formed by flow cytometry, which is very expensive and time consuming. Therefore the separation centers try to find less expensive and more effective leukapheresis procedures that would mean fast laboratory results, minimization of excessive administration of growth factors, and reduction of ineffective harvests. *Aims*. We introduced new methods of PBSC determination. One of them was the detection of hematopoietic progenitor cells (HPC) by hematology analyzer Sysmex. The principle of this method is exposure of the cells to high-frequency current penetrating into them and direct current flowing around them. The cells are separated according to their inner density and size. This method is fast, simple and inexpensive. Another enzymatic method is the determination of aldehyddehydrogenase (ALDH) in PBSC by flow cytometry. The third method applied is the determination of $CD133^+$ cells by flow cytometry. *Design and Methods*. We examined a group of 54 persons (M30, F24, aged 20-67, median 56 yrs) suffering from multiple myeloma (n=28), lymphoma (n=19), acute leukemia (n=1), solid tumor (n=2), and healthy donors (n=3). In the period from August 2007 to December 2008, we performed 159 leukaphereses (the mean 3 at one person). We determined the PBSC count in the peripheral blood (PB) before, and in the cell concentrate (CC) after the collection, making use of all the methods. We correlated new methods with the CD34+ cells method using Spearman rank correlation coefficient. Further, we evaluated the sensitivity and specificity of the HPC method. *Results*. The correlation of CD34+cells vs. HPC (R=0.592) and $CD34^+$cells vs. ALDH (R=0.574) in PB was good, and the correlation of $CD34^+$ vs. CD133+cells (R=0.907) and $CD34^+$ vs. $Cd34^+/CD133^+$ cells (R=0.915) in PB was very good. The correlation after separation in CC was very good in $CD34^+$cells vs. ALDH (R=0.865), $CD34^+$ vs. CD133+cells (R=0.971) and $CD34^+$ vs. $Cd34^+/CD133^+$cells (R=0.972), the correlation $CD34^+$cells vs. HPC (R=0.244) was, however, very low. We found that with increasing HPC count in specimens the sensitivity of HPC method decreases and the specificity increases. *Conclusions*. The HPC method appears acceptable for the improvement of leukapheresis procedures. The HPC count 30/mL (sensitivity 92.3%, specificity 60.3%) in PB may be considered the minimum count to start the PBSC collection. The HPC count 10/mL (high sensitivity 96.9%) in PB may be the limit to exclude the collection and investigation of $CD34^+$ cells. The HPC method cannot substitute the determination of $CD34^+$ cells in CC. Flow cytometry methods are comparable with the $CD34^+$cells method (correlation, time, costs) but disadvantageous for investigation of PB. The ALDH method may be, however, suitable for determination of the PBSC vitality in CC.

CLINICAL RESULTS OF DONOR LYMPHOCYTE INFUSIONS (DLI) AFTER ALLOGENEIC STEM CELL TRANSPLANTATION: ROLE IN THE TREATMENT OF MIXED CHIMERISM AND RELAPSE

M. Kwon, I. Buno, D. Serrano, P. Balsalobre, G. Rodriguez Macías, J. Gayoso, A. Gomez Pineda, J.L.D.M. Diez Martin

Hospital Gral. Univ. Gregorio Marañon, MADRID, Spain

Background. DLI have proven to be effective in different settings after allogeneic stem cell transplantation (SCT) such us treatment of leukemic relapse, especially in CML, and management of persistent mixed chimerism (MC). Few reports have evaluated its usefulness in the setting of graft rejection. Aim. To evaluate the role of DLI in the treatment of persistent MC, MC with incipient graft rejection, and the treatment of disease relapse after allogeneic SCT. Design and Methods. 32 patients (pts) who underwent allogeneic SCT between 1996 and 2008 were retrospectively studied. Pts characteristics are shown in Table 1 and 2. Thirteen pts received a myeloablative SCT from an HLA-matched sibling donor, 2 from an unrelated donor, and 2 from a haploidentical donor. Six patients underwent a RIC SCT. Seven patients received CD3 depleted grafts. *Results*. A total of 12 DLI were used to treat MC in 9 pts: in 5 pts due to persistent MC and in 4 pts with MC in the context of incipient graft rejection. Five pts of this group had received a manipulated graft (CD3 depleted). CD3 doses and time of infusion are shown in Table 1. Seven out of 9 pts (77%) showed response (return to CC in PB and/or BM with normal blood count) after a median of 100 days (61-228). Two patients did not respond: an AML pt who relapsed shortly after DLI and a pt with hamophagocytic syndrome as underlying disease. GVHD rate was 77%, mostly acute grade II-III. After a median follow-up of 34 months (1.8-106), 4 pts are alive with an OS of 44%. On the other hand, 30 DLI were used to treat relapse in 14 pts, 9 of which received an escalating dose scheme (Table 2). Interestingly, a high proportion of the underlying disease of this group of pts were lymphoid malignancies (9/14). Only two pts had received a manipulated graft for SCT. Six patients received chemo/radiotherapy for the relapse before DLI. Only 5 out of 14 pts (35%) showed response, among them 2 were CML-CP pts. GVHD rate was 50% (acute II-IV in 4 pts and chronic in 2). This lower incidence could be associated to shorter survival in this group after DLI. After a median follow-up in this group of 21 months (2.9-99), only 3 pts are alive, two of them in remission. *Conclusions*. Although these results arise from a heterogeneous and small group of patients, in our experience, the clinical benefit of DLI after allogeneic SCT is limited to the management of MC, both persistent MC and MC with incipient graft rejection. DLI was not successful in the management of relapse, even in pts receiving chemo/radiotherapy before. These data suggest that novel strategies such us prophylactic DLI should be considered in high risk pts instead of DLI in visible phase.

HIGH CD4/CD8 RATIO IN ALLOGRAFTS PREDICTS ADVERSE OUTCOMES IN UNMANIPULATED HLA-MISMATCHED/HAPLOIDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR CHRONIC MYELOID LEUKEMIA

H. Xiao-Jun, L.P. Xu, X.H. Luo, Y.J. Chang, D.H. Liu, K.Y. Liu, Y.H. Chen

Peking University People's Hospital & Peking University Institute of Hematology, BEIJING, China

Background. HLA-mismatched/haploidentical hematopoietic stem cell transplantation (haplo-mismatched HSCT) has improved the outcome of chronic myeloid leukemia (CML) in patients without an HLA-matched donor [*Ann Medi 2008,40:444*].

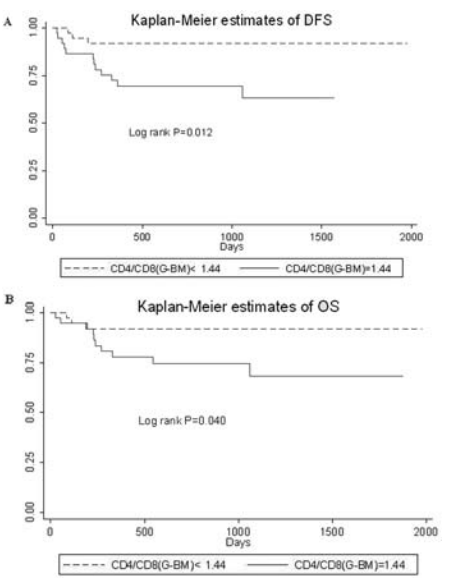

Figure 1. Kaplan-Meier estimate of disease free survival.

Aims. To further improve the treatment outcome of haplo-mismatched HSCT in CML, a modiable prognostic factor needs to be found. *Design and Methods*. The cellular composition of grafts obtained from 75 HLA-mismatched/haploidentical related donors was prospectively correlated with the outcome of patients with CML undergoing haplo-mismatched HSCT following a modified regimen of BU/CY 2 plus antithymocyte globulin. *Results*. The concentration of T-cell subsets, $CD14^+$, and $CD34^+$ cells and their relative proportions were analyzed. In univariate analyses, disease free survival (DFS) and overall survival (OS) conversely correlated with the CD4/CD8 ratio in primed bone marrow graft (G-BM) (p=0.012 and p=0.040); similarly, CD4/CD8 ratio in total grafts was also negatively associated with DFS and OS (p=0.018 and p=0.020). In multivariate analyses, a CD4/CD8 ratio in G-BM higher than the median value remained the only factor negatively affecting DFS (p=0.030; 95% confidence interval [CI]:1.166-19.341) (Figure 1A and 1B). Expectedly, high CD34+ cell dose was associated with accelerated platelet engraftment (p=0.009; 95% CI=1.181-3.271), after controlling for a high risk of disease. No other clinical parameter was influenced by graft composition. *Conclusions*. Our results suggest that a high CD4/CD8 ratio in allografts may predict adverse survival in patients undergoing an haplo-mismatched HSCT.

FACTORS PREDICTING ALLOGENEIC PERIPHERAL BLOOD STEM CELL (PBSC) MOBILIZATION AFTER G-CSF TREATMENT IN HEALTHY DONORS

E. Brissot,[1] P. Chevallier,[2] J. Delaunay,[2] S. Ayari,[2] T. Guillaume,[2] A. Devys,[3] V. Stocco,[3] P. Moreau,[2] J.L. Harousseau,[2] M. Mohty[2]

[1]Department of Hematology-Hotel Dieu, NANTES, France; [2]Department of Hematology, NANTES, France; [3]EFS, NANTES, France

G-CSF mobilized PBSCs are increasingly used in allogeneic stem cell transplantation (allo-SCT) due to their relative ease of collection and because higher $CD34^+$ cell doses may be associated with improved transplant outcomes in some settings. However, some healthy donors may show poor mobilization response to G-CSF and poor subsequent CD34+ apheresis yields. Therefore, identifying donors at risk for poor mobilization and a reliable estimate of a healthy donor's $CD34^+$ cell mobilization response to G-CSF and subsequent $CD34^+$ cells yield could be of value in optimising transplantation approaches. The aim of this single centre report was to analyze factors associated with PBSC mobilization and yield in an ethnically homogeneous caucasian population (n=95; 53% males) of healthy allogeneic adult donors. All donors received G-CSF dosed at 10 μg/kg/d for 5 days followed by large volume leukapheresis. Complete blood counts (total WBC, Hb, Platelets) were measured for all donors at baseline before G-CSF administration, before and after PBSC collection. Peripheral blood $CD34^+$ cell counts were also measured prior to apheresis. 69 donors (73%) were healthy sibling donors, while 26 (27%) were healthy volunteer donors for HLA-identical unrelated transplants. All donors were undergoing their first PBSC mobilization. In this cohort, donors' demographic characteristics were as follow (median; range): age, 47 (18-81) years, weight, 69 (43-106) kg, height, 170(150-187) cm, body-mass index (BMI), 23.9 (15.2-35.7) kg/m^2. As per institutional policy, the targeted total number of $CD34^+$ stem cells was between 4 and 8x10^6/kg recipient body weight to be collected in a maximum of 3 apheresis sessions. Overall, the median number of collected $CD34^+$ cells was 6.25x10^6/kg (range, 1.7-16.6), with 16 donors (17%) yielding less than 4x10^6/kg $CD34^+$ cells. In univariate analysis, female gender, lower weight, height, pre-G-CSF and post G-CSF Hb levels, and low CD34+ cell counts prior to first apheresis, were associated with significantly lower total $CD34^+$ stem cells yields (<6.25x10^6/kg). In multivariate analysis, male donor gender and higher post-G-CSF CD34+ cell counts prior to the first apheresis were most strongly associated with a higher total number of collected $CD34^+$ stem cells (OR=6.17, 95%CI (2.39-15.93), p=0.0001; and OR=3.95, 95%CI (1.53-10.19), p=0.004 respectively). Also, when considering the group of 16 "poor" mobilising donors ($CD34^+$ stem cells yield <4x10^6/kg), in multivariate analysis, we found that a higher post-G-CSF CD34+ cell count prior to the first apheresis was the strongest parameter significantly associated with a higher total number of collected CD34+ stem cells (OR=6.36, 95%CI (1.68-24.15), p=0.006). *Results*. From our study indicate that a quick assessment of risk for poor mobilization response in healthy donors can be achieved through simple demographic and routine parameters. Indeed, knowledge of predictive factors for mobilization to G-CSF may be of high interest, with the development of newer mobilizing agents like CXCR4 antagonists, and may result in overall benefit both to donors and patients

HAPLOIDENTICAL STEM CELL TRANSPLANTATION: A SINGLE CENTER EXPERIENCE

R.B. Ferreira,[1] F. Campilho,[1] C. Pinho Vaz,[1] A. Teixeira,[1] A. Martinho,[2] S. Roncon,[1] A. Carvalhais,[1] A. Campos[1]

[1]Instituto Português Oncologia, Porto, PORTO, Portugal; [2]Centro de Histocompatibilidade do Centro, COIMBRA, Portugal

Introduction. Over the last years haploidentical stem cell transplantation (SCT) has become a treatment option for patients without a full matched donor. The availability of a partially mismatched related donor in most cases has potential advantages in this setting. *Aims and Methods.* We performed a retrospective analysis of all haploidentical allogeneic SCT performed in our center between 1999 and 2008. *Results*. In this period 468 allogeneic SCT were performed in 402 patients. Of these, 16 procedures (3,4%) were haploidentical and performed in 15 patients (8 males and 7 females), with a median age of 6 years (range: 6 months to 40 years old). Diagnosis were: primary immunodeficiency: 2 patients; congenital amegakaryocytic thrombocytopenic purpura: 1; acute myeloid leukaemia: 7; myelodisplastic/ myeloproliferative syndrome: 1; myeloid metaplasia: 1; Ph^+ chronic myeloid leukemia: 1; and acute lymphoid leukaemia: 2. Haploidentical SCT was performed as the first allotransplantation option in 11 patients, and in 5 as salvage therapy after graft failure of a previous transplant. All the patients had one of their parents as donor (mother in 6, and father in 9). Graft consisted of mobilized peripheral-blood progenitor cells in all cases. Patients received a median of 10.5x10^6 $CD34^+$ cells per kilogram (range: 2,86 to 15,2x10^6), after positive CD 34^+ *in vitro* selection. A median of 1.5x10^5 (range: 0.5 to 11.4x10^5) of $CD3^+$ cells was infused. Nine conditioning regimens were nonmyeloablative and 5 were myeloablative. In 9 patients bussulfan based regimens have been used. TBI was not performed. Alentuzumab as part of the conditioning was used in 6 transplants and ATG in 7. No conditioning was made in 2 cases: one primary immunodeficiency; the other a second transplant performed in the same patient. Graft-versus-host disease (GVHD) prophylaxis with calcineurin inhibitor was done in 10 patients. Grade II to IV acute GVHD occurred in 3 patients, 2 of them with evolution to chronic GVHD. At 1 year post transplantation, evaluable patients presented the following median peripheral blood cell counts: 228,5/μL (range: 9 to 936/μL) of CD4+, 420/μL (range: 0 to 3888/μL) of CD8+ and 574/μL (range: 0 to 1148/μL) of CD19+. One year TRM was 27,8% (+11.9%). Death due to disease progression occurred in 3 patients (18.75%). Eleven patients (73,3%) established successful engraftment at a median of 14 days (range: 9 to 22) post transplantation. Of those who failed to engraft, 1 received a second transplant and died of the disease. Median overall survival has not yet been attained. Median follow-up of the alive patients is 2,7 years (range: 9 months to 8 years), with a 4 year overall survival of 52% (+13%). *Conclusions*. In selected clinical situations, haploidentical SCT may be considered given the facts that the probability of finding a sibling HLA-matched donor is low, that identifying an unrelated one in the acceptable time frame can be a challenge, and in some patients with rare haplotypes or of an ethnic minority this probability can be remote.

1154

KINETICS OF CD34 POSITIVE CELLS MOBILIZATION IN PATIENTS WITH NON-HODGKIN'S LYMPHOMA TREATED WITH THE DHAP REGIMEN PLUS FILGRASTIM OR PEGFILGRASTIM

F. Gaudio,[1] D. Pastore,[1] M. Delia,[1] A. Giordano,[1] T. Perrone,[1] A. Mestice,[1] L. Cazzato,[2] C. De Risi,[1] A. Spina,[1] M. Leo,[1] G. Nardelli,[1] C. Spinosa,[1] V. Liso,[1] G. Specchia[1]

[1]Hematology, BARI, Italy; [2]Immunohematology, BARI, Italy

High-dose chemotherapy and autologous stem cell transplantation play an important role in achieving long-term remission in certain groups of patients with non-Hodgkin's lymphoma (NHL). A potential advantage of using mobilized peripheral blood stem cells (PBSC) is the possibility of harvesting a great number of hematopoietic stem cells and committed precursors, capable of more rapid engraftment. The DHAP regimen has thus been integrated into various treatment plans tailored for NHL patients as a salvage chemotherapy and mobilizing regimen. Fil-

grastim is commonly used to mobilize PBSC. A single injection of pegfilgrastim has been shown to be equivalent to daily filgrastim in enhancing neutrophil recovery after chemotherapy, whereas the experiences with pegfilgrastim in PBSC mobilization are limited The study included 72 patients (mean age 37 years, range 17-60) with NHL (42 follicular and 30 large cells). Sixty-four patients (88.9%) had stage III-IV disease; 48 patients (66.7%) had bone marrow involvement. Systemic B symptoms were present in 42 patients (58.3%). Mobilization chemotherapy regimens were DHAP plus filgrastim in 38 patients (52.7%) or pegfilgrastim in 34 (47.2%). Pegfilgrastim 6 mg was given subcutaneously on day +6; filgrastim 5 microg/kg/day from day +6. In 65 of 72 patients a median of 12.3x10^6/CD34+ cells (range 2.5-28.9) was harvested after a median of 13 days (range 8-16 days), with a single apheresis procedure in 58 (80.6%) cases. Failure to mobilize, defined as failure to reach a circulating CD34+ cell count of 10/mcl, occurred in 5 patients (13.2%) in the Filgrastim group and 8 (23.5%) in the pegfilgrastim group (p=n.s.). No difference was found in terms of pre-apheresis CD34$^+$ cell count. The mean number of CD34+ cells collected was 13.2x10^6/kg in the pegfilgrastim group and 12.3x10^6/kg in the filgrastim group (p=n.s.). A median of CD34+ > 10 cells/microl in peripheral blood was reached in 12 days (range 8-14) in the filgrastim group and in 15 days (range 12-18) in the pegfilgrastim group (p=n.s.) The median duration of CD34+ >10 cells/microl in peripheral blood was 4 days (1-5) in the filgrastim group and 7 days (3-12) in the pegfilgrastim group (p<0,05). All patients had grade 3-4 neutropenia, median duration was 4 days. The only adverse event was mild bone pain. To date, 65 patients have been autografted with a median of 5.4x10^6 CD34+ cells/kg (range 2.5-12.9), achieving rapid and sustained engraftment. *Conclusions*. The results confirm the efficacy and feasibility of PBSC mobilization with chemotherapy and single-dose pegfilgrastim in patients with non Hodgkin lymphomas. In less heavily pretreated patients, 6 mg of pegfilgrastim after chemotherapy induced adequate mobilization, whereas after numerous cytotoxic regimens dose and schedule need further investigation.

1155

DOES EXTENSIVE CHRONIC GRAFT VERSUS HOST DISEASE REPRESENTS FREQUENT COMPLICATION AFTER PERIPHERAL BLOOD STEM CELL TRANSPLANTATION IN COMPARISSON TO BONE MARROW TRANSPLANT- RESULTS OF LONG TERM FOLLOW UP

D. Stamatovic, Lj. Tukic, B. Balint, O. Tarabar, M. Elez, G. Ostojic, B. Todoric-Zivanovic, Z. Tatomirovic, O. Tasic-Radic, B. Cikota, M. Malesevic, S. Marjanovic

Military Medical Academy, BELGRADE, Serbia

During previous years, many studies have compared efficacy of allogeneic stem cell transplantation (SCT) from peripheral blood (PB) with bone marrow (BM), but final conclusion concerning this treatment modality is still not well defined. AIM: to compare efficacy of PBSCT with BMT in the treatment of hematological malignancies with respect to engraftment, transfusion need, frequency and severity of acute (mukositis, acute graft versus host disease- aGvHD, transplant related mortality- TRM) and late complications (chronic- cGvHD, relapses) and overall survival (OS). *Design and Methods*. We have analyzed 132 patients (pts), median age 27 years (9-52), male/female 84/48, with various hematological diseases (severe aplastic anaemia- 18, chronic myelod leukemia- 31, acute myeloid leukoemia- 29, acute lymphoblastic leukemia- 38, myelodisplastic syndrome- 8, myeloma multiplex- 2, Morbus Hodgkin- 2, Granulocytic sarcoma- 2) in whom we perfomed allogeneic SCT from 1989 till 2008. In 15 pts we perfomed secondary allogeneic SCT in due to graft rejection (2) or relapses (13 pts). Pts were divided into two groups concerning SC origin- 69 pts in BM group and 63 pts in PB group. All pts had HLA-DR sibling transplant (5 singeneic, 121 fully matched, 4 mismatched and 2 haploidentical). SC were collected from BM up to standard method and from PB with one apheresis after five days aplication of granulocytic growth factor. All pts have received unmanipulated suspension of SC. Conditioning were adjusted to primary diseases and GvHD prophylaxis was mostly combination of Cyclospirine A and Metothrexate. Prevention of infections were standard. *Results*. Pts with SC originate from PB have received significantly more mononuclear cells (10.07±7.31 vs 2,33± 0.79, p<0.001) in comparisson with BM. Engraftment was more rapid (p<0.001) in the PB group approximately for 6 days. Transfusion requirements were much higher in BM group (p<0,01). Those pts had more frequent oropharingeal mukositis grade 3-4 (33,33% vs 9,5%, p<0.05). There were no difference in the incidence of acute (44,4% vs 49,2%, ns) or chronic GvHD (38,6% vs 54,5%, ns). Pts with PBSCT had significantly more frequent extensive cGvHD (29.5% vs 12,4%, p<0.05). There were no difference considering TRM (10.1% vs 15.1%, ns) or relapses (21.7% vs 22.2%, ns). Pts with BMT had better overall survival but with no statistical significancy. *Conclusions.* Results of this retrospective analysis mostly corresponds with other studies showing that PBSCT have rapid engraftment and less acute complications. PBSCT is connected with more frequent extensive chronic GvHD that is potentialy fatal, making results of this particular treatment option less better. Definite estimation of PBSCT efficacy in comparisson to BMT should be done in homologous groups.

1156

HIV+ AND HIV- LYMPHOMA/MYELOMA PATIENTS SHOW SIMILAR IMMUNE RECONSTITUTION (IR) AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT)

J.M. Sanchez Ramirez, A. Perez-Corral, J. Anguita, C. Muñoz Novas, D. Serrano, G. Rodriguez Macias, I. Buño, P. Balsalobre, E. Sarmiento, A. Gomez Pineda, J.L. Díez-Martín

Gregorio Marañon Hospital, MADRID, Spain

Introduction. Short to medium term IR after ASCT in HIV+ patients with lymphoma and myeloma (HIV+pt.), remains poorly known due to the low frequency of this procedure. However, its knowledge may constitute an important factor in preventing infections and disease relapses. Aims: To analyze and compare, prospectively, the IR of HIV+ and HIV- pt. with lymphoma or myeloma after ASCT and its influence on their clinical evolution. *Design and Methods*. IR was analyzed by flow cytometry quantifying naive, memory, memory-activated, activated and effector lymphocytes at time of transplantation as well as 3 and 6 months after ASCT. Neutrophil and platelet engraftment (>0.5x10^9/L and >20x10^9/L respectively) and infectious complications were recorded. Patients in both groups had received a median number of 3 (1-3) treatment lines prior to transplant, including local involved field radiotherapy in 2 cases. All received transplantation in complete remission. HIV+pt. cohort: 3 patients (4 ASCT) with a median age of 44 years old (42-47) (1 non-Hodgkin lymphoma-NHL; 1 Hodgkin lymphoma-HL; 1 myeloma-MM). All pt. received BEAM conditioning regimen, except for Melfalan 200 in the case of MM. The HL case received a second ASCT as consolidation treatment with BuxCy conditioning regimen. All pt. underwent ASCT with a median CD34$^+$ cells of 3.75x10^6/Kg (2.45x10^6-5.8x10^6) infused. All cases were on highly active antiretroviral therapy (HAART) during ASCT, but it was discontinued (day+9 to day+19) due to liver toxicity in NHL pt. They presented undetectable viral load, except for the NHL patient who had >50 copies due to a poor adherence to treatment. All patients had more than 400 CD4$^+$ cells/mm3. HIV-pt. cohort: 4 patients (3 NHL; 1 HL) with a median age of 29 years old (22-57). All received BEAM conditioning regimen and ASCT with a median CD34$^+$ cells of 4.3x10^6/Kg (4x106-6.4x10^6) infused. *Results*. Quantification of the different lymphoid subpopulations in the two study cohorts is shown in table 1. Both cohorts reached neutrophil engraftment at a median time of 13 days (11-15). Platelet engraftment was reached at a median time of 36 days (20-78) and 15 days (13-27) in HIV+pt. and HIV-pt. respectively. In HIV+pt., MM patient suffered a pulmonary aspergillosis 36 days after ASCT treated with Liposomal amphotericin B and there were 2 cytomegalovirus antigenemia positive tests in NHL and MM pts. Both were successfully treated. At 3 months the HIV+ group had already reached the pre-ASCT levels of the analyzed lymphoid subpopulations. Lymphocyte counts of the HIV- group at the same time point were better than pre-ASCT levels. An increase in activated lymphocytes has been described in the literature in HIV+pt. significantly associated with a worse prognosis. On the contrary, in the present study, both HIV+ and HIV-pts. showed similar values of activated lymphocytes. *Conclusions*. In our experience, we do not observe any significant differences in IR after ASTC between HIV+ and HIV-, although the only pts. who had serious infectious complications were in the HIV+ group. However, a larger number of cases is required to obtain more significant results.

IS BEAM JUST NOT GOOD ENOUGH? A SINGLE CENTER EXPERIENCE OF DIFFERENT TRANSPLANTATION STRATEGIES IN TRANSFORMED NON-HODGKIN'S LYMPHOMA

M.J. Wondergem, M.L. de Rooij, O.J. Visser, P.C. Huijgens, J.J. Zijlstra

VUMC, AMSTERDAM, Netherlands

Background. Transformed non-Hodgkin's lymphoma has a poor outcome with conventional therapy, with median survival of 11-22 months. Therefore, consolidation treatment with more intensive regimens is commonly used to improve overall survival (OS). Autologous transplantation (AuSCT) is reported to result in 5 year OS ranging from 30-70%. Myeloablative allogeneic transplantation results in 2 year OS of 39-64%, with high treatment related mortality (TRM) and relapse rates. Results are best for upfront transplantation. However, since transformed lymphoma is usually diagnosed at higher age, myeloablative allografting is not an option for most patients. Non-myeloablative allogeneic transplantation is only reported in a small series, with a disappointing OS of <20% at 3 years. Aims: Evaluation of clinical outcome of patients with transformed NHL treated with AuSCT preceded by BEAM or Zevalin-BEAM (Z-BEAM) conditioning or treated with non-myeloablative allogeneic transplantation. *Design and Methods*. In this single center retrospective analysis we reviewed clinical records of all patients with transformed NHL treated with stem cell transplantation between January 1992 and January 2009. We defined three groups: patients treated with AuSCT preceded by BEAM, treated with AuSCT preceded by Z-BEAM, and treated with allogeneic non-myeloablative transplantation after fludarabine-cyclophosphamide conditioning. EFS and OS were estimated using the Kaplan-Meier method and compared using the Breslow test. EFS is defined as follow-up until relapse, disease progression or death of any cause. *Results*. Mean age at transplantation was 53 years (range 32-67 years). The BEAM group consisted of 32 patients, the Z-BEAM group of 6 patients and 8 patients were treated with allogeneic transplantation. Mean follow up was 40 months in the BEAM and allogeneic transplant group and 6 months in the Z-BEAM group. The groups were not significantly different with respect to age, disease stage at diagnosis, lines of chemotherapy and remission status before transplantation. In the BEAM group 13 patients were in CR and 17 in PR before transplantation, with 4 patients in CR and 4 in PR in the allogeneic group. A mean of 2 lines chemotherapy were given before transplantation (range 0-6). EFS proved to be significantly better in the group after allogeneic transplantation compared to the BEAM group. (median EFS 14 vs 58 months, p=0.049, Figure 1).

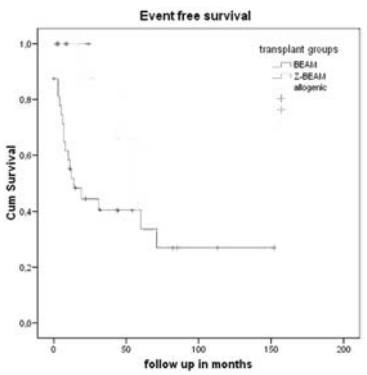

Figure 1.

Moreover, 2 year OS was also better in the allogeneic transplant group: 87% compared to 63% in the BEAM group, although this is not yet statistically significant different (p=0.09). OS and EFS were 100% in the Z-BEAM group, but follow up of this group is to short to reach statistical significance. *Conclusions*. In patients with transformed lymphoma long term survival can be reached with various transplantation strategies. In this retrospective analysis non-myeloablative allogeneic transplantation accomplished a better EFS and showed a trend towards better OS compared to AuSCT after BEAM conditioning. Since radioimmunotherapy has been introduced recently, the promising survival curve of the Z-BEAM group can only be compared after longer follow up.

1158

A RADIATION-FREE, TREOSULFAN CONTAINING, CONDITIONING REGIMEN IS EFFECTIVE IN HAEMOPOIETIC STEM CELL TRANSPLANT (HSCT) FOR HIGH RISK INFANT ACUTE LYMPHOBLASTIC LEUKAEMIA (ALL)

Y.S. Sorour, A. Vora

Haematology Department, Sheffield Children's Hospital NHS Foundation Trust, SHEFFIELD, UK

Introduction. A combination of age < 6 months, re-arrangement of the MLL gene and WCC >300x10μ/L or a poor response to the prednisone prophase identifies a very poor risk sub-set of infant ALL with a 2 year EFS of < 20%. The efficacy of allogeneic HSCT using standard myeloablative conditioning is uncertain in this sub-group. Additionally it is associated with significant toxicity including severe mucositis and veno-occlusive disease (VOD) of the liver. Treosulfan (l-threitol-1,4-bis-methanesulfonate) is a conditioning agent that promises a favourable toxicity profile compared with busulfan or TBI. *Design and Methods.* Between July 2004 and July 2008, 6 infants with ALL and high risk features (MLL gene rearrangement present in 5/6 patients, white cell count >300x10 m/L in 3/6 patients, 4 patients were <6 months of age, 2 had primary refractory disease, including the patient with germ line MLL, and one patient was transplanted in CR2) underwent allogeneic HSCT at our centre using treosulfan in place of busulfan. Donor sources included; one identical sibling and five unrelated cord blood. Of the unrelated cord transplants, 2 patients were 6/6 match, 2 patients were 1/6 loci mismatches and 1 patient was 2/6 loci mismatch. All patients received treosulfan 12 g/m^2 IV days '6, '5 and '4, and cyclophosphamide 60 mg/kg IV days '3 and '2. Four patients received additional immunosuppression (antithymocyte globulin 1-2.5 mg/kg). All patients received ciclosporin (5 mg/kg), with one patient also receiving a short methotrexate course (10 mg/m^2 days +3 and +6) as graft-versus-host disease (GvHD) prophylaxis. *Results*. Primary engraftment occurred in all patients with 100% donor chimerism at day +100. Median discharge was day +22.5 (17-57 days) with median platelet recovery >20-10^9/L at day +27.5 (18-66 days), >50 - 10m/L at day +32 (27-83 days) and neutrophil count >1-10^9/L at day +29.5 (17-53 days). Toxicity was minimal, no patients developed mucositis or VOD of the liver (despite one having recently recovered from thioguanine-related VOD). All six patients developed transient mild skin aGvHD, grade I-II. One patient relapsed and died at 10 weeks post-transplant. The remaining patients are alive in remission at a median follow-up of 25 months (range 8-56 months). *Conclusions*. Treosulfan/Cyclophosphamide is associated with minimal toxicity and provides sufficient anti-neoplastic activity in high risk infant ALL.

1159

INTERMEDIATE DOSE ARA-C IS A SAFE AND EFFECTIVE REGIMEN TO COLLECT PERIPHERAL BLOOD PROGENITORS CELLS IN PREVIOUS POOR MOBILIZER NON HODGKIN'S LIMPHOMA AND MULTIPLE MYELOMA PATIENTS

P.R. Scalzulli,[1] G. D'Arena,[1] M. Dell'Olio,[1] L. Melillo,[1] A. Falcone,[1] G. Sampaolo,[1] G. Fania,[2] N. Dello Iacono,[2] P. Marchesani,[2] A. Giacobazzi,[3] A. Guarini,[3] M.R. Valvano,[4] L. Di Mauro,[2] N. Cascavilla[5]

[1]IRCCS Casa Sollievo della Sofferenza, SAN GIOVANNI ROTONDO FG; [2]Blood Bank IRCCS Casa Sollievo della Sofferenza, SAN GIOVANNI ROTONDO FG; [3]Hematology Unit IRCCS Ospedale Oncologico, BARI; [4]Biostatistics Unit IRCCS Casa Sollievo della Sofferenza, SAN GIOVANNI ROTONDO FG; [5]Hematology and Transplant Unit IRCCS Casa Sollievo della Sofferenza, SAN GIOVANNI ROTONDO FG, Italy

Background. Autologous peripheral blood progenitor cells (PBPCs) transplantation is the best therapy for patients with relapsed/refractory hematologic malignancies. Several lines of treatments, use of alchilating agents, cisplatin and fludarabine, are all factors adversely affecting PBPCs mobilitation. *Aims*. In this study we assessed the efficacy and safety of intermediate dose ARA-C given to mobilize PBSCs. *Design and Methods* Twenty patients (12 M; 8 F; median age 60 yrs; range 26-69 yrs) with hematologic malignancies: 13 non-Hodgkin's lymphoma (NHL) and 7 multiple myeloma (MM), who have failed a previous attempt between January 2007 and April 2008, were scheduled to receive intermediate dose ARA-C to mobilize PBSCs.. Patients were primed using intermediate dose of ARA-C administered intravenously at a dose of 800 mg/m^2 every 12 h for 6 consecutive doses, + rhG-CSF 5 or 10 microgr/Kg subcutaneously. *Results*. A median of 2 chemotherapeutic regimens (range

2-6) were previously given and all patients failed prior harvesting of PBSCs. Two patients with MM were given two consecutive autotransplants with Melphalan 200 mg/mq as conditioning regimen. Collection of PBSCs was successfull in 18 out of 20 patients (90%) (13 NHL and 5 MM). Two patients whit MM were no mobilizers with intermediate dose of ARA-C also (one of them received two consecutive autologous PBSC while one other showed a refractory disease at the time of mobilization). Harvesting of PBSCs was performed at a median time of 9 days (range 8-12 days) after ARA-C administration. The median number of subcutaneous injections of rhG-CSF was 7 (range 7-14). The median number of WBC count was 4550/mmc (range 2300-14800) at the time of collection with CD34+ median number of 1.53 % (range 0.3-6). In all mobilizer patients the required number of CD34 + cells were harvested after a single leukapheresis. The median number of CD34 + cells collected was $7x10^6$/Kg (range 2.41-25) with 4 as a median number of cryopreserved bags (range 2-8). All patients experienced neutropenia < 500/microL, and 7 out of 18 had febbrile neutropenia (1 to 4 days). Thirteen patients received a median of 1 packed red cell transfusions (range 1-3) and 16 patients a median of 1 apheretic platelet products (range 1-3). No patients experienced WHO grade III-IV mucositis and diarrhoea. *Results*. Our experience, showed that PBSC collection using intermediate-dose of ARA-C + rhG-CSF is safe and effective in poor mobilize patients with NHL and MM. Mobilization and collection of PBPCs were found independent from the number and type of previous chemotherapies.

IV BUSULFAN AND FLUDARABINE (BUXFLU) AS TRANSPLANT CONDITIONING REGIMEN IN ACUTE MYELOID LEUKEMIA (AML) PATIENTS: ANALYSIS OF A SINGLE CENTRE EXPERIENCE

G. Rodriguez Macias, C. Muñoz, D. Serrano, J. Gayoso, P. Balsalobre, I. Buño, C. Encinas, A. Gomez-Pineda, J.L. Diez-Martin

Hospital Universitario Gregorio Marañon, MADRID, Spain

Background. Fludarabine (Flu) inhibits lymphocyte proliferation, thus causing potent immunosuppression enhancing engraftment and hematologic recovery and it is known to have a synergistic tumor-killing effect with Busulfan (Bux). Furthermore, as it has shown a safe toxicity profile, lower treatment related mortality (TRM) would be anticipated in the allogeneic transplantation setting when replacing cyclophosphamide for conditioning. Due to these properties, Flu has been successfully used in reduced intensity conditioning (RIC) regimens especially with Bux, and more recently in combination with myeloablative doses of busulfan. Aims: To analyze our experience regarding the feasibility, efficacy, and security of intravenous (IV) BuxFlu-based conditioning regimen in patients with AML undergoing stem cell transplantation.

Table.

Table: Patient features and	Auto	Allo	
		RIC	Myeloablative

Estimated PFS (%) at 9 months after SCT	100%	60%	80%

SCT: Stem cell transplantation; CR: Complete remission, MRD: minimal residual disease; PFS: progression-free survival

Design and Methods. Patients with high or intermediate-risk AML were transplanted at our center using IV BuxFlu as a conditioning regimen. The myeloablative regimen consisted of IV Flu 40 mg/m2/day and Bux 3.2 mg/kg/day given on days -6 to -3 (Total dose: Flu 160 mg/m2 and Bux 12.8 mg/Kg). RIC included: Flu 30 mg/m2/day on days -7 to -3 and Bux 3.2 mg/Kg/day on days -6 to -5 and 1.6 mg/Kg on day -4 (Total dose: Flu 150 mg/m2 and Bux 8 mg/Kg). Cyclosporine and methotrexate were used as graft-versus-host disease (GvHD) prophylaxis in HLA-identical allogeneic transplants. Thymoglobulin (ATG) (2.5 mg/kg x 3 days) was administered to those who received unrelated donor grafts. *Results*. Since March 2005 to January 2009 14 patients were transplanted using BuxFlu based-conditioning regimen. Main results are summarized in Table, according to graft type and conditioning intensity. Neutrophil and platelet engraftment occurred in all patients but 1 RIC patient who died due to disease progression on day +23. The most common conditioning-related toxicity was mucositis, present in all patients. Grade-1 liver toxicity was observed in 25% of autologous and 20% of allogeneic transplants. Three allo-grafted patients relapsed or progressed (1, 3 and 9 months after transplant). Two of them underwent rescue treatment and are alive 9 and 12 months after transplant. With a median follow-up of 9.5 (1-48) months, progression-free survival (PFS) was 100% for autologous and 70% for allogeneic transplant patients. No cases of TRM were observed. *Conclusions*. These preliminary results regarding the use of BuxFlu-based conditioning regimen in intermediate-high risk AML patients show that this approach is safe in terms of toxicity and TRM, feasible in terms of engraftment and effective in terms of disease control. These results are at least similar to those observed in patients conditioned with BuCy. Nevertheless a longer follow-up and a comparative formal analysis are needed to confirm these results.

1161

LARGE PERICARDIAL EFFUSION AS A MANIFESTATION OF CHRONIC GRAFT-VERSUS-HOST DISEASE AFTER ALLOGENEIC PERIPHERAL BLOOD STEM CELL TRANSPLANTATION

A. Tomaszewska, B. Nasilowska-Adamska, B. Marianska

Institute of Hematology and Transfusion Medicine, WARSAW, Poland

Background. Chronic graft-versus-host disease (cGvHD) is main determination of long-term outcome after allogeneic hematopoietic stem cell transplantation (HSCT). The clinical features of cGvHD resemble those of several autoimmune disorders. Pericardial effusion has rarely been reported as a manifestation of cGvHD. We describe a patient with large pericardial effusion developing one year after HSCT due to cGvHD. *Design and Methods*. A 35-year-old woman with myelofibrosis (with extramedullary haematopoiesis and unfavourable cytogenetic abnormalities without JAK2 mutation) underwent allogeneic HSCT in July 2007 from her HLA-identical sister following myeloablative conditioning. GvHD prophylaxis consisted of mycophenolate mofetil and short-term methotrexate. The early post-transplantation phase was complicated by aGvHD treated with methylprednisolone and tacrolimus. Besides she developed a CMV reactivation requiring foscavir and cidofovir therapy. 4 months after transplantation she followed up as an out-patient with well controlled cGvHD-the dose of steroid was reduced until discontinuation in July 2008; patient remained on tacrolimus and typical antibacterial, antiviral and antifungal prophylaxis . Three weeks after steroid discontinuation she was presented to our clinic with general weakness, cough, keratitis sicca and subfebrile body temperature. Chest X-ray revealed cardiomegaly, echocardiography confirmed the presence of a large pericardial effusion with imminent cardiac tamponade.The 600 mL of haemorrhagic exudative pericardial fluid was drained. This fluid contained mononuclear cells and granulocytes without malignant cells; there were no laboratory findings suggestive of viral, bacterial or fungal infection. Our patient received 1 mg/kg mehylprednisolone intravenously and repeated echocardiography confirmed resolution of pericardial effusion. After three months after this treatment she remained in a good clinical status, without features of exudative pericarditis on small dose of oral methylprednisolone and tacrolimus. *Conclusions.* CGvHD remains the most significant complication after allogeneic HSCT although its pathophysiology is still poorly understood. Our report indicates that pericardial effusion might be a manifestation of cGvHD in the late period after transplantation. The diagnosis and distinguishing from infection could be difficult. It is worth remembering this possibility in diagnostic procedures in patients with cGvHD and atypical signs and symptoms.

1162

CHIMERISM STATUS ANALYSIS AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION ON GRANULOCYTES AND MONONUCLEAR CELLS OF PERIPHERAL BLOOD

M. Parma, E. Doni, F. Colnaghi, A. Colombo, E. Elli, P. Pioltelli, E. Terruzzi, E.M. Pogliani

Ospedale San Gerardo, MONZA, Italy

Background. Chimerism Status (CS) analysis is employed to evaluate

donor cells engraftment after allogeneic haematopoietic stem cell transplantation (HSCT). The largest performed method is based on the evaluation of the DNA sequences "Short Tandem Repeats" (STR) and Variable Number Tandem Repeats" on marrow or peripheral blood derived cells. Their high polymorphism permits to differentiate donor or recipient origin of the analysed cells. PCR amplification and DNA sequencing permit their quantification. Complete CS (CCS) correlates with a favourable outcome of HSCT, conversely the mixed CS usually predicts disease relapse or transplant rejection, particularly when recipient amount rises along the time (increasing mixed CS-IMCS). AIMS: we investigated CS in granulocytes and mononuclear cells at +30, +60, +90, +120 days after HSCT. Data obtained were correlated with the different blood population at the time of analysis. *Design and Methods*. Granulocytes and mononuclear cells were obtained after double gradient centrifugation. A semi-quantitative method, based on multiplex PCR amplification of 16 STR markers using a commercial kit (PowerPlex® 16 System-Promega), was applied to define the difference between donor and recipient. We assumed the CS in granulocyte population as expression of myeloid engraftment. We also correlated the CS in mononuclear population, with the different leukocyte subpopulations (lymphocytes, monocytes) in peripheral blood count and with the reconstitution of lymphocyte subpopulations (B, T cells and NK cells) at the same time point of analysis, in order to compare the reciprocal course. We evaluated 22 mieloablative HSCT performed on 21 patients (1 was double transplanted for a rejection) affected by onco-hematologic disease in first (14) or next (6) remission. 14 HSCT were from sibling related donor (SRD) and 8 from matched unrelated donor (MUD). All the MUD-HSCT patient and one of the SRD-HSCT received Anti-Thymocyte-Globulin (ATG), 13/14 SRD-HSCT did not received ATG nor other T-depletion procedures. *Results*. 20/22 HSCT were evaluable in every four timepoints. In granulocytes CCS was observed in 19/22 HSCT since the first control, 3/22 evolved to CCS in the successive times, 1 evolved to IMCS. In mononuclear cells 13/22 HSCT presented stable CCS since the first control, 3/22 evolved to CCS in the successive times, 2/22 presented stable mixed chimerism. 4/22 HSCT presented IMCS with 2 relapse and 1 rejection,. Considering the different leucocyte populations we observed that the mononuclear cells amount was constituted for only 50% from lymphocytes, the remaining 50% was represented from monocytes. Therefore the analysis of lymphocyte subpopulations showed that T-lymphocytes were virtually absent (either T4 or T8) till to +120 in patients who received ATG. In these ones CS analysis in mononuclear cells was virtually performed only in monocytes, B and NK cells. Conversely patients who did not received ATG presented complete and more rapid reconstitution of all the lymphocyte subpopulations. *Conclusions*. our method is simple and rapid in analyzing CS. Granulocytes CS reflect the engraftment of myeloid lineage. Instead CS in mononuclear cells must be considered in the context of the type of transplantation (MUD or SRD, T-depletion or T repletion) and correlated with the single subpopulations of peripheral blood.

1163

UNCONTROLLED-RATE FREEZING BY IMMERSION IN A METHANOL BATH OF PERIPHERAL BLOOD STEM CELLS (PBSC) FOR TRANSPLANTATION AT HIGH CELL CONCENTRATION IN 5-PERCENT DMSO. SINGLE-CENTRE EXPERIENCE

M.H. Bañas Llanos,[1] R. Arrieta,[2] E. Pardal de la Mano,[3] J. Prieto,[1] M.L. Martín Mateos,[1] C. Cabrera,[1] M.J. Arcos,[1] M. Bengochea,[1] F. Carnicero,[1] C. Martín,[1] J. García Blanco,[1] J.M. Bergua Burgués[1]

[1]Hospital San Pedro de Alcántara, CÁCERES, Spain; [2]Hospital La Paz, MADRID, Spain; 3Hospital Virgen del Puerto, PLASENCIA, Spain

Background. In last years, new and simpler methods for cryopreservation of PBSC and freezing techniques are still being developed. In particular, non-programmed cell freezing at -80°C after addition of autologous fresh plasma with DMSO in a methanol bath permit to obtain constant cooling rates (mean velocity of 1.2°C/min) and clinical results similar to programmed cryopreservation (F. Hernández-Navarro et al., 1998). On the other hand, previous studies have demonstrated that PBPC can be cryopreserved at higher cell concentrations than classically recommended without loss of engraftment. *Design and Methods.* We retrospectively analyzed the dates of 45 PBSC collections from 25 valuable patients (pts) autotrasplanted between September 2007 and February 2009, as well as their haematological recovery (1 out of the 26 pts was discarded from the analysis for death before engraftment due to a lung infection). 14/25 pts were male. All the pts, except one (solid tumor), have haematological diseases. Median age was 52 years (22-69). Mobilization was performed with G-CSF (10-20 mg/Kg/d) alone or in combination with chemotherapy. Harvesting was performed with a COBE-Spectra cell separator. Before freezing, the cell count was adjusted with autologous plasma to a concentration of 250-300 x 106/ml. Thereafter PBSC were mixed with equivalent volumes of a DMSO/plasma solution to obtain a 5% final DMSO concentration. Finally, cryopreservation was carried out by freezing cells to -80° in a methanol bath and non-programmed freezer. After 24 h, the pack was placed in liquid N2 container and stored. The stem cells CD34+ were analyzed according to a method based on the ISHAGE guidelines. *Results*. The mean number of procedures needed to harvest an appropriated number of PBSC was 1.92±0,9 (1-4). The cell concentration was 283.65±50.3x10^6/mL (159-380.5; median 291.5). Patients received a mean of 6.59±3.8x10^8 MNC/kg (0.76-12.9; median 6.17) and 4.71±2.6x10^6 CD34+/kg (1.8-11.3; media 3.88). Viability after thawing was 90.7% (74-99; median 90%). All patients showed rapid and sustained engraftment. The mean time to granulocyte engraftment >0.5x10^9/L and platelet engraftment >20x10^9/L was 12.08±2.5 (9-20; median 11) and 14.04 (7-25; median 13) days, respectively. Most of these pts are alive and in remission. *Conclusions.* Our results confirm this procedure as very simple, safe and cost-effective for PBSC cryopreservation and later autologous transplant. Moreover, it diminishes the amount of DMSO infused to pts, as well as its toxicity.

1164

THE EFFECT OF TOTAL PARENTERAL NUTRITION ON ENGRAFTMENT IN ADULT HEMATOPOIETIC STEM CELL TRANSPLANTATION

O. Salim,[1] N. Gültekin,[1] R. Ören,[1] T. Toptas,[2] A. Timuragaoglu,[1] I. Karadogan,[1] L. Ündar[1]

[1]Akdeniz University, School of Medicine, ANTALYA, Turkey; [2]Marmara University, School of Medicine, ISTANBUL, Turkey

Background. Mucositis caused by chemo- and radiotherapy as a part of conditioning regimens of hematopoietic stem cell transplantation (HSCT) frequently lead to oral nutritional problems. The patients often need to take total parenteral nutrition (TPN) during the course of mucositis. Aim: We investigated the possible effect of TPN on engraftment time based on our clinical observations. *Design and Methods*. Engraftment time of patients who received TPN (TPN+) during HSCT (n=18) were retrospectively compared with those did not (TPN-) (n=20). Oliclinomel® N7 emulsion for infusion (Baxter) was used as a TPN solution at a dose of 1000-2000 mL/day with various durations. *Results.* There was no significant difference between TPN+ and TPN- groups according to transplantation type, conditioning regimen, and initial diagnosis. The engraftment time of granulocytes and platelets were found to be longer in TPN+ patients (median 16.5 vs 11 days, p=0.016 and 19 vs 14 days, p=0.004, respectively) (Figure 1).

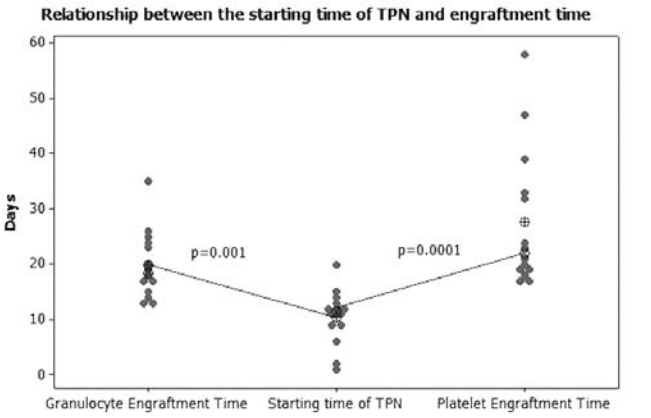

Figure 1.

Severe mucositis, the use of morpine and anaerobic antibiotics were also more frequent in TPN+ group (100% vs 60%, p=0.004, 56% vs 10%, p=0.008, 33% vs 0%, p=0.007, respectively). Survivors in TPN+ group were significantly lower than those in TPN- group (66% vs 100%, p=0.001) . *Conclusions*. The use of TPN was observed to prolong time-to-engraftment in patients after the HSCT. The patients who needed TPN had frequently more severe mucositis, hence it was not surprising that these patients had more nutritional problems and were prone to risk of infection. Thus these factors could have influenced the engraftment time and survival. But because TPN solutions are not fully replacible with oral nutrition, ingredients of TPN solutions and proportions probably have an effect on engratment time in HSCT patients.

1165

USE OF GLUTAMINE IN ALLOGENEIC STEM CELL TRANSPLANTATION - EFFECT ON RELAPSE RISK AND OVERALL SURVIVAL

E. Nicholson, A. Clark, A. Parker, G. McQuaker

Beatson West of Scotland Cancer Centre, GLASGOW, UK

Background. Veno occlusive disease (VOD) of the liver arises following damage to the sinusoids and hepatic venules. One proposed mechanism leading to VOD post allogeneic transplant is depletion of glutathione (GSH). GSH and GSH-dependent enzymes are important antioxidants that play a role in conversion of drugs to non toxic metabolites in the liver and glutamine is rate limiting for the supply of GSH. Studies have suggested a possible protective role for glutamine supplementation in prevention of VOD. However, there are theoretical concerns that glutamine supplementation may increase tumour growth and this may limit its use clinically Aims: This study assessed whether use of glutamine as prophylaxis for VOD increased the risk of relapse post allogeneic transplant. *Design and Methods.* We analyzed the outcome of 261 patients who underwent allogeneic stem cell transplant within our centre from January 2000 until July 2007. Patients felt to be at high risk for development of VOD received glutamine prophylaxis, administered at a dose of 20g IV until time of engraftment. 114 (44%) patients received glutamine and 147 (56%) patients did not. *Results*. The median follow up of all patients was 1580 days. Follow up was less in the glutamine arm as it was not introduced into use until 2002. The median overall survival of the patients who received glutamine was 537 days compared to 878 days for those patients who did not receive glutamine (p=0.075, log rank test). There was only one death secondary to VOD in the glutamine arm. There was no increase in risk of relapse between the two treatment arms - 25% of the patients treated with glutamine relapsed compared to 26% of patients who did not receive glutamine (p=0.646). Subgroup analysis according to transplant type (sibling or unrelated) or conditioning regimen (myeloabalative or reduced intensity) has no increase in relapse risk between the two treatment arms. Subgroup analysis according to stem cell source has shown that there was an increase in relapse risk in the glutamine arm in patients who received bone marrow as the stem cell source (p=0.045). While not significant, the difference appeared more marked in those that received myeloablative conditioning and glutamine supplementation. *Conclusions*. This study has demonstrated that overall, there has been no increase in relapse risk seen and no significant decrease in overall survival in patients who received glutamine prophylaxis for prevention of VOD. There was an increased risk of relapse in patients who received glutamine who had bone marrow as a stem cell source. It is possible this could relate to a less marked GvL effect and more reliance in the efficacy of the conditioning regimen in this group although further studies are required to determine the true significance of this. Glutamine administration appears to be effective at preventing VOD and there is no increase in the risk of relapse in patients receiving PBSC transplants. However, glutamine should be used with caution in patients receiving bone marrow as the stem cell source.

1166

OVERNIGHT STORAGE OF CORD BLOOD CELLS BEFORE CRYOPRESERVATION DOSE NOT AFFECT SHORT & LONG-TERM REPOPULATING CAPACITY

J.H. Won, Y.S. Jung, K.H. Kim, H.J. Kim, S.H. Kim, H.J. Kim, S.C. Lee, S.B. Bae, C.K. Kim, N.S. Lee, K.T. Lee, S.K. Park, D.S. Hong, H.S. Park

Soonchunhyang University Hospital, SEOUL, South-Korea

Background. We need to know whether overnight storage of cord blood cells affect short and long-term repopulating capacity or not because delivery may happened at night and holiday. We used UCB mononuclear cells for this study because mononuclear cells, not $CD34^+$ cells, usually were stored in clinical cord blood banks. *Design and Methods*. Five individual UCB were analysis by colony assay, apoptotic cell counts, and long term bone marrow culutre under four different conditions (fresh, overnight, immediate cryopreserved, overnight cryopreserved). *Results*. The numbers of colony forming unit-granulocyte macrophage(CFU-GM) were 116.2±20.1 in the fresh and 90.8±15.8 in the overnight storage group. There is no staistically difference. After cryopreservation, the numbers of CFU-GM were similar between immediate and overnight storage group, 86.9±31.2 in the initial and 83.8±37.2, respectively. Immediate cryopreservation group had significantly lower numbers of CFU-GM compared with fresh group(p<0.05). The apoptic cells were detected 21±6.8 % in the fresh and 24.2±2.4 % in the overnight storage group. There is no staistically difference. After cryopreservation, the apoptic cells were similar between immediate and overnight storage group, 32.6±11.5% and 31.7±8.2 %, respectively. Fresh group had significantly lower numbers of apoptic cells compared with immediate cryopreservation group(p<0.05). After long term stromal based culture, the mean production of CFU-GM colonies were the similar in all groups (P>0.05). *Conclusions*. This results shows that cryopreserved cord blood mononuclear cells affect short term repopulating capacity, but, does not affect long term repopulating capacity. Overnight storage before cryopreservation does not affect short and long term repopulating capacity. These results support the continue use of overnight storage of UCB before cryopreservation as a convenient and cost reduction measure.

1167

HYPOCALCEMIA-DERIVED COMPLICATIONS ARE AVOIDED WITH A MODIFIED TECHNIQUE FOR PERIPHERAL BLOOD STEM CELLS COLLECTION: A SINGLE CENTER EXPERIENCE

J.J. Gil Fernandez, T. Pascual, E. Magro, J. García-Suárez, Y. Martin, M. Callejas, M.A. Calero, M. Lopez-Rubio, C. Burgaleta

Hospital Universitario Principe de Asturias, MADRID, Spain

Background. Peripheral Blood Stem Cells (PBSC) collections might be complicated by symptomatic hypocalcemia or secondary effects due to calcium-supplements. In December 2006, we decided to modify our technique for PBSC collections after observing several cases of severe symptomatic hypocalcemia or calcium-supplements secondary effects. Aims Analyze the efficacy and safety of a modified technique to reduce the total amount of the sodium citrate dextrose (ACDA) anticoagulant administered during the lymphocytoapheresis to collect PBSC in candidates for autologous PBSC transplantation. *Patients and Methods*. Consecutive PBSC collections performed at our department with a modified-technique to avoid symptomatic hypocalcemia or calcium- supplements secondary effects. Briefly the modified-technique consisted of the addition of 3,000 units of sodium heparin at 1% inside the bag containing 500 milliliters (mls) of ACDA, modifying the fixed ACDA ratio from 16 to 24 (1 mL of ACDA per 23 mls of blood) and reducing the total amount of ACDA administered during the lymphocytoapheresis. We did not perform calcium monitoring during the procedure and oral or intravenous replacements of calcium were avoided. *Results*. From December 2006 to February 2009, 31 consecutive PBSC collections were performed in 20 patients (11 males and 9 females), median age of 49 (23-65) years at collection, by using with the described modified-technique. Hematological diseases were as follows: 12 multiple myeloma, 4 non-hodgkin's lymphoma, 3 hodgkin´s lymphoma and 1 acute myelogenous leukemia. In 17 patients, PBSC mobilization consisted of only filgrastim at a median dose of 12 mg/Kg/day for 4 consecutive days, starting apheresis on the 5 th day. A semirigide Sheldom catheter was placed on a femoral vein (18 patients) or subclavian vein (2 patients). A median of 1 (range 1 to 3) lymphocytoapheresis procedure was performed per patient. The median blood volume processed per patient was 12,06 liters (6,60-15,67). Median ACDA volume administered per apheresis was 538 milliliters (227- 924). As a result of PBSC collections we obtained a median MNC of 7,84 x108/Kg (1,65- 18,72) and CD34+ of 3,55x106/Kg (1,03- 7,41). No cases of symptomatic hypocalcemia or calcium-supplements secondary effects were observed. The major secondary effects observed were 2 cases of femoral catheter thrombosis on the second day of apheresis. No clinically significant haemorragic complications were observed in our series. *Conclusions*. We conclude that this modification of the classical technique for PBSC collection is safe, effective and avoid calcium monitoring and hypocalcemia-derived complications.

1168

THE EFFECT OF OMEGA-3 AS A DIETARY SUPPLEMENT IN A MOUSE MODEL OF STEM CELL TRANSPLANTATION (SCT)

A. Al-Hashmi,[1] B. Sadeghi,[1] Z. Hassan,[1] M. Lindskog,[2] M. Hassan[1]

[1]Karolinska Institute, STOCKHOLM; [2]Uppsala University Hospital, UPPSALA, Sweden

Background. Several studies reported the importance of nutrition on SCT outcome. Many food components have been shown to affect the immune system and to interact with a number of drugs used in conditioning and in prophylactic treatment during SCT. Omega-3 fatty acids have immuno-modulatory effects via improving endothelial function, protection against oxidative DNA damage and by suppressing $CD4^+$ T-cell function and proliferation. In the present study we examined the effects of omega-3 on the immune system in mice undergoing SCT. *Aims*. To evaluate the effect of omega-3 on conditioning regimen To evaluate the effect of omega-3 on bone marrow transplantation *Method*. Female BALB/c mice, 8 - 12 weeks, were randomised to receive either diet enriched with menhaden fish oil (omega-3) or, corn oil (rich in omega-6). Both groups were fed for two weeks prior to conditioning (Day 0 was set to be the day of transplantation). Both groups injected intraperitoneally with 80mg/kg busulfan (Bu) for four days (day -7 to day -4) followed by 200 mg/kg cyclophosphamide (Cy) for two days (days -3 & -2). At day 0, half of the mice of both groups were killed and bone marrow, spleen and thymus were harvested and analysed with FACS to evaluate the lymphoid and myeloid cell phenotype. Serum was collected for analysis of cytokines. The remaining mice in both groups were transplanted with allogeneic bone marrow from 8-12 weeks male C57BL/6 mice ($2.0x10^7$ bone marrow cells and $3.0x10^7$ spleen cells). *Results*. Mice fed an omega 3-rich diet showed significant decrease in bone marrow and spleen cellularity compared to that observed in the corn oil group. In particular, the splenic B-cell population was severely affected, showing a 50% decrease in the omega-3 group compared to that seen in corn oil group. The T-cell populations of omega-3 fed mice were also affected, with a significant decrease by 10 to 20 % in the number of $CD4^+$ cells. In contrast, no difference was observed for CD8+ cells, compared to corn oil-fed mice. In the thymus, the number of activated T-cells was decreased by 50% in the omega-3 compared to that observed in corn oil group. NK cells were decreased by 50% in the spleens of omega-3 fed mice. In bone marrow, the myeloid cells ($CD11b^+$) were significantly lower in omega-3 fed mice compared to corn oil-fed controls. All transplanted mice that had received an omega-3 enriched diet died within the first week. These data can be compared to our previous results where more than 60% of mice receiving standard diet survive during the first week and of which at least 20% reach day+21. *Conclusion.* Omega-3 administration as a dietary supplement for two weeks prior to conditioning regimen showed significant effects on the immune system in terms of a pronounced alteration in the balance of different cells lineages in both bone marrow and spleen. Rapid death of omega-3 fed animals after allogeneic transplantation was observed. Further studies are warranted to investigate the role of omega-3 on the outcome of stem cell transplantation

1169

INFLUENCE OF STEM CELL SUBSETS ON MARROW REPOPULATION CAPACITY OR SOLID ORGAN REGENERATIVE POTENTIAL

A. Rafajlovski,[1] M. Todorovic,[2] S. Marjanovic,[1] S. Obradovic,[1] B. Balint,[1] M. Jevtic[1]

[1]Military Medical Academy, BELGRADEì; [2]University Clinical Center, BELGRADE, Serbia

Background. Stem cells (SCs) could be defined as cells having 'unlimited' self-renewal and multilineage differentiation capacity, as well as extensive proliferative potential which guarantee the homeostasis of the hematopoietic or other tissue-generating systems. The clinical use of SCs represents an unique and well-working regenerative therapeutic maneuver. Aims: to determine SC-harvesting protocol with optimized cell source, collection time-point, CD34+ threshold-dose, as well as to evaluate the effects of immature vs. mature SC (CD34+ cell) subset ratio on the SC-therapy outcome. *Design and Methods*. Patients with hematological malignancies and myocardial setting (myocardial infarct, coronary-bypass) as well as liver failure, underwent to allogeneic (120 pts) or autologous (120 pts) SC-transplants and cell-based regenerative therapy (50 pts) were included in this study. SCs were mobilized by rHuG-CSF 5-10 microg/kgbm (allogeneic) or chemotherapy plus rHuG-CSF 8-16 microg/kgbm (autologous) and rHuG-CSF 10 microg/kgbm (cell-based therapy). SCs were harvested from peripheral blood using Cobe-Spectra (SC-transplants and liver cell-therapy) or collected by aspirations from marrow (myocardial setting). Total nucleated and mononuclear cell (TNC and MNC) count was determined by flow cytometry. Cell viability was measured by AAD-viability-dye test. The SC surface antigens (CD34-subsets markers) by the EPICS XL-MCL device were investigated. For cryopreservation, our own controlled-rate freezing protocol (with optimized DMSO) using Planer 560-16 equipment was applied. *Results*. In SC-transplant setting, the CD45+/CD34+ yields were $12.3\pm6.4x10^6$/kgbm vs. $10.8\pm3.4x10^6$/kgbm (allogeneic vs. autologous), respectively. In myocardial cell-therapy setting, the quantity of TNCs and $CD45^+/CD34^+$ cells applied was $24\pm21x10^7$ and $8.4\pm5.2x10^6$, respectively. The count of collected $CD45^+/CD34^+$ cells for liver cell-therapy was $10.3\pm4.5x10^6$. The use of large volume vs. conventional (standard) cell harvesting resulted with higher immature vs. mature CD34-subset ratio. The $CD45^+/CD34^+$ percentage was elevated in marrow vs. peripheral blood harvest. Quicker hematopoietic reconstitution was obtained when SCs from peripheral blood were applied (for leukocytes on the 9.4th and for platelets on the 12.9th day). Cell-therapy resulted in a improved myocardial perfusion and systolic activity, as well as liver function repair. All patients tolerated the use of intensive cell-therapy well, without any adverse effects. *Conclusions*. The use of large volume vs. standard apheresis resulted in improved $CD34^+$ cell yield and better immature vs. mature CD34-subsets ratio, which following superior marrow repopulation capacity. Marrow-derived SCs assured better organ repair due to higher tissue-colonizing and lineage-plasticity potential, although the ideal source and type of cells in the field of regenerative medicine (in myocardial or liver setting) have not been completely defined yet.

1170

SUCCESSFUL MOBILITATION OF PERIPHERAL BLOOD STEM CELLS USING IFE/G-CSF IN PATIENTS WITH MALIGNANT LYMPHOMA

C. Albo, J. Vazquez, M. Rodríguez, C. Ares, B. Cabanas

Complexo Hospitalario Universitario de Vigo, VIGO, Spain

Background. High-dose chemotherapy (HDT) and haematopoietic stem cell transplantation (SCT) are effective in patients with relapse, refractory and chemotherapy-sensitive PR non-Hodgkin lymphoma (NHL). Several studies suggest also a benefit for patients in first CR with the presence of poor prognostic factors. Collection of sufficient numbers of stem cells is a prerequisite for such a therapy. IFE regimen has been integrated into various treatment plans tailored for NHL patients as a second line in PR patients or as intensification and mobilizing regimen in CR high-risk patients. *Aim.* We evaluate the efficacy for the mobilization of peripheral blood stem cells (PBSC) and treatment outcome of IFE (ifosphamide, etoposide) in combination with G-CSF in patients with NHL in our centre. *Patients and methods* We report mobilisation details and treatment outcome of 21 patients, median age 49 years (range 14 - 66) with NHL treated with 1-3 cycles of IFE (ifosphamide 10 g/m^2, etoposide 150 mg/m^2/12 h on days 1-3) with G-CSF 5 (n=1) or 10 (n=18) mg/kg/d, two patients received 6 mg of PEG G-CSF, between September 2002 and December 2008. 8 were female (38.1%) and 13 male (61.9%). Patients were treated with the intent to proceed to auto-SCT. All patients have written informed consent. The indication for IFE was failure to achieve CR with four previous escalated CHOP therapy plus rituximab (R-MegaCHOP or R-CHOP-14) (n=19) and front-line therapy in high-risk T-cell NHL (n=1) and relapse disease (n=1). 10 patients (47.6%) had bone marrow involvement at diagnose but neither of them at collection. At the time of PBSC mobilization 19 patients (90.4%) were in partial remission (PR), 1 (4.8%) in complete remission (CR), and 1 (4.8%) with sensitive response minor than PR. *Results*. The median time between IFE and collection was 15 days (range 13 - 22). The median total number of mobilised $CD34^+$ cells was $8.42x10^6$/kg (range 1.94 - 34.5) and the median CFU-GM colonies $12.12x10^4$/kg (range 2.37 - 22.34). Cells were collected with a median of 1 (range 1 - 5) leukapheresis per patient processing a median of 4.5 volumes (range 1.5-22). Only one patient failed a mobilization attempt (CD34 cell count $<2x10^6$/kg). 17 of the 21 (80.9%) patients achieved CR after IFE, 3 (14.3%) PR and one patient (4.8%) progressed. *Conclusions*. IFE combined with G-CSF is an effective mobilising regimen and has a satisfactory response rate in chemotherapy-sensitive patients. The patients who are successfully mobilized with this regimen and proceed to auto-SCT can achieve a sutained remission.

1171

HOW THE POST-THAWED CELL CONTROLS IN TEST-TUBE REPRODUCE THE QUALITY OF THE CRYOPRESERVED PBPC IN THE BAG TO BE INFUSED

G. Salgado,[1] M.J. Majado,[2] C. Gonzalez-Garcia,[2] M. Blanquer,[2] A. Parrado,[3] C. Funes,[2] A. Morales,[2] J.M. Moraleda[2]

[1]Hospital V de la Arrixaca, MURCIA; [2]Servicio de Hematologia. H. Virgen de la Arrixaca, MURCIA; [3]Servicio de Inmunologia. H. Virgen de la Arrixaca, MURCIA, Spain

Cryopreservation can alter the quality of the cells for autologous PBPC transplantation. In most laboratories a test tube is frozen with the cells bags in order to test the effect of cryopreservation in cells. The objective of our study is to examine if the results obtained in the test tube are the same as those of the bag infused, that is to say, if the measures of the test tube indicate the real state of the cells to be infused. A total of 397 PBSC apheresis products harvested from 167 patients, 81 male and 86 female, aged 49 (2 to 71) years, were studied. A total of 119 PBSC products were harvested from 61 patients with MM, 115 from 43 patients with NHL, 54 from 26 patients with breast cancer (BC), 35 from 12 patients with HD, 28 from 9 patients with AML, and 46 from 16 patients with other diagnoses. PBPCs were obtained using a continuous blood cell separator (Fenwal CS3000; Baxter, Deerfield, IL) and were cryopreserved in special bags (Cryocyte; Nexell Therapeutics, Irvine, CA), mixed with DMSO at a final concentration of 9-10%. After DMSO mixture, 0.5 mL of the PBPC concentrates were transferred to small freezing test tubes (Cryovial; Simport, Quebec, Canada) and put into the freezing machine together with the collection bag. Cryopreservation was performed by a controlled rate freezing equipment (CM-25; Carburos Metálicos, Barcelona), lowering temperature at a rate of 1-2°C/min. CD34+ cells were measured by flow cytometry on a FACS Calibur (Becton-Dickinson, -BD- San José, CA). All PBSC products were tested for: viability (Tripan-blue exclusion), CD34+x10^6/L, lymphocytes, monocytes, granulocytes, and CFU-GM, before criopreservation and post-thawing (in tube and bag). Student-t-test for paired samples was used for statistical analysis. The study was performed in the total group of patients and in MM, HD, NHL, AML and BC groups. Freezing decreases cell viability and CFU-GM in tube and bag respect to pre-freezing samples (p<0.001); but, in MM group, viability was lower in bag than in tube (p=0.35) and CFU-GM were lower in tube than in bag (p=0.01). Granulocytes were lower post-freezing in both samples, significantly lower in tube than bag in total group (p=0.02) and MM (p=0.01). Monocytes and lymphocytes were higher post-thawing both in the cryotube and in the bag than in the pre-freezing amount in all samples, but monocytes higher in bag than in tube in MM and in NHL(p<0.01); lymphocytes were higher in bag in MM (p=0.02). The CD34+x10^6/L count was not different post-thawing compared with pre-freezing values except in he tube of MM (p<0.01), there were no differences between cryotube and bag. According to our study, the tube seems to be a good control for the most important parameters in most diseases, although it does not reflect exactly the effect of freezing in MM, even though we do not know if these findings have clinical relevance.

1172

THE CLINIC EFFECTIVENESS OF USING HEMATOPOIETIC STEM CELL TRANSPLANTATION TO CURE 156 CASES OF MALIGNANT HEMATOLOGIC DISEASES

L.M. Ma, L.H. Yang

The Second Hospital of Medical University,Shanxi, China, TAIYUAN, China

Objective. To retrospective analysis and explore different conditioning regimen and different transplantation methods to treat malignant hematological diseases and to evaluate the effectiveness and the risk associated with transplantation. *Design and Methods*. Altogether156 patients accepted transplantation, auto-HSCT without cleaning (auto-HSCT) (n=33), peripheral blood stem cells plus auto- activated bone marrow transplantation (PBSCT+ABM) (n=37), myeloablative allogenic bone marrow transplantation (allo-HSCT) (n=36), nonmyeloablative allogenic bone marrow or peripheral blood stem cell transplantation (allo-NSCT) (n=48) and cord blood stem cell transplantation (allo-CBT) (n=4). PBSCT+ABM, Auto-HSCT and allo-HSCT all applied with MAC or BuCY regimen chemotherapy. PSCT+ABM were infused with autologous peripheral blood stem cells and activated bone marrow about 750 mL .Those who accepted allo-BMT were infused on the zero day of transplantation with donor's bone marrow stem cells .The allo-NSCT was applied with two kind of low dose conditioning regimen FAAC and MAAC, after transplantation, according to the formation of chimerism to infuse donor lymphocytes as increasing depressively. Among the patients who accepted cord transplantation, two adopted stem cells from cord bank and more than four sites coincided as HLA zygosity reported , and two cases adopted sibling's cord stem cells, all of them accepted preconditioning of FAAC and procedures were the same with above mentioned. Those who accepted allogenic transplantation used Cyclosporin A and methotrexate or mycophenolic acid routinely. According to the recovery of leukocytes, platelets and bone marrow, the analysis of blood type and the formation of chimerism as the evidence of implantation successfully and aGVHD was analyzed by luckshezg standard and cGVHD were analyzed by Shulman standard. *Results.* Among the 156 patients, except one patient with CML died of bone marrow failure on the fortieth day after nonmyeloablative transplantation and Two AML patients died of cerebral hemorrhage before the recovery of haematogenesis, the other 153 cases all recovered haematogenesis as expectancy. The incidence of aGVHD and cGVHD of allogenic transplantation was 18.10% and 26.10% respectively. Until the time of collected materials, the survival statistics for those patients were 30.33% for ABMT(n=33), 64.49% for PBSCT+ABM(n=37), 69.51% for allo-BMT (n=27), 45.83% for NSCT (n=48) and 50.00% for CBT(n=4) respectively. *Conclusions.* At present, it was thought that hemopoietic stem cell transplantation was one curable methods for malignant diseases. With multiple forms of transplantation application generally, more and more patients profited from them especially the emergence of nonmyeloablative transplantation, which cased essential alteration in the domain of transplantation, it not only enlarged application and indication but also more safety and inexpensive. But relapse and GVHD remain the mainly causes of transplantation failue.

1173

TORQUETENOVIRUS VIREMIA LEVELS AFTER HIGH-DOSE CHEMOTHERAPY AND AUTOLOGOUS STEM CELL TRANSPLANTATION CORRELATE WITH IMMUNOPHENOTYPIC MARKERS OF IMMUNE FUNCTION

D. Focosi,[1] F. Maggi,[1] M. Albani,[1] J. Rocchi,[1] V. Ricci,[1] S Gragnani,[1] S. Di Beo,[1] M. Ghimenti,[1] F. Papineschi,[1] G. Antonelli,[2] M. Bendinelli,[1] M. Pistello,[1] L. Ceccherini-Nelli,[1] M. Petrini[1]

[1]University of Pisa, PISA, Italy; [2]Sapienza University, ROME, Italy

It is common experience that retreating patients too early after a course of intensive chemotherapy predisposes to opportunistic infections despite apparently normal lymphocyte levels. The extent of replication of persistent viruses that cause no obvious disease (and hence need no treatment) might serve as a marker to better define when a patient has recovered from this functional immune deficiency.

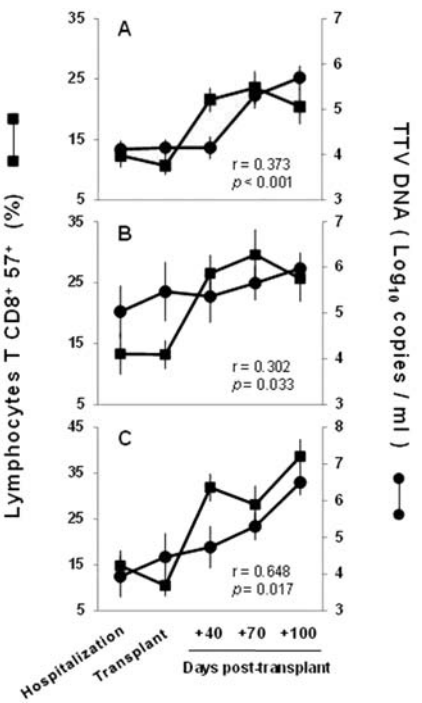

Figure.

We used real-time polymerase chain reaction to monitor the kinetics of plasma torquetenovirus (TTV) viremia in hematological patients undergoing autologous hematopoietic stem cell transplantation as support to high-dose chemotherapy (HSCT). Independently from underlying hematological disease and therapeutic regimen, TTV viremia increased post HSCT, and this increase paralleled the increase of circulating CD8+CD57+ T lymphocytes, known to represent an indirect marker of functional immune deficiency. Subsequently, within a matter of months, TTV levels returned to baseline values, at a pace that appeared to be constant over time. Collectively the findings indicate that monitoring of TTV viremia represents a unique opportunity to follow functional immune reconstitution in immunosuppressed patients. Also, the size of the TTV viremia increases resulting from immunosuppressive treatments might be of guidance in determining the appropriate time interval before delivery of a next course of therapy.

1174

IMMUNOLOGIC RECOVERY AFTER AUTOLOGOUS TRANSPLANT IN MULTIPLE MYELOMA AND PROGRESSION FREE SURVIVAL

R. Bergantim, P. Pinto, F. Trigo, J. Guimarães

Hospital S.João, PORTO, Portugal

Immunologic abnormalities, such as suppression of polyclonal immunoglobulin production and decreased CD4/CD8 ratio, have been widely documented in patients with Multiple Myeloma (MM), after autologous stem cell transplant (ASCT). These abnormalities when persistent appear to be associated with disease progression. We retrospectively analyzed a series of 50 consecutive patients with MM who underwent ASCT in our centre, from 2000 to 2008, regarding recovery of IgM levels and CD4/CD8 ratio by day +100 post-transplant. Progression-free survival (PFS) was assessed from the day of the transplant to disease progression or death. The median age of patients was 57 years (range - 37 to 67), 25 were females. Median follow-up was 12 months (range - 1 to 40 months). Twenty-one (42%) patients recovered normal IgM levels by day +100 and 29 (58%) did not. Comparison of Kaplan-Meyer curves for the two groups did not show any statistically significant difference (log rank test, p=0.08) but it appears to be a difference between median PFS of the non-recovered immunoglobulin group (14 months) and the recovered immunoglobulin group (29 months). CD4/CD8 ratio by day +100 was significantly reduced (median 0.3, range - 0.12 to 1.0), essentially due to a decrease in absolute number of CD4 cells (median 262x10^6/L, range - 53 to 767x10^6/L). No association was found between CD4/CD8 ratio and PFS. In conclusion, we could not find a definite relationship between immune function recovery and PFS although there is a trend to a better outlook of patients who recover normal IgM levels shortly after ASCT. One can speculate that prompt recovery of diversity of antibody production and other immune functions may have an impact in disease outcome.

1175

ALEMTUZUMAB ONLY NON CHEMOTHERAPY BASED HAEMATOPOIETIC ALLOGENIC STEM CELL TRANSPLANTS

J. Gandla,[1] M. Martin,[1] L. Connelly-Smith,[1] J. Dyer,[2] E. Hunter[2]

[1]University Hospitals of Leicester, LEICESTER; [2]University hospitals of Leicester, LEICESTER, UK

Background. Minimally toxic conditioning regimens using low dose (200cGy) total-body irradiation (TBI) along with mycophenolate mofetil (MMF) and ciclosporin (CSP) have been used in non myeloablative haematopoietic stem cell transplants. We present for the first time haematopoietic stem cell allografts using non chemotherapy based conditioning using alemtuzumab and MMF/CSP. Aims: We present 4 cases of haematopoietic stem cell allografts using non chemotherapy based conditioning with alemtuzumab and MMF/CSP. *Design and Methods.* Patient 1 was a 58y old male who had heavily pre-treated T-cell prolymphocytic leukaemia (T-PLL) with chlorambucil, alemtuzumab, MCOP (mitoxantrone, cyclophosphamide, vincristine, and prednisolone) and cladrabine. He received peripheral blood stem cells from matched unrelated donor. Patient 2 was a 59y old male with acute myeloid leukaemia (AML) who was treated with 2 courses of FLAG-Ida and had prolonged cytopenias. He was rescued with bone marrow stem cells from matched sibling. Patient 3 was a 54y old male with acute myeloid leukaemia who had prolonged cytopenias after 2 courses of FLAG-Ida and had transplant using bone marrow stem cells from matched unrelated donor. Patient 4 was a 42y old male with chronic myeloid leukaemia which failed to respond to imatinib and transformed to myeloid blast crisis. His acute myeloid leukaemia was treated with FLAG-Ida and dasatinib resulting in prolonged cytopenias. He was rescued with peripheral blood stem cells from his sibling. Conditioning regimen used in all 4 patients was campath-1H 30 mg/d i.v from day-4 to day-2 i.e. 90mg in total. Ciclosporin 5 mg/kg/d and mycophenolate mofetil 1gram/d was commenced on day-1 as GVHD prophylaxis. *Results*. Follow up ranged from 2 - 60 months. All patients and donors were CMV negative. Donor stem cell CD34 counts ranged from 3.83x10^6/kg to 6.6x10^6/kg. G-CSF was initiated in all 4 patients. Patient 1 was heavily pre-treated with chemotherapy while the remaining 3 patients had prolonged severe cytopenias following chemotherapy and had fungal pneumonia at the time of transplant. Patient 1 had normal full blood count prior to conditioning and had no pancytopenic period and at 3 months donor chimerism was 22%. He received one dose of DLI (1x10^6/kg CD3+ve cells) and at 6 months this achieved 100% donor chimerism. Engrafted was prompt in patient 2 and 4 within 21-32 days. Patient 3 started to engraft but died from progressive pneumonia 15 days post transplant. All patients alive were transfusion independent within 50 days post transplant. Patient 1 developed grade 2 chronic GVHD while other patients did not develop GVHD. Patient 1(T-PLL) remained in complete remission for 30 months before relapsing. Patient 2 (AML) continues to remain in complete remission at 60 months post transplant. Patient 4 (AML) is 60 days post transplant in complete remission. *Conclusions*. In patients who are unable to tolerate non myeloablative cytotoxic based conditioning, haematopoietic stem cell engraftment can be achieved using non chemotherapy based conditioning with alemtuzumab, mycophenolate mofetil and ciclosporin. This can induce durable remissions and needs further evaluation in future clinical trials.

1176

EFFECTIVE PERIPHERAL BLOOD PROGENITOR CELL MOBILIZATION WITH G-CSF AND PLERIXAFOR: A PROMISING MOBILIZATION TREATMENT?

M. Ortiz, A. Contento, P. Galera, M. Barrios, M.C. Villalta, M.J. Pascual, M.A. Cuesta, A.I. Heiniger

Hospital Regional Carlos Haya, MÁLAGA, Spain

Background. In different circumstances, basically depending on age, type and number of prior treatments, patients with hematological diseases have problems in mobilizing sufficient peripheral blood hematopoietic stem cells (PBSCs) for autologous hematopoietic stem cell transplantation (auto-SCT). Plerixafor is a novel molecule used as mobilizing agent in combination with G-CSF. Plerixafor is a reversible inhibitor for the binding of stromal derived factor-1 α to its receptor CXCR4. This complex plays a role in the retention of HSC within the bone marrow and its inhibition can lead to an increased number of PBSCs. *Aim.* To describe the results of the Plerixafor use in patients with at least one previous failure in PBSCs mobilization. *Design and Methods.* Five patients from a single institution were retrospectively analyzed, 1 female and 4 males, with a median age of 52 (range 30-62) and diagnosis of Non-Hodgkin's lymphoma (4) and Hodgkin's disease (1). The patients were exposed to different mobilization regimens in order to achieve a minimal number of PBSCs (2x10^6 CD34$^+$ cells/kg) sufficient to proceed to auto-SCT. The cells obtained in each collection attempt were added until the minimum required amount was reached. Four patients had received one previous conventional mobilization (G-CSF, 10 µgr/kg/daily, or G-CSF in combination with cyclophosphamide, 1,5 gr/m^2) and one patient two previous treatments (Firstly G-CSF, secondly G-CSF plus cyclophosphamide), without collecting enough CD34$^+$ cells. In the last mobilization, Plerixafor (240 gr/kg/daily SC) was associated to G-CSF in the fourth day. PBSCs were collected on a COBE Spectra apheresis system (Gambro BCT, Lakewood, CO, USA). *Results.* In Plerixafor mobilization, G-CSF was administered a mean of 5,8 (range 5-7) days, whilst with the other treatments the mean was of 6,6 (range 5-8). The minimum number of CD34$^+$ cells could be completed with only one Plerixafor dose in three patients. After the first Plerixafor exposure, the patients had peripheral blood CD34$^+$ count and collected CD34$^+$ cells/kg means of 18,64/µL (range 4.4-31.5) and of 1,35x10^6/kg (range 0.4-2.94), respectively. With the other schedules, the counts were: mean of peripheral blood CD34$^+$ cells 9,1/µL (range 4,96-17,92) and mean of collected CD34$^+$ cells 0,47x10^6/kg (range 0.41-0.62). No adverse events were reported. Two patients underwent auto-SCT, with median time to neutrophil engraftment (>0.5x10^9/L) on day 12 and platelet engraftment (>20x10^9/L for 7 days without transfusion) on day 15. *Conclusions.* Plerixafor administered in conjunction with G-CSF could be an effective way to salvage patients who have failed other mobilization attempts and need to proceed to auto-SCT. With this drug, our patients have improved

the peripheral blood basal CD34+ cells and CD34+ cells in the apheresis products, without observing side effects. However, it is necessary to include more patients to confirm this hypothesis.

1177

AMD3100 IN POOR MOBILIZER PATIENTS WITH HEMATOLOGIC MALIGNANCIES

A. Ostuni, V. Pavone, M. Caputo, A. Musaro, M.R. Morciano, R. De Francesco, C. Del Casale, A. Mele, A. Messa, A. Rana, S. Sibilla

Az. Ospedaliera Card.Panico, TRICASE, Italy

Background. About 20% of patients (pts) affect by haematological malignancies is considered 'poor mobilizer' with a very low CD34 yield at collection without the possibility to perform hi-dose chemotherapy and autologous stem cell transplantation (ASCT). CXCR4, a stromal derived growth factor, interacts with the receptor of the stem cell stopping the bound with the stromal chemokine factor-1 (SDF-1α) expressing a regulator action on stem cells flow in the microvessel from and toward the bone marrow.

Table 1, 2, 3, 4.

Table – 1 Patient clinical characteristics	
Diagnosis	
NHL	3
MM	1

CD34 positive harvest	39/μL (9 – 117)
CD34/Kg/apheresi	1 (0,7 - 2)
%Efficiency apheresi	37 (10 – 60)

Table – 4		
	CD34/Kg harvest	*Day of apheresis*
Patient 1 – NHL	0,37/ μL	+16 +17
Patient 2 – NHL	0,35/ μL	+12 +13
Patient 3 – NHL	3,71/ μL	+12 +13
Patient 4 – MM	1,96/ μL	+11 +12 +13

The antagonist molecule of CXCR4 (plerixafor - AMD3100) allows the release of the HPC determining an increase of the CD34 positive cells in the peripheral blood. AIMS In the attempt to reduce the risk of an unsussesfull mobilization of HPC in high risk pts, poor mobilizer with previous regimens, we utilized the new mobilizing factor plerixafor, in combination with G-CSF and chemotherapy. *Design and Methods.* We treated 4 pts, 3 high risk NHL (2 in CR; 1 PR) 1 MM in PR. All of 4 patients had failed previous mobilization with a number of CD34 after mobilization minor than 10/μL. in table 2. Pt-1 was treated with Hi-Dose ARAC+Peg-filgastrim; ARAC HD+G-CSF + growth hormone. Pt-2 and 3 with DHAP protocol + GCSF, while Pt-4 with MM by EDX +Peg-filgastrim, EDX+ G-CSF + growth hormone. Clinical pts characteristics and previous regimens of mobilization are listed in Table 1. After chemotherapy, G-CSF was started from day 5 at a dose of 10 g/Kg/die and having associated to Plerixaflor from day 10, with evening administration at the dose of 240 mg/kg/die. HPC collection data are summarized in table 4 and 5. Two pts (nb 3 and 4) collected a sufficient number of CD 34^+ HPC able to perform ASCT. *Conclusions*. This study confirm the efficacy of Plerixafor to mobilize CD34 positive cell in a subset of patient unresponsive to previous mobilizing strategy. Harvest was negatively influenced by chemotherapy load, use of some chemotherapic agents (so fludarabina, lenalidomide), and by chemorefractory disease status. Our data in a small series of pts confirm the possibility to reduce the risk of poor mobilizer phenomena in about 50% of haematological pts.

1178

PLERIXAFOR IS ABLE TO MOBILIZE A HIGH PROPORTION OF LYMPHOMA AND MYELOMA PATIENTS THAT PREVIOUSLY FAILED A PBSC MOBILIZATION: A SINGLE CENTER STUDY

E. Marturano,[1] E. Mauro,[2] S. Leotta,[3] M. Poidomani,[3] F. Crispi,[3] A. Spadaro,[3] S. Mercurio,[3] G. Avola,[3] M.G. Camuglia,[3] A. Di Marco,[3] G. Milone[3]

[1]Ospedale Ferrarotto, CATANIA; [2]Ematologia-ferrarotto, CATANIA; [3]Ematologia-Ferratotto, CATANIA, Italy

We have employed PLERIXAFOR (AMD3100) in patients who failed a previous cycle of PBSC mobilization. Each patients was used as an internal control and thus results of plerixafor -mobilization were compared to data obtained during the previous PBSC mobilization in the same patient. We studied six patients affected with NHL (3), MM (2) and HL (1), patients were aged 23-63 years. All patients had failed a first cycle of mobilization chemotherapy using disease-oriented chemotherapy (VP 16 containing cycle in 3 patients, CTX containing cycle in 3 patients) plus G-CSF at dose of 10 mcg/Kg. Failure was defined as a CD34+ cells in P.B. less than 20/mmc (5 pts) or by an CD34+ harvest < $1.5x10^6$/Kg (1 pts). 4/6 of all patients had at start of second mobilization using plerixafor a Platelet count <$140x10^9$/L and 4/6 patients had WBC count <$4.0x10^9$/L. G-CSF therapy was administered daily at 10 mcg/Kg/d and starting from the evening of, the forth day, Plerixafor was administered at dosage of 240 mcg/Kg as s.c. injection in outpatient clinic. Median value of maximum $CD34^+$ cells obtained in P.B. during the first unsuccessful PBSC mobilization cycle was $12,8x10^6$/L while $CD34^+$ peak after G-CSF+Plerixafor was $26.7x10^6$/L (t-test for paired data: p=0.07). Percentage of patients reaching criteria for a successful mobilization (threshold of $CD34^+$ cell in P.B. >$20x10^6$/L) after G-CSF+Plerixafor was 83% (5/6 pts), significantly higher than results achieved during first cycle (16%) (χ^2 test: p=0.02). Mean apheresis number was 2 for each patients and median total $CD34^+$ harvested were $4,6x10^6$/Kg (range 0.8-8.2). Median collection efficiency during plerixafor+G-CSF therapy was 35%. Plerixafor was well tolerated and the only adverse event registered in 2 patients was rash at injection site. 2/6 of patients mobilized using Plerixafor had already received autologous PBSC transplant at our institution after BEAM and HD-PAM schedules and neutrophils engraftment was obtained at day+15 and + 18.

1179

COTRANSPLANTATION OF THIRD PARTY MSC TO FACILITATE ENGRAFTMENT OF HAPLOIDENTICAL STEM CELLS IN A PATIENT HAVING EXPERIENCED GRAFT-FAILURE

M. von Bonin, A. Kiani, U. Platzbecker, J. Schetelig, K. Hölig, U. Oelschlägel, C. Thiede, G. Ehninger, M. Bornhäuser

University Hospital Carl-Gustav-Carus, DRESDEN, Germany

Background. Graft failure is a life-threatening complication after allogeneic hematopoetic stem cell transplantation (HSCT) and efforts to achieve secondary engraftment are challenging. *Design and Methods.* Here, we describe the clinical course of a young AML patient suffering from graft-failure after haploidentical peripheral hematopoietic stem cell

transplantation. In the current case, third party mesenchymal stem cells (MSC) were cotransplanted to facilitate engraftment of a second T depleted graft from the same HLA-mismatched donor. In order to increase the progenitor content of the second graft, the CXCR-4 antagonist AMD3100 was added to the second cycle of G-CSF mobilisation. *Results*. The higher number of CD34+ cells transplanted and the cotransplantation of MSC resulted in a rapid and sustained trilineage hematologic engraftment. Complete donor chimerism in myeloid and lymphatic cells was achieved. Graft-versus-Host disease occurring after the second transplantation required combined immunosuppressive treatment. *Conclusions*. Alternative progenitor cell mobilisation and MSC cotransplantation might be useful in the management of graft-failure after HLA-partially matched HSCT, but further studies have to be performed to confirm the safety of this approach with respect to the incidence of GvHD and relapse.

1180

PATIENTS UNDERGOING ALLOGENEIC BONE MARROW TRANSPLANTATION IN NON-ONCOLOGICAL DISEASES: EXPERIENCEOF A SINGLE CENTER

G. De Simone, M.R. D'Amico, M.T. Buonanno, M. Ripaldi

Pausilipon Hospital, NAPLES, Italy

Background. From 1995 to today, in our center were performed 69 transplants of allogeneic bone marrow donor from sibling. *Design and Methods*. In 17 children, 19 transplants have been performed for non-oncological diseases (2 patients underwent a second transplant). The diseases for which have been used for transplantation are as follows: 3 patients with Fanconi Anemia, 2 patients with Thalassemia intermedia, 1 patient with HBS, 2 patients with Cooley's disease, 2 patients with Aplastic Anemia, 1 patient with bthal/HbS, 1 patient with Blackfan-Diamond, 1 patient with Osteopetrosi, 3 patients with SCID (Severe Combined Immunodeficiency Disease), 1 patient with deficiency of FAS. The distribution regard the sex is the following: 11 patients were males, 6 females. The average age was 8.8 years (range: 4 months - 15 years). Donors have been nine cases in males and females in eight cases, the source of stem cells was bone marrow, except one case where we used a cord. *Results*. The TRM at 100 days was 0%. No patient died within the first hundred days from bone marrow reinfusion. In 6 patients there was a graft versus host disease (GVHD) skin grade I-II, 3 patients in a limited chronic GVHD of the skin to load in two cases of hepatic parenchyma in a case. Two patients died in the following complications: the first, after four months from transplantation to engraftment failure, remaining in aplasia associated with infectious episodes and exitus for acute renal failure, the other after six months from transplantation, for complications related to acute bacterial infection and a liver disease post-anesthetic. The event free survival was 2.8 years. The overall survival was 88%. *Conclusions*. Our experience, although on a limited number of patients, allows us to believe that the transplantation of allogeneic bone marrow in patients with non-oncological diseases, some very severe and disabling (such as osteopetrosi undermining the development of the brain parenchyma, vision and hearing, as well as abnormal skeletal development and psycho-motor-somatic and SCID, severe immunodeficiencies and potentially lethal) is a valide therapy, with a fatality and an acceptable toxicity.

1181

IS FEASIBLE CD34 CELLS ENUMERATION BY HEMATOLOGY AUTOANALYSER?

A. Lemes, T. Molero, P. Martin, S. De la Iglesia, L. Guerra, C. Campo

Hospital Universitario de Gran Canaria Dr Negrín, LAS PALMAS DE GC, Spain

Background. CD34+ detection methods based on cytofluorometric (CF) assays is, nowadays, without any doubt the best method to monitorise the moment the haematopoietic precursors (HP) apheresis should be initialised. It is also an outstanding method for CD34+ quantification in the afore mentioned product. Some autoanalysers are capable to semi-automatically process blood samples using monoclonal antibodies (MoAb) marked with florochromes. An excellent correlation has been demonstrated between lymphocyte population analysis by Cell-Dyn Sapphire /4000 autoanalyser and the reference method (flow cytometry). Aim The aim of this study was to compare CD34+/CD45dim progenitor count using both methods mentioned above (Cell-Dyn Sapphire and flow cytometry), in peripheral blood and apheresis product samples from patients and donors enrolled in HP transplantation programs. *Material and Methods*. 28 PH apheresis products and 11 peripheral blood samples in EDTA were processed after mobilization with growth factors. MoAbs used were antiCD45FITC/CD34PE (Becton Dickinson) and prepared using a standard method for FC. At the same time, these samples were also marked with the same MoAbs following the open tube technique, 5 minutes incubation, lysis and washing being automatically performed by Cell-Dyn Sapphire. Files were downloaded into a memory device USB and were then analysed through the FCS Express v3.0 program. *Results*. Time consumed per sample using the autoanalyser was 7 minutes, compared to 20 minutes per sample using FC analysis. Bland-Altman and Passing-Bablock tests were applied, where the identity line in both measurements of the apheresis product was (y= 0.885x +0.0144) with a slope of 0.086 for a CI of 95%. In peripheral blood a correlation was obtained at (y= 0,75x + 0.0175) with a slope of 0.750 for the same CI. *Conclusions*. In our series of results, CD34 count using Cell-Dyn Sapphire showed a good correlation with the reference method (FC). However, flow cytometry comparison was better when dealing with apheresis samples. These differences could be explained by the different quantity of positive events on both sample types. HP quantification by the autoanalyser could be used as a deciding tool as to when to start the apheresis and to estimate their concentration in the obtained product. A bigger amount of samples should be analysed in order to confirm our data. The technique should be enhanced so that in the near future CD34 quantification could be performed by an autoanalyser with total confidence.

1182

TRANSFORMING GROWTH FACTOR β-1 LEVELS IN INFLAMMATORY BOWEL DISEASE

S. Ayaz,[1] S. Yilmaz,[1] M. Yalinkilic[2]

[1]T Yuksek Ihtisas Hospital, ANKARA, Turkey; [2]T.Yuksek Ihtisas Hospital, ANKARA, Turkey

Background and aim. Transforming growth factor β 1(TGF-β1) levels was intended to increase during the inflammation of human colon mucosa. In this study we aimed to show the correlation between TGF-ß1 levels that increase in the activation period of inflammatuar bowel disease (IBD)and in healty group. *Material and Method*. For the study, 70 patients were taken. 40 of the patients were Ulcerative colitis(UC) while 30 of them were Crohn's disease(CD). In the UC group 18 of them were women and 22 of them were men. The average of the UC group was 40.7+ 1.6(16-69) years. In the CD group, 13 patients were women and 17 were men. The average age of the group was 36.9+1.9(18-63) years. In the healty control group, 10 women and 10 men were taken and the average age of the group was 35.65+8.21(22-49) years. All the patients had stopped to use the drugs for one month before the sample were taken. Crohn disease activation index and Rachmilewitz Endoscopic Index were used for the estimation of clinical activation of IBD . The activation period was accepted when the Crohn disease activation index was over 150 and the Rachmilewitz Endoscopic Index was over 4. At the same time CRP, sedimentation rate, fibrinogen level, thrombocyte and white blood cell count were measured fort he estimation of activation period. TGF-β1 levels were studied with ELISA (Bender-Med, Austria). *Results*. The average level of TGF-β1 in CD was 1230.0+572.71 pg/ml, in UC group it was 1362.5+880.6 pg/mL and in control group it was 1133.3+766.5 pg/ml. No statistical difference was found between these groups. In the activation group of CD,TGF-β1 level was 1310.0+719.9 pg/mL and in the remission group it was 956.6+795.0 pg/ml. No statistical difference was found between these groups and the control group. Also between activation and remission groups of CD, the levels of TGF-ß1 were showed no statistical difference. In UC during the activation period, TGF-β1 was found 1952.5+5543.7 pg/mL and during the remission period TGF-β1 was found 772.5+167.8pg/ml. We found statistically difference between the levels of activated group of UC and the healty group ($p<0.05$).Between the activated and remission groups of UC we also found statistically difference for the TGF-β1 ($p<0.05$). *Conclusions*. We found that in the UC patients group, if there was activation, TGF-β1 levels were statistically higher than the patients in remission and the control group. This result supported that during the activation, as cytokines were increased due to the Inflammation, TGB-β1 was also increase. This increase had also affected the inflammation. Because TGF-β1 was produced and secreted from the small intestine and colon mucosa. Although TGF-ß1 controled the proliferation and differentation of healty epithelial cells, it also had a role during the mucosa healing and the increase of fibrosis. In our study we couldn't find any correlation between the patients in activation and the remission periods of CD. In some studies this correlation was estimated, through some studies were

supported our results. In the study of Del Zoto, he said that, in CD and UK the stimulation of cytokine activation was occurred with different mecanisms and these cytokines had affected the production of TGF-β1 with different ways. As the results of the studies, the increase of TGF-β1 levels was accepted as one of the activation criteria in ulcerative colitis.

1183

THE ROLE OF TGF-β-1 PROTEIN AND TGF-β-R-1 RECEPTOR IN IMMUNE ESCAPE MECHANISM IN BLADDER CANCER

A. Hussein,[1] A. Helmy,[2] O. Hammam,[2] T. El Lithy,[2] M. Wishahi[3]

[1]Theodor Bilharz Research Institute, CAIRO, Egypt; [2]CAIRO, Egypt; [3]Mohamed Mohi El Din Wishahi, CAIRO, Egypt

Background. Tumor cells have numerous immune surveillance escape mechanisms as well as means of resistance to apoptosis. This study tried to clarify one of these mechanisms in bladder cancer with the hope of being able to develop targeted therapy that will sensitize the tumor cells to immune mediated apoptosis. *Design and Methods*. In this study, light and electron microscopic examination and expression of TGF-β-1protein and TGF-β-R-1 receptor using immunocytochemical and immunoelectronmicroscopic techniques in urine and peripheral blood mononuclear cells (PBMNCs). Samples were obtained from 5 healthy controls (Group 1) and 60 patients are studied and classified according to the cytopathologic examination of their urine into 2 main subgroups: chronic cystitis (bilharzial and nonbilharzial, (Group 2, n = 15) and bladder cancer (transitional cell carcinoma and squamous cell carcinoma, (Group 3, n=45), whether associated with schistosomal infection or not associated. Results: Urine examination by both immunocytochemical and immunoelectronmicroscopic techniques revealed a statistically significant decrease in the percentage of positive cases expressing TGF-β-R1 receptor in bladder cancer in comparison with either chronic cystitis cases or controls ($p<0.01$), while TGF-β-1 protein was significantly increased ($p<0.01$). By light and electron microscopic examination, exfoliated necrotic malignant epithelial (urothelial) cells and many inflammatory cells were detected in malignant

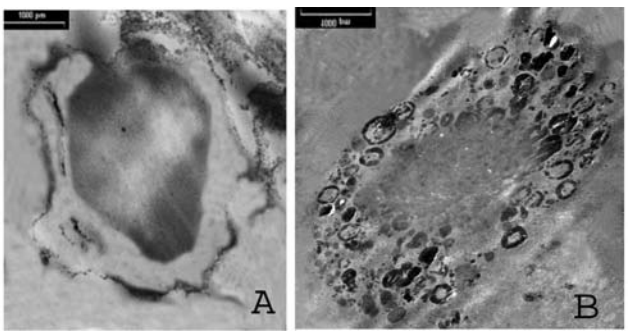

Figure 1. TEM photomicrograph of immunoperoxidase-labeled PB.

Examination of PBMNCs by immunocytochemical and immunoelectronmicroscopic techniques showed a significant increase in the percentage of positive cases expressing both TGF-β-1 protein and TGF-β-R-1 receptors in bladder cancer in comparison to the control group ($p<0.01$ and $p<0.05$, respectively) and to chronic cystitis cases ($p<0.05$). By light and electron microscopic examination, 42 out of 45 bladder cancer cases (93.3%) revealed remarkable apoptotic changes represented by cell shrinkage, surface blebs, nuclear chromatin condensation, and vacuolated cytoplasm. *Conclusions*. This work helps researchers and clinicians to better understand one of the escape mechanisms in bladder cancer that may facilitate the reverse of tumor escape from the immune system. It also draws attention to TGF-β-1 protein and TGF-β-R1 receptor; TGF-β-1 protein can be used as attractive target for anticancer therapy, and the absence of TGF-β-R1 can be considered a marker for malignant transformation of urothelial cells in bladder cancer.

1184

INACTIVATION OF ICSBP BY PROMOTER METHYLATION IS LIKELY INVOLVED IN PROGRESSIVE LEUKEMOGENESIS

N. Otto,[1] C.M. Niemeyer,[2] H. Döhner,[3] A. Ganser,[1] B. Schlegelberger,[1] D. Steinemann[1]

[1]MHH, HANNOVER, Germany; [2]Universitätsklinikum Freiburg, FREIBURG, Germany; [3]Universitätsklinikum Ulm, ULM, Germany

Background. Screening of PubMed GEO database showed a down-regulation of ICSBP (interferon-consensus site binding protein), a transcription factor of the IRF family involved in myeloid cell differentiation, preferentially in AML with t(8;21), t(15;17) and del(7q)/7, and in therapy-induced MDS/AML presenting del(5q). *Aim*. The aim of this study was to investigate whether ICSBP promoter methylation may be responsive for down-regulation in these cytogenetically defined subtypes of AML *Design and Methods*. DNA extracted from blood or bone marrow from patients diagnosed with primary AML (15: 5 t(15;17), 8 t(8;21), 2 with 5q-), secondary AML (14: 6 complex aberrant, 4 with 7-/7q-, 2 with trisomy 8, 4 with normal karyotype), childhood MDS (18: 1 with complex aberrant, 8 with 7-/7q-, 1 with trisomy 8, 1 with der(1) t(1;6), 7 with normal karyotype), and adult MDS (63: 8 complex aberrant, 16 with 7-/7q-, 8 with trisomy 8, 28 with 5q-, 8 with 5q- and additional aberrations) were screened for *de novo* methylation in the proximal promoter of ICSBP by methylation specific PCR. Additionally, *de novo* methylation of the ICSBP promoter was analyzed in four cancer cell lines and the restoration of the ICSBP function was investigated in one cell line after 5-azacytidine treatment. *Results*. Taken together, we observed ICSBP promoter methylation in 27 out of 116 patients (23%). Hypermethylation occurred most frequently secondary AML (8/20; 40%), compared to AML (4/15; 27%), adult MDS (13/63; 21%), and childhood MDS (2/18; 11%). Within the cytogenetically defined subtypes, ICSBP promoter methylation was found most frequently in patients with trisomy 8 (4/11, 36%), 7-/7q- (6/23, 26%), 5q- (7/30, 23%), complex karyotypes (2/15, 17%), t(8;21) (3/8, 37,5%), and t(15;17) (1/5, 25%). The ICSBP promoter was methylated in the Kasumi-1 and HL-60 cell lines, and unmethylated in the U937 and F-36P cell lines. Accordingly, ICSBP expression was absent in the cell lines with methylated promoter, as detected by Western blot analysis. 5-azacytidine treatment of the Kasumi-1 cell line induced a demethylation of the promoter, and after addition of interferon-g, a reexpression of ICSBP protein. *Conclusion*. Loss of expression ICSBP due to promoter methylation is a frequent event in myeloid neoplasias, particularly in secondary AML and in distinct cytogenetic subgroups like complex karyotype, 5q-, 7-/7q- and trisomy 8. ICSBP may be a target for epigenetic therapy, since reexpression was induced by 5-azacytidin treatment.

1185

DEATH-ASSOCIATED PROTEIN KINASE 1 IS EPIGENETICALLY SILENCED IN NK AND NK/T CELL LINES, BUT NOT IN T-ALL CELL LINES

S. Röhrs, J. Romani, M. Zaborski, H.G. Drexler, H. Quentmeier

DSMZ - Deutsche Sammlung von Mikroorganismen und Zellkulturen, BRAUNSCHWEIG, Germany

Background. T-cells and natural killer (NK)-cells are derived from pluripotent stem cells and can be distinguished by the expression of various marker proteins. The most important markers are the T-cell receptor and specific NK-cell receptors. For quite some time now there is the focus on epigenetic markers for the discrimination of different cell types and neoplasias. Epigenetic inactivation of tumor suppressor genes (TSG) by promoter CpG island hypermethylation is a common hallmark of malignant diseases. Specific profiles of hypermethylated CpG islands have been described to be unique for different neoplasias. *Aims*. Here, we screened for TSG promoter hypermethylation to find out whether the methylation status of a defined set of TSG allows for the discrimination of T-acute lymphoblastic leukemia (T-ALL) from NK-cell-derived cell lines. *Design and Methods*. We analyzed the methylation status of 24 different TSG in 20 cell lines representing T-ALL, NK, NK/T and T-anaplastic large cell lymphoma malignancies. For this approach we used a methylation-specific Multiplex Ligation-dependent Probe Amplification (MS-MLPA) assay. Characteristic methylation patterns were verified by methylation-specific PCR (MSP). Furthermore, data were validated at the mRNA expression level by quantitative real time PCR and at the protein level by western blot analysis. *Results*. The screening for TSG methylation showed that one of the analyzed genes - Death-associated protein kinase 1 (DAPK1) - was typically methylated in NK and NK/T cell lines, but not in T-ALL cell lines. The observed DAPK1 methylation

pattern could be confirmed by MSP. Furthermore, hypermethylation of DAPK1 promoter inversely correlated with DAPK1 mRNA and protein expression. Incubation of DAPK1 hypermethylated cell lines with the demethylating agent 5-Aza-2'deoxycytidine reactivated DAPK1 gene expression confirming that promoter hypermethylation was indeed responsible for transcriptional silencing of DAPK1 in NK and NK/T cell lines. *Conclusions.* Hypermethylation of the TSG DAPK1 differentiates NK and NK/T cell lines from T-ALL derived cell lines. Future investigations with patient samples will show whether the DAPK1 methylation status can be used to differentiate between T-ALL and malignant NK-cells.

MODULATION OF ALTERNATIVE RNA SPLICING BY AMILORIDE IN K562 CELL LINE

W.H. Chang,[1] T.C. Liu,[2] J.G. Chang[2]

[1]Kaohsiung Medical University, KAOHSIUNG, Taiwan; [2]Department of Laboratory Medicine, Kaohsiung Medical University Hospital, KAOHSIUNG, Taiwan

Background. Alternative splicing plays an essential role in the control of many biological processes, such as embryonic development, cell growth, and apoptosis. Since many apoptotic genes have alternatively splice variants with antagonistic function, aberrant splicing of these genes is associated with malignant growth and is a characteristic of different kinds of cancer including leukemia. Modulation of apoptotic genes by alternative splicing, therefore, has been proposed to be potential for cancer

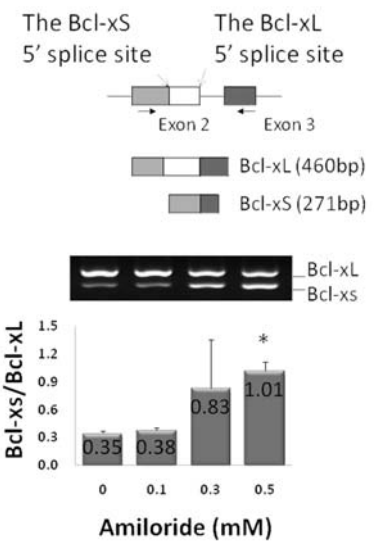

Figure 1.Modulation the Bcl-x alternative splicin

Aim. Although several small molecules have been proposed to modulate alternative splicing of RNA recently, additional molecules are still needed to be surveyed. *Design and Methods*. First, we detected the Bcl-x mRNA alternative splicing in k562 cell line under the treatment of a clinical proved drug, amiloride, by RT-PCR. To evaluate the mechanism of alternative splicing, we analyzed the expression of serine-arginine-rich proteins (SR proteins) by Western blot. To validate whether amiloride regulates Bcl-x alternative splicing has related to the cell apoptosis, we examined cell cycle and viability by flow cytometry. The signal pathway of apoptosis including Bcl-2 family proteins and multiple protein kinases were evaluated by Western blot. Finally, exon array was performed to genome-wide analyze the alternative splicing by Human Exon 1.0 ST Arrays (Affymetrix). *Results*. Treatment of K562 cell line with amiloride downregulated the expression of Bcl-xL mRNA and upregulated the expression of Bcl-xS in a dose- and time-dependent manner (Figure1).5-(N-ethyl-N-isopropyl)- amiloride, the amiloride analogue, however, did not modulate alternative splicing of Bcl-x mRNA. The expression of SF2/ASF was reduced prominently but hnRNPA1 was highly expressed after amiloride treatment. Moreover, most of the SR proteins, including SRp 55, SRp40, SRp30, and SRp20, were dephosphorylated after amiloride treatment. In addition to the modulation effects of alternating splicing, cell cycle analysis demonstrated S phase arrest and apoptosis after amiloride treatment.We also found that the proapoptotic protein Bax and Bcl-xS were upregulated and the antiapoptotic protein Bcl-2 and Bcl-xL were downregulated during amiloride-induced apoptosis. Besides, ERK1/2 dephosphorylation, a dose-dependent increase of phospho-JNK, and phospho-p38 MAPK were also found in amiloride-treatment cells. Exon array analysis showed that there are 59 genes have alternative splicing after amiloride treatment. *Conclusions*. In this study, we found that amiloride can modulate Bcl-x alternative splicing. Consistent with its RNA expression, the antiapoptotic protein Bcl-xL was down- regulated and the proapoptotic protein Bcl-xS was up-regulated and cause the cell apoptosis. The modulation effect of amiloride to alternative splicing is mainly through SR proteins, and amiloride may play a role in the cancer treatment.

1187

SOCS-1 EXON 2: DEMETHYLATION BY AZACYTIDINE INCREASED THE RELATIVE EXPRESSION OF SOCS-1 AND ASSOCIATED WITH TRANSCRIPTIONAL SILENCING IN LEUKAEMIC CELL LINES

M.F. Johan,[1] A.C. Goodeve,[2] J.T Reilly[3]

[1]Universiti Sains Malaysia, KUBANG KERIAN, KELANTAN, Malaysia; [2]University of Sheffield, SHEFFIELD, UK; [3]Royal Hallamshire Hospital, SHEFFIELD, UK

Background. Mutations in genes such as FLT3, KIT and RAS have been identified to provide a proliferative signal in acute myeloid leukaemia (AML) and serve as targets for drug treatments. In addition, epigenetic may play a major role in the pathogenesis of AML where aberrant methylation is a major mechanism for silencing of tumour suppressor genes. Hypermethylation of the suppressor of cytokine signalling-1 (SOCS-1) gene has been reported to cause inactivation in leukaemogenesis. However, there is an issue in the use of different locations of SOCS-1 gene being amplified (exon 2 and 5'UTR) that gave discrepant methylation results in AML. *Aims*. The aim of the study was to determine the role of SOCS-1 exon 2 methylation in haematopoietic cell lines and the relative expression of the gene after the addition of either azacytidine or deoxyazacytidine as the conversion agent of methylcytosine. *Design and Methods*. The relative expression level of SOCS-1 gene in four leukaemic cell lines was compared to determine the gene expression in SOCS-1 exon 2 methylated and unmethylated cell lines. Demethylation technique was established by treating the cell lines using either azacytidine or deoxyazacytidine. Methylation-specific PCR (MS-PCR) was employed to determine if demethylation using the conversion agent would convert methylcytosine into cytosine in the SOCS-1 exon 2 methylated cell lines. Quantitative reverse transcription PCR (RQ-PCR) were used to analyse the relative expression of SOCS-1 in haematopoietic cell lines and calculated using the 2-ΔCT equation. *Results*. There was a decrease in the relative expression level of SOCS-1 gene in SOCS-1 exon 2 methylated cell lines (ME-1 and Jurkat) compared to unmethylated cell lines. The demethylation technique was established using 1 μM of azacytidine and harvested after three days. The use of azacytidine is favoured instead of deoxyazacytidine because of the greater toxicity of the latter to the cells. The demethylation experiments showed that there was a marked increase in relative expression of SOCS-1 in ME-1 and Jurkat cell lines after the addition of azacytidine with MS-PCR results showed evidence of cytosine conversion in both. The mean expression level of SOCS-1 gene in ME-1 and Jurkat cell lines were 17 folds and 7 folds higher respectively compared to untreated controls. RQ-PCR results showed that SOCS-1 exon 2 methylation is associated with the transcriptional silencing of SOCS-1 gene in haematopoietic cell lines. *Conclusions*. The treatment of SOCS-1 exon 2 methylated cell lines with demethylating agent azacytidine resulted in the re-expression of SOCS-1 gene and it was the methylation of SOCS-1 exon 2 but not 5'UTR may lead to epigenetic silencing of SOCS-1 in leukaemic cell lines.

1188

RELEASE OF CYTOCHROME C FROM MITOCHONDRIA PRECEDES BAX TREANSLOCATION/ACTIVATION IN TRITON X-100-INDUCED APOPTOSIS

N. Domae, K. Inami, Y. Katao, H. Sawai

Osaka Dental University, HIRAKATA CITY, Japan

Background. The mechanisms of apoptosis have been profoundly investigated in the last decade. In the mitochondrial pathway,

cytochrome c is released from mitochondria into the cytosol and forms the apoptosome, leading to activation of executioner caspases. Among various stimuli, sublytic concentrations of nonionic detergents, such as Triton X-100 (TX) have been shown to induce apoptosis. However, the mechanisms by which detergents induce apoptosis remain unclear. 2. *Aims*. Recently, it was reported that conformational change of Bax was observed when Bax translocated from the cytosol to mitochondria in apoptosis induced by various stimuli including anti-Fas antibody and TNF-a. Therefore, we investigated whether activation of Bax might play a crucial role in Triton X-100- induced apoptosis (TXIA) in cells. 3. *Design and Methods*. 1) Human monoblastic leukemia cell line U-937 was used in our studies. 2) Apoptosis was assessed by typical apoptotic morphological changes (under light microscope), nuclear condensation and fragmentation (under fluorescent microscope), cellular DNA content (propidium iodide staining and FACS analysis) and exposure of phosphatidylserine on the surface of apoptotic cells (stained with FITC-conjugated Annexin V and PI, and analyzed by FACS). 3) Caspase activity in TX-induced apoptotic cells was detected by fluorescence of DEVD-MCA (by using ARVO 1420 multilabel counter). 4) Effects of caspase inhibitors (z-VAD-fmk and z-DEVD-fmk) were assayed by cellular DNA content of those cells. 5) Western blot analysis for cytochrome c and Bax was performed in the cytosolic and mitochondrial fractions of those cells. The images were obtained using VersaDoc imaging system. 6) To confirm the results obtained by Western blot analysis, those cells were immunostained with anti-activated Bax antibody or anti-cytochrome c antibody. Images were obtained by FV300 laser scanning confocal microscope. 4. *Results*. 4.1) Most of U-937 cells showed typical apoptotic membrane blebbing and nuclear changes at treatment of 0.01% TX. 4.2) Rapid activation (at 5min after TX treatment) of caspases-3 and -9 was observed, whereas activation of caspase-8 seemed slower than other two caspases. 4.3) Pretreatment with caspase inhibitors completely inhibited TXIA. Although Bax translocation/activation was inhibited by caspase inhibitors, they did not affect cytochrome c release from mitochondria. 4.4) TX induced rapid release of cytochrome c from mitochondria to the cytosol in TXIA. 4.5) Translocation and activation of Bax from the cytosol to mitochondria occurred in TXIA. 4.6) The Immunostaining experiments of conformational changes of Bax and cytochrome c confirmed the results obtained by Western blot analysis. *Conclusions*. We suppose that in TXIA, mitochondria seems to be the primary target and cytochrome c release from mitochondria induces caspase activation, which further induces Bax translocation/activation. Furthermore, our results suggest that activation of caspase-3 may occur in the mitochondrial pathway of apoptosis through formation of the apoptosome including caspases-9. Since Fas-induced apoptosis depends on caspase-8, the mechanism of TXIA is quite distinct from that of Fas-induced apoptosis. At the very least, the extremely rapid kinetics of apoptosis induction by sublytic concentrations of TX represents a novel and powerful tool to probe specific mechanisms of apoptosis.

1189

CYTOTOXIC EFFECT OF TETEACYCLINE ANALOGUES (DOXYCYCLINE, MINOCYCLINE AND COL-3) ON ACUTE MYELOID LEUKEMIA HL60 CELLS

M. Fares,[1] H. Song,[2] K.R. Maguire,[2] Å. Sidén,[2] Z. Hassan[2]

[1]Novum Karolinska University Hospital Huddinge, STOCKHOLM, Sweden; [2]Karolinska Institute, STOCKHOLM, Sweden

Background. Despite progress in the treatment of acute myeloid leukemia, so far the treatment outcome is not satisfactory. Side effects of chemotherapy are major limiting factors due to unspecific cytotoxicity. New effective treatment strategies with fewer side effects are required for further improvement. New mechanisms-based targeted drugs have been developed. Tetracycline analogues (TCNAs) have been shown to possess besides antibiotic properties also non-antibiotic activities. They have been shown to induce apoptosis in several cancer cell lines. Three major families of TCNAs have been identified, natural products, semisynthetic compounds and chemically modified tetracyclines. Doxycycline (DOXY) and minocycline (MINO) belong to semi-synthetic tetracyclines, while COL-3 is chemical modified tetracycline-3. Chemically modified tetracyclines do not possess antibiotic properties. Aim In this study, we investigated the cytotoxic effect of TCNAs DOXY, MINO and COL-3 in human myeloid leukemia cell line HL60. *Design and Methods* HL60 cells were cultured in complete RPMI 1640 medium (supplemented with 10% fetal bovine serum). Stock solution of DOXY and MINO were prepared in sterile water, while COL-3 was dissolved in DMSO. Cells were treated with DOXY, MINO and COL-3 in final concentrations ranging from 0.5 to 100 µg/mL until 24 h. The control cells were incubated with complete drug-free medium. Cells treated with DMSO in a final concentration of 0.2% were used in the experiments with COL-3 as a control for solvent toxicity. Cell viability was studied using resazurin assay. Apoptosis was assessed using morphological criteria using May-Grünwald-Giemsa staining. Loss of mitochondrila membrane potential was investigated using tetramethylrhodamine methyl ester and flow cytometry. Protein cleavage pattern was studied using SDS-PAGE and immunoblotting. Pretreatment with pancaspase inhibitor Z-VAD-FMK in concentration 100 µmol/L for 1 h followed by incubation with TCNAs was used to confirm the caspase-dependent apoptosis. *Results*. All three drugs induced concentration-dependent decrease in viability of HL60 cells at 24 h of incubation. The greatest effect was observed after incubation with COL-3 (IC50 was 0.9 µg/mL for COL-3 and 9.6 µg/mL for DOXY and MINO, respectively). Apoptotic morphology was detected already 6 h after the incubation start and it became more pronounced in a concentration and time-dependent manner. Apoptosis was caspase-dependent as detected by caspase activation and confirmed by Z-VAD-related decrease in percentage of apoptotic cells. Loss of mitochondrial membrane potential and cleavage of Poly-ADP-ribose polymerase (PARP) and BCL-2 were detected. The order of apoptotic events differed among the TCNAs. *Conclusions*. Cytotoxic effect of TCNAs on leukemic HL60 cells was exposure dependent. All three TCNAs induced apoptosis in the HL60 myeloid cell line in a mitochondrial and caspase-dependent way. COL-3 had the most potent anti-proliferative and pro-apoptotic effect and thus, TCNAs may have treatment potential in acute myeloid leukemia.

