklinik Tübingen, TÜBINGEN; [4]Universitätsklinik Heidelberg, HEIDELBERG; [5]Medizinische Hochschule Hannover, HANNOVER; [6]Universitätsklinikum Essen, ESSEN; [7]Universitätsklinikum Leipzig, LEIPZIG; [8]Deutsche Klinik für Diagnostik, WIESBADEN; [9]Klinikum Nürnberg, NÜRNBERG; [10]Charite, BERLIN; [11]Universitätsklinik Münster, MÜNSTER, Germany

Background. Patients with Ph+ALL in whom bcr-abl transcripts reappear after allogeneic SCT are at high risk of relapse. In a previous study, approximately 50% of Ph+ALL patients with minimal residual disease (MRD) after SCT converted to PCR negativity in response to Imatinib (IM), started a median of 4.4 months after SCT. As failure to rapidly (within about 2 months) achieve PCR negativity was associated with relapse, we hypothesized that initiation of IM in the setting of a lower leukemic cell burden. i.e. earlier after SCT, may increase response rates and improve outcome. *Aims*. In this prospective, randomized multicenter clinical trial, we compared two strategies of intervention with respect to tolerability and duration of molecular and hematologic remission: the interventional administration of imatinib, triggered by PCR positivity after SCT, and the earliest possible initiation of IM after SCT, irrespectively of the patient´s MRD status. *Methods*. This report is a planned interim analysis of the first 40 enrolled patients, who within 6 weeks after SCT were randomly assigned to receive IM either up-front (cohort 1) (n=20) or subsequent to detection of MRD by real time quantitative and/or nested rtPCR (cohort 2)(n=20). Bcr-abl transcripts were assessed in peripheral blood and bone marrow samples every 3 and 6 weeks, respectively. Target dose of IM was 600 mg, 400 mg was permitted if deemed necessary. IM administration was scheduled for one year of PCR negativity. Informed written consent was obtained from all patients prior to enrolment. *Results*. SCT was performed in CR1 in 17 pts. of cohort 1 and in 18 pts. of cohort 2, 2 each were transplanted in CR2 and 1 with active disease (cohort 2). IM was started in 17/20 patients in the up-front IM and 10/20 in cohort 2. The majority of patients received 400 mg IM (13/17 pts. and 6/10 pts., respectively). Median time from SCT to start of IM was 45 days (cohort 1) and 89 days (cohort 2). Three patients (all in cohort 1) died in CR, only 1 one of whom had actually received IM. After a median follow-up of 438 days (131-1329d) and 577 d (196-1316d) in cohorts 1 and 2, respectively, none of the 35 pts. transplanted in CR 1 and 2 of 5 with SCT in CR2 or active disease have relapsed. IM was discontinued prematurely in 10/17 pts. in the IM up-front arm and 3/10 in the MRD-triggered IM cohort, due mostly to gastrointestinal toxicity (n=5) and GvHD (n=3). *Conclusions*. Administration of imatinib after SCT is associated with a low relapse rate and no evidence of increased non-relapse mortality both with the up-front and MRD-triggered schedules. Although imatinib appears to be less well tolerated when started very early after SCT, its routine use after allogeneic SCT is a promising strategy to improve outcome of patients with Ph+ALL.

FLOW-CYTOMETRIC IMMUNOBEAD ASSAYS FOR THE DETECTION OF FUSION PROTEINS IN PRECURSOR B- ACUTE LYMPHOBLASTIC LEUKEMIA AND ACUTE MYELOID LEUKEMIA

E.H.A. Dekking,[1] A.L. Noordijk,[1] A. van der Linden,[1] V.H.J. van der Velden,[1] N. Boeckx,[2] J.J.M. van Dongen[1]

[1]Erasmus Medical Center, ROTTERDAM, Netherlands; [2]Department of Hematology, University hospital de Gasthuisberg, LEUVEN, Belgium

At present, the prognostic classification of acute leukemias is generally based on the presence or absence of specific genetic aberrations, particularly fusion genes, as detected by karyotyping, FISH or PCR. However, these techniques are time consuming and demand specialized laboratories. Therefore we are developing fast and easy flow cytometric bead assays (CBA's) for detection of fusion proteins in lysates of the leukemic cells that contain a well-defined fusion gene aberration. Previously, we developed CBA's for the diagnosis of BCR-ABL positive leukemias and PML-RAR· positive APL (AML-M3). Now we develop two multiplex CBA tubes: the precursor-B-ALL tube (detecting BCR-ABL, TEL-AML1, E2A-PBX1 and MLL-AF4 fusion proteins) and the AML tube (detecting PML-RAR·, AML1-ETO and CBF,-MYH11 fusion proteins). For each of the different fusion proteins two monoclonal antibodies were generated of which one is directed against the N-terminus and one against the C-terminus of the protein. The antibody binding sites on the various fusion proteins were carefully selected in order to recognize all variants of a fusion protein which result from translocations in the different breakpoint cluster regions. First "singleplex" CBA's were developed in which one antibody was coupled to BD CBA Flex beads to function as a catcher antibody and the other antibody was conjugated to biotin or a fluorochrome to serve as a detector antibody. A robust and specific signal in the flow cytometer was only detectable when the relevant fusion protein was present in the cell sample analyzed. When samples were analyzed that did not contain the fusion protein, no signal was obtained in the assay, since wild type proteins are not recognized by both antibodies of the couple. The assays are specific and sensitive and detect at least 10% (or less) of fusion protein positive leukemic cell lines diluted in a "background" of normal PB-MNCs or WBC's. Importantly, lysates of PB-MNC's or BM-MNC's of leukemia patients positive for the relevant fusion gene as assessed by PCR techniques, generated robust and specific signals in the assays. We conclude that the assays are sensitive, specific and can be performed within 4-5 hours in a routine diagnostic setting, without the need of special equipment other than a flow cytometer. The new immunobead assays can be used for fast and easy diagnosis and classification of AML and precursor B-ALL patients expressing the various fusion proteins. This makes it possible to include these patients at an early stage in the right treatment protocols, much faster than by use of current techniques. At this moment, we are combining the singleplex assays into two multiplex tubes, thereby aiming at an easy flow cytometric approach for molecular diagnostics, which can be run in parallel to routine immunophenotyping, also applicable in countries that lack advanced molecular diagnostics.

Myelodysplastic syndromes

0486

ACQUIRED MUTATIONS IN TET2 ARE COMMON IN MYELODYSPLASTIC SYNDROMES AND ACUTE MYELOID LEUKEMIA

Kamping,[1] G.E. Verhoef,[2] E. Verburgh,[2] A. Hagemeijer,[2] P. Vandenberghe,[2] T. de Witte,[1] B.A. van der Reijden,[1] J.H. Jansen[1]

[1]University Medical Center Nijmegen St Radboud, NIJMEGEN, Netherlands; [2]University Hospital Leuven, LEUVEN, Belgium

Background. Myelodysplastic syndromes (MDS) represent a heterogeneous group of neoplastic hematopoietic disorders. They are characterized by dysplasia of the myeloid, megakaryocytic and/or erythroid lineages. Diagnosis of MDS is often difficult as many conditions (like infections, medication, toxic agents) may give rise to cytopenias and dysplasia without clonal disease. 30% of the patients eventually develop acute myeloid leukemia (AML). Several recurrent chromosomal aberrations have been associated with MDS, but the genes affected have remained largely unknown. The identification of genes that are mutated in MDS would facilitate a proper diagnosis of clonal disease, and could help to devise more targeted forms of therapy, comparable to the developments in chromic myeloid leukemia in the past decade. *Aims*. To identify relevant genetic lesions involved in the pathogenesis of MDS. *Methods*. We performed SNP-array-based genomic profiling of 102 MDS patients and subsequently genomic sequencing in a cohort of MDS and AML patients. *Results.* Six MDS patients showed aberrations on the long arm of chromosome 4, of which four patients showed uniparental disomy (UPD) of the 4q arm and two patients showed mono-allelic deletions. The smallest region of overlap contained two genes, TET2 and PPA2. Genomic sequencing showed homozygous mutations of TET2 in the patients with UPD of the 4q arm and hemizygous TET2 mutations in the patients with the deletions. Subsequently, missense and nonsense mutations in TET2 were found in 26% of our cohort of 102 MDS patients. Nonsense mutations were predominantly present in the N-terminal and central regions of the gene, while missense mutations were exclusively found in two evolutionary conserved C-terminal domains. Mutations of TET2 were also detected in a cohort of AML patients. Expression profiling of TET2 in healthy tissues showed highest TET2 levels in mature granulocytes compatible with a role for this gene in myelopoiesis. *Conclusions*. We conclude that TET2 is a novel gene important in the pathogenesis of MDS and AML.

0487

PREVALENCE AND PROGNOSTIC IMPACT OF TET2 MUTATIONS IN MDS

F. Kosmider,[1] V. Gelsi-Boyer,[2] M. Cheok,[3] S. Grabar,[4] P. Guardiola,[5] O. Beyne-Rauzy,[6] B. Quesnel,[3] E. Solary,[7] N. Vey,[2] M. Hunault-Berger,[5] P. Fenaux,[8] V. Mansat de Mas,[6] F. Viguie,[9] C. Lacombe,[10] W. Vainchenker,[11] C. Preudhomme,[3] D. Birnbaum,[2] F. Dreyfus,[10] O.A. Bernard,[12] M. Fontenay[10]

[1]Institut Cochin, APHP, PARIS; [2]INSERM UMR891, IPC, MARSEILLE; [3]INSERM U837, IRCL, LILLE; [4]Department of Biostatistics, Université Paris Descartes, PARIS; [5]CHU, ANGERS; [6]CHU Purpan, TOULOUSE; [7]INSERM U790, VILLEJUIF; [8]Hopital Avicenne, Université paris 13, BOBIGNY; [9]APHP, Université Paris Descartes, PARIS; [10]INSERM U567, APHP, Université Paris Descartes, PARIS; [11]INSERM U790, Université Paris XI, VILLEJUIF; [12]INSERM E210, Université Paris Descartes, PARIS, France

Background. Genetic pathways involved in the development and progression of MDS remain poorly known. In addition, no gene mutation has demonstrated independent prognostic value in MDS. We recently showed TET2 gene, a member of Ten-eleven translocation family located at the 4q24 locus, to be frequently mutated in myeloid malignancies (F. Delhommeau, N. Engl. J. Med., in press) *Aims*. To establish the prevalence and prognostic impact of TET2 mutations in MDS. *Methods*. We retrospectively analyzed TET 2 mutations and their prognostic value, in 206 MDS and AML post MDS enrolled in GFM multicenter trials (41 RA/RCMD/MDS-U/5q-, 18 RCMD, 28 RARS/RCMD-RS/RARS-T, 43 RAEB 1, 32 RAEB 2, 44 AML post MDS). Univariate and multivariate survival analyses were conducted with Cox hazard proportional model. *Results*. We found 59 mutations of the TET2 gene by direct sequencing of exons 3 to 11 (27 frameshifts, 21 nonsense and 11 missense mutations in conserved domains) in 43/206 pts. The frequencies according to the WHO subtypes were 21.8% in RA, 5.2% in RCMD, 21.4% in RARS/RARS-T/RCMD-RS, 34.9% in RAEB 1, 15.6% in RAEB 2, 18.2% in AML post MDS. Other anomalies of the 4q24 region were found including a deletion in 1/46 pts analyzed by CGH and 3 LOH and 2 deletions in 5/23 pts analyzed SNP arrays. Thus, the overall prevalence of 4q24 anomalies was 22.3% pts (46/206). 20 pts had two anomalies of TET2 identified by direct sequencing (17 pts), or sequencing plus SNP array (3 pts), indicating that the two copies of the gene were targeted in 43.5% of mutated pts. Comparison between the 43 pts with TET2 coding sequence mutations and unmutated patients found no significant differences in initial characteristics for sex, age, previous exposure to chemo or radiotherapy, Hb level, WBC count, ANC, plt count,% bone marrow blasts, multilineage dysplasia, WHO and FAB subtypes, karyotype and IPSS. Five-year overall survival was 77.6% in mutated versus 46.4% in unmutated cases (p=0.0097). After excluding pts with AML post MDS, AML transformation at 5 years was 7.0% in mutated versus 49.7.% in unmutated pts (p=0.0018). In multivariate analysis (Cox hazard proportional model) adjusted for age, sex and IPSS, presence of TET2 mutation remained an independent favourable prognostic factor of overall survival [HR=3.3 (CI95%, 1.4-7.7) p=0.006]. *Conclusion*s. TET2 mutations are observed in about 20% of MDS, and are seen in all WHO or FAB subtypes. TET2 mutations constitute, to our knowledge, the first described independent molecular favourable prognostic factor of survival in MDS.

0488

GAIN-OF-FUNCTION MUTATIONS OF C-CBL TUMOR SUPPRESSOR IN MDS AND MDS/MPD ASSOCIATED WITH 11Q UPD

Myelodysplastic syndromes (MDS) are heterogeneous neoplastic hematopoietic disorders, in which acquired uniparental disomy (aUPD) is a common genetic feature, as well as other allelic imbalances. However, the precise role of aUPD in the pathogenesis of MDS is not fully understood because of the scarcity of information about the gene targets of common aUPD. Through the genome-wide analysis of allelic imbalances in 171 MDS using high-density SNP arrays, we identify that a homozygous mutation of c-Cbl is the genetic target of the 11qUPD. aUPD is a common feature of cancer genomes, leading to loss of heterozygosity (LOH). aUPD is associated not only with loss-of-function mutations of tumor suppressor genes but also with gain-of-function mutations of proto-oncogenes in homozygous state. Here we show that homozygous gain-of-function mutations of c-Cbl tightly associated with aUPD in 11q have unique oncogenic properties, which are responsible for the pathogenesis of myeloid neoplasms. c-Cbl proto-oncogene, a cellular homologue of a viral oncogene, v-Cbl, encodes an E3 ubiquitin ligase, which negatively regulates signal transduction of tyrosine kinases. Homozygous c-Cbl mutations were found in most 11q aUPD-positive myeloid neoplasms, including MDS and MDS / MPD, as well as MDS-derived AML. We demonstrated that c-Cbl functionally and genetically acted as a tumor suppressor gene in hematopoietic cells as well as other cell types. c-Cbl mutants inhibited the E3 ligase activity of wild-type c-Cbl and lead to prolonged activation of tyrosine kinases in hematopoietic cells. When mutant c-Cbl was transduced, hematopoietic progenitors acquired increased sensitivity to a wide variety of cytokines, includ-

ing stem-cell factor, thrombopoietin, IL3, and Flt3 ligand with concomitant activation of downstream signaling, which was prominently enhanced in the c-Cbl'/' background. Our result clarified a unique relationship between a tumor suppressor proto-oncogene and its gain-of-function mutations. The phenotypes induced by mutant c-Cbl in c-Cbl'/' cells unequivocally indicated the presence of gain-of-function that are not ascribed to a simple loss-of-function or an inhibitory action against c-Cbl, which may explain the observation that c-Cbl mutations were associated with loss of wild-type c-Cbl alleles and the latter was predominantly caused by copy number (CN)-neutral, but not CN-reduced, LOH. Our findings provide a novel insight into the genetic role of aUPD associated with gain-of-function mutations of a tumor suppressor gene in the development of human neoplasm.

0489

IS ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION A REASONABLE THERAPEUTIC OPTION FOR ELDERLY (= 60 YEARS) PATIENTS WITH DE NOVO MYELODYSPLASTIC SYNDROMES ?

U. Platzbecker,[1] R. Trenschel,[2] K. Schaefer-Eckart,[3] C. Theuser,[1] G. Ehninger,[1] M. Bornhäuser,[1] D. Beelen[2]

[1]Universitätsklinikum "Carl Gustav Carus" Dresden, DRESDEN; [2]Klinik für Knochenmarktransplantation Universitätsklinikum Essen, ESSEN; [3]Klinikum Nürnberg, NÜRNBERG, Germany

With the rare exception of patients, who achieve long lasting remissions with chemotherapy, allogeneic hematopoietic cell transplantation (HCT) is currently the only modality with proven curative potential for MDS patients (pts). However, given the heterogeneity of MDS, and the potential complications associated with HCT, it is often difficult to decide when and in whom to perform an allogeneic HCT. A survival advantage with early transplantation in patients with MDS classified as intermediate-2 or high risk by IPSS criteria was demonstrated. However, this study was restricted to MDS patients below the age of 60 years. In fact, the results are therefore not a reflection of the "true" elderly MDS population who were, up to recently, not considered candidates for allogeneic HCT. Therefore, this study tried to investigate the outcome of 89 elderly (median age 64 years [range 60-71]) de novo MDS patients receiving allogeneic HCT between 2000 and 2008. MDS categories prior to HCT were either RA (n=3), RCMD (n=2), RAEB-1/CMML-1 (n=18), RAEB-2/CMML-2 (n=25) or secondary AML out of MDS (n=41). Almost all of the latter group had received at least one cycle of chemotherapy prior to HCT with 51% achieving a CR. Median time from MDS diagnosis to HCT was 10 months and HCT-comorbidity index (HCT-CI) ranged from 0 to 5 (median 1). The conditioning was of standard or reduced intensity in 30 and 59 pts, respectively and followed by donor cells from either related (n=29) or unrelated (n=60) donors. The graft versus host disease prophylaxis was cyclosporin A or tacrolimus based in all cases. With a median follow-up of 28 months the 3-year overall survival (OS) rate was 40% patients for all patients and was not different (p=0.5) between related and unrelated donor based HCT. OS differed according to marrow blasts (median 8%, range 0-80) prior to Tx (< 20%: 44% vs. ≥20%: 29%, p=0.04). In contrast, grouping pts according to IPSS cytogenetic risk group revealed no statistically significant differences (p=0.5). Of note was the observation that pts with HCT-CI of less or equal to 2 had a significant better OS compared to pts with more advanced comorbidities (50 vs. 18%, p=0.003). In a multivariate analysis only time from diagnosis to HCT (p=0.017), HCT-CI (p<0.001), and type of conditioning (p<0.001) influenced the overall outcome whereas age, donor type, cytogenetics and HLA-mismatch did not. These data demonstrate that allogeneic HCT is not only feasible but can also be associated with long-term disease control in elderly MDS pts. However, patient selection seems to be a definite prerequisite in order to prevent excess mortality. With the availability of new agents prospective randomized studies seem to be warranted in order to define the exact role and time point of allogeneic HCT in the treatment algorithm of advanced MDS.

ANALYSIS OF THE MITOCHONDRIAL FERRITIN PHYSIOPATHOLOGICAL ROLE IN SIDEROBLASTIC ERYTHROPOIESIS

R. Invernizzi,[1] M.G. Della Porta,[1] V. Rosti,[1] A. Gallì,[1] E. Travaglino,[1] P. Santambrogio,[2] C. Marseglia,[1] V. Matti,[1] L. Malcovati,[1] G. Bergamaschi,[1] M. Cazzola,[1] S. Levi[2]

[1]University of Pavia and Fondazione IRCCS Policlinico S. Matteo, PAVIA; [2]Vita-Salute San Raffaele University and IRCCS H. San Raffaele, MILANO, Italy

Recently, in the erythroblasts of refractory anemia with ring sideroblasts (RARS), we identified a novel mitochondrial ferritin (FtMt) that may play an important role in regulating iron homeostasis and toxicity. FtMt may protect mitochondria from oxidative damage and increase cell resistance to the apoptotic signals. To clarify the possible role of FtMt in the ineffective erythropoiesis of RARS, we assessed its distribution in RARS erythroid progenitors and searched for possible correlations between FtMt expression and erythroid maturation, apoptosis, proliferation, clonogenic capacity. Moreover, we investigated the possible influence of experimentally induced FtMt overexpression on erythroid differentiation and its capacity to induce a sideroblastic phenotype in normal hematopoietic progenitors. CD34+ bone marrow cells from 24 patients with RARS, 20 patients with refractory anemia (RA) and 8 healthy donors were cultured for 14-21 days in a liquid medium according to a procedure which allows the expansion of high numbers of erythroid progenitors in the presence of Il-3, IL-6, stem cell factor and erythropoietin. At various days, cytospins were performed for FtMt, H-ferritin (HFt) and L-ferritin (LFt) immunocytochemical analysis, and samples of cultured cells were removed for other biological studies. Furthermore, we developed a lentiviral vector encoding FtMt under the control of the ubiquitous PGK promoter, which allowed the transduction of normal CD34+ bone marrow cells with an efficiency of some 30-40%, as evaluated by immunocytochemistry on day 7. FtMt transduced cells from 5 healthy donors were cultured by the same above procedure that allowed their differentiation to the erythroid lineage. RARS erythroid progenitors showed an early expression of FtMt and a continuous increase during the culture period (5-24%, day 4-14), with an inverse correlation between FtMt and HFt levels (p=0.04); studies of FtMt mRNA gene expression demonstrated the presence of the transcript even in cells lacking the protein. LFt levels were variable, while HFt expression was higher in RA (p<0.001). Cell growth was very low in all pathological samples. RARS and RA progenitors showed a tendentially higher apoptotic rate and an inverse correlation between apoptosis levels and BFU-E number. In RARS, apoptotic rate was higher in FtMt+ cells than in FtMt- cells (p<0.0001), whereas in RA a positive correlation between apoptotic rate and HFt expression was observed (p=0.005). Lentivirus-mediated FtMt transduction of normal CD34+ progenitors did not inhibit cell growth nor did it abrogate their ability to terminally differentiate but increased apoptosis of differentiated erythroid cells and reduced their HFt levels and heme content. In conclusion, we have demonstrated an abnormal phenotype characterized by mitochondrial or cytosolic iron overload in RARS and RA erythroid progenitors. The association of this phenotype with low proliferation and increased apoptosis suggests a close relationship between impaired iron metabolism and pathogenesis of myelodysplasia. Experimental overexpression of FtMt in normal erythroid progenitors may modify mitochondrial iron availability, impair heme synthesis and alter the balance between cell growth and death.

Chronic lymphocytic leukemia - Biology and Clinical

INHIBITION OF LEF-1 EFFECTIVELY INDUCES APOPTOSIS IN CHRONIC LYMPHOCYTIC LEUKEMIA IN VITRO AND IN VIVO

R.K. Gandhirajan,[1] I. Gehrke,[1] G. Plickert,[2] A. Schlösser,[3] E.K. Schmitt,[4] M. Hallek,[1] K.A. Kreuzer[1]

[1]University Clinic Cologne, COLOGNE, Germany; [2]Institute of Zoology, university at Cologne, COLOGNE, Germany; [3]Novartis Pharmaceuticals Inc, NÜRNBERG,GERMANY, Germany; [4] Natural Products Unit, Novartis Institutes of Biomedical Research, BASEL, Switzerland

Background. A variety of aberrantly active signaling pathways has been associated with chronic lymphocytic leukemia (CLL), with one of them being the wnt/β-catenin/lef-1 cascade. Recent reports suggest autocrine activation of wnt signaling in CLL, with elevated levels of several wnts, fzd-3 and lef-1. Abnormal activation of this cascade induces expression various target genes involved in regulation of leukemic cell adhesion, B cell proliferation and survival. Hence, wnt/ β-catenin/lef-1 signaling is speculated to be involved in the prolonged survival of the CLL cells and therefore to be a potential target for CLL therapy. *Aims.* The aim was to investigate the role of lef-1-signaling in CLL cell survival. Furthermore we aimed on characterizing the effect of specific small molecules against β-catenin/lef-1 interaction on CLL cells *in vitro* and *in vivo*, to determine the suitability of β-catenin/lef-1 inhibition for CLL treatment. *Methods*. Enriched CLL-cells and healthy B-cells were used in this study. Protein levels of lef-1 target genes were detected by immunoblotting using specific antibodies. siRNA mediated knock down of lef-1 in primary CLL cells and JVM-3 cell lines was done using nucleofection, and viability was assayed by flow cytometry. *In vitro* cytotoxicity and LC50 of two small molecules inhibiting the β-catenin/lef-1 interaction was assessed using ATP based cell viability assay. Apoptotic response was investigated in time course experiments with different apoptotic markers. Specificity of the small molecules was demonstrated by co-immunoprecipitation experiments for the lef-1/β-catenin interaction. *In vivo* efficacy of the small molecules inhibitors were studied using a JVM-3 subcutaneous xenograft model in nu/nu mice. *Results*. We confirmed the overexpression of lef-1 in CLL at both, the mRNA and protein level. Knocking down of lef-1 led to increased apoptosis in CLL cells *in vitro* indicating that lef-1 has a vital role in extended survival of CLL cells. The viability was correlated to the lef-1 knock down by western blot. This observation was extended by using two small molecule inhibitors of β-catenin/lef-1 signaling (CGP049090 and PKF115-584) which induce apoptosis of CLL-like cell lines and primary CLL cells (LC50: ranging from 0.7μM to 0.9μM) Healthy B cells were not significantly affected, as ascertained by LC50 values of 8.5μM (CGP049090) and 5.7μM (PKF115-584). Co-immunoprecipitation proofed the selective disruption of β-catenin/lef-1 interaction. Further, a decrease of the lef-1 target genes c-myc, cyclin D1 and lef-1 could be demonstrated by immunoblotting upon incubation with inhibitors. We tested the *in vivo* efficacy of both inhibitors in a JVM-3 xenograft model. Mice treated with 25mg/kg for 14 days exhibited tumor inhibition of 69% with CGP049090 and 57% with PKF115-584 and the intervention was well tolerated. Kaplan-Meier survival analysis of this treatment significantly improved median survival by 12.5 days with CGP049090 and 15.5 days with PKF115-584 (p value <0.003). *Conclusions and Summary*. We showed lef-1 inhibition effectively induces apoptosis in CLL cells, via both, siRNA mediated knockdown, as well as inhibition of the active β-catein/lef-1 complex, which we additionally confirmed in an *in vivo* model. Therefore, targeting lef-1 signaling can be considered a potential attractive strategy for CLL treatment.

TP53 MUTATION IN THE ABSENCE OF 17P DELETION DEFINES A GROUP OF PATIENTS WITH POOR OUTCOME IN CLL: ANALYSIS WITHIN THE CLL4 TRIAL (F VS. FC) OF THE GCLLSG

T. Zenz,[1] B. Eichhorst,[2] R. Busch,[3] T. Denzel,[1] S. Häbe,[1] D. Winkler,[1] A. Bühler,[1] M Hallek,[2] H. Döhner,[1] S Stilgenbauer[1]

[1]University of Ulm, ULM; [2]University of Cologne, COLOGNE; [3]University of Munich, MUNICH, Germany

Introduction. CLL patients with 17p deletion have a dismal prognosis after treatment. The exact prognostic role of TP53 mutations in the absence of 17p deletion and any differential impact of the mutation in cases with 17p deletion (vs. sole deletion) are currently unclear. *Methods*: We assessed the incidence, profile and prognostic impact of TP53 mutations in a well characterized patient population from a prospective trial (CLL4 trial GCLLSG: 1st line F vs. FC). We studied 340 of 375 CLL4 trial patients with available material. The population is well characterized and detailed genetic characteristics are available (genomic aberrations, VH-Status). We used DHPLC to detect TP53 mutations in the coding exons (2-11). Aberrant profiles were confirmed by sequencing including the use of fragment collection in cases with low grade mutations. *Results*. We found an overall incidence of TP53 mutations of 8.2% (28/340 patients). The mutations were exclusively located in the DNA binding domain. We observed 2 splice site mutations, 3 deletions, 2 insertions but the majority of mutations were missense mutations in exons 5-8. Two patients had 2 different mutations. Transitions were found in 11/24 missense mutations whereas transversions were seen in 13 of 24 mutations. Fourteen of 16 patients with 17p deletions had a TP53 mutation (87.5%). Interestingly, the 2 patients with a 17p deletion in whom no TP53 mutation was identified showed a low proportion of 17p- cells (19-21%) suggesting that detection limits of the technique might explain this finding. We found TP53 mutations in the absence of 17p deletions in 4.3% (14/326). Median progression-free survival and overall survival were significantly decreased in the group with TP53 mutation (PFS 23.4 vs. 61.8 months (p<0.001) and OS 29.2 vs. 84.6 months (p<0.001)). There were no significant differences in PFS or OS between the two treatment arms in the group with TP53 mutation. None of the patients with TP53 mutation showed a complete response (vs. 39/284 without TP53 mutation). Of the cases without response, 10/36 (28%) showed TP53 mutations. To assess the effect of the TP53 mutation in the absence of 17p deletion, we compared this group with the group with 17p deletion and found identical overall survival (Figure 1). These data suggest that the group of patients with TP53 mutation in the absence of 17p deletion forms a new prognostic subgroup with similar outcome as 17p deletion cases. Multivariate analysis of genomic aberrations, VH-Status, clinical parameters and serum markers revealed that TP53 mutation was the strongest negative prognostic marker regarding PFS (HR 25.6, p<0.001) and OS (HR 11.61, p<0.001). When comparing treatment results of the two arms among patients without TP53 mutation (n=312), there was a significant difference in OS with superior outcome for patients receiving FC (p=0.029).

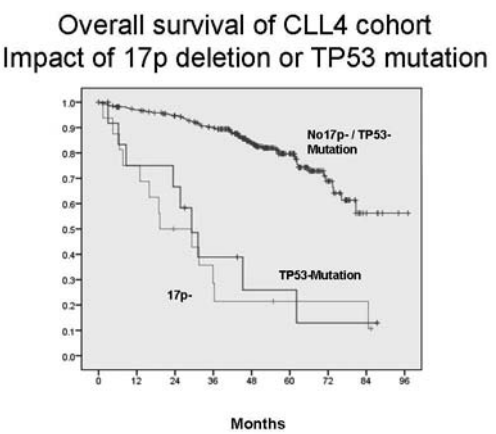

Figure 1. Survival by 17p-/TP53 mutation.

Conclusions. In this first line treatment trial population, TP53 mutations without 17p deletion occurred in 4.3% (14/326) of patients and the majority of cases with 17p deletion also have TP53 mutations. CLL with TP53 mutation carries a poor prognosis independent of the presence of the deletion 17p suggesting that alternative treatment approaches are needed for this group of patients. TP53 mutation emerged as the strongest prognostic factor in multivariate analysis in this trial population.

DIFFERENTIAL GENOME-WIDE METHYLATION PROFILES IN PROGNOSTIC SUBSETS OF CHRONIC LYMPHOCYTIC LEUKEMIA

M. Kanduri, N. Cahill, H. Göransson, C. Enström, A. Isaksson, R. Rosenquist

Uppsala University, UPPSALA, Sweden

Background. Chronic lymphocytic leukemia (CLL) is a biologically heterogeneous disease, characterized by accumulation of neoplastic B-cells due to deregulation of both apoptosis and proliferation. CLL can be classified into clinical subgroups depending on the presence or absence of somatic hypermutations in the immunoglobulin heavy-chain variable (IGHV) genes. Studies from previous investigations have shown that aberrant DNA methylation may play an important role in leukemogenesis. However, limited knowledge exists regarding the global methylation pattern in CLL. *Aims*. We here investigated genome-wide methylation using array-based technology in 27 CLL samples belonging to favourable (e.g. IGHV mutated CLL) and poor-prognostic subsets (e.g. IGHV unmutated and IGHV3-21 CLL). Methods: We applied a genome-wide methylation array from Illumina based on bisulfate conversion covering 28,000 CpG sites spanning 14,000 genes. The raw data was processed using Bead studio followed by bioinformatic analysis where the arcsin transformed data was used in a moderated t-test to find differentially methylated genes. Also, only genes with a large absolute difference between the groups were included. Methylation-specific PCR and realtime-PCR were also employed to verify the array data on selected genes. Furthermore, samples were treated with methyl-inhibitors to induce re-expression of methylated genes. *Results.* Overall, our results demonstrate a large number of differently methylated genes between the IGHV mutated and IGHV unmutated/IGHV3-21 groups. Specifically, we identified eight tumor suppressor genes (e.g. VHL, ABI3 and IGSF4) that were methylated in IGHV unmutated/IGHV3-21 CLL patients as well as ten genes involved in proliferation and tumor progression (e.g. ADORA3, LOC340061 and RASGRP3) which were overexpressed in these poor-prognostic groups. On the other hand, these latter genes were silenced by methylation in IGHV mutated CLL patients, whereas anti-apoptotic genes, such as BCL2 and PLD1, remained unmethylated in this subgroup. The methylation status was confirmed for four genes (BCL10, PRF1, ADORA3 and IGSF4) and the expression status of seven genes was verified using real-time RT-PCR (BCL10, PRF1, ADORA3, IGSF4, NGFR, ABI3 and VHL). We also re-expressed seven genes (e.g. NGFR, ABI3, VHL and IGSF4) by inhibiting DNA methylation using the methyl-inhibitor 5-aza-2'-deoxycytidine combined with and without the HDAC inhibitor trichostatin A. *Conclusion*. Our data reveals, for the first time, differences in global methylation profiles between favourable and poor-prognostic CLL subgroups, which appear to affect pathways involved in control of apoptosis and proliferation. Our novel data could possibly reveal new epigenetic-based silencing mechanisms of pathogenetic importance in these subsets.

Background. Patients with fludarabine-refractory CLL also refractory to alemtuzumab (FA-ref) or ineligible for alemtuzumab due to bulky (>5 cm) lymphadenopathy (BF-ref) have poor outcomes with available salvage regimens. Ofatumumab, a unique human monoclonal antibody that targets a membrane-proximal small-loop epitope on the CD20 molecule, elicits potent *in vitro* complement-dependent cytotoxicity against malignant B cells with low CD20 expression, such as CLL cells. *Aims*. We evaluated the efficacy and safety of ofatumumab in patients with FA-ref and BF-ref CLL. Here we report updated results from the prospectively planned interim analysis of an international pivotal trial. *Methods*. Patients received 8 weekly infusions of ofatumumab followed by 4 monthly infusions (Dose 1, 300 mg; Doses 2-12, 2000 mg). The primary endpoint was overall response rate (ORR; 1996 NCI-WG criteria) over a 24-week period assessed by an Independent Review Committee (IRC). Secondary endpoints included duration of response, progression-free survival (PFS), overall survival (OS) and safety. *Results*. The interim analysis included 59 FA-ref and 79 BF-ref patients; 90% of patients received ≥8 infusions. Median age was 64 and 62 years, respectively, and median (range) number of prior regimens was 5 (1-14) and 4 (1-16), respectively. The ORR (99% confidence interval) was 58% (40, 74%) in the FA-ref and 47% (32, 62%) in the BF-ref groups based on IRC evaluation; all but one were partial remissions. The median time to onset of response was 1.8 months for both groups and the duration of response was 7.1 months in the FA-ref group and 5.6 months in the BF-ref group (response was sustained for approximately 2 months following cessation of treatment). Median lymph node, spleen and liver sizes decreased during the course of treatment. Median PFS and OS were 5.7 and 13.7 months, respectively, in the FA-ref group and 5.9 and 15.4 months, respectively, in the BF-ref group. A landmark analysis at Week 12 showed a significantly longer median OS (by ≥10 months) among responders (those responding by Week 12) versus non-responders; median OS had not yet been reached for responders in either FA-ref or BF-ref groups compared with 9.8 (p=0.04) and 10.2 months (p<0.0001), respectively, for non-responders. In addition to NCI-WG responses, improvements (maintained for ≥2 months) in important clinical parameters were observed in a large proportion of patients (Table). Resolution of B-symptoms, hepatomegaly, or reductions in lymphadenopathy, occurred in about 50% of patients. Median hemoglobin and platelet counts increased during the study; neutrophils remained relatively stable, with only 5 events of grade 4 neutropenia reported among 4 patients. Treatment was well tolerated, with transient grade 1 or 2 infusion-related reactions in approximately 60% of all patients. The most common grade 3 or 4 adverse events during the treatment period were infections (FA-ref, 24%; BF-ref, 23%). Early death (≤8 weeks from treatment initiation) occurred in 4 FA-ref and 2 BF-ref patients, none of which were considered related to ofatumumab. *Conclusions*. Ofatumumab monotherapy results in high ORR, improves disease symptoms and has a favorable safety profile in heavily pretreated patients with FA-ref and BF-ref CLL.