EVALUATION OF PHOSPHOLIPIDS CHANGES WITH APPLICATION OF IN VITRO 31P MRS DURING APOPTOSIS INDUCED BY ARA-C ON PATIENTS WITH ACUTE LEUKAEMIA

M. Kulisziewicsz-Janus,[1] J. Niedoba1, B. Jazwiec,[1] S. Baczynski[2]

[1]Wroclaw Medical University, WROCLAW, Poland; [2]Faculty of Chemistry, University of Wroclaw, WROCLAW, Poland

Background. Phospholipids play an important role in the biological events of the progression of cancer. 31P magnetic resonance spectroscopy (MRS) can be a powerful method for non-invasive investigations aiming at an explanation of phospholipid mechanisms in the tumor tissue. The 13P MRS spectra of the phospholipid extracts from bone morrow mononuclear cells (BMMC) consisted of 7 resonant peaks due to PC - phosphatidylcholine, CPLAS - phosphatidylcholine plasmalogen, SM - sphingomyelin, PE - phosphatidylethanolamine, PI - phosphatidylinositol, PS - phosphatidylserine, CL - cardiolipin. *Aims.* To continue our previous studies on the application of 31P MRS to the analysis *in vitro* of phospholipids changes in bone marrow mononuclear cells from patients with AL, we decided to evaluate this method to see if it gives satisfactory results during apoptosis of blast cells induced with Ara-c *in vitro*. *Design and Methods.* The investigation was carried out on BMMC from 20 patients with acute leukemia (AL). Mononuclear cells were cultured without and with 20 g/mL Ara-C for a 24-hour period. Subsequently, flowcytometric analyses were performed with Anexin-V and Propidium Iodide staining, measured by apoptosis. Phospholipids were extracted with a modified Folch method from the same BMMC. The spectra 31P were received on an AMX 300 Brukner (7.05T) spectrometer. Calculation of phospholipid concentration was based on peak integral intensities in the 31P NMR spectra for the individual compounds and methylenediphosphonic acid (MDPA). *Results.* On the basis of our investigations we divided the patients into two groups. The first one (A), from which the percentage of apoptotic cells after 24 hours of incubation with Ara-C was less than 25% (the average being 17%) we noted as non-responsive to Ara-C. The second group (B), from which the percentage of apoptotic cells was over 25% (the average being 46.8%) was classified as responding to Ara-C. In group A, a significant difference between the concentrations of phospholipids in cells cultured with and without Ara-C only for CPLAS could be verified. The average increase of the concentration is 7.0 mol/l ($p<0.15$). In group B, a significant difference between the concentration of phospholipids in cells cultured with and without Ara-C for the following phospholipids PI and PE was observed. An average decrease PI 17.9 µmol/l ($p<0.20$) and PE 20.1 mol/l ($p<0.15$) with the given level of significance could be verified. *Conclusions.* The study of the above application of *in vitro* 31 MRS for early detection resistance of Ara-C in blast cells in patients with AL, may show a difference in the concentration of phospholipids observed during apoptosis induced by Ara-C *in vitro*. Moreover, investigated changes of phospholipids concentrations with 31P MRS may suggest their participation in Ara-C induced cell apoptosis.

1191

ANTIPROLIFERATIVE AND APOPTOTIC EFFECTS OF AN ORAL IRON-CHELATING AGENT DEFERASIROX ON HUMAN LEUKEMIC CELL LINES

C.W. Choi,[1] J.-L. Kim,[1] H.-N. Kang,[1] M.-H. Kang,[1] Y.A. Yoo,[1] B.S. Kim,[2] J.S. Kim[1]

[1]Korea University Guro Hospital, SEOUL; [2]Korea University Anam Hospital, SEOUL, South-Korea

Background. Iron chelation therapy has been proved to have antiproliferative and apoptotic effects in rat and human cell lines, including hepatoma, neuroblastoma and leukemia. However, most studies were regarding the effect of deferoxamine (DFO), and it is still unknown whether a new oral iron chelating agent deferasirox has the antiproliferative effect on human leukemic cell lines or not. *Aims.* The purpose of this study was to investigate the antitumor effect of deferasirox on human leukemic cell lines. *Design and Methods.* Two human leukemic cell cultures (HL-60 and KG-1) were maintained in the RPMI1640 with L-glutamine (300 mg/L), 25 mM HEPES, 25 mM NaHCO3 and fetal bovine serum. Deferasirox was added at the concentrations of 50 or 100 uM. DFO was used as an iron chelator reference. Cell proliferation was evaluated daily by MTT assay for 72 hours. Cell cycle was analyzed by flow cytometry. Apoptosis assay was done by flow cytometry with use of Annexin V and propidium iodide (PI). We also studied the change of proteins involved in the apoptosis pathway by western blot. All experiments were repeated at least three times. *Results*. MTT assay showed that deferasirox had antiproliferative effect on both cell lines. As early as day 1, cell proliferation was started to be suppressed in the deferasirox-treated group ($p<0.001$), and this suppression effect continued until culture day 3. This antiproliferative effect was dose-dependent. Cell cycle analysis revealed that increased subG1 fraction compared to control (no treatment group). On day 1, subG1 fractions were 6.6% (control), 88.9% (50 uM), and 96.4% (100 uM), respectively. On day 2 and 3, this fraction increased up to 95-99% in the deferasirox-treated group. Increased apoptosis was also confirmed by Annexin V and PI staining. Western blotting showed that decreased expression of bcl-2 in deferasirox-treated KG-1 cell line. *Conclusions*. We demonstrated that a new oral iron-chelating agent deferasirox had antiproliferative and apoptotic effects on human leukemic cell lines. *in vivo* study and investigation of synergism with current antileukemic drugs are warranted.

1192

THE INFLUENCE OF FORODESINE USED ALONE OR IN COMBINATION WITH OTHER CYTOTOXIC DRUGS ON THE VIABILITY AND APOPTOSIS OF CLL CELLS IN VITRO- PRELIMINARY RESULTS

A. Korycka,[1] I. Franiak-Pietryga,[1] A. Zaborowska,[2] B. Cebula,[3] J.Z. Blonski,[2] P. Smolewski,[2] T. Robak[2]

[1]Medical University, LODZ; [2]Medical University, Department of Hematology, LODZ; [3]Medical University, Department of Experimental Hematology, LODZ, Poland

Background. Recent observations suggest that forodesine (F), a novel inhibitor of purine nucleoside phosphorylase (PNP), may have clinical activity in chronic lymphocytic leukemia (CLL). The main mechanism of action of F is induction of apoptosis by intracellular accumulation of deoxyguanosine triphosphate (dGTP) unlike other purine analogs, cladribine (2-CdA) and fludarabine (FA) which are incorporated into DNA. Bendamustine (BEN), an alkylating drug and another promising agent in CLL, may also exert an antineoplastic effect by triggering tumor cell apoptosis. *Aims.* The aim of our study was to evaluate the effect of F alone or in combination with 2-CdA, FA or BEN on CLL cell viability and apoptosis. The type of interaction was also tested. *Design and Methods*. Peripheral blood mononuclear cells (PBMCs) were obtained from 30 untreated CLL patients who gave informed consent. In preliminary experiments, the following concentrations of drugs were used: 1, 2, 3 or 4uM of F alone; deoxyguanosine (dGuo): 10 or 20uM alone or in combination with F; 2-CdA: 25, 50 and 100nM, FA: 0.8, 1.6 and 3.2uM, BEN: 20, 40 and 80 ug/mL. Concentrations of 1 or 2 uM F + 20uM dGuo were chosen for further experiments and the effects of these drugs alone and in combination with 2-CdA, FA or BEN were tested. Cultures with initial PBMCs' concentration of $0.5x10^6$ cells/mL, were maintained for 24 and 48h. Cells maintained in cultures without drugs were used as controls. Cell viability was measured by flow cytometry after staining with propidium iodide, whereas apoptosis was detected by Annexin V assay. Compensating apoptotic index (CAI) was calculated by subtraction of spontaneous apoptosis in parallel control cultures from apoptosis measured in cultures with drug additions. Statistical differences between obtained values were evaluated by Wilcoxon signed-rank test. The combination index (CI) was used to estimate synergistic, additive or subadditive interaction. A CI value<0.8 was defined as synergism, 0.81-1.2 as addition and >1.21 as subaddition. *Results*. F or dGuo as single agents did not significantly influence CLL cell viability, whereas the combination F+dGuo resulted in significant apoptosis compared to either control or those agents alone ($p<0.01$). CAIs for all combinations of F used jointly with different dGuo concentrations, after 48h incubation were higher than 10%. The highest proapoptotic effects were obtained for 2uM F+20 uM dGuo and 3uM F+20uM dGuo (CAIs 22.5% and 23.8%, respectively). Moreover, median CAIs in samples treated with 2 uM of F +20 uM dGuo in combinations with the highest concentrations of BEN (40 ug/mL), 2-CdA (50nM) and FA (1.6uM) were significantly higher than in controls ($p=0.001$, $p=0.002$, and $p=0.0009$, respectively). F in combination with BEN acted synergistically (CI=0.8), whereas F used either with 2-CdA or FA showed subadditive interaction. *Conlcusions*. Our results demonstrated, that F combined with dGuo induce apoptosis of CLL cells. Additionally, the combination of F with BEN exerts synergistic effects, suggesting that clinical studies on the efficacy of F alone or in combination with BEN in CLL patients are warranted.

1193

THE STUDY OF APOPTOTIC MECHANISMS INDUCED BY ARSENIC TRIOXIDE AND AMIFOSTINE IN HUMAN ACUTE PROMYELOCYTIC LEUKEMIA CELL LINES HL-60 IN VITRO

L.H. Ma

Second Hospital of Shanxi Medical University, China, TAIYUAN, China

To explore the mechanisms of apoptosis induced by arsenic trioxide and amifostine in human acute promyelocytic leukemia cell lines HL-60. *Design and Methods*. HL-60 cells were given different concentrations of arsenic trioxide alone and combined with amifostine.The inhibitory ratio of the cells were measured by MTT assay, cell cycle was examined by flow cytometry(FCM), and the expression of survivin was detected by semi-quantitate RT-PCR.Result Proliferation of HL-60 cells exposed to arsenic trioxide dropped down with increasing dose of the drug and this effect was significantly higher when arsenic trioxide was used in combination with amifostine. HL-60 cells was arrrested at G1 phase and decreased remarkably in S phasein in time and dose-dependently manner after exposure to arsenic trioxide combinated with amifostine. Furthermore,there was a more significant decrease in survivin expression in HL-60 cells trated with arsenic trioxide in combination with amifostine as compared to the cells trated only with arsenic trioxide. *Conclusions.* Arsenic trioxide induced HL-60 cells form apoptosis by arrresting at G2/M phase and probably downregulating the expression of survivin.Amifostine enhanced the sensitivity of HL-60 cells to arsenic trioxide by arrresting at G1 phase (perhaps this is the non-expression phase of survivin) thus educed its promoting apoptosis effect.

1194

THE ROLE OF SIMVASTATIN IN INDUCING APOPTOSIS AT PATIENTS WITH MALIGNANT HAEMOPATHIES

A. Mihaila,[1] L. Mocanu,[2] E.C. Rezi,[2] A. Catana,[2] O. Flucus,[2] L. Bera,[1] R. Mihaila,[3] M. Deac[1]

[1]Lucian Blaga University, SIBIU; [2]County Clinical Hospital, SIBIU; [3]Public Health Authority, SIBIU, Romania

Background . The inhibition of protein geranylgeranylation by statins led to reduction of cell viability of malignant cells in a time and dose-dependent way, process mediated by both induction of apoptosis and inhibition of proliferation. *Aims.* Our aim was to study the effect of Simvastatin on the expression of annexine V at patients with chronic lymphoproliferations. *Design and Methods*. We have studied a group formed by 23 consecutive patients with malignant lymphoproliferations which were hospitalised in the Haematology Department of the County Clinical Hospital from Sibiu during April-June 28 and had no contraindications for statins. They all received Simvastatin 12 mg/day, three days. Before, and after, we have performed the next immunological, haematological and biochemical tests: annexine V, haemoleucogram, glycaemia, creatinine level, ALAT, ASAT, bilirubin, cholesterol, triglycerides and total lipids. The dosing of anexine V was performed with a CYTOMICS FC5 flowcytometer, which can simultaneous recognize 4

different fluorocroms. The protocol for annexine V for patients with chronic lymphoproliferations (except patients with multiple myeloma) was Annexin V-FITC, PIPE, CD2-ECD, CD5-PC5, and for those with multiple myeloma was Annexin V-FITC, PIPE, CD45-ECD, CD38-PC5. The results were statistically analysed using the SPSS program. *Results*. The average age of the patients from the studied group was 65.78±1.91 years. The medium survival period from the moment of diagnosis was 28.6±3.39 months. At them, there was performed an average number of 1.17±1.11 therapeutic lines and they had the next diagnoses: chronic lymphocytic leukemia - 8 patients, non-Hodgkin malignant lymphoma - 8 patients and multiple myeloma - 7 patients. The cholesterol and total lipids level decreased significantly after the treatment with Simvastatin (from 192.17±41.95 mg/dL to 166.83±45.91, and from 691.76±193.96 to 597.74±189.17 mg/dL, respectively) (p<0.001, respectively p=0.016). The increasing level of ASAT was at the limit of statistically significance and did not overgrow the normal range, while ALAT registered a decrease, but without statistically significance. The early and late apoptosis, estimated by the flowcytommetric dosage of the annexine V, increased significantly after the treatment with simvastatin (p=0.007, respectively p=0.003). *Summary.* The Simvastatin administration could have an adjuvant effect in the treatment of patients with malignant lymphoproliferations, by inducing apoptosis.

This abstract is a part from CEEX 179/2006 grant, financed by the Educational and Research Ministry from Romania.

PROTEOMIC ANALYSIS OF CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

M. Braoudaki,[1] Ch. Papathanassiou,[1] K. Karamolegou,[3] A.K. Anagnostopoulos,[2], K. Vougas,[4] G.Th. Tsangaris,[4] F. Tzortzatou-Stathopoulou[3]

[1]*University of Athens, Aghia Sophia Children's Hospital, ATHENS, Greece;* [2]*University of Athens, Aghia Sophia Children's Hospital, ATHENS, Greece;* [3]*Medical School, University of Athens, Aghia Sophia Children's Hospital, Athens, ATHENS, Greece;* [4]*Center of Basic research II, Biomedical Research Foundation of the Academy of At, Nederland*

Background. Acute lymphoblastic leukemia (ALL) is a malignant disease of the blood and the bone marrow and is considered the most common type of childhood cancer. Although the rates of success in treatment of ALL are steadily increasing, further attempts may lead to a more favorable therapeutic outcome. The use of proteomic technology could prove beneficial on knowledge regarding early cancer detection, monitoring response to treatment, or identification of the most informative diagnostic markers. *Aims*. In a clinical practice, plasma represents an opportunity for proteomic research to benefit prognosis and response to therapy. The purpose of this study was to verify and validate a list of protein candidates relevant to the prediction of the clinical behavior and personalized treatment of childhood ALL when performed on plasma from bone marrow (BM) and peripheral blood (PB). *Design and Methods*. Twenty eight plasma samples from BM and PB collected from patients with confirmed childhood ALL at diagnosis were analysed. Diagnosis was based on morphology, cytochemical staining, cytogenetic analysis, molecular and immunophenotypic study. As controls, four plasma samples from BM and PB from non-leukemic pediatric patients were studied in parallel. Differential proteomic analysis was performed by two two-dimensional gel electrophoresis (2-DE) followed by protein identification by matrix-assisted laser desorption and ionization time-of-flight (MALDI-TOF) mass spectrometry. In the first dimension, in order to increase sensitivity, all samples were run on several gels each with different pH range starting from 3-10NL and following with the smaller 4-7L pH range. The second-dimension electrophoresis was carried out in 12% SDS-polyacrylamide gels in a PROTEAN apparatus. The gels were stained with colloidal Coomassie blue, scanned in a GS-800 Calibrated Densitometer and analyzed using the PDQuest image processing software. The Swiss-Prot database (*http://ca.expasy.org/sprot/*) was used to search for protein identification. *Results*. Fifty proteins were found differentially expressed from ALL BM plasma samples and 60 proteins were found to be expressed from PB plasma as compared to control. By these, 35 proteins were detected in both the BM and the PB plasma of the ALL pediatric patients. The majority of the identified proteins included suppressor genes, metabolic enzymes, structural proteins and signal transduction mediators. *Conclusions*. Our study demonstrates the potential of proteomic technology for the identification and confirmation of protein composition in plasma. However, a comprehensive knowledge of the value of these proteins is required in order to elucidate its relevance on childhood ALL screening, diagnosis and treatment outcome.

1196

PROTEOMIC ANALYSIS OF CHILDHOOD ACUTE MYELOID LEUKEMIA

M. Braoudaki

University of Athens, Aghia Sophia Children's Hospital, ATHENS, Greece

Background. Childhood acute myeloid leukemia (AML) is a frequent hematological malignancy that shows a high degree of heterogeneity in response to therapy. Given the diverse nature of AML and the inherent variability in individual protein levels, it seems likely that the best approach to screen for AML will be to determine the protein profile using proteomic technology. *Aims*. We studied two cases of childhood AML, in order to identify proteins, whose function could regulate the clinical characteristics and the treatment outcome of the disease. By these, one was diagnosed with myelodysplastic syndrome (MDS) before AML diagnosis, whilst the other with confirmed AML. *Design and Methods*. Six bone marrow plasma (BM) and six peripheral blood plasma (PB) samples were obtained before diagnosis, at diagnosis of AML and three months following initiation of treatment. As controls, two plasma samples from BM and two from PB from non-leukemic pediatric patients were studied in parallel. Differential proteomic analysis was performed by two-dimensional gel electrophoresis (2-DE) of overlapping pH ranges from 3 to 10, followed by protein identification by matrix-assisted laser desorption and ionization time-of-flight (MALDI-TOF) mass spectrometry analysis. For the detection of the differential expressed proteins, gels were scanned in a GS-800 Calibrated Densitometer and analyzed using the PDQuest image processing software. *Results*. Comparison of plasma samples from BM and PB of the AML pediatric patients with the controls revealed differences in various molecular mass ranges with different isoelectric points. Forty one proteins were found differentially expressed between the BM samples as compared to the control. Among these, 10 were found expressed from the BM sample derived from the MDS case before AML diagnosis as compared to the control, whilst the remaining 31 proteins were found differentially expressed from the BM samples at diagnosis. In addition, 8 proteins (Vitamin D-binding protein precursor, Serotransferrin precursor, Complement C3 precursor, Clusterin precursor, β-2-glycoprotein 1 precursor, Apolipoprotein E precursor, Apolipoprotein C-II precursor and Antithrombin-III precursor) were found differentially expressed from the follow-up BM samples. Regarding the proteins extracted from PB plasma samples, 26 were found differentially expressed between the PB samples as compared to the control. Among these, 4 proteins were found expressed from the PB sample derived from the MDS case before AML diagnosis as compared to the control, whilst the remaining 22 proteins were found differentially expressed from the PB samples at diagnosis. Eight proteins (α-2-macroglobulin precursor, Apolipoprotein A-I precursor, Clusterin precursor, Gelsolin precursor, Keratin type I cytoskeletal 10, Leucine-rich α-2-glycoprotein precursor, Prothrombin precursor and Transthyretin precursor) were found differentially expressed from the follow-up PB samples. In general, functional analysis showed that the majority of the detected proteins were metabolic enzymes, structural proteins, signal transduction mediators and immunoglobulins. *Conclusions.* Proteome analysis of plasma seems to offer a useful approach for profiling pediatric patients with AML. Additionally, the current technology was shown to provide significant insight into the presence and/or absence of several proteins that might serve as useful biomarkers for childhood AML. However, further analyses are warranted to validate and uncover the role of these findings.

A COMPARISON OF IN SILICO AND IN VITRO SEARCH FOR A GENE EXPRESSION PATERN SPECIFIC FOR STEROID RESISTANCE OF LEUKEMIC CELLS COLLECTED FROM PEDIATRIC PATIENTS WITH ALL

J. Pierlejewski,[1] M. Borowiec,[1] M. Bulas,[1] A. Sokol,[2] B. Kazanowska,[2] W. Fendler,[1] B. Zalewska-Szewczyk,[1] W. Mlynarski[1]

[1]*Medical University of Lodz, LODZ;* [2]*Medical University of Wroclaw, WROCLAW, Poland*

Background. Among recent research concerning THE treatment of ALL, neoplasmatic cell genetic profile analysis is one of the most far-reaching. The expression of genetic material is surely one of the main areas of interest for molecular analysis. The involvement of bioinformatics into molecular research may be a way to avoid inconsistancy of the results, and establishing new genetic prognostic factors. Aims: Using a bioinformatic analysis for objective selection of candidate, prognosticaly important for ALL, genes, which have not been yet associated with this disease's clinical outcome. Analysis of expression of selected genes in

leukemic cells, and correlation between them. *Design and Methods*. The bioinformatic analysis was performed with genomic data fusion method. The ENDEAVOUR software was used. As a training set we used 3 genes which have been already recognized as important for response to chemotherapy in ALL (NR3C1, FKBP5, NFkBIA). In a group of 36 children with ALL, the molecular analysis was performed on leukemic cells collected at the day of diagnosis. To evaluate the increase of product of amplification reaction in real-time the RT-PCR technique was used. *Results*. The algorithm of bioinformatic analysis results with selection of for genes to further analysis. Among those genes there were: JunB - encoding transcription factor, CCL3 - encoding chemokine, NCC27 - encoding chloride channel in nuclear membrane and RBM14 - encoding the co-activator protein for transcription factors.

Table 1. Correlation matrix between gene expression levels.

Values given as Spearman rank correlation

Variable	Delta NFKBIA	Delta FKBP5	Delta JUNB	Delta CCL3	Delta RBM14	Delta NCC27	Delta NR3C1
Delta NFKBIA		0,24	0,12	0,21	0,51 p<0,01	0,42 p<0,05	0,31
Delta FKBP5	0,24		-0,12	-0,28	0,11	0,24	0,51 p<0,01
Delta JUNB	0,12	-0,12		0,14	0,54 p<0,001	0,34 p<0,05	-0,56 p<0,001
Delta CCL3	0,21	-0,28	0,14		-0,01	-0,05	-0,24
Delta RBM14	0,51 p<0,01	0,11	0,54 p<0,001	-0,01		0,87 p<0,001	0,02
Delta NCC27	0,42 p<0,05	0,24	0,34 p<0,05	-0,05	0,87 p<0,001		0,21
Delta NR3C1	0,31	0,51 p<0,01	-0,56 p<0,001	-0,24	0,02	0,21	

Those genes where selected as never before associated in research reports with ALL biology and outcome. The expression level of reported genes was given as delta value in relation to GAPDH expression (housekeeping gene) and mean values was; ΔNR3C1 = 4.40±1.55, ΔNFkBIA = 1.59±1.59, ΔFKBP5 = 4.15±1.35, deltaJUNB = -0.65±5.2, ΔCCL3 = 5.48±3.6, ΔRBM14 = 3.15±2.13, ΔNCC27 = -0.11±1.67. Non-parametric statistical analysis revealed strong correlations between the expression level of RBM14 and NCC27, JUNB plus between NR3C1 and JUNB (p<0.001). The correlation between NFkBIA and RBM14 expression, and also in apply to NR3C1 and FKBP5 expression was also statistically significant (p<0.01). For the relation of expression of NCC27 gene with JUNB and NFkBIA (p<0.05). Correlation matrix of mRNA expression of selected genes is shown in Table 1. *Summary*. Our results shows that the usage of bioinformatics leads to objective selection of a small group of genes connected with glucocorticoid resistance of ALL cells, what have been proved with correlation matrix of mRNA expression in leukemic cells *in vitro*.

1198

DESIGN AND DEVELOPMENT OF HIGHLY SPECIFIC CLONAL ANTIBODIES FOR THE CHARACTERIZATION HUMAN, BOVINE AND OVINE PRION PROTEIN

V.C. Cucak, T.M. Dobransky

DB Biotech, Ltd., KOSICE, Slovakia

Quantification of differences in structural conformation of two physiologically different but by aminoacid composition identical prion proteins, PrPC and PrPSC, is one of the main target in basic studies concerning the spongiform encephalopathy (SE). The characterisation of those two forms of the disease-related main infectious agent, including the related proteome, is crucial for the characterisation of signalling pathways involved in potential transmission of SE from bovine spongiform encephalopathy (BSE) and sheep (scrapie) to human, developing Creuzfeld-Jacob Disease (CJD). The new approach in design and production of clonal antibodies based on detailed proteomic characterization of antigen molecule was applied for the prions. The basic idea was to develop the antibody which will recognize both forms of protein, and the antibodies which recognize only PrPC. Difference in obtained signals may quantify the potential conformational change and formation of pathological PrPSC. Outside of antibody production, we introduced the mammalian cell lines for stable and transient expression of PrPC, which may serve for potential studies of prion transmission, as well as studies for its pathological conversion. Four clonal antibodies were produced and their quality characterized by western blot. First clonal antibody recognizes human, bovine and ovine prions, and was designed to the epitope at the N-terminal sequence of prion protein (within the sequence T33 - R48). The second antibody was produced to the epitope within aminoacid sequence R136 - E152 corresponding to the part of α-helical domain 1 of PrPC. This region may be changed to β-sheet structure in PrPSC, therefore may be used for structural changes in prions for human, ovine and bovine proteins. C-terminal sequence of α-helical domain 3 (Q223 - F235) is characterized by the third clonal antibody and may be applied for the studies of conformational changes as well. This clone is human prion specific. The fourth clone, which covers the bovine and ovine prions (E232 - F246) recognizes PrPC of human and ovine. The COS-7 and HEK293 cells were PrP depleted by knock-out and dually co-transfected with combination of vectors containing the gene of human, bovine and ovine PrP. The transfected cells were used for investigation of PrP interspecific interactions simulating disease transmission among humans, beef-cattle and sheep. The present work demonstrate the potential of clonal antibodies for application in prion conformational changes studies. The quick, efficient and easy to use test may help in testing the potential of PrPSC in human, bovine and ovine tissues/biological fluid samples. This is of intense need in today's diagnostics/prevention studies.

This work was supported by the research grant from Slovak Research and Development Agency (APVV, VMSP-P-0048-07) to TD.

HIGH PREVALENCE OF MTHFR GENE A1298C POLYMORPHISM IN IRAN

F. Atashrazm,[1] F. Zaker,[1] M. Aqaeipour,[1] V. Pazhakh,[1] B. Sadeqi[2]

[1]Iranian University of Medical Science, TEHRAN; [2]Tarbiat Modares University, TEHRAN, Iran

Background. Mutations in the 5,10-methylenetetrahydrofolate reductase (MTHFR) gene could reduce the enzyme activity and via different mechanisms can lead to several diseases such as vascular disease in particular, coronary artery disease and deep vein thrombosis and also cancers. *Aims*. The aim of this study was to assess the prevalence of the two most common polymorphisms, C677T and A1298C, which have not been studied in the Iranian population so far. *Design and Methods.* We randomly selected 160 healthy individuals. Using PCR and RFLP analysis, we studied the prevalence of the C677T and A1298C MTHFR genotypes in these cases. *Results*. We found that for C677T, the prevalence of C/C, C/T, and T/T genotypes was 63.1%, 29.4%, and 7.5%, respectively with an allelic frequency of 0.22. However, the A1298C genotypic prevalence of A/C, A/A, and C/C was 56.3%, 30.6%, and 13.1%, respectively, with an allelic frequency of 0.41. *Conclusions*. Our results about the prevalence of C677T variant between Iranian populations were similar to other reported studies in Asia. Otherwise, Compared to most other populations reported so far, the Iranian population showed a high prevalence of the MTHFR A1298C polymorphism. This is an important finding to be followed in terms of clinical significance in this community. Atashrazm F, Hematology department, IUMS, Tehran, Iran

1200

INCIDENCE OF MUTATIONS OF CLASS III RECEPTOR TYROSINE KINASE (KIT AND FLT3) IN PEDIATRIC AND ADULT ACUTE LEUKAEMIC PATIENTS

F. Zaker,[1] M. Mohammadzadeh,[1] M. Sheikhy,[1] M. Mohammadi,[2] A. Kazemi[1]

[1]Iran University of Medical Sciences, TEHRAN; [2]Iran Blood Transfusion Organization, TEHRAN, Iran

Background. C-kit and FLT3 are member of the class III receptor tyrosine kinase family. The mutations in these genes lead to uncontrolled proliferation of leukemic cells and unfavorable prognosis. *Aims*. The data concerning the incidence and associations with patient's characteristics vary in different studies. The purpose of this study was molecular charcacteristic of leukemia, diagnosis and frequency determination of these mutations with different subtypes in AML and ALL patients. *Design and Methods*: Blood or Bone Marrow samples from newly diagnosed acute leukemic patients with various FAB classifications were obtained in hematologic and blood transfusion centers of Iran during 3 years (Informed consent was obtained from patients). The diagnosis and the assignment of FAB classification were based on morphology and

immunophenotype. DNA extraction was performed on all the blood samples by proteinase K and phenol method. The mutations of ITD (exon 11 and 12 and interon 11) and D835 (exon 20) of Flt3 gene in patients with acute leukaemia were studied by PCR and PCR-RFLP respectively. The resulted PCR products was electrophoresed on 8% PAGE. Exon 8 and exon 17 (D816) mutations in c-kit were analyzed by PCR followed by CSGE and RFLP respectively. Subsequently, PCR products of positive ITD and exon 8 of c-kit have been confirmed by sequencing techniques. *Results*. The median age of adult AML was 47 +/- 12 (range from18-75) years and in pediatric acute leukemia was 5.5 +/- 1.6 (range from 1-17) years. There was no correlation between patients with mutation status and gender and age. A positive correlation with high presenting WBC > 20000/micl (58%) was demonstrated in flt3-ITD positive (p<0.05). In 212 adult AML, Flt3 ITD and D835 mutations occurred in 18% and 6% respectively. The highest frequency of ITD and D835 mutations (16% and 4% respectively) occurred within M3 subclasses and characterized by the t (15;17). Exon 8 mutations of c-kit were diagnosed in 1.3% of AML patients and 4.7% of patients showed D816 mutations with different findings in subtypes of AML. C-kit mutations demonstrated mostly in M2&M4 cases characterized by T8-21 and INV16 (CBF leukemia). 30% of patients with CBF leukemia showed mutation in exon 17. Mutations in exon 8 were novel and confirmed by sequencing method and documented in Gene Bank (FJ189474 and FJ177639). In 91 pediatric acute leukemia (18 AML and 73 ALL), Flt3 ITD and D835 mutations occurred in 7.7% and 2.1% respectively. The frequency of ITD mutations in AML found 23% with highest occurrence in M3 subclasses (11.2%) characterized by the t (15;17). The frequency of ITD mutations in ALL found 4.1%, which occurred only in early pre B subclasses. Interestingly, ITD not found in pre B, B and T ALL. The frequency of D835 mutations in AML found 5.2% and it was found only in M3 subclasses characterized by the t (15;17). The frequency of D835 mutations in ALL found 1.3%, which occurred only in pre B subclasses. Interestingly, D835 not found in early pre B, B and T ALL. The sequencing of PCR products of ITD showed different insertions of nucleotides in JM region of ITD such as 27, 47 and 63 bp insertions which were in similar with those literature reported previously. *Conclusion*. We demonstrated that the FLT3-ITD mutations are frequent molecular lesions in AML patients. The presence of ITD was associated significantly with M3 morphology with T15-17. The frequency of ITD in ALL was significantly lower than AML and it was only found in early pre B. Mutations of c-kit resulted in 5.6% of adult AML (one patient had both mutation together), which was significantly associated with M2 and M4 with T8-21 and INV16.

MEGAKARYOCYTIC BLAST CRISIS IN PATIENT WITH RARE VARIANT OF PHILADELPHIA REARRANGEMENT T(9;22;22) AND ADDITIONAL TRANSLOCATION T(3;7)

R. Kroll,[1] M. Jarmuz,[2] A. Przybylowicz-Chalecka,[3] B. Ratajczak,[3] M. Gniot,[3] M. Komarnicki[3]

[1]University of Medical Sciences, Poznan; [2]Institute of Human Genetics, Polish Academy of Sciences, Poznan; [3]Department of Haematology, Poznan University of Medical Sciences, Poznan, Poland

Megakaryoblastic crisis is extremely rare and accounts for less than 3% of chronic myelogenous leukemia (CML) in blastic transformation. The variant translocation in CML is reported for 2-10% of CML. We present an unusual case of megakaryocytic blast crisis with variant Philadelphia rearrangement t(9;22;22) and additional translocation t(3;7). Patient, a 73-year old woman diagnosed for chronic myeloid leukemia with suggested an accelerated phase of CML was admitted to the Department of Hematology. Past history was significant typical attributable for CML in a chronic phase (2003). The patient started therapy with alfa-interferon. Treatment with alfa-interferon was immediately discontinued because of intolerance and the patient was treated further with imatinib mesylate (2004). In November 2006 she was admitted to the Departament because of deep venous thrombosis of left inferior extremity. Laboratory studies showed platelets 3144 G/l. Afterwards the secondary therapy with imatinib mesylate combined with hydroxyurea was started. The patient showed a positive haematologic response. In Jun 2007 she was diagnosed as having CML in megakaryoblastic transformation. CBC showed anemia, WBC 30 G/l, platelet count 5972G/l. The bone marrow aspirate was hypercellular with megakaryocytic hyperplasia and increased in the myeloblast count (12%) was detected. Molecular analysis by RT-PCR showed an occurrence of D276G mutation of BCR/ABL oncogen. The presence of this mutation is correlated with resistance to the treatment with imatinib mesylate. The patient was treated with dasatinib. All 20 metaphases analysed showed the abnormal chromosomes 3, 7, 22 and second homologue chromosome 22. The suggested karyotype was described as follows 46,XX,t(3;7)(p25;q34),t(9;22;22)(q34;q11;q13). The FISH analyses have confirmed an occurrence of chromosome translocations as showing classical cytogenetics. The karyotype analysed after 8 months of continous treatment with dasatinib was showing 6 cells with the translocations of both types and 14 cells only with translocation between short arm of chromosome 3 and long arm of chromosome 7. It means 70% metaphases did not contain Philadelphia chromosome. In clinical terms in relation to the beginning of treatment the patient was found responsive to dasatinib treatment. The translocation t(3;7) could be constitutional translocation because it is relatively stable during treatment. The alternative explanation is that translocation t(9;22) is of secondary origin and arises after translocation t(3;7) which is persistent in the treatment. The breakpoint in 22q13 region could be causative for an increase number of megakaryocytes in our patient. This region includes the gene MKL1, which is involved in a specific translocation that creates a fusion with RBM15 gene (1p13), this translocation has been associated with acute megakaryoblastic leukemia. Some genes, which play a role for platelets growth and their function {PDGFB (22q13.1), TCF20 (22q13.3), and FBLN1 (22q13.31)} are also located in 22q13 region.

BONE MARROW VERSUS PERIPHERAL BLOOD: COMPARISON OF THE CHIMERISM ANALYSIS

O. Horky,[1] J. Mayer,[1] L. Kablaskova,[1] M. Krejci,[2] Y. Brychtova,[2] D. Dvorakova[1]

[1]Centre of Molecular Biology and Gene Therapy, University Hospital Brno, BRNO; [2]Department of Internal Medicine and Hematooncology, University Hospital Brno, BRNO, Czech Republic

Background. Bone marrow (BM) examination is routinely performed for minimal residual disease monitoring in leukemia patients. By contrast, chimerism is usually tested from peripheral blood (PB), and, surprisingly, little is known about the clinical impact of the chimerism status in BM. *Patients and Methods.* 226 pairs of PB and BM samples obtained from 102 adult patients were investigated. Frequencies of diagnoses within samples were as follows: AML 42%, CML 24%, ALL 11%, CLL 7%, MDS 7%, other hematological malignancies 9%. Assessment of chimerism was performed using either capillary electrophoresis with fluorescence detection, or quantitative real-time PCR with one order of magnitude higher sensitivity of mixed chimerism detection. *Results.* Mixed chimerism in BM was detected even more than 9 years after transplantation, however, on the other hand, complete donor chimerism was also observed as early as day +35. Proportion of autologous cells detected in BM comparing to PB was: higher in 140/226 cases (62%), equal in 67 (30%), and smaller in 19 instances (8%). Within the group with higher autologous fraction in BM, 75/140 (54%) pairs were those with complete donor chimerism in PB and mixed chimerism in BM at the same time; the majority (61/75; 81%) of such BM samples contained only very small amount of autologous cells (bellow 0.1%). Nevertheless 18/140 cases (13%) possessed clear clinical relevance and all but one were from AML patients: chimerism detected in both compartments varied from 0.1% to 60% and corresponded to either impending relapse (n=16) or a graft failure (n=2). *Conclusions.* Our data indicate that chimerism analysis in BM can provide new information in contrast to PB analysis in AML patients. Highly discrepant results with high autologous recovery in BM can be considered as a sign of imminent relapse or a graft failure. Two important questions are remaining to be further explored: what are the residual autologous cells causing the persisting mixed chimerism in the BM, and what is the best timing for BM chimerism analysis.

The work was partially supported by grant of the Ministry of Education, Youth and Sports, No. MSM0021622430.

1202

PROGNOSTIC SIGNIFICANCE OF FLT3-ITD, FLT3-D835 MUTATIONS AND NPM1 MUTATIONS IN ACUTE MYELOGENOUS LEUKEMIA

L. Zamora,[1] M. Cabezón,[1] J. Ribera,[1] S. Marcé,[1] M. Morgades,[1] D. Dominguez,[1] J. Grau1, B. Patiño,[2] R. Guardia,[3] I. Granada,[1] N. Ruiz-Xivillé,[1] N. Lloveras,[1] I. Rodriguez,[1] J. Junca,[1] A. Oriol,[1] R. Duarte,[2] A. Fernandez de Sevilla,[2] J.M. Ribera,[1] F. Millá,[1] E. Feliu[1]

[1]Hospital Germans Trias i Pujol - ICO, BADALONA; [2]Hospital Duran i Reynals - ICO, BARCELONA; [3]Hospital Josep Trueta - ICO, GIRONA, Spain

Background. Cytogenetic aberrations are one of the most important independent prognostic factors in AML. However 40-50% of the patients have a normal karyotype conferring an intermediate risk, but their survival is highly variable. FLT3 mutations or internal tandem duplication (ITD) and NPM1

mutations play an important role in these patients. The presence of FLT3 aberrations is associated with an unfavourable prognosis whereas NPM1 mutations, when isolate, confer better prognosis. Some studies have described that increased values of the ITD/wild-type (WT) allele ratio confer a worse outcome. The aim of the study is to characterise the prognostic significance of the ratio of ITD/WT alleles, FLT3-D835 mutations and NPM1 mutations. *Patients and Methods*. One hundred fifty-eight patients with AML (93 patients with non promyelocytic AML, 15 with acute promyelocytic leukaemia, 36 AML with multilineage dysplasia and 14 with secondary AML) were examined for the presence of FTL3 and NPM1 mutations. Most of them were treated according the AML-03 multicenter protocol of the Spanish Group (CETLAM). Risk groups were defined according to results of standard cytogenetic analysis as high risk, intermediate risk and low risk. Patients with promyelocytic AML were included in the PETHEMA APL-05 trial and had been excluded for the prognosis analysis. The presence of FLT3-ITD was performed on genomic DNA. Polymerase chain reaction (PCR) products were analysed on standard 3% agarose gels. Ratio from patients with ITD and NPM1 mutations were established using a fluorescently labelled primer (Nakao M et al. Leukemia 1996 and Gale R et al. Blood 2008, respectively) and analysed by Genescan. FLT3-D835 mutations were determined using an ECORV restriction enzyme digestion after PCR amplification. *Results*. From the 158 patients, 84 had an intermediate-risk karyotype (53.1%) and 31 harbour an ITD (19.6%). Twenty-two of these 31 patients (71%) had an intermediate-risk karyotype. FLT3-ITD/WT ratio ranged from 0.041 to 5.431 (median 0.46). In patients with intermediate-risk karyotype the presence of FLT3-ITD was associated with more percentage of blasts in bone marrow (p=0.014), high WBC count (p<0.001), inferior OS (p=0.001) and CR (p=0.002). Neither the FLT3-ITD/WT ratio nor the FLT3-D835 mutations had impact on DFS or OS in the present series. Patients with FLT3-D835 mutations had a trend for higher relapse (p=0.060). A total of 21% of patients had NPM1 mutations. These mutations were seen more frequently in intermediate-risk patients (p<0.001) and the patients had more percentage of blasts in bone marrow (p<0.001) and high WBC count (p=0.012). The good prognosis of NPM1 mutations disappeared with the concomitant presence of FLT3-ITD (p=0.055). *Conclusions*. The presence of FLT3-ITD and NPM1 mutations is associated with higher percentage of blasts in bone marrow and high WBC count. Although FLT3-ITD has poor prognostic significance in patients with AML and intermediate-risk karyotype, the FLT3-ITD/WT ratio, FLT3-D835 and NPM1 mutations (and FLT3-ITD) did not have impact on prognosis in these patients from the present series.

Supported in part by grant P/EF-08 from the Josep Carreras Leukemia Foundation and RD06/0020/1056 from RETICS.

POLYCYTHEMIA VERA WITH JAK2V617F AND JAK2C618R MUTATIONS: A MOLECULAR AND FUNCTIONAL STUDY

A. Vaz,[1] E.P. Silva,[1] P.H. Matos,[1] J. Pita,[1] A.M. Pereira,[3] P. Jordan,[1] L.M. Vieira[1]

[1]*Instituto Nacional de Saúde Dr. Ricardo Jorge, LISBOA;* [2]*Hospital do Montijo, MONTIJO;* [3]*Hospital Garcia de Orta, ALMADA, Portugal*

Polycythemia vera (PV) is a chronic myeloproliferative disorder (MPD) characterized by somatic activating mutations in the JAK2 gene. JAK2V617F is the predominant mutation occurring in over 90% of patients. We describe a molecular and functional study of two combined JAK2 mutations which were identified in an 83 year-old caucasian man with PV. Allele-specific polymerase chain reaction (AS-PCR) assay for JAK2V617F confirmed the presence of this mutation in peripheral blood cells of the patient. Direct sequencing of exon 14 showed heterozigosity for JAK2V617F but also revealed a heterozygous thymine for cytosine substitution at cDNA position 1852 (T1852C). This alteration leads to incorporation of an arginine residue instead of a cysteine at codon 618 (JAK2C618R). To exclude that T1852C is a rare polymorphism, we confirmed its absence in 200 chromosomes of normal caucasian individuals by PCR and restriction enzyme digestion using a BtgI restriction site created by the T1852C substitution. In addition, sequencing analysis of JAK2 exon 14 in DNA obtained from peripheral blood mononuclear cells of the patient showed that both nucleotide alterations were present only in a minor proportion comparatively to whole blood cells, indicating that T1852C was also an acquired alteration. Cloning of exon 14 PCR product followed by screening of individual bacterial colonies showed that JAK2V617F and JAK2C618R mutations were present in cis. We then designed a reverse primer for detection of JAK2C618R and included it in the AS-PCR assay instead of the JAK2V617F-specific primer. Using this approach we analysed peripheral blood DNA samples of 48 JAK2V617F-positive PV patients, 43 JAK2V617F-negative patients with erythrocytosis, and of 74 patients with essential thrombocythemia (39 JAK2V617F-positive and 35 JAK2V617F-negative). The JAK2C618R mutation was not detected in any of the 165 patients. For functional analysis, the full-length JAK2 cDNA was amplified from a normal individual sample and cloned into a N-terminal GFP expression vector. The JAK2V617F and JAK2C618R mutations were introduced alone or in conjunction using site-directed mutagenesis. Proliferation assays are now being performed to compare proliferative potential of differentially-mutated JAK2 clones. In conclusion, the results of DNA analysis show that JAK2C618R is a rare mutation in MPD patients and also suggest that selection of a mutant clone carrying JAK2C618R may be dependent on the acquisition of the JAK2V617F mutation.

1204

TRISOMY 8 IN PDGFRB-NEGATIVE CELLS IN A PATIENT WITH IMATINIB SENSITIVE CHRONIC MYELOMONOCYTIC LEUKAEMIA AND THE T(5;16)(Q33;P13)/PDGFRB/NDE1 FUSION

F. Cavazzini,[1] A. Bardi,[1] M. Ciccone,[1] G.M. Rigolin,[1] P. Gorello,[2] R. La Starza,[2] C. Mecucci,[2] A. Cuneo[1]

[1]*Section of Hematology, FERRARA;* [2]*IbiT Foundation, Fondazione IRCCS, University of Perugia, PERUGIA, Italy*

Background. The development of clonal chromosome abnormalities in Philadelphia-chromosome negative cells was well documented in chronic myeloid leukaemia (CML) responding to interferon-α (IFN) and imatinib (IM). Fusion genes involving the platelet-derived growth factor receptor β (PDGFRB) were identified in Ph-negative chronic myeloproliferative disorders (CMPD) generating a constitutive tyrosine kinase activity usually sensitive to IM. We identified a novel PDGFRB translocation partner (i.e. NDE1) in a patient affected by chronic myelomonocytic leukemia (CMMoL) with t(5;16)(q33;p13). *Aims*. Here we describe the clinical evolution of this patient who responded to IM while developing a clone with trisomy 8 in PDGFRB negative cells. *Design and Methods* and *Results*. The patient, affected by Noonan syndrome with PTNP mutation and normal constitutional karyotype, was diagnosed with CMMoL in august 2004, age 30. Sequential hematological and cytogenetic features are shown in Table 1. Following the demonstration of PDGFRB involvement by fluorescence *in situ* hybridization (FISH), the patient was commenced on IM 400 mg daily on October 2004. After one month, complete hematological response with normal white blood cell count and differential and disappearance of splenomegaly was recorded, along with a major cytogenetic response (Table 1).

Table 1. Hematologic and molecular cytogenetic findings in a patient with CMMoL and t(5;16)(q33;p13) - PDGFRB/NED1 fusion.

date / phase	WBC (a) (monocytes)	BM findings	Hb (a)	Plts (a)	Karyotype (b)	FISH analysis (c)	
						Trisomy 8	*PDGFRB* translocation
May 2004 / diagnosis, hydroxyurea 20 mg/Kg/day	38,6 (13,0)	M/E 6/1; increased monocytes, DysE; DysMeg ALIP+	13,5	336	46,XX, t(5;16)(q32;p13) [13] / 46,XX [1]	<1%	83%
October 2004 / Imatinib 400 mg/day	8,5 (0,90)	M/E 5/1 Increased monocytes	9,5	70	46,XX, t(5;16)(q32;p13) [7] / 46,XX [12]	<1%	ND
November 2004 Imatinib 400 mg/day	7,0 (0,35)	ND	10,1	319	46,XX, t(5;16)(q32;p13) [3] / 46,XX [33]	<1%	11%
October 2005 Imatinib 400 mg/day	4,3 (0,27)	normal	11,8	161	46,XX [20]	<1%	<1%
April 2007 Imatinib 400 mg/day	4,1 (0,21)	normal	11,8	208	46,XX [20]	<1%	<1%
December 2007 Imatinib 400 mg/day	4,1 (0,90)	normal	10,2 (d)	165	47,XX, +8 [3] / 46,XX [20]	16,5%	<1%(e)
April 2008 Imatinib 400 mg/day	4,5 (0,82)	normal	12,1	178	46,XX [20]	3%	<1%

Abbreviations: DysE: dyserythropoiesis; DysMeg: dysmegakaryocytopoiesis; ALIP+: presence of abnormal localization of immature precursors
WBC: white blood cells; Hb: Hemoglobin (g/dL); Plts: platelets; ND: not done
(a) WBC, monocytes and Plts are expressed as absolute counts X 10^9/L; Hb is expressed as g/dL
(b): Constitutional karyotype on PB lymphocytes: 46, XX [20]
(c): % cells with the anomaly; the cut-off point for positivity was 3% for trismy 8 and 3% for *PDGFRB* translocation
(d): iron-deficiency anemia responsive to treatment
(e): RT-PCR for *PDGFRB/NDE1* fusion negative

A complete cytogenetic remission was achieved in October 2005. In December 2007 BM aspirate showed normal morphology, whereas cytogenetic and FISH documented the appearance of a clone with trisomy 8. No evidence of t(5;16) was found by cytogenetics. FISH and molecular (RT-PCR) studies excluded the presence of PDGFRB/NDE1 fusion. Hybridization of chromosome-8-centromeric probe was performed on BM smear and granulocyte precursors showed trisomy 8 in 12/50 cells, whereas only a minority of erythroid precursors (2/30 cells) displayed three signals. Four months later the patient was still on IM, her hematological conditions stable. Trisomy 8 was no more detectable by cytogenetics and FISH. *Conclusions.* Our finding of a complete response by RT-PCR in a patient with a new variant PDGFRB translocation is noteworthy. The appearance of an unrelated trisomy 8 in IM-sensitive Ph-negative CMPD was not reported before. In our patient +8 was noted 38 months after the start of IM and was no more detectable after 4 months. Fluctuations of the size of the abnormal clone were both described in cases with or without disease transformation (acute myelogenous leukemia, myelodysplastic syndrome). Fluctuating trisomy 8

populations were previously described in MDS. We documented the involvement of the granulocytic lineage by trisomy 8, whereas erythroid cell involvement was of borderline significance. The development of an unrelated clonal abnormality in a patient with IM-sensitive CMPD with PDGFB rearrangement shows that this phenomenon is not restricted to IM-sensitive CML and suggests that it may represent a general phenomenon in CMPD in which the founder clone is inhibited in its growth by an effective drug. Though the development of aneuploidy unrelated with the dominant clone appears to be part of the natural history of , in part reflecting genetic instability, a possible effect TK inhibitors on the mechanisms underlying chromosome segregation at anaphase cannot be ruled out, since TK may be involved in the assembly of the mitotic spindle.

BONE AFECTATION IN TYPE 1 GAUCHER DISEASE: ROLE OF PROIMMFLAMMATORY CYTOKINES

P. Giraldo,[1] J. Gervas,[1] L. Quintana,[1] M. Pocovi,[2] P. Giraldo[1]

[1]Miguel Servet University Hospital, ZARAGOZA; [2]Biochemistry and Molecular and Celular Biology Department, ZARAGOZA, Spain

Background. Skeletal alterations are observed in 80% of patients with Gaucher Disease (GD). Bone disease may be the most debilitating and disabling aspects of GD, leading to bone marrow infiltration by Gaucher cells, failure of remodelling, osteopenia, osteonecrosis, osteosclerosis, bone crisis and chronic bone pain including pathological fractures. The mechanism of skeletal manifestations is unclear, but they appear to result from infiltration of the medullar space by Gaucher cells. They do not cause bone resorption directly, but could induce secretion of cytokines increasing osteoclast activation with secondary bone resorption. Therefore, the pathogenesis of the bone changes may be due to the increased bone resorption caused by Gaucher cells. Aims of study: To indentify a cytokine profile in type 1 GD patients with or without bone disease. *Design and Methods*. Two panels of different cytokines including: a) IL2, IL4,IL13, IL17, EGF, Fractalkine, INFg, MCP1, MIP1b, TGFa; b) IL4, IL6, IL7, IL10, IL13, MIP1a, MIP1b and TNFa were analysed in plasma samples by Luminex®100 platform and Millipore cytokine kit. A total of 16 type 1 GD patients (females 50%, mean age: 42 year; range:14-83) and 18 controls (females 63%; mean age: 45 years; range 23-63) were studied at diagnosis. Descriptive analysis and mean comparative non parametric χ^2 test was performed. Results: We had observed in type 1 GD a significant high plasma IL-2 (p=0.01), IL-17(p=0.001), TGFa(p=0.001)and lower IL4 (p=0.001), IL13 (p=0.001)concentrations vs controls. In addition we have detected a significant increase of IL13 and IL17 (p<0.01) in patients with vs without bone disease. No significant differences the cytokine profiles related age and gender had been observed. *Comments*. In our experience Luminex®100 technology is a sensible and accurate technique useful to determine cytokine profile in plasma. A different significant cytokine profile was observed between GD patients and controls as well as between GD patients with and without bone affectation.

This work has been partially sponsored by a grant from CIBERER.

THE VALUE OF BONE MARROW ASPIRATE SMEARS COMPARED WITH BONE MARROW TREPHINE BIOPSIES IN ROUTINE DIAGNOSTICS - A COMPARATIVE STUDY OF 77 CASES

E. Lalla, P. Konstantinides, S. Papachristou, A. Kostourou, M. Matsis, I.K. Constantinidis

Pammakaristos, ATHENS, Greece

Background. Bone marrow examination is often requested for the diagnosis and staging of the haematological diseases. It is also useful in the assessment of patients with fever of undetermined origin as well as in the diagnosis of various storage and infiltrative disorders. Current knowledge indicates that both procedures (bone marrow aspirate smears, BMAS, and bone marrow trephine biopsies, BMTB) have advantages and disadvantages in establishing the final diagnosis.*Aim.* The present study compares the value of the two methods in terms of the clinical outcome, as they are routinely processed and analysed by haematologists, pathologists and internists. *Design and Methods.* 77 samples were collected. All samples were subjected for diagnostic purposes in both methods. Smears were prepared according to standard procedures and routinely stained with May-Grunwald-Giemsa and iron technique. At least 300 cells were valued microscopically. Marrow cores involved samples ≥1 cm and valued using also mAbs. For the comparisons of proportions Fisher's exact test was used.10 patients (13%) had lymphoma, 5 patients (6.5%) had monoclonal gammopathies, 11 patients (14.3%) had myeloproliferative disorders (MPD), 23 patients (29.9%) had myelodysplastic syndromes(MDS), 26 patients (33.8%) had non-malignant alterations (bone marrow reactive disease) and 2 patients (2.6%) had metastases of solid tumors. *Results.* The sensitivity for the detection of bone marrow diseases was 68,8% and 96,1% for BMAS and BMTB respectively. The proportion of agreement, independently of the disease category was 66,2 % (95% CI:55,4%-77,0%). The higher level of agreement between the 2 methods 88% (95% CI:75,3%-100%) was found for non malignant alterations. The afore mentioned level of agreement was significantly lower in the cases concerning MPD 27,3% (95% CI: 0%-58,7% p=0.01). The proportion of agreement concerning MDS was 69,5% (95% CI:49.2-89,9% p=0.10). As far as lymphoma was 60% (95% CI:23.1-96.9% p=0.076), while agreement concerning the five cases of monoclonal gammopathies and two cases of metastases was 60% and 50% respectively. *Conclusions*. Our data show that bone marrow trephine biopsy is more accurate in the final diagnosis than bone marrow aspirates. Regarding MPD BMAS is believed to be of lower diagnostic accuracy (p<0.005) due to the presence of fibrosis, the absence of specific diagnostic findings as well as the overlap (cover) with other accompanying lesions. Aspiration alone may be adequate for non malignant alterations.

1207

NEW STRUCTURAL CHROMOSOME ALTERATIONS IN PLASMA CELL DISORDERS

F. Stella, E. Pedrazzini, I. Slavutsky

Academia Nacional de Medicina, CIUDAD AUTÓNOMA DE BUENOS AIRES, Argentina

Background. Multiple myeloma (MM) and related disorders are neoplasms of terminally differentiated B-cells. Cytogenetic information is often limited by the low proliferative activity of plasma cells. Finding of clonal chromosome aberrations is considered one of the most important and independent factor of adverse prognostic in plasma cell disorders. Aim: To report new chromosome structural aberrations observed in patients with MM and plasma cell leukemia (PCL). *Design and Methods*. A total of 40 patients with plasma cell disorders cytogenetically studied in our laboratory showed chromosome alterations. Among them, 10 (25%) cases (7 males: mean age 65 yr; range 45-80 years) were selected for inclusion in the present report based on the presence of new structural rearrangements. Seven patients were at diagnosis and three at relapse. Nine patients had diagnosis of MM and one case showed PCL. All patients gave their informed consent and the study was approved by the Ethics Committee of our Institution. Chromosome analysis was performed on BM cells processed by direct method and unstimulated 24-72 hs cultures, in F-12 medium supplemented with 20% fetal calf serum. G-banded technique was used. Karyotypic abnormalities were described according to the International System of Human Cytogenetic Nomenclature. FISH (fluorescence *in situ* hybridization) analysis using centromeric, locus specific, painting and Spectra Vision DNA probes (Vysis-Abbot) were performed according to manufacturer´s protocols. *Results.* In MM, a total of 24 new chromosome structural alterations were found: 19 translocations (16 unbalanced) and 5 complex rearrangements. Chromosome 1 was the most frequently involved (10 alterations), followed by chromosomes 13 (4), X, 2, 11 and 16 (3 each) and, 3, 5 and 7 (2 each). The most common aberrations of chromosome 1 were unbalanced translocations involving chromosomes: X, 2, 5, 7, 20 and 21, most of them determining 1q gains (60%). Four patients showed more than one abnormality of this chromosome. Complex rearrangements of chromosome 1 were: psu dic(X;1)(q24;p11), der(1)dup(1)(q25q32)t(1;4)(p12;p12) and psu dic(1;11)ins inv(1;11)(q10;p11q25)dup(1p?). New alterations of chromosome 13 were: t(6 ;13)(p15;q14), der(11)t(11;13)(p15;q14), der(13)t(2;13)(q11;p11) and der(14)t(13;14)(q14;q32). The patient with PCL had five new abnormalities: psu dic(15;1;22)(p12;q11;q10), del(4)(p15.2), del(6)(q25), del(7)(q11q32) and del(10)(p12.2). Almost alterations were confirmed by FISH using painting and/or Spectra Vysion DNA probes. FISH analysis also detected del13q14 (2 cases), IGH rearrangements (2), and del17p13 (1). *Conclusions.* We found new chromosome alterations and regions of cytogenetic deletion in patients with plasma cell disorders. More studies must be necessary to determine the recurrence of these abnormalities and their potential importance in lymphomagenesis.

1208

PROGNOSTIC RELEVANCE OF FLT3/ITD, NPM1 AND CEBPA MUTATIONS IN ACUTE MYELOID LEUKAEMIA PATIENTS WITH NORMAL KARYOTYPE- THE SINGAPORE GENERAL HOSPITAL EXPERIENCE

G.-F. How, L.-C. Lim, G.-C. Wong

Singapore General Hospital, SINGAPORE, Singapore

Background. In the management of patients with Acute Myeloid Leukaemia (AML), the identification of prognostic markers is an important part of the evaluation as it helps to predict response to therapy and long term outcome.

Conventionally patients with normal karyotype- AML are classified into the intermediate risk category, but in reality, this is a highly heterogeneous group as the clinical outcomes of these patients vary greatly. Recently, it has been reported that a comprehensive assessment of known molecular prognostic markers would help identify clinically relevant subgroups among normal karyotype-AML patients. *Aims*.: To assess the incidences and prognostic relevance of mutations in the FLT3 (FMS-like tyrosine kinase 3), NPM1 (Nucleophosmin) and CEBPA (CCAAT/enhancer-binding protein α) genes in a series of adult normal karyotype- AML patients seen at our institution. *Design and Methods.* Consecutive newly diagnosed AML patients (n=61) with normal karyotype were analyzed for the presence of FLT3/ITD, NPM1 and CEBPA gene mutations. We compared the mutational status of these genes with clinical outcome in patients who were below 65 years of age and had undergone standard induction/consolidation chemotherapy with a minimum 1-year follow-up. *Results*. FLT3/ITD, NPM1 and CEBPA gene mutations were detected in 43% (26/61), 51% (31/61) and 23% (14/61), respectively, of the patients tested. While FLT3/ITD mutations occurred at similar incidences in M1, M2 , M4 and M5 subtypes, the incidence of NPM1 mutations was higher in M5 subtype (8/10, 80%). CEBPA mutations, however, appeared to be greatly associated with M1 and M2 subtypes. FLT3/ITD mutations varied in size from 18 bp to 210 bp. NPM1 mutations always resulted in a net insertion of 4 bp with Type A mutation being the most frequently occurring. About 52 % (16/31) of NPM1 mutated patients were also FLT3/ITD-positive. Of the 14 patients who had CEBPA N-terminal nonsense mutations, 13 patients had at least an additional in-frame C-terminal mutation. In this study, seven novel CEBPA N-terminal mutations which would result in a predicted loss of C/EBPα function were identified. Relapse-free survival (RFS) and overall survival (OS) analyses were calculated by Kaplan-Meier method and statistics were compared with the log-rank chi-square test. Patients with FLT3/ITD mutations, regardless of their NPM1 and CEBPA mutation status, had a significantly shorter median RFS (16.63 months, p=0.03) and shorter median OS (20.17 months, p=0.07) compared with patients without FLT3/ITD mutations (last event was at 66.67 months). Patients with NPM1 or CEBPA mutations without ITD mutations had longer median RFS and OS compared with patients with other genotypes (ITD-positive, triple negative). Median RFS and OS of the former cohort were not reached whereas they were 13.73 months and 20.17 months respectively for the cohort with other genotypes (p=0.002, p=0.06). *Conclusions.* Our study that mutational status of CEBPA, NPM1 and FLT3-ITD in normal karyotype-AML patients has significant prognostic implications. Although this is a small scale study, the results do suggest statistically significant impact in some aspects, thus corroborating the importance of systematic analysis of these three markers in newly diagnosed AML patients, particularly those without cytogenetic abnormality.

Table.

Effects of FLT3-ITD, NPM1 and CEBPA mutation status on clinical outcomes				
	Median RFS, months		Median OS, months	
All with normal karyotype (n=37)	20.17		*	
ITD+ (n=20)	16.63		20.17	
Vs		*p=0.03*		*p=0.07*
ITD- (n=17)	*		*	
NPM1+/ITD- (n=5), CEBPA+/ITD- (n=7)	*		*	
Vs		*p=0.002*		*p=0.06*
ITD+, others (n=25)	13.73		20.17	

*Value has not been reached at the end of study

P values of less than 0.05 were considered to indicate statistical significance

1209

IDENTIFICATION AND CHARACTERIZATION OF NEW MOLECULAR PATTERNS IN SOME DIFFICULT THALASSEMIA CASES

R. Talmaci,[1] L. Dan,[2] D. Coriu,[1] C. Tecuceanu,[2] M. Dogaru,[3] S. Badelita,[1] F. Vladareanu[4]

[1]*University of Medicine and Pharmacy Carol Davila, BUCHAREST, Romania;* [2]*Genetics Institute of Bucharest University, BUCHAREST, Romania;* [3] *Fundeni Clinical Institute, BUCHAREST, Romania;* [4]*National Institute of Transfusional Hematology, BUCHAREST, Romania*

Background. Thalassaemia is one of the most serious hereditary disorders in the Mediterranean and worldwide. It results from an inherited abnormality of globin gene production: α-globin genes in α-thalassemia and β-globin genes in β-thalassemia. In our project we are focused on characterizing the genetic determinants that lead to a better understanding of genotype-phenotype interaction in thalassemia, namely α-thalassemia mutations, interaction of β-thalassemia, determinants of HbF level, etc. *Aims*. The strategy of the project is based on multiple feedback from phenotype-to-genotype and genotype-to-phenotype, submitting the samples through different filters performing haematological tests, haemoglobin electrophoresis, HPLC, biochemical tests and molecular analysis. *Design and Methods.* As we demonstrated in our previous works the majority of β-thalassemia mutations in Romanian population are of Mediterranean origin and the patterns of allele distribution are according with the specific profile of population from South-East Europe. In this work, some of dificult cases samples were analyzed. Usually, we performe the mutational analysis in two steps: gene scanning by Denaturing Gradient Gel Electrophoresis (DGGE), followed by direct detection PCR methods based on specific identification (ARMS-PCR, PCR-RFLP, Real-Time Genotyping). After the application of this methodology, there were selected a number of 26 samples suspected for β-thalassaemia and a number of 8 samples presenting a genotype that was not entirely consistent with the phenotype. *Results*. Scanning for mutations of the α-globin gene. For the Romanian population there is not any known data on the mutation screening of the α-globin gene causing β-thalassaemia. Although it is expected that the β-thalassaemia mutations will be more frequent, in generally their study is a difficult task because the severe forms have a much lower occurrence. The majority of a-thalassaemias (80%) are given by gene deletions according with the mutation analysis follows a Gap-PCR approach. According to the haematological data there were selected a group of 26 patients suspected of β-thalassaemia due to the low MCV / MCH and low HbA2 values and ruling out other causes of hypochromia and mycrocytosis. They were submitted to the Gap-PCR molecular analysis for the most common mutations in the Mediterranean region: α3.7, αααα, MED I, α20.5, MED II, αPolyA. The results are shown in the Table 1. Sequencing of β-globin gene was performed for those samples that revealed a new pattern by the previous DGGE analysis or for those samples without any abnormal DGGE pattern but the patients presented some features that indicated the presence of a mutation in the β-globin gene. By direct DNA sequencing method it was possible to identify the presence or the absence of any mutation or polymorphism. The results are shown in the Table 2.

Table 1 and 2.

Table 1.

Nr	Genotype β	Genotype α	Hb A	F	A2	RBC	Hb	MCV	MCH
1	N/N	A MED/N	97,7		2,3	5,36	10,8	63,1	20
2	N/N	A MED/N				4,28	9,4	75.5	22
3	N/N	A MED/N	97.6		2.4	5.3	12	71.5	22.5
4	cd8/N	AAA/N	94,5		5,5	4,45	8,4	55,5	18,9
5	N/N	A 3.7/N	97.1		2.9	5.24	12.5	72.9	23.9

Table 2.

No. of patients	β-globin mutation	Silent polymorphisms	Polymorphism status
1	IVS I-1 (G→A)	IVS II-74 (G→T)	homozygote
2	cd 51 (-C)	IVS II-74 (G→T)	heterozygote
2	IVS II-1 (G→A)	IVS II-74 (G→T)	heterozygote
1	+1570 (12 nts 5' to the polyA site)		
1	cd17 (A→T)	IVS II-16 (C→G) IVS II-74 (G→T)	heterozygote homozygote
1	+3 (A→T)	IVS II-74 (G→T)	heterozygote

Also, direct DNA sequencing gave us possibility to identify the presence of one novel mutation and some silent polymorphisms, previously unknown in the Romanian population. The new pattern belongs to a young thalassaemic patient with an intermedia clinical phenotype transfusion dependent. The new CAP +3 (A-T) mutation is inherited from the father and is linked to IVS I-1 (G-A) mutation inherited from the mother. This genotype was found resulting in a β-thalassaemia intermediate status and was confirmed by allele specific amplification (ARMS-PCR). *Conclusions*. These data have a major implications on the genotype-phenotype correlation of intermedia status of β-thalassaemia disease. Molecular diagnosis of homozygotes and identification of carriers of β-thalassemia may improve clinical management of patients with this disorder and can help reduce the birth rate of new homozygotes cases in our country. Also a better prediction of the phenotype starting from the genotype will substantially increase the genetic counselling services.

QUANTIFICATION OF MUTATED NPM1 IN COMPARISON TO WT1 IN THE FOLLOW UP OF ADULT AML PATIENTS

O. Zach, M. Födermayr, S. Machherndl-Spandl, H. Kasparu, O. Krieger, M. Girschikofsky

Elisabethinen Hospital, LINZ, Austria

Background. The expression of Wilms' tumor gene (WT1) is a reliable marker for monitoring minimal residual disease (MRD) in peripheral blood (pB) and bone marrow (BM) of AML patients without specific molecular markers. However, due to low WT1 expression in normal hematopoietic cells, an artificial cut-off limit defining WT1 overexpression has to be introduced into real-time RT-PCR assays. Therefore, WT1 expression near cut-off limits are difficult to translate into clinical decisions. Mutations in the nucleophosmin-gene (NPM1) are present in about 50% of AML patients with normal karyotype and are a feasible MRD marker for these patients, too. *Aims*. Comparison of both markers in the follow up of AML patients. *Design and Methods*. For quantification of WT1 transcripts, a TaqMan RT-PCR assay was used (*Ogawa H et al: Blood 101 [2003], 1698ff*). NPM1 mutations were screened via a melting curve based LightCycler assay (*Schnittger S et al: Blood 106 [2005], 3733ff*) and quantified with TaqMan RT-PCR (*Dvorakova D et al: Leukemia Oct 2 2008 epub ahead of print*). *Results*. In 20 AML patients (13 female, 7 male, median age 59 years [35-84]) NPM1 mutations were detected and in 19 of them transcripts were quantifiable with TaqMan RT-PCR. During follow up, 212 pB and BM samples of these patients were tested for WT1 and mutated NPM1 in parallel. 204 samples yielded concordant results: NPM1 was positive when WT1 was overexpressed and negative in samples with normal WT1 expression. However, three NPM1 negative samples (1 pB, 2 BM) expressed WT1 at high levels at that time, conversely five NPM1 positive samples (4 pB, 1 BM) had normal WT1 expression. *Conclusions*. Quantification of WT1 and NPM1 mutations yields highly concordant results in the follow up of AML patients. NPM1 facilitates the interpretation of WT1 results, especially in samples with WT1 expression near cut-off limits and is a valuable supplement to routine MRD monitoring.

1211

CEBPA GENE MUTATIONAL STATUS: A COMPLETE SCREENING USING HIGH-RESOLUTION MELT CURVE ANALYSIS

F. Rázga,[1] D. Dvoráková,[1] J. Mayer[2]

[1]*Center of Molecular Biology and Gene Therapy, BRNO, Czech Republic;* [2]*Department of Internal Medicine-Hematooncology, BRNO, Czech Republic*

In recent years, several independent prognostic factors in cytogenetically normal acute myeloid leukemia (CN-AML) have been reported. Mutations or the expression levels of certain genes have been often used as molecular markers for patient's outcome prediction or for treatment outcome evaluation. One of them, gene encoding CCAAT/enhanced binding protein α (CEBPA), plays an important role in myeloid differentiation and when mutated, confers favorable prognosis for patients with CN-AML. Recent studies have shown that these mutations act as independent prognostic markers for overall survival and remission duration. Moreover, they can be used as markers for real-time monitoring of minimal residual disease, considering the fact that the same CEBPA gene mutations occur (if presented) in AML diagnosis and relapse, but simultaneously disappear during remission. Regarding this, the intimate knowledge about CEBPA gene mutational status is clinically important and it is necessary to identify CEBPA mutant leukemias as quickly as possible after diagnosis. Complete mutation screening of the CEBPA gene is therefore necessary and requires fast, precise and sensitive diagnostic tool. Using direct sequence analysis (i.e. gold-standard screening approach) we identified among a cohort of 90 AML patients a subset of 4 (4%) CEBPA mutations, 25 (28%) CEBPA gene polymorphisms and 61 (68%) CEBPA wild type genes, what indicates that more than 50% of all samples are CEBPA mutation/polymorphism (alteration) negative. Due to this, we found HRM analysis useful as feasible and reliable criterion to distinguish between alteration positive/negative samples. Thus, for routine diagnostics, we developed screening method using high resolution melt curve analysis prior to direct sequencing where only alteration positive samples (according to reference) are further sequenced. It leads to significant time and cost effectiveness comparing to "gold-standard" considering the fact that more than half of all samples may not be further analyzed and are considered wild types. Reported methodology was tested and evaluated on cohort of 28 AML patients, where 11 were analyzed retrospectively and 17 were investigated *de novo*. With this approach, all alteration positive/negative patients were successfully distinguished and the results obtained were in absolute concordance with the direct sequence analysis. The estimated robustness is 10-4 (i.e. 0.005 ng of gDNA in initial sample) and detection limit reaches 4% of mutated allele. Additionally, detailed comparison with "gold-standard" approach is given and discussed.

Background. With the introduction of new drugs for the treatment of CML such as TKIs, quantification of the bcr/abl mRNA by Q-PCR has shown a good correlation in clinical trials. However diversity of molecular approaches and different techniques lead to incomparable results between laboratories. This situation makes standardization an important step towards the optimization of CML management in the region and the plan represents a first attempt to attune the different methodologies in the region and make them comparable among them. *Design and Methods*. Thirteen laboratories in six Latin-American countries (Argentina-2, Brazil-5, Colombia-2, Costa Rica-1, Mexico-2 and Venezuela-1) planned to start this project in October 2007. At the first meeting, the group discussed the process that involves four essential steps: Total RNA extraction: 10-30x10^6 WBC do not select cellular populations. 60% use Trizol® reagent and 40% a commercial kit. cDNA synthesis: All labs use MMLV-RT and random hexamers. PCR amplification: three different PCR platforms (7 AB7500, 5 LightCycler 2.0, 1 RotorGen) with different control genes (BCR 2, ABL 7, GUS 1, G6PDH 3). All labs use a commercial plasmid dilution to generate a control curve. *Data evaluation*. Labs will report the results in absolute transcripts counts (bcr-abl/control gen) expressed in percent.

Table 1.

Samples	Lab 1	Lab 2	Lab 3	Lab 4	Lab 5	Lab 6	Lab 7	Lab 8
cDNA1	45 (69)	Nd	58 (77)	190	61 (120)	51 (57)	85	9 (170)
cDNA2	28 (44)	Nd	110 (147)	122	35 (70)	43 (48)	101	4.4 (83)
cDNA3	21 (32)	Nd	27 (36)	59	20 (39)	31 (34)	84	2.4 (45)
ARN1	4.1 (6.3)	458 (199)	Nd	453	15 (30)	Nd	108	0.9 (17)

PCR platform	AB7500	LC 2.0	AB7500	AB7500	Rotor Gen	AB7500	LC 2.0	LC 2.0
Control Gene	BCR	ABL	ABL	ABL	BCR	ABL	GUS	G6PDH

Each laboratory will send the baseline count that will be established calculating the median BCR-ABL levels of 30 CML patients in chronic phase without treatment whose samples was received in the laboratory. In order to define a common starting point, each laboratory's baseline percentage will become 100% (International Scale). In November 2007, 8 labs (Argentina-1, Brazil-5, Colombia-1, Venezuela-1) received the first samples, 3 different cDNA from 3 new CML-CP patients. RNA was extracted and reversed transcription performed with the techniques agreed previously. Each laboratory processed the three samples with their current Q-PCR methodology. Samples were random labeled, so the BCR/ABL levels were not known by the participants and every lab received a lab-code to send results to be centrally decoded. In August 2008 Labs received a second group of samples, 3 different Trizol® pre-

served PB cell lysates from patients after sign an informed consent. Labs perform RNA extraction and cDNA synthesis proceeding to Q-PCR. Results: 7/8 Labs reported results of cDNA samples and 6/8 RNA samples, 6/8 Labs sent the baseline count then only was possible express results using International scale in 5 Laboratories. Table 1 (image) summarizes results of samples expressed in %bcr-abl/control gene, (%International Scale), Nd: not done. *Conclusions*. Results of pre-treatment CML patients in chronic phase cDNA samples expressed in (IS) are quite similar. 75% of the Labs show good correlation in results of RNA samples but 50% of them show more than 0.5 log differences. In December 2009 we started a new phase, Laboratories proceed to test a β-version Kit (MDmolecular) that contain plasmids, reference sample, positive, negative and MMR controls, primers and enzymes.

1213

THE CORRELLATION BETWEEN METHYLATION STATUS OF THE MDR-1 GENE AND YB-1-GENE EXPRESSION IN PATIENTS WITH HEMATOLOGY MALIGNANCIES

V. Marinitch

Byelorussian Hematology Center, MINSK, Belarus

Recently the success of treatment of hematological malignancies is very dependent on the understanding molecular mechanisms of disease creation and development. The MDR1/ P-gp expression closely correlates with clinical prognosis and outcome of leukemia patients. Y-box binding protein (YB-1) is well-known as member of the cold-chock domain protein family. At the same time YB-1 regulates gene transcription and translation, including of MDR1. The correlation between MDR1 methylation status and YB-1-gene expression was investigated. The investigation was performed on the DNA of lymphocyte cultures of healthy volunteers and on the DNA of leukemic cells of patients with acute lymphoblastic leukemia (ALL), acute myeloid leukemia, chronic myeloid leukemia (CML) and chronic lymphoid leukemia (CLL) patients was investigated. Totally 44 nucleic acid samples (from 6 ALL, 15 AML, 3 CML, 10 CLL and 10 normal donors) obtained from mononuclear cells of peripheral blood or bone marrow were involved in the study. Both whole blood and fractionated samples of blood were used. The methyl sensitive (HpaII) and methyl insensitive (MspI) restriction endonucleases were used for the digestion of the DNA-samples, as well as Real-Time PCR-method was applied. The results were also compared with the expression of cell surface P-glycoprotein (Pgp). Overexpression (and demethylation) of the MDR1 gene has been known in association with poor clinical outcome in various hematological malignancies, including acute leukemias. We have revealed a reverse correlation between the methylation status of the MDR-1 gene and YB-1-gene expression in patients with with progressive status (resistant forms, relapse or late stage of chronic leukemias). The intensity of the MDR-1 gene methylation progressively decreased, whereas YB-1-expression was going up. Our results suggests, that these two markers (MDR-1 methylation and YB-1-gene expression) might be a good prognostic tandem and a promising tool in clinical disease evaluation.

1214

CYTOGENETIC ABERRATIONS IN MONOCLONAL B-CELL LYMPHOCYTOSIS

S.I. Papadhimitriou,[1] G.S. Paterakis,[1] G. Androutsos,[1] A. Tassidou,[2] G. Gortzolidis,[1] D. Skoumi,[1] I. Kostopoulos,[1] E Goumakou,[3] E. Griva-Kritikou,[4] D. Pavlidis,[1] K. Papghi[1] N.I. Anagnostopoulos1, M. Georgiakaki[1]

[1]G. Gennimatas Athens Rgional Hospital, ATHENS; [2]Evangelismos Athens Regional General Hospital, ATHENS; [3]General Hospital of Athens G.Gennimatas, ATHENS: [4]G.Gennimatas District Hospital, ATHENS, Greece

Background. Monoclonal B-cell Lymphocytosis (MBL) is currently under intensive investigation as a preclinical stage of chronic lymphoproliferations. However, certain important aspects of the disorder, including cytogenetic features, remain unclear. We report here on our attempt to detect cytogenetic aberrations in 10 individuals with documented MBL. *Design and Methods*. The study included 4 men and 6 women with MBL, according to the currently established diagnostic criteria. Flow cytometry showed a CLL-like phenotype in 9 cases and a "non-indicative"profile (CD5-, CD23-) in 1 case. An interphase FISH study was performed on peripheral blood cells for the detection of chromosomal abnormalities frequently observed in chronic lymphoproliferative diseases, namely 13q-, +12, -11/11q-, -17/17p-, -6/6q-, t(11;14) and rearrangement of the BCL2 and IGH genes. In cases with a low B-cell count (<15% of nucleated peripheral blood cells) the FISH study was performed on immunomagnetically purified B-cells. *Results*. The only aberration detected was 13q14 deletion, found in 6 cases, including that with the atypical (CD5-, CD23-) phenotype. Deletion was hemizygous in 4, homozygous in 1 and hemizygous coexisting with homozygous in 1 case, respectively. No deletion of 13q34 region was seen. In all cases, 13q14 deletion involved the whole population of the target-cells. All individuals were followed-up for at least 18 and up to 36 months. There was no evolution into clinical disease during the follow-up period. *Conclusions*. 13q14 deletion seems to be a frequent feature of MBL, at a rate comparable to that of overt CLL. Though this correlation implies that MBL may evolve into low-risk CLL, evidence for clonal evolution (namely homozygous and concurrent hemizygous/homozygous 13q14 deletion) indicate genetic instability already at the preclinical stage. Thus, further investigation on more individuals and with longer follow-up is warranted to elucidate whether transformation into clinical disease results form the acquisition of additional genetic lesions or whether MBL is a prodromal stage of low-risk lymphoproliferations.

1215

ABSENCE OF MUTATIONS IN THE TYROSINE KINASE AND JUXTAMEMBRANE DOMAINS OF VEGFR-1 (FLT-1) AND VEGFR-2 (KDR) GENES IN CHRONIC MYELOMONOCYTIC LEUKEMIA (CMML)

E. Such,[1] J. Cervera,[1] A. Valencia,[1] M.L. Senent,[1] E. Gamero,[1] M. Mallo,[2] R. Collado,[3] V. Amigo,[4] A. Vicente,[5] E. Luño,[6] J.C. Hernandez-Boluda,[7] R. Andreu,[1] L. Arenillas,[2] S. Oltra,[1] F. Solé,[2] M.A. Sanz,[1] G. Sanz[1]

[1]Hospital Universitario La Fe, VALENCIA; [2]Hospital del Mar, BARCELONA; [3]Hospital General Universitario, VALENCIA; [4]Hopital Arnau de Vilanova, VALENCIA; [5]Hospital de La Ribera, VALECIA; [6]Hospital Central de Asturias, ASTURIAS; [7]Hospital Clínico de Valencia, VALENCIA, Spain

Background. Chronic myelomonocytic leukemia (CMML) is a heterogeneous disease sharing features of myelodysplastic syndromes (MDS) and chronic myeloproliferative disorders (cMPD). Recent analyses driven to characterize cMPD have shown the important role that tyrosine-kinase cell signalling pathways plays in their pathogenesis. Several activating mutations in tyrosine-kinase genes like RAS, FLT3 and JAK2 have been described. Vascular endothelial growth factor (VEGF) is a potent angiogenic peptide with biologic effects that include regulation of hematopoietic stem cell development. Autocrine production of VEGF may contribute to leukemia progenitor self-renewal and inflammatory cytokine elaboration in CMML and MDS. The activities of VEGF are thought to be mediated primarily by its interaction with two high-affinity tyrosine kinase receptors, VEGFR-1 (FLT-1) and VEGFR-2 (KDR). Mutations in the activation loops and/or juxtamembrane domain on FLT1 or KDR could lead to constitutive tyrosine kinase activity. *Aim*. To screen the exon coding sequences of the activation loop and juxtamembrane domain of FLT1 and KDR genes by direct sequencing for the presence of mutations in patients with CMML. *Patients and methods*. We studied bone marrow samples from CMML patients at the time of diagnosis (47M/10F; median age, 71 yr; median WBC, $15.2x10^9$/L; median hemoglobin level, 11.3 g/dL; and median platelet count: $163x10^9$/L) for the presence of FLT1 (TK domain n=38; JM domain n=40) and KDR (TK domain n=50; JM domain n=20) mutations. Genomic DNA was amplified using specific primers for the activation loops and/or juxtamembrane domain (*Loriaux et al, 2008. Blood.111:4788*). PCR products were cleaned with standard procedures and direct sequencing was performed on an ABIPRISM 310 DNA Analyzer (Applied Biosystems, Foster City, CA). Sequence analysis was checked with GeneBank Accession NC_000013.9 to FLT-1 and NC_000004.1. Bone marrow DNA from healthy donors was used as negative control. *Results*. No mutations in the amplified sequences of the activation loop and/or juxtamembrane domain of the FLT1 and KDR genes were evident in any of the samples analyzed. *Conclusions*, These results demonstrate that the incidence of FLT1 and KDR tyrosine kinase and juxtamembrane domain mutations in patients with CMML is, if present, extremely rare.

This study was supported in part by Instituto de Salud Carlos III grants RD06/0020/0031 and PI05/1224.

VARIANT T(4;12;13)(Q21;P13;Q12) TRANSLOCATION INVOLVING ETV6 AND FLT3 GENES IN A CASE OF ACUTE MYELOID LEUKEMIA WITH EOSINOPHILIA

A. Aventín,[1] R. La Starza,[2] J. Sánchez,[3] A. Parente,[4] P. Barba,[5] J.F. Nomdedéu,[6] C. Mecucci[2]

[1]Hospital Sant Pau, BARCELONA, Spain; [2]Hematology, Policlinico Monteluce, PERUGIA, Italy; [3]Hematology.Hospital Sant Pau, BARCELONA, Spain; [4]Hematology. Hospital Sant pau, BARCELONA, Spain; [5]Hematology,. Sant Pau, BARCELONA, Spain; [6]Hematology Hospital Sant Pau, BARCELONA, Spain

Background. Several different genes partners have been described to be rearranged with the ETV6 gene, which is located at band 12p13, resulting in the formation of a chimeric gene. Aims. We characterized a complex translocation t(4;12;13)(q21;p13;q12) by using fluorescence *in situ* hybridization (FISH) and reverse transcriptase polymerase chain reaction (RT-PCR) analysis. *Design and Methods*. Conventional cytogenetic analysis (CCA) was performed on 24-hour unstimulated bone marrow cells. Chromosomes were G-banded with Wright stain. Karyotypes were described according to the International System for Human Cytogenetic Nomenclature (2005). FISH technique was performed with probes for 13q12/FLT3 (RP11-179F17, RP11-153M24), 12p13/ETV6 (cos148B6, cos179A6), 4q12/CHIC2 (BAC 3H20, BAC 120K16, BAC 24O10). RT-PCR for ETV6-FLT3 rearrangement was performed using previously reported primers and conditions. *Results*. A 65-year-old man was diagnosed with an acute myelomonocytic leukemia with eosinophilia. CCA revealed a 46,XY,t(4;12;13)(q21;p13;q12)[12]/50,XY,+X,t(4;12;13)(q21;p13;q12),+10,+11,+12[4] karyotype. Metaphase-FISH showed a breakpoint on chromosome 13, inside the clone RP11-153M24 containing the FLT3 gene and on chromosome 12, cos148B6 remained at 12p13 and cos179A6 was translated on 13q12 confirming that ETV6 gene was disrupted by the translocation. RT-PCR analysis revealed the presence of ETV6/FLT3 fusion transcript. Amplified band (1241 bp) was sequenced with forward and reverse primers. Additional FISH and RT-PCR studies showed that FIP1L1, PDGFRA and CHIC2 genes were not rearranged. *Conclusions*. Translocation t(12;13)(p13;q12) involving ETV6 and FLT3 genes has been reported in a case of myeloproliferative disorder with hypereosinophilia. We suggest that the chromosome rearrangement described here may be considered a variant of the t(12;13) translocation associated with myeloid hematological malignancies with eosinophilia.

1217

DETECTION OF NPM1 MUTATIONS IN AML PATIENTS

V Pazhakh, F. Zaker, F. Atashrazm, F. Razmkhah, E. Shahabi, P. Rasi Qaemi

Iran University of Medical Science, TEHRAN, Iran

Background. NPM1/Nucleophismin/B23 is a phosphoprotein with high expression in the proliferating cells. C-terminal mutations of NPM1 gene in exon 12 are very frequently reported in AML cases with normal karyotype. Regarding the discriminating role of NPM1 mutations in prognosis of AML, assessing the frequency of these mutations in AML patients seems necessary. *Aims*. The purposes of this study are: the assessment of the frequency of NPM1 mutations among Iranian AML patients, the relationship between these mutations and FAB classification, and also the assessment of sequence of these mutations. We decided to use CSGE technique in detecting of NPM1 mutations. *Design and Methods*. Bone marrow and peripheral blood samples of 131 AML patients were randomly collected, and their DNA was extracted through standard methods. Then, PCR was applied to the fragment of NPM1 gene with specific primers. PCR products were electrophoresed using CSGE method. In the end, the positive samples were sequenced to confirm the presence of NPM1 mutations. *Results*. Out of 131 patients, 23 (17.55%) were known to have NPM1 gene mutation. The highest frequency of occurrence of such mutations was found to be among the subtypes of M4 (30.4%), M3 (21.7%), and M5 (13%). out of 23 patients with NPM1 mutation, 14 cases had mutated allele A (60.8%), 5 cases allele D (21.7%) and 4 cases allele B (17.4%). *Conclusions*. The results of this research was in line with other reports in terms of the frequency of NPM1 gene mutations in monocytic subtypes of FAB classification (M4, M5), although the total frequency of NPM1 mutations among Iranian AML patients seems to be lower, compared to other reports. High frequency of these mutations in M3 subtypes as well as allele D in all subtypes can be considered as interesting points of the results.

1218

OCCURRENCE OF THE ACTIVATING JAK2 TYROSINE KINASE MUTATION V617F IN INDIAN PATIENTS WITH CHRONIC MYELOPROLIFERATIVE DISORDERS

S. Sazawal, J. Bajaj, B. Sharma, R. Bhargava, R. Chaubey, M. Mahapatra, R. Saxena

All India Institute of Medical Sciences, DELHI, India

Background. Chronic myeloproliferative disorders (CMPD's) are clonal hematopoietic stem cell disorders and include polycythemia vera (PV), essential thrombocythemia (ET), idiopathic myelofibrosis (IMF). Sometimes it is not possible to differentiate some cases from reactive disorders however, recently described point mutation JAK2V671F a potential candidate aids in this differentiation. Since, its frequency varies in different populations we looked for the presence of JAK2V617F mutation in Indian patients with CMPD's. *Design and Methods*. A total of 150 patients; PV (n=80), ET (n=19), IMF (n=51), 35 non MPD patients and 25 healthy controls were studied. Suspected MPD cases were subjected to haemogram, red cell mass, erythropoietin. All cases and controls were screened for JAK2 V617F mutation detection by two sensitive PCR-based methods; allele specific (ASO) polymerase chain reaction (PCR) followed by restriction enzyme analysis and DNA tetra-primer amplification refractory mutation system. *Results*. The JAK2 V617F mutation was positive 85% of PV, 70% of ET and 52 % of IMF. The mean age of JAK2 positive patients was 53years (range 28-73years) and JAK2 negative was 44years (range15-83 years) (p=0.01). The overall presence of JAK2 mutation was associated with a higher hemoglobin level (p=0.041), a higher white blood cell count (p=0.007), higher age (p=0.01). Homozygosity was observed in 75% of PV, 100% of ET and 56% of IMF. The mutation was not detected in any of the non MPD patients or the healthy controls. *Conclusions*. The JAK2 V617F mutation can be frequently detected in Indian patients with MPD disorders hence should be incorporated into the initial evaluation of patients suspected of MPD. Thus, mutation screening for V617F serves as a tool to diagnose MPD's and may determine a subgroup which would require special therapy.

1219

PREDICTORS OF SKELETAL CHANGES IN PREPUBERTAL CHILDREN WITH B- THALASSAEMIA MAJOR

A. Elbostany,[1] A. Tantawy,[2] A. Elghoroury,[2] R. Rageb,[1] H. Mater[2]

[1]National Research Center, CAIRO, Egypt; [2]AinShamsUniversity,MedicineCollage, CAIRO, Egypt

Background. The pathogenesis of thalassaemic osteopathy is a multifactorial, limited information exists about bone accrual and bone mineral density (BMD) in prepuburtal thalassaemic children. Aim: To investigate some potential genetic and biochemical bone markers as possile early predictors of osteopathy and bone mineral density variations in children with β- thalassaemia major before puberty. *Method*. The study included thirty one prepubertal children with β- Thalassaemia major, and forty three children as control group.Patients were recruited from Pediatric Haematology Unit, Children´s Hospital, Ain Shams University and the Pediatric Haematology Clinic of the National Research Center in Egypt. Patients and controls were subjected to the followings: medical history and clinical examination, BMD assessment by DEXA, VDR gene polymorphisms (BSM1, FOK1) and biochemical bone markers (serum osteocalcin , propeptide I procollagen (PIP) and urinary Deoxypyridinoline (DPD) excretion assay). *Results*. BMD was reduced in 25% of thalassaemics at the spine and 15.4% at hip . Significantly higher levels of urinary deoxypyridinoline and lower serum propeptide I procollagen levels were found in thalassaemic children compared to controls (p<0.001). Significant correlation was present between reduced BMD in either spine or hip and the patients' age (r - 0.64, p 0.0002 and r - 0.62, p 0.001 respectively). There was significant gender difference of BMD. Reduced BMD were found more frequently in male patients with genotype bb and Ff but not in females. Significantly higher serum osteocalcin levels were detected in thalasseamic males with bb genotype than in either BB or Bb alleles. No significant differences of the biochemical indices were detected between patients with reduced and those with normal BMD. Reduced BMD did not correlate with the mean pretransfusion hemoglobin or serum ferritin. *Conclusions*. Routine BMD screening with DEXA is proposed to be a sensitive predictor for early bone changes, in particularly at lumbar spine. Egyptian male thalasseamic children with genotype bb and Ff had higher rate of bone turnover; support-

ing the involvement of Bsm1and FOK1 gene as determinants of BMD before puberty.

COMPARISON OF DIFFERENT REFERENCE GENES TO DETERMINE JAK2 ALLELE BURDEN BY TAQMAN PCR TECHNIQUE

H. Alchalby,[1] A. Badbaran,[1] O. Bock,[2] B. Fehse,[1] N. Kröger[1]

[1]University Hospital Hamburg, HAMBURG, Germany; [2]Institute of Pathology, University Hospital Hannover, HANNOVER, Germany

Background. JAK2V617F is a somatic point mutation of the pseudokinase autoinhibitory domain of Janus kinase 2 (JAK2) that occurs in a significant number of patients with myeloprofilerative disorders. There is now growing evidence that the allele burden of JAK2V617F mutation plays a role in clinical phenotype, vascular complications and disease evolution to myelofibrosis. Several groups reported different estimation techniques of JAK2V617F mutation. The most sensitive technique relies on polymerase chain reaction which allows theoretically a reliable quantification of allele burden. We developed a highly sensitive Taqman qPCR method for detection of JAK2V617F mutation in samples of peripheral blood. We have determined the % JAK2V617F by comparison to a control gene (Hemopoietic cell kinase, HCK).With a high sensitivity (0.01%) this technique proved to be reliable in monitoring minimal residual disease (MRD) after allogeneic stem cell transplantation (ASCT) for myelofibrosis. *Aims and Methods*. To determine allele burden of JAK2V617 mutation in patient samples we compared this sensitive Taqman PCR method with the same method but using the wild type of JAK2 as a reference gene. *Results*. We have tested this method using known dilutions of the UKE-1 cell line in Buffy coat DNA from healthy donors reliably quantified using pyrosequencing technique resulting in a good accuracy for the levels of interest when estimating the allele burden (mutational load > 10%). We controlled our results for these known dilutions by measuring the samples again using a Taqman PCR based commercial kit (JAK2 V617F MutaQuant' Kit, Ipsogen, *http://www.ipsogen.com/*). Using wild type of JAK2 mutation as reference gene resulted in a better correlation (Correlation factor of 0,99) with the known concentrations in the high mutational load samples in comparison to the HCK gene, and it was also able to detect and quantify the mutation in dilution up to 0,01%. *Conclusions*. We conclude that measuring the allele burden of JAK2V617F mutation using the wild type JAK2 gene as a reference gene is feasible and yield a good accuracy for the higher mutational loads and is as sensitive as our original method using HCK gene.

This work was supported with an EBMT-AMGEN fellow-ship grant.

1221

HIGH RESOLUTION MELTING ANALYSIS FOR RAPID DETECTION OF BCR-ABL KINASE DOMAIN MUTATIONS IN CHRONIC MYELOGENOUS LEUKEMIA PATIENTS WITH IMATINIB RESISTANCE

H. Andrikovics,[1] N. Meggyesi,[1] A. Bors,[1] G. Halm,[2] S. Nahajevszky,[2] S. Lueff,[2] A. Batai,[2] P. Remenyi,[2] T. Masszi,[2] A. Tordai[1]

[1]Hungarian National Blood Transfusion Service, BUDAPEST; [2]St. Istvan and St. Laszlo Hospital, BUDAPEST, Hungary

Background. Imatinib, a targeted BCR-ABL tyrosine kinase inhibitor (TKI) has become the standard drug for the treatment of chronic myelogenous leukemia (CML). Mutations in the kinase domain (KD) of BCR-ABL contribute to imatinib-resistance which occurs in 10-15% of patients with CML. High resolution melting (HRM) analysis is an emerging technique for detection of nucleic acid sequence variations. Aims of our study was to develop HRM assay for the rapid screening of BCR-ABL KD (aa. 230-490) mutations. *Design and Methods*. We designed oligonucleotide primers to selectively amplify the BCR-ABL KD in 3 overlapping fragments. For the HRM-analyses, a LightCycler 480 instrument (Roche) was used to scan amplicons of the BCR-ABL KD after two step nested PCR. 38 patients (36 CML and 2 ALL) with imatinib-resistance were tested for 3 fragments (total fragments tested: 114). KD mutation(s) (aa. change M244V, G250E, Y253H, E255V, D276G, E279K, T315I, M351T, F359I/V, L384M, L387M) were confirmed in 21 patients by direct sequencing. Results: Following HRM analysis with an instrument sensitivity setting of 0.43, 11 mutations of 12 (91%) were detected. A single mutation, F359I (caused by an A>T substitution) could not be detected by HRM probably as a consequence of the reduced efficiency of melting curve discrimination. HRM results became fully concordant to sequencing if, 100% mutant F359I samples were mixed with wild type cDNA to create heteroduplexes. Alternatively, if the instrument sensitivity setting was increased to 0.65, 12/12 (100%) mutations were detected by HRM-analysis without the need for creating heteroduplexes. However at this instrument setting, the number of false positive fragments increased from 14/95 to 30/95. Thus, increasing instruments sensitivity did not prove to be a favorable alternative. Summary: HRM is a rapid and efficient method of screening for BCR-ABL point mutations prior to sequencing.

1222

AUTOMATED EXTRACTION OF HUMAN RNA AND DNA FOR QUALITATIVE AND QUANTITATIVE ANALYSIS OF HAEMATOLOGICAL PARAMETERS: COMPARISON OF THE NUCLISENS EASYMAG, THE QIASYMPHONY AND MANUAL COLUMN METHODS

F. Hillen, A. Broekmans, R. Smets, B. Maes

Virga Jesse Hospital, HASSELT, Belgium

Background. The accurate analysis of gene expression and genetic aberrations in haematological cells derived from whole blood, bone marrow and lymphoid tissues is of great interest in the diagnosis of haematological malignancies. Since clinical laboratories are facing an increasing number of samples each year, the application of automated extraction of high quality nucleic acids is emerging. Different possibilities for automated extraction for microbiological samples have been developed the last decade. However, the automated extraction of human RNA and DNA for applications in haemato-oncology is still challenging. Aims In a comparative study we evaluated the automated Nuclisens easyMAG (EM, Biomerieux, France, Marcy l'Etoile) and the QIAsymphony (QS, Qiagen, Germany, Hilden) versus the manual Qiagen column technique. The presence of clonal IGH gene rearrangements out of blood, bone marrow, fresh lymphoid and paraffin tissues (91 samples) for the diagnosis or follow-up of B-cell malignancies and the quantitative analysis of BCR-ABL aberrant fusion transcripts in whole blood and bone marrow (60 samples) in Chronic Myeloid Leukemia (CML) was tested. *Methods/Results*. The isolation of human DNA was similar in ratio for the manual method and the QS; the yield was slightly higher for the manual method. For the isolation with the EM, the starting volume had to be reduced to avoid bead contamination in the eluate and inhibition of subsequent PCR and fragment analysis, impairing sensitivity. Evaluation of amplified IGH genes by fragment analysis showed the best performance with the QS in peak intensity and minimal inhibition. Human RNA isolated by the specific B protocol on EM demonstrated inhibition of up to 3 to 10 times less ABL copies, depending on the amount of starting cells, in comparison to the manual method and the QS. The isolation of human RNA with the manual and QS method was equally efficient in yield and ratio. Evaluation of RNA quality with the Agilent

Bioanalyser showed severe genomic DNA contamination in EM eluates, while the quality of the QS eluates were similar or even better than for the manual method. Correlations of the ratios of the two methods were highly significant ($p<0.001$). Quantitative RT-PCR analysis showed similar BCR-ABL/ABL ratio. Sensitivity evaluation was similar for both the manual method and the QIAsymphony: ratios of BCR-ABL/ABL of 0,002% could be demonstrated. In view of work load relieve, QS met expectations, in contrast to EM for which many off-board handlings were still required. *Summary*. In conclusion, the automated extraction of DNA with both instruments was similar to the manual method, but EM DNA analysis was hampered by bead contamination. For automated RNA extraction, only the QS could reach similar results as the manual method. The implementation of the QS in a haemato-oncology diagnostic laboratory would greatly facilitate work load, both for RNA and DNA tests, and standardise the extraction, allowing reduction of variation which is of great clinical importance e.g. in CML follow-up.

MOSAIC ISOCHROMOSOME XP IN A GIRL WITH SHORT STATURE AND BONE MARROW FAILURE

C. Morerio, E. Tavella, A. Casalaro, E. Cappelli, C. Dufour, C. Panarello, E. Tassano

IRCCS Istituto Giannina Gaslini, GENOA, Italy

A 18-month girl, second daughter of unrelated parents, was diagnosed with bone marrow (BM) failure and treated with cyclosporine ad steroids, with partial response. At 6 years of age, she was referred to us for anemia, low white bood cell and platelet counts. BM aspirate showed no blasts or myelodysplasia; bone biopsy showed reduced cellularity and megakaryocyte number. Her height was <3rd centile due to partial GH deficiency. MR showed Chiari I malformation. Slight somatic dysmorfisms were observed. DEB tests and cell cycle analysis on peripheral blood (PB) lymphocytes and fibroblasts were negative. NBS1 protein was present in western blot and the lymphoblastoid cell line was not sensitive to ionizing radiation. Nijmegen Breakage Syndrome was excluded. c-Mpl gene associated with amegakaryocytic congenital thrombocytopenia, is not mutated.The Q-banded karyotype of PHA-stimulated PB lymphocytes was 46,X,i(X)(p10)[6]/46,XX[43]. Dual color FISH analysis using Xp- and Xq-arm partial paints confirmed the staining of the entire two isochromosome p-arms and revealed a subtle q-arm signal in the centromeric region. Compared to the normal X, the size of centromere signal (DXZ1 coupled with STS Xp22.3) was larger, suggesting an isodicentric chromosome. FISH with subtelomeric Xpter (RP11-215A12) probe and RP13-216E22 BAC probe, which specifically hybridizes to the XIST locus on Xq13.2, showed the absence of the inactivation center on i(X)(p10). Subtelomeric Xpter FISH analysis on BM cells demonstrated three signals in 11/300 nuclei. Fibroblast karyotype was 46,XX. Uncommon acquired i(X)(p10) associated with hematologic disorders as well as one case of constitutional mosaic i(X)(p10) in a girl with failure to thrive and thrombocytopenia have been reported in the literature. Our case seems to confirm the i(X)(p10) involvement in bone marrow failure.

1224

UNCOMMON PML-RARA TRANSCRIPT VARIANTS IN PATIENT WITH ACUTE PROMYELOCYTIC LEUKEMIA TREATED WITH ATRA

M. Gniot, K. Lewandowski

University of Medical Sciences, POZNAN, Poland

Background. Acute promyelocytic leukaemia (APL, AML M3), a subtype of acute myelogenous leukaemia, is a haematological disorder characterized by a differentiation block of myeloid cells at the promyelocyte stadium, usually caused by translocation t(15;17)(q22;q12) resulting in PML-RARA fusion gene. Recently some publications suggested that the presence of uncommon PML-RARA transcript variants could be ralated to all-trans retinoic acid (ATRA) insensitivity. *Aims*. In this study we attemted to identify the character and origin of uncommon PCR products observed at diagnosis in APL patient and determine if there are any significant changes in response to ATRA-based treatment. *Design and Methods*. Blood samples were collected from the patient in regular periods during and after the treatment. DNA and RNA was extracted from leukocytes acquired from peripheral blood. Reverse transcription of total RNA was performed with Qiagen Omniscript reverse transcriptase. PML-RARA fusion transcript was detected using BIOMED-1 protocol. After electrophoresis, bands representing various transcript variants were excised from gel, purified and directly sequenced. Acquired chromatograms were analyzed with DNA Star Lasregene 8.0 in comparison to sequences obtained from GeneBank. *Results*. Three isoforms of PML-RARA transcript were identified: a normal bcr-1, a variant lacking exon 5 and an out-of-frame variant without exons 5 and 6. No changes in the intron areas surrounding exon 5 (in the splicing signalling sequences) were foundin comparison to reference sequence. During the treatment transcripts disappeared sequentially, which suggests different sensitivity of cells expressing certain isoforms to ATRA. In molecular relapse only two atypical variants were detected, however further treatment eradicated them as well. For now, the patient is in molecular remission for 8 months. *Conclusions*. Our observations suggest that PML-RARA variant lacking exon 5 has slightly lesser sensitivity to ATRA than more common ones. The character of out-of-frame variant lacking exons 5 and 6 still remains unlcear, however it's highly probable that it doesn't play any role in leukemic transformation, and cells expressing this transcript have normal phenotype, therefore it's lack of response to ATRA should not be any surprise. However, coexistence of out-of-frame transcript and variant lacking exon 5 may lead to assumption, that the non-malignant clone carrying t(15;17) can switch to produce transcript leading to APL, and therefore could be indirectly responsible for a relapse.

Figure 1. Observed PML-RARA transcript variants.

CYTOGENETIC ABNORMALITIES, CLINICAL FEATURES AND OUTCOME IN A SERIES OF 106 PEDIATRIC ACUTE MYELOID LEUKEMIA (AML) PATIENTS IN GREECE

K.N. Manola,[1] A. Parcharidou,[2] E. Hatzipantelis,[3] M. Pagoni,[4] V. Papadakis,[2] A. Vourtsi,[4] F. Tzortzatou-Stathopoulou,[5] M. Baka,[6] M. Kalmanti,[7] E. Poulakidas,[8] G. Pantelias,[1] C. Sambani,[1] S. Polychronopoulou[2]

[1]NCSR Demokritos, ATHENS; [2]Aghia Sophia Children's Hospital, ATHENS; [3]Hippokration General Hospital, THESSALONIKI; [4]Evangelismos Hospital, ATHENS; [5]Aghia Sophia Children's Hospital, ATHENS; [6]Children's Hospital Aglaia Kyriakou, ATHENS; [7]University Hospital of Heraklion, CRETE; [8]401 Military Hospital, ATHENS, Greece

Background. Acute myeloid leukemia (AML) accounts for approximately 17% of all childhood acute leukemias. Cytogenetics is considered one of the most valuable prognostic determinants in AML while current risk-group classification in the limited cases of pediatric AML, is mainly based on cytogenetics and early treatment response. *Aims*. We reviewed the clinical and cytogenetic characteristics and the outcomes of 106 cases of childhood AML in order to investigate the incidence of the main FAB subtypes, the incidence of chromosome abnormalities, and the correlation between specific chromosome abnormalities and outcome in greek pediatric AML patients. *Design and Methods*. Chromosome studies were performed on unstimulated bone marrow cells, derived from 105 pediatric AML patients, who were ≤21 years of age at the time of diagnosis. Results: Sixty one patients were male and 45 were female. The median age of patients at diagnosis was 11.52 years. Eighty seven patients were classified according to FAB classification while in 19 patients FAB classification was not available. Five patients were classified as M0 (5.7%), 8 as M1 (9.2%), 29 as M2 (33.3%), 14 as M3 (16%), 11 as M4 (12.6%), 10 as M5 (11.5%), 5 as M6 (5.7%) and 5 patients as M7 (5.7%). Cytogenet-

ic analysis was performed at diagnosis in 105 patients and results were obtained in 99 (94.2%). Normal karyotype was found in 29 patients (29.3%) and abnormal in 70 patients (70.7%). Chromosome analyses showed t(8;21)(q22;q22) in 12 cases, t(15;17)(q22;q21) in 10, +8 in 11, -7/del(7q) in 7, del(9q) in 5, abn(7p) in 5, inv(16) in 4, del(6q) in 4, t(9;11)(p22;q23) in 3, other abnormalities of 11q in 5, -X in 5, -Y in 4, acquired +21 in 4, t(16;21) in 2, abn3q in 2, del(5q) in 1, del(16q) in 1, other abnormalities in 14 and complex karyotype (≥3 abnormalities) in 17 cases. The majority of children with t(15;17), t(8;21) and inv(16) had a good outcome. Patients with -7, inv(3q), del(5q) and 11q rearrangements had a bad outcome. Surprisingly, patients with del(7q), and dup(3q) had a good outcome. In children younger than 2 years, the most common FAB subtypes were M5 and M7, the most common abnormality was 11q rearrangement and the 5-year overall survival (OS) was 46%. In children older than 2 years and younger than 15 years the most common FAB subtype was M2, the most frequent abnormality was t(8;21) and 5-year OS was 53.6%. In children older than 15 years and younger than 21 years, the most common subtypes were M2 and M4, the most frequent abnormalities were +8, and t(8;21), and 5 year OS was 47%. *Conclusions*. The main FAB subtypes showed a distribution similar to that reported in the literature with the exception of M4 and M5 which were significantly lower, and M3 which was higher in our study. The 5-year OS ranged from 46% to 53.6% among the different age groups. The incidence of t(8;21), t(15;17) and -7/del(7q) was higher compared to that reported in other countries.

1226

A CYTOGENETIC STUDY OF 310 CHRONIC LYMPHOCYTIC LEUKEMIA CASES IN GREECE

K.N. Manola, M. Karakosta, C. Stavropoulou, V. Georgakakos, G. Pantelias, C. Sambani

NCSR Demokritos, ATHENS, Greece

Background. Cytogenetics is an important diagnostic and prognostic factor in Chronic Lymphocytic Leukemia (CLL), although its prognostic value is limited by the cytogenetic diversity of the disease. AIM: The aim of this study was the detection of chromosome abnormalities and their incidence in B-CLL greek patients by conventional cytogenetics. *Patients and Methods.* Chromosome studies were performed on unstimulated and stimulated with tetradecanoyl phorbol acetate (TPA) bone marrow cells, derived from 310 CLL patients, aged 16-88 years. Patients were karyotyped at diagnosis or during the course of the disease between 1998 and 2008. *Results*. Two hundred and twelve patients were male and 98 were female. The median age was 64.61 years. Cytogenetic analysis was successful in 288 patients (93%). Normal karyotype was found in 174 patients (~60%), and abnormal in 114 patients (~40%). Chromosome analyses showed a complex karyotype in 32 cases (28%), +12 in 33 cases (29%), -Y in 20 (17.5%), abnormal (abn) 14q in 18 (15.8%), abn 17 in 17 (14.9%), del(6q) in 11 (9.6%), abn 3 in 10 (8.7 %), abn 18 in 9 (7.9%), del(13q) in 7 (6.1%), add(12p) in 3 (2.6%), del(7q) in 6 (5.3%), del(11q) in 6 (5.3%), t(11;14) in 3 (2.6%), t(11;18) in 1 (0.9%), -X in 6 (5.3%), abn 19 in 5 (4.4%), +8 in 5 (4.4%), del(5q) in 3 (2.6%), chromosome markers in 13 (11.4%), and other abnormalities in 51 cases (44.8%). *Conclusions.* The sex ratio was 2.2M/1F, similar to that reported in the literature. Trisomy 12 was the most common abnormality. Surprisingly, -Y was the second most common abnormality, either as a disease associated aberration or as a consequence of advanced age. The low percentage of abnormal karyotypes, due to the low mitotic *in vitro* activity of B-CLL cells, indicates the need for new B-CLL cell stimulators. The cytogenetic complexity and heterogeneity of CLL emphasizes the value of conventional cytogenetics which permits an overview of all microscopically visible chromosome abnormalities.

NESTED DUPLEX PCR BCR/ABL (B2A2, B3A2) IN COMPLETE AUTOMATIZED SYSTEM

F. Culurgioni, S. Lilliu, G. Pala, D. Cardia, E. Usala, E. Angelucci

Cancer Institute A.Businco, CAGLIARI, Italy

Introduction. Gene expert is a new complete system in real time pcr for Rna extraction, Cdna and nested real time duplex PCR. Once hematology diagnosis by quantification of P210 (b2a2, b3A2 isoforms) of BCR/ABL gene in chronic myeloid leukaemia was utilized. Objective i)To characterize BCR/ABL rearrangements for chronic myeloid leukemia diagnosis. ii)To utilize at diagnosis, follow-up and in minimal residual disease evaluation. Peripheral blood, bone marrow and crio persevered with standardize protocol.3) The understanding of pathology process in chronic myeloid leukemia diagnosis and in all myeloproliferative disease for development of other new target therapy in specific target therapy resistance. *Materials and Methods.* Were analyzed 209 cases; 6 CML at diagnosis, 192 CML in follow up, 6 myeloid acute leukemia at diagnosis, 9 post BMT follow up and 29 control with negative BCR/ABL gene transcripts. Of this case/control, 188 (78,9%) were peripheral blood and 50 (21%) were bone marrow samples. Ten samples were cryopreserved cells from peripheral blood obtained by ficoll separation, 200 of peripheral blood, or 200 microliter of bone marrow with 1;20 dilution or 200 microliter of cryopreservated cell in PBS dilution within 48 hours were used. In cartridges were performed lisys , sds- tween and guanidium salt, bind to column, wash for elute pcr inhibitor and water DEPC elution. were performed RT-pcr- nested and duplex pcr. As endogenous control Abelson gene was used. Results were validates with ABL end point fluorescence value (≥200) and BCR ABL endpoint fluorescence value (≤40). *Results and conclusions*. Excellent result was obtained with 200 microliter of peripheral blood, but if we use bone marrow samples of 50 of these 10(20%) were aborted for pump problems. If we use 1: 40, PBS 1x dilution all samples were evaluated. Oresults were obtained with cry preserved cell from wbc (by dry pellet diluted in 1 mL PB 1x at 1:40 dilution before 1 week of cry preservation. Gene expert is easy and highly sensitive, Patients in imatinib mesylate therapy with CML require in clinical laboratory new rapid equipment for level transcript monitoring. Gene expert is easy, speed, with 4 way for fluorescence revelation, utilize micro fluidic cartridge minimize all contamination risks in nested duplex PCR real time reaction.

1228

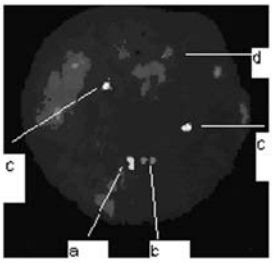
MOLECULAR CYTOGENETICS OF ETV6/RUNX1 GENE FUSION AND OTHER ABNORMALITIES INVOLVING ETV6 AND RUNX1 GENES IN PEDIATRIC B-LINEAGE ACUTE LYMPHOBLASTIC LEUKEMIA

S.I. Salem, M. Abd El-Rahman

Children's Cancer Hospital, Egypt, CAIRO, Egypt

Background. The translocation (12;21)(p13;q22)/ ETV6-RUNX1 gene fusion is the most common genetic abnormality found in childhood acute lymphoblastic leukemias (ALL). This cryptic translocation is not detected by conventional cytogenetic techniques but it can be readily detected using fluorescence *in situ* hybridization (FISH). Aim: We carried out cytogenetics and FISH studies on 50 children with B-lineage ALL in order to measure the frequency of this translocation in the Egyptian population in comparison to other genetic subgroups, the frequency of ETV6 and/or RUNX1 gene alterations, and their correlation with clinical evolution and prognosis. *Design and Methods*. Bone marrow samples were obtained from 50 pediatric B-lineage ALL patients who presented to the National Cancer Institute in Cairo. An informed consent was obtained from parents of all participants and from participants above the age of 12. Karyotyping and FISH using probes for ETV6-RUNX1 extra signal, BCR-ABL dual fusion, and MLL break apart (Vysis) were performed. The signal pattern of RUNX1 and ETV6 genes were analyzed using FISH. Patients were treated according to the National Cancer Institute protocols and followed up for a period of 18 to 42 months (median 19 months) *Results.* In the current study, successful karyotyping was obtained in 43/50 (86%); when adding FISH 46/50 (92%) cases showed informative results. Using FISH, ETV6-RUNX1 gene fusion was detected in 7/50 cases (14%) while cytogenetics could not reveal the translocation (12;21). Normal karyotype was found in 13/50 when using conventional cytogenetics (CC) only, while when combining both FISH and CC two cases revealed ETV6-RUNX1 gene fusion. Other chromosomal abnormalities that were frequently encountered in ETV6-RUNX1 positive cases were either, deletion of the nontranslocated allele of ETV6 in 2 cases, gain of der(21)t(12;21) in one case and gain of normal chromosome 21 in one case. These abnormalities correspond to: lack of ETV6 signal, extra ETV6-RUNX1 fusion signal and extra RUNX1 signals, respectively as detected by FISH. Whereas CC failed in 7 cases, when FISH was performed MLL gene translocation was detected in one case and ETV6-RUNX1 gene fusion in 2 cases. Hyperdiploidy was found in 22%, t(1;19)(q23;p13) in 8%, BCR-ABL in 6%, MLL gene translocation in 6%, t(8;14)(q24;q32) in 6%, hypodiplody in 2 cases, and RUNX1 gene amplification in one case. Best overall survival correlated with ETV6-RUNX1 positive cases and high hyperdiploid cases with mean overall survival (OS) being 28.3 (p=0.103) and 26.3 (p=0.0757)months respectively. Worst overall survival was associated with all other chromosomal abnormalities having mean OS of 14.6 months (p=0.0134). Cases with normal karyotype had a mean OS of 22.2 months (p=0.6337), while cases with abnormal-

ities of ETV6 or RUNX1 genes other than ETV6/RUNX1 fusion had a mean OS of 21.8 months. *Conclusions*. ETV6/RUNX1 fusion is found in 14% in our series and had a favorable outcome. Other ETV6 and RUNX1 genes abnormalities are detected in 14/50 cases (28%) and associated with intermediate OS.



FISH using ETV6/RUNX1 dual color extra signal probe (Vysis) showing translocation ETV6/RUNX1 with two fusion signals from an additional derivative 21.
a: Normal ETV6 gene. b: Normal RUNX1.
c: ETV6/RUNX1 gene fusion with an extra fusion signal. d: Residual RUNX1.

GENETIC COUNSELLING DIFFICULTIES IN THALASSEMIA: NEWBORN PHENOTYPE UNCERTAINTY IN ASSOCIATION WITH A NOVEL β GLOBIN MUTATION

M.P. Cappabianca,[1] A. Amato,[1] T. Roscioli,[2] M. Lerone,[1] P. Grisanti,[1] M. Hinchliffe,[2] S. Cole,[2] I. Zaghis,[1] R.J. Trent[2]

[1]ANMI Onlus, ROME, Italy; [2]Royal Prince Alfred Hospital, University of Sidney K25, CAMPERDOWN NSW, Australia

Background. The risk determination for β thalassemia carriers of having affected children represents a significant genetic counseling question. Phenotypic predictions are difficult in the presence of rare or novel mutations. Prenatal diagnosis seeks to predict the child's clinical phenotype however this may be variable, depending on the parental mutations or the co-inheritance of other genetic determinants (i.e. α and γ genes defects). AIMS We report the case of a non-consanguineous pregnant couple who are both β globin mutation heterozygotes (novel in the mother and previously reported in the father). *Design and Methods*. Routine hematology, separation of the Hb fractions with measurement of the Hb A2 and Hb F levels and globin chain synthesis; molecular analysis by A.R.M.S.-PCR and direct sequencing (Beckman Coulter CEQTM 8000 Genetic Analysis System). *Results.* The Italian father was a heterozygote for the Mediterranean IVS I-6 (T->C) mutation, detected by A.R.M.S.-PCR. The mother, an Australian woman, with paternal Indian ancestry, presented with microcytic hypochromic parameters (Hb = 10.8; RBC = 5.18; MCV = 63; MCH = 20.8) without iron deficiency (ferritin = 38 ng/mL), a high Hb A2 level (6.0%) and Hb F (3.4%) consistent with β globin gene mutation heterozygosity carrier. The globin chain synthesis ratio was 1.55 also consistent with β thalassemia carrier status despite the absence of additional investigations (mRNA and cDNA tests) or family studies. β globin gene sequencing detected a 12 base deletion located at the start of the second intron of the β globin gene [IVS II-2 (-12 bp)]. The analysis of the most common defects in the α and in the γ genes did not detect additional abnormalities. *Conclusions*. The novel 12 bp deletion is assessed as resulting in a severe β thalassemia phenotype when in combination with known pathogenic β globin mutations due to hematological parameters, mutation position within intron 2 (splicing site) and an alpha/non-α globin ratio of 1.55. As this mutation has not been reported previously and the mRNA has not characterized, we have classified it as a *probable* mutation. The combination of this mutation and the IVS I-6 mutation is likely to result in a full β thalassaemia phenotype.

1230

MULTIPLEX RT-PCT FOR THE DETECTION OF LEUKEMIA-ASSOCIATED TRANSLOCATIONS - SINGLE CENTER EXPERIENCE

M. Colita,[1] C. Arion,[1] L. Barbarii,[2] B. Iancu,[2] D. Coriu,[1] D. Jardan[3]

[1]CArol Davila University of Medicine,Fundeni Institute, BUCHAREST; [2]National Institute for Forensic Medicine Mina Minovici, BUCHAREST; [3]Carol Davila University of Medicine, BUCHAREST, Romania

Background. The current pathological approach to the diagnosis of acute leukemia is a complex, involving morphology, cytochemistry, and immunophenotyping, cytogenetic and molecular studies. Each of these components is important to appropriate diagnostic evaluation but, there is increasing evidence that major disease-defining, prognostic relevant, and therapy-determining data are provided by the genetic and molecular analyses. Most translocations, when evaluated at the molecular level, are detected by reverse transcription-polymerase chain reaction (RT-PCR) in the routine diagnostic setting. RT-PCR detection of the major leukemia translocations has numerous advantages over conventional cytogenetics, including shorter turn-around time, no requirement for dividing cells, detection of translocations that may be missed by conventional cytogenetics and providing a sensitive marker for subsequent minimal residual disease testing. Aim. The aim of this study was to validate the application of a commercially available multiplex RT-PCR assay (HemaVision 28 System) for 28 most common leukemia translocations for routine molecular diagnosis. *Material and methods*. We analyzed 30 samples of bone marrow and peripheral blood of 30 new diagnosed children with acute lymphoblastic leukemia (ALL). The samples were cryopreseved with RNAlater® (Ambion) and stored at -20°C. We centrifuged 200-500 mL fixed-cell suspension, and pellets were washed with ethanol. Then RNA was prepared using the RiboPure Blood Kit (Ambion) according to the manufacturer's recommendations. Samples were analyzed using a multiplex RT-PCR assay (HemaVision) according to the manufacturer's instructions. The assay discriminates between 28 different fusion transcripts. Reverse transcription was performed with a mixture of translocation-specific complementary DNA (cDNA) primers and PCR amplification in 8 parallel nested multiplex master reactions. Each of the master solutions contains several primers that are specific for particular fusion transcripts and a pair of control primers that amplifies a ubiquitously expressed gene. Thus, each of the master reactions identifies various chromosomal aberrations that, due to the heterogeneity of the breakpoints on the genomic level and/or alternative splicing, generate different messenger RNA (mRNA) variants. To verify the presence of a specific fusion transcript in a positive multiplex reaction, a nested split-out analysis with individual translocation-specific primer sets was performed. The specific translocation and splice variant was classified by comparing the respective pattern with the interpretation table provided by the manufacturer. Results. The RNA concentration from 30 samples was 10.35-1608.4 ng/μL. We obtained higher RNA concentrations from peripheral blood comparing with bone marrow samples. In 14 cases (46,66%) the test failed to identify a molecular abnormality; in 11 cases (36,66%) the low quantity of RNA isolated was insufficient for a definitive diagnosis; in 5 cases (16,66%) we identified molecular abnormalities - 2 cases (6.66%) BCR/ABL p190, 1 case (3.33%) TEL/AML1, 1 case (3.33%) E2A/PBX, 1 case (3.33%) MLL1/AF4. The results in positive cases were comparable with conventional cytogenetics. *Conclusions*. We consider that molecular based screening, via a multiplex RT-PCR system evaluated here, is still extremely valuable in clinical practice, but have to be evaluated together with other cytogenetic methods.

1231

SERUM BAFF (B-CELL ACTIVATING FACTOR OF THE TNF FAMILY) PREDICTS TIME TO FIRST TREATMENT IN EARLY B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA

S. Molica,[1] G. Digiesi,[2] G. Cutrona,[3] R. Mirabelli,[1] F. Iuliano,[4] D. Giannarelli,[2] I. Sperduti,[2] F. Morabito,[5] M. Ferrarini[3]

[1]Azienda Ospedaliera Pugliese-Ciaccio, CATANZARO; [2]Clinical Pathology, IRCCS Regina Elena, Roma, ROMA; [3]Medical Oncology C, IST Genova, GENOVA; [4]Medical Oncology Department, ROSSANO (CS), Italy; [5]Hematology Department- A.O. Cosenza, COSENZA, Italy

We analyzed the correlation between well-established biological parameters of prognostic relevance in B-cell chronic lymphocytic leukemia [CLL] (i.e, mutational status of the immunoglobulin heavy chain variable region [IgVH], ZAP-70- and CD38-expression) and serum levels of BAFF (B-cell activating factor of the TNF family) by evaluating

the impact of these variables on the time to first treatment [TFT] in a series of 125 previously untreated Binet stage A B-cell CLL patients. By using a commercial ELISA (R & D Systems, USA) we found that higher levels of BAFF characterized more frequently females (p=0.01), patients with Rai stage 0 (p=0.03), mutated IgVH (p=0.008) and low ZAP-70 expression (p=0.04). In contrast, age (p=0.35), peripheral blood lymphocytosis (PBL)(p=0.09), hemoglobin (Hb) (p=0.64), platelet (PLT) count (p=0.12), serum β2-m (p=0.49), LDH (p=0.85) and percentage of CD38-positive B-CLL cells (p=0.63) did not reflect circulating levels of BAFF. We used an optimal cut-point search to determine how to best split soluble BAFF data. Maximally selected log-rank statistics plots identified a BAFF serum concentration of 311 ng/mL as the best cut-off (p<0.0001). Accordingly, patients who had BAFF levels higher than 311 ng/mL experienced a longer TFT (median 108 months) in comparison to patients whose BAFF levels were lower than 311 ng/mL (median 30 months; p<0.0001). The univariate Cox proportional hazard model identified lower serum concentration of BAFF, Rai sub-stage I-II (p=0.003), lower PLT count (p=0.04), higher PBL count (p=0.01), increased LDH (p=0.01), ZAP-70 expression > 20% (p=0.02) and absence of mutation in IgVH (p<0.0001) as predictor of shorter TFT. In multivariate analysis only soluble BAFF (Hazard ratio [HR], 6.13; CI 95%, 2.31-16.25) and mutational status of IgVH , (HR= 2.99; CI 95% 1.33-6.76, p=0.008) maintained their discriminating power. The effects of BAFF on TFT were masked by mutational status of IgVH in patients with unmutated IgVH. However, serum levels of BAFF and mutational status of IgVH had a joint effect on TFT in patients with mutated IgVH which translates into a segregation of patients with mutated IgVH in two groups with different TFT according to BAFF levels (HR= 8.9; p<0.0001). Our results indicate that in early B-cell CLL biological profile including among other parameters soluble BAFF may provide a useful insight into the complex interrelationship of prognostic variables. Furthermore, BAFF along with mutational status of IgVH can be adequately used to predict clinical behaviour of patients with low biological risk.

1232

DELETION OF CHROMOSOME 5Q AS A RARE BUT NON RANDOM ABNORMALITY IN CHRONIC LYMPHOCYTIC LEUKEMIA

K.N. Manola,[1] M. Karakosta,[1] A. Tsakiridou,[2] I. Korantzis[3]

[1]NCSR Demokritos, ATHENS; [2]General Hospital of Patras, A. Andreas, PATRAS; [3]Papageorgiou General Hospital, THESSALONIKI, Greece

Backround. Chronic lymphocytic leukemia (CLL) is associated with cytogenetic abnormalities at diagnosis or during the course of the disease. However, most of them have not been completely determined due to the low mitotic *in vitro* activity of B-CLL cells. Aim: We present a conventional and molecular cytogenetic study of two CLL cases with deletion 5q [del(5q)] as a sole abnormality in order to contribute to the identification of rare recurrent aberrations and their prognostic impact in CLL. *Patients and Methods*. Patient 1, a 66-year-old man, and patient 2, a 59-year-old woman were diagnosed with B-CLL in September 2008 and in October 2007 respectively. Both received no therapy and are still in excellent clinical condition 5 and 17 months later correspondingly. Cytogenetic studies were performed on unstimulated and stimulated bone marrow cells at diagnosis. Fluorescent *in situ* hybridization (FISH) studies were performed on the same specimens using commercial DNA probes for detection of deletions of 5q31 (EGR1/D5S23), 5q33-q34 (CSF1R/D5S23, DS5721), 17p13 (TP53), 11q22.3 (ATM), 13q14/13q34 (D13S319/13q34) and trisomy 12 (CEP 12). Results: Chromosome analysis revealed del(5q) as a sole abnormality and FISH demonstrated normal hybridization pattern for 13q14, 13q34, ATM, p53 and CEP12 regions in both patients. Furthermore, in patient 1, FISH showed a normal hybridization pattern for 5q31 but a single signal for 5q33-q34 region. FISH results for del(5q) were not obtained for patient 2 due to lack of cytogenetic material. *Conclusions*. This study presents the first case reports of del(5q) in CLL and demonstrates that del(5q) as a sole aberration, is a rare but non random abnormality, possibly not associated with an adverse prognosis. It also indicates that 5q33-q34 could be the potential critical region. Further studies are required to delineate the prognostic value of del(5q) in CLL, and to identify candidate genes with potential role in the pathogenesis of the disease.

RARE GROSS DELETION IN TCIRG1 GENE IN IRANIAN FAMILY WITH INFANTILE MALIGNANT OSTEOPETROSIS

A. Modaresi, R. Abbaszadegan, E. Dadkhah, E. Khadivi Zand, E. Velayati

Mashhad University of Medical Sciences, MASHHAD, Iran

Background. Infantile malignant osteopetrosis (OMIM: 259700) is an autosomal recessive disorder, manifests by severe osteosclerosis within the first decade of life. Mutations in TCIRG1 (T-cell immune regulator 1) gene encoding osteoclast-spesific 116-kD subunit of H+-ATPase named as a3 subunit were found as the cause of infantile malignant osteopetrosis type. Recent research found that mutations in TCIRG1 gene are responsible for about 50% of patients. We found the first Iranian patient with a rare gross deletion identified in this gene. Case presentation: Z.A. was a 5 year old girl referred to hematology department of Dr Sheikh pediatric hospital with macrocephaly, facial dysmorphism, blindness, mental retardation and hepatosplenomegaly. Laboratory investigations revealed pancytopenia. Radiological images showed osteosclerotic changes in skull and limb. With these findings she was referred for molecular analysis of osteopetrosis disease. Molecular analysis was performed using RT-PCR for exon 10-19 of TCIRG1 gene followed by whole gene sequencing using an ABI 3730 capillary system automated sequencer. The patient showed a 275bp unexpected amplified segment in PCR experiment. Sequencing of the PCR product revealed a gross deletion in exon 10-15 transcript region of TCIRG1. This deletion affected codon 389 to 518 including entire exon 11 to 13 of the gene. *Conclusions*. Various types of mutations in the TCIRG1 gene in infantile malignant osteopetrosis have been reported in different populations; however, gross deletions are reported rarely. This gross deletion of exon 11-13 in infantile malignant osteopetrosis is the first mutation reported among Iranian patients in this gene. This deletion is also the largest deletion of TCIRG1 gene reported until now.

CORRELATIVE STUDY BETWEEN IMMUNOMODULATORY ACTION OF PROPOLIS ON CULTURED PBMNCS AND ITS SCHISTOSOMICIDAL ACTIVITY

A. Hussein,[1] A. Helmy,[2] S. Badr,[2] L. Ghanem,[2] S. Mahmoud,[2] M. Shalabi,[2] E. Hassan[2]

[1]Department of Electron Microscopy (Haematology), [2]Theodore Bilharz Research Institute; Oncology Diagnostic unite Ain Shams facuty of medicine; [3]Department of Parasitology, Theodore Bilharz Research Institute

Propolis, a beehive product widely used in folk medicine as an anti-inflammatory agent, has been attracting researchers' attention to scientifically elucidate its biological properties and therapeutic activities. This study aimed to spot light on the value of propolis as an immune-stimulant and to evaluate the influence on schistosome hematobium infection cure rate. To achieve this goal we estimated the effect of propolis on cultured peripheral blood mononuclear cells activation *in vitro* by IL-2 and NO determination. We also evaluated the effect of *in vivo* treatment with propolis on schistosomL haematobium worm and bone marrow by parasitological and ultrastructural studies. Twenty S. haematobium infected golden hamsters were included in the study, subdivided into two groups each of 10 animals Group 1: Infected Control with 300+10 cercariae of S. haematobium by abdominal skin exposure. Group 2: Animals were treated with propolis three months post the infection. Our *in vitro* results revealed that propolis induces a discreet elevation in IL-2&NO release in PBMNCs cultures supernatant of S.hematobium infected hamsters. Mean level of IL-2 was 16.17±1.67 pg/mL in the presence of propolis and 3.31±0.76 in its absence with highly statistically significant difference (p<0.001). Regarding NO, Mean level of NO was 7.76±1.30 U/mL in the presence of propolis and 2.6±0.42 in its absence with highly statistically significant difference (p<0.001). Also, propolis caused observed activation and absence of apoptotic changes at the ultrastructural level of cultured PBMNCs. *in vivo* results, revealed significant reductions in mature worm loads (either male or female), tissue egg loads (either intestinal or hepatic) 21.00 and 19.79% respectively and Percentage reductions of egg developmental stages was 68.07% with statistically significant difference compared with infected control group (p<0.05). Ultrastructural study of S.hematobium worm revealed implantation and degeneration of the spines within vesiculated tegument and for the bone marrow it revealed evidence of lymphocyte and promonocyts activation in addition to remarkable increase in the num-

ber of the activated natural killer cell. Data suggest that propolis acts as immunmodulator activating immuncompittent cells. This information would provide new insights in considering propolis to have a potential therapeutic benefit if used in conjunction with anti-schistosomal drug in treatment of schistosomiasis infection. KEY WORDS: propolis, schistosome haematobium, PBMNCs, IL-2, nitric oxide ,electron microscopy

PREVENTIVE EFFECTS OF BILE ACIDS ON BILIRUBIN-INDUCED APOPTOSIS OF HUMAN BRAIN MICROVASCULAR ENDOTHELIAL CELLS

M. Correia,[1] F.L. Cardoso,[1] D. Sousa,[1] I. Pamela,[1] A.R. Vaz,[1] S.L. Silva,[1] A.S. Falcão,[1] A. Fernandes,[1] R.F.M. Silva,[1] K.S. Kim,[2] D. Brites,[1] M.A. Brito[1]

[1]IMed.UL, Faculdade de Farmácia, University of Lisbon, LISBOA, Portugal; [2]Division of Pediatrics Infectious Diseases, J. Hopkins Univ. School of Medecine, BALTIMORE, USA

Background. Unconjugated bilirubin (UCB) is known for its potential neurotoxicity, particularly during the neonatal period, although remaining unclear the mechanisms underlying its access to the brain. In fact, there is only one study on the effects of UCB on bovine brain endothelial cells where it was shown that UCB induces apoptosis. So, the injury to the endothelial cell lining of the blood-brain barrier (BBB) that might explain the underlying mechanisms of UCB access to brain deserves to be studied, and novel therapeutic approaches are needed to prevent cell damage. Ursodeoxycholic acid (UDCA) is an endogenous bile acid widely used for the treatment of chronic cholestatic liver diseases. Following oral administration, it is conjugated in the liver, originating tauroursodeoxycholic acid (TUDCA) and, mostly, glycoursodeoxycholic acid (GUDCA). In previous studies, we showed several beneficial effects of UDCA or its conjugates, namely their ability to abrogate UCB-induced oxidative disruption and inflammatory responses, therefore preventing nerve cell death. *Aims*. In this study, we used a simplified model of the BBB, constituted by human brain microvascular endothelial cells (HBMEC), to investigate whether: (i) physiologically relevant concentrations of UCB induce cell death by apoptosis; (ii) UDCA and GUDCA are able to prevent apoptotic cell death from occurring and (iii) establish the temporal window of therapeutic intervention. *Design and Methods*. A HBMEC cell line, that showed to maintain morphologic and functional characteristics, was used. Cells were exposed to 50 or 100 M UCB, in the presence of 100 μM human serum albumin to solubilise UCB, for 4, 24 and 48 h at 37°C. To evaluate the protective role of UDCA and GUDCA, cells were separately treated for 1 h with 50 μM of each of the bile acids prior to the 48 h incubation with UCB. To establish the therapeutic window, another set of experiments was performed by addition of the modulators 8 hours after exposure to UCB. Assays with bile acids alone were also included. Apoptosis was assessed by the analysis of nuclear morphology after incubation with Hoechst dye 33258 (Sigma) using a fluorescence microscope. *Results.* Exposure of HBMEC to UCB led to a time- and concentration-dependent increase in apoptotic cell death (statistically significant differences were obtained for all data points vs. respective control, except for 4 h incubation with 50 mM UCB). Both bile acids were able to counteract UCB-induced cell death by apoptosis, being the greatest protection (≥50 %, $p<0.05$) achieved by addition of the therapeutic compounds prior to the beginning of the incubation with the toxic insult. Interestingly, even after 8 h exposure to UCB, the therapeutic molecules were able to abrogate cell death by nearly 30 % ($p<0.05$). *Conclusions*. The present results provide the first demonstration of the disruption of the endothelial cell lining of the human BBB by UCB. They also demonstrate the ability of the bile acids UDCA and GUDCA to abrogate UCB-induced apoptosis, therefore disclosing a novel therapeutic approach to apoptotic cell death resulting from exposure to an endogenous circulating molecule.

NOVEL TREATMENT OF MULTICENTRIC CASTLEMAN'S DISEASE WITH LENALIDOMIDE

J. Krawczyk, T. Murphy, R. Swords, T. Meenaghan, M. O'Dwyer

Galway University Hospital, GALWAY, Ireland

Introduction. Multicentric Castleman's disease is a rare lymphoproliferative disorder that is characterized by lymph node hyperplasia, a marked systemic inflammatory response and a tendency to evolve into an aggressive lymphoma. It typically presents with systemic symptoms including night sweats, weight loss, and lethargy. Therapeutic options are limited and multiple agents including steroids, thalidomide, rituximab, and tocilizumab have been used to treat the condition. *Aims/Method*s. A 49-year-old HIV negative patient was eventually diagnosed with Castleman's disease having had an atypical presentation with progressive marrow failure due to fibrosis, marked systemic symptoms and serositis with pleural effusions and ascites. His clinical course was complicated by peritonitis and sepsis on several occasions. After initial stabilization with rituximab he had progression of disease and was retreated with rituximab in combination with cyclophosphamide, vincristine and steroids. Despite this he had on going progression of disease with worsening ascites and general deterioration. As there are anecdoctal reports indicating activity of thalidomide a trial of thalidomide 200 mg once daily was given. While there was a clinical response to thalidomide it had to be stopped due to hyperkalaemia. Based on a a similar mode of action patient was started on lenalidomide 25 mg once daily for 21 days in every 28-day cycle in combination with dexamethasone. The dose of steroids was gradually reduced and the patient has continued single agent lenalidomide since. To date he has received 18 cycles of lenalidomide and remains in clinical remission. The main toxicities that were observed during lenalidomide therapy included thrombocytopenia and an episode of desquamative rash on his hands and feet which required temporary cessation of therapy and short course of oral corticosteroids and subsequent dose reduction of lenalidomide to 15 mg. *Conclusion*. The standard therapy of Castleman' disease is not established. Published evidence consist of mainly of case reports and small case series. There is growing evidence that the use of rituximab can result in durable remissions and therefore it is emerging as the likely treatment of choice for most patients. There are anecdotal reports that thalidomide was active in symptomatic control of the disease. However there is no published evidence on the use of lenalidomide in the Castleman's disease. Our patient tolerated lenalidomide very well and achieved satisfactory disease control. This represent a novel approach and offers another treatment option in patients not responding to or intolerant of other therapeutic modalities.

ANTITUMOR ACTIVITY OF NAMPT INHIBITION AND SYNERGY WITH CYCLOSPORIN A AND HDACIS TO PROMOTE APOPTOSIS IN PRIMARY LEUKEMIC CELLS

M.C. Cea,[1] A. Cagnetta,[2] A. Garuti,[3] G. Zoppoli,[3] I. Rocco,[3] E. Moran,[3] A. Ballestrero,[3] I. Pierri,[2] M. Gobbi,[2] A. Nencioni,[3] F. Patrone[3]

[1]Università di genova, GENOVA; [2]Institute of Haematology, University of Genova, GENOVA; [3]Department of internal medicine, university of Genoa, GENOVA, Italy

Background. During the neoplastic transformation, nicotinamide phosphoribosyltransferase (NAMPTase), a key enzyme involved in NAD biosynthesis, performs an important role since becomes upregulated to compensate for increased metabolic demands. Therefore, drugs capable to inhibit this enzyme such as FK866, are highly sought for their poten-

tial as cancer therapeutics. The NAD depletion, as formerly reported by a lot of authors, is associated with mitochondrial dysfunction and autophagy triggering cell death. The cytotoxic effect of these compounds seems to be selective for malignant, as opposite to normal cells. Nevertheless NAMPT inhibitors alone induce a mild cell death on primary leukemic cells. We have made use of FK866 in combination with traditional drugs cyclosporin and valproate, to improve this results. *Design and Methods*. We collected peripheral blood samples from B-CLL (previously untreated and treated; n=22) and AML (n=8; different FAB subtypes) patients. The mononuclear cell were isolated by density-gradient centrifugation using Ficoll-Hypaque and immediately seeded in RPMI 1640-based culture medium. Consequently 2,5x105 primary leukemic cells/well were plated in 96 well plates and treated with increasing concentrations of FK866 (range 10-9-10-6 M) either alone and in combination with cyclosporin (10-6-10-4M) or valproate (10- 4-10-5 gr/mL). Viability was assessed at 96 h from the beginning of the treatment by propidium iodide exclusion using a FACS Calibur. In selected cases, Annexin-V/propidium iodide staining was done to detect early- vs. late-apoptotic leukemia cells in response to FK866 alone and in combination treatment. Intracellular NAD content was measured using a biochemical assay; the pan-caspase inhibitor (zVAD-fmk), the caspase 9 and 8 specific inhibitors were used to value apoptosis; flow cytometric assay was used to detect P-glycoprotein and to determine intracellular FK866 fluorescence. *Results*. We observed an heterogeneous response to FK866 growing doses with an average of 50% of death cell at 10nM; since primary leukemic cells were mildly susceptible to apoptosis via NAMPT inhibition, we tested the FK866 in combination with valproate and cyclosporin showing a much weaker antiproliferative effect. Also the intracellular NAD levels lowered mainly in the combination treatment. To evaluate the additive or synergistic effect, a co-operative index (CI) was calculated for each sample with following formula: CI= sum of specific apoptosis of single agent treatment/specific apoptosis upon combined treatment. CI values <1,=1 and >1 mean that the effect is synergistic, additive or infra-additive effect respectively. The co-operative index was <1 in both drugs associations showing a synergistic effect for both the two ones. This result suggests that, in addition to Nampt inhibition, the two drugs may act through others machanisms. In detail, valproate might improve FK866 antileukemic activity via concomitant stimulation of complementary apoptotic pathways; cyclosporin, through the P-gp inhibition, induces an increment of intracellular FK866 improving its owns activity. Furthermore, we investigated the role of ADP-ribosyl cyclase CD-38 and we did not observe different susceptibility to FK 866 in CD 38 +/- cells. *Conclusions*. Our data indicate a novel strategy for the treatment of hematological malignances since valproate and cyclosporin may improve the outcome of monotheray with FK866 and provide a potential alternative leukemia treatment.

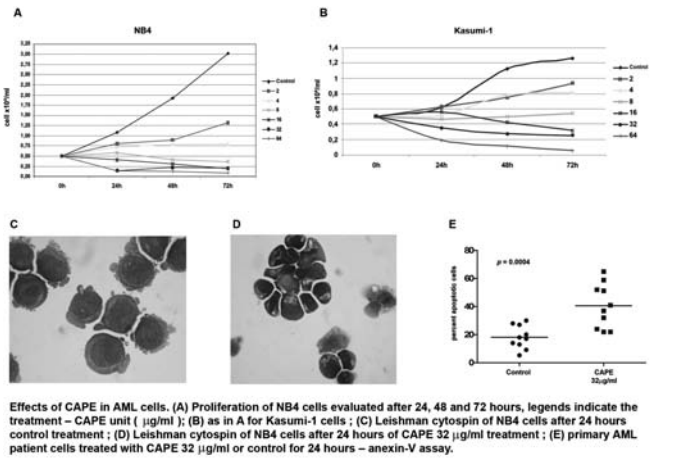
CAFFEIC ACID PHENETHYL ESTER INDUCES APOPOSIS IN ACUTE MYELOID LEUKEMIA CELLS

P.S. Scheucher, G.A. dos Santos, H.L. Gimenes Teixeira, R.P. Falcão, E.M. Rego

Faculdade de Medicina de Ribeirão Preto, RIBEIRAO PRETO, Brazil

Caffeic acid phenethyl ester (CAPE) is an active phenolic compound present in propolis obtained from honeybee hives. It is reported to present a broad spectrum of biological activities including antioxidant, anti-inflammatory and antitumoral. The antitumoral activity of CAPE as evaluated by several studies *in vitro* and *in vivo* seems to be related to distinct effects like the inhibition of angiogenesis, invasion and metastasis and the induction of apoptosis or differentiation of cancer cells. However the demonstration of apoptosis induction in acute myeloid leukemia (AML) cells and the demonstration of enhancement of all-trans-retinoic acid (ATRA) induced differentiation in acute promyelocytic leukemia (APL) by CAPE is restricted to the HL-60 cell line. HL-60 is a very sensitive cell to apoptosis induction by diverse treatments and is not a model of APL differentiation by ATRA since do not posses the PML-RAR-α rearrangement. Our aim was to evaluate the effects of CAPE treatment on APL cell lines NB4 and NB4-R2 (a cell resistant to ATRA-induced differentiation) and on AML cell line Kasumi-1 (a cell representative of core binding factor leukemias with AML1-ETO rearrangement). Also to evaluate the effect of CAPE on the induction of apoptosis in primary AML samples. Proliferation and viability was evaluated by direct cell count with tripan blue exclusion dye in Neubauer chamber at fixed time intervals. Differentiation was evaluated by flow cytometer determination of CD11b expression. Cell cycle distribution and apoptosis were evaluated by flow cytometer determination of propidium iodide- DNA fluorescence and apoptotic cells were defined as sub-G0 fraction. Also apoptosis was detected by the anexin-V method. Leishman stained cytospins for light microscopy were used to confirm apoptosis or differentiation. CAPE did not induce differentiation in the cell lines NB4, NB4-R2 or Kasumi-1 and did not alter the differentiation induced by ATRA in NB4 cells. CAPE inhibited the proliferation of AML cell lines in in a time and dose dependent fashion (Figure A, B) CAPE induced apoptosis in all cell lines. In the NB4 cell line CAPE induced cell death (tripan blue assay), estimated ED50 was 32.1 mcg/ml. ED50 for induction of apoptosis in the more sensitive assay using anexin-V in NB4 cells after 24h was 7.5mcg/mL and for Kasumi-1 was 10.2mcg/ml. CAPE (32 mcg/ml) significantly induced apoptosis in cells from AML patients, mean IC50 (29.26 - 51.76) versus control treated cells 18.16 % ; IC95% (12.27 - 24.05); p=0.0004 (Figure E) One possible mechanism for CAPE cytotoxicity in leukemia cells is NFK-B inhibition. This hypothesis is currently under investigation in our laboratory. In conclusion, CAPE do not induce differentiation in APL cells but induces apoptosis and inhibition of proliferation in a dose and time dependent manner in AML cells lines and also induces apoptosis in patient samples. These properties are interesting and need further investigation.



Effects of CAPE in AML cells. (A) Proliferation of NB4 cells evaluated after 24, 48 and 72 hours, legends indicate the treatment – CAPE unit (µg/ml); (B) as in A for Kasumi-1 cells ; (C) Leishman cytospin of NB4 cells after 24 hours control treatment ; (D) Leishman cytospin of NB4 cells after 24 hours of CAPE 32 µg/ml treatment ; (E) primary AML patient cells treated with CAPE 32 µg/ml or control for 24 hours – anexin-V assay.

Figure.

1239

RITUXIMAB THERAPY FOR IMMUNE THROMBOCITOPENIC PURPURA

P. Minga, M. Capponi, F. Falcinelli, L. Flenghi

Istituto di ematologia, PERUGIA, Italy

Background. Standard therapy for autoimmune diseases (drugs with non-specific immunosoppressive capacities) is associated with infections and toxicity. As the anti-CD20 monoclonal antibody Rituximab induces complement- or cell-mediated lysis of autoreactive lymphocyte clones, we assessed its efficacy in patients who were resistant to standard therapy for immune thrombocytopenic purpura (ITP). *Design and Methods*. Rituximab was administered as a weekly infusion of 375 mg/m^2 for 4 consecutive weeks. *Aims*. The objective of this study was to evaluate the efficacy and safety of Rituximab in the treatment of patients with ITP. *Patients*. 17 patients were observed, with median age 47,5 years (range 14 - 81years), 13F, 4 M. 15 patients had idiopathic thrombocytopenic purpura (ITP), 1 had non Hodgkin Lymphoma, another had Sjogren's disease. All had platelet counts ≤10000/m^3 and had received steroids and high dose, intravenous immunoglobulin. One had received Azathioprine (Sjogren's disease), another has received Cyclophosphamide in the previous 2 months. Chemotherapy had failed in the patient with non Hodgkin Lymphoma and splenectomy in four patients with ITP. Result: Median follow-up was is 32,5 months (range 3-62). Of the 17 treated patients, complete remission was achieved in 14 patients and no response in 3 patients; 3 months after treatment platelet counts were over 120 000/mmc in 14 patients, 2 patients reached normal platelet counts after splenectomy, 1 good responder requested a second Rituximab cycle after 16 months and obtained a second response with a persistent normal platelet count after 58 months. Rituximab was well tolerated. *Conclusions*. Younger age and shorter interval from diagnosis to Rituximab appeared indicators of better outcome. Rituximab is an effective agent for the treatment of ITP resistant to standard immunosuppressive drugs with tolerable toxicity.

1240

RITUXIMAB TREATMENT OF REFRACTORY AUTOIMMUNE HEMOLYTIC ANEMIA AND REFRACTORY AUTOIMMUNE THROMBOCYTOPENIC PURPURA

S. Raptis,[1] M. Mantzourani,[1] L. Dimitrakopoulou,[1]
T. Vassilakopoulos,[1] P. Tsirkinidis,[2] G. Pangalis,[1] G. Vaiopoulos[1]

[1]National and Kapodistrian University, Faculty of Medicine, Goudi, Athens, ATHENS; [2]Laikon Hospital, ATHENS, Greece

Background. The B lymphocyte plays a major role in the pathogenesis of autoimmune diseases. Targeted therapy against CD20 positive B lymphocytes may be an effective treatment of Autoimmune Hemolytic Anemia (AHA) and Autoimmune Thrombocytopenic Purpura (ITP). Aims: The objective of this study is to determine the role of Rituximab as a therapeutic means against the two autoimmune hematological diseases. *Design and Methods*. Patients who have been under Rituximab treatment were studied retrospectively: 3 AHA patients [2/3 with an underlying lymphoproliferative disease (LPD)] and 11 ITP patients (5/11 with no underlying disease, 3/11 with underlying LPD, 1/11 with underlying LPD and collagonosis, 1/11 with collagonosis and 1/11 with common variable immunodeficiency). Rituximab was administered IV weekly in doses of 375 mg/m^2 for 4 weeks. The monthly infusions that followed were absolutely related to each patient's response to the treatment. All the patients had been treated for their underlying conditions except one with AHA and CLL. In addition, all the ITP patients had responded poorly or not at all to any previous treatment. *Results*. Two patients with underlying LPD and AHA completely responded after 6 cycles of RItuximab treatment while another patient with refractory AHA didn't respond after 4 cycles and quit. As far as ITP patients were concerned, 4/6 with an underlying disease responded completely and 1/6 partially, maintaining his PLT levels between 30000/l-50000/μL. A female patient with common variable immunodeficiency relapsed a year after receiving 8 cycles of treatment and responded after repeating the therapy. As for the patients with no underlying conditions (5/11), one of them responded completely and three of them partially, while one did not respond at all. *Conclusions*. Despite the small number of patients, it seems that Rituximab can be a safe and effective treatment for autoimmune hematological diseases.

1241

INCREASING INTRACELLULAR GENERATION OR ACCUMULATION OF CERAMIDES INCREASED CYTOTOXIC EFFECTS OF RESVERATROL IN HUMAN K562 CHRONIC MYELOID LEUKEMIA CELLS

M. Kartal,[1] G. Saydam,[2] F. Sahin,[2] Y. Baran[1]

[1]Izmir Institute of Technology, IZMIR, Turkey; [2]Ege University, Department of Hematology, Bornova, IZMIR, Turkey

Backround. Resveratrol, trans-3,5,4'-trihydroxystilbene, is a naturally occurring phytoalexin produced by various plants in response to stress, injury, ultraviolet (UV) irradiation, and fungal infection, and also skin and seeds of red grapes. Resveratrol affects the processes underlying tumor initiation, promotion and progression. Many studies in human cell cultures indicate that resveratrol can modulate multiple pathways involved in cell growth, apoptosis, and inflammation. Ceramides are second messenger of the sphingomyelin pathway, and they constitute a signaling mediator of various biological activities including cell cycle arrest, cell senescence, cell migration and adhesion, differentiation or apoptosis in normal and tumor cells from various tissues. While ceramide is an apoptotic molecule, conversion of ceramides to glucosyl ceramide or sphingosine-1-phosphate by glucosylceramide synthase (GCS) or sphingosine kinase-1 (SK-1) enzymes, respectively, result in cell growth and proliferation. Thus, increasing intracellular concentrations of ceramide by induction of *de novo* synthesis or inhibition of GCS by N-(2-hydroxy-1-(4-morpholinylmethyl)-2-phenylethyl)-decanamide, hydrochloride (PDMP) or SK-1 by sphingosine kinase-1 inhibitor may be one of possible pathways of stress-induced cell death. *Aims*. We have shown in our previous studies that resveratrol can trigger cell death in human K562 chronic myeloid leukemia (CML) cells. But there is no detailed information about the mechanisms of resveratrol-induced apoptosis. More importantly, the involvement of ceramide metabolising genes and their end products in resveratrol-induced apoptosis are not investigated in CML. In this study, we tried to show the possible roles of ceramide, glucosylceramide and sphingosine-1-phosphate in resveratrol-induced apoptosis in human K562 cells. *Design and Methods*: Cytotoxicity analyses of resveratrol, C8:ceramide, PDMP and SK-1 inhibitor and combinations of resveratrol with C8:ceramide, PDMP or SK-1 inhibitor in K562 cells were analysed by XTT cell proliferation assays and possible synergistic analyses were examined. *Results*. IC50 values of resveratrol and C8:ceramide or IC90 value SK-1 inhibitor and PDMP were found to be 80 μM and 60 μM or 7 μM and 20 μM, respectively. There were 8-, 18-, 43-, 45-, and 59% decreases in cell proliferation of K562 cells in response to 1-, 10-, 50-, 70-, and 100 μM resveratrol, respectively. Combination of the same doses of resveratrol with 20 μM PDMP decreased proliferation of K562 cells to 29-, 46-, 55-, 58-, and 68%, respectively, as compared to untreated controls. On the other hand, application of 60 μM C8:ceramide in combination with the same doses of resveratrol decreased cell proliferation to 87- to 90%, as comparing to untreated controls. 7μM of SK-1 inhibitor in combination with 1-, 10-, 50-, 70-, and 100 μM of resveratrol resulted in 23-, 42-, 54-, 72-, and 73% decreases in cell proliferation. *Conclusions*. In this study, we aimed to show cytotoxic effects of resveratrol, exogenous ceramide, C8:ceramide, GCS inhibitor, PDMP, and SK-1 inhibitor on K562 cells. The results of this study showed for the first time that there were synergistic effects of combination of resveratrol and IC50 value of C8:ceramide or IC90 values of SK-1 inhibitor and PDMP. Taking together all these results showed that ceramides may be involved in resveratrol-induced apoptosis in K562 cells.

1242

RITUXIMAB THERAPY FOR REFRACTORY SLE-EVANS SYNDROME

D. Atay1, A. Akcay2, G. Ozturk3, S. Anak3

[1]Okmeydani Education and Research Hospital, ISTANBUL, Turkey; [2]Bakirkoy Maternity and Children's Hospital, Department of Pediatric Hematology, ISTANBUL, Turkey; [3]Istanbul University, Istanbul School of Medicine, Dep of Pediatric Hematology, ISTANBUL, Turkey

Background. Targeted depletion of B lymphocytes is an alternate approach to treatment of autoimmune disorders. Rituximab, a chimeric, human, IgG1a monoclonal antibody, is specific for the CD20 antigen and can selectively deplete B-cells by antibody-dependent cell-mediated cytotoxicity, complement- mediated cytotoxicity, and inhibition of cell proliferation with direct induction of B cell apoptosis. Several studies have shown the efficacy and safety of Rituximab in autoimmune disorders such as chronic idiopathic thrombocytopenic purpura (ITP), idiopathic autoimmune thrombocytopenia and/or autoimmune hemolytic anemia - (Evans syndrome), rheumatoid arthritis (RA), SLE, mixed cryoglobulinemia. Case Report: We describe a 16 year-old male with SLE-Evans syndrome refractory to glucocorticosteroids, intravenous immune globulin (IVIG) therapy, Mycophenolate mofetil and plasmapheresis. The patient responded to four weekly infusions of rituximab and maintains this remission now for 36 months. Therapy was well tolerated, and no infectious complications occurred. *Result*. Rituximab appears safe, effective and feasible in a variety of autoimmune diseases. After rituximab administration the patient had a favorable response to this treatment and since 36 months, he showed no more thrombocytopenia. *Conclusions*. These datas indicate that rituximab is effective and feasible in most pediatric patients with autoimmune diseases but we still need more experience. We think that it's logical to use rituximab as therapy for Evans syndrome resistant to first-line therapy and ciclosporin/MMF as an alternative to intensive immunosuppressive therapies or splenectomy. By the recurrence of thrombocytopenia or anemia, second treatment course is feasible and may be successful in controlling the disease

1243

THE EFFECTS OF EMODIN ON PROLIFERATION AND APOPTOSIS IN JURKAT CELLS AND ITS MECHANISM

J.D. Hu, T.N. Wei, Y.Y. Chen, Z.H. Zheng, J. Zheng, L.H. Lv

Fujian Institute of Hematology, Union Hospital, Fujian Medical University, FUZHOU, China

Aims. To investigate the effects of Emodin on inhibiting proliferation and inducing apoptosis in leukemia cells. Acute T lymphoblastic leukemia cell line Jurkat was chosen to be investigated. *Design and Methods*: MTT assay was used to explore the cell proliferation. Cell cycle analysis, Annexin V/PI analysis, TUNEL and DNA ladder were used to investigate cell apoptosis. RT-PCR was taken to test the expression of apoptosis related gene and Western Blot was used to test the expression of related proteins. *Results*. Emodin could remarkably inhibit proliferation in Jurkat cells with the IC_{50} of 20 umol/L. Cell cycle analysis, Annexin V/PI assay and TUNEL showed that Emodin could effectively induce apoptosis in Jurkat cells with a time and does dependent manner in a range of concentration. After the treatment of Emodin, the expression

of c-myc and bcl-2 was down regulated in both gene and protein expression level. Western blot showed the expression of procaspase-3,8,9 decreased, while activated cleaved fragment caspase-3 increased in a time dependent manner. *Conclusions.* Emodin could effectively inhibit proliferation and induce apoptosis in Jurkat cells, and c-myc, bcl-2 and caspase family may have involved in the process stated above which was induced by Emodin.

1244

RITUXIMAB THERAPY FOR IMMUNE ANEMIA AND THROMBOCYTOPENIA: THE STUDY OF 06 CASES

N. Mesli,[1] B. Bereksi Reguig,[1] H.A. Hemche[2]

[1]Haematology, TLEMCEN; [2]Department of English, TLEMCEN, Algeria

Background. Immune thrombocytopenic purpura (ITP) and autoimmune hemolytic anemia (AHA) may respond to the chimeric anti-CD20 monoclonal antibody rituximab, even when refractory to conventional therapy. Aims: to evaluate the effect of rituximab in the two autoimmune diseases cited above. *Design and Methods*. Our study is retrospective on 03 years. We have collected the files of 06 patients; 02 of whom had AHA, and 04 had ITP. Those patients have not responded to the corticotherapy, and have undergone, then, a splenectomy. After that, they have been given rituximab. The hemoglobin count was between 05 and 09 gr/dL whereas the platelet count varied between 4000 and 11000/uL. *Results.* 02 of the 04 ITP patients have shown complete response (CR), with platelet count >400000/uL. 01 partial response (PR) with platelet count 20000-50000/uL. 01 failure with platelet count <10000/uL. Both of the 02 AHA patients have shown complete response (CR), with hemoglobin count >10 gr/dL. *Conclusions*. Rituximab has given good results on this small population, it would be more interesting to include more patients, and do further multicenteric studies.

1245

STUDY OF THE RESISTANCE IN ANTIPLATELET DRUGS, BY DETERMINATION OF GLYCOPROTEIN ON THE PLATELET MEMBRANE

P.E. Makris, M.P. Makris, M.K. Moschou, G. Koliakos

Aristotle University of Thessaloniki, THESSALONIKI, Greece

Introduction. Several studies have been made in order to determine why some individuals that are under anti-platelet treatment have relapses of thromboembolic episodes. The platelets function in individuals under aspirin or clopidogrel was checked using aggregometer, PFA-100, thromboxane derivative 11-dehydrothromboxane B2 in the urine. In order to follow up the changes of platelet membrane receptors in patients under anti-platelet treatment, we decided to examine the glycoproteins: Gp-Ib, Gp-Ibβ, Gp-IIb, Gp-IIIa and P-selectins. The reason for this was to see if these receptors were inhibited by this treatment. Material: We studied 83 people (36M and 47F with mean age 45,2±23,9 and 52,3± 19,1 correspondingly). From these; 43 {12Ms and 31Fs} without treatment and 29 {15Ms and 14Fs) under aspirin, 7 under clopidogrel {5M and 2F} and 4Ms were under both. *Design and Methods*. We applied platelet aggregation with AA and ADP. Also PFA-100 with Colla/EPI and Colla/ADP cartridges. In the same time we determined the CD41a, 42a, 42b, 61 and 62P antibodies with flow cytometry. The determination of glycoproteins was made in PRP. In order to evaluate the accuracy of this method we determined the glycoproteins in one person 10 times. As shown by CV our method has good reproducibility. Our results are shown a significant decrease of the number of all glycoproteins receptors in the patients under antiplatelet treatment except for the P-Selectins. Comment: It is a method of confirmation of the other methods as it presents the decrease in the number of the receptors. After the ascertainment that the resistance in clopidogrel is related with mutation CYP2C19*2 (a large gene of more than 90 kb in size, including nine exons, on chromosome 10q24.1-q24.3), we tested with a strip assay 2 patients with clopidogrel resistance and confirmed the presence of the homozygote mutation CYP2C19*22. Proving in the same time the genetic base of clopidogrel resistance.

1246

AZACITIDINE AND PEGYLATED G-CSF: OEDEMATOUS SWELLING OF THE TONGUE AS POTENTIAL SIDE EFFECT OBSERVED IN TWO PATIENTS

C. Busemann,[1] A.G. Beule,[2] C.A. Schmidt,[3] T. Neumann,[3] W. Krüger,[4] B. Kallinich,[5] G. Dölken,[3] S. Langner[6]

[1]Universitiy Hospital Greifswald, GREIFSWALD, Germany; [2]Dept. of ORL, Universitiy Hospital, GREIFSWALD, Germany; [3]Dept. of Hematology, University Hospital, GREIFSWALD, Germany; [4]University-Hospital Greifswald, GREIFSWALD, Germany; [5]Dept. of Hematology, Vivantes Neuköllln, BERLIN, Germany; [6]Dept. of Radiology, University Hospital, GREIFSWALD, Germany

Background. Indications for treatment with azacytidine are presence of a myelodysplastic syndrome, intermediate-2 or high risk, chronic myelomonocytic leukemia with excess of blasts >10% or acute myeloid leukemia with 20-30% blasts and myelodysplasia-related changes. Reported adverse reactions concern mainly the hematological, cardiovascular, central nervous, dermatological and respiratory systems. Potential fatal side effects of pegylated G-CSF are adult respiratory distress syndrome and rupture of the spleen. We here report for the first time occurrence of a rare, but potentially life threatening risk seen after combination of these medicaments in two patients. Patient 1 (46 year, male) received azacitidine 75 mg/m^2/d for seven days, due to a relapse of an acute myeloblastic leukemia after allogeneic stem cell transplantation. Following chemotherapy pegylated G-CSF was administered. On day +18 after treatment start an asymmetrically swelling of the tongue was observed. No further complaints like dyspnoe or dyspahagia were present. An ultrasound examination was suspicious of a hematoma. The MRT-scan with contrast medium showed a diffuse enhancement indicating an inflammatory process. Antibiotics and platelets were given. The swelling disappeared within four days. Patient 2 (67 years, male) presented with a refractory anemia with excess of blasts (REAB-2, IPSS intermediate-2) and was treated with azacitidine (75 mg/ m2/d for seven days). Seventeen days after start of chemotherapy and seven days after application of pegylated G-CSF the patient complained dysphagia and hypersalivation. The CT- and MRT-scan showed similar findings interpreted with swelling of the tongue and the adjacent tissue. The antibiotic treatment was escalated and corticosteroids were given. The complaints and clinical findings resolved within five days. *Summary*. The parallel occurrence of clinical symptoms and radiological signs of tongue swelling after application of azacitidine and pegylated G-CSF is indicative for a potential association of one or both of these two drugs. For none of the other prescribed medicaments an association with tongue swelling has been reported. Furthermore, other potential causes like bacterial infection, hematoma of allergic reaction seem to be unlikely upon clinical presentation. However, the pathophysilogical background of this localized reaction remains to be clarified. Since enoral edema is a potential life threatening risk and combination of these two drugs are used routinely, we report this rare clinical complication.

1247

CYTOTOXICITY BY COMBINED TREATMENT OF WARFARIN AND DOXORUBICIN ON LEUKEMIC CELLS IN VITRO

T. Ulutin

I.U. Cerrahpasa Medical Faculty, ISTANBUL, Turkey

Background. Previous results from our laboratory gave evidence that warfarin treatment may enhance the toxic effect of radiation in leukemic cell. Doxorubicin (DOX) is an antitumor drug commonly used as single and in combination with other chemotherapeutic agents, for treatment of wide range of human malignancies. *Aims*. This study investigated combinations of DOX with warfarin for their cytotoxicity against leukemic cells following a 72 h exposure *in vitro*. *Design and Methods*. Cell proliferation and apoptosis assays with various concentrations of warfarin with or without DOX (1 μM) were done on two leukemic cancer lines, human chronic myelogenous leukemic K562 cells and promyelocytic leukemic HL-60 cells, and on normal human peripheral blood mononuclear cells (PBMC). Results: The warfarin at the lower concentrations (<50 μM) with DOX treatment also induced in additive manner apoptosis in K562 and HL-60 cells. Combined treatment also attenuated cell proliferation in both cell lines. Presence of 100 μM N- acetylcysteine, as antioxidant, in the cell culture did not impair the cytotoxicity of DOX and warfarin. *Conclusions*. The present results indicate that warfarin treatment may enhance the toxic effect of DOX in leukemic

cells. The mechanism by which warfarin potentiate this cytotoxicity is unclear, but it may not be directly due to toxic damage induced by warfarin-generated free radicals, since co-treatment with N- acetylcysteine was unable to prevent this toxicity.

1248

WARFARIN RESISTANCE INDUCED BY OXCARBAMAZEPIN

O. Nevruz,[1] M. Yokusoglu,[1] O. Baysan,[1] F. Avcu,[2] T. Çetin,[2] U. Ural[2]

[1]Gülhane Military Medical Academy, ANKARA, Turkey; [2]Gata Military Medical Academy, ANKARA, Turkey

A sixteen years old male patient who had prosthetic aortic valve replacement six years ago was referred to our clinic for low INR values despite warfarin use. The patient was taking oxcarbamazepine because of a seizure-like episode he experienced one year ago. However, INR value decreased from normal target range at the 6th months of oxcarbamazepine therapy and reached a value of 1.23 at 12th months. We discontinued oxcarbamazepine therapy, but, the patient's INR values were still at the subtherapeutic levels. We increased daily warfarin dose to 20 mg with resulting INR of 1.5. We searched for genetic defects leading to warfarin resistance and found VKORC1 1173CC genotype and CYP2C9 *2 allele. Based on these findings we decided to use clopidogrel 75 mg - aspirin 300 mg per day combination. Warfarin resistance is a rare clinical problem which can be caused by genetic or acquired causes. Although our patient had VKORC1 1173CC genotype which requires higher warfarin dose, he also had CYP2C9 *2 variant which is associated with lower warfarin dose. We suggested that oxcarbamazepine-warfarin metabolism interaction which may be via VKORC1 1173CC mutation can cause a continuous decrease in warfarin's ability to suppress vitamin K epoxide reductase enzyme in our patient.

1249

HIGH LEVELS OF SOLUBLE IL2R AND PDL1 EXPRESSION MAY INHIBIT ANTITUMOR IMMUNITY IN CHRONIC MYELOID LEUKEMIA

H. Christiansson,[1] C. Lindqvist,[2] T. Tötterman,[2] B. Simonsson,[3] U. Olsson-Strömberg,[3] A. Loskog[2]

[1]Uppsala University, UPPSALA; [2]Clinical Immunology Division, UPPSALA UNIVERSITY, UPPSALA; [3]Division of Hematology, UPPSALA UNIVERSITYHOSPITAL, UPPSALA, Sweden

Background. Cancer patients are known to exhibit immune escape mechanisms that complicate the development and use of immunotherapy in these patients. For example, many solid tumors are infiltrated by suppressor cells. These cells effectively inhibit tumor immunity by direct contact and the release of immune modulators such as TGFβ and IL10. Many tumors exhibit immunomodulatory function including release of suppressive cytokines. Lately, the expression of Programmed Death receptor Ligand 1 (PDL1) on tumors has been linked to escape from tumor immunity. The increased presence of suppressor cells and other immune escape mechanisms have been reported to include hematological cancers as well although little is known about their role in chronic myeloid leukemia (CML). Aims The aim of the project was to investigate the immunological profile exerted by tumor cells in CML patients. *Design and Methods*. Blood from CML patients (n=15) and healthy controls (HC, n=22) was evaluated for the presence of T regulatory cells, PDL1 expression on CD34+ cells using flow cytometry and cytokines by the use of ELISA and cytometric bead array. Results Our results demonstrate that CML patients only have a minor increase of Treg cells compared to healthy controls. However, the level of Treg cell-associated molecules such as soluble IL2R (sCD25) and IL10 in plasma was higher in CML patients than in controls. Five out of 11 evaluated patients had expression of PDL1 ranging from 1-36% of the total $CD34^+$ population demonstrating that this molecule may be involved in controlling tumor immunity in 50% of CML patients. PDL1 expression on bulk tumor cells remains to be investigated. *Conclusions.* Taken together, these results show that CML patients only have a minor increase of Treg cells but tumor immunity may be kept under control by other mechanisms such as high levels of systemic IL2R and IL10 as well as tumor expression of PDL1.

1250

MATURATION STIMULI-DEPENDENT DIFFERENTIAL INDUCTION FROM X-IRRADIATED HUMAN MONOCYTES TO DENDRITIC CELLS

H. Yoshino, K. Takahashi, I. Kashiwakura

Hirosaki University Graduate School of Health Sciences, HIROSAKI, Japan

Background. Dendritic cells (DCs) are a type of antigen-presenting cell which play an essential role in the immune system. Recent immunotherapeutic research has been focused on the use of DCs as potential cellular vaccines against malignant tumors. However, little is known whether the DCs generation is affected after chemotherapy and radiotherapy. In particular, the influence of ionizing radiation remains to be elucidated. Therefore, the current study focused on human peripheral blood monocytes, which are the DC precursors of myeloid DCs, and found that X-irradiated monocytes can differentiate into DCs and then mature after TNF-α stimulation in terms of phenotypic characteristics, while many of their functions such as the matrix metalloproteinase-9 (MMP-9) activity and the ability to stimulate allogeneic T cells are impaired in comparison to controls (*J. Radiat. Res., 49, 2008*). [Aims] Recent reports propose various types of maturation stimuli, including proinflammatory cytokines and pathogen-derived components on processing DCs for immunotherapies. Therefore, the present study investigated whether X-irradiation of monocytes influenced the maturation of DCs in response to specific maturation stimuli. *Design and Methods*. The use of human buffy coats was approved by the Committee of Medical Ethics of Hirosaki University Graduate School of Medicine. Monocytes were separated from the buffy coat and exposed to X-rays at 0, 2, 5 and 10 Gy. To prepare immature DCs (iDCs), irradiated monocytes were cultured in the presence of rhGM-CSF and rhIL-4. To prepare mature DCs (mDCs), iDCs were stimulated by LPS or a stimulus mixture (MIX; [rhTNF-α, IL-1α, IL-6, PGE2]) for 48 hr. The phenotype of the DCs was analyzed by flow cytometry and the MMP-9 activity was assayed by gelatin zymography. Furthermore, intracellular reactive oxygen species (ROS) were measured using 2', 7'-dichlorodihydrofluorescein diacetate. *Results.* When LPS was used as the maturation stimulus, the expression level of the co-stimulatory molecule CD80 and DCs' maturation marker CD83 on the DCs from X-irradiated monocytes was lower than that of the DCs from non-irradiated monocytes. However, no decrease was observed in the DCs stimulated by MIX. When iDCs were stimulated by LPS, the MMP-9 activity in the culture supernatants was impaired in the DCs from the X-irradiated monocytes in comparison to DCs from non-irradiated monocytes. However, in the case of MIX stimulation, MMP-9 activity in the culture supernatants of DCs from X-irradiated monocytes was largely maintained in comparison to non-irradiation. The intracellular ROS is an important mediator of TLR4-mediated signal transduction, which is receptor for LPS. Therefore, the behavior of intracellular ROS after LPS stimulation was measured. As a result, the intracellular ROS level of DCs from X-irradiated monocytes was lower than that from non-irradiated monocytes. *Conclusions*. These results suggest that the influence of X-irradiation on monocytes in the maturation of DCs depends on the type of maturation stimulus, and that MIX stimulation may therefore be preferable to immunotherapy using monocyte-derived DCs after radiotherapy.

1251

POTENT HUMAN MONOCYTE-DERIVED DENDRITIC CELLS (DCS) CAN GENERATE BY MATURATION WITH NATURAL KILLER (NK) CELLS IN THE PRESENCE OF TOLL-LIKE RECEPTOR (TLR) AGONIST

T.N. Pham,[1] C.Y. Hong,[1] B.H. Choi,[1] D.H. Yang,[2] J.S. Ahn,[3] Y.K. Kim,[3] J.H. Nam,[1] I.J. Chung,[2] H.J. Kim,[3] J.J. Lee[2]

[1]Research Center for Cancer Immunotherapy, JEOLLANAMDO; [2]Research Center for Cancer Immunotherapy, Chonnam Natl. Univ. Hwasun Hospital, JEOLLANAMDO; [3]Chonnam National University Hwasun Hospital, JEOLLANAMDO, South-Korea

The interaction between DCs and NK cells can play a key role in inducing the maturation of DCs for subsequent T cells priming *in vivo*. DCs play an additional role in NK cell activation and NK cells are also able to activate DCs leading to maturation. TLRs on the surface of immature DCs (imDCs) and NK cells induce the maturation and activation of these cells. We investigated what kind way of culture condition *in vitro* was more effective for generation of potent mature DCs by activate these DCs with activated or inactivated NK cells. Immature DCs differentiated form monocytes ($CD14^+$ cells) of healthy donor was maturated by coculturing directly or indirectly with NK cells that were activated with various cytokine combination. Direct contact between imma-

ture DCs and NK cells showed more potent DCs, based on the higher expression of several molecules and more IL-12 production, than indirect culture using filter membrane. Immature DCs stimulated with NK cells in the presence of cytokine could induce more potent DCs than those stimulated with activated NK cells that were previously activated with cytokines. Among the various combination of cytokines, the stimulation of IL-2, poly I:C (TLR 3 agonist) and IFN-α was the most useful combination to induce potent DCs, in terms of phenotypic expression on DCs, production of IL-12p40 and IL-12p70 by DCs, IFN-α production by NK cells, allogeneic T cell stimulatory capacities, and CTL assay using IFN-α ELISPOT assay with standard chromium release or DNA fragmentation assay, and recently new CD38 molecule expression on DCs. These studies suggest that potent DCs differentiated from human monocytes can generate by the direct contact culture between human monocytes-derived DCs and NK cells in the presence of combination of IL-2, TLR 3 agonist and IFN-α.

1252

THE STUDY ON THE POTENCY TEST FOR HUMAN IMMUNOGLOBULIN PREPARATIONS

P.S. Kim, H.J. Oh, S.N. Kim, Y.L. Kim, N.R. Lee, K.S. Kim, J.H. Kim, M.J. Cho, J.A. Kim, H.J. Kim, J.S. Seo, S.Y. Kang

Korea Food and Administration, SOEUL, South-Korea

Backgrounds. Immunoglobulin manufactured by using normal plasma currently applies the anti-measles assay using the cell culture as lot release potency test in Korea. It is difficult to obtain the international reference standard (NIBSC 97/648, 3rd) for the anti-measles because of limited quantity. The European Pharmacopoeia is already adopted the anti-HBs assay. This is why the demands for improving or substituting the test method instead of the anti-measles assay. *Aims*. Through this study, first, it makes the domestic manufacturers reduce the dependence of the international reference standard for the anti-measles assay. Second, the national standard (KFDA 08/026) for the potency test of Human Hepatitis B Immunoglobulin can be utilized for the anti-HBs assay instead of the anti-measles assay. *Design and Methods*. In order to introduce the anti-HBs assay for Human Immunoglobulin preparations, the collaborative study was performed with four research laboratories including Korea Food and Drug Administration (KFDA) and 3 manufactures. We investigated to examine the validity for the introduction of the anti-HBs assay, to validate the test method, and to establish the specification. In preliminary examination, each laboratory performed tests two times, once a day, duplicate per one test in order to decide the dilution range. In main examination, the anti-HBs assay was performed three times, once a day, duplicate per one test, with 18 lots of pooled plasma, 10 lots of Human Normal Immunoglobulin, and 20 lots of Human Normal Immunoglobulin in Maltose (pH 4.25), respectively. *Results.* he anti-measles assay is set up in South Korea, Japan, and the United States (anti-diphtheria and anti-polio are also used in the US), and the anti-HBs assay is set up in Europe, Australia, and England. As a result of the anti-HBs assay, it is found that the anti-HBs titer is 0.343±0.093 IU/mL in pooled plasma, 4.731±0.687 IU/mL in Human Normal Immunoglobulin, and 2.363±0.722 IU/mL in Human Normal Immunoglobulin in Maltose (pH 4.25), respectively. *Conclusions*. Based on this study, the draft specification of the anti-HBs assay is established, and the potency is different depending on the source (domestic or import) and the type (pheresis or recovered) of plasma. Compared to the specification in Europe and England, it is over 32 times higher in Human Normal Immunoglobulin and over 7 times higher in Human Normal Immunoglobulin in Maltose (pH 4.25). In conclusion, for the potency test in Human Immunoglobulin preparations, it is suggested that the anti-HBs assay can be used as a potency test instead of the anti-measles assay in Korea. It is also expected that the anti-HBs assay is more reproducible than the anti-measles assay and that the national lot release test and the quality control of the manufacturer are internationally harmonized.

1253

HAPLOTYPE ANALYSIS OF β THALASSEMIA PATIENTS IN WESTERN IRAN

Z. Rahimi, H. Mozafari

Kermanshah University of Medical Sciences, KERMANSHAH, Iran

Background and Aims. β-thalassemia (β-thal) is the most common single gene disorder in Iran. The aim of present study was to find the haplotype background of β thalassemia mutations in Western Iran. Patients and *Design and Methods*. We studied β-globin gene cluster haplotypes in 314 β-thal and 70 βA chromosomes with a Kurd ethnic background from the province of Kermanshah, Iran using PCR-RFLP. β-thal mutations were analyzed using PCR-ARMS, RFLP and direct genomic sequencing. Haplotypes were constructed by analyzing the pattern of seven restriction sites through the β-globin gene cluster. *Results*. Haplotype I was the most prevalent haplotype (35.7%) among β-thal chromosomes followed by haplotype III (28.6%). βA chromosomes similar to β-thal chromosomes were linked to diverse haplotypes but predominantly with haplotype I (42.9%). The predominant IVSII-1 (G'A) mutation in this population (33%) was strongly linked to haplotype III (66.1%) but was also found on chromosomes with haplotypes I, II, V, X and atypical. The second prevalent mutation was CD8/9 +G (13.5%) and showed a strong association with haplotype I (96.4%) and a weak association with haplotype V (3.6%). Haplotype background for Kurdish mutations among our studied population was similar to those among Kurdish Jews and people of Kurdistan of Iran. *Conclusions*. Identification of the most common mutations on different haplotype backgrounds can be explained by a variety of gene conversion and recombination events.

1254

A NEW INDEX FOR DISCRIMINATION BETWEEN IRON DEFICIENCY ANEMIA AND β-THALASSEMIA MINOR: RESULTS IN 284 PATIENTS

M.A. Ehsani,[1] F. Seighali,[2] E. Shahgholi,[1] A. Rashidi[1]

[1]Tehran Universty of Medical Sciences, TEHRAN, Iran; [2]Research Department,IBTO, TEHRAN, Iran

Discrimination between β-thalassemia trait (β-TT) and iron deficiency anemia (IDA), the two most common causes of microcytic hypochromic anemias, is important. We recently proposed an easily calculable index, MCV - (10 - RBC), for this purpose, and studies have started to evaluate this index. We report our results in 284 carefully selected patients (130 patients with IDA and 154 with β-TT). Sensitivity, specificity and Youden's index were compared between the proposed index and four other indices, namely England-Fraser, Mentzer, Srivastava and RBC count. The new index correctly identified 263 (92.96%) patients, standing inferior only to Mentzer which correctly diagnosed 269 (94.71%) patients. The best discrimination index according to Youden's criteria was Mentzer (Youden's index = 90.1) followed by the new index (Youden's index = 85.5). Larger studies are needed to confirm the results obtained in the present study.

Table.

	IDA (n = 130)	β-TT (n = 154)	Total number of correctly diagnosed patients (n = 284)	Percentage correctly diagnosed (%)
England-Fraser IDA > 0 β-TT < 0	129 1	47 107	236 (129 + 47)	83.09
Mentzer IDA > 13 β-TT < 13	122 8	7 147	269 (122 +147)	94.71
Srivastava IDA > 3.8 β-TT < 3.8	115 15	22 132	247 (115 + 132)	86.97
RBC count (×106) IDA < 5 β-TT > 5	112 18	3 151	263 (112 + 151)	92.61
New index IDA > 15 β-TT < 15	117 13	7 147	264 (117 + 147)	92.96

1255

PHENOTYPIC AND FUNCTIONAL STUDIES OF NATURAL KILLER (NK) CELL SUBSETS IN β-THALASSEMIA MAJOR PATIENTS

B. Atasever,[1] S. Erdem Kuruca,[2] Z. Karakas,[3] B. Erman,[4] A. Ergen,[5] T. Isbir,[5] G. Gunal[4]

[1]Istanbul University, Istanbul Faculty of Medicine, ISTANBUL, Turkey; [2]Istanbul University, Istanbul Faculty of Medicine, Physiology, ISTANBUL, Turkey; [3]Istanbul University, Istanbul Faculty of Medicine, Pediatrics Department, ISTANBUL, Turkey4Sabanci University, Biological Sciences & Bioengineering Program, ISTANBUL, Turkey; [5]Istanbul University, Institute of Experimental Medicine, Molecular Medicine, ISTANBUL, Turkey

Background, β-thalassemia major are hereditary disease that character-

ized by absence of β-globin chain production. In most patients, multiple blood transfusions and iron overload can induce to immunomodifications in lymphocyte subsets and cytokine levels. NK cells are lymphocyte subpopulations that are important effectors of innate immune responses against infectious pathogens and tumor cells. The cytotoxic activity of NK cells is regulated by positive and negative signals from multiple receptors expressed on their cell surface and cytokines that are secreted from immune cells. *Aims*. The aim of this study was to evaluate factors influencing NK activity in β-thalassemia major patients. *Design and Methods*. This study was carried out to investigate details NK cell function of 27 patients with β-thalassemia and 18 controls. The mean age of patients and controls was 18,48±7,59 and 19,38±4,79, respectively. The female: male ratio was 2:1 for both patients and controls.We analyzed their cytolytic function against K562 cells in both pure NK cells and PBMC. Before and after the experiment, CD16, NKp30, NKp44, NKG2D receptors are examined in $CD56^{dim}$, $CD56^{bright}$ subsets by flow cytometry. The supernatants of NK cells inside PBMC were collected before and after induced K562 and were measured IL2, IL12, IFNγ, TNFα IL10, IL15, TGF-β1 levels by ELISA. *Results*. We observed that β-thalassaemia patients had lower activities of pure NK cells and inside PBMC than controls. While CD16 of $CD56^{dim}$ NK subsets in PMNC was significantly increased in controls after experiment on the contrary it was increased in CD56bright subset of β-thalassemia patients but was not changed in pure NK cells. These differences were lower in β-thalassemia patients than controls. NKG2D receptor was not changed in both groups. While NKp30 receptor of $CD56^{dim}$ subset in pure NK and inside PBMC was decreased in controls after experiment it was only decreased in pure NK cells of β-thalassemia patients and this difference was low compare with controls. NKp44 receptor of $CD56^{bright}$ subset in pure NK cells was significantly increased in β-thalassemia patients after experiment and it was not changed in controls however it was higher than patients as significantly. IL2, IL12, IFNγ, TNFaα levels were not changed but IL10, IL15, TGF- β1 levels were significantly high in patients compare to controls. *Conclusions*. These findings demonstrate that environmental factors such as ineffective cytokine production and defective function of monocytes and NK cells, may cause low NK activity in beta-thalassaemia patients.

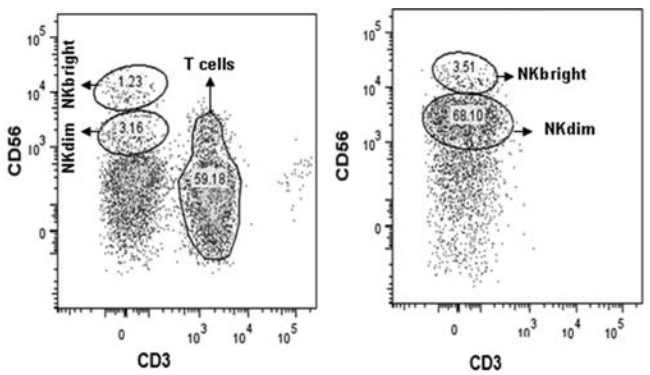


Figure 1. NK subsets in both pure NK cells and PBMC.

1256

PARTICULAR MANIFESTATIONS OF COBALAMINE DEFICIENCY: RETROSPECTIVE ANALYSIS

M. Bradai,[1] S.A. Lahachi,[2] R. Bachircherif,[1] L. Bendali[1]

[1]Institue of Medicine, BLIDA, Algeria; [2]Institute of Medicine, BLIDA, Algeria

Background. Anemia is the common manifestation of cobalamine (Cob)/vit B12 deficiency. However neuropsychiatric disturbance, thrombotic events, gonodal dysfunction may occur as the main or sole symptom in the absence of hematological manifestation. Aims: we analyzed retrospectively patients who were diagnosed in our center with the aim to determine the incidence atypical or no classic presentation of Cbl deficiency and to describe clinical manifestation and their evolution. *Patients and methods*. From 1994 to December 2008,575 were diagnosed, 340 M and 225 F, mean age 57±23 years. Diagnosis was suspected on abnormalities of blood numeration, as decrease of hemoglobin (Hb) and/or macrocytis, megaloblastosis at the myologram and confirmed by low B12 level and/or therapeutic test (IM injection of 1 micg B12, 3days, expect bust of reticulocytes). Homocystemia performed only in some patients. *Results*. among 575 patients, 47 had middle amemia (Hb>10 g /dL) and 13 without anemia (HB>12 g/dL) (2.3%). Forty five (8%) studied had atypical manifestations and hospitalized in neuropsychiatric, cardiologic ophthalmology department. Nine revealed by thrombotic events, peripheral vein thrombosis(3), ischemic stroke(1), myocardial infarction(1), central vein retina thrombosis (CVRT) (1), large vessel thrombosis (1), sever retinopathy in 2 sibling with congenital transcobalamine (TC II) deficiency, mean Hb was 7,6 g/dl(6,1'11,7). Ten patients oriented from neurology for severe peripheral neuropathy with combined degeneration of spinal cord, 4 of them had inadequate intake of folate or B12, average Hb 9(7,1'13,1). We reported 10 cases of young patients (mean age 43 years, 8M/2F), who presented psychotic symptoms: cognitive impairment (4), schizophrenia (2), depression (2), dementia (1), anemia was severe in those patients, Hb 4,4(3,9'5,6). In 3 women diagnosis was oriented by checkup of sterility (2 primary 1 secondary) mean Hb 10 g/dL. Atypical hematological expression reported in 11 patients with severe pancytopenia (Hb:4,3, WBC: 1300/μL, Platelet:19000), and in 3 others had hemolytic expression (enlarged splenomegaly). Biermer's disease was confirmed in 13 patients. All patients received parenteral B12 supplementation; 2 deaths (1 pulmonary embolism, 1 cardiogenic shock), 8 had partially reversible neuropsychiatric manifestations, 1acute blindness after CVRT. Newborn obtained only in 1 patient despite appropriate B12 supplementation. One patient died from gastric carcinoma. *Conclusions*. B12 deficiency can be revealed or complicated by various non hematological events, with risk of mortality and definitive sequels.

1257

REFRACTORY IDIOPATHIC PURE RED CELL APLASIA (PRCA) DARBEPOETIN DEPENDENT SUCCESSFULLY TREATED WITH ALEMTUZUMAB

M.J. Sayas, P. Ribas, R. Andreu, M.L. Juan, A. Tolosa, M. Pedreno, N. Yague, M.J. Cejalvo, P. eon, S. Ferrer, F.J. Rafecas

Hospital Universitario Dr. Peset, VALENCIA, Spain

Idiopathic PRCA is a rare immune mediated haematological disease with unpredictable reponse to conventional therapy. Alemtuzumab has been shown to be effective in this condition although the experience is very limited. We report a woman wih refractory idiopathic PRCA darbepoetin dependent successfully treated with alemtuzumab. A 33 year old woman presented with PRCA in 2003. Exhaustive study of underlying causes including PCR for TCRγ gene rearrangement was negative. The patient was treated with prednisone without response and she required 2 units of red blood cells monthly with mean Hb 5-6 g/dl prior to transfusion. She received treatment with cyclosporine and antithymocyte globulin simultaneously with subcutaneus moderate-high doses of β epoetin without response. In 2005 a second course of ATG was administered and β epoetin was changed by darbepoetin with effective response but with recurrence of severe anaemia when tapering it, requiring the patient continuous every two weeks subcutaneous darbepoetin administration to mantain Hb about 10 g/dl. In June 2006 she received rituximab (375 mg/m^2 weekly x4) but darbepoetin coudn´t be discontinued. In April 2008 subcutaneous alemtuzumab was administered, to a total dose of 230 mg, and darbepoetin was given up with stable complete remission. In this patient the PRCA was not induced by erythropoiesis-stimulating agents, in contrast she had a very good reponse to subcutaneous darbepoetin. But in spite of inmunosuppressive treatments she became darbepoetin dependent and finally, after being treated with alentuzumab the darbepoetin could be discontinued. We conclude that alentuzumab is an effective treatment for PRCA and, should be considered as an option to treat refractoy patients.

1258

SIGNIFICANCE OF SERUM LEVELS OF LEPTIN IN PATIENTS WITH β THALASSEMIA INTERMEDIA AND SICKLE CELL ANEMIA. CORRELATION WITH BODY MASS INDEX (BMI) AND IRON METABOLISM

G. Sortino, M.P. Azzaro, S. Toscano, A. Privitera, E. Fichera

Ospedale Ferrarotto, CATANIA, Italy

The leptin is a protein of 167 amino acids transcribed by the gene 'ob' located on chromosome 7q31.It is a hormone produced by adipocytes. This protein acts as a signal molecule in the hypothalamus producing variable effects on appetite, on energy expenditure and on neuroendocrine axes. These different metabolic effects involve specif-

ic receptors located on the central nervous system and on the peripheral tissues. Such receptors belong to Class I cytokine receptors, to interferon receptor and to growth hormone receptor. Leptin receptors, expressed in the hypothalamus, have been recently identified. The leptin is able to overcome the blood-brain barrier through a saturable transport system. It was reported that the leptin-deficient mice have a complex phenotype including hypogonadism, delayed sexual maturity, and infertility due to the lack of hypothalamus-pituitary hormones. The exogenous administration of leptin will allow the recovery of reproduction. Experimental studies have shown that iron is well represented in adipocytes of the subcutaneous tissue and that iron ions can inhibit the activity of adipocytes. Based on this background, we conducted the research on the serum levels of leptin and correlates it with body-mass index (BMI) and iron metabolism in patients with β-thalassemia intermedia and sickle cell anemia (HbS) in order to verify whether it can occur a dysfunction of adipose tissue as a further endocrine disease. Our results demonstrate that even in patients with β-Th intermedia, serum levels of leptin are lower compared to healthy subjects as control. The mild high level of serum iron and the moderate iron overload present in patients with -Th-intermedia, all under regular transfusion and iron chelation therapy, are the major determinants of reduced leptinemia for altered activity of the adipocytes in the subcutaneous tissue and bone marrow mediate by iron ions. With regard to the BMI, we do not found changes in patients with β-Th-intermedia as compared to control groups. The male patients with β-Th intermedia show leptinemia values markedly reduced when compared to those of women with β-Th-intermedia and even more compared to healthy subjects with the same BMI. This finding confirms the data reported in the literature that serum concentrations of leptin are higher in women than men for the same BMI, percentage of body fat and age. It has in fact demonstrated *in vivo* the ability of estrogen, to increase the production of leptin, unlike testosterone, which inhibits the gene expression and the secretion of the adipose tissue. The increase in iron serum level and ferritin even if mild in patients with β-Th-intermedia would be involved in reduced secretion of leptin by the adipocyte for the inhibitory effect of iron ions on the activity of the adipocytes. Finally considering the endocrine mechanism of action of leptin, the present study on the levels of circulating leptin in patients with β-Th intermediate and βTh/HbS, shows that even a disfunction in the adipose tissue occur, as further endocrine disease, in these congenic hemolytic anemias.

1259

NATURAL KILLER ACTIVITY AND EFFECT OF IL-2 IN PATIENTS WITH β-THALASSEMIA MAJOR

Z. Karakas,[1] B. Atasever,[2] S. Erdem Kuruca,[2] B. Erman,[3] A. Ergen,[4] T. Isbir4, L. Agaoglu[5]

[1]Istanbul University, School of Medicine, ISTANBUL; [2]Istanbul University, School of Medicine, Department of Physiology, ISTANBUL; [3]Sabanci University, Biological Sciences & Bioengineering Program, ISTANBUL; [4]Istanbul University, The Institute of Experimental Medicine, Molecular Medicine, ISTANBUL; [5]Istanbul University, School of Medicine, Pediatrics,Hematology/Oncology, ISTANBUL, Turkey

Background. A depressed level of natural killer (NK) activity is one of the various immunological abnormalities in patients with thalassemia major. NK cells play role in controlling infections and malignancy. Defective NK cell functions can be partially restored *in vitro* by interleukin IL-2. *Aim*. Aims of this study evaluate which factors effect on NK cytotoxicity and modulation of the defective natural killer activity. *Patients and Design and Methods*. The study includes 26 patients with thalassemia major (TM) with age ranged 7-35 (median age was 18, 17 of them were female and 9 male), and sex and and age matched 16 normal healthy subjects as controls. Fourteen of the patients were splenectomized. Patients regulary chelated with deferasirox (n:16), deferipron (n: 8) and desferroxamin (n: 2). NK cells were isolated from PBMC of subjects by using RosetteSep. The cytotoxic activity of NK cells and IL2-activated Killer cells was assessed by 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay. We analyzed their cytolytic function against K562 cells. *Results*. NK cytotoxicity was found to be lower in patients with thalassemia major ($p<0.015$) when compared to controls. We have previously shown that thalassemia children have had decreased NK cells. Patients with above 18 years old had significantly lower NK activity than below 18 years old. Sex, presence of splenectomy and chelation type did not effect on NK activity (p>0.05). NK cytotoxicity significantly increased by IL-2 stimulation in 26 patients ($p<0.001$). *Conclusions*. Lymphokine activated killer cells activity was significantly higher in the patients. According to these results, IL-2 may have potential therapeutic effect to improve the defective NK activity in patients with thalassaemia major patients.

This study was supported by Istanbul University Research Fund.

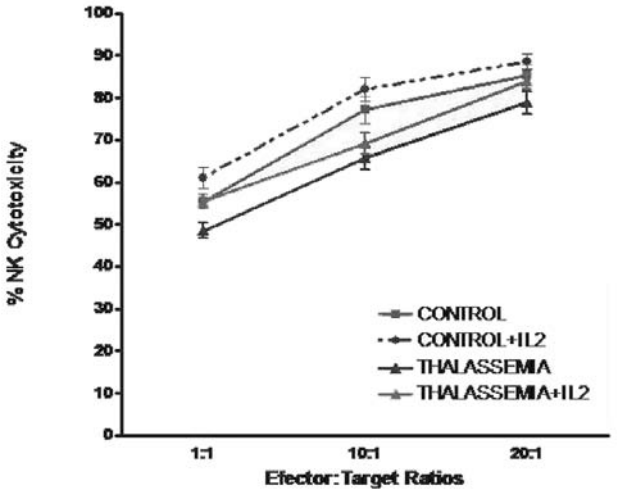

Figure 1. IL2-activated NK cells activity in TM patients

SUCCESSFUL TREATMENT WITH THE COMPLEMENT INHIBITOR ECULIZUMAB OF PAROXYSMAL NOCTURNAL HEMOGLOBINURIA (PNH)-ASSOCIATED BUDD-CHIARI SYNDROME

A. De Vivo,[1] C. Clissa,[1] C. Finelli,[1] M. Arpinati,[1] M.C. Morelli,[2] P. Ricci,[1] M. Baccarani[1]

[1]Institute of Hematology Seràgnoli, BOLOGNA; [2]Department of Internal Medicine and Gastroenterology, University of Bologna, BOLOGNA, Italy

Background. Paroxysmal nocturnal hemoglobinuria (PNH) is an acquired clonal disease caused by a mutation of the X-chromosome gene PIG-A, characterized by severe hemolytic anemia, peripheral blood cytopenia and an an increased risk of severe venous thrombosis, particularly in cerebral, hepatic, portal, mesenteric, splenic and renal veins. Budd-Chiari syndrome, a condition characterized by intrahepatic vein thrombosis with pronounced ascites and hepatomegaly, is one of the most serious and life-threatening thrombotic complications caused by PNH. Budd- Chiari syndrome can be treated by medical (thrombolysis, anticoagulation) and surgical (angioplasty, shunting) therapy, and may require liver transplantation (LT) in refractory cases, but thrombosis may recur after LT, especially if the underlying predisposing condition (PNH) is still active. Eculizumab, an anti-complement antibody targeting the C5 complement component, has proven effective not only in counteracting intravascular hemolysis, but also in preventing thrombotic complications. *Aims*. On the basis of these data, we administered eculizumab to a PNH patient with persistent symptoms of portal hypertension, caused by a previous Budd-Chiari syndrome, and with transfusion-dependent anemia. *Design and Methods*. The patient, a 40 yr-old male, was affected by PNH since 1995, and was receiving packed red cell transfusions (2-4 units/month) since 1999, because of severe hemolytic anemia, refractory to medical treatment (iron, folic acid and erythropoietin). On december 2007 he was admitted to hospital because of right upper quadrant abdominal pain, ascites and hepatomegaly: a diagnosis of Budd-Chiari syndrome was made, on the basis of Doppler ultrasound (US) and computer tomography scan of the abdomen, showing thrombosis of the hepatic veins (right, median and left), and enlargement of left and caudate lobe and splenomegaly. He was treated with anticoagulation, and came to our observation on February 2008. At that time persistent clinical signs ad symptoms of portal hypertension were present, in association with severe transfusion-dependent hemolytic anemia. Blood laboratory data were: hemoglobin (Hb): 8.8 g/dL (transfused), leukocytes: $6.5x10^9$/L, platelets: $164x10^9$/L, total bilirubin: 9.4 mg/dL, conjugated bilirubin: 5.0 mg/dL, LDH: 6.000 U/L, PNH clone (granulocytes): 84%.

Eculizumab treatment was started on april 2008, following the approved dosing schedule: 600 mg every week for the 1st 4 weeks, followed 1 week later by 900 mg, and then by a maintenance dose of 900 mg every 2 weeks. *Results*. Immediately after the 1st dose of therapy the patient experienced a brisk improvement of well-being and a decrease of urine hyperpigmentation and of LDH level (1130 U/L after 2 weeks, 443 U/L on January 2009). The transfusional need progressively decreased, and on july 2008 completely ceased. On may 2008 Doppler US documented a complete resolution of ascites and full restoration of previously impaired hepatic veins (median, left and right) flux. The patient is still maintaining a satisfactory clinical condition, under eculizumab therapy. *Conclusions*. To our knowledge, a complete recovery (clinical and echografic) of PNH-associated Budd-Chiari syndrome after eculizumab has not been reported previously. Successful treatment of PNH with eculizumab may therefore be followed by resolution of late consequences of this dangerous thrombotic complication.

1261

SUCCESFUL RESPONSE TO AUTOLOGOUS STEM CELL TRANSPLANTATION IN A PATIENT AFFECTED BY PRIMARY ACQUIRED PURE RED CELL APLASIA

M. Romero, J. Martinez, J. de la Rubia, M. Sanz

Hospital la Fe, VALENCIA, Spain

Background. Primary Acquired Pure Red Cell Aplasia (PAPRCA) is a rare disease characterized by anemia, reticulocytopenia and erythroid aplasia in bone marrow. This disease seems to be mediated by an inmunological mechanism. Thus, inmunosuppressive therapy has been widely used and generally induces hematologic responses. Despite this, about 30% of patients relapse and almost 25% are refractory. For these patients, allogenic stem cell transplantation has been ocassionally reported with some succes, but this treatment approach is associated with considerable morbidity and mortality. Interestingly, autologous stem cell transplantation (ASCT) has been reported in the literature in six cases, with succesful and durable response in only one case. *Aims*. Our objective is to report a case of PAPRCA refractory to different lines of inmunosuppressive/cytotoxic therapies who achieve a success and durable hematologic response after ASCT. *Design and Methods*. A 32-year old man, black race, was diagnosed as having PAPRCA in July 2006. At diagnosis, the hemoglobin was 7.3 g/dL; hematocrit 21.2%, reticulocytes 0.34%. Platelet and white blood cell counts were in normal range. The initial aproach was transfussion support with Red Blood Cell (RBC) units and inmunosuppressive therapy with high dose steroids. Different therapies were applied, including cyclosporine A, cyclophosphamide, azathioprine, anti-CD20 monoclonal antibody and anti-interleukin2 receptor antibody (Daclizumab). Other treatments used were danazol, subcutaneous erythropoietin and intravenous inmunoglobulins. Besides all of that, the patient did not reach hematological response and became transfussion dependent (two units of RBC every two weeks). Oral quelation therapy was started. There was no HLA-matched related donor available and ASCT was decided. Peripheral blood stem cell mobilization was acomplished with subcutaneous granulocyte-colony stimulating factor (10 ug/kg/day, 5 days). $CD34^+$ cells collected were $5.2x10^6$/Kg. Conditioning regimen consisted of intravenous cyclophosphamide 50 mg/Kg/day (days -6 through -3) and intravenous rabbit tymoglobulin 6 mg/kg/day (days -5 through -3). Complications post-ASCT were: grade 1 oral mucositis, asymptomatic synus bradicardia and one non-neutropenic febrile episode. Time to reach an ANC of 500 cells/mm3 was 11 days. Before ASCT106 RBC units were transfussed. After transplant procedure, patient only received four RBC units, all of them during the first two weeks post-ASCT. Since day +38, hematological response was observed and it is maintened and durable during 10 months of follow up. Last complete blood cells count is: hemoglobin 14 g/dL, reticulocytes 1.29%, platelets 162.000/mm^3, white blood cells 6.000/mm^3. *Conclusions*. In this case, ASCT was a feasible and safety procedure in a patient refractory to several inmunosuppressive/cytotoxic therapies. Furthermore, our patient achieved complete and durable (10 months of follow up) hematological response. This case is the second report of a successful result for ASCT in PAPRCA.

GINKGO BILOBA EXTRACT DECREASES TERT-BUTYL HYDROPEROXIDE INDUCED HEMOLYSIS IN GLUCOSE-6-PHOSPHATE DEHYDROGENASE DEFICIENT ERYTHROCYTES

F. Foroughinia,[1] M. Karimi,[2] A. Afrasiabi,[3] J. Imanifard[3]

[1]Thrombosis and Hemostasis Unit, Hematology Research Center, Shiraz, TEHRAN; [2]Thrombosis and Hemostasis Unit, Hematology Research Center, Dept, of Pediatrics, SHIRAZ; [3]Haemostasis and Thrombosis Unit, Haematology Research Center, Shiraz Medical Uni, SHIRAZ, Iran

Background. Glucose-6-phosphate dehydrogenase deficiency (G6PD) is the most common form of enzymopathy of red blood cells that affected more than 400 million people worldwide. G6PD deficient erythrocytes show decreased level of antioxidant capacity, therefore; they are more susceptible to oxidative stress and this predisposes them to chemical induced hemolysis following ingestion of Fava beans and drugs such as antimalarial drugs, antipyretics, and analgesics. Antioxidants play a pivotal role in the prevention of oxidative damage to the erythrocyte membrane. *Aim*. Since the incidence of G6PD deficiency is relatively high in our country, IRAN, and considering to the serious complications of G6PD deficiency and the debate on the curative effect of the investigated antioxidants, in this study, we evaluate the effect of Ginkgo biloba extract (EGb), a potent water-soluble antioxidant. *Design and Methods*. To assess the property of EGb to prevent hemolysis in G6PD deficient erythrocytes, tert-butyl hydroperoxide (t-BHP), an oxidant, was used to induce hemolysis. Different concentrations of EGb (100, 200, 300, 400 µg/mL) were used in this experiment. First, Aliquots of RBC suspensions of known G6PD deficient patients were challenged with t-BHP in the presence and absence of EGb and then the percent of hemolysis were calculated. Results: According to our data, EGb significantly decreased the percent of hemolysis at all investigated concentrations, compared to control group.This makes EGb good candidate for further *in vitro* and *in vivo* studies. *Conclusions*. We propose that EGb may decrease chemical induced hemolysis and the following complications in G6PD deficient patients .EGb exerts its effect through several mechanisms such as its antioxidant property, its increasing effect on poly unsaturated fatty acids (PUFAs), and finally by up regulating heme oxygenase-1 gene expression and activity.

1263

IRON DEFICIENCY ANEMIA AND LATENT IRON DEFICIENCY AMONG YOUNG FEMALE MEDICAL STUDENTS

M. Elhabbash, A. Alwindi, F. Alkhanshoush

Tripoli Medical Center, TRIPOLI, Libya

Background. Iron deficiency anemia has worldwide prevalence. Iron deficiency anemia has 5% prevalence in the world, but in developing countries it is 18% among adult women and 10% in adult men. The serum ferritin level correlate with total body iron stores, thus the serum ferritin is the most accurate laboratory parameter to estimate iron stores. Decreasing serum ferritin levels are regarded to be an important laboratory sign for negative balance although the hemoglobin may remain normal. Aims To study the frequency of Hypoferritinemia and iron deficiency anemia in fifth year female medical student according to eating habits and menstruation cycle. *Design and Methods*. 472 young normal female medical students were in fifth year of Medicine. Stratified random sample (sampling error=0.07) comprised 109 students were included in the study. A full blood count, serum iron concentration, Transferrin saturation and serum ferritin were measured. Iron deficiency anemia was diagnosed if hemoglobin <11.5 g/dL, Ferritin <15 ng/mL and saturation index <16%. Latent iron deficiency have ferritin <15 ng/mL and saturation index <16%. Exclusion criteria were pregnancy and iron therapy before and during study period and history of malabsorbation or congenital anemia. Accordingly 6 students were excluded. *Results*. 103 female students were studied. Mean age was 22.6 years, age range from 21-26 years. Only 41.7% of students were found to have normal ferritin. Iron deficiency anemia diagnosed in (12/103)11.7%. (48/103)46.6% have low ferritin level. Out of these students (21/48) 43.8%have normal saturation index, and 27/48 (56.2%) have low saturation index <16%. *Conclusions*. Iron deficiency anemia is common among female medical students, and latent iron deficiency is more common affecting more than 46% of female medical student.

1264

MYOCARDIAL VELOCITY AND SPEED DATA IN PATIENTS WITH HEMOLYTIC ANEMIA

T. Cetin,[1] O. Baysan,[2] B. Bugan,[2] O. Nevruz,[3] M. Yokusoglu[2]

[1]Gulhane medical faculty, ANKARA, Turkey; [2]Gulhane Medical Faculty Cardiology Dept., ANKARA, Turkey; [3]Gulhane Medical Faculty Hematology Dept., ANKARA, Turkey

Background. Some cardiac complications have been reported in patients with some hemolytic anemias such as thalassemia and sickle cell anemia. Conventional two dimensional and Doppler echocardiography including tissue Doppler imaging have been used for detecting cardiac involvement in hemolytic anemia. However, angle dependency is a main limitation for Doppler-based echocardiographic techniques. Recently, speckle tracking on two-dimensional images has been introduced to clinical use with which myocardial velocities can also be measured without angle dependency. *Aims*. We aimed in this study to determine left ventricular myocardial velocities in apical and short axis views by using relatively new software (QLAB version 6.0) in patients with hemolytic anemia and healthy subjects. *Design and Methods*. Twelve male patients with hemolytic anemia (mean age: 22.3±1.2 years) and twelve healthy male subjects (23.1±1.5 years) were included in the study. Transthoracic echocardiography was performed with an I33 machine equipped with S5-1 transducer (Philips, USA). In addition to short axis images in mitral valve level, we obtained apical four and two chamber images. All recorded images were transferred to DVD media and evaluated with QLAB software (version 6.0) with six segment model in each view. Resulting data including speed and velocity data were exported to a dedicated excel spreadsheet for further analysis. Maximum speed, maximum velocity (radial in all planes) and percent time of these events were calculated. We used SPSS 15.0 for statistical analysis. Continuous data showing normal distribution was compared with Student t test, otherwise, Mann Whitney U test was used. *Results*. Myocardial speed and velocity data are presented in Table 1. The patient group had significantly higher myocardial maximum speed (5.1±1.1 vs 3.8±1.1 cm/sec, $p<0.001$) and radial velocity (4.0±0.8 vs. 2.5±0.2, $p<0.001$) than control subjects at short axis plane. Moreover, maximum speed time percent was significantly lower in the patients compared to the controls at short axis plane (40.6±21.3 vs. 58.9±11.9, $p=0.049$). Conversely, time percent of maximum speed was significantly longer in the patient group than the control group (Table 1). *Conclusions*. Increased myocardial speed and radial velocity in only short axis may reflect altered left ventricular mechanics in patients with hemolytic anemia. We thought that increased time for reaching maximum speed or velocity at short axis plane also points to possible alterations in left ventricular mechanics.

Table 1.

	Maximum Speed (cm/sec)			Maximum Velocity (cm/sec			Maximum speed time percent (%)			Maximum velocity time percent (%)

1265

MALIGNANT LYMPHOMA AND ACUTE LYMPHOBLASTIC LEUKEMIA AFTER APLASTIC ANEMIA: TWO CASE REPORTS AND REVIEW OF JAPANESE LITERATURE. IS IT UNDERESTIMATED?

Y. Suzuki,[1] R. Horie,[1] K. Miyazaki,[1] R. Ishii,[1] T. Katayama,[1] M. Osaka,[1] M. Danbara,[1] T. Yoshida,[1] T. Shichishima,[2] M. Higashihara[1]

[1]Kitasato University, SAGAMIHARA; [2]Fukushima Medical University, FUKUSHIMA, Japan

Background. Aplastic anemia (AA) is characterized by diminished or absent hematopoietic precursors in the bone marrow, most often due to injury to the pluripotent stem cell. There is an appreciable risk of progression to a clonal disorder (myelodysplastic syndrome (MDS), acute myeloid leukemia (AML), following treatment for AA. However; lymphoid clonal diseases like malignant lymphoma (ML) and acute lymphoblastic lymphoma (ALL) are very rare. We have two cases of malignant lymphoma after AA. We've already reported one case (Acta hematologica, in press). *Aim.* We conduct this study to clarify the type of lymphoid clonal disease, cause of the lymphoid malignancy, and duration after AA therapy. *Design and Methods*. We show our two cases. And we conducted literature review by Pubmed and Japanese Centra Revuo Medicina. *Results*. Case1-1: 61 years old Japanese man suffered from Non-Hodgkin's Lymphoma 24 month after Antithymocyteglobulin (ATG) and CyclosporinA (CyA) therapy for AA. Case 1-2(same with 1-1): 66 years old Japanese man developed NHL of left thigh four months after the second ATG/CyA. He needs to take chemotherapy and radiation (RT). Case 2: 67 years old Japanese man developed chronic lymphocytic lymphoma (CLL) twenty years after methyl predonisolone(mPSL) therapy for AA. We also show the result of literature review (Table). Sixteen patients are reported. All B-NHL patients developed lesion in extranodal site (GI tract 3, tonsil 1, skin 1, soft tissue 1). Eight out of sixteen patients had history of using CyA, five cases had history of using ATG, and four cases had history of using mPSL. The median duration until onset of ML and LL from AA treatment was 16(1.5-120) month. *Conclusions*. We speculated about the onset of ML and ALL. 1) Small malignant clone may have existed at the onset of aplastic anemia. 2) Certain virus like EB virus may've been activated by ATG or CyA, and it caused the ML. 3) It was just an accident. As far as we searched, 1) and 2) are suspected to be the main reason of these ML and ALL. Although, they are very rare complication for aplastic anemia, it may be serious and fatal.

Table.

ETIOLOGY OF COBALAMIN DEFICIENCY IN TUNISIANS PATIENTS

A. Belguith, S. Mahjoub, R. Ellouze, H. Baccouche, H. Kallel, Z. Manai, N. Ben Romdhane

Hôpital la Rabta, TUNIS, Tunisia

Background. Vitamin B12 or cobalamin deficiency occurs frequently (> 20%) among elderly people, but it is often unrecognized because the clinical manifestations may be subtle. They are also potentially serious (neuropsychiatric and hematological perspective). Causes of the deficiency include, most frequently, food cobalamin malabsorption syndrome (>60% of all cases), pernicious anemia (20% of all cases), insufficient dietary intake (<5% of all cases) and other malabsorption. Aims: The aim of this work was to establish the etiology of cobalamin B12 deficiency. *Materials*. Data were collected prospectively in 70 Tunisians patients with established cobalamin deficiency. An exhaustive exploration was conducted in this cohort of patients (intrinsic factor and gastric parietal cells antibodies, digestive endoscopy, and dietary intake). *Results*. The median patient age was 52,9 years; 40 patients were women. The most common clinical manifestations were physical asthenia (88, 5%), glossitis (82,8%), neurologic (paresthesia (55,7%), sensory polyneuropathy (21.4%), confusion (7.1%)). Hematologic abnormalities were reported in all patients: anemia (98.5%), leucopenia (40%), thrombopenia (44,3%), and pancytopenia (27.1%). The mean hemoglobin level was 7.13 g/dL and the mean erythrocyte cell volume 111.17 fl. All patients had low serum vitamin B12 levels (<180 pg/mL), and a mean total serum homocysteine level of 65, 74 µmol/l. Intrinsic factor antibodies were detected in 32 patients (45.7%), and gastric parietal cells antibodies in 59 patients (84, 2%). Atrophic gastritis was described in 51/53 patients (96.2%). The etiology of cobalamin deficiency included pernicious anemia in 57 patients (81.4%), Food cobalamin malabsorption in 9 patients (12.8%) and nutritional deficiency in 3 patients (4.3%) and undetermined in one patient (1.4%). Correction of the serum vita-

min B12 levels and hematologic abnormalities was achieved in patients treated with intramuscular cyanocobalamin. *Conclusions*. This study suggests that etiologies of cobalamin deficiency are multiple. They are dominated by pernicious anemia in our patients contrarily to the literature.

1267

COMPLETE HAEMATOLOGICAL RESPONSE AFTER LOW DOSE RITUXIMAB IN A PATIENT WITH REFRACTORY WARM-TYPE AUTOIMMUNE HAEMOLYTIC ANAEMIA

A.P. Peli,[1] M. Malagola,[1] C. Filì,[1] C. Skert,[1] C. Bergonzi,[1] F. Zaja,[2] A.M. Roccaro,[1] D. Russo[1]

[1]Unit of Blood Disease and Cell Therapy, University of Brescia, BRESCIA; [2]Chair and Division of Haematology, Stem Cell Transplantation Unit Carlo Melzi, UDINE, Italy

Background. The use of rituximab administered with the same schedule used for treatment of B-cell non Hodgkin's lymphomas (375 mg/sqm weekly for 4 weeks) has been extended to the management of autoimmune cytopenias, such as the idiopathic thrombocytopenic purpura (ITP), the cold agglutinin disease and the warm-type autoimmune haemolytic anaemia (AIHA). The optimal schedule has not been established yet and standard dose might be an overtreatment. Low dose rituximab (100 mg weekly for 4 weeks) has been recently tested in patients with ITP and in a case with AIHA. In that latter case, a partial response was reported but no further details on degree and duration of response has been described. *Aims*. We report here the effects of low dose rituximab (LD-R) in a patient with relapsed/refractory AIHA. The absence of an underlying lymphoproliferative disease and the purpose to reduce the immunosuppressive effects of rituximab were the reasons of the use of LD-R. *Design and Methods*. LD-R (100 mg weekly for 4 weeks) was administered in a 78-year old man with a long lasting and symptomatic IgG warm-type idiopathic AIHA who was ineligible to splenectomy and resistant to steroids, immunosuppressive agents and high-dose intravenous immunoglobulins. The haematological and laboratory data before rituximab therapy were the following: haemoglobin (Hb) 8,9 g/dl (supported with 4 packed red-cell transfusions in the previous 2 months), lactate dehydrogenase (LDH) 250 U/L, indirect bilirubin 3,8 mg/dl, haptoglobin 0 mg/dL, reticulocyte count 84". According to the criteria reported by D'Arena *et al.*, complete remission (CR) was defined as stable Hb level > 12 g/dL, transfusion independence and absence of clinical and laboratory signs of haemolysis for at least 4 weeks after rituximab treatment, irrespective of direct antiglobulin test positivity. *Results*. CR was rapidly achieved at the 6th week and maintained until the 29th week. After 6 months of CR, AIHA relapsed (Hb 8,3 gr/dL, LDH 170 U/L, indirect bilirubin 2,27 mg/dl, haptoglobin 24 mg/dl and reticulocyte count 35") and a second course of LD-R (100 mg weekly for 4 weeks) was administered. A second CR was documented after 15 weeks and maintained until 24th week. After 6 months from the second course, a maintenance therapy with 100 mg of rituximab every 2 months was started and up to now (17 months from the first course of therapy and 11 months from the second course) the patient is still in CR. A deep B-cell depletion was documented during all the period of the first and second course of treatment but neither infections nor other toxicities were observed. *Conclusions.* Our report suggests that LD-R may induce a CR in refractory/relapsed warm AIHA as well as the standard dose. A new CR can be obtained in case of relapse. In our case, we observed a slower time of response than the one observed during the first course (6th vs 15th week). Considering the efficacy and the good safety profile, LD-R could be tested in a larger series of patients with warm AIHA.

1268

PRODUCTION OF ENDOGENOUS ERYTHROPOIETIN AND EXPRESSION OF RECEPTORS TO ERYTHROPOIETIN AT THE PATIENTS WITH LYMPHOPROLIFERATIVE DISEASES WITH THE ANAEMIC SYNDROM

A. Lyamkina,[1] T. Pospelova,[1] I. Nechunaeva[2]

[1]The State Medical University, NOVOSIBIRSK; [2]City Haematological Centre, NOVOSIBIRSK, Russian Federation

Background. Erythropoietin (EPO) plays a key role in the adaptation of erythropoiesis to metabolic requirements for oxygen. Inadequate production EPO is one of the reasons of development of an anaemia at patients with haemoblastosis and solid tumors. Aims. To investigate level of erythropoietin of blood whey (s-EPO), receptors to EPO on a surface of erythrokariocytes of a bone marrow and to estimate efficiency of use of recombinant erythropoietin (rch-EpO) at patients with lymphoproliferative diseases and anaemia. *Design and Methods*. It is surveyed 109 patients with lymphoproliferative diseases and anaemia (indolent and aggressive lymphomas, Hodgkin,s disease and plural myeloma). Level of serum erythropoietin (s-EPO) was investigated at all patients. Level of an expression of receptors to erythropoietin has been researched on a surface erythropoietin - sensory cells of a bone marrow for 23 persons. *Results*. The average level s-EPO has made 46.8±8,16 mIU/mL at patients with indolent lymphomas. It is reduced (16.8±2.55 mIU/mL) at 24 person (60%). The average level s-EPO has made 36.9±7.97 mIU/mL at patients with aggressive lymphomas. It is decreased (16.4±2,35 mIU/mL) at 31 patients (79.5%). The average level s-EPO has made 30.6±8,07 mIU/mL at patients with Hodgkin,s disease, is reduced (20.9±2.44 mIU/mL) at 14 person (82,3%). The average level s-EPO has made 38.8±12.42 mIU/mL at patients with plural myeloma, is decreased (17.6±3.91 mIU/mL) at 8 patients (61,5%). Thus, EPO production was inadequate at 70,7% of the surveyed patients in all groups of patients. Average quantity of EPO-R-positive (EPO-R +) cells 22.2±4.23% in a bone marrow. Average quantity of erythrokariocytes has made 24.1±4.06% in a bone marrow. Quantity of EPO-R-positive cells (26.4±4.81%) corresponded to quantity of erythrokariocytes in a bone marrow (26.4±4.75%) only at 73,9% of patients. Quantity of EPO-R-positive cells (10.2±3.93%) was much lower than quantity of erythrokariocytes in a bone marrow (17.7±4.26%) at 26.1% of the surveyed patients (p<0.0001). *Conclusions*. Thus, the received data specify a significant role inadequate production of erythropoietin in pathogenesis of anaemias at patients with lymphomas. Reduction expression of receptors to erythropoietin on surface erythroid cells of a bone marrow is one of the reasons of development of anaemia at a part of patients with lymphomas and anaemic syndrome. It can cause resistance of erythrokariocytes a bone marrow to endogenous erythropoietin and inefficiencies of therapy by preparations recombinant human erythropoietin.

1269

ACQUIRED PURE RED CELL APLASIA (APRC) IN CHURG-STRAUSS SYNDROME; REVERSAL WITH CORTICOSTEROID THERAPY.

M.L.A. Balea,[1] S. Tanaseanu,[1] F. Staniceanu,[1] A. Razvan,[1] M.I. Balea[2]

[1]Clinical Hospital Colentina, BUCURESTI; [2]National Institute of Pneumology Marius Nasta, BUCHAREST, Romania

We report a case of 17 years old woman, with known β thalassemia minor evaluated for severe anemia: 5.2 g%. She presented with prolonged febrile syndrome, recurrent Quincke edema, lymph node enlargement, splenomegaly, recurrent dysphonia, papillomatous laryngeal lesions; CT imaging shows alveolar infiltration, mediastinal and abdominal lymph nodes enlargement, normal Thymus and hepatosplenomegaly. Biologically associated to anemia which has the characteristics of β thalassemia we observe low serum iron, neutrophilia, lymphopenia with severely low number of CD 4 lymphocytes, negative HIV serology, thrombocytosis, severe reticulocytopenia (0%); we consider necessary IHC and histopathological examination of the lymph node indicating reagent and HP and IHC examination of papillomatous laryngeal lesions showing granulomatous lesions and perivascular inflammatory infiltrated. The immunologic evaluation results indicate anti pANCA antibody and APL / LA antibody mostly positive, maximal IgE concentration, C1q inhibitor with normal values. The bone morrow was hypercellular, with a small numbers of dysmorphic vacuolated proerythroblasts (1.5%), increased numbers of plasmocytes (18%), aggregated and diffusely scattered, increased granulopoiesis and megakariocytopoiesis. Data presented support the diagnosis of Churg-Strauss syndrome complicated with pure red cell aplasia; It initiates corticosteroid therapy: Solumedrol pulse therapy with 3g spout corticosteroid therapy followed by 60 mg / day; revaluation at 10 and 21 days indicate reticulocytes 15%, correction of anemia, inflammation regression with normal biological VSH, PCR, fibrinogen, disappearance of symptoms. We highlight that before diagnosis the patient had been in the care of infectious diseases, pneumology clinics etc. *Conclusions*. Along with another malignant lymphomas and hematologic malignancies, thymoma, nonhematologic solid tumors, systemic lupus erythematosus, rheumatoid arthritis, infections, intoxication, severe kidney failure, hemolytic anemia we can state that Churg-Strauss syndrome is a potential cause of APRC.

1270

HYDROXYUREA-INDUCED HEMATOLOGICAL RESPONSE IN TRANSFUSION-INDEPENDENT β-THALASSEMIA INTERMEDIA

M.A. Ehsani,[1] F. Seighali,[2] A.A. Hedayati-Asl,[3] E. Shahgholi,[1] R. Rashidi,[1] S. Zeinali[4]

[1]Tehran University of Medical Sciences, TEHRAN, Iran; [2]Research Department,IBTO, TEHRAN, Iran; [3]Baghiatollah University of Medical Sciences, TEHRAN, Iran; [4]Pasteur Institute, TEHRAN, Iran

The efficacy of hydroxyurea (HU) in β-thalassemia intermedia (TI) is unclear. We treated 16 transfusion-independent TI patients (8 males,8 female) aged 10.7±5.0 years with HU, 20 mg/kg/day four days per week, for 6 months. Treatment was well tolerated, there was a significant increase in both Hb and HbF (p<0.001), and the increments were strongly correlated (r=0.94; p<0.001). XmnI polymorphism was not correlated with hematological response. Hb (p=0.026) and HbF (p=0.046) showed a more significant rise in patients with a Fr8/9 allele than those with one or two IVS-II-1 alleles.

Table 1. Hematological response to HU in TI patients.

Study	No.	Response	Comments
Ehsani *et al.*, 2008	16	Hb: rise 1.6 g/dL HbF: rise 1.7 g/dL	- Duration of treatment: 6 months- No correlation between response and Xmnl polymorphism- Fr8/9 allele predicted good response- No correlation between response and age or sex- Hb rise and HbF rise strongly correlated
Koren *et al.*, 2008	7	Hb: rise 2 g/dL	- Mean duration of treatment: 46 months - Xmnl polymorphism predicted good response - No correlation between response and beta mutation
Bradai *et al.*, 2007	9	Hb: rise 3.7 g/dL	- Duration of treatment: 1year- Xmnl polymorphism predicted good response- No correlation between response and beta mutation
Dixit *et al.*, 2005	37	Hb: rise > 2 g/dL in 17 patients; 1-2 g/dL in 9 patients	-No correlation between response and beta mutation - No correlation between response and Xmnl polymorphism - Older age and low baseline HbF predicted poor response
Karimi *et al.*, 2004	16 13	Hb: rise ~1 g/dL HbF: rise ~1.5 g/dL	- Duration of treatment: 1 year
Hoppe *et al.*, 1999	5	Hb: rise 2.2 g/dL HbF: rise 2.6 g/dL	- No correlation between Hb rise and HbF rise

1271

ANAEMIA AND SERUM ERITROPOETIN LEVELS IN THE INFLAMMATORY BOWEL DISEASES

S. Ayaz, S. Yilmaz, S. Aktas

T Yuksek Ihtisas Hospital, ANKARA, Turkey

Background and Aim. In chronic diseases, anaemia is a seriuos problem. Inflammatory bowel disease (IBD) which is involving the gastroentestinal system primarly,is also a . Chronic disease but the etyology is not known yet. In IBD, refracter anaemia affects the prognosis and the quality of patient's life negatively. The main reason of refracter anaemia in chronic inflammation, is the inhibitor effect of proinflammatuar citokines on erythropoetin (EPO) which is a growth hormon, control the erythropoesis. Erythropoesis is a process which is controled by the end point feedback mechanism between hemoglobin and the erythropoetin levels. In this study, as IBD is a chronic inflammatuar ,we searched the reason of chronic anemia in these group of patients and try to examine the role of supressed EPO although there is anaemia. *Material and Method*. 145 patients (55 patients with ulcerative colitis (UC), 51with Crohn's disease (CD) and 39 with gastrointestinal bleeding-GIB) and 16 healty controls were included in the study. UC was diagnosed with clinic findings, endoscopic processes and laboratory findings. Patients and controls both gave permission for the study. 11 gr/dL of hemoglobin level was accepted for the anaemia in women with UC and CD and 12 gr/dl for men. The anaemia in patients were grouped as ıron deficiency and chronic disease anaemia. All the blood sample were taken from brachial vein after 12 hours hungry. Hemogram parameters were studied in automatic blood counters(in coulter LH 750); serum ıron, iron binding capacity and ferritin levels were measured in autoanalizators (Roche System, Germany).Eritropoetin levels were studied with ELSA (Bender Med System,Viana, Australia). *Results*. The reverse corelation between Hb and Log EPO was found in CD with IDA and GIB group. But this corelation was not found in CD with chronic disease anaemia that showed there was no answer for EPO. n groups which UC and CD patients were divided according to the activation and remission, no difference was found in Hb and EPO levels between two groups but high EPO levels were found in CD patients who were in remission. These results showed that when remission was occured ,the inhibitor effect of citokins on EPO was disappered and EPO levels began to raise. When the UC patients were grouped according to the localization of the disease, only reverse correlation between Hb and Log EPO was found in women patients with pancolit . The 85 percent of these women were under 50 years old and during the premenapose period. The 26 percent of this group women was diagnosed as IDA and 13 percent as CDA. *Conclusions.* When the anaemia in patients with IBD was investigated, we found that there was an inhibition on Hb levels which caused the CDA. But ın patients with UC, this result was not seen so more investigations must done on this subject.

1272

INVESTIGATION OF ANEMIA BASED ON MCV AND MCH IN CHILDREN

D. Konstantelos, V. Katsaros, N. Sismanoglou, A. Koulouri, S. Daliani, I. Moutzouris, P. Giannakopoulou

Kalamata general hospital, ATHENS, Greece

Background. Mean Corpuscular Volume (MCV) and Mean Corpuscular Hemoglobin (MCH) constitute useful erythrocytic indices of significant clinical value. MCV and MCH obtained by hematological analyzers therefore are the first step in the investigation of anemia. Based upon MCV and MCH, anemia is divided into micro-, normo- and macrocytic anemia, as well as into hypochromic and normochromic anemia. *Aims*. The aim of the study is to register and investigate children with anemia based on MCV and MCH. *Design and Methods*. Complete Blood Counts (CBCs) of healthy children aged 2-12 that attended our department for regular check up during 2007-2008 were studied. SYSMEX XE-2100 was the hematological analyzer in use, that provided Hemoglobin (Hb), Hematocrit (Hct), MCV and MCH. *Results*. Among 2758 CBCs, 2113 were normal concerning anemia. Hb was higher than 11,5g/dl and Hct was higher than 34-35%. 645 counts were ubnormal, presenting anemia with Hb<11,5g/dl and Hct<34-35%. Among these 645 children with low Hb and Hct, 320 were aged 2-6 years and the remaining 325 were 6-12. In the 2-6 age group 183 children were boys and 137 were girls. Among children with 6-12 years of age 154 were boys and the rest 171 were girls. The frequency of micro-, normo- and macrocytosis as well as normo- and hypochromia according to sex and age are displayed at the table below. *Conclusions*. The classic values given by all hematologic analyzers are useful, easy to obtain and constitute the first step in the algorithm of anemia's investigation. In our study most common type of anemia in 2-12 years old children is hypochromic microcytic anemia, which in Greece is usually due to iron deficiency or Thalassaimia's syndromes. Macrocytic anemia on the grounds of hypothrepsia is extraordinary.

Table.

CHILDREN WITH ANEMIA		2-6 YEARS Hb<11,5g/dl and Hct<34%		6-12 YEARS Hb< 11,5g/dl and Hct<35%	
MCV (fl)	MCH(pg)	MALES	FEMALES	MALES	FEMALES
<80	27-32	14	2	2	1
<80	<27	137	104	130	136
80-100	27-32	20	28	22	35
80-100	<27	9	3	0	0
>100	27-32	3	0	0	0
>100	<27	0	0	0	0

REFLECTION OF HEAMATOCRIT CHANGES TO LIPIDEMIC PROFILE

S. Patiakas,[1] N. Barbantonakis,[2] D. Mitsikaris,[3] M. Tsigaridaki,[4] M. Mountzou,[1] T. Mylonas[1]

[1]General Hospital of Kastoria, THESSALONIKI; [2]General Hospital of Rethymno, RETHYMNO, CRETE; [3]Diagnostic Center Hemotest, THESSALONIKI; [4]General hospital of Rethymno, Crete, RETHYMNO, Greece

Background and Aims. To study the possible variation of the lipidemic profile as a result of heamatocrit and heamoglobin chagnges. *Design and Methods*. We studied 61 patient cases (27 men and 34 women) mean averege age of 71.8±11.2 years, to whom their lipidemic profile was calculated, before and after the correction of heamatocrit. The study included hospitalised patients of our hospital and others in outpatient basis to whom though their initial hematocrit value was measured low (due to prior heamorrage or other past conditions), it was restored to a normal value. It is noted that all the tests for all the patients took place in the same laboratory, -so that the results could be compared-, while the statistical analysis was performed with the SPSS package. *Result*. As you can see at the Table. *Conclusions*. It is therefore proven that, an increse to a patients heamoglobin and heamatocrit, leads to statistically significat raise to most of the lipidemic profile variables, like the value of triglycerides and cholesterol (total, HDL and LDL). Hence, these values should be accounted for only when the blood heamatocrit and heamoglobin are stable. Otherwise, before the "correction" of the patients heamatocrit the measurement is of no clinical value and in contrast might lead to wrongful conclusions.

Table.

PARAMETERS	PERIOD I	PERIOD II	p
Heamatocrit (%)	25,2 +/- 5,5	36,3 +/- 2,8	0,18
Heamoglobin (g/dl)	7,9 +/- 2	10,5 +/- 1,9	0,45
Total Cholesterol (mg/dl)	146 +/- 47	163 +/- 46	0,001
HDL - Cholesterol (mg/dl)	11,8 +/- 7,1	41,5 +/- 10,2	0,001
LDL - Cholesterol (mg/dl)	82 +/- 50	94 +/- 38	0,001
Triglycerides (mg/dl)	110+/- 40	128 +/- 43	0,006

1274

THE CASE OF HEMOPHAGOCYTIC SYNDROME IN 24 YEARS OLD WOMAN

R. Wichary,[1] D. Woszczyk,[1] J. Bojko,[1] G. Krasowski,[1] A. Lange[2]

[1]District Hospital in Opole, BYTOM; [2]Lower Silesian Center For Cell Transplant, WROCLAW, Poland

The hemophagocytic syndrome (hemophagocytic lymphohistiocytosis) is a rare clinical condition included fever, splenomegaly, jaundice and pancytopenia as a sign of hemophagocytosis. This disease while not hereditary is usually followed by viral infections like EBV, HHV6, HHV8, CMV or some tropical diseases and malignancies like T-cell lymphomas. The aim of this paper is to demonstrate a severe case of probably viral infection associated hemophagocytic syndrome in young woman very successfully treated in our hospital. 24-years old woman was admitted to hematological ward in very severe clinical condition with signs of extended haemolytic anemia, jaundice and fever, also with slight hepatosplenomegaly. Initially haemoglobin level was 3.8 g/L, platelets 177 G/L, total bilirubine 51 mg%, ferritine 5987 ng/mL, triglyceride 414 mg% .Other biochemical signs of internal organs damage including liver disfunction with markedly enzymes elevating and transient renal insufficiency with plasma creatinine level up to 2 mg%. In bone marrow aspirate smear we found a signs of hemophagocytosis. Then despite of initial therapy with high dose of steroids (5 times 1g i.v.) clinical status and morphological and biochemical parameters were down to nadir of hemoglobin 2.2 g/L and platelets 9 G/L. Then we introduced immunoglobulins 1 g/kg and therapeutic plasma exchange (TPE) that was made 9 times and further simultaneously rituximab (3 times 600 mg i.v.). In the clinical course there was a severe complication after TPE probably central venous catheter triggered massive bilateral lower extremities deep vein thrombosis successfully treated with e.g. small moleculed heparins which forced us to stop this procedure. After those procedures there was a slight both clinical and biochemical improvement. Then the clinical course was complicated with the splenic abscess that was treated by an urgent splenectomy. After that the therapy was continued by steroids and new introduced mofetile mycofenolate 1500 mg/day and also still keeping an intensive supportive therapy as erythrocyte substitution and some antibiotics and intravenous fluids. In the end our young lady left the hospital after 7 weeks therapy within excellent condition with all normal values of prior extremely disordered parameters shown above. Our patient despite of initial critical clinical status after a long therapy achieves a long lasting complete remission. Present immunosupressive maintenance therapy with methyloprednisolone and mofetile mycofenolate allows to keeping her in perfect clinical condition without signs of disease for already one year from a disease onset. Finally we would like to discuss over used treatment options in this case especially in the situation of lacking the international treatment standards in this rare although difficult to diagnosing and treating clinical syndrome. The open question remains how long we should continue our present maintenace therapy or we have to use some other treatment options like alloBMT considered as a therapy of choice in hereditary hemophagocytic syndrome. We also would like to propose our therapeutic schedule in this case as a standard in severe viral infection associated or unclear origin hemophagocytic syndrome.

1275

STEPS TOWARDS THE DEVELOPMENT OF A SPECIFIC SANDWICH ELISA FOR MEASURING HEPCIDIN IN SERUM

A. Mamalaki, V. Koliaraki

Hellenic Pasteur Institute, ATHENS, Greece

Background. Hepcidin is the key regulator of iron homeostasis in humans and it has been implicated in the pathogenesis of several iron disorders. Therefore, hepcidin quantification in human blood or urine is expected to provide further insight in the pathogenesis of anaemia in various diseases and might also prove to be a valuable tool for its differential diagnosis. Several methods for hepcidin quantification, mostly based on mass spectrometry, have been published, during the past few years and are still undergoing standardization. Our group has also recently reported the development of an immunochemical method for hepcidin quantification in human serum, based on the use of a recombinant hepcidin peptide and a polyclonal antibody against it. This assay had specificity, accuracy, reproducibility and provided biologically significant results. *Aim*. The aim of this study was to provide tools in order to further improve our previously reported quantification technique. For this purpose we developed a sandwich ELISA by using the previously reported polyclonal antibody and a new monoclonal antibody against the recombinant hepcidin peptide. The clinical value of the method is under investigation. *Design and Methods*. The recombinant hepcidin25-His was expressed in yeast P. pastoris, purified by Ni2-NTA affinity and size exclusion chromatography and the isolated monomer was tested for its biological activity (*Koliaraki et al., Biochimie, 2008*). New Zealand white rabbits were immunized subcutaneously with recombinant hepcidin and after three re-immunizations, polyclonal antiserum was obtained and extensively purified by affinity chromatography (*Koliaraki et al., PLoS ONE, 2009*). Furthermore, C57/BL6 mice were also immunized with the recombinant peptide and spleen cells were fused with the sp2/0 myeloma cell line in order to produce anti-hepcidin hybridoma clones. The monoclonal antibody was purified from the culture supernatant by protein-G affinity chromatography. *Result*s. From the fusion selection procedure one clone was finally chosen, which had both high affinity and specificity for the antigen and was also stable during its production. The purified monoclonal antibody was then used, along with the previously described anti-hepcidin polyclonal antibody, for the development of a sandwich ELISA. The optimal concentration of both monoclonal and polyclonal antibodies were determined as well as the analytical characteristics of the sandwich ELISA. The recombinant hepcidin25-His peptide was used for the construction of the calibration curve. First results show that this new method can identify between serums coming from patients with different iron disorders (such as juvenile hemochromatosis and Hodgkin's lymphoma) and healthy volunteers. *Conclusions*. In this study we described the development of a sandwich ELISA for hepcidin quantification in human serum. This ELISA assay displays sufficient accuracy and reproducibility using a minimal amount of serum and therefore is potentially a valuable tool for research and clinical applications.

1276

A NOVEL DELETION IN UDP-GLUCURONOSYLTRANSFERASE GENE IN A PATIENT PRESENTING CRIGLER-NAJJAR SYNDROME TYPE I

C. Elísio,[1] E. Vieira,[2] A.I. Lopes,[3] M.J. Saldanha,[4] D. Brites,[5] R. Dos Santos[2]

[1]Instituto de Ciências da Saúde of Universidade Católica Portuguesa, PORTO; [2]Centro de Genética Médica Dr. Jacinto de Magalhães, INSA, PORTO; [3]Unidade de Gastrenterologia Pediátrica, Hospital de Santa Maria, LISBOA; [4]Unidade de Neonatologia, Hospital de Santa Maria, LISBOA; [5]Faculdade de Farmácia da Universidade de Lisboa, LISBOA, Portugal

Hepatic glucuronidation of bilirubin is catalyzed by isoenzyme 1A1 of uridine 5'-diphosphate-(UDP-) glucuronosyltransferase (UGT1A1), which is essential for its efficient biliary excretion. Genetic alterations causing absence, or severe reduction, of UGT1A1 enzymatic activity result respectively in Crigler-Najjar syndrome (CNS) type I and type II (MIM #218800 and MIM #606785). Diagnosis of CNS type I patients is of major relevance because presently liver transplantation is the sole curative treatment. We report the molecular characterization of a Portuguese patient presenting clinical and biochemical features of CNS type I since the neonatal period. The infant was born at full term after an uneventful pregnancy, by eutocic delivery, from non-consanguineous parents and without family history of jaundice. Serum total bilirubin was 15 mg/dL on the second day of life. The child was exposed to intensive phototherapy on the 15th day, when she presented 28.8 mg/dL of serum total bilirubin levels. At 5 weeks of age, total/conjugated bilirubin in serum was 34.7/0.9 mg/dL. Enzymatic induction by phenobarbital (20 mg/kg followed by daily administration of 5 mg/kg) was inefficient in significantly reducing the serum unconjugated bilirubin concentration. Bile profile of bilirubin species showed 90% of unconjugated bilirubin, 6% of bilirubin monoglucuronide and 4% of bilirubin diglucuronide, supporting the diagnosis of CNS type I. Genetic analysis of the patient and her parents was performed on genomic DNA, isolated from blood samples using standard methods. The three individuals were screened for the TA duplication in the promoter region of UGT1A1 gene. Direct sequencing of the five exons and of the phenobarbital-responsive enhancer sequence (c.-3576 to c.-3209) was also performed. Sequencing of the five exons of the UGT1A1 gene from the patient revealed the presence of a novel 24 bp deletion (c.609_632del) encompassing the first exon. Both parents were found to be carriers, thereby confirming homozygosity in the patient. Screening for the TA duplication in the promoter region of UGT1A1 showed a normal number of repeats in the patient and in her parents. None of the three presented the c.-3279T>G polymorphism in the phenobarbital-responsive enhancer module of UGT1A1 gene, known to be associated with Gilbert syndrome. This novel gross mutation predictably gives rise to an internally deleted polypeptide (p.His203_Lys211delinsGln). Besides its use in antenatal screening and in extending our knowledge of the spectrum of disease variants, the identification of this deletion in exon 1 of the UGT1A1 gene, which is known to encode the substrate specific region of bilirubin-UDP-glucuronosyltransferase, may contribute towards a better understanding of the molecular pathology of the disorders characterized by severe unconjugated hyperbilirubinemia.

1277

CONTRIBUTION OF RED CELL MASS AND UGT1A1 ALLELES IN SERUM BILIRUBIN LEVELS OF THE PORTUGUESE POPULATION

C. Rodrigues,[1] E., Costa,[3] A. Santos-Silva,[3] R. Santos,[4] E. Bronze-da-Rocha[3]

[1]Faculdade de Farmácia Universidade do Porto, PORTO; [2]ICS da Universidade Católica Portuguesa and IBMC - Universidade do Porto, PORTO; [3]IBMC and Faculdade de Farmácia da Universidade do Porto, PORTO; [4]Unidade de Genética Molecular, Centro de Genética Médica Dr. Jacinto de Magalhãe, PORTO, Portugal

Hepatic glucuronization of insoluble bilirubin is catalyzed by isoenzyme 1A1 of UDP-glucuronosyltransferase (UGT1A1), which is essential for efficient biliary excretion of bilirubin. The main cause of Gilbert syndrome (GS) in all populations studied to date is a TA duplication [(TA)7 allele] in the repetitive TATA-box sequence of the gene promoter, which normally consists of six TA repeats. However, this genetic polymorphism is not sufficient for the clinical phenotype of GS. By this reason, some studies have been performed to provide information about additional factors that could contribute to the pathogenesis of this disease. Recently, it was described that increased red cell mass probably plays a role in the pathogenesis of GS (*Buyukasik et al. 2008 Am J Med Sci. 335,115-119*). The aim of this work is to investigate the putative role of increased red cell mass and the (TA)7 allele in bilirubin serum levels, in the Portuguese population. This study was performed in 109 volunteer healthy young adults (20.3±1.9 years) without liver and/or hematological disorders, chronic infection, recent inflammation, malignancy, hemorrhage and medication. Blood samples were collected and processed in order to determine bilirubin serum levels, complete blood cells count, and DNA extraction. The TATA-box region was analyzed by PCR amplification followed by subsequent analysis by automated capillary electrophoresis. Among our population, 6 were homozygous for the (TA)7 allele, 55 were heterozygous and 48 were homozygous for the normal allele. One of the subjects was a compound heterozygous for the (TA)5 and (TA)7 alleles. Comparing the blood cells counts and the bilirubin serum levels according to the UGT1A1 genotype, we found statistically differences only in bilirubin levels [(TA)6/(TA)6: 0.49±0.20 mg/dL; (TA)6/(TA)7: 0.70±0.32 mg/dL; (TA)7/(TA)7: 1.10±0.74 mg/dL, $p<0.05$]. A positive statistically significant correlation ($p<0.05$) were found between bilirubin serum levels and haematocrit and mean cell volume. Our work showed that higher bilirubin serum levels are correlated with an increase red blood mass. However, no association was found between higher red blood mass and abnormal number of TA repeats in the promoter of UGT1A1 gene. This data suggests that in our population the presence of abnormal number of TA repeats in the UGT1A1 gene is associated with increased bilirubin levels but not with higher red blood mass, as previously described for GS patients.