Table. Measures of clinical improvements with a minimum duration of 2 months.

	FA-ref		BF-ref	
Improvement in clinical parameter from baseline to Week 24, %	N*	n (%)†	N*	n (%)†
Complete resolution of B-symptoms	31	15 (48)	46	29 (63)
Complete resolution of lymphadenopathy (<1 cm nodes)	55	9 (16)	74	8 (11)
≥50% reduction in lymphadenopathy	55	34 (62)	74	36 (49)
Complete resolution of splenomegaly	30	14 (47)	46	16 (35)
Complete resolution of hepatomegaly	18	9 (50)	21	11 (52)
Neutrophil count from <1.5 × 10^9/L to ≥1.5 × 10^9/L	19	1 (5)	17	5 (29)
Hemoglobin from ≤11 g/dL to >11 g/dL	26	8 (31)	42	11 (26)
Improvement in platelet count from ≤100 × 10^9/L to 50% increase or >100 × 10^9/L	29	12 (41)	44	17 (39)

*Total number of patients with abnormal baseline parameters; †Number of patients with improvement (lasting for at least 2 months) from baseline to Week 24
FA-ref=fludarabine- and alemtuzumab-refractory; BF-ref=bulky fludarabine-refractory

0495

PHASE I STUDY OF RO5072759 (GA101) IN RELAPSED/REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA

G. Cartron,[1] T. Lamy,[2] F. Morschhauser,[3] N. Milpied,[4] C. Thieblemont,[5] H. Tilly,[6] J. Birkett,[7] P. Pisa,[7] G. Salles[8]

[1]CHU Montpellier, MONTPELLIER, France; [2]CHU Rennes, RENNES, France; [3]CHU Lille, LILLE, France; [4]CHU Bordeaux, BORDEAUX, France; [5]Hôpital Saint Louis, PARIS, France; [6]CHU Rouen, ROUEN, France; [7]F.Hoffmann-La Roche, WELWYN, UK; [8]Hospices Civils de Lyon, LYON, France

Background. RO5072759 (GA101) is the first humanized and glyco-engineered type II monoclonal anti-CD20 antibody in clinical trials. Glycoengineering results in a significant increased antibody-dependent cytotoxicity (ADCC) compared to rituximab. Additionally, high affinity to a type II epitope on CD20 is characterized by reduced complement-dependent cytotoxicity (CDC) and strongly enhanced direct cell death compared to type I antibodies. *Aims.* In this Phase 1/2a study, RO5072759 was administered as a single agent to patients with CD20+ malignant disease for whom no therapy of higher priority was available in order to determine the safety, tolerability and pharmacokinetics of RO5072759. After reporting an encouraging activity of RO5072759 in lymphoma patients (Salles et al., ASH 2008), we present here for the first time the data for B-CLL patients. *Methods.* Patients were treated with RO5072759 by i.v. infusion (premedication: acetaminophen, antihistaminics, allopurinol/adequate hydration and no steroids) administered as a flat dose on Days 1, 8 and 22 and every 3 weeks thereafter for a total of 9 infusions. The dose was escalated based on the safety in a 3+3 design. *Results*. Thirteen B-CLL patients received RO5072759 at doses from 400 mg up to and including 2000 mg. Median age was 64 years [46-81], hemoglobin at baseline 12.6 g/dL [9.4 -14.9], WBC 51.8x10^9/L [10 -124], platelets 191x10^9/L [48-404]. The median duration of CLL was 8 years (2.8-15.7), median prior regimens 3 [1-8]. All 13 patients had received prior fludarabine therapy and 8 (62%) rituximab-containing regimen. To-date 7 of 11 evaluable patients have responded to treatment with responses (assessed by IWCLL criteria) observed with doses given at 400-2000 mg (best response): 1 CR, 6 PR and 4 SD. All patients showed an almost total and sustained reduction of CD19+ blood cell count following the 1st infusion. RO5072759 was well tolerated with no DLTs and no dose reductions. Grade 1 or 2 (CTCAE V3.0) infusion related reactions were associated with the 1st infusion with Gr 3 in 2 pts. Patients responded well to the slowing or interruption (10 pts) and steroids (11 pts) during the 1st infusion (2 during any subsequent infusion). Grade 3/4 AEs were: transient neutropenia in 9 patients (recovering spontaneously or with G-CSF), and transient thrombocytopenia (3 pts). SAEs were reported in 3 patients (febrile neutropenia, thrombocytopenia, bronchitis, tooth infection, neutropenia and tumor lysis syndrome. Infections were Grade 1-3 in 10 patients. The pharmacokinetics of RO5072759 showed a dose dependent increase in exposure with significant inter- and intra-patient variability. Time-dependent clearance was noted, which is consistent with a reduction in target-mediated antibody clearance with increasing duration of treatment. *Conclusion*. These preliminary results indicate that RO5072759 has promising activity in B-CLL patients with a 64% response rate as single agent in pretreated patients and has a similar safety profile to that observed in NHL patients treated with RO5072759 with the observation of an increased incidence of neutropenia in B-CLL.

Stem cell transplantation - Experimental and Clinical

0496

AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT) VS ALLOGENEIC STEM CELL TRANSPLANTATION (ALLO-SCT) AS FIRST TRANSPLANT PROCEDURE IN PATIENTS WITH WALDESTRÖM MACROGLOBULINEMIA. RESULTS OF A RETROSPECTIVE ANALYSIS OF THE LYMPHOMA WORKING PARTY OF THE EBMT.

A. Sureda,[1] C. Canals,[1] C. Kyriakou,[2] C. Gisselbrecht,[3] M. Gramatzki,[4] M. Kazmi,[5] J.Y. Cahn,[6] N. Milpied,[7] K. Kolbe,[8] W. Arcese,[9] P. Corradini,[10] D. Niederwieser,[11] J.P. Jouet,[12] K. Thomson,[13] R.M. Hamladji,[14] K. Indrak,[15] N. Schmitz[16]

Michallon, GRENOBLE, France; [7]Hôpital Haut-leveque, BORDEAUX, France; [8]Johannes-Gutenberg-University, MAINZ, Germany; [9]Policlinico Universitario Tor Vergata, ROMA, Italy; [10]University of Milano, MILANO, Italy; [11]University Hospital Leipzig, LEIPZIG, Germany; [12]Hopital Claude Huriez, LILLE CEDEX, France; [13]University College London Hospital, LONDON, UK; [14]Centre Pierre et Marie Curie, ALGER, Algeria; [15]University Hospital, OLOMOUC, Czech Republic; [16]Asklepios Klinik St. Georg, HAMBURG, Germany

The role of both autologous (ASCT) and allogeneic stem cell transplantation (allo-SCT) in the treatment of patients with Waldeström macroglobulinemia (WM) is not clearly defined at the present time. Herein, we present the results of a retrospective analysis that compares the long-term outcome in a group of 230 patients (147 males and 83 females, median age at diagnosis 48 (20-67) years, median age at transplant 52 (23-71) years) that underwent an ASCT (n = 153) or an allo-SCT (n = 77) as first transplant between 1995 and 2005 and were reported to the EBMT Database. In the allogeneic group, 63 patients (82%) were allografted from a HLA identical sibling donors and the remaining 14 (18%) from matched unrelated donors. In 34 patients, a conventional conditioning regimen was used and in 43 (56%) patients, a reduced intensity procedure. Patients treated with an allogeneic procedure did show poorer prognostic features before transplantation than those treated with an autograft; time interval between diagnosis and transplant was significantly longer [31 (5-310) months vs 20 (3-244) months, p= 0.01) and the percentage of patients receiving ≥3 treatment lines before the transplant was significantly higher (67% vs 33%, p<0.001). In addition, patients treated with an allo-SCT more frequently showed chemorefractory disease at the time of transplantation (30% vs 7%, p<0.001). Patients treated with an ASCT were significantly older [median age at transplant 53 (25-70) years vs 49 (23 - 64) years, p=0.006). With a median follow up for the surviving patients of 53 (6-130) months (allo-SCT group) and 48 (6-155) months (ASCT group) (ns), 5-yr non-relapse mortality (NRM), relapse rate (RR), progression free survival (PFS) and overall survival (OS) were of 12.7 (95%CI 9 - 18), 42.1 (95%CI 35 - 50), 45.2 (95%CI 38 - 53) and 66.7 (95%CI 60 - 74), respectively for the whole series. In the multivariate analysis, allo-SCT was significantly associated with a higher NRM [relative risk 2.7 (95%CI 1.1 - 6.6), p= 0.03] as well as a poor performance status at the time of transplant [relative risk 4.2 (95%CI 1.5 - 11), p=0.006] and the use of bone marrow [relative risk 2.8 (95%CI 1.2 - 6.6), p=0.02]. On the contrary, ASCT was significantly associated with a higher RR [relative risk 4.1 (95%CI 2.0 - 8.5), p<0.001] together with refractory disease [relative risk 2.5 (95%CI 1.2 - 5), p= 0.01], ≥3 lines of therapy before transplant [relative risk 2 (95%CI 1.2-3.2), p=0.004] and poor performance status [relative risk 4 (95%CI 1.3-12), p=0.01]. The impact of the type of transplant on both PFS and OS was non-proportional over time. ASCT was an independent adverse prognostic factors for both outcomes in the second time period (≥24 months after transplantation) [relative risk 4.2 (95%CI 1.8 - 9.8), p= 0.003 and relative risk 5.1 (95%CI 1.8-14.6), p= 0.002, respectively]. Type of transplant was not a prognostic factor for both PFS and OS in the first time period. Other adverse independent prognostic factors for PFS were refractory disease [relative risk 2.0 (95%CI 1.2 - 3.5), p=0.01], ≥3 lines of therapy [relative risk 1.8 (95%CI 1.2 - 2.7), p= 0.007] and poor performance status [relative risk 3.6 (95%CI 1.7 - 7.6), p= 0.001] and for OS, ≥3 lines of therapy [relative risk 2.2 (95%CI 1.3-3.6), p=0.004] and poor performance status [relative risk 3.4 (95%CI 1.4 - 7.8), p=0.005]. In summary, both transplants procedures are feasible in a selected population of young patients with WM. Although NRM is

higher in the allogeneic setting, the over time decreased relapse rate due to the additional immune effects favors allo-SCT in the long run.

Oncologia Medica, Ospedale San Camillo de Lellis, RIETI, Italy

Background. New agents have been introduced as induction prior to autologous stem cell transplant (ASCT) and as consolidation/maintenance thereafter to improve complete response (CR) rates. *Aims*. In this phase II study we evaluate a sequential approach with bortezomib as induction prior to autologous transplantation followed by lenalidomide as consolidation-maintenance. Primary endpoints were safety (incidence of grade 3-4 adverse events) and efficacy (response rate). *Methods*. Newly diagnosed multiple myeloma (MM) patients, aged 65-75 years, were eligible. The induction included four 21-day cycles of bortezomib (1.3 mg/m^2 days 1,4,8,11), pegylated-liposomal-doxorubicin (30 mg/m^2 day 4) and dexamethasone (40 mg: days 1-4, 8-11, 15-18, cycle 1; days 1-4, cycles 2 to 4) (PAD). Autologous transplantation was tandem Melphalan 100 mg/m^2 and stem-cell support (MEL100). Consolidation included four 28-day cycles of lenalidomide (25 mg/day days 1-21) plus prednisone (50 mg every other day) (LP), followed by maintenance with lenalidomide (10 mg/day days 1-21 every 28 days) (L) until relapse. *Results*. One-hundred and two patients have been enrolled. In a per-protocol analysis, PAD induced: 58.5% at least very good partial response (VGPR), including 12.8% complete response (CR); MEL100 autologous transplantation: 82.0% at least VGPR and 38.6% CR; LP-L consolidation-maintenance: 86.0% at least VGPR and 66.0% CR. Eleven of fifty patients showed a further improvement in response rate during LP-L consolidation-maintenance. After a median follow-up of 20.3 months, the 3-year progression-free survival was 68.8%, the 3-year time to progression (TTP) was 74.7% and the 3-year overall survival was 86.3%. By exploratory subgroup analyses, patients with high risk cytogenetic profile - including del17 or t(4;14) or t(14;16) - and patients with standard cytogenetic profile had similar TTP (HR 0.49; 95% CI, 0.13-1.81; p=0.28). The results did not change with the inclusion of patients with del13q in the high risk group (HR 0.62; 95% CI, 0.20-1.97; p=0.42). During PAD induction, grade 3-4 adverse events included thrombocytopenia (16.7%), neutropenia (9.8%), peripheral neuropathy (15.7%), and pneumonia (9.8%). During LP-L consolidation-maintenance grade 3-4 adverse events were neutropenia (16.5%), thrombocytopenia (6.3%) and cutaneous rash (3.8%). *Conclusions*. Bortezomib as induction before transplantation, followed by lenalidomide as consolidation-maintenance induced very high response rate and prolonged 3-year progression-free survival.

ALLOGENEIC STEM CELL TRANSPLANTATION IN ELDERLY PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) IN FIRST COMPLETE REMISSION: EXPERIENCE OF THE GMALL STUDIES

R. Arnold,[1] D. Beelen,[2] M. Bornhaeuser,[3] D. Bunjes,[4] J. Finke,[5] N. Kroeger,[6] M. Stadler,[7] M. Stelljes,[8] N. Goekbuget,[9] D. Hoelzer[10]

[1]Charité University Medicine Berlin, BERLIN; [2]University Hospital Essen, Department of Bone Marrow Transplantation, ESSEN; [3]University Hospital, Dresden, Medical Clinic I, DRESDEN; [4]University Hospital Ulm, Department of Internal Medicine III, ULM; [5]University Medical Center Freiburg, Department of Hematology/Oncology, FREIBURG; [6]University Hospital of Hamburg, HAMBURG; [7]Medical Center University of Hannover, Department of Hematology/Oncology, HANNOVER; [8]University of Muenster, Department of Hematology/Oncology, MUENSTER; [9]J.W.G. University Frankfurt, Medical Department II, FRANKFURT; [10]J.W.G. University Hospital Frankfurt, FRANKFURT, Germany

In the German Multicenter ALL studies (GMALL) patients aged over 55 years with high risk (B lineage ALL with WBC at diagnosis >30000, late CR, t (4; 11), complex aberrant karyotype or prae T or mature T ALL) or very high risk (Ph+/BCR-ABL+) ALL in first complete remission are increasingly candidates for allogeneic stem cell transplantation (SCT) with a HLA identical sibling donor (MRD) or a matched unrelated donor (MUD). Here, we report on 27 elderly patients transplanted within the GMALL studies 06/99 and 07/03. Median age of the patients was 60 years (56 - 65). 19 patients belonged to the very high risk group, VHR (Ph+ ALL) and 8 patients to the high risk group, HR (prae T ALL n=5, mature T ALL n= 1, pro B ALL n=1, prae B ALL, Ph- n=1). 9/27 patients were transplanted from a HLA identical sibling donor and 18/27 from a matched unrelated donor. Conditioning regimens for MRD SCT were myeloablative (MAC) in 6 patients (TBI 12 Gy and chemotherapy n=2, radioimmunotherapy + chemotherapy n=2, chemotherapy only n=2) and 3 patients received reduced intensity conditioning (RIC).Conditioning regimens for MUD SCT changed over time with an increasing number of RIC in the study 07/03. In total, 7/18 patients received MAC (TBI 12 Gy and chemotherapy n=5, chemotherapy only n=2) and 11/18 patients received RIC. *Results*. After allogeneic SCT 14 out of 27 patients (52%) are alive in complete remission (CCR) with a median follow up of 1052 days (24 - 2321). 13/27 patients died (48%). Causes of death were transplant related mortality (TRM) in 9/13 patients (69%) in median on d+129 (18 - 736) and relapse in 4/13 patients (31%) between d+761 and d+1071 after SCT. Risk factors for TRM: In MRD transplantation 2/9 patients (22%) died due to TRM in contrast to 7/18 patients (39%) after MUD SCT, mainly due to infection and GvHD. With standard conditioning (MAC) 7/13 patients (54%) died due to TRM in contrast to 2/14 patients (14%) with RIC. All 7 patients receiving TBI 12 Gy and chemotherapy are dead, 6/7 patients due to TRM. Therefore, conditioning with TBI 12 Gy is omitted in further studies. In Ph+ ALL patients 8/19 died due to TRM vs 1/8 patients with Ph- ALL. Risk factors for relapse: In MRD transplantation 3/9 patients (33%) died due to relapse in contrast to 1/18 patients (6%) after MUD SCT. After allo SCT and MAC 2/13 patients (15%) died due to relapse and 2/14 patients (14%) after RIC. Due to the small number of patients, no difference between MAC and RIC regarding relapse after allo SCT could be found. In Ph+ ALL patients 1/19 died due to relapse vs 3/8 patients with Ph- ALL. *Conclusions*. Our data show that allo MRD but also MUD SCT is very effective in a selected population of elderly ALL patients. Since the survival of elderly patients with chemotherapy only at 3 years is about 20%, more patients should be encouraged to have an allogeneic SCT, even from an unrelated donor.

AUTOLOGOUS STEM CELL TRANSPLANTATION FOR MULTIPLE SCLEROSIS PATIENTS: A 10-YEAR EXPERIENCE OF THE RUSSIAN-AMERICAN COOPERATION

A. Novik,[1] Y. Shevchenko,[1] A. Kuznetsov,[1] B. Afanasiev,[2] I. Lisukov,[3] O. Rykavicin,[4] A. Myasnikov,[5] T. Ionova,[1] V. Melnichenko,[1] D. Fedorenko,[1] K. Kurbatova,[1] R. Ivanov,[1] N. Osipova,[2] A. Kulagin,[3] S. Shamansky,[4] R. Kruglina,[1] A. Kartashov,[1] G. Gorodokin[6]

[1]Pirogov National Medical Surgical Center, MOSCOW, Russian Federation; [2]Pavlov State Medical University, ST. PETERSBURG, Russian Federation; [3]Institute of Clinical Immunology, NOVOSIBIRSK, Russian Federation; [4]Burdenko Central Military Hospital, MOSCOW, Russian Federation; [5]Republican Hospital, PETROZAVODSK, Russian Federation; [6]New Jersey Center for Quality of Life and Health Outcome Research, NEW JERSEY, USA

During the last decade high dose chemotherapy (HDCT) with autologous haematopoietic stem cell transplantation (AHSCT) has been used as a therapeutic option for multiple sclerosis (MS) patients. The goal of our research was to study safety and efficacy of HDCT+AHSCT in MS patients both with progressive and remitting disease course. 152 patients with MS (secondary progressive - 59 patients, primary progressive -26, progressive-relapsing - 10 and relapsing-remitting - 57) were included in this study (mean age - 32.0, range: 17-54; male/female - 64/88). BEAM or BEAM-modified conditioning was used. Median EDSS at base-line was 5.0 (range 1.5 - 8.5). The mean follow-up duration was 21 months (range 6 - 120 months). Neurological evaluation was performed at base-line, at discharge, at 3, 6, 9, 12 months, and every 6 months thereafter; MRI examinations - at baseline, at 6, 12 months, and at the end of follow-up. Transplantation procedure was well tolerated by the patients with no transplant-related deaths. The efficacy analysis was performed in 79 patients who had had follow-up for at least 6 months. At 6 months post transplant the following distribution of patients according to clinical response was observed: 42 patients (53%) achieved an objective improvement of neurological symptoms; 37 patients (47%) had disease stabilization. At long-term follow-up clinical response was classified as improvement in 40 patients (50.6%) and stabilization in 34 patients (43.1%). One patient relapsed 9 months post-transplant. Two patients deteriorated to a worse score after 18 months of stabilization; 2 other patients progressed after 12 and 30 months of improvement, respectively. All of the patients with clinical stabilization and improvement had negative MRI scans. All the patients without disease progression were off therapy throughout the post-transplant period. In conclusion, HDCT+AHSCT resulted in clinical improvement or stabilization in the vast majority of MS patients included in the analysis. The results obtained point that HDCT+AHSCT is effective both for progressive and for remitting disease course. Further studies should be done to establish the best timing for transplantation and to validate HDCT+AHSCT regimens.

Background. Intravenous infusion (IV) is the method conventionally used to transplant hematopoietic stem cells (HSC) despite the relatively low seeding efficiency. This problem is particularly important in cord-blood transplantation (CBT). CBT potentially represents an effective treatment for haematological diseases, but only a small proportion of adult patients can undergo this procedure because the combination of low number of nucleated cells contained in a cord-blood unit with HLA disparity is associated with delay or failure of neutrophil, and especially platelet, recovery. To solve this problem, after preclinical experiments in mice, a phase II trial in 32 patients with acute leukaemia has suggested that IBM transplant might be associated with better engraftment and faster platelet recovery. *Aims*. In order to validate this initial observation, we performed a matched pair analysis by selecting in the Eurocord data base, single CB unit injected IV (IVT) (patient 129) in patients with haematological malignancies and compared with 69 patients transplanted with CB cells injected IBM. *Methods*. The matching criteria were: patient age, number of cells collected, number of HLA disparities, conditioning regimen, status of the disease at transplant and previous autologous transplantation. IBM patients (n=69) were matched to 129 IVT recipients. The median follow-up was 13 vs 12 months in IVT and IBM groups. There were no statistical differences between the 2 groups according to diagnosis (60 and 59% had acute leukaemia), age (median 35 and 38 years), number of cells collected (median 2.8×10^7/kg), HLA disparities (5/6, n=39, 4/6 n=152 and 3/6 n=7), previous autograft (18%), status of the disease at transplant (60% were in advanced phase) and conditioning regimen (RIC: 13% in the IVT group vs 16% in the IBM group). However, IBM group patients were transplanted more recent (2003 vs 2007) ($p<0.001$). *Results*. The cumulative incidence (CI) of neutrophil recovery at day 60 was 74±5% in IVT group vs 80±6% in IBM group ($p=0.12$); the median day to achieve >500/mm3 was 26 and 23 days respectively. Patients receiving CB IBM had higher CI of platelets recovery at day 180 (72±6%) compared to IVT group (50±4%; $p<0.0001$); also time to platelet recovery was quicker in IBM 35 days (16-70) compared to 51 days (16-348) in IVT group. If we consider adult patients receiving myeloablative conditioning the results are: CI of neutrophil recovery was 75±5% vs 77±6% ($p=0.32$); CI for platelets recovery 48±5% vs 76±6% ($p=0.00001$) for IVT and IBM respectively. In the overall population, cumulative incidence of acute GVHD grade III-IV at d100 was 0% compared to 11±3%, ($p<0.001$) respectively. Overall survival at one year was 39±5% compared to 50±7% ($p=0.26$) for IVT and IBM respectively. *Conclusions*. The transplantation of CB cells via IBM is associated with better engraftment and faster platelet recovery. The reduced severity of acute GVHD observed in IBM patients is intriguing and promising.

Hodgkin - Clinical

[1]Internal Medicine I, COLOGNE, Germany; [2]German Hodgkin Study Group, University Hospital of Cologne, COLOGNE, Germany; [3]University Hospital Ulm, ULM, Germany; [4]Klinikum Oldenburg, OLDENBURG, Germany; [5]University Hospital Magdeburg, MAGDEBURG, Germany; [6]University Hospital Brno, BRNO, Czech Republic; [7]University Hospital Leipzig, LEIPZIG, Germany; [8]Klinikum Nürnberg, NÜRNBERG, Germany; [9]University Hospital Würzburg, WÜRZBURG, Germany; [10]AK St. Georg, HAMBURG, Germany; [11]Hospital de la Santa Creu i Sant Pau, BARCELONA, Spain; [12][11]Radboud University Nijmwegen Medical Centre, NIJMWEGEN, Netherlands; [13]Netherland Cancer Institute, AMSTERDAM, Netherlands

Background. In patients with relapsed Hodgkin lymphoma (HL), high dose chemotherapy (HDCT) followed by autologous stem cell transplantation is being regarded as standard of care. However, the optimal regimen and intensity of chemotherapy is unclear. Therefore, the European intergroup study (HDR2) performed by the GHSG, EORTC and EBMT evaluated the impact of additional sequential high dose chemotherapy (sHDCT) after 2 cycles of DHAP and before BEAM to improve the efficacy of the standard regimen without sHDCT. *Methods*. Patients with histologically confirmed relapsed HL in first relapse with CR > 3 months or second relapse without prior HDCT were included. Responding patients after two cycles of DHAP were randomized between BEAM or sequential high dose (CTX, MTX, VP-16) followed by BEAM. Freedom-from-treatment-failure (FFTF) was the primary end point and progression-free survival (PFS) and overall survival (OS) were secondary end points. Kaplan-Meier estimates were used for the evaluation of survival and follow-up time. A prognostic score based on stage of disease, relapse type and presence of anemia before treatment (Josting *et al.*, JCO 2002) was used to predict PFS. *Results*. A total of 284 patients were included in this trial. The median follow-up time was 42 months. 240 patients were randomized after DHAP and first restaging. There were no major differences in patient characteristics between the two arms with most of the patients in late first relapse (CR > 12 months). The intensified experimental arm showed significantly longer mean treatment duration, more frequent WHO-Grade IV toxicity before BEAM and more frequent protocol violations ($p<0.05$). Although there was slightly lower mortality in the intensified arm (16% vs. 20%), there were no differences in terms of FFTF, PFS and OS. The respective 3-year-rates for the standard arm vs. the intensified arm were: FFTF: 71% vs. 67%, PFS: 72% vs. 69%, and OS: 87% vs. 83%. Patients with Ann-Arbor stage IV, early or multiple relapse and anemia had a significantly higher risk of recurrence of HL (all single bivariate $p<0.05$, combined $p<0.001$). *Conclusions*. Both regimens tested showed equally favorable results in outcome and survival. Since further intensification did not improve results, 2 cycles of DHAP followed by BEAM are the standard of care for patients with relapsed HL in our hands.

0502

EARLY CHEMOTHERAPY INTENSIFICATION WITH BEACOPP IN HIGH-RISK, INTERIM-PET POSITIVE ADVANCED-STAGE HODGKIN LYMPHOMA, IMPROVES THE OVERALL TREATMENT OUTCOME OF ABVD: A GITIL MULTICENTER CLINICAL STUDY

A. Gallamini,[1] F. Fiore,[1] R. Sorasio,[1] A. Rambaldi,[2] C. Patti,[3] C. Stelitano,[4] S. Viviani,[5] F. Di Raimondo,[6] T. Feldman,[7] A. Biggi,[1] A. Rossi, [2]A. Mistretta,[3] V. Bonfante,[5] A. Chiarenza,[6] M. Cantonetti,[8] P. Gavarotti,[9] C. Tarella[9]

[1]Azienda Ospedaliera S. Croce e Carle, CUNEO; [2]Ospedali Riuniti di Bergamo, BERGAMO; [3]Ospedale V. Cervello, PALERMO; [4]Policlinico Bianchi e Melacrino, REGGIO CALABRIA; [5]Istituto Nazionale Tumori, MILANO; [6]University of Catania, CATANIA; [7]Hackensack University Medical Center, HACKENSACK, NJ, USA; [8]Università Tor Vergata, ROMA; [9]Università di Torino, TORINO, Italy

Background. Early interim-PET after two courses of chemotherapy (PET-2) is the most powerful tool to predict treatment outcome in advanced-stage Hodgkin Lymphoma (asHL) treated with ABVD. The 2-year (2-y) Progression Free Survival (PFS) of PET-2 positive (PET-2+) patients is only 12%, but the optimal treatment for this patient subset is still unknown. *Aims*. for this reason a treatment strategy was designed by GITIL (Gruppo Italiano Terapie Innovative nei Linfomi) to early intensify chemotherapy with BEACOPP (4 escalated + 4 baseline cycles) for all the HL patients with a PET-2+ after 2 ABVD courses consecutively admitted to GITIL centers from January 2006 till December 2007. *Patients and methods.* 164 patients, 120 in stage IIB-IVB and 44 (26%) in stage IIA with adverse prognostic factors (more than 3 nodal sites, ESR > 50 mm, bulky lesion), were treated with two ABVD courses and re-evaluated with PET-2. Four PET-2+ patients treated with other therapies for medical decision were excluded from the analysis. Twenty-four (15%) showed a PET-2+ (Arm A) and 136 a PET-2- (Arm B), respectively. The two cohorts of patients were well matched in terms of prognostic factors: age, male sex, stage III-IV, bulky, hemoglobin, leukocyte and lymphocyte count, albumin, and B-symptoms. IPS ≥3 was equally frequent in both arms (29% and 28%, $p=0.95$). The median interval between the end of 2nd ABVD course and PET-2 was 11 days (3-29). Interim-PET scans were interpreted with a five-point, semiquantitative score with the mediastinal vessels and liver as reference organs for FDG residual uptake. PET scans were centrally reviewed: the results of the review will be presented. *Results.* After a mean follow-up of 20 months (4-37), 142 patients remain in continuous CR (CCR) and 18 experienced treatment failure for disease progression (12) or relapse (6). Of the 24 arm A patients, 15 (62%) are in CCR after BEACOPP therapy and 9 progressed; the mean duration of CR for the responding patients was 18 months (11-37). In Arm B 127 patients (93.5%) are in CCR after standard ABVD therapy and 9 progressed/relapsed. The 2-y PFS of Arm A+B, Arm A and Arm B was 87%, 56% and 93%, respectively. The positive and negative predictive value of interim-PET on 2-y PFS were 37.5% and 93.5%, respectively. The 2-y overall survival was 96%: 3 patients died for progressing lymphoma (1 in Arm A and 2 in Arm B) and 3 for treatment related toxicity. In multivariate analysis the only factor turning out significant for PFS was PET-2+ (HR 6.33, 95% CI 2.4-16.9, $p=0.0002$). *Conclusions.* These data seem to suggest that: (1) in asHL a risk-adapted therapy based upon interim-PET results after 2 ABVD courses improves the overall efficacy of standard ABVD treatment; (2) The positive Predictive Value of PET-2 drops from 90% after ABVD to 37.5% after BEACOPP intensification; (3) for PET-2 negative patients the most appropriate treatment is standard ABVD chemotherapy (4) the 2-y PFS of PET-2+, ABVD-treated HL patients can be substantially improved (from 12% to 56%) by early switching to BEACOPP chemotherapy.

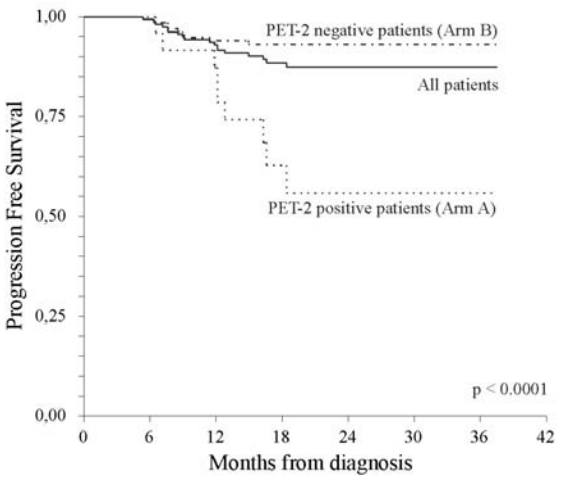

Figure 1.

ROBUST ANTITUMOR ACTIVITY OF THE ANTIBODY-DRUG CONJUGATE SGN-35 WHEN ADMINISTERED EVERY 3 WEEKS TO PATIENTS WITH RELAPSED OR REFRACTORY CD30 POSITIVE HEMATOLOGIC MALIGNANCIES IN A PHASE 1 STUDY

A. Younes,[1] A. Forero-Torres,[2] N.L. Bartlett,[3] J.P. Leonard,[4] D.A. Kennedy,[5] E.L. Sievers[5]

[1]M.D. Anderson Cancer Center, HOUSTON; [2]University of Alabama at Birmingham, BIRMINGHAM; [3]Washington University School of Medicine, ST. LOUIS; [4]Weill Medical College of Cornell University, NEW YORK; [5]Seattle Genetics, Inc., BOTHELL, USA

Background. SGN-35 is an antibody-drug conjugate (ADC) that is being developed for treatment of CD30-expressing malignancies such as Hodgkin lymphoma (HL) and systemic anaplastic large cell lymphoma (sALCL). SGN-35 consists of an anti-CD30 antibody conjugated to the antitubulin agent monomethyl auristatin E (MMAE). Upon binding to CD30 on the cell surface, SGN-35 is internalized and MMAE released. Subsequent binding of MMAE to tubulin disrupts the microtubule network, leading to cell cycle arrest and apoptosis. *Aims*. To characterize the safety and antitumor activity of SGN 35 in patients with relapsed or refractory CD30 positive hematologic malignancies. *Methods*. A Phase 1, multicenter, dose-escalation study was conducted in patients with relapsed or refractory CD30-positive lymphomas. Informed consent was obtained prior to initiating therapy. SGN 35 was administered every 3 weeks as a 2 hr outpatient IV infusion; dose levels between 0.1 and 3.6 mg/kg were evaluated. Patients who had stable disease or better after 2 doses were eligible to receive additional SGN-35 treatment. Investigator assessment of tumor response was done between Days 15-21 of the second cycle. CT scans were also retrospectively reviewed by an independent review facility (IRF) and the level of concordance between investigator and IRF assessment of tumor reduction was determined. *Results*. A total of 45 patients (HL: n=42, sALCL: n=2, angioimmunoblastic T cell lymphoma: n=1) were treated in this study. Median age was 36 years (range 20-87). Patients had received a median of 3 prior chemotherapy regimens (range 1-8) and 73% of patients had previously received an autologous stem cell transplant. Treatment-emergent adverse events occurring in ≥20% of patients were fatigue (42%), pyrexia (33%), peripheral neuropathy (31%), diarrhea (22%), nausea (22%), headache (20%), tachycardia (20%), and vomiting (20%); most events were Grade 1 or 2. Dose-related neutropenia was also observed. The maximum tolerated dose was identified as 1.8 mg/kg every 3 weeks. Reductions in target lesion size were seen in 86% of patients per investigator and IRF CT assessment. Of the 28 evaluable patients treated at doses of 1.2 mg/kg or higher, 26 patients (93%) had tumor reductions and 15 patients (54%) had objective responses (complete remission [CR] + partial remission [PR]); the CR rate was 36% (n=10). In addition, 2 patients, who were treated at 0.6 mg/kg, had PRs. The median progression free survival for patients treated at doses of 1.2 mg/kg or higher is 27 weeks (range 2-54+) vs. 9.7 weeks for patients treated at lower doses. *Summary and Conclusions*. SGN-35 was generally well tolerated at doses up to 1.8 mg/kg and induced durable objective responses in heavily pretreated patients with HL and sALCL. Strong concordance was observed between investigator and retrospective independent evaluation of tumor reduction. A pivotal trial of SGN-35 in Hodgkin lymphoma has been initiated.

PET-CT ADAPTED THERAPY AFTER 3 CYCLES OF ABVD FOR ALL STAGES OF HODGKIN LYMPHOMA. RESULTS IN 118 PATIENTS

S. Pavlovsky, A. Pavlovsky, I. Fernandez, L. Zoppegno, I. Cerutti, M.A. Pavlovsky, M.V. Prates, A. Basquiera, C. Corrado, G. Milone, M. Cabrejo, H. Fernandez Grecco, G. Avila, V. Flores Dutrus, C. Gumpel, V. Cabanne, S. Saba, F. Lastiri

GATLA Grupo Argentino de Tratamiento de Leucemia Aguda, BUENOS AIRES, Argentina

Background. ABVD can be considered as first line treatment for Hodgkin Lymphoma (HL). Our cooperative group has an experience with 584 patients in early or advanced stage treated with 3 or 6 cycles of ABVD plus involved field radiotherapy (IFRT) with a complete remission (CR) of 91% and an event free survival and overall survival at 60 months of 79% and 95%. A negative PET-CT, either early during treatment of ABVD or after completion of it, has shown to be a powerful prognostic tool (Hutchings: Blood 2006; Gallamini: Haematologica 2006). *Aims*. Test the feasibility and efficacy of treatment to all stages of HL adjusted to PET-CT results after 3 cycles of ABVD. Evaluate the outcome of patients who have a negative PET-CT after 3 cycles of ABVD and receive no further treatment. Offer more intense therapy to patients who have persistent hypermetabolic lesions in PET-CT after 3 cycles of ABVD. *Method.* Since October 2005, 141 newly diagnosed patients with HL have been included in a prospective multicenter trial, 118 have already finished treatment. Patients with more than 50% of anatomic reduction of mases but persistent hypermetabolic lesions after 3 ABVD were considered in partial response (PR) and completed 6 cycles of ABVD and IFRT on PET-CT positive areas. Those patients with less than PR after 3 cycles received high doses of chemotherapy and an autologous stem cell transplant (ASCT). All patients were reevaluated at the end of treatment. The median age at diagnosis was 28 years. Ninety five (80%) had localized stage at diagnosis (I-II) and 23 (20%) presented with advanced stage (III-IV). Sixty (57%) patients had IPS 0-1, 38 (36%) had IPI 2-3 and 8 (7%) patients had IPI 4-5. Seventeen (14%) patients had bulky disease at diagnosis. *Results.* All patients completed treatment as planned. One hundred (85%) achieved CR with negative PET-CT after 3 cycles of ABVD. Eighteen were PET positive, two with PD who achieved CR after ESHAP and ASCT. The other 16 patients completed a total of 6 cycles of ABVD + RT in PET positive areas. Fourteen achieved CR and 2 persisted with hypermetabolic lesions. One died of progressive disease and the other one is in CR after third line treatment. Seven patients relapsed after achieving CR with ABVD x 3 and are now all in 2nd CR after salvage treatment. With a median follow up of 18 months, 107 (91%) are in first CR after 1st line treatment, 5 in CR after 2nd or 3rd line treatment, 2 relapsed after ASCT, 1 died of disease and 3 under treatment. The event free survival and overall survival at 18 months is 87% and 97% respectively. *Conclusion.* Treating patients with ABVD, evaluating response after 3 cycles with PET-CT, and adapting further therapy, leads to a higher rate of CR and reduces the number of cycles of ABVD and need for IFRT, avoiding long term toxicity. A larger number of patients and further follow-up is needed to confirm these preliminary results.

PANOBINOSTAT HAS ACTIVITY IN TREATMENT-REFRACTORY HODGKIN LYMPHOMA

D.J. DeAngelo,[1] A. Spencer,[2] O.G. Ottmann,[3] T. Fischer,[4] T. Kindler,[4] K.N. Bhalla,[5] A. Liu,[6] K. Parker,[6] H. Rupani,[6] N. Homji,[6] E. Ashton,[7] M. Jalaluddin,[6] G. Laird,[6] J.W. Scott,[6] H.M. Prince[8]

[1]Dana-Farber Cancer Institute, BOSTON, USA; [2]Alfred Hospital, MELBOURNE, Australia; [3]University of Frankfurt, FRANKFURT, Germany; [4]Johannes Gutenberg-University, MAINZ, Germany; [5]Medical College of Georgia Cancer Center, AUGUST, GA, USA; [6]Novartis Pharmaceuticals Corporation, EAST HANOVER, NJ, USA; [7]VirtualScopics, Inc, ROCHESTER, NY, USA; [8]Peter MacCallum Cancer Center, MELBOURNE, Australia

Background. Panobinostat (LBH589) is a potent pan-deacetylase inhibitor (DACi) targeting epigenetic and non-epigenetic oncogenic pathways. Panobinostat is currently under clinical investigation in a variety of solid tumors and hematologic malignancies. This Phase IA/II trial evaluates oral panobinostat in patients with advanced hematologic malignancies. *Aims*. To determine the overall response rate (ORR) to panobinostat in a subset of patients with treatment-refractory Hodgkin lymphoma (HL), and to compare response assessments between the

study sites and a central reading facility. *Methods*. Patients with a range of hematologic malignancies are treated with two schedules of oral panobinostat: once-a-day on Monday/Wednesday/Friday (MWF) every week (qwk) or every other week (qowk). Each schedule is assessed in two groups of patients, which are defined by the underlying disease and the definition of dose-limiting hematologic toxicity: Group X - leukemias or high-risk myelodysplastic syndrome; Group Y - lymphoma or myeloma. PET and CT data are evaluated for best response by both the site investigators and a central reading facility. PET images are evaluated by institutional criteria for site assessment, and are classified as either progressive disease (PD; ≥25% sSUVmax ↑ or new lesions), partial response (PR; ≥25% sSUVmax, no new lesions), or stable disease (SD) by central assessment. CT scans are evaluated by Cheson criteria (1999 and 2007 for site and central assessments, respectively). *Results*. Patients in Group Y (n=49) have been treated with oral panobinostat (MWF): 20-60mg qwk or 30-60mg qowk. Safety analysis in Group Y (cut-off Oct 17, 2008) reveals that the most common Grade 3/4 AEs (≥5%) have been thrombocytopenia (71.4%), neutropenia (28.6%), fatigue (18.4%), and anemia (6.1%). The maximum tolerated dose for patients in Group Y is 40mg MWF qwk or 60mg MWF qowk. As of Nov 20, 2008, 31 patients with HL have been treated MWF, at doses ranging from 30 to 60mg qwk or 45 to 60mg qowk. Twenty-eight patients with HL are evaluable for assessment of response. Prior therapies (not available for one patient) included: surgery (19 patients), radiotherapy (24 patients), stem cell transplantation (SCT; 24 patients), and cytotoxic chemotherapy (all 27 patients). The median number of prior chemotherapeutic regimens was five (range 3-16). ORR by PET was 68% by the study sites (4% CR + 64% PR) and 64% by the central reading facility (5% CR + 59% PR). ORR by CT was 42% by the study sites (4% CR + 38% PR) and 35% by the central reading facility (35% PR). Of the 22 patients with HL who achieved CR or PR by PET or CT in either site or central reads, 15 received panobinostat MWF, qwk and 7 received panobinostat MWF, qowk. Of these 22 patients, 19 had prior SCT, and 13 had at least five chemotherapy regimens. *Summary and Conclusions*. Panobinostat shows promising clinical activity in heavily pretreated patients with HL. ORRs are similar between the study sites and the central reading facility. A global Phase II study of panobinostat at 40mg/day MWF, every week in patients with HL is currently underway.

Table 1.

Assessments		Responders (CR + PR), n (%)	Number of responders treated with the following number of chemotherapy regimens**:		
			3–4	5–6	7–16
PET	Site reads (N=25)	17* (68%)	5	8	3
	Central reads (N=22)	14* (63.6%)	3	8	2
CT	Site reads (N=26)	11 (42.3%)	4	5	2
	Central reads (N=20)	7* (35%)	2	2	2

*for one patient, prior medications are unknown; **patients were treated with a minimum of 8 to a maximum of 21 different drugs.

NIPA CHECKPOINT CONTROL IS ESSENTIAL FOR EFFICIENT ONCOGENIC TRANSFORMATION BY C-MYC

A.L. Illert,[1] C. Fritz,[1] H. Kawaguchi,[2] S.W. Morris,[2] C. Peschel,[1] U. Keller,[1] J. Duyster[1]

[1]*Klinikum rechts der Isar der TU München, MÜNCHEN, Germany;* [2]*Department of Pathology, St. Jude Children's Research Hospital, MEMPHIS, USA*

The regulated oscillation of protein expression is an essential mechanism of cell cycle control. The SCF class of E3 ubiquitin ligases is involved in this process by targeting cell cycle regulatory proteins for degradation by the proteasome, with the F-Box subunit of the SCF specifically recruiting a given substrate to the SCF core. We previously reported the cloning of NIPA (Nuclear Interaction Partner of ALK) in complex with constitutively active oncogenic fusions of ALK, which contributes to the development of lymphomas and sarcomas. Subsequently we characterized NIPA as a F-Box protein that defines an oscillating ubiquitin E3 ligase targeting nuclear cyclin B1 in interphase thus contributing to the timing of mitotic entry. Using a conditional knockout strategy we inactivated the gene encoding NIPA. NIPA-deficient animals are viable, but sterile due to a block of spermatogenesis. Moreover, our studies demonstrate that loss of NIPA has no substantive effect on the physiological cell cycle progression of primary MEFs indicating that this cell cycle checkpoint is inactive under optimal proliferation conditions. Interestingly, NIPA checkpoint control can be unmasked by oncogenic transformation by c-Myc. Here we show that transformed focus formation assays revealed higly significant differences in c-Myc-induced transformation in NIPA-null and wild-type MEFs. c-Myc transduction caused a pronounced upregulation of cyclin-B in NIPA-null MEFs, which was completely reversible by ectopic NIPA expression. This increased cyclin-B1 expression after c-Myc transduction in the absence of NIPA has considerable functional consequences for the cells: Focus formation ability of c-Myc-infected Nipa-/- MEFs was greatly reduced in comparison to wild-type MEFs (24.6% vs. 100%). Moreover, c-Myc expression caused 12.8% apoptotic subG1 cells in wild-type MEFs, whereas Nipa-/- MEFs were more affected by c-Myc-induced apoptosis (22.45%). By contrast, transduction with other oncogenes like k-Ras in p53 knockdown Nipa-/- and Nipa+/+ MEFs showed no differences in various transformation and apoptosis assays pointing out the exclusive role of the G2/M checkpoint NIPA in c-Myc induced transformation. Furthermore, we investigated the impact of these findings for the pathogenesis of c-Myc induced tumorigenesis *in vivo*. Recipient mice transplanted with c-Myc transduced wild-type bone marrow rapidly developed an AML-like disease (median survival 33 days) characterized by bone marrow infiltration and expression of the myeloid lineage markers CD11b and Gr1. In contrast, animals transplanted with c-myc transduced NIPA knockout BM showed a substantially delayed onset of leukemia and survived significantly longer compared to the control group (median survival 52 days, $p<0.01$). Taken together, our data demonstrate that NIPA is required for efficient c-Myc transformation *in vitro* and and *in vivo* in a murine bone marrow transplantation model. Moreover, our results highlight the functional importance of NIPA in cell cycle regulation and suggest that deregulation of the protein provides a substantial contribution during the process of tumorigenesis.

ABERRANT INTRACELLULAR RETENTION OF MUTATED RECEPTOR TYROSINE KINASE FLT3 IN HUMAN LEUKEMIC CELLS AS A POTENTIAL MECHANISM SUPPORTING THE PATHOGENESIS OF ACUTE MYELOID LEUKEMIA

S.K. Koch,[1] M. Ryser,[1] A. Jacobi,[1] M. Bornhäuser,[1] G. Ehninger,[1] C. Thiede,[1] Study All on behalf of the SAL[2]

[1]*University Hospital Carl Gustav Carus Dresden, DRESDEN, Germany;* [2]*Germany*

The exact regulation of FLT3 expression, a type III receptor tyrosine kinase (RTK), contributes to controlled proliferation and differentiation of blood cells at different stages during hematopoiesis. Activating mutations of FLT3 are found in AML, ALL and MDS and contribute to their pathogenesis, but it is unknown how mutant FLT3 deregulates hematopoiesis. It has been reported that murine mutant FLT3 signal transduction, namely with the most frequent Internal Tandem Duplication (ITD), differs from FLT3 wild type signalling. A key question for the

treatment of leukaemia is what are the mechanisms causing the aberrant constitutive signalling of FLT3-ITD which contribute to the pathogenesis of leukemia. Therefore, the aim of this study was to investigate if the intracellular trafficking of mutant FLT3 is altered compared to wild type (wt) FLT3 and if an altered localization might represent one possible mechanism for a different signalling quality leading to pathogenic effects observed in leukemia, like it has been shown for the other mutated type III RTKs PDGFR and KIT, which are aberrantly localized in human cancer. The localization of mutant FLT3-ITD as well as wild type FLT3 was investigated in retrovirally transduced COS7 cells, human leukemic primary cells and cell lines as well as in primary CD34$^+$ hematopoietic stem cells, enriched by MACS technique with an anti-CD34 antibody. Subcellular distribution of FLT3 was determined by confocal laser scanning microscopy. Internalization kinetics was studied by fluorescently labelling the FLT3 ligand (FL), time lapse imaging, and flow cytometry. The protein glycosylation status and effects on signal transduction were investigated by Western blot analysis of protein size and protein phosphorylation for FLT3 and downstream targets (ERK, STAT5, PIM1). FLT3wt localized to the plasma membrane, whereas mutant FLT3-ITD accumulated in the trans Golgi network (TGN). Consistently, FL was not internalized in FLT3-ITD expressing cells, while internalization in FLT3wt expressing cells started at around 4 min. The STAT5 pathway was FL-independently activated only by FLT3-ITD, but not by FLT3wt. The inhibition of the constitutive FLT3-ITD phosphorylation by the inhibitor PKC412 led to a shift of FLT3 accumulation out of the TGN towards the plasma membrane. At the same time the predominant high mannose form, typical for FLT3-ITD, shifted to complex glycosylation, characteristic for the FLT3wt protein. After PKC412 treatment, surface FLT3-ITD was internalised when stimulated with FL, similar to FLT3wt. Taken together, our data show that TGN accumulation of human FLT3-ITD and the lack of FL internalization might support FL-independent autonomous signalling from intracellular compartments similar to signalosomes. This TGN retention appeared to be induced predominantly by the constitutive phosphorylation of the FLT3-ITD protein instead of an aberrant protein folding or altered protein conformation. The TGN environment may provide interactions with additional/different substrate(s), altering subsequent signalling quality (as shown here for STAT5) and thereby favouring uncontrolled proliferation of undifferentiated cells. In conclusion, our data further unravel the mechanisms of the aberrant signalling of mutant FLT3-ITD and the effects of a specific inhibitor.

CSF-1-INDUCED OSCILLATIONS IN PI3K/AKT ARE REQUIRED FOR CASPASE ACTIVATION IN MONOCYTES UNDERGOING DIFFERENTIATION INTO MACROPHAGES

A.J. Jacquel, N.M. Benikhlef, P.J. Paggetti, N.L. Lalaoui, G.L. Guery, E.K.D. Dufour, M.C. Ciudad, C.R. Racoeur, O.R. Micheau, L.D. Delva, N.D. Droin, E.S. Solary

INSERM UMR866, DIJON, France

Background. The differentiation of human peripheral blood monocytes into resident macrophages is driven by CSF-1 (colony-stimulating factor-1) that, upon interaction with its specific receptor, CSF-1R, induces within minutes the phosphorylation of its cytoplasmic tyrosine residues and the activation of multiple signaling complexes. Caspase-8 and -3 are activated later, at day 2-3 after CSF-1 stimulation, and contribute to macrophage differentiation. The connection between activated CSF-1R and caspase activation remained unknown. *Aims*. To identify the signaling pathways connecting CSF-1R interaction with its ligand to downstream caspase activation. *Results*. Here, we demonstrate that the phosphatitidylinositol-3 kinase (PI3K) and the downstream serine/threonine kinase AKT connect CSF-1R activation to caspase-8 cleavage. Most importantly, we demonstrate that successive waves of AKT activation with increasing amplitude and duration are required to provoke the formation of the caspase-8 activating molecular platform. Inhibition of the PI3K/AKT pathway 24 hours after CSF-1/CSF-1R interaction still prevents caspase activation. Although CSF-1R is partly down-regulated, inhibition of its phosphorylation by an ATP-competitive inhibitor prevents further oscillation of the AKT pathway. The ERK1/2 pathway is activated with a coordinated oscillatory kinetics in a CSF-1R-dependent manner but plays an accessory role in caspase-8 and -3 cleavage and activation. *Conclusions*. Altogether, our results reveal that CSF-1 stimulation activates a molecular clock that involves PI3K and AKT to promote caspase activation. This oscillatory signaling pathway, which is coordinated with ERK1/2 oscillatory activation, may involve the CSF-1R and control the terminal differentiation of monocytes into macrophages.

EVIDENCE FOR AN ANTI-CANCER BARRIER IN A MIXED LINEAGE LEUKEMIA MOUSE MODEL IN VIVO

S. Takacova,[1] J. Bartek,[2] P. Luzna,[1] V. Divoky[1]

[1]Faculty of Medicine, Palacky University, OLOMOUC, Czech Republic; [2]Institute of Cancer Biology, Danish Cancer Society, DK-2100 COPENHAGEN, Denmark

Mixed Lineage Leukemia (MLL) mutations identify a unique group of acute leukemias with distinct biological and clinical features. Although the role of MLL in leukemogenesis has been extensively studied, a precise mechanism of leukemia development is not known. We generated a switchable MLL-ENL-ERtm mouse model, in which the MLL-ENL oncogene has been introduced by homologous recombination and is controlled by the endogenous MLL promoter, thus, expressed at physiological levels. The activity of the MLL-ENL-ERtm protein is dependent on continuous provision of tamoxifen or 4-hydroxytamoxifen. The MLL-ENL-ERtm mice have developed a myeloproliferative disorder (MPD) characterized by persistent mature neutrophilia after 484,5±75,68 days of latency on a tamoxifen diet, in association with high white cell counts in peripheral blood, splenomegaly and occasionally with anemia. Blood smears showed large numbers of mature myeloid elements consisting of 40-80% neutrophils (band forms in abundance), admixed with immature myeloid elements, 3-11% monocytes and 2-6% myeloblasts. The phenotype of MPD also involved myelomonocytic proliferation with 35% immature monocytic cells in one animal and severe anemia with increased numbers of immature erythroid cells in peripheral blood in another animal. High penetrance and long latency of leukemia in our model permits the study of early leukemia development. In preleukemic animals (3-6 months after tamoxifen treatment) that represents the initial phase of MLL-ENL-driven cell transformation, bone marrow smears revealed expansion of band and segmented neutrophils indicating reactivation of self-renewal/proliferation properties in committed progenitors. We observed that a myeloid cell population mainly consisting of band neutrophil elements and showing granulocyte/ macrophage surface marker expression (CD34-CD43+Mac-1+Gr-1+CD16/32+) infiltrates the spleen at the very early stage of the disease. Infiltration of spleen correlates with increased proliferation rate measured by 5-bromo-2-deoxyuridine (BrDU) incorporation *in vivo* compared to wild-type matched control. Interestingly, the preleukemic bone marrow showed subsequent decline in BrDU incorporation associated with increased expression of p21CIP1 and p16INK4A and activation of senescence-associated ß-galactosidase activity typical for cellular senescence. Paralelly, we also detected apoptosis using the TUNEL assay in the preleukemic bone marrow. Our results suggest activation of a potential tumor suppressor mechanism in response to activated MLL-ENL - induced aberrant proliferation in early stages of cellular transformation. We are currently investigating potential tumor suppressor pathways that might provide a barrier to malignant progression in MLL.

A HISTONE H3 LYSINE 9 TRIMETHYLATION SIGNATURE PREDICTS SURVIVAL IN AML PATIENTS

C. Müller-Tidow,[1] H.U. Klein,[1] A. Hascher,[1] F. Isken,[1] N. Thoennissen,[1] S. Agrawal,[1] Y. Wang,[2] A. Becker,[3] C. Thiede,[4] G. Ehninger,[4] U. Zur Stadt,[5] S. Koschmieder,[1] M. McClelland,[2] W.E. Berdel,[1] M. Dugas,[1] H. Serve[6]

[1]University of Münster, MÜNSTER, Germany; [2]Sidney-Kimmel Cancer Center, SAN DIEGO, USA; [3]University of Freiburg, FREIBURG, Germany; [4]University of Dresden, DRESDEN, Germany; [5]Kinderkrebszentrum, HAMBURG, Germany; [6]University of Frankfurt, FRANKFURT, Germany

Regulation of chromatin organization by histone modification is known to be crucial for fundamental regulatory processes. Its dysregulation is increasingly anticipated to play an essential role in leukemogenesis. However, little is known about histone modification patterns in acute myeloid leukemia or other cancers. Chromatin-Immunoprecipitation coupled with microarray hybridization (ChIP-Chip) was used to identify global histone modification patterns in acute leukemias and their association with survival. ChIP-Chip assays were performed for Histone H3 acetylation (H3Ac) (n=161) and lysine 9 tri-methylation (H3K9me3) (n=173) in acute myeloid and lymphoblastic leukemia, in $CD34^+$ hematopoietic progenitor cells, and in white blood cells. ChIP-Chip analyses revealed disease specific histone modification signatures in AML and ALL patients *in vivo*. Both histone modifications distinguished AML from ALL and from normal $CD34^+$ hematopoietic progenitor cells. Alterations in histone modification patterns were associated with transcription factor binding sites especially of ETS and CREB family members. A signature derived from the pattern of H3K9me3 modification predicted survival in AML patients significantly better than clinical parameters such as karyotype, age and NPM/FLT3 mutations alone. These data establish that gene-specific histone modification patterns in acute leukemias. These patterns are determined by the type of disease and the hematopoietic differentiation status. These signatures bear prognostic implications and might aid in establishing novel clinical and prognostic subgroups.

Developmental hematopoiesis, stem cells and microenvironment

0511

THE PERIPHERAL CANNABINOID RECEPTOR REGULATES HUMAN AND MOUSE HEMATOPOIESIS, BONE MARROW RECOVERY, AND HEMATOPOIETIC STEM AND PROGENITOR CELL MOBILIZATION

M. Alberich Jorda,[1] S. Jiang,[2] R. Zagozdzon,[2] K. Parmar,[3] P. Mauch,[3] Y. Fu,[2] A. Makriyannis,[4] A.M. Zvonok,[4] D.G. Tenen,[1] S. Avraham,[2] J.E. Groopman,[2] H.K. Avraham[2]

[1]Harvard Stem Cell Institute, BOSTON; [2]Beth Israel Deaconess Medical Center and Harvard Medical School, BOSTON; [3]Dana-Farber Cancer Institute, BOSTON; [4]Center for Drug Discovery, Northeastern University, BOSTON, USA

Endocannabinoids, as well as exogenous cannabinoid ligands, bind to and activate the cannabinoid receptors CB1 and CB2. Both receptors are G protein-coupled seven transmembrane receptors (GPCRs), and are highly conserved during evolution. The CB1 receptor is one of the most abundant GPCRs expressed in brain, whereas the CB2 receptor is predominantly expressed in immune cells, such as B cells, natural killer cells, monocytes, neutrophils and T cells. In the hematopoietic system, GPCRs play an important role in regulating the spatial distribution of immature and mature hematopoietic cells, including their release into the circulation and their homing to hematopoietic compartments. The mobilization of hematopoietic stem and progenitor cells (HSPCs) from their main site of production in the bone marrow into circulation is a complex and incompletely understood process. While several studies have addressed the expression and function of cannabinoid receptors in mature hematopoietic cells, the effect of cannabinoids on hematopoiesis and mobilization of HSPCs has not been investigated in depth. Therefore, in this study we focus on analyzing the expression and function of cannabinoid receptors in human and murine HSPCs. We observe that both CB1 and CB2 receptors are expressed in human $CD34^+$ cells, murine side population and LSK (Lin^-, $sca1^+$, $ckit^+$) cells. Given the expression of cannabinoid receptors in immature cells, we investigate the effect of cannabinoid ligands in HSPC, and demonstrated that cannabinoids induce chemotaxis and colony formation of human $CD34^+$ cells and murine HSPC. Murine transplantation assays allowed us to study the effect of cannabinoids *in vivo*, and showed that Cb2 cannabinoid agonists induce mobilization of murine short-term and long-term HSC. In addition, we demonstrated that 20 weeks after transplantation the cannabinoid-mobilized cells contribute to the tri-lineage reconstitution (B-, T-, and myeloid cells) with similar efficiency than the G-CSF-mobilized cells. Finally, we provide evidence that Cb2 deficient mice present reduced numbers of hematopoietic stem cells, and impaired recovery following sublethal irradiation, while irradiated mice treated with Cb2 agonist show accelerated bone marrow recovery after damage. Altogether, these results demonstrate that the cannabinoid system regulates hematopoiesis and cell mobilization, and may be therapeutically applied in clinical conditions, such as bone marrow transplantation and irradiation induced bone marrow failure.

0512

THE NOVEL CDK-INHIBITOR P26-INCA1 CONTROLS THE RESPONSE OF HEMATOPOIETIC STEM CELLS TO AGING ANG TOXIC STRESS

N. Bäumer,[1] L. Tickenbrock,[1] S. Koschmieder,[1] P. Tschanter,[1] S. Diederichs,[1] S. Agrawal,[1] M. Stehling,[2] G. Köhler,[1] W.E. Berdel,[1] H. Serve,[3] C. Müller-Tidow[1]

[1]University of Münster, MÜNSTER; [2]Max-Planck Institute of Molecular Biomedicine, MÜNSTER; [3]University of Frankfurt, FRANKFURT, Germany

The hematopoietic stem cell (HSC) compartment is strictly regulated to sustain blood cell production but to avoid exhaustion. CDK inhibitors and their regulatory mechanisms are thought to play a crucial role in maintaining stem cell quiescence. A better understanding of stem cell regulatory mechanisms is essential for a wide range of therapeutic interventions in stem cell research, transplantation as well as cancer therapy. We identified p26INCA1 as a novel inhibitor of Cyclin - CDK2 complexes. Recombinant p26INCA1 inhibited Cyclin A-CDK2 complex activity in a dose dependent manner. CDK inhibition by p26INCA1 required a Cyclin interaction domain and was associated with cell cycle arrest and reduced growth of hematopoietic progenitors. Aging p26INCA1 knockout mouse harbored an increased number of HSC. Predominantly, long-

term HSC numbers were increased and Inca1-deficient bone marrow showed improved long term reconstitution properties. Exposing Inca1-/- animals to the myeloablative agent 5-FU resulted in premature death of Inca1-/-mice due to exhaustion of hematopoietic progenitors cells. Inca1-/- bone marrow cells exhibited increased proliferation upon competitive transplantation and a higher replating efficiency in colony formation assays. Further, INCA1 expression was induced by growth factor deprivation but suppressed by the mutant Flt3 tyrosine kinase. These findings demonstrate that p26INCA1 provides an additional layer of CDK-mediated stem cell regulation. Our results suggest a novel mechanism of growth factor regulated stem cell control. p26INCA1 could be an important target for HSC expansion and therapy of leukemic stem cells.

0513

STRUCTURE-FUNCTION ANALYSIS OF HUMAN HEMATOPOIETIC PBX INTERACTING PROTEIN (HPIP): A NOVEL HUMAN STEM CELL REGULATORY PROTEIN

P. Kaur,[1] C. Stadler,[1] H. Wolfgang,[1] K.R. Humphries,[2] C. Buske,[1] M. Feuring-Buske[1]

[1]Helmholtz- Muenchen, MÜNCHEN, Germany; [2]The Terry Fox Laboratory, VANCOUVER, Canada

Human hematopoietic PBX interacting protein (HPIP) is a 731 amino acid protein, discovered as a novel interacting partner of the PBX homeodomain protein. HPIP inhibits the ability of PBX-HOX heterodimers to bind to target sequences and strongly inhibits the transactivation activity of E2A-PBX1 [t(1;19) translocation, which occurs in 25% of pediatric pre-B cell acute lymphocytic leukaemia] (Abramovich C. *et al.* JBC, 2000; Oncogene, 2002). HPIP cDNA was cloned in pMSCV-IRES-YFP cassette. Umbilical cord blood enriched with $CD34^+$ population of stem cells was obtained to perform *in vitro* and *in vivo* experiments. Mutants, with deletions of the microtubule binding region (ΔMBR-HPIP), and nuclear receptor and PBX1 interacting motif (ΔNRPID-HPIP) were generated and tested *in vitro* and *in vivo*. The constitutive expression of HPIP wt and ¢MBR-HPIP in human cord blood cells ($CD34^+$) enhanced erythroid colony formation in CFC assay (p=0.008, n=6) while the ΔNRPID-HPIP mutant nullified the effect. Both mutants of HPIP augmented significantly, the formation of primitive colonies (GEMM and GM) in methylcellulose assay ($p \leq 0.01$, n=6) as compared to YFP control and HPIP wt. In replating CFC assays ΔNRPID-HPIP showed an increased number of myeloid colonies ($p \leq 0.01$, n=6) and GM (p=ns) colonies but a decrease in granulocytic colonies ($p \leq 0.05$, n=6) compared to YFP control and HPIP wt. Long-term culture initiating cell assay (LTC-IC) demonstrated that HPIP protein enhanced the frequency of LTC-IC ($p \leq 0.1$, n=3) while mutants did not show any significant increase as compared to control YFP. HPIP wt and the mutants did not enhance the yield of LTC-IC derived CFC per million cells (p=ns, n=3). Infected cells were transplanted into NOD/SCID mice. HPIP induced, a significant increase in $CD34^+CD19^+$, $CD10^+$ and $CD117^+$ ($p \leq 0.05$ and $p \leq 0.1$) cells. Intriguingly, there was a significant increase in scid repopulating cell frequency as compared to control YFP in NOD/SCID mice.

THE ROLE OF THE MADS TRANSCRIPTION FACTOR MEF2C IN REGULATING MLL-LEUKEMIC AND HEMATOPOIETIC STEM CELLS

C. Stocking,[1] A. Schüler,[1] M. Schwieger,[1] S. Horn,[1] R. Slany,[2] R. Delwel,[3] J. Valk,[3] U. Müller[1]

[1]Heinrich-Pette-Institute, HAMBURG, Germany; [2]University of Erlangen, ERLANGEN, Germany; [3]Erasmus University, ROTTERDAM, Netherlands

AML is maintained by a small population of leukemic stem cells (LSC), which share two main characteristics with hematopoietic stem cells (HSC): 1) self-renew ability, thereby creating daughter cells with the capacity to replicate almost indefinitely; and 2) differentiation capacity, by which progressively differentiating cells are generated. In addition, other common attributes have been described, including efficient engraftment, quiescence of cell cycling, cytoprotection, and surface marker expression. Fusion proteins generated from translocations involving the MLL gene on chromosome 11q23, which are associated with infant mixed-lineage leukemia (MLL) and adult AML with poor prognosis, have been shown to generate LSC from committed myeloid progenitors. MLL regulates gene transcription at the chromatin level and MLL leukemias are invariably associated with aberrant expression of selected HOX and TALE homeobox genes. More recently, the MEF2C transcription factor, encoded by a member of the (MCM1-agamous-deficiens-serum response factor) MADS family of homeotic genes, has also been implicated in the establishment of MLL-induced LSC. Taking advantage of a conditional Mef2c knock-out mouse strain, we have investigated the role of Mef2c in the MLL-induced LSC and in normal HSC. We demonstrated that Mef2c deficiency does not impair the establishment nor maintenance of LSC generated *in vitro* by MLL/ENL fusion proteins - however, its loss led to compromised homing and invasiveness of the tumor cells. Similarly, although the number of HSC, as defined by a lineage negative, Sca1+, Kit+ (LSK) phenotype, in Mef2c deficient mice was normal, competitive repopulation assays demonstrated a strikingly reduced ability of the Mef2c-/- cells to repopulate hematopoiesis in mice. This defect in the LSK compartment could be attributed to reduced homing to the bone marrow. Mef2c-dependent targets included several genes encoding matrix metalloproteinases and chemokine ligands and receptors, providing a mechanistic link to the homing defect shared by both HSC and LSC lacking Mef2c.