1278

LONG TERM SAFETY AND EFFICACY OF IRON CHELATION WITH DESFERRIOXAMINE(DFO) AND DEFERIPRONE(DFP) IN MULTITRANSFUSED THALLASSAEMICS NINE YEARS EXPERIENCE

S. Fragatou,[1] I. Tsourveloudis,[1] D.T. Tsiapras,[2] M. Fragatou,[3] M.D. Douskou[4]

[1]G.A.H. G.Gennimatas, ATHENS; [2]Onassion Cardiology Center, ATHENS; [3]Dromokaition Mental Hospital, ATHENS; [4]Bioiatriki, ATHENS, Greece

Introduction. Transfusion dependent thalassaemia patients are at risk of developing iron overload leading to serious organ damage and premature death. Optimal chelation therapy can prevent iron accumulation, improves organ function and quality of life resulting in extended survival. Co-administration of two chelators , DFP and DFO, in adequate doses, appears to produce an additive chelating effect and minimize the toxicity of chelators. Objective: Estimation of effectiveness and safety of combination regimen with two chelating agents (DFP and DFO) in severely iron loaded thalassaemia patients with multiorgan complications and the possibility of reversing organ damage, mainly heart and liver, in a nine-year follow-up. *Patients and methods*. We selected 14 multitransfused heavily iron loaded thalassaemics, mean age 32 years, 7 males and 7 females switching from DFO/DFP monotherapy to combined chelation therapy with oral DFP and subcutaneous (sc) DFO. Group I. 4ps with established cardiomyopathy were treated with DFP 75 mg/kg/day and DFO 40 mg/kg x24hours, 6-7 days per week . Group II. 10ps asymptomatic referred to cardiac disease, received DFP 75 mg/kg/day and DFO 40 mg/kg x 24hours, 2 days per week. Four patients, 2 of each group, had medical history of diabetes mellitus type II and another 2p one of each group, HCV-infected, progressed to chronic hepatitis C. Measurements included: White blood cells weekly, compliance estimated by compliance index, biochemical markers (ALT, AST and γ-GT) and serum ferritin monthly. ECHO cardiography focusing on myocardial contractility markers including Fraction Shortening (FS), Left Ventricular Ejection Fraction (LVEF) and End Systolic Diameter (ESD) as well as Heart/Liver iron assessed by Magnetic Resonance Imaging (MRI T2, T2*) were annually performed. *Results*. Compliance with treatment was good (medium to high) and no side-effects were noticed. Overall patients' serum ferritin dramatically decreased ($p<0.0001$) and liver enzymes in non HCV infected patients were reduced and normalized 5 years after beginning of therapy (p: 0.010). Patients with preexisting cardiac dysfunction completely recovered and clinical symptoms improved relatively shortly after initiation of chelation (3 to 4 months). Contractility markers significantly improved (almost normalized after 5-6 years) as well as heart and liver MRI T2 and T2*.In asymptomatic patients with normal LVEF, it improved even more during treatment. Heart T2/T2* and liver T/T2* increased significantly after 4 to 5 years ($p=0.001$ and $p=0.010$ respectively). *Conclusions*. Combined chelation therapy with DFO and DFP is effective and preferred treatment in removing cardiac iron and reversing cardiac damage in severely iron loaded thalassaemic patients without serious side effects. Reduction of liver iron and

improvement of liver function in this cohort of patients, achieved after prolonged treatment, should be attributed to serious liver damage by long-lasting iron deposition while hepatic viruses (HBV, HCV) constitute an additive harmful factor in infected patients.

TREATMENT WITH DEFERASIROX FOR NON-TRANSFUSIONAL IRON OVERLOAD IN PATIENTS WITH THALASSEMIA INTERMEDIA

V. Ladis, H. Berdoussi, A. Kattamis

University of Athens, ATHENS, Greece

Background. Patients with thalassaemia intermedia (TI), though rarely transfused, may develop iron overload. The mechanism of iron loading is similar to that observed in hereditary hemochromatosis, with inappropriately low hepcidin levels due to enhanced erythropoiesis, leading to increase intestinal iron absorption. *Aims*. In this study, we evaluated the efficacy and safety of treatment of iron overload with deferasirox in patients with TI. P*atients and Methods*. Eleven patients (6 male, 5 female, mean age: 31.7 years, age range: 24-40 years) with TI and iron overload were included in this study. Two patients had never been transfused, six had received <3 lifetime transfusions and the rest <20. All patients but one, were splenectomised. Patients were treated with deferasirox for a period of 1 year, while 4 for 1 additional year. Seven patients initiated treatment with 10 mg/kg/day and 4 with 20 mg/kg/day. Dose adjustment was implemented only after completing one year of treatment according to the severity of iron burden. Efficacy of treatment was evaluated with ferritin levels and degree of hepatic and cardiac iron overload, which were estimated by MRI (T2* sequence). Safety parameters included transaminases, creatinine and cystatin C levels. *Results*. Mean, SD and range of the baseline evaluation showed: ferritin: 1356±1039 ng/mL (536-4086 ng/mL), liver iron concentration (LIC): 17.6±9.9 mgFe/g d.w. (2.1-31.8 mgFe/g d.w.), cardiac T2*: 35.6 ms (28.9-40.2ms), and left ventricular ejection fraction (LVEF): 66.7±4.5 ms (59.6-73.2%). Ferritin levels correlated well with LIC (R=0.84, $p<0.005$), but with a different slope that the one observed in transfusion-dependent thalassemic patients. No cardiac siderosis was observed. After 1 year of treatment, only one patient, who was non-compliant, did not show decrease of iron overload. Mean serum ferritin and LIC decreased significantly ($p<0.05$) to 914 ng/mL (range: 127 - 4400 ng/mL) and to 10.7 mgFe/g d.w. (range: 1.2 - 32 ng/mL), respectively. Three patients reached levels of ferritin <250 ng/mL and LIC < 4 mgFe/g d.w. Changes in LIC and ferritin levels were related to deferasirox dose, but even patients with severe iron load, treated with 10 mg/Kg/day responded well. There were no changes in cardiac T2* and in LVEF. Improvement continued on the 2nd year of treatment, but it did not reach statistical significance. Treatment was well tolerated and no serious adverse events were noted. Creatinine and cystatine C levels did not change during the treatment. Significant decrease in transaminases levels was noticed during both the 1st ($p=0.0002$) and the 2nd year of treatment ($p=0.024$). This improvement is probably due to decreased hepatic siderosis. *Conclusions*. Rarely or non-transfused patients with TI can present with significant iron overload, which predominantly affect the liver. Treatment with 10 mg/Kg/day of deferasirox is effective in chelating this iron excess. Dose of 20 mg/Kg/day in severely iron-loaded patients achieves increased iron excretion and is not associated with side affects.

CORRELATION OF BCL11A SNPS AND FETAL HEMOGLOBIN LEVELS IN SICKLE CELL PATIENTS FROM OMAN

V. Pathare1, S. Alkindi,[1] S. Al Farsi,[1] N. Huneini,[1] A. Al Zadjali,[1] L. Misquith,[1] J. Dennison,[1] R. Krishnamoorthy[2]

[1]Sultan Qaboos University, MUSCAT, Oman; [2]INSERM 763, Hopital Robert Debre, PARIS, France

Background. Recently, genetic association studies have shown several single nucleotide polymorphisms(SNPs) that are linked to expression of HbF into adulthood. These SNPs are located in the gene BCL11A on chromosome 2 and HBSIL-MYB on chromosome 6. *Aims.* To assess the BCL11A SNPs associated with high HbF in Sickle cell disease (SCD) patients from Oman. *Design and Methods*. Genomic DNA was isolated using the semi-automated 6100 nucleic acid extractor. Sickle mutation was defined by direct sequencing of the β globin gene (ABI 3100 genetic analyzer). Sickle haplotypes were defined using previously described techniques by RFLP using specific restriction enzymes(HincII5'to e, XmnI 5' to Gg, Hind III within Gg and Ag, Taq1 within Gg and Ag, Hinc II within and 3'to b and Hinf I and RsaI5' to b) Direct sequencing of intron 2 of BCL11A gene was performed and three BCL11A haplotypes were constructed as A, B and C using five SNPs (rs7557939, rs7584113, rs4671393, rs34211119 & rs11886868). *Results*. 160 SCD patients (SS) aged between 7-41 years, with a mean age 21.5 + 7.2(SD) were consecutively enrolled. There were 85 males. bs haplotyping revealed that 54,22, and 31cases were homozygous Benin, Bantu and Arab-Indian(AI) haplotypes respectively, with the remaining 53 being mixed heterozygous. BCL11A haplotyping with regards to the 5 SNPs revealed that 32(20%), 82 (51.25%) and 46(28.75%) showed AA(Wild/Wild), AC or AB(Wild/Mutant) and BC,BB,CC(Mutant/Mutant) haplotypes respectively. There was a significant difference in the HbF amongst the wild v/s mutant haplotypes in the SS group overall as well as in the bs haplotypes namely Ben/Ben; Ban/Ban & AI/AI homozygotes (Figure). *Conclusions*. The study reveals a good correlation of the BCL11A SNPs with fetal hemoglobin levels in SCD patients. The same results within the SS SCD bs haplotypes indicate that BCL11A SNPs independently regulate the fetal hemoglobin levels in adulthood. rs 4671393 and BCL11A B haplotype were significantly associated with raised fetal hemoglobin levels in this patient population.

Table 1.

BCL11A Haplotypes	AA [Wild/ Wild]	AB [Wild/ Mutant]	AC [Wild/ Mutant]	BC [Mutant/ Mutant]	BB [Mutant/ Mutant]	CC [Mutant/ Mutant]
HbF [Mean± SD]	8.34 ± 6.5	11.54 ± 8.2	9.97 ± 6.7	12.84 ± 6.3	14.53 ± 6.5 AA v/s p=0. 007	9.58 ± 8.9
Arab-Indian SS SCD			AA	AB		BB/BC/CC
HbF [Mean±SD]			13.08 + 6.7	21.1 + 6.0 AA v/s p=0.02		16.9 + 2.8 AA v/s p=0.8

PANCREATIC AMYLASE, A POTENTIAL INDICATOR OF CARDIAC IRON OVERLOAD

R. Grosse, J. Yamamura, R. Engelhardt, G.E. Janka, P. Nielsen, G. Adam, R. Schneppenheim, R. Fischer

University Medical Center Hamburg-Eppendorf, HAMBURG, Germany

Regular transfusion therapy in thalassemia major (TM) is improving patients quality of live, but creates a state of iron overload with the consequence of iron deposition in parenchymal tissues such as endocrine glands, hepatocytes and myocardium. Cardiac iron in TM patients is nowadays assessed by fast MRI-R2* methods. However, TM patients will not be measured before the age of 10 years due to compliance problems with MRI measurements. Unfortunately do some TM patients exhibit R2* (1/T2*) relaxation rates >50s^{-1} corresponding with increased cardiac iron concentrations already at that age. The underlying mechanisms of iron accumulation into cardiomyocytes may also be involved in other cells such as pancreatic cells, anterior pituitary gland cells, and neurons. Especially, calcium channels offer a pathway for ferrous iron, which is not down regulated in iron overload conditions. A significant but loose correlation was found between cardiac and pancreatic T2* relaxation times [*Au et al, 2008*], however, the association with endocrine function tests is spoiled by fatty infiltration of the pancreas in thalassemia patients with impaired function [*Papakonstantinou et al, 2007*]. A decreased pancreatic exocrine function with subnormal serum amylase levels was found to be associated with pancreatic iron index measured by MRI in TM patients [*Midiri et al, 1999*]. In a clinical setting of 20 transfusion dependent TM patients (age 11 - 41 years, 9 female), we measured cardiac iron by MRI-R2*, liver iron by biosusceptometry and pancreatic exocrine function by serum amylase. ROC analysis revealed a high specificity (78%) for elevated cardiac iron (R2* > 50 s-1 or T2* < 20 ms) at amylase levels ≤13 U/L ($p=0.02$). In contrast, liver iron concentration could not predict cardiac iron ($p=0.9$). Using pancreatic serum amylase as an indicator for exocrine pancreatic function may help to

indicate patients at risk of cardiac iron overload and could lead to an intensified iron chelation therapy in these patients. TM patients with low pancreatic serum amylase levels should undergo a more investigative diagnosis by MRI.

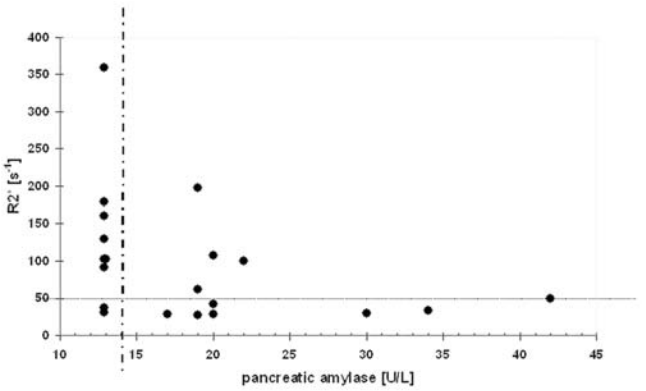

Figure 1. Relationship between cardiac mid-papillary.

THE PLASMA HYPERCOAGULABILITY AND VASCULAR ENDOTHELIUM ABNORMAL CYTOKINES' RELEASE MAY INFLUENCE THE PROGRESSION OF THE OSTEOPATHY IN HOMOZYGOUS β-THALASSEMIA PATIENTS

M.D. Musso,[1] D. Cultrera,[2] M. Musso,[3] A. Cipolla,[1] R.M. Rosso,[1] C. Grazia,[1] G. Giulia,[1] B. Ximenes,[1] F.G. Ferro[1]

[1]Hematology Division and Thalassemia Unit, Haemophilia & Thrombosis Centre, CATANIA; [2]Division of Hematology, Ospedale Ferrarotto, CATANIA; [3]Hematology Specialization School,University of Catania, CATANIA, Italy

Background. It is well known that a chronic hypercoagulation and vascular endothelium dysfunction are responsible for thromboembolic events in homozygous β-thalassemia(β-Th). *Aim*. In this scenario, an other severe complication such as the osteopathy,which becomes certain in adult β-Th patients, has recently evidenced and mainly referred to the several endocrine deficiencies,while the contribution of the hypercoagulation and abnormal vascular endothelium cytokines' release has not been considered. *Design and Methods*. 11 Sicilian homozygous β-Th patients(6 females and 5 males),aging 24-66 yrs, were studied. 11 sicilian heterozygous β-Th subjects and 10 healthy individuals of comparable age served as controls. Bone density scans showed severely low bone mass in 7/11 and low bone mass in 4/11 respect to the control groups. The osteoblastic cytokines' net-work as the Platelet-derived growth factor(PDGF),Transforming growth factor-β (TGF-β)and Interferon-α (IFN-α)together with the osteoclastic cytokines such as the Interleukin-1(IL-1), Interleukin-6 (IL-6) and Tumor necrosis factor-β (TNF-β)were determined by ELISA. *Results*. Our results showed a significant (p<0.001) increase of the osteoclast cytokines in homozygous β-Th respect to those observed in the controls groups.The osteoblastic cytokines were in normal range in all groups. *Conclusions*. From these observations we suggest that the chronic red blood cells haemolysis, blood transfusions and iron chelation 'quoad vitam' would determine continuously biochemical changes in β-Th leading also to an abnormal release of several cytokines from injured vascular endothelium of the bone microenvironment. The osteoclastic cytokines' formation is dominant over the osteoblastic one and by reducing bone mineral density so potentiating the osteoporosis as observed in adult homozygous β-Th patients by clinical diagnostic findings. In this context, the chronic vascular endothelium suffering of the bone microenvironment together with the hypercoagulability,leukocytes' and platelet hyper-activation could enhance further the osteoclast cells functions in β-Th.

HYDROXYUREA EXPERIENCE IN THE MENAGMENT OF ALGERIAN PATIENTS AFFECTED WITH SEVERE HEMOGLOBINOPATHIES

M. Bradai, R. Boukari, Y. Boukhatem

Institue of Medicine, BLIDA, Algeria

Background. Conventional treatment of severe hemoglobinopaties is limited in the many countries. Hydroxyurea (HU) is the first widely used treatment ,as an alternative to blood transfusions, to have an impact on severity of sickle cell disease (SCD).Its effects in thalassemia (Thl) are controversial, particularly in Thl major (TM). *Aims*. to assess long-term use of HU in the management of Algerian patients with severe SCD and Thl, previously treated with blood transfusion (BT) by the evaluation of hematological response, hemochromatosis, growth velocity, sexual maturation, compliance side effects and also the coast of this approach. Patients and methods: since 2000 total of 123 patients were enrolled in HU protocol. Forty six with SCD (33 SS, 14 Sβ Thl, and 1SC), medium age at the initiation of treatment was 15 years (3 to 25yrs), 38 with history of >vaso-occlusive-crisis and/or >1 acute chest syndrome, 6 with severe anemia (Hb <6 g/dL), 2 priapism, 1 nephropathy. The main daily dose of HU was 19,5 mg/kg/d(14 to 24) . Seventy nine were THL patients, 69 TM and 10 Intermediate (TI), median age was 11 yrs (3 to 21), 13 firsts patients were included for major BT complication. Mean daily dose was 16,1 mg/kg(13 to 21) We defined good response when decrease in annual BT requirement greater 70% with sustained Hb above 7 g/dl. Management of hemochromatosis in both groups was based on Deferoxamine (DFO) administered subcutaneous bolus infusion (2 injections 4 to 5 d/w) and phlebotomy performed when Hb level≥8 g/dL. Serum ferritin was evaluated every 3 months, cardiac function every year, growth and sexual development by measurement of high, weigh and Tanner stage. We also compared the coast per year of this approach and an optimal conventional treatment by assessment of coast of blood units, DFO, day hospitalisations (DH). *Results*. Median follow-up for SCD was 82 months, significant decrease of annual rate of VOC, ACS, BT and DH. Stopped BT obtained in 33 patients, mean gain Hb was 1,4g/dl (0,8 to 3,3), 1 had stroke, 1 recurrent priapism, 4 developed hip osteonecrosis 2 patient died(1 sepsis, 1 renal deficiency). For7patients with initial ferritin>2000, level fell from 3500 to 870ng/mL with DFO (32 mg/kg/d) and phlebotomy (7ml/kg every 3 week). Only 5 patients have growth retardation. The annual coast was reduced around 85 percent. In the group of THL good response was obtained in 36 (9 TI and 27 TM), no response in 31, and partial response in 11 cases (reduction 50% of BT need) Response is associated with older age at the first TS(p=0.02) ,higher preHU Hb(p=0.0004),codon6(-A)mutation (p=0.002), TI(p=0.03), history of splenectomy(p=0,05), Xmn1 polymorphism (p=0,008) ((*Bradai M et al. Transfusion 2007; 47:1830-36*). Portal venous thrombosis PVT occurred in 4 patients and 3 others had autoimmune anemia, treated with steroids and Immunoglobulin. In group of good responders mean ferritin level fell from 4100 to 2100ng/ml, with DFO 35mg kg/d and phlebotomy performed in 14 patients (5 ml/kg/3w). Growth retardation is observed in 7 patients, Cardiac function is conserved. Six patients died, 3 from cardiac deficiency and 1 after PVT, 1 sepsis and 1 acute leukaemia. Compliance was excellent, No serious acute toxicity was seen. In this group the annual coast is reduced around 75 percent. *Conclusion*. HU appear a good alternative of conventional treatment and seem have favourable cost effectiveness in Algerian SCD and THL patients, particularly when blood supplies are limited.

1284

ROLE OF αα/αααANTI-3.7 TRIPLICATIONS ON THE PHENOTYPE OF SICKLE β THALASSEMIA PATIENTS

S. Shree Sanjoo, V. Sharma, T. Seth, R. Saxena

All India Institute of Medical Sciences, NEW DELHI, India

Background. HbS occurs due to A - T substitution at codon 6 of the β globin gene leading to the nonsynchronous replacement of valine for glutamic acid. Sickle patients have a very variable clinical phenotype. Some of the possible explanations for the observed variable clinical severity are coinheritance of α-deletions and triplications. *Objective*. To determine the frequency of α deletion and triplication in Sickle β thal patients and to study their effect on the phenotype of Patients. *Design and Methods.* Subjects were 25 Sickle cell patients who attended the Hematology out patient department of the institute diagnosed by HPLC.Patients were divided into three subgroups according to a scoring system based on seven clinical criteria as mild (score 0-3.5), moderate (score 4-7) and severe (score7.5-10). α deletions and triplication were studied by GAP-PCR

and multiplex-PCR respectively. *Results*. α deletion was found in 8 (32%) out of these 8 patients 6 (αα/-ααα$^{3.7}$) were from Gp1 and 2 (αα/-ααα$^{3.7}$) were from Gp2.β triplication was found in 2 (8%) both of these were (αα/-ααα$^{3.7}$) from Gp3. *Conclusions*. Phenotype of Sβ^{thal} largely depends on coexisting β gene abnormality. α$^{3.7}$deletion showed Milder phenotype while β triplication showed severe phenotype.

Table. Effect of a globin gene numbers on the phenotype of sβ patients.

MAGNETIC RESONANCE IMAGING R2 MAPPING ACCURATELY ESTIMATES IRON OVERLOAD IN SICKLE CELL DISEASE PATIENTS

A. Inati,[1] M. Taha,[2] K. Musallam,[3] F. Ziade,[4] Y. Rachkidi,[5] A. Taher[3]

[1]Rafik Hariri University Hospital, BEIRUT, Lebanon; [2]Lebanese American University, BYBLOS, Lebanon; [3]American University of Beirut Medical Center, BEIRUT, Lebanon; [4]Lebanese University, BEIRUT, Lebanon; [5]Nini Hospital, TRIPOLI, Lebanon

Background. The majority of patients with sickle cell disease (SCD) require episodic blood transfusions on a chronic basis which makes them at risk for developing iron overload. The principal methods of determining body iron levels are measurement of serum ferritin levels and assessment of liver iron concentration (LIC) from biopsy tissue. Non-invasive approaches for determining liver iron concentration are increasingly used as an alternative to biopsy. R2 magnetic resonance imaging (MRI) is currently the only validated approach. A significant correlation between serum ferritin and liver iron concentration has been established in regularly transfused patients with thalassemia major. Data on patients with SCD is limited. *Aims*. To study the correlation between LIC determined by R2 MRI and serum ferritin levels in chelation-naïve SCD patients. Correlation between LIC and total number of lifetime transfusions, patient- and disease-related characteristics will be made. The data reported here represents the largest investigation of this correlation in SCD patients, and thus, provides valuable information on the relationship between these parameters in this specific patient population. *Design and Methods*. This was a cross-sectional study of randomly selected patients with SCD treated at two comprehensive Lebanese SCD centers: Rafik Hariri University Hospital (RHUH) and Nini hospital. The sampling frame consisted of 200 chelation-naïve SCD patients >2 years of age and a simple random sample was obtained. Data on patient demographics, transfusional history, status of the spleen, and comorbid illnesses or infections was obtained. Blood samples were obtained for assessment of steady state serum ferritin, hemoglobin and liver enzyme levels. Direct determination of LIC was performed using R2 magnetic resonance imaging. Written informed consent was provided by all patients. LIC values <3, 3-7, >7 mg Fe/g dry weight and serum ferritin levels <1000, 1000-2500, >2500 ng/mL were considered normal, mildly overloaded, and severely overloaded; respectively. *Results*. Data from 52 SCD patients was included in the analysis (Table 1). None of the patients had evidence of hepatitis C or B infection, or elevation in liver enzymes. A significant positive correlation was observed between LIC and serum ferritin (Pearson correlation 0.874; $p<0.0001$). Moreover, 20.0 vs. 15.4% had severe, 12.0 vs. 15.4% had mild, and 68.0 vs. 69.2 had absence of iron overload by LIC and serum ferritin measurement; respectively. Neither LIC nor serum ferritin had a significant correlation with age or hemoglobin level; however both correlated positively with the total number of lifetime transfusions ($p<0.001$). There was no statistically significant difference in mean LIC and serum ferritin levels between males and females, splenectomized and non-splenectomized patients, or patients with or without persistent splenomegaly (>6 years). *Conclusions*. Hepatic R2 MRI values correlate well with serum ferritin level and the total number of lifetime transfusions in SCD patients, thus, confirming the value of this technique for assessing iron overload in this patient population. Moreover, iron levels in the study population demonstrate that many chelation-naïve patients with SCD have serum ferritin and LIC levels above the recommended threshold levels identified in patients with thalassemia major, indicating a risk of significant morbidity and mortality.

Table 1. Patient, disease and iron overload characteristics.

Parameter	Value
Mean age ± SD, years (range)	18.54 ± 9.0 (4-49)
Male/Female	5/8
Splenectomized, (%)	16 (30.8)
Persistent splenomegaly[a], (%)	21 (42)
Mean transfusions[b] ± SD, n (range)	50.9 ± 61.4 (0-300)
Mean hemoglobin ± SD, g/dL (range)	8.6 ± 1.4 (5.6-11.9)
Mean SF ± SD, ng/mL (range)	987.5 ± 1230.3(16-6190)
Mean LIC ± SD, mg Fe/g dw (range)	5.9 ± 9.4 (0.3-50.0)

SF = serum ferritin at steady state; LIC = liver iron concentration; dw = dry weight.

[a]For more than 6 years.

[b]Total number of lifetime transfusions.

None of the patients had evidence of hepatitis C or B infection, or elevation in liver enzymes. A significant positive correlation was observed between LIC and serum ferritin (Pearson correlation 0.874; $p<0.0001$). Moreover, 20.0 vs. 15.4% had severe, 12.0 vs. 15.4% had mild, and 68.0 vs. 69.2 had absence of iron overload by LIC and serum ferritin measurement; respectively. Neither LIC nor serum ferritin had a significant correlation with age or hemoglobin level; however both correlated positively with the total number of lifetime transfusions ($p<0.001$). There was no statistically significant difference in mean LIC and serum ferritin levels between males and females, splenectomized and non-splenectomized patients, or patients with or without persistent splenomegaly (>6 years). *Conclusions*. Hepatic R2 MRI values correlate well with serum ferritin level and the total number of lifetime transfusions in SCD patients, thus, confirming the value of this technique for assessing iron overload in this patient population. Moreover, iron levels in the study population demonstrate that many chelation-naïve patients with SCD have serum ferritin and LIC levels above the recommended threshold levels identified in patients with thalassemia major, indicating a risk of significant morbidity and mortality.

MAGNETIC RESONANCE IMAGING T2* IN THE EVALUATION OF CARDIAC IRON OVERLOAD IN PATIENTS WITH SICKLE CELL DISEASE

A. Inati,[1] K. Musallam,[2] M. Taha,[3] F. Ziade,[4] A. Taher[2]

[1]Rafik Hariri University Hospital, BEIRUT, Lebanon; [2]American University of Beirut Medical Center, BEIRUT, Lebanon; [3]Lebanese American University, BYBLOS, Lebanon; [4]Lebanese University, BEIRUT, Lebanon

Background. In patients with thalassemia major, cardiac dysfunction resulting from iron overload is the leading cause of morbidity and mortality. Although systemic and hepatic iron overload have been recognized in patients with sickle cell disease (SCD), data on iron overload associated cardiac dysfunction is quite limited. Few studies have reported absence of cardiac involvement. Therefore, monitoring cardiac iron levels in such patients is justified. The use of magnetic resonance imaging (MRI) T2* to detect cardiac iron overload is becoming increasingly common because of its non-invasive and highly reproducible nature. AIMS: To use MRI T2* to measure myocardial iron overload in patients with SCD; and to establish its correlation with echocardiographic findings and body iron parameters. *Design and Methods*. This was a cross-sectional study of randomly selected patients with SCD treated at two comprehensive Lebanese SCD centers: Rafik Hariri University Hospital (RHUH) and Nini hospital. The sampling frame consisted of 200 non-chelated SCD patients > 2 years of age and a simple random sample

was obtained. Patient charts were reviewed for drug use, transfusional history, status of the spleen, and comorbid illnesses or infections. Blood samples were obtained for assessment of steady state serum ferritin, and liver enzyme levels. Doppler echocardiography to detect pulmonary hypertension (PHT) and assess left ventricular ejection fraction (LVEF) was done. Cardiac iron levels were measured by MRI T2*. Direct determination of liver iron concentration (LIC) was performed using R2 magnetic resonance imaging. In this study, cardiac T2* >20 ms was considered normal. Written informed consent was provided by all patients. *Results*. Data from 23 patients were included in this analysis. The mean age was 24.4±9.7 years (range: 4-49 years) with a male to female ratio of 15:8. None of the patients had a history of iron chelation therapy, evidence of hepatitis C or B infection, or elevation in liver enzymes. Six patients (26.1%) were splenectomized, and 9 patients (40.9%) had evidence of persistent (>6 years) splenomegaly. The mean total number of lifetime transfusions was 73.8±80.6 (range: 1-300). The mean LVEF was 64.6±5.3% (range: 58.0-76.0%). Six patients (27.3%) had evidence of PHT. Mean steady state serum ferritin level was 997.7±1110.9 ng/mL (range: 41-3430 ng/mL) and mean LIC value was 4.6±7.0 mg Fe/g dry weight (range: 0.3-21.7 mg Fe/g dry weight). None of the patients had evidence of cardiac iron overload (mean cardiac T2*=37.3±6.2.3 ms; range: 21.9-46.8 ms). Moreover, cardiac T2* did not correlate with either serum ferritin (p=0.75) or LIC (p=0.97). There was no correlation between LVEF or presence of PHT and cardiac T2* values. All remaining study variables (age, gender, splenectomy, persistent splenomegaly, total number of lifetime transfusions, and hemoglobin level) showed no correlation with cardiac T2* values. *Conclusions*. The results of this study show that SCD patients do not have evidence of cardiac iron overload as measured by T2* MRI. This is consistent with previous data showing that patients with SCD are generally less prone to cardiac iron overload associated morbidity and mortality.

1287

IRON CHELATION IN PATIENTS WITH THALASSEMIA INTERMEDIA AND OTHER NON TRANSFUSION DEPENDENT CONGENITAL HEMOLYTIC ANEMIAS

A. Alves Pereira,[1] M.P. Silveira,[2] M.L. Ribeiro[1]

[1]*Centro Hospitalar de Coimbra, COIMBRA, Portugal;* [2]*Centro Hospitalar de Lisboa Ocidental E.P.E., LISBOA, Portugal*

Iron overload is one of the main causes of morbimortality in patients with congenital anaemias. Erythroid hyperplasia and chronic tissue hypoxia increase iron absorption in non transfusion dependent anaemic patients, most of them requiring iron overload monitoring and, eventually, iron chelation. Cardiac disease and pulmonary hypertension are the leading cause of death among these patients, nevertheless myocardial iron is not usually significantly increased. The aim of this study was to analyse iron chelation data on 22 non transfusion dependent patients with congenital anaemias. In a group of 22 patients (18 β-thalassemia intermedia, 2 piruvate kinase deficiency, 1 pyrimidine 5' nucleotidase deficiency and 1 hereditary xerocytosis), ALT, AST, serum ferritin level and liver iron concentration (LIC) by MRI were determined before and 42±5 weeks after iron chelation therapy. Cardiac iron overload was evaluated by MRI T2* only at the end of the observational study (Table 1).

Table 1. Evaluation of patients with congenital hemolytic anemias, not transfusion dependent, before and after 42±5 weeks of iron chelation therapy. DFO: deferoxamine; DFP: deferiprone. *Patient with HCV.

Age	Sex	Pathology	Hb g/dL	Initial evaluation		Re-evaluation		Myocardial T2* ms	Treatment
				Serum ferritin ng/mL	LIC µmol/g	Serum ferritin ng/mL	LIC µmol/g		
18	M	β-TI	8	859		69	55	75	DFO

56	M	PSN deficiency	10,5	1219	220	183	90	34	DFP
55	M	Hereditary xerocytosis	14	936		210	220	30	Phlebotomy

All the patients had normal liver enzymes, except one with active hepatitis C, and most of them presented high initial serum ferritin levels and significant hepatic iron overload. Patients with good therapeutical compliance had a very significant serum ferritin decrease, with a less significant decrease on LIC. There was no consistent correlation between serum ferritin levels and LIC especially after iron chelation. Myocardial T2* was above 20 ms (normal) in all the patients. In conclusion: according to the present data, iron overload in patients with non transfusion dependent congenital anaemias may be underestimated by serum ferritin levels alone. Assessment of LIC in these patients may establish the need for iron chelation to prevent liver dysfunction, and to monitor the treatment

1288

BONE MARROW MITOGEN-STIMULATED DIRECT ANTIGLOBULIN TEST IN A CASE OF ERYTHROBLASTIC SYNARTESIS

A. Zaninoni, F.G. Imperiali, M. Pomati, W. Barcellini

Fondazione IRCCS Ospedale Maggiore Policlinico Mangiagalli e Regina Elena, MILAN, Italy

Background. Erythroblastic synartesis is a rare disease in which an autoimmune phenomena against erythroblasts has been hypothesised. Recently, anti-erythroblast autoimmunity has been demonstrated in half patients with early MDS (RA or RARS) by means of mitogen-stimulated direct antiglobulin test (MS-DAT) performed on bone marrow (BM) aspirates. *Aims*. To report a case initially diagnosed as unclassified myelodisplastic syndrome characterized by hyperplastic erythropoiesis and haemolytic anemia, who showed the presence of anti-erythroblast autoimmunity (positive BM MS-DAT), together with morphological features of erythroblastic synartesis. *Design and Methods*. MS-DAT was performed by stimulating BM with PMA and PHA and antibodies were detected in supernatants by competitive solid phase ELISA. Control BM cells were separated by magnetic beads in $CD45^+$ (myeloid cells) and CD45- cells (erythroblasts) and patient's BM culture supernatant was tested on both BM populations. The growth of normal BM progenitors on methylcellulose medium was evaluated in the presence (or not) of patient's BM culture supernatant. Smears were obtained from CFU after 14 days of culture. *Results*. The propositus is a 44 years old male, with a history of anemia since 1998 and numerous BM aspirates showing hyperplastic and dysplastic erythropoiesis, T and NK infiltrate, increased iron deposition and various non conclusive diagnoses (initial pure red cell aplasia, T-large granular lymphocyte lymphoma, myelofibrosis), and the patient was treated with steroids and cyclosporin with some response. After admission to our Hospital, the patient's records showed Hb 9 g/dL, reduced reticulocytes ($20x10^9$/L), and slightly alteration of hemolytic markers (unconjugated bilirubin 1.8 mg/dL, LDH 550 U/L, haptoglobin <20 mg/dL); the study of red cell enzyme activity, membrane proteins, and autoimmune tests were negative. BM aspirate showed hyperplastic erythropoiesis with some dysplastic features, mostly binuclear erythroblasts; in addition, clusters of closely linked erythroid cells at different maturation stages and small lymphocyte aggregates were observed. These features resembled those of the uncommon disorder named erythroblastic synartesis, first described in 1973, in which an autoimmune phenomena against erythroblasts was hypothesised. Thus, MS-DAT was performed on BM samples, giving positive results (389 ng/mL BM mononuclear cell-bound IgG in unstimulated cultures, 408 ng/mL in PHA-, and 534 ng/mL in PMA-stimulated cultures). Patient's BM culture supernatant showed greater levels of IgG binding to normal erythroblast cells (CD45-) than to myeloid ones (CD45+); moreover it induced dyserythropoietic signs (nuclear atypia i.e. multiple nuclei, nuclear inclusions, and intercellular bridges) and erythroblastic clustering of CFU growing of normal BM samples. The patient was treated with steroids (prednisone 50 mg/die followed by slowly tapering) achieving clinical and hematological response. The patient is still on regular follow-up without further relapse. *Conclusions*. In this case characterised by morphological features of the erythroblastic synartesis we demonstrated by MS-DAT an autoimmune reaction against erythroid precursors resulting in erythroid hyperplasia/dysplasia.

1289

EFFICACY, EFFICIENCY AND SAFETY OF DEFERASIROX FOR TREATING TRANSFUSIONAL IRON OVERLOAD IN NON-ACTIVELY TRANSFUSED PATIENTS

A. Kattamis, N. Lazopoulou, E. Rigatou, S. Kostaridou, A. Lourida, V. Ladis

University of Athens, ATHENS, Greece

Background. Deferasirox has been approved for the treatment of transfusional iron overload in patients with various types of anemias. The studies on deferasirox, reported so far, focused mainly on patients with a continuing need of transfusion therapy, in whom efficiency of deferasirox was estimated to be around 27%. Herein, we evaluated treatment of iron overload with deferasirox in non-transfusion-dependent patients. *Patients and Methods*. Eleven patients (9 males, 2 female, mean age: 31.7 years, age range: 21.1-44.8 years) with iron overload were included in this study. Eight patients had thalassemia intemedia, 2 sickle cell disease, and 1 congenital dyserythropoetic anemia II. Patients had been previously regularly transfused, usually until splenectomy, but had not had any transfusions for >3 years. Lifetime transfusions ranged from 50-350. Mean dose at the 1st year of treatment was 16 mg/kg/day (range: 10-20 mg/kg/day, 11 patients) and 17.9 mg/kg/day (range: 10-20 mg/kg/day, 7 patients) at the 2nd year. Efficacy was evaluated with ferritin levels and degree of hepatic and cardiac iron overload, which were estimated by MRI (T2* sequence) (9 patients). Safety parameters included transaminases, creatinine and cystatin C levels. Chelation efficiency was determined as the% iron excretion versus the theoretical iron binding capacity of the chelator. Iron excretion was calculated based on the changes of liver iron concentration (LIC) and the variation in body iron load according to Angelucci et al. (N Engl J Med 2000;343:327). RESULTS: Mean, SD and range at baseline showed: ferritin: 1634±903 ng/mL (352-3176 ng/mL), LIC: 20.6±13.6 mgFe/g d.w. (4.7-39.1mgFe/g d.w.), cardiac T2*: 34.3±4.7ms (25.6-40ms) and left ventricular ejection fraction (LVEF): 66.7±4.5 ms (63.1-70.3%). All patients showed a steady decrease in iron overload. Mean serum ferritin decreased significantly to 1061±570 ng/mL (range: 125-2014 ng/mL) after 1 year and to 504±391 ng/mL (range: 159-1058 ng/mL, 7 patients) after 2 years (p<0.05). Mean LIC decreased significantly (p<0.05) to 13.6±7.79 mgFe/g d.w. (range: 2.6 - 28.9 ng/mL) after 1 year (p<0.05) and to 8.06±6.6mgFe/g d.w. (range: 2.1 - 16.1 ng/mL, 3 patients), after 2 years. There were no changes in cardiac T2* and LVEF. Treatment was well tolerated. No serious adverse events were noted, including hematological toxicity, even though in 7 patients concomitant medications included hydroxyurea. Creatinine and cystatine C levels did not change. Significant improvement in transaminases levels was noticed, probably due to decreased hepatic siderosis. Chelator efficiency ranged considerable in between patients (median:20.4%, range:3.5-42.3%). It did not changed significantly in the 2nd year of treatment. This calculated chelator efficiency is different than previously described, either because deferasirox achieves slower iron excretion, or because LIC underestimates total iron body stores in these patients. *Conclusions*. Treatment with deferasirox in non-actively-transfused patients is effective and well tolerated in chelating excess iron, which has accumulated from previous transfusions. The rate of iron overload improvement may be lower than previously observed. Larger studies are required to verify these conclusions.

1290

CROSS-TALK BETWEEN INFLAMMATION AND IRON STATUS, AND ITS ASSOCIATION WITH RESISTANCE TO RECOMBINANT HUMAN ERYTHROPOIETIN THERAPY IN HAEMODIALYSIS PATIENTS

C. Elísio,[1] S. Rocha,[2] P. Rocha-Pereira,[3] E. Castro,[2] F. Reis,[4] F. Teixeira,[4] V. Miranda,[5] S. Sameiro-Faria,[5] A. Loureiro,[6] A. Quintanilha,[7] L. Belo,[2] A. Santos-Silva[2]

[1]Instituto de Ciências da Saúde of Universidade Católica Portuguesa, PORTO; [2]Faculdade de Farmácia and IBMC, Universidade do Porto, PORTO; [3]IBMC and Centro de Investigação em Ciências da Saúde, UBI, COVILHÃ; [4]Instituto de Farmacologia e Terapêutica Experimental, Fac. de Medicina of UC, COIMBRA; [5]FMC, Dinefro - Diálise e Nefrologia, SA, PORTO; [6]Uninefro - Sociedade Prestadora de Cuidados Médicos e de Diálise, PORTO; [7]IBMC and ICBAS, Universidade do porto, PORTO, Portugal

It is known that the inflammatory stimulus has an important impact in iron metabolism, by mobilizing iron from erythropoiesis traffic to storage sites within the reticuloendothelial system, inhibiting erythroid progenitor proliferation and differentiation. This change in iron mobilization way lead to an iron depleted erythropoiesis. Furthermore, recently, a complex regulatory network that governs iron traffic emerged, and points to hepcidin as a major evolutionary conserved regulator of iron distribution. The synthesis of hepcidin is stimulated by inflammation, and has been reported to be increased in haemodialysis (HD) patients. Given the importance of iron mobilization for erythropoiesis, we hypothesized that alterations in iron traffic could be related to resistance to recombinant human erythropoietin (rhEPO) therapy in HD patients. The aim of our study was to assess possible relations between iron status and inflammatory markers in HD patients, as well as its association with resistance to rhEPO therapy. Sixty-tree HD patients and 26 healthy controls were enrolled in the study. Among HD patients, 31 were non-responders and 32 were responders to (rhEPO) therapy. Red blood cell and reticulocyte counts, haemoglobin (Hb) concentration and circulating levels of ferritin, iron, transferrin, C-reactive protein (CRP), soluble interleukin 2 receptor (s-IL2R), soluble transferrin receptor (s-TfR), interleukin 6 (IL-6) and prohepcidin were measured in all patients and controls. HD patients showed statistically significant higher reticulocyte count and circulating levels of ferritin, s-TfR, CRP, IL-6, s-IL2R and prohepcidin. Lower number of erythrocyte count, and decrease levels of Hb and transferrin were also found in HD patients when compared to healthy controls. Higher levels of s-TfR and CRP, and lower levels of Hb and prohepcidin were observed among non-responders compared to responders. Prohepcidin levels correlated negatively with s-TfR and reticulocyte count. The weekly rhEPO/Kg dose was found to be positively correlated with CRP, Hb and s-TfR. In conclusion, our data show that a close interaction exists between inflammation, iron status and prohepcidin serum levels that ultimately regulate intracellular iron availability. Prohepcidin and s-TfR, together with CRP, may prove to be good markers of resistance to rhEPO therapy in HD patients. Moreover, HD non-responders patients to rhEPO therapy seem to present a "functional" iron deficiency, characterized by the presence of adequate iron stores as defined by conventional criteria, but apparently with an inability to sufficiently mobilize iron to adequately support erythropoiesis.

1291

INTERACTION OF AZOTOBACTIN WITH BLOCKING AND MOBILIZING AGENTS IN THE MEASUREMENT OF NON TRANSFERRIN BOUND IRON IN HEMATOLOGICAL DISORDERS

M. Sharma, N. Gohil

Indian Institute of Technology Delhi, NEW DELHI, India

Background. Hematological disorders involving non transferrin bound iron result in multiple organ damage, caused due to its potentially toxic nature which can be attributed to free radical generation. However NTBI is not employed as a routine parameter to diagnose iron overload particularly in India, because of lack of a direct and reliable assay. Accurate estimation of NTBI requires two key issues to be addressed efficiently; complete mobilization of the available NTBI from all putative ligands in serum and blocking of endogenously present apotransferrin, which could scavenge the mobilized NTBI. These two critical conditions if not optimized may lead to underestimation or false estimation of NTBI concentration. Simultaneously the selected blocking and mobilizing agents should also be compatible with the fluorophore in the given experimental conditions of a fluorescence assay. *Aims.* In this study we therefore sought to examine the interaction of different blocking (Co3+ and Ga3+) and mobilizing agents (EDTA, sodium oxalate and nitrilotriacetate) with azotobactin, the bacterial siderophore utilized in the developed assay. The main aim was to study the spectroscopic characteristics of azotobactin in the presence of these agents and also the effect of these agents on the binding kinetics of azotobactin and Fe3+ under defined experimental conditions. *Design and Methods*. A very simple methodology involving UV-Visible spectrophotometry and fluorescence spectrometry was adopted to study the interaction of above agents with the probe molecule azotobactin. The nature and degree of interference offered by the blocking and mobilizing agents was studied for selection of the suitable agent. We have also investigated the competitive complex formation of Co3+ / Ga3+and Fe3+ for azotobactin in aqueous medium at pH 4.4. Association kinetics of scavenged serum NTBI with different mobilizing agents and then the displacement of scavenged NTBI by azotobactin from mobilizing agents were also established. Results: Results indicate that Co3+ in specific anionic complexes is effective in blocking apotransferrin- Fe3+ binding sites. Even at concentrations as high as 0.5mM there is no shift or decrease in the fluorescence emission spectrum of azotobactin as compared to Ga3+ which significantly affects the fluorescence properties. Competitive binding experiments also indicate that Co3+ does not interfere in the binding of Fe3+ to azotobactin.

Among the mobilizing agents studied, nitrilotriacetate being a mild chelating agent than the rest, efficiently scavenges all the available NTBI in serum and easily donates to azotobactin for its accurate quantification. The threshold concentration for NTA was found to be 80 mM. *Conclusions.* The present study shows that Co3+ and nitrilotriacetate are suitable intermediate agents for blocking apotransferrin and mobilizing NTBI respectively, since they do not affect either the spectroscopic properties of azotobactin or the binding kinetics of azotobactin and Fe3+.

1292

THE METHODOLOGY OF THE 'IRON ABSORPTION TEST'; ITS IMPORTANCE IN THE DIAGNOSIS OF IRON DEFICIENCY ANEMIA SECONDARY TO IRON MALABSORPTION

M.L.A. Balea, V. Grecu

Clinical Hospital Colentina, BUCURESTI, Romania

We have performed the iron absorption curve with the examination of the serum iron concentration after 30, 60, 90, 120 and 180 minutes, subsequent to the administration of 325 mg ferrous sulfate, on a hundred normal subjects. The curves obtained show 50% - 200% increases of the iron level, (iron concentration) with the peak plasma level's values recorded after 90-120 minutes subsequent to the administration of the ferrous sulfate (after ingestion of iron salts). In this context, the methodology applied in the diagnosis of iron malabsorption has the following steps: Time 0: we take the sample for the basal iron level (concentration) and the immediate administration of 325 mg ferrous sulfate. Time 90 minutes: we take the sample for the second determining of (serum) iron concentration. Interpretation: an increase greater than 50% indicates a perfectly normal absorption of iron; increases lower than 20% indicate the iron malabsorption; increases between 20% and 50% require monitoring and reevaluating the subject. By applying this methodology, we have identified the frequency of occurrence of anemia through the malabsorption of iron as 3% of a sample consisting of 1323 subjects presenting the anemic syndrome, a frequency close to that of the occurrence of megaloblastic anemia (4%) and anemia caused by hemoglobinopathies (3.25%) in our sample. If we refer only to the 444 subjects with iron deficiency anemia the frequency of anemia through the malabsorption of iron amounts to 9% of the investigated subjects. We stress the fact that 25% of the subjects diagnosed with the iron malabsorption syndrome had previously been diagnosed as MDS-RA. The etiology of iron malabsorption identified in the 40 subjects has been represented by: Celiac sprue: 30%, Subtotal gastrectomy with Billroth anastomosis: 17.5%, Atrophic gastritis: 15%, Achlohydria: 7.5%, Exudative gastroduodenitis: 7.5%, Progressive systemic sclerosis: 5%, Polypoid lesion: 2.5%, erosive gastritis: 2.5%, subtotal pancreatectomy: 2.5%, Crohn disease: 2.5% exudative enteropathy: 2.5%, retroperitoneal lymphadenopathy: 2.5%, celiac sprue associated to subtotal gastrectomy: 2.5%. We stress the possibility of transitory iron malabsorption, as observed in 15% of the monitored subjects. *Conclusions*. The iron absorption test is indicated for subjects with iron deficiency anemia with unidentified etiology and that do not respond to the iron oral therapy. We underline the frequency of diagnostic error in these cases labeled as: MDS-RA, neoplastic disease, etc. The test will not be performed before PNH and the presence of gastric lesions with hemorrhagic potential has been excluded (ruled out). The methodology is simple, non-invasive, and the cost is reasonable.

1293

TREATMENT SATISFACTION (TS) OF THALASSAEMIA PATIENTS WITH IRON CHELATION THERAPY IN RELATION TO COMPLIANCE WITH CHELATING AGENTS AND DEPRESSION

S.. Fragatou,[1] I. Tsourveloudis,[1] M. Fragatou,[2] P. Paterakis[2]

[1]G.A.H. "G.Gennimatas", ATHENS, Greece; [2]Dromokaition Mental Hospital, ATHENS, Greece

Introduction. Treatment satisfaction was referred to play a significant role regarding compliance with treatment followed by patients with a chronic disease. Also compliance with iron chelation therapy in thalassaemia patients was well documented as a prerequisite for patients' survival and was negatively affected by depression. *Objective*. To investigate patients' treatment satisfaction with different chelation regimens during one year period, in relation to compliance with different iron chelators such as Desferrioxamine (DFO), Deferiprone (DFP) alone or in combination, Deferasirox (DFX),as well as depression. *Design and Methods.* We studied 45 thalassaemics,21 males, 24 females, mean age 39,2 years, divided according to iron chelation into four groups. Group A: 14p on DFO(40 mg/kgx24 hsx6 days/week s.c.), Group B:10p switched to DFP(75 mg/kg/day p.o.), Group C:11p on combination therapy, Group D: 10p switched from DFO to DFX(30 mg/kg once daily p.o.). Every patient was privately interviewed exactly before starting new chelation scheme, and 1 year later . Treatment Satisfaction rating scale (TS-rs), Version 1.0, graded from 1 to 7, was used as adapted for Greek population. Compliance was estimated by Compliance Index. Depression level was determined by Hamilton rating scale (HAM-D). HAM-D score=>20 indicates depression. Psychological support applied for all patients and psychiatric treatment protocols for depressed patients did not change during the study period. *Results*. According to baseline data low TS, grade 3, in overall patients was detected, associated with increased HAM-D score>20 (80.2%), with medium and poor compliance. One year later no significant change in TS-rs was unexpectedly observed for patients either on DFO (from 3 to 4) or DFP (from 3 to 4-5), while encouraging was the improvement of HAM-D score=19 in depressed patients on DFP (25%). Although TS-rs increased for patients on combination therapy (Group C) from 3 to 5 and on DFX (Group D) from 3 to 6-7 , all patients in Group C remained depressed (HAM-D >20) while 80% of patients on DFX were detected with HAM-D=15 (p<0.001). *Conclusions*. In our series of patients depression was detected in a high percentage (80.2%). Treatment satisfaction was a very important factor associated directly with the route and frequency of chelator's administration, while TS improved significantly depression, as well as compliance with certain chelation regimens.

1294

EVALUATION OF IRON STATUS IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA)

A. Barbullushi, D. Alia

UHC Mother Theresa, TIRANA, Albania

Background. Anemia is the most common extraarticular manifestation of RA and is virtually always the result of either iron deficiency, active inflammation, or both. *Aim*. of the study was to evaluate the diagnostic efficiency of laboratory tests including serum transferring receptor and prohepcidin measurements in the diagnosis and differentiation of anemia in RA patients. *Materials and methods*. Blood samples were obtained from 32 RA patients. The samples were analysed for full blood count, iron, ferritin, transferrin, sTfR (serum soluble transferrin receptor) and prohepcidin. The TfR-F index (sTfR-log ferritin index) was also calculated. Results: Anemia was observed in 17 patients(53.1%), 8 of which had anemia of chronic disease(ACD) and 5 patients had iron deficiency anemia(IDA). The mean MCV, MCH, iron and Hb level was significantly lower in anemia RA patients compared with no anemia patients (p<0.001). The prohepcidin level was significantly lower in IDA patients compared with ACD and ACD+IDA patients(124.5 ng/mL versus 324.68ng/mL and 454 ng/mL; p<0.001). sTfR levels in IDA group was significantly higher than the ACD patients(4.49±0.95µg/mL versus 1.25±0.75µg/ml). We have found a high TfR-F index(3.9±0.82) in the IDA patients compared with ACD group(0.599±0.648). ACD+IDA patients had high sTfR and high TfR-F index compared with ACD patients(p<0.001). *Conclusions*. We conclude that the sTfR, TfR-F index and prohepcidin measurements represent efficient tests for the clinical evaluation and differentiation of anemia in RA patients.

1295

THE CARDIAC EFFECTS OF DESFEROXAMINE DEFERIPRONE COMBINATION THERAPY AND DESFEROXAMINE MONOTHERAPY IN THALASSEMIC PATIENTS

S. Unal, T. Hazirolan, B. Beton, E. Karabulut, F. Gumruk

Hacettepe University, ANKARA, Turkey

Background. In the absence of adequate chelation therapy, cardiomyopathy due to iron overload and heart failure remains the leading cause of death in patients with β-thalassemia major (β-TM). The use of iron chelators is the mainstay of treatment in β-TM patients in order to ameliorate the inevitable complications of iron overload due to regular transfusions. *Aim*. The efficacy in reduction of myocardial iron and maintaining left ventricular functions of combinational therapy with deferoxamine and deferiprone was compared with single deferoxamine group using the gold standard measurement method of cardiac iron, T2* MRI. *Design and Methods*. The inclusion criteria for patient screening with cardiac T2* MRI were diagnosis of β-TM currently maintained on subcutaneous deferoxamine monotherapy; age ≥10 years and maintaining pre-transfusion hemoglobin > 9 g/dL. The patients were either initiated

combined therapy (n=26, Group 1) with oral chelator deferiprone 20-25 mg/kg/dose, tid in addition to subcutaneous deferoxamine 3-5 times a week 30-40 mg/kg/day or continued previous deferoxamine therapy as a single agent (n=13, Group 2). Exclusion criteria were previous initiation of deferiprone, neutropenia (ANC <1.5x10^9/L) or thrombocytopenia (<50 x109/L) at screening and liver enzymes above three times upper limit of normal. All patients were scanned on baseline and prospectively continued to be scanned every six months. The changes between initial and last MRI screenings' T2*, ejection fraction (EF) values and serum ferritin levels at these two points were compared with Wilcoxan Signed Rank for individual drug and for both drugs Mann Whitney U Test. Results The mean age of patients in Group 1 and Group 2 were 18.1±5.2 and 17.6±7.2 years, respectively. The groups were similar in terms of age and gender. The groups were also similar in terms of splenectomy (76.9% and 53.8%, respectively) and Hepatitis C virus (positive in 19.2% and 7.6%, respectively) status. The mean duration of treatments were similar (22.2±7.8 vs 19.6±7.5 months). There was no significant difference between groups in terms of initial serum ferritin levels (3357±2038 vs 2557±1105 ng/ml, respectively). The initial baseline T2* value of Group 1 was significantly lower compared to Group 2 (8.8±4.1 vs 23.7± 6.9 ms, p<0.001) and initial EF was significantly lower in Group 1, as well (48.7±9.2 vs 58.1±3.6%, p<0.001). In group 1, T2* value and EF measured at last MR significantly increased (12.8±7.3 ms, p<0.001 and 56.6±8.6%, p=0.001) compared to initial value of the same group. Whereas, T2* change was insignificant in Group 2 (24.4±5.6 ms, p 0.807), but EF increased to 61.5±4.9 and significant (p 0.039). When the T2* and EF changes compared between two study groups, the differences between T2* and EF values between groups were comparable (p>0.05). *Conclusions*. The results indicate that combinational therapy is effective in decreasing the iron overload in patients with β-TM, in terms of increasing T2* and EF values, compatible with the previously reported literature data.

1296

DEFERASIROX MONOTHERAPY MAINTAINS THE GOOD CARDIAC IRON STATUS IN THALASSEMIC PATIENTS

S. Unal, T. Hazirolan, G. Eldem, E. Karabulut, F. Gumruk

Hacettepe University, ANKARA, Turkey

Background. In the absence of adequate chelation therapy, cardiomyopathy due to iron overload and heart failure remains the leading cause of death in patients with β-thalassemia major (β-TM). The use of iron chelators is the mainstay of treatment in β-TM patients in order to ameliorate the inevitable complications of iron overload due to regular transfusions. Aim The effects of deferasirox on cardiac iron load are limited mostly to the gerbil models and unfortunately there is limited data on its effects in humans. The efficacy in reduction of myocardial iron and maintaining left ventricular functions of deferasirox was investigated using the gold standard measurement method of cardiac iron, T2* MRI. *Design and Methods*. The inclusion criteria for patient screening with cardiac T2* MRI were diagnosis of β-TM a wash-out period from the previous chelation for 24 hours; age ≥10 years and maintaining pre-transfusion hemoglobin > 9 g/dL. The patients were initiated deferasirox therapy as a single agent in a dose of 32±5.9 mg/kg/day (n=17). Exclusion criteria were neutropenia (ANC <1.5x10^9/L), thrombocytopenia (<50 x10^9/L) at screening, serum creatinin exceeding the normal upper limit for age, liver enzymes above three times upper limit of normal. 10 mg/kg dose reduction in deferasirox dose was established if serum creatinin increases more than 50% of the baseline value, but still within normal limits. All patients were scanned on baseline and prospectively continued to be scanned every six months. The changes between initial and last MRI screenings' T2*, ejection fraction (EF) values and serum ferritin levels at these two points were compared with Wilcoxan Signed Rank. Results The mean age of patients were 18.1±7 years (10-33). The male to female ratio 9/8. All of the patients were HBsAg negative and Anti-HBs positive, whereas 1 (5.8%) patient was HCV positive. The splenectomy was performed in 43.7% of the patients. The mean duration of treatment was 11.9±5.9 months. The initial serum ferritin level was 2630±1430 ng/mL (917-7293). The initial baseline T2* and EF values were 25.8±6.4 ms (15.4-39.5) and EF 61.4±5.1% (43.4-73.2), respectively. By the end of the follow-up T2* and EF measured as 24.6±5.2 ms (18.3-36.3) and 63.3±6.8% (50.8-72), respectively; the differences being insignificant. *Conclusions.* Our data on cardiac efficacy of deferasirox is limited, although the initial gerbil studies reported suggest promising data. The initial T2* values of all of the patients in study were above 15 ms, indicating a mild cardiac iron accumulation. But these results may indicate the maintenance of good iron status be deferasirox in at least mildly affected patients. The most important limitation in our knowledge of deferasirox is its being a new drug and the time and further prospective studies will enlighten the efficacy better, especially in the patients with lower intial T2* values.

A RARE HEMOCHROMATOSIS TRANSFERRIN RECEPTOR 2 MUTATION

P. Koliou,[1] G. Baxevanos,[2] E. Dokou,[2] L. Dova,[2] N. Kolaitis,[2] G. Vartholomatos[2]

[1]University Hospital Ioannina, IOANNINA, Greece; [2]Haematology Laboratory, Molecular Biology Unit, University Hospital of Ioannina, IOANNINA, Greece

Background. Hereditary hemochromatosis, a disorder of iron metabolism causes iron overload due to high intestinal absorption with several clinical complications and is prevalent in whites. Usually hemochromatosis presents with mutations in the HFE gene on chromosome 6. About 85% of persons with the established disease are homozygous for the C282Y mutation. The H63D mutation may contribute to the development of hemochromatosis (1.5%), together with the S65C. Other gene mutations include the transferring receptor 2 and the ferroprotein. *Aims*. To establish the genetic basis of a patient with clinical presentation suspicious of hemochromatosis. A 70-year old Caucasian woman from Epirus, Greece with previous history of arterial hypertension, coronary heart disease and a permenant pacemaker, type II diabetes mellitus, and chronic renal failure presented to the outpatient clinic with severe dyspnea and vomiting. *Design and Methods*. General blood analysis, biochemichal liver and iron related tests and genetic testing with Haemochromatosis Strip Assay A (TM) (VIENNA LAB, AUSTRIA). *Results*. On clinical examination orthopnoia, bilateral pleural effusion, enlarged liver size, splenomegaly and ascites were detected. General blood analysis showed leucocytosis (19.72x10^9/L) and mild thrombocytopenia (102x10^9/L). The biochemical tests revealed markedly increased liver function tests ALT 925 IU/L, AST 286 IU/L, GT 397 IU/L, total bilirubin 2.8 mg/dL, direct bilirubin 1.2 mg/dl, serum ferritin 17709 ng/mL and normal TIBC and iron. HBV, HCV and HIV serology was negative. Based on the clinical features and laboratory tests an abdomen ultrasound was performed which confirmed the enlarged liver without the presence of any intra- or extrahepatic findings. Due to the excessively high serum ferritin levels, the clinical findings and the patient history, genetic testing for the presence of hemochromatosis was ordered. The analysis showed wild-type HFE gene for hemochromatosis and a T-->A transversion (T515A), which causes a Methionine-->Lysine substitution at position 172 of the protein (M172K) on TFR2 gene. M172K has a complex effect: it causes a missense in the α-form, but it may also prevent the β-form production because it affects its putative initiation codon. *Conclusions*. The mutation has a variable severity, from asymptomatic to severe clinical expressions. The mutated TFR2 gene detected in the patient implicates that all patients with suspected hemochromatosis should be tested for TFR2 mutation in addition, if an HFE genotype is not mutated or has the heterozygote form. Last, there is a current attempt to approach 1st degree relatives of the patient in order to establish a family pedigree for the rare TFR2 mutation in our region.

1298

MTHFR MUTATION IN PATIENTS WITH SICKLE CELL ASSOCIATED OSTEONECROSIS OF THE FEMORAL HEAD

A.K. Almomen,[1] T. Owaidah,[2] N. Nakshabandi,[1] R. Hasanato,[1] A. Aleem,[1] M. Zamzami,[1] J. Teitel,[3] A. Fauser[4]

[1]King Saud University, RIYADH, Saudi Arabia; [2]King Faisal Specialist Hospital & Research Center, RIYADH, Saudi Arabia; [3]St. Michael Hospital, TORONTO, Canada; [4]Hematology-Oncology-BMT Center, IDAR-OBERSTEIN, Germany

Sickle cell disease is commonly associated with Osteonecrosis (Avascular Necrosis) of the head of femur even in patients with mild sickle cell disease. Suspected risk factors include associated MTHFR gene mutation, α thalassemia trait, elevated HbF level and elevated hematocrit. We studied 55 patients with severe sickle cell disease (32 males and 23 females,(aged 18-43 years), 31 with Osteonecrosis of the femoral head (ON group, 24 males and 7 females) and 24 without Osteonecrosis of the femoral head (Control group, 8 males and 16 females). Each patient gave a consent and had a complete medical history and physical examination,examination,complete blood count, magnetic resonance imaging (MRI) of both hip joints, Hb electrophoresis, molecular diagno-

sis of MTHFR mutation by PCR-RFLP method, Hb F and Hb A2 level by column chromatography Results MTHFR mutation was found in 7 ON patients (3 males & 4 females=0.22) and 5 patients in the control group (one male & 4 females =0.21) without any significant difference between the two groups. Similarly, high Hb F level (>10%), and high Hb A2 (> 3.5%) were similar in both groups. *Conclusions*. There was no evidence that MTHFR mutation, elevated HbF or HbA2 (β Thalassemia) are risk factors or associated with Osteonecrosisof the femoral head in patients with sickle cell disease.

1299

PREDICTIVE VALUE OF HDL & CHOLESTEROL/HDL RATIO IN THALASSAEMIA MAJOR PATIENTS

K.F. Farmaki,[1] Ch. Pappa,[1] A. Papayianni,[1] Ch. Kroupis[2]

[1]Thalassaemia Unit, CORINTH, Greece; [2]Attikon University Hospital, ATHENS, Greece

Background. A low level of high density lipoprotein (HDL<35 mg/dL) is an important risk factor for atherosclerosis and overt Coronary Heart Disease. Total cholesterol to HDL ratio is also suggested to have greater predictive value for CHD than serum total or LDL-cholesterol. Although the prolonged survival in thalassaemia major, heart mortality remains the major cause of death. These patients are characterized by a hypercoagulability state and a high incidence of thromboembolic events. Aim: Investigate the influence of standard serum lipid profile in cardiac and other co-morbidities in β-Thalassemia major patients (TMps). *Design and Methods*. 46 TMps, 23 males, mean age 33.9±1.8, and 23 females, mean age 37.6±0.5 were assessed. -Lipid profile included measurements of total cholesterol, triglycerides, LDL and HDL-cholesterol -Genetic thrombophilia mutations were investigated by PCR analysis of a sample of DNA for Factor V Leiden G1691A, Factor II G20210A, MTHFR C677T and PAI 4G/5G. -Cardiac function was assessed by echo-Doppler - Endocrine function by dynamic tests (OGTT) and hormonal screening (TSH, FT4) -Statistical analyses were performed using SPSS (p<0.05 was considered significant). *Results*. 20/23 (87%) males, had HDL<35mg/dL but only 8/23 (35%) an abnormal LDL>80 mg/dL and 9/23 (39%) high triglyceride concentration >150 mg/dL. All of them had normal cholesterol=120.3±22.5mg/dL. Inversely total cholesterol/HDL ratio was abnormal >5 in 15/23 (65%). The low levels of HDL and high cholesterol/HDL ratio in males TMps were correlated with: cardiac dysfunction: mean LVEF=60.6±6.9% (normal values for TMps >63%); Glucose metabolism disturbances (r=0.629, p<0.01); 7/15 (47%) were hypothyroid (TSH 5-10mU/mL and normal or decreased FT4) ; 13/15 (87%) carried abnormal (homozygous or heterozygous) MTHFR or/and PAI. 12/23 (52%) females had HDL<35 mg/dL but only 9/23 (39%) an abnormal LDL>80 mg/dL and 3/23 (13%) high triglyceride concentration >150mg/dL. All of them had normal cholesterol=130.5±36.2 mg/dL. Inversely total cholesterol/HDL ratio was abnormal >5 in 7/23 (30%). The low levels of HDL and high cholesterol/HDL ratio in females TMps were correlated with: Glucose metabolism disturbances (r=0.568 p<0.02); 2/7 (29%) had compensated hypothyroidism; 6/7 (86%) carried abnormal (homozygous or heterozygous) MTHFR or/and PAI; Normal cardiac function: mean LVEF=65.3±3.8%. In TMps with low levels of HDL and high cholesterol/HDL ratio mean Body Mass Index (BMI) was greater 23.6±3.1 than in TMps with normal HDL and cholesterol/HDL ratio (22.3±1.8). (iii) no correlation was found with mean Ferritin levels and Liver Iron Concentration or liver function. *Conclusions*. The predictive value of HDL & Cholesterol/HDL ratio appears to be high in Thalassemia major patients for whom we must exercise vigilance for close follow up of diabetes (as the lipid pattern is largely related to the glycemic control because is be due in part to hyperinsulinemia and can be detected before the onset of overt hyperglycemia), thyroid and cardiac function mainly in male TMps. Among thrombophilic mutations no prevalence of factor V Leiden and prothrombin G20210A mutations were found in TMps with low levels of HDL and high cholesterol/HDL ratio, but 86-87% had abnormal (homozygous or heterozygous) MTHFR or/and PAI.

1300

EFFECT OF IRON FORTIFIED MILK ON HEMATOLOGICAL CHANGES IN NON-IRON DEFICIENT THAI-SCHOOL CHILDREN

K. Sanchaisuriya,[1] N. Panomai,[2] P. Sanchaisuriya,[3] S. Lowirakorn,[3] S. Yamsri,[4] G. Fucharoen,[4] S. Fucharoen,[4] F. Schelp[3]

[1]Faculty of Associated Medical Sciences, Khon Kaen University, KHON KAEN, Thailand; [2]Graduate School, Khon Kaen University, KHON KAEN, Thailand; [3]Department of Nutrition, Faculty of Public Health, Khon Kaen University, KHON KAEN, Thailand; [4]Center for Research and Development of Medical Diagnostic Laboratories, KHON KAEN, Thailand

Background. Iron deficiency has been known as a major cause of anemia in school aged children. To prevent iron deficiency anemia in this group, implementation of iron fortified milk has been proposed among other strategies. *Aims*. To determine the short term effect of iron fortified milk on hematological parameters of 4thgrade Thai-school children. *Design and Methods*. One-hundred and fifty-five 4th-grade apparently healthy Thai-school children were recruited. Written informedconsent was obtained from their parents. Subjects were divided into two groups; i.e. group 1 (intervention group) comprised 76 children who received 200 mL milk fortified with 5 mg iron (NaFeEDTA) daily, and group 2 (control group) comprised 78 children who received 200 mL of non-fortified milk daily. Blood samples were taken before starting the implementation and after three months when the implementation was terminated. Hematological parameters and ferritin were determined from all blood samples taken. Hb and DNA analyses were performed to detect thalassemia and hemoglobinopathies. *Results*. Based on ferritin level less than 20 ng/mL, none of the subjects had iron deficiency. No significant difference in the proportion of thalassemia trait between the two groups was observed. Hematological analysis in the intervention group revealed no significant difference in mean Hb levels before and after implementation (12.2 g/dL vs. 12.3 g/dL). For control group, a significant reduction in mean Hb levels was observed (from 12.6 g/dL to 12.3 g/dL). Although the MCV and MCH values significantly increased for both groups, the increment (2.6 fl for MCV and 0.5 pg for MCH) was significantly higher for the intervention group in comparison to the control group (2.1 fl for MCV and 0.2 pg for MCH). *Conclusions*. Although Hb concentrations in children who received iron fortified milk did not increase, a constant Hb level and a significantly higher MCV and MCH values suggest that iron fortified milk may be one of the strategies to maintain Hb level in school children living in areas with a well known high prevalence of iron deficiency.

1301

SAFETY, EFFICACY AND EFFECT ON QUALITY OF LIFE OF PARENTERAL IRON SUCROSE INFUSION IN PEDIATRIC PATIENTS

M. Economou, A. Teli, N. Gompakis, M. Athanassiou-Metaxa

Hippokration General Hospital of Thessaloniki, THESSALONIKI, Greece

Backround. Intravenous (iv) iron administration is used as a blood transfusion alternative in cases where blood parameters must be raised rapidly or for patients where oral administration is not indicated. However, experience on parenteral iron therapy is based mainly on adult patients receiving hemodialysis. Data regarding children, including iron pharmacokinetics and maximum tolerated doses of iv infusion, is limited. *Aims*. We aimed to determine the effects of iv iron therapy on blood parameters in pediatric patients who do not tolerate or fail to respond to oral iron therapy for various reasons; also, to define adverse events following iron infusion and to correlate possible side effects to infusion dose; finally to assess the effect of multiple parenteral infusions with regards to both safety as well as to quality of life of children receiving serial iv iron administration. *Design and Methods*. Iv iron was administered to 17 children, aged 14 months to 15 years (mean 6.5±4.3 years). Children received parenteral iron due to malabsorbtion, gastrointestinal blood loss, oral supplementation intolerance or bad compliance. In detail, 2 patients were diagnosed with celiac disease, 2 with allergy to cow's milk proteins, 1 with ulcerative colitis, 4 with cerebral palsy, 1 with autism, 1 with Aicardi syndrome, 1 with mental retardation, 1 with Down syndrome, 1 with immune deficiency, 2 with refractory anemia of unknown cause and 1 with inadequate iron intake due to sole breast-feeding (at the age of 14 months). Blood samples were taken before infusion (day 1), as well as 15 and 45 days following infusion. Hemoglobin values, erythrocyte indices and serum ferritin levels were measured. Iron sucrose was used as an intravenous iron preparation and a test dose, although not required, was used. Total iron to be infused was

determined by the formula: *total iron [mg] = weight [kg] x (expected Hb - patient Hb) [g/dl] x 3, where expected Hb = 12.5 g/dl.* In total 55 infusions were administered (1-12 infusions per patient), with a mean dose of 8.76±4.47 mg/kg (max 17.7 mg/kg) and the total single infusion dose not exceeding 200 mg. Results: A statistically significant elevation occurred between the time of diagnosis and the time of follow-up in all parameters. No adverse events were noted and no features of systemic iron toxicity encountered, even when large doses or multiple infusions were used. Children receiving multiple infusions remained free of oral iron during follow-up, both children and their parents reporting a significantly improved quality of life during the period of infusions with regards to school performance, physical activity and sense of general well being. *Conclusions*. Parenteral iron therapy in children is a rapid, easy and definitive solution and can replace oral therapy in a variety of pediatric diseases which lead to severe iron deficiency and where oral iron administration is contra-indicated. Intravenous iron seems to be safe even when administered to very young children or infants. Multiple infusions can be administered when required, offering a better quality of life to children suffering from chronic diseases.

1302

EFFICACY AND SAFETY OF PREOPERATIVE RECOMBINANT HUMAN ERYTHROPOIETIN ADMINISTRATION IN PATIENTS UNDERGOING SURGERY FOR HIP FRACTURE REPAIR. A PROSPECTIVE OBSERVATIONAL STUDY

J.A. García-Erce,[1] J. Cuenca,[1] S. Haman-Alcober,[2] B. Soria,[1] D. Rubio,[3] A. Herrera,[2] M. Muñoz[4]

[1]SALUD, ZARAGOZA, Spain; [2]Orthopaedic Surgery, HU Miguel Servet, ZARAGOZA, Spain; [3]Haematology, UH Miguel Servet, ZARAGOZA, Spain; [4]GIEMSA. Medicina Transfusional, Universidad Málaga, MÁLAGA, Spain

Background. Preoperative anaemia is a major risk factor for allogeneic blood transfusion (ABT) in patients undergoing hip fracture repair. Aims. We prospectively investigated the effect of a blood conservation protocol on ABT requirements in 196 consecutive hip fracture patients presenting with haemoglobin (Hb) between 10 g/dL and 13 g/dL. *Design and Methods*. The blood conservation protocol consisted of the application of a restrictive transfusion trigger (Hb<8 g/dL) and the peri-operative administration of IV iron sucrose (3x200 mg/48 h) (Group 1, n=115). Additionally, 81 patients received recombinant human erythropoietin (rHuEPO, 40,000 IU sc) on admission to the orthopedic ward. *Results*. Overall, 103 out of 196 patients (52.5%) received at least one ABT unit (2.1±1.0 U/patient). However, there were significant differences in perioperative ABT rates between groups (60% vs 42%, for groups 1 and 2, respectively; p=0.013). Postoperative Hb on postoperative days 7 and 30 were higher in Group 2 than in Group 1. In addition, in Group 2, Hb levels were higher on postoperative day 30 than on admission (12.7±1.0 g/dL vs. 11.9±0.8/dL, respectively; p=0.030). ABT, but not rHuEPO, increased postoperative complication and 30d mortality rates. Only 3 mild IV iron adverse effects were witnessed. *Conclusions*. Peri-operative IV iron and single doses of rHuEPO plus restrictive transfusion trigger seem to be safe and effective in reducing ABT in anaemic hip fracture patients. However, appropriate diffusion and a persisting awareness is needed to avoid protocol violations and to limit further the exposure to ABT and ABT-related risks.

1303

EVALUATION OF DIAGNOSTIC RELIABILITY OF DIFFERENT RBC INDICES IN THE DIFFERENTIATION OF MICROCYTIC HYPOCHROMIC ANAEMIAS

M. Ferrara, L. Capozzi, R. Russo

Second University of Naples, NAPLES, Italy

Background. Iron deficiency anaemia (IDA) and β-thalassemia trait (βTT) are the most common causes of hypochromia and microcytosis in adults as well as in children. *Aim*. This study evaluates the diagnostic reliability of various red blood cell (RBC) indices and formulas in the differentiation of IDA and βTT. *Design and Methods*. In 458 children of both sexes (260 males, 198 females) aged between 1.8 and 7.5 years (mean age 5.6±1.7 yrs) with hypochromia and microcytosis certainly diagnosed on the bases of blood count, iron assessment and quantitative identification of HbA2 by HPLC (253 IDA, 105 βTT), we have evaluated the diagnostic reliability of the following indices and formulas: *Red Distribution Width index (RDWI), Mentzer index (MI), Green & King index (G&K), England & Fraser index (E&F)*. The discrimination indices incorporate MCV, MCH, RBC, RDW and Hb in various combinations. The Sensitivity (SENS), Specificity (SPEC), Positive and Negative Prognostic Value (PPV and PNV), Efficiency (EFF) and Youden's Index (YI) were calculated. Gauss curves were also constructed to evaluate the reliability of each index and formula. *Results*. In children with IDA haematological data were: RBC 4.75±0.35x10^{12}/L, Hb 10.2±1.7 g/dl, MCV 71.7±3.1 fl, RDW 17.3±3.1%; in children with β-TT mean values of RBC were 5.5±0.9x10^{12}/L, Hb 11.3±1.5 g/dl, MCV 63.2±2.6 fl, RDW 16.2±3.4%. The G&K shows the highest reliability, with SENS 78%, SPEC 97%, PPV 99, NPV 56, E&F 82, YI 71. The other calculated indices show lower reliability. *Conclusions*. Our study shows that all discrimination indices that were examined cannot be relied on for a safe differentiation between IDA and β-TT. The G&K Index results highly specific but its sensitivity is not satisfactory. We conclude that the certainly differential diagnosis between IDA and β-TT must be performed by blood count, iron assessment and quantitative identification of HbA2.

1304

SCREENING OF HIGH RISK ETHENIC GROUP FOR HEMOGLOBINOPATHIES: IS IT MORE COST EFFECTIVE THAN NO SCREENING

A. Abd ELmoneim, A. Abo-Elwafa, O. Hamad

Sohag University, SOHAG, Egypt

Background. Egypt is an African country and at the same time is one of the Mediterranean area countries. Consequently, mutations of ß-globin and a-globin genes can occur resulting in high incidence of ß-thalassemias and a-thalassemias among children. Similarly, sickle haemoglobin is common in African ethnic group and in association to a-thalassemia with proposed increase in incidence of sickle cell disease (SCD) in Egypt. In this analysis we examined blood samples from Egyptian newborns in a trial to determine whether screening for hemoglobinopathies is more cost effective than no screening. Aim. Our primary goal is to identify diseased phenotypes. *Design and Methods*. Peripheral blood samples were collected from 2000 Egyptian newborns, after taking written consents from parents, and examined for hemoglobinopathies using hemoglobin electrophoreses. Haemoglobin (Hb) phenotype nomenclature follows a standardized format in which the order of the letters indicates a relative quantity of Hb present (i.e. HbFSA indicates HbF>HbS>HbA in the sample). High performance liquid chromatography was used to determine the variant β-globins (e.g. D, E, G). *Results*. 280 neonates are HbF phenotype, of them 230 are thalassemia major and the remaining 50 are extreme premature. 150 neonates are HbAF phenotype (transfused phenotype). 34 neonates are HbFA2 phenotype (thalassemia trait). 3 neonats are HbFS phenotype (SCD) and 6 neonates are HbFAS, HbFAC or HbFAD phenotype (trait phenotype). 1527 neonates are HbFA phenotype (normal phenotype). Identification of homozygous βs (HbSS or SCD) or Thalassemia major (HbF only) at birth allows a comprehensive clinical care and decreases mortality. Identification of trait phenotypes requires no specific hematologic follow up but family studies with genetic counselling can clarify the risks of disease in future children, especially in populations with high carrier rates. *Conclusions*. Screening of Egyptian newborns as a high risk ethnic group is more cost-effective than no screening. Practitioners should be familiar with the screening programs in Egypt and similar areas of high risk ethnic group.

1305

CEREBROVASCULAR ACCIDENT ASSESSMENT IN A POPULATION OF HBS/B-THALASSAEMIA PATIENTS

K. Karasmanis

Hippokration GN, THESSALONIKI, Greece

Background. Cerebrovascular accident (CVA) is a potential complication of sickle cell anemia, which ranges from overt stroke (with abrupt onset of neurological deficit) to silent infarcts, which are not acutely clinically apparent but are associated with cognitive impairment and increased risk of secondary overt stroke. In populations of mostly HbSS patients, the prevalence of silent infarcts in children with sickle cell disease has ranged from 17% to 22-35%, while 11% will have a clinically apparent stroke by age 20 years and 24% by age 45 years. *Aims*. We assessed the incidence of CVA in a population of exclusively HbS/β-thalassaemia patients. *Design and Methods*. Brain MRI was obtained from each patient in a population of 20 HbS/β-thalassemia patients and was analyzed for evidence of CVA. Their age ranged between 5 and 33 years old (mean age = 17.7 years). All patients were in steady state with no neurological signs. *Results*. Seven patients had prior brain MRI 8 years

before, with silent infarcts having been identified in two of them. In the follow up, one of these two presented the same MRI condition, with no new findings added up, and the second presented a normal MRI. While the study was in progress one patient with a prior normal scan, underwent a clinically overt stroke confirmed by a new brain MRI. All other patients scanned had normal findings. Transfusion regimens have shown to reduce both primary and secondary risk for CVA. In our cohort four patients were under transfusion regimen at some point before the scan, for a period of 3 to 12 months (median = 4 months), 3 while treated for Avascular Necrosis of the Femoral Head and one during a period of excess spleen enlargement. Also hydroxyurea as an alternative to transfusion therapy for secondary CVA prevention was proposed since a decade ago. Four of our patients are under hydroxyurea treatment for a period of 1.5 to 8 years (median = 2 years). Notably the patient showing improvement in the follow up underwent both treatments. *Conclusions*. One overt stroke was noted (5%).The incidence of silent infarcts in the population of our study was 5%(1 of 20), which is slightly lower from that noted by other researchers, and can be attributed to the lighter clinical course of HbS/β-thalassaemia patients. More studies are needed to establish new therapeutic protocols in order to further reduce CVA risk in sickle cell disease.

1306

PARAOXONASE AND ARYLESTERASE ACTIVITY WITH OXIDATIVE STATUS IN CHILDREN WITH THALASSEMIA MAJOR

A. Cakmak,[1] M. Soker,[1] A. Koc,[1] O. Erel[2]

[1]Hematology, SANLIURFA, Turkey; [2]Department of Clinical Chemistry, SANLIURFA, Turkey

Background. Paraoxonase deficiency is related to increased susceptibility to low density lipoprotein oxidation and development of atherosclerosis. *Aim*. The aim of this study was to study paraoxonase and arylesterase activities along with oxidative status parameters, and to find out if there is any increased susceptibility to atherogenesis, which might be reflected with increased oxidative stress and decreased serum Paraoxonase/arylesterase activity in β-thalassemia major (BTM) patients. *Design and Methods*. Eighty-seven subjects with BTM and 33 healthy subjects were enrolled in the study. Results: Paraoxonase and arylesterase activities were significantly lower in BTM subjects than controls (for all $p<0.0001$), while total oxidant status, total peroxide concentration levels and oxidative stress index were significantly higher ($p<0.0001$, $p<0.0001$ and $p<0.001$; respectively). In BTM subjects were correlations found between serum iron and ferritin and levels of total oxidant status, oxidative stress index, total antioxidant capacity. Significant correlation were found with serum total peroxide concentration levels and paraoxonase and arylesterase activities in patients with BTM. *Conclusions*. It was seen that oxidative stress increases, while serum paraoxonase activity is decreased in BTM subjects. Decrease in paraoxonase activity seems to be associated with both the degree of oxidative stress and anemia. BTM subjects may be more prone to development of atherogenesis due to low serum Paraoxonase/arylesterase activity.

1307

ERYTHROCYTES ACID AND ALKALINE FRAGILITY AS A CHARACTERISTIC OF THE MEMBRANE-ACTING PROPERTIES OF A CU/CD ACETATE COMPLEX WITH ETHYLENEDIAMINE - A POTENTIAL THERAPEUTIC AGENT

I.V. Byelinska, T.V. Rybalchenko, O.V. Nesterova, V.N. Kokozay, V.K. Rybalchenko

National Taras Shevchenko University of Kyiv, KYIV, Ukraine

Background. In previous study was shown bactericidal, fungicidal and antitumor (cytotoxicity effect on human erythroleukemia cell (K562), breast cancer cell (MCF-7) and Lewis lung carcinoma cell (LLC)) activities of a novel Cu/Cd acetate complex with ethylenediamine (code PO244). The aim is to study of Cu/Cd acetate complex with ethylenediamine cells memrane effects. *Method.* Erythrocytes fragility under action of PO244 [Cu(en)2][Cd2(CH3COO)6] and 0.75 mM or 7.5 mM HCl (acid fragility), or 7.5 mM NaOH (alkaline fragility) has been studied. *Results.* The Cu/Cd acetate complex with ethylenediamine interacts with membranes of erythrocytes what is manifested by increasing of the fragility of these cells to acid or alkaline action. PO244 increases the fragility of "old" and middle life cycle erythrocytes. The most active component of the complex towards membranes of erythrocytes must be copper (II) what is supported by hemolysis of 100% erythrocytes immediately after an injection of acid or alkaline after incubation of the cells with 10-4 M CuCl2. The influence of lower concentrations (10-6, 10-7 M) of these ions gives evidence that acid resistance of both "old" and "young" erythrocytes is decreased. The harmful influence of copper(II) exceeds that of PO244 more than four times at the same concentration of copper. Cadmium(II) ions (10-4 M) do not change acid fragility but decrease alkaline fragility of erythrocytes. Ethylenediamine increases fragility of "old" and middle life cycle erythrocytes. Sodium acetate increased in fragility of "young" and the middle life cycle erythrocytes. *Conclusions*. The influence of PO244 on erythrocytes is a result of the action of the initial compound and not the products of its decomposition what is confirmed by the different influence on the erythrocytes stability of the complex investigated itself and its "components": salts of copper (II) and cadmium, ethylenediamine and sodium acetate.

1308

IRON CHELATION THERAPY WITH DEFERASIROX IN ADOLESCENTS AND YOUNG ADULTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA

N. Katzilakis, C. Perdikogianni, I. Pelagiadis, E. Markaki, E. Stiakaki, M. Kalmanti

University Hospital of Heraklion, HERAKLION CRETE, Greece

Background. Deferasirox is one of the main iron chelation agents for patients with hemoglobinopathies and myelodysplastic syndromes. Its role as iron chelation therapy has not been studied in patients with acute lymphoblastic leukemia (ALL). *Aim.* The investigation of the safety and effectiveness of Deferasirox as iron chelation therapy in young patients with acute lymphoblastic leukemia (ALL) who were over transfused with packed red cells during intensive chemotherapy. *Design and Methods*. Two patients with ALL aged 17 and 19 years old at diagnosis who were treated with intensive chemotherapy according to the high risk arm of the ALL-BFM 2000 protocol, were studied regarding the iron overload due to blood transfusions during their treatment and deferasirox administration. *Results*. Both patients started on deferasirox in a mean dose of 10 mg/kg, after the completion of intensive chemotherapy, during maintenance phase therapy with daily oral 6-Mercaptopurine and oral Methotrexate once weekly. The first patient had serum ferritin levels 8798 ng/mL after he had received 280mg iron/kg in an11month period (0.84 mg iron/kg/day) while the second one had ferritin levels 3533ng/mL following the transfusion of 338mg iron/kg during 2 years period (0.45mg iron/kg/day). The second patient has already finished his treatment protocol and is currently on follow up. Both patients had good compliance with deferasirox without any adverse effect. Temporary elevation of serum creatinine was reduced to normal with deferasirox dose adjustment. Six months after deferasirox initiation the first patient had serum ferritin levels 3100 ng/mL and the second one 2445ng/mL respectively. Both are still on iron chelation therapy and on follow up by cardiac T2* and liver iron concentration (LIC) measurements. *Conclusions*. Iron chelation therapy probably should be considered for high risk adolescents and young adults with ALL who are treated with very intensive protocols essential for cure to be achieved. The dose of deferasirox is under consideration.

1309

DETERMINATION OF β-GLOBIN GEN HAPLOTYPE IN SICKLE CELL ANEMIA PATIENTS IN AHWAZ AT 2007

M. Kadkhodaei Elyaderani, H. Hosseni, M. Noor Behbahani, M. Pedram, B. Keykhaei, K. Zandian

Ahwaz Jundishapour University of Medical Sciences, AHWAZ, Iran

Introduction. The hemoglobinopathies affect the blood red cells are the most common monogenic disease world wide. The high frequency and clinical severity of hemoglobinopathies make them a major public health problem. Sickle cell disease is the most common hemoglobinopathy in the world. Clinical manifestation in some patients are severe and in some are mild. It is suggested that β-globin gene haplotype influence the clinical presentation of sickle cell disease. *Aim of study.* In this study the aim was to determine the origin of sickle cell mutation by determination of common haplotypes of βS gene cluster in sickle cell patients from Ahwaz ; a city in Southwest province of Iran. Method: Molecular genetic studies were undertaken to determine the haplotypes of chromosomes carrying the sickle-cell allele. From each SS patient 5 mL EDTA blood was taken and stored at -20. DNA prepared from the subjected leukocytes by DNA extraction kit. Haplotype analysis of the b-globin like gene cluster was performed by using the following restriction endonucleases: Hind II, Hind III, Xmn1, Ava II. Agarose gel electrophoresis of PCR and enzyme digested products were performed using 2%

agarose. *Results.* All seven haplotypes were found in our study patients. Arab-Indian haplotype was found to be the most prevalent haplotypes in this study population. This haplotype accounted for 12.9% as the homozygous form in total SS patients, while 51.8% of the chromosomes had Arab-Indian haplotype. Benin haplotype with prevalent of 12.9% and BantueA2 with prevalent of 11.1% were the second and third prevalent haplotype among all patients. Incidence of homozygote haplotype was 44.4%.. *Discussion and Conclusion*. The presence of the Arab-Indian haplotype as the predominant haplotypes might be suggestive of a gene flow from Saudi Arabia or India to this area and presence of Benin , Bantue A2 and Senegal haplotypes in this area must have occurred during the Arab slave and trade with Arabian countries.

1310

USEFULNESS OF THE PARAMETER RET-HE IN THE INITIAL DIAGNOSIS APPROACH OF THE ANEMIA DUE TO CHANGES OF THE IRON METABOLISM IN SUBSTITUTION OF THE STANDARD BIOCHEMISTRY DETERMINATION (SERUM FERRITIN)

C. Rodríguez, De la Iglesia S, Navarro N, Martín P, Lopez J, Quiroz K, Fumero S, Gomez M, Lemes A, Molero

HUGC Dr. Negrín, LAS PALMAS, Spain

Background. Recently, there have appeared new generation autoanalyzers which have brought new parameters to the semiology of the red series such as the 'Content of Haemoglobin Reticulocytes'. This series is a marker capable of providing information about the contribution of iron to erythropoieisis, allowing the detection of iron deficiency in the synthesis of haemoglobin. Among these are the 'Chr' of Advia autoanalyzer and the "Ret-He' of the Sysmex 5000. Several groups have reported the presence of statistically significant differences between mean values of Content of Hemoglobin reticulocytes in Chronic Diseases Anemia (CDA) regarding to the Ferropenic Anemia (FA) and health control. These findings appeared at the same time with the contribution of knowledge to the CDA pathophysiology that became hepcidin. They also define the mechanism by which inflammation is an iron sequestration at the mononuclear phagocytic system, and would be consistent with values "Ret-He" intermediate between the FA and the healthy controls. *Aims*. 1-Describe the middle values of Ret-He in the patients diagnosed of FA and CDA during 2006-2007 in our service, as well as control group. 2-Analyze the usefulness of the parameter Ret-He in the initial diagnosis approach of the anemia due to changes of the iron metabolism in substitution of the standard biochemistry determination (level of serum ferritin). *Design and Methods*. A total of 672 samples were processed with the autoanalyzer Sysmex 5000, of which 385 were FA, CDA 130, and 157 normal controls. Statistical analysis was performed with SPSS 14.0 software. *Results*. Statistical analysis using the Student t for samples with different population variances showed that the difference in the mean value of "Ret He" was statistically significant (p<0001) To test the potential usefulness in the initial approach to study the probability of diagnosis by the design of contingency tables that cover the following variables: FA if Hb<10 gr/dl , MCV <78 fl and ferritin <20 mg/dl, FA if Hb<10 gr/dl , MCV<78 fl and Ret-He <23 pg, CDA if Hb<10 gr/dl , MCV 80-100 fl and Ferritin >200 mg/dl, CDA if Hb<10 gr/dl, MCV 80-100 fl and Ret-He 26-30pg. In FA found in a similar probability for the diagnosis (169 cases with Ferritin and 160 in Ret-He group) with an advantage for the reason 'Diagnostico FA Ret-he <23' of 49x (95% CI 19,8-121, 5) against not. For the group of CDA, we found a difference in value against the Ret-He versus standard ferritin (33 of 17 cases) with an advantage for the reason, 'Diagnosis of CDA Ret-He26-30 'only 3.1 x (IC 95% 1,63-5,89) against not. *Conclusions.* In this work, we found significantly different statistical Ret-He values for the different groups of patients (CDA, FA, normal) coherent with present phisiopatologic knowledge. We found similar probability for the diagnosis of FA to replace the standard "Ferritin" with this new parameter, however this is not reproducible advantages for patients in group CDA.

Table.

	Average	Median
FA (n=385)	22,41 pg/dL	21,82
CDA (n=130)	28,41 pg/dL	28,45
NORMAL (n=157)	33,29 pg/dL	33,40

1311

PROMPT RECOVERY OF END STAGE ACUTE HEART FAILURE IN β-THALASSAEMIA MAJOR AFTER INTENSIVE COMBINED CHELATION: A CASE REPORT

K.F. Farmaki, I. Tzoumari, P. Kolimpianaki, Ch. Pappa

Thalassaemia Unit, CORINTH, Greece

Background. Heart failure (HF) caused by myocardial iron overload, is the leading cause of mortality in Thalassaemia major patients (TMps). Continuous IV Deferoxamine is considered to be the standard of care in these cases. Although combined chelation has been demonstrated to be of clear benefit in the treatment of cardiac siderosis in TMp, its role in the management of severe end-stage HF has not been specifically addressed. Aims: To evaluate the effectiveness of an intensive combined chelation protocol in the case of an end-stage acute HF of a 28 year-old male TMp. *Patient*.A transfusion dependent splenectomised TMp, non-compliant to chelation therapy who the last 3-5 years developed non insulin-dependent diabetes, subclinical hypothyroidism (reduced FT4, FT3), hypoparathyroidism (PTH=5.2 pg/mL), hypocalcemia=6.3 mg/dL and Hypogonadism (reduced LH & Testosterone). He was presented with acute decompensate HF (NYHA) class IV: fatigue, weakness, inability to perform usual activities, weight gain, abdominal distention, generalized edema and dyspnoea. *Design and Methods*. Echo-Doppler: dilated cardiomyopathy, Left Ventricular (LV) systolic & diastolic dysfunction with concomitant Right Ventricular (RV) enlargement & systolic dysfunction and dilatation of vein cave, abdominal ultrasound: hepatomegaly (22 cm) & abundant ascetic collection. Laboratory tests: BNp=414 pg/mL, important increase of ALT, AST. Iron load was evaluated by Ferritin (MEIA), Signa-MRI 1.5 Tesla T2* sequences for the heart & the liver and Liver Iron Concentration (LIC) calculated by Ferriscan. He was hospitalized in a specialist center for close monitoring. The treatment focused on two goals: intensive combined chelation with Deferiprone 120 mg/kg/d & IV Deferoxamine 60 mg/kg/d in order to decrease heart hemosiderosis and management of heart dysfunction (IV diuretics, Sodium & fluid restriction, hemodynamic stabilization, support of oxygenation and symptom relief). *Results.* After 6 months of outcome treatment with diuretics, β blockers, Calcium, vit D and intensive combined chelation (Deferiprone 120 mg/kg/d & SC Deferoxamine 60 mg/kg/d): serum Ferritin decreased dramatically from 6.839 μg/L to 632 μg/L, MRI T2*H increased from 1.6 ms (very severe hemosiderosis) to 3 ms (severe hemosiderosis) and T2*L improved significantly from 0.5 ms (severe hemosiderosis) to 5.5ms (mild iron load), LIC decreased significantly from 52 mg/g/ dwt (very severe hemosiderosis) to 4.8 mg/g/dwt (mild iron load), progression from HF NYHA class IV (severe) to class II (mild) with substantial regression of symptoms: weight loss (25Kg), no edemas, no dyspnoea and a slight limitation of physical activity. Echo-Doppler: improvement of systolic & diastolic LV function and LVEF from 27% to 43% and regression of RV systolic dysfunction. Regression of hepatomegaly and normalization of ALT, AST. No more ascetic collection. No adverse events were observed from intensive combined chelation. *Conclusions*. This case report demonstrates that intensive combined chelation with Deferiprone 120 mg/kg/d & Deferoxamine 60 mg/kg/d along with symptomatic treatment could improve end-stage acute HF promptly and preserve TMp life. It is the first time that Deferiprone was used in the dose 120mg/kg/d without any side effects and so tremendous and rapid results. The cardio-protective effect of Deferiprone, as reported in many publications, give us the expectation of complete restoration of cardiac function in short term.

1312

CHELATION THERAPY IN MAJOR β THALASSEMIA

N. Mirbehbehani

Taleghani Hospital, Hematologist, Faculty of medicine, Research center of thalassemia and hemophilia ,Golestan university of medical sciences, Gorgan, Iran

Background. Progressive iron overload is the life-limiting complication of transfusion therapy.Effective and convenient iron chelation remains one of the main targets of clinical management of thalassemia major. The combined treatment with deferoxamine (DFX) and Deferiprone (DFO) could have an increased chelation efficacy. Aims: Deferiprone may play a role in shuttling iron within membranes and within intracellular pools.We compare DFX alone with combined therapy with DFX and DFO in β thalassemia patients with iron overload. *Design and Methods*. We studied 28 patients with β thalassemia major in two group (mean age±SD, 20.02±5.3; range 10-34 years) attending the day care unit for regular transfusional support. They received packed red

cells every 3-4 weeks to maintain pretransfusion hemoglobin major concentration above 9 g/dl. They had been receiving DFX at a daily dose of 40 mg/kg/d by subcutaneous infusion for 8-10 h on 5-6 nights each week for the past several years. (DFX) alone (40-50 mg/kg/d S.C. over 8-12 h, five times weekly) was compared with combined DFX 40 mg/kg/d (3times a week) and DFO 75 mg/kg/d daily over 6 months period. Serum ferritin level and side effects were monitored over a 6 month period. *Results*. Serum ferritin fell from98/3434±83/7539 µg/L (mean±SD) to 26/2706±66/4848 µg/L(p<0.001) and to75/2308±33/4338 (p<0.001) after three and six month in the combined group and raised from83/3613±00/5668 µg/L to 93/3940±81/6210 µg/L (P153/0≤) and to99/3205±07/5742 (p/0≤902) after three and six month in the DFX group. The most common adverse events were gastrointestinal symptoms (8.25%) and joint pain (8.25%) and transaminasemia (21%) in combined therapy. *Conclusions*. The availability of effective oral chelators would be a major clinical advance.Acording our study combined therapy with DFX and DFO is a practical and effective procedure to decrease severe iron overload in patients with thalassemia major.

1313

ANTIOXIDANTS SUPPLEMENTATION DURING PREGNANCY PREVENT PRE-ECLAMPSIA AND PROVIDE FETAL ERYTHROCYTE STABILITY

A. Abo-Elwafa, S. Abd El-Moneim, E. Ameen, S. Ahmed, A. Abd ELmoneim

Sohag Faculty of Medicine, SOHAG, Egypt

Background. Pre-eclampsia affects 2.8% of all pregnancies, characterized by vasoconstriction, cell damage and coagulation disorders. About 30% of maternal deaths are due to pre-eclampsia. Also, environmental, nutritional status, genetic factors all are predisposing factors lead to placental ischaemia endothelial cells dysfunction and decreasd blood flow. Free radicals play a part in the genesis of the disease Natural antioxidant have antioxidative, antiproliferative and anti-inflammatory effects. Newborns, especially the preterm ones have a limited antioxidant protective capacity. The protective system against free radicals on red blood cell membrane includes vitamins A,E,C ,trace element selenium(Se) and enzymes as glutathione peroxidase (GSH-Px). *Design*. Aim of the study : To investigate the possibility of preventing pre-eclampsia and protect feotal erythrocytes from haemolysis through antioxidant therapy during late pregnancy. *Design and Methods*. The study was done on the peroid from December (2006) to December (2008) on one handered and thirty pregnant females , group I (18-40 year old) whome are risky for developing pre-eclampsia and had received antioxidant therapy in the early pregnancy (first trimester), this patients repeat their hospital visit for follow up, and other one handered pregnant females, group II (of the same age and risk factors), that had not been received antioxidants as a control group. Both group were subjected for lab. investigation (C.B.C on H-Max Coulter system , coagulation profile : PT, aPTT, Fibrinogen, TT, D-dimer on Sysmex system, vWF by latex agglutination method , Platelet activation by ADP/Collagen on PFA-100 , blood chemicistry as uric acid, total cholesterol, low density lipoprotein, liver and renal function also blood glucose). The neonates of both groups were subjected to complete blood count & reticulocytes, total and direct serum billirubin, RBCs antioxidant enzymes (GSH) & (G6PDase) . Samples from all females and babies of both group were subjected to measurement the level of antioxidant (Vitamines: C, E, A, D) in the circulation by high performance liquid chromatography HPLC method. Results: Antioxidant therapy during pregnancy in high risk female can improve the clinical condition of pre-eclampsia to minimal degree, the Bl.P is not affected, L.L. oedema is non significantly improved,only the platelate activity, D-dimer and vWF are significantly decreased (p<0.05), C.B.C including platelet count is not affected. As regard coagulation parameters P.T and a.P.T.T are not significantly changed, T.T and plasma fibrinogen is significantly decreased in the treated group, renal function, liver function- s.albumin and lipogram are non significantly affected. Neonatal improvement by maternal antioxidant therapy is noticed mainly on indirect s.billirubin level which is highly significantly decreased (p<0.005), RBCs and reticulocytes count are significantly improved (p<0.05), As regard WBCs ,the neutrophiles count is not significantly changed, the staff(band) is significantly decreased (p<0.05). Birth wt is significantly increased (p<0.05). neonatal deaths is significantly decreased (p<0.05), still birth is not affected. *Conclusions*. Antioxidant therapy during pregnancy in high risk females for preeclampsia is penificial in improvement neonatal hyperbilirubinaemia and to some degree improved clinical condition to the mothers

IN VITRO STUDY OF NEUTROPHIL APOPTOSIS IN CHRONIC HEPATITIS C PATIENTS

A. Hussein, F. Essawy, M. El Ansary, K. Ima, H. Helmy, M. Moustafa, M. El Razki

Theodor Bilharz Research Institute, CAIRO, Egypt, CAIRO, Egypt

The apoptotic process appears to be a host defence mechanism against viral infections and tumourigenesis. However, many viral genomes encode proteins which repress apoptosis so as to escape from immune attack by the host. Apoptosis of liver cells may play a significant role in the pathogenesis of hepatitis C. The hepatitis C(HCV) core protein exhibits both proapoptotic or antiapoptotic actions. This study aimed to detect the role of neutrophil apoptosis as a mechanism of liver cell injury in chronic hepatitis C in order to determine its relation to shortened neutrophil survival in HCV patients, accounting in part for the mechanism of neutropenia as a trials to use therapeutic inhibitors of apoptosis in HCV patients, which might be an effective cure of the associated neutropenia. Thirty patients with chronic HCV infection and 15 normal controls were included in this study. HCV patients classified into 2 groups (Group I) 15 patients with chronic HCV without neutropenia, (Group II) 15 patients with HCV with neutropenia. They were subjected to full clinical examination ,abdominal ultrasono- graphy, haematological profile, liver and kidney function tests, hepatitis markers for HBsAg and HCV AB , qualitative HCV-RNA detection by PCR in patient groups and parasitological examination. Neutrophils were separated using Percoll density gradient and cultured , then neutrophil viability was assessed by the trypan blue dye exclusion test where viability was >98%. For detection of apoptosis , quantitative assay using flow cytometry to measure Annexin V as a marker of early apoptosis and a semiquantitative assay using terminal deoxynucleotidyl transferase mediated deoxyuridine triphosphate nick end labeling test (TUNEL) system which measures nuclear DNA fragmentation as well as the level of soluble Fas (sFas) on neutrophils in culture supernatant by enzyme linked immunosorbent assay(ELISA) in addition to the detection of the morphological features of apoptosis by light and electron microscopy. The results showed that the level of annexin V by flow cytometery decreased with the progression of the hepatitis in relation to the control group because annexin V is a marker of early apoptosis. We noticed that with the progression of the hepatitis C there was increase in the neutrophil apoptosis with DNA fragmentation , that is why the cells which uptook PI dye (necrotic cells) increased with the progression of the disease in relation to the control group.TUNEL test revealed a significant increase in group I in comparison to the control group and to group II but there was no significant difference between group II in comparison to the control group . Soluble Fas (sFas) showed a significant increase between group II in comparison to the control group but there was no significant difference between group I in comparison to the control or in comparison to group II. LM & EM examination revealed that apoptotic cells were detected in 100% of neutropenic HCV patients while it was 30% in HCV patients alone and we could observe the sequence and steps of apoptosis represented by intense perinuclear chromatin condensation , fragmented nucleus , vacuolated cytoplasm , apoptotic bodies with intact cell membrane and finally release of apoptotic bodies.We concluded that sFas, tunnel tests and EM examination are more significant in detecting apoptosis in HCV patients rather than annexin V. We can use some inflammatory mediators for delaying neutrophil apoptosis in HCV patients to give chance for neutrophils to interrupt viral replication and elimination of viral infected cells by the host.

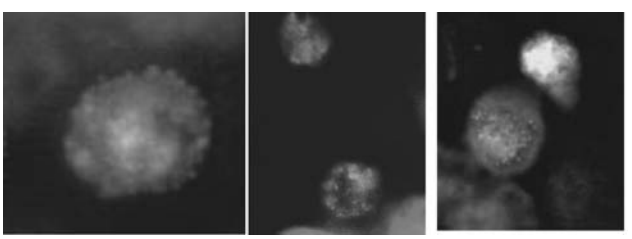

Figure 1. The nuclei with fragmented DNA were labeled.

INCIDENCE OF CHEMOTHERAPY-INDUCED NEUTROPENIA IN LYMPHOMA PATIENTS AND USE OF PROPHYLAXIS WITH GRANULOCYTE COLONY-STIMULATING FACTORS IN CLINICAL PRACTICE

A. Salar,[1] A. López,[2] J. Pío Torres,[3] M.D. López,[4] M.D. Caballero,[5] E. Prieto,[6] M. Batlle,[7] P. Giraldo,[8] A. Blasco,[9] P. Benedit,[10] T. Garrido[10]

[1]Hospital del Mar, BARCELONA; [2]Hospital Vall d'Hebron, BARCELONA; [3]Hospital Juan Canalejo, A CORUÑA; [4]Hospital Santa María del Rosell, CARTAGENA; [5]Hospital Universitario de Salamanca, SALAMANCA; [6]Fundación Jiménez Díaz, MADRID; [7]Hospital Germans Trias i Pujol, BADALONA; [8]Hospital Miguel Servet, ZARAGOZA; [9]Hospital General Universitario de Valencia, VALENCIA; [10]Departamento Médico, Amgen S.A., BARCELONA, Spain

Background. Lymphoma patients receiving chemotherapy (CT) frequently develop neutropenic complications. Subsequent dose delays and/or dose reductions may reduce CT efficacy. Current European and US guidelines (2006) recommend primary prophylaxis with granulocyte colony-stimulating factors (G-CSF) for patients at ≥20% risk of febrile neutropenia (FN) due to CT and patient-related factors. *Aims*. To evaluate the incidence of grade 3-4 neutropenia (G3-4N) and FN over the first four cycles of CT regimens with high or intermediate FN risk (FN risk ≥20% or 10-20%, respectively) in lymphoma patients, and to describe the use of G-CSF prophylaxis in clinical practice. *Design and Methods*. This multicentre, prospective, observational, single-cohort study, included adult patients with lymphoma initiating a new CT regimen (≥10% FN risk), with at least four planned cycles and a minimum expected survival time of 3 months. Patients initiating daily CT or with active infection were excluded. The primary endpoint was incidence of G3-4N, defined as absolute neutrophil count $<1.0x10^9$/L. Secondary endpoints included incidence of FN, percentage of patients receiving full dose on schedule (FDOS, defined as ≤15% dose reduction and ≤3 days dose delay) and number and duration of hospitalizations. Patients were recruited consecutively from 21 Spanish centres between Nov-2005 and Dec-2008. Each patient was followed-up until the end of CT or for a maximum of 8 cycles. Descriptive analyses were mainly centered in the subgroup of patients receiving G-CSF. *Results*. The study included 294 patients (96.6% with non-Hodgkin lymphoma and 3.4% with Hodgkin lymphoma), with a median age of 58.0 years (range:19-85), 52.4% male, 87.4% with ECOG 0-1 and 61.7% at stage III-IV (44.5% at stage IV). At least four CT cycles were completed by 88.8% of patients (median cycle duration of 21 days, range:14-42), and the most common CT regimen was CHOP±rituximab-based (75.7%). G-CSF prophylaxis was used in 83.8% of pts [of which 76.6% was primary prophylaxis (PP) and 23.4% secondary prophylaxis (SP); 48.3% filgrastim (70.3% PP) and 51.7% pegfilgrastim (78.8% PP)]. The incidence of G3-4N over the first four cycles was 40.4% in the overall group. The incidence of G3-4N in patients receiving filgrastim was 50.0% vs 41.1% with pegfilgrastim. Patients treated with PP showed a trend to lower incidence of FN (15.8%) than patients with SP (21.8%). In total, 30 out of 244 (12%) patients treated with G-CSF were hospitalized due to FN. The mean (SD) duration of hospitalization due to FN was shorter for patients receiving pegfilgrastim (5.9[5.8] days versus 12.4[11.1] days in patients receiving filgrastim. FDOS was achieved in 67.8% and 66.1% of patients with PP and SP, and 61.2% and 72.1% of patients with filgrastim and pegfilgrastim. *Conclusions*. In this study of Spanish clinical practice, more than one third of lymphoma patients at high or intermediate FN risk developed grade 3-4 CT-induced neutropenia. The use of primary prophylaxis with G-CSF is becoming widely adopted in Spain. Our descriptive data suggest that, relative to filgrastim, use of pegfilgrastim prophylaxis may reduce the duration of neutropenia-related hospitalization and allow better CT delivery. Study sponsored by Amgen S.A.

1316

ASSOCIATION OF NEUTROPHIL MYELOPEROXIDASE INDEX (MPXI) WITH SUBSETS OF BACTERIAL INFECTIONS

K. Yonezawa,[1] O. Horie,[1] A. Yoshioka,[2] S. Matsuki,[2] T. Tenjin,[2] Y. Tsukamura,[2] M. Yoneda,[2] K. Shibata,[3] Y. Koike,[2] T. Nomura,[2] Y. Yokoyama,[2] M. Ito[1]

[1]Kobe University Graduate School of Health Sciences, KOBE, Japan; [2]Hyogo Prefectural Awaji Hospital, SUMOTO, Japan; [3]Siemens Healthcare Diagnostics, TOKYO, Japan

Background. Mobilization of neutrophils in inflammatory conditions may be associated with an increased myeloperoxidase level or, as a result of azurophil degranulation, decreased level. [Aims] This study was aimed to elucidate the pattern of changes in neutrophil myeloperoxidase levels in specific subsets of infectious and non-infectious inflammatory diseases. *Design and Methods.* The mean myeloperoxidase index (MPXI) produced as part of a routine complete blood count (CBC) performed by a flow cytochemistry blood autoanalyser was used as a parameter in this study. The study was performed at the regional central hospital of Awaji Island in central Japan, where most of the island's 150,000 population were referred. Hence the spectrum of diseases treated in this hospital represented the general health status of typical Japanese regional population. *Results.* The average MPXI levels among healthy adults (n=50) and children (n=40) were 0.05 and -0.40 with the standard deviations of 2.74 and 2.95, respectively. There were no sex or age-related differences. In patients with bacteremia documented by positive blood culture tests (n=51), the mean WBC and CRP were elevated to 15050/μL and 10.87 mg/dL, respectively, while the mean MPXI was significantly lowered to -2.10, at the date of culture. Moreover, in most of the cases, the MPXI values further decreased during the septic courses. By contrast, among patients with bacterial infections (n=40), where bacteremia and tuberculosis were excluded, the mean WBC, CRP and MPXI were all significantly elevated to 10850/μL, 11.47 mg/dl and 5.50, respectively. Intriguingly, the MPXI values paralleled specifically with CRP during the individual courses. Tuberculous patients (n=37) showed the elevated WBC and CRP levels (means 7520/μL and 5.05 mg/dL, respectively), but the MPXI was unchanged (mean -.050), at the presentation. Similarly, patients with viral diseases (n=60) exhibited the elevated WBC and CRP levels (means 10740/μL and 2.17, respectively) but the MPXI level was unchanged (mean -0.50). Non-infectious inflammatory diseases, such as rheumatoid arthritis, showed that the mean MPXI was unchanged and no correlation of MPXI with CRP or other disease parameters was demonstrated. Next, the correlation of MPXI with other laboratory data was assessed. Among parameters of inflammation, solely CRP was very weakly correlated with MPXI levels ($y=0.7505x+3.3434$; $r=0.58$). The correlation was stronger when the MPXI and CRP in non-septic and non-tuberculous bacterial infections were extracted and assessed, but vanished when non-septic and non-tuberculous bacterial infections were excluded. In contrast, there was no correlation between MPXI and other laboratory tests including WBC and neutrophil counts. Thus, MPXI appeared to be a candidate biomarker that was independent of other markers of infectious diseases. *Conclusions*. These results indicate that MPXI is specifically correlated with some specific infectious states, namely, the low MPXI level in bacteremia and the high MPXI level in bacterial infections excluding sepsis and tuberculosis. MPXI appears to be an independent parameter of bacterial infection and might be a useful biomarker for the diagnosis (and follow up) of some inflammatory diseases, especially when serial MPXI levels are evaluated in the disease courses of individual patients.

1317

IMPROVING CONGENITAL NEUTROPENIA DIAGNOSIS: MUTATIONAL ANALYSIS OF ELA2 AND HAX1 GENES. A SINGLE CENTRE EXPERIENCE

A. Catala, S. Rives, T. Toll, R. Berrueco, M. Camos, N. Conde, A. Quintero, J. Estella

Hospital Sant Joan de Deu, BARCELONA, Spain

Severe chronic neutropenias are represented by a heterogeneous group of disorders with very different clinica outcomes. Recently, genetic mutations causing many of these diseases have been identified. Mutations in the ELA2 gene represent the most common cause of congenital neutropenia. They are responsible for familial and sporadic cases of cyclic (CN) and severe congenital neutropenia (SCN) whereas HAX1 mutations cause autosomal recessive congenital severe neutropenia (Kostmann disease). *Aims*. To evaluate mutations in the ELA2 and HAX1 genes to highlight their use as a new tool in the diagnosis of severe neutropenia. *Design and Methods*. Since February 2007 we have evaluated the mutational status of both genes in every child with severe chronic neutropenia, either by specific amplification of known mutations, or by gene sequencing. *Results*. Twenty-one patients were evaluated. The mutated cases are shown in theTable. *Conclusions*. All our patients affected of NC or NCS had ELA2 gene mutated. The study of the mutational status is been of great help as a new diagnostic tool at our hospital. It should be implemented in the routine study of severe chronic neutropenia. Although further work is needed, recent studies were able to relate certain ELA2 mutations with more severe phenotype and increased risk of developing leukemia/myelodisplasia. Such patients could benefit

from a more exhaustive follow up or even early bone marrow transplantation.

Table. (*): not reported, (+): possible polymorphism, OP: osteopenia, LPT:liver pseudotumor AI: autoimmune neutropenia.

1318

LEUCOCYTOSIS AS PARANEOPLASTIC SYNDROME OF HEPATOCELLULAR CARCINOMA

T. Austein, B. Demme, M. Middelborg, V. Hager, J. Bigge

Clinic of Internal Medicine, BRAKE, Germany

Background. Paraneoplastic syndromes are diseases of predominantly solid tumours, which can precede or accompany malignancies. Most common are thrombosis, endocrinological disorders (e.g. hypercalcemia, hyperglycemia), myopathies (e.g. Lambert-Eaton-Syndrome, polymyositis or dermatomyositis), polyneuropathy and osteo-arthropathy (Pierre-Marie-Bamberger-Syndrome). We report about a case of pronounced leucocytosis due to hepatocellular carcinoma. *Case report*. A 50-year-old male was admitted to hospital with oedema of the lower legs, jaundice, night sweat and reduced general state of health. 15 years before he had undergone sinistral nephrectomy due to Wilms' tumour. Laboratory tests showed a marked leucocytosis of 91.000/µL accompanied by a mild anaemia and thrombocytopenia. γ-GT was increased to 1300 U/l and bilirubin to 7 mg/dL. The main results of laboratory tests on admission are shown in Table 1.

Table 1.

Parameter	[reference range]	Finding
leukocytes	[4.0000-10.000/µL]	91.000
hemoglobin	[14-18g/dl]	11,9
platlets	[150-400 *1000/µL]	134
INR	[0,9-1,25]	1,5
ALT	[0-45 L]	37
γ-GT	[0-5l]	1300
AP	[50-136 U/L]	349
bilirubin	[0,2-1,5 mg/dL]	9,2
γ-fetoprotein	[<10 ng/mL]	4,1 e 1

On abdominal ultrasound, a tumour of 8 cm in diameter in the right lobe of the liver as well as several hepatic metastasis and numerous enlarged lymph nodes along the abdominal aorta were seen. Analysis of bone marrow and peripheral blood smear (Figure 1) did not give any indication to the existence of a myeloproliferative syndrome or any other hematological disease.The result of liver biopsy confirmed the existence of undifferentiated hepatocellular carcinoma. Immediately after liver biopsy, the patient was started on chemotherapy following the CHOP scheme (cyclophosphamide, doxorubicin, vincristin, prednisolone) but to no avail. Four days following admission, the patient died. *Summary*. Leucocytosis in the context of paraneoplastic syndromes is rare. Some case reports also refer to leucocytosis as high as 50.000 leucocytes/µL in bronchial, pancreatic, corpus carcinoma and in malignant melanoma. Leucocytosis of more than 90.000/µL is an extremely rare finding. A tumour-induced G-CSF stimulation is the cause of paraneoplastic leucocytosis. In case of a marked leucocytosis without the existence of hematological disorder it is essential to consider the possibility of paraneoplastic syndrome.

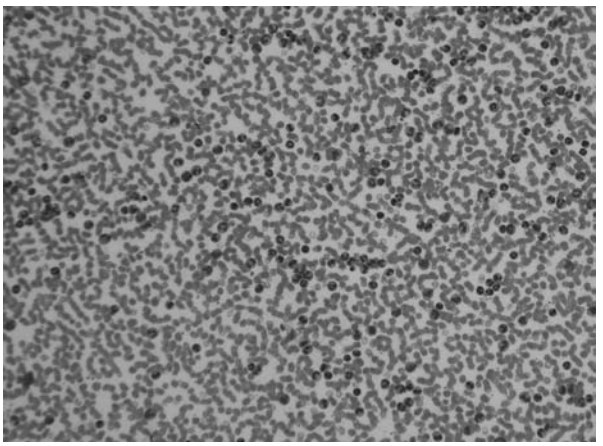

Figure 1. Peripheral blood smear (Pappenheim stain).

IDIOPATHIC THROMBOCYTOPENIC PURPURA (ITP) - ANALYSIS OF ITS PREVALENCE, DIAGNOSTICS AND THERAPY IN THE SOUTH MORAVIAN REGION (CZECH REPUBLIC)

L. Cervinek, M. Doubek, J. Mayer

University Hospital, BRNO, Czech Republic

Introduction. The reported annual incidence of ITP in adults in the world is approximately 5.8-6.6 cases of 100 000 inhabitants; the annual incidence in children is about 4-5 cases of 100 000 inhabitants. The exact incidence of ITP in the Czech Republic was not known yet. Diagnostics of patients with ITP are not fully standardized yet and therapy is a subject of expert recommendations. *Design and Methods*. To find out what the exact incidence and prevalence of ITP is and how the patients with ITP are treated at various outpatient clinics, we have proposed a questionnaire study of adult ITP in the South Moravian Region. In our questionnaire study we have focused on to find out data of ITP prevalence, ITP diagnostics and therapeutic preference of physicians. We sent the questionnaires to all of outpatient clinics in the South Moravian Region, where 1127718 inhabitants live according to the last population census. Results. All hematologists filled the questionnaires out. At the date of analysis, 564 adults with ITP were registered (406 patients with chronic ITP; 69 patients with the chronic resistant type of ITP; and 18 patients with Evans syndrome). According to our analysis, the annual incidence of ITP is 6 cases of 100 000 inhabitants, and its prevalence is 50.3 cases of 100 000 inhabitants. We have not recorded any death due to ITP (hemorrhage) in our patients. Our data demonstrated that the hematologists prefer diagnostics of ITP per exclusionem (88%). 47% of hematologists perform diagnostic bone marrow puncture. Radiolabeled scintigraphy before splenectomy is preferred by 53% of physicians. The key treatment modalities are corticosteroids and splenectomy. During pregnancy, intravenous immunoglobulins are used. The therapy of the chronic ITP is based on the use of cyclosporin A (53%) and the use of cyclofosfamide (29%). The use of danazol, rituximab and mycophenolate mofetil was limited to one main central department. *Summary*. The gained epidemiologic data of ITP confirm the worldwide data. The diagnostic and therapeutic procedures of the hematologists in our region reflect a considerable heterogeneity of diagnostics and the treatment, first of all, in the patients with the chronic type of ITP.

1320

ALTERATIONS OF PLATELET FUNCTION IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA

I. Popov,[1] H. Bumbea,[2] A.M. Vladareanu,[3] C. Socoliuc,[4] S. Radesi,[2] M. Onisai,[2] T. Savopol,[4] A. Nicolescu,[2] E. Kovacs[4]

[1]County Hospital Emergency Arges, PITESTI; [2]Emergency University Hospital, BUCHAREST; [3]Hematology, University Emergency Hospital, Carol Davila University of Medicine, BUCHAREST; [4]Biophysics; [4]Hematology, Carol Davila University of Medicine and, BUCHAREST, Romania

Background. Patients with chronic myeloid leukemia (CML) present alterations of platelet function due both to BCR-ABL mutation and to medication. *Aims*. The aim of this study is to highlight alteration in platelet function in these patients relative to usual medication. *Design and Methods*: This prospective study included 24 patients diagnosed with CML during 3 years in the Hematology Department of the Universitary Emergency Hospital Bucharest. Patients were analyzed separately according to the administered medication. Platelet function was investigated by platelet aggregation on Chrono-log aggregometer and flowcytometry on BD FACS Calibur. Samples were done from PRP and PPP obtained by centrifugation. As stimuli, we used ADP, collagen, epinephrine and ristocetin. A group of 24 healthy volunteers was used for comparative results. Statistics was performed using ANOVA 2. *Results*. We obtained a much weaker response to epinephrine and collagen of platelets from patients with chronic myeloid leukemia versus controls (p<0001). This response matched both amplitude and slopes of aggregation curve. The slope and amplitude of ristocetin curves in patients are comparable with healthy volunteers, but the expression of CD42a and CD42b is lower (p<0.001). The lag phase of ADP and collagen curves is altered in patients with CML recorded a length and a greater amplitude without statistical significance.

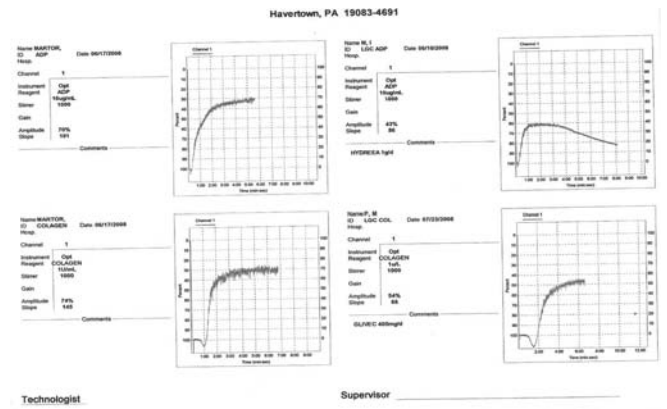

Figure 1.

Deaggregation was observed in 9/24 cases analyzed and it was not found on any control. When both tests were performed, we found an association between the weak expression of CD41 and deaggregation (2/5cases), but without statistically significance. The analysis on separate groups according to the received medication showed significant changes to the group of patients who received hydroxyurea. The amplitude and slope of aggregation curves, as well as the expressions of CD41 and CD61 were much smaller in the group of patients who received hydroxyurea (p<0001) followed by the group of patients who received imatinib and by the group receiving interferon. Also, patients who received hydroxyurea or purinethol have a greater length and amplitude of the lag phase for both ADP and collagen. Patients receiving hydroxyurea had more frequently platelet deaggregation - 5/8 cases compared to patients receiving Interferon (1/4) or imatinib (2/11). We also observed a weak expression on CD41 in 2 of the patients receiving hydroxyurea (from the group where flowcytometry was accessible). Explanation could be c-GMP generation by activating soluble guanil-cyclaze, because hydroxyurea is known to influence the induction of NO generation. Dasatinib proved to have an Aspirin-like influence that could explain the frequent hemorrhages of these patients. *Conclusions*. Poor response of patients with CML to different stimuli may have many explications, both BCR-ABL mutation itself and through various membrane or pool storage defects. We were able to identify the influence of different medications taken by CML patients on the aggregation pattern.

1321

QUALITY AND IN VIVO RECOVERY OF WASHED PLATELET CONCENTRATES (PRELIMINARY RESULTS)

E. Stavroulaki,[1] E. Lydaki,[2] E. Bolonaki,[2] E. Nikoloudi,[2] N. Andrulakis,[3] E. Symvoulakis,[2] M. Kaparou,[4] P. Kanellou,[4] H.A. Papadaki,[4] K. Fountouli[2]

[1]University Hospital of Iraklion, Blood Transfusion Department, IRAKLION, CRETE, Greece; [2]Blood Transfusion Department, Univercity Hospital of Iraklion, IRAKLION, CRETE, Greece; [3]Hematology Laboratory,Univercity Hospital of Iraklion, IRAKLION, CRETE, Greece; [4]Hematology Department, Univercity Hospital of Iraklion, IRAKLION, CRETE, Greece

Background. Transfusion of plasma containing blood components such as proteins, immunoglobulin A or cytokines have been associated with anaphylactic life-threatening or severe non-hemolytic transfusion related reactions. It appears to be clinically rational to apply washing platelet concentrates (PCs) for sensitized thrombocytopenic patients who had experienced severe transfusion related allergic reactions or IgA deficiency, as well as for infants with neonatal alloimmune thrombocytopenia who require maternal PLTs. However, evidence on *in vitro* and *in vivo* quality of washed platelets (PLTs) is limited. *Aim*. The purpose of this study was to evaluate the characteristics: mean platelet volume (MPV), PLT count and aggregation of PCs before and after washing procedure and the *in vivo* post transfusion platelet recovery (PPR). The possible transfusion related reactions among the patients were also registered. *Design and Methods* We obtained 5 consecutive PCs from normal volunteer donors by automated platelet apheresis (Fresenius Com.tec). PCs were separated in 2 units with 3x1011 PLT /280-300 mL for each. One unit was washed manually with 150 mL of 15% ACD solution and the other part was stored unwashed. Platelet sedimentation was reached by centrifugation for 8 min at 3500g. After removal of supernatant plasma and a storage time of 30 min, the platelet pallet was re-suspended in 300 mL N/S 0.9% and was transfused 3-6h after the procedure. The MPV, the PLT number and aggregation (ADP, collagen, epinephrine) were evaluated in all units. Washed and unwashed PCs were transfused to the same patient in 2 consecutive days. PLT counts were obtained one hour after transfusion for PPR calculation. Transfusion related reactions were also recorded to all the involved patients. *Results*. A 9.2% and 0.3% reduction was observed, in PLT count and in MPV respectively after washing procedure. Washing PCs showed a decreased in ADP, collagen and epinephrine induced ability of aggregation compared with the unwashed PCs. The PPR of the patients who received washed PLTs was 7.5% lower compared to the patients who received unwashed PCs. Allergic reactions were not reported when washed PCs were transfused, even in the cases with positive history of allergic episodes. *Summary.* Washing stresses PLTs and as a result seems to impair aggregation in ADP, collagen and epinephrine. However, PLT counts after transfusion of washing PCs seem to be comparable to those unwashed and the lack of adverse events may support the utility and feasibility of this procedure within blood donation departments. Clinical and large scale studies need to define the functional hemostatic capacity of the washed PCs.

1322

SUCCESSFUL TREATMENT WITH RITUXIMAB OF THROMBOTIC THROMBOCYTOPENIC PURPURA IN A PATIENT WITH IGA DEFICIENCY

M.G. Franzese,[1] G. Palumbo,[2] G. Spinosa,[2] N. Mangialetto,[2] A. Ricciardi,[2] S. Capalbo[2]

[1]Ospedali Riuniti Azienda Ospedaliero-Universitaria, FOGGIA, Italy; [2]Hematology OORR Foggia, FOGGIA, Italy

Background. Thrombotic thrombocytopenic purpura (TTP) is a rare disease characterized by microangiopatic haemolytic anemia, thrombocytopenia, altered neurological symptoms, renal impairment and fever. The use of plasma exchange (PEX), plus corticosteroids or other immunosuppressive agents, has dramatically decreased the mortality rate. Complete remissions have been described in some patients with refractory TTP treated with rituximab. In patients with IgA deficiency, plasma infusion may be followed by severe allergic reactions. Aim: We describe the first case of TTP with Ig A deficiency successfully treated with rituximab. *Case report*. A 48 year old woman with anemia and thrombocytopenia was referred to our centre in June 2007. At admission, she presented asthenia and some petechiae in abdomen and legs without neurological signs and fever. Hematological findings were: hemoglobin (Hb) 6.3 g/dL, platelets (Plt) 89x10^9/L and withe blood cells (WBC) 4.7 x10^9/L. The peripheral blood smears showed a large number of schis-

tocytes. Total bilirubin (TB) level was 1.14 mg/dL and lactate dehydrogenase (LDH) was 2917 U/l.; ADAMTS13 activity was 32% (reference value 46-160); antibodies against ADAMTS13 were not detectable. The diagnosis of TTP was made and the patient underwent treatment with PEX. During the first PEX, the patient presented chills, fever and dyspnoea. Prednisone (1mg/Kg body weight/day) was started; moreover the remaining 11 PEX were associated with steroid premedication without other side effects. The patient achieved a complete remission of anemia and thrombocytopenia, but in June 2008 the TTP relapsed. Main hematological findings were: Hb 8 g/dL; Plt 97x10^9/L; LDH 1299 U/L). Treatment with prednisone and PEX was started, but anaphylactic shock (severe hypotension, dyspnoea, laryngospasm, chills, fever) occurred after the first plasma infusion. The dosage of IgA showed a serum level <0.05 mg/dl. In absence of plasma from Ig A-deficient donors, treatment with high-dose intravenous v.) Immunoglobulin was made without improvement. Treatment with rituximab (375 mg/mv./weekly/ x 4) was started. After five days from the first dose of rituximab, the platelets were 110x10^9/L and LDH was 420 U/l. After four doses of Rituximab, the patient was discharged and she is still in complete remission without treatment. *Conclusions*. The Ig A deficiency is generally associated to severe reaction following plasma infusion. In our TTP patient, the first treatment caused hypersensitivity to plasma and prevented carrying out PEX in occasion of the relapse. The treatment with rituximab induced a durable complete remission of her TTP in our patient. To our knowledge, this is the first case report of TTP with IgA deficiency, successfully treated with rituximab.

1323

INTRAVENOUS METHYLPREDNISOLONE PULSE THERAPY IN ACUTE ITP CHILDREN WITH OVERT HEMORRHAGE

T.K. Chang, F.L. Huang, M.-C. Wu, J.D. Wang

Division of Pediatric Hematology/Oncology, TAICHUNG, Taiwan

Background and Aims. Immune thromobocytopenia purpura (ITP) is an acquired hemorrhage disorder characterized by immune-mediated platelet destruction. However, single-institution, long-term data with initial intravenous methylprednisolone pulse therapy are limited. The objective of this study is to review the clinical response of ITP with overt hemorrhage received intravenous methylprednisolone pulse therapy and risk factors for chronic ITP at a single medical center. *Design and Methods*. 52 newly diagnosed, previous untreated acute ITP children with overt hemorrhage and platelet count less than 20K admitted and treated with intravenous methylprednisolone pulse therapy from Jan.1997 to Dec. 2007. The dosage of methylprednisolone is 30 mg/kg/day (max. 1gm) for 3 days. A complete response (CR) to pulse therapy was defined as platelet count ≥150K. A partial response (PR) was defined as an increase platelet count ≥50K. No response (NR) was defined as no response to pulse therapy with persisted platelet count less than 50K. *Results*. Among the 52 children, the median age was 45 months (range 7-186 months), 31 male and 21 female. The median initial platelet count was 6K (range 1-19K). A preceding infection was found in 32 and vaccination in 4. The intravenous methylprednisolone pulse therapy response rate (CR+PR) was 86.5% (45/52). No response rate was 13.5% (7/52). 16/52 (30.7%) cases became chronic ITP. 14/16 cases were initial pulse therapy responders. No significant adverse effects noted during intravenous methylprednisolone pulse therapy. By uni-variate analysis, we found the age over 10 years old was the risk factor for chronic ITP. (p<0.05). *Conclusions*. Initial intravenous methylprednisolone pulse therapy in our experience is an effective, safe and less expensive treatment for childhood acute ITP, with high response rate initially to prevent the overt hemorrhage during severe thrombocytopenic period. Age over 10 years old of acute ITP patients still had higher risk for subsequent chronic disease.

1324

TREATMENT OF IMMUNE THROMBOCYTOPENIC PURPURA ; 15 YEARS EXPERIENCE OF A SINGLE MEDICAL CENTER

C. Ionita,[1] I. Ionita,[1] M. Iordache,[1] M. Cheveresan,[2] D. Calamar,[1] D. Oros,[1] H. Ionita[1]

[1]UMF Victor Babes, TIMISOARA, Romania; [2]City Clinical Hospital, TIMISOARA, Romania

Background. Idiopatic thrombocytopenic purpura (ITP) also reffered as immune or autoimmune thrombocytopenic purpura is an aquired disease characterised by low platelet count, normal bone marrow, usually with an increased number of megakariocytes and the absence of any other disease. The majority of patients respond on short term, at an initial corticosteroid therapy, which is used as first line therapy. Sometimes after steroid therapy disease relapse and in this case there can be used other lines of therapy including splenectomy. *Aims*. We tried to evaluate the therapeutic results in a group of patients with ITP which have been treated in a single medical center. *Method*. From I 1990 to I 2005, 207 patients were hospitalised and treated in the Hematology Department of Timisoara, the Western part of Romania, 132 female and 75 males. The median age of patient at diagnosis was 34, 12 years (range 16-68 years). The mean time from diagnostic was 19, 31 months. The mean platelet count before treatment was 23,520/µl with limits between 1000 and 110.000/µL. Petechial and ecchymosis were the most commun components presenting symptoms at 51% patients, 34% have presented gastro-intestinal bleedings, 10% had bleedings in the central nervous system and 5% had other bleedings. In our department, the corticotherapy was the first line of treatment and it was applied to 68% of patients. Patients with platelet counts <20x10^9/L and/or major bleeding symptoms were treated with high dose methilprednisone (HDMP) intravenous immunoglobulin (IVIG) and/or combination therapy of HDMP and IVIG (21%). The rest of the patients (11%) which didn't respond appropriately to the steroidic therapy received combined treatment of steroid and IVIG, vinca alkaloids. Approximatelly 41% of patients received transfusions of thrombocytes between 1 and 7 days, in gastrointestinal major bleeding cases, cerebral and severe thrombocytopenia. Complete remission (CR) was defined as the maintenance of platelet count 150x10^9/L and partial response (PR) was defined as symptomatic improvement with an increase in platelet count to more than 50x10^9/L. Platelet counts below 50x10^9/L were defined as non-response. Patients were put under watch for 3,5 years (6 months to 14,2 years). Results: The overall response was 68% with 48% CR, and 20% PR. The other 32% of the patients were considered in non-remission and 20% of them presented late remission after a median evolution period of approximatelly 1,3 years. During the evolution, 53% of the patients have relapsed, 41% of the patients have been splenectomized; 26% of the patients which have been splenectomised presented CR and 11% of patients presented PR. The long therm follow-up in CR and PR proves a good stabil and durable response in time for more than 7 years. *Conclusions*. The natural coure of the disease is variable. Patients with ITP chronic can have a good initial response at the steroid therapy and/or IVIG. Those that fail during this therapy can get a sigur and durable response after the splenectomy. Modern treatments like monoclonal antibodies can bring a bigger benefit.

1325

GALANTAMINE HAS NO EFFECT ON PLATELET FUNCTION IN THE ELDERLY

K. Kaptan, A. Isik, E. Bozoglu, T. Celik, C. Beyan

Gulhane Military Medical Academy, ANKARA, Turkey

Background. Galantamine, a centrally-acting cholinesterase inhibitor, has been used in the treatment of mild-to-moderate dementia of Alzheimer Disease. Increased mortality, mainly due to cardiovascular events such as myocardial infarction and stroke, was observed in placebo-controlled trials of galantamine. It is not clear whether galantamine might produce functional influence on platelet response. The aim of the present study is to investigate the effect of galantamine on *in vitro* aggregation of human platelets, since increased *in vitro* platelet aggregation appears to be predictive of cardiovascular events. *Design and Methods*. 15 healthy, non-smoker elderly subjects, without any co-morbidity and medication, were selected. Average plasma concentration of galantamine at steady state is 42 ng/mL. So, galantamine solutions were prepared in three different concentrations as 20, 40, and 80 ng/mL similar to galantamine concentrations in the plasma that observed after clinical therapeutic oral applications. Venous blood samples were drawn from the ante-cubital vein and anticoagulated with sodium citrate solution. The hematocrit was determined and the blood sample was divided into four equal parts. According to the amount of plasma (derived from the hematocrit), the calculated volume of galantamine solution and the diluent without galantamine as control were added to blood samples which yielded 0, 20, 40, and 80 ng/mL galantamine concentrations in the plasma. We isolated the platelet-rich plasma (PRP) from supernatant. Turbidometric aggregation performed according to the protocol. Platelet aggregation responses were evaluated with 5 µM adenosine diphosphate (ADP) and 2 µg/mL collagen. Platelet aggregation curves were calculated automatically by the device and maximal aggregation (%) was obtained from the aggregation curve. *Results*. Percentages of maximum aggregation (Mean±SEM) were 51.33±4.61, 54.20±5.30, 55.07±5.07 and

57.07±4.16 for ADP and 61.87±3.40, 60.40±4.90, 65.27±3.36 and 63.40±2.36 for Collagen (Control, 20, 40 and 80 ng/mL galantamine, respectively). Galantamine showed no effect on platelet aggregation induced by ADP and collagen in human PRP in a dose-dependent manner. *Conclusion*- We have thought that platelet aggregation is not associated with the mechanisms of the increased mortality mainly due to cardiovascular events observed in placebo-controlled trials of galantamine. Further *in vivo* studies with larger populations are needed to evaluate platelet aggregation and other risk factors in the galantamine usage.

1326

LDH IS PREDICTOR OF DISEASE DURATION IN THE FIRST ONSET OF THROMBOTIC THROMBOCYTOPENIC PURPURA

R. Scandellari,[1] G. Berti De Marinis,[1] A. Lombardi,[1] T. Tison,[2] M.L. Randi,[1] F. Fabris[1]

[1]University of Padua Medical School, PADOVA, Italy; [2]Apheresis Unit, Blood Transfusion Service, University Hospital of Padova, PADOVA, Italy

Background. Acquired thrombotic thrombocytopenic pupura (TTP) is an acute disorder characterized by microangiopathic hemolytic anemia, consumptive thrombocytopenia and widespread microvascular thrombosis with diffuse ischemic damage, most of all caused by an immunomediated deficiency of the von Willebrand factor-cleaving protease, ADAMTS-13. It can be fatal in 90% of patients when untreated and have potentially short and long term devastating consequences. A severe deficiency of ADAMTS-13 is sufficient but not necessary for clinical manifestations and outcome of TTP. The introduction of plasma exchange (PE) as first-line treatment improved survival to the acute event. However, TTP may worsen after an initial response during plasma therapy, and the number of PE sessions required to achieve remission is variable. Nowadays no clinical and laboratory parameters are still well established as markers predicting clinical response. *Aim*. To determine whether patient characteristics, clinical presentation, and laboratory features could correlate with response after the first episode of acute TTP.

Table 1. Main features of patients at first episode of TTP.

Number of patients	21
Age; mean ± SD	36 ± 11
Gender; F/M	16 / 5
Idiopathic TTP	14 (67%)
Secondary TTP	7 (33%)
Presenting features	
- Fever	8 (38%)
- CNS impairment	14 (67%)
- Renal impairment	4 (19%)
Platelet count, x10^9/L; mean ± SD	25 ± 26
Hb, g/L; mean ± SD	84 ± 22
LDH, U/L; mean ± SD	1291 ± 906
PE sessions; median (mean ± SD)	8 (11 ± 6)
PE response	15 (71%)
Post-PE platelet count, x10^9/L; mean ± SD	210 ± 138
Duration of acute event, days; median (range)	14 (5-56)
Deceased	2 (10%)
Relapsed	7 (33%)

CNS, central nervous system; Hb, hemoglobin; LDH, lactate dehydrogenase; PE, plasma exchange

Patients and Design and Methods. We retrospectively analyzed clinical and laboratory records of patients presenting with their first episode of acute TTP. Inclusion criteria were the presence of at least three of the following: 1) thrombocytopenia (<150x10^9/L) without other explaination; 2) negative direct Coombs' test hemolytic anemia with schistocytes on peripheral-blood smear; 3) increased serum levels of lactate dehydrogenase (LDH>400 U/L); 4) presence of signs or symptoms consistent with CNS or other organ ischemia. Other thrombotic microangiopathies should be excluded. Between 2000 and 2008 we enrolled 21 adult patients, 16 females and 5 males, mean age being 36±11 years. TTP was idiopathic in 14 patients (67%), whereas 7 patients (33%) had a secondary TTP, due to an underlying autoimmune disease. In 14 patients ADAMTS-13 activity and IgG anti-ADAMTS-13 were assessed at presentation using commercially available FRETS-VWF73 and ELISA assays respectively. Severe protease activity deficiency was considered as equal or less than 10%. A high IgG titer was defined as levels of 50 U/mL or more. Response to PE was defined as normalization of platelet count (>150x10^9/L) and LDH (<400 U/L) for at least 2 days after PE discontinuation. *Results.* Clinical and laboratory patient characteristics are shown in Table 1. ADAMTS-13 activity was severely reduced in 86% whereas autoantibodies were present with high titre in 57% of patients. The median number of PE sessions performed was 8 (mean 11±6, range 3-39). 15 patients (71%) achieved a remission after PE sessions; 4 patient failed to respond to PE treatment and needed adjunctive immunosuppressive therapy other than steroids. The event was fatal in two patients. The median time of episode was 14 days (mean 20±16, range 5-56). Among clinical and laboratory characteristics, there was a direct correlation between LDH values at presentation and the term of acute event (r=0.594, p=0.007). However, LDH levels were not significantly different in PE responders and refractory patients. *Conclusions*. Higher LDH level at diagnosis does not seem to be predictive of poor PE response but it may be a useful parameter for identification of patients with a more serious disease, needing a more intensive apheretic treatment to achieve a clinical remission.

1327

PLATELET COUNT AND SERUM THROMBOPOIETIN LEVEL AS PREDICTORS FOR MORBIDITY AND/OR MORTALITY IN THROMBOCYTOPENIC NEONATES

Y. Al-Tonbary, M.S. Al-Haggar, O. Salama, M. Abul-Kheir, A.M. El-Alfy, M. Hafez

Mansoura University Children's Hospital, MANSOURA, Egypt

Background. Platelet count is not a predictor of serum thrombopoietin level in thrombocytopenic and non-thrombocytopenic neonates. Serum thrombopoietin in thrombocytopenic infants is largely related to the cause of thrombocytopenia and the underlying disease. Many perinatal factors can affect thrombopoietin level like sepsis, birth asphyxia, respiratory distress, maternal hypertension, and even type of delivery. *Aim*. To evaluate the role of platelet count and serum thrombopoietin levels in prediction of the morbidity and mortality in newborns with thrombocytopenia. *Design and Methods*. A prospective study on 119 thrombocytopenic neonates; 54 full term and 65 preterm (Mean platelet count 40.13±33.1, gestational age range 28-42 wks) had been conducted. Congenital malformations known to be associated with thrombocytopenia or platelets dysfunction, infants who received blood, platelets or plasma transfusion or underwent exchange transfusion were excluded. Sera from venous blood were stored at -70 oC for thrombopoietin assay which was done using a qualitative ELISA technique (Quantikine RD systems, Inc. Minneapolis, USA). The test was repeated on the change of clinical status (recovery or deterioration). Results: A well-defined trend for lowering of thrombopietin level was noted on clinical recovery of bleeding and reversal of platelet count to normal (p<0.001 for matched pairs whether preterm or full term). Survival is significantly related to the basal platelet count in full term (Mean rank was 16.32 and 9.94 in alive and died full terms respectively with p=0.04), but insignificant among thrombocytopenic preterms. Platelet count is statistically negative correlated to thrombopoietin level in neonates in general and especially in preterm (r=-59, -0.69 respectively, with p<0.001), yet no statistically significant correlation between platelet count and duration of recovery was noted in preterms. Platelet count was found to be a better predictor for duration of recovery of thrombocytopenic neonates when compared to other factors specially thrombopoietin level. *Conclusions*. Thrombocytopenic neonates had very high levels of thrombopoietin. Despite the high thrombopoietin level in neonates died with severe thrombocytopenia, yet, mortality is related to the cause and outcome of thrombocytopenia rather than the serum thrombopoietin level. It is recommended to diagnose and treat the underlying cause of thrombocytopenia rather than to generalize the therapy based on thrombopoietin level.

1328

THE EFFECT OF ZINC SUPPLEMENTATION ON THE WHITE BLOOD CELL AND PLATELET COUNT LEVELS DURING VIRUS C HEPATITIS THERAPY

A. Helaly

Faculty of Medicine, ALEXANDRIA, Egypt

Background. Zinc is essential for the structure of over than 300 tissue enzymes. Also, zinc has been suggested to have an antiviral activity; however some claimed that the value of zinc intake is controversial in some cases. Zinc is relatively safe and well tolerated when taken orally. It plays an important role in alteration of oxidant-mediated tissue injury, and phagocyte cells formation It Prevents damage of cells participating in innate immunity besides it enhances the activity of natural killer cell function. Free oxygen radicals can produce tissue damage .zinc as antioxidant Is important for neutralizing free radicals, including enzymes like

super oxide dismutase, catalase and glutathione peroxides. Patients with chronic hepatitis C have significant glutathione deficiency. During treatment of virus C by the combination of interferon and ribavirin, follow up with WBC count and platelets count are routinely done and cessation or changes of the therapy if reduction of these parameters occur. Aims:leucopenia and thrombocytopenia is a problem during the treatment with interferon and ribavirin, this work try to find the value of zinc supplementation in the prevention of some side effects in order to avoid the cessation of the course of therapy if this effect *Design and Methods.* 44 patients with chronic C hepatitis diagnosed by positive PCR and liver biopsy, they are divided into two of matched age and sex groups. White blood cell count (WBC) and platelet values were estimated before and after they received twice weekly standard doses of interferon and daily oral doses of ribavirin therapy, half of them added 175 mg zinc gluconate orally (equal 25 mg zinc) three times daily (group I) and to the other half (Group II) placebo was added. This is for 24 weeks, three patients from group I and five patients from group II are excluded as they did not continue due to the occurrence of side effects or failure to response. Results The result of this work shows signficant lower values of both WBC ($p<0.05$). And platelets count ($p<0.05$). In the group II than group I .The mean value of the WBC is 4.2* 1000 per m m3 and 5.8 *1000 per mm^3 respectively and the mean value of platelets is 121*1000 per mm 3 and 188* 1000 per mm 3 respectively. *Conclusions.* This preliminary study shows that zinc supplementation may be added to the therapy of interferon and ribavirin in chronic c hepatitis in an attempt to minimize the side effects. We advise further work on this subject with the use of more white and platelet function study in addition to their count and performing sternal puncture, also more patients will be needed.

1329

SHARING INFORMATION TO BUILD KNOWLEDGE: ESTABLISHMENT OF NEW NATIONAL REGISTRIES FOR THROMBOTIC THROMBOCYTOPENIC PURPURA AND NEONATAL ALLOIMMUNE THROMBOCYTOPENIA

N. Polizzotto,[1] E. Phillips,[2] K. McQuilten,[1] S. Cohney,[3] H. Savoia,[4] F. Cole-Sinclair,[5] M. Wood[1]

[1]Australian Red Cross Blood Service, MELBOURNE, Australia; [2]Monash University, MELBOURNE, Australia; [3]The Royal Melbourne Hospital, MELBOURNE, Australia; [4]The Royal Children's Hospital, MELBOURNE, Australia; [5]St. Vincent's Hospital, MELBOURNE, Australia

Background. Thrombotic Thrombocytopenic Purpura (TTP) and Neonatal Alloimmune Thrombocytopenia (NAIT) are uncommon, but associated with significant morbidity and mortality. Resource implications of management, including provision of specialised blood products, are substantial and increasing. In NAIT, appropriate screening, early intervention, and management are areas of uncertainty. In TTP, the application of diagnostic tests, management of relapsed or refractory disease, and the role of emerging therapies all remain undefined. *Design and Methods.* Clinical registries provide a means to aggregate the full range of community experience with a condition and provide data to inform management in diseases where conduct of clinical trials is difficult. Monash University Department of Epidemiology and Preventive Medicine have extensive registry experience and an established methodology, which was employed in these projects in conjunction with the clinical expertise and networks of the Australian Red Cross Blood Service as part of the Transfusion Outcomes Research Collaborative (TORC). Results New registries have been established for each of these diseases to determine incidence and natural history, explore factors influencing clinical outcomes, inform patient management and inspire further research. For each registry, patients are identified and registered by the treating clinician. Data are recorded via specifically designed web-based forms, capturing details of presentation, management and outcomes. An independent Steering Committee comprising stakeholders and clinical experts monitors each registry. Sharing information with participating clinicians and hospitals is also a high priority. Participating hospitals represent every state and territory in Australia. For TTP, over 25 hospitals are participating, and over 15 hospitals for NAIT, including all tertiary referral centres for these diseases. Approximately 100 cases annually of TTP and 30 of NAIT are anticipated. *Conclusions*. Even major centres encounter relatively few cases of TTP or NAIT. Consequently it is difficult to establish optimal management, and there is significant variation in clinical practice. Rarity also hampers clinical trials. These national registries for TTP and NAIT will improve clinical practice and inform future clinical trials.

1330

GESTATIONAL THROMBOCYTOPENIA, IS IT NOT SIMPLY PHYSIOLOGICAL HYPERSPLENISM?

S. Bulvik, M.J. Niven

Laniado Hospital, NETANYA, Israel

Background. Thrombocytopenia is an ominous sign during pregnancy. Although one of the main reason for it is gestational thrombocytopenia, a benign condition occurring in 8% of all pregnancies and accounting for more than 70% of cases of thrombocytopenia in pregnancy, there is no pathonomonic sign for it and the diagnosis is by exclusion of other, sometimes emergent, causes of thrombocytopenia, such as HELLP syndrome, DIC, Pre Eclampsia, TTP, ITP etc. *Aims*. To establish a simple test for the diagnosis of gestational thrombocytopenia. *Design and Methods*. Nineteen pregnant women with an eventual diagnosis of gestational thrombocytopenia were investigated including standard physical examination, blood film, coagulation testing, liver function tests and abdominal ultrasonography. *Results*. Of the 19 women, 16 had splenomegaly on both physical examination and ultrasound. In the remaining 3 spleen size was at the upper limit of normal on ultrasonography. The reason for this was physiological gestational splenomegaly, which resolved immediately after the pregnancy. *Conclusion*. We suggest that in pregnant women with asymptomatic thrombocytopenia a finding of physiological splenomegaly strongly suggests the diagnosis of gestational thrombocytopenia. Larger studies are needed to confirm this hypothesis that gestational thrombocytopenia is simply due to hypersplenism secondary to the pregnancy.

1331

EVALUATION OF THE EFFICACY AND SAFETY OF A HUMAN RECOMBINANT ACTIVATED FACTOR VII (HRFVIIA) PREPARATION IN A PEDIATRIC PATIENT WITH GLANZMANN THROMBASTHENIA

J. Szamosújvári,[1] G. Losonczy,[2] L. Muszbek,[2] J. Kappelmayer,[3] C. Kiss[1]

[1]Department of Pediatric Hematology-Oncology, Institute of Pediatrics, DEBRECEN, Hungary; [2]Clinical Research Center, University of Debrecen, Hungary; [3]Department of Clinical Biochemistry And Molecular Pathology, University of Debre, Hungary

Background. The absence of agonist-induced platelet aggregation and the lack of fibrinogene receptor (GPIIb/IIIa) on the platelet surface proved the diagnosis of Glanzmann thrombasthenia in a male pediatric patient of Romany descent with severe hemorrhagic manifestations. DNA sequencing revealed a novel homozygous deletion of cytosine (1619delC) in the gpIIb gene. Neither GPIIb nor its truncated form could be detected in the platelets of the patient by Western blotting while a small amount of GPIIIa was demonstrated. Aims. We wanted to evaluate the efficacy and safety of a human recombinant activated Factor VII preparation (hrFVIIa, Novoseven®, Novo Nordisk, Bagsvaerd, Denmark) preparation, administered for the treatment of severe bleeding episodes of this patient in the clinical setting. *Design and Methods*. We have studied the patient data files and sheets retrospectively between 2004-2007, and joining the International Glanzmann Thrombasthenia Registy, and prospectively from 2008. *Results*. The patient presented here had bleeding episodes that had recurred every 2 to 3 months, initially as mild nosebleeds; these were replaced subsequently by more severe gingival bleeding episodes. As these progressive bleeding episodes were unresponsive to standard haemostatic therapy, the patient has been put on rhFVIIa therapy since 2004. The 20 bleeding episodes (between March 18, 2004 and December 30, 2008) reviewed here comprised epistaxis in 15 and gingival bleeding in 5 instances, for which the patient received hrFVIIa treatment on 313 occasions altogether. Between 2004 and 2007, 90 μg/kgbw doses, administered at 3-hour intervals for 5 to 6 consecutive days (a mean cumulative dose of 7500 μg/bleeding episode) were required to stop bleeding. In 2008, the intensity as well as the duration of bleeding episodes increased - while therapeutic efficacy declined. The patient required an augmented doses of 120 μg/kgbw dose for 14 and 20 days, respectively (a cumulative dose of 20,818 μg and 15,210 μg, respectively). No severe adverse effects were noticed in any case of hrFVIIa administration. *Conclusions*. In summary, the tested hrFVIIa preparation has proven effective in controlling the hemorrhagic episodes without significant side effects of this patient with Glanzmann thrombasthenia. Nevertheless, the long and increasing duration and intensity of individual bleeding episodes - as observed during the clinical course of this patient - may suggest that alternative treatment modalities should

be considered in the treatment of Glanzmann thrombasthenia in general and in the case of the presented patient in particular.

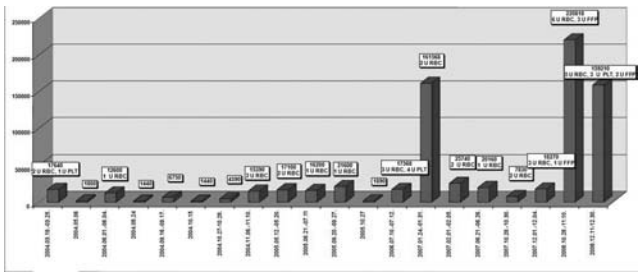

Figure 1. Cumulative dose (μg).

1332

MEAN PLATELET VOLUME IN ST ELEVATION AND NON-ST ELEVATION MYOCARDIAL INFARCTION

O. Nevruz,[1] R. Ulusoy,[2] M. Yokusoglu,[1] A. Kirilmaz,[2] O. Baysan,[1] F. Kiliçarslan,[2] S. Cebeci[2]

[1]Gülhane Military Medical Academy, ANKARA, Turkey; [2]GATA Haydarpasa Military Hospital, ISTANBUL, Turkey

Background. Platelet activation is thought to play a key pathogenetic mechanism in acute coronary syndromes. It was shown that platelet size correlates with their reactivity. *Aim*. We investigated the mean platelet volume (MPV) and platelet count in patients with both ST elevation myocardial infarction (STEMI) and non-ST elevation myocardial infarction (NSTEMI). *Design and Methods*. Fifty-two patients with NSTEMI, 56 patients with STEMI were enrolled in the study. Age- and gender-matched 50 healthy subjects constitute the control group. Venous blood samples for whole blood analysis were drawn on admission and analyzed by an autoanalyser. *Results*. There was statistically no difference between the STEMI and NSTEMI groups in investigated parameters. However, MPV was significantly higher in STEMI patients than NSTEMI patients and controls. Moreover, platelet counts for both STEMI and NSTEMI groups were significantly lower than controls. Platelet counts in the STEMI and NSTEMI patients did not show any statistical difference. *Conclusions*. Our study showed higher MPV values in STEMI as compared to NSTEMI patients and controls. MPV but not platelet count differs between STEMI and NSTEMI patients. The underlying mechanism should be investigated in further researches, which may shed light on developing new therapeutic strategies for this particular acute coronary syndrome.

1333

NIEMANN-PICK TYPE B DISEASE IN A MIDDLE AGE MAN

S. Gomes,[1] A. Pereira,[2] G. Caetano,[2] J. Azevedo,[2] M.P. Valadao,[2] G. Tamagnini,[2] M.L. Ribeiro[2]

1IPOFG Lisbon, LISBON, Portugal; [2]Departamento de Hematologia, Centro Hospitalar de Coimbra, Portugal, COIMBRA, Portugal

Niemann-Pick Type B is a rare autosomal recessive lysossomal storage disease caused by deficient acid sphingomyelinase activity and the consequent accumulation of Sphingomyelin. The diagnosis is usually made in infancy or childhood following the investigation of a splenomegaly. These patients also have mild, but progressive, interstitial lung disease, growth retardation and pancytopenia caused by secondary hypersplenism. Most of them have little or no neurological involvement and often survive into adulthood. The presence of the characteristic foam cell in the bone marrow supports the diagnosis that has to be confirmed by measuring the acid sphingomyelinase activity in peripheral leucocytes, cultured fibroblasts and/or lymphoblasts. The disease is pan ethnic and is associated to allelic mutations in the ASM gene. Enzyme replacement therapy clinical trial has recently begun in adult patients. The authors report a Niemann-Pick type B disease presented in a male at the age of 44 years. He complained of abdominal discomfort which ameliorated with a cholesterol-lowering drug. Case report: A 44 year old Caucasian male sought medical attention for abdominal discomfort and mild dyspnoea for medium exercise. Referred no other complains, has normal stature and had been a regular blood donor for the past 8 years. He presented an enlarged spleen (20x18x14cm by ultrasound), mild thrombocytopenia (100.000/mL) and dyslipidemia. Bone marrow slides, staining by May-Grünwald-Giemsa, showed many blue-staining foamy macrophages, "sea blue" histiocytes like. The diagnosis was confirmed by a low sphingomyelinase activity in cultured fibroblasts (2.06 nmol/h/mg of protein; normal: 18-300). HDL cholesterol was low (0.57 mmol/L N 0.9-2.3) and chitotriosidase was high (342 nmol/mL N10-85). Hb 17.6 g/dL, HTC 52%, leucocytes 7.5x10^9/L, neutrophyles 4.2x10^9/L, platelets 98x10^9/L. Respiratory function tests showed low CO diffusion and rest hypoxemia. He was started on Ezetimibe10mg/Sinvastatin 20 mg and few months later he referred no dyspnoea, neither abdominal discomfort. At the age of 49 years he remains asymptomatic, the spleen size is stable, hematological and biochemistry parameters are similar and there are no functional signs of pulmonary disease progression. *Discussion*. The Niemann-Pick Type B clinical case described here is a very mild form of the disease, diagnosed in the fourth decade of life, with a very slow disease progression. During the last 5 years cholesterol-lowering drug Ezetimibe /Sinvastatin reduced patient abdominal discomfort; however, it is not clear whether it has any influence on disease progression.

1334

THE EFFECT OF 3RD GENERATION COLLOIDS ON PRIMARY HAEMOSTASIS IN PREGNANT WOMEN

A. Perdiou, A. Kousoulakou, G. Papadopoulou, G. Leveta, A. Trigka, M. Andromida, K. Statherou, V. Tsoukanas, O. Petropoulou

Tzaneio General Hospital, PEIRAIUS, Greece

Background. Although the effect of colloids in haemostasis have been demonstrated in many studies, limited data exist with regards to potential changes in primary haemostasis after fluid preloading with colloids in pregnant women. *Aims*. The aim of this study was to evaluate the effects on primary platelet- mediated haemostasis in response to preloading with 6% Hydroxyethyl starch (HES) colloid solution and Pinger's Lactate (LR) in healthy pregnant women, prior to spinal anaesthesia for Cesarean delivery (CD). *Design and Methods*. We enrolled 20 healthy pregnant women with uncomplicated pregnancies at term (37-41 weeks of gestation) presenting for CD under spinal anaesthesia. Women with significant medical or obstetric co-morbidity and patients receiving drugs affecting haemostasis, were excluded from the study. Demographic and baseline obstetric characteristics were similar among groups.

Table.

1. Significant Difference

Patients were randomized to receive fluid preloading with either 1500 mL RL (group A) or 500 mL 6% HES (group B). Prior to preloading an initial blood sample was obtained (T0 samples). The fluid preloading was administrated over 30 min. A second sample (T1 sample) was subsequently taken from the contralateral arm. We measured in samples T0 and T1 the following parameters: Hb , Hct , PLT, platelet function using Platelet function Analyzer (PFA-100, Dade Behring), vWF activity (vWFR-Co). Platelet function was assisted with collagen/epinephrine and collagen/ADP as agonists. Results were expressed as closure time. Platelet count was measured using XT-1800 blood analyzer (Sysmex) and vWFR-Co using BCS XP coagulation analyzer (Dade Behring). *Results*. Statistical analysis was performed with the use of SPSS 16. Data were analyzed with ANOVA test. We observed no significant differences in all param-

eters between groups A and B in T0 samples. We found statistically significant differences (p<0.05) only in col/epi and col/ADP after preloading with fluids (T1 samples). Despite difference, closure times remained in normal ranges. *Conclusions*. Our results suggest that HES have a mild effect on platelet function, probably without clinical significance, but further studies with larger number of patients are needed to confirm this.

1335

THE EFFECTIVENESS OF RITUXIMAB IN CLINICAL AND LABORATORY IMPROVEMENT OF TTP: REPORT OF THREE CASES

R. Scandellari,[1] G. Berti De Marinis,[1] A. Lombardi,[1] P. Marson,[2] P.F. Ballerini,[3] F. Fabris[1]

[1]*University of Padua Medical School, PADOVA, Italy;* [2]*Apheresis Unit, Blood Transfusion Service, University Hospital of Padova, PADOVA, Italy;* [3]*De Gironcoli Hospital, SC Med 2 Nucleo Ematologico Operativo, CONEGLIANO, Italy*

Background. Thrombotic Thrombocytopenic Purpura (TTP) is a rare disorder characterized by thrombocytopenia, microangiopathic haemolytic anemia and microvascular thrombosis. Unless a prompt diagnosis is made, TTP shows a poor prognosis with a mortality rate reaching more than 90% in some case series. Idiopathic forms are usually associated with the presence of antibodies against ADAMTS-13, a circulating protease that cleaves von Willebrand factor multimers under high shear stress conditions.

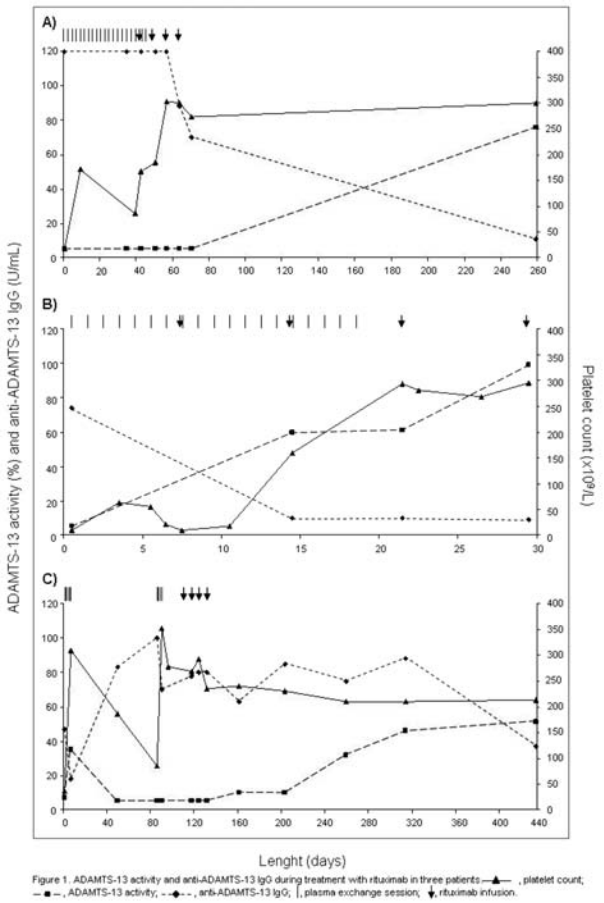

Figure 1. ADAMTS-13 activity and anti-ADAMTS-13 IgG during treatment with rituximab in three patients —▲— , platelet count; —●—, ADAMTS-13 activity; - -●- - , anti-ADAMTS-13 IgG; |, plasma exchange session; ↓, rituximab infusion.

Figure 1.

Prognosis of TTP has been improved by plasma exchange (PE) therapy, but mortality of disease has remained at 20%. Moreover in 20 to 50% of patients who achieve remission experience a chronic relapsing form, needing different approaches. In the last few years rituximab, an anti-CD20 monoclonal antibody, came up as both rescue therapy in the acute PE-refractory episodes and prophylactic treatment in patients who maintain a high titer of anti-ADAMTS-13 antibodies even through clinical remission. *Aim*. We describe the clinical and laboratory course of three patients affected by idiopathic TTP treated with 4 weekly infusions of rituximab 375 mg/m^2. Two patients were treated during their first PE-refractory episode and the third one was prophylactically treated during remission following his first relapse. ADAMTS-13 activity and IgG autoantibodies were assessed at onset and during rituximab treatment using commercially available FRETS-VWF73 and ELISA assays respectively *Results*. Patients 1 (Figure 1A) and 2 (figure 1B) were treated during acute event. They both had severe reduction in ADAMTS-13 activity (<10%) and high titre IgG anti-ADAMTS-13 (>120 and 74 U/mL respectively). The episodes lasted 47 and 24 days and the number of PE sessions performed was 20 and 19 respectively. Clinical and haematological remission (platelets count > 150x10^9/L) was achieved only after first rituximab administration in both cases. ADAMTS-13 activity normalization and anti-ADAMTS-13 antibody disappearance were demonstrated after 7 months and one week since the first infusion in patient 1 and 2 respectively. Patient 3 (figure 1C) experienced two episodes of acute TTP both responsive to PE. During remission following his second acute event he was prophylactically treated with rituximab because of persistent drastically reduced ADAMTS-13 activity (< 5%) with high titre of anti-ADAMTS-13 antibodies (70 U/mL). We observed a sustained clinical and haematological remission lasting for 15 months with normalization of ADAMTS-13 activity 11 months after first dose infusion (51%), but persisting low titre of autoantibody (37 U/mL). *Conclusions*. Rituximab is a useful immunosuppressive treatment both in acute PE-refractory and chronic relapsing TTP related to anti-ADAMTS-13 antibodies; however, despite an immediate clinical response in patients with an acute episode of TTP, we observed a variability in timing of ADAMTS-13 activity normalization and autoantibody disappearance, whose causes deserve further investigations.

1336

THE INFUENCE OF ANTIPLATELET DRUG THERAPY TO LIPID AND GLUCOSYLATED HAEMOGLOBIN LEVELS OF DIABETIC PATIENTS (MULTI-CENTERED STUDY)

S. Patiakas,[1] N. Barbantonakis,[2] D. Mitsikaris,[3] C. Charalampous,[4] M. Tsigaridaki,[5] F. Girtovitis[6]

[1]*General Hospital of Kastoria, THESSALONIKI, Greece;* [2]*General Hospital of Rethymno, RETHYMNO, CRETE, Greece;* [3]*Diagnostic Center "Hemotest", THESSALONIKI, Greece;* [4]*Internal Department of Psychiatric Hospital of Thessaloniki, THESSALONIKI, Greece;* [5]*General hospital of Rethymno, Crete, RETHYMNO, Greece;* [6]*General Hospital of Thessaloniki "ACHEPA", THESSALONIKI, Greece*

Background-Aims. To study a possible effect of anti-platelet drugs to HbA1C levels and the lidis of diabetic patients. *Design and Methods*. The study included 194 diabetic patients, 106 men and 88 women, wtih mean age, respectively, 60.9±11.3, 56.2±11.8 years, who where in combined anti-diabetic (metphormin), and anti-lipid (atorvastatin)therapy. From them, 85 where additionaly taking anti-platelet drug therapy (aspirin or clopidogrel), on either primary prevention level, (9 patients), or, more likely, secondary prevention level (76 patients), due to coronary disease, brain stroke, peripheral angiopathy etc.. All the patients where examined and evaluated for Total Cholesterol, LDL Cholesterol and -bA1C. *Results*. Mean avarege and standard deviation where like this (as you can see at the Table).

Table.

Test (n=194)	Under Anti-Platelet Therapy (n=85)	No Anti-Platelet Therapy (n=109)
HbA1C (%)	7,3 (±1,9)	7,9 (±2)
Total Cholesterol (mg/dl)	217 (±31,9)	239 (±30,6)
LDL Cholesterol (mg/dl)	98,2 (±20,4)	113,5 (±16,9)
Triglycerides (mg/dl)	139,6 (±28,2)	145,2 (±35,1)

Conclusions. Diabetic patients under anti-platelet drug therapy present much satisfactory levels as compared to the rest. HbA1C levels, Total Cholesterol and LDL cholesterol between the two groups, present statisticaly significant difference (p<0.01). 2) On the contrary, triglyceride levels seems to be unaffected from combined or not use of anti-platelet drugs (p>0.01). 3) Therefore the need for anti-platelet drug therapy for diabetic patients is a neccesity, not only for secondary prevention strategy, but for primary one as well, and in greater extent since the latter is oddly poor.

1337

EDTA-DEPENDENT PSEUDOTHROMBOCYTOPENIA AFTER CHANGING INSULIN THERAPY IN A CASE WITH INSULIN-DEPENDENT DIABETES MELLITUS

C. Beyan, K. Kaptan, I. Ifran

Gulhane Military Medical Academy, ANKARA, Turkey

Background. EDTA-dependent pseudothrombocytopenia (PTP) could be observed in healthy subjects, but it could also accompany certain diseases. Aims. In this report, development of PTP after changing insulin therapy in a case with insulin-dependent diabetes mellitus (IDDM) is presented. *Case Report*. A 36-year old male patient was evaluated for thrombocytopenia. It was learned from his history that IDDM was diagnosed eight years ago and Humulin M 70/30 (70% NPH isophan suspension mixed with 30% regular insulin produced with recombinant DNA technology) was started with the doses of 18 unit in the morning and 10 unit in the evening. Approximately half and a year ago, Humulin M 70/30 was stopped and NovoRapid FlexPen (Insulin aspart-fast acting human insulin analogous produced with recombinant DNA technology) 8 unit in the morning, 12 unit in the midday and 10 unit in the evening and Lantus Optipen (insulin glargine-long acting insulin analogous) 12 unit at night were started. The patient was not taking any other medication. There was no remarkable finding on physical examination. The values of complete blood count in which thrombocytopenia was detected were as follows: WBC 8.3x10^9/L, RBC 4.87x10^{12}/L, hemoglobin 15.4 g/dl, hematocrite 43.4%, mean corpuscular volume 89.0 fl, mean corpuscular hemoglobin 31.6 pg and platelets 56x10^9/L. Complete blood count freshly from EDTA-anticoagulated blood was as follows: WBC 5.2 x10^9/L, RBC 4.97 x10^{12}/L, hemoglobin 15.3 g/dl, hematocrite 44.2%, mean corpuscular volume 89.0 fl, mean corpuscular hemoglobin 30.7 pg and platelets 226x10^9/L. Huge platelet clusters were observed in peripheral blood film prepared from EDTA-anticoagulated blood after one hour delay. After diagnosing PTP as the cause of thrombocytopenia, we checked his previous medical reports, and we have noticed that his platelet count was in normal range (e.g. 243x10^9/L, 148x10^9/L, 278 x10^9/L, 225x10^9/L and lastly 188 x10^9/l five months before changing of insulin therapy). WBC and platelets were counted as 7.2x10^9/L and 41x10^9/L, respectively after two months of insulin changing; at the same laboratory blood was recounted freshly and at this occasion WBC and platelet count was found as 4.5x10^9/L and 221x10^9/L, respectively and this situation was interpreted as due to coagulation in first sample. The patient and the doctor managing insulin therapy were informed about the cause of thrombocytopenia was PTP and the possible reason for this situation might be due to change in insulin therapy according to his medical reports. *Conclusions*. This is the first case report of PTP related to insulin-dependent diabetes mellitus and insulin or insulin analogous therapy.

1338

CLASSIC SPLENECTOMY VERSUS LAPAROSCOPIC SPLENECTOMY FOR IMMUNE THROMBOCYTOPENIC PURPURA IN PATIENTS WITH SEVERE REFRACTORY THROMBOCYTOPENIA

A.M. Gaman, G.D. Gaman

University of Medicine and Pharmacy Craiova, CRAIOVA, Romania

Splenectomy is an effective therapeutic modality for the treatment of immune thrombocytopenic purpura (ITP) with a rate of 70-90% of hematologic response at patients with refractory ITP. The objective of the surgery is to stop the bleeding by eliminating the organ responsible for the clearance of antibody-coated platelets. *Aim of study*. Evaluating the eficacy of classic splenectomy versus laparoscopic splenectomy for immune thrombocytopenic purpura in patients with severe refractory thrombocytopenia. *Design and Methods*. we studied 44 patients with ITP hospitalized in Clinic of Hematology from Craiova (Romania) between 2003-2008. All patients were diagnosed as having ITP, other causes of thrombocytopenia were ruled out by bone marrow aspiration. All patients were initial treated with corticosteroids (prednisone or high dose dexamethasone). Indications for splenectomy were thrombocytopenia with bleeding manifestations and/or lack of response to conservative treatment and low platelet count while on massive steroid. Results: 9 patients from 44 had indications for splenectomy. 3 of them received classic splenectomy and 6 laparoscopic splenectomy. 8 patients had a complet hematologic response after splenectomy. After a period of 2- 4 years 4 of 6 patients with laparoscopic splenectomy relapsed because of accessory spleens. *Conclusions*. classic splenectomy is preferable to laparoscopic splenectomy for ITP at patients with severe refractory thrombocytopenia, because the existence of the risk of relapse through accessory spleens.

1339

STUDY OF THE USE OF ANTIPLATELET MEDICATION BY DIABETIC PATIENTS IN PERIPHERAL HOSPITALS (POLYCENTRIC STUDY)

S. Patiakas,[1] N. Barbantonakis,[2] K. Akritopoulou,[3] F. Girtovitis,[4] K. Kirdas[5]

[1]General Hospital of Kastoria, THESSALONIKI, Greece; [2]General Hospital of Rethymno, RETHYMNO, CRETE, Greece; [3]General Hospital of Goumenissa, GOUMENISSA, Greece; [4]General Hospital of Thessaloniki "ACHEPA", THESSALONIKI, Greece; [5]General Hospital of Drama, DRAMA, Greece

Background and Aims. To register the percentage of diabetic patients who receive antiplatelet medication in a peripheral hospital, considering that the main cause of the morbidity but also the mortality in these patients, is related to vascular complications (either as microangiopathy, or as macroangiopathy), and consequently, this medication aims to the primary as well as the secondary prevention of these complications. On the other hand, the further goal is to underline the necessity of this medication's broader usage. *Material and Methods*. In total, the study involved 347 cases of diabetic patients (136 men and 211 women), with the average age of 63,9±11,9 years and mean time from the disease's appearance the 9,2±4,3 years. Results: As it was found out, 61 patients received in total antiplatelet medication, that is percentage 17,58%. This group included 34 men (percentage 25%) and 27 women (percentage 12,8%). It should be underlined that after further control it was found out that 48 of these patients (percentage 78,7%) suffered already from established coronary disease and received the antiplatelet medication because of the existing disease and also many times after the appearance of relative episodes. *Conclusions*. Considering the previous mentioned, worryingly low percentages of antiplatelet medication in diabetic patients in these county regions, it becomes evident that the prevention in this sector is particularly inefficient and is almost never applied on time. 2) It is, therefore, necessary to ensure the sufficient knowledge and the further activation of all the doctors and particularly the general practitioners at the level of primary health care, since they are in direct and frequent contact to the patients of these difficult of access borderlands, so that these patients get adequately informed about the importance of the preventive receive of antiplatelet medication and its usage is finally generalized.

PLATELET FUNCTION IN BILHARZIAL HEPATIC FIBROSIS BEFORE AND AFTER SPLENCTONY

M. Awad,[1] F. Ezzat,[1] H. Ghoneim,[2] H. Abd EL-Gaghar,[1] S. El-sharawy[1]

[1]Faculty of Medicin, MANSOURA, Egypt; [2]Hayam Rashad Ghoneim, MANSOURA, Eritrea

Schistosomiasis is an endemic disease in Egypt Bilharzial hepatic fibrosis is one of its serious complication, leading to portal hypertentison and oesophageal varices. Many factors have been incriminated in the pathogenesis of bleeding in schistosomal patients, including rupture of oesophageal varices. Thrombocytopenia, thrombosthenia, defective coagulation mechamism as welll as increased fibrinolytic activity. In whom hepatosplenic schistosomiasis coexistence with chronic active hepatitis, unresolved hepatitis and/or cirrhosis an additive factor for pathogenesis of bleeding have incriminated. *Aim of work*. We have planned this work in order to assess platelet aggregation as atest for platelet function in hepatosplenic schistosomiasis and to evaluate the role of splenectomy and spleno renal shunt in improvement of platelet aggregation. *Design and methods*. We revised all clinical, hematlogical, haemostatic and platelet aggregation of 72 case of bilharzial hepatosplenomegally, portal hypertension and variceal bleeding presented at gastrointestinal surgery centre in Mansoura university out of these cases, splenectomy was done to 51 cases 32 (with bilharzial hepatic fibrosis, chronic active hepatitis (C.A.H), 7 with bilharzial hepatic fibrosis+unresolved hepatitis and 2 with mixed cirrhosis). spleno renal shunt (SRS) was done to 10 cases (6 cases with bilharzial hepatic fibrosis, 3 cases with bilharzial hepatic fibrosis+unresolved hepatitis and one case with mixed cirrhosis) and others were mangad by sclerotherapy. Follow up of the splenectomized and post SRS cases after 1d, 3d, 5d, 7d, 14d, 1m, 3m, 6m postoperative for clinical, neurological, medical assessment, blood counts, coagulation profiles and platelet aggregation (yardumain; etal 1989). Result Preoperative analysis of our data revealed that:-Platelet count, bleeding time, prothrombin time, activated partial thromboplastin time fibrinogen concentration, antithrombin 111 concentration are significant decreased in all groups however despite of the lower level of antithrombin 111, thrombosis is rare complication because of low prothrombin level, normal amount of antithrombin111 surface-bound com-

plex and normal or elevated β 2 macroglobulin which could partially compensate for antithrombin111 deficiency.Platelet aggregation with collagen, ADP, ristocetin, thrombin and arachidonicacid are significant decrease, in all groups and more evident in whom bilharzial hepatic fibrosis coexists with C.A.H and unresolved hepatitis due to the presence of platelet antibodies which is an additive factor for much impairment of platelet aggregation. post operative analysis of our data revealed that: splenectomay improved hypersplenic cytopenia and resulting in icreased in platelet count reaching its maximum after 2 weeks. Splenectomy improved hemostatic parameters including prothrombin activity, activated partial thromboplastin time, fibrinogen concentration and increased in anti thrombin 111 these changes together with thrombocytosis indicated hypercoagulable state having take place but the high anti thrombin 111 level counteract the observed hypercoagulable state. Splenectomy improve platelet aggregation to ADP, collagen, ristocetion, thrombin and arachidonic acid in patient with bilharzial hepatic fibrosis reaching its maximum after 2 weeks and persist till 6 months. In whom bilharzial hepatic fibrosis coexists with C.A.H and unresolved hepatitis, platelet aggregation to ADP, collagen and ristocetin are increased post splenectomy reaching its maximum after 3 months and persists till 6 months. However, in those with mixed cirrhosis platelet aggregation are increased postsplenectomy but not to extent as those with bilharzial hepatic fibrosis. Spleno renal shunt(SRS) improved hypersplenic cytopenia but not extent as splenectomy, because, spl enectomy not only improve congestion but also remove the organ responsible for blood cell sequestration. Spleno renal shunt(SRS) improve haemostatic parameter because of relief of congestion. Spleno renal shunt (SRS) improve platelet aggregation to ADP, collagen and ristocetin in all groups. However in those with unresolved hepatitis the increase is no more as those postsplenectomy because in shunt procedure, the spleen which may be responsible fore antibody formation not remove. *Conclusions*. Patients with more lowered antithrombin 111 preoperatively & more increased in platelet aggregation postoperatively are more liable to thrombosis post operatively. Patients with high F.D.ps preoperative & no more improvement in platelet aggregation postoperatively are more liable to bleeding postoperativly.

EVALUATION OF PLATELET FUNCTION DURING PREGNANCY USING THE PLATELET FUNCTION ANALYZER (PFA-100)

A. Kousoulakou, A. Perdiou, G. Papadopoulou, G. Leveta, A. Trigka, K. Statherou, M. Andromida, V. Tsoukanas

Tzaneio General Hospital, PEIRAUS, Greece

Background. The PFA-100 is a point-of-care platelet function analyzer which measures the speed of formation of a platelet plug *in vitro*, expressed as closure time (CT) in seconds. This device could potentially be used to assess primary haemostasis. *Aim*. This study aimed to evaluate platelet function during uncomplicated pregnancy using the PFA-100 and compare PFA values between pregnant and non-pregnant women . *Design and Methods*. The study population was divided in two groups: Group I (n=20) healthy non pregnant women (control group) , Group II (n=20) healthy pregnant women. Platelet function was evaluated in whole blood with the PFA-100 (Platelet function Analyzer PFA -100, Dade Behring), using collagen/epinephrine (col/epi) and collagen/ADP (col/ADP) as platelet agonists. Results were expressed as closure time (sec). We also measured platelet count and Hct using XT-1800 blood analyzer.

Table.

	Group A			Group B		
	Mean	Sd.	Min-max	Mean	Sd.	Min-max
col/epi	115, 5	16, 74	88 - 141	107, 85	33, 26	71 - 221
col/ADP	80, 75	10, 82	62 - 100	78, 05	13, 89	56 - 110
Hct	42, 94	3, 16	39,50 - 50,4	37, 64	3, 93	30,60 - 48,30
PLTs	253, 55	65, 82	155 - 368	230, 60	67, 99	131 - 402

Results. Age and platelet count were similar across the two groups (p>0.05), while Hct values were different at a statistical significant level as expected due to pregnancy anemia. Results are reported as mean, std deviation and min-max. Statistical analysis was performed with the use of SPSS 16 and data were analyzed with T-test. A p<0.05 was considered significant. *Conclusions*. In normal pregnant women, platelet reactivity is known to be increased. The mean CTs of our normal pregnant population were lower than that of non pregnant population but still in normal ranges and without statistical difference. This is suggestive of mildly enhanced primary haemostatic function. This study provides a normal range of PFA CT for our healthy pregnant populations and confirms the platelets activation of normal pregnancy. Further studies with larger number of patients could possibly reveal a statistically significant difference.

1342

RITUXIMAB IN REFRACTORY IDIOPATHIC THROMBOCYTOPENIC PURPURA TREATMEN IN CHILDREN

G. Abdilova, K. Omarova, A. Tulebayeva, O. Pankova, I. Nadenova

Scientific center of pediatriscs and children's surgery, ALMATY, Kazakhstan

Background. Immunosuppressive therapy is a method of choice for refractory idiopathic thrombocytopenic purpura (ITP) treatment in children. In last years the monoclonal CD-20 antibodies are more used in treatment. *Design and Methods*. Rituximab was used in treatment of three children with refractory idiopathic thrombocytopenic purpura. Informed concern forms had been obtained before starting the treatment. All patients did not respond to the basic steroid therapy (platelets count was less than $30x10^9$/L). All of them had a presence of hemorrhagic syndrome's features such as nasal bleedings and skin hemorrhagic syndrome. Rituximab was used once a week, 375 mg/m^2, during four weeks. Efficacy evaluation was based on both platelet count normalization and disappearance of hemorrhagic syndrome. After four injections of Rituximab, two patients reached a complete hematological response (platelets count increased up to 184-218$x10^9$/L) and one child had a partial hematologic response, and his plateles count increased up to $59x10^9$/L. A retrospective analysis has indicated that response has still been present, i.e. longer than for five months. There are no side effects detected. Thus, administration of Rituximab in treatment of refractory ITP allows us to achieve a significant effect. The latter would have been impossible should steroids have been used. In addition, the administration both leads to avoiding of long time usage of high dose steroids and their side effects, and significantly improves quality of life.

INVESTIGATION OF THE FREQUENCY AND THE NECESSITY OF ANTICOAGULANT MEDICATION IN ELDERLY PEOPLE (POLYCENTRIC STUDY)

S. Patiakas,[1] N. Barbantonakis,[2] I. Alexidis,[3] F. Girtovitis,[4] M. Alexandridis[3]

[1]General Hospital of Kastoria, THESSALONIKI; [2]General Hospital of Rethymno, RETHYMNO, CRETE; [3]General Hospital of Goumenissa, GOUMENISSA; [4]General Hospital of Thessaloniki ACHEPA, THESSALONIKI, Greece

Background and Aims. The study of the use of anticoagulants in elderly people, and the estimate of the potential benefit in relation to the possibility of hemorrhage. *Design and Methods*. Patients with risk factors for thrombo-embolic episodes, such as an old thrombo-embolic episode and atrial fibrillation, participated in the study. The receive or not of anticoagulant medication was investigated, the cases of patients with an INR level out of the therapeutic limits were registered, and all the inpatients but also the newly hospitalized patients with hemorrhagic tendency because of the anticoagulant medication, were included in the study. *Results.* In total 109 patients over 60 years old were found, who had at least one risk factor for thrombo-embolic episode. Only 43 of those (percentage 39,4%) received anticoagulant medication, while about one in three under medication with dicumarol derivatives had the INR level within the therapeutic limits. The majority (about 2/3) of the rest had higher values than the desirable and fewer (about 1/3) lower values. *Conclusions*. It is, therefore, evident that, although the anticoagulant medication is particularly valuable for the prevention of thrombo-embolic episodes in people with certain risk factors, in many cases it's not used. On the other hand, it is shown that, especially in the elderly people who apparently run a greater risk of hemorrhage, the anticoagulant medication should be used after caution and careful thought, since the possible benefit should be always weighed in relation to the possibility of

hemorrhage. Finally, it should be underlined that the percentage of cases where the effect of the dicumarol derivatives stands out of the therapeutic limits is quite high, fact that imposes a frequent and careful control of the INR.

1344

SERUM ADIPONECTIN AND RESISTIN LEVELS AND THE OCCURRENCE OF MYELODYSPLASTIC SYNDROME

M. Dalamaga,[1] A. Lekka,[2] K. Karmaniolas,[2] J. Chamberland,[3] A. Hsi,[3] M. Triantafilli,[2] G. Sotiropoulos,[2] A. Dionyssiou-Asteriou,[1] C. Mantzoros[3]

[1]Attikon General University Hospital, ATHENS, Greece; [2]NIMTS General Hospital, ATHENS, Greece; [3]Beth Israel Deaconess Medical Center, BOSTON, USA

Background and Aims. Recent evidence suggests that obesity may be implicated in the etiology of myelogenous leukemia and myelodysplastic syndrome (MDS). We thus attempted to explore whether altered secretion of the adipokines: adiponectin and resistin, a hormonal system linked with several obesity and insulin resistance associated malignancies including leukemia, may underlie this association. We have designed a case-control study to investigate the role of serum total and high molecular weight (HMW) adiponectin and resistin, in the etiopathogenesis of MDS after adjusting for a potential confounding effect of body mass index (BMI), height, weight and leptin. We also explored associations between adiponectin and resistin and established MDS prognostic factors. *Design and Methods*. Blood samples were collected from 101 cases with incident, histologically confirmed primary MDS, and 101 hospital controls, admitted for non-neoplastic and non-infectious conditions, matched on gender, age and year/month of diagnosis (±1 month) between 2004 and 2007. Serum total adiponectin and resistin concentrations were determined by radioimmunoassay (LINCO Research Institute, St Charles, MO). Moreover, serum HMW adiponectin was measured using ELISA (ALPCO Diagnostics, Salem, NH). Statistical analysis of the data was performed with SAS 9.1 for Windows XP. *Results*. Cases presented significantly higher height and weight than control subjects ($p<0.001$), while differences of BMI were only of borderline significance ($p=0.12$). Cases had significantly lower serum levels of adiponectin, HMW adiponectin and resistin than controls ($p<0.001$, $p=0.003$ and $p=0.019$ respectively). HMW adiponectin levels were significantly different in MDS type ($p=0.028$) being higher in chronic myelomonocytic leukemia (CMML) but both HMW adiponectin and resistin were not significantly different amid IPSS stratification schemes both before and after adjusting for age, gender and BMI. Although, total and HMW adiponectin were both significantly inversely associated with MDS when modeled either in quartiles or continuously, HMW didn't offer any substantial additional predictive value over total adiponectin (OR=0.91 v. 0.93 for a 1 μg/mL change, respectively). Also, adjusting for age, gender, BMI, adiponectin and leptin, serum resistin levels were significantly inversely associated with MDS occurrence (OR= 0.20, 95% CI: 0.08-0.52). *Conclusions*. Total and HMW adiponectin may present a protective role in MDS, whereas resistin levels may be decreased via a compensatory response to the upregulation of other inflammatory parameters etiologically linked to myelodysplasia. These observations need to be replicated and warrant further investigation.

1345

TREATMENT OF PATIENTS WITH HIGH-RISK MYELODYSPLASTIC SYNDROMES RECEIVING AZACITIDINE WHO ARE ENROLLED IN AVIDA, A LONGITUDINAL PATIENT REGISTRY

L. Grinblatt,[1] X. Narang,[2] M. Malone,[3] A. Sweet,[4] S. Dunne,[4] A. Sullivan[4]

[1]NorthShore University HealthSystem, EVANSTON, USA; [2]Alliance Hematology Oncology, WESTMINSTER, USA; [3]Oncology-Hematology Medical Associates of the Central Coast, SAN LUIS OBISPO, USA; [4]Celgene Corporation, SUMMIT, USA

Background. A phase III study demonstrated that azacitidine, a hypomethylating agent, provides clinical benefit including prolonged survival in high-risk MDS patients (*Fenaux et al, Blood. 2007;110:Abstract 817*). Use of azacitidine in high-risk patients in the community-based setting has not been well characterized. *Aims*. Investigate the characteristics, treatment patterns, and transfusion status of patients with high-risk MDS who are enrolled in AVIDA (a longitudinal, multicenter patient registry designed to prospectively collect data from community-based hematology clinics on the natural history and management of MDS patients who are treated with azacitidine). *Design and Methods*. Patients with an International Prognostic Scoring System (IPSS) risk classification score of intermediate-2/high at baseline were included in the analysis. Transfusion independence was defined as no transfusions for at least 56 days in patients with historical (6 months prior to AVIDA) transfusion requirements and at least 56 days treatment duration. The first day of the 56-day period with no transfusions was noted as the time at which patients first achieved transfusion independence. *Results*. As of January 5, 2009, 79 patients (55 males, 24 females; median age 74 years [range, 45-88]) with an IPSS score of intermediate-2/high have been enrolled in AVIDA; 60 (76%) with intermediate-2 and 19 (24%) with high score. Median time from first MDS diagnosis until azacitidine treatment was 1 month (range, 0-103), suggesting minimal delay in treatment. At baseline, 64 (81%) patients had 5% or higher bone marrow blasts and 38 (48%) had a "poor-risk" karyotype. Cytopenias were reported in 2 or 3 lineages for 61 (77%) patients. A total of 281 cycles of azacitidine have been administered either by subcutaneous (48%) or intravenous (52%) route. These intermediate-2/high-risk patients have received a median of 3 cycles (range, 1-14); 49/79 (62%) patients have received at least 2 cycles. Red blood cell (RBC) transfusion status data are available for 23 patients who received RBC transfusions in the 6 months prior to treatment and at least 56 days of azacitidine. Of these, 10 (44%) achieved RBC transfusion independence; 9/10 (90%) first achieved RBC transfusion independence during the first 2 cycles. Platelet transfusion status data are available for 5 patients who received platelet transfusions in the 6 months prior to treatment and at least 56 days of azacitidine. All 5 (100%) have achieved platelet transfusion independence during the first 2 cycles. In these high-risk patients, azacitidine was generally well tolerated; most common adverse events were fatigue (23%), constipation (19%), nausea (17%), and thrombocytopenia (17%). *Conclusions*. These data demonstrate that patients with an IPSS score of intermediate-2/high are being treated in the community-based setting and can achieve transfusion independence while receiving azacitidine at a rate comparable to that reported a clinical trial (Aza-001). AVIDA provides a unique opportunity to characterize the MDS patient population that is receiving chemotherapy in the community-based setting. Effect of azacitidine on the outcome and overall quality of life in this patient subpopulation will become clearer as more patients with high-risk MDS are treated.

1346

ERYTHROID FLOW CYTOMETRY IMMUNOPHENOTYPE IN MYELODISPLASTIC SYNDROMES. PRELIMINARY RESULTS IN PERIPHERAL BLOOD

A. Macedo,[1] A. Monteiro,[2] P. Amantegui,[2] J. Martinez,[2] M.C. Faria,[2] A. Orfao[3]

[1]Universidade da Beira Interior, COVILHA, Portugal; [2]Centro Hospitalar Cova da Beira, COVILHA, Portugal; [3]Universidad de Salamanca, SALAMANCA, Spain

Background. Cytomorphology has been the main approach to the diagnosis of Myelodisplastic Syndromes (MDS) for many decades. Recent studies show that multiparameter flow cytometric characterization of specific bone marrow population according to their lineage and maturation stage is of great clinical utility for the diagnosis of MDS. Actually, bone marrow needle aspiration is necessary for the diagnosis and classification of MDS and there is no peripheral blood screening that easily diagnoses this common hematologic malignancy. Erythroid dysplasia is found in almost all patients with MDS and is the only morphological abnormality in those with refractory anemia, that is, the pure erythroid disorders of the WHO classification. Although flow cytometry immunophenotyping is a reliable method for quantitative and qualitative evaluation of hematopoietic cells and can provide better reproducibility than morphology, evaluation of erythroid dysplasia represents a challenge in the immunophenotypic analysis of MDS, mainly because of the limited availability of specific antibodies. Recent the availability of monoclonal antibodies to the erythrocyte antigens have made such a study possible. *Aim*. The purpose of this study was to develop a flow cytometric approach (immunophenotype and forward and side scatter characteristics - FSC/SSC) to the evaluation of erythroid dysplasia in peripheral blood cells of patients with MDS, to easily diagnose early stages of this malignancy. *Design and Methods*. We evaluated peripheral blood samples from 16 *de novo* adult low grade MDS patients and 16 adult healthy blood donors. Informed consent was obtained in all cases. Whole peripheral blood samples were stained using a direct or indirect immunofluorescence technique without lyse in which the following monoclonal antibodies where used in triple staining against mem-

brane proteins like human blood groups, glycophorins, Transferrin receptor and hemolisis inhibitor proteins : CD36, CD55, CD59, CD71, CD174, CD236R, CD238, CD239, CD240DCE, CD240R and Glycophorin A. For reticulocyte identification DRAQ 5 dye was used. Acquisition was performed in a FACScalibur flow cytometer with CellQuest software and low flow, with FSC and SSC parameters at logarithmic scale. Data analysis was performed with Infinicyt software. Statisitc tests T-student and U-Mann-Whitney were used with SPSS software. *Results*. Comparison of FSC/SSC characteristics of normal healthy donors samples and MDS patients samples allowed the identification of aberrant phenotypes in MDS patients. The FSC and SSC parameters permitted the characterization of five different red blood cells subpopulations that presented abnormal distribution in MDS samples. Immunophenotypic aberrancies were detected in reticulocytes and also in mentioned red blood cells subpopulations. Low expression of CD236R, CD240DCE and Glycophorin A were the aberrant phenotypes with statistic significance. *Conclusions*. These results suggest that peripheral red blood cells flow cytometry studies can be useful in the earliest diagnosis of low grade MDS patients by the identification of aberrant immunophenotypes and abnormal FSC/SSC characteristics.

1347

PROGNOSTIC SIGNIFICANCE OF EOSINOPHILS AND BASOPHILS IN MDS: EVALUATION OF A CORE DATA SET OF 1008 MDS PATIENTS

F. Wimazal,[1] U. Germing,[2] M. Kundi,[3] T. Noesslinger,[4] S. Blum,[2] P. Geissler,[5] C. Baumgartner,[5] M. Pfeilstoecker,[4] P. Valent,[5] W.R. Sperr[5]

[1]Department of Obstetrics and Gynecology, Med Univ of Vienna, VIENNA, Austria; [2]Dept of Hematology, Oncology & Clinical Immunology, Heinrich-Heine-Universty, DÜSSELDORF, Germany; [3]Institute of Environmental Health, Medical University of Vienna, VIENNA, Austria; [4]3rd Med Dept, Hanusch-Hospital and Ludwig-Boltzmann-Inst for Leukemia Research, VIENNA, Austria; [5]Dept of Int Med I, Div of Hematology & Hemostaseology, Med Univ of Vienna, VIENNA, Austria

Background. Myelodysplastic syndromes (MDS) are a group of myeloid neoplasms characterized by abnormal differentiation and maturation of myeloid cells, reduced bone marrow (BM) function, and a genetic instability with enhanced risk to transform to secondary acute myeloid leukemia (AML). Among other factors, lineage involvement and maturation arrest are considered to be of prognostic significance in MDS patients. However, whereas the prognostic value of neutropenia, thrombocytopenia, and monocytosis have been documented, little is known about the impact of eosinophils and basophils. Patients and *Design and Methods*. We examined the prognostic significance of eosinophils and basophils in 1,008 patients with de novo MDS. Patients were enrolled from 3 centers of the Austrian-German MDS workinggroup and were analyzed retrospectively. Blood eosinophils and basophils were quantified by light microscopy, and their impact on survival and leukemia-free survival calculated by Cox regression. *Results*. Eosinophilia (>350/µL) and basophilia (>250/µL) were found to indicate a significantly reduced survival (p<0.05) without showing a significant impact on leukemia-free survival. The absence of eosinophils and basophils was also found to indicate poor survival. In multivariate analyses, eosinophilia and basophilia were found to be LDH-independent prognostic variables with IPSS-specific impact. Whereas an elevated LDH was found to be a major prognostic determinant in IPSS LOW, INT-1, and HIGH subgroups, eosinophilia and/or basophilia was found to be a superior prognostic indicator in INT-2 patients. *Conclusions*. Evaluation of eosinophils and basophils in MDS is helpful and may complement the spectrum of variables to optimize prognostication in MDS.

1348

RETROSPECTIVE EVALUATION OF IRON OVERLOAD PREVALENCE IN MYELODYSPLASTIC SYNDROMES AT THE DIAGNOSIS

B.M. Ricerca, M.T. Voso, M. Greco, L. Fianchi, L. Pagano, G. Giordano, S. Piano, S. Storti, G. Leone

Catholic University of Sacred Heart, ROME, Italy

Background. In the practical management of myelodysplatic syndromes (MDS), iron balance is carefully evaluated overall in transfused patients to select those eligible for iron chelation. Serum-Ferritin (s-F) is the only reliable laboratory parameter to assess IOL in such patients. *Aim of the study*. There are few reports about the prevalence of iron overload (IOL) in not transfused patients. We wanted to evaluate this prevalence using different approaches *Design and Methods* We retrospectively examined data concerning iron balance of 81 MDS patients at the diagnosis, never transfused. We identified IOL not only by s-F (available in 74 subjects) but also by Transferrin Saturation Index (TSI) (available in 62). In 55 patients both parameters were present. TSI was calculated as percentage of the ratio between serum iron and total iron binding capacity (TBIC); s-F was routinely assayed. We chose this approach because in other clinical setting like Hereditary Hemochromatosis (HHc), TSI is indicated as an early marker of IOL and it has a diagnostic value also before the rise of s-F. Moreover, s-F can rise for liver damage and inflammation, loosing its specificity as IOL indicator. *Results*. Table 1 shows the results obtained. In our experience, the prevalence of cases with severe IOL (ferritin >1000 ng/mL) is similar to that reported by other Authors (*Gatterman. Hematol Oncol Clin North Am 2005*).

Table 1.

Iron balance evaluated according TSI n=62	TSI>50%	21/62	33,8%
Iron balance evaluated According s-F n=74	>300 ng/ml	29/74	39,2%
	>500 ng/ml	18/74	24,3%
	>1000 ng/ml	4/74	5,4%
Iron balance evaluated According TSI and s-F n=55	TSI>50% n=18 18/55(32,7%)	and s-F>300 ng/ml 13/18 Total cases 13/55	72% 23,6%
	TSI>50% N=18	and s-F>500 ng/ml 10/18 Total cases 10/55	55% 18,2%
	TSI>50% n=18	and s-F>1000 ng/ml 4/18 Total cases 4/55	22% 7,2
Iron deficient patients	TSI<20% n=9	and s-F<20 ng/ml 3/9 Total cases 3/55	30% 5,4%
Inflammatory iron balance	TSI<20% n=9	and s-F>50 ng/ml 6/9 Total cases 6/55	66,6% 10,9%
Normal iron balance	n=19	19/55	34,5%

Nevertheless, the prevalence of a quite relevant IOL (s-F>500 ng/mL and<1000) is not unimportant (14/74 patients; 18.9%). On the other hand, if IOL is evaluated according to the criteria recommended for HHc (TSI>50% alone or together with s-F>300 ng/ml), its prevalence is much higher (33.8%; 23.6% respectively). In the group with both TSI and s-F available, the prevalence of IOL, identified according to TSI>50%, is significantly higher than that identified according s-F>1000 (32.7% versus 7.2% Fisher's exact test: p=0.0015) In addition, the contemporary evaluation of TSI and s-F allows recognizing MDS with inflammatory pattern of iron metabolism. In our group of MDS patients 10,9% showed this condition. *Conclusions.* We retain that iron balance, in not transfused MDS, should be investigated both by ferritin and TSI. This approach seems to be more sensitive in individuating IOL, and it allows recognising other alteration of iron balance. Further studies should clarify if the less severe IOL states are able to generate oxidative stress in the complex clinical context of MDS. This is a very important issue because many evidences support the link between oxidative stress and the DNA damage as a fundamental contribution to neoplastic evolution of MDS (*Rassool Cancer Res 2007*).

1349

TREATMENT OF CMML BY AZACYTIDINE (AZA): A PRELIMINARY REPORT ON 23 PATIENTS (PTS)

A. Wolfromm, R. Itzykson, S. Thepot, F. Dreyfus, A. Stamatoulas, S. de Botton, T. Prebet, C. Pautas, I. Lafon, B. Quesnel, C. Gardin, P. Fenaux, L. Ades

Groupe Francophone des Myelodysplasies, BOBIGNY, France

Background. Treatment of CMML remains difficult, with no drug having shown a clear clinical benefit. AZA has demonstrated a survival benefit in higher risk MDS, in a study that included a small number of CMML (*Lancet Oncol, 2009, online*). *Design and Methods*. The French health agency (AFSSAPS) designed a still ongoing pt named program (ATU) of AZA in higher risk MDS and poor risk AML. 24 pts with CMML or AML arising from CMML included in this program, before April 08 and having completed 1 cycle of AZA (75 mg/m^2/d during 7 days per 28 d cycle) are analysed here. Response was evaluated according to IWG 2006 criteria for MDS, and IWG-AML 2003 criteria for AML. *Results*. Median age was 66y (range 52-85), M/F: 16/7. At inclusion, 6 patients had CMML-1, 10 CMML-2 and 7 AML secondary to CMML according to WHO classification. Karyotype was normal (n=9), isolated -7/7q- (n=2), +8 (n=2), del20q (n=1), other single (n=8) complex (n=1) and a failure (n=1). Median interval from diagnosis to treatment was 1.5 years (range 0 months-5.6 years). Previous treatment consisted of low dose chemotherapy (n=1), Intensive chemotherapy (n=7), Allogeneic SCT (n=2), ATO (n=3) or ESA (n=9). The median number of cycles of AZA administered was 4 (range 1-19). 2 pts received only 1 cycle due to early death (n=1) and progression (n=1). 4 additional pts received less than 4 cycles due to hematological toxicity (n=3) or physician's decision (n=1). 7 pts (30%) responded including 3 CR, 3 marrow CR and 1 HI-E. Sex, Age, WBC count, monocyte count, Hb level, platelet count, WHO diagnosis, previous high dose chemotherapy and cytogenetics did not differ significantly between responders and non responders. 7/17 (41%) pts who received more than 4 cycles responded. Among the 16 MDS pts who received more than 1 cycle, 6 (38%) responded (3 CR, 2 marrow CR and 1 HI-E). Only one AML responded (marrow CR lasting 13 mos). 3 of the 7 responders relapsed after 13, 14 and 19 mos, and 4 remained responders after 10+, to 17+ mos. Median overall survival was 29 months in responders and 6.7 months in non responders. *Conclusions*. Those preliminary results confirm the activity of AZA in advanced CMML.

1350

α-DEFENSINS SECRETED BY IMMATURE DYSPLASTIC GRANULOCYTES INHIBIT THE DIFFERENTIATION OF MONOCYTES IN CHRONIC MYELOMONOCYTIC LEUKEMIA

A.J. Jacquel,[1] J.B. Hendra[2]

[1]INSERM UMR866, DIJON, France; [2]University of Burgundy, CLIPP Platform, DIJON, France

Background. Chronic myelomonocytic leukemia (CMML), which is the most frequent myelodysplastic/myeloproliferative disorder, occurs in elderly patients. One of the main diagnosis criteria of this clonal hematopoietic disease is a persistent peripheral blood monocytosis. We observed recently that, in most patients with CMML, part of the cells that accumulate in the peripheral blood and are usually classified as monocytes are actually dysplastic granulocytes with a CD14$^-$/CD24$^+$ phenotype. *Aims*. Compare the proteome profile of CD14$^-$/CD24$^+$ cells with the one of CD14$^+$/CD24$^-$ monocytes from CMML patients or healthy donors. *Design and Methods*. Clinical and laboratory findings were evaluated for several CMML patients. *Results*. The proteome profile of CD14$^-$/CD24$^+$ cells is dramatically distinct from the one of pathological and normal CD14$^+$/CD24$^-$ monocytes. More specifically, CD14$^-$/CD24$^+$ CMML cells synthesize and secrete large amounts of α-defensin 1-3 (HNP1-3). Recombinant HNP3 inhibits the M-CSF driven differentiation of human peripheral blood monocytes into macrophages, e.g. prevents characteristic morphological changes, the expression of CD71 and CD163 surface markers. Using transwell and suramin inhibition of ATP receptor or antibody-mediated depletion experiments, we demonstrate that HNP1-3 secreted by CD14$^-$/CD24$^+$ cells inhibit M-CSF-induced differentiation of CD14$^+$/CD24$^-$ cells from healthy donors or CMML patients. *Conclusions*. Altogether, these results suggest that a population of immature granulocytes, namely CD14$^-$/CD24$^+$ cells, contributes to the CMML phenotype through inhibiting the differentiation capabilities of monocytes.

NEUT-X AND NEUT-Y PARAMETERS ARE USEFUL TO DETECT NEUTROPHIL DISPLASIA IN MYELODYSPLASTIC SYNDROMES

J.R. Furundarena Salsamendi, M. Araiz Ramirez, M. Uranga Uranga, R. Sainz Arroniz, A. Aguirre Aguirezabala, M. Trassorras Arriaran, N. Uresandi Iruin, C. Montes Fernandez, N. Argoitia Ituarte

Donostia Ospitalea, DONOSTIA, Spain

Background. Diagnosis of myelodysplastic syndromes (MDS) relies on the morphological features seen on the blood or bone marrow. In peripheral blood we can see nuclear anomalies as hypolobulation, clumping, nuclear sticks and hypersegmentation and citoplasmic anomalies as hypogranulation. *Aims*. The main objective of this study is to see if hematology analyzers can detect neutrophil displasia. *Design and Methods*. Hemograms procesed in Sysmex XE-2100 hematology analyzers generate some research data like NEUT-X and NEUT-Y parameters. Blood samples anticoagulated with EDTA-K3 were analyzed before 6 h after extraction. Neutrophil granularity were optically graded as normal, hypogranular or both types of neutrophils in the same sample. Statistical analysis was performed using SPSS. *Results*. Between Aug 08 and Jan 09 we evaluated a control group of 50 cases, 50 deliveries, 50 anemias, 50 idiopathic leukopenias, 50 cases with hypergranulated neutrophils and 50 MDS. In the control group the mean and standard deviation (SD) were 1346±28.2 and 420±19.3 respectively for NEUT-X and NEUT-Y. In anemia group values were 1341±30.9 and 420±24.6 (p>0.05) and in the leukopenia group: 1346±30.2 and 427±34.0 (p>0.05). Deliveries group and hypergranulated neutrophils cases had significantly higher values: 1371±30.0 and 453±17.8 , 1394±38.3 and 556±111.4 (p<0.05). The mean and SD for MDS group were 1286±72,8 and 385±50,9 significantly lower than all other groups (p<0.05). In the group of MDS we included 4 refractory anemia, 11 refractory anemia with ringed sideroblasts, 1 5q- syndrome, 8 refractory cytopenia with multilineage dysplasia, 8 refractory cytopenia with excess blasts, and 18 chronic myelomonocytic leukemia (this type is included in myelodysplastic/myeloproliferative syndromes in the OMS classification). There were not significant differences in NEUT-X and NEUT-Y values between morphological types of MDS. In the subgroup of MDS with optic hypogranulation the mean and SD for NEUT-X and NEUT-Y were 1255±65.1 and 368±43.6; values were 1338±49.4 and 414±41.8 for MDS without optic hypogranulation (p< 0.05). NEUT-X and NEUT-Y less than 1285 and 375 respectively had a specificity of 98% and a sensitivity of 48% and 44% for MDS detection. The same cutoff will detect 68% and 58% respectively of MDS with optic hypogranulation. *Summary.* NEUT-X and NEUT-Y parameters are useful to detect neutrophil displasia in MDS.

1352

CLINICAL AND BIOLOGICAL EFFECTS OF 5-AZACITIDINE FIVE DAYS/MONTHLY SCHEDULE IN SYMPTOMATIC LOW-RISK (IPSS: 0-1) MYELODISPLASTIC PATIENTS

C.F. Filì,[1] C. Bergonzi,[1] C. Skert,[1] M. Malagola,[1] A.M. Roccaro,[1] A. Peli,[1] A. Turra,[1] C. Colombi,[1] G. Martinelli,[2] C. Finelli,[2] C. Clissa,[2] I. Iacobucci,[2] E. Ottaviani,[2] L. Cocco,[3] M.Y. Follo,[3] A. Candoni,[4] E. Simeone,[4] M. Gobbi,[5] M. Miglino,[5] D. Russo[1]

[1]Unit of Blood Disease and Cell Therapy, University of Brescia, BRESCIA, Italy; [2]Institute of Haematology and Medical Oncology, University of Bologna, BOLOGNA, Italy; [3]Cellular Signalling Laboratory, University of Bologna, BOLOGNA, Italy; [4]Chair and Division of Haematology, Stem Cell Transplantation Unit Carlo Melzi, UDINE, Italy; [5]Department of Haematology and Oncology, University of Genova, GENOVA, Italy

Background. Nucleoside 5-Azacitidine (5-Aza) administered at a dose of 75 mg/m^2/day subcutaneously for 7 days, every 28 days, induces high hematologic response rates and reduces progression to acute myeloid leukaemia (AML) in the high risk MDS patients. *Aim*. The use of 5-Aza in the earlier phases of MDS could reduce the proliferative advantage of MDS clone and favours the regrowth of normal hematopoiesis. In the setting of low-risk MDS patients lower doses of 5-Aza could be enough to induce hematologic responses. We attempted to use an alternative schedule, 75 mg/m^2 subcutaneous daily for 5 consecutive days every 28 days, for a total of 8 courses, to evaluate its efficacy and tolerability in low risk MDS patients. Pharmacogenomic studies (the gene expression profile and single nucleotide polymorphism analysis), and the determination of cytokine's pattern, before and after 5-Aza treatment, were planned to identify new biological markers to predict the response. The first step will be to performe biological studies in 5 responsive and 5

resistent patients; based on these results the analysis could be extended to more patients. *Design and Methods*. Between May and December 2008 we enrolled 15 patients in the multicentric clinical trial. According to WHO criteria 6 patients had refractory anemia (RA), 5 patients refractory cytopenia with multilineage dysplasia (RCMD) and 4 patient refractory anemia with excess blasts-1 (RAEB-1); all patients were classified as Low Risk (IPSS score 0-1). Age at diagnosis ranged between 56 and 82 years. All patients failed EPO therapy and were in chronic red blood cell (RBC) supportive care with a median transfusions requirement of 4 units/monthly. *Results*. The response treatment criteria was according to IWG 2006. 5 out of 15 patients completed the 8 courses of therapy; 4 patients obtained an hematologic improvement (HI) with an erythroid response whereas 1 patient maintained a stable disease. The others 10 patients are ongoing. The drug was very well tolerated. Hematologic toxicity consisted in neutropenia (WHO grade III) and thrombocytopenia (WHO grade II) in one patient but it was transitory and no delay of treatment was necessary. *Conclusions*. Our preliminary results show that the 5-Aza five days/monthly schedule is very well tolerated and it appears to have an efficacy similar to the seven days/monthly schedule, at least in low-risk MDS setting. Considering that the optimal schedule and duration for demethylating agents has not yet been established, further MDS patients recruitment is warranted to confirm the efficacy of this alternative 5-Aza low dose regimen. Biological studies will be performed after the clinical study and they will be correlated to the treatment response. The results could be useful to elucidate the genetic bases for individual susceptibility to the beneficial (or adverse) effect of 5-AZA, in order to optimise the therapy.

1353

SECONDARY RADIATION-INDUCED MYELODYSPLASTIC SYNDROME: APOPTOSIS AND TELOMERE LENGTH

D. Bazyka, I. Ilyenko, O. Belyaev

Research Center for Radiation Medicine, KYIV, Ukraine

Background. Myelodysplastic syndromes (MDS) in radiation exposed are characterized by a combination of ineffective hematopoiesis with late radiation post-effects. Increase of apoptosis and changes of telomere length were demonstrated in irradiation experiments and exposed humans. Aim of the study was to reveal possible modifying role of the late radiation induced changes on apoptosis and telomere length in myelodysplasia. *Design and methods*. Peripheral blood samples were studied in 17 exposed (mean dose 0,42 Sv) and 6 non-exposed MDS-RA patients and 10 non-exposed controls. Apoptosis was studied in Annexin-V test, telomere length - by PNA flow-FISH assay. *Results*. MDS-RA samples have demonstrated high levels of granulocyte and lymphocyte apoptosis and significantly lower relative telomere length (RTL) index in comparison with healthy controls. Lower RTL indices and no difference in apoptosis were shown between MDS-RA subgroups due to the fact of previous irradiation. Mean RTL indices in the exposed RA subgroup were lower than in comparison group. Correlations with age were demonstrated with early apoptosis but not RTL. AML cases in comparison with MDS showed marked decrease of cell numbers at all stages of apoptosis but no difference of group RTL from control due to individual variation. *Summary*. This study shows a possibility of relationship between apoptosis induction and the telomere region changes in MDS-RA at the remote period after radiation exposure.

1354

A RATIO OF LYMPHOCYTES AND NEUTROPHILS GRANULARITY AS A NEW APPROACH FOR SCREENING MYELODYSPLASTIC SYNDROM BY FLOW CYTOMETRY

E.B. Rusanova,[1] Y.E. Zueva,[1] R. Simon-Lopez[2]

[1]Saint-Petersburg State Medical University, SAINT-PETERSBURG, Russian Federation; [2]Beckman Coulter, NYON, Switzerland

Background. The myelodysplastic syndrome (MDS) is a group of clonal bone marrow disorders characterized by peripheral cytopenia, inefficient hematopoiesis, and unilineage or multilineage dysplasia. It is known that the level of granularity of neutrophils is the most important morphologic feature of MDS. The genetic features of MDS often include clonal, nonrandom chromosomal deletions (e.g., 7q-, 5q-, 20q-, 6q-, 11q- and 13q-) that appear to inactivate tumor suppressor genes required for the normal development of myeloid cells. The aim of this study is a creation of simple and modern screening test for first step diagnostic of MDS. *Design and methods*. 20 patients with median age 68 (58-83) years diagnosed with MDS and 20 samples of healthy individuals were enrolled into this study. The protocol of study included peripheral blood smears microscopy, evaluation of blood cell populations by hematological analyzer (GenS, Beckman Coulter, USA), and flow cytometry (FC500, BC). It was used a single tube protocol of multiparametric flow cytometry using a panel of monoclonal antibodies: D14-FITC, CD16-PE, CD33-PC5 and CD45-PC7 (BC). Neutrophils and lymphocytes were identified using the special gating strategy and the combinations of FS/SS, CD45/SS, CD45/CD16 and CD33/CD14. Molecular genetic tests were performed for identification specific genetics abnormalities for MDS. Results. There were determined the mean scatters (MS) of neutrophils and lymphocytes of peripheral blood. The ratio between neutrophils and lymphocytes MS was significantly lower in MDS patients than in the group of healthy individuals (p=0.016), AUC=0.824, sensitivity 81.8%, specificity of 81.2%. Based on cytogenetic results, patients with MDS can be subdivided into cases with (i) normal karyotypes (75% cases), (ii) del(5q-) (15% cases), (iii) del(6)(q23) (5% cases), and (inv) del(7)(q22q31) (5% cases). *Conclusions*. The information about hypogranularity of the neutrophils is a well known feature of MDS. We have suggested single tube flow cytometry protocol to determine the level of granularity of different leukocytes populations. The lymphocyte MS is constant for healthy individuals and for MDS patients. The ratio between neutrophils and lymphocytes MS allows to differentiate peripheral blood of healthy individuals and MDS patients regardless of the severity of disease. These data are numerical, quantitative and objective. The ratio between neutrophils and lymphocytes MS might be useful tools to detect or flag the neutrophil hypogranularity and helps in the differential diagnosis of MDS.

1355

EXPRESSION OF CYCLIN A1 MRNA IN PATIENTS WITH MYELODYSPLASTIC SYNDROME AND ITS CLINICAL SIGNIFICANCE

J. Jia,[1] S.R. Xu[2]

[1]Institute of Hematology, People Hospital, Beijing University, MARSEILLE, France; [2]Department of Hematology, Affiliated Second Hospital, Hebei Medical University, SHIJIAZHUANG, China

Background. Myelodysplastic syndromes are bone marrow stem cell disorders resulting in disorderly and ineffective hematopoiesis manifested by irreversible quantitative and qualitative defects in hematopoietic cells. In a majority of cases, the course of disease is chronic with gradually worsening cytopenias due to progressive bone marrow failure. Approximately one-third of patients with MDS progress to AML within months to a few years. Aims: The purpose of study was to evaluate the expression of cyclin A1 mRNA in patients with myelodysplastic syndrome (MDS) and their clinical value. *Design and Methods*. The expression of cyclin A1, cdk2 and p21 cip1 mRNA in the bone marrow from 56 patients with MDS and 10 normal control were measured with Quantitative real-time reverse transcriptase polymerase chain reaction (RQ-PCR) technique. *Results*. The positive rate and the expressing level of cyclin A1 in MDS patients (69.64%; 0.964±1.879) were significantly lower than those in nromal control (0%; 0.012±0.014) (p<0.01). Among de novo MDS patients, the expressing mRNA level of cyclin A1 was higher in the MDS-RAEB group (1.895±1.769) than that in MDS-RA group (0.629±1.583) (p<0.01). The expressing mRNA level of cyclin A1 in post-treatment group was significantly lower than that in prior treatment group (p<0.01). *Summary*. It is concluded that the mRNA expression of cyclin A1 in MDS patients is higher than normal control, the abnormal expression of cyclin A1 might be a prognostic marker in MDS patients.

RISK FACTORS AND OUTCOME OF SEVERE INFECTIOUS OR HEMORRHAGIC EVENTS DURING THE COURSE OF MYELODYSPLASTIC SYNDROMES

T. Challan-Belval, K. Delavigne, L. Sorin, A. Chabrol, C. Récher, L. Laurent, D. Adoue, O. Beyne-Rauzy

CHU Purpan, TOULOUSE, France

Background. Neutropenia and thrombocytopenia are common cytopenias in myelodysplastic syndromes (MDS). *Aim*. To evaluate the impact of severe infectious or hemorrhagic events on morbidity and mortality during the course of MDS is unknown. *Design and Methods*. A retrospec-

tive study was conducted to describe infectious or hemorrhagic events requiring hospitalization in MDS. The impact of risk factors on the outcome was also evaluated: comorbidities, prior treatment, disease status, degree of neutropenia or thrombopenia, treatment. Results-Thirty infectious events (IE) occurred in 22 MDS (3 RA, 2 RARS, 10 RAEB-1, 3 RAEB-2, 4 AML according to WHO's classification). Mean IPSS was 1.43 and high risk MDS (IPSS >1) represented 53% with a mean age of 72.4yr (min.54-max.90). Four patients required intensive unit care transfers due to acute respiratory distress syndrome (3 cases) or hypovolemic choc (1 case) and all died. Overall mortality rate was 13%. Site of infection was commonly pulmonary (10 cases), cutaneous (5 cases) and digestive tract (4 cases). Microorganisms category was proved in 6 cases (5 bacteria, 1 virus) and supposed to be bacterial in 19 cases or fungal in 4 cases. Mean absolute neutrophils count (ANC) was 2.4 G/L, 17 patients have neutropenia (ANC <1.5G/L) with 11 ANC <0.5G/L. Mean period of hospitalization was 12.7 days (min.1-max. 45) and increased with neutropenia degree, 15.8 and 8.5 days for ANC <1.5 or >1.5G/L respectively. Most IE received more than 1 treatment, mean 1.9 drugs. Favorable outcome was observed in 80% of events. Twenty four hemorrhagic events (HE) occurred in 17 MDS (2 RA, 1 RCMD, 5 RAEB-1, 4 RAEB-2, 5 AML). Mean IPSS was 1.5 and high risk MDS (IPSS >1) represented 55%, mean age was 72.1yr (min.57-max.86). Localizations of bleeding were commonly cerebral (7 cases), cutaneous or mucous (13 cases). Mean platelets count was 21G/L. Mortality rate was 29% and reached 71% for cerebral bleeding. No risk factor (platelet count, prior therapy) was correlated with the occurrence of HE except disease progression. Fatal outcome was associated with an increased Charlson comorbidity index (respectively 4.85 versus 3.35). In the same period MDS hospitalizations for IE, HE, red blood cells transfusions or treatment procedures represented 6.8, 15.0, 57.1, 21.1% respectively. *Conclusions*. IE and HE were common events wich represented 20% of MDS hospitalizations and have high mortality rate of 13 and 29% respectively. Poor outcome is observed in cerebral bleeding and comorbidities worsened prognosis. At the opposite IE outcome was favorable in 80% of cases and degree of neutropenia was correlated with increased hospitalization period.

1358

PROGNOSTIC SIGNIFICANCE OF β2 MICROGLOBULIN PREDICTING SURVIVAL IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES

A. Galanopoulos,[1] D. Gogos,[2] A. Aggelidis,[2] S. Papanikolaou,[2] A. Argyrou,[2] T. Marinakis,[2] E. Michalis,[2] G. Gortzolidis,[1] V. Grigoraki,[2] E. Griva-Kritikou,[3] I.N. Anagnostopoulos[2]

[1]*G.Gennimatas Hospital, ATHENS, Greece;* [2]*Clin.Hematology, G.Gennimatas Hospital, ATHENS, Greece;* [3]*Lab.Hematology, G.Gennimatas Hospital, ATHENS, Greece*

Background. β2 microglobulin (β2M) is a 12-kDa light chain protein that binds to the β chain of class I MHC (MHC1) molecules. Serum β2M levels are known to reflect renal function and membrane turnover, which is associated with tumor mass and growth rate. Elevated serum levels of β2M are reported to predict poor survival in several hematologic malignancies. *Aims*. To evaluate the significance of β2M as a prognostic marker in patients with myelodysplastic syndromes (MDS) in our Center. *Design and Methods*. We examined 199 patients with MDS who were admitted to our Center from 2000 through 2007. B2M levels were measured in 154 patients. Of these 154 patients, 12 patients with a diagnosis of chronic myelomonocytic leukemia and 5 patients with RAEB-T were excluded from subsequent analysis. The remaining 137 patients provided the database for this analysis. B2M and karyotype were recorded along with other hematologic, biochemical and clinical covariates. Diagnosis was established using World Health Organization (WHO) and IPSS criteria. Serum β2M was quantified by a radioimmunoassay. Results. Nine patients (6%) had refractory anemia (RA), 35 (25%) refractroy anemia with excess of blasts-1(RAEB-1), 20 (14%) refractory anemia-2 (RAEB-2), 15 (11%) refractory anemia with ringed sideroblasts (RARS), 45 (33%) refractory cytopenia with multilineage dysplasia (RCMD) and 15 (11%) refractory cytopenia with multilineage dysplasia with ringed sideroblasts (RCMD-RS). The median β2M level was 2,75 mg/L (range: 1,02-15,73 mg/L). It did not differ significantly among the WHO groups (RA, 3.88 mg/L; RARS, 3.4 mg/L; RCMD, 2.83 mg/L; RCMD-RS, 2.66 mg/L; RAEB-1, 2.47 mg/L; RAEB-2, 2.72 mg/L; 5q-, 2.34 mg/L) as well as among IPSS risk groups (low, 2.96 mg/L; Int-1, 2.52 mg/L; Int-2, 2.95 mg/L; high, 2.81 mg/L). Patients with β2M levels > 2 mg/L had a worse survival compared to those with levels < 2 mg/L (p= 0.046). Univariate analysis identified cytogenetics, hemoglobulin level, platelet count, bone marrow blasts, intensive treatment and β2M levels as significantly associated with survival. Patients who received intensive treatment had significantly shorter survival than other patients (38 months vs 57 months), probably due to selection of RAEB-1 and RAEB-2 for intensive treatment. High β2M was associated with shorter survival both in patients with good/intermediate and poor karyotype (p=0.002). Multivariate analysis confirmed that β2M provided additional prognostic information to that provided by IPSS. *Conclusions*. High β2M is associated with a worse survival in MDS patients. ts measurement is strongly recommended, as it can be used, additionally to IPSS, as a prognostic tool for a better stratification of MDS patients.

1359

MYCOPHENOLATE-PREDNISONE PLUS ERYTHROPOIETIN IN THE TREATMENT OF MYELODYSPLASTIC SYNDROMES

A.F. Remacha,[1] B. Arrizabalaga,[2] A. Julia,[3] J. Bargay,[4] J.A. Muñoz,[5] C. Pedro[6]

[1]*Complejo Hospitalario Toledo, TOLEDO, Spain;* [2]*Hospital de Cruces, BARCALDO, VIZCAYA, Spain;* [3]*Hospital Vall d'Hebrón, BARCELONA, Spain;* [4]*Hospital Sant Llatzer, PALMA DE MALLORCA, Spain;* [5]*Hospital Puerta del Mar, CÁDIZ, Spain;* [3]*Hospital del Mar, BARCELONA, Spain*

Background. Response rate to Erythropoietin (Epo) in patients with myelodysplastic syndromes with high level of serum erythropoietin and transfusions is very low. Moreover, most of MDS patients with an initial response to Epo loss this response during the follow-up. Aims: To evaluate the efficacy and safety of mycophenolate-prednisone before recombinant Epo β (ML20559 study) in the rescue of MDS patients that loss the response to Erythropoietin or with very low probability of response to Erythropoietin (Scandinavian Score). *Design and Methods*. In a multicenter study, 10 patients with MDS and loss the response to Erythropoietin or with very low probability of response to Erythropoietin (Scandinavian Score) because of basal serum Epo >300 u/L and transfusion requirements, were treated with oral mycophenolate 2000 mg/d plus 0.5 mg/kg/d of prednisone during 12 weeks, prednisone was tapered to 10 mg/d. Mycophenolate and prednisone were maintained along the treatment. After 12 weeks, recombinant erythropoietin β (NeorecormonR) 30000 u/week was added to non-responders from 12 to 18 weeks. In non-responders, from 18 to 24 weeks Neorecormon was increased to 60000 u/week. For response IWG criteria were used. Results. After 2 weeks of treatment one patient withdrew the treatment, the remaining 9 cases completed it. In 5 cases an erythroid response (HI-E) was observed including 2 HI-E minor responses (1 case decreased transfusion requirements > 50% with Epo 30000 u/w, and 1 patient increased Hb from 8.5 to 10.1 with Epo 60000 u/w) and 3 HI-E major responses (in one transfused patient the Hb after mycophenolate-prednisone was 8.9 g/dl without transfusion and increased to 9.7 with Epo. In a second case with an initial Hb of 8.1 g/dL, the level increased to 9.9 with mycophenolate-prednisone, minor response, and to 10.9 with Epo 60000 u/w, major response. In the third case, a sideroblastic anemia under transfusions, Hb using Epo 30000 u/w was 8.3 g/dl without transfusions and increased to 9.6 g/dl with Epo 60000 u/w). The treatment was well tolerated. However, 4 cases developed diarrhea and 1 case hyperglycemia, those adverse events were managed with medical treatments and all patients completed the treatment. *Conclusions*. In this preliminary study including MDS patients that loss the response to Epo or very low predictive score of response to Epo, mycophenolate-prednisone followed by the addition of Epo β could be a promising therapy. More extensive studies should be carried out to explore this combination therapy and to clarify its role in MDS treatment.

1360

EFFECT OF DEFERASIROX ON OXIDATIVE STRESS AND VASCULAR DYSFUNCTION IN MDS PATIENTS WITH IRON OVERLOAD

R. García-Delgado, A. Fernández-Ramos, A. Rosell, A.I. Gallardo, M. Martín, A. Campos, M.P. Queipo de Llano, S. De la Torre, S. Del Castillo

Hospital Clínico Virgen de la Victoria, MÁLAGA, Spain

Background. Secondary iron overload due to frequent blood transfusions has been related to the pathogenesis of ischemic cardiovascular disease.

Table.

Molecular marker	Before deferasirox treatment MIF±SD	After deferasirox treatment MIF±SD	p
VCAM-1	194.5 ± 5.8	169.8 ± 4.6	0.005
ICAM-1	201.0 ± 8.0	145.3 ± 5.2	<0.001
E-Selectin	89.8 ± 2.2	70.3 ± 2.2	<0.001
P-Selectin	43.0 ± 1.8	21.3 ± 1.7	<0.001
β1-Integrin	34.8 ± 1.0	21.3 ± 1.7	<0.001
EPC	0.002 ± 0.001	0.036 ± 0.020	0.015
EC	0.020 ± 0.010	0.095 ± 0.040	0.011
Total leukocyte hydrogen peroxide	163.1 ± 17.9	93.0 ± 20.2	0.002
Total leukocyte intracellular glutathione	120.5 ± 33.9	228.0 ± 109.4	0.109
Total leukocyte mitochondrial membrane potential	14.5 ± 7.7	23.68 ± 8.9	0.169

Abbreviations: EC: Endothelial cells; EPC: Endothelial progenitor cells; E-selectin: Endothelial selectin; ICAM: Intercellular adhesion molecule; MFI: Mean fluorescence intensity; P-selectin: Platelet selectin; VCAM: Vascular cell adhesion molecule.

Iron burden can lead to endothelial dysfunction and vascular injury by promoting the generation of reactive oxygen species (ROS), which, in turn, impairs vasodilatation and promotes platelet and leukocyte adhesion, thereby contributing to plaque disruption and thrombosis (*Circulation 2003;107[20]:2601-6*). Iron chelators, including the novel chelator deferasirox, have demonstrated to effectively suppress generation oxidative stress markers (*Arterioscler Thromb Vasc Biol. 2005 Nov;25(11):2282-8*). *Aims*. To evaluate the effect of deferasirox on endothelial progenitor cells (EPCs) and other molecular markers of atherosclerotic progression in patients with myelodysplastic syndrome (MDS) and secondary iron overload. *Design and Methods*. Chelation treatment consisted of deferasirox 20 mg/kg/day, which had to be administered uninterruptedly for at least one month. Oxidative stress biomarkers were studied by flow cytometry in white blood cells (WBCs) as total leukocytes, neutrophils, lymphocytes and monocytes. Mitochondrial membrane potential, ROS, intracellular glutathione levels and the expression of the following adhesion molecules VCAM-1, ICAM-1, E-selectin, P-selectin and β1-integrin in monocytes and neutrophils were analyzed using a dual-laser FACSCalibur and Cell Quest software (Becton Dickinson and Company). *Results*. These preliminary results correspond to the first four patients with low-risk MDS and iron overload enrolled. The inclusion period of this study is still open. No adverse events related to deferasirox administration were observed. Mitochondrial membrane potential, intracellular glutathione and endothelial progenitor cells were increased after treatment with deferasirox in all cell types, whereas generation of ROS and adhesion molecules significantly decreased after deferasirox treatment in most cell types. *Conclusions.* Treatment of iron overload with deferasirox may help to reduce vascular injury and atherosclerotic progression through a mechanism involving reduction of EPC levels, oxidative stress, and adhesion molecules. Final results will be presented at the meeting.

1361

CLINICO HEMATOLOGICAL CHARACTERISTICS AND TREATMENT OF 150 NEW MDS PATIENTS. SINGLE CENTER EXPERIENCE DURING 7 YEARS (2000-2007)

I. Ionita,[1] M. Cheveresan,[2] C. Ionita,[1] L. Cheveresan,[1] D. Calamar,[1] H. Ionita[1]

[1]UMF Victor Babes Timisoara, TIMISOARA, Romania; [2]City Clinical Hospital, TIMISOARA, Romania

Background. Myelodisplastic syndroms (MDS) are clonal hematopoietic stem-cell disorders characterized by ineffective dysplastic hematopoiesis involving one or more cell-lineages and characterized by peripheral blood cytopenias and high risk of progression to acute myeloid leukemia (AML). *Aims*. We gathered data on patient characteristics and treatment of 150 MDS patients seen in our hematology center during a period of 7 years (2000-2007). *Design and Methods*. We studied all new MDS cases diagnosed and treated since January 2000 in our Clinic. All patients were studied on admission with full blood count, bone marrow aspirate smears (BMA) and some were studied with cytogenetics and bone marrow biopsy specimens (BMB). We evaluated morphological features for all MDS patients including the availability of May Grunwald-Giemsa well stained BMA smears and BMB specimens. BMA were examined for diserythropoiesis (DE), disgranulopoesis (DG) and dismegakariopoesis (DM) as defined by WHO criteria. For all MDS patients, we analyssed the percentage of blasts and ringed sideroblasts. *Results*. From the 150 patients, 89.33% (134 patients) had primary MDS and 10.6(16 pat.) were diagnosed as treatment related MDS. The M:F ration was 1.42, median age 69 years (range 20-83 years). The median presenting Hb was 8,3 g/dL (range 3,5 -11,3), platelet count $73x10^9$/L (range 2.0-610.0) and WCC $3,1x10^9$/L (1,1-3,9). The distribution among MDS types was RA 21,33%, RA-RS 11,33%, RCMD 12%, RCDM-RS -2%, RAEB-13,33%, RAEB 2-16%, MDS-U-16% and 5q-syndrome- 8%. A karyotype analysis was available in 69,33% of patients (104 patients) and 66.66% were with a normal karyotype. According to the International Prognostic Scoring System (IPSS), 34.67% of the patients belonged to the low-risk, 30% to the Intermediate-1, 20% to the Intermediate -2 and 15.33% to the high-risk group. There were 88 males and 62 females. From the 150 patients that we studied 81,33% were treated in our Hematology Department; 24,6% of those were treated in daycare hospital and 75,6% were admitted on the hospital. The reasons for hospitalization were high-risk group patients, disease progression, disease complications like: infections, hemorrhages and bad general conditions. From all the treated patients, in 41 cases, patients were admitted for intensive chemotherapy and any kind of treatment that requires inpatient care. None of the patients received a Stem-Cell Transplantation. 84.66% of patients received at least one unit of packed red-cells and 60% received at least one unit of platelets. The median number of hospitalizations per patients was 2 (1-11). With a mean follow-up of 30,5 months (range 0,31-82,6) 54% (81 pts)died, 12% (18 pts) transformed to AML after a median of 13,21 months. 60 patients died of MSD related complications- 68.33% sepsis,15% bleeding, 10% AML, 6.67% (4pts) deaths, were not related to MSD. The median OS was 27,8 months. The median OS in RA/RAPS, RCMD/ RCMD-RS, RAEB-1, RAEB-2 were 79,11; 75,10, 10,52 and 5,34 months respectively. *Conclusions*. With regard to MDS subtype distribution, patients seen in our hematological center did not differ much from the MDS population as a whole. Our patient needed hospitalization for inpatient care either for management of MDS related complications or intensive treatment of the underlying bone marrow disease.

CLINICAL EFFECTS OF DECITABINE IN MYELODYSPLASTIC SYNDROME (MDS)

A.K. Golenkov, G.A. Dudina, I.V. Buravtsova, N.V. Oparina, E.V. Katayeva

M.F. Vladimirsky Moscow Regional Research Clinical Institute, MOSCOW, Russian Federation

Background. MDS is characterized by heterogeneous clinical presentation, involving multilineage dysplasia, ineffective hematopoiesis and transformation to acute leukemia. MDS pathogenesis is characterized by hypermethylation of DNA and abnormal histone acetylation, affecting functions of oncogenesis and tumor suppressor genes. By reducing hypermethylation of tumor suppressor genes ("desilencing"), decitabine may balance gene expression and normalize cell function. Study objective: Assessment of clinical effects of decitabine in patients with MDS. *Design and Methods*. We prospectively observed 16 patients with MDS (7 men and 9 women; mean age 62 years) treated with decitabine 15 mg/m^2 i.v. q8h for 3 days within each 6-week cycle. According to FAB classification, 14 patients were diagnosed with RAEB and 2 patients with RAEBT. Abnormal karyotype was found in 6 patients, including hypodiploidy in 2 patients, del 5q in 2 patients, and complex abnormalities in 2 patients. Results: Of the 16 patients, 9 have completed 3-4 cycles of decitabine therapy and 7 have completed 1-2 cycles; 14 are still on therapy and 2 died after 1-2 cycles from disease progression. Mean Hb level was 74.8±8 g/l at baseline and 96.9±8 g/l after 3-4 cycles of therapy (p=0.05). Among patients who completed 3-4 cycles of therapy, the mean number of red blood cell transfusions per 6 weeks decreased from 4 to 2, mean platelet count increased from 70.6±13x10^9 to 136.6±3.5x10^9 (p<0.001), and blast cell counts in bone marrow decreased from 9.9±2.1% to 3.9±0.8% (<0.01). There was no hematological response in patients who completed 1-2 cycles of therapy. Assessment of response according to modified IWG criteria (*Cheson BD. Blood 2006;108:419*) in patients completing 3-4 cycles of decitabine treatment gave the following responses: 1 complete response (CR), 6 complete marrow responses (mCR), and 2 stable disease (SD). Median time to first response was 3 cycles and median time to best observed response was 4 cycles. Mean duration of response was 6.5 months. The non-hematological adverse events were reported following 1-2 cycles of treatment: upper respiratory tract infections (n=8), mucous mycotic lesions (n=4), and herpes infection (n=1). Following 3-4 cycles of therapy, upper respiratory tract infections were reported in just 2 patients. No other serious complications were reported. *Conclusions*. This study demonstrated that decitabine is characterized by clinical effect, and longer treatment duration led to better response rates. Decitabine was well tolerated and no apparent signs of cumulative toxicities were detected throughout treatment. Thrombocytopenia and leucopenia were transient and did not require adjustment of dose and treatment-free intervals for decitabine. Continuation of decitabine treatment for at least 3-4 cycles in MDS patients is well tolerated and is appropriate to obtain the best response, while continued therapy beyond reaching best response is instrumental to reach prolonged survival.

1363

5-DAYS SCHEDULE OF DECITABINE MAY BE EFFECTIVE AS IN HIGH RISK MDS EITHER IN RELAPSED AML

A.V. Kokhno,[1] E.N. Parovichnikova,[1] I.B. Kaplanskaya,[1] E.V. Domracheva,[1] O. Samoylova,[2] N. Obidina,[3] V. Mashuk,[4] O. Bocharnikova,[5] T. Pospelova,[6], V. Savchenko[1]

[1]National Research Center for Hematology, MOSCOW; [2]Hematology department, N.NOVGOROD; [3]Hematology department, Central Military Hospital, MOSCOW; [4]Hematology department, regional Oncology Center, KRASNODAR; [5]Hematology department, Moscow Medical academy, MOSCOW; [6]City Hematological Center, NOVOSIBIRSK, Russian Federation

Hypomethylating agents have provided a new option in the treatment of the patients with myelodysplastic syndromes. Coming up from seventies as antileukemic drugs azacitidine (AZA) and decitabine (DAC) after schedule and dose modification were proved to be very active in myelodysplastic syndromes. The overall response rate in intermediate and high risk MDS was reported to be as high as 73%-81% with 34%-36% of CR for decitabine in 5-days schedule in monocenter trial (H.Kantarjian, Blood 2007, 109, 52-57; Cancer 2007;109:265-273) and 60% with 7% CR for AZA in a CALGB randomized trial (*Silverman JCO, 2002; 20: 2429-40*). It was also demonstrated that AZA gave a significant OS advantage in randomized comparison with conventional care regimens (*P. Fenaux, 2007 ASH abstr 817*). The big point of the reported studies is low general toxicity of the drugs. This promising data became a basis for initiating by Russian leukemia Study group a multicenter trial testing the efficacy of the 5-days schedule of DAC in high risk MDS and relapsed AML presenting as MDS. *Design and Methods.* From Aug 2007 till February 2009 18 patients from 6 hematological centers were enrolled in the study: median age 49y (26-77 yy), RAEB-9pts (IPSS Int-2 - 3pt, high risk-4, 1-no cytogenetics, 1- secondary MDS), RCMD-3 pts (IPSS Int-1 - 1pt, Int 2 -2 pt), RARS (IPSS Low - 1 pt), AML - 4 pts (de novo -2, relapsed after MUD -1 pt, relapsed after MDS transformation -1 pt) CMML 1 pt. 7 patients were pretreated with different therapies. DAC was used in a 5 days schedule: 20 mg/m^2 once daily 1-hour i.v. infusion for 5 days, three courses were applied till response evaluation. The treatment was stopped at AML progression or absence of any improvements after 3 courses. Median number of courses is 3 (1-9), median follow-up from treatment start - 9 mo (1-17 mo). *Results*. Among 9 RAEB and 3 RCMD pts we observed 2 stable CR (after 2-3 courses), 1- mCR, 1 HI (after 3 courses), 5 progression to AML after 1-4 courses (Me-2), 1 pts did not respond. So, 4 of 10 advanced MDS pts (40%) achieved hematological remission and a mediana response duration of 10 months. DAC was ineffective in low risk RARS patient with prolonged disease history (2 years). CR was registered in one CMML patient after 3 courses with 6 months response duration, after progressed to AML and died. In 2 out 4 AML patients marrow CR was obtained, two patients progressed to overt AML and died. In one pt CR is stable (+10 mo), the other one relapsed at 9 months of mCR and died. It worth to note that this mCR was the third in this pt and DAC was applied after MUD allogeneic transplantation. Cytogenetic response was documented in 3 of 9. General toxicity of DAC was acceptable, though the majority of the patients experienced after DAC prolonged neutropenia with infections and thrombocytopenia transfusion dependant. All patients were hospitalized at least once. *Conclusions*. Though the studied group is small and rather heterogeneous we nevertheless may conclude that decitabine provided 7of 16 (44%) CR+HI in very high risk MDS and AML patients. Effect was usually achieved after the 3rd course. Decitabine may be an option for relapsed after stem sell transplantation AML and in AML secondary to MDS, though AML should not be highly proliferative. The drug should be used in leukemia departments by doctors aware of myelosupression complications.

1364

LOW FREQUENCY OF RAS GENE AND ABSENCE OF FLT3-ITD GENE MUTATIONS IN INDIAN PATIENTS WITH MYELODYSPLASTIC SYNDROMES: AIIMS STUDY

R. Chaubey, S. Sazawal, R. Mir, B. Bohra, R. Kumar, M. Mahapatra, R. Saxena

All India Institute of Medical Sciences, NEW DELHI, India

Background. Chromosomal abnormalities and molecular detection has potential importance for diagnosis and prognosis of MDS, although the mechanisms underlying the development of MDS and their progressive evolution to AML are still largely unknown. Since, no studies have been reported from India on the prevalence of N-RAS, K- RAS point mutation in codon 12 and FLT3-ITD mutations in patients with MDS, we undertook this study. *Objectives*. To find out the frequency of RAS and FLT3-ITD mutations in Indian MDS patients Method DNA and RNA were extracted from bone marrow/peripheral blood. Using RT-PCR the patients were screened for length mutations in FLT3 gene. PCR-RFLP and nested PCR-RFLP were used for the detection of point mutation in codon 12 of N-RAS and K-RAS. *Results*. A total of 53 patients (median age 39 yrs, range 9-78yrs; M: F 2:1; median TLC-3.9x10^9/L, range 0.8-116x10^9/L. Median platelet count- 87x10^9/L, range 1-349x10^9/L, Median hemoglobin -6.8 g/dl , range 2.7- 16.1 g/dL, were studied. One out of 53 patients (2%) was found positive for N-RAS and four patients were positive for K-RAS (8%) mutation. FLT3-ITD mutation was studied in 60 patients; all the patients were found negative. The mean observation of all the patients was 30 months and the median overall survival was 28 months. Nine patients died during follow up. The presence of N-RAS codon 12 mutation was associated with the poor survival. FLT3-ITD mutation was not observed in any of our cases, which is in contrast to 3% reported from the West. *Conclusions*. Thus, it appears that the RAS and FLT3 mutations are uncommon in MDS patients in India.

DETECTION AND MANAGEMENT OF IRON OVERLOAD IN MDS: A EUROPEAN SURVEY

A. Giagounidis,[1] P. Fenaux,[2] K. Heptinstall,[3] D. Jasmine,[4] S. Leto,[5] S. Ille[6]

[1]St. Johannes Hospital, DUISBURG, Germany; [2]Hôpital Avicenne/ Université Paris, PARIS, France; [3]MDS Foundation, Inc., CROSSWICKS, NJ, USA; [4]European School of Haematology, University of Paris, PARIS, France; [5]Novartis Oncology, Region Europe, ORIGGIO, Italy6GFK, NUERNBERG, Germany

More than 90% of all patients with myelodysplastic syndromes (MDS) will present with anaemia at the time of diagnosis, and 60% will experience severe anaemia at some stage during the course of their disease. Patients requiring regular red cell transfusion are at risk of developing iron overload. There is evidence to show that iron overload is often poorly detected and managed in the MDS setting and the reasons for this are not well understood. MIDIS - the MDS Iron-overload Detection Insight Survey - aims to gain insight into important barriers to optimal detection and management of iron overload in MDS. This European survey is being carried out by the MDS Foundation and the European School of Haematology in partnership with Novartis Oncology. A questionnaire was developed and reviewed by MDS experts to ensure that the questions were relevant, accurate and appropriately phrased. The English questionnaire was translated into French, German, Dutch, Spanish, Swedish and Italian. Physicians involved in the management of MDS were invited to complete either paper or on-line versions of the questionnaire. 125 responses were received from 24 countries by March 2009. Data are currently being analysed to identify key barriers and determine relationships between variables. Final results will be available in April 2009 and will be presented at the meeting. The results of the survey will be used to guide initiatives aimed at promoting optimal detection and management of iron overload in patients with MDS.