STAT5 MEDIATES MASSIVE EXPANSION OF LEUKEMIA STEM CELLS

M. Heuser,[1] L. Sly,[2] C. Lai,[3] B. Argiropoulos,[3] F. Kuchenbauer,[3] M. Leung,[3] G. Lin,[3] C. Brookes,[3] S. Fung,[3] G. Krystal,[3] R.K. Humphries[3]

[1]Hannover Medical School, HANNOVER, Germany; [2]Child and Family Research Institute, VANCOUVER, Canada; [3]British Columbia Cancer Agency, VANCOUVER, Canada

Background. Leukemias are considered hierarchically organized being maintained by a leukemia stem cell (LSC). Whereas LSCs become the primary focus for targeted therapies, little is known about the pathways regulating LSC function. *Methods*. Using retroviral gene transfer of MN1, NUP98HOXD13 (ND13), or HOXA9 oncogenes and limiting-dilution transplantation before and after a 6-day culture period of leukemic cells we modelled murine leukemias with different LSC frequencies, characterized the LSC expansion potential, and validated critical signaling pathways mediating LSC expansion by loss-of-function analysis. *Results*. It was shown previously that constitutive expression of MN1 is sufficient to induce a rapidly lethal AML in mice. We found that in MN1 leukemias LSC numbers increased 68-fold over an *in vitro* culture period of 6 days, whereas in MN1 leukemias cotransduced with a second oncogene, the HOX fusion oncogene ND13 (MN1+ND13), LSC numbers increased 9000-fold as determined by the competitive repopulation unit (CRU) assay (132 fold difference comparing MN1 vs. MN1+ND13 leukemias). To screen for functional differences of the two models we screened for differential cytokine responses *in vitro*. Interestingly, MN1+ND13 expressing cells proliferated in response to GM-CSF, whereas MN1 cells or ND13 cells did not. This was confirmed as well for MN1+HOXA9 expressing cells compared to MN1+CTL or HOXA9+CTL expressing cells. We found that downstream members of the GM-CSFR pathway Stat1, Stat3, Stat5, and Erk1/2 were selectively phosphorylated upon cytokine stimulation in MN1+ND13 and MN1+HOXA9 cells compared to single-oncogene transduced cells. To characterize the role of Stat1 and Stat5b in LSC expansion, Stat1 -/- and Stat5b -/- cells were co-transduced with MN1 and HOXA9 and compared to wildtype cells *in vivo*. CRU assays with MN1+HOXA9-transduced Stat1 -/- and Stat5b -/- cells demonstrated that during a 6-day culture period *in vitro* LSC expansion was 6 and 77 fold lower, respectively, than in wildtype control mice. Thus, Stat5b is one of the key mediators of LSC expansion in MN1+HOXA9 leukemias. As MN1 and HOXA9 are upregulated in distinct subsets of normal karyotype AML we speculated that their combined overexpression may model subsets of complex karyotype AML. We performed gene set enrichment analysis on cytogenetic subsets of previously published gene expression data from 285 AML patients. 12 of 13 Stat-related pathways were enriched in complex karyotype patients compared to 4 and 8 of 13 Stat-related pathways in inv(16) and normal karyotype AML, respectively, thus supporting a critical role of Stat activation in LSCs of AML with multiple active pathways like complex karyotype AML. *Conclusions*. Here we establish the concept that LSCs have a massive but variable expansion potential depending on the number of activated oncogenes, and functionally prove that Stat5b mediates massive LSC expansion in MN1+ND13 induced leukemias. Stat5b may become an important therapeutic target in complex karyotype AML.

ETV6/RUNX1 ABROGATES THE SPINDLE CHECKPOINT AND DIRECTLY TARGETS ITS KEY PLAYER MAD2L1

R. Panzer-Grümayer,[1] G. Krapf,[1] U. Kaindl,[1] A. Kilbey,[2] G. Fuka,[1] A. Inthal,[1] R. Joas,[1] J.C. Neil,[2] O.A. Haas[3]

[1]St. Anna Kinderkrebsforschung, CCRI, VIENNA, Austria; [2]Molecular Oncology Laboratory, Institute of Comparative Medicine, Univ. of Gl, GLASGOW, UK; [3]St. Anna Kinderspital, VIENNA, Austria

ETV6/RUNX1 (E/R) is expressed in 25% of childhood acute lymphoblastic leukemia (ALL) with t(12;21) chromosomal translocation. The fusion gene encodes a protein that contains the N-terminal region of ETV6 fused to the almost entire RUNX1, retaining the runt domain (RD) required for DNA binding and heterodimerization of RUNX1. The fusion gene acts as an aberrant transcription factor and represses or disrupts the regulation of RUNX1 target genes. Recently, a near tri- or tetraploid karyotype has been strongly associated with the E/R fusion gene in B cell precursor ALL, accounting for overall 5% of cases in this genetic subgroup. Moreover, 15% of E/R positive leukemias have a somatically acquired trisomy 21. Assuming that these types of chromosomal imbalances are caused by a common mechanism, the chromosome mis-segregation during mitosis, this would imply that E/R generally interferes with the spindle assembly checkpoint (SAC), the respective surveillance mechanism. The aim of this study was to assess the function of SAC in E/R expressing model systems and leukemias and to explore the molecular mechanisms leading to the proposed attenuation of SAC. Here, we show that E/R expressing Ba/F3 and leukemic cells had significantly reduced proportions of cells arrested in mitosis (determined by DNA content analysis and phospho-histone H3 stain) in the presence of nocodazole, consistent with a weak SAC. To gain insight into the molecular mechanism of SAC attenuation, we focused on the mitotic arrest deficient 2 (Mad2) protein MAD2L1. MAD2L1 is an essential member of SAC and its deregulation has been shown to concur with aneuploidy. Furthermore, micro array data suggest a differential regulation of MAD2L1 in E/R positive leukemias. The reduction of MAD2L1 expression was confirmed at mRNA and protein levels in E/R expressing cell lines. Based on the presence of several consensus RUNX binding motifs in the promoter region we assumed that MAD2L1 is directly regulated by E/R. We thus tested the transcriptional activity of RUNX1 and E/R in luciferase-based reporter assays. Two constructs containing endogenous MAD2L1 promoter sequences with one or three perfect RUNX sites were used and revealed a consistent dose-dependent, up to two-fold reduction of RUNX1-induced activation by E/R. An E/R construct containing a point mutation in the DNA binding domain, previously reported to greatly reduce DNA binding, did not show these effects. To validate the direct interaction of E/R, the ability to bind to the endogenous promoter was assessed by chromatin immune precipitation. In fact, using myc-RUNX1 or myc-E/R stably expressing 293 cells we clearly demonstrate that both, RUNX1 and E/R, bind to the RUNX sites of MAD1L1. Together, these data provide first evidence for the direct regulation of MAD2L1 and attenuation of SAC by E/R and link the fusion gene to the mitotic checkpoint. renate.panzer@ccri.at Financial support: FWF P17551-B14 and GENAU-CHILD GZ200.136/1-VI/1/2005 to ERPG.

LEUKEMIA-INITIATING CELLS ARE FREQUENT IN VERY HIGH RISK CHILDHOOD PRECURSOR B ACUTE LYMPHOBLASTIC LEUKEMIA

M. Schmitz,[1] P. Mirkowska,[1] M. Stanulla,[2] M. Schrappe,[2] J.-P. Bourquin,[1] B. Bornhauser[1]

[1]University Children's Hospital Zürich, ZÜRICH, Switzerland; [2]University Hospital Schleswig Holstein, KIEL, Germany

Poor risk acute lymphoblastic leukemia (ALL) has been proposed to arise from a limited immature leukemia-initiating cell (LIC) compartment that may confer treatment resistance. Functional assessment of LIC frequency using syngeneic leukemia mouse models and recent data showing that different ALL subpopulations, sorted based on expression of CD19, CD34 and CD38, can reconstitute ALL in NOD/SCID mice challenge this view. We have established xenotransplantation of primary ALL cells in immunodeficient NOG mice (NOD/SCID strain with additional IL-2 receptor common gamma chain deletion), starting from carefully selected very high risk (VHR) and standard risk (SR) ALL patients classified by the ALL-BFM study group. Here we show that ALL cells from VHR and from SR patients display heterogeneous immunophenotypes, some having a large $CD34^+/CD19^+$ compartment while others have a large $CD34^-/CD19^+$ compartment. Moreover, analysis of immunophenotypes of VHR and SR-ALL cells reveals heterogenous staining patterns and does not identify subtype specific subpopulations. In addition, aldehyde dehydrogenase expression, a marker of hematopoietic stem cell and progenitor function, was also heterogeneous. Thus it appears unlikely that the LIC compartment can be identified in ALL with such markers. To functionally evaluate the number of unsorted cells required for reconstitution of VHR-ALL in immunodeficient mice, we performed orthotropic xenotransplantation of primary ALL cells using intrafemoral injection in NOG mice. One million of unsorted ALL cells generated leukemia in NOG mice in 5/5 cases, and 100 cells were sufficient for engraftment (in 3/5 cases) without conditioning, despite the xenograft barrier. The leukemia immunophenotype as well as the hepatosplenic and bone marrow involvement pattern was conserved, and secondary transplantations demonstrate conserved self-renewal properties. Based on these observations it is conceivable that most if not all ALL cells can engraft immunodeficient mice, recapitulate the whole leukemia phenotype and thus retain LIC properties.

0518

THE CALM INTERACTOR CATS REPRESSES THE TRANSACTIVATION CAPACITY OF THE LEUKEMOGENIC FUSION PROTEIN CALM/AF10 AND INTERACTS WITH KEY PROTEINS OF THE APOPTOTIC PATHWAY

L. Fröhlich Archangelo,[1] P.A. Greif,[2] L. Fontanari Krause,[2] S.T.O. Saad,[1] S.K. Bohlander[2]

[1]Hematology and Hemotherapy Center, CAMPINAS, Brazil; [2]Dep. of Medicine III, Hospital Grosshadern, MUNICH, Germany

Background. CATS is the CALM (PICALM) interacting protein expressed in thymus and spleen. The CATS interaction region of CALM is contained in the leukemogenic fusion protein CALM/AF10. In T-ALL with T-cell receptor (TCR) gamma/delta rearrangement, the CALM/AF10 fusion is the most frequent rearrangement found in up to 30% of cases. CATS increases the nuclear and nucleolar localization of CALM/AF10. When fused to heterologous DNA-binding domain (GAL4-DBD), CATS functions as a repressor of transcription in reporter gene assays. *Aims*. We previously showed that CALM/AF10 is a nuclear-cytoplasmatic shuttling protein, which can be retained in the nucleus upon interaction with CATS. Therefore we investigated the potential transcriptional property of the CALM/AF10 fusion protein and whether CATS might influence this property of CALM/AF10. In addition, we analyzed CATS protein expression in resting and proliferating cells, and identified CATS interacting proteins. Methods. A GAL4-based reporter gene assay was used. Vectors expressing the GAL4-DBD-CALM/AF10 fusion protein, the CATS gene as well as a luciferase reporter gene were cotransfected into mammalian cells. We analyzed CATS expression in activated and resting lymphocytes by Western blotting. Primary human peripheral blood lymphocytes (PBLs) were stimulated for 3 days with phytohemagglutinin. For the initial identification of protein interactions we used the yeast two-hybrid system. Protein interactions identified were confirmed by coimmunoprecipitation. *Results*. GAL4-DBD-CALM/AF10 activates the reporter gene expression under the control of a GAL4-tk responsive promoter 4.2-fold compared to GAL4-DBD alone. Coexpression of CATS leads to a dose dependent up to 2.5 fold decrease of CALM/AF10-mediated transcriptional activation. Western blot analysis showed that the CATS protein is only detectable in activated PBLs, whereas no CATS protein was observed in the quiescent cells. Finally, our yeast two hybrid screen identified HAX-1 and SIVA-1 as CATS interacting partners. Both proteins are involved in the regulation of apoptosis. HAX1 has been found in anti-apoptotic signaling counteracting the pro-apoptotic effects of BAX. HAX1 was identified as a protein interacting partner of HS1 (hematopoietic lyn substrate 1), which is part of the B-cell and T-cell receptor signaling cascade. SIVA is a pro-apoptotic protein and important intracellular signaling molecule that transduces CD27-, GITR- and TCR-mediated apoptotic responses. *Summary and Conclusions*. This study demonstrates for the first time that CALM/AF10 has transcriptional activation potential. Moreover, we show that CATS antagonizes the transactivation capacity of CALM/AF10 in a dose-dependent manner. The absence of CATS in resting lymphocytes and its rapid appearance in activated lymphocytes, together with the fact that CATS interacts with HAX-1 and SIVA suggests that CATS might be

involved in regulating the apoptotic and proliferative response of lymphoid cells. Thus our results suggest a link between the leukemogenic fusion protein CALM/AF10 and T- and B-cell receptor signaling.

IDENTIFICATION OF GENETIC MUTATIONS THAT COOPERATE WITH CONSTITUTIVELY ACTIVE FLT3 IN THE INDUCTION OF ACUTE LYMPHOBLASTIC LEUKEMIA (ALL)

A.N. Lehmann,[1] B. Niebuhr,[1] K. Schulz,[1] M. Ziegler,[1] J. Meyer,[2] S. Horn,[1] C. Stocking[1]

[1]Heinrich-Pette-Institute, HAMBURG; [2]Medizinische Hochschule Hannover, HANNOVER, Germany

Acute lymphoblastic leukemia (ALL) is the most common form of childhood malignancy and is a heterogeneous disease with subtypes that differ markedly in their cellular and molecular characteristics, as well as their response to therapy and subsequent risk of relapse. The FMS-like receptor tyrosine kinase FLT3 contributes to normal differentiation, proliferation and apoptosis of primitive hematopoietic cells in both early myeloid and lymphoid lineages. Mutations constitutively activating the FLT3 receptor are commonly found in acute leukemias of both lineages, making FLT3 one of the most frequently mutated genes in hematological malignancies. The availability of FLT3 inhibitors provides an attractive therapeutic strategy for patients harboring these mutations. In ALL, FLT3 mutations are associated with either MLL or hyperdiploid subtypes, raising the question if specific genetic events synergize with FLT3 mutations in ALL induction and if inhibiting FLT3 activation alone will be effective in leukemia treatment. To better understand the role of FLT3 activating mutations in ALL, we have established an allograft mouse model, in which bone marrow (BM) progenitors were transduced with a retroviral vector expressing FLT3 with an internal tandem duplication (FLT3-ITD), followed by transplantation into syngenic recipients. Mice receiving murine FLT3-ITD bone marrow succumbed to aggressive leukemia with a mean latency of 45 days. Based on surface marker analysis and immunoglubulin (Ig) gene rearrangements, these tumors could be classified as pre-B-cell tumors. The disease was transplantable down to a cell number <200 and clonal (based on retroviral integration sites). Strikingly, the FLT3 inhibitor PKC412, as well inhibitors of the PI3K and MAPK pathways or dominant-negative forms of STAT5, profoundly inhibited proliferation of leukemic cells *in vitro* but did not induce apoptosis. However, anti-apoptotic stimulus provided in methylcellulose cultures was necessary to maintain leukemic cells in culture, which coincided with upregulation of surface expression of the Ig heavy chain of the preB-cell receptor (preBCR). These results suggest that the preBCR is active in these tumors but progression to the B-cell stage is blocked, either through FLT3 signaling and/or through independent lesions. Strikingly, each leukemia contained up to 6 to 8 independent retroviral integrations sites, a much higher number than would be expected given the circa 15-20% infection frequencies of BM cells before transplantation. The high number of integrations could reflect two events: 1) preferential infection of a subset of cells more permissive to infection; and/or 2) the preferential outgrowth of these infected cells due to the increased likelihood that cooperating genes were activated through the integration site. To determine if integration of the retroviral vector near putative oncogenes or tumor suppressors contributed to the induction of leukemia, retroviral integration sites were analyzed. Consistent with this hypothesis, integrations were found near genes that have been identified as 'common integration sites' (CIS) or loci that are targeted in independent tumors - an event highly unlikely to occur merely by chance. Based on the function of gene products deregulated by the retroviral integration, we predict that disruption of the preBCR signaling pathway is necessary for FLT3-induced preB-cell leukemia.

0520

PHOSPHO-PROFILING IN PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) REVEALS CONSTITUTIVE AND CYTOKINE INDUCED SPECIFIC SIGNATURES

M. Queudeville, H. Kunze, S.M. Eckhoff, K.-M. Debatin, L.H. Meyer

University of Ulm, ULM, Germany

Oncogenesis and tumor progression are supported by alterations in cellular signaling. We used phospho-specific antibodies in flow cytometry to analyze specific signaling profiles of leukemia cells at a single cell level in 7 B cell precursor (BCP)- ALL leukemia cell lines and 12 primary pediatric BCP- ALL xenograft samples. Peripheral blood lymphocytes gated on CD19-positive B cells were used as normal nonmalignant controls. Cells were stimulated by different stimulants and cytokines and activation of various phosphoepitopes was analyzed and compared to the basal state of unstimulated samples. Signaling profiles of normal B-lymphocytes were compared to those of the BCP- ALL cell lines as well as to the BCP- ALL xenograft samples. In a second step signaling profiles of the primary xenograft samples were analyzed in respect to prognostic subgroups. Basal phosphorylation for all signaling molecules analyzed was significantly higher in the leukemia cell lines and leukemia xenografts than in normal B-lymphocytes. Interestingly, the BCP- ALL cell lines also had significantly higher basal phosphorylation levels than the primary BCP- ALL xenografts with the exception of Stat5, which was strongly phosphorylated in all leukemia samples. However, when comparing the amounts of phosphorylation before and after stimulation, normal B-cells displayed significantly higher profiles for most phosphoepitopes compared to the leukemia cell lines and xenografts. The leukemia cell lines and the primary xenograft samples both displayed high levels of constitutive phosphorylation in general, reducing their ability to react to a given stimulus compared to normal B-lymphocytes. With the most important exception of Stat5: we consistently found that Stat5 phosphorylation is increased in ALL cell lines and primary xenografts after stimulation with IL-7 compared to normal B-lymphocytes despite the already strong activation of this transcription factor in unstimulated samples. Stat5 is known to enhance proliferation and protect from apoptosis and has been shown to play an essential role in a variety of hematological malignancies, predominantly AML. Our data now strongly suggest that Stat5 and Stat5 dependent pathways are critically involved in leukemogenesis of pediatric BCP- ALL. Analyzing the xenografted primary patient samples according to prognostic subgroups, we identified a marked difference in p38 phosphorylation after treatment with anisomycin. The patient samples with favorable prognosis demonstrated significantly higher levels of pp38 after stimulation with anisomycin, although there were no differences in basal phosphorylation. Anisomycin is a potent inducer of apoptosis through p38-signaling and these results therefore suggest that leukemia samples of patients with good prognosis are more prone to undergo apoptosis after a given stimulus than the samples from patients with a poor prognosis, the weaker reaction suggesting a more apoptosis resistant phenotype. Since we could identify significant and specific phosphorylation signatures characteristic for BCP- ALL cells that also distinguish prognostic subgroups, this provides a strategy to define pathways important for continued survival, proliferation and resistance of leukemia and allows identification of therapeutic targets and novel biomarkers associated with clinical outcome.

FACTOR V LEIDEN MUTATION INCREASES THE RISK FOR VENOUS THROMBOEMBOLISM IN PATIENTS WITH MALIGNANCY

I. Pabinger, D. Dunkler, R. Vormittag, C. Ay, C. Marosi, R. Simanek, C.C. Zielinski, C. Mannhalter

Medical University Vienna, VIENNA, Austria

Background. Patients with malignancy frequently develop venous thromboembolism (VTE). The most common genetic risk marker for VTE, the factor V Leiden (FVL), has not yet been prospectively evaluated in patients with malignancy. *Aims*. It was the aim to investigate in our prospective Vienna Cancer and Thrombosis Study (CATS), if carriers of FVL have an increased risk for VTE during their course of disease. *Methods*. CATS is an ongoing observational study initiated in 2003 in patients with newly diagnosed cancer or progression of disease after remission. FVL was determined by the allele specific, mutagenically separated PCR method, the investigators were blinded with regard to the thrombosis history of the patients during the study. Until 12/2008 we evaluated 954 patients (median age =62 years, 430 women, 520 men), of whom 122 had glioblastoma, 141 carcinoma of the breast, 137 of the lung, 156 of the gastrointestinal tract, 64 of the pancreas, 104 of the prostate, 140 had hematologic and 90 other malignancies. Patients were contacted in 3-4 months intervals during the study period to obtain information on new development of VTE. The study was approved by the Ethics Committee and all patients provided written informed consent. *Results*. Of these 954 consecutive patients evaluated in the study, 68 (7.1%) were carriers of FVL (66 heterozygous, 2 homozygous). This prevalence is consistent with the frequency in the Austrian population. In our cohort, 10/68 (15%) patients with and 63/886 (7%) without FVL developed objectively confirmed VTE during the observation period. Multivariable analysis showed that FVL carriers had a significantly increased risk for VTE after adjustment for age, sex, surgery, chemotherapy, and radiotherapy (hazard ratio 2.3, 95% confidence interval, 1.2-4.4, p=0.017). The cumulative probability of developing VTE after 6 months was 14% in patients with FVL and 5.7% in those without (p=0.012). *Conclusions*. We conclude that carriership of FVL is independently associated with a more than 2fold increased risk for VTE in patients with malignancy, which adds to the already high VTE risk in this group. FVL is rather easy to determine, and results are independent of clinical circumstances. Determination of FVL could help to individually assess the risk of thrombosis in cancer patients and to improve prophylactic strategies in these high risk patients.

0522

A POOLED ANALYSIS OF FOUR PIVOTAL STUDIES OF RIVAROXABAN FOR THE PREVENTION OF VENOUS THROMBOEMBOLISM AFTER ORTHOPAEDIC SURGERY: EFFECT ON SYMPTOMATIC VENOUS THROMBOEMBOLISM AND DEATH, AND BLEEDING

G.G. Turpie,[1] M.R. Lassen,[2] A.K. Kakkar,[3] B.I. Eriksson,[4] F. Misselwitz,[5] T.J. Bandel,[5] M. Homering,[5] T. Westermeier,[5] M. Gent[1]

[1]McMaster University, HAMILTON, Canada; [2]Nordsjællands Hospital, HOERSHOLM, Denmark; [3]Thrombosis Research Institute/Barts, LONDON, UK; [4]Sahlgrenska University Hospital/Ostra, GOTHENBURG, Sweden; [5]Bayer HealthCare AG, WUPPERTAL, Germany

Background. Rivaroxaban is an oral, direct Factor Xa inhibitor approved in the EU and several other countries for the prevention of venous thromboembolism (VTE) after total hip or knee replacement (THR/TKR). Four randomized, double-blind, phase III studies (RECORD1, 2, 3 and 4) investigated rivaroxaban for the prevention of VTE after THR or TKR. A total of 12,729 patients received either oral rivaroxaban 10 mg once daily (od), starting 6-8 hours after surgery, or subcutaneous enoxaparin 40 mg od starting the evening before surgery (RECORD1-3) or 30 mg twice daily starting 12-24 hours after wound closure or adequate haemostasis (RECORD4). In RECORD1 and 2, patients undergoing THR received rivaroxaban for 31-39 days. Enoxaparin was given for 31-39 days in RECORD1 or 10-14 days followed by placebo up to day 31-39 in RECORD2. In RECORD3 and 4, patients undergoing TKR received prophylaxis for 10-14 days. All patients were followed up for 30-35 days after the last dose of study medication. In each study, rivaroxaban regimens significantly reduced the incidence of the primary efficacy endpoint (total VTE; the composite of any deep vein thrombosis, nonfatal pulmonary embolism [PE] and death) compared with enoxaparin regimens, with similar rates of bleeding. *Aims*. Analysis of the pooled RECORD data to investigate rivaroxaban for the prevention of symptomatic VTE and death in patients undergoing THR and TKR. *Methods*. This prespecified analysis was performed on all randomized patients who received ≥1 dose of double-blind study medication to evaluate the effect of rivaroxaban on the composite of symptomatic VTE and death, and bleeding. These primary outcomes were analysed in the total treatment duration pool (planned treatment period), the total study duration pool (treatment and follow-up), both of which included the RECORD2 placebo phase, and also in the day 12±2 active treatment pool (enoxaparin-controlled period common to all studies). *Results*. Rivaroxaban significantly reduced the respective incidence of symptomatic VTE and death compared with enoxaparin regimens in the total treatment duration pool (0.57% vs 1.32%; p<0.001), the total study duration pool (0.81% vs 1.63%; p<0.001) and at day 12±2 (0.47% vs 0.97%; p=0.001). Rivaroxaban significantly reduced the composite of PE and death compared with enoxaparin in the total study duration pool (0.47% vs 0.76%, respectively; p=0.039). Respective rates for major bleeding with rivaroxaban and enoxaparin regimens were: total treatment duration pool, 0.39% vs 0.21% (p=0.076); total study duration pool, 0.44% vs 0.27% (p=0.135); day 12±2 pool, 0.34% vs 0.21% (p=0.175). Respective rates for the composite of major plus clinically relevant non-major bleeding were: total treatment duration pool, 3.19% vs 2.55% (p=0.039); total study duration pool, 3.35% vs 2.76% (p=0.064); day 12±2 pool, 2.85% vs 2.45% (p=0.186). Rivaroxaban reduced the composite outcome of death, myocardial infarction, stroke, symptomatic VTE and major bleeding in the total study duration pool compared with enoxaparin regimens. *Summary and Conclusions*. Rivaroxaban significantly reduced the incidence of symptomatic events compared with enoxaparin regimens in patients undergoing elective THR and TKR surgery. Major bleeding rates were similar for rivaroxaban and enoxaparin regimens.

0523

RESIDUAL VEIN THROMBOSIS FOR ASSESSING THE OPTIMAL DURATION OF LOW-MOLECULAR WEIGHT HEPARIN AFTER CANCER-RELATED DEEP VEIN THROMBOSIS: THE CANCER DACUS STUDY

S. Siragusa,[1] Cancer Dacus Investigators[2]

[1]University of Palermo, PALERMO; [2]Investigators, ITALY, Italy

Background . Type and duration of anticoagulation is still matter of debate in cancer patients with acute Deep Vein Thrombosis (DVT) of the lower limbs. Residual Vein Thrombosis (RVT) has been proven to be effective for assessing the optimal duration of oral anticoagulants in non cancer patients (Siragusa S *et al.* Blood 2008:112:511-5). In the present study we evaluate the role of a RVT-based management of anticoagulation with Low-Molecular Weight Heparin in cancer patients with acute DVT. *Materials and Methods*. Cancer patients with a first episode of DVT were treated with LMWH at therapeutic dosage for 1 month followed by dose reduction of 25% in the next 5 months. At this time, they were managed according to RVT findings: those with RVT were randomized to continue anticoagulants for 6 additional months (Group A1) or to stop (Group A2), while patients without RVT stopped LMWH (Group B). Outcomes were recurrent venous thromboembolism and/or major bleeding. *Results*. Over a period of 18 months, 134 patients were evaluated across 12 centers in Italy; total duration of follow-up was 30.5 years and median duration of follow-up was 1.2 + 0.2 years. RVT was detected in 92 (68.6%) patients; recurrent events occurred in 23.4% of those who discontinued and 15.5% of those who continued LMWH (Figure 1). The adjusted Hazard Ratio (HR) for age and sex (Group A2 vs A1) was 1.58 (95% confidence interval [CI], 0.85-2.93; p=0.145). Of the 42 (31.3%) patients without RVT, one had a recurrence (2.3%) (Figure 1).

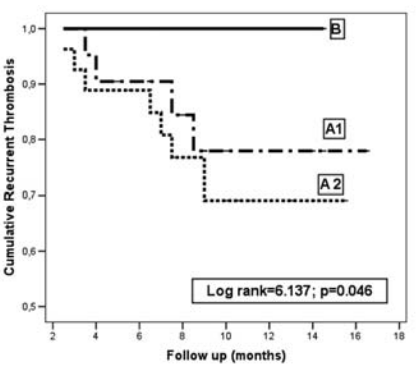

Figure 1. Kaplan-Meyer curve for recurrent events.

The adjusted HR (B vs A1) was 4.54 (CI 2.3-6.66; p=0.028). One major bleeding event occurred in each group of patients who stopped (Group A2 and B) and 2 in those who continued anticoagulation. Overall, 31 (23.1%) patients died due to cancer progression after a median follow-up of 13.2 months after randomization. *Conclusions*. The Cancer DACUS is the first study evaluating an individual marker for assessing duration of anticoagulation in active cancer population. This interim analysis shows that absence of RVT identifies a group of patients at low risk for recurrent thrombosis who can safely stop LMWH after 6 months.

Background. The risk of venous thromboembolism (VTE) is high in newly diagnosed myeloma (MM) patients who receive thalidomide-based regimens. Anticoagulant prophylaxis is recommended. Controversies exist concerning the best thromboprophylactic regimen to be used. *Aims*. In this prospective, multicenter phase III trial we evaluated the safety and the efficacy of low-molecular weight heparin (LMWH) or low-dose aspirin (ASA) or low-fixed dose warfarin (WAR) as anticoagulant prophylaxis. *Methods*. In a GIMEMA study, newly diagnosed MM patients were randomized to VTD (Velcade 1.3 mg/m^2 d 1,4,8,11; Thalidomide 200 mg/d; Dexamethasone 320 mg/21 d) or TD (Thalidomide 200 mg/d; Dexamethasone 320 mg/21 d) or VMPT (Velcade 1.3 mg/m^2 d 1,8,15,22; Melphalan 9 mg/m^2 d 1-4; Prednisone 60 mg/m^2 d 1-4; Talidomide 50 mg/d) or VMP (Velcade 1.3 mg/m^2 d 1,8,15,22; Melphalan 9 mg/m^2 d 1-4; Prednisone 60 mg/m^2 d 1-4). In a sub-study, patients treated with VTD or TD or VMPT were randomly assigned to receive LMWH (Enoxaparin 40 mg/d) or ASA (Aspirin 100 mg/d) or WAR (Warfarin 1.25 mg/d) for the duration of the induction therapy. Patients treated with VMP did not receive any prophylaxis and were used as controls. End-points were incidence of VTE, acute cardiovascular events, sudden death, bleeding and any other serious adverse events. A total of 950 patients have been included in this study. *Results*. A total of 761 patients completed at least 3 cycles and were analyzed, 40 patients were excluded from sub-study because of indication for anticoagulant/antiplatelet therapy or high-risk of bleeding. Of the 761 evaluable patients, 193 were randomized to LMWH, 199 to ASA, 195 to WAR and 174 to the control group (VMP). Patient characteristics were similar in all groups. The incidence of VTE was 3.1% in the LMWH group, 5.5% in the ASA group and 5.6% in the WAR group (p not significant). VTEs were 2.3% in the VMP group. The rates of cardiovascular events were 0.5% in WAR, 1% in LMWH, and 1.1% in ASA group while they were 0.5% in the control group. No sudden deaths were reported. The incidence of all grades bleeding was 0.6% in the LMWH group, 0.6% in the WAR group and 1.5% in the ASA group while it was 3.7% among the controls. The distribution of the major risk factors was comparable in the 3 arms, 40% of patients had at least 2 risk factors. *Conclusions.* The overall incidence of VTE was less than 10% in all groups and was not superior to that expected during the natural course of MM. The rate of VTE was comparable among patients receiving either ASA or WAR, LMWH patients had lower risk for VTE, although no statistical difference was observed. LMWH, WAR and ASA are likely to be effective thromboprophylactic regimens. An update of these data will be presented at the meeting.

SCREENING FOR OCCULT MALIGNANCY IN PATIENTS WITH IDIOPATHIC VENOUS THROMBOEMBOLISM -THE TROUSSEAU INVESTIGATORS-

J.M.M.B. Otten,[1] F.F. van Doormaal[2]

[1]Slotervaart ziekenhuis, AMSTERDAM; [2]Academic Medical Center, AMSTERDAM, Netherlands

Background. Patients presenting with idiopathic venous thromboembolism (IVTE) have a ± 8% risk to develop a malignancy in the following two years. Controversy exists whether screening for occult malignancies improves prognosis. *Aims*. To investigate the influence on mortality of screening for malignancy in patients with an IVTE. *Methods*. We performed a center-controlled study in 11 hospitals in the Netherlands. In 6 centers patients underwent a standardized basic investigation only consisting of medical history, physical examination, laboratory tests and chest X-Ray (arm A). In 5 centers, an identical basic investigation was followed by thoracic and abdominal CT plus a mammography in women (armB). Outcomes were: the proportion of patients with cancer found at entry, the additional diagnostic yield of screening, the incidence of malignancies during follow up and overall mortality. *Results*.Between 2003 and 2008, 630 patients were included. The main patient characteristics were similar for both groups. In 7 of the 288 patients in arm A basic investigation resulted in the diagnosis of malignancy (2.4% 95%CI, 0.98-4.9) compared to 12 of 342 patients in arm B (3.5%, 95%CI 1.8-6.1). In arm B, 302 patients underwent CT scanning (+ mammography). In 6 patients a malignancy was found (yield 2.0%, 95%CI 0.74 to 4.3), of which 3 were stage 4. During a median follow up of 30 months, in arm A 15 new malignancies were found (5.3%, 95%CI 3.0-8.7). In arm B during a median follow up of 31 months, 12 new cancers were diagnosed (3.7%, 95%CI 1.9-6.4). In arm A 8.3% died during the study period compared to 7.6% in arm B (HR 0.87; 95% CI 0.48-1.60). *Conclusions*. The additional clinical utility of screening with spiral CT and mammography is limited after standardized basic investigation. The incidence of cancer during follow up was comparable. Extensive screening did not result in a survival benefit.

Chronic myeloid leukemia - Biology I

0526

AT THE TIME OF DIAGNOSIS, PH+ CELLS FROM BOTH CHRONIC PHASE CHRONIC MYELOID LEUKEMIA AND ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS ALREADY HARBOUR BCR-ABL KINASE DOMAIN MUTATIONS

S. Soverini,[1] A. Poerio,[1] A. Vitale,[2] A. Gnani,[1] S. Colarossi,[1] F. Castagnetti,[1] I. Iacobucci,[1] A. Lonetti,[1] F. Palandri,[1] G. Rosti,[3] M. Amabile,[1] S. Paolini,[1] C. Papayannidis,[1] G. Gugliotta,[4] M. Vignetti,[2] F. Mandelli,[2] M. Baccarani,[1] R. Foà,[2] G. Martinelli[1]

[1]Department of Hematology/Oncology Seràgnoli, University of Bologna, BOLOGNA; [2]Dept. of Cellular Biotechnologies and Hematology, La Sapienza University, ROME; [3]Insitute of Hematology Seragnoli, BOLOGNA; [4]University of Bologna, BOLOGNA, Italy

Background and Aims. Mutations in the Bcr-Abl kinase domain (KD) are often detected at the time of resistance to tyrosine kinase inhibitor (TKI) therapy in Philadelphia-positive (Ph+) leukemias. Mutations in rare Ph+ cells have been detected in some imatinib-naïve advanced-phase chronic myeloid leukemia (CML) patients (pts), but it is still unclear whether and with what incidence low level mutations may already be detectable at the time of diagnosis in Ph+ acute lymphoblastic leukemia (ALL) pts and in chronic-phase (CP) chronic myeloid leukemia pts. We therefore analyzed cDNA samples from 24 newly diagnosed pts with Ph+ ALL (n=13) or CP-CML (n=11) who subsequently received TKI therapy (imatinib, dasatinib or nilotinib). *Methods*. Screening for low level mutations was performed by cloning the Bcr-Abl KD (a.a. 206-524) in a bacterial vector and sequencing 200 independent clones for each pt. *Results*. All pts had evidence of aberrant KD sequences. Three to twelve different mutations were detected in each pt. Each mutation was present in two to five independent clones. A total of 115 mutations (including 41 silent, 5 nonsense, and 69 missense mutations) were observed. The vast majority (107/115, 93%) have never been reported in association with TKI resistance and are likely not to confer any advantage under TKI selective pressure. Interestingly, 103/115 (90%) mutations were transitions: G>A (n=30), A>G (n=25), C>T (n=25), T>C (n=23). Such a high prevalence of transitions (normally occurring 1.4 times more frequently than transversions) suggests that a specific mechanism generating mutations is active in Ph+ cells (activation-induced cytidine deaminase?). One of the eleven CP-CML pt received hydroxyurea for 6 months before starting imatinib therapy. In this pt, high-sensitivity mutation screening was performed again immediately before imatinib start and showed further accumulation of mutations. Eight Ph+ ALL pts and three CML pts subsequently relapsed with evidence of mutations, but only two with a mutation (T315I) that was already detectable at diagnosis. The remaining thirteen pts are in persistent remission after a follow up ranging from 12 to 52 months, although four of them were harbouring known imatinib-(H396P, D276G, E355G) or dasatinib-(F317L) resistant mutations at low levels. *Conclusions*. Our observations suggest that: a) Bcr-Abl KD mutations can probably be found at diagnosis in all CP-CML and Ph+ ALL pts; b) mutations seem to arise randomly and most of them are silent or not conferring any growth advantage under the selective pressure of TKIs; c) generation of mutations seems to be linked to Bcr-Abl-driven genetic instability; d) TKI-resistant mutations present at low levels at diagnosis do not always outgrow and lead to relapse, probably because some of them arise in cell clones with limited self-renewal capacity. This warns against high-sensitivity mutation screening of all CML and Ph+ ALL pts before the start of TKI therapy.