VITAMIN C SHOW ANTITUMOR ACTIVITY AGAINST MYELODYSPLASTIC SYNDROME CELLS

A. C. Gonçalves,[1] V. Alves,[2] T. Silva,[1] A.B. Sarmento-Ribeiro[2]

[1]Faculty of Medicine, University of Coimbra, COIMBRA, Portugal: [2]Faculty of Medicine and CIMAGO, University of Coimbra, COIMBRA, Portugal

Vitamin C has few pharmacological actions and cancer is one of the most common diseases for which a beneficial role of vitamin C has been claimed. However, the use of vitamin C as an alternative for cancer treatment is controversial. Vitamin C is a potent water-soluble antioxidant, but, depending on concentration, may also have pro-oxidant and even mutagenic effects in the presence of transition metals. Myelodysplastic syndrome (MDS) is a heterogeneous stem cell bone marrow disorder characterized by the underproduction of one or more blood types cells, due to hematopoiesis dysfunction. This disease affect older adults and frequently progress to acute leukemia. MDS may arise de novo or may be secondary to treatment with chemotherapy or radiation therapy for another disease. For most MDS patients, the currently available treatments do not offer a chance for a cure and the only curative therapy for MDS is bone marrow transplantation. In this context, we aimed to evaluate the therapeutic potential of vitamin C in MDS, as in monotherapy and/or as adjuvant to conventional therapies. To attempt this purpose we use a well-established MDS cell line, the F36P cells, and incubated them in absence and presence of increasing concentrations of ascorbic acid (AA) or dihydroascorbic acid (DHA) and/or cytarabine (Ara-C), added at the beginning of the incubation time or daily, during 96 h. Cell growth and viability was evaluated using Trypan blue exclusion and the efficacy of the drugs determined by the IC50 using a dose response curves based on cell viability. Cell death analysis was performed by morphological studies and by flow cytometry, using annexin-V/propidium iodine incorporation. In order to evaluate the involvement of oxidative stress and mitochondria in the cytotoxicity induced by the vitamin C, we evaluated the production of ROS and GSH and mitochondrial membrane potential by flow cytometry. ROS generation were determined by staining cells with H2DCF-DA and DHE, the content of reduced GSH was measurement by staining with mercury orange and the evaluation of mitochondrial membrane potential was determined using JC1 dye. Our results show that both reduced (AA) and oxidized (DHA) form of vitamin C induced reduction in cell viability of MDS cells with IC50 values ranging from approximately 1 mM for DHA to 2,5 mM for AA, after 48h. These compounds induced cell dead in F36P cells by apoptosis in a time-, dose- and administration-dependent manner. Vitamin C-induced apoptosis was mediated by increased ROS production, especially by increasing superoxide production (DHA, 2,2-fold; AA, 1,8-fold). We also observed an increase in mitochondrial membrane potential depolarization (DHA, 4,2-fold; AA, 6,2-fold) (reduction of mitochondrial transmembrane potential). In summary, vitamin C may be a new therapeutic option for treatment of MDS as monotherapy or as adjuvant of conventional chemotherapy.

This work was support by Center of Investigation in Environment Genetics and Oncobiology (CIMAGO) and Clinical Hematology Service of University Hospitals of Coimbra (HUC).

1367

ARA-C - ATRA - EPO COMBINATION TREATMENT IN ELDERLY PATIENTS WITH MYELODISPLASTIC SYNDROME

A.M. Gaman, G.D. Gaman

University of Medicine and Pharmacy Craiova, CRAIOVA, Romania

Myelodysplastic syndrome (MDS) represents a heterogeneous group of clonal hematopoietic disorders characterized by hypercellular marrow with dysmyelopoiesis and peripheral blood cytopenias resulting from ineffective blood cell production. *Aim of study*: evaluating the response of treatment with all-trans retinoic acid (ATRA) combined with low-dose of cytosinearabinoside (ARA-C) and erythropoietin (EPO) in elderly patients with MDS. *Design and Methods*. we studied 21 patients with MDS hospitalized in Clinic of Hematology from Craiova (Romania) between 2007-2008 devised by age, sex, classified by FAB classification. The elderly patients with MDS received ARA-C 20 mg s.c twice daily in combination with ATRA 45mg/m^2/day for ten days.Anemia was treated with transfusions when haemoglobin value was less than 8g/dl, and with EPO 30.000 UI/week, s.c, when haemoglobin value was more than 8 g/dl. Response was evaluated monthly. *Results*. Median age of the patients was 73 years, with equal frequency at men and women. FAB classification showed: RA- 4 patients, RARS - 2 patients, RAEB - 7 patients, RAEB-t - 3 patients, unclassified - 5 patients. Response was maintained in 75% of responders after 12 weeks, and in 9.7% after 24 weeks of treatment. ARA-C - ATRA - EPO combination was well tolerated, the most frequent side effect was mucosites of ATRA. EPO - induced trombosis was present in one case. *Conclusion*s. ARA-C - ATRA - EPO combination is safe and determined significant response in elderly MDS patients who cannot banefit of more aggressive therapy.

1368

EFFICACY OF HYPOMETHYLATING AGENTS ON RHEUMATOLOGIC MANIFESTATIONS IN HIGH RISK MYELODYSPLASTIC SYNDROMES: FIRST REPORT OF A POTENTIAL INDICATION FOR THIS EMERGING THERAPY

S. Reutenauer,[1] G. Moulis,[2] G. Martin-Blondel,[2] K. Delavigne,[2] G. Laurent,[3] D. Adoue,[2] O. Beyne-Rauzy[2]

[1]CHU Purpan, TOULOUSE, France; [2]Department of Internal Medicine, CHU Purpan, TOULOUSE, France; [3]Department of Hematology, CHU Purpan, TOULOUSE, France

Background. Rheumatologic manifestations (RM) are frequently associated with myelodysplastic syndromes (MDS) and can occur before, at the same time or after the diagnosis of the MDS. Moreover, therapeutic approach is difficult and requires, to being effective, either rheumatologic or haematological or both medications. The use of immunosuppressive therapy (i.e. corticosteroids) during the course of the disease is complex due to increased risk of infections and other harmful complications. *Aim*. We report two observations of RM associated with MDS treated with hypomethylating agent with a spectacular effect on both haematological and rheumatologic features. *Design and methods*. Description of the two cases and comparison with RM characteristics observed in a 500 MDS cohort referred to our hospital during a four year period (2004-2008). *Results*. Case 1: a 74 year-old man with a polymyalgia rheumatica preceding MDS progression (RAEB-t) was treated with high dose corticosteroids. Decitabine was used, RM disappeared after 2 cycles and corticosteroid therapy was discontinued at cycle 5. One year later, complete remission of both diseases was confirmed. Case 2: an 82 year-old woman had seronegative polyarthritis, fever, altered performance status and RAEB-1 with complex karyotype and high level of RBC transfusions. She received Azacitidine. After the first course, apyrexia was obtained; after 4 cycles corticosteroid therapy was definitively stopped. With a period of follow up of six months, both situations remained in

complete remission. Prevalence of RM in our cohort was 4.5%. Main features are polymyalgia rheumatica, seronegative polyarthritis, psoriatic arthritis and remitting seronegative symmetrical synovitis with pitting edema. RM outcomes were various: either favourable with immunosuppressive therapy and independent of the MDS evolution, or unfavourable and identical to MDS outcome. *Conclusions*. Therapeutic approaches of RM associated to MDS have to be discussed after the emergence of new therapies of high risk MDS. Hypomethylating agents showed for the first time a positive impact on extra-haematological features in MDS. The same question could be asked about cutaneous manifestations of these diseases.

1369

RED BLOOD CELL TRANSFUSION INDEPENDENCE FOLLOWING THE INITIATION OF IRON CHELATION THERAPY IN MYELODYSPLASTIC SYNDROME: A CASE REPORT AND REVIEW OF THE LITERATURE

H.A. Leitch,[1] J. Chase,[2] L. Vickars[1]

[1]St. Paul's Hospital, University of British Columbia, VANCOUVER, Canada; [2]University of British Columbia, VANCOUVER, Canada

Background. Iron chelation therapy (ICT) is often used to treat iron overload (IOL) in patients (pts) requiring transfusion of red blood cells (RBC) for chronic anemia. During treatment of a pt with myelodysplastic syndrome (MDS) and IOL with ICT, RBC transfusion requirement (TR) ceased and he became transfusion independent (TI). *Aims*. Here we report the clinical course of our pt and review the reported cases of TI or decreased RBC TR in pts with MDS receiving ICT. *Design and Methods*. The pt chart was reviewed. Reported cases were identified by PubMed search using the terms 'MDS' and 'ICT', and reviewing references cited in reports identified. Results: A 76 year (y) old man was referred in 2004 for management of MDS diagnosed in 1997, when investigations showed: white blood cell (WBC), $2.4x10^9$/L; neutrophils, $0.7x10^9$/L; hemoglobin (Hb), 133g/l; platelets, $108x10^9$/L. Bone marrow aspiration and biopsy showed refractory anemia (RA), karyotype +8 and -Y. IPSS was intermediate-1. Erythropoitin (epo) level was 148.3mIU/mL and stem cell assay showed no epo-independent growth. In 2004 the Hb dropped to 60g/l prompting initiation of RBC transfusion support. He required 3 RBC units every 4 weeks to maintain a Hb >90 g/L and complained of fatigue and functional limitation. Ferritin in 2004 was 1293 ug/L and 2197ug/L in 2006. He declined ICT with deferoxamine (DFO) but in 2006 agreed to receive deferasirox (DFX). Two months (mo) after starting ICT, the Hb increased spontaneously to 109 g/L and he has not required RBC transfusion since. Mean Hb over 24 months since starting ICT was 122g/l and ferritin decreased to 1356 ug/L in 2008. He reports excellent energy and an improved quality of life. There are 18 other cases reported of MDS showing improvement in Hb with ICT; 9 became TI. Characteristics of the 10 TI pts were: median age at MDS diagnosis 58 (range 18-74)y; male, n=5. MDS subtype: RA, n=5; RARS, n=2, RCMD, n=1; RAEB, n=2. IPSS (n=8): low, n=1; int-1, n=5, int-1/2, n=1; high, n=1. ICT was: DFO, n=7; DFX, n=3. Median time to RBC TI was 17.5 (1-24)mo and TI duration 13 (3-28)mo to date. *Conclusions*. 19 cases of MDS to date have been reported in whom improved Hb followed initiation of ICT; 9 had a decrease in RBC transfusion requirements, and RBC transfusion independence occurred in 9, our pt being the 10th. The remarkable course of our pt adds to evidence that ICT may be of clinical benefit for patients with MDS and IOL. The mechanism by which these effects occur remains an area for future investigation.

1370

AEE788 IS A VASCULAR ENDOTHELIAL GROWTH FACTOR RECEPTOR TYROSINE KINASE INHIBITOR WITH A POTENT IN VITRO ACTIVITY IN ACUTE MYELOID LEUKEMIA

N. Barbarroja, L.-A. Torres, R.M. Carretero, M.J. Luque, A. Rodriguez-Ariza, F. Velasco, Ch. Lopez-Pedrera

Hospital Reina Sofia, CÓRDOBA, Spain

Aberrant activation of tyrosine kinase receptors is frequently observed in Acute Myeloid Leukemia (AML). Activating mutations of the protein tyrosine kinase FLT3 can be found in approximately 30% of patients with acute myeloid leukemia, thereby representing the most frequent single genetic alteration in AML. AEE788, a novel dual receptor tyrosine kinase inhibitor of the EGF and the VEGF, is being studied in several solid tumors with remarkable success. It is not known, however, about the efficacy of this inhibitor in the treatment of AML. Therefore, we investigated the effect of AEE788 in the treatment of four human AML cell lines. Cell proliferation and apoptosis in NB4, THP-1, MOLM-13 and MV4-11 cells (the two last showing the FLT3/ITD mutation) incubated with 0.5-15 microM AEE788 were quantified though XTT colorimetric assay and combined annexin V/PI staining, respectively. Using ELISA, EMSA, inmunoprecipitation and Western blot analysis, we also studied the activation of VEGF/VEGFRs loop, FLT3 and their downstream effectors (Akt, ERK, STAT5 and NF-kB) after AEE788 treatment. Our data showed that AEE788 was a tyrosine kinase inhibitor of FLT3 and had a potent antiproliferative and proapoptotic activity in AML-derived cell lines that endogenously expressed an activated FLT3 receptor (THP-1, MOLM-13 and MV4-11). Consistently, in these cells AEE788 abrogated VEGF/VEGFRs activation and many survival signaling pathways, including Akt, ERK, STAT5 and NF-kB. Taken together, the potent activity of AEE788 might represent a promising new option of targeting FLT3 for the treatment of AML patients.

1371

AN IN VITRO COMPARISON OF AZACITIDINE AND DECITABINE ACTIVITIES IN ACUTE MYELOID LEUKEMIA

P. Hollenbach, A. Nguyen, H. Brady, C. Heise, K. MacBeth

Celgene, SAN FRANCISCO, USA

Background. Vidaza (azacitidine; 5-azacytidine; AZA) is a nucleoside analog that is approved for the treatment of adult patients with intermediate-2 and high-risk myelodysplastic syndromes (MDS), and certain types of chronic myelomonocytic leukemia and acute myeloid leukemia (AML). AZA demonstrated the ability to significantly extend overall survival in a phase III clinical trial (*Fenaux, Lancet Oncology*); however, Dacogen (decitabine; 2'-deoxy-5-azacytidine; DAC), a structurally similar nucleoside analog, failed to show a survival benefit over conventional therapy in a similar trial. Given the different outcomes of these phase III clinical studies, we undertook an *in vitro* comparison of AZA and DAC mechanisms of action in AML cell models. *Design and Methods*. Five human AML cell lines were tested for sensitivity to AZA and DAC in 72hr cell viability assays (CellTiter-Glo). Two cell lines, KG-1a and THP-1, were selected for analysis of time- (24-72hr) and dose- (0.03- 3uM) dependent effects of AZA and DAC on cell cycle and molecular endpoints, including markers of DNA incorporation, DNA damage and apoptosis. Western analyses were performed for DNA methyltransferase 1 (DNMT1), phospho (Ser139) histone-H2A.X and cleaved poly (ADP-ribose) polymerase (PARP) proteins. DNA methylation was evaluated using LINE1 pyrosequencing and the Illumina GoldenGate platform. Flow cytometry was used to measure staining with NIM-DAPI and annexin V/7-AAD. AZA and DAC-mediated changes in gene expression were also evaluated, using Affymetrix GeneChip microarrays. Results: All AML cell lines were sensitive to both AZA and DAC in viability assays. High AZA concentrations (5-30uM) reduced cell viability to less than 15%, whereas equivalent concentrations of DAC failed to reduce cell viability below 50%. In KG-1a and THP-1 cell lines, both AZA and DAC decreased the level of DNMT1 protein and reduced DNA methylation in a dose- and time-dependent manner, with DAC mediating maximal changes at lower concentrations than AZA. Both drugs increased levels of the DNA damage marker phospho (Ser139) histone-H2A.X and DNA hypomethylation. Additionally, both drugs increased levels of the apoptosis marker, cleaved PARP, and increased staining for annexin V and 7-AAD. Differences between the drugs were observed in cell cycle analyses. At drug concentrations that induced DNA damage, AZA and DAC both increased cell death, as measured by the sub-G1 cell cycle population; however G2/M growth arrest was only observed with DAC. Finally, gene expression analyses revealed similarities and differences in the signaling pathways that were modulated by AZA and DAC. *Conclusions*. In summary, similarities and differences were observed in the molecular and phenotypic responses of AML cell lines to AZA and DAC *in vitro*. Detailed analyses in two human AML cell lines showed that both AZA and DAC caused DNMT1 depletion, DNA hypomethylation, and increases in markers of DNA damage and apoptosis; however, distinct effects on cell viability, cell cycle and gene expression were observed.

1372

DNA METHYLATION STATUS OF THE CORE AND UPSTREAM REGION PROMOTER AND GENE EXPRESSION LEVELS OF C/EBPA IN BRAZILIAN ACUTE PROMYELOCYTIC LEUKEMIA PATIENTS AT DIAGNOSIS

B.A. Santana-Lemos, A. Krause, A.R. Lucena-Araújo, A.P.A.L. Lange, T.D.S. José, M.T.L. Benício, A.S.G. Lima, E.M. Rego

University of Sao Paulo, RIBEIRÃO PRETO, Brazil

Background. The transcription factor CCAAT enhancer binding protein α encoded by the C/EBPA gene is crucial for the differentiation of granulocytes. Mutations in C/EBPA gene are reported in approximating 5-14% of acute myeloid leukemia patients. Furthermore, different negative regulation mechanisms of C/EBPA have been described in myeloid leukemia. These observations imply that the suppression of C/EBPA expression may contribute in the disruption of granulocytic differentiation in myeloid leukemogenesis. Recently, aberrant DNA methylation in the upstream promoter region of C/EBPA has been reported in lung and head and neck tumors and in myeloid leukemia leading to a down regulation of the gene expression. *Aims*. Based on these findings we analyzed expression, core promoter methylation status and bisulfite sequencing of upstream promoter region of C/EBPA gene in bone marrow (BM) samples of Brazilian patients with acute promyelocytic leukemia (APL) at diagnosis. *Design and Methods*. C/EBPA gene expression of BM samples of 18 APL patients and 7 healthy controls was accessed by Real Time PCR and normalized to GAPDH expression. Methylation core promoter status of BM samples of 40 APL patients and peripheral blood (PB) samples of 9 healthy controls was evaluated in genomic DNA bisulfite treated by Methylation Specific PCR (positions of methylated and unmethylated primers: -286 to -66 and -287 to -65 bp from transcription start site (TSS), respectively). To perform the sequencing of C/EBPA upstream promoter region in 11 APL patients (BM) and 3 healthy controls (PB), DNA was treated with sodium bisulfite and amplified by PCR (primers position: -1423 to -1121 bp from TSS). The PCR products were cloned into a vector, transformed bacteria were cultured overnight and the plasmid DNA was isolated and sequenced. For this study the percent methylation at individual CpG site was counted and an average methylation level was calculated for each patient (25 CpG sites were analyzed in each clone). *Results*. BM samples of APL patients (n=18) presented significantly lower levels of C/EBPA gene expression compared to healthy controls (n=7) (0.37±0.04 vs 1.13±0.23, respectively, p=0.0001). To understand the molecular mechanism of the low C/EBPA expression we investigated the DNA methylation status in core and upstream promoter region of C/EBPA using MSP and bisulfite sequencing, respectively. Regarding to core promoter, we detected no methylation in 40 APL samples, neither in 9 samples of healthy controls. On the other hand, the analysis in the upstream promoter region showed that 10 of 11 APL samples were methylated (median, 26%; range, 0-56%), with 5 patients showing methylation levels of >30%. DNA methylation levels in samples of healthy controls were low (median, 0%; range 0-4%). *Conclusions*. Our data support recent findings showing that APL patients present the upstream promoter region of C/EBPA hypermethylated, however, we detected a higher percentage of methylation in our samples compared to published data.

PEDIATRIC ACUTE MEGAKARYOBLASTIC LEUKEMIA (M7) SHOWS MARKED MORPHOLOGICAL AND IMMUNOPHENOTYPIC HETEROGENEITY

A.M. Kamel, H.S. Moussa, Y.H. El-Nahass, N.M. El-Sharkawy, K.M. Shaaban, I. Sidhom, A. El-Haddad

NCI, Cairo University, CAIRO, Egypt

Background. M7 was first recognized, by the FAB group, as a separate subtype of AML in 1985. Since then variability in its relative frequency has been reported. A major cause of this variability could be attributed to morphological heterogeneity. Aims: In this work we aimed to investigate the true relative frequency of M7 within pediatric AML diagnosed at the NCI, Cairo University and to emphasize the morphologic heterogeneity that might lead to missing a diagnosis of M7. *Design and Methods*. In the years 2003-2008, 510 cases were diagnosed as pediatric AML (age <18 years). The diagnosis was established according to standard methods including clinical picture, complete blood count, bone marrow aspirate/biopsy, cytochemistry and immunophenotyping. *Results.* M7 was encountered in 31/510 (6.1%) of the cases. Patients included 17 male and 14 female. They showed an age range of 2 days- 14years, median 14 months. Four of them were associated with Down's syndrome including the 2 days old one. Typical M7 morphology with large blasts showing cytoplasmic blebbing was obtained in 22 cases (71.0%); one of them showed many micromegakaryocytes with platelet budding and thrombocytosis of 750x10^9/L. This latter case expressed BCR/ABL fusion gene, P210 and proved to be acute crisis on top of CML. The other 9 cases (29.0%) showed morphology suggestive of AML in eight and of ALL in one case. Bone marrow blasts was < 20% in 5 cases and the diagnosis relied upon bone marrow trephine biopsy. Cytochemistry showed a characteristic pattern of acid phosphatase in all cases with strong cytoplasmic positivity distributed in the whole cell. Diagnosis was confirmed in all cases by expression of CD61 and/or CD41. Coexpression of other myeloid antigens namely CD13 and/or CD33 was encountered in 17 cases, CD7 in five cases, CD4 in four, CD56 in three, CD2 in two and CD 34 in 12 cases. Two cases were true biphenotypic TALL/M7, one of them expressing CD56 as well. *Conclusions.* M7 shows marked morphological heterogeneity with 29.0% lacking the typical features. These cases could be missed especially if they are expressing other myeloid markers or occasionally markers of other lineages. CD61 and CD41 should be tested in all cases of AML as well as in cases lacking other lineage markers. Cytochemistry especially the characteristic pattern of acid phosphatase could be highly suggestive of M7 and direct the attention to testing for CD61 and CD 41 expression.

1374

THE EFFECTS OF CERAMIDE, GLUCOSYLCERAMIDE AND SPHINGOSINE 1 PHOSPHATE IN RESVERATROL INDUCED CELL DEATH IN HL60 ACUTE PROMYELOCYTIC LEUKEMIA CELLS

C. Zeynep,[1] G. Saydam,[2] F. Sahin,[2] Y. Baran[1]

[1]Izmir Institute of Technology, IZMIR, Turkey; [2]Ege University, Department of Hematology, Bornova, IZMIR, Turkey

Background. Resveratrol (3,5,40-trihydroxy-trans-stilbene) is naturally occuring phytoalexin, which presents in grapes, and some other natural products. It is a potential anticancer agent which inhibits tumor initiation, promotion, and progression. This inhibitory effect of resveratrol causes cell cycle arrest and trigger apoptosis in various cancer cells. Ceramides are the central compounds of sphingolipids metabolism. They are known as second messengers regulating various cellular processes including cell growth, proliferation, differentiation and apoptosis. While ceramide acts as a strong apoptotic molecule, glucosylceramide and sphingosine-1-phosphate trigger cell growth and proliferation and inhibit apoptosis. Sphingosine kinase-1 (SK-1) is an enzyme catalyzing the phosphorylation of sphingosine to sphingosine-1-phosphate while glucosylceramide synthase (GCS) that converts ceramide to glucosylceramide. Thus, inhibition of GCS by N-(2-hydroxy-1-(4-morpholinylmethyl)-2-phenylethyl)-decanamide, hydrochloride (PDMP) or SK-1 by sphingosine kinase-1 inhibitor, or exogenous application of ceramide analog (C8:ceramide) result in increased accumulation of ceramides. *Aims*. It was shown by our and some other groups that resveratrol induces apoptosis in human HL60 acute myeloid leukemia cells. However, mechanistic information about resveratrol-induced apoptosis is not clearly defined. More importantly, the involvement of ceramide metabolising genes and their end products are not investigated in acute myeloid leukemia cells. In this study, we examined the roles of ceramide, glucosylceramide and sphingosine-1-phosphate in resveratrol-induced apoptosis in HL60 cells. *Design and Methods*. HL60 cells were grown in RPMI1640 medium containing 10% FBS and 1% penicilline-streptomycine. Cytotoxicity analyses of resveratrol, C8:ceramide, PDMP and SK-1 inhibitor were conducted by XTT cell proliferation assay. Then combinations of resveratrol with C8:ceramide, PDMP or SK-1 inhibitor were applied to HL60 cells and possible synergistic analyses were examined. Results: IC50 values of resveratrol and C8:ceramide or IC90 value SK-1 inhibitor and PDMP in HL60 cells were found to be 75 μM and 45 μM or 5 μM and 11 μM, respectively. There were 3-, 5-, 15-, 29-, 45-, and 55% decreases in cell proliferation of HL60 cells in response to 1-, 5-, 10-, 20-, 50-, and 100 μM resveratrol, respectively. Combination of resveratrol with 45 μM C8:ceramide decreased proliferation of HL60 cells to 75-, 76-, 79-, 80-, and 81%, respectively, as comparing to untreated controls. 11 μM of SK-1 inhibitor in combination with 1-, 10-, 15-, 20-, and 50 μM of resveratrol resulted in 19-, 39-, 45-, 54-, and 70% decreases in cell proliferation, respectively. Although PDMP induced cell death in HL60 cells in a dose dependent manner, we did not observe any synergy with combination of resveratrol. *Conclusions*. In this study, we aimed to show cytotoxic effects of resveratrol, exogenous ceramide analog,

C8:ceramide, GCS inhibitor, PDMP, and SK-1 inhibitor. The results of this study showed that increasing intracellular concentrations of ceramides or application of exogenous ceramides significantly increased cytotoxicity in HL60 cells. More importantly, it was shown for the first time by this study that there were synergistic effects of combination of resveratrol and SK-1 inhibitor or C8:ceramide but not PDMP at IC90 value in. Taking together all these results showed that ceramides may be involved in resveratrol-induced cell death.

1375

PROGNOSTIC IMPLICATION OF NRAS GENE MUTATIONS IN EGYPTIAN ADULT ACUTE MYELOID LEUKEMIA

M. Salah-Eldin,[1] D. Elghannam,[2] N. Abo Samra,[2] D. Shahin,[2] H. Azzam,[2] E. Azmy[2]

[1]Mansoura Oncology center, MANSOURA, Egypt; [2]Faculty of Medicine, MANSOURA, Egypt

Background. The pathogenesis of acute myeloid leukemia (AML) involves the cooperation of mutations promoting proliferation/survival and those impairing differentiation. Point mutations of the N-RAS gene are the most frequent somatic mutations causing aberrant signal-transduction in acute myeloid leukemia (AML). *Aim*. To study the frequency and prognostic significance of NRAS gene mutations (NRASmut) in de novo Egyptian adult AML. *Design and Methods*. Bone marrow specimens from 150 patients with de novo acute myeloid leukemia and 10 controls were analyzed by genomic PCR-SSCP at codons 12, 13 (exon 1), and 61 (exon 2) for NRAS mutations. *Results.* NRASmut was found in 19/150 (12.7%) AML cases, represented more frequently in the FAB subtype M4eo (P = 0.028), and at codon 12, 13 (14of 19; 73.7%). Patients with NRASmut had a significant lower peripheral, marrow blasts (p=0.004, p=0.03) and non significant improved clinical outcome than patients without mutation. Complete remission rate was (63.2% vs 56.5%; p=0.46), resistant disease (15.8% vs 23.6%; p=0.51), 3 year overall survival (44% vs 42%; p=0.85) and disease free survival (42.1% vs 38.9%, p=0.74). Multivariate analysis showed that age was the strongest unfavorable factor for overall survival (relative risk [RR], 1.9; p=0.002), followed by cytogenetics (p=0.004). FAB types, NRAS mutation and leukocytosis were less important. *Conclusions*. NRAS gene mutation frequency and spectrum differ between biologically distinct subtypes of AML but do not significantly influence prognosis and clinical outcome.

1376

THE PROGNOSTIC SIGNIFICANCE OF ANTIGEN EXPRESSION BASED ON CYTOGENETICS IN 246 ADULT PATIENTS WITH ACUTE MYELOID LEUKAEMIA

A.R. Hussein,[1] S.J. Richards[2]

[1]Universiti sains Malaysia, KUBANG KERIAN, Malaysia; [2]Haematological Malignancy Diagnostics Service, St James's University, LEEDS, UK

Background. A chromosomal abnormality is one of the most important independent prognostic factors in acute myeloid leukaemia (AML). Other parameter which may influence the prognosis is the expression of certain surface markers on the blast cell populations. The aims of the study were to determine the various antigen expressions in AML and also to determine the relationship between antigen expression and cytogenetics. *Design and Methods*. Antigen expression profiles of 13 cellular antigens of the blast cell populations from samples of peripheral or bone marrow in 246 patients were determined by a 4- colour flow cytometric immunophenotyping. The determination of the antigen positivity of the blast cell populations was based on the criteria of the cut-off point of 20%. Routine conventional cytogenetic analysis from bone marrow aspirate or peripheral blood was carried out in these patients. *Results*. The expression of the 13 cellular antigens in 246 patients with descending trend of CD33$^+$, CD13$^+$, CD117$^+$, HLA-DR$^+$, MPO$^+$, CD64$^+$, CD34$^+$, CD15$^+$, CD56$^+$, CD7$^+$, CD19$^+$, CD14$^+$ and CD2$^+$ occurred in 94%, 92%, 86%, 73%, 71%, 69%, 57%, 55%, 19%, 18%, 16%, 15% and 7%, respectively. There were significant associations between CD34 expression and karyotype (p<0.05), between expression of CD34 and CD7 (p<0.05) and between expression of CD34 and CD56 (p<0.05). However, the associations between expression of CD34 and CD19 (p=0.684) and with CD2 (p=0.608) were not significant. CD19$^+$, MPO$^+$ and CD2$^+$ were predominantly occurred in 43%, 100% and 22%, respectively in patients with favourable outcome group with CD7$^+$, 0.1% the least expressed. On the other hand, CD34$^+$ was predominantly occurred in 93% of patients with adverse prognosis. Other antigens expressions were relatively variable with regard to the prognosis. Sixty eight percent of patients with t(15;17) had the composite of CD34-/CD33$^+$/CD13$^+$/HLA-DR-, whereas 46% and 92% of patients with t(8;21) had the phenotypes of CD19$^+$/CD34$^+$ and CD19$^+$/CD15$^+$, respectively. *Conclusions*. The three most common antigens expressed in the patients were CD33, CD13 and CD117. The expression of CD34 and CD7 were found mostly in the adverse prognostic group of patients. Individual expression of MPO, CD19 and CD2 were the three most common expressed antigens in the favourable group. The majority of AML patients with t(15;17) expressed the composite of CD34$^-$/CD33$^+$/CD13$^+$/HLA-DR-, whereas the composite of CD19$^+$/CD15$^+$ was found in the majority of AML patients with t(8;21).

1377

ARRAY-CGH ANALYSIS FOR THE DETECTION OF CRYPTIC GENE DOSE CHANGES IN ACUTE MYELOID LEUKEMIA WITH NORMAL KARYOTYPE

K.R. Jun, E. Seo, S. Jang, C.J. Park, H.S. Chi, J.H. Lee, J.H. Lee, K.H. Lee

University of Ulsan College of Medicine, Asan Medical Center, SEOUL, South-Korea

Background. A large proportion, 40-50%, of AML cases have either a normal karyotype or non-recurrent chromosomal alterations. Normal karyotype AML (N-AML) is a clinically and molecularly heterogeneous group with gene expression changes and frequently mutated genes, such as NPM1 and FLT3. Especially, cryptic gene dose changes could be identified by the introduction of array CGH (aCGH) technology and explain some of the heterogeneity of N-AML. *Aims*. To establish the frequency of cryptic gene dose changes and understand their potential significance in patients with N-AML. *Design and Methods*: Bone marrow samples were selected from of 8 patients with AML, diagnosed with normal karyotype by G-banding. They were negative for recurrent genetic abnormalities, AML1/ETO, BCR/ABL, MLL, CBFB and PML/RARA rearrangements, and confirmed by FISH or RT-PCR. Their percentages of blasts were average 75.5% (range 55~98%). The CGH analysis were performed with Agilent's 244K whole-genome oligonucleotide array according to the manufacturer's Oligonucleotide Array-Based CGH for Genomic DNA Analysis protocol version 2 (Agilent Technologies, CA, USA). Scanned images were quantified with Feature Extraction software version 9.0 and analyzed with DNA Analytics 4.0.76 software (Agilent Technologies). We used the signal-to-noise ratio and the normalized log2 ratio with male reference DNA (Promega, WI, USA). Results: Fourty intervals having the high frequency of gene dose changes, i.e. more than 80% (>4 among 8 patients with N-AML), were detected except sex chromosomes. These included 35 known genes and 4 unknown genes. Gains of gene were found at higher frequency than losses (36 and 3 respectively). Seventeen genes (48.6% among known genes) were previously reported as CNV region. Eight of the CNV genes (47.1%) contained partially CNV region. The most frequently amplified gene, EEF2, was founded in all patients, and the frequency of IRF2BP2, TOP2B and DDX5 were 87.5%. The CDK6, NUP98 and DNMT1 were also significantly amplified with high frequency and known as genes associated with tumor suppressor activity. *Conclusions*. Our study using aCGH revealed that gene dose changes are a common features in N-AML, although they don't have the recurrent genetic abnormalities by FISH or RT-PCR. Some genes with dose change were known as ones associated with tumor suppressors . These results should reveal the possibility that genomic patterns be used to segregate N-AML patients into groups with the potential role in the prediction of prognosis and the rational therapy. Further studies in as many patients as possible may help to confirm our findings and should be followed by functional analyses to explain the implications of our regions of interest in leukemia.

1378

PREAL-TIME QUANTITATIVE PCR DETECTION OF WILMS' TUMOR GENE EXPRESSION IN CHILDREN WITH ACUTE MYELOID LEUKEMIA AND ITS IMPACT ON PROGNOSIS

A.A.M. Adly, S .E.E. Ezz El-Arab, A.M. Abd El Wahab

Ain Shams, CAIRO, Egypt

Background. Wilms' tumor gene 1 (WT1) expression in a subpopulation of early CD34+ cells has suggested its involvement in hematopoiesis. WT1 expression at diagnosis has been associated with unfavorable prognosis in adult acute myeloid leukemia (AML). *Aims.* To assess the biological significance and the prognostic impact of WT1 mRNA expression, in pediatric patients with AML, using a real time quantitative reverse transcription polymerase chain reaction (Q-RT-PCR). *Design*. Twenty-eight newly diagnosed paediatric AML patients were included. They

were subjected to history taking and clinical examination, Laboratory investigations included ; complete blood count, bone marrow examination and chromosomal analysis for cytogenetic stratification. Quantitative assessment of WT1 transcripts by Q-RT-PCR. Patients were compared to twenty healthy subjects served as controls. All patients were followed up over the period of the study to detect the clinical course and outcome stressing on the event of remission, relapse or any adverse events. *Resuts*. WT1 expression was significantly higher in AML patients compared to controls ($p<0.001$). Although a highly significant increase in mean WT1 levels were elicited in cases with high risk cytogenetics compared to those with low and intermediate risk ($p=0.007$), yet no significant difference was detected between different FAB subtypes ($p=0.22$). Higher WT1 expression at diagnosis was detected in patients resistant to first course chemotherapy compared to those who experienced complete remission ($p=0.0003$), in dead cases compared to alive cases ($p=0.002$) as well as in patients who experienced relapse versus remitted cases till the last follow up ($p=0.01$). The 5- year survival rate was 47% and 100% among those with WT >1 and WT1 <1, respectively (log rank test gave $p=0.05$). On multivariate analysis , cytogenetic risk had the most significant effect, followed by WT1 expression on survival rate.In Kaplan-Meier curve patients with WT1 >1 experienced relapse after a shorter time than cases with WT <1 ($p=0.04$). WT1 expression had the most significant effect on relapse. *Conclusions*. Higher WT1 expression in AML patients compared to controls and was an independent prognostic factor for relapse prediction. Higher WT1 expression was associated with unfavorable prognosis with shorter survival time and shorter relapse free time. WT1 could be included as part of the initial evaluation of AML to establish more defined risk groups.

1379

ACUTE MYELOGENOUS LEUKEMIA BLASTS CONVERT INTO ADHERENT MYOFIBROBLASTS

N.S. Shirafuji, H. Tashiro, R. Shirasaki, Y. Oka, T. Sugao, N. Akiyama, K. Kawasugi

Teikyo University School of Medicine, TOKYO, Japan

Background. It is evidenced that a microenvironment has an important role for the transformation and proliferation of malignant clones from the epithelial cells, in which the cytokines produced from the normal stromal cells make the microenvironment for the chronic inflammation and create the place for the growth of malignant cells. The stroma-forming cells are reported to be derived from normal cells. Also, there has been reported that when fibrosis is observed in hematological malignancies, these fibroblast cells are originated from the normal clone. *Aims*. We show in this report that non-adherent leukemia blasts can convert into myofibroblasts to create a microenvironment for the proliferation of leukemia blasts in acute myelogenous leukemia (AML) cases. *Design and Methods*. When myeloblasts were cultured long term *in vitro*, their morphology changed into myofibroblasts, which had similar molecular characteristics to the original myeloblasts, and cytokines such as granulocyte colony-stimulating factor, interleukin-6 and vascular endothelial growth factor, were produced significantly. When cultured onto the expanded leukemia blast-derived myofibroblasts, the original leukemia blasts proliferated extensively. The generated myofibroblasts expressed CD133, which is one of the important markers for cancer stem cells. When non-adherent AML cells were transplanted into severe combined immunodeficiency (SCID) mouse, leukemia was observed after 2 months. Cells were prepared from SCID mouse, and adherent cells were analyzed, in which the leukemia-derived myofibroblasts were identified. *Conclusions.* These results indicate that leukemia blasts can create their own microenvironment for the proliferation.

AN ANTI-APOPTOTIC PATTERN CORRELATES WITH MULTIDRUG RESISTANCE IN ACUTE MYELOID LEUKEMIA PATIENTS: A FLOW CYTOMETRY AND MOLECULAR STUDY OF PRO-APOPTOTIC AND ANTI-APOPTOTIC MOLECULES AND THE MDR1 GENE

M. Guenova,[1] V. Nikolova,[1] G. Balatzenko, [1]B. Spassov,[1] S. Konstantinov[2]

[1]National Haematological Hospital, SOFIA, Bulgaria; [2]Dept. of Pharmacology, Pharmacotherapy and Toxicology, Medical University Sofia, SOFIA, Bulgaria

Background. In recent years important advances have been achieved in the treatment of patients with acute myeloid leukemia (AML). However, resistance to the cytotoxic effects of chemotherapy has remained the main obstacle in obtaining a cure. The insights into the molecular pathways leading to drug resistance might provide particularly powerful prognostic markers for response to therapy and opportunities to identify potential targets for the development of new molecularly designed therapeutic strategies Aim: Based on these premises, the aim of the present study was to evaluate the expression of such as active Caspase-3 (aC-3), Bcl-2, cleaved Poly (ADP-ribose) polymerase (cPARP), and survivin (an IAP gene family member) in comparison to MDR1 gene expression in AML patients. *Design and Methods*. Bone marrow samples were analyzed in 17 AML patients with a mean age of 53,5±16,8 years, 6 females and 11 males, diagnosed on the basis of morphology, cytochemistry, immunophenotype and complementary cytogenetic and molecular genetic studies according to WHO criteria. The intracellular levels of aC-3, Bcl-2 and cPARP were measured by CBA (Cytometric Bead Array) and flow cytometry. The expression of Survivin and MDR1 genes was defined by RT-PCR. *Results*. The analysis detected heterogeneous patterns of the studied proteins in AML pts. Activated C-3 varied from 0-215,0 U/mL (mean 34,6±52,5 U/mL); the lowest intracellular levels of bcl-2 were detected at 275,3 U/mL reaching as high as 6000 U/mL in 4/17 patients (mean 3268,4±2055,2 U/mL); cPARP varied from 0 to 97,8 U/mL (mean 24,59±29.97 U/mL). No correlation was observed among the studied variables. Molecular analysis by RT-PCR revealed heterogeneous patterns of over-expression of survivin in 9/17 pts (52,9%), while MDR1 gene was over-expressed in 10/17 pts (58,8%). Interestingly, 7 of 9 survivin(+) pts (77,8%) were also MDR1(+), while MDR1 over expression was found in only 3/8 survivin(-) pts (37,5%) though p value was estimated as n.s.. Besides, pts with high levels of survivin mRNA showed significantly lower cPARP (11.8±14.3 U/mL vs 53.9±31.9 U/ml, $p=0,005$) and a tendency towards higher aC-3 (49.3±70.0 U/l vs 18.1±9.9 U/mL, $p>0.05$). In contrast, no association was found between th e MDR1 gene status and the intracellular levels of the examined proteins. In total, no significant relationship was found with relevant clinical and laboratory, except for patients with favourable recurrent cytogenetic/molecular abnormalities none of whom showed survivin over-expression compared to 9/13 (69,2%) of the remaining patients who were positive (Fisher's Exact test, $p=0.029$). Interestingly, patients with high survivin expression had low therapeutic response rate, as complete remission was achieved in only 16,7% of the cases, and poorer clinical outcome with a mean overall survival of 138 days, compared to 75% complete responders with a mean survival of 641 days in the survivin-negative group. *Conclusions*. The detection of survivin gene expression defined a subgroup of patients of anti-apoptotic profile, characterized by significantly lower levels of apoptosis as defined by the intracellular quantity of cPARP that showed unfavorable clinical behaviour, which might be also due to higher MDR1 gene expression levels. A possible explanation of this finding may be the overlap of common signal pathways that trigger their expression. Our results support the potential relevance of apoptosis-related markers in AML for further understanding the disease; however the heterogeneity and complexity of molecular interactions warrants further prospective studies.

Studies were funded by the National Fund, Bulgarian Ministry of Education (BIn-04/06; VU-L-203/06).

1381

MMTV-HOMOLOGOUS SEQUENCES IN CHILDREN WITH ACUTE MYELOID LEUKEMIA

A. Lushnikova, V. Peredereeva, I. Sokova, A. Parokonnaya, N. Lyubchenko, B. Polevaya

N.Blokhin Cancer Research Center, MOSCOW, Russian Federation

Background. MMTV-homologous sequences were found earlier in tumor tissue and lymphoid cell DNA from sporadic breast cancer (BC) and Non-Hodgkin's lymphomas +BC patients. Two female BC patients in our cancer register had children suffered with acute myeloid leukemia (AML). Earlier retrovirus-like particles were found in peripheral blood cell of the patients with acute myeloblastic leukemia (*Seman et al., 1973*). We have analyzed children with AML treated in Moscow clinics to verify these observations. *Design and Methods*. Peripheral blood and bone marrow (BM) DNA samples were obtained from 14 patients with primary AML with t(8;21) in their karyotype and 6 ones with acute lymphoblastic leukemia (ALL). DNA samples extracted from 2-3 day cell culture or from the frozen BM cells (fixation with methanol : acetic acid, 3:1) were analyzed by PCR using specific primers for gp52-coding area of the env MMTV gene and Sag-coding area of 3'LTR MMTV. PCR products of 675 bp and 785 bp were cloned in pGEM-T vector and sequenced. RT PCR using RNA from the fresh BM cells and primers specific for the env MMTV gene was performed to evaluate MMTV-homologous sequence expression. *Results*. 6/14 (42.9%) BM DNA sam-

ples obtained from 4 girls and 2 boys of 5-15 years old, were env /LTR MMTV-positive, one boy has mother with BC and young healthy brother. While 6 ALL patients (3-11 years old) were MMTV-negative by PCR. Sequencing of the env MMTV and 3'LTR - related cloned PCR products has found 93-94% homology to the exogenous env MMTV gene (C3H strain, Mus musculus MMTV) and 92% homology to SAG protein gene of Mus musculus MMTV. The sequence transcripts were revealed by RT PCR in 4 RNA samples. ORF finder has shown 1 ORF of 567 bp long in gp 52-coding area of the env MMTV sequence and 1 ORF in Sag-coding sequence. BLAST analysis puts the sequences into tree clusters between endogenous MMTV RNA env gene/ right LTR and Mus musculus mammary gland cDNA branches. *Conclusions*. MMTV-homologous sequences were revealed in 6/14 children with AML. It indicates that MMTV-related retrovirus might involves both in human lymphomas and AML progression by infection of dendritic and/or pluripotent hemopoetic stem cells - blast progenitors.

1382

ACUTE PROMYELOCYTIC LEUKEMIA WITH T(15;17) (Q22;Q21) DEVELOPING INV(16)(P13Q22) SECONDARY AML

J. Akiki,[1] S. Jeffries,[1] Ch. Craddock,[2] M. Griffiths[1]

[1]West Midlands Regional Genetics Lab, BIRMINGHAM; [2]Haematology, University Hospitals Birmingham NHS Foundation Trust, BIRMINGHAM, UK

Background. We describe a 50 year old female with acute promyelocytic leukemia (APML) with an abnormal karyotype of 47 chromosomes with a t(15;17) translocation and trisomy 8. Molecular analysis confirmed a PML-RARA (bcr3) gene fusion and the patient was entered into the MRC AML15 trial. She achieved a good induction response (4.7 log reduction, laboratory mean=2.54), and molecular remission post second course. The molecular remission for PML-RARA has continued, monitored typically every 3 months. Three years post diagnosis she developed pancytopenia and morphological assessment indicated the presence of blasts in the marrow. Arsenic trioxide treatment was commenced due to the suspicion of APML relapse. However, she was PML-RARA negative by cytogenetics and molecular analysis, therefore a diagnosis of therapy related AML was considered rather than relapsed APML. Cytogenetic analysis identified a pericentric inversion of chromosome 16, and a CBFB-MYH11 (type D) gene rearrangement was confirmed by molecular analysis. The patient achieved a dramatic response to FLAG with a complete molecular response (>4.7 log reduction) post course 1 and has since remained in molecular remission for both PML-RARA and CBFB-MYH11 transcripts. *Aims*. To carry out retrospective RQ-PCR analysis of the CBFB-MYH11 gene fusion and gain a unique insight into the kinetics of emergence of AML. *Design and Methods*. Serial blood and/or marrow RNA, banked as a consequence of the PML-RARA monitoring, was retrospectively analysed by RQ-PCR for CBFB-MYH11 transcripts. Results: CBFB-MYH11 transcripts were first identified 9 months post diagnosis of APML, 27 months pre secondary leukemia. Transcripts were detectable only at relatively low levels for 18 months before rapidly expanding. It is presumed that the pre-expansion plateau represented a clone with just a CBFB-MYH11 gene fusion, from which emerged a clone with a second mutation, that proliferated rapidly resulting in emergence of the secondary leukemia. *Summary*. The bi-phasic kinetics of emergence of the CBFB-MYH11 leukemia supports a two mutation model of AML. The appearance of CBFB-MYH11 transcripts after only 9 months, and the subsequent kinetics of the CBFB-MYH11 clone, suggests this clone may already have been present at diagnosis of APML, although it remains possible that it was induced early in the treatment of the original leukaemia. The kinetics of the clone once rapid expansion was observed suggests the second mutation, driving the more proliferative phase, may have occurred during subsequent courses of treatment for APML.

CYTOKINE RECEPTORS EXPRESSION ON ACUTE MYELOID LEUKEMIA CELLS

A. Dascalescu,[1] M. Zlei,[1] G. Grigore,[1] C. Danaila,[1] C. Aanei,[1] C. Burcoveanu,[1] E. Carasevici,[2] E. Hanganu-Turtureanu[2]

[1]St. Spiridon University Hospital, IASI, Romania; [2]Gr. T." Popa Medicine and Pharmacy University, IASI, Romania

Background. Interleukin (IL)-3, IL-7, CCL5 and CXCL12 have been previously reported to induce growth, development, recruitment, and tissue localization of several hematopoietic malignancies, including acute myeloid leukemia (AML). *Aims*. The expression level of four cytokine receptors on AML cells was analyzed in relation to their FAB subtype, differentiation status, aberrant phenotype, and response to induction therapy; as knowledge of their receptor profile on AML cells may be valuable for the prognosis, pathobiology, subclasification and therapeutic decisions during the medical management of AML patients. *Design and Methods*. Mean Fluorescence Intensity Ratio (MFIR) of CD123, CD127, CXCR4 and CCR5 on CD34+ or CD117+ cells from EDTA/bone marrow samples of 21 newly diagnosed AML patients (M0=4, M1=2, M2=1, M4/5=14) and 3 healthy donors were detected by flow cytometry. Six-color combinations of markers were used to optimally gate the cell population of interest and to establish the differentiation status according to CD133 and CD34 level. Marker combinations used and the gating strategy are detailed in Figure 1. The cut-off value for positive MFIR was 2. *Results*. In 8 out of the 21 AML cases, leukemic cells expressed intermediate levels of CD127 (MFIR=2-5). Seven of them where AML M0-2; 5 expressed intermediate levels of CD133, high levels of CD34, and at least one phenotypic aberrancy. No CD127 expression was detected in the control group. Although CD127 has been previously reported to be restricted to lymphoid lineage, the role of IL-7 as a growth factor for certain hematological malignancies and breast cancer has been established and attributed to activation of STAT-5 and up-regulation of the anti-apoptotic molecule Bcl-2. 15/21 AML patients showed intermediate (n=6) and high (n=9, MFIR>5) CXCR4 expression. CXCR4 levels significantly correlated with the M4/M5 FAB subtype (p=0,04) but there was no correlation with the differentiation status or the presence of phenotypic aberrancies. One intermediate expression was determined within the control group. 13/21 AML patients expressed intermediate (n=10) and high (n=3) CD123 levels. Interestingly, two of the three high expressers were of AML M4/5 subtype and expressed high CD133 and CD34 levels and at least one phenotypic aberrancy. CD123 expression was found in 7 cases with one or more phenotypic aberrancy. We found significant correlation between CD123 expression and the illicit presence of lymphoid markers on AML cells (p=0,001). In line with previously published data, no CD123 expression was detected within the control group. CD123 expression was further correlated with poor response to induction therapy in our group (p=0,07). 11/21 AML patients expressed intermediate (n=7) and high (n=4) CCR5 levels. The expression level of CCR5 seemed to be inversely related to the differentiation status of leukemic clone. *Conclusions*. Cytokine receptor analysis in AML may provide important information of diagnostic relevance, such as the degree of differentiation and phenotype aberrancy of the malignant clone. Measuring their expression levels will also contribute to the detection of minimal residual disease and become prognostic candidates when larger groups of patients involved.

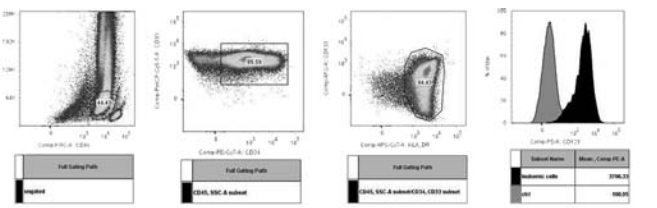

Fig. 1: Measurement of CD123 expression level on one AML representative case (M4 FAB subtype) by flow cytometry. The combination of markers used for gating was CD45-FITC/ CD123 PE/ CD33PC5.5/ CD34PC7/ CD133APC/ HLA DR APC/C7 for the sample tube and CD45-FITC/ IgG1- PE/ CD33PC5.5/ CD34PC7/ CD133APC/ HLA DR APCC7 for the control tube. MFIR was calculated by dividing MFI values of the samples and isotype control, respectively. Images were generated using the Flow Jo, Tree Star, Inc analysis software; data acquisition was performed with a three laser BD FACSCanto II instrument.

1384

IMMUNOLOGICAL AND PROTEOMIC ANALYSIS OF FRESH AND CULTURED ACUTE MYELOID LEUKEMIA CELLS

P. Stockbauer

IHBT, PRAGUE, Czech Republic

Background. Acute myeloid leukemia (AML) is a disease caused by dysregulation of proliferation, differentiation and death of immature myeloid leukemia stem cells. *Aims*. To assess the role of leukemic stem cells in the acute myeloid leukemia we attempted to isolate these cells and performed their immunological and proteomic analysis. *Design and Methods*. Leukemic cells were separated from bone marrow and peripheral blood samples of untreated first diagnosed patients with AML. Primary cultures of leukemic cells were established in the presence and absence of immunologic (antibody to CD34 molecule) or epigenetic

modulators of the gene expression - valproic acid and SAHA. Fresh and cultured cells were analysed for cell cycle, differentiation, apoptosis and senescence. Proteomic analysis was also performed by two dimensional electrophoresis and electrofocusation in polyacrylamide gels. The results were compared with myeloid leukemia cell lines MOLM-7, MOLM-9, JURL-MK1 and HL-60. *Results*. Leukemic cells of 25 consent patients with acute myeloid leukemia classified as M1 - M5 were separated by density gradient centrifugation and cultured for a period of 3-7 days in the presence of valproic acid, SAHA or antibody to the CD34 molecule. The proteomic analysis showed at least 1000 protein spots. We were however not able to identify the minor proteins responsible for dysregulation as products of oncogenes, transcription factors or tyrosine kinases in the resolution. Both compounds - valproic acid and SAHA inhibited the cell cycle, induced the programmed cell death and/or senescence both in primary cultures of patients cells and cell lines, however in different concentration ranges. Monoclonal antibody to the stem cell molecule CD34 inhibited the proliferation of CD34 positive myeloid cell lines but not CD34 negative HL-60 cells.*Conclusions*. Primary cultures of acute myeloid leukemia cells in the presence of fetal bovine serum result in the slow inhibition of proliferation, spontaneous differentiation and prolonged slow cells death or senescence. This process is associated with morphological, immunological and proteomic changes. All compounds used in the study inhibited cellular proliferation and induced cell death, however no direct correlation was found with disease stage or prognosis.

Supported by grant MZO 0002373601 of the Internal Grant Agency of the Ministry of Health of the Czech Republic.

TREATMENT OF LEUKEMIC CELLS WITH HSP90 INHIBITOR 17-AAG INDUCES G2/M ARREST AND APOPTOSIS

J.M. Napper, V.E. Sollars

Marshall University School of Medicine, Huntington, WV, HUNTINGTON, USA

Background. Acute myelogenous leukemia (AML) is among the deadliest of the lymphatic and bone marrow cancers. Patients diagnosed with AML have a five year survival rate of 21.3%. AML is characterized by an accumulation of undifferentiated and functionless myeloid precursors in the bone marrow and blood. Heat shock protein 90 (Hsp90) is a molecular chaperone that is highly conserved among all living organisms. It serves a critical function in many different signaling cascades by ensuring proper protein structure, activity, proteolytic turnover, and localization. Hsp90 constitutes 1-2% of total cellular protein. In spite of this, it is often upregulated in cancer. It has been proposed that Hsp90 serves in a buffering capacity to stabilize mutated proteins and may help the cancer cells survive in the harsh environment of the host. Because Hsp90 affects many different signaling mechanisms, intense research has been undertaken in treating cancer with Hsp90 inhibitors. *Aims*. 17-AAG, an analog of geldanamycin, is a potent Hsp90 inhibitor. It is currently undergoing clinical trials for the treatment of various blood malignancies. We sought to determine the effects of Hsp90 inhibition in AML cell lines. *Design and Methods*. The AML cell lines KG-1a and HL-60 were treated with varying concentrations of 17-AAG in cell viability assays. For all other assays, clinically relevant concentrations, 3 μM or less, were used. Cell viability assays were performed by counting live cells via dye exclusion. Proliferation and differentiation effects of treatment were measured by assessing the expression of cell surface markers CD71 and CD11b, respectively. Annexin V labeling was used to measure apoptosis with treatment. Cell cycle analysis was performed by cell fixation in ethanol, followed by propidium iodide staining. Marker experiments and cell cycle analysis were analyzed using flow cytometry. *Results.* After 48 hours of treatment, the cells remained static, which prompted further differentiation and proliferation studies. CD11b expression did not increase which indicates differentiation was not induced. CD71, a transferrin receptor, was markedly decreased with treatment showing that the cells were becoming less proliferative. Cell cycle analysis has revealed that the cells undergo G2/M arrest within 48 hours of treatment. Annexin V labeling increased on the cells over time demonstrating long term treatment was inducing apoptosis. *Summary*. These results suggest that inhibition of Hsp90 causes these leukemic cells to cease proliferating which is due to an arrest in G2/M phase of the cell cycle. Furthermore, extending treatment of the cells eventually leads to induction of apoptosis. Further studies are ongoing to determine the mechanism behind these observations.

INTERNAL TANDEM DUPLICATION OF FLT3 GENE IN EGYPTIAN ADULT ACUTE MYELOID AND ACUTE LYMPHOBLASTIC LEUKEMIA

N. El Sharkawy, T. Abdel Hamid

National Cancer Institute, Cairo University, CAIRO, Egypt

Background. FLT3 plays an important role in stem cell proliferation, differentiation, and survival. The most common mutation in the FLT3 gene is an internal tandem duplication (FLT3/ITD). Several studies have demonstrated that FLT3 mutations are a strong detrimental prognostic factor in AML and ALL. Aim: Our study was designed to evaluate the effect of FLT3/ITD status in AML and ALL on response to treatment and overall survival. *Design and Methods*. This study was carried out on 110 newly diagnosed adult acute leukemia cases including 61 AML and 49 ALL. Bone marrow or peripheral blood cells were collected from patients at diagnosis. All samples were analyzed for mutation in exon 11 of the FLT3 gene using genomic PCR method. ALL cases were treated according to our risk adapted chemotherapy protocol while mature B phenotype cases were excluded from the study. AML cases received induction with 3&7 regimens. Evaluation of response was carried out at the end of induction regimen. *Results*. ITD appears as an extra PCR band (mutant band) in addition to the 133-bp wild band was found in 21.3% (13 / 61) of AML cases. The highest frequency of FLT3/ITD was associated with M3 (40%) followed by M5 (37.5%) and M4 (33.3%) FAB subtypes, less frequent in M2 (13.6%), M1 (13.3%) and none in M0 and M7. In ALL cases FLT3/ITD was detected in (5/44) 10.2%. The highest frequency was associated with precursor B phenotype (11.7%) and less in T- ALL patients (7.1%). No association was detected between the status of FLT3/ITD on one side and age, gender, high leucocytic count, BM blasts, DNA index or CD34 expression on the other side in either AML and ALL. We couldn't find statistically significant difference in response to treatment between FLT3/ITD positive and negative AML and ALL cases. *Conclusions*.FLT3/ITD + in our AML patients was 21.3% as that reported in the literature, however the in adult ALL it was much higher than that reported in literature. Further study on a large scale is recommended to identify the prognostic impact of FLT3/ITD in adult ALL.

1387

MOLECULAR CHARACTERIZATION OF RARE TRANSLOCATION T(11;12)(P15;Q13) GENERATING NUP98-HOXC13 FUSION IN THE CASE OF *DE NOVO* FLT3-ITD POSITIVE ACUTE MYELOID LEUKEMIA

S. Pavlovic,[1] N. Tosic,[1] M. Stojiljkovic,[1] N. Colovic,[2] M. Colovic[2]

[1]*Institute of Molecular Genetics and Genetic Engineering, BELGRADE, Serbia;* [2]*Insitute of Hematology, Clinical Center Serbia, BELGRADE, Serbia*

Leukemia is frequently associated with recurrent chromosome translocations. One of the most promiscuous fusion partner gene involved in chromosomal translocations is NUP98 gene at 11p15 that encodes a component of nuclear pore complex. The most frequently observed fusion partners of NUP98 are the homeobox family of transcriptional factors (HOX), required for regulation of embryonic morphological development. This is the first case of de novo AML (Acute Myeloid Leukemia) patient with simultaneous presence of the t(11;12)(p15;q13) and FLT3-ITD (fms-like tyrosine kinase 3-internal tandem duplication) mutation. Molecular characterization of the t(11;12)(p15;q13) translocation was done using semi-nested RT-PCR analysis and direct sequencing. For detection of FLT3-ITD mutation we used PCR method. The position and size of ITD was determined using sequencing analysis. Molecular analysis showed that the exon 16 of NUP98 was fused in frame with exon 2 of HOXC13, giving raise to the functional fusion protein NUP98-HOXC13, that acts as aberrant transcriptional factor. Sequencing analysis of the FLT3-ITD revealed in-frame duplication of 82 bp in exon 14, involving juxta-membrane domain of FLT3, giving raise to the functional protein that provokes uncontrolled proliferation of the cells bearing this mutation. Our results represent another contribution to the theory of cooperating mutations necessary to cause acute leukemia (two hit hypothesis). Namely, NUP98-HOXC13 fusion and FLT3-ITD mutation act in collaboration in the process of leukemogenesis, in the way that FLT3-ITD provides proliferative advantage to myeloid progenitors whose differentiation is impaired by NUP98-HOXC13 fusion.

PROGNOSTIC SIGNIFICANCE OF FLT3 MUTATIONS IN NORMAL KARYOTYPE ACUTE MYELOID LEUKEMIA PATIENTS IN INDIA

B. Kumar,[1] K. Syed Hasan,[2] V. Sharma,[1] B. Asthana,[1] R. Kumar,[1] H. Anand,[1] M. Mahapatra,[1] R. Saxena[1]

[1]All India Institute of Medical Sciences, NEW DELHI, India; [2]University of Tor Vergata, ROME, Italy

Background. Acute myeloid leukemia patients without clonal chromosome aberrations at diagnosis constitute the largest cytogenetic group of AML, approximately 45%, and are classified in the intermediate prognostic category. It is important to identify prognostic markers that predict patients' outcome more precisely, thereby allowing development of molecular risk-adapted treatment strategies that may improve the clinical outcome. FLT3, a member of receptor tyrosine kinases 3 family is involved in differentiation and proliferation of hematopoietic stem cells. Flt3 mutations represent one of the most frequent molecular aberrations in acute myeloid leukaemia(20-35%). Flt3-ITD mutations in the juxtamembrane domain leads to ligand independent proliferation and thus cell survival, the other point mutation(5-10% frequency) present in kinase domain 2 of the receptor. Many AML patients with Flt3 mutations lack chromosomal aberrations (up to55%). Recent studies have shown that patients with FLT3 mutation show poor prognosis. Aim:- Aim of the study was to find out prognostic significance of FLT3 mutations in normal karyotype AML patients. *Design and Methods*. 104 normal karyotype AML patients were selected for the study, their diagnosis was based FAB classification. The distribution of AML patients in to subtypes was as follows:M0-7, M1-9, M2-33, M4-29, M5-18, and M6-7 and M7-2. Bone marrow samples were collected at presentation, after induction, after consolidation, at relapse and patients were followed up to 2 years. RT-PCR was performed for FLT3-ITD and FLT3-TKD(D835Y) mutations. Sequencing was done find out ITD length and domain mutation confirmation. The statistical analysis was performed by Chi-square and Mann-Whitney tests. *Results*. A total of 34 patients showed FLT3 mutations (28 with ITD and 6 with D835Y). The ITD length ranged from 20 bass to 220 bases. Patients with FLT3-ITD positive had a significantly higher median white cell count ($38.6x10^9$/L) than those with wild type ($5.4x10^9$/L (p=0.001). Complete remission was achieved by 81% of patients without a FLT3-ITD and by 44% of patients with the mutation. CR rates were further lower in patients whose ITD size was larger than 50 bases. More patients with FLT3 mutations experienced induction death (57%) than those without these mutations (19% (p=0.01). Six relapsed cases had FLT3-ITD mutation were positive for ITD and this mutation could have been responsible for lower EFS in cases of ITD positive cases compared to wild type FLT3 patients. No significant difference was observed in terms of overall survival between the two groups. No correlation was found in terms of WBC at presentation, CR rates, EFS and OS amongst wild type and mutated D835Y FLT3. *Conclusions*. Thus it can be assumed that the presence of FLT3/ITD in AML patients confers a worse prognosis in terms of CR rate, induction failure and EFS. Therefore prognostic markers like FLT3 mutation apart from cytogenetics may be useful in identifying high-risk patients for closer monitoring and possibly more prolonged and intensive therapy. Further FLT3 can also be used as a marker for minimal residual disease detection in cytogenetically normal patients.

1389

THE ROLE OF CDK1, CDK2 AND CYCLIN A1 IN ALL-TRANS-RETINOIC ACID MEDIATED DIFFERENTIATION OF U-937 LEUKEMIC CELLS

Å.E. Ehlén

Lund University, MALMÖ, Sweden

All-trans-retinoic acid (ATRA) is a candidate for cancer therapy, in particular for the treatment of leukemia. The ATRA-induced cellular effect is complex, and probably involves multiple mechanisms. The aim of our present study is to investigate whether the key cell cycle regulatory proteins cyclin A1, CDK1 and CDK2 may contribute to ATRA-induced differentiation and cell cycle arrest in leukemic cells. In the present study, we treated U-937 cells with ATRA for 24, 48 and 72 hours. Terminal differentiation induced by ATRA was characterized by morphology changes and expression levels of the surface markers CD11b and CD11c measured by flow cytometry analysis. ATRA-induced differentiation correlated well with an accumulation of cells in G0/G1 phase. Real time PCR studies revealed that ATRA treatment significantly increases the mRNA level of the retinoic acid receptor β and decreases the levels of the retinoic acid receptor γ, the retinoic X receptor γ and cyclin A1. Further, ATRA-induced differentiation appears to be related to downregulation of protein expression of CDK1 and CDK2, the major kinase partners associated with cyclin A1. The reduction of protein expression was observed predominantly in the nuclear compartment. To further investigate the role of cyclin A1, CDK1 or CDK2 in ATRA-mediated cell cycle arrest and differentiation, we depleted these proteins in U-937 cells via siRNA-mediated knockdown. We are currently characterizing the effect of single knockdown or double knockdown of these proteins on differentiation, cell cycle progression and the cellular responses to ATRA-induced differentiation.

1390

PRIMARY HUMAN ACUTE MYELOGENOUS LEUKEMIA CELLS SHOW CONSTITUTIVE RELEASE OF SEVERAL MATRIX METALLOPROTEASES AND THEIR INHIBITORS

H. Reikvam,[1] K.J. Hatfield,[2] A.M. Olsnes,[2] A.M. Øyan,[3] K.H. Kalland,[3] Ø. Bruserud[1]

[1]Institute of Internal Medicine, University of Bergen, BERGEN, Norway; [2]Institute of Internal Medicine, BERGEN, Norway; [3]The Gade Institute, BERGEN, Norway

Background. Angiogenesis seems to be important both for leukemogenesis and chemosensitivity in human acute myelogenous leukemia. Angiogenesis is regulated by the balance between pro- and antiangiogenic cytokines, but matrix metalloproteases and their natural inhibitors; tissue inhibitors of metalloproteases, may also be important. Aims:To investigate the constitutive release of matrix metalloproteases and tissue inhibitors of metallopoteases for a large group of consecutive acute myelogenous leukemia patients. *Design and Methods*, Primary human acute myelogenous leukemia cells were cultured *in vitro* either alone or together with microvascular endothelial cells and levels of matrix metalloproteases and tissue inhibitors of metalloproteases were determined in culture supernatants. *Results*. Primary human acute myelogenous leukemia cells showed constitutive release of matrix metalloproteases. For all patients detectable matrix metalloprotease 10 release was observed, and most patients showed detectable release of at least one addition matrix metalloprotease, usually matrix metalloprotease 9. Matrix metalloprotease release was increased by Protein kinase C agonists. Endothelial cells showed high release of matrix metalloproteases 10, and these levels were further increased by the presence of acute myelogenous leukemia cells during culture. *Conclusions*. Matrix metalloproteases may be important for leukemogenesis and chemosensitivity in human acute myelogenous leukemia.

1391

PROGNOSTIC IMPLICATIONS OF GENE ABNORMALITIES IN ACUTE MYELOID LEUKAEMIA WITH NORMAL KARYOTYPE (NK-AML): A SINGLE-CENTRE EXPERIENCE

P. Silva-Coelho, I. Carvalhais, R. Pinto, J. Martins, P. Guimarães, T. Melo, R. Bergantim, F. Trigo, J.E. Guimarães

Hospital de São João, PORTO, Portugal

Research into genotypic leukaemia-specific alterations in the broad group of NK-AML has contributed to unravel this highly heterogeneous group of entities. Gene mutations, gene expression abnormalities and other molecular alterations affect critical functions in AML cells, and may exert profound effects on therapeutic response and outcome of disease. To ascertain the association between the presence or absence of a set of molecular markers and clinicopathological features and treatment outcome in NK-AML, diagnostic samples derived from 28 patients with NK-AML, consecutively diagnosed between December 2006 and January 2008, were analysed for FLT3-ITD, FLT3-TKD (D385), NPM1, CEBPA and MLL-PTD mutations. Median patient age at diagnosis was 66 years (15-79) and fifty-four percent were female. Thirty-nine percent had WBC>30x10^9/l at presentation. Twenty-five percent (7/28) were deemed as not meeting criteria to undergo intensive chemotherapy. Mutations prevalence was as follows: 50% NPM1+ (14/28 cases); 37% FLT3+ (10/27, all ITD, ranging from 1 to 10 duplications); 11% MLL-PTD+ (3/28); 11% CEBPA+ (3/27). Concurrency of genetic abnormalities was observed in 29% (8/28) of cases; one FLT3-ITD+/MLL-PTD+ case was observed; no cases of concurrency between NPM1+ and CEBPA+ and/or MLL-PTD+ were observed. Of NPM1+ cases, 54% (7/13) were also FLT3-ITD+ (p=0.089). NPM1+ cases were predominantly female (64%, p=0.256) and displayed higher peripheral blood WBC (57% >30x10^9/l, p=0.060). The overall incidence of NPM1+ was higher in FAB-M4 and M5, as compared with other subtypes (75% vs. 33%,

p=0.085); no association was detected between FAB subtype and FLT3 mutational status. Regarding immunophenotype, we observed a significant association between CD34+ and NPM1- (92%, 12/13, p=0.001) and that NPM1+ cases more frequently expressed monocytic lineage markers, such as CD11b (62%, 8/13, p=0.055). FLT3-ITD- cases displayed lower WBC counts (71% <=30x10^9/L, p=0.285). No other associations were apparent between clinico-analytical variables and mutational status. The observed induction death rate was 14% (3/21); CR rate was 83% (15/18) without significant influence of mutational status, although a higher frequency of CR achievement was observed in NPM1+ patients (89% vs. 78%, p=0.500). With a median follow-up of 8 months and a median DFS of 10 months, the observed cumulative OS and DFS were, respectively, 50% at 37 months and 59% at 36 months. By univariate analysis, higher but not significant OS and DFS were observed in NPM1+ (64% vs. 29% at 37 months, p=0.415 and 64% vs. 50% at 34 months, p=0.445, respectively); cumulative OS (p=0.891) and DFS (p=0.517) were, respectively, 53% at 35 months and 67% at 34 months for FLT3-ITD+ and 52% at 37 months and 55% at 36 months for FLT3-ITD- patients. In NPM1+ patients, concurrent FLT3-ITD+ did not appear to result in worse cumulative OS (71% vs. 66% at 35 months, p=0.245). MLL-PTD and CEBPA were excluded from follow-up analysis due to limited number of patients. In this single-centre sequential cohort of NK-AML patients treated with intensive chemotherapy, we observed a higher although not significant frequency of CR achievement and higher cumulative OS and DFS in NPM1+ cases. Documented CR, cumulative OS and DFS were similar for both FLT3-ITD- and FLT3-ITD+ patients.

1392

SELENIUM AND GLUTATHIONE PEROXIDASE STATUS IN ADULT EGYPTIAN PATIENTS WITH ACUTE MYELOID LEUKEMIA

I. Asfour, N.M. El-Kholy, A.S. Ayoub, M.B. Ahmed, A. Bakarman

Ain Shams University, CAIRO, Egypt, CAIRO, Egypt

This study was undertaken to evaluate selenium and glutathione peroxidase status in patients with newly diagnosed acute myeloid leukemia (AML) before and after induction therapy. Twenty five patients with newly diagnosed AML and fifteen healthy age and sex matched control subjects were included in this study. Serum selenium (Se) level by the graphite furnace atomic absorption spectrometric (GFAAS) technique and glutathione peroxidase (GPX) activity by an adaptation of Beutler method was performed for the patients before and after receiving the induction therapy. Serum selenium level was significantly lower in patients with AML versus control subjects (63.1µg/L ±8.8 vs. 77µg/l ±8.8 before therapy p<0.01 and 69 µg/l±6.8 vs. 77µg/L ±8.8 after therapy with a p<0.01).GPX activity was significantly lower in patients with AML versus control subjects (1.6 µ/gm protein ±0.4 vs.3.4 µ/gm protein ±0.7 pretreatment p<0.01and 1.9 µ/gm±0.6 vs.3.4 µ/gm protein ±0.7 post induction treatment with a p<0.01).serum selenium level and GPX activity significantly increased in AML patients after treatment. Patients who accomplished complete remission after induction harbored significantly higher selenium levels than resistant patients before and after treatment. There was no significant correlation between serum selenium level and GPX activity. Decreased selenium level and reduced GPX activity in AML patients support the association of carcinogenesis and subnormal selenium states.

1393

A SIMPLE PROGNOSTIC SCORING SYSTEM FOR NEWLY DIAGNOSED ACUTE LEUKAEMIA PATIENTS WITH NORMAL KARYOTYPE: A RETROSPECTIVE ANALYSIS ON 173 CASES

M. Malagola,[1] C. Skert,[2] D. Damiani,[2] A. Candoni,[2] M. Tiribelli,[2] G. Martinelli,[3] P.P. Piccaluga,[3] S. Paolini,[3] F. Lauria,[2] M. Bocchia,[2] M. Gobbi,[2] M. Clavio,[2] M. Miglino2, I. Pierri,[2] A. Zaccaria,[4] E. Zuffa,[4] P. Mazza,[4] G. Priccolo,[4] L. Gugliotta,[4] A. Bonini,[4] G. Visani,[4] A. Isidori,[4] C. Bergonzi,[2]A.M. Roccaro,[5] A. Peli,[2] C. Filì,[2] R. [1]Chair of Haematology, Brescia, BRESCIA, Italy; [2]Chair of Haematology, BRESCIA, Italy; [3]Institute of Haematology Seràgnoli, BOLOGNA, Italy; [4]Division of Haematology, RAVENNA, Italy; [5]Dana Farber Cancer Institute, BOSTON, USA

Background. Cytogenetics is the most important prognostic factor for acute myeloid leukaemia (AML), enabling to categorize AML patients in three risk categories: favourable [t(15;17), t(8;21), inv(16)], intermediate [normal karyotype (NK), +8, abnormalities not included in other categories] and unfavourable [abnormalities of chromosome 3, -7/-7q, -5/-5q, abnormalities 11q23, complex karyotype]. The post-induction therapeutic strategy, including or not allogeneic-SCT, is not well established in patients with NK, who account for at least the 40 - 50% of cases and show an extremely variable long term survival, ranging from 20 to 70%. *Aims*. The aim of the study is to provide a simple prognostic scoring system, to better define the disease-risk in AML patients with NK and to optimally address the issue of post-induction therapy. *Design and Methods*. We retrospectively analyzed 173 AML patients with NK (NK-AML) consecutively treated from 1990 to 2005. Induction regimen was FLAI in 110 patients (64%) and ICE/DCE in 63 cases. After the first consolidation, patients were addressed to intensification therapy including allogeneic-SCT if aged less then 45 yrs, with a HLA compatible donor and at least one other high risk feature (WBC over 30x10^9/L, secondary AML, non response to the first induction therapy, multidrug-resistance Pgp over-expression and presence of Flt3-ITD). An allogeneic-SCT was performed in 59/173 cases (34%). By univariate analysis age at least 50 yrs, female sex, FAB subtype, Pgp positive phenotype, presence of Flt3-ITD, WBC count over 19x10^9/L significantly affected the CR rate. Moreover, age at least 50 yrs, FAB subtype, WBC count over 19 x 10^9/L and no response to the first induction cycle significantly affected disease free survival (DFS) and overall survival (OS). By multivariate analysis, age at least 50 yrs and female sex significantly affected the CR rate, whereas age at least 50 yrs, WBC count aver 19 x 10^9/L and no response to induction significantly affected the DFS and OS. Univariate and multivariate analysis were conducted using the logistic regression model for CR rates and the Cox proportional hazard model for survival. A numerical score was derived from the regression coefficients of each independent prognostic variable and was 1 for WBC count over 19 x 10^9/L and age at least 50 yrs and 2 for no response to first induction regime. The prognostic score for each patient was then calculated by totalling up the score of each independent variable. *Results*. The allotransplanted patients were censored at the time of SCT. For what concerns DFS, patients could be stratified in low (score=0), intermediate (score = 1) and high risk group (score=2), with a median DFS of 28, 10 and 5 months, respectively (p=0.0003). For what concerns OS, patients could be stratified in low (score=0), intermediate (score = 1 - 2) and high risk group (score = 3) with a median OS of 120, 17 and 5 monhts, respectively (p=0.0001). *Conclusions.* these preliminary retrospective data suggest that common available clinical variables may still represent a valid approach for determining a prognostic stratification for NK-AML patients.

This work was supported in part by FONDI 60% 2006 and 2007.

A PHASE II STUDY WITH CP-4055 AS SECOND SALVAGE THERAPY IN PATIENTS WITH AML

S. O'Brien,[1] D. Rizzieri,[2] N. Vey,[3] F. Ravandi,[1] U. Krug,[4] M. Sekkeres,[5] M. Dennis,[6] A. Venditti,[7] K. Seiter,[8] T.F. Jacobsen,[9] K. Staudacher,[9] B.I. Nilsson,[9] F.J. Giles[10]

[1]University of Texas, M. D. Anderson Cancer Center, HOUSTON, USA; [2]Duke University Medical Center, DURHAM, USA; [3]Institut Paoli-Calmettes, MARSEILLE, France[4]University Hospital Münster, MÜNSTER, Germany; [5]Cleveland Clinic, CLEVELAND, OHIO, USA; [6]Christie Hospital, MANCHESTER, UK; [7]University Hospital Tor Vergata, ROME, Italy; [8]New York Medical Centre, VALHALLA, NEW YORK, USA; [9]Clavis Pharma ASA, OSLO, Norway; [10]CTRC at the University of Texas Health Science Center, SAN ANTONIO, TEXAS, USA

Background. CP-4055 (elacytarabine [pINN]) is a novel cytotoxic nucleoside analogue. CP-4055 has similar mechanism of action to cytarabine, but unlike cytarabine, it is independent of nucleoside transporters for cellular uptake. *Aims*. To assess efficacy and safety of CP-4055 when given as second salvage therapy to patients (pts) with acute myeloid leukemia (AML). *Design and Methods*. CP-4055 2000 mg/m^2/d was administered over 24h (CIV) in a d1-5 q3w schedule to adult pts who had received at least 2 previous chemotherapy regimens and who had refractory/relapsed AML [CR after first salvage therapy lasting less than 6 months] and from whom informed consent was obtained. After every 20-pt cohort, an Independent Data Monitoring Committee (IDMC) evaluated the results for futility and safety for recommendation of study continuation. *Results*. The IDMC recommended continuation of enrolment based on the first 20-pt cohort evaluation. Forty pts [28 male and 12 female, median age 58 yrs (range 26-82)] have been treated at 8 centres. The majority of the pts had previous ara-C based therapy, 12 pts had not obtained CR1 or CR2. Only 1 pt did not receive CP-4055 d1-5

dosing. The most frequently reported related adverse events (AEs) >= grade 3 (CTCAE v3.0) were thrombocytopenia, leukopenia, febrile neutropenia, lymphopenia, fatigue and pyrexia. Four deaths occurred within 4 weeks after start of treatment. None of these were related to CP-4055. Clinical activity (IWG criteria for AML) was recorded for 6 patients, 4 CRs and 2 CRp, representing a response rate of 15%. Two of the responders had refractory disease (first induction after >= 2 regimens), three pts were in first relapse with one pt having duration of first CR < 6 months, two patients having duration of first CR > 12 months. One responder was in second relapse with duration of first CR < 6 months. The median time from start of treatment to remission was 32 days (range 28-126 days) and the median duration of remission was 61 days (range 6-130+ days). The median overall survival was 88 days (range 8-292+ days). *Conclusions*. CP-4055 administered at 2000 mg/m2/d CIV in a d1-5 q3w schedule to patients with late stage AML showed manageable toxicity. Encouraging clinical activity was recorded with a CR/CRp rate of 15% in this difficult-to-treat patient population.

1395

MITOXANTRONE, ETOPOSIDE, ARA-C AND LOW DOSE GEMTUZUMAB OZOGAMICIN (MY-MEC) AS SALVAGE THERAPY FOR RELAPSED-REFRACTORY AML PATIENTS

M. Clavio, A. Ghiso, A. Cagnetta, L. Vignolo, C. Ghiggi, R. Varaldo, F. Ballerini, S. Aquino, F. Olcese, M. Miglino, M.V. Lucchetti, I. Pierri, L. Canepa, P. Canepa, M. Gobbi

Haematology University of Genova, GENOVA, Italy

Background and aims. Conventional salvage regimens for AML patients are often badly tolerated and induce few long lasting remissions. Gemtuzumab ozogamicin (GO) has shown promising activity in relapsed-refractory AML patients. We therefore explored the feasibility and the efficacy of a regimen combining mitoxantrone, etoposide and Ara-C (MEC) with low dose GO. *Design and Methods*. We present the first analysis on 30 patients with CD33+ refractory-relapsed AML receiving mitoxantrone 12 mg/sqm, etoposide 100 mg/sqm, Ara-C 1 g/sqm (days 1-4 in patients < 65 years and 1-3 in patients ≥65) and GO 5 mg at day 5 or 4. Responding patients were administered the same regimen as consolidation and allogeneic stem cell transplant when indicated. Patients: The median age of patients was 64 (range 33-74); M / F ratio was 22 / 8; FAB subtypes were M0 in 4 patients, M1 in 8, M2 in 10, M4 in 3, M5 in 3, M6 in 2. Thirteen patients were refractory to first line induction therapy, 17 were in first relapse (median first CR length 6 months, range 3-19). Previous induction regimens mainly included combinations of fludarabine with Ara-C and anthracyclines±GO. Twenty-one patients had *de novo* AML; in 9 patients AML was secondary to MDS (7) or myeloproliferative disorders (2). Cytogenetic analysis revealed a poor prognosis alteration in 5 patients (complex karyotype) and an intermediate alteration in the other 25. Haematological parameters before therapy were the following: WBC $5x10^9$/L (range 0,8-105); Hb 9,2 g/dl (8-13); Plt 66 x 10^9 / L (10-255). *Results*. The neutrophil (PMN > $0,5x10^9$/L) and platelet (>$25x10^9$/L) recovery required a median of 17 (range 12-25) and 20 days (range 14-36) from the end of therapy. Therapy was well tolerated, with 2 deaths occurring during induction (7%). Thirteen infectious complications were observed (9 sepsis, 2 pulmonary aspergillosis, 2 broncopneumonia). No VOD were reported and mild and transient signs of liver toxicity were observed in 3 patients only. Fourteen pts (47%) achieved CR, 3 (10%) showed a partial response, 11 (36%) did not respond; 2 (7%) patients died before response evaluation. Three patients underwent allogeneic stem cell transplant. Complete remission and survival lasted a median of 7 (range 3-26) and 8 months (range 1-27), respectively. Five out of 13 patients treated for refractory disease achieved CR (38%) whereas CRs have been 9 among 17 patients treated in first relapse (53%). Poor prognosis cytogenetics at diagnosis had a negative impact on CR rate (0% compared to 56% in patients with intermediate prognosis karyotype). CR rates have been 52% and 33%, in de-novo and secondary AML respectively. Eigth out of 14 patients in CR have relapsed. Overall 25 patients have died. *Conclusions*. In our hands MY-MEC proved to be a well tolerated and effective salvage treatment for refractory-relapsed patients with intermediate prognosis karyotype. However the short duration of CR requires the early application of allogeneic stem cell trasnsplant or innovative consolidation therapies.

1396

CLOFARABINE IN THE TREATMENT OF POOR RISK ACUTE MYELOID LEUKAEMIA - GALWAY UNIVERSITY HOSPITAL EXPERIENCE

J. Krawczyk, N. Ansar, T. Murphy, B. MacDonagh, T. Meenaghan, R. Swords, P. Hayden, A. Hayad, M. Murray, M. O'Dwyer

Galway University Hospital, GALWAY, Ireland

Background. Despite immense progress in the diagnosis and therapy of haematological malignancies, treatment of unfavourable risk Acute Myeloid Leukaemia (AML) remains a challenge. We present our 2 year experience (December 2006-December 2008) of clofarabine both as a single agent and in combination as treatment of unfavourable risk AML patients at our institution who were not suitable for standard therapy. *Aims*. We retrospectively analysed the efficacy and safety of clofarabine in the setting of unfavourable risk AML. *Design and Methods*. The medical records and data from laboratory system were analysed. *Results*. Over a period of 24 months 22 AML patients (11 M, 11 F) with poor risk features, deemed unsuitable for standard therapy, were treated with clofarabine, alone (8 patients) or in combination (14 patients) for up to 3 cycles of treatment. The median age was 67.5 years (24 to 76) with 16 patients > than 60. Cytogenetic data were available in all 22 patients (no favourable karyotype , 18% normal karyotype 45% - adverse karyotype 36%) had an abnormal karyotype, which was neither favourable nor adverse. Eighteen patients had active AML at the time of clofarabine therapy. In the majority of patients during induction and consolidation, clofarabine was administered as a 1-hour intravenous infusion at 20 mg/m2 daily dose for 5 consecutive days. In five younger patients (< 60 years) clofarabine was administered as a 1-hour intravenous infusion at 40 mg/m2 daily for 5 days. A second induction cycle was given to patients in the absence of progressive disease after the first induction cycle. Cycles were repeated every 4 to 8 weeks depending on response, marrow recovery and absence of ongoing toxicity. Selected patients also received daunorubicin and/or gemtuzumab ozogamycin as a part of initial induction chemotherapy. Up to 3 cycles of clofarabine based treatment were administered (median number of cycles in patients with active AML was 1.5). Four patients intolerant of standard induction received clofarabine as consolidation (20 mg/m2 daily for 5 consecutive days). A majority of patients received G-CSF. The overall response rate (ORR) for the 18 patients with active AML was 61%, 9 patients (50%) achieving a complete response (CR). The CR rate in adverse cytogenetics group was 50%, in normal cytogenetics group 50% and 62% in abnormal other than complex. 38% of patients did not respond to therapy (50% in adverse cytogenetics group, 50% in normal cytogenetics group and 25% in abnormal other than complex). Induction and consolidation were well tolerated with no unexpected toxicities. Predictably, all patients developed grade 4 neutropenia but the median duration was only 20 days (17-120). Induction mortality was acceptable at 17%. The median survival since diagnosis for the 18 patients treated for active AML is approximately 11 months. *Discussion*. In our experience clofarabine was very well tolerated as a single agent, both in induction and even more so as consolidation therapy. Clofarabine, both as a single agent and in combination therapy, is active in unfavourable risk AML with an acceptable safety profile. Our data are comparable with that published to date and demonstrates the feasibility of this treatment approach in routine practice. Clofarabine should be considered as a potential therapeutic option in unfavourable risk AML patients unsuitable for more intensive therapy or in the relapsed/refractory setting.

IMMUNOHISTOCHEMISTRY (CD123, CD56 AND CD4) REVEALS MINIMAL BONE MARROW INVOLVEMENT IN CASES OF BLASTIC PLASMACYTOID DENDRITIC CELL NEOPLASM

K. Hwang, C.J. Park, H.S. Chi, S. Jang, S.J. Park, J.R. Huh, J.H. Lee, C. Suh, K.H. Lee

Asan Medical Center, SEOUL, South-Korea

Background. Blastic plasmacytoid dendritic cell neoplasm has been included as a new disease entity in 2008 WHO classification of myeloid neoplasms. It is a highly aggressive and rare form of hematologic neoplasm. Almost all patients show cutaneaous manifestation at initial presentation and approximately 60-90% of patients have bone marrow involvement. Typically, tumor cells of blastic plasmacytoid dendritic cell neoplasm show CD4, CD56 and CD123 positive phenotype. *Aims*. It is difficult to diagnose minimal bone marrow involvement of blastic plasmacytoid dendritic cell neoplasm by morphologic examination only. In this situation, immunohistochemical stain can be helpful to confirm min-

imal bone marrow involvement. This study was purposed to demonstrate the usefulness of immunohistochemistry to reveal minimal bone marrow involvement of blastic plasmacytoid dendritic cell neoplasm. *Design and Methods*. 8 patients who were diagnosed as blastic plasmacytoid dendritic cell neoplasm from June 2000 to September 2008 were investigated. Except 2 patients who didn't receive bone marrow study, immunohistochemistry of CD4, CD56 and CD123 were done on biopsy or clot section to confirm minimal bone marrow involvement. *Results*. On initial morphologic diagnosis, bone marrow involvement was found in only 1 patient of 6 who received bone marrow biopsy. But Immunochemistry revealed minimal bone marrow involvement of 3 patients (CD123:3/3, CD56:2/3, CD4:2/3) whose bone marrow had been morphologically normal. *Conclusions*. Minimal bone marrow involvement of blastic plasmacytoid dendritic cell neoplasm can be precisely detected by immunohistochemistry. So we recommend CD4, CD56 and CD123 immunohistochemistry for the patients with blastic plasmacytoid dendritic cell neoplasm even though initial bone marrow study shows normal morphology.

COMPARISON OF SECONADRY ACUTE MYELOID LEUKEMIA WITH *DE NOVO* AML: CLINICAL FEATURES AND TREATMENT OUTCOME

Y.S. Choi, J.H. Lee, D.Y. Kim, J.H. Lee, S.H. Kim, S.N. Lim, S.D. Kim, M. Seol, S.I. Kang, K.H. Lee, J.Y. Kim, Y.S. Lee, Y.A. Kang, S.G. Ryu, K.Y. Lee

Asan Medical Center, SEOUL, South-Korea

Background. Secondary acute myeloid leukemia (AML) includes AML in patients who were exposed to chemo- and/or radiotherapy previously (t-AML) or AML evolving from myelodysplasia or myeloproliferative disorder (m-AML). Aims: We intended to investigate the clinical features at diagnosis and the therapeutic outcomes of t-AML and m-AML, comparing with those of *de novo* AML (d-AML). *Design and Methods*. Between June 1989 and July 2008, 886 consecutive patients with newly diagnosed AML in Asan Medical Center, Seoul, Korea were included in our retrospective analysis. Patients were classified into the three groups of d-AML (n=816, 92.1%), m-AML (n=46, 5.2%) and t-AML (n=24, 2.7%). The data of clinico-pathologic findings and clinical outcomes were retrieved from the Asan Medical Center Leukemia Registry. *Results*. Median number of peripheral blast count at diagnosis was lower in patients with m-AML ($1.41x10^3$/uL) and t-AML ($2.09x10^3$/uL) than patients with d-AML ($6.15x10^3$/uL) (p=0.01). Proportion of blasts in bone marrow nucleated cells was also significantly different among the three groups (66.4%, 43.6%, and 55.0% for d-AML, m-AML and t-AML respectively; p<0.001). More than 80% of patients in each group received induction chemotherapy. The complete remission (CR) rate after remission induction chemotherapy in patients with m-AML was significant lower than those with d-AML and t-AML [11/38 (28.9%) vs 560/720 (77.9%) and 13/20 (65.0%), respectively, p<0.001]. The 5-year actuarial overall survival (5-OS) rate in t-AML and m-AML patients was lower than d-AML patients (9.8% and 12.8% vs. 32.1%, respectively; p<0.001). But we observed no statistically significant difference in disease free survival (DFS) and event free survival (EFS) among the three groups. More patients with t-AML tended to die of non-relapse causes than those with m-AML after the first CR achievement [4/13 (30.7%) vs 4/38 (10.5%)]. HCT was performed for 184 (22.5%) of 816 patients with d-AML, 12 (26.1%) of 46 patients with m-AML, and 3 (12.5%) of 26 patients with t-AML. All of the 4 patients whose HCT was the initial therapy for m-AML did not relapse but 1 died of non-relapse cause, whereas 3 (37.5%) of the 8 patients whose HCT followed remission induction chemotherapy for m-AML, relapsed and died. For t-AML, three patients undertaken HCT in the first complete remission state followed by remission induction chemotherapy but 2 (66.6%) of 3 patients relapsed after transplantation, and all subsequently died. *Conclusions*. Our results suggest that prompt HCT may be more preferable therapeutic option particularly for patients with m-AML. To improve the overall outcome of patients with t-AML, novel therapeutic strategies are needed.

1399

THE ADDITION OF BORTEZOMIB TO INDUCTION THERAPY OF REFRACTORY ADULTORY AML, PRELIMINARY RESULTS

M. Udvardy, A. Kiss, B. Telek, P. Batar, G. Remenyi, R. Szasz, L. Rejto

Debrecen Medical University, DEBRECEN, Hungary

Background. Proteasome inhibition, the block of angiogenesis, modification of the NF-κ-B system seems to be a important target in refractory acute myeloid leukemia (AML). *in vitro* data clearly support, that bortezomib possesses antiproliferative and pro-apoptotic effects in different AML cell-lines, moreover bortezomib was able to improve anthracyclin and possibly ARA-C sensitivity in different AML cell-lines . More recently, a Phase I trial showed bortezomib monotherapy efficient (only in few percents) in childhood refractory acute leukemia. AIms We have tried bortezomib containing first or second line combinations in 35 (18 female, 17 male, mean age 59.76 years) patients with refractory or poor risk AML, in a retrospective fashion, analysing responses and safety.. *Design and Methods*. The combinations were as follows: HAM or Flag-Ida, combined with bortezomib 1,3 mg pro sqm, day O and seven). The following groups were considered as refractory or poor risk AML: 1.*De novo* AML, 2nd line: Lack of remission to first line standard treatment ("3+7"), n=4 (Velcade- Flag-Ida treatment) 2. *De novo* AML 1st line: bilineal or biphenotypic (flow-cytometry) n=3 (Velcade-Flag-Ida treatment) 3.De novo AML with complex karyotype or with flt-3 mutation, n=13, 1st line (Velcade-Flag-Ida n=10, Velcade-HAM protocol, n=3) 4.Secondary AML or AML with evidence of previous MDS, n=15, 1st line: (Velcade-Flag-Ida n=10, Velcade-HAM n=5) Results Complete remission (CR) 16/35, partial remission (PR) 10/35, no remission 8/35, progression during treatment: 1/35. CR had been achieved in all patients of group, and group 2 (biphenotypic, bilineal). The CR rate was quite appreciable in group 3, i.e. 9/13 (complex karyotype or normal karyotype with FLt-3 mutation) - the response rate was excellent with flt-3 mutated cases). In group 4. (MDS, secondary AML) the results were less impressive. There were no differences according to protocol (Flag-Ida or HAM). Allogeneous stem cell transplantation could have been performed in 1st CR in two patients (one from group 1. and another from group 2.) One of them died due to relapse, the other one is in CR since then. The combinations seem to be relatively safe. Induction related death rate was low (1 MDS/AML patient, thrombocytopenic bleed). 9 other patients had severe neutropenic sepsis (2 with fatal outcome). Pulmonary syndrome, which may follow Velcade+ARA-C had not been documented. Other adverse events did not differ from the pattern observed with standard induction therapies. The addition of bortezomib to induction therpay might imrpove responsiveness in different cohorts of refractory AML, without significant additional risk.

THERAPEUTIC REGIMENS INCLUDING CLOFARABINE IN ADULT PATIENTS WITH RELAPSE OR REFRACTORY ACUTE LEUKEMIA

F.S. Simonetti, F. Caracciolo, E. Benedetti, F. Papineschi, E. Sordi, M. Petrini

U.O. Ematologia - Università di Pisa, VIAREGGIO, Italy

Background. Clofarabine is a new generation purine nucleoside antimetabolite effective in the treatment of Relapse or Refractory Acute Leukemias either in children and in adults. *Aims*. The aim of our study was to demonstrate the effectiveness and the tolerability of a treatment regimen including Clofarabine or Clofarabine plus Cytarabine in adults with AML and ALL refractory to standard treatment. *Design and Methods*. In 2008 at the Department of Hematology of the University of Pise (Italy) we treated 11 adults with refractory leukemias with chemotherapy regimens Clofarabine based. Patients' diagnosis were as follows: 7 with AML and 4 with ALL. Of them, 4 patients were treated with Clofarabine as second-line therapy, 6 patients as third-line therapy and 1 patient as fourth-line therapy. Clofarabine based regimens were as follows: -Cycle A - 7 patients (4 AML, 3 ALL): Clofarabine 20 mg/mg days 1-5; -Cycle B - 3 patients (AML): Clofarabine 40 mg/mq days 1-5, Cytarabine 1 gr/mq days 1-5. Cycle A and B were repeated every 3 to 5 weeks based on response to the previous one (CR, PR or non-response) and were started when hematopoiesis was fully recovered. Patients were allowed to receive a maximum of 2 cycles of induction therapy or until a CR, CR with incomplete platelet recovery (CRp) or partial response (PR) was achieved. A CR required normalization of the marrow (5% blasts) and peripheral counts with no circulating blast cells, a neutrophil count ≥$1x10^9$/L and platelet counts ≥$100x10^9$/L. A PR consisted of a blood count recovery as for CR, but with persistence of 5% to 25% marrow blasts. A CRp had criteria similar to a CR, but without recovery of platelets ≥$100x10^9$/L. 6 patients received just one cycle of therapy and 5 patients received two cycles. During the treatment, transient liver dysfunctions were common in most patients. Myelotoxicity was grade III-IV in all patients; neurotoxicity never occurred. Mucosytis grade III-IV occured in 3 patients and also bacterial sepsis in 3 patients (colonized before the treatment). *Results*. Our results have shown an overall response rate (CR+PR) to Clofarabine higher than 70%: 8 out of

11 patients responded to treatment, one patient was a non-responder and 2 patients died of sepsis before any possible marrow evaluation. Out of 8 responding patients, 3 obtained a CR and 5 a PR. Of the 8 responders, a fully ablative allogenic transplant was performed in 2 CR patients and in 5 PR patients. One is still in CR 6 months far from treatment. *Conclusions*. Our preliminary results show that Clofarabine is a very effective and well tolerated drug for adult patients with Refractory Acute Leukemia and allowed us to obtain good response in high risk patients. Furthermore Clofarabine based regimens provided to obtain response in chemorefractory patients allowing thus to perform subsequent fully ablative allogenic transplant without additional toxicity.

1401

HIGH DOSE CYTARABINE, CLOFARABINE AND GEMTUZUMAB OZOGAMICIN (CLAC-MYL) IN RELAPSED OR REFRACTORY AML PATIENTS

B.S. Scappini,[1] G. Gianfaldoni,[1] M.C. Susini,[2] R. Fanci,[2] S. Baldini,[2] R. Fjerza,[2] F. Mannelli,[2] G. Longo,[1] A. Bosi[2]

[1]Azienda Ospedaliero Universitaria Careggi, FLORENCE, Italy; [2]University of Florence, FLORENCE, Italy

Background. Clofarabine has been shown to be effective in AML patients, both as single agent and mainly in association with high dose cytarabine. *Aims*. On the basis of these reports, we conducted a preliminary study combining clofarabine, high dose cytarabine and gemtuzumab ozogamicin (Mylotarg) in AML patients who relapsed or failed to respond to at least two induction therapies. *Design and Methods*: we treated 10 patients affected by relapsed/refractory AML with a regimen including clofarabine at 22,5 mg/m^2 daily on days 1-5, followed after three hours by cytarabine at 1 gr/m^2 daily on days 1-5, with the addition of gemtuzumab ozogamicin 6 mg/m2 on day 6 (CLAC-Myl). *Results*. Among the ten patients, four were in first relapse, three in second relapse, three with resistant disease. The mean age was 53.2 years (range 33-68 years), the white blood count at the accrual was 31.500 mcc (range 2140-153.000). 5/10 patients achieved a complete remission, 1/10 obtained a partial response with less than 10% bone marrow blasts, 3/10 had resistant disease and died of their AML, 1/10 died of complications during the aplastic phase (multiorgan failure in a woman 62 years old, at the third relapse after allogeneic bone marrow tranplantation, diagnosed with liver GVHD before starting the treatment). The most frequent non haematologic adverse events were vomiting (4/10), diarrhea (5/10), transient liver toxicity (2/10 grade 3-4), infections microbiologically documented (7/10), febrile neutropenia (3/10). Comparing with other salvage strategies, in this small cohort of patients we did not observe a significant delay in bone marrow recovery (median time to ANC recovery 25 days), and the addition of gemtuzumab seemed not to increase the haepatic toxicity. Interestingly, the three non-responding patients were all primary resistant AML Among the six responding patients, 4 received a further consolidation cycle with clofarabine at 22,5 mg/m2 and cytarabine at 1 gr/m^2 day 1-4, and underwent allogeneic bone marrow transplantation, one relapsed after 6 months, and one not eligible for transplant procedures is still in complete remission with a follow up of 6 months. *Conclusions*. Our very preliminary results suggest that the CLAC-Myl regimen is effective in this particularly poor prognosis category of patients, with safety data consistent with previously reported salvage therapies. Further studies are warranted.

1402

GEMTUZUMAB OZOGAMICIN, FLUDARABINE, ARA-C AND CYCLOSPORINEA (MFAC) REGIMEN AS INDUCTION THERAPY IN RELAPSED OR REFRACTORY CD33+ ACUTE MYELOID LEUKEMIA PRIOR TO ALLOGENEIC HEMATOPOETIC STEM CELL TRANSPLANTATION: A SINGLE-CENTER EXPERIENCE

M. von Bonin, U. Platzbecker, U. Oelschlägel, B. Mohr, C. Thiede, M. Bornhäuser, G. Ehninger, T. Illmer

University Hospital Carl-Gustav-Carus, DRESDEN, Germany

Background. Gemutzumab ozogamicin (GO) has been used as a single agent, as well as in combination with conventional chemotherapy in CD33+ acute myeloid leukemia (AML). *Design and methods*. We report 26 patients with CD33+ primary refractory or relapsed AML receiving the MFAC regimen (GO, fludarabine, ara-C and ciclosporin) directly followed in aplasia by reduced intensity conditioning (RIC) for allogeneic hematopoetic stem cell transplantation (HSCT). *Results*. Early treatment assessment revealed an overall response (OR) of 65.4%. Grade III/IV hepatic toxicity after MFAC occured in 30.8% of the patients. The median time to allograft was 22.5 days. 77% of all patients proceeded to allogeneic HSCT. Grade III/IV hepatic toxicity after allografting was observed in 25%, including one patient with veno-occlusive disease (VOD). When summarizing the sequential regimens, CTC grade III/IV hepatic toxicity (including hyperbilirubinemia and transaminitis) was seen in 16 patients (=61.5%). Median follow up was 8.2 months (range 0.3 - 39.7 months). Estimated twelve-month overall survival (OS) was 52.4%. discussion MFAC directly followed by RIC for allogeneic HSCT seems to be active and feasible, but with an increase in hepatic toxicity.

1403

A FLOW CYTOMETRIC IMMUNOBEAD ASSAY FOR THE DETECTION OF PML-RARA FUSION ONCOPROTEIN IN ACUTE MYELOID LEUKEMIA

E.H.A. Dekking,[1] A.L. Noordijk,[1] A. van der Linden,[1] E. Dixon,[2] A. Wang,[3] Y.P. Liu,[3] T. Hendriksson,[3] R. Varro,[3] C. Bush-Donovan,[3] J.J.M. van Dongen[1]

[1]Erasmus Medical Center, ROTTERDAM, Netherlands; [2]BD Technologies, Tripath, DURHAM, USA; [3]BD Biosciences, SAN JOSE, USA

Acute promyelocytic leukemia (APL or AML-M3), a subtype of acute myeloid leukemia, is one of the most lethal forms of acute myeloid leukemia when not diagnosed and treated expeditiously. Genetically, APL is characterized by a translocation between chromosomes 15 and 17, (t(15;17)(q22;q21), which fuses the retinoic acid receptor α (RARA) gene on chromosome 17 with the PML gene on chromosome 15. Depending on the position of the PML breakpoint, a long (bcr1) or a short transcript isoform (bcr3) is produced. The PML-RARα fusion protein arrests the maturation of myeloid cells at the promyelocytic stage, which leads to an increased proliferation of promyelocytes. Most APL patients are treated with all-trans-retinoic acid (ATRA) in combination with chemotherapy, to avoid side effects of ATRA and to deplete the leukemic cells. ATRA activates the retinoid receptor RAR (present as wild type RARα and as part of the fusion protein) which causes the promyelocytes to differentiate and mature, which deters them from proliferation. Using this therapy. a complete remission can be obtained in most APL patients. At present, diagnosis of APL is based on the detection of the t(15;17) translocation by karyotyping, FISH or PCR. However, these techniques are laborious and demand a specialized laboratory. To circumvent these restrictions and to decrease the time for detecting the fusion protein, a novel research-based flow cytometric bead assay, using the BD' Cytometric Bead Array (BD Biosciences), was developed using a bead-bound anti-PML antibody and a PE-conjugated anti-RAR_ detection antibody. This research-based immunobead assay detects the presence of the PML-RAR_ fusion protein within 4 to5 hours in cell lysates of blood or bone marrow. The antibody-binding sites on the fusion protein were carefully selected to recognize all variants of the PML-RARα fusion protein. The assay is specific and sensitive, detecting less than 10% of the APL cell line NB4 (bcr1) in a background of normal PBMCs and WBCs. Additionally, the immunobead assay had 100% concordance (16/16) with PCR for detection of the fusion protein in individuals newly diagnosed with AML-M3 (either bcr1 or bcr3). We conclude that this novel immunobead assay can be used for fast and easy detection of PML-RAR_ fusion protein in AML-M3 patients. The assay is sensitive, independent of the PML breakpoint region, fast (completed within 4 to 5 hours) and can easily be performed in a standard laboratory using routine flow cytometry. Future studies are needed to demonstrate the full clinical utility of this assay.

1404

AN 'INTENTION-TO-TREAT' FACTOR IN 299 AML PATIENTS - SINGLE CENTER EXPERIENCE

T. Szotkowski,[1] J. Muzik,[2] K. Chroust,[2] K. Indrak[1]

[1]Faculty Hospital Olomouc, OLOMOUC, Czech Republic; [2]Institute of Biostatistics and Analyses, BRNO, Czech Republic

Background. Initial intention of acute myeloid leukemia patients' treatment is not always kept during the course of therapy. There are many factors influencing the clinicians' decision-making about changes of intended treatment. Neither these changes nor their effect on patients' survival have been analyzed generally. *Aims*. The aim of analysis was to compare the initially intended option of consolidation treatment (based on prognostic factors, performance status, comorbidity, CR achievement etc) with subsequently realized one and explore the effect of this decision and its parity or disparity with realized treatment on treatment outcomes. *Design and Methods*. Data of 299 consequently curatively treated AML patients (1996-2008; APL were excluded) in Olomouc were ana-

lyzed; M:F = 45.5% : 54.5%; 50.5% of pts were younger (<55); cytogenetic risk distribution : good prognosis 10.7%, intermediate 48.5%, poor 31.4% (9.4% NA). 55.9% of pts were intended to be consolidated with chemotherapy, 10% of pts with autologous transplantation and 34.1% of pts with allogeneic transplantation. *Conclusions.* There was significantly higher proportion (87.9%) of younger pts in groups intended to be transplanted when compared with patients intended to be consolidated with chemotherapy (21%; $p<0.001$). We found significant difference in distribution of cytogenetic risk among groups of pts according to intention-to-treat. An intended treatment has been kept in comparable proportion of pts (48-56%) of all groups. We found the highest proportion of untreated (without consolidation) pts in the group intended to be consolidated with chemotherapy and the lowest one in the group intended to be transplanted with autologous stem cells. Both the highest incidence of changes in treatment course and the best survival were found in the group of pts intended to be treated with autologous transplantation. However, there was the highest proportion of pts with good cytogenetic prognosis and younger pts in this group, too. The treatment outcome and survival were worse in pts intended to be treated both with chemotherapy and allogeneic transplantation. The pts both intended to and treated with autologous transplantation did have comparable survival with pts intended to be treated with autologous transplantation and treated with another treatment option subsequently. The pts both intended to and treated with allogeneic transplantation did have better survival when compared with pts intended to be treated with allogeneic transplantation and consolidated with another treatment option finally. The pts both intended to and treated with (any) transplantation did have better survival when compared with pts intended to be transplanted and consolidated with chemotherapy. The worst outcome we found in pts intended to be treated with allogeneic transplantation and consolidated with chemotherapy only.

A SIMPLE MOLECULAR PROFILE AT DIAGNOSIS MAY PREDICT THE PROBABILITY OF ACHIEVING COMPLETE REMISSION IN NON-M3 AML PATIENTS: A PRELIMINARY ANALYSIS ON 85 PATIENTS.

M. Miglino,[1] N. Colombo,[1] R. Grasso,[1] G. Pica,[2] M. Clavio,[1] C. Ghiggi,[1] R. Varaldo,[3] G. Beltrami,[2] M. Bergamaschi1, F. Ballerini,[1] A. Ghiso,[1] L. Vignolo,[1] A. Cagnetta,[1] S. Aquino,[1] F. Olcese,[1] G. Catania,[2] I. Pierri,[1] L. Canepa,[1] M. Sessarego,[1] A.M. Carella,[2] M. Gobbi[1]

[1]Institute of Haematology University of Genova, GENOVA, Italy; [2]Division of Haematology, S Martino Hospital, Genova, GENOVA, Italy; [3]Nstitute of Haematology University of Genova, GENOVA, Italy

Background. FLT3 mutations and expression of NPM, WT1, BAALC and other genes may exert a relevant role in AML . *Design and Methods*: A molecular profile was performed in 85 untreated non M3 AML patients receiving induction chemotherapy with the aim of predicting CR rate and long term outcome. Expression levels were obtained by Real-Time-PCR upon normalization on Abl expression. *Patients*. Median age was 60 years (17-80). Sixty-one patients (72%) had *de novo* AML, 24 (28%) had a secondary disease. The karyotype was favourable (FK) in 2 patients , intermediate (IK) in 64, including 59 patients with normal karyotype (NK), unfavourable (UK) in 17. In 2 patients could not be evaluated. FLT3 (85 patients): 12 (14%) had ITD and 6 (7%) had exon 17 mutations. WT1 (83 patients): in 10 (12%) expression was < 100, in 10 (12%) between 100 and 500, in 17 (20%) between 500 and 1000, in 46 (56%) >1000. NPMA (81 patients): in 56 (69%) expression was ≤1000 (66% with NK, 4% with FK, 25% with UK); in 9 (11%) between 1000 and 10 000 (78% with NK, 22% with UK); in 16 (20%) was > 10000 (94% with NK, 6% with UK). NPM B (81 patients): in 66 (81%) expression was ≥ 1000 (67% with NK, 3% with FK, 30% with UK); in 8 (10%) between 1000 and 10 000 (88% with NK, 12% with UK); in 7 (9%) was >10000 (100% with NK). BAALC (84 patients): in 34 (41%) expression was <1000, in 28 (33%) between 1000 and 10 000, in 22 (26%) >10 000. *Results*. 11/12 patients with FLT3 ITD achieved CR (91%) relapse (58%). Four out 6 with FLT3 mutations in exon 17 reached CR (67%) relapse (25%). Level of WT1 expression did not correlate with CR rate. 31/56 (55%) with NPM A 1000 achieved CR (15 relapsed); 5/9 (55%) with NPM A between 1000 and 10 000 reached CR (2 relapsed); 13/16 (81%) with NPM A > 10 000 reached CR (4 relapsed). 34/66 (51%) with NPM B 1000 achieved CR (15 relapsed); 8/8 (100%) with NPM B between 1000 and 10 000 reached CR (5 relapsed); 7/7 with NPM B > 10 000 reached CR (2 relapsed). 29/34 (85%) with BAALC < 1000 achieved CR (28 had NK; 11/29 relapsed); 11/28 (39%) with BAALC between 1000 and 10 000 achieved CR (11 relapsed); 11/22 with BAALC > 10 000 reached CR (5 relapsed). The highest CR rates have been reported in patients with BAALC <1000, NPM A >10 000 (13/14, with 4 relapses); BAALC <1000, NPM A >10 000 , without FLT3 mutations (11/11, with 1 relapse); BAALC <1000, NPM B >10 000 (6/6, with 1 relapse). *Conclusions.* A simple molecular analysis at diagnosis based on BAALC and NPM expression may predict the probability of achieving CR. A longer observation is needed to evaluate whether this will be associated with improved outcome also.

1406

FLT3 TYROSINE KINASE DOMAIN (TKD) MUTATIONS IN PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML)

J. Markova, P. Michková, J. Maaloufová, P. Cetkovsky, J. Schwarz

Institute of Hematology and Blood Transfusion, PRAGUE 2, Czech Republic

Background. Although the point mutations involving TKD of the FLT3 gene are less frequent than internal tandem duplications (FLT3/ITD), they still occur in about 10% of AML cases. These changes most commonly affect codons Asp835 and Ile836 and their prognostic impact is not as yet fully clarified. Aims: To study the frequency of FLT3/TKD mutations and their prognostic significance in our patients with AML. *Design and methods*. A cohort of 298 newly diagnosed adult AML cases was studied. The median patients' age was 54.0 years (range: 18.3-81.7), the male/female ratio was 148/150. The initial median WBC count was $18.2x10^9$/L (range 0.4-488.0). The median follow-up was 8.3 months (range 0-153.7). To detect mutations in the TKD of the FLT3 gene, exon 20 was amplified by RT-PCR. The resulting products were digested with EcoR V and separated on 3% agarose gel. Undigested bands were directly sequenced in order to specify the mutation. *Results*. Out of 298 AML patients, 30 (10.1%) harboured FLT3/TKD mutation. It was found in 10/56 (17.9%), 11/129 (8.5%) and 5/66 (7.6%) patients with a favourable, intermediate and poor-risk cytogenetic profile, respectively. The prevalence of FLT3/TKD mutations decreased with the age of patients. In the group of patients<30 years, 7/41 (17.1%) had the mutation, among patients between 30 and 60 years 15/161 (9.3%) were mutated and in the group over 60 years only 8/95 (8.4%) harboured the mutation. The most frequent was the Asp835Tyr change, which was found in 15 (50%) patients, followed by Asp835Val and Asp835Glu substitution (4 patients each), Asp835His and del836Ile (3 patients each). One patient carried del(835-837)/ins mutation. According to the FAB classification, FLT3/TKD mutations were most frequently present in subtypes M4 (9/49 patients), M5 (3/17) and M3 (6/37). On the other hand, none of 12 patients with M0 subtype harboured the mutation. Patients with FLT3/TKD mutation had a significantly higher initial WBC count when all patients were analyzed together (p=0.002), as well as when APL and FLT3/ITD-positive patients were excluded (p=0.005). Patients with Asp835Tyr substitution had higher initial WBC count when compared to patients carrying any other FLT3/TKD mutation (p=0.047). Out of the 268 patients without FLT3/TKD mutation, 147 (56.3%) reached complete remission (CR), while among 30 mutated cases, 19 (63.3%) achieved CR (p=0.231). When 186 patients without APL or FLT3/ITD were evaluated separately, 91/163 (55.8%) unmutated reached CR and 16/23 (69.6%) mutated cases reached CR (p=0.106). The incidence of relapse was slightly higher in FLT3/TKD mutated patients (11/19 cases relapsed; 57.9%) compared to non-mutated ones (61/137; 44.5%; p=0.137). This trend was confirmed when APL and FLT3/ITD-positive patients were excluded from analyses (11/16; 68.8% mutated cases relapsed vs. 43/84; 51.2% unmutated ones relapsed; p=0.098). The overall survival (OS) was not influenced by the presence of the FLT3/TKD mutation either when all patients were analyzed together (p=0.618) or when APL and FLT3/ITD-positive patients were excluded (p=0.699). *Conclusions*. We have confirmed the prevalence of FLT3/TKD mutations in about 10% of AML patients. In our group of patients, these mutations seemed to cause higher initial WBC counts. Insignificant tendencies towards higher CR rates and to more frequent relapses were noted for the mutated patients, so that the resulting OS was unaffected by FLT3/TKD mutations.

METRONOMIC APPROACH FOR TREATMENT OF ACUTE MYELOID LEUKEMIA (AML): DOSE INTENSITY DOES NOT ALWAYS MATTER!

M. Sengar, R. Nair, S.D. Banavali, H. Menon

Tata Memorial Centre, MUMBAI, India

Background. Recent developments in AML therapeutics are remarkable, however their applicablility in economically less-resourced countries is limited as many patients cannot bear the cost of conventional chemotherapy and supportive care and die untreated. For them we need to develop novel therapeutic approaches which can control leukemia, require less supportive care and are affordable. In one such attempt we have treated patients with acute myeloid leukemia who were financially challenged and/or had underlying organ infections making them unsuitable for standard chemotherapy with oral metronomic therapy based on Etoposide, 6-thioguanine and Prednisolone. *Aim.* To test the efficacy of metronomic chemotherapy in patients with *de novo* acute myeloid leukemia who were not eligible for standard chemotherapy. *Methods*, In this retrospective study, consecutive patients diagnosed to have adult de-novo acute myeloid leukemia between january- november 2008 at a tertiary care center were analyzed. We enrolled patients who were not eligible for standard chemotherapy due to financial constraints or documented organ infections and were willing for oral metronomic therapy. Treatment included 28 days cycle of chemotherapy with once daily administration of tab. 6-thioguanine 40 mg, tab Prednisolone 40 mg/m^2 and cap Etoposide 50 mg/m^2 for 21 days on outpatient basis. Supportive care with antibiotics, antifungal, packed red blood cell and platelet transfusion was given as indicated. Response assessment was done at the end of first cycle. Those patients who responded were given either post remission therapy with high dose ara-c or continued on oral metronomic therapy till finances were arranged for post remission treatment. *Results*. Ten patients (male: female 1:1) with median age of 35 years (range 16-57 years) with confirmed diagnosis of AML were analyzed. Four patients had probable fungal pneumonia with respiratory insufficiency at presentation. Median time between onset of symptoms and diagnosis was 2 months (range 1-5 months). Median presenting total leucocyte count was 18,950/cumm (range 1250-1,85,000/cumm). Favorable cytogenetics i.e. t(8;21) and inv(16)was found in 2 patients. Remaining patients had normal cytogenetics. Median number of oral chemotherapy cycles were 1 (range 1-6). At the end of first cycle, 8/10 patients were in complete morphological remission. Among patients who did not achieve hematological remission one patient could be started on conventional chemotherapy as her fungal pneumonia improved on oral metronomic therapy. At median follow up of 6 months (range 2-9 months) all patients continue to be in remission. The remarkable feature was that 6/10 patients received treatment as outpatient and only who required antifungals were admitted. The need for packed cell transfusion and platelets was minimal - median 1 (range 0- 2) and median 2 (1-5) respectively. This is quite lower than what is required with standard induction therapy. *Conclusions*. Metronomic therapy for treatment of de-novo adult AML seems to be effective and required much less supportive care in this small retrospective analysis form a developing country. Patients who have underlying infections at presentation, which limit the application of full dose induction chemotherapy or who have financial constraints can be considered as potential candidates for this treatment.

THREE CASES OF THERAPY-RELATED ACUTE MYELOID LEUKAEMIA IN PATIENTS WITH MULTIPLE SCLEROSIS: THE ROLE OF ARSENIC TRIOXIDE IN THE TREATMENT OF SECONDARY APL

R. Porrini,[1] E. Montefusco,[1] M. Pacilli,[1] S.K. Hasan,[2] T. Ottone,[2] G. La Verde,[3] A. Moscetti,[1] F. Saltarelli,[1] A. Ferrari,[1] E. Conte,[1] M.C. Cox,[1] M.A. Aloe Spiriti,[1] C. Guglielmi,[1] B. Monarca[1]

[1]Ospedale Sant'Andrea, ROMA, Italy; [2]Dipartimento di biopatologia e diagnostica per immagini university tor vergata, ROME, Italy; [3]A.O. Sant'Andrea, ROME, Italy

Multiple sclerosis (MS) is an autoimmune disease characterised by a relapsing-remitting course caused by immune activity directed against central nervous system antigens. Treatment of MS include the use of immunosuppressive chemotherapy with Mitoxantrone (Mtz), a DNA-topoisomerase II inhibitor that induces DNA cleavage and may lead to chromosome aberrations. Therapy-related acute myeloid leukaemia (t-AML) is a well-recognized complication in cancer or in autoimmune disease treated with agents targeting topoisomerase II . We report three cases observed in our Institution of acute myeloid leukaemia (2 APLs; 1 M2-AML) developed in patients affected by primary progressive MS (PPMS) following treatment with Mtz. The first patient, a 40-year-old-man affected by PPMS since 1995, was unsuccessfully treated with β interferon from January 2001 to December 2004. In January 2005, he started Mtz therapy at dose of 16 mg (8 mg/m^2) every 3 months until June 2007 (total dose 160mg). In that period blood tests showed Hb 10.1g/dl, WBC 1.4x10^9/L and PLT 89x10^9/L and morphology, molecular and cytogenetic analysis of bone marrow were compatible with a diagnosis of a typical APL (FAB M3). The second patient, a 48-year-old-female with PPMS since 2004, after unsuccessful treatment with β Interferon (January 2005 to November 2005), was treated with Mtz 20mg every 3 months (from December 2005 until June 2008; total dose 200mg). While she was receiving the last course of Mtz, blood tests showed pancytopenia; the bone marrow examination, molecular analyses and imunophenotyping were consistent with a diagnosis of APL. Both patients were treated according to AIDA protocol in induction (all-trans retinoic acid plus idarubicin) and achieved hematologic CR (HCR). Considering the cumulative anthracycline dose (Mtz for MS and idarubicin for APL induction), further chemotherapy was discarded and both patients were given consolidation with ATRA plus Arsenic Trioxide (ATO) for a total of 16 cycles according to protocol reported by Estey et al. (Blood 2006). Either patients achieved molecular remission (MR) after 1 cycle of ATRA plus ATO and are presently in MR after eight and one months from achievement of HCR, respectively. The third patient (a 50-year-old-male) was affected by PPMS since 1997. In October 2005 he started treatment with Mtz 18mg every three months. (toal dose 216mg). Four months after completion of Mtz therapy, blood and bone marrow morphological and immunological analyses disclosed 50% of blast cells compatible with a diagnosis of AML-M2. Chromosome analysis, demonstrated 46;XY with (3) and (21) deletion. Molecular studies showed a t(16;21) involving AML1 and resulting in a AML1-ETO2 gene fusion. Patient was treated with two cycles of induction chemotherapy according to the FLAG protocol, achieving complete remission. Consolidation therapy consisted of 2 courses of high dose of Ara-C). He is presently in HCR eight months after the end of consolidation therapy. After consolidation therapy the patient maintained HCR The occurrence of therapy-related acute myeloid leukemia after exposure to DNA-topoisomerase II inhibitors such as Mtz is well known; however, the emerging problem of sAML cases after MS raises important issues for optimal treatment of both MS and sAML. The therapeutics subcommittee of the American Academy of Neurology has recently recommended the use of Mtz only for patient affected by PPMS. As to sAPL, ATO plus ATRA seems a valid option to consolidate HCR and could also be considered front line treatment as an alternative to ATRA plus chemotherapy.

1409

INTENSIVE TREATMENT OF ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA OR MYELODYSPLASTIC SYNDROME: A SINGLE CENTER EXPERIENCE

A. Crotta, M. Tassara, C. Messina, S. Malato, F. Ciceri, M. Bernardi

San Raffaele Scientific Institute, MILAN, Italy

Background. Acute myeloid leukemia (AML) and myelodysplastic syndrome (MDS) peak incidence is in the seventh decade of life. The outcome of elderly patients (pts) with AML or advanced MDS is dismal because of the unfavourable characteristics of the disease and the frequent co-morbidities. Intensive chemotherapeutic programs, with or without haematopoietic stem cells transplantation (HSCT), are not usually offered to pts older than 60-65 as most of them are considered too frail to tolerate the side effects of such treatments; alternatively, they receive palliative and supportive care, or experimental targeted molecules. We here review data from elderly pts with AML or MDS, treated at our Center with an intensive approach. *Aim*: retrospective evaluation of feasibility and efficacy of different intensive treatments administered to AML/MDS elderly pts, at our Center. *Design and Methods*. period March 1999-Jenuary 2009, 52 pts, median age 69 (range 65-78), PS 0-2, renal, hepatic, cardiac and pulmonary function were within normal limits. Diagnosis (WHO): RAEB1 2, RAEB2 9, MDS/MPD 1, AML MD 23, AML 17. Cytogenetic risk (47 pts): high 7, intermediate 38, low 2. All pts received at least one cytarabine-containing induction cycle. Pts in CR were addressed to post-remission treatments according to their age, clinical condition, prognosis and donor availability. *Results*. CR rate was 63.4% (33 pts) after 1 or 2 cycles without significative difference comparing subgroups of pts according to diagnosis and cytogenetics. Induction mortality was 13.4% (7 pts). Post-remission treatment: 15 pts received ≥2 cycles of standard or high-dose chemotherapy, 18 pts

(54.5%) received an HSCT. HSCT (20 pts, 2 with residual disease after induction): 15 autologous (AUTO), 1 allogeneic from a sibling donor (SIB), 2 from an haploidentical familiar donor (HAPLO). Relapses: 19 pts (57.5%), 18 received salvage treatments, 10 (55.5%) obtained a second CR. At last up-date 18 pts were alive (34.6%), 13 in CR, with a median follow-up of 696 days (range 86-2677). Median survival of all pts from start of treatment was 408 days (range 20-2657). *Conclusions*. Different intensive approaches proved feasible and effective in our elderly pts with AML or poor prognosis MDS. A significative rate of long term survivors free from disease was documented. Our results suggest that transplantation can be a therapeutic option for selected elderly pts. In our opinion, palliative and supportive care should be offered only to pts with serious co-morbidities; alternatively, these pts could be enrolled in experimental trials with new targeted molecules.