IDENTIFICATION OF NEW GENES SUSTAINING BCR-ABL ONCOGENIC SIGNALLING AND CML PROGRESSION THROUGH A GENETIC TOOL BASED ON HUMAN BCR-ABL TRANSGENIC DROSOPHILA MELANOGASTER (DM)

F. Messa,[1] R. Bernardoni,[2] M. Pradotto,[1] F. Arruga,[1] E. Bracco,[1] S. Carturan,[1] C. Maffè,[1] E. Messa,[1] C. Panuzzo,[1] I. Iacobucci,[2] T. Kalebic,[3] G. Martinelli,[2] M. Baccarani,[2] G. Saglio,[1] D. Cilloni[1]

[1]University of Turin, ORBASSANO, Italy; [2]University of Bologna, BOLOGNA, Italy; [3]Novartis Oncology Clinical Development, EAST HANOVER, USA

Background. despite the role of Bcr-Abl in the pathogenesis of Chronic Myeloid Leukaemia (CML) is well established, the mechanisms responsible for CML progression are largely unknown. *Aims*. the aims of the study were to perform a genetic screening to identify new genes and pathways leading to CML progression. Methods: we developed a genetic model based on human p210 Bcr-Abl transgenic Dm. We generated a transgenic fly expressing h-p210 wt, in a tissue specific manner such as fly eyes or lymph gland, which represents the Dm haematopoietic system. A wide modifier screening was performed using 300 fly stocks carrying well characterized chromosome deletions within the whole genome. The resulting progeny was screened using eye phenotype as first read-out system. As second step, in order to clarify the role of Bcr-Abl in altering blood cells homeostasis, we drove its expression into lymph gland, in which resides the production of hemocytes, using specific drivers. Furthermore each deletion responsible for phenotype changes was analyzed either by expressing it into lymph gland as second read-out system, in order to analyzed their function into a haematopoietic background and to excluded genes involved in eye development, such as genes able to modify the eye phenotype even without being directly involved in Bcr-Abl oncogenic signalling (false positives). As final point, loss of function mutants of each gene included in the identified regions, were tested and the data obtained were validated analyzing samples from CML patients. *Results.* hBcr-Abl expression resulted into a severe eye glazed phenotype strictly dependant on p210 protein amount and induced the formation of melanotic tumors (clusters of hemocytes, clearly identifiable by their blak colors) when expressed in the lymph gland and in each hemocyte type. The analysis of eye/lymph gland-phenotypes in the progeny obtained from screening crosses, shows a first group of flies (38%) displaying a more aggressive phenotype since they lack genes encoding for Bcr-Abl negative regulators and a second group (32%) showing a mild phenotype due to the absence of genes involved in the oncogenic signalling. By now we have identified 25 new genes responsible for phenotype changes, including Fax, Disabled, Prospero, Dock and Rab5. Loss of function mutations of these genes induced a worse eye phenotype suggesting their role as enhancers of Bcr-Abl signalling. Further confirmation of their involvement in human disease comes from the analysis of their expression by Real Time PCR in 35 CML patients at diagnosis and during progression in which these genes result highly down-regulated with respect to 20 BM samples from healthy donors. Moreover, transfection of CML cell lines with gain of function constructs reduced proliferation and induced apoptosis. By contrast, loss of function of ENA, the CRKL hortologous, didn't induce phenotype changes, suggesting that ENA and presumably CRKL don't represent key regulators of Bcr-Abl signalling. Conclusions: these new genes caught with Dm system, seem to be crucial for human Bcr-Abl oncogenic signalling thus supporting the idea that Dm is a powerful genetic tool which allows the identification of new genes involved in CML development and progression.

FREQUENT INACTIVATING MUTATIONS OF TET2 AND CBL ARE ASSOCIATED WITH ACQUIRED UNIPARENTAL DISOMY IN ATYPICAL CHRONIC MYELOID LEUKEMIA

T. Ernst,[1] A. Chase,[1] C. Hidalgo-Curtis,[1] K. Zoi,[2] C. Zoi,[2] A. Hochhaus,[3] A. Reiter,[3] W. Vainchenker,[4] F. Grand,[1] N.C.P. Cross[1]

Atypical BCR-ABL negative chronic myeloid leukemia (aCML) and related myelodysplastic/myeloproliferative neoplasms (MDS/MPN) such as chronic myelomonocytic leukemia (CMML) have been associated with mutations that activate tyrosine kinase signalling; however, the molecu-

lar pathogenesis of the majority of cases remains unknown. Recent evidence has shown that acquired uniparental disomy (aUPD) is a novel mechanism by which pathogenetic mutations in cancer may be reduced to homozygosity. In this study we sought to investigate if aUPD characterizes MDS/MPN of unknown molecular etiology, and whether it could be used as a tool to help identify novel driver mutations. We performed genome wide high resolution SNP 6.0 array analysis on leukocyte DNA extracted from 121 patients with aCML (n=58) or CMML (n=63), all of whom were negative for BCR-ABL, JAK2 V617F, FIP1L1-PDGFRA and cytogenetic indicators of other tyrosine kinase fusion genes. Homozygous copy neutral SNP calls >20 Mb, considered indicative of aUPD, were seen in 32 (26%) patients. In total, 15 different chromosomes were involved with the most common recurrent abnormalities being seen at 7q (n=10), 11q (n=7), and 4q (n=6). Sequencing of candidate genes in the minimally affected regions excluded the involvement of tyrosine kinases and several other genes. Mutations in CBL, encoding a key regulator of tyrosine kinase signalling, were identified in 4 cases with 11q aUPD and analysis of 574 additional MPN and MDS/MPN revealed a total of 27 CBL variants in 26 patients with aCML (12/152; 8%), CMML (10/78; 13%), myelofibrosis (n=3/53; 6%) or hypereosinophilic syndrome (n=1/96; 1%). Most variants were missense substitutions in exons 8 or 9 (encoding the linker/RING domain) that abrogated CBL ubiquitin ligase activity and conferred a proliferative advantage to 32D cells that overexpressed FLT3. Following the identification of TET2 at 4q24 as a putative novel tumor suppressor gene of unknown function in patients with MPN and MDS (Delhommeau et al., ASH 2008), we established a sensitive high resolution melting (HRM) assay for high-throughput scanning of this large gene. Homozygous TET2 variants were found in 5/6 cases with 4q aUPD and analysis of 64 additional cases revealed variants in aCML (13/38; 34%) and CMML (13/26; 50%). In total, 38 TET2 variants were identified that were spread throughout the 6kb coding region. Of these, 21 were likely causative changes predicted to result in premature chain termination (nonsense, n=10; deletion, n=8; insertion, n=3) and 17 were missense substitutions that have not been reported as SNPs but are currently of unknown pathogenicity. We conclude that aUPD is common in atypical CML and related disorders and that inactivating mutations of TET2 and CBL are associated with aUPD at 4q and 11q, respectively.

PH-NEGATIVE HEMATOPOIESIS EMERGING AFTER SUCCESSFUL TREATMENT OF CHRONIC MYELOGENOUS LEUKEMIA DYSPLAYS SEVERE AND PERSISTENT TELOMERIC LOSS AND IMPAIRED FUNCTIONAL PERFORMANCES

C. Lobetti Bodoni,[1] D. Ferrero,[2] E. Genuardi,[3] D. Sia,[4] M. Genuardi,[2] V. Giai,[2] A. Rocci,[2] L. Monitillo,[2] D. Drandi,[2] A. Risso,[2] S. Ferrero,[2] G. Isaia,[5] M. Lunghi,[6] R. Passera,[2] G. Gaidano,[6] M. Boccadoro,[2] C. Carlo-Stella,[4] M. Ladetto[7]

[1]University of Turin, TORINO; [2]University of Turin Hematology Department, TURIN; [3]University o f Turin, Ematology department, TURIN; 4University of Milan Hematology Department, MILAN; [5]University of Turin, Department of Geriatry, TURIN; [6]University of Novara, Department of Hematology, NOVARA; [7]University of Turin hematology department, TURIN, Italy

Background . Most chronic myelogenous leukemia (CML) patients (pts) restore non-neoplastic hematopoiesis following treatment with tyrosine kinase (TK) inhibitors. However little is presently known on the functional and genetic integrity of Ph-negative hematopoietic cells (HC) repopulating the bone marrow after successful treatment. Indeed, the frequent detection of cytogenetic abnormalities (CA) reminiscent of those seen in myelodysplastic syndromes suggests the potential presence of functional and genetic defects. These issues have been addressed using short and long term HC cultures and telomere restriction fragment length (TRF-L) analysis, which is considered a reliable marker of proliferative and oxidative damage. *Aims and Methods*. We investigated 77 CML pts in stable complete cytogenetic remission (CR) (CR had to be documented at least one year before the analysis). 67 pts were treated with Imatinib and 10 with α-interferon associated or not to ara-C. Median age was 64 (23-88), M/F ratio was 1.5, median time from diagnosis and from complete CR were 53 (7-915), and 39 months (12-150). 33 pts had low Sokal score, 24 intermediate, and 13 high. For 7 patients it has been impossible to evaluate Sokal score. Complete and partial molecular responders were 35 and 24, respectively. 11 pts showed evidence of acquired CA in Ph-negative HC. TRF-L analysis was performed by Southern Blotting as previously described (Ladetto M et Al, Blood 2004), both on polymorphonucleates (PMN) and on monocyte-depleted PBMC (MD-PBMC) (as described by Rocci et al Exp Hematol 2007) to monitor both the myeloid and lymphoid compartment. Colony-forming unit granulocyte-macrophage (CFU-GM), burst-forming unit erythroid (BFU-E) and colony forming unit-mix (CFU-Mix) along with long-term culture-initiating cells (LTC-ICs) have been so far performed on 30 patients, using bone marrow mononuclear cells as previously described (Sutherland HJ et al Blood 1994). For both TRF-L and cell culture studies a control database of 86 healthy subjects has been used for comparison. *Results*. PMN from CML patients showed a striking erosion of their telomeric DNA (Figure 1A). Also MD-PBMC showed a degree of telomere shortening although the finding was much less pronounced and not statistically significant (mean telomeric loss in PMN 1767 pb $p<0.001$; in MD-PBMC: 584 pb, $p=0.1$) We found no correlation between TRF-L and previously mentioned clinical parameters. Telomeric erosion is more severe in younger CML pts, resulting in loss of the association between TRF-L and age, typically seen in healthy subjects (Figure 1B) Telomere shortening was observed regardless of the use of TK inhibitors. When a multivariate analysis on pts and healthy controls was performed, the presence of CML resulted a stronger predictor of telomeric damage compared to age. We found no correlation between TRF-L and previously mentioned clinical and demographic parameters. Telomeric erosion show no evidence of recovery on 46 follow-up samples taken after a median time of 10 months (range 6-15). Moreover, Ph-negative HC of CML pts were functionally impaired compared to controls with reduced numbers of CFU-Mix (median 2,62 vs 4, $p=0,01$), CFU-GM (median 99,5 vs 181, $p<0,0001$) and particularly of LTC-IC (median 88 vs 198, $p<0,0001$) (Figure 1C). *Conclusions*. Ph-negative HC repopulating the bone marrow after successful CML treatment display severe telomeric DNA erosion, roughly comparable to 35 years of physiological aging. Moreover they display major defects in their functional performances. These findings underline the need of additional investigations and careful clinical monitoring of the Ph-negative haemopoietic compartment in these subjects.

Background. Dasatinib and nilotinib are second-generation tyrosine kinase inhibitors (TKIs) active against many imatinib-resistant Bcr-Abl mutated forms. However, both dasatinib and nilotinib have been shown to retain some 'Achilles heels'. *Methods*. We have monitored Abl KD mutation status in a total of 121 pts who received dasatinib (n= 78) or nilotinib (n=43) as 2nd TKI after imatinib failure since February 2005. Results: Fifty-eight (48%) pts had chronic phase (CP) chronic myelogenous leukemia (CML), 63 pts (52%) had accelerated phase (AP) or blast crisis (BC) CML or Philadelphia-positive (Ph^+) acute lymphoblastic leukemia (ALL). Median age was 55 years (range, 18-76); median time from diagnosis was 49 months (range, 4-181); median time on imatinib was 32 months (range, 4-66). Median follow-up of all pts who received a 2nd TKI is 7 months (range, 1-38). Median follow-up of pts who are still on 2nd TKI treatment is 32 months (range, 28-38). Relapses after an initial response have so far been observed in 46/121 pts. Thirty-eight out of these 46 pts had AP/BC CML or Ph^+ ALL at the time 2nd TKI was started. Forty-one out of 121 (34%) pts have experienced relapse after an initial response during the first 12 months of 2nd TKI treatment (median time to relapse, 6,5 months; range 4-12 months), while only five of the 45 (11%) pts who were still on 2nd TKI treatment after >12 months have relapsed (at 13, 15, 18, 20, 33 months, respectively). Interestingly, none of these 5 pts had never achieved more than a minor cytogenetic response (CgR), and 4/5 pts were receiving a reduced TKI dose because of toxicity. In 36/46 (78%) cases, relapse was associated with newly acquired Abl KD mutations. In particular 26/30 (87%) pts who relapsed on dasatinib and 10/16 (63%) pts who relapsed on nilotinib had evidence of a newly acquired KD mutation presumably responsible for treatment failure. Newly acquired mutations in pts who relapsed on dasatinib as 2nd TKI were T315I (n= 12 pts) F317L (n= 8 pts) T315A (n=3 pts); V299L (n=3 pts); F317I (n=2 pts); 2 pts had multiple mutations. Newly acquired mutations in pts who relapsed on nilotinib as 2nd TKI were E255K (n=2); E255V (n=2); Y253H (n=2); T315I (n=2); F359V (n=1); F359C (n=1). *Conclusions*. a) newly acquired mutations leading to relapse in Ph+ leukemia pts receiving dasatinib or nilotinib as 2nd TKI usually arise rapidly; the likelihood of mutation selection consistently decreases over time, and seems mainly confined to advanced phase pts and to pts with no or minor CgR; b) almost all (87%) cases who developed resistance to dasatinib had newly acquired KD mutations - suggesting that the higher potency with respect to imatinib can overcome Bcr-Abl gene amplification and that Src kinase inhibition may turn off Bcr-Abl-independent resistance mechanisms; c) a lower incidence (63%) of newly acquired KD mutations was observed in pts who developed resistance to nilotinib; b) with the exception of T315I, there is little if no overlap between dasatinib and nilotinib-resistant mutants.

Hematology, Université Paris VI, PARIS; [3]INSERM U790, VILLEJUIF; [4]INSERM E210, Université Paris Descartes, PARIS; [5]INSERM U876, Université Bordeaux 3, BORDEAUX; [6]INSERM U567, APHP, Université Paris Descartes, PARIS; [7]INSERM U728, APHP, Université Paris 7, PARIS; [8]APHP, Université Paris Descartes, PARIS; [9]INSERM U790, Université Paris XI, VILLEJUIF, France

Background. Myeloid malignancies include myelodysplastic syndromes (MDS), myeloproliferative diseases (MPD) and acute myeloid leukemias (AML) that are all clonal hematopoietic stem cell disorders (HSC). The molecular mechanisms driving the MDS appearance remain poorly understood. *Aims*. We hypothesized that an early genetic event targeting the HSC could be common to all these myeloid disorders. *Methods*. TET2 coding sequence was analyzed in DNA from bone marrow samples of myeloid malignancies by PCR and sequencing. *Results*. We have previously described 3 cases of de novo (n) or secondary (s) AML and 3 MDS patients with acquired 4q24 chromosomal rearrangements. Fluorescence *in situ* hybridization (FISH) on metaphase chromosomes narrowed a common 500 kb minimal deleted region which uncovered the structure of a single gene, Ten Eleven Translocation (TET) 2. Five/6 patients harbored a deletion of a single copy of the gene while both copies were deleted in one case. We identified nucleotide changes in the sequence of the 8 coding exons and of their splice sites in 4/5 patients: 2 cases with missense mutation, one case with a C'T leading to an in frame stop codon and one with a 4 bp insertion leading to a frameshift. We confirmed that the observed changes were somatically acquired, by sequencing non-tumoral samples in 2 AML and 1 MDS. These data indicate that TET2 is a bona fide tumor suppressor gene. To establish whether mutation of TET2 could also occurs independently of a chromosomal abnormality, an additional series of 111 patients: 81 MDS, 21 sAML, 9 CMML and in 198 MPD were analyzed. Sequence abnormalities were observed in 22/111 (19.8%) MDS/sAML/CMML, and in 24/198 (12.1%), showing the high prevalence of TET2 defects in myeloid malignancies. To investigate whether the mutations could be observed in immature progenitors, sorted $CD34^+CD38^-$ and $CD34^+CD38^+$ cells from 3 MDS and 2 sAML were genotyped by PCR-restriction fragment length polymorphism (RFLP). The percentage of mutated allele in $CD34^+CD38^-$ was lower than in $CD34^+CD38^+$ cells in 3 cases, equal in one case. Sorted hematopoietic progenitors from 1 MDS were seeded at one cell per well in growth-promoting conditions. TET2 mutation was identified in 8/32 and 18/30 single cell colonies derived from $CD34^+CD38^-$ and $CD34^+CD38^+$ cells, respectively. These data demonstrate that TET2 mutations target a $CD34^+CD38^-$ cell and suggest that TET2 mutated cells have a selective advantage. *Conclusions*. We report the acquired genetic defects of TET2 as a common early event in human MDS and MDS-related AML. In MDS patients, TET2 mutations are observed in various subtypes, as previously reported for the LOH and interstitial deletions at 4q24. These events target the hematopoietic stem cell and indicate an important function for TET2 in the onset of myeloid neoplasms.

LEUKEMIA FUSION PROTEINS ARE NOT SUFFICIENT TO INITATE THE ABERRANT METHYLATION PROFILE ASSOCIATED WITH FULL LEUKEMIC TRANSFORMATION

S. Alvarez,[1] J. Suela,[1] M. Wunderlich,[2] J. Wei,[2] X. Aguirre,[3] I. Martín-Subero,[4] A. Maiques,[1] F. Acquadro,[1] S. Rodriguez-Perales,[1] M.J. Calasanz,[3] R. Siebert,[4] F. Prósper,[3] J.C. Mulloy,[2] J.C. Cigudosa[1]

[1]Spanish National Cancer Research Centre, MADRID, Spain; [2]Cincinnati Children's Hospital Medical Center, CINCINNATI, USA; [3]University of Navarra, PAMPLONA, Spain; [4]University Hospital Schleswig-Holstein Campus Kiel/Christian-Abrechts University, KIEL, Germany

Background. Genomic aberrations resulting in activation of oncogenes, inactivation of tumour suppressor genes or in the formation of novel chimeric genes are currently considered the main cause of the malignant phenotype in AML. There is now increasing evidence that in addition to genetic aberrations, therapeutically reversible epigenetic events also play a critical role in the pathogenesis of human leukemias. *Aims*. We used high-throughput methylation profiling to explore systematically the epigenomic variation underlying the biologic and clinical heterogeneity in AML. *Methods*. Using the Illumina GoldenGate Methylation Cancer Panel that spans 1,505 CpG loci, a detailed methylation profile of 116 AML patients distributed along all the cytogenetic prognostic subgroups was established. In addition, controls (BM and CB) and human progenitor cells expressing AML1/ETO, CBFB/MYH11 or MLL/AF9 fusion proteins were analysed. Unsupervised and supervised hierarchical cluster were performed, and a selection of the most significantly differentially methylated loci (delta beta (DB) of at least 0.34 and FDR <0.05) calculated as DB= (sample mean beta value) - (control mean beta value) was done. *Results*. AML samples were correctly separated from BM controls and segregated in two main categories. While one of them showed a profile (Group I) similar to the one observed in the control bone marrow samples (only 7 probes showed a mean DB>0.34), the other (Group II) presented a defined aberrant methylation signature (24 probes showed a mean DB>0.34). The distribution of the AML cases among the two methylation categories was significantly different based on their cytogenetic characterization. Eighty percent of the cases included on the adverse cytogenetic prognostic group clustered in Group I and 80% of the cases included in the good prognosis cytogenetic group clustered in Group II. In contrast, normal karyotype AML cases were evenly distributed between the two groups. No significant differences were observed for other variables such as FLT3 mutational status. Overall survival was not significantly different between AML Group I and II cases with intermediate cytogenetic prognostics, of the 60 patients with available clinical data included in these groups. Taking advantage of our model of primary human hematopoietic progenitor cells stably transduced with leukemia fusion genes[1-3] we observed that the epigenetic signature of the MLL leukemias is also observed in human progenitor cells fully transformed "*in vitro*" by the MLL-AF9 oncogene. In contrast, human cells expressing the AML1/ETO or CBF/MYH11 fusion proteins, which are immortalized upon oncogene expression but are not fully transformed by these leukemia fusion proteins, do not recapitulate the methylation signature observed in the AML primary cases. Summary and Conclusions.We conclude that a large number of epigenetically modified genes is observed in the presence of single cytogenetic abnormalities including t(8;21), t(15;17) and MLL rearrangements. However, based on our data, it appears that a full leukemic transformation is required for the acquisition of a specific aberrant methylation profile, suggesting that the presence of the recurrent fusion proteins such as AML1/ETO or CBF/MYH11 is not sufficient to initiate the aberrant methylation signature.

REFINEMENT OF CYTOGENETIC CLASSIFICATION IN AML: DETERMINATION OF PROGNOSTIC SIGNIFICANCE OF RARE RECURRING CHROMOSOMAL ABNORMALITIES AMONGST 5635 YOUNGER ADULTS TREATED IN THE UK MRC TRIALS

J. Grimwade,[1] R. Hills,[2] A.V. Moorman,[3] H. Walker,[4] S. Chatters,[4] A.H. Goldstone,[4] K. Wheatley,[5] C.J. Harrison,[3] A.K. Burnett[2]

[1]King's College London School of Medicine, LONDON; [2]Dept. of Haematology, University of Wales College of Medicine, CARDIFF; [3]Leukaemia Research Cytogenetics Group, Northern Institute for Cancer Research, NEWCASTLE UNIV, NEWCASTLE-UPON-TYNE; [4]Dept. of Haematology, University College London Hospitals, LONDON; [5]University of Birmingham Clinical Trials Unit, BIRMINGHAM, UK

Background. Diagnostic karyotype provides a major determinant of treatment approach in younger adults with acute myeloid leukaemia (AML). There is a general consensus that presence of t(15;17)(q22;q21), t(8;21)(q22;q22) or inv(16)(p13q22)/t(16;16)(p13;q22) predicts a relatively favourable outcome and conversely that cases of AML lacking any of the aforementioned abnormalities but in which cytogenetic analysis shows inv(3)(q21q26)/t(3;3)(q21;q26), del(5q), -5, -7 or a complex karyotype generally have a very poor prognosis. However, the number of unrelated cytogenetic changes used to define a "complex karyotype" predicting a particularly adverse prognosis has been a matter of contention, differing between trial groups and ranging between 3 and 5 or more abnormalities. There has also been little consensus as to the most appropriate risk group assignment for cases with rare recurring cytogenetic abnormalities (i.e. individual incidence <2%) which together account for approximately 10% of AML and have variably been considered to predict an intermediate or adverse prognosis. In the original Medical Research Council (MRC) cytogenetic classification (Grimwade et al, Blood 1998), rarer abnormalities occurring at a frequency of ≤1% were not considered separately on statistical grounds and when combined were found to have an intermediate prognosis. *Aims and Methods*. Since it was recognized that AML cases with rare recurring cytogenetic abnormalities are likely to be heterogeneous with respect to biology and treatment response, we studied outcome of these patients, derived from 5635 cases aged 16-59 years treated in consecutive MRC AML trials (AML10, n=1238; AML12, n=2252; AML15, n=2145). *Results*. Having excluded 1462 cases with t(15;17)(q22;q21), t(8;21)(q22;q22) and inv(16)/t(16;16) and after adjusting for age, presenting WBC and type of AML (de novo/secondary), Cox regression analyses revealed no new abnormalities conferring a relatively favourable prognosis. However, the outcome of patients (n=25) with the t(3;5)(q21~25;q31~35), which is associated with the NPM1-MLF1 fusion and would have been assigned to the "adverse risk" category according to the original MRC cytogenetic classification, did not differ significantly from the normal karyotype group (5 year OS, 33% vs 43%, p=0.3). Outcome for t(11q23) patients (n=192) was significantly worse than for normal karyotype patients (p<0.00001); there was possible evidence of differences in outcomes across the t(11q23) group according to involved chromosome, with 5 year survival for the t(9;11)(p21-22;q23) comparable to that for normal karyotype, although this heterogeneity did not reach statistical significance (p=0.10). In univariate analysis, there was some evidence of poorer survival in patients (n=33) with the t(6;9)(p23;q34) as compared to those with normal karyotype (31% vs 43%, p=0.04). In multivariable analyses, various abnormalities were found to be predictive of a significantly poorer outcome (all p-values <0.0001), namely: inv(3)/t(3;3), other 3q abnormalities [excluding t(3;5)], add(5q), del(5q), -5, add(7q), -7, t(6;11), t(10;11), t(9;22), -17 and abn(17p) with other changes. Patients lacking these aberrations, but with more than 3 unrelated abnormalities also exhibited a significantly poorer prognosis (p<0.0001 adjusted for other prognostic factors). *Conclusions*. These data allow further refinement of the hierarchical MRC cytogenetic classification scheme and may facilitate development of consensus in the reporting of karyotype data allowing more reliable comparison between clinical trials involving younger adults with AML.

CEBPA GENE MUTATIONS AFFECTING THE TAD AND BZIP REGION SHOW DIFFERERENCES IN THEIR ASSOCIATION WITH CLINICAL PARAMETERS AND PROGNOSIS: AN ANALYSIS IN 1779 ADULT PATIENTS WITH AML

F. Taube,[1] T. Illmer,[1] M. Schaich,[1] F. Kroschinsky,[1] U. Oelschlägel,[1] B. Mohr,[1] U. Platzbecker,[1] G. Ehninger,[1] C. Thiede,[1] On behalf of the SAL[2]

[1]University Hospital TU Dresden, DRESDEN; [2]Study Alliance Leukemia, (D), Germany

Mutations of the CEBPA gene coding for the key myeloid transcription factor CCAAT/enhancer binding protein alpha have been reported in up to 20% of patients with AML and normal karyotype. In addition CEBPA mutations appear to be associated with an improved outcome after chemotherapy. This led to the inclusion of CEBPA-mutations as provisional entity into the most recent release of the WHO classification. However, most studies published so far investigated selected patient populations or relatively small cohorts. To gain further insight and to study this abnormality in an unselected cohort, including older patients and all karyotype abnormalities, we analyzed 1779 newly diagnosed AML patients for the predominant types of CEBPA mutation, namely insertion/deletion mutations affecting the transactivation domains (TAD) or the basic-/ leucine zipper-region (bZip). Outcome was analyzed for those 1435 patients treated in the AML96 protocol of the Study Alliance Leukemia (SAL). Screening for CEBPA mutations was done on DNA isolated at the time of diagnosis using high resolution fragment analysis and direct sequencing. *Results.* Overall, 152 individual CEBPA mutations were identified in 103 of the 1779 patients (5.8%), 49 patients had combined TAD/bZIP mutations, 24 had only a TAD-mutation and 30 had only a mutation in bZip. The mutation rate was significantly higher in normal karyotype (NK) patients (84/836; 10%) compared to patients with aberrant karyotype (AK) (15/814; 1.8%; $p<0.001$). Median age of patients with CEBPA-mutations was 49 years vs. 60 years in patients with wt-CEBPA ($p<0.001$). When the different mutation types were analyzed separately, we realized that this age difference was due to the lower age of patients with bZip mutations (med. age 46 yrs.) or combined bZip/TAD (47.5 yrs.) mutations, whereas patients with only a mutation in the TAD-domain were significantly older (64 yrs.). In addition, patients with TAD-mutations differed significantly in their WBC counts, the rate of secondary AML and the frequency of additional NPM1-comutations from the other two patient groups with bZip ±TAD mutations. Overall, patients with CEBPA mutations had a significantly higher rate of complete remissions (CR CEBPA-mut: 74.7% vs. -wt: 49.4%; $p<0.001$), which translated into a significantly better overall survival (OS: CEBPA-mut: median 33.6 months vs -wt: 12.6 months; $p=0.001$). Interestingly, in patients with aberrant karyotype, CEBPA also predicted a significantly better OS (med. mutant not reached vs. 10.5 months for wt; $p=0.002$), but was not associated with improved outcome in older patients (>60 years). When analyzed separately, the OS differed significantly between patients with bZip-mutations and TAD-mutations (med.: OS: bZip: 50.2 mo vs. TAD 12.2 mo; $p=0.05$). In a multivariate analysis, CEBPA mutations represented an independent predictor of CR-rate and overall survival. *Conclusions*. Taken together, our data indicate that CEBPA mutations show a distinct association with clinical parameters and suggest a previously unrecognized association between the localization of the mutation and their effect on the leukemia, which might be due to the differential formation of the truncated p30 variant of the protein.

A POLYMORPHIC CONSTITUTIONAL TFG-GPR128 FUSION IN HEALTHY INDIVIDUALS IDENTIFIED BY TARGETED ARRAY CGH

J. Chase,[1] A. Fiebig,[2] T. Ernst,[1] F. Grand,[1] A. Reiter,[3] P. Erben,[3] S. Schreiber,[4] N. Cross[1]

[1]Wessex Regional Genetics Laboratory, SALISBURY, UK; [2]POPGEN, University of Kiel, KIEL, Germany; [3]Medizinische Fakultät Mannheim der Universität Heidelberg, MANNHEIM, Germany; [4]Institute for Clinical Molecular Biology, University of Kiel, KIEL, Germany

Somatically acquired oncogenic fusion genes are widespread in haematological malignancies. Whilst much is known about fusions associated with cytogenetically visible abnormalities, the prevalence and nature of those arising from cryptic rearrangements remains largely unexplored. The aim of our study was to systematically search for cryptic fusion genes in patients with atypical myeloproliferative neoplasms (aMPNs), exploiting the fact that most of these abnormalities are associated with small genomic copy number changes that interrupt the target genes. To achieve this, we designed a custom comparative genomic hybridization (CGH) array using the Agilent 4x44K platform that targeted 500 candidate genes, including all tyrosine kinases, genes involved in oncogenic rearrangements and a selection of other oncogenes and haemopoietic signalling molecules. In an initial screen of 37 aMPNs, one case with hypereosinophilic syndrome (HES) showed an amplification with a breakpoint within TFG. This gene is a known target of acquired chromosomal translocations that generate fusions with ALK, NTRK1 and NOR1 in anaplastic large cell lymphoma, thyroid carcinoma and skeletal mixoid chondrosarcoma. The breakpoints were clarified by hybridization of the same sample to an Agilent 244K whole genome array, which demonstrated an amplicon of 111kb with breakpoints in intron 3 of TFG and intron 1 of the proximal gene, GPR128 (G-protein coupled receptor 128). In their normal configuration at 3q12, both genes are in identical orientations, with TFG immediately downstream of GPR128. FISH analysis showed single signals on each chromosome 3 with no evidence of episomal amplification and thus the amplification most likely results in a TFG-GPR128 fusion situated between the two normal parental genes. RT-PCR analysis confirmed the presence of an in frame chimaeric TFG-GPR128 mRNA and analysis of 575 further aMPNs revealed seven additional fusion positive cases. Unexpectedly, TFG-GPR128 mRNA remained strongly positive in a remission sample from one of these individuals. Analysis of healthy individuals revealed TFG-GPR128 at the same frequency (0.02) as that seen in MPNs, indicating that the fusion is a constitutional variant resulting from a polymorphic copy number variant (CNV) rather than an acquired somatic mutation. Analysis of POPGEN cohorts (N=1259), a German population based biobank, uncovered a further 16 positive cases with either one or two copies of TFG-GPR128, but no association with any clinical phenotype was observed. The TFG and GPR128 breakpoint regions in all cases share a region of microhomology (11/12bp identical) and flanking marker analysis indicates a single ancestral origin. Whilst it is remarkable that TFG is also the target of acquired oncogenic translocations, based on published breakpoints there is no evidence for a common mechanism of somatic and germline TFG fusion gene formation. An extensive in silico search of EST databases failed to reveal any other CNV-associated fusion transcripts, suggesting this is an uncommon event. Nevertheless, the finding of a polymorphic constitutional gene fusion adds another layer to the complexity of human genome variation.