1410

FLOW-CYTOMETRIC IMMUNOBEAD ASSAY FOR THE DETECTION OF PML-RARA FUSION PROTEINS IN ACUTE MYELOID LEUKEMIA

E.H.A. Dekking,[1] A.L. Noordijk,[1] A. van der Linden,[1] E. Dixon,[2] C. Bush-Donovan,[3] R. Varro,[3] B. Warner,[3] H. Wai,[3] J.J.M. van Dongen[1]

[1]Erasmus Medical Center, ROTTERDAM, Netherlands; [2]BD Technologies-Tripath, DURHAM, USA; 3BD Biosciences, SAN JOSE, USA

Acute promyelocytic leukemia (APL or AML-M3) is one of the most lethal forms of acute myeloid leukemia when not diagnosed and treated in time. Genetically APL is characterized by a translocation between chromosomes 15 and 17, t(15;17)(q22;q21), which fuses the retinoic acid receptor α (RARA) gene on chromosome 17 with the PML gene on chromosome 15. Depending on the position of PML breakpoint, a short (bcr1) or a long transcript isoform (bcr3) is produced. The PML-RARα fusion protein arrests the maturation of myeloid cells at the promyelocytic stage which leads to the increased proliferation of promyelocytes. Most APL patients are now treated with all-trans-retinoic acid (ATRA) in combination with chemotherapy, to avoid site effects of ATRA and to deplete the leukemic cells. ATRA activates the retinoid receptor RAR (present as wild type RARα and as part of the fusion protein) and causes the promyeloctes to differentiate and mature which deters them from proliferation. Using this therapy, a complete remission can be obtained in most APL patients, of which few relapse. Since treatment of APL is specifically aimed at the fusion protein, detection of t(15;17) or the presence of PML-RARα is necessary to predict treatment response. At present diagnose of APL is based on the detection of t(15;17) by karyotyping, FISH or PCR. However, these techniques take relatively long and demand a specialized laboratory. To prevent the need of specialized laboratories and to decrease the time for diagnosing APL, a novel flow cytometric bead assay (CBA) was developed using a bead-bound anti-PML antibody and a PE-conjugated anti-RARα detection antibody. This CBA detects and quantifies the presence of the PML-RARα fusion protein in cell lysates of blood or bone marrow samples of APL patients within 4-5 hours. The antibody binding sites on the fusion protein were carefully selected in order to recognize all variants of the PML-RARα fusion protein, independent of the breakpoint position. The assay is specific and sensitive and detects less than 10% of the APL cell line NB4 (bcr1) in a background of normal PBMCs and WBC's. Moreover, lysates of PBMC's of AML-M3 patients (either bcr1 or bcr3), previously diagnosed by PCR techniques, generated robust and specific signals in the assay. We conclude that this novel immunobead assay can be used for fast and easy diagnosis of AML-M3 patients which makes it possible to include these patients at an early stage in the right treatment protocols, much faster than by use of current techniques. The CBA is sensitive, independent on the PML breakpoint region and fast (completed within 4-5 hours) and can easily be performed in a standard diagnostic laboratory using routine flow cytometry. Furthermore, as this assay involves PML-RARA protein rather than RNA or DNA, it will measure the presence of cells that are sensitive to ATRA therapy. Futher clinical studies will reveal whether the new CBA is sufficiently sensitive for monitoring of minimal residual disease and detection of early relapse.

1411

THE PERCENTAGE OF MYELOPEROXIDASE-POSITIVE BLAST CELLS IS A GOOD PROGNOSTIC FACTOR IN ACUTE MYELOID LEUKEMIA (AML) IN ELDERLY PATIENTS

T. Marinakis,[1] G. Paterakis,[1] D. Gogos,[2] A. Argyrou,[1] C. Papadimitriou,[2] D. Skoumi,[2] I. Kontonis[2], N. Savvidou,[1] E. Michalis,[1] A. Galanopoulos,[1] G. Gkortzolidis,[1] V. Grigoraki,[2] A. Tsakri,[2] M. Georgiakaki,[1] N.I. Anagnostopoulos[1]

[1]General Hospital of Athens "G.Gennimatas", ATHENS, Greece; [2]GENERAL HOSPITAL OF ATHENS "G.GENNIMATAS", ATHENS, Greece

Background. The percentage of myeloperoxidase-positive blast cells (MPO+) has considered to be important for the diagnosis of AML while some recent studies have shown the prognostic significance of MPO-positivity in AML (T. Matsuo et al, Leukemia 2003;17:1539-1543). Aims: to examine whether the percentage of MPO+ blast cells is a useful prognostic factor for AML patients. *Design and Methods*. 61 elderly patients suffering from AML, were treated in our Clinic with MAC protocol (combination of mitoxantrone and cytarabine) from January 2002 to March 2008. Our population consisted of 33 patients with de novo and 28 patients with secondary AML, classified according to FAB as follows: M0 (4), M1 (11), M2 (24), M4 (7), M5 (7), M6 (5), M7(1), hybrid-leukemia (2). Their mean age was 70,48 (±4,33) yrs and M/F ratio was 38/23. Cytogenetic analysis was performed in 57/61 cases: 6 failed to produce metaphases, 40/57 revealed intermediate risk abnormalities (thirty with normal karyotype, five with trisomy 8, five with other abnormalities) and 11/57 cases had adverse risk abnormalities. MPO positivity was assessed with flow cytometry analysis on blast cells at diagnosis, and it was confirmed with cytochemistry. Patients were categorized into four groups according to MPO-positive percentage among the leukemic blast cells: Group A: <25%, Group ': 25-49%, Group C: 50-74%, Group D: 75-100%. The characteristics of the four groups (number of patients, existence of secondary leukemia, cytogenetics (Adverse Risk/AR, Intermediate Risk/IR, Without Metaphases or not done/WM) and the status of the disease after therapy (Complete Remission/CR, Refractory disease/RD) are shown in Table 1.

Table 1. Characteristics of patients.

GROUP	n	IR	AR	WM	sAML	CR	RD
A	17	8/17	5/17	4/17	5/17	9/17	8/17
B	10	5/10	1/10	4/10	4/10	3/10	7/10
C	7	5/7	2/7	0/7	3/7	5/7	2/7
D	27	22/27	3/27	2/27	16/27	14/27	13/27

Statistical analysis was done with Kaplan-Meier (log Rank test) and multivariable interpretation Cox. *Results*. 1. Patients with low MPO survive much less than the patients with high MPO: Overall Survival in Groups and ' was 7,77 and 8,27 months vs 36,10 and 20,79 months in Groups C and D respectively (p value <0.05). The duration of disease-free survival (DFS) is much greater in patients with high MPO than patients with low MPO: DFS in Groups C and D was 31,87-20,75 months vs 5,32 and 5,0 months in Groups A and B respectively (p value <0.05). The above findings prove bad prognosis in patients with low percentages of MPO+ blasts in myelogram at the time of diagnosis and indicate the importance of the MPO assessment at the time of the diagnosis in elderly patients with AML.

1412

HYDROXYUREA + VINDESINE IN THE TREATMENT OF ELDERLY AML PATIENTS UNFIT FOR INTENSIVE CHEMOTHERAPY

G. Loglisci, R. Latagliata, F. Natalino, M. Breccia, I. Carmosino, L. Cannella, C. Stefanizzi, V. Federico, F. Vozella, L. Napoleone, P. Volpicelli, C. Mercanti, S.G. Morano, G. Alimena

Ematologia - Università "La Sapienza", ROME, Italy

Background and aims. In order to improve the dismal results obtained in elderly patients with Acute Myelogenous Leukemia (AML) not eligible for Intensive Chemotherapy (IC), we tested the addition of Vindesine (VND) to standard palliative chemotherapy with Hydroxyurea (HU). *Design and methods*. From 12/2001 to 12/2007, 38 elderly patients [M/F 24/14, median age 77.6 yrs, interquarile range (IR) 74.0-81.6] with newly diagnosed AML and not eligible for standard IC were enrolled into the study. Twelve patients had a previously documented myelodysplastic phase, 4 patients had a PS (WHO) > 2 and 5 patients had a documented infection at onset. Median Hb, WBC, PLTS and marrow blasts were 9.0 g/dl, 15.1x10^9/L, 63x109/l and 54%, respectively. Clinical criteria for exclusion from IC were age >75 yrs (21 patients), cardiological disease (7 patients), PS >2 (4 patients), renal disease (3 patients) or other organ failures (3 patients). The primary endpoint was to achieve a phase of stable disease (WBC <10x10^9/l for > 2 months during treatment). After diagnosis, patients were observed weekly and the association of HU (initial dose 1500 mg/day) and VND (5 mg iv every 15 days) was started in the presence of WBC >10x10^9/l or a doubling time shorter than a week. Results Median time from diagnosis to treatment was 13 days (IR 3 - 49). Three patients (7.9%) achieved a morphological and/or cytogenetic Complete Remission (CR), 2 (5.3%) an haematological improvement (HI), 12 (31.5%) a stable disease and 21 (55.3%) showed a disease progression. As to the 3 patients in CR, 1 with an abnormal karyotype (47 XY,+13) at diagnosis, achieved both morphologic and cytogenetic CR that lasted 14 months; the other 2 patients with normal karyotype at diagnosis achieved CR lasting 4 and 16 months, respectively. Documented infections (14 broncopneumonic episodes, 4 abscesses and 1 bacterial sepsis) were the most common complications during treatment. Median time of hospitalization was 10 days (IR 5 - 20). Median overall survival was 108 days (IR 55 - 262), with 14/38 patients (36.8%) surviving > 6 months and 4/38 (10.5%) surviving > 12 months. Median survival of responding patients (CR + HI + stable disease) was 298 days (IR 206 - 333), median survival of patients with progressive disease was 68 days (IR 48 - 133) (p=0.0017). After a minimum observation period of 18 months, no patient is still alive, 5 patients were lost to follow-up and 33 died, 24 from disease progression and 9 in stable disease from infections (5), acute myocardial infarction (2), haemorrhage (1). *Conclusions*. The addition of VND to HU seems to ameliorate the response rate (CR + HI) as compared to HU historical controls, but it does not seem to affect overall survival. The role of VND in this subset of frail patients remains unclear and further studies with different doses and associations might be tested.

1413

PROGNOSTIC VALUE OF MULTIPARAMETER FLOW CYTOMETRIC ASSESSMENT OF MINIMAL RESIDUAL DISEASE IN ADULT ACUTE MYELOID LEUKEMIA PATIENTS

M. Guenova, V. Shivarov, N. Stoyanov, V. Nikolova, G. Balatzenko, P. Ganeva, G. Michailov

National Haematological Hospital, SOFIA, Bulgaria

Background. Most patients receiving current induction treatment for acute leukemia enter in complete remission (CR). However, many patients will eventually relapse later due to the presence of resistant to chemotherapy leukemic cells, which are undetectable by conventional light microscopy and referred as minimal residual disease (MRD). Multiparameter flow cytometry (MFC) has been shown to be a useful approach for evaluation of MRD based on the detection of aberrant phenotypes on the leukemic cells. The aim of the study was to detect residual blast cells with aberrant antigen expression by MFC in patients with acute myeloid leukemia (AML) in CR and to determine whether the level of MRD would be predictive of subsequent overt relapse and overall survival. *Design and methods*. Thirty-three patients with AML were monitored for MRD after the achievement of CR. Among them, 21 were males and 12 females (median age 37 years, range 19-67). Median follow-up time was 24 months (range 1-125,7). At diagnosis, MFC allowed for defining a "leukemia immunophenotypic fingerprint" for each patient by staining leukemic cells with several combinations of monoclonal antibodies conjugated to fluorochromes. CellQuest and FACS Diva (Becton Dickinson) softwares were used for acquisition and analysis of flow cytometric data. Blast cells were gated according to CD45/SSC properties. MRD studies during remission were performed on erythrocyte-lysed whole BM samples using antibody combinations defining the specific "leukemia immunphenotypic fingerprint", at completion of induction therapy and at completion of consolidation therapy. Relapse rate, overall survival (OS) and event free survival (EFS) were investigated in relation to the influence of MRD presence. For statistical analysis, Kaplan-Meier was used. Results: Eleven of the evaluated patients (35%) relapsed after an average period of 16 months [ranging 4,8 - 29 months]. The mean MRD value in the group of relapsed patients was 3,2 x 10-4, SE 1,1 x 10-4 compared to a mean of 0,8 x 10-4, SE 0,5 x 10-4 in patients who were still in remission after a mean period of 20 months of follow up [ranging 1,5 - 55,5 months] (p=0,049). A threshold discriminating MRD(negative/low) from MRD(high) cases was set at 3,5 x 10-4 residual leukemic cells, a level that allowed optimal sensitivity and specificity for prediction of EFS but also OS. The mean EFS in patients with negative/low levels of MRD was estimated as 41,2 months compared to 18,4 months in patients with high MRD (log rank test, p = 0.02). Similarly, high MRD levels significantly correlated with poorer OS - 2-years survival was estimated at 57% with a mean OS of 20 months, compared to patients with undetectable or low MRD levels, characterized with a 2-years relative survival of 100% with a mean OS not reached after a follow up of 31,9 months [range 1,4 - 125,7 months] [log rank test, p=0.04]. *Conclusions*. Our results suggest that MRD detection during therapy of adult AML is a negative prognostic indicator for (OS) and (EFS), the independency of which has to be confirmed after prolonged follow-up time and increased number of cases.

Studies were funded by the National Research Fund, Bulgarian Ministry of Education and Science.

1414

CAN ESTIMATION OF WT-1 IN PERIPHERAL BLOOD HELP US IN MONITORING RESIDUAL DISEASE OF PML/RARα-POSITIVE AML PATIENTS?

C. Haskovec, J. Polak, J. Markova, J. Schwarz

ÚHKT, PARAHA 2, Czech Republic

Background. Monitoring of residual disease (MRD) is now a gold standard in the treatment of AML patients. MRD in many of AML patients is estimated by expression of AML-specific genes in bone marrow aspirates. Unfortunately, bone marrow aspiration is a painful procedure for the patients and is a limiting factor for more frequent monitoring of MRD in the patients. *Aims*. We tested whether estimation of Wt-1 in peripheral blood could partially substitute PML/RARA estimation in bone marrow. *Design and Methods*. Expression of PML/RARA and Wt-1 was performed by quantitative real-time RT-PCR. The results were referred to expression of gene ABL. *Results*. In 31 PML/RARA-positive AML patients the quantitative estimation of Wt-1 in peripheral blood was found to be at least as sensitive as PML/RARA one in bone marrow. Also the course of the residual disease in peripheral blood monitored by Wt-1 expression correlated with the MRD course monitored by PML/RARA in bone marrow very well. Monitoring of MRD by Wt-1 in peripheral blood can thus partially substitute estimation of PML/RARA in bone marrow. Of course, when a considerable increase in Wt-1 expression above the upper limit is noticed, the estimation of PML/RARA in bone marrow is performed. *Summary*. According to our results, monitoring of the residual disease by Wt-1 expression in peripheral blood can help us in monitoring PML/RARA-positive AML patients.

The study was financially supported by IGA MZCR grant: NR 8748-3.

1415

LEUKEMIA IN PREGNANCY; 9 CONSECUTIVE CASES IN 9 MONTHS FROM A SINGLE INSTITUTION IN SAUDI ARABIA

T. Al Beirouti

King Fahd Medical City, RIYADH, Saudi Arabia

Background. Cancer incidence during pregnancy is 0.07% to 0.1%. Leukemia e.g. AML, ALL, and CML are often seen in women of childbearing age. So the management of these disorders may be complicated by a coexistent pregnancy. There is no standard approach for this clinical dilemma - in part because of variables such as; the type of malignancy, the seriousness of the symptoms; the patient's personal beliefs. In many cases, the diagnostic work up has to be altered because of the pregnancy. Often the treatments available have varying risks to the fetus.

In most situations, the course of the pregnancy does not seem to be affected by the presence of leukemia and the course of the malignancy does not seem to be affected by the pregnancy. Most leukemias don't seem to behave differently during pregnancy. *Aims*. The aim of this report is to summarize the type and treatment outcome of 9 consecutive cases of pregnant patients with Leukemia who were referred and evaluated at our Prince Sultan Hematology & Oncology Center (PSHOC) at King Fahd Medical City (KFMC) within a short period of 9 months.*Design and Methods*. Between May 20007 till January 2008 a total of 9 consecutive cases of leukemia were referred, diagnosed and treated in our institution of PSHOC at KFMC, Riyadh, Saudi Arabia. The clinical, laboratory, and treatment outcome information of theses cases were summarized and analyzed along with addressing the legal and religious issues related to these cases. Results: In the specified period a total of 9 consecutive pregnant women with suspected hematological malignancies were referred to our center over a short period of 9 months. 6 cases were diagnosed as AML (2 cases AML-M5, 2 cases AML-M2, 1 case AML- M0, and 1 case as AML-NOS but patient was Philadelphia +ve for BCR-ABL p210? Blast crisis of CML) and 3 cases as Ph +ve CML. The median age was 27 year. High WBC was the main laboratory presentation in all of these cases. Our approach for AML management during pregnancy consisted of; first trimester AML to terminate the pregnancy due to high teratogenic effect of chemo in this period (in one case of AML M0 who died later because of disease & sepsis) and early delivery and symptomatic management during the third trimester using leukopheresis and hydroxyurea (in one case who had AML M2 with t(8;21) but CD56+ she received 3+7 followed by one HIDAC then allogeneic BMT from MRD at KFSHRC in Riyadh). We had 3 cases of AML during second trimesters and our approach to use 3+7 as induction followed by 2+5 as a consolidation. The last patient was diagnosed in the post partum period and she received the standard treatment protocols. *Conclusions*. Leukemia complicating pregnancy is not uncommon medical problem in our society where there is a high fertility rate and large number of young age population. The management of leukemia during pregnancy is challenging but is achievable. Using our approach in AML pregnant patients we were able to achieve a high remission rate 83% (5/6 patients) with an acceptable mortality and morbidity of 17% (1/6 patients). 50% (3/6 patients) underwent Allogeneic HSCT.

THE ROLE OF CYTOGENETICS AND MOLECULAR GENETICS IN THE MANAGEMENT OF ACUTE MYEOID LEUKEMIA. THE EXPERIENCE OF THE HEMATOLOGY CLINIC CLUJ-NAPOCA, ROMANIA

A.M. Cucuianu,[1] D. Dima,[1] H. Dohner,[2] K. Dohner,[2] M. Schmidt,[2] R. Schlenk,[2] L. Petrov[1]

[1]"Ion Chiricuta" Cancer Institute, CLUJ-NAPOCA, Romania; [2]University of Ulm, ULM, Germany

Background. The overall prognosis of acute myeloid leukemias (AML) remains poor despite progress achieved over the past decade. Cytogenetics define three risk groups (good, intermediate and poor), based on the presence or absence of certain chromosomal abnormalities. Molecular genetics may further subdivide the group of patients with normal karyotype. *Aims*. Between October 2007 and October 2008, thanks to a collaboration between our institution and the University of Ulm, Germany, funded by the German José Carreras Leukemia Foundation, we analyzed systematically from a cytogenetic and molecular genetic point of view our adult AML patient population. *Design and Methods*. There were 40 patients (23 men, 17 women) aged 21-79 years (median 48 years). Besides the routine cytological, cytochemical and immunophenotypical analysis, karyotyping was applied in all cases and in those cases with normal karyotype the mutational status of the NPM1 and FLT3 genes was assessed. Results. Four cases (10%) were in the cytogenetically defined good-risk group (1 case with t(15;17), 2 cases with t(8;21), 1 case with inv16). Twenty cases (50%) were in the intermediate-risk group (2 cases with trisomy 8, 2 cases with trisomy 22, 16 cases with normal karyotype). Sixteen patients (40%) were included in the poor-risk group (13 cases with multiple abnormalities, 1 case with -5, 1 case with -7, 1 case with inv(3). The molecular analysis in patients with normal karyotype revealed the presence of the NPM1 mutation alone in 4 patients, the association of NPM1 and FLT3 mutation in one patient and the presence of mutated FLT3 alone in another 4 patients. Out of the 40 patients, 34 were treated with curative intent. In 3 patients with NPM1 mutation as sole abnormality, all-trans retinoic acid (ATRA) was added to chemotherapy. In 17 patients (50% of those treated with curative intent) complete remission (CR) was achieved. Based on cytogenetic and molecular data, we divided the patients into 2 broad prognostic groups: favorable cytogenetic/molecular profile, comprising patients with low-risk cytogenetics as well as those with normal karyotype and the NPM1 mutation as sole molecular abnormality and a second group of unfavorable cytogenetic/molecular profile, comprising patients with poor-risk cytogenetics, as well as those with intermediate-risk cytogenetics except those with NPM1 mutation as sole abnormality. When comparing the treatment outcome between these two groups, there was a significantly better response and survival in the favorable cytogenetic/molecular profile group. Three out of four patients harboring mutated NPM1 and treated with chemotherapy + ATRA achieved a complete remission. None of the patient with a mutated FLT3 gene entered complete remission. *Conclusions*. This study represents the first attempt in our center towards a modern, systematic categorization of AML cases. Our results emphasize the bad prognosis of cases with unfavorable cytogenetics and the presence of the FLT3 mutation as well as the favorable prognosis of patients with good-risk cytogenetics and the NPM1 mutation. Complex, cytogenetic and molecular diagnosis is essential in the 21st century, considering the fact that targeted small molecules against several mutated sites may soon become available.

EXPLORING WILMS TUMOR GENE (WT1) IN ACUTE MYELOID LEUKEMIA - INITIAL EXPERIENCES

L. Rejto,[1] S. Biro,[2] G. Vargha,[2] Zs. Ujj1, P. Batar,[1] R. Szasz,[1] B. Telek,[1] A. Kiss,[1] Gy. Remenyi,[1] L. Mehes,[1] M. Udvardy[1]

[1]Univ. of Debrecen Health Science Center, DEBRECEN, Hungary; [2]University of Debrecen, Dept. of Human Genetics, DEBRECEN, Hungary

Background. The Wilms tumor gene (WT1) that is normally expressed only in podocytes, is expressed in peripheral blood of at least 75-80% of acute leukemia patients. It may contribute to the development of acute leukemia. There are some suggestions in the literature, that the higher the WT1 expression, the less likely to achieve complete haematological remission (CHR), therefore the prognosis is worse. Patients showing WT1 expression at diagnosis can turn into WT1 negative at CHR. After the reappearance of WT1 transcripts, relapse is expected, which makes detection of WT1 transcripts eligible for testing minimal residual disease (MRD). *Aims*. We aim to demonstrate the potential usefulness of WT1 to establish the quality of remission in AML patients and for the early identification of patients at high risk of relapse. *Design and Methods*. Peripheral blood (PB) samples were collected at diagnoses, after induction and consolidation chemotherapy (1-5 days after the achievement of a neutrophil count 0.5x109/l) from 26 AML patients. The median follow-up was 6 month (mean 7.4, range 0.1-24). We measured AML patients' WT1 expression with Applied Biosystems 7500 Real Time PCR. The assay of the gene is based on TaqMan reaction, using the Applied Biosystems Hs00240913-m1 assay. The expression of WT1 was normalized with that of the housekeeping gene GAPDH. No WT1 expression was detected in healthy controls. *Results*. There was no correlation between WT1 expression and WBC count at diagnoses. We did not find correlation between the amount of WT1 transcript at diagnoses and survival time, FAB and cytogenetic risk subgroups or FLT3 mutations. The worst survival time was found, when the degree of WT1 expression did not fall after chemotherapy. (The median survival time was 5 month, range 1-14). Better survival time was observed (median 8.5 month, range 6-13), when the amount of WT1 transcripts substantially decreased after chemotherapy. The disappearance of WT1 transcripts was detected only in one patient. This patient is in complete remission (CR) since 11 month. In all of the patients, who reached a favorable WT1 value after chemotherapy and achieved CR and later relapsed, increased WT1 expression was detected well before the signs of relapse was observed. *Conclusions*- Our results show that detection of WT1 expression is a possibility to estimate the prognosis and to follow up AML patients more accurately. Consistent and repeated quantitative analysis of WT1 expression may provide prognostic information and early identification of patients at highest risk of relapse.

1418

FLAG-IDA IN THE TREATMENT OF REFRACTORY/RELAPSED ACUTE LEUKEMIA: A SINGLE CENTRE EXPERIENCE

M. Delia,[1] D. Pastore,[1] P. Carluccio,[2] A. Ricco,[1] P. Manduzio,[1] C. Ingrosso,[1] N. Sgherza,[1], V. Fesce,[1] P. Mongelli,[1] M. Giannoccaro,[1] R. Angarano,[1] M.C. Longo,[1] A. Mazzone,[1] V. Liso,[1] G. Specchia[1]

[1]Hematology, University of Bari, BARI, Italy; [2]Hematology, University of bari, BARI, Italy

Background. Relapsed or refractory adult acute myeloid leukaemias (AML) have poor prognosis. The strategy for treating these patients is by reinduction chemotherapy followed by allogeneic stem cell transplantation, provided that the toxicity of the salvage regimen is acceptable. High or intermediate dose cytarabine has been reported to be effective in the salvage treatment of AML; addition of the purine analogue fludarabine to cytarabine increases the rate of accumulation of cytarabine in leukemic blasts and the response to chemotherapy may be improved by the addition of idarubicin, an anthracycline that is less susceptible to multidrug resistance. AIMS Based on these considerations, we evaluated the efficacy and the toxicity of FLAG-IDA in a series of 95 refractory/relapsed AML patients. *Design and Methods*. Sixty-five patients (68%) were in first relapse and 30 (32%) were refractory to conventional chemotherapy. The patient group included 51 males and 44 females with a median age of 41 years (range 15-63). All patients were treated with fludarabine (30 mg/m^2/day iv for 5 days), cytarabine (2 gr/m^2/day iv for 5 days), idarubicin (10 mg/m^2/day iv for 3 days) and G-CSF (5 mcg/Kg/day subcutaneous 24 h after completing chemotherapy and until neutrophil regeneration). *Results*. The overall CR rate was 55% (52 of 95): 39 of 65 (60%) in relapsed and 13 of 30 (43%) in refractory patients; there were 6 (6%) deaths during therapy: 2 due to cerebral hemorrhage and 4 to infection. In patients achieving remission, the median time to reach an absolute neutrophil count (ANC) more than 0.5x10^9/L and 1x10^9/L was 21 (range 16-26) and 24 days (range 20-28) from the start of chemotherapy, respectively. Platelets levels of more than 20x10^9/L and 100x10^9/L were achieved in a median time of 24 (range 19-26) and 32 days (range 28-39) days, respectively. Fever higher than 38.5°C was observed in 77 of 95 patients (81%): 45 had fever of unknown origin and 32 documented infections. Non hematological side effects consisted mainly of mucositis (75/95 or 79%) and transient liver toxicity increase (40/95 or 42%). All 52 patients who achieved CR received a second course with FLAG-IDA, and 27 received allogeneic stem cell transplantation, 8 patients received autologous stem cell transplantation, 9 were judged unable to receive any further therapy, and 8 refused other therapy. The median overall survival (OS) for all 95 patients was 4 months (range 2 - 86); for all 52 responders patients, the disease free survival (DFS) and OS were 9 (range 3-86) and 11 (range 7-86) months, respectively; particularly, the 28 patients who received allogeneic transplantation had a DFS of 53 (range 7 - 86) months. *Conclusions.* In our experience, FLAG-IDA treatment seems to improve a good clinical outcome and its duration in patients with poor prognosis. It has shown to be a well-tolerated regimen in refractory/relapsed AML enabling patients with CR (55%) to undergo further treatment, including transplantation

1419

SERUM VITAMIN D LEVELS ARE ASSOCIATED WITH PROGNOSIS IN HEMATOLOGICAL MALIGNANCIES

X. Thomas, Y. Chelghoum, N. Fanari, G. Cannas

Hopital Edouard Herriot, LYON, France

Background. Vitamin D, a steroid hormone produced in skin, acts through a nuclear transcription factor to regulate many aspects of cellular growth and differentiation. The major circulating metabolite of vitamin D is serum 25-OH vitamin D. Vitamin D is a membrane antioxidant, and observational studies have indicated that inadequate vitamin D levels are a risk factor for certain types of cancer. Recently, it has been reported an associated of low serum levels of 25-OH vitamin D with increased breast cancer risk and with a poor prognosis (ASCO 2008, abstract 511). *Aims*. We examined vitamin D levels in a cohort of 105 patients with hematological malignancies at different stage of their disease, seen between June and November 2008. *Design and Methods*. 25-OH vitamin D was measured by radioimmunoassay. Normal levels ranged from 12 to 40 ng/ml. *Results*. Mean serum 25-OH vitamin D level±standard deviation (SD) was 22.9 ng/ml±10.5 ng/ml. Fourteen patients had vitamin D deficiency, while 4 were above the normal range. Lower vitamin D levels were associated with higher malignant cell burden as indicated by the correlation observed between the stage of the disease in acute leukemias and levels of vitamin D. The difference was significant between patients with long-term disease-free survival and those tested at diagnosis (p=0.001) or those tested at the time of relapse (p=0.05) (Figure). Similarly in patients with Philadelphia-positive leukemias, the study of molecular residual disease showed a correlation between molecular response and levels of vitamin D (p=0.01). In patients with progressive disease, vitamin D levels were not significantly different among myeloid and lymphoid malignancies. In acute leukemia patients tested at the time of diagnosis, we did not find any correlation between vitamin D levels and age. No difference was noted when vitamin D was drawn in summer (June-August) versus autumn (September-November) months. Vitamin D levels were also not associated with gender or with the index of corporal mass (IMC). However, the two patients presenting with under weight at diagnosis (IMC < 18.5 kg/m^2) showed low vitamin D levels (15 and 16 ng/ml). *Conclusions*. Vitamin D deficiency appeared uncommon in hematological malignancies, but lower levels appeared related to the stage of the disease, response to therapy, and therefore aggressiveness of the disease. Whether lower vitamin D levels has other explanations remains a challenge, like the exact role of vitamin D in malignant cells and its potential need for a therapeutic or preventive approach.

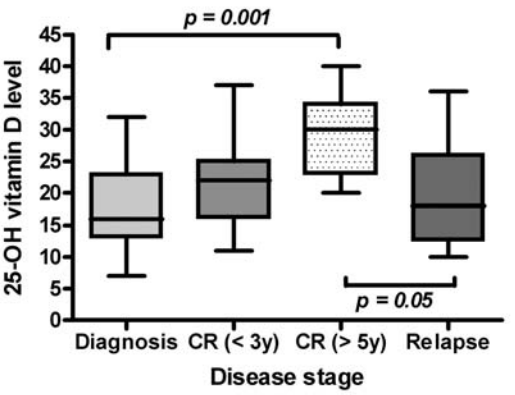

Figure.

1420

EARLY BONE MARROW BLAST CLEARANCE BY INDUCTION CHEMOTHERAPY PREDICTS SUPERIOR OUTCOME AND DISEASE FREE SURVIVAL IN ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML)

T. Marinakis, A. Argyrou, I. Michail, M. Pergaminou, A. Galanopoulos, E. Michalis, G. Gkortzolidis, N. Savvidou, G. Paterakis, E Goumakou, E. Griva, M. Georgiakaki, N.I. Anagnostopoulos

General Hospital of Athens G.Gennimatas, ATHENS, Greece

Background. Risk assessment in AML using pretreatment characteristics may be improved by incorporating parameters of early response to therapy. It is reported that the early blast clearance in the bone marrow after induction therapy is related to the outcome of the *disease(Kern W et al, Blood 2003;101:64-70*). *Aims*. Assessing bone marrow response to therapy on day 16 after the induction therapy and correlating it to achievement of complete remission and long term outcome in AML. *Design and Methods*. 46 patients with AML (29 Males, 17 Females) were treated with MAC (combination of mitoxandrone and cytosine-arabinoside) in our Clinic from January 2002 to March 2008. Their median age was 71 (60-81) years and their mean age 70,1(±4) years. According to the FAB classification they were classified as M0(3), M1(9), M2(17), M4(4), M5(4), M6(7), hybrid-diphenotypic leukemia(2). 21/46 patients presented with secondary AML(sAML). Leukocytosis (>50x10^9/L) was noted in 6/46 patients and leukopenia (<5x10^9/L) in 23/46 patients. Cytogenetic analysis was performed in 43/46 patients: 3/43 cases failed to produce metaphases, 29/43 cases revealed standard risk abnormalities (21/29 patients presented with normal karyotype-intermediate prognosis) and 11/43 cases had poor risk abnormalities (unfavourable prognosis). Bone marrow examinations were carried out on day 16 after induction therapy. Both cellularity and the amount of residual leukemic blasts of the bone marrow were evaluated in all cases. Patients were classified in the

following groups: Group A: aplastic bone marrow, Group B: blasts 0-4%, Group C: blasts 5-9%, Group D: blasts 10-24%, Group E: blasts 25-49%, Group F: blasts >50%. The number of patients in every group, their cytogenetics (intermediate cytogenetics/IC, unfavourable cytogenetics/UC, without metaphases or without cytogenetics/WC), the presence of sAML, the outcome after the induction therapy, achievement of complete remission(CR) or presence of residual disease(RD) in every group are shown in the table. *Results.* 1.Patients from groups A and B, having aplastic bone marrow or bone marrow in remission on day 16, present higher percentages of CR compared to those from the other groups who present higher percentages of RD. 2.Patients from groups A and B present significantly better overall survival compared to those from the other groups: the median survival was 22(±2,49) and 15,33(±2,35) months for groups A and B and 7,88(±2,59), 9,85(±5,1), 9,42(±3,05), and 7(±1,99)months for groups C, D, E and F respectively (p<0.05). *Conclusions*. Despite of the small number of patients of this study, it is clear that the early bone marrow blast clearance on day 16 after induction therapy in elderly patients with AML is a very important prognostic factor for achievement of complete remission and long term outcome in AML

Table 1. Characteristics of evaluated patients.

GROUP	n	IC	UC	WC	sAML	CR	RD
A	5	5/5	0/5	0/5	2/5	4/5	0/5

CD2+ ACUTE PROMYELOCYTIC LEUKEMIA IS ASSOCIATED WITH A POOR PROGNOSIS AFTER CHEMOTHERAPY±AUTOLOGOUS TRANSPLANTATION

C. Butler

Centerbury Health Labs, CHRISTCHURCH, New Zealand

Background. The classical form of acute promyelocytic leukaemia is characterised by hypergranular promyelocytes with absent CD34 and HLA-DR expression and the long or bcr1 form of the PML/RAR transcript. CD34 expression has been associated with the hypogranular M3 variant form of APL and frequently with expression of CD2 and the short or bcl3 PML/RAR transcript. Some but not all published series report a worse prognosis in CD34+ CD2+ APL. *Design and Methods.* We conducted a retrospective review of patients presenting with APL to examine their laboratory features at presentation and correlate remission rate and long term survival with CD2+ expression. Results: 12 patients presenting with APL between 1992 and 2008 were identified from an electronic database. Median age was 28 years (range 10-72). Immunophenotyping was available for 11 patients. 6/11 patients were CD2+ APL, 4/6 patients co-expressed CD34 and 3/4 were CD34+HLA-DR-. 5/6 CD2+ patients had the short/bcr3 APL/RAR isoform. The remaining CD2+ patient was not analysed. All CD2- patients were CD34-HLA-DR- and expressed the long/bcr1 isoform. The most commonly administered treatment was the PETHEMA regimen (n=9). 3/6 CD2+ patients and 6/6 CD2- achieved CR with induction therapy. All six CD2- patients remain in CR1 after a median 40 months (17-140) post diagnosis. 3/6 CD2+ died during induction therapy due to intracerebral haemorrhage (n=2) and DIC-related multi-organ failure. 2/6 CD2+ patients relapsed and received an autologous transplant in CR2. One patient died 6 months after presentation and the other relapsed. One CD2+ patient received an allogeneic transplant in CR1 and remains disease free at 153 months post diagnosis. *Conclusions*. In our patients CD2+ APL was associated with early death and relapse after conventional chemotherapy or autologous transplantation in our patients. Recognition of this less common phenotype is clinically important in identifying a group of patients at high risk of early death and/or treatment failure. CD2+ patients with an HLA-matched sibling donor may benefit from allogeneic transplant or novel therapies.

BIPHENOTYPIC AND MIXED ACUTE LEUKEMIA IN PEDIATRIC PATIENTS

G. Radulescu,[1] I. Neamtu,[2] A. Sfichi,[3] I. Burleanu,[1] T. Tudoran,[1] E. Mihut,[2] V. Horak[1]

[1]Synevo Laboratory Cluj-Napoca, Romania, CLUJ-NAPOCA, Romania; [2]Oncological Institute Prof. dr. I. Chiricuta Cluj-Napoca, CLUJ-NAPOCA, Romania; [3]Immunological Central Laboratory, Medical Clinic I, CLUJ-NAPOCA, Romania

Background. Recent studies have demonstrated that lineage fidelity (myeloid or lympphoid) is not preserved in some cases of acute leukemia. This minority of acute leukemia is represented by biphenotypic or hibrid acute leukemia (BAL) characterized by co-expression of lymphoid and myeloid surface markers in the same leukemic cell and mixed or bilineal acute leukemia (MAL) characterized by two separate clones of myeloid and lymphoid leukemic blasts. The aim of this study was: to corelate the expression of lymphoid and myeloid antigen with clinical, hematological and biological parameters, to analize the diagnostic criteria for BAL and MAL, the impact on the response to treatment and the prognosis. *Design and Methods.* For this study we describe: the clinical features,blast morphology from peripheral blood and bone marrow aspirates, cytochemical stains including myeloperoxidase (MPO), Sudan black B (SBB), periodic - acid Schiff (PAS and the immunological markers (lymphoid and myeloid) expressed by the blasts of four children diagnosed as BAL and MAL at the Oncological Institute in Cluj-Napoca. Results: These four pedriatic patiens studied: two females and two males with ages ranged from 2 years to 13 years (median 9 years) were identified as BAL (patiens no. 2, 3) and MAL (patients no. 1, 4) according to FAB criteria and immunophenotyping. Flow-Cytometric analises was performed for: HLA-DR; CD45; CD10; CD19; CD20; CD22; CD5; CD7; CD13; CD 33; CD34; CD14; CD117; Of the four cases, only two MAL type (cases no. 1, 3) with favorable evolution, achieved a complete remission with intensive myeloid like therapy, if the immunophenothyping has been evidenced precursor B-ALL with myeloid antigenes; In the other cases (no. 2, 4) BAL type we established an unfavorabile evolution: case 2 - death after 17 mounths; case 4 -candidat for bone marrow transplant. Discussion: The cases described as BAL and MAL, with minor incidence 3-4% from all adult and pedriatic acute leukemia, are uncommon types of leukemia, originating more probably from a pluripotent progenitor cell with the potential to differentiate along both myeloid and limfoid lineages.The morphological and cytochemical characteristic features of these cases were: the presence of two distinct blast populations in the same patient: one of small size, with hight nucleus-cytoplasm ratio, condensed nuclear cromatin, small or inconspicuous nucleoli; hand mirror morphology and PAS block positive, resembling lymphoblast and the other myeloid larger with more abundant cytoplasm with or without azurophilic granulations and Auer rods, monocytoid features, cytoplasmic buds, MPO and SBB-posititive blasts. Crucial value in diagnosis of BAL and MAL is holded by the immunophenotyping. According to the scoring sistem (EGIL) a case is considered BAL when point values are greater than two for myeloid and one for lymphoid. From our study result that the immunophenotypic characteristics alone do not predict clinical outcome. Outcome- related prognostic factors are : age, response to treatment, complications, in close corelation with hematological, cytogenetic and molecular aspects. The treatment applied was not unitary, because until now a protocol for these rare forms of acute leukemia with reserved prognostic is not established. At this time we recommend an aggressive and long treatment. In conclussion we stress:-The rarity and the difficulty of differentiation between BAL and MAL.-The complexity of the multidisciplinary investigations in the diagnosis of thiese uncomnom forms.-The essential value of the immunophenotyping in interpretation concomytantly with the cytogenetical and molecular studies.-The immnunophenotyping studies performed in a single laboratory confirm the existence of a distinct subsets.-AML and ALL showing so-called lineage infidelity.-Eradication of BAL and MAL it's possible by association of the intensive therapy with the bone marrow transplantation.

THE IMPACT OF FLT3 - ITD IN ADULT /ELDERLY ACUTE MYELOID LEUKAEMIA(AML) PATIENTS: A SINGLE CENTER RETROSPECTIVE ANALYSIS

A. Chierichini,[1] B. Anaclerico, [1]S. Fenu,[1] V. Bongarzoni,[1] S. Cortese,[1] M. Cedrone,[1] F. Calvieri,[2] S. Lavorgna,[3] F. Lo Coco,[3] L. Annino[1]

[1]Haematology Azienda Ospedaliera S.Giovanni Addolorata, ROME, Italy; [2]Cytogenetic Laboratory,Azienda Ospedaliera S.Giovanni Addolorata, ROME, Italy; [3]Department of Biopathology,University Tor Vergata, ROME, Italy

Background. FLT3-ITD represents one of the most frequent genetic aberrations of AML as they occur in the 20-30% of cases with normal karyotype. Several studies recognized this mutation as a negative prognostic factor although its role in elderly patients is less clear . Aims: We have retrospectively reviewed the frequency and prognostic impact of FLT3-ITD mutation in a consecutive series of adult and elderly (>65y) patients with AML series diagnosed and treated at a single Institution. . *Design and Methods.* Between January 2007 and January 2009 among 60 consecutive AML patients with median age 69yrs were observed at our center. A FLT3-ITD was detected in 11(18,3%) cases. Of these, 9 had intermediate and 2 unfavourable risk karyotype and only 1 patient had concomitant NPM1 mutation. Initial Hb median value was 8.5 gr/dl(range 6.5-12.4 g/dl), median WBC count 43x10^9/L (range 4.- 264 x10^9/l), median PLT count was 51x10^9/L (range 15.-312.x10^9/L). Five patients were treated according to the EORTC-GIMEMA AML12 protocol, while the remaining 6, who were unfit or not eligible for intensive treatment, received differentiating (ATRA+LoDAC) or supportive therapy (HU). Results: Of the 11 FLT-ITD+ cases , 2 are too early, 3 (27%) achieved 1st CR, 6 died during induction. Among patients died during induction, 3 were older than 60y (60,72,80y), and 3 had WBC >/= 40.x10^9/L (42.2, 202., 264x 10^9/L). As of February 2009, 5 patients are alive, with a median OS of 2 months(range 1- 17 mo); 2 are in 1st CCR for 1.5+ and 3+ months, respectively; while a 3rd CR patient (a 72y-old woman), who received as 1st induction ATRA+LoDAC relapsed 14 months after CR achievement, and died during 2nd intensive induction. *Conclusions*. CR rate were disappointingly low in this small series of FLT3-ITD pts, most likely due to concomitant high risk factors (elderly age and hyperleucocytosis). As recently highlighted in a large German study (Buchner et al, 2009) also in our series age, high WBC count and NPM1-gerline status were additional factors negatively influencing outcome. However, differentiating treatment allowed to obtain better survival with respect to intensive chemotherapy. If confirmed in larger series, this observation may suggest that non intensive treatment associated with novel targetd agents represents a valid therapeutic option for elderly FLT3-ITD AML patients.

1424

THE PROGNOTIC VALUE OF THYMIDINE KINASE LEVEL IN BLOOD SERUM IN PREDICTION OF SURVIVAL POTENCIAL IN ACUTE MYELOID LEUKEMIA PATIENTS

N.M. Tretyak,[1] N.V. Goryainova,[1] O.A. Kyselova,[1] O.V. Myronova[2]

[1]Institute of hematology and transfusiology of UAMS, KIEV, Ukraine; [2]State medical academy, KIEV, Ukraine

Background. Being a cell proliferating enzyme, thymidine kinase (TK) can reflex a speed of tumor cell division, aggressive of leukemia clone and can be useful in prognosis of decease progression and treatment results. Aims. The purpose of the current investigation is determination of blood serum TK value in prediction of survival potential in acute myeloid leukemia (AML) patients. *Design and Methods*. The main epidemiology (sex, age), hematology and clinical features (proliferate syndrome, hemorrhage syndrome, infection complication etc) and TK level in blood serum (measured by radioimmunoassay using 5-125 I-iodedeoxy uridine as a substrate) were defined in 127 AML patients in different phase of course of decease (first acute period - 79 patients, relapse - 48 patients). During the observation time (2003-2008 years) there were documented 40 death incidents among all patients under investigation (21 death incidents in first acute period, 19 - in the time of relapse). Died patients according to the aim of investigation also were divided into the following groups: I - patients, whose death was a result of decease progression (n=14); II - those, whose death was a result of different complications (n=26). *Results*. The TK level in blood serum was significant increased in the time of diagnosis in the patients, died during the observation period in comparison with the TK level in blood serum in the patients, who achieved satisfactory treatment results (43.95±7.46 U/L vs. 14.23±1.46 U/L, < 0.01). There wasn't observed any significant difference in the TK level in the group of the patients in connection with the sex and age. On the contrary, significant difference existed in the TK level in blood serum among the patients, whose death was a result of decease progression (52.28±8.22 U/L) and different complication (11.925±1.165 U/L), (p<0,005). *Conclusions*. Establishing results confirm, that upper TK level in blood serum in the time of AML diagnosis can predict an aggressive course of decease. TK level more, than 30.0 U/L prognoses bad treatment results due to the chemotherapy resistance. TK level more, than 50.0 U/L predicts high risk uncontrolled decease progression and death.

1425

A DESCRIPTIVE STUDY OF FLOW CYTOMETRIC ANALYSIS OF 151 ACUTE LEUKEMIA PATIENTS : A SINGLE INSTITUTE EXPERIENCE IN EGYPT

A. abd Alwahed, N. Kassem, A. Sobeih, A. Ahmed, R. abd Alreheem, H. Nasrat, N. Nagy

Kasr Alaini Centre for Oncology and Radiation, CAIRO, Egypt

Background. This study was carried out to analyze the proportion of acute myeloid leukemia (AML), acute lymphoblastic leukemia (T / Pro and Pre B-ALL), biphenotypic lineage and Undifferentiated acute leukaemia among 151 acute leukaemia(AL) patients .We also analyzed the coexpression of AML with lymphoid cell surface markers (T / B) and ALL with myeloid cell surface markers. By this method more than 98% of acute leukemia cases can now be precisely allocated to their respective lineages (*Channa J et al.J Coll Physicians Surg Pak 2000;10(5):158-60*). *Aim*. To determine the proportions of each lineage and the coexpression of myeloid and lymphoid cell surface markers for later detection of their prognostic impact. *Design and Methods.* Data of 151 consecutive cases of AL were analyzed in our study between Jan 2005 through Feb 2009. Flow cytometry was performed on all AL cases using the standard protocols. Myeloid associated markers included (MPO, CD 13, CD33, CD117, CD15, CD14 and CD64); T-lymphoid associated markers (Tdt, CD2, CD3, CD5 and CD7); B-lymphoid associated markers (Tdt, CD10, CD19, CD20 and CD22); Lineages non specific markers (CD34, HLADR) and panleucocytic marker(CD45). Florescence labeled antibodies were obtained from (Becton Dickinson, U.S.A) and run on FACSCALIBER using CELLQUEST software. *Results*. Eighty nine patients were AML, 61 were ALL, 3 biphenotypic and 2 undifferentiated AL. Five(6.25%) out of 80 AML patients showed CD19 coexpression ; 7(8.75%) with CD7, 3(3.7%) with CD15.Three(4.9%) out of 80 ALL patients with CD 13 coexpression and 3(4.9%) with CD 33 coexpression. *Conclusions*. Flow cytometry enabled us to determine the proportions of each lineage of acute leukaemia as well as the coexpression of cell surface markers between different lineages. Follow up of the prognostic impact of this coexpression on our patients is still in progress

SERUM SOLUBLE TRAIL LEVELS WERE DECREASED IN PATIENTS WITH T(8;21) ACUTE MYELOID LEUKEMIA

L.G. Liu

Shanghai fifth people's hospital & Daopei hospital, Fudan university, SHANGHAI, China

Background. TRAIL apoptotic pathway is important in the pathogenesis of leukemia. There are some reports that TRAIL pathway might has some changes in leukemia. Serum soluble TRAIL(sTRAIL) could be detected easily. The levels of sTRAIL in acute myeloid leukemia(AML) with t(8;21) is unknown. *Aims*. To detect the serum sTRAIL levels in AML patient with t(8;21) and investigate its clinical significance. *Design and Methods*. Serum sTRAIL was analyzed by ELISA, compared with normal control and non-t(8;21) AML M2 patients. *Results*. Thirty-eight patients with t(8;21) , 32 normal control and 31 non-t(8;21) AML M2 were enrolled in the study. The levels of serum sTRAIL in patients with t(8;21), non t(8;21) AML M2 and normal control were 450.84±313.91ng/ml, 938.95± 395.08ng/mL and 856.43±298.9ng/mL respectively. The levels of sTRAIL were significantly lower than non-t(8;21) AML M2 (p=0.001) and normal control(p=0.013). *Conclusions*. Our pilot study showed that serum sTRAIL levels in t(8;21) AML were low, it might be related to the pathogenesis of this type of leukemia.

1427

RESULTS OF TREATMENT IN CHILD ACUTE MYELOID LEUKEMIA IN TUNISIAN PATIENTS

L. Aissaoui, H. Ben Neji, R. Ben Amor, R. Jeddi, K. Kacem, W. Bouteraa, R. Ben Lakhal, H. Ben Abid, Z. Belhadjali, B. Meddeb

Aziza Othmana Hospital, TUNIS, Tunisia

Introduction. Acute Myeloid Leukemia (AML) is a relatively rare malignancy in the pediatric population, comprising only 15 to 20% of the acute leukemia diagnosed in this age group. It remains a challenging disease with an inferior treatment outcome compared with pediatric acute lymphoblastic leukemia. Despite high-dose cytarabine consolidation and allogenic bone marrow transplantation(BMT), about 40% of the children with AML still died of their disease. *Design and Methods*. In department of hematology(pediatric and adult) of Aziza Othmana Hospital, among 156 children acute leukemia enrolled between January 2003 and June 2008, 26 (16,6%) *de novo* AML (Down's syndrome and FAB M3 excluded) were noted. The median age was 12 years(2.2-17);WBC was > $20x10^9$/L in 11 patients. The diagnosis of AML was done by BM smears and immunophenotyping (CMF) using EGILE scoring. Karyotype was done in all patients and it was informative in 22 cases(85%).According to the Medical Research Council's Trial(MRC): 8 patients were classified into favorable or CBF leukemia,13 into intermediate group and only 1 into unfavorable. All patients were treated according to the French multicenter protocol ELAM02 with a common induction treatment by cytarabine and mitoxantrone than 3 courses of consolidation therapy among them 2 courses with high dose cytarabine. Patients in CR with HLA identical family donor have allogenic stem cell trasnsplantation. *Results*. Twenty two patients (85%) achieved CR after one course and 23(88.5%) after 2 courses. Toxic death and induction failure were both at 7.7%. Fourteen patients had a matched sibling donors, but stem cell transplantation was done only in 6 patients because of problems of feasibility. Two of them died by GVHD but no relapse occurred in this group. Relapse occurred in 8 patients (36%) in median period of 9 months. EFS (18 months)was 65%. When studied separately, the patients with CBF leukemia who were treated by chemotherapy alone and all the other group who were treated by chemotherapy alone or chemotherapy with stem cell transplantation , the EFS (18 months) were respectively 83.5% vs 46.5%. OS(3years) was 59%. *Conclusions*. Despite of the low number of patients, our results seem to be near those reported in large studies, and to improve them more we had to indicate stem cell transplantation to more patients with a better management of graft complications.

1428

COMPARISSON OF TRANSPLANT PROCEDURES WITH CONVENTIONAL THERAPY IN THE TREATMENT OF ACUTE MYELOID LEUKEMIA- LONG TIME FOLLOW UP

M. Elez, D. Stamatovic, Lj. Tukic, O. Tarabar, B. Balint, B. Todoric-Zivanovic, V. Skuletic, O. Tasic-Radic, S. Marjanovic, M. Malesevic

Military Medical Academy, BELGRADE, Serbia

Introduction. There are three approaches for consolidation of patients (pts) with acute myeloid leukemia (AML) (with exception of acute promyelocitic leukemia). Post remission treatment changes over years mostly by intensification or including new drugs. Those approaches are either allogeneic or autologous stem cell transplantation (SCT) or conventional therapy. AIM: We have analyzed retrospectively 74 pts with AML divided into three groups- conventional group, autologous stem cell transplantation (SCT) group and allogeneic SCT group with respect to relapses, time to progression (TTP) and overall survival (OS). *Design and Methods*. We have treated 110 pts with AML in our clinic from 2001. till 2008. Nine of them had acute promyelocytic leukemia and 27 pts have showed primary resistance. We have enrolled 74 pts into these analysis- 30 pts into "conventional group", 30 pts in the "autologous transplant group" and 18 pts in the "allogeneic transplant group". After one or two courses of standard induction chemotherapy ("7+3"), pts have received three more cycles of consolidation (MAE, MidAC and ICE) and last one was used for mobilization of autologous peripheral stem cells in pts with approved complete remission. Both transplant groups immediately undergone conditioning up to standard BuCy2±IDA regimen and "conventional group" have received maintenance therapy consisted of Thioguanin 160 mg daily per os and Cyto ARA 100 mg subcutaneously daily for 5 days (mostly due to their own rejection of autologous SCT or their age). Prophylaxis of graft versus host disease in allogeneic group is combination of Cyclosporine A and Metothrexate. RESULTS: On intention-to-treat analysis number of relapses was significantly lower in allogeneic SCT group (5,55%, p<0,005) while there were no difference between other two groups (autologous 12/26 - 46% vs 13/30 - 43,3%, ns). TTR was longer in autologous group but not significantly (9,4 range 2-42 vs 8,7 range 1-48 months). There huge significance in OS in allogeneic group compared to others while there is no significance between autologous and conventional group (log rank test-au:al 2,88, p<0,01; con: al 2,69, p<0,01; au:con 0,57, ns) independent from risk groups formed considering to cytogenetics. Median survival in allogeneic group was 37,5 months (range7-86months). *Discussion.* Allogeneic transplant is absolutely superior in treatment of AML pts over other two post remission options. To improve results of autologous SCT more attention should be given on the control of minimal residual disease and also probably by using bone marrow as an origin of stem cells.

1429

TREATMENT OUTCOME IN UNSELECTED PATIENTS WITH ACUTE MYELOID LEUKAEMIA: THE SINGLE CENTRE EXPERIENCE OF THE WILHELMINEN HOSPITAL

M.S. Schreder,[1] K. Strasser-Weippl,[1] N. Zojer,[1] B. Brigitte,[1] J.G. Meran,[2] H. Ludwig[1]

[1]Wilhelminenspital Wien, VIENNA, Austria; [2]Krankenhaus der Barmherzigen Brüder Wien, VIENNA, Austria

Background. Acute myeloid leukaemia (AML) occurs with an annual incidence of 2-3/100.000 population, its frequency rising with age. Treatment is based on combination chemotherapy with cytosine arabinoside and anthracyclines and has not changed during the last 30 years. Allografting is a valuable option in younger patients with high-risk features or those relapsing after standard chemotherapy. *Aims*. To assess treatment outcomes in an unselected patient population treated in our institution since April 1999. *Design and Methods*. 144 consecutive patients diagnosed with AML between April 1999 and February 2009 have been included in the study. Median age at presentation was 67.5 years (range, 19.2 - 93.6 years) with a gender distribution of 76 male and 68 female patients. Patients were stratified based on age and performance status and treated according to the current protocols of the "Ostdeutsche Studiengruppe fuer Haemato-Onkologie (OSHO)". Briefly, patients below 60 years of age were scheduled to receive 1 or 2 courses of standard induction chemotherapy with intermediate-dose Ara-C (1g/m^2 twice over 3 hours on days 1,3,5,7) and mitoxantrone (10 mg/m^2 on days 1-3) or idarubicine (12 mg/m^2 on days 1-3). Patients achieving complete remission (CR) after induction therapy received 3 cycles of consolidation chemotherapy using a five-day course of the same drugs as during induction. Patients over 60 years of age considered fit for intensive treatment received induction chemotherapy as described above with two consolidation cycles, whereas for the remaining patients, palliative chemotherapy or supportive care only, was offered. Results: All of the 42 patients below 60 years of age were submitted to standard therapy with curative intent. CR was achieved in 79% of these patients after 1 or 2 courses of induction therapy. Median progression-free survival in this cohort was 44.4 months, with an overall survival of 58% at 5 years. However, 14% of patients did not reach CR after double induction and 7% of patients died during the first cycle, mainly due to infectious complications. Allogeneic bone marrow transplantation was performed in 5 patients, resulting in long-term survival in 4 of these patients. Of the elderly patients among the study population, only 45 (44%) were judged to be in a clinical condition that would allow assignment to a curative treatment approach. CR was achieved in 59% of patients, whereas early deaths occurred in 20% of patients. Progression-free survival (median, 14.4 months) was found to be significantly shorter compared to younger patients, with a 5-year overall survival of only 19%. 57 patients received palliative chemotherapy (administered orally or subcutaneously) or best supportive care only. Median survival in these cohorts was 2.8 and 0.3 months, respectively, showing an only modest, albeit statistically significant impact of palliative chemotherapy on treatment outcome. *Conclusions*. These single institution data reflect the 'real life' spectrum of patients with AML, with the majority presenting at age above 60 years. Results compared favourably with treatment outcomes reported in large clinical trials.

1430

FOURNIER'S GANGRENE ASSOCIATED WITH ATRA

M. Gleeson, R. Desmond, P.T. Murphy

Beaumont Hospital, DUBLIN 9, Ireland

Background. Genital ulceration is a rare and poorly understood side effect of all-trans-retinoic acid (ATRA). Fournier's gangrene is the most severe manifestation of this complication. *Aims*. To promote awareness of this complication and to highlight that it may occur within the first week of ATRA therapy, which is earlier than previously thought. To demonstrate this complication does not preclude subsequent use of ATRA. *Case History*. We report the case of a 21-year old male who developed Fournier's Gangrene secondary to ATRA during week 1 of induction therapy for acute promyelocytic leukaemia (APL). Following diagnosis, he was commenced on idarubicin 12 mg/m^2 IV and ATRA 45 mg/m^2 orally, as part of the Spanish protocol. On the seventh day of induction chemotherapy he became febrile and complained of painful scrotal lesions, which had appeared several days earlier. He did not exhibit any other features of the retinoic acid syndrome (RAS). On examination there were several necrotic scrotal ulcers. Microbiology work-up was negative and fever failed to resolve with broad-spectrum antimicrobial therapy. A scrotal biopsy showed an acute inflammatory or necrotic process, consistent with the clinical diagnosis of Fournier's gangrene. The patient proceeded to urgent surgical debridement. Histopathology of debrided tissue confirmed Fournier's gangrene. Following debridement, he became apyrexial and the ulceration resolved completely. He continued on ATRA throughout induction therapy until molecular remission of APL. He received ATRA with subsequent consolidation courses and maintenance therapy, in accordance with the treatment protocol, without recurrence of the ulceration. His leukaemia remains in complete remission to date. Discussion: In the literature, there are reports of scrotal ulcer healing on discontinuation of ATRA and treatment with either topical or systemic steroids. In our patient, this treatment approach was not attempted in view of the need for urgent surgical debridement. The pathogenesis of scrotal ulceration in association with ATRA is not fully understood. Different histology findings are reported varying from acute and chronic inflammation to necrotising vasculitis. All previous case reports have documented scrotal ulceration occurring in week 2 of ATRA therapy. Uniquely in our case, scrotal lesions appeared early during week 1 of treatment. *Conclusions*. Clinicians and patients should be alert to this complication of ATRA therapy, which can occur earlier than previously thought. Following surgical debridement there was complete resolution of the ulceration and we were able to continue ATRA therapy according to protocol without subsequent recurrence. The development of Fournier's gangrene, the most severe complication of ATRA-induced genital ulceration does not preclude the subsequent use of this important therapy in patients with APL.

1431

ACUTE MYELOID LEUKEMIA AND TYPE II DIABETES MELLITUS IN COMPLETE REMISSION AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

D.M. Dima,[1] A. Cucuianu,[1] S. Arghirescu,[2] M. Serban,[2] L. Petrov[1]

[1]"Ion Chiricuta" Cancer Institute, CLUJ-NAPOCA, Romania; [2]Children's Hospital, Hematology and Transplant Department, TIMISOARA, Romania

Background. Bone marrow transplantation has become an important part of the treatment of hematologic disorders, but also of metabolic disorders and autoimmune diseases. Using animal models for autoimmune diseases it has previously been demonstrated that allogeneic bone marrow transplantation can be used to treat autoimmune diseases such as insulin-dependent diabetes mellitus. Aims. To present the case of a patient diagnosed with acute myeloid leukemia (AML) and type II diabetes mellitus, both in remission after allogeneic stem cell transplantation. *Design and Methods*. A.S. is a female AML patient, 54 years old, diagnosed in our institution with AML- M1, normal kariotype (FLT3 and NPM1 wild type) in January 2008. Between January and July 2008 she was treated with 3+7+Etoposide (ICE) induction chemotherapy and 4 courses of high dose Ara-C and Idarubicine consolidation chemotherapy. The patient had previously been diagnosed with type II Diabetes Mellitus and she was under insulin treatment, maintained during the entire chemotherapy schedule. In October 2008 the patient underwent sibling HLA-identical allogeneic stem cell transplantation, with Busulfan+ Cyclofosfamide conditioning. Since then, the patient was under immunosuppressive treatment with cyclosporine. Results. Complete hematological remission was obtained after the induction chemotherapy and was maintained ever since. After the stem cell transplantation the hematological recovery was satisfactory with the persistence of mild thrombocytopenia, anemia and lymphocytosis. The chimerism is 99%. Immediately after the transplantation was done there was no need for insulin treatment, since the blood glucose was constantly under 150 mg/dl. There was an episode of acute hepatic and cutaneous GVHD which resolved after corticosteroid therapy and an increase in cyclosporine dosage. No significant increase of serum glucose was observed despite corticosteroid therapy. Currently, there is a grade I chronic GVHD of the liver and the patient is under cyclosporine treatment, 200 mg/day. *Conclusions*. Our patient's case is a fortunate one where remission of both a hematologic disorder and an autoimmune disease was obtained by allogeneic stem cell transplantation. As autoimmunity seems to play a role in type 2 insulin-dependent diabetes mellitus, it would be interesting to see what happens when immunosuppressive treatment will eventually be tapered and stopped. It is possible that in the near future allogeneic stem cell transplantation will become a powerful strategy for treating patients with hematologic disorders and various intractable diseases, including autoimmune diseases.

1432

LEUKEMIC INFILTRATION OF RETINA IN AML, A CASE REPORT AND LITERATURE REVIEW

G. Shoja e Razavi, N. Borumand

Gorgan university of Medicine, GORGAN, Iran

Background. Leukemic infiltration of the retina without CNS involvement is a rare complication of AML, Here we report a case with retinal infiltration of Leukemic cells with typical fondoscopic features which presented during relapsed disease and was treated with systemic High Dose Cytarabin. The case was a 48 year old male,known case of AML ,M5 subtypewith normal cytogenetic study done through conventional method, who received conventional chemotherapy with 7/3 regimen during remission induction followed by 5/2 as consolidation.He was asymptomatic for 5 months and was following the stem cell transplant primary steps. Afterward he presented with fever and thrombocytopenia and bone marrow study proved relapsed disease.He was admitted again for salvage chemotherapy while he complained of blurred vision.Ophthalmologic consultation showed diffuse red spots with sharp margin and typical features of leukemic infiltration.The CNS cytologic study at the same time was negative as well as MRI of the brain with contrast. High Dose Cytarabin with 3 gr/m2 bid for 3 days together with Mitoxantrone 12 mg/m^2 for D1 and D2 was given as salvage chemotherapy. The visual symptoms were not changed for about 2 months although the patient achieved a complete remission after prolong neutropenia lasting about 38 days and complicated with neutropenic fever and disseminatec Herpes infection. Visual acuity returned to 8/10 after about 3 months without any specific ophthalmologic therapy and no CNS radiotherapy was done either ,due to lack of CNS infiltration. The patient is still in complete remission after 8 months and is able to read with little difficulties. Allogeneic stem cell transplantation from matched related donor is planned for the patient. Leukemic infiltration of the retina is a rare complication for AML and topical treatments are generally not aplicable because of the disseminated nature of the lesions, High dose Cytarabine might be effective in these infiltration as well as in CNS involvement and relapses.

1433

PRIMARY MYELOID SARCOMA (MS) OF THE STOMACH: A CASE REPORT

C.-D. Badrakhan, S. Dreke, M. Heinsch, S. Haase, A. Giagounidis, C. Aul

St. Johannes Hospital, DUISBURG, Germany

Myeloid sarcoma is an uncommon solid extramedullary accumulation of myeloid blasts. Most often it is diagnosed in the course of acute leukemia, an isolated manifestation is very rare. We report on a 63-year-old male patient who underwent examination for melena and significant anemia. A tumor of the small gastric curvature with a size of 4 cm was discovered. Although malign lymphoma was diagnosed in the first place a comprehensive histopathological and immunhistological examination revealed a manifestation of acute myeloid leukemia. Immunhistologically, the malign cells displayed positivity for CD33, CD34, CD43, CD117, TdT, Lysozym, ASD and MPO. In line with the diagnosis of MS negativity for CD2, CD3, CD20, CD30, CD56, CD61, CD68, CD79, Glycophorin C and S100 was shown. In FACS-analysis, positivity for CD13,

CD33, CD34, CD45, CD11b, HLA-DR and MPO could be observed. Neither peripheral blood nor bone marrow presented signs of acute leukemia. The patient received two courses of intensive AML-type chemotherapy according to the protocol of the German AML Cooperative Group. Although there was just a moderate decrease of tumor size chemotherapy was continued with cytarabine and mitoxantron. The following examinations did not show any change in tumor size but a still viable tumor. Operation, radiotherapy and combination of both were discussed to continue treatment. At this time FACS-analysis and light microscopy of the bone marrow showed for the first time an infiltration with myeloid blasts. These cells were marked by the same antigen pattern as those blasts initially isolated from the gastric tumor. Cytogenetic examination revealed a complex aberrant karyotype with an involvement of 15 chromosomes. The antileukemic treatment was continued with chemotherapy according to the FLAG-Ida protocol. After regeneration of hematopoiesis bone marrow blast count had increased from 50% to 90%. Subsequently the patient was transferred to another center to receive allogeneic bone marrow transplantation. Isolated gastric manifestation of MS is an outspoken rariety with just a few cases published world-wide. Thus its diagnosis is a challenge for clinicians and pathologists. In almost all reported cases primary MS heralded the imminent development of acute leukemia. Therefore, they should be considered as the initial manifestation of a systemic disease rather than a localized process. Prognosis is generally poor. Allogeneic bone marrow transplantation seems to offer best chances for prolonged survival or cure. On this account, MS should be considered in the differential diagnosis of gastric tumors to avoid incorrect treatment of a potentially curable condition.

DOES INTENSIVE ANTI-LEUKAEMIC THERAPY REALLY IMPROVES THE PROGNOSIS FOR PATIENTS SUFFERING FROM ISOLATED MYELOID SARCOMA?

D. Antic, D. Tomin, I. Elezovic, M. Perunicic, G. Jankovic, N. Suvajdzic, M. Gotic, A. Vidovic, J. Bila, I. Djunic, M. Mitrovic

Clinical Center Serbia, BELGRADE, Serbia

Introduction. Myeloid sarcoma /MS/ represents the tumour mass made from blasts, or immature myeloid cells, which can appear as solitary tumours, or multiple changes in different tissues and organs. Acute myeloid leukaemia /AML/ develops within 10.5-11 months in almost 90% patients with isolated MS who initially do not receive any treatment. The optimal therapy has not been defined yet. Chemotherapy, stem cell transplantation /SCT/, radiotherapy, surgical resection, or combination of these methods has been used, from case to case. Aim: Study goal is to estimate the efficacy of anti-leukaemia therapy in patients with isolated MS, overall survival and period until systemic disease develops. *Design and Methods*. This study included patients with isolated MS, who had been diagnosed at Institute of Haematology of Clinical Centre of Serbia, from 2002 until 2008. Group was included patients diagnosed for MS based on WHO criteria and who did not have signs of AML, chronic myeloid proliferative disorder or MDS in bone marrow at the point of establishing the diagnosis for MS. *Results*. Average age of our patients was 37.8 years /range: 19-67/. The diagnosis of uterus MS was established for two female patients, as well as the diagnosis of MS localized in the spine, heart, chest, testicles, skull base, tonsils, and lymph nodes, each for one patient. Intensive anti-leukaemic therapy was applied in five patients, whilst initial surgical treatment was performed in four patients. Complete remission /CR/, induced with this initial treatment therapy model, was achieved in all patients who had been treated surgically, and in three patients who had been treated with anti-leukaemia therapy. Currently four patients are alive, and all in CR. Average overall survival in the whole group amounts 27.5 months. Average survival in the group of patients on chemotherapy was 23.3 months, and in the group with initial surgical treatment and monitored afterwards, survival was 31.5 months. One patient of five who had been initially treated with systematic approach, developed therapy resistant AML, and the other died in the course of treatment due to the development of sepsis. SCT had been performed in three patients treated with anti-leukaemia therapy /in two allo SCT and one auto SCT/, and all of them are alive and achieved CR. Two patients among four, initially treated surgically, developed systemic disease, and in other two extramedullar relapse occurred. Only one of them is alive and is in CR, 49 months after completing AML treatment. In our group, average survival until the development of systemic leukaemia was 21.9 months. Average survival in the group of patients who had not developed systemic leukaemia was 29.2 months, and in the group of patients who developed systemic leukaemia average survival time was 25.3 months. *Conclusions*. Our study did not show that anti-leukaemia therapy improved survival in patients with myeloid sarcoma, but further investigations, which would include more patients and long time follow up period, are needed.

1435

ACUTE MYELOID LEUKEMIA AND BLEEDING DISORDERS AT DIAGNOSIS. A SINGLE CENTRE EXPERIENCE

E. Kapsali, Ch. Tsaousi, L. Benetatos, P. Bouranta, K. Bourantas

University Hospital, IOANNINA, Greece

Backround. Bleeding manifestations at diagnosis of Acute Myeloid Leukemia(AML) can occur with a frequncy as 50%. Their cause is thrombocytopenia because of marrow infliltration or Disseminated Intravascular Coagulation(DIC) that can complicate acute leukemia, mainly acute promyelocytic type. *Aim*. We searched for incidence of coagulation disorders and bleeding manifestations in our AML patients and whether this could influence their clinical course. *Design and Methods*. Forty AML patients are included in this study and from their records we had their coagulation test results and full blood count at diagnosis and whether they presented with sings of bleeding or not.Platelets $<100x10^9$/L ,INR>1.2,APTT>30 sec and fibrinogen levels <200mg/dl were considered abnormal. *Results*.- This study included 28 men of average age 68 years (range 37-89) and 12 women of average age 65 years (range 45-86). De novo AML was diagnosed in 29 patients and secondary AML in 11 (7 patients had MDS, 2 patients had CMML, 1 patient had PV and 1 had ET). Acute promyelocytic leukemia(APL) was diagnosed in 2 patients. During diagnosis bleeding manifestations were reported in 10 patients (6 patients had thrombocytopenia (15%), and 4 patients had DIC (10%)). Among patients with DIC 2 had APL.Prolongation of INR was recorded in 7 patients while prolongation of APTT in 5, low fibrinogen levels were noted only in AML patients with DIC. There was no episode of severe bleeding manifestation(e.g. cerebral bleeding) that could threaten the life of patients. Four of the male patients are alive with a median overal survival(OS) of 51 months, all of them are younger than 60 years and four women are alive with a median overal survival of 29 months, 3 of them are younger than 60 years. *Conclusions*. Bleeding manifestation at diagnosis of AML is quite often and we search our records for its frequency in our patients. Although this is a small group of patients we record a frequency of 25%. Bleeding is mainly complicating DIC which is a prominent feature of APL. Even when it is present bleeding diathesis does not play an important role in patients OS. Age is an important factor for AML patients survival.

1436

FLAG-IDA REGIMEN IN THE TREATMENT OF REFRACTORY/RELAPSED ACUTE MYELOBLASTIC LEUKEMIA: SINGLE-CENTER EXPERIENCE

G. Genadieva-Stavrik,[1] B. Georgievski,[2] L. Cevreska,[2] O. Karanfilski,[2] A. Pivkova,[2] Z. Stojanoski,[2] S. Krstevska-Balkanov,[2] D. Dukovski[2]

[1]University hematology Clinic, SKOPJE, Macedonia; [2]University Hematology Clinic, SKOPJE, Macedonia

Background. Conventional chemotherapy is highly effective in the treatment of acute myeloblastic leukemia (AML). About 50-80% of adult patients with *de novo* acute myeloblastic leukemia achieve complete remission (CR) with currently available chemotherapy regimens consisting of antracyclines and cytarabine. However, relapse develops in more that 40% of the cases within two years, and 15-25% of patients fail to achieve complete remission because resistant to treatment or death. The management of cases with primary refractory and /or relapse disease is very difficult and prognosis in this subset of patients after several different chemotherapy combinations is still very poor with a CR rate 33-41%, and median duration of CR 6-24 months. Refractory/relapsed acute myeloblastic leukemia has always been a challenging problem for hematologist. *Aims*. We evaluated efficacy and toxicity profiles of FLAG-Ida combination chemotherapy in patients with refractory/relapsed AML. *Methods and Results*. At the University Hematology Clinic in Skopje, Macedonia, in the period 2006-2008, fifteen patients with refractory/relapsed acute myeloblastic leukemia were treated with FLAG-Ida regiment. Patients were between 16-52 years old, 4 female and 11 male. They were treated with fludarabine 30 mg/m^2, cytosine arabinoside (AraC) 2 g/m2 for 5 days, Idarubicin 10 mg/m^2 for 3 days, and granulocyte colony stimulating factor G-CSF 5 μg/kg from day 0 till neutrofil recovery (ANC >1.0 x10^9/l). Complete remission were achieved in 7 patients (47%), there patients (20%) died of post chemotherapy com-

plications, and 5 failed to achieve complete remission. Out of 7 patients who achieved complete remission, 3 went autologous bone marrow transplantation, 2 went allogeneic bone marrow transplantation, and 2 are being evaluated for the same. Major complication encountered were mucosistis, transient hepatic toxicity, fungal and bacterial infections. *Conclusions*. Our experience confirmed that FLAG-IDA regimen is well tolerated and effective therapy in relapsed/refractory acute myeloid leukemia. The toxicity is acceptable, enabling most patients to receive further treatment, including transplantation procedures. FLAG-Ida is a good choice in cases with refractory/relapsed acute myeloblastic leukemia for salvage chemotherapy and it is wise to consolidate it with hematopoetic stem cell transplantation.

1437

DIFFERENT MOLECULAR REMISSION ACHIEVEMENT TIME IN INFANTS WITH MLL-REARRANGED ACUTE LYMPHOBLASTIC LEUKEMIA CORRESPONDS TO OUTCOME - REPORT FROM MLL-BABY STUDY GROUP

G. Tsaur,[1] T. Nasedkina,[2] A. Ivanova,[3] Y. Yakovleva,[1] T. Riger,[3] A. Popov,[4] E. Shorikov,[3] L. Saveliev,[4] L. Fechina[3]

[1]Regional Children's Hospital, Institute of Medical Cell Technologies, EKATERINBURG, Russian Federation; [2]Engelgardt Institute of Molecular Biology, MOSCOW, Russian Federation; [3]Regional Children's Hospital, EKATERINBURG, Russian Federation; [4]Ural State Medical Academy, EKATERINBURG, Russian Federation

Background. MLL-baby protocol, containing all-trans retinoic acid (ATRA), for the treatment of infants with acute lymphoblastic leukemia (ALL) has recently been introduced. Aim. To find out a single time point (TP) for minimal residual disease (MRD) monitoring by RT-PCR of fusion gene transcripts (FGt), that clearly discriminate patients (pts) with different outcomes. *Design and Methods*. To date 35 pts were enrolled into MLL-Baby study. MLL rearrangements were detected in 26 pts (74.5%). Monitoring of FGt was performed in 17 infants with defined MLL translocation partner genes and more than 4 follow-up samples. MRD-negativity was defined as absence of FGt verified by nested RT-PCR with sensitivity 1E-5. Median follow-up in observed group was 25.1 months (range 5.7-65.3). There were 12 pts with MLL-AF4, 2 pts with MLL-MLLT10, 2 pts with MLL-EPS15, 1 patient (pt) with MLL-MLLT1. Bone marrow samples were obtained at the time of diagnosis, at day 15 of remission induction (TP1), end of remission induction (TP2), after one week of first ATRA administration (TP3). The next TPs depended on the arm of treatment. Pts with MLL-AF4 were stratified into high-risk (HR) arm, thus TPs for MRD were scheduled before each HR blocks followed ATRA administration (TP4-TP9). Pts with MLL rearrangements other than MLL-AF4 were recruited into intermediate risk group, where MRD was estimated before each reinduction (TP4-TP6). Written informed consent was obtained in all cases.

Table.

	First group	Second group	P
Total N of patients	12	5	
MLL-AF4	7	5	0.09
MLL-MLLT1	1	0	0.64
MLL-MLLT10	2	0	0.88
MLL-EPS15	2	0	0.88
Median age, mo (range)	7.00 (0.03-10.83)	5.43 (1.70-6.93)	0.17
Initial WBC × 10^6 /uL, (range)	99.35 (19.6-410)	131 (21.5-370)	0.71
≥ 1000 blasts at day 8	2	0	0.88
CNS involvement	3	2	0.97
Number of relapses	2	2	0.39
In CCR	10	3	0.69

Results. All pts were MRD-positive at TP1. 3 pts (two MLL-AF4-positive and one MLL-MLLT10-positive) became MRD-negative at TP2. By TP3 one MLL-AF4-positive and all MLL-AF4-negative pts were MRD-negative. At TP4 other six MLL-AF4-positive pts totally eliminated FGt. The latest TP when pt achieved molecular remission was TP9. It was detected in one pt with successive reduction of MRD value, measured by real-time quantitative PCR (RQ-PCR). 2 pts with MLL-AF4 who never achieved MRD-negativity relapsed at TP8 and at Protocol II (TP10). Alternatively, MLL-AF4-positive girl who had achieved molecular remission at TP4, converted to MLL-positive status at TP8 and subsequently relapsed at TP9. Another relapse that occurred in well-responded group was in MLL-EPS15-positive boy during maintenance therapy. *Conclusions*. Retrospectively, based on achievement of MRD-negativity and outcome, we divided pts into 2 groups. Detailed pts characteristics are presented in table 1. First group included 12 pts who achieved molecular remission by TP4, where 2 relapses occurred (MLL-AF4-positive and MLL-EPS15-positive). Thus 70-months RFS was 83%±10%. Among second group, consisted of 5 MLL-AF4-positive pts that had not achieved molecular remission by TP4, there were 2 relapses. In 3 others consecutive reduction of MRD value till the undetectable level was observed. RFS was 60%±21%. Hence, absence of FGt by TP4 for the pts with MLL-AF4 and by TP3 for the other MLL rearrangements allows us to distinguish low risk pts.

1438

BAX / BCL-2 EXPRESSION IN CHILDHOOD AND ADOLESCENTS' ACUTE LYMPHOBLASTIC LEUKEMIAM

Kaparou,[1] M. Kalmanti,[2] D. Choumerianou,[2] C. Perdikogianni,[2] E. Stiakaki[1]

[1]University Hospital of Heraklion, University of Crete, Greece, HERAKLION, Greece; [2]University Hospital of Heraklion, University of Crete, HERAKLION CRETE, Greece

The mitochondrial'mediated pathway of apoptosis is regulated by the bcl-2 family of antiapoptotic (bcl-2, bcl-xl, mcl-1) and proapopotic proteins (bax, bad, and bak). Although over-expression of bcl-2 associated with poor outcome in hematological malignancies and high bax levels related with a good prognosis in AML, studies in ALL yielded conflicting results. Western blotting studies determined the level of bcl-2 in childhood ALL and showed a correlation between high bax expression and increased relapse probability. However, it has been suggested that the bax/bcl-2 ratio may be more important than either marker alone in determining apoptosis. Aim. The estimation of Bax, Bcl-2 and Bax /Bcl-2 expression ratio in childhood ALL compared with benign cytopenias and solid tumors as well as the correlation of these values with ALL prognostic factors. *Design and Methods*. Sixty nine children were enrolled in the study. Bone marrow from 19 children with ALL at diagnosis, 19 months-18years old and 16 children with ALL in remission on day 33, were studied. Twenty children with benign cytopenias and 14 children with solid tumors without bone marrow involvement were studied as control groups. Five hundred nanograms of extracted RNA were used for cDNA synthesis (Reverse Transcription System, Promega). Real-Time RT-PCR was performed using commercial primer sets (Quantitect Primer Assay, QIAGEN) and SYBR Green (Quantitect SYBR Green, QIAGEN). The cell line HL-60 was used for the creation of a standard curve including GAPDH. Duplicate reactions were set up for each sample and were run in ABI PRISM 7700 Sequence Detection System. Bax, bcl-2 expression and Bax/Bcl-2 ratio were studied within the ALL group at diagnosis in correlation with prognostic factors such as age, White Blood Count, haemoglobin levels and the risk group according BFM ALL-2000 treatment protocol. Analysis was also performed between the ALL group at diagnosis compared with ALL patients in remission and the control groups, using the SPSS program. Results. The analysis within the ALL group at diagnosis did not show any statistical significant difference for the values of bax, bcl-2 and bax/bcl-2 ratio in relation with the age, haemoglobin, leucocytes values and the risk group. The comparison between ALL at diagnosis and the control groups did not reveal any significant difference although the levels of bcl-2 were much higher in ALL compared with the solid tumors. Statistically significant higher values of bax /bcl-2 ratio (0.713 vs 0.17 p=0.046) were estimated in the older children (>10 years) within the ALL high risk group compared with the younger ones. Within the ALL high risk group the bax/bcl-2 ratio was statistically higher at diagnosis compared to remission (0.34 vs 0.0365, p=0.028). *Conclusions*. The bax, bcl-2 and bax/bcl-2 expression ratio did not show any statistical difference in relation with ALL prognostic factors. Nevertheless, significantly higher values of bax /bcl-2 ratio were estimated for high risk patients at diagnosis compared to remission and for older children versus younger ones. Higher levels of bcl-2 were estimated also in ALL compared with the control groups. The prognostic implications of these data are under investigation.

1439

C677T AND A1298C MTHFR POLYMORPHISMS ROLE IN GRADE 3-4 TOXICITY AFTER CHEMOTHERAPY WITH HIGH DOSE METHTREXATE (HDMTX)

P. Martin-Cabrera,[1] M.T. Gomez-Casares,[1] J. Perez,[1] A. Molines,[2] J.D. Gonzalez-San Miguel,[3] J. Lopez,[1] A. Suarez,[1] T. Ramirez,[1] T. Molero[1]

[1]Hospital Dr. Negrin, LAS PALMAS DE GRAN CANARIA, Spain; [2]Hospital Materno Infantil, LAS PALMSA DE GRAN CANARIA, Spain; [3]Hospital Insular, LAS PALMAS DE GRAN CANARIA, Spain

Background. Polymorphisms in genes affecting drug transport, metabolism, or drug targets may directly influence drug response. Thus, MTHFR polymorphisms could potentially modify the therapeutic effects of any drug that interferes with folate transport or metabolism, such as methrotexate (MTX), as well as play an important role in MTX mediated toxicity. More over, a relationship has also been described between MTHFR polymorphisms and the incidence of ALL. *Aim*. The aim of this study was to determine whether the combined effect of HDMTX treatment and decreased activity of MTHFR associated to C667T and A1298C polymorphisms could play any role in MTX related toxicity. Patients & *Design and Methods*. DNA from peripheral blood and/or bone marrow samples of 26 ALL patients (15 adults and 11 children) were analysed for the MTHFR C677T and A1298C polymorphisms using Q-PCR and Melting Curve analyses to determine their genotype. All patients were treated according to PETHEMA LAL-AR/2003 (adults) and LAL-AR-N/2005 (paediatric patients) protocols, with high dose methrotexate (HDMT) at 3mg/m^2 for adults and 5 mg/m^2 for pediatric patients. Grade 3-4 renal, lung, cutaneous and mucous toxicities, as described by the WHO Common Toxicity Criteria v2, were then recorded for each patient. *Results*. Grade 3-4 HDMTX related toxicity was detected in six (23%) patients, all of them adults, carrying a given polymorphism. Their genotypes were: C667T in 66% (2 heterozygous and 1 homozygous), A1298C in 50% (2 heterozygous) and 16% double heterozygous.This group was then compared to the group of adults that did not develop any toxicity or grade 1-2 toxicity. This group's genotypes were: C677T in 66% (3 heterozygous and 1 homozygous), A1298C in 33% (1 heterozygous) and 22% double heterozygous. Three of the patients (15%) did not have MTHFR polymorphisms. The overall incidence of MTHFR polymorphisms in the ALL population studied was 88% compared to 66% in the healthy population used as control. *Conclusions*. No significant association was found between the different polymorphisms and grade 3-4 HDMTX related toxicity. However, if the adult population is analysed separately, a higher involvement of the A1298C polymorphism can be seen in relation to toxic effects (50% in those patients who developed toxicity in contrast to 33% in those who did not). With an incidence of HDMTX related toxicity of 23%, which varies widely in the literature, and with no MTHFR polymorphism associatd in particular to toxicity, we doubt whether MTHFR polymorphisms should be routinely performed in ALL patients at diagnosis as a predictor of severe adverse effects to come. A lower incidence in the A1289C homozygous genotype was found in comparison to northern Eurpean populations. A higher incidence of MTHFR polymorphisms was found in the ALL population when compared to healthy donors, making us think further studies should be carried out to determine a potential role in ALL pathogenisis in particular, ant tumorigenesis in general.

1440

T-CELL RECEPTOR AND IMMUNOGLOBULIN GENE REARRANGEMENT PATTERNS IN POLISH PEDIATRIC T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS

M.D. Kraszewska,[1] M. Dawidowska,[1] L. Sedek,[2] M. Wojnowska,[1] A. Gaworczyk,[3] I. Malinowska,[4] M. Niedzwiecki,[5] K. Derwich,[6] J. Trelinska,[7] K. Muszynska-Roslan,[8] I. Olejnik,[9] A. Mizia-Malarz,[10] W. Badowska,[11] M. Lejman,[3] J. Kowalczyk,[3] M. Witt1, T. Szczepanski[2]

[1]Institute of Human Genetics, Polish Academy of Sciences, POZNAN, Poland; [2]Department of Pediatric Hematology and Oncology, Medical University of Silesia, ZABRZE, Poland; [3]Children's University Hospital, LUBLIN, Poland; [4]Department of Pediatric Hematology and Oncology, Medical University of Warsaw, WARSZAWA, Poland; [5]Dept. of Pediatric Hematology, Oncology and Endocrinology, Medical University, GDANSK, Poland; [6]University of Medical Sciences, POZNAN, Poland; [7]Dept. of Pediatric Oncology, Hematology and Diabetology, Medical University, LÓDZ, Poland; [8]Department of Pediatric Oncology, Medical University, BIALYSTOK, Poland; [9]Chorzów Center of Pediatrics and Oncology, CHORZÓW, Poland; [10]Department of Pediatrics, Medical University of Silesia, KATOWICE, Poland; [11]Regional Specialistic Pediatric Hospital, OLSZTYN, Poland

Background. Using current treatment protocols, it is possible to cure approximately 70% of children with T-cell acute lymphoblastic leukemia (T-ALL). Leukemia relapse remains the main cause of therapy failure. This reflects significant biological and clinical heterogeneity of this disease. T-cell receptor (TCR) gene rearrangement patterns in T-ALL are known to reflect the maturation stage arrest of the malignantly transformed thymocytes and hence provide data on the biological subclassification of this malignancy. Additionally, identification of the TCR gene rearrangements is a prerequisite for RQ-PCR-based minimal residual disease (MRD) monitoring, which provides insight into the therapy response and prognosis in T-ALL patients. *Aims*. We aimed at identification of TCR gene rearrangement pattern in Polish T-ALL patients. *Design and Methods.* The study group consisted of 48 consecutive children with T-ALL treated at the centers of Polish Pediatric Leukemia and Lymphoma Study Group (PPLLSG). Detection of TCR and immunoglobulin (Ig) gene rearrangements was performed with heteroduplex PCR analysis using primers and protocols established by BIOMED-1 and BIOMED-2 Concerted Actions. The analyses comprised the rearrangements in TCRG, TCRD, TCRB loci and incomplete IGH gene rearrangements. Additionally, we screened patients for SIL-TAL1 rearrangements that are specific targets for MRD monitoring because of their unique junctional sequence. Results: We have detected 166 clonal TCR/Ig gene rearrangements in total, 3.5 per patient on average (range 0-7). At least one rearrangement was detected in 43 patients (90%) and at least 2 rearrangements in 42 patients (88%). No rearrangements were detected in 5 patients (10%). A total of 76 TCRG rearrangements were detected in 40 patients (at least one in 83% of T-ALL) and at least two rearrangements were found in 34 patients (71%). Twenty four TCRD rearrangements were identified in total; at least one rearrangement was detected in 19 patients (40%) and two TCRD rearrangements were detected in 5 patients (10%). At least one TCRB gene rearrangement was detected in 36 patients (75%), at least two rearrangements were detected in 16 patients (33%). SIL-TAL1 rearrangements were detected in 4 patients (8%). There were 7 incomplete IGH rearrangements detected in 7 patients (15%). Conclusion: The incidence of particular Ig/TCR gene rearrangements in Polish children with T-ALL is comparable to the data reported in literature, which indicates that there are no particular distinct ethnical Polish features of the immunogenotype as compared to other nations. Our results also prove that the BIOMED-1 and BIOMED-2 protocols enable detection of Ig/TCR gene rearrangements in most pediatric T-ALL patients, which form basis for introduction of routine MRD monitoring in childhood T-ALL in Poland.

1441

THE MTHFR POLYMORPHISMS AND SUSCEPTIBILITY TO CHILDHOOD ALL

F. Atashrazm, F. Zaker, M. Aqaeipour, V. Pazhakh, P. Rasi Qaemi, E. Shahabi, F. Razmkhah

Iranian University of Medical Science, TEHRAN, Iran

Background. Folate plays an important role in DNA methylation, synthesis and repair. Reduction of 5,10 methylenetetrahydrofolate - a donor for dUMP to dTMP- is catalyzed by methylenetetrahydrofolate reductas (MTHFR). Two common polymorphisms (C677T and A1298C) in the gene coding for MTHFR reduce MTHFR enzyme activity and have been shown to associate with the susceptibility to malignancies. Aim: Studies on the role of these two polymorphisms in the susceptibility to acute lymphoblastic leukemia (ALL) led to discrepant results. Moreover assessment of the prevalence of the two most common polymorphisms of MTHFR has not been studied in the Iranian population so far and it is presented for the first time. *Design and Methods*. Using PCR and RFLP analysis, we studied the prevalence of the C677T and A1298C MTHFR genotypes in 103 pediatric ALL patients and 160 age-sex matched control. We calculated Odds ratio of MTHFR genotypes to examine if one or both of these polymorphisms are associated with childhood ALL. Results: No significant association between two common polymorphisms of MTHFR and risk of ALL were observed. The other result was the high prevalence of 1298CC which was significantly higher than that reported for most Asian and European population. Conclusion: Our findings suggest that the MTHFR C677T and A1298C gene variants do not have a major influence on the susceptibility to pediatric ALL, but despite of absence of significant association, the frequency of MTHFR 677TT among cases was lower comparatively to control supporting previous indications that it might confer protection against ALL.

1442

CLINICAL USEFULNESS OF ARRAY COMPARATIVE GENOMIC HYBRIDIZATION FOR DETECTION OF CHROMOSOMAL ABNORMALITIES IN CHILDHOOD PRECURSOR B-ACUTE LYMPHOBLASTIC LEUKEMIA

H.Y. Chung, K.H. Kim, K.R. Chun, S.S. Jang, C.J. Park, H.S. Chi, H.J. Im, J.J. Seo, E.J. Seo

Asan Medical Center, SEOUL, South-Korea

ETV6-RUNX1, generated by the chromosomal translocation t(12;21)(p13;q22), is the most prevalent fusion gene in pediatric precursor B-ALL. Secondary abnormal changes are commonly found in these groups, occurring in some 60-80% of ETV6-RUNX1 cases. However, not all ETV6-RUNX1 positive patients have identifiable secondary chromosomal changes, as found by standard routine cytogenetics. We report here multiple gains and losses that are undetectable by cytogenetics but identifiable by high resolution array comparative genomic hybridization (array-CGH). A 6-year-old boy presented for uncontrolled epistaxis, was diagnosed for precursor B-ALL. ETV6-RUNX1 rearrangement is positive by FISH and RT-PCR. Karyotype was analyzed from the diagnostic bone marrow as follows: 46,XY,add(1)(p13),del(2)(q33q37),del (6)(q15),add(11)(q22),add(12)(p11.2),del(15)(q26)[2]/46,idem,add(1)(p22)[4]/46,idem,-2,der(5) t(2;5)(p11.2;p11.2),+mar[3]/46,XY[21] FISH with a dual-color extra signal probe showed a ETV6/RUNX1 fusion and non-translocated ETV6 deletion. The array-CGH using 244K whole genome microarray provided comprehensive information about genomic alterations. The patient had a deletion of 4Mb on 12p13, encompassing the ETV6 gene. Array-CGH exhibited a gain of 6q14.3, from 90651516-91067469 base pairs and a loss of 11q13.4-q23.2, from 75277556-115420958 base pairs. These regions contains gene for BACH2 and ATM respectively. Loss of ATM or gain of BACH2 has not been reported in precursor B-ALL. Losses of 3q3q26.1, 6q26 and 14q32.3 were also found but these regions are known to be copy number variations. The results of array-CGH are consistent with conventional karyotype partially, but additional chromosomal abnormalities were found. This case shows genomic array-CGH may become a powerful tool to discover subtle chromosomal imbalance changes in patients with malignancies.

TREATMENT RELATED MORTALITY IN INFANTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA DURING ALL TRANS-RETINOID ACID CONTAINING MLL-BABY THERAPY

L. Fechina,[1] E. Shorikov,[1] O. Streneva,[2] O. Khlebnikova,[1] G. Tsaur,[2] L. Saveliev,[3] A. Popov,[3] D. Litvinov,[4] N. Myakova,[4] K. Kondratchik,[4] E. Inyushkina,[4] A. Shamardina,[1] E. Boichenko,[5] O. Aleinikova,[6] A. Karachunsky,[4] A. Roumiantsev[4]

[1]Regional Children's Hospital, EKATERINBURG, Russian Federation; [2]Research Institute of Cell Technologies, EKATERINBURG, Russian Federation; [3]Ural State Medical Academy, EKATERINBURG, Russian Federation; [4]Federal Research Center of Pediatric Hematology and Oncology, MOSCOW, Russian Federation; [5]City Children's Hospital 1, ST. PETERSBURG, Russian Federation; [6]State Center of Pediatric Oncology and Hematology, MINSK, Belarus

Background. Different international study groups have reported adverse prognostic factors and unfavorable events negatively influenced on clinical outcome in infants with acute lymphoblastic leukemia (ALL). Besides high proportion of early relapses, treatment related toxicity also resulting in poor survival in this age group. *Aim*. To estimate treatment related mortality rate during induction and post induction therapy in infants treated with ATRA containing MLL-Baby Protocol. To determine main cause of treatment related deaths in this cohort of patients. *Design and Methods*. MLL-Baby Protocol intended for infants' ALL treatment is recently applied therapy regimen in Russia and Belarus. Preliminary data indicates that this treatment approach results in significant early relapses prevention. Between July 2003 and November 2008, 35 babies with newly diagnosed ALL were treated with MLL-Baby Protocol, which consisted of short 7-14 days ATRA courses in daily doses 25 mg/m2 and conventional chemotherapy. Among this cohort of patients, 19 infants were stratified to intermediate risk-group (ImRG) and 16 to high risk-group (HRG) schedules according to the type of MLL-rearrangement and remission status on day 36/43. *Results*. Three patients (8.5%) died during remission induction treatment prior to start of first ATRA administration. All of them have had high initial WBC count (73; 612 and 1250 /μl); were younger 6 months (17 days, 2 and 3 months old); had MLL-rearranged BI-ALL: two with t(4;11)/MLL-AF4 and one with t(11;19)/MLL-ENL. All of these patients were dexamethasone poor responders. Two children with initial WBC > 600 /μL died on days 52 and 58 due to severe infection associated with prolonged neutropenia and hypocellular bone marrow without signs of normal regeneration. Youngest patient died on day 9 from septic shock. Three patients (9.4%) out of 32 who have achieved complete remission (CR) died within first month after induction therapy completion. All of them were diagnosed with MLL-rearranged BI-ALL: two had t(4;11)/MLL-AF4 and one - t(11;19)/MLL-ENL and were stratified to HRG and ImRG arms respectively according to MLL-Baby stratification criteria. One 8 months old patient from ImRG has died from ATRA-syndrome developed during second course of ATRA, one died from severe infection and one from other reason. *Conclusions*. 1. Although, the proportion of treatment related deaths was rather high: 5 (14.3%) cases in 35 patients, ATRA associated death has been registered in one case (2.8%). This death might be prevented by timely ATRA discontinuation and ATRA-syndrome treatment. Our data demonstrates acceptable safety profile of ATRA administration in infants with ALL. 2. More frequently, 4 out of 5 patients died from severe infections (11.4%). Young age - below 6 months, presence of MLL rearrangements, profound immunosupression have maintained poor response to standard infectious prophylaxis and treatment. Dexamethasone in daily dose 6 mg/m^2, also seems to adversely influence on the life threatening infections rate in our patients.

CLINICAL UTILITY OF MINIMAL RESIDUAL DISEASE IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA: 7 YEAR EXPERIENCE IN A PEDIATRIC HEMATOLOGY-ONCOLOGY UNIT

K. Katsibardi, M. Moschovi, K. Karamolegou, Ch. Papathanasiou, M. Braoudaki, F. Tzortzatou-Stathopoulou

Medical School, University of Athens, "Aghia Sophia" Children's Hospital, Athens, ATHENS, Greece

Background. Rearrangements of the immunoglobulin heavy chain (IgH) and the T-cell receptor (TCR) genes constitute a universal target for minimal residual disease (MRD) detection in childhood acute lymphoblastic leukemia (ALL). Aim: The aim of the present study was to evaluate the clinical utility of MRD in children diagnosed with ALL, within a 7-year period. *Design and Methods*. Totally 716 polymerase chain reactions (PCRs) were performed using DNA extracted from bone marrow samples of 91 patients (8 PCRs per patient). Patients were diagnosed with B-cell ALL (N=85) and T-cell ALL (N=6). Sequential monitoring of MRD was performed at diagnosis, at the end of induction and at regular time points during chemotherapy and after treatment completion. Seven VH primers (VH family) were used to detect rearrangement of the IgH gene (CDRIII region) by PCR. In patients with T-ALL nested PCR was performed to detect rearrangements of the TCRα, TCRβ and TCRγ genes. Results: Rearrangement of the IgH was detected in 69/85 (81%) patients with B-ALL, at diagnosis. The commonest clone at diagnosis was VH3 (72%). In 3/16 patients without identified rearrangement at diagnosis, positive PCRs were detected during chemotherapy treatment, prior to relapse. PCR was negative at the end of induction, as well as, in most samples during and after treatment in 59/69 (85%) patients with identified IgH rearrangement at diagnosis. PCR remained positive at the end of induction in 10/69 patients. However, 4/10 had negative PCRs in all subsequent samples and were in clinical remission. Furthermore, in 8/69 patients, with negative PCR at the end of induction, PCR positivity reappeared 1-12 months after treatment completion. These 8 patients were in clinical remission, with all followed samples being negative for MRD. Finally, 9/85 (10%) patients with B-ALL relapsed. Six of them had positive PCR at diagnosis, at the end of induction and in most samples during chemotherapy treatment. In the other 3/9 patients that relapsed, IgH rearrangement was not detected at diagnosis, but in most samples prior to the relapse. In the 6 patients with T-ALL, rearrangement of the TCRδ gene was identified in most cases (4/6). All these patients reached clinical remission. *Conclusions*. Rearrangement of the IgH by PCR is a significant tool for MRD monitoring and prognosis in acute lymphoblastic leukemia. In the present patient cohort, persistence of PCR positivity, at the end of induction and/or during treatment, was associated with clinical relapse. PCR negativity at the end of induction is usually related to favorable outcome.

THE PROGNOSTIC SIGNIFICANCE OF MINIMAL RESIDUAL DISEASE IN ADULT PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA

A. Samra,[1] M. Kamel,[2] M. El Sharkawy,[1] M. Abd El Fatah,[1] M. Ghaleb,[3] M. Kamel,[1] Th. Abdelhamid,[4] M. Elemary[1]

[1]National Cancer Institute, Cairo University, CAIRO, Egypt; [2]Cairo University, CAIRO, Egypt; [3]Ophthalmology Research Institute, GIZA, Egypt; [4]National Cancer Institute-Egypt, CAIRO, Egypt

Background. The results of the large prospective MRD studies in adulthood ALL indicate that MRD analysis gives highly significant prognostic information superior to other standard criteria (age, sex, and WBC) in distinguishing patients at high, intermediate and low risk of relapse. *Aims.* to determine whether MRD investigation is valuable in predicting outcome in adult ALL patients (except mature B phenotype). *Design and Methods*. This study was carried out on 57 adult ALL patients, 44 cases (77.2%) were males and 13 cases were females (22.8%). The median age of the cases in our study was 22 years with a mean of 24.4+ 6.8 years (ranges from 18 to 49 years). MRD was assessed by 4-color flowcytometry on bone marrow samples collected during three time points in the first 24 months of treatment. The relationship between MRD status and clinical outcome was investigated and compared with age, sex, immunophenotype, and initial TLC. Results: There was no statistically significant difference in cumulative overall survival according to age and sex (p=0.579& 0.518) however, with initial TLC <30000 in B lineage and in T-lineage <100000, the differences were of statistically borderline significance (p=0.089). There was statistically significant correlation between cumulative overall survival at 2 years and response to chemotherapy (p=0.0007) as well as GMALL risk stratification (high-risk vs. low risk group) (p=0.018). The cumulative disease free survival at 2 years was 34.1% for B-lineage ALL (35 cases) and 61.6% for T-lineage ALL (18 cases). The difference was statistically significant (p = 0.038). Disease free survival (DFS) rates for MRD-positive and MRD-negative patients and log-rank testing established that MRD positivity was associated with increased risk of relapse at all time points (p<0.05) but was most significant after induction. The difference was also statistically significant (p=0.009) in case of MRD after consolidation between low risk and high risk. Correlation between cumulative overall survival at 2 years and MRD was also statistically significant (p<0.001). *Conclusions*. The association of MRD results and DFS was independent of and greater than other standard predictors of outcome and is therefore important in determining treatment for individual patients. Flowcytometric immunophenotyping is the method of choice for detection of MRD in our institution especially post-induction.

1446

RISK ADAPTED CHEMOTHERAPY TREATMENT FOR ADULT ACUTE LYMPHOBLASTIC LEUKEMIA: LONG TERM FOLLOW UP

Th. Abdelhamid,[1] H. Mahmoud,[2] H. Ezzat,[2] A. Kamel,[2] H. Shaker,[2] N. Elsharkawy[2]

[1]National Cancer Institute-Egypt, CAIRO, Egypt; [2]National Cancer Institute, CAIRO, Egypt

Background. ALL is a heterogeneous disease, the application of risk adapted treatment protocols in now a well established strategy. The aim of this study was to asses the five years leukemia free survival and overall survival of our first risk adapted adult ALL protocol initiated in 1999. *Design and methods*. Hundred and fifteen patients were included in this study conducted at the Medical Oncology Department - NCI .Cairo in the period between 1999 to 2004.The diagnosis was ALL in all patients. The patients were stratified according to their prognostic factors into standard, high, and very high risk groups. Mature B phenotype were excluded and treated with a separate protocol. The treatment plan included: Prephase for patients with high TLC and/or organomegaly. Induction phase I: Four drugs: Vincristine, Doxorubicin, L-Asparaginase and prednisone with intrathecal MTX. Patients that attained CR were subjected to cranial irradiation with 24 Gy and intrathecal MTX for four injections. Phase II induction with Cyclophosphamide and Cytarabine. Consolidation phase I: Vincristine, Doxorubicine and prednisone with Triple intrathecal. Phase II consolidation: Cyclophosphamide, Cytarabine and Etoposide with triple intrathecal. Maintenance therapy: two years with 6 mercaptopurine and methotrxate. For patients with high and very high risks, one cycle of high dose cytarabine and mitoxantrone (HAM regimen) was added between induction and consolidation. Very high risk patients with available donor were referred to transplantation in CR1.Informed consents were signed by all cases. Results: The median age was 25 years (range 16to60). The study included 73 males and 42 females. CNS involvement at presentation was reported in 14 cases (12.2%). Immunophenotyping were pro B (7%), C. ALL &Pre B (56.5%) and T phenotype (20.9%).The BCR-ABL fusion gene transcript was positive in 15 cases. Forty five patients (39.1%) reported to have standard risk, while 55 (47.8%) and 15 (13%) were high and very high risk respectively. Complete remission was achieved in 76.5% (n = 88) while 23.5% (n=27) showed no CR. The CR rate of the standard risk group was 88.9% versus 70.9% and 60% for the high and very high risk respectively (p=0.029).The median survival for all patients was 14 months (95% CI, 9.2 to18.8). Survival at 60 months was 28.24%, it was 34%, 21% and 20.1% for the standard, high and very high risk respectively (p=0.017). There was significant difference in survival between patients with pro-B, pre-B&CALL, and T phenotype (p=0.0019). The median time to progression was 16 months (95% CI, 13.5to 18.5). At 60 months 35.2% were still in remission. Time to progression was 44, 12 and 14months for the standard, high and very high risk groups respectively (p=0.047). Time to progression between patients with Pro-B, pre-B&C-ALL, and T phenotype were 3, 17 and 16 months respectively (p=0.0007). *Conclusions*. The CR rate, LFS and survival of the standard risk are satisfactory while those of the high and very high risk are still in need to be improved , whether we can achieve this by higher post remission chemotherapy, targeted therapy or stem cell transplantation remains to be investigated.

1447

PARASITIC INFECTION IN EGYPTIAN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA

H. Hassab,[1] Z.Sh. Shaibat-El-Hamd,[2] S.M. El-Masry,[2] A.H. Hassan,[2] A.H. Hassanein[2]

[1]Faculty of Medicine Alexandria University, ALEXANDRIA, Egypt; [2]High Institute of Public Heath, University of Alexandria.Egypt, Nederland

Background. Parasitic infections continue to be a major public health problem in developing countries. Immunosuppressed patients are at increased risk of serious complications associated with some parasitic diseases. Aims: To determine the frequency of some endo-parasites among children with acute lymphoblastic leukemia (ALL) in relation to controls. Subjects: The study included 234 children divided into 117 children with acute lymphoblastic leukemia their age ranged from 2-14 years and 117 immunocompetent children with matched age and sex as control group. *Design and Methods*. Laboratory study included examination of stool using five different staining techniques, urine, cerebrospinal fluid (CSF) and serological tests. *Results*. The overall percentage of parasitic infections was significantly higher among children suffering from ALL (90.6%) as compared to the controls (58.1%) [X2 32.37, p<0.001]. Protozoa recorded the highest percentage of infection among the leukemic children (66.7%) as compared to controls (44.4%) [X2 11.70, p<0.001]. Followed by microsporidial infection (60.7% vs. 11.1%) [X2 62.47, p<0.001], then by coccidial infection (53.8% vs. 41.9%) and helminthes infection (2.6% vs. 12%) [X2 7.68, p<0.006]. Microsporidia was the only parasite detected in the CSF in 54.7%. Neither Toxoplasma gondii by Giemsa stain, nor Acanthameba was detected in the sediment of the CSF. Higher percentage of infection was found among children living in rural areas and among those who followed bad personal hygiene. *Conclusions*. There were a high percentage of parasitic infections among leukemic children mainly protozoa, adding to their morbidity. Routine examination of CSF for the presence of microsporidia is recommended in such cases especially those having neurological manifestations.

1448

QUANTITATIVE ASSESSMENT OF WT1 EXPRESSION BY REAL TIME PCR IN ALL AS PROGNOSTIC MARKER

A. Selim, W. Metnawey, H. Sadek, E. Abdelmohsen, A. Elshakankiry

Cairo University, CAIRO, Egypt

Background. WT1 gene was first identified in patients with Wilms tumor ,coding for a zinc finger transcription factor located on chromosome 11p13,which is involved in differentiation and proliferation of hematopoietic precursor cells as well as some other tissues like kidney, ovary, heart, etc. It has been reported to be expressed in almost all hematological malignancies including ALL,AML ,CML and MDS, being a useful marker in minimal residual disease (MRD) detection and leukemia management. *Aims.* To assess the efficacy of WT1 as a predictor for

relapse in acute lymphoblastic leukemia. *Design and Methods*. This study was conducted on peripheral blood samples from 30 ALL patients (17adults=6.6% and 13children=43.3%; 19 males=63.3%and 11females=36.6%) were analyzed for the expression level of WT1 in mRNA using quantitative real time reverse transcriptase QR-PCR (using Taqman fluorescent probes; ABI prism 7700 Applied Biosystems). Pretreatment and post-induction samples were obtained, only 20 patients (66.6%) could be followed up . Eight samples from normal individuals matching in age and sex were used as control. For exact quantification of gene expression (WT1) , an endogenous reference (housekeeping gene ABL) was used to correct for differences in the amount of total RNA added to the reaction ,for compensation of different RT efficiencies and for compensation of PCR inhibitors in the sample. Standard curve were plotted and the exact quantities were estimated relatively as ratio of target to housekeeping gene. *Results*. Samples from patients newly diagnosed and others from relapsed patients(only 3 out of 20 who were followed-up 15%)proved to have significantly higher WT1 expression levels (p<0.01) compared to samples from patients in complete remission(CR)(85%)orhealthy individuals(controls).Our study revealed that rising ofWT1 expression could be used as an indicator of forthcoming relapse. *Conclusions*. WT1 represents a candidate prognostic molecular marker in acute lymphoblastic leukemia .Additional studies are needed in order to assess the potential role of WT1 in the monitoring of the patients response to treatment and in the detection of hematological relapse prior to its occurrence.

1449

DEPOCYTE TREATMENT FOR LYMPHOMATOSIS MENINGITIS - ROMANIAN WORKING GROUP FOR ADULT ACUTE LEUKEMIA' EXPERIENCE

A.D. Moicean,[1] A.C. Catana,[2] R. Stoia,[1] O.F. Georgescu,[1] E. Benedek,[3] C. Danaila,[4] A. Cucuianu,[4] A. Vladareanu,[5] G. Gaman,[4] L. Calustian[6]

[1]Fundeni Clinical Institute, BUCHAREST, Romania; [2]Districtual Hospital, SIBIU, Romania; [3]Department of Hematology and BMT, TARGU MURES, Romania; [4]University of Medicine, IASI, Romania; [5]University Hospital, BUCHAREST, Romania; [6]Oncological Institute, BUCHAREST, Romania

DepoCyte, a liposomal formulation of cytarabine with a prolonged half-life for intra-thecal (IT) administration has been shown to be safe and effective in the neoplastic meningitis. After legal availability of liposomal cytarabine in Romania (covered by National Health Insurance), Romanian Working Group for Acute Leukemia Study (RWGALS) have begun an observational study on patients with lymphomatous meningitis. Liposomal cytarabine was given to the 15 patients, aged 28-62 year, 50 mg as a single agent, on a different schedule (weekly, every-2-weeks, monthly or more rarely), concurrent with 16 mg systemic dexamethasone for 4 days, in order to reduce the incidence of the latter toxicity. Concurrent high doses systemic chemotherapy with agents that penetrate the blood-brain barrier as well as concurrent radiation therapy that potentiate the neurotoxicity associated with liposomal cytarabine were avoided, but conventional doses of chemotherapy were allowed for 3 patients with relapsed nonhodgkin lymphomas with central nervous system (CNS) disease and one patient with lymphoblastic phase of chronic myeloid leukemia (CML). Three patients with acute lymphoblastic leukemia (ALL) received Depocyte monthly as SNC prophylaxis schedule. One patient received Depocytes once a month as prophylaxis for SNC relapse after match related donor (MRD) allotransplant for B-ALL with meningitis leukemia. He had a very good tolerance with any adverse event at 10 months after stem cell transplant (SCT). A 28 year old patient with lymphoblastic blast-phase of CML with blasts cells meningitis had a very good liquor clearance of blasts cells and showed a very good tolerability with 10 times of Depocyte IT weekly administrations. Two patients with B-ALL experienced severe cytopenia but the relationship with Depocyte was not clear because they received in the same time systemic conventional chemotherapy. Depocyte had any influence on the diffuse large B cell lymphoma (DLBCL) cerebral tumor for a 55 year old female with SNC DLBCL relapse, and just before her death, IRM showed leptomeningitis. A patient had severe neurological adverse event and shown a CNS tuberculosis after 3 IT Depocyte administrations. Three patients had moderate intensity headache the day the drug was administrated. Death related disease appeared at 3 patients during Depocytes prophylaxis for SNC lymphomatousis disease. Liposomal cytarabine 50 mg given IT is an attractive alternative, considering the ability to reduce the frequency and total number of IT treatments and the potential to further efficacy improvement of the current CNS prophylaxis regimen and even curative regimen. Concurrently administration with corticosteroids reduces the incidence of arachnoiditis

1450

CEREBRAL THROMBOEMBOLISM IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA

N. Conde, A. Quintero, T. Toll, A. Català, M. Camós, S. Rives, J. Estella

Sant Joan de Deu Hospital, BARCELONA, Spain

Background. Cerebral Venous Thromboembolism (CTVE) is an uncommon but severe complication in children affected by Acute Lymphoblastic Leukemia (ALL). Several risk factors have been described, the incidence may vary according to the risk profile of the patient. Objectives: 1. To know the incidence of the CVTE within the patients affected by ALL and treated in Hospital Sant Joan de Deu, Barcelona between January 2002 and December 2008. 2. To identify the risk factors associated to CVTE. *Aims*. A retrospective analysis of the children diagnosed of ALL between January 2002 and December 2008 in our Hospital. CVTE and their risk factors were reviewed. *Results*. During the referenced period 123 patients were diagnosed of ALL. Three of them (2%) presented CVTE during the induction treatment period. The mean age was 9.3 years. Two were ALL-B and one T. Two of them were treated according to the protocol of the Sociedad Hemato-Oncológica Pediátrica Española (SHOP) 1999 and one according to SHOP protocol 2005. All three belong to the ALL high risk patient group. The differences between the two protocols is the dose of L-Asparaginase (15.000 UI/m2/24 hours from day +15 to day +24 in SHOP 99; and 10.000 UI/m^2/48 hours from day +15 to day +33 in SHOP 2005). The most frequent symptom was a persistent headache (100%). Two patients had episodes of seizures associated. All patients were diagnosed by computerized tomography. Two of three patients had thrombosis of transverse sinus and the other longitudinal sinus thrombosis. Two patients had also lesions with hemorrhagic component. The basic study included the most important genetic risk factors for thrombosis (V Leiden factor, deficiency of Antithrombin III (AT III), Protein C and Protein S deficiency, Prothrombin Mutation G20210A). All three patients had low levels of AT III in the moment of the diagnosis. However one out of three was heterozygote for V Leiden Factor. The treatment included removal of L-ASP; infusion of frozen plasma and AT III; treatment of seizures with phenytoin (then GABA or Valproate); Low Molecular Weight Heparin (LMWH) (1 mg/kg/day if hemorrhagic component was found or 1,5mg/kd/day if not). After acute treatment further management was individualized depending on the clinical situation. Neurological recovery was complete in all of them, but two died 2 months and 10 months later after induction due to infectious complications. *Conclusions*-. The incidence of CTVE in children affected by ALL and treated in our Hospital is according to other publications. All the CVTE diagnosed during the ALL treatment appeared during the induction period. The presence of persistent headache during induction period is highly suspicious of CVTE. The treatment with plasma, antithrombin and LMWH was effective in all cases.

1451

RESULTS OF TREATMENT WITH HYPER-CVAD IN ADULT ACUTE LYMPHOCYTIC LEUKEMIA: SINGLE CENTER EXPERIANCE

M. Mitrovic-Vasiljevic, I. Djunic, D. Tomin, N. Suvajdzic, I. Elezovic, M. Todorovic, G. Jankovic, A. Vidovic, D. Antic

Institute of hematology CCS, BELGRADE, Serbia

Background. Hyper-CVAD is a highly active regimen which has improved the outcome in adult ALL compared to conventional regimens, with complete remission (CR) rate of 80%, and a long-term survival rates ranging from 30 to 45%. *Aims*. To evaluate the efficacy of Hyper-CVAD in adults with de novo ALL, treated in the Institute of Hematology, CCS. *Design and Methods*. From November 2006 to November 2008, 17 newly diagnosed adult ALL patients, were treated with standard Hyper-CVAD regimen. Treatment consisted of four cycles (cy) of hyperfractionated cyclophosphamide, vincristine, doxorubicin and dexamethasone, alternating with four cy of methotrexate (MTX) and ara-C, together with intrathecal CNS prophylaxis (MTX and ara-C on days 2 and 7 of the first 3-4 courses), and supportive care with antibiotic prophylaxis and granulocyte colony-stimulating factor therapy. Oral POMP (6-MP, vincristine, MTX, prednisone) maintenance was administred for at least 2 years. *Results*. Pretreatment patients characteristic were as follows: median age of 29 years (range: 18-55), 2 patients were ≥50 years old; 11/17 were male. Leucocytosis of more then 50x10^9/l was registered in 6/17 patients. CNS disease at diagnosis was present in 1/17 patients; mediastinal mass was not registered. FAB L1 type was present in 5/17, L2 in 10/17 and not classified/mixed in 2/17 patients. The T-cell

immunophenotype was present in 5/17, B in 11/17 and byphenotypic (B and T) in 1/17 patients. Myeloid marker positivity was registered in 4/17 patients. There was not mature B ALL. Philadelphia (Ph) positive disease was present in 3/17, and t(4;11) in 2/17. 10/17 of patients had a high risk for relapse according to Hoelzer prognostic model. Risk stratification for CR duration was assessed according to M.D.Anderson Cancer Center (age≥45 years, WBC≥50x10^9/L, ECOG score 3-4, Ph-positivity, French-American-British L2 morphology, > 1cy to achieve CR, day 14 bone marrow blasts > 5%) for 9 patients. Low and intermediate risk had 3 and 6 patients, respectively. Overall CR rate was 94% while one patient had resistant disease. There were not deaths during induction therapy. After a 24 months-long follow-up 9/17 patients remained alive, 8 of them in first CR, with median CR duration of 7.5 months (range 3-22) and median survival time of 12 months (range 8-23). Eight patients relapsed: two between the 4th cy and 5th, four between 8th cy and start of maintenance therapy, one during maintenance and one after allogenic SCT. This last patient co-expressed initially myeloid markers positive (CD13, CD113) and received 7 cy of Hiper-CVAD before transplantation. AML relapse occurred after allogenic SCT. Eight patients died: one due resistant disease and 7 after leukemia recurrence. Their median survival time was 11 months (range 6-23). Ph-positive patients had a CR of 100%, with median CR duration of 6 months and median survival of 12 months. One patient is still a live, without being transplanted. *Conclusions*. Hyper-CVAD is a highly aplicatable regiment for ALL treatment with acceptable toxicity profile.

1452

CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA: A SINGLE CENTER EXPERIENCE

M.F. Abdullah, J. Al Mistarihi, M. Gharaibeh, A. Alzoebie

Sheikh Khalifa Medical City, ABU DHABI, United Arab Emirates

Background. Childhood Acute Lymphoblastic Leukemia ALL, is the most common malignancy in children. The survival rates for ALL have been improving steadily during the past four decades, and reaching 80% in developed countries. This improvement can be attributed, in part, to intensification of therapy using agents previously shown to be effective in the treatment of ALL, in addition to the risk-adapted treatment, taking into account clinical features and biologic features, which are used to maximize cure rates while minimizing long-term side effects. *Aims*. To study the outcome (overall survival and event free survival for Acute Lymphoblastic Leukemia (ALL) in children at Sheikh Khalifa Medical City (SKMC). *Design and Methods*. All children age 0-13 years that were diagnosed with ALL and started on treatment at SKMC between 2000 and 2008, were studied retrospectively with respect to their clinical, immunological, and cytogenetic features at presentation and their relation to the treatment outcomes. Kaplan-Meier and Cox Proportional-Hazards regression were used for statistical analysis. *Results*. A total of 44 patients were eligible for the study, Mean age at diagnosis was 5.2 years (1-13.4 years) and median age 4.3 years. There were 23 males and 21 females with ratio of 1.1:1. 37 (84%) had B-lineage and 7 patients (16%) had T-lineage ALL. All patients received risk adapted treatment according to Children Oncology Group (COG) risk categorization which included 20 (45.5%) and 24 (54.5%) patients in standard and high risk groups respectively. The mean duration of follow up was 2.6 years (3 months- 7.5 years) and median of 2.45 years. All patients achieved remission at the end if induction. 34 patients had evaluation for early response based on the bone marrow study on day 7 or/and day 14 of induction, Only 4 (12%) patients had slow early response (SER) and the remaining 30 (88%) patients had rapid early response (RER). 5-year Overall survival probability (OS) was 90.9±8.3 and 5-year Event Free Survival (EFS) was 91.5±6.7. There were no statistical significant differences in both OS and EFS among different risk groups including the age, gender, or lineage. *Conclusions*. According to our data, children with acute lymphoblastic leukemia who were and being treated at SKMC. Although the total number of patients who were eligible for the study is small, however the survival analysis indicates that the OS and EFS are superb and this result is comparable to the major pediatric oncology center. The lack of significant influence of the COG and/or NCI risk factors on the survival probable is due to the small number of the cohort or/and the risk adapted treatment those patients have received.