Acute myeloid leukemia - Biology I

RNAI-BASED IDENTIFICATION OF NOVEL SENSITIZERS TO 5-AZACYTIDINE IN MYELOID LEUKEMIAS

R. Tibes, J. Bogenberger, A. Choudhary, I. Monzon, D. Chow, J. Kiefer, O. Azorsa

Translational Genomics Research Institute, SCOTTSDALE, USA

Background. New therapy approaches for patients with acute myeloid leukemia (AML) are urgently needed. Aberrant methylation plays a crucial roles in leukemogenesis. Hypomethylating agents like 5-Azacytidine (5-Aza) show promise in AML. However, complimentary mechanisms, such as kinase activating events and interference with apoptosis and cell-cycle contribute to malignant transformation. Consequently, single agents activity of epigenetic therapies is limited. However, which are the targets whose inhibition augments 5-Aza's effectiveness is largely unknown. *Aims*. The aim was to identify, confirm and functionally validate novel candidate genes identified by High-Throughput RNA interference (HT-RNAi), that sensitize to epigenetic therapies in AML. Therefore, a HT-RNAi platform for transient gene silencing in acute myeloid leukemia cells was developed and a large-scale RNAi gene silencing screen (572 kinase, 500 cancer associated genes) in combination with 5-Aza was performed. *Methods*. Using lipid-based reverse transfection, cells were incubated with 2 different siRNA sequences per gene targeting 572 kinases and 500 cancer genes (i.e. anti-apoptotic, cell-cycle checkpoints etc). At 48 hrs, 5-Aza at IC15 and 30 was added and cell proliferation measured using a luminescence-based assay at 96 hrs. Data was background corrected and analyzed using the B-score method to report strength and statistical significance of growth inhibition compared to untreated controls ± siRNA. B-scores of <-2 indicate statistical significance with $p<0.05$ (>95% confidence); B-scores <-1.5 provide >87% confidence and were used as lowest cutoff given screens were focused and contain validated siRNA. 4x RNAi (4 siRNA sequences/gene) validation was performed. *Results*. Two independent RNAi screens per line in three cell lines (TF-1, ML-2, THP1) were performed with 5-Aza at the IC15 and 30 respectively. Transfection efficacy was between 65% (ML-2) to >90% (TF-1) compared to non-silencing and buffer control. Results suggest universal as well as cytogenetic and FAB subgroup specific sensitizing targets. Analysis of TF-1 and ML-2 kinome data identified 14 and 11 kinases respectively, whose silencing by 2/4 siRNA sequences at a B-score <-1.5 from both screens sensitized to 5-Aza. In ML-2 cells, 2 kinases were highly significant with a B-score for both siRNA <-2. Three kinases were common targets in both cell lines with growth inhibition for 2/4 siRNA per line of at least <-1.5, making these kinases potential universal modifiers of 5-Aza response in myeloid cells. THP-1 data will be used as independent confirmation. From the 500 cancer gene RNAi, few strong 5-Aza sensitizers emerged. Among the top hits are cyclin-dependent kinase (CDK) and anti-apoptotic BCL-2 family member proteins/genes, which have validated in secondary RNAi screens with 4x coverage. Several other high-priority candidate targets were identified and combination experiments with small molecules targeting identified genes are ongoing (presented at the meeting). *Summary and Conclusions*. Herein, we present the first large-scale RNAi screen in myeloid cells in combination with 5-Aza. Specific kinases and genes were identified that sensitize to hypomethylating agents. Functional genomics using RNAi provide a fast and attractive approach to identify molecular targets in AML and this approach holds particular promise to develop and design rational combination therapies that can be rapidly translated into the clinic.

0537

TWO DIFFERENT EVI1 EXPRESSING POOR-RISK AML SUBGROUPS WITH DISTINCT EPIGENETIC SIGNATURES UNCOVERED BY GENOME WIDE DNA METHYLATION PROFILING

S. Lugthart,[1] M.E. Figueroa,[2] L. Skrabanek,[2] P.J.M. Valk,[1] Y. Li,[2] C. Erpelinck,[1] B. Lowenberg,[1] A. Melnick,[2] R. Delwel[1]

[1]Erasmus MC, ROTTERDAM, Netherlands; [2]Weill Cornell Medical College, NEW YORK, USA

Background. Acute myeloid leukemia (AML) constitutes a heterogeneous group of diseases with variable clinical outcomes. The development of patient-specific therapy could potentially significantly improve therapeutic efficacy. We are interested in better understanding the biological features associated with aberrant expression of the EVI1 oncogene, which is associated with an extremely poor prognosis. EVI1 is located on chromosome 3q26. This nuclear zinc-finger transcriptional repressor interacts with HDACs, CtBPs, histone methyltransferases and MBD3. We hypothesize that abnormal EVI1 alters epigenetic programming in AML. *Aims*. We wished to elucidate whether EVI1 over-expression in human AML may act as an epigenetic regulator and is associated with specific epigenetic signatures. *Methods*. We studied genome wide DNA methylation in 295 AML patients (including 26 EVI1 AMLs) and 8 $CD34^+$ normal bone marrow controls (NBM) using the HELP assay (HpaII tiny fragment enrichment by ligation-mediated PCR), which measures with >95% accuracy the abundance of DNA methylation covering ~13,000 promoter regions. *Results*. Unsupervised analysis using hierarchical clustering segregated a cohort of 295 AMLs into 16 unique epigenetic clusters. Among these well-defined clusters we could find known subtypes of AMLs: Cluster 6 contained all inv(16) cases, cluster 1 was 100% t(15;17), cluster 4 contained only CEBPA mutant cases and cluster 8 was significantly enriched for t(8;21). The EVI1 AMLs did not cluster into any of these well-defined groups, but we rather found that 6/26 and 7/26 cases clustered in two separate clusters; the remaining cases (n=13) scattered throughout the 16 clusters. Focusing on EVI1 AMLs, hierarchical clustering (Pearson correlation distance with Ward's clustering method) readily separated the EVI1 AMLs from NBMs. Supervised analysis using a moderate t-test comparing EVI1 cases to NBM identified 303 promoter sequences differently methylated ($p<0.001$ and methylation change >1.5). Of these genes 80% were hypermethylated in EVI1 patients. Sequence analysis revealed significant over-representation of portions of the first EVI1 binding domain (TGACAAGATAAGATAA) of respectively 6 and 4 bp in the hypermethylated promoter regions. The 26 EVI1 leukemias further segregated into two distinct subgroups using hierarchical clustering: One cluster (n=14) was enriched for AML cases carrying 3q26 abnormalities (n=7). The other cluster (n=12) mainly harbored AMLs carrying 11q23 translocations (n=7) an aberration associated with EVI1 over-expression. Supervised analysis comparing these two EVI1 clusters revealed that the 3q26-enriched group featured a 122-gene signature ($p<0.001$ and methylation change >1.5) consisting entirely of hypermethylated genes. Comparing each EVI1 cluster independently to NBM controls using a moderated t-test, the 3q26-enriched group contained a hypermethylated gene signature containing 429/476 hypermethylated loci. In contrast, the MLL-enriched subgroup showed more equally distributed methylation levels, i.e. 226/384 hypermethylated genes. *Summary and Conclusions*. These data show that genome-wide methylation analysis in AML identifies novel and biologically relevant subgroups of AML. Furthermore, EVI1 over-expression is associated with specific alterations in epigenetic programming vs. normal $CD34^+$ cells. We showed that EVI1 AMLs form two epigenetically distinct AML subtypes. Specifically, the 3q26-subgroup displays a marked hypermethylation signature. This hypermethylation profile of the EVI1 3q26-subgroup AMLs suggests that these patients might benefit from treatment with DNA methyltransferase inhibitors.

MICRORNA 29B FUNCTIONS IN ACUTE MYELOID LEUKEMIA

R. Garzon,[1] C.E.A. Heaphy,[2] V. Havelange,[2] S. Kornblau,[2] G. Marcucci,[2] M. Andreeff,[3] C.M. Croce[4]

[1]The Ohio State University, COLUMBUS, USA; [2]Nederland; [3]University of Texas - M D Anderson Cancer Center, HOUSTON, USA; [4]Ohio State University, COLUMBUS, OH, USA

Background. MicroRNAs (miRNAs) are associated with cytogenetics and molecular subtypes of acute myelogeneous leukemia (AML), but their impact on AML pathogenesis is poorly understood. *Aims*. We have previously shown that miR-29b expression is deregulated in primary AML blasts. In this work, we investigated the functional role of miR-29b in leukemogenesis. *Methods*. Using synthetic miR-29b oligonucleotides we transfected (nucleoporated) K562, Kasumi-1 cell lines (both with absent miR-29b expression) and primary AML blasts and examined cell viability, proliferation and apoptosis. A xenograft leukemia mouse model was developed to test the *in vivo* effects of miR-29b over-expression. To investigate the mechanism of miR-29b tumor suppressor function we analyzed the global transcriptome changes using Affymetrix microarrays after miR-29b over-expression in K562 cells. Microarray data was analyzed using the BRB software. Results were validated using quantitative RT-PCR, luciferase assays and Western blotting. Finally, a cohort of 45 primary AML samples was used to investigate the correlation (Spearman) between miR-29b expression and the mRNA transcriptome as detected by Affymetrix and miRNA microarrays. *Results*. Transfection of miR-29b into K562 and Kasumi-1 cells decreased cell viability, prolif-

eration and increased apoptosis by 3.4 and 2 fold respectively with respect to the controls (p=0.01 and p=0.04, t-test). Apoptosis induction by miR-29b was associated with caspase 3 and 7 activation as shown by Western Blotting. Furthermore, over-expressing miR-29b in both cell lines enhanced cytarabine induced apoptosis by 1.6 fold (p=0.007). Restoration of miR-29b in there primary AML blasts resulted in apoptosis induction and increased chemotherapy sensitivity. Next, we tested whether miR-29b could reduce tumorigenicity in a xenograft model; ~10 million viable K562 cells were inoculated subcutaneously in both flanks of immunocompromised mice. When tumors reached 50 mm3, synthetic miR-29b (left side) or scrambled oligonucleotides (right side) were injected directly into the tumors. At 10 and 14 days following the first injection, tumors injected with synthetic miR-29b (n=12) were significantly smaller than the scrambled oligonucleotide (n=12) and mock controls (n=6) (p=0.003). At day 14, the average tumor weights for control and the synthetic miR-29b inoculated mice were 0.79g and 0.089 g, respectively (p=0.001). Transcriptome analysis after ectopic transfection of synthetic miR-29b into K562 cells indicates that miR-29b target apoptosis (MCL-1), cell cycle (CDK6, CCND2) and proliferation pathways genes (IGFR, JAK2). Among the 360 genes down-regulated after miR-29b transfection, 68 genes were miR-29b predicted targets according to TargetScan. We validated the microarray results for MCL1, CDK6, CCND2 and CXXC6 using using qRT-PCR, Western blotting and luciferase assays. Last we correlated miR-29b expression with whole mRNA expression in 45 primary AML samples. A significant enrichment for apoptosis genes, including MCL-1, was found among the mRNAs inversely correlated with miR-29b expression (p=0.0007). *Conclusions*. Restoration of miR-29b in AML cell lines and primary samples induces apoptosis, increases chemotherapy sensitivity and dramatically reduces tumorigenicity in a xenograft leukemia model. Together, the data support a tumor suppressor role for miR-29b and provide a rationale for the use of synthetic miR-29b oligonucleotides as a novel strategy to improve treatment response in AML.

0539

ABERRANT METHYLATION OF WNT PATHWAY INHIBITORS AND ITS COOPERATION WITH OTHER GENETIC ALTERATIONS WITH DISTINCT CHARACTERISTICS IN ACUTE MYELOID LEUKEMIA

H.-A. Hou, W.-C. Chou, L.-I. Lin, C.-Y. Chen, J.-L. Tang, M.-H. Tseng, C.-F. Huang, Y.-C. Chiang, M. Yao, S.-J. Wu, S.-Y. Huang, B.-S. Ko, W. Tsay, Y.C. Chen, H.-F. Tien

National Taiwan University Hospital, TAIPEI, Taiwan

Background and Aims. Wnt signaling pathway has been shown to play a pivotal role in stem cells self-renewal and proliferation and be crucial to the organ system development. Emerging evidences show that aberrant activation of Wnt signaling and downstream effectors is involved in several human malignancies, including acute myeloid leukemia (AML). We therefore evaluated the abnormal promoter methylation of several Wnt inhibitors in patients with AML and correlated the results with clinical and biologic features. *Methods*. We investigated the promoter hypermethylation of 8 Wnt inhibitors (Wif-1, HDPR1, sFRP1, sFRR2, sFRP4, sFRP5, DKK1, and Wnt5A) using methylation specific polymerase chain reaction (MS-PCR) in a cohort of 165 patients with newly diagnosed de novo AML at the National Taiwan University. The results were correlated with clinical features, laboratory data, immunophenotypes and other gene mutations. *Results*. Among the 165 patients, 95 were males and 70 were females. The median age was 47 years. The frequencies of hypermethylation of Wnt inhibitors at diagnosis (in descending order) were as follows: 36.9% for DKK1, 33.9% for sFRP1, 31.5% for sFRP2, 21.9% for Wif-1, 21.8% for sFRP5, 11.5% for Wnt 5A, 3.6% for sFRP4 and none for HDPR1. Taken together, 116 AML patients (70.3%) had hypermethylation of at least one (ranging from one to 7) Wnt inhibitor. Among them, 69 patients (59.5%) had 2 or more genes hypermethylation. The patients with aberrant methylation of at least one Wnt inhibitor had lower WBC count and LDH value at diagnosis (p=0.0023 and 0.0243, respectively) and tended to be older (p=0.0802) than others. The majority (75%) of patients with Wnt inhibitor hypermethylation had concurrent Class II gene mutations that affect transcription factors resulting in impaired hematopoietic differentiation. Wif-1 hypermethylation occurred more frequently in the patients with t(15;17) than in those with other chromosomal abnormalities (p=0.0459), while DKK-1 hypermethylation was preferentially demonstrated in those with t(8;21) (p=0.0087). Hypermethylation of Wif-1 and Wnt-5A is positively correlated with CEBPA mutation (p=0.0107 and 0.0239, respectively) and sFRP-2 hypermethylation was positively correlated with MLL/PTD (P=0.0334). On the other side, hypermethylation of DKK-1, sFRP-1 and sFRP-5 was negatively associated with NPM1 mutation (p=0.0015, 0.0258 and 0.0375, respectively). In term of outcome, the complete remission rate, disease-free survival (DFS) and overall survival (OS) of the patients with hypermethylation of at least one Wnt inhibitor were similar to others. However, subgroup analysis did reveal that the Wnt inhibitor hypermethylation was a poor risk factor for DFS and OS in those patients with favorable karyotype (p=0.031 and 0.05, respectively). For individual Wnt inhibitors, hypermethylation of sFRP1, sFRP4 and DKK-1 was closely associated with poor outcome in this subgroup of patients. *Conclusions*. These results provide evidence that AML patients afflicted with Wnt inhibitor hypermethylation had distinct biologic characteristics and the methylation might be associated with poor prognosis in subsets of patients. The Wnt inhibitor hypermethylation might cooperate with other genetic alterations in leukemogenesis.

USING RNAI TO IDENTIFY NOVEL MOLECULAR VULNERABILITIES IN MYELOID LEUKEMIAS

R. Tibes, J. Bogenberger, A. Choudhary, I. Monzon, J. Kiefer, D. Chow, S. Mousses, S. Mousses, O. Azorsa

Translational Genomics Research Institute, SCOTTSDALE, USA

Background. Treatment strategies and outcomes of patients with Acute Myeloid Leukemia (AML) remain dismal. Largely, because critical targets regulating myeloid cell viability remain elusive. In order to improve treatment strategies for AML, we adapted a functional genomics approach using RNA interference (RNAi) to identify novel molecular targets that are vital to the growth of myeloid cells. Herein we report the first large-scale RNAi kinome gene-silencing screen in AML. *Aims*. A high throughput screen was developed for the efficient reverse siRNA transfection of AML cell lines in order to utilize RNAi to systematically evaluate molecular vulnerabilities in AML to advance patient care. *Methods*. Eight commercially available cationic lipid-based transfection reagents were tested for their ability to transfect myeloid cell lines with siRNA. Extensive transfection optimization experiments identified several AML lines (i.e. TF-1 and ML2) with up to 95-100 and 65-75% transfection efficiency, respectively. Three independent replicate kinome screens were performed on both cell lines using a siRNA library targeting 572 kinase genes with 2 siRNA/gene, as well as a 500 cancer siRNA gene set. At 96 hours post transfection, cell proliferation was assessed and the B-score method was used to background correct and analyze the screening data. B-scores of <-2 indicate statistical significance with p<0.05. Top hits were validated using 4x siRNA coverage (4 sequences/gene). *Results*. Several siRNA to specific kinases were identified that significantly inhibit cell proliferation of up to ~40-88%. In TF-1 the strongest hit was positive for 6/6 siRNA (both sequences) at a B-score <-2. This gene exerts essential control during the cell-cycle. Two additional genes were found to have 5/6 and 4/6 siRNA at B<-2, one of them Polo-like Kinase (PLK). In ML-2 two genes had 3/3 siRNA of a single sequence and 18 genes had 2/3 siRNA at a B-score <-2 (one of them PLK), respectively. A total of 32 hits (8%) at the least stringent criteria (2/3 same sequence siRNA, B<-2) were found in TF-1 and 18 hits (3%) in ML-2 out of 572 kinases. Two hits were overlapping between different cell lines representing potential universal myeloid growth controlling genes. Several hits were advanced into 2nd screening and the 6/6 hit validated powerfully. Confirmation of gene silencing and functional validation is currently underway for a subset of genes. Among the strongest hits are siRNA targeting PLK1, as well as siRNA targeting other kinase-genes involved in regulating cell cycle progression and checkpoints. Gene ontology (GO) analysis showed enrichment in cell cycle and cell cycle-checkpoint processes. *Summary and Conclusions*. Here, we present the successful establishment of a high-throughput reverse RNAi transfection platform in myeloid suspension cells. Excellent and specific transfection efficacy was achieved with little non-specific toxicity. Specific kinases and genes were identified, including PLK and other cell cycle genes/kinases that could be exploited therapeutically. Importantly, the RNAi approach is being used to generate a list of validated candidate targets that centrally govern myeloid cell growth and survival. These candidates represent novel molecular vulnerabilities which could serve as targets for therapeutic intervention and guide AML drug development.

Biology of B-cell disorders

GENOME-WIDE ANALYSIS IDENTIFYS FREQUENT INACTIVATION OF A20 IN B-CELL TYPE MALIGNANT LYMPHOMAS

M. Kato,[1] M. Sanada,[1] I. Kato,[2] Y. Sato,[3] J. Takita,[1] K. Takeuchi,[4] A. Niwa,[2] Y. Chen,[1] K. Nakazaki,[1] J. Nomoto,[5] Y. Asakura,[5] Y. Akatsuka,[6] Y. Hayashi,[7] H. Mori,[8] T. Igarashi,[1] M. Kurokawa,[1] S. Chiba,[1] S. Mori,[9] Y. Ishikawa,[4] K. Okamoto,[5] K. Tobinai,[5] H. Nakagama,[5] T. Nakahata,[2] T. Yoshino,[3] Y. Kobayashi,[5] S. Ogawa[1]

[1]University of Tokyo Hospital, TOKYO; [2]University of Kyoto, KYOTO; [3]University of Okayama, OKAYAMA; [4]The Cancer Institute of Japanese Foundation for Cancer Research, TOKYO; [5]National Cancer Center Hospital, TOKYO; [6]Aichi Cancer Center Reserch Institute, NAGOYA; [7]Gunma Children's Medical Center, SHIBUKAWA; [8]Showa University Fujigaoka Hospital, YOKOHAMA; [9]University of Teikyo, TOKYO, Japan

Background. Malignant lymphomas of B-cell lineages are mature lymphoid neoplasms arising from various lymphoid tissues that consist of different pathological entities. Although the presence of balanced chromosomal translocations is among conspicuous genetic features characterizing specific histology types, unbalanced genetic changes, i.e., gains and deletions of chromosomal segments, are also common abnormalities in B-lineage lymphomas and thought to be involved in the pathogenesis of lymphoma. *Aims*. To obtain a comprehensive registry of genetic lesions in B-lineage lymphomas, and to identify the genes relevant to lymphomagenesis, we performed a SNP array analysis of 238 primary B-cell lymphoma specimens of different histologies. *Methods*. We used Affymetrix GeneChip 250K genomic microarray for 238 primary lymphoma samples, including 64 samples of diffuse large B-cell lymphomas (DLBCL), 52 of follicular lymphomas (FL), 35 of mantle cell lymphomas (MCL), and 87 of mucosa-associated tissue (MALT) lymphomas. Three Hodgkin lymphoma (HL) derived cell line was also analyzed. Twenty four HL primary samples were also included for mutation analysis. *Results*. Through a genome-wide analysis, we identified that each histology type had a unique genomic signature, suggesting a distinctive underlying molecular pathogenesis for different histology types. Genetic lesions on the NF-κB pathways were common in B-cell lymphomas and found in approximately 40% of the cases, which underpinned the importance of aberrant NF-κB activation in lymphomagenesis. However, our most notable findings is that A20, a key regulator of NF-κB signaling, is a common genetic target in B-lineage lymphomas and frequently inactivated by somatic mutations and/or deletions in MALT lymphoma (21.8%) and HL of nodular sclerosis histology (33.3%), and to a lesser extent, in other B-lineage lymphomas. When re-expressed in a lymphoma-derived cell line with no functional A20 alleles, wild-type A20, but not mutant A20, resulted in suppression of cell growth and induction of apoptosis, accompanied by down-regulation of NF-κB activation. The A20-deficient cells stably generated tumors in immunodeficient mice, whereas the tumorigenicity was effectively suppressed by re-expression of A20. The cell growth and NF-κB activity that were suppressed by re-expressed A20 in the A20-deficient cells, depended at least partly on signals through cell surface receptors, including TNF receptor. *Conclusions*. We found that uncontrolled signaling of NF-κB caused by loss of A20 function is involved in the pathogenesis of subsets of B-lineage lymphomas. Considering the physiological function of A20 in the negative modulation of NF-κB activation induced upon a variety of upstream stimuli, our observations provide an intriguing insight into an association between inflammation and lymphomagenesis.

MIR-17~92 UPREGULATION IN B-CELL LYMPHOMA CELLS AFTER CRYPTIC INSERTION AT BCL6

B. Schneider, S. Nagel, M. Kaufmann, H.G. Drexler, R.A. MacLeod

DSMZ - German Collection of Microorganisms and Cell Cultures, BRAUNSCHWEIG, Germany

Background. Although micro-RNA (miR) genes undergo transcriptional deregulation by genomic deletion or amplification, evidence for deregulation by chromosome translocations (which provide clues to regulatory DNA/chromatin) remains tentative. We recently described t(3;7)(q27;q21) in diffuse large B-cell lymphoma (DLBCL) whereby BCL6 is joined to a common chromosomal fragile site (FRA7H) hosting miR-29-b1 which was conspicuously downregulated (Schneider *et al.*, Leukemia 22: 1222-6, 2008) thus providing an indirect link between chromosome fragility, rearrangement and miR gene deregulation. *Aims*. We now describe a more direct link between chromosome fragility, oncogenic chromosome rearrangement and miR deregulation. *Methods*. Fluorescence *in situ* hybridization (FISH) using tyramide amplification and long distance Inverse (LDI) - PCR were used to screen and map BCL6 rearrangements in DLBCL cell lines. Reverse-transcriptase (RT) and genomic quantitative (q)-PCR, were used to quantify genomic dosage and expression. 3´-rapid amplification of c-DNA ends (RACE) was used to detect novel fusion transcripts. Stress induced duplex destabilization (SIDD) analysis which measures local GC content and DNA superhelicity was used to predict genome stability in silico. *Results*. We characterized a new BCL6 translocation t(3;12)(q27;p11) and showed it to join 5´-BCL6 to ITPR2, a gene preferentially expressed in germinal center B-cells. LDI-PCR unexpectedly revealed junction of 5´-BCL6 to chromosome 13 sequences inside the miR-17~92 host gene MIRH1 (alias C13orf25). FISH using MIRH1 clones confirmed cryptic BCL6-MIRH1 rearrangement. Despite chromosomal involvement with BCL6, 3´-MIRH1 primers RT-qPCR revealed only weak MIRH1 expression. Repeating the assay with primers covering the embedded miR-17~92 cluster region showed 5x upregulation of pri-miR and 13-18x upregulation of mature miRs. Interestingly, 3'-RACE revealed a novel MIRH1 transcript which was truncated by 3.1 kbp. Genomic qPCR and FISH both excluded miR-17~92 genomic copy number amplification. LDI-PCR showed multiple DNA cuts at 3q27, 12p11, and 13q31 - the last including a complex excision/inversion/insertion. Thus we identified a novel BCL6 fusion transcript (ITPR2-5´BCL6) from which MIRH1 sequences predicted from LDI-PCR data had been spliced out. Treatment with histone deacetylase inhibitor (trichostatin) further upregulated expression of 5´-BCL6 fusion mRNA (15x), MIRH1 (4x), and individual miR-17~92 cluster genes (2-3x), while control cell lines showed downregulation. SIDD analysis which predicts DNA fragility revealed that 6/7 breaks in the t(3;13)(q27;q31)t(13;12)(q31;p11) precisely coincide with fragility peaks. *Summary and Conclusions*. Our data document massive miR-17~92 upregulation in DLBCL cells due to chromosome rearrangement at regions of genomic fragility. Since SIDD fragility peaks host promoter regions, replication origins in yeast, and (regulatory) scaffold/matrix-attachment regions in mammalian cells, we propose that miR deregulation may involve de novo generation of regulatory DNA sequences and acetylation-responsive chromatin by chromosome rearrangement. Taken together, these data also suggest a possible role for BCL6 translocations in the deregulation of miR genes near sites of chromosome or DNA instability. Future studies will address the putative regulatory roles of superhelical DNA regions and chromatin proteins in mediating miR gene dysregulation.

EBV MICRORNA EXPRESSION IN AN IN-VITRO MODEL OF B-CELL DIFFERENTIATION AND LYMPHOMAGENESIS

P. Nourse, K. Jones, P. Crooks, M.K. Gandhi

Queensland Institute of Medical Research, BRISBANE, Australia

Background. Lymphomagenesis is a complex process, which in part reflects the nature of the transforming event, as well as the stage of differentiation of the cell. The majority of B-cell lymphomas are derived from germinal centre (GC), or post-GC B-cells. The Epstein Barr virus (EBV) is implicated in a range of GC and post-GC derived B-cell lymphomas including Post-Transplant Lymphoproliferative Disorders and a subset of Diffuse Large B cell Lymphomas. EBV infects and activates naïve B-cells through a process paralleling the GC reaction. Interruption of this process by a transforming event may result in a clonal proliferation where differentiation of the cell is blocked at this stage. Human models of B-cell differentiation are lacking, however the use of EBV infection of isolated human naïve B-cell may provide an in-vitro model of this process. MicroRNAs (miRNAs) are small non-coding RNAs, which act as negative regulators of gene expression. miRNA expression has been demonstrated to be associated with the developmental lineage and differentiation state of several human cancers. EBV expresses at least 39 miRNAs from two clusters within the BART and BHRF1 regions of the viral genome. EBV miRNAs are differentially expressed in tumour cell lines, suggesting distinct roles during EBV-driven B-cell differentiation and lymphogenesis. We propose that EBV miRNAs may play a role in EBV-driven B-cell differentiation and lymphomagenesis. *Aims*. To determine if EBV miRNAs may be associated with the EBV-driven differentiation of naïve B-cells. *Methods*. Using high efficiency EBV infection of isolated naïve B-cells the expression levels of EBV miRNAs, along with host markers of B-cell differentiation were determined by real time RT-

PCR. The expression profile of the EBV miRNAs was then correlated with the differentiation state of the cells as determined by the expression of host marker genes. *Results*. Alterations in the expression of genes associated with the differentiation of the naïve B-cell were observed within 24 hours of infection. Levels of BCL6 were rapidly down regulated within 24 hours indicating activation of the naïve B-cell. Levels of the memory cell marker CD27 steadily increased over 24 to 96 hours, while BLIMP1 expression increased, peaking at 48 hours. Finally an increase in AID expression over 8 to 48 hours was suggestive of somatic hypermutation. These observations are indicative of B-cell differentiation taking place within four days of infection in a process exhibiting many similarities to the GC reaction. Examination of 28 EBV miRNAs revealed the majority to exhibit distinct expression profiles within 72 hours of infection. Interestingly one group (BARTs 20-3p, 4 20-5p and 1-5p) was rapidly expressed within 8 hours of infection and then down regulated after 24 to 48 hours. The only EBV miRNA not expressed during the time course examined was BART11-3p. *Conclusions*. The finding of distinct EBV miRNA expression kinetics, coincidental with several gene expression changes indicative of B-cell differentiation, suggests the possibility these regulatory molecules may be involved in this process. Current work in our lab involves the elucidation of EBV miRNA cellular targets that may play a role in EBV driven B-cell differentiation.

HIGH EARLY MORTALITY AND POOR OUTCOMES FOR PATIENTS WITH AL AMYLOIDOSIS PRESENTING WITH HIGH SERUM FREE LIGHT CHAINS - A NEW RISK STRATIFICATION MODEL

A.D. Wechalekar,[1] N. Wassef,[2] H. Lachmann,[1] P. Sattianayagam,[1] S.D.J. Gibbs,[1] J. Gillmore,[1] P.N. Hawkins[1]

[1]*University College London Medical School (Royal Free Campus), LONDON;* [2]*Royal Free Hospital, LONDON, UK*

Background. The prognosis of patients with AL amyloidosis has significantly improved over the last decade with a median survival of nearly 5 years. However, a substantial proportion of patients remain at risk of early death and there is a need to identify such patients at diagnosis to allow for appropriate risk stratified treatment. Markers of organ function, ECOG performance status and cardiac biomarkers like NT-ProBNP have all been described for risk stratification. We report for significantly poorer outcomes and a very high risk of early death for patients with high presenting free light chain from a large cohort of 644 unselected of patients with newly diagnosed AL amyloidosis and should be added to the factors for AL risk stratification. *Methods*. All patients with systemic AL amyloidosis attending the UK National Amyloidosis Centre with complete data sets for FLC and conventional serum and urine monoclonal protein prior to any treatment between Jan 2001 and March 2008 were identified from the database and 644 such cases were identified. *Results*. Median age was 64 years (range 26-88), male: female ratio was 1.3:1. Median serum creatinine was 149 µmol/L (37-1079), and 24 hour proteinuria 3.9g (<0.1- 20g) with renal involvement being the commonest followed by cardiac. The FLC ratio was abnormal in 507 (79%) patients, with a lambda bias in 370 (57%) cases and a kappa bias in 137 (21%); concentration of the abnormal class of FLC exceeded 100mg/L in 308 (83%) cases for lambda and in 117 (85%) with a kappa, and median values were 256mg/L and 379mg/L respectively. In serum, a monoclonal was identified in 446 (69%) patients [median 6g/L and in 336 (52%)]. The median overall survival (OS) of the cohort was 27 months with no significant difference in the OS for patients with either kappa or lambda as the abnormal component. Patients with an abnormal FLC ratio were stratified by the absolute FLC value in three best fit cohorts according to the presenting abnormal component (aFLC). The median survival of patients with presenting aFLC <150mg/L was 63 months, with aFLC of 151-500mg/L was 22 months and those with aFLC >500mg/L was only 10 months (log rank p<0.0001). These differences in survival were especially significant for patients presenting with a creatinine clearance of >30mL/min (median survival of 14, 28 and 63 months respectively) but also for patients presenting with a creatinine clearance <30mL/min was 14, 5 and 7 months respectively. There was a very high early mortality in patients presenting with high free light chains with 30%, 55% and 70% of each group respectively dying by 2 years of evaluation. The correlation of presenting free light chains and organ involvement will be presented. *Conclusions*. The absolute presenting free light chain value is a strong prognostic factor for patients with AL amyloidosis. Patients presenting with an absolute FLC of >500mg/L have a very poor overall survival and high risk of early mortality. Free light should be used for AL risk stratification and the poor risk cohort may benefit from treatment (like bortezomib or CTD) achieving very rapid light chain responses.

Background. The quantification of bone marrow (BM) plasma cells (PC) by conventional morphology (CM) in multiple myeloma (MM) patients has shown limited prognostic value, whereas the use of multiparameter flow cytometry (MFC) immunophenotyping is still considered investigational. *Aims*. To compare the BMPC quantification by CM and MFC and to assess the prognostic value of both techniques in a large series of uniformly treated MM patients.

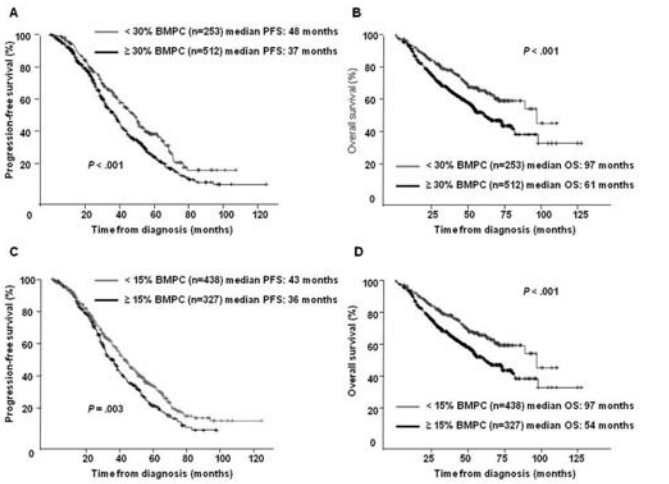

Figure 1.

Methods. A total of 765 untreated symptomatic MM patients were included in the present study, all of them uniformly treated according to the Spanish GEM2000 protocol. BM "first-pull" aspirate samples were used for morphological assessment, stained with May-Grümwald-Giemsa and using a conventional optical microscope. The PC quantification was obtained from a 200-cell differential count. For MFC analysis, BM samples were stained using a four-color direct immunofluorescence technique that allowed the identification of PC. *Results*. As expected, the median percentage of BMPC measured by CM (40%; range: 1% - 100%) was significantly higher (p<0.001) than by MFC (11%; range: 0.05% - 95%). Higher infiltration by CM was detected in the majority of patients (93%, N=709), with equal PC levels in 3% of cases (N=27), and only in 4% of cases (N=29) the percentage of PC obtained by MFC was superior to CM. Interestingly, PC enumeration showed a significant correlation between both CM and MFC techniques (R2= 0.46; p<0.001). The PC count assessment by CM as well as MFC discriminate different risk groups, with an optimal cut-off value of 30% and 15% BMPC for CM and MFC assessment, respectively. Thus, patients with <30% BMPC detected by CM at diagnosis showed significantly longer PFS (median 48 vs. 37 months; p<0.001; Figure, Panel A) and OS (median 97

vs. 61 months; $p<0.001$; Panel B) than patients with ≥30% BMPC. Considering MFC, cases with <15% BMPC had significantly longer PFS (median 43 vs. 36 months; $p=0.003$; Panel C) and OS (median 97 vs. 54 months; $p<0.001$; Panel D) than cases with ≥15% BMPC. Other baseline factors with significant impact on univariate analysis for survival were: age, anemia, high levels of calcium and serum creatinine, ISS III, percentage of PC in S-phase >1.5% and high-risk cytogenetics (t(4;14), t(14;16), or del(17p)). By multivariate analysis, only high-risk cytogenetics was selected as an independent prognostic factor for both PFS and OS (Hazard ratio, HR: 2.7; $p<0.001$ and HR: 2.6; $p<0.001$, respectively), and also age (HR: 1.6; $p=0.03$) and the percentage of PC detected by MFC (HR: 2.3; $p=0.006$) showed independent prognostic value for OS. *Conclusions.* Our results show in a very large series of patients uniformly treated that MFC immunophenotyping is a valid method for the evaluation of the PC burden in the BM of symptomatic MM patients at diagnosis, with a significant correlation with CM, and, more important, with independent prognostic value for the prediction of survival. Taken together, these results support the incorporation of MFC immunophenotyping in the diagnostic routine evaluation of all MM patients.

Allogeneic stem cell transplantation

0546

FACTORS DETERMINING SURVIVAL AFTER UNRELATED DONOR ALLOGENEIC STEM CELL TRANSPLANTATION IN PRIMARY REFRACTORY ACUTE MYELOID LEUKAEMIA

C. Craddock,[1] M. Labopin,[2] C. Schmid,[3] V. Rocha[4]

[1]Queen Elizabeth Hospital, BIRMINGHAM, UK; [2]Hopital St Antoine, PARIS, France; [3]Klinikum Augsburg, AUGSBURG, Germany; [4]Hopital St Louis, PARIS, France

Background. Allogeneic stem cell transplantation from an HLA identical sibling donor has the capacity to produce long term disease free survival in a significant number of patients with primary refractory acute myeloid leukaemia (AML). The increased availability of volunteer unrelated donors now permits allogeneic transplantation to be performed in patients with primary refractory AML but there has been no systematic analysis of outcome in this setting. *Aims*. We have analysed the outcome and factors determining overall survival after unrelated donor transplantation in patients with primary refractory AML. *Methods*. 186 adults with primary refractory AML who underwent an unrelated donor transplant from 1995 to 2006 in Europe were studied. All patients were refractory to induction chemotherapy having received a mean of 2.2 courses of chemotherapy (range 1 to 6). Cytogenetic status at diagnosis is available in 96 patients: 3 patients had good risk cytogenetics, 60 intermediate risk and 33 adverse risk cytogenetics by MRC criteria. The median interval from diagnosis to transplant was 4.2 months (range 2-6 months). 141 patients underwent transplantation from a 6/6 matched unrelated donor and 45 from a mismatched unrelated donor. 150 patients were transplanted using GCSF mobilised peripheral blood stem cells. 136 patients were transplanted using a myeloablative conditioning (MAC) regimen. 50 patients were transplanted using a reduced intensity conditioning (RIC) regimen of whom 30 received a low dose TBI based regimen. *Results*. The 2 year overall survival for the whole group was 31% and 43% for patients who achieved a CR post-transplant. 137 patients achieved a complete remission (CR) post-transplant. The day 100 non-relapse mortality was 16% (19% for MAC allografts v 9% for RIC allografts). In univariate analysis time to transplant (<4.2 months), presentation white blood cell count, the absence of circulating blasts at the time of transplant, and the use of a RIC regimen were associated with improved survival. Adverse risk cytogenetics at diagnosis was associated with a decreased OS. In multivariate analysis a short time from diagnosis to transplant ($p=0.05$), the absence of adverse risk cytogenetics ($p=0.02$) and the use of a RIC regimen (p=0.036) were associated with improved survival. The improved survival in patients receiving a reduced intensity transplant occurred despite their increased age at the time of transplant (54 years v 40 years). *Conclusions*. On the basis of this study we conclude that there is an important role for unrelated donor transplantation in the management of primary refractory AML-particularly if performed early after diagnosis. The encouraging results obtained using a RIC require further examination

0547

A RANDOMIZED CONTROLLED CLINICAL STUDY : COINFUSIONG OF MESENCHYMAL STEM CELLS IN HAPLOIDENTICAL HEMATOPOIETIC STEM-CELL TRANSPLANTATION CAN FACILITATE PLATELET RECOVERY BUT FAIL TO PREVENT GVHD

K.Y. Liu,[1] C.H. Zhao,[2] Y.H. Chen,[1] L.P. Xu,[1] H. Chen,[1] D.H. Liu,[1] X.H. Zhang,[1] W. Han,[1] Y. Wang,[1] T. Zhao,[1] J.Z. Wang,[1] J. Wang,[1] Q. Han,[2] Y. Zeng,[2] X.J. Huang[1]

[1]Institute of Hematology, People's Hospital, Peking University, BEIJING, Cocos Islands; [2]Basic Institute of Chinese Academy of Medical Science, Center of Tissue Engineer, BEIJING, China

Background. HSCT is an effective tool to treat hematological tumors and some non-malignant diseases. However, many of the patients can not find a HLA-matched donor. Over the past decade, it has been possible to induce the donor-recipient immunological tolerance through increasing the load of infused stem cells or by modulating cellular functions and graft composition, which greatly enhance the efficacy of haploidentical transplantation. In spite of those, the issues of graft rejection and graft-versus-host disease (GVHD) remain crucial. As confirmed by animal experiments, mesenchymal stem cells (MSC) do not only support hematopoietic functions, but also suppress the proliferation of lymphocytes in a dose-dependent fashion. Clinical studies have suggested that use of MSC may promote hematopoietic reconstitution and treat severe

acute hormone-resistant GVHD. No toxic side-effects related to MSC infusion have been reported till now. With regard to the issue of whether or not MSC could prevent the occurrence of GVHD, there were conflicting findings in animal models. *Aims*. To assess whether co-infusion with MSC in haploidentical HSCT would facilitate the hematopoietic recovery or decrease the rate of aGVHD. *Methods*. An open-label, randomized controlled phase II clinical study had been conducted. The control group received the routine institutional procedure of simple HSCT, whereas the treatment group was given a pre-infusion dose of 3-5-105 MSC cells/kg within 24 h. The study protocol was approved by the Peking University Ethics Committee. All the participating patients and donors provided written informed consent. *Results*. From June 2007 to June 2008, a total of 55 patients diagnosed with leukemia completed the entire study (27 in treatment group vs. 28 in control group) and follow-up continued until December 2008. The characteristic of patients were matched in both groups. All patients except one in the control group got myeloid engraftment. The mean time of WBC and platelet engraftment were 12 days (10-21 days) and 19.5 days (8-52 days) in treatment group, which were comparable with the 12 days (10-23 days) and 20 days (10-80 days) in control group. However, within 100 days, the time to platelets >50-109/L in the treatment group as compared with control group was markedly faster (22 days vs. 28 days; p=0.028). The accumulative occurrence rate of degree II above aGVHD were 51.8% (GVHD II : 13) and 38.9% (GVHD IV: 1; aGVHD II: 8) in treatment and control group (P=0.422). The overall accumulative occurrence rates of cGVHD were 45.4% and 61.9%, respectively (p=0.200). After a mean follow-up of 10 months (0.7-18.5 months), 1 patient in control group and 2 patients in the treatment group had the hematological relapse and 9 patients died during the study(control group:6; treatment group:3). The overall survival rate were 72.4% and 86.0% (p=0.306). Not any immediate or long-term toxic side-effects related to MSC infusion had been found. *Summary*. The use of MSC was both safe and feasible, and facilitates platelet recovery. Further studies are warranted to address the questions of whether MSC can be adopted to pretend the GVHD.

0548

A MULTICENTRIC COMPARATIVE ANALYSIS OF OUTCOMES OF HLA IDENTICAL RELATED CORD BLOOD AND BONE MARROW TRANSPLANTATION IN PATIENTS WITH BETA-THALASSEMIA OR SICKLE CELL DISEASE

N. Kabbara,[1] F. Locatelli,[2] V. Rocha,[1] S. Grafakos,[3] A. Ghavamzadeh,[4] I. Roberts,[5] C.K. Li,[6] F. Bernaudin,[7] C. Vermylen,[8] J.H. Dalle,[9] J. Stein,[10] R. Wynn,[11] P Lutz,[12] C. Catherine,[13] F. Pinto,[5] E. Angelucci,[14] G. Socie,[1] E. Gluckman,[1] M. WaltersV

Background. Most patients with beta thalassemia major (TM) or sickle cell disease (SCD) can be cured by hematopoietic stem cell transplantation (HSCT) from either cord blood (CB) or bone marrow (BM). One advantage of CB is the absence of risk associated with donation. *Aims*. In order to compare outcomes after HSCT with CB or BM, we studied 459 patients with TM or SCD who received HLA identical sibling CB (n=70) or BM (n=389) allografts between 1994 and 2005. *Methods*. In order to avoid center and period effect, only centers that performed both types of HSCT during the same period were included. We compared the incidence of hematopoietic recovery, acute and chronic graft-versus-host disease (GvHD), survival and disease-free survival (DFS) after CB and BM transplantation. *Results*. Compared to BM, CB recipients were significantly younger (median of 6.1 y versus 8.1 y), smaller (19 kg vs 23 kg), and were transplanted more recently (in 2001 vs 1999). In the BM group, there were 130 (33%) SCD and 259 (67%) TM patients, and in the CB group, 26 (37%) SCD and 44 (63%) TM patients. The indications for transplantation in SCD were not statistically different between CB and BM groups, however, more TM patients belonging to Pesaro II-III risk classes received BM (67%) compared to CB (39%) (p=0.01). There were also differences in the conditioning regimen (more frequent use of ATG/ALG in BM group and of Fludarabine and Thiotepa in the CB group) and GVHD prophylaxis (more methotrexate-containing therapy in BM compared to CB). Moreover, the nucleated cell content was 10 times higher in BM compared to CB. The table below shows the non-adjusted univariate analysis for outcomes for all patients according to the stem cell source used. After HSCT for TM, the 5 year-DFS rates were 86% and 77% for BM and CB recipients respectively, and after HSCT for SCD, 92% and 89% respectively. In a multivariate analysis adjusted for age and type of hemoglobinopathy, DFS was not statistically different between CB and BM recipients (RR= 1,4, p=0.11). *Summary*. Patients with TM or SCD had excellent outcomes after HSCT whether they received CB or BM from an HLA identical sibling. These results strongly suggest that CB transplantation from HLA identical siblings should be pursued when possible to avoid the discomfort and risks of a bone marrow harvest.

Table 1. Non-adjusted univariate analysis of outcomes for a.

Non-adjusted univariate analysis of outcomes for all patients (TM and SCD) after HLA-identical related HSCT according to the stem cell source used

Source	Neutrophil recovery	Acute GVHD II-IV	Chronic GVHD	5y Survival	5y DFS
CB	90%	10%	5%	96%	81%
BM	93%	20%	12%	95%	88%
p value	*0.002*	*0.04*	*0.15*	*0.92*	*0.11*

Leiden University Medical Center, LEIDEN, Netherlands

Allogeneic stem cell transplantation (allo-SCT) followed by donor lymphocyte infusion (DLI) is used as a curative treatment for patients with hematological malignancies. Donor derived T cells contribute to graft versus tumor responses by targeting minor histocompatibility antigens (mHag) that are encoded by single nucleotide polymorphisms (SNP). Applicability of immunotherapy targeting these mHag, however, is hampered due to limited numbers of known mHag. Recently, it has been demonstrated that Whole Genome Association scanning (WGAs) is a useful tool for identification of unknown mHag. From patients that displayed immune responses following allo-SCT and DLI, several mHag specific T cell clones were isolated. Panel studies revealed that the majority of these T cell clones recognized unknown mHag expressed in HLA-A*02 or HLA-B*07 with population frequencies ranging from 30% to 70%. To generate a whole genome map containing SNP genotypes, a panel of 90 HLA-A*02 and HLA-B*07 positive EBV transformed B cell lines was generated. DNA was isolated from these cell lines and 1,2 million SNP genotypes were determined using bead array techniques. This panel of SNP genotyped EBV cells was used to measure T cell recognition by 4 HLA-A*02 and 12 HLA-B*07 restricted T cell clones. The recognition pattern of each T cell clone was compared with all SNPs in the whole geno map and significance of association was calculated using Fisher's exact test. Highly significant association between recognition pattern and a defined genomic region was found in 14 out of 16 cases. In most cases, the associating region contained a single gene. Associating regions were located on chromosomes 5, 6, 7, 10, 12, 17, 19, 20 and 22. Online gene expression data were available for 12 of the identified genes. As expected, 10 genes were clearly overexpressed in EBV transformed B cells. Furthermore, overexpression restricted to hematopoietic cell types was observed in 8 genes whereas 4 genes were also overexpressed in testis derived tissues and prostate. To investigate whether the identified genes encoded the mHag, patient derived genes were specifically amplified, transfected and tested for T cell recognition. In addition, the identified genes from both patient and donor were sequenced to detect polymorphisms. T cell recognition was observed in 7 out of 11 genes tested. In all 7 cases a SNP difference between donor and patient was present. Based on HLA binding prediction algorithms, peptides spanning the SNP of interest were synthesized. Recognition of the peptides was used to confirm that these genes encoded the mHags, allowing functional studies of target tissues. In conclusion, we demonstrate that WGAs is a very efficient method for mHag discovery and therefore allows high throughput in depth analysis of clinical immune responses and selection of appropriate mHag for development of new immunotherapies.

EXTRACORPOREAL PHOTOCHEMOTHERAPY FOR ACUTE AND CHRONIC GVHD, A REPORT OF 102 PATIENTS TREATED IN A SINGLE INSTITUTION

E.J. Dann, A. Badian, T. Stravets, E. Kertsman, S. Phenklbaum, T. Zuckerman, N. Haddad, R. Elhasid, L. Bonstein, J.M. Rowe

Rambam Medical Center, HAIFA, Israel

Background. Acute GVHD and chronic GVHD remain the leading cause of morbidity and mortality of allogenic stem cells transplantation. Immunosuppressive therapy is the common practice to combat GVHD, however it heavily influences post-transplant rate of infection and is associated with secondary malignancies, affecting both morbidity and mortality. *Aims*. Exracorporal phototherapy (ECP) has been previously reported to be a useful modality treating patients with cutaneous T cells lymphoma, various autoimmune diseases and GVHD. Reported here is eight-year experience in a single institution of the use of ECP for patients with acute and chronic GVHD. *Methods*. Mononuclear cells were collected using Cobe-Spectra version 7 manual operation for adults and version 6 for pediatric patients. One and a half to 2 blood volumes were circulated through the cell separator with a product of approximately 5 x 109 mononuclear cells. When product hematocrit was less than 3%, volume was added to 300ml and when the hematocrit was more than 3%, volume was added to 500 ml. 8 Methoxy psoralen (8MOP) was added to final concentration of 0.2ug/mL. The product was transferred to irradiation bag and exposed to 2 Joule /cm^2 of UVA (365nM) (Biogenetic Vilber Lourmat). Cells were then retransfused. The treatment protocol consisted of 2 consecutive ECP performed at biweekly intervals until clinical improvement. One hundred and two patients, 66 males and 36 females, aged 1 year to 66 years (median 33 years), were treated. Patients underwent allogeneic bone marrow transplantation for the following indications: AML - 39, ALL - 28, CML - 11, CLL - 4 Thalasemia - 6, NHL - 8, MDS -5, MM -1, melanoma -1. Thirty six were treated for acute GVHD and 66 for chronic GVHD. Diffuse GVHD of skin was diagnosed in 84, liver involvement in 56, gastro-intestinal tract in 26 and joint involvement in 22 patients. Patients had from 2 to 125 ECP (median 10 for Ac-GVHD and 32 for Ch-GvHD). *Results*. 38 patients succumbed, 20/36 with Ac-GVHD and 18/66 with Ch-GVHD (p=0.005). At a median F/U of 19 months (1-108) response rate for chronic GVH was 60/66 (92%) and for acute GVH was 23/36 (64%) (p=0.001). Complete resolution of GVHD, partial response and no response were seen respectively in 33%, 60%, and 7% for patients with chronic GVHD and 0%, 56% and 44% for those with acute GVHD. Overall response rate was 46/56 (82%). Response rate for patients with GVHD grade I-III was significantly higher than for those with grade IV - 78/89 and 5/13, respectively (p=0.015). *Conclusions*. ECP is a useful modality of therapy and is most effective in patients with chronic GVHD. It is effective for both liver and skin involvement and less effective for patients with scleroderma. We suggest that this therapy should be used in early management of these patients concomitantly with immunosuppressive therapy in order to improve quality of life and reduce long-term side effects.

CONGENITAL DYSERYTHROPOIETIC ANEMIA TYPE II IS CAUSED BY MUTATIONS IN SEC23B GENE

P. Bianchi, E. Fermo, C. Vercellati, C. Boschetti, W. Barcellini, A. Zanella

Foundation IRCCS Ompmare, MILAN, Italy

Background . CDAII, the most frequent type of congenital dyserythropoietic anemia family, is an autosomal recessive disease characterized by ineffective erythropoiesis, peripheral hemolysis, erythroblasts' morphological abnormalities and hypoglycosylation of some RBC membrane proteins. Recent studies indicated that CDAII is not a distinct glycosylation disorder but caused by a defect disturbing Golgi processing in erythroblasts. Linkage analysis located the CDAII gene in a 5 cM region on chromosome 20 but the molecular basis is still unknown. We recently investigated the cytoplasmic proteome of human red blood cells (RBCs) using a combinatorial peptide ligand library as a capturing agent to amplify the signal of low- and very-low abundance proteins: 1578 proteins, most of them unexpected, were identified allowing a deep exploration of the RBC pathways (Roux-Dalvai, 2008). *Aims*. To investigate the molecular defect of CDAII using a proteomic-genomic approach based on the recently acquired data on cytoplasmic RBCs proteins and the known chromosomic localization of CDAII locus. *Results*. The analysis of RBCs cytoplasmic proteome allowed us to identified 17 proteins codified by genes located in the chromosomic region between 20p11.23 and 20q11.23: SNX5, SEC23B, DTD1, NAT5, GINS1, BCL2-L1, MAPRE1, CHMP4B, EIF2S2, AHCY, ACSS2, GSS, EIF6, CPNE1, EPB41L1, C20orf77, TGM2. Most of them were excluded because found to be associated to other diseases, already excluded in CDAII (EPB41L1) by previous works, or because not related by function to CDAII. Among the remaining proteins we focus on SEC23B for its possible role in the endoplasmic reticulum-to Golgi trafficking and its localisation on 20p11, the region with the highest LOD-score in CDAII after the recent mapping of the markers on the current contigs (Denecke, 2009). The 20 exons and intronic flanking regions of SEC23B gene were analysed by direct sequencing in 10 CDAII patients form 8 families, finding 10 different mutations: 2 frameshift, 2 stop-codon, 1 splicing and 5 missense; all the missense mutations affected highly conserved aminoacids, and were not found in 100 normal alleles examined, ruling out the possibility of polymorphism. Patients' data are summarised on the Table 1 (* = members of the same family). *Conclusions*. We found that CDAII patients are mutated in SEC23B gene. The protein encoded by this gene has similarity to yeast Sec23p component of COPII, which is the coat protein complex responsible for vesicle budding from the ER. SEC23B is therefore implicated in vesicle trafficking and its alterations may account for the cellular phenotype observed in CDAII, with particular regard to the impaired glycosylation of erythrocyte membrane proteins. Further analysis and animal models, are necessary to unravel the role of SEC23B in the pathogenesis of CDAII.

HIGH-THROUGHPUT RNA INTERFERENCE SCREENING IDENTIFIES SYNTHETIC LETHALITY BETWEEN ONCOGENIC KRAS DEPENDENCY AND SUPPRESSION OF STK33

S. Fröhling,[1] C. Scholl,[1] I. Dunn,[1] A. Schinzel,[2] D. Barbie,[2] S.Y. Kim,[2] S. Silver,[3] P. Tamayo,[3] R. Wadlow,[4] S. Ramaswamy,[4] K. Döhner,[5] L. Bullinger,[5] P. Sandy,[6] J. Boehm,[3] D. Root,[3] T. Jacks,[6] W. Hahn,[2] G. Gilliland[1]

[1]Brigham and Women's Hospital, BOSTON, USA; [2]Dana-Farber Cancer Institute, BOSTON, USA; [3]Broad Institute of Harvard and Massachusetts Institute of Technology, CAMBRIDGE, USA; [4]Massachusetts General Hospital, BOSTON, USA; [5]University Hospital of Ulm, ULM, Germany; 6Massachusetts Institute of Technology, CAMBRIDGE, USA

Background. Activating KRAS mutations are among the most common pathogenetic events in a broad spectrum of hematologic malignancies and epithelial tumors. However, oncogenic KRAS has thus far not proven to be a tractable target for therapeutic intervention. An alternative to direct targeting of known oncogenes is to perform "synthetic lethality" screens to identify genes that are selectively required in the context of specific cancer-causing mutations. Using this approach, we have discovered a synthetic lethal interaction between mutant KRAS, the most frequently mutated oncogene in human cancer, and inactivation of the gene encoding the STK33 serine/threonine protein kinase. *Aims and Methods*. To identify genes that are essential for cell viability and proliferation in the context of mutant KRAS, we performed high-throughput loss-of-function RNA interference (RNAi) screens in 8 human cancer cell lines (KRAS mutant, n=4; KRAS wildtype, n=4), representing 5 different tumor types (acute myeloid leukemia [AML], colon cancer, breast cancer, prostate cancer, glioblastoma), as well as normal human fibroblasts and mammary epithelial cells. We screened each cell line with a subset of the short hairpin RNA (shRNA) library developed by the RNAi Consortium that consists of 5024 individual shRNA constructs targeting 1011 human genes, including the majority of known and putative protein kinase genes and a selection of protein phosphatase genes and known cancer-related genes. *Results*. Suppression of STK33 preferentially inhibited the viability and proliferation of cells that were dependent on mutant KRAS, whereas STK33 was not required by KRAS-independent cells. The differential requirement for STK33 based on oncogenic KRAS dependency was confirmed in 10 additional hematopoietic (AML, n=5; T-cell acute lymphoblastic leukemia, n=3; multiple myeloma, n=2) and 7 additional epithelial cancer cell lines using *in vitro* transformation assays and human tumor xenograft models. Mechanistic studies support the hypothesis that STK33 promotes cancer cell growth and survival in a kinase activity-dependent manner by regulating the activity of S6K1 selectively in mutant KRAS-dependent cells. Molecular genetic characterization of cancer cell lines and analysis of patient-derived genomic data sets demonstrate that STK33 is not recurrently mutated or overexpressed in human tumors. 4. *Conclusions*. These observations indicate that targeting of STK33 may offer a substantive therapeutic window in a broad spectrum of cancers associated with mutant KRAS, thus providing a rationale for the development of STK33 inhibitors. Furthermore, our approach illustrates the potential of RNAi for discovering critical functional dependencies created by oncogenic mutations that cannot be identified using other genomic technologies, and represents a strategy for targeting other "undruggable" genetic alterations, such as MLL fusions in acute leukemias or mutant TP53 in lymphoproliferative and epithelial neoplasms.

DOSE-INTENSIFIED COMBINED MODALITY TREATMENT WITH 2 CYCLES OF BEACOPP ESCALATED FOLLOWED BY 2 CYCLES OF ABVD AND INVOLVED FIELD RADIOTHERAPY (IF-RT) IS SUPERIOR TO 4 CYCLES OF ABVD AND IF-RT IN PATIENTS WITH EARLY UNFAVOURABLE HODGKIN LYMPHOMA (HL): AN ANALYSIS OF THE GERMAN HODGKIN STUDY GROUP (GHS

M. Engert,[1] P. Borchmann,[2] A. Pluetschow,[2] M. Fuchs,[2] J. Markova,[3] A. Lohri,[4] Z. Kral,[5] R. Greil,[6] M.S. Topp,[7] M. Villalobos,[8] J.M. Zijlstra,[9] M. Sökler,[10] H. Stein,[11] H.-T. Eich,[12] R.-P. Mueller[12]

Background and Aims. Combined modality treatment consisting of 4 cycles of chemotherapy and IF-RT is the standard treatment for early unfavourable HL. Overall survival (OS) and freedom from treatment failure (FFTF) in this group of patients was 91% and 83%, respectively, at 5 years in our prior HD8 study. Thus, the rationale for HD14 was to improve on these results by increasing dose intensity using BEACOPP escalated. *Methods*. Between January 2003 and January 2007, 1.216 patients aged 16-60 with untreated early unfavourable stage HL (CS I, IIA with one of the following risk factors: large mediastinal mass (a), extranodal disease (b), elevated ESR (c), or ≥3 nodal areas (d); IIB with risk factors c and d) were randomized to either 4 cycles of ABVD (arm A) or 2x BEACOPP escalated followed by 2x ABVD (arm B). All patients received 30Gy IF-RT after chemotherapy. Primary objective was the improvement of the FFTF. Here we present the results of the predefined 3rd interim analysis within the prespecified group sequential test design. *Results*. Of the 1.216 patients included, 1.010 were evaluable for this analysis. Patient characteristics were well balanced between both arms. At 3 years, the FFTF for arm A is 90% (95% CI: 87%-93%), and for arm B 96% (95% CI: 94%-98%). Since the observed inverse normal test statistic exceeds the critical level, the null hypothesis of equal FFTF in each arm can already be rejected. The improved FFTF is mainly due to differences in progression and early relapses (arm A 5.9% versus arm B 1.8%). Protocol adherence for chemotherapy was high and not different in both arms (arm A 98.8%, am B 97.3%). Though the chemotherapy-intensity was higher in the experimental arm, safety was comparable to the standard treatment. Secondary neoplasias occurred in 8 patients in each arm so far. *Conclusions*. Based on the significantly superior FFTF of the intensified therapy (2x BEACOPP escalated + 2x ABVD + IF-RT) compared to the prior standard (4x ABVD + IF-RT), this more aggressive treatment strategy will become the new standard for early unfavourable HL patients within the GHSG. Whether the improved FFTF translates into an improved overall survival must be awaited. Future strategies should aim at identification of those patient subgroups that profit most from this approach.

0554

DELETION OF DICER1 FROM OSTEOPROGENITOR CELLS IS SUFFICIENT TO INDUCE MYELODYSPLASIA AND HEMATOPOIETIC NEOPLASIA

M.H.G.P. Raaijmakers,[1] S. Mukherjee,[1] S. Guo,[1] T. Kobayashi,[1] J. Schoonmaker,[1] B. Ebert,[2] F. Al-Shahrour,[2] R. Hasserjian,[1] E Scadden,[1] M. Merkenschlager[3], C. Lin,[1] D.T. Scadden[1]

[1]Massachusetts General Hospital and Harvard Medical school, BOSTON, USA; [2]Hematology Division, Brigham and Women's Hospital, BOSTON, USA; [3]Lymphocyte Development Group, Imperial College London, LONDON, UK

Background. Cells of mesenchymal origin are known to alter the growth of malignant and normal cells and participate in tissue development. Specific mesenchymal cell populations contribute to the specialized microenvironments or niches that regulate stem cells. In hematopoiesis, cells of the osteoblastic lineage participate in the hematopoietic stem cell niche. However, these cells have largely revealed their role as regulators of normal stem cell and hematopoietic physiology. How these cells, which have been relegated a relatively non-descript role of 'stroma,' participate in processes that result in disease is relatively understudied *Aims*. To explore the role of Dicer1, the endonuclease essential for miRNA biogenesis, in osteolineage cells in the bone marrow microenvironment and its effects on hematopoiesis. *Methods*. Dicer1 was conditionally deleted from osteoprogenitor cells by intercrossing transgenic mice expressing the GFP-Cre recombinase under the transcriptional control of the osteoblastic lineage specific osterix promoter to mice containing conditional (floxed) Dicer1 alleles. *Results*. Deletion of Dicer1 in osteoprogenitor cells induces markedly disordered hematopoiesis. Hematopoietic changes were complex, affecting multiple lineages and recapitulating key features of human myelodysplastic syndrome (MDS), including ineffective hematopoiesis with cytopenia, multilineage dysplasia, increased proliferation and intramedullary apoptosis of primitive hematopoietic cells, decreased B-cell progenitors, increased bone marrow vascularity and the propensity to develop hematopoietic neoplasms (myeloid sarcoma and acute monocytic leukemia-like disease). These changes were entirely microenvironment dependent with intact Dicer1 in hematopoietic cells. In addition, they were not observed when Dicer1 was deleted in mature osteoblasts. *Summary and Conclusions.* The data demonstrate that differentiation stage-specific perturbations in osteolineage cells can induce a complex hematological disorder and indicate the central role individual cellular elements of 'stroma' can play in tissue homeostasis. Further, they reveal that primary changes in the microenvironment can initiate secondary neoplastic disease.

Epidemiological data and family studies have indicated that inherited factors may predispose to the development of myeloproliferative neoplasms (MPN). To explore the role of inherited factors in more detail, we initially analyzed JAK2-spanning SNPs in homozygous MPN cases (%V617F >50%; n=142) using pyrosequencing, which provides a quantitative readout of allele ratios. The mitotic recombination that gives rise to V617F homozygosity typically involves most of chromosome 9p and thus SNPs within this region are also reduced to homozygosity; consequently the haplotype on which V617F arose could be read directly from allele ratios that were significantly greater than the expected value of 0.5. In many cases the residual haplotype (i.e. the haplotype on which V617F had not arisen) could also be read. Strikingly, of the 142 V617F alleles, 109 (77%) had an identical haplotype (subsequently designated 46/1) within the JAK2 gene compared to only 9/74 (12%) residual wild type alleles (p= 1.4e-20, Fisher's exact test). These results indicated that homozygosity for V617F occurred preferentially when this mutation was present on the 46/1 haplotype. Analysis of data generated by the Wellcome Trust Case Control Consortium (WTCCC) showed that 46/1 is present at a frequency of 0.24 in 1500 UK healthy blood donors, and identified tagged SNPs that were then used to screen for this haplotype in further cases. V617F-associated disease was strongly associated with 46/1 in all three disease entities compared to healthy controls (PV, n=192, p=2.9e-16; ET, n=78, p=8.2e-9 and MF, n=41, p=8.0e-5) and allele-specific PCR demonstrated that V617F specifically arose on the 46/1 allele in most cases. We suggest two hypotheses to account for this observation: (i) V617F may arise randomly on all haplotypes but 46/1 is in linkage disequilibrium with an unknown constitutional functional variant that interacts with V617F in a manner that makes the development of clinically manifest disease more likely compared to V617F on a non-46/1 haplotype or (ii) there is a specific mutational mechanism by which V617F preferentially arises on a 46/1 haplotype. To investigate the possibility that JAK2 on 46/1 is functionally different from other JAK2 alleles, we tested if JAK2 haplotype influences myeloid colony formation in hematologically normal individuals (n=56). Healthy individuals that carried at least one 46/1 allele (n=26) grew significantly fewer peripheral blood CFU-GM than individuals without 46/1 (n=30), consistent with the hypothesis that JAK2 on 46/1 is functionally different from other JAK2 alleles. Furthermore, compared to controls 46/1 was more frequent in MPNs with JAK2 exon 12 mutations (N=50; P=0.003), MPL 515 mutations (N=157; p<0.001) as well as those that tested negative for all mutations (n=318; p=0.003). In summary, our data indicate that 46/1 is a strong predisposition factor for development of V617F associated diseases (OR=3.7; 95% CI 3.1-4.3; RR=2.6; 95% CI 2.3-2.9) as well as being relatively weakly but significantly associated with other MPNs. We estimate that this haplotype accounts for approximately 50% of the population risk of developing an MPN described in epidemiological studies.

THE SOMATOSTATIN RECEPTOR 2 INDUCES A REVERSIBLE NEUTROPHILIC DIFFERENTIATION BLOCK

M.L. Solernó,[1] M.A. Jordà,[2] I.M.A. Louwers,[3] L.J. Hofland,[4] H.R. Delwel[3]

[1]Erasmus University Medical Center Rotterdam, ROTTERDAM, Netherlands; [2]Harvard Stem Cell Institute and BIDMC, BOSTON, MA, USA; [3]Department of Hematology, Erasmus University Medical Center, ROTTERDAM, Netherlands; [4]Department of Internal Medicine, Erasmus University Medical Center, ROTTERDAM, Netherlands

Background. Previous studies have shown that the cannabinoid receptor 2 (cnr2), a GPCR abnormally expressed in 47% of the AML samples studied, could induce migration and a complete and reversible block in neutrophilic differentiation *in vitro*. Both effects were mediated by Gai and MEK/ERK. To assess whether other GPCRs would induce the same effects, we studied multiple receptors, including sstr2. The somatostatin receptor 2 is a seven transmembrane receptor normally expressed in immature CD34$^+$ human hematopoietic cells. It has previously been shown that, similarly to cnr2, stimulation of sstr2 with octreotide results in migration of hematopoietic cells. However, it remains unknown whether activation of the sstr2 might also interfere with the normal neutrophilic differentiation. *Aims*. To investigate whether stimulation of the somatostatin receptor 2 by octreotide may alter normal hematopoiesis *in vitro*. *Methods*. Sstr2-expressing cells. The human sstr2 gene was cloned into pLNCX. Site-directed mutagenesis was used to mutate the DRY motif into the DRA and DAY motifs. 32D/G-CSF-R cells were infected with virus containing these constructs, and single clones were obtained. Migration. Migration assays were performed using trans-wells with or without 1 nM octreotide placed in the lower chamber. The migrated cells were counted after 4 hours of incubation. Neutrophilic differentiation. The 32D/G-CSF receptor cell line was cultured in RPMI 1640 medium supplemented with 10% Fetal Calf Serum and murine IL-3 (10 ng/mL) or human G-CSF (10 ng/mL). Ligands were added to the cultures to a final concentration of 1 nM octreotide, 100 ng/mL pertussis toxin, and 25 mM PD98059. The cell density was daily readjusted to 2x10^5 cells/mL. Cell morphology was determined by microscopy on May-Grünwald-Giemsa stained cytospins at day 3, 5 and 8. *Results.* The expression of the sstr2 was functionally determined by migration assays. When 32D/G-CSF-R/sstr2 cells were cultured in the presence of G-CSF and octreotide, differentiation was fully blocked, whereas in the absence of octreotide or the receptor, cells differentiated into mature neutrophils at day 5. Neutrophilic differentiation was reestablished by PD98059, a MEK1 inhibitor, and by pertussis toxin. These ligands showed no effect on control cells. Finally, only the sstr2 DAY-mutants were not capable to migrate upon octreotide stimulation nor could they interfere with G-CSF induced differentiation following exposure to octreotide, indicating G-protein dependency of the two effects of sstr2 in myeloid cells. *Summary and Conclusions.* In this study we show that neutrophilic differentiation could be blocked upon stimulation of the sstr2. Similarly to cnr2, sstr2-induced effects were mediated by Gai and MEK/ERK. However, it remains unclear whether activation of MEK/ERK involves Gbg or occurs in a G-protein-independent fashion. In addition, our results suggest that the arginine aminoacid present in the DRY motif is crucial for sstr2 functions. Possibly, the non-blocking GPCRs would block differentiation upon stimulation with the correct agonist. Given the similar effects induced by cnr2 and sstr2, it is tempting to look at the underlying mechanism of GPCR pathways involved in leukemic transformation.

SUSTAINED INCREASE OF CD69 ON ACTIVATED LYMPHOCYTES MEDIATED BY MESENCHYMAL STROMAL CELLS AND ITS POTENTIAL IMMUNOMODULATORY ROLE

F. Araujo, [1]R.A. Panepucci,[2] K.M. Farias,[2] A.G. Araujo,[2] M.D. Orellana,[2] F.P. Careta,[2] C.C.B. Menezes,[2] P.B.V. Palma,[2] S.K. Haddad,[2] D.T. Covas,[2] M.A. Zago[2]

[1]Universidade de São Paulo, RIBEIRÃO PRETO; [2]INCTC-FUNDHERP, FMRP-USP, RIBEIRÃO PRETO, Brazil

Background. Mesenchymal stromal cells (MSCs) exert an immune regulatory function and suppress T-cell proliferation. One of the ways by which MSCs may modulate immune responses is by the induction of regulatory T cells (Treg). TGF-B is known to induce the expression of FOXP3 and to drive the generation of Tregs. Despite the importance of secreted factors, cell to cell contacts promote increased lymphocyte immune modulation. Interestingly, TGF-B is known to induce the expression of TGFBI, a secreted extracellular matrix adaptor protein, whose expression is higher on hematopoietic stem cells adherent to MSC. *Aims.* To uncover new potential immunomodulatory mechanisms on lymphocytes, mediated by MSC. *Methods*. Peripheral blood CD3$^+$ T cell from 3 individuals were activated by anti-CD3/CD28 beads, cultured for 5 days either in the presence or in the absence of MSC (5:1), were profiled by whole genome microarrays. Additionally, peripheral blood mononuclear cells (PBMC) from 6 individuals where similarly activated and cultured, and collected 1, 3 and 5 days after activation. Percentage of CD69$^+$ cells and proliferation of activated lymphocytes were evaluated by flow cytometry. Transcripts levels of TGF-B, TGFBI, FOXP3 and IL10 were determined by RT-PCR. *Results*. As expected, proliferation of lymphocytes co-cultured with MSC was significantly inhibited. Microarray analysis revealed many differentially expressed genes involved in immune response. Interestingly, among these, CD69 and components of the NFkB pathway were at higher levels on co-cultured lymphocytes. CD69 is the earliest activation marker of T cells and is only transiently expressed. As expected, activation of lymphocytes from PBMC cultured alone was evidenced by the expression of CD69 in 5% of cells in the first day (mean percentage), followed by a decrease in subsequent days (4% and 3%, respectively). In line with microarray results, lymphocytes co-cultured with MSC displayed a completely different pattern, with a similar initial activation (7%) followed by a significant increase in the 3rd and 5th days (16% and 14%, respectively). Interestingly, the expression of CD69 is controlled by NFkB and recent literature indicates that this receptor may modulate the inflammatory response, by inducing TGF-B production. Accordingly, TGF-B and FOXP3 levels in the 5th day were significantly higher on PBMC co-cultured with MSC, compared to PBMC cultured alone. Furthermore, TGFBI and IL10 were both expressed at significantly higher levels on PBMC co-cultured with MSC, in all days evaluated, compared to PBMC alone. In addition, their transcript levels decreased faster on PBMC cultured alone. In the other hand, *Conclusions*. We demonstrate for the first time that MSC promotes a sustained increase of the CD69 marker on CD3+ lymphocytes, which is accompanied by increased levels of TGF-B, TGFBI, FOXP3 and IL10 on total PBMC. Our results are in line with the proposed immunoregulatory role of CD69. In addition, higher TGFBI levels on PBMC may increase lymphocyte adherence to MSC, thus favoring immune modulation. Supported by FINEP,CNPq and FAPESP.

MACROPHAGES AS NOVEL TARGETS FOR ERYTHROPOIETIN

L. Lifshitz,[1] M. Gassmann,[2] M. Mittelman,[1] D. Neumann[1]

[1]Tel-Aviv University, Sackler Faculty of Medicine, TEL-AVIV, Israel; [2]Institute for Veterinary Physiology, University of Zurich, ZURICH, Switzerland

Background. The immunomodulatory effects of erythropoietin (EPO) on the cellular and humoral compartments of the immune system were originally described by our group in multiple myeloma patients and have been further elucidated in murine experimental models (Mittelman, 2001; Prutchi-Sagiv, 2006; Katz, 2005; 2007). However, the mechanism of action by which EPO affects lymphocyte number and function are still unkown, particularly since lymphocytes do not seem to carry EPO receptors (EPO-R). Our search for possible mechanisms led us to the novel discovery that dendritic cells (DCs) express the EPO-R, and that stimulation with EPO enhances their survival and function (Prutchi-Sagiv, 2008; Lifshitz, 2009). Here we focus on macrophages as an additional EPO target, since in analogy to DCs, macrophages are also antigen presenting cells, and serve as key effectors of the innate immune response. *Aims*. This study was designed to explore the possibility that macrophages are either direct or indirect targets of EPO. *Methods*. The in-vitro effects of EPO were investigated in a model of murine bone marrow derived macrophages (BMDMs) treated with recombinant human EPO (rHuEPO). These cells were subjected to biochemical analysis, phenotyping, and analysis of phagocytic activity and cytokine secretion. The *in vivo* effects of EPO on macrophages were assessed by analysis of macrophage phenotype molecules in rHuEPO-treated mice and in human EPO-overexpressing transgenic tg6 mice, in comparison to their control counterparts (diluent-injected and wt littermates, respectively). *Results*. Relying on murine models, we found that BMDMs express EPO-R mRNA, as detected by RT-PCR. *In vitro* stimulation of the BMDMs with rHuEPO activated multiple signaling pathways. EPO treatment of the BMDMs up-regulated their surface expression of CD11b, F4/80 and CD80, as well as enhanced their phagocytic activity. EPO treatment of LPS- stimulated BMDMs decreased IL-10 secretion. These results are supported by in-vivo experiments in rHuEPO-injected mice, as well as in tg6 mice. EPO treatment was associated with an increase in the size of the splenic macrophage population, as detected by F4/80 expression, and an increase in the number of macrophages expressing CD11b, CD80 and MHC class II. *Summary*. Our results show that macrophages are direct targets of EPO and that EPO treatment enhances their maturation and function. These findings point to the multifunctional role of EPO and may advance its clinical applications as an immunomodulator.

MEMBRANE AND SOLUBLE CD40 LIGAND HAVE DIFFERENT EFFECTS ON BCL-6 EXPRESSION AND PRODUCE DIFFERENT PROTEIN/DNA COMPLEXES AT A SITE IN EXON 1 OF THE BCL-6 GENE

A. Batlle,[1] V. Papadopoulou,[2] A.R. Gomes,[3] S. Willimott,[3] J.V. Melo,[4] K. Naresh,[2] E.W. Lam,[3] S.D. Wagner[3]

[1]IFIMAV, SANTANDER, Spain; [2]Imperial College, LONDON, UK; [3]MRC, LONDON, UK; [4]Institute of Medical and Veterinary Science, ADELAIDE, Australia

Bcl6 is a zinc finger transcription factor that is highly expressed in germinal centre B-cells and is a potent transcriptional repressor. It is essential for germinal centre formation and T-dependent antibody responses. Deregulated expression of this gene has been associated with the development of non-Hodgkin's lymphomas including lymphocyte predominant Hodgkin's lymphoma and other tumours such as breast cancer. Tight regulation of Bcl6 is, therefore, essential but there are large gaps in our understanding of the signals involved. The inhibition of Bcr-Abl by the tyrosine kinase inhibitor, Imatinib, is known to up-regulate Bcl6 in Ph^+ lymphoid cell lines. We demonstrated that this effect is due to p38 MAPK. We also demonstrated that p38 is, in part, responsible for Bcl6 expression under basal conditions in the Burkitt lymphoma cell line, Ramos. Bcl6 was further up-regulated in Ramos cells by soluble CD40 ligand, but membrane bound CD40 ligand reduced Bcl-6 expression by a mechanism involving NF-kB mediated IRF4 up-regulation. Soluble CD40 ligand did not activate NF-kB to the same extent as membrane CD40 ligand although both activated p38, thus supporting a role for p38 in driving Bcl6 transcription. Next we sought to find out the sequences responsible for mediating the effects of p38. Utilizing Anisomycin we showed that a 300bp sequence around exon 1 was responsive to p38. Gel shift assays demonstrated that membrane bound CD40 ligand induced a different protein/DNA complex at a site within this 300bp region, corresponding to the terminal portion of exon 1, from soluble CD40 ligand. We conclude that p38, activated by CD40 ligand, up-regulates Bcl6. However, the effects of CD40 ligand depend on whether the soluble or membrane bound form of the molecule is used. It is possible that a repressive complex is formed at a site in exon 1 in response to membrane CD40 ligand stimulation.

0561

ALTERNATIVE USE OF EXON 1 AND DIFFERENTIAL REGULATION OF EXPRESSION OF DOCK10 ISOFORMS BY INTERLEUKIN-4

A. Parrado, M.J. Alcaraz-García, M.V. Bernardo, M.J. Majado

Hospital Virgen de la Arrixaca, MURCIA, Spain

Background. The Dock or CZH proteins are a family of non classical guanine exchange factors (GEF) for Rho GTPase proteins. We identified Dock10, one of the eleven members of the CZH family, as an Interleukin 4 (IL4)-inducible gene in B lymphocytes and chronic lymphocytic leukemia (CLL) cells. In addition, we obtained the 5'-end cDNA sequence from a Dock10 transcript by RACE-PCR, and cloned a full length cDNA by RT-PCR (accesion no. EU236710, encoding for 2180 amino acids; Yelo *et al.*, Mol. Immunol. 2008; 45: 3411-3418). This cDNA differs from the validated Dock10 transcript (accesion no. NM_014689.2, encoding for 2186 amino acids) in the sequences corresponding to exon 1, suggesting the existence of two isoforms of the human Dock10 gene. *Aims* To confirm the existence of two transcripts of the human Dock10 gene and to describe the effect of IL4 stimulation on their expression. To check whether equivalent transcripts of the ortolog murine Dock10 gene are expressed. *Methods*. B lymphocytes were isolated from the peripheral blood (PB) of CLL patients by using a RosetteSep Human B Cell Enrichment Cocktail (StemCell Technologies) followed by ficoll centrifugation. Total RNA was obtained from a sample before culture and after 24 hours of culture in the presence of 10 ng/mL of IL4 (BD Pharmingen). Expression of the Dock10 transcripts was studied by RT-PCR. To this purpose, forward oligonucleotide primers were designed from the respective exons 1, designated hDOCK10.45 (for our novel isoform) and hDOCK10.104 (for the validated isoform), and a reverse oligonucleotide primer from exon 5, designated hDOCK10.50, common for both isoforms. The amplicons were cloned by TA cloning and sequenced. Their levels of expression were compared by quantitative RT-PCR. Homology searches between human and mouse Dock10 sequences were conducted using the LFASTAn-LALIGNn program. RNA obtained from the mouse hematopoietic pluripotent cell line FDCP1 was used to check by RT-PCR whether a mouse Dock10 transcript equivalent to the novel human Dock10 isoform exists. Forward and reverse oligonucleotide primers, designated mDOCK10.4 (exon 1) and mDOCK10.8 (exon 6), respectively, were designed for this PCR. *Results*. Two isoforms of the human Dock10 gene were expressed in CLL cells, which differ in their exon 1. Within the Dock10 gene, exon 1 of the validated isoform is 95 kb upstream of exon 1 of the novel isoform, which in turn is 15 kb upstream of the common exon 2. Culture with IL4 strongly induced the levels of the novel isoform, but did not affect the levels of the validated one. These data suggests that expression of the Dock10 gene is controlled by two different promoters which drive expression of two isoforms, each one with a different exon 1, therefore encoding different amino terminal sequences. The structure of the mouse Dock10 gene ressembles that of the human Dock10 gene. A homologous sequence to exon 1 of the novel human Dock10 isoform was found 93 kb downstream of exon 1 and 16 kb upstream of exon 2 of the mouse validated Dock10 isoform. We confirmed by RT-PCR the existence of a novel isoform of mouse Dock10 in FDCP1 cells. *Summary and Conclusions*. Human and mouse Dock10 ortolog genes share a similar structure and produce two isoforms which arise from the alternative use of a different exon 1 for each isoform. IL4 induced expression of only one of the isoforms, suggesting that expression of Dock10 isoforms is driven by two promoters: an upstream promoter unresponsive to IL4, and a downstream promoter inducible by IL4.

0562

BIOEQUIVALENCE OF A NEW BIOSIMILAR FILGRASTIM AND NEUPOGEN: PHARMACOKINETIC, PHARMACODYNAMIC AND SAFETY DATA FROM TWO RANDOMISED, PHASE I, HEALTHY-VOLUNTEER STUDIES

C.F. Waller,[1] M.H. Bronchud,[2] S.J. Mair[3]

[1]Freiburg University Medical Center, FREIBURG, Germany; [2]Hospital General of Granollers, BARCELONA, Spain; [3]Charles River Clinical Services, EDINBURGH, UK

Background. Since its launch in 1991, recombinant human granulocyte colony-stimulating factor (G-CSF; filgrastim) has been established as an integral part of supportive therapy across multiple clinical indications. Consequent to patent expiry 3 years ago, Hospira has developed a biosimilar form of filgrastim, which could provide a bioequivalent alternative to Amgen's Neupogen. *Aims*. To compare the pharmacokinetic, pharmacodynamic and safety profile of Hospira filgrastim with that of Neupogen in healthy volunteers. *Methods*. Two phase I, single-centre, randomised, crossover trials were undertaken. In the first study (GCF061), which had a primary objective to demonstrate equivalence in pharmacokinetic characteristics, 48 healthy volunteers were randomised to intravenous (i.v.) or subcutaneous (s.c.) dosing and then further randomised to order of treatment. Subjects in each of the two dosing groups received a single 10 µg/kg dose of Hospira filgrastim followed by 10 µg/kg Neupogen or vice versa. In the second study (GCF062), which had a primary objective to demonstrate equivalence in pharmacodynamic characteristics, 50 healthy volunteers were randomised to one of two dose levels (5 or 10 µg/kg) and further randomised to order of treatment. All subjects received five daily s.c. doses of Hospira filgrastim or Neupogen (at 5 or 10 µg/kg), with subsequent crossover to the alternative treatment (at a matching dose level). Bioequivalence was evaluated by analysis of variance. If the estimated 90% confidence intervals (CIs) for the ratio of *test* to reference treatment means were within the conventional equivalence limits of 0.80-1.25, then bioequivalence was concluded. In both studies, subjects provided written informed consent before undertaking any study-specific procedures. *Results*. In GCF061, 46 subjects completed the study. The geometric mean AUC0-tlast for plasma G-CSF (primary endpoint) was similar in subjects treated with Hospira filgrastim and Neupogen following either i.v. (ratio of means: 0.96; 90% CI: 0.90-1.02) or s.c. (ratio: 1.02; 90% CI: 0.95-1.09) dosing. In GCF062, 48 subjects completed the study. The geometric mean absolute neutrophil count (ANC) AUC0-tlast at day 5 (primary endpoint) was comparable in subjects who received Hospira filgrastim or Neupogen in both the 5µg/kg (ratio: 0.98; 90% CI: 0.92-1.05) and 10 µg/kg (ratio: 0.97; 90% CI: 0.93-1.01) dose groups. In both studies, 90% CIs for the ratio of *test* to *reference* treatment means associated with the primary endpoints were within the predefined range necessary to demonstrate bioequivalence. With regard to secondary endpoints, bioequivalence of the two treatments was demonstrated for AUC0-infinity, Cmax, Tmax and T1/2 in the single-dose study following both i.v. and s.c. dosing, and for ANCmax, ANCmin and $CD34^+$ cell counts at day 5 in the multiple-dose study at both dose levels; thus, confirming the biological similarity of the two drugs. Hospira filgrastim was well tolerated and there were no additional or unexpected safety concerns associated with its use. *Conclusions*. These two studies support the bioequivalence of Hospira filgrastim and Neupogen, and provide a rationale for further clinical evaluation of the biosimilar filgrastim.

0563

AKT AND PKC AS REGULATORS OF DIFFERENTIATION AND TELOMERASE ACTIVITY IN LEUKEMIC CELLS

O. Yamada,[1] K. Ozaki,[1] M. Nakadake,[2] M. Akiyama,[3] K. Kawauchi,[4] R. Matsuoka[1]

[1]Tokyo Women's Medical University, TOKYO, Japan; [2]Institut Gustave Roussy, VILLEJUIF, France; [3]Jikei University School of Medicine, TOKYO, Japan; [4]Tokyo Women's Medical University Medical Center East, TOKYO, Japan

Background. Several mechanisms for the regulation of telomerase have been reported, including transcriptional, translational, and post-translational mechanisms, suggesting that telomerase activity is controlled in a complex manner. *Aims*. To determine the mechanisms that modulate telomerase activity during granulocytic and monocytic differentiation of hematopoietic cells. *Methods*. A human acute myeloblastic leukemia cell line (HL60) was induced to undergo monocytic differentiation by exposure to VD3, while granulocytic differentiation was induced by exposure to ATRA. Changes of several signaling proteins during differentiation were examined and the *in vitro* kinase assay was performed. The effect of RNA interference with some signaling proteins was also assessed. Furthermore, the level of telomerase activity and the expression of human telomerase reverse transcriptase (hTERT) protein and mRNA were examined. *Results*. Rapid down-regulation of telomerase transcription occurred during early differentiation of HL60 cells into both lineages prior to G1 arrest. Each differentiation agent caused a significant increase of several signaling proteins (including Akt, mTOR, p70S6K, p21, PKC, Raptor, and Rictor) and a decrease of 4EBP1 at 3 days after the induction of differentiation. In addition, recombinant AKT or PKC-α caused dose-dependent activation of telomerase derived from serum-starved HL60 cells. Telomerase protein disappeared before activation of AKT or PKC-α during the late stage of differentiation, which might explain the repression of telomerase activity in differentiated cells. To further examine the role of the active form of AKT or PKC-α in differentiated cells, rictor was knocked down. The results suggested that mTOR/rictor kinase activity was essential for phosphorylation of both AKT and PKC in differentiated cells. Preincubation with a PI3K inhibitor (LY294002) or a PKC inhibitor (bisindolylmaleimide) did not alter the expression of surface markers, but led to a decrease of NBT reduction and esterase activity. *Conclusions*. There was a decrease of telomerase activity and hTERT (protein and mRNA) expression during granulocytic or monocytic differentiation stimulated by ATRA or VD3, respectively. The active forms of Akt, PKC-α, p70S6K, mTOR, and mTOR-associated rictor protein showed an increase on day 3 after the induction of differentiation. It has been reported that Akt promotes the transcription of hTERT and post-translational activation of telomerase. PKC was also reported to activate telomerase via a post-translational mechanism, and we found that recombinant PKC-α and AKT caused a dose-dependent increase of telomerase activity in HL60 cells. In differentiated cells, telomerase protein disappeared before the activation of AKT and PKC-α occurred, suggesting that these proteins contribute to cell function after differentiation. The present findings indicate that telomerase activity is regulated by at least two mechanisms during granulocytic and monocytic differentiation, with one being transcriptional and the other being post-translational and involving both Akt and PKC.

0564

A PHASE II RANDOMIZED STUDY COMPARING PEGFILGRASTIM VS FILGRASTIM AFTER HIGH-DOSE CHEMOTHERAPY AND AUTOLOGOUS PERIPHERAL BLOOD STEM CELL SUPPORT

L. Castagna, S. Bramanti, A. Levis, M.G. Michieli, A. Anastasia, B. Sarina, L. Giordano, E. Todisco, R. Mazza, A. Santoro

Istituto Clinico Humanitas, ROZZANO(MILANO), Italy

Background. HDC with peripheral autologous stem cell support is widely accepted as standard care in many hematological malignancies and some solid tumors. The ASCO guideline recommends the use of growth factor after PBSC infusion. The use of Pegfilgrastim (PEG) after high dose chemotherapy (HDC) and peripheral blood stem cell (PBSC) PBSC has been evaluated in retrospective, single-arm phase II study or case-control study, all suggesting that PEG worked as well as filgrastim (FIL) to accelerate the hematological reconstitution rate. *Aims*. The aim of this study was to demonstrate the non-inferiority of one fixed dose of PEG compared to daily FIL, in patients (pts) receiving HDC and PBSC. *Methods*. Criteria for elegibility were: at least 3×10^6/kg $CD34^+$ reinfused; age >18 years; normal cardiac, renal, liver and pulmonary function; signed written informed consent. Pts were randomized to receive on

day+1 subcutaneously (sc) fixed-dose PEG (6 mg) or sc FIL 5 mcg/kg/d until an absolute neutrophil count (ANC >1.0×10⁹/L) was reached. Primary end points were number of days with an ANC <0.5×10⁹/L and the number of days to achieve an ANC > 0.5×10⁹/L. Secondary end points were: number of days to achieve an ANC >1.0×10⁹/L, number of days with fever >38°C, duration of antibiotic therapy, and number of documented infections. *Results*. The analysis was performed on 76 patients (36 pts in each arm). The mean number of CD34⁺ reinfused was similar. Considering the primary endpoint it can be claim that PEG is non-inferior to FIL because the upper two-side 95% CI for the difference in the duration of ANC <0.5×10⁹/L was less than the non-inferiority margin of delta=1.67, presenting a mean value of 0.18 with a CI 95% of -0.83; +1.19. The same results were found considering time to reach an ANC more than 0.5×10⁹/L, time to ANC >1.0×10⁹/L, days with fever, and days to discharge. Regarding platelet recovery and extra-hematological toxicities no statistical differences were observed between the two groups. *Conclusions*. This phase II randomized study shows that PEG was not inferior to FIL in terms of hematological reconstitution (primary end point). PEG could be safely used after PBSC infusion.

Table 1. Patient characteristic.

	FIL** N (%)	PEG** N (%)
	40 (100)	40 (100)
Median age (range)	48 years (21-72)	45 years (20-72)
Sex (M/F)	22/18	23/17
Disease		
Multiple Myeloma	6 (15)	6 (15)
Non-Hodgkin lymphoma	19 (48)	16 (40)
Hodgkin lymphoma	11 (27)	14 (35)
Acute leukemia	2 (5)	1 (2)
Solid tumors	2 (5)	3 (8)
Disease status		
Complete remission	30 (75)	29 (73)
Partial remission	8 (20)	9 (22)

COMPARATIVE EFFECT OF FILGRASTIM VS. PEGFILGRASTIM AFTER CHEMOTHERAPY ON HIGH GRADE NON HODGKIN LYMPHOMA

E. Magro Mazo,[1] J.J. Gil-Fernandez,[1] J. Garcia Suarez,[2] M. Callejas Charavia,[1] Y. Martin Guerrero,[3] T. Pascual Garcia,[2] M. Lopez-Rubio[2]

[1]Hospital Príncipe de Asturias, MADRID; [2]Hospital Principe de Asturias, MADRID; [3]Hospital Píncipe de Asturias, MADRID, Spain

Background. The use of growth factors may reduce the duration of neutropenia induced by chemotherapy. New pegylated form may be of further benefit for movilization of haemopoietic precursors and is under evaluation associated to chemotherapy. *Aims*. We performed a comparative study to evaluated the capacity to prevent fever associated to neutropenia and the recover of highly myelosuppressor post-chemotherapy neutropenia with haematopoietic growing factor (Filgrastim: 300µg/dayx5days) and the pegylated form (Pegfilgrastim 6mg:). Haematopoietic Progenitors Cells (HPC) were determined by two different methods: quantification of CD34⁺ cells by flow cytometry (FCM) and in the Sysmex XE-2100 auto-analyzer. *Material and Methods*. 56 cycles administered in patients with high grade NHL were analyzed. Median age was 63 years (47-76). Male/female proportion was 62,5% and 37,5% respectively. Treatment regimens were CHOP-R14 and EDOCH-R14 (VP-16 at 50mg/ m² /d x 4d, Adriamicine 10mg/ m²/d x 4 d, Vincristine 0.4 mg/m²/d x 4 d, Cyclophosphamide 750 mg/ m²/d x 1 d, Dexamethasone 40 mg/m²/d x 5d y Rituximab 375 mg/m²/d). Selection was based on age and IPI. Patients were randomized to receive Filgrastim 5 µg/Kg/day sc during 5 days vs. Pegfilgrastim 6 mg SC, in unique dose in the day +4. Feverish neutropenia and side effects were examined in both branches. Periodic determinations of HP were performed on days 6-7, 8-9, 11-12 post-QT, with the intention of analyzing neutropenia nadir and the exit of it in the cycles. The number of CD34⁺ cells circulating in peripheral blood was analyzed by FCM with FASCALIBUR, and counting HPC in the IMI channel with the Sysmex XE-2100 analyzer. *Results*. Neutropenia episodes: 16/56 (28%), feverish neutropenia admittances: 5/56 (9%), (3 received Peg-filgrastim (1CHOP-R and EDOCH-R) and 2 Filgrastim (1 CHOP-R). Neutropenia median (<500) on the day +11 for EDOCH-R and +10 in CHOP-R. Most of neutropenia episodes (12/16, 75%) were after EDOCH-R. Feverish neutropenia episodes with no admittance were only 2/56 (3,5%). Number of delays in the neutropenia cycle administration were 2/56 (3,5%). Only one case of severe bone pain was reported after administration of Pegfilgrastim. HPC were not detected with any of the two methods before day +11. HPC were detected by both methods. The coefficient of correlation between HPC counts by Sysmex XE-2100 and CD34⁺ cells by FCM was r=0.68. *Conclusions*. 1. No significant differences to prevent febrile neutropenia were observed between the two haemopoietic growing factors in this study. 2.No difference in the neutropenia nadir was observed. 3.The measure of the HPC demonstrates its presence in the cycle nadir (day +10 and +11), by both methods.

AN ERYTHROPOIETIN AND CYCLOPHOSPHAMIDE COMBINATION ADDITIVELY ENHANCES IMMUNOGLOBULIN PRODUCTION IN MICE

A. Berger, L. Lifshitz, M. Mittelman, D. Neumann

Sackler Faculty of Medicine, Tel Aviv University, TEL AVIV, Israel

Background. Erythropoietin (EPO) is an important component in the treatment of cancer related anemia, and it is usually combined with chemotherapy. Cyclophosphamide (CP) is a known cytotoxic alkylating as well as immune suppressing agent, widely used in cancer chemotherapy. The anti-neoplastic activity of CP at low doses is attributed to enhancement of cellular and humoral immunity. We have previously shown that EPO displays anti-neoplastic activity (Mittelman, 2001; 2004) and that EPO treatment is associated with enhancement of both the humoral and cellular immune responses (Prutchi-Sagiv, 2006; Katz, 2007). We have recently examined a murine model of anti DNP-KLH immunization, in order to assess the effect of EPO on immunoglobulin (Ig) production. We have shown that administration of high doses of recombinant human EPO (rHuEPO) (180u x 3/wk) to DNP-KLH-injected BALB/c mice resulted in an increase in anti-DNP IgG1 production (Katz, 2007). *Aims*. Here we focused on the humoral immunomodulatory effects of combined CP+EPO treatment both administered at low doses, thus simulating clinical conditions. *Methods*. Low dose CP (12.5mg/kg) was administered for 2 days before antigen (DNP-KLH) administration, followed by rHuEPO injection (90u x 3/wk). We compared anti-DNP Ig serum levels in DNP-KLH-injected C57BL mice that were treated with either EPO or CP alone, or with CP+ EPO combination. *Results*. CP treatment alone resulted in increased anti-DNP IgG1 serum levels (CP-O.D.450 nm = 0.38±0.06 vs. non-treated-O.D.450nm = 0.18±0.06, $p<0.05$). In contrast, EPO treatment alone enhanced IgG2a levels (EPO-O.D.450 nm = 0.47±0.09 vs. non-treated-O.D.450nm = 0.18±0.07, $p<0.05$). Moreover, the combined CP+EPO treatment maintained the increase in both IgG1 and IgG2a subtype levels (CP+EPO-O.D.450nm = 0.38±0.06, CP+EPO-O.D.450nm = 0.49±0.1, respectively). With respect to anti-DNP total Ig, while neither CP nor EPO alone conferred any significant effect, the combined CP+EPO treatment resulted in markedly increased total Ig serum levels (CP+EPO-O.D.450nm = 0.48±0.05 vs non-treated-O.D.450 nm = 0.28±0.07, $p<0.05$), most likely reflecting the higher levels of IgG1 and IgG2a. Hence, the combined CP+EPO treatment additively improves Ig production, compared to treatment with either CP or EPO alone. *Summary*. We thus demonstrate that in the context of chemotherapy treatment, EPO can enhance the humoral immunity in addition to its erythropoietic activities. Our findings emphasize the potential role of EPO as an immunomodulator, particularly when given as a part of a combined treatment.

ATYPICAL WHIM SYNDROME ASSOCIATED WITH GRANULOMATOSIS: REPORT OF TWO CASES

A.-V. Doncker,[1] K. Balabanian,[2] C. Bellanne-Chantelot,[3] S. de Guibert,[1] F. Bachelerie,[4] T. Lamy[1]

[1]Pontchaillou Hospital, RENNES; [2]INSERM U764, Université Paris-Sud 11, CLAMART; [3]Centre de génétique Moléculaire et chromosomique,Hôpital de la Pitié-Salpêtrière, PARIS; [4]Unité de Pathogénie Virale, Institut Pasteur, PARIS, France

We report on two cases of young females presenting with extended granulomatosis, warts, recurrent infections, severe B-cell lymphopenia, and neutropenia sensitive to granulocyte-colony stimulating factor. One patient granulomatosis was successfully treated with upfront interferon α2-a. Three years later, the patient developed severe post-cytomegalovirus hemophagocytic syndrome. The other patient died of mycobacterium avium septicemia, two years after the initial presentation. These two patients were suspected of WHIM syndrome, a rare immunodeficiency disorder associated to dysfunctions of the CXC chemokine receptor 4, which combines Warts, Hypogammaglobulinemia, Infections and Myelokathexis. Genetic analysis of CXCR4 concluded with a wild type genotype whereas functional analyses of CXCR4 revealed a defective internalization upon CXCL12 stimulation. However, WHIM diagnosis could not strictly be asserted due to the absence of myelokathexis on bone marrow histology. These two clinical observations of granulomatosis with immuno-hematological disorder related to CXCR4 dysfunctions could be assimilated to an atypical WHIM syndrome.

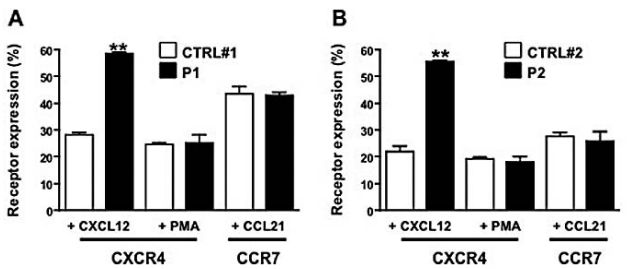

Figure 1. Impaired CXCL12-induced internalization of CXCR4.

THE PHYSICOCHEMICAL PROPERTIES OF A BIOSIMILAR FILGRASTIM ARE COMPARABLE TO THOSE OF NEUPOGEN

A. Skrlin,[1] I. Radic,[1] M. Vuletic,[1] D. Schwinke,[2] D. Runac[1]

[1]8PLIVA Croatia Ltd, ZAGREB, Croatia; [2]Hospira Inc, ILLINOIS, USA

Background. Recombinant human granulocyte-colony stimulating factor (rhG-CSF; filgrastim) is a therapeutic protein used primarily to reduce the incidence and duration of severe neutropenia and associated complications. Following patent expiry, Hospira and PLIVA have worked together to co-develop a biosimilar filgrastim (Hospira filgrastim) that is highly comparable to Neupogen®, the filgrastim originally produced by Amgen. The complexity of manufacturing a biopharmaceutical such as filgrastim is much greater than that of conventional, low-molecular weight generic medicines. Thorough comparability analyses are required to demonstrate similarity to the reference medicinal product before regulatory approval is granted. *Aims*. To assess the physiochemical similarity of Hospira filgrastim to Neupogen®. *Methods*. An extensive characterisation study was performed to compare Hospira filgrastim to Neupogen®. Both drugs were supplied in 1mL glass, single-use, prefilled syringes (five batches of each product at 480 μg/0.5mL and one batch of each product at 300 μg/0.5mL). State-of-the-art analytical methods were used to evaluate physicochemical properties and molecular characteristics (appearance, colour, clarity, pH, intact molecule mass, protein concentration, isoelectric point, secondary protein structure, amino acid sequence and disulphide bridges position), assay, purity and biological activity. A side-by-side comparability exercise was performed on samples stored in long-term storage conditions (2-8°C), as well as on stressed samples (40°C), in order to compare degradation impurity profiles between Hospira filgrastim and Neupogen®. All methods were validated in accordance with ICH or Ph. Eur. guidelines. *Results*. All tested batches of Hospira filgrastim and Neupogen® stored at long-term storage conditions were within the acceptance criteria for all parameters tested. All batches of the two drugs complied with the circular dichroic and fluorescence spectra for the secondary and tertiary structure of filgrastim. The amino acid sequence and disulphide bridges position in all tested batches were consistent with those previously reported. SDS-PAGE and isoelectric focusing showed that Hospira filgrastim and Neupogen® have comparable molecular masses and isoelectric points. All detected impurities in both products were at similar levels. The biological activity of Hospira filgrastim and Neupogen® were similar and within the accepted range. There were no significant differences in profile and quantities of the product-related impurities between Hospira filgrastim and Neupogen® following storage for 12 weeks under stress conditions. *Conclusions*. These data, acquired using rigorous analytical methodology, show that the physicochemical profile of Hospira filgrastim is highly comparable to that of Neupogen®. If these similarities are borne out in clinical studies, Hospira filgrastim may prove to be a valuable and cost-effective alternative to Neupogen®.

Table 1.

Assessment	Hospira filgrastim	Neupogen
Identification by SDS-PAGE and isoelectric focusing	Principal band in similar position to reference solution	Principal band in similar position to reference solution
Impurities by SDS-PAGE and isoelectric focusing	No band is more intense than reference solution	No band is more intense than reference solution
Impurities with molecular mass higher than that of filgrastim by size exclusion chromatography	<0.20%	<0.20%
Filgrastim assay by RP HPLC†	0.89–0.94mg/mL	0.84–0.85mg/mL
Impurities by RP HPLC#	1.82–2.20%	1.51–2.37%
Impurities by ion chromatog.#	<0.20%	0.30–0.46%
pH‡	4.0–4.1	3.9–4.0
Protein (UV/Vis)‡	0.92–0.94mg/mL	0.88–0.91mg/mL
Intact molecule determination‡	18,800Da	18,800Da
Biological activity assay‡	95.8–98.2x10^6 IU/mL	78.9–93.5x10^6 IU/mL

†For 480μg/0.5mL presentation, excluding expired batches
#Results for both presentations, excluding expired batches
‡Data from independent data set of three batches each of Hospira filgrastim and Neupogen