1453

PREVALENCE OF BONE DISEASES IN PEDIATRIC HEMATOLOGY/ONCOLOGY PATIENTS

S.K. Al-Jaouni, A.M. Al-Agha, A. Hussein, S. Ashoor

King Abdulaziz University Hospital, JEDDAH, Saudi Arabia

Background. Osteopenia and osteoporosis are known to occur frequently in children with cancer at diagnosis, during and after completion of chemotherapy. Moreover, many studies in the literature have reported pathological fractures during and after therapy, osteonecrosis and skeletal abnormalities. Many therapeutic regimens in cancer treatment carry the risk of causing or favouring the development of osteoporosis. *Aims*. To assess the prevalence of bone disease among paediatric oncology in our institute. *Design and Methods*. A total of ninety seven patients were enrolled in the study age range from 1- 16 years old. Fifty children with acute lymphoblastic leukaemia (ALL), ten patients with AML, twelve with NHL and twenty five children with other malignancies during 2007 and 2008. These patients were treated and followed at the King Abdulaziz University Hospital, Jeddah, Kingdom of Saudi Arabia. All patients were assessed clinically. Blood and urine samples were obtained for the determination of biochemical and hormonal profiles included PTH, 25 OH vitamin D3. Bone maturation was assessed by radiological bone age. Bone mineral density (BMD) by DEXA was determined patients. Bone formation markers (bone-specific alkaline phosphate, CTX and osteocalcin) and bone resorption markers were analysed for patients whom had BMD and referred for treatment. Results: High prevalence of reduced low bone mass (LBM) among the majority of screened patients. BMD is reduced in early phase of disease. Patients with ALL had significantly reduced lumbar volumetric (-0.77) and femoral areal and volumetric BMDs (-1.02 and -0.98, respectively). In patients with other malignancies, femoral areal and apparent volumetric BMDs were significantly decreased (-0.70 and -0.78, respectively). Half of the patient associated with hypovitaminosis D. *Conclusions*. High prevalence of osteopenia among patient with oncology disorders. A follow up of BMD during and after chemotherapy is highly indicated. Causes of osteoporosis are multifactorial: related to disease nature, antineoplastic treatments, physical inactivity, and non healthful lifestyle. Prevention can be achieved with early diagnosis and treatment also through supplements by vitamin D and calcium, encouraged exercise and sun exposure.

THE ROLE OF DYNAMIC RESEARCH OF SERUM FERRITIN LEVEL IN CHILDREN WITH ACUTE LEUKEMIA

G. Bebesko, K. Bruslova, N. Tsvietkova, T. Pushkareva, S. Yatsemirskii, O. Kuznetsova

SI Research Center for Radiation Medicine AMS of Ukraine, KIEV, Ukraine

Background. Failure of iron methabolism are described for children with acute leukemia. Enhanceable maintenance of iron in the organism of patients can be related both to initial disturbances of ironkinetics processes and by the phenomena of diserithropoiesis, or red blood cells transfusions . The iron overload can influence on activity of all organs and systems of organism in a whole. *Aims*. to investigate the serum ferritin level (SFL) of children with acute leukemia in the dynamics of leukemia process taking into account the phenomenon of diserithropoesis (morphological changes in erythroid elements and bone marrow syderoblasts number), amount of red blood cells transfusions , life-span of patients and reasons of their death. *Design and Methods*. 128 children with acute leukemia are inspected (ALL - 98, AML - 30). Clinical, morophological, byochemical, immunoenzyme and statistical methods were used. *Results*. At 60% of children the debut SFL was higher as compared to normative level (r<0,01). In the dynamics of leukemia process the SFL rose also. In the I acute period of disease this index was 338,2±10,4 ng/ml, in the II acute period - 794,5±21,6 ng/mL and in the III acute period - 1274,4±43,8 ng/ml. Direct cross-correlation dependence is revealed between SFL - number of bone marrow sideroblasts (r= + 0,51), SFL - diserythropoiesis manifestation, especially in the period of hemopoiesis renewal (r=+ 0,37), and SFL - red blood cells transfusions number (r= + 0,47). SFL did not influence on life-span of children (r= - 0,19). However, for children with debut SFL 864,1±18,3 ng/mL different manifestations of cardiac - vascular failure were detected and duration of these patient's life was 27,7±2,2 years, that in 2,1 time shorter as compared to children with SFL less than 200 ng/ml. *Conclusions*. Serum ferritin level in children with acute leukemia is the marker of diserythropoiesis and criterion of prognosis of cardio-vascular complications . This research is needed for timely diagnostics of haemopoiesis failure and providing of prophylaxis measures of complications in course of acute leukemia in children.

1455

ACUTE NEUROTOXICITY SECONDARY TO TREATMENT OF PEDIATRIC ACUTE LIMPHOBLASTIC LEUKEMIA

R. Berrueco, S. Rives, T. Toll, N. Conde, M. Camós, J. Estella

Hospital Sant Joan de Deu, BARCELONA, Spain

Background. Central nervous system (CNS) prophylaxis is a central element in the treatment of childhood acute lymphoblastic leukemia (ALL). However, acute neurotoxicity has been reported during this treatment, although the exact incidence of neurotoxicity complications is difficult to determine (3.7-7.8%). *Aims*. To know the incidence of acute neurotoxicity in patients affected by ALL and treated in a single University Hospital in Barcelona between January 1993 and December 2008. To identify the drugs associated to this toxicity. *Design and Methods.* A retrospective study was performed to describe severe neurological complications (grade III-IV) in children treated for ALL in a single center during a 15-year period. The patients were treated according to four sequential trials of the "Sociedad española de hematología y oncología pediatrica" (SHOP). *Results.* During this period 211 children were diagnosed with ALL at our institution. Eleven of them (5.23%) presented acute neurotoxicity. The median age was 5 years. Nine cases were ALL-B and one ALL-T (7 high risk, 2 very high risk and 2 standard risk patient). Neurological symptoms occurred in induction (n=4 cases), consolidation (n=3) and continuation (n=4) treatment and included: transient neurological deficits in 4 patients, seizures in 4 cases, severe headache in 1 and polyradiculoneuritis in 2 patients. Cranial computed tomography and magnetic resonance imaging showed CNS thromboembolism in 3 of the patients (2 of them with secondary hemorrhage), suggestive images of leucoencephalopathy in other 3 cases and CNS stroke in 1 of them. The related drugs were intrathecal methotrexate as well as systemic high-dose methotrexate in six of the patients, asparaginase in three (thrombo-hemorrhagic events), and vincristine in two of them (polyradiculoneuritis). In most children the symptoms improved in 24-48 hours; however four patients had a poor outcome with persistence of neurological damage. *Conclusions*. The incidence of acute neurotoxicity in our series is similar to that previously reported. Drugs involved in neurological complications were methotrexate, asparaginase and vincristine. Drug neurotoxicity is a rare but severe complication of treatment of children with ALL that in some cases can have devastating sequelae.

1456

IMPACT OF CYTOGENETICS ON THE OUTCOME OF ADULT ACUTE LYMPHOBLASTIC LEUKEMIA: RESULTS FROM A SINGLE INSTITUTION

I. Gómez, J. Cervera, E. Such, A. Valencia, D. Martínez, E. Barragán, O. Fuster, L. Senent, J. Martínez, J. Sanz, G. Sanz, P. Montesinos, M. Sanz

Hospital Universitario La Fe, VALENCIA, Spain

Background. Except for the t(9;22), the impact of cytogenetics on prognosis in adults with acute lymphoblastic leukemia (ALL) is much less clear than in childhood ALL. *Aims*. To assess the prognostic significance of cytogenetics in a relatively large series of adults with ALL from a single institution. *Design and Methods.* From January 1977 to July 2008, cytogenetic analysis was carried out in 206 adults with ALL at our hospital. The median age was 34 yrs (range, 15-90) with a ratio M/F of 1.48:1. Most patients were treated with intensive chemotherapy PETHEMA regimens (LLA-93, LLA-96 and LLA-2003). Complete remission (CR) was achieved in 84%. Fourteen patients underwent allogeneic stem cell transplantation in first CR (7 ALL-Ph+ and 7 with other high-risk characteristics, such as hyperleukocytosis or slow response to induction therapy). Results: Ninety eight patients (47%) had inadequate cytogenetic analysis, either by absence or poor-quality metaphases. Of 108 patients with evaluable karyotype, 35 (32%) were normal (NK), whereas 73 patients (68%) had a clonal cytogenetic abnormality. The most frequent abnormality was t(9;22) (n=24), followed by t(8;14) (n=7) and del(9p) (n=6). The remaining 36 patients had t(4;11) (n=4), t(14q11) (n=2), del(6q) (n=2), abn(11q23) (n=1), complex karyotype (n=1) or other numerical (n=7) or structural abnormalities (n=10). Nine additional patients were classified according to the grade of ploidy as low hypodiploidy (<39 chromosomes) (n=3), low hyperdiploidy (47-49 chr.) (n=1) and high hyperdiploidy (>60 chr.) (n=5). The impact on the outcomes was assessed in 99 patients who received intensive treatment. Patients with NK or del(9p) showed a better outcome (standard-risk group) than patients with the rest of abnormalities (high-risk group). Overall Survival (OS) of the standard-risk group was significantly longer compared with the high-risk group (median OS 37 vs. 12 months, respectively, p=0.048). Relapse-free survival was also statistically different between these cytogenetic groups (52 vs. 11months, p=0.023). Conclusions: Cytogenetic abnormalities were found in 68% of adults with ALL, being t(9;22) the most frequently observed. According to karyotype, two risk groups were identified: the standard-risk group, which included patients with normal karyoptype and del(9p), and the high-risk group (all other abnormalities).

Funding: this study was supported in part by the Instituto de Salud Carlos III grants RD06/0020/0031 and CA08/00141.

ACUTE LYMPHOBLASTIC LEUKEMIA IN CHILDREN ASSOCIATED WITH 1P36 DELETION SYNDROME

M. Colita,[1] C. Arion,[1] M. Asan,[2] A. Dumitrescu,[2] M. Passino,[3] M. Lancioti,[3] C. Panarello,[3] G. Dini[3]

[1]CArol Davila University of Medicine,Fundeni Institute, BUCHAREST, Romania; [2]Fundeni Institute, BUCHAREST, Romania; [3]Instituto Gianina Gaslini, GENOA, Italy

Background. Deletion of material from chromosome 1p (1p36 region) is common in neuroblastoma. It is possible that a tumor suppressor gene may be present in this region, though no specific gene has yet been identified. Monosomy 1p36 is a recently delineated contiguous gene syndrome, which is now considered to be the most common subtelomeric microdeletion syndrome. From the recent literature it appears as if 1p36 deletions account for 0.5-1.2% of idiopathic mental retardation. The deletions can be detected by high resolution cytogenetic studies in a

minority of patients, and fluorescence *in situ* hybridisation (FISH) is required in most. 1p36 deletion syndrome is characterized by distinct craniofacial features, associated with developmental delay/mental retardation, hypotonia, muscle hypotrophy, seizures, brain abnormalities (ventricular enlargement), optic nerve atrophy, deafness and heart defects. *Design and Methods*. We diagnosed in June 2000 a 1 year old girl with acute lymphoblastic leukemia, L1 FAB, B common CD10+. At that time we cannot perform cytogenetic and molecular diagnostic. She was treated with INTERFANT protocol and she obtained first complete remission (CR1). In 2004 she relapsed with the same morphological and immunophenotypic aspect and she was treated according COOPRALL 97 protocol obtaining CR2. The follow-up relieved a moderate mental retardation, ventricular enlargement on MRI and optic nerve atrophy with secondary cecity. We consider at that time these complications as secondary effects after intrathecal chemotherapy. Four year later, in 2008, she relapsed again and we performed complete diagnostic in Gaslini Institute, Genoa and we observed the same morphological and immunophenotyping aspect. The cytogenetic analysis showed hipoploidy associated with complex cariotype and 1p36 syndrome - 44XX, del(1)(p36), -7, -12, add(12)(p13), -15, del (15)(q15)+mar. The patient failed to obtain CR3 with FLAG protocol and died secondary to pulmonary and cerebral aspergillosis. *Conclusions*. The 1p36 deletion syndrome wasn't reported until now in association with acute leukemia, but is common in patients with neuroblastoma. It is associated with poor outcome with standard chemotherapy and further studies are required to a better understanding of malignant process.

1458

TREATMENT RELATED ADVERSE EVENTS IN ADOLESCENTS AND YOUNG ADULTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA TREATED WITH PEDIATRIC PROTOCOLS

C. Perdikogianni, E. Stiakaki, I. Pelagiadis, E.-A. Markaki, N. Katzilakis, M. Kalmanti

University Hospital of Heraklion, HERAKLION, Greece

Background. Historically, adolescents and young adults (AYA) have a worse outcome than children that had been attributed to higher incidence of T-immunophenotype and less favourable cytogenetics. Recent reports suggest that AYA with acute lymphoblastic leukemia (ALL) have far superior outcomes when treated on more intensive pediatric regimens. Current BFM based pediatric protocols are characterized by dose-intensive use of non-myelosuppressive drugs such as vincristine, L-asparaginase, corticosteroids and continuous antimetabolite-based maintenance. However, toxicity increases with age and children >10 years have a higher incidence of side effects especially of glucocorticosteroids and L-asparaginase. *Aims*. To assess treatment related adverse events and tolerability of current pediatric BFM based ALL protocol applied in AYAs. *Design and Methods*. Four male patients with newly diagnosed B-lineage ALL aged 17-20 years old at diagnosis treated with intensive chemotherapeutic regimen according to the high risk arm of the ALL-BFM 2000 protocol in a single Department of Pediatric Hematology-Oncology from 2006-2008 were enrolled. AYA accounted for the 22% of patients with ALL treated in the Department during this period. No patient had Ph+ ALL. *Results*. Three out of the four patients presented delayed methotrexate (MTX) excretion at the indicated by the protocol dose in the high-risk blocks and received reduced doses at subsequent administration. All received rescue therapy with carboxypeptidase G2. One patient presented substantially elevated triglyceride levels (up to 2385 mg/dL) correlated with asparaginase administration at the induction and subsequent treatment phases that returned to normal with dietary restrictions. Other metabolic disorders such as drug-related diabetes mellitus were observed in one patient after steroid administration. Three patients presented high levels of both SGOT and SGPT during different treatment phases, with maximum values 1025U/l and 2068U/l, 819U/l and 918U/l, 741U/l and 345U/l respectively for each patient, the third patient with concomitant elevation of both γGT and bilirubin. Infectious-inflammatory complications were also observed. One patient was diagnosed with pulmonary aspergillosis and subsequently a severe serositis occurred that responded only to corticosteroid administration. Another patient presented a severe pneumonitis that necessitated admission to Intensive Care Unit. The oldest patient in this study developed severe aseptic femoral necrosis due to high dose dexamethasone in intensification blocks and a severe peripheral neuropathy due to vincristine. No deaths occurred during induction or in first remission. One patient had resistant ALL, with early extramedullary relapse after matched sibling donor bone marrow transplantation and succumbed to the disease. *Conclusions*. Although older patients seem to have less tolerance to L- asparaginase, steroids and vincristine compared to children, treatment-related side effects are generally manageable. The administration of pediatric regimens to adolescent and young adults although offering better outcomes compared to protocols designed for adult patients, poses certain difficulties over treatment toxicity and tolerance that may result in significant protocol modifications or delays in the treatment completion. Further prospective studies could reassess the treatment of adolescents and young adults as well as the tolerability and efficacy of pediatric dose-intensive protocols.

1459

OUTCOME OF THE >55 YEAR OLD PATIENTS WITH ACUTE LEUKEMIA - RESULTS OF THE ROMANIAN WORKING GROUP OF ACUTE LEUKEMIA STUDY

A.D. Moicean,[1] C. Danaila,[2] A.C. Catana,[3] V.M. Teleanu,[4] A. Gaman,[2] G. Gaman,[2] V Popov,[5] G Rauta,[5] M. Balea,[6] I. Benedek,[7] M. Brinza[1]

[1]Fundeni Clinical Institute, BUCHAREST, Romania; [2]University of Medicine, IASI, Romania; [3]Districtual Hospital, SIBIU, Romania; [4]RWGALS, BUCHAREST, Romania; [5]Department of Hematology, Districtual Hospital, PITESTI, Romania; [6]Colentina Hospital, BUCURESTI, Romania; [7]Department of hematology and BMT, TARGU MURES, Romania

Acute leukemia patients aged more than 55 years are a challenging field for the therapeutical approach. On the one side many of them have a good condition for intensive chemotherapy, on the other side the curative treatment like myeloablative stem cell transplantation is prohibitive for these patients. We conducted a retrospective study on the outcome of the acute leukemia patients aged more than 55 years in charge on the last 5 years. We had 213 acute myeloblastic leukemia (AML) patients and 116 acute lymphoblastic leukemia (ALL) patients. Median age for ALL patients was 64 (the upper limit was 83 years) and for AML, median age was 68 (the upper limit was 82 years). Intensive chemotherapy or low dose chemotherapy were chosen according to the comorbidities of the patients. Any patient received stem cell transplantation. 58% of the AML patients received conventional intensive chemotherapy and 40% low doses chemotherapy. 68% of the ALL patients received conventional intensive age adapted chemotherapy and 28% palliative treatment with vincristine and prednisone, or mercaptopurine and low doses of metotrexate. 40% of the AML patients and 67% of the ALL patient receiving conventional intensive chemotherapy had complete remission (CR). Only 5% of the ALL patients and 7% of the AML patients with low doses chemotherapy achieved CR. All patients with ALL Ph+ achieved CR with chemotherapy and low dose imatinib (100-200 mg/d). ALL Ph+ patients were only 5, due to the fact that genetic approach for acute leukemia diagnosis was not routinely performed. EFS for ALL patients was average 8 months and for AML patients 5 months. OS for ALL patients was average 14 months and for AML patients 11 months. 72% of all deaths were infections related and disease related in the same time and only 25% were vital organ failure and age related in the same time. Five percent of the aged patients had a second solid malignancy (genital, gastrointestinal). From all more than 55 years old patients, 96 requested transfusion supplies, and 75% requested growth factor or erythropoietins treatment. Seventy percent of aged patients showed severe depression and requested psychological assistance. Romanian National standards have upper age limit for SCT at 55 years. Outcome of the more than 55 year old acute leukemia patients wiould be improved by new drug formulation or target new drug. A high incidence of psychological disturbance characterize the third age acute leukemia patients.

1460

PREDECTION OF EARLY RELAPSE OF ACUTE LYMPHOPLASTIC LEUKIMIA BY INFRARED SPECTROSCOPY

S. Al-Jaouni, G. Raouf

King Abdulaziz University Hospital, JEDDAH, Saudi Arabia

Background. Despite advances in the treatment of childhood acute lymphoplastic leukemia (ALL), the risk of relapse remains about 30%. The presence or absance of residual disease or early relapse has been assesed by flow cytometry and PCR. *Aims*. To assess early relapse or minimal residual disease by Fourier transform infrared spectroscopy (FTIR) *Design and Methods*. Adeeb a known case of Acute biphenotypic leukemia (myeloid and B lineage), off chemotherapy for one month which had been re-admitted to Pediatric wards at King Abdulaziz University Hospital, Jeddah, KSA, because he had progressive weakness in both lower limbs, neurologic examination showed bilateral symmetri-

cal ascending paraplegia with intact cranial nerves. The patient has been assessed clinically and laboratory. Repeated CSF and bone marrow examination were normal and negative for blasts. MRI brain and spine were normal, given a differential diagnosis of transverse myelitis or Gillian-Barre' syndrome. Patient diagnosed at that time as leukemia in remission. Bone marrow samples were collected from this case at different events to be studied by Fourier transform infrared spectroscopy (FTIR). The first sample while the patient in remission at the end of his treatment (Adeeb I).The second sample after the patient presented to pediatric ward with complete paralysis of the lower limb (Adeeb 2), 2 months later he had symptoms suggestive of increased intracranial tension, another workup revealed combine BM & CNS relapse B-lineage ALL, a third sample was sent. A fourth sample analysed after the patient had induction and two cycles of chemotherapy and radiotherapy. All samples were kept at -80oC and lyopholized prior to FTIR measurements. The lyopholized samples were dispersed in potassium bromide (KBr) to form 1% concentration discs.

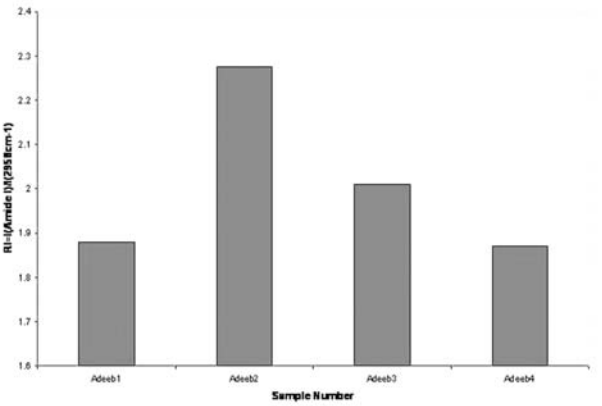

Fig.2. Variation in I(Amide I)/ I(2958cm-1) Ratio from Adeeb 1,2,3 and 4 bone marrow samples. The data points are the average of three different measurements on each sample

Figure.

Results: Fourier transform infrared spectroscopy (FTIR) was explored as a means to distinguish newly diagnosed of acute leukemia from disease free bone marrow samples. Characteristic bands alterations were identified in both healthy and diseased samples arising from cellular protein, lipid and DNA. There were specific changes that affected the secondary structure of proteins appeared in the FTIR spectra confirmed with the second derivative analysis. The overall protein structure in the control sample consists primarily of α-helix, whereas in ALL sample it has a relatively high proportion of anti-parallel β-sheet proteins constituents presumably due to leukemia. Different absorbance's ratios for specific bands were calculated and plotted versus the patient samples. There are significant fluctuations in the ratios under investigation which can be attributed to the changes in the biomolecular structure between normal and leukemic samples Our results indicate that the absorbance of amide A and B in the range 3340-3000, the lipid/protein ratio and the phosphate/amide II ratio are all yielding statistically significant differences parameters, that it can be used as a biomarker in differentiating acute leukemia (samples 2 & 3) from leukemia free bone marrow (sample 1 & 4), also a good predictor of an early relapse, as seen in Figure 1 (samples 1 & 2). *Conclusions*. This study provides evidence that FTIR spectroscopy is a valuable tool in detecting early relapse and minimal residual disease. Several interesting and consistent spectral differences between patient and control spectra may be considered as a promising basis for a future study with large number of samples and as a routine study in predicting minimal residual disease.

INCREASING *DE NOVO* SYNTHESIS OF CERAMIDES INCREASED NILOTINIB INDUCED APOPTOSIS IN HUMAN MEG-01 CHRONIC MEGACARYOBLASTIC CELLS

Y. Baran,[1] E.B. Gencer, [1]A.U. Ural,[2] F. Avcu[2]

[1]Izmir Institute of Technolology, IZMIR, Turkey; [2]Gulhane Medical School, Department of Hematology, Etlik, ANKARA, Turkey

Background. The sphingolipids are a family of membrane lipids with important structural roles in the regulation of the fluidity and subdomain structure of the lipid bilayer. These molecules have significant roles in cell growth, proliferation, apoptosis, cell migration and senescence. Many sphingolipid-regulated functions have significant and specific links to various aspects of cancer initiation, progression and response to anticancer treatments. It is very well known that accumulation of intracellular ceramides induce apoptosis while the conversion of ceramides to some other metabolites result in resistance to anticancer agents. Nilotinib is a novel anti cancer agent used for the treatment of chronic myeloid leukemia. *Aims*. In this study, we tried to examine the possibility of increasing sensitivity of Meg-01 cells to dasatinib by increasing intracellular concentrations of ceramide through exogenous addition of C:8 ceramide to growth medium. By this way de novo synthesis of ceramide is induced and ceramide accumulation is provided. *Methods*. The Ph (+) human Meg-01 cells were exposed to increasing concentrations of nilotinib and a ceramide analog (C8:ceramide) and combination of both. IC50 values of nilotinib and C8:ceramide was calculated from cell proliferation plots obtained by XTT cell proliferation assay. Changes in caspase-3 enzyme activity were determined using the caspase-3 colorimetric assay. The mitochondrial membrane potential (MMP) was measured using JC-1 MMP detection kit. Results: IC50 values of nilotinib and C8:ceramide were found to be 2.2 nM and 70 μM in Meg-01 cells. There were 19-, 22-, 45-, and 82% decreases in cell proliferation in 0.01-, 0.1-, 1-, and 10 nM nilotinib applied Meg-01 cells, respectively, while the combination of these doses with 70 μM C8:ceramide resulted in 72-, 76-, 80-, and 88% decreases in cell proliferation, respectively, as compared to untreated controls. There were 1.9- and 3.62 times increases in caspase-3 enzyme activity in 1- and 10 nM nilotinib applied cells while their combination with 70 μM C8:ceramide resulted in 9.67- and 12.54 times increases comparing to untreated controls. 70 μM C8:ceramide alone resulted in 2.1 times increase in caspase-3 enzyme activity. Similar results were obtained for changes in MMP. There were 1.1- and 1.2 times increases in MMP in 1- and 10 nM nilotinib applied cells while their combination with 70 μM C8:ceramide resulted in 22.3- and 26.1 times increases comparing to untreated controls. 70 μM C8:ceramide alone resulted in 10 times increase in MMP. *Conclusions*. By these results we have shown for the first time that increasing de novo synthesis and accumulation of C8:ceramide resulted in significant sensitivity of Philadelphia positive chronic megacaryoblastic cells to nilotinib.

1462

DETECTION OF BCR-ABL BREAKPOINTS IN SAMPLES OF CML PATIENTS UTILIZING THE QUANTITATIVE RT-PCR ASSAY COMBINED WITH THE MELTING POINT ANALYSIS USING SYBR GREEN

E. Hanusovska,[1] K. Markova,[2] P. Krizan[2]

[1]Medirex, a.s., BRATISLAVA; [2]Medirex a.s., BRATISLAVA, Slovakia

Background. Chronic myeloid leukemia (CML) is a model of a disease with targeted and tailored therapy. Monitoring of CML patients, treated by tyrosine kinase inhibitors, is based on evaluation of hematological, cytogenetic and molecular response. Quantification of BCR-ABL fusion gene transcripts in leukemic blasts are measured by quantitative real time PCR with reverse transcription (QRT-PCR). The type of BCR-ABL breakpoint is typically performed by nested reverse transcription PCR (RT-PCR) and visualized on agarose gel. *Aims*. To characterize the most frequent BCR-ABL breakpoint types (b3a2 and b2a2) using a simple melting point analysis with SYBR Green instead of the time-consuming nested RT-PCR simultaneously with quantification of BCR-ABL transcript´s levels by QRT-PCR assay. Methods. Samples from CML patients (n = 162), which have been treated with tyrosine kinase inhibitors, were obtained from 6 hematological clinics in Slovakia. RNA was isolated from PK or BM after separation of WBC and stabilization in RNAlater solution. cDNA was obtained by using TaqMan Reverse Transcriptase system. RQ-PCR was performed by real time PCR system using a specific BCR-ABL TaqMan probes. The quantification of fusion transcripts were evaluated according to ELN guidelines as BCR-ABL/ABL

ratio (NCN values = Normalized copy number). The type of BCR-ABL breakpoint was provided by the denaturation melting point analysis on real time PCR systems using SYBR Green and universal primers for major-BCR-ABL fusion transcripts b3a2 and b2a2 used in QRT-PCR assay (M-bcr_For: 5´TCCGCTGACCATCAAYAAGGA, ABL_Rev: 5´CACTCAGACCCTGAGGCTCAA). The amplification profile was identical as in TaqMan quantification protocol but with additional dissociation step. Control samples were verified by nested RT-PCR and the type of breakpoint was detected on 1.5% agarose gel.

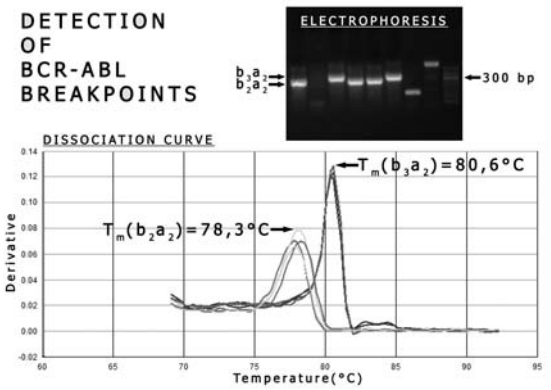

Figure 1. Detection of BCR-ABL breakpoints.

Results. Quantification of BCR-ABL fusion transcripts of CML patients by QRT-PCR has been provided every 3 months and results were expressed in NCN values. During the first period of our study types of BCR-ABL breakpoints were detected by nested RT PCR. Samples (cDNA) with b3a2 and b2a2 breakpoints were used as positive controls in denaturation melting point analysis in the second part of our study. This method utilizing the incorporation of SYBR green during amplification and its release at melting temperature (Tm) was used. From the derivative curve of amplicons, melting temperatures of Tm= 78.3±0.5°C for b2a2 and of Tm= 80.6±0.5°C for b3a2 were obtained. Preliminary results (n=52) were obtained from newly diagnosed and monitored patients with at least value NCN ≥0.005 (average NCN= 1.2). *Conclusions*. We have established a simple method for the detection of most common breakpoint BCR-ABL fusion transcript type (b3a2 and b2a2) by denaturing melting point analysis using SYBR green. This analysis can be in general provided simultaneously with BCR-ABL quantification using TaqMan probes on real time PCR system.

EFFECT OF IMATINIB MESYLATE ON PLATELET AGGREGATION ABNORMALITIES IN BCR-ABL + CML PATIENTS

S.U. Mogalluru

Kokilaben Dhirubhai Ambani Hospital, MUMBAI, India

Background. Bleeding and thrombotic events complicate the clinical course of chronic myeloproliferative disorders (CMPDs). A spectrum of platelet aggregation abnormalities have been described in CML. Clonal involvement of megakaryocytopoiesis is regarded as the main origin of these abnormalities. Effects of cytoreductive drugs on platelet aggregation abnormalities have been studied which showed no significant corrective effect. Effect of Imatinib mesylate on platelet aggregation abnormalities has not been studied so far. *Purpose of the study*. Our study aims at assessing the effect of imatinib mesylate on platelet aggregation abnormalities in BCR-ABL positive CML patients. *Design and Methods.* A total of 50 newly diagnosed BCR-ABL positive CML patients and 30 normal healthy volunteers were enrolled in the study. BCR-ABL by RT-PCR and Platelet aggregation parameters by CHRONOLOG aggregometer using arachidonic acid (AA), collagen, adrenaline (ADR), adenosine diphosphate (ADP) and ristocetin as agonists were measured both at diagnosis and after a minimum of 3 months of imatinib therapy. Platelet aggregation parameters measured for each agonist were Degree of aggregation (DOA) and Rate of Aggregation (ROA). DOA was calculated by increase of transmissions for 1 minute/ total maximum transmissions in 2 minutes measurement of platelet aggregation and expressed as percentage. ROA was calculated as the number of 1mm squares under the platelet aggregation curve in 60 seconds. These parameters were calculated for each agonist for all patients and controls and their mean + 2SD were analyzed. *Results*. Forty-eight cases were in chronic phase (CP), accelerated (AP) and blast phase (BP) constituted one each. DOA and ROA parameters in 39/48(81%) cases in CP and both AP and BP cases measured with ADP, AA, and ADP as agonists in the pre-imatinib phase showed a statistically significant lower values compared to healthy controls. 3/48 (6%)CP cases showed hyperaggregation with ADR only and 6/48(13%) showed normal aggregation parameters. In the post-imatinib phase, the abnormal aggregation parameters normalized in 32/39(82%) CP cases. 7/39 (18%) CP, AP and BP cases persistently showed lower values. No significant difference is noted in parameters measured using ristocetin and collagen as agonists when compared among pre and post imatinib phases and controls. *Conclusions*. The normalization of aggregation parameters may be attributed to either partial or complete suppression of clonal abnormal megakaryocytopoiesis and restoration of normal megakaryocytopoiesis by imatinib mesylate therapy in BCR-ABL positive CML.

ACCUMULATION OF APOPTOTIC CERAMIDES INCREASED APOPTOTIC EFFECTS OF NILOTINIB IN PHILADELPHIA POSITIVE MEG-01 CELLS SYNERGISTICALLY

Y. Baran,[1] E.B. Gencer,[1] A.U. Ural,[2] F. Avcu[2]

[1]Izmir Institute of Technolology, IZMIR, Turkey; [2]Gulhane Medical School, Department of Hematology, Etlik, ANKARA, Turkey

Background. Glycolipids, in addition to being essential membrane structural elements, are involved in cell proliferation, differentiation, and oncogenic transformation. Several findings by our and some groups suggest that alterations in ceramide metabolism could be, at least in part, responsible for the acquisition of a multidrug resistance (MDR) phenotype in cancer cells. The roles of ceramides in apoptosis were demonstrated by the finding that alterations in ceramide metabolism, whereby pro-apoptotic ceramide is converted to its non-cytotoxic glucosyle ceramide (GlcCer) metabolite. Several tumor cell lines and clinical samples have been shown to overexpress the glucosyl ceramide synthase (GCS) enzyme, which transfers glucose from UDP-glucose to ceramide and produces GlcCer. Accumulation of GlcCer is a characteristic of some multidrug-resistant cancer cells of breast, ovarian, colon, and epithelioid carcinomas. Nilotinib is a recently developed agent used for the treatment of philadelphia positive chronic myeloid leukemia. *Aims*. In this study, we investigated a strong GCS enzyme inhibitor, PDMP, induced chemosensitization to nilotinib in philadelphia positive human Meg-01 chronic megacaryoblastic leukemia cells. It was observed that a non-toxic dose of PDMP induced apoptosis in Meg-01 cells synergistically in response to nilotinib. *Design and Methods*. The Ph (+) human Meg-01 cells were exposed to increasing concentrations of nilotinib and PDMP and combination of both. IC50 value of nilotinib and IC90 value of PDMP was calculated from cell proliferation plots obtained by XTT cell proliferation assay. Changes in caspase-3 enzyme activity were determined using the caspase-3 colorimetric assay. The mitochondrial membrane potential (MMP) was measured using JC-1 MMP detection kit. Results: IC50 value of nilotinib and IC90 value of PDMP were found to be 2.2 nM and 50 μM, respectively, in Meg-01 cells. There were 19-, 22-, 45-, and 82% decreases in cell proliferation in 0.01-, 0.1-, 1-, and 10 nM nilotinib applied Meg-01 cells, respectively, while the combination of these doses with 50 μM PDMP resulted in 67-, 72-, 74-, and 95% decreases in cell proliferation, respectively, as compared to untreated controls. To get more specific results about the synergistic effects of these agents, we performed caspase-3 and MMP analyses. There were 1.08- and 1.91 times increases in caspase-3 enzyme activity in 0.1- and 1 nM nilotinib applied cells while their combination with 50 μM PDMP resulted in 2.45- and 2.59 times increases comparing to untreated controls. 50 μM PDMP alone resulted in 1.42 times increase in caspase-3 enzyme activity. Similar results were obtained for changes in MMP. There were 1.24- and 1.85 times increases in MMP in 0.1- and 1 nM nilotinib applied cells while their combination with 50 μM PDMP resulted in 3.21- and 3.62 times increases comparing to untreated controls. 50 μM PDMP alone resulted in 1.5 times increase in MMP. *Conclusions*. By these results we have shown for the first time that increasing intracellular ceramide concentrations by inhibition of conversion of apoptotic ceramide to anti-apoptotic glucosyl ceramide increased apoptotic effects of nilotinib in human Meg-01 cells.

GENETIC VARIANTS IN THE CANDIDATE GENES OF THE APOPTOSIS PATHWAY AND SUSCEPTIBILITY TO CHRONIC MYELOID LEUKEMIA

D.H. Kim,[1] W. Xu,[2] C. Ma,[2] H.J. Jun,[3] K.H. Kim,[1] C.W. Jung,[1] S. Kamel-Reid,[1] J.H. Lipton[2]

[1]Korea, SEOUL, South-Korea; [2]Princess Margaret Hospital, TORONTO, Canada; 3Konyang University Hospital, DAEJUN, South-Korea

Chronic myeloid leukemia (CML) is a clonal myeloproliferative disorder, characterized by the presence of BCR/ABL fusion gene. It is unclear which cellular events drive BCR/ABL gene translocation or initiate leukemogenesis in CML. Bcl-2 promotes survival of hematopoietic stem cells. Accordingly, apoptosis-related pathway may involve in the leukemogenesis of CML. In the current study, we evaluated 80 SNP markers involved in the pathways of apoptosis (n=30), angiogenesis (n=7), myeloid cell growth (n=14), xenobiotic metabolism (n=13), WT1 signaling (n=7), interferon signaling (n=4) and others (n=5) in 170 CML patients and 182 healthy controls. In a single marker analysis, following SNPs were identified including VEGFA, BCL2, CASP7, JAK3, CSF3 and HOCT1. In the multivariate logistic model with these SNPs and covariates, only BCL2 (rs1801018) was significantly associated with the susceptibility to CML (p=0.05; adjusted-OR 2.16, [1.00-4.68]). In haplotype analyses, haplotype block of BCL2 consistently showed significant association with the susceptibility to CML. Risk allele analysis showed that a greater number of risk alleles from BCL2 SNP correlated to increasing risk of CML (overall p=0.1, OR 1.84, [1.06-3.22] for 3-4 risk alleles vs. 0-1 risk alleles). The current study indicated that BCL2 SNP seemed to be associated with increasing susceptibility to CML.

IN VITRO ACTIVITY OF TYROSINE KINASE INHIBITORS ON NATURAL KILLER CELLS FROM CML PATIENTS AND HEALTHY CONTROLSB

A Kircher

KrimbacherMedical University Innsbruck, INNSBRUCK, Austria

The introduction of orally available tyrosine kinase inhibitors (TKIs) for the treatment of chronic myelogenous leukemia (CML) had an enormous impact on the outcome of this disease. However, different resistance mechanisms or intolerance, which may be overcome in the majority of patients by second-generation TKIs, and growing evidence that TKIs can display immunomodulatory or even immunosuppressive effects, are the major obstacles for this therapy. Natural killer (NK) cells have the capacity to detect changes in transformed cells in the absence of inflammatory signals and may therefore be involved in leukemia cell killing. To date, the knowledge regarding the effect of TKIs on natural killer cells is limited. Thus, aim of the study was to analyze the effect of imatinib mesylate and nilotinib on NK cells. The *in vitro* activity of these compounds was tested on NK cells from five CML patients and three healthy controls. Their effectiveness was analyzed regarding NK-specific surface molecule expression, cytotoxicity and interferon-γ release. CD56 expression of NK cells from CML patients and healthy controls remained unchanged after exposure to imatinib and nilotinib at various concentrations. Further, CD16 expression of NK cells was not influenced by nilotinib and and low-dose imatinib mesylate, but exposure to higher concentrations of imatinib mesylate (25, 50 μM) significantly diminished CD16 expression of normal and leukemic NK cells. After a 24-hour incubation with imatinib mesylate (10 μM) and nilotinib (5 μM) the number of viable NK cells decreased: This cytotoxic effect was more pronounced for leukemic NK cells compared to normal NK cells. Natural killing capacity and interferon-γ production of NK cells decreased after treatment with imatinib mesylate to a similar degree in CML-derived and normal NK cells. Notably, the suppressive effect of nilotinib on natural cytotoxicity was less pronounced. In summary, imatinib mesylate and nilotinib at higher concentrations can exert negative *in vitro* effects on the viability and cytotoxicity of NK cells from CML patients and healthy controls.

EVALUATION OF HUMAN TELOMERASE REVERSE TRANSCRIPTASE (HTERT) EXPRESSION IN PATIENTS WITH CHRONIC MYELOGENOUS LEUKEMIA (CML) AT DIFFERENT PHASES OF THE DIDEASE

Y. Mortazavi,[1] A. Amini2, S.H. Ghaffari,[2] N. Eynolahi,[3] K. Alimoghaddam,[2] S.H. Rostami,[2] Y. Jahani,[3] A. Ghavamzadeh,[2] A.R. Khademolmelleh[1]

[1]Zanjan Medical School, ZANJAN, Iran; [2]Hematology-Oncology and BMT Research Center, Shariati hospital, TEHRAN, Iran; [3]Tehran University of Medical Sciences, TEHRAN, Iran

Background. Chronic Myelogenous Leukemia (CML) is a clonal hematopoietic stem cell disorder characterized by a translocation between chromosome 9 and 22 called Philadelphia Chromosome. Telomerase- essential enzyme that adds telomeric repeats into the telomeres- maintains integrity of chromosomal ends. Most normal somatic cells do not express hTERT (catalytic subunit of telomerase) but it is expressed in most neoplastic and cancer cells. Aims. Our aim of this study was to evaluate the hTERT expression in patients with CML at different phases of the disease. *Design and Methods*. In this cross sectional study 73 samples of 45 patients with CML were studied. Twenty six of samples were taken from patients in chronic phase before therapy. Tewenty six samples were also taken from theses patients at least three month after therapy. Nine samples were taken from patients in accelerated phase and 12 from patients in blastic phase. RNA was extracted from peripheral blood mononuclear cells and cDNA was made using random hexamers. hTERT expression was studied by qualitative RT-PCR and the results were analyzed using Fisher's Exact test, χ^2, McNemar and Mann-Whitney tests. *Results*. 73% of patients were male and 27% were female. Patients were divided into three age groups; 17-29, 30-40 and 41-75 years. Of 73 samples, 43 samples (58.9%) were positive for hTERT and 30 samples (41.1%) were negative for this gene. In chronic phase (before therapy) 69.2% of the samples were PCR positive, but only 38.5% remained PCR positive after therapy. In accelerated and blastic phases 55.6% and 83.3% of samples were PCR positive respectively. The hTERT positivity was differently significant (p<0.05) among different phases of the disease. *Conclusions*. Our results showed that significant difference between hTERT expression in different phases of CML disease can be used as a useful molecular marker for fallowing up, prognosis and disease progression after treatment

MOLECULAR MONITORING: AN ESSENTIAL COMPONENT IN THE CLINICAL MANAGEMENT OF PATIENTS WITH CHRONIC MYELOGENOUS LEUKEMIA TREATED WITH TYROSINE KINASE INHIBITORS

R. Talmaci,[1] D. Coriu,[1] M. Müller,[2] D. Jardan,[1] M. Dragomir,[3] M. Damian,[4] M. Crisan,[3] A. Colita[1]

[1]University of Medicine and Pharmacy Carol Davila, BUCHAREST, Romania; [2]III.Medizinische Klinik, Universitätsklinikum Mannheim, University of Heidelberg, MANNHEIM, Germany; [3]Fundeni Clinical Institute, BUCHAREST, Romania; [4]Nat. Inst. of Research-Development for Microbiology and Immunology Cantacuzino, BUCHAREST, Romania

Background. The success of imatinib therapy for Chronic Myeloid Leukemia (CML) has brought new challenges; these include optimizing disease monitoring, imatinib resistance, and use of novel, more potent tyrosine kinase inhibitors. Thus, there is a need to establish new best practices for CML management in the post-imatinib era. In Romania imatinib therapy has been introduced since 2002, but for some financial reasons the molecular diagnosis is not routinely available so far. In 2007 using research grants we have set up in our institution, "Fundeni" Clinical Institute, a Molecular Biology Laboratory and here we report our results. *Methods and Results*. A Real-Time quantitative reverse transcriptase-polymerase chain reaction (RT-PCR) using LightCycler® technology was used to quantify BCR-ABL transcript levels in 207 peripheral blood samples collected from 113 patients with positive BCR-ABL transcript before and in the course of the imatinib treatment. Quantification of BCR-ABL was performed by RQ-PCR assay according to the European LeukemiaNet (ELN) protocol. Total RNA is extracted from 2 x 107 cells by Chomczynski et al protocol. Total amount of extracted RNA is transformed by reverse transcription PCR in to cDNA. Quantification of BCR-ABL transcripts is performed with Abl control gene. Total ABL transcripts were quantified as internal control and results were expressed as the ratio BCR-ABL/ABL. From total investigated cases, 74 patients are at first molecular investigation and 39 are in periodical investigation in our

laboratory for MRD monitoring. The median of relative quantity of BCR-ABL in the blood before imatinib therapy was 50%. The number of the transcripts in imatinib-sensitive subjects decreased to 2,62% in 6 months. After 12 months of the treatment the BCR-ABL median was 0,038%. Multiplex PCR and Nested PCR were performed for transcript type identification and revealed b3a2 and b2a2 BCR-ABL transcripts in 67% of cases and 33% respectively. In one case was identified a dual b3a2+b2a2 BCR-ABL type. Seven patients were resistant to imatinib with the BCR-ABL range of 12-48% during the treatment. For these patients direct sequencing of the ABL KD was performed. We identified some BCR-ABL mutations - T315I, L387M and Q215H, so this assay generate clinically useful information regarding the therapy with new Bcr-Abl inhibitors. *Conclusions*. This study, the first in Romania, indicates that quantitative PCR and screening of mutations in BCR-ABL kinase domain could provide practical indications capable of directing therapeutic interventions for CML patients, so the molecular monitoring must be a essential part in the clinical management of patients with Chronic Myeloid Leukemia treated with tyrosine kinase inhibitors.

This work was supported by the grant PN II 41-045 and PN 41-087/2007 from the Romanian Ministry of Research and Technology. The authors express their gratitude to European LeukemiaNet for their permanent support.

THREE NEW MUTATIONS FOUND IN CHRONIC MYELOID LEUKEMIA (CML) PATIENTS RESISTANT TO TYROSINE KINASE INHIBITORS (TKI)

C. Couto Mascarenhas

University of Campinas, CAMPINAS, Brazil

Background. Point mutations within the ABL kinase domain are the most frequent mechanism for reactivation of kinase activity of the BCR-ABL gene and have been associated with clinical resistance to TKI in CML patients, conferring a poor prognosis. For optimal clinical management of CML patients treated with TKI, early detection of mutations may help in defining alternative therapeutic strategies. Aims: Screening of mutations in exon 6 of the BCR-ABL gene in patients with CML resistant or intolerant to TKI and correlate the presence of mutations with patient outcome. *Design and Methods*. Genomic DNA was extracted from peripheral blood samples from 93 CML patients (5 intolerants and 88 resistants). The study population was classified according to criteria of the Leukemia Net as failure or sub-optimal response to imatinib. Patients resistant or intolerant to imatinib were treated with dasatinib or nilotinib. The study was approved by the Ethics Committee of the University of Campinas and prior to the study informed consent was obtained. The PCR product of BCR-ABL exon 6 amplification was analyzed by D-HPLC, and the patients samples with abnormal D-HLPC profiles were submitted to sequencing, using specific primers. Survival analysis for the whole group and for both groups (mutation vs no mutation) were performed using the Kaplan-Meier method for survival curves and proportional hazards regression model for statistical significance between groups. Overall survival (OS) was calculated from start of imatinib therapy until death or last follow-up. *Results*. Twenty-three out of 93 samples (25%) showed an abnormal elution profile. Sequencing confirmed the presence of a nucleotide change in 19 out of 23 cases. In four cases no mutation was found in sequencing. Mutations identified were: one polymorphism (T315T), T315I, F317L, V339L, M351T, E355G, F359V and three novel mutations: C305R, D325D and I360S. Patients presenting the new mutations located in imatinib contact site (C305R and D325D) had primary resistance or progression after dasatinib treatment. The I360S mutation is located in catalytic domain and was found in a patient with sub-optimal response with imatinib and in a patient with treatment failure that achieved complete hematological response with dasatinib. Overall survival (OS) for whole group was 80% in a median observation time of 30 months. OS was 87% and 56% for patients with no mutation and with mutation, respectively (p<0,0001) (RR=68). *Conclusions*. In this study we screened mutations in exon 6 of BCR-ABL gene and identified 3 novel mutations. In fact, the majority of mutations that confer resistance to dasatinib and imatinib are predicted to involve drug contact residues. In four cases with abnormal profile sequencing, we were unable to identify mutations, probably due to the sensitivity of the method, which requires a relatively high concentration of amplicons with mutation. In the survival analysis, patients presenting mutations had clearly a poor outcome. In conclusion, D-HPLC is a practical and sensitive method for routine clinical monitoring of kinase domain mutations and may be useful for optimizing therapy and decision making for alternative treatment in CML.

This work was funded by Fundação de Amparo a Pesquisa do Estado de São Paulo (FAPESP).

EFFICACY OF IMATINIB DOSE ESCALATION (IDE) IN CHRONIC MYELOID LEUKEMIA (CML) PRETREATED WITH INTERFERON-α (INF-α)

E. Faber, A. Kuba, S. Rozmanova, M. Divoka, R. Plachy, I. Skoumalova, M. Holzerova, M. Jarosova, K. Indrak

University Hospital, OLOMOUC, Czech Republic

Background. In case of imatinib (IM) failure or suboptimal response IDE to 600-800 mg daily has been recommended as the first option for management of patients with CML according to guidelines of European Leukemia Net. However there are only a few publications focused on the topic. *Aims.* Our study has been aimed on evaluation of IDE efficacy in INF-α pre-treated patients. *Design and Methods*. A retrospective study was performed. Patient´s risk at diagnosis, presence of additional cytogenetic abnormalities (ACyA), cause of IM resistance and response to therapy were evaluated for influence on IDE efficacy. 4. Results 65 INF-α pretreated CML patients were analysed. Median interval since diagnosis up to IM therapy was 15 months (range, 1-102 months). Median follow-up from diagnosis was 81 months (range, 32-169 months), while the median follow-up from initiation of IM was 60 months (range, 7-98 months). In 14 patients (21,6%) IDE was used for hematologic resistance in 1 patient, cytogenetic relapse or progression in 9 and suboptimal response in 4 patients. In IDE patients median interval since the start of standard dose IM up to dose escalation was 28 months (range, 4-54 months). Previous response to standard dose IM was complete CyR in 8 patients achieved after median 10 months and lasted for median 8 months. The median period of IDE therapy was 9 months (range, 6-14 months). After IDE 5 patients achieved complete CyR and 7 patients major CyR with average duration of 9 and 14 months. However, only 2 patients achieved major molecular response. Majority of the patients were switched to second generation tyrosine kinase inhibitors due to hematologic (2 patients; 14,3%) or cytogenetic resistance (6 patients; 42,9%) and suboptimal response (1 patient; 7,1%). Only 4 patients (28,6%) continue with IDE presently. *Conclusions*. In most INF-α pretreated patients IDE resulted in transient CyR that was shorter than one year. Response to IDE seems to be associated with absence of ACyA and BCR-ABL tyrosine kinase domain mutations and achievement of major molecular response, but with no other variables including Sokal risk or response to standard dose of IM. Larger groups of patients are needed to be analysed in order to assess the actual role of IDE in INF-α pretreated patients with CML.

Study was supported by the grants NS9949-3 IGA, MSM 6198959223 and MSM 6198959205.

MONITORING T315I MUTATION IN CHRONIC MYELOID LEUKEMIA BY ARMS PCR

D.M. Dima,[1] A.P. Trifa,[2] A. Cucuianu,[1] R.A. Popp,[2] L. Petrov[1]

[1]"Ion Chiricuta" Cancer Institute, CLUJ-NAPOCA, Romania; [2]University of Medicine and Pharmacy, Department of Medical Genetics, CLUJ-NAPOCA, Romania

Background. The introduction of imatinib mesylate has revolutionized the treatment of chronic myeloid leukemia (CML). Even though experience with imatinib mesylate is limited, clinical resistance has already been observed. In order to overcome imatinib resistance, more potent tyrosine kinase inhibitors such as nilotinib and dasatinib have been developed with demonstrable activity against most BCR-ABL mutations with the notable exception of T315I mutation. More, with the increased use of newer tyrosine kinase inhibitors it has been suggested that the spectrum of mutations may change, possibly selecting the pan-resistant T315I. *Aims*. To assess the prevalence of the T315I mutation in a cohort of Romanian CML patients in order to adapt the treatment at any time the clinical and hematological aspects change. *Design and Methods*. There were 41 CML patients (21 women, 20 men) with a median age of 56,73 years (24-85) diagnosed and treated in our institution between august 1996 and december 2008. At the moment of sampling, 34 patients were in chronic phase, 2 patients in accelerated phase and 5 patients in blastic phase. 32 patients had been treated with tyrosine kinase inhibitors (TKI), for variable intervals (1-60 months, median 21,37). 32 patients had received imatinib, 400-600 mg/day (12 as first line treatment, 20 as second and third line) and 3 patients had received dasatinib (2 as second line and one as third line treatment). The T315I mutation was studied by an ARMS PCR (Amplification Refractory Mutation System - Polymerase Chain Reaction) technique. *Results*. At the moment of sampling 2 patients (0,84%) were in major molecular response (MMR), 1 patient

(0.42%) was in minor molecular response (mMR), 11 patients (4,62%) in complete cytogenetic response (CCyR), 1 patient (0,42%) in partial cytogenetic response (PCyR), 1 patient (0,42%) in minor cytogenetic response (mCyR) and 12 patients (5,04%) were in complete hematological response (CHR).The 2 patients with MMR were both treated with imatinib as the patient with mMR. Among the 11 patients in CCyR, 10 were treated with imatinib and 1 with dasatinib. Of the 12 patients in CHR, 9 were under imatinib and 3 patients were treated with hydroxiurea. The T315I mutation was found in only one patient, diagnosed in 1998 who was in clinical and hematological relapse after several lines of treatment (interferon + Ara-C, imatinib, dasatinib). *Conclusions*. The T315I mutation was a very rare event in our patient population, despite a high proportion of patients who had a suboptimal response after TKI treatment. An explanation could be the fact that few of our patients were treated as first line therapy with TKIs; also, few patients were treated with high-dose TKIs. Therefore it is possible that there was not enough time and selective pressure for the emergence of the T315I mutation. Further follow-up of the patients treated as first line-therapy TKI may result in a higher rate of T315I detection. This aspect is of utmost importance as such CML patients may be the ones who will actually benefit from allogeneic stem cell transplantation.

Background. Nilotinib, a potent and highly selective BCR-ABL inhibitor, has been approved in more than 50 countries including Mexico. Nilotinib is indicated for the treatment of Philadelphia chromosome-positive chronic myelogenous leukemia (Ph^+ CML) patients (pts) in chronic (CML-CP) or accelerated phase (CML-AP) resistant or intolerant to prior therapy including imatinib (IM). Before the approval of nilotinib by FDA or EMEA a CUP of nilotinib was initiated in Mexico. Aims: To evaluate the rates of cytogenetic and molecular responses to nilotinib in IM-resistant or -intolerant Ph^+ CML included in the CUP of nilotinib in Mexico. *Design and Methods*. The pts included in this program were adults pts with imatinib-resistant or intolerant CML-chronic phase (CP),-accelerated phase (AP), or -blast crisis (BC). IM resistance was considered if pts had failure to standard doses of IM or had loss of response and/or progression and were treated with higher doses of IM (600 mg/day or 800 mg/day) and did not respond to these dose escalation, IM intolerance/resistance was considered if pts with previous failure to standard doses of IM did not tolerate the dose escalation and needed a subsequent dose reduction.Physical examination, EKG, bone marrow aspiration, karyotyping and BCR-ABL mutation screening were performed in all pts before starting nilotinib. All pts signed an informed consent. Nilotinib was administered orally at a dose of 400 mg twice daily (BID). No dose escalation was allowed. All pts were monitored with karyotyping. Patients that achieved CCyR were evaluated with quantitative RT-PCR for molecular evaluation (Quest Diagnostics and Molecular MD) The results of CUP of nilotinib in Mexican patients are reported in this abstract including the cytogenetic, qRT-PCR and mutational analysis in a highly-resistant CML patient population. Results: Between October 2006 and June 2007, 47 pts were included in the nilotinib CUP in Mexico. The median age was 41.7 years (range 22-68) and 20 (44%) were men. Of the 47 pts, 28 (59.6%) had advanced phase CML which includes 7 (14.9%) blastic phase (BP) and 21 (44.7%) accelerated phase (AP) pts. 19/47 pts (40%) were in chronic phase (CP) of CML. Most patients were resistant to IM (86%) and 14% were IM-intolerant/resistant. The median duration since CML diagnosis was 74 months (range 14-183). The median duration of prior IM use was 27 months. All pts had been treated with hydroxyurea, interferon, and/or cytarabine prior to IM. At the time of starting nilotinib 17/47 pts (36.12%) had BCR-ABL mutations (P-loop mutations in 3 pts, IM binding mutations in 5 pts, catalytic domain mutations in 5 pts, and A-loop mutations in 4 pts). Only 3/47 pts (6.38%) had T315I mutation. The median duration of exposure to nilotinib was 403 days (range 19-840). Most pts tolerated nilotinib well. One patient developed long-term myelosupression. At the time of data cut-off (January 31th, 2009), 25 pts (53.2%) remain on therapy. Reasons for discontinuation of therapy were: a) lack of efficacy in 7/47 pts (14.9%) including 3 pts with T315I mutation; b) disease progression in 13/47 (27.5%); c) adverse events in 1/47 (2.1%); d) lost of follow-up in 1/47 (2.1%). The cytogenetic and molecular evaluation was performed after 12 and 18 months of treatment with nilotinib, respectively. The rate of overall hematological response (HR) was 79%. The major cytogenetic response (MCyR) according the phase of the disease were as follows: 57% in CP, 40% in AP and no MCyR was observed in BP. Of the 47 pts, 11 (23.4%) achieved CCyR (7 pts with CP-CML and 4 pts with AP-CML), five patients (10.63%) achieved molecular responses (3 pts with CP-CML and 2 pt with AP-CML) including 2 pts (4%) with complete molecular response (CMR) and 3 (6%) with major molecular response (MMR). *Conclusions*. Nilotinib showed efficacy in IM-resistant or -intolerant CML pts in Mexico regardless of the presence or absence of BCR-ABL mutations. Nilotinib induced complete cytogenetic and molecular responses in some of resistant CP and AP-CML patients.

1473

KINETICS OF BCR-ABL TRANSCRIPTS IN PATIENTS WITH CHRONIC PHASE CML (CML-CP) TREATED WITH IMATINIB MESYLATE (IM): A PREDICTOR OF RESPONSE AND PROGRESSION FREE SURVIVAL (PFS)

H.K. Mahmoud,[1] Y.H. El Nahas,[1] M.A. Samra,[2] R.M. Abdel Fattah,[2] M.A. El Emary,[2] W.H. El Metnawy[1]

[1]Cairo University, CAIRO, Egypt; [2]Nasser Institute of Health, CAIRO, Egypt

Aims. To assess whether early kinetics of molecular response to IM therapy is a predictor of PFS, and sustained hematological and cytogenetic responses in newly diagnosed patients with CML-CP. *Design and Methods*. Ninety-five newly diagnosed Egyptian patients with CML-CP were treated with a daily oral dose of IM 400 mg unless otherwise indicated. Conventional karyotyping and fluorescent *in situ* hybridization (FISH) analysis were performed at diagnosis, every 6 months during the first 2 years of treatment, and then annually or as necessary during a median follow-up period (FUP) of 26 months (range 6-64 months). Molecular monitoring by real time quantitative polymerase chain reaction (RT-QPCR) was performed at diagnosis and at regular intervals every 3 months during the FUP. Mutational analysis of the ABL kinase domain was performed by allele-specific oligonucleotide PCR (ASO-PCR). *Results*. The study demonstrated that 98% of patients achieved a hematological response after three months of therapy with IM 400 mg/day. Fifty-nine of 95 patients (62%) showed a 2-log reduction of the BCR-ABL/ABL ratio at 6 months of IM therapy, of whom 49 patients (83%) achieved a complete cytogenetic response (CCyR) and 42 of 59 (71%) of patients achieved a major molecular response (MMR) at 12 months. BCR-ABL transcripts remained undetectable in 22 patients (37%) after 26 months of consecutive measurements and these patients remained in CCyR at the time of data cut-off. Among the 36 patients who did not achieve a 2-log reduction of the BCR-ABL/ABL ratio at 6 months, only 5 patients (15%) achieved a CCyR and MMR by 12 months. There was a statistically significant difference between both groups in the duration of cytogenetic and molecular responses ($p<0.0001$). Failure to achieve a 2-log reduction at 6 months of IM therapy correlated with a decreased rate of PFS at 2 years ($p<0.03$) and with the presence of ABL kinase domain mutations ($p<0.001$). All primary resistant cases (16/16, 100%) and 16/18 (89%) suboptimal IM responders failed to achieve a 2-log reduction of BCR-ABL transcripts after 6 months of IM treatment versus 2/59 (3%) of the optimally responding group ($P < .0001$). Among 15 patients (10 suboptimal responders and 5 with primary resistance), ABL kinase domain mutations were detected in 11/15 (73%) of these patients. *Conclusions*. The present data demonstrate the predictive value of an early molecular response to IM for patients with CML-CP. Less than a 2-log reduction in BCR-ABL transcripts at 6 months of IM treatment could

be considered a cut off level that may predict resistance, lower probability of achieving a CCyR, and decreased rate of PFS at 2 years or suggest the need for IM dose escalation.

1474

TOWARDS A NEED IN OPTIMIZING CML MANAGEMENT IN SUBOPTIMAL RESPONDERS: DATA FROM THE SCREEN REGISTRY

F. Stagno,[1] P. Vigneri,[2] S. Stella,[2] V. Del Fabro,[1] M. Massimino,[2] A. Cupri,[1] A. Antolino,[3] V. Abbadessa,[4] M. Brugiatelli,[5] F. Morabito,[6] C. Musolino,[5] M. Russo,[7] R. Scimè,[8] A. Messina,[2] F. Di Raimondo[1]

[1]Section of Hematology, CATANIA, Italy; [2]Section of General Pathology, CATANIA, Italy; [3]SIMMT, Paternò-Arezzo Hospital, RAGUSA, Italy; [4]Hematology Section, Policlinico Hospital, PALERMO, Italy; [5]Hematology Section, Papardo Hospital, MESSINA, Italy; [6]Hematology Section, Annunziata Hospital, COSENZA, Italy; [7]Hematology Section, S. Vincenzo Hospital, TAORMINA, Italy; [8]Hematology Section, Cervello Hospital, PALERMO, Italy

Background. The introduction of Imatinib Mesylate (IM) has produced major advances in the treatment of Chronic Myeloid Leukemia (CML). High rates of stable response continue to be reported, with >85% of patients (pts) achieving complete hematologic and cytogenetic responses after 5 years of treatment. However, residual resistant disease after IM treatment may occur in CML and the incidence of resistance increases in the more advanced phases. Given this evidence, IM failure has been defined on the basis of hematologic, cytogenetic and molecular responses at set time points as well as progression and warning signs. Current studies indicate that accurate monitoring of IM response is required to identify CML pts who respond poorly or lose response in order to assess whether a change in therapy strategy could be appropriate. Moreover, a proportion of CML patients still remains who present minimal residual disease to IM therapy and are at high risk of disease progression: they are the suboptimal responders. *Aims and Methods*. To address this clinical topic, we screened a consecutive series of *de novo* 210 pts with CML. All of them were included in the SCREEN registry (Sicilian CML Registry Enterprise) which started on April 2005 and is still open to enrolment, now even in the region of Calabria. The registry was designed in order to create a regional network that will perform the molecular monitoring of IM-treated CML patients and to assure the same standard of care all over the regions. A preliminary data analysis on 140 CML pts, allowed us to identify 26 pts as suboptimal responders. *Results and Conclusions*. Here we will report CML suboptimal responders' baseline features, molecular monitoring of bcr-abl transcript (according to ISS), clinical outcome to tyrosine kinase inhibitor (TKI) therapy and follow-up and, whenever indicated, bcr-abl mutational analysis of this cohort of pts. Our CML suboptimal responders represented 18% of the total enrolled CML population and this data is in accord to the IRIS findings. Of interest, CML suboptimal responders showed a high bcr-abl molecular transcript at diagnosis as compared to normal responders (median bcr-abl transcript 0,73 vs. 0.57 on the ISS). Three out of 26 (11%) suboptimal pts shifted to second line treatment (1 BMT, 2 second TKI). Further, the issue of suboptimal responders who achieved CCyR but failed to achieve MMolR at 18 mo. will be addressed. Our preliminary data strongly support the critical need in identifying and optimizing CML management with second line therapy (high IM doses, second TKIs) in suboptimal responders to IM treatment.

TREATMENT OF 171 PATIENTS WITH CHRONIC MYELOID LEUKEMIA IN EARLY AND LATE CHRONIC PHASE WITH IMATINIB MESYLATE. EXPERIENCE OF A SINGLE INSTITUTION AT MEDICAL SCHOOL AT UNIVERSITY OF SAO PAULO - BRAZIL

I. Bendit, M. Conchon, L. Nardinelli, M.M.Y. Novaes, L. Dias, P.B. Ferreira, C.A. Kumeda, A.R.L. Ruiz, P.T. Bueno, D.A.F. Chamone, P.E. Dorlhiac-Llacer

University of Sao Paulo, SAO PAULO, Brazil

Chronic myeloid leukemia is characterized by the presence of Ph chromosome where the BCR-ABL chimeric gene is a target for the tyrosine kinase inhibitor imatinib mesylate (IM). Molecular monitoring became the method of choice to follow patients treated with IM. Objective: Compare the complete cytogenetic response (CCR), and major molecular response (MMR) in a population of a single institution (HC-FMUSP), and then correlate with overall survival (OS), event free survival (EFS), and progression free survival (PFS). *Design and Methods*. 171 serial patients with CML-CP were evaluated, and divided in 2 groups: early chronic phase (77/171), define as the interval from diagnosis to the beginning of IM less than 6 mo and late chronic phase (94/171) as more than 6 mo. Cytogenetic studies were done by G-banding karyotyping and molecular monitoring and gene expression were done by QRT-PCR. Mutational analysis was performed by direct sequencing when resistance was identified or progression of the disease. *Results*. CCR was achieved in 71.9% of the patients with a median time of 11.2 months. The ECP patients CCR was achieved in 71.3% and 87.7% at 12 and 60 months what is in agreement with the IRIS study. In the LCP the CCR was 34.8% and 58.9% at 12 and 36 months of treatment. Molecular monitoring was performed only in 86.5% (149/171) of the patients and MMR in the ECP group was 40%, 60% and 74% at 12, 18 and 24 months of treatment, on the other hand, patients with LCP reach a MMR of 15% and 47% at the same time (p=0.005). The best molecular response at 3 months of treatment has a high probability in achieving a MMR when compared to those who do not achieve a 1-log reduction at 3 months (p=0.03). The estimated risk of resistance in the group with the best molecular response was 0%. Mutational analysis detected 6 muation where 5 in LCP patientes.There were no statistical difference between those 2 groups regarding OS, EFS and DFS. Resistance was more frequent in the LCP when compared with ECP (p=0.02). *Conclusions*. For the first time is reported the outcome comparing patients treated with IM before 6 mo and after 6 mo from the diagnosis, demonstrating that within 6 mo is the optimal timeframe for treatment starting regarding CCR and MMR, but not OS, DFS and PFS.

1476

RETROSPECTIVE EVALUATION OF PATIENTS TREATED WITH DASATINIB FOR PHILADELPHIA POSITIVE LEUKEMIAS: TURKISH EXPERIENCE OF 16 MONTHS

G. Saydam,[1] I.C. Haznedaroglu,[2] Y.T. Temiz,[3] T. Soysal,[4] G. Sucak,[5] M. Tombuloglu,[1] H. Ozdogu,[6] A.S. Yavuz,[7] A. Altintas,[8] Z. Gulbas,[9] O. Ilhan[10]

[1]Ege Faculty of Medicine, IZMIR, Turkey; [2]Hacettepe Faculty of Medicine, ANKARA, Turkey; [3]Bristol-Myers Squibb, ISTANBUL, Turkey; [4]Cerrahpasa Faculty of Medicine, ISTANBUL, Turkey; [5]Gazi Faculty of Medicine, ANKARA, Turkey; [6]Adana Baskent Faculty of Medicine, ADANA, Turkey; [7]Istanbul Faculty of Medicine, ISTANBUL, Turkey; [8]Dicle Faculty of Medicine, DIYARBAKIR, Turkey; [9]Osmangazi Faculty of Medicine, ESKISEHIR, Turkey; [10]Ankara Faculty of Medicine, ANKARA, Turkey

Background. Dasatinib, *in vitro* 325 fold more potent bcr-abl inhibitor than imatinib, has been registered for use in patients with the diagnosis of CML or Ph$^+$ ALL and AIMS: The aim of this study is to retrospectively evaluate the Turkish patients treated with dasatinib for the diagnosis of either CML or Ph$^+$ ALL under the program of compassionate use. *Design and Methods*. The 130 patients accepted to compassionate use program (sponsored by Bristol-Myers Squibb) between the dates of November 2006 and April 2008 were enrolled into this study. Patients were evaluated according to the age, gender, time from the diagnosis, the reasons for dasatinib treatment, and the stage of the disease, last imatinib doses, last treatment status with dasatinib, adverse events under dasatinib treatment, and response status to dasatinib treatment retrospectively. RESULTS: Of 130 patients, 57 women and 73 man had 48.7±13.7 (18-75) and 45.4±15.7 (19-83) years of age respectively. Median time from diagnosis to dasatinib treatment was calculated as 73.96±52.65 (1-288) months. The disease status at the beginning of dasatinib treatment was as follows; chronic phase of CML in 75 patients (57.7%), accelerated phase of CML in 25 patients (19.2%), blastic phase of CML in 18 patients (13.8%), and Ph$^+$ ALL in 12 patients (9.2%). The reason for initiating dasatinib treatment were grouped as; progression under imatinib treatment in 37 patients (40.2%), resistance to imatinib therapy in 30 patients (32%), intolerance to imatinib in 16 patients (17.4%)and combination of these in 9 patients (9.8%). The last imatinib dose prior to initiation of dasatinib was 613.79±169.93 (300-1000) mg/day. Twenty patients died due to mainly disease progression (12 of 20), and 8 patients were excluded from the program, 5 patients could not start the drug, and remaining 97 patients (74.6%) are still on treatment. There have been no reported adverse events for 90 patients (69.2%); disease progression and grade 1-2 myelosupression were the most frequently reported events. Median duration of treatment with dasatinib was 7.94±4.53 (1-17 +) months at the last follow up. Most of the patients who continued their treatment with dasatinib were under complete hematological response and molecular and cytogenetic statuses of the patients were still under evaluation at the last follow up. *Conclusions*.

Dasatinib treatment in Turkish patients with CML or Ph+ ALL was well tolerated and resulted in favorable outcomes with only mild side effects in most cases during the period of observation of patients with accessible data so far.

1477

COEXISTENCE OF A JAK2 MUTATED CLONE MAY CAUSE HEMATOLOGIC RESISTANCE (HRES) TO TIROSYN-KINASE INHIBITORS (TKI) IN CHRONIC MYELOID LEUKEMIA (CML)

C. Fava,[1] G. Rege-Cambrin,[1] D. Ferrero,[2] S. Ulisciani,[1] A. Serra,[1] E. Giugliano,[1] M. Fava,[1] E. Gottardi,[1] L. Giaretto,[1] G. Saglio[1]

[1]San Luigi Hospital, ORBASSANO (TO), Italy; [2]Department of Hematology-University of Turin, TORINO, Italy

Background. Among the classic myeloproliferative neoplasms (MPN), only CML is characterized by the chromosomal translocation t(9;22) resulting in the BCR-ABL oncogene. The discovery that JAK2-V617F mutation is found in virtually all patients with policytemia vera and approximately 50% of those with either essential thrombocytopenia (ET) or primary myelofibrosis (PMF), has refined current diagnostic criteria in MPN. *Aims*. Most systematic investigations showed that JAK2 mutation and BCR-ABL were virtually exclusive and their coexistence has been described in rare patients. We report 3 such cases. *Methods and Results.* Patient 1 was diagnosed of CML, following the discovery of thrombocytosis. She started imatinib 400 mg then increased to 800 mg for HRes, but platelet control was never achieved and hydroxiurea was added. She could not tolerate IFN so started nilotinib for leucocytosis, thrombocytosis and 100% Ph-positivity. Bone marrow (BM) showed granulocytic and megakaryocytic hyperplasia. In six months she was in complete cytogenetic response (CCyR) but the improvement of the counts was transient. We thus researched the Jak-2 mutation that resulted positive. Interestingly the Jak2-V617F was present since nilotinib start, but its expression increased, achieving the maximum concomitantly with the CCyR. Unfortunately the patient died in CCyR because of a cardiovascular event. Patient 2 was diagnosed of PMF because of leukocytosis, thrombocytopenia and splenomegaly. BM was hypocellular with trilinear dysplasia and collagen fibrosis. Ph-chromosome was not detected. After 2 years with no treatment, BM analyzed for a symptom worsening, demonstrated 15% myeloblasts with hyperplastic myeloid series and 100% Ph-positivity. The patient was initially treated with IFN, and then with imatinib for HRes, although a partial cytogenetic response. After an initial improvement, a new progressive increase of leucocytes and platelets followed. BM at this time was consistent with an MPN, with normal karyotype. Imatinib was increased with no improvement and hydroxiurea added, but hematological control remained unsatisfactory and imatinib was stopped. The patient stayed on hydroxiurea, maintaining a CCyR, with insufficient hematologic response for more than one year, until he developed a Ph-negative myeloblast crisis with homozygosis for JAK2-V617F. Going back to older samples, we found that before imatinib the patient had a 50% JAK2 mutated phenotype and after 3 months of therapy, more than 70%. Patient 3 was diagnosed of ET with a normal karyotype. A good control of the thrombocytosis was obtained with hydroxiurea, which continued for 10 years and then the patient refused therapy for the next 3 years of stable disease, until he developed bone pain, leukocytosis, enlarged spleen, with normal platelets. Conventional cytogenetics was normal but FISH disclosed a 47% Ph-positivity. The patient started imatinib, which induced a rapid decrease of leucocytes; however, the platelets raised and hydroxiurea was added. After 3 months the BM showed 7.4% Ph-positive cells. JAK2 was investigated and came back mutated from imatinib start. *Conclusions*. This report suggests the presence of two different clones, one Ph-positive and the other JAK2 mutated and the prevalence of the latter when the former was inhibited by a TKI. The presence of a JAK2 positive clone may be a rare cause of HRes to TKI.

1478

IMPACT OF HIGH SENSITIVE DETECTION, INCIDENCE AND SIGNIFICANCE OF T315I MUTATION IN CHRONIC MYELOID LEUKEMIA PATIENTS TREATED WITH IMATINIB MESYLATE (FIRST STUDY FROM INDIA)

R.M. Ab, R. Saxena, S. Sazawal, B. Bohra, R. Chobey, P. Mishra, A. Chopra, R. Saxena

All India Institute of Medical Sciences, NEW DELHI, India

Background. The onset of BCR-ABLT315I mutations during the treatment of CML with TKIs remains challenging, because this mutation is the most frequently identified in IM-treated patients, and none of the TKIs clinically available to date retain any activity *in vitro*. The fastness, simplicity, and sensitivity of ASO-PCR assays can be used for routine monitoring of BCR-ABLT315I mutation. *Objectives*. To study the high sensitive detection and incidence of T315I mutation in imatinib resistant CML patients. To study the clinical outcome of the imatinib resistant CML patients carrying T315I mutation. *Design and Methods*. One hundred consecutive patients who presented with a haematological diangosis of CML had blood examined by RT-PCR for BCR-ABL transcripts. They were started on treratment with imaitinib by mouth. All patients were monitored for hematologic and molecular responses, time to progression, survival and toxicity Early screening for the T315I mutation was performed by allele specific-oligonucleotide-PCR (ASO-PCR). The ASO-PCR primer sets were designed which were similar to according to the Roche-Lestienne C et al for T315I ABL gene mutations. The sensitivity of ASO-PCR is superior to that of direct sequencing as it could detect one mutant allele in 100~100,000 wild type sequences. Mutated and wild-type alleles were specifically amplified in a 50 ul and mixture 100 ng of gDNA. *Results*. Only 100 Imatinib resistant CML patients (CP-CML 20, Late-CP-CML 30, AP-CML 20 and BC-CML 30) were selected who were treated with imatinib at 400mg to 800mg/day . Median time since diagnosis was 40 months, and progression occurred 20 months after IM initiation, regardless of disease phase. A T315I mutation was detected by ASO-PCR in 30% of resistant patients (CP-CML 01, Late-CP-CML 06 ,AP-CML 08 and BC-CML15). All patients progressed after the 6 to 9 months of T315I positive mutation discovery (1 CP-CML , 3 late-CP-CML and 3 AP-CML).Thirty of five died .Survival and time-to-progression curves were obtained from Kaplan-Meier method. There was a significant difference in the survival rate of patients with or without T315I mutations. Side-effects of imatinib included Anemia (n=30), Thrombocytopenia(n=20) and hypopigmentation of skin (n=10). This mutation seems related to or (partially?) responsible for progression and poor survival. *Conclusions*. ASO-PCR proved to be very economical, sensitive and rapid technique for detection of T315I mutation and is more sensitive than mutation detection by sequencing. The detection of T315I kinase domain mutation was associated with imatinib resistance and poor prognosis

1479

STABLE RESPONSE TO IMATINIB MESILATE IN CHRONIC MYELOID LEUKAEMIA THREE YEARS AFTER DISCONTINUATION OF THERAPY

L. Virgolini, M. Danini, A. Ermacora, E. Mauro

Med 2, PORDENONE, Italy

The possibility of stopping imatinib mesilate therapy in patients achieving a complete haematological, cytogenetic and molecular response is still an object of debate. In February 2002 we saw a 76 years old woman presenting a chronic myeloid leukaemia in accelerated phase. Her leukocytes were 191.000 per mm^3 with percentages of 37 neutrophils , 42 neutrophil precursors and 4 blasts. She had the typical finding of Philadelphia chromosome translocation and the resulting BCR-ABL fusion gene. One month later a therapy with imatinib mesilate at a daily dose of 600 mg was started. Hematological, cytogenetic and molecular response was easily obtained in twelve months though a cell line with +8 chromosome appeared. In 2005 she began to experience abdominal pain , nausea and repeated vomiting episodes that usual therapy and the reduction of imatinib dosage could not improve . A progressive body weight loss was present but the patient refused an endoscopic examination and decided to stop imatinib therapy. Her symptoms briefly regressed and the patient in some weeks obtained a condition of very good health. Three years after having stopped the therapy the peripheral blood counts still remain in the normal values with 7,600 leukocytes per mm^3 and normal differential counts . On cytogenetic analysis trisomy of chromosome 8 is still present . On quantitative polymerase chain reaction-based assay BCR-ABL m RNA is not detectable so proving that a complete molecular response is still present.

T(6;9;22): NEW VARIANT TRANSLOCATION IN CHRONIC MYELOID LEUKEMIA

G. Menna,[1] F. Petruzziello,[1] L. Vicari,[2] A. Leszl,[3] R. Parasole,[1] N. Marra,[1] B. Izzo,[4] G. Muccioli Casadei,[4] M. Tarsitano,[2] A. Misuraca,[1] F. Menna,[1] S. Buffardi,[1] V. Poggi[1]

[1]Pausilipon Hospital, NAPLES, Italy; [2]UOC Genetica Medica, A. Cardarelli Hospital, NAPLES, Italy; [3]Department of Pediatric Hematology Oncology, University of Padua, PADUA, Italy; [4]BBM Department, Ceinge Institute, University of Naples, NAPLES, Italy

Background. Chronic myeloid leukemia (CML) is a myeloproliferative disorder, rarely observed in childhood. It accounts for only 2-3% of all paediatric leukemias and predominates in children older than 4 years, with a F/M ratio of 1,6:1. CML is characterized by presence of Philadelphia chromosome [t(9;22)(q34;q11)] with the fusion of the BCR and ABL genes, resulting in the synthesis of a 210-kilodalton dysregulated tyrosine kinase. This kinase is the target of Imatinib, a tyrosine kinase inhibitor, gold standard in the treatment of CML. In 5-10% of CML are present variant translocations, involving chromosomes other than 9 and 22. Until today it is not established the prognostic significance and the effect on imatinib-response of these cytogenetic variants. *Patients and Design and Methods*. We report a rare case of paediatric CML in a 3 year-old boy with a novel cytogenetic variant translocation. He was admitted in our Institution on December 2008 for massive leukocytosis (WBC 163,540/mmc) and mild anemia (Hgb 10,9 g/dL). On physical examination he presented mild hepato-splenomegaly. RT-PCR on bone marrow specimens revealed the presence of b2/a2 BCR/ABL transcript with quantitative reverse transcriptase-polymerase assay of 49,3 IS (International Scale; Blood 2006; 108 (1): 28-37). FISH analysis revealed a 46,XY, t(6;9;22)(q26;q34;q11) karyotype. *Results*. We started Imatinib therapy (200 mg/die) and we observed a good haematological response (GB 4,170/mmc after 1 month; absence of hepato-splenomegaly) and a sub-optimal molecular response; after 1 and 2 months of therapy RT-PCR revealed a transcript number of 27,5 IS and 18,5 IS, respectively. Side effects of Imatinib therapy were anemia, neutropenia, synthomatic thrombocytopenia that required reduction and temporary discontinuation of drug; non-haematological toxicity was not observed. *Conclusions*. At best of our knowledge, t(6;9;22) is a novel translocation in CML, not described until now. This translocation may influence Imatinib response, because the patient presented a good haematological but a poor molecular response. A further follow-up is necessary to clarify a possible correlation

BCR-ABL TYROSINE KINASE MUTATIONS IN IMATINIB MESYLATE RESISTANT CML PATIENTS FROM OMAN: SINGLE CENTRE EXPERIENCE

V. Pathare, S. Alkindi, A. Al Zadjali, S. Al Farsi, N. Huneini, B. Zia, J. Dennison

Sultan Qaboos University, MUSCAT, Oman

Background. Point mutations in the kinase domain of the BCR-ABL tyrosine kinase are a frequent mechanism for reactivation of kinase activity, the most common cause of imatinib resistance. These mutations affect amino acids involved in tyrosine kinase inhibitors binding or in regulatory regions. *Aims*. To investigate and delineate the cause of sub-optimal or poor response to imatinib mesylate in CML patients. *Design and Methods*: We prospectively enrolled and studied 41 cases of CML patients who received imatimib mesylate with a dose ranging between 400-800mg, [Median-400mg] as the first line treatment over the past 7 years at our institution. 8 cases were referred to our laboratory because their response was defined either as failure (n=3 pts) or as suboptimal (n=5 pts) according to recently published recommendations (Baccarani et al, Blood 2006). We performed the RT-PCR amplification of the entire kinase domain of the BCR-ABL mRNA using a 5'BCR primer (5'tgaccaactcgtgtgtgaaactc3') and a 3'ABL primer (5'tccacttcgtctgagatactggatt3'). A nested RT-PCR using the same reverse primer but a different forward primer (5'cgcaacaagcccactgtct3') was done to generate an 863 bp PCR product. Direct sequencing with dye terminator chemistry was performed using PCR-purified products. *Results*. The study group consisted of 41 patients (21 males), with a mean age of 41.9yrs + 15.5(SD), range of 9-70 yrs. All patients were serially followed with regular CBC's, 3 monthly FISH and cytogenetic studies. Complete Haematological Response(CHR) as defined by a white cell count of less than 10X10^9/L, a platelet count of less than 450x10^9/L, no blast in peripheral blood; and disappearance of clinical signs & symptoms with resolution of organomegaly was seen at a median of 21 days[range, 4-35 days]. The CHR was further characterized by cytogenetics [Standard & FISH] and molecular techniques [RT-PCR and RQ-PCR] as complete cytogenetic response (CCyR) - Ph positivity : 0%, Partial cytogenetic response (PCyR) : Ph positivity 1-35%; Minor Cytogenetic Response (MCyR) : Ph Positivity 36-65%; Minimal Cytogenetic Response : Ph positivity 66-90% and No response -Ph positivity >90%. CCyR was achieved in a median [range] of 11.5[2-26] months; MCyR was achieved at a median of 7[4-14] months and MCyR at a median of 5[4-14] months respectively in this study patients. Amongst the 25 evaluable patients, 17 (68%) showed good response, but in 8(32%) patients who showed suboptimal response, we were able to identify two previously reported mutations namely E355G and E279K in one patient each as shown in the figure below. *Conclusions*. This is the first report of mutation analysis in patients receiving imatinib mesylate as initial therapy for CML amongst a cohort of 41 omani patients from a single centre. Interestingly, both these patient had a high Sokal score of >1.2. Thus early detection of an emerging mutant clone may help in decision-making for alternative treatment especially in patients with a high Sokal score.

MOLECULAR RELAPSE IN CHRONIC MYELOID LEUKEMIA PATIENTS AFTER IMATINIB DISCONTINUATION: DOES IT ALWAYS NEED THERAPY?

G. Rege-Cambrin, C. Fava, S. Ulisciani, E. Giugliano, E. Gottardi, M. Fava, L. Giaretto, G. Saglio

Internal Medicine, ORBASSANO, Italy

In patients with BCR-ABL-positive chronic phase (CP) chronic myeloid leukemia (CML) it is generally accepted that molecular responses have prognostic significance. A major molecular response (MMR) has been defined as a ratio of BCR-ABL transcripts compared with a standardized control gene (normally ABL) of 0.1% (equivalent to a 3-log lower level), by quantitative polymerase chain reaction (QPCR). Com-

plete molecular remission (CMR) has been defined as the absence of any detectable BCR-ABL transcript. CML-CP patients who achieve early molecular responses are more likely to experience durable complete cytogenetic responses (CCyR) and are less likely to undergo disease progression, while on treatment. However, some studies have suggested that patients who achieve CCyR may not derive an additional prognostic benefit from achieving a major molecular response. On the other hand, rising BCR-ABL transcript levels may also provide an early indication of loss of response. The clinical significance of rising levels of QPCR in patients who discontinue imatinib while in CMR has not been analyzed in details. About half of these patients showed a molecular relapse, in keeping with the hypotesis that continuous imatinib exposure is essential for inhibiting the neoplastic population. Reappareance of BCR-ABL transcript occurred within few months with the latest described at month 10; however, follow-up of patients who discontinued is still limited in time. In those who recurred imatinib treatment was restarted and all patients proved to be still sensitive to the therapy. We report a case of a patient with CML who started imatinib in association with Pegylated-IFN as front line treatment in 2001, achieving a CCyR whithin 3 months. Peg-IFN was stopped for skin toxicity after 4 months and 2 months later the patient achieved a CMR, that was stable for 45 months before imatinib discontinuation due to intolerance. The patient stayed off treatment in confirmed CMR for 28 months, with undetectable BCR-ABL transcript on BM and PB, in multiple serial samples, until a QPCR analysis on PB disclosed a BCR-ABL/ABL ratio of 0,0208% consistent with a MMR. She refused to start imatinib again, and control samples 3 and 6 months later were again positive at very low leves, with a ratio of 0,0087% and 0,0018% respectively. Our patient is currently off-therapy after 1 year, still in CCyR, and the last BM and PB QPCR remained in the MMR range (0,0314% and 0.0176% respectively). This finding shows two previously unreported phenomenons: first, although most patients who stop imatinib treatment relapse early, late recurrence may occur; second, the presence of minimal residual disease is not invariably associated with the expansion of the leukemic clone even in the absence of TK inhibition. This points to alternative mechanism which can contribute to longterm disease control.

1483

THE EFFECTIVE THERAPY WITH IMATINIB IN PATIENT WITH CHRONIC MYELOID LEUKEMIA ASSOCIATED WITH HEPATITIS C, CRYOGLOBULINEMIA AND GLOMERULONEPHRITIS

M. Cioch, M. Legiec, W. Legiec, A. Dmoszynska

Medical University in Lublin, LUBLIN, Poland

There is known clinical association between hepatitis C, cryoglobulinemia, glomerulonephritis and hematologic malignancies. We present a patient (pt) with chronic myeloid leukemia (CML) associated with these additional diseases who was successfully treated with imatinib. Case report In a 53-year-old patient in 1999 year nephrotic syndrome and an insufficiency of renal function were found. Furthemore diagnostics showed that these disorders were consequences of hepatitis C, which was resulted in type II mixed cryoglobulinemia with mesangiocapillary glomerulonephritis, neuropathy and a various types of vessel changes including a myocardial infarction. The pt was treated with metylprednisolone, cyclophosphamide, cyclosporine and ribavirin. The therapy with interferon α caused greater proteinuria, higher creatinine level and an appearance of vascular purpura. In January 2006 the pt had one more myocardial infarction. Soon, it was observed the increase WBC number (59,5 G/l) and the spleen enlargement (16 cm). After positive test on BCR/ABL p210 protein chronic myeloid leukemia was recognized. In December 2006 year therapy with imatinib in a dose 400 mg was started. After 6 weeks of therapy complete hematological remission was obtained but the dose of imatinib was reducted to 300 mg because of neutropenia. The major (10% of Ph) and the complete cytogenetic remissions were achieved after 6 and 12 months respectively. After an increasing dose of imatinib dose to 400 mg and next 6 months complete molecular response was achieved. Very important benefits associated with imatinib therapy were normalization of renal function tests, disappearance of proteinuria and vessels changes. We conclude that imatinib therapy is effective and safe in patients with CML complicated by cryoglobulinemia and glomerulonephritis.

1484

CHRONIC MYELOD LEUKEMIA IN PEDIATRIC PATIENTS; OUR EXPERIENCE

O. Muratovska

University Pediatric Clinic, SKOPJE, Macedonia

Background. Pediatrics Chronic myeloid leukemia (CML) is very rare disease (<5% of all pediatric leukemia). There are some different between pediatric and adult CML: origin of the disease, comparable biology, valid prognostic index and treatment strategy. There is dilemma about treatment of pediatric CML with HSCT, which is potentially curative, but with immediate risk, versus tyrosine kinase inhibitors with reducing immediate risk but are generally non curative. Also, the juvenile myelomonocytic chronic leukemia (JMML) is specific form of myeloprolipheration in childhood with frequency of 1-2% of all leukemia, very early appearance of the disease, under 3 month age and associations with some genetic changes in 80% of the patients. Aim. To describe the clinical and diagnostic features and treatment results of our patients with CML and JMML. *Design and Methods*. Date about CML and JMML patients are from the state with two million inhabitants and four hundred thousand child population. In the period from 1998 to 2008 were diagnosed five CML patients with median age of 9, 6 years and 3 JMML patients with median age of 9 months. All of them had significant splenomegaly. Median WBC count was $90x10^9$/l in CML patients and $100x10^9$/l in JMML patients. Philadelphia chromosome was positive in all CML patients and negative in all JMML patients. All three patients with JMML had elevated level of HbF. Results. At the diagnosis, four patients with CML was treated with: one with busulfan, four patients with hydroxiurea, three with interferon. Five years ago, we have a possibility to change the treatment in two patients with Imatinibe masylate. They had acutisation of the disease in acute monocytic leukemia and acute myeloic leukemia, after one and two years of treatment with Imatinibe. Two patients were transplanted from HLA-matched sibling donors and they are in optimal condition 6 and 10 years after transplantations. The patients with JMML were treated with Cytosin arabinoside and 6 Mercaptopurine. One of them died after one year of the treatment, the other one had transformation in acute monocytic leukemia and the third one is still in chronic faze under treatment. All of the patients with JMML had not suitable donor for HSCT.Conclusions. Pediatric CML patients may require a different treatment algorithm then adults. One potential treatment strategy would be to give imatinibe at the diagnosis. If an HLA identical sibling donor is available, transplant the patient after cytoreduction regiment. Additional studies are needed to further define the biology, prognosis and the best course of pediatric CML treatment.

1485

THE EFFICACY OF IMATINIB MESYLATE TREATMENT PATIENTS WITH CHRONIC MYELOGENOUS LEUKEMIA PH' POSITIVE (CML) REFRACTORY TO PREVIOUSLY INTERFERON THERAPY (CML) - THE OWN POLISH STUDY REPORT

B. Ceglarek, L. Konopka, K. Warzocha

Institute of Hematology and Blood Transfusion, WARSAW, Poland

Background. Imatinib Mesylate is one of the selective inhibitor of BCR/ABL tyrosine kinase which is present at the most patients with CML and in nearby 20% patients with acute lymphocytic leukemia (ALL). The aim of study : analysis of efficacy and safety Gleevec therapy in 112 CML Ph' positive patients resistant to previously given therapy (102/112pts) i.e. Interferon and others (Hydrea, Mercaptopurine, ARA-C, Vincristine, Epirubicine, relapse after BMT) and 7/59 evaluated pts received Gleevec as the first line treatment. *Design and Methods*. 102 patients were eligible for the 72 months study: -98 patients in chronic phase-CP of CML -04 patients in accelerated phase-AP of CML The patients received Gleevec in a daily oral dose of 400 mg in CP and 600 mg in AP of CML. Doses were modified (400-600mg daily) in a case of : side effects or an incomplete achieved hematologic response. *Results*. Complete hematologic responces were reported for 97% evaluated CML treated patients after 2-3 months therapy and complete cytogenetic responses for 45.1% (46/102) CP-CML patients after 2-42 months has been lasting 22.3 months. There were maintained the primary hematologic resistance in 2.9% (3/102) patients, and the cytogenetic ones in 22.5% (23/102). The acquired hematologic resistance were in 5.9% (06/102) pts., and cytogenetic ones in 20.6% (21/102) patients. Complete molecular response (CMR) and partial molecular response (PMR) were received in 35.3% (36/102) patients. During study partial cytoge-

netic response (PCR) was observed in 16.7% (17/102) after 4.5 -37.0 mo (median 8.1 mo), which has been lasting 2.0 - 59.0 mo (median 10.3 mo+). Minimal cytogenetic response lasting median 4.0 mo was received in 11.8% pts.(12/102) after 6.0 mo Gleevec therapy. Gleevec was rather well tolerated Side effects (1-4o WHO) were observed at 25.5% (26/102) patients : leucopenia,neutropenia, rash, hypoplasia medullae ossium, thrombocytopenia, bone and abdomen pain, increased AST/ALT level, allergic reactions, fever, hiperhidrosis. Overall survival since Gleevec therapy is 25.5 - 94.0 mo - at CP-CML patients. *Conclusions*. Gleevec is very high well effective drug and good tolerated inhibitor of BCR / ABL tyrosine kinase -Imatinib mesylate can be useful in CP-CML patients as the first and second line therapy and may prolong life survival

1486

IMATINIB THERAPY IN CHRONIC MYELOID LEUKEMIA. THE ROLE OF PHILADELPHIA CHROMOSOME IN THE THERAPEUTICAL RESPONSE MONITORING

H. Ionita,[1] I. Ionita,[1] D. Calamar,[1] L. Cheveresan,[1] M. Cheveresan,[2] M. Ionita,[1] D. Oros[1]

[1]UMF Victor Babes, TIMISOARA; [2]City Hospital, TIMISOARA, Romania

Background. Imatinib is an effective first line therapy for chronic myeloid leukemia (CML) and has substantially changed its biological and clinical behavior. Durable complete cytogenetic responses (CCyR) were reported in the majority of patients, with a rather benign side effect profile, despite the "off-target" inhibition of several other kinases, including kit, PDGFR and Lck. CML has substantially improved survival with the application of Imatinib, however, the patients with advanced CML such as in the accelerated phase (AP), or black crisis (BC) have a bad prognosis even in the era of tyrosine kinase inhibitors. *Aims*. We analysed the hematological and cytogenetic response of Imatinib therapy in CML, the cytogenetic response monitoring in order to diagnose the AP and BC, the important side effects including secondary malignancy and the toxicity of the therapy regarding the quality of life. *Design and Methods*. We studied 58 CML patients diagnosed and treated in the Timisoara Hematology Department, which started Imatinib therapy during 2003-2007, patients from the west part of Romania. Were included 48 patients in chronic phase and 10 patients with advanced disease. Median age was 48 years (range 34-65). There were 37 males and 21 females. We evaluated hematological and cytogenetic response following NCCI cryteria. In a small number of cases we evaluated the molecular response. Patients started with 400 mg Imatinib every day. Cytogentic evaluation was made by conventional standard cytogenetics at diagnosis, after 6 months, 12 months, and than every year if patient obtained CCyR. *Results*. Ten patients (17,24%) died in BC. 7 patients (12,1%) progressed to AP and are being treated with 600mg or 800 mg Imatinib. 48 patients (82,76%) are still alive, 42 of those are in chronic phase. CCyR was obtained in 34 patients (58,62%). This patients are still monitorised every 6 month by conventional standard cytogenetics and molecular analyssis from the peripheral blood by quantitative PCR (RQ-PCR, TagMan). 16 patients lost CCyR, in 10 of them the progresion to AP or BC was seen in peripheral blood and bone marrow exams. The most frequent side effects were hydrosaline retention 12 patients (20.69%), 2 pts. presented congestive cardiac failure due to Imatinib therapy. No secondary malignancy was seen in the studied group. 6,9% of the Imatinib patients presented abdominal cramps, diarhea, skin fragility. Only 4 patient discontinued the therapy and other 2 pts. received 300 mg Imatinib/day for a while. *Conclusions*. Imatinib therapy was well supported and with litle side effects. Conventional standard cytogenetics monitoring is a highly used evaluation method in the response of patients with Imatinib. It is necessary to complete the response evaluation with molecular examination in order to rapidly diagnose the disease progression.

1487

EPIDEMIOLOGY OF CHRONIC MYELOID LEUKEMIA IN IRAQI PATIENTS

Alameri A,[1] Al-khudhair M,[2] Batool G,[3] Al-Mudhafer A,[3] Murad N[4]

[1]National Center of Hematology. [2]I-mustansiriyah medical school; [3]Bagdad medical school; [4]Al-Nahren medical school, Iraq

Background. Chronic Myeloid Leukemia (CML) is a colonal myeloproliferative disorder with a biphasic or triphasic course and some often, a fatal outcome. The molecular abnormality involve the balance translocation t (9; 22) (q34; q11), and/or the BCR-ABL rearrangement in the peripheral blood or bone marrow cells. Incidence in the U.S. is 1.8/100 000/year. Median age at the diagnosis is ~65 years. In Sweden median age at the diagnosis is ~60 year. This is the only abstract which review the epidemiology of CML in Iraq. *Aim*. to study the natural history of chronic myeloid leukemia in Iraq, through proper epidemiological assessment of data from the central Iraqi registry of CML in the national center of hematology, Baghdad. *Patients' characteristics. T*he study involved 669 patients who had been referred to the national center of hematology in Baghdad/Iraq according to the Iraqi program to treat all the patients with CML in a single center. Between 2002-2006 all patients, who had diagnosed CML, or newly diagnosed; should be referred to our center in Baghdad for evaluation, registration, and prescription of treatment (imatinib). Analysis of patients had been done by teamwork and patients

Table.

region	North of Iraq	Middle Iraq	South Iraq	Total
No. of patients	121	396	82	599
percentages	20.2%	66.1%	13.6%	100%
No. of patients per 100,000	1.85	2.404	1.413	2.079

Age distribution is between 14-70 years, with median age of 37 years. 51.6% were males and 48.4% females. 65% were liberal workers, and 70% have a history of being military employees within 5-10 years of presentation. 15% of our patients were in either accelerated or blast phase of CML. *Conclusions*. This is the major data for CML patients in the Iraqi cancer registry. The age incidence is definitely lower in Iraqi patients. In cover to traditional believe that north and south have increased rate of cancer due to the possible pollution, our data came with increased number in the middle of Iraq. Although a better statistical analysis is important after releasing the total population in Iraq.

1488

SOKAL RISK INDEX PREDICTS CHRONIC MYELOID LEUKEMIA RESPONSE TO IMATINIB

J.V. Garcia Gutierrez, P. Herrera, M. Calbacho, J. Lopez-Jimenez, M. Jimenez Rolando, M.L. Ramos, A. Chinea, A. Valles, J. Odriozola

Hospital Ramón y Cajal, MADRID, Spain

Background. The 5-years analysis of the International Randomized Study of Interferon and STI571 (IRIS) has proven a 87% cumulative Complete Cytogenetic Response (CcyR) and an estimated 89% overall survival (OS) for patients treated with Imatinib (IM). Thereafter, quality of response to IM has been recognized as the most important prognostic factor for survival and progression free survival. Although some possible genetic markers are under study, the question of which group of patients (pts) are more prone either to response or to resistance is still unsolved. Sokal Risk Index, elaborated 25 years ago on the basis of clinical criteria and of the different survival-scores of pts treated with conventional chemotherapy, has made its way as one possible prognostic factor for pts on IM treatment. *Aims*. We have analyzed whether Sokal risk formulation predicts responses to IM as evaluated according to the European-Leukemia.Net criteria (ELN).

Table.

Responses to EuropeanLeukemia Net criteria at 12 months p=,007	Optimal Response		Suboptimal Response		Failure	
	n	%	n	%	n	%
Low Risk	26	76	7	21	1	3
Intermediate Risk	21	63	2	6	10	31
High Risk	4	50	0	0	4	50
Responses to EuropeanLeukemia Net criteria at 18 months p=,065						
Low Risk	12	52	8	34	3	13
Intermediate Risk	9	36	6	24	10	40
High Risk	3	38	1	12	4	50

Design and Methods. 83 pts in chronic-phase Ph+ CML received IM 400 mg daily, -among them, as many as 52% had been otherwise treated previously (second line IM). The cases were classified as to their response to treatment, after the recommendations published by the

ELN, as failures, suboptimal and optimal responses. In 80 pts Sokal risk score at diagnosis could be assesed. In 75/56 respectively, responses at 12 and 18 months have been evaluated. *Results*. Sokal risk score was LOW in 42,5%, INTERMEDIATE in 47% and HIGH in 10% of the pts. Percents of responses at 12 months (according to the ELN criteria): failure 36%, suboptimal 24% and optimal 38%. Of note is that no therapeutical changes before this interval (12 months) were undertaken. Distribution of response at 18 months: failure 25%, suboptimal 12% and optimal 63%, the pts considered to be in failure at 12 months have received alternative therapies thereafter. Responses by Sokal risk score at 12 and 18 months are shown in Table 1. *Conclusions*: Sokal Risk Index should be considered a useful prognostic aid to predict CML responses to Imatinib.

1489

EFFICACY OF UPFRONT IMATINIB IN CML CHRONIC PHASE: INDIAN STUDY

S. Aggarwal, D. Gupta, N. Banerji, M. Jauhri, S. Kohli, A. Negi, G. Goel

Sir Ganga Ram Hospital, NEW DELHI, India

Background. 50 patients were enrolled starting from 2001. All patients were positive for either Philadelphia chromosome or bcr-abl gene tested by FISH/PCR. There were 35 males and 15 females. Median age of males was 42 yrs (6-72), and females was 51 yrs (21-68). The median TLC was 110 thous/µl (13-340). Blasts were seen in all patients with TLC>100 thous/µl (blasts ranging from 2-6%), at the time of diagnosis. *Design and Methods*. Patients were given Hydroxyurea to bring the counts in the normal range, after which, patients were given 400 mg of Imatinib daily (except 1 pediatric patient on 200 mg). Median follow-up of patients on Imatinib was 48 months. 49 out of 50 patients achieved complete hematological remission (CHR) (98%). Information of major molecular response (MMR) was available for 30 patients. *Results*. 20 out of these 30 patients achieved MMR at median follow-up of 36 months. 3 patients achieved complete molecular remission (CMR). Side effects included nausea/vomiting (20%), muscle pain (20%), depigmentation (95% pts), periorbital edema (80% pts), temporary neutropenia and thrombocytopenia (20% pts). The latter responded to dose reduction of Imatinib to 300 mg and use of G-CSF. 2 patients continue on 300 mg imatinib. Nausea/vomiting resolved within 2-3 months on its own. Lack of response was seen in 12 patients - 1 had primary resistance, 4 had only molecular relapse and 7 had hematological relapse. All 4 patients with molecular relapse responded to increased doses of imatinib. Of the 7 patients with hematological relapse, 2 underwent successful allogeneic BMT, 2 are on higher dose imatinib, 2 on second-generation TKI, and 1 died due to progressive disease (PD). 43 patients continue to take imatinib. Mutational analysis was done on 10 patients with relapse. Out of these, 3 patients were positive for mutations - 1 had M 351 T, and 2 had F 311 I mutations. Till date, 3 patients have died - 1 from PD, 1 during BMT (done for CML-CP) and 1 due to unrelated cause (myocardial Infarction).

1490

TREATMENT OF PHILADELPHIA - POSITIVE CHRONIC MYELOID LEUKEMIA WITH IMATINIB: ONE CENTER EXPERIENCE

C. Danaila,[1] A. Dascalescu,[1] C. Bujoran,[2] G. Dorohoi,[3] E.V. Gorduza,[2] I. Ivanov,[2] C. Burcoveanu,[3] E. Hanganu-Turtureanu[1]

[1]*Universitatea de Medicina si Farmacie Gr.T.POPA/ Spitalul SF SPIRIDON, IASI, Romania;* [2]*Laboratorul de Imunologie si Genetica - Policlinica nr. 1, IASI, Romania;* [3]*Spitalul Clinic de Urgente Sf Spiridon, IASI, Romania*

Background. Imatinib mesylate, a targeted inhibitor of the BCR-ABL tyrosine kinase, is the standard of care for chronic myeloid leukemia (CML). Imatinib has demonstrated a high level of efficacy and is associated with significant less toxicity than previously used therapies. Aims. To review the efficacy and safety of imatinib in patients with CML in chronic phase. *Design and Methods*. A retrospective review of patients in one department of hematology with a diagnosis of Ph/BCR-ABL positive CML and received imatinib. Criteria for treatment responses were according to the recommendations from the expert panel of European LeukemiaNet. *Results.* From 15.02.2002 to 15.02.2008, 48 patients in CML-CP received imatinib were introduced in the study. The median age at diagnosis was 34 years old (range 13 to 72) with 54% women. Sokal score was 1,30 (0,39-4,05) and Hasford score 1012 (58-2435). All patients had positive karyotiping for Philadelphia chromosome. Treatment and outcome. 16 (33%) patients received imatinib as upfront therapy, the others as second or third line treatment after hydroxiureea and/or interferon α, the mean time to initiate imatinib was 25 months (range 1-104). All the patients received a starting dose of 400 mg/day. Clinical assessment and laboratory investigations including cytogenetics studies were performed at regular intervals. The RT-PCR studies for bcr-abl were performed from 2007. Responses rate. After starting imatinib, a CHR was achieved at 3 months by 87,5% patients. The CyR achieved was major in 59,6% (an equal number of complete and partial responses), no CyR in 12 patients (25%). The molecular response was complete in 6 (12,5%) and major in 9 (18,8%) patients. Better cytogenetic responses were achieved by those who were treated with upfront imatinib (87,5 vs 45,2% *p* 0.006) and those who received imatinib up to 24 months from diagnosis (73,1% vs 42,9 p 0,043). The doses were increased in 5 patients but an improved response was achieved in only one. Three patients were switched to Dasatinib with an MjCyR in one patient at 12 months. Seven patients developed under imatinib additional cytogenetic anomalies : supplemental chromosome 8 (6), duplication of Ph1 (2), trisomy 17 and 19 (1). Survival data. The median of follow-up was 53 months (range 10-144) and under imatinib was 26 months (range 3-76). Seven patients died: five of blastic transformation (44-104 months after diagnosis) one of septic shock and one of caschexia (in CMR). The Sokal score was a better predictor than Hasford's. Safety profile. Adverse events were registered in 14 patients (29%). Ten experienced hematological toxicities but grade 3 or 4, only in four, without future consequences. One patient experienced a secondary MDS, and four an important edema. *Conclusions*. The age at diagnosis in CML patients was decreasing during the last decades. Imatinib remains effective and well tolerated treatment for most of the patients, but there are still a significant number of patients who did not achieve a CyR. The responses and survival were not influenced by the previous treatments but the earlier introduction of imatinib is better. The Sokal score seems to have a better prognostic role.

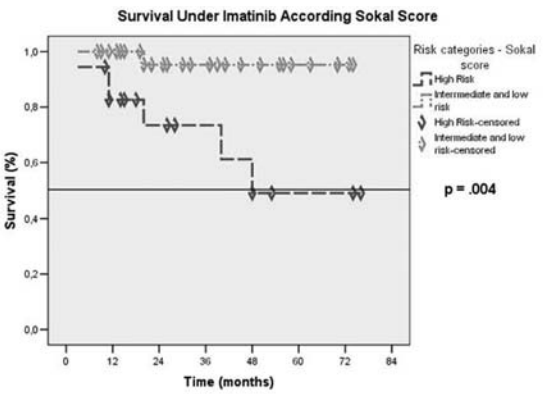

Figure 1. Survival of patients with CML after imatinib.

1491

B-LYMPHOID BLAST CRISIS OF P190 CHRONIC MYELOID LEUKEMIA RESPONSIVE TO DASATINIB: A CASE REPORT

G. Palumbo,[1] A.M. Carella,[2] M.G. Franzese,[3] M.R. Lipsi,[3] G. Spinosa,[3] N. Cascavilla,[2] S. Capalbo[3]

[1]*Ospedali Riuniti Azienda Ospedaliero-Universitaria, FOGGIA, Italy;* [2]*Hematology IRCCS Casa Sollievo Sofferenza, SAN GIOVANNI ROTONDO, Italy;* [3]*Hematology OO RR Foggia, FOGGIA, Italy*

Background. Chronic myeloid leukemia (CML) is characterized by involvement of Philadelphia chromosome (Ph), which derived from a reciprocal translocation between chromosome 9 and 22. The breakpoint on the BCR gene occurs within the major breakpoint cluster region (M-BCR) and the BCR/ABL fusion gene codes for p210 protein. In two-third of patients with positive Ph-positive, acute lymphoblastic leukemia (ALL) and in rare case of CML, the breakpoint occurs within the minor breakpoint cluster region (m-BCR). In these cases the first BCR exon is fused to ABL exon 2 (e1a2) junction and a BCR/ABL protein of 190 kDA is formed (p190). Aim: We report a case of p190 CML in B-lymphoid blast crisis (B-Ly BC) responsive to dasatinib treatment. Case report: In March 2007, a 48 years old woman suffering from anemia, was referred to our centre. On the admission the patient had palpable liver but no splenomegaly. Hematological findings were: hemoglobin (Hb) 5.9 g/dl, platelets $104x10^9$/l and white blood cells (WBC) $25.2x10^9$/L (45% neutrophils, 5% metamyelocytes, 10% eosinophils, 1% basophils, 16%

lymphocytes, 10% monocytes and 10% blasts). The neutrophils alkaline phosphatase score was 3. A bone marrow (BM) aspirate showed marked hypercellularity, myeloid hyperplasia and 11% blasts. Cytogenetic analysis of BM showed 46 XX t(9;22) metaphases. Reverse transcriptase-polimerase chain reaction (RT-PCR) analysis showed a p190 BCR-ABL transcript (e1a2). A diagnosis of CML p190 was made and the patient was treated with imatinib 400 mg/day. The patient achieved complete hematological remission (CHR), but after 4 months she lose CHR. Main hematological findings were: WBC 40.2x10^9/l with 50% blasts and 40% blasts on BM smears. The blasts immunophenotype was CD10+, CD19+, CD22+, CD13+, CD33+, CD34+, DR+. Cytogenetic analysis of BM showed the presence of 46 XX t(9;22) methaphases and RT-PCR analysis showed a p190 BCR-ABL transcript. A diagnosis of B-Ly BC was made. The patient was treated with a polichemotherapy including vincristine, daunorubicin and prednisone and achieved CHR. Then she was treated with consolidation therapy with HAM protocol (ARA-C + mitoxantrone) and achieved complete molecular response (CMR). Therefore she started maintenance therapy with dasatinib 50 mg x 2/day until august 2008. CMR was costantly mantained. At this time, the patient received an allo-transplant from an HLA identical sibling donor using conditioning regimen with cyclophosphamide and Total Body Irradiation. Today, six months after the transplant, the patient is still in CMR with full donor chimerism, without therapy. *Conclusions*. To our knowledge, this is the first case of p190 CML B-Ly BC which lose CHR to imatinib and maintained with dasatinib the CMR obtained after polichemotherapy including antracyclines and cytosine arabinoside. This case comfirms the efficacy of dasatinib in patients with BC of CML also in the rare cases with p190 BCR-ABL transcript.

PV AND ET PATIENTS PRESENT WITH ACQUIRED STORAGE POOL DISEASE LIKE PHENOTYPE

M. Coucelo, A. Estevinho, M. Fortuna, S. Santos, C. Bento, P. Pina-Cabral, M. Duarte, T. Fidalgo, N. Martins, J.S. Kaeda, C. Menezes, L.M. Ribeiro

Centro Hospitalar de Coimbra, COIMBRA, Portugal

Acquistion of Janus Kinase 2 (JAK2) V617F mutation heralds unregulated expansion of myeloid haematopoetic lineages which present as polycythaemia ruba vera (PV), essential thrombocythaemia (ET) or primary myleoifibrosis (PMF). These disorders are also associated with increased risk of thrombotic and hemorrhagic events, a major cause of morbidity and mortality. Therefore we studied the peripheral blood (PB) hemostatic status by measuring expression of platelet cell markers, pre and post stimuli to a number of agonists by flow cytometry (FCM), thereby assessed their function by measuring both P-selectin (CD62P) and CD63. In total 76 (F:40;M:36) patients (PV: 34; ET: 42) with median age 69.0 (range 30-94) were studied and 26 normal controls, Control Group (CG) (F:17;M:9); median age 28.3 (range 20-53) were included. With patients' informed written consent their asprin administration was withdrawn for 10 days prior to collection of blood. PB samples were collected into tri-sodium citrate and subsequently diluted 1:10 in physiological saline prior to incubation with the agnosists. The samples were then analysed by FCM within 1 hour of PB collection. Unstimulated patients´ platelets had higher basal level than the CG as measured by expression of CD62P. But, exposure to TRAP6 elicited a sub-optimum response from patients' platelets compared to the CG (see Table).

Table 1. Platelet cell marker expression data pre and post stimualtion with agonist.

	CD62P (%)	CD63 (%)	CD62P (%)	CD62P (%)		CD63 (%)		CD62P (%)	Peripheral blood counts at diagnosis	
	Basal levels	Basal levels	A.A 0.1mM	TRAP6 5μM	TRAP6 25μM	TRAP6 5μM	TRA6 25μM	ADP 5μM		
CG n=26	3.1 (1-8)	1.7 (0.8-3.9)	12.9 (4-79.6)	83 (10-99)	97 (88-99)	37 (2-89)	83.1 (46-97)	74 (50-93)	WBC (x10^9/l)	PLT (x10^3/l)
PV n=34	7.8 (1.6-36)	2.7 (0-22)	28.5 (4-77.5)	65 (5-93)	87 (49-98)	25.6 (3-76)	53.2 (15-96)	76.6 (38-88)	10.7 (4.2-24)	429 (454-1065)
ET n=42	5.1 (0-38)	2.6 (0-17.5)	19.9 (3-72)	64.8 (3-98)	91 (7-99)	22.2 (15-93)	63.5 (5-93)	70.8 (15-93)	9.0 (4.6-32)	821 (458-1697)

Median values are recorded with the range in parenthesis. CG: Control Group; PV Polycythaemia ruba vera; ET: essential thrombocythaemia. AA: Arachadonic acid. ADP: Adenosine diphosphate

Furthermore, PV and ET platelets response to AA was increased but in proportion to that seen in the CG. But no difference was seen in CD62P expression following stimulation with ADP. Together these data are reminiscent of acquired storage pool disease (ASPD). Therefore we tested the platelets for mepacrine uptake and release using FCM. We found 26 of 32 PV and 22 of 42 ET patients were negative, whilst all CG samples were positive. These observations mimic acquired storage pool disease (ASPD) phenotype and concur with the decreased CD63 expression post TRAP6 and normal response to ADP activation. However, we found no correlation between positivity for V617F mutation and the mepacrine test data. The increased basal expression of P-selectin and ASPD like phenotype imply dysregulated haemostatic function that probably contributes to the thrombohaemorrhagic events frequently observed in myeloproliferative disorders.

THROMBOCYTE GLYCOPROTEINS MODIFIED STRUCTURE AND FUNCTIONAL STATUS IN CHRONIC MYELOPROLIFERATIVE DISORDERS - A MODEL OF ACQUIRED THROMBOPATHIESA

M. Vladareanu,[1] H. Bumbea,[1] S. Radesi,[1] M. Onisai,[1] A. Nicolescu,[1] M. Dervesteanu,[1] D. Cisleanu,[1] I. Voican,[1] C. Ciufu,[1] C. Marinescu,[1] A.M. Vintilescu,[1] A. Ichim,[1] C. Baluta[1], O. Cazaceanu,[1] V. Popov,[2] M. Leabu,[3] M. Hinescu,[3] T. Savopol,[3] E. Kovacs[3]

[1]Universitary Emergency Hospital Bucharest, BUCHAREST, Romania; [2]County Hospital, PITESTI, Romania; [3]Carol Davila University of Medicine and Pharmacy, BUCHAREST, Romania

Background. Chronic myeloproliferative disorders (CMPD) are highly associated with altered platelet homeostasis generating hemorrhage and thrombosis.Different laboratory methods are used for better understanding thrombocyte functional abnormalities. *Aims*. Combining methods to a complete investigation of platelet functional changes in CMPD - investigation of surface and intracellular expression of von Willebrand factor (vWF) receptor and αIIb-β3 integrin by flowcytometry, respectively western-blot method, and platelet functional status by aggregometry. *Design and Methods*.Whole blood flowcytometry for platelet surface glycoproteins-(Gp) (vWF receptor-GpIb-IX [CD42b,CD42a], fibrinogen receptor-GpIIb-IIIa [CD41,CD61], P-selectin [CD62P], granulophysin [CD63]) was performed in 42patients with Ph-negative CMPD and 13controls. CMPD group included 14patients with Myeloid Metaplasia, 12patients with Polycythemia Vera, 9patients with Essential Thrombocythemia and 7patients with Unclassified-CMPD. Platelet aggregometry after stimulation with collagen, ADP, ristocetine and epinephrine was completed in 41patients with CMPD. *Results*. Platelet immunophenotyping analysis revealed:1) statistically significant reduced expression of adhesion markers (CD42b, CD42a) in CMPD group vs. control (median of mean fluorescence intensity: 31% vs. 78.1%, $p<0.05$, respectively 20.22% vs. 80.04%, $p=0.003$);2)low expression of CD41 in CMPD vs. controls (median: 44% vs. 70.3%; $p=0.01$), without any differences in CD61 expression;3)no differences for the level of activation markers.[figure1a]. No platelet immunophenotyping differences were detected among specific CMPD subgroups. The aggregometry analysis revealed:1)CMPD cases vs. controls presented reduced amplitude (median 48% vs. 74%, $p= 0.003$) and slope at ADP stimulation (median: 73% vs. 99%, $p=0.027$) and also at epinephrine stimulation (median amplitude 3% vs. 68% and median slope 34% vs. 82%: $p<0.07$). We also noticed a drop in collagen slope in case groups (median 47% vs. 82%: $p<0.69$) without any significant differences in collagen amplitude.2)No statistically significant variations were noted in ristocetin response. [Figure1b]. Western-blot analysis for vWF Receptor revealed: subunit 42b presented reduced levels of expression in cases vs. controls; 42a and 42c components had no change; 42d unit was under the detection limit of the method. Examination of αIIbβ3-integrin showed a higher expression in cases vs. controls for αIIb subunit and no alteration for β3 subunit. [Figure1C]. *Conclusions*. Our data show that western-blot and flowcytometry are equally sensitive methods for investigating platelet glycoproteins expression. Ib-alfa subunit of vWF receptor had a reduced expression on cell surface and in platelet lysate, signifying either reduced production, or an inhibiting expression mutation, or transient suppression of synthesis. The decreased expression doesn't have functional implications when detected by aggregometry (normal response to ristocetin). Expression of GpIX(CD42a) and GpIIb(CD41) is reduced on cell surface, but it is normal/respectively over-expressed in platelet lysate, suggesting that these glycoproteins are initially present and then inter-

nalized, or deficiently expressed. Neither method showed any alteration in the expression of β3 subunit of the fibrinogen receptor. Analysis of activation markers (P-selectin,granulophysin) on platelet surface doesn't show any variation of platelet activation in patients vs controls.Aggregometry showed alterations suggesting acquired Glanzmann thrombasthenia, with noticeable decrease up to flatting of response to ADP and epinephrine. Finally, it appears that the functional role of GpIIb is much higher than it was believed-fibrinogen binds effectively to CD61 or activation doesn't induce conformational changes necessary to expose fibrinogen binding site.

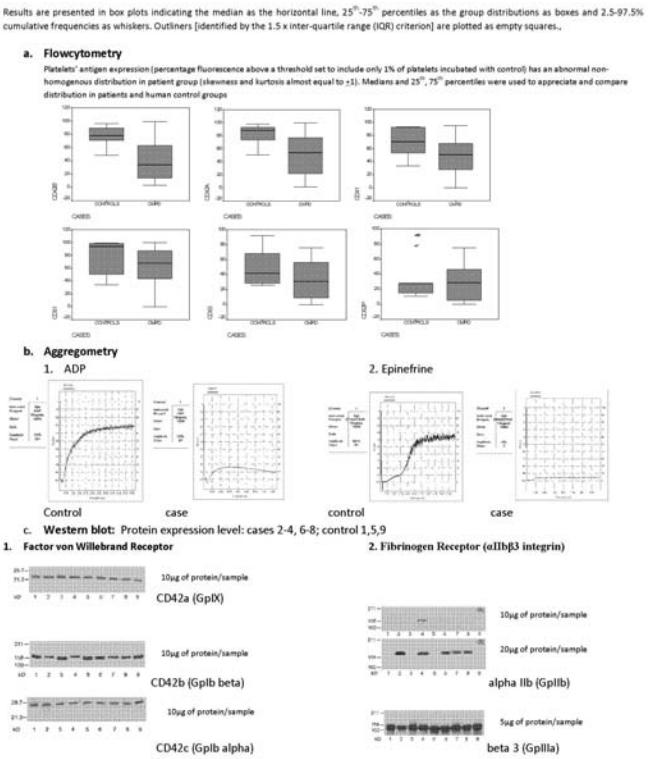

Figure 1. Multi method investigation of platelet behaviour in CMPD.

QUALITITATIVE AND QUANTITATIVE ANALYSIS OF JAK2V617F MUTATIONS UNRAVELS HIGHER RESPONSIVENESS OF JAK2+ ET PATIENTS TREATED WITH HYDROXYUREA

M. Bonamino,[1] V. Scholl,[1] F. Gomes,[1] C. Sternberg,[1] M. Praxedes,[2] A. Daumas,[3] I.R. Zalcberg[1]

[1]INCA, RIO DE JANEIRO, Brazil; [2]Antonio Pedro University Hospital, NITEROI, Brazil; [3]University Antonio Pedro Hospital, NITEROI, Brazil

Background. JAK2V617F mutations are relevant genetic events that had been shown to be correlated to BCR-ABL negative myeloproliferative diseases. The large majority of PV patients, and 50-70% of Essential Trombocytemia (ET) patients, harbor the V617F allele. Recently, the allelic ratio (AR) of mutated to wild type JAK2 genes found in blood samples was suggested to be related to worst prognosis as the AR increases. Most of the AR determinations have been performed in cDNA samples, but this approach poses a real problem to laboratories that stored only DNA extracted from large granulocytic fractions collections. To approach the quantitative analysis of former stored DNA samples, we set a new methodology based on DNA and fluorescent-primer for a quantitative-based PCR approach. These extend our previously analyses with a qualitative JAK2 PCR and allowed the calculation of the AR ratio. Aims:To evaluate the JAK2 mutation status in PV and ET patients, it's impact in the response to Hydroxyurea and to correlate JAK2 allelic ratio to patient's response ratios. *Design and Methods*. PV (10 patients) and ET (27 patients) blood samples were separated in Ficoll gradient and the red cell/granulocitic fractions were submitted to hypotonic lysis and DNA isolation(DNAzol®). All patients included tested negative for BCR-ABL transcripts. Qualitative Allele-Specific PCR for JAK2 mutation was performed as described by Baxter *et al*. For Quantitative PCR, 6-FAM fluorescent-primers, adapted from Jones et al, were synthesized. A patient sample carrying high allelic rate mutation was selected and PCR fragments were cloned in TOPO-TA plasmid. Dilution curves of mutated and wild-type JAK2 templates were performed, PCR amplified and analyzed into a 377 DNA sequencer. *Results*. Using the qualitative JAK2 PCR essay, we found 90% of PV samples carrying the Val617Phe mutation (JAK2+). All PV patients were treated with Hydroxyurea (0,5-2,5g) before testing. Amongst JAK2+ patients, 72% had platelet counts above 450.000 at diagnosis and 50% of them reached platelet counts lower than 450.000 after treatment. ET patients tested JAK2+ for 55,6% of the samples. Of those, 82% were previously treated with Hydroxyurea (0,5-2,5g). Amongst the treated patients in JAK2- group, only 13,3% showed platelets counts <450.000. In contrast, 58,3% of JAK2+ treated ET patients showed platelets counts >450.000 (p=0.037, Fisher`s exact test). Median values for platelet counts at diagnosis were similar in both JAK2+ or negative groups with no statistic difference. Hydroxyurea doses used for the treatment of JAK2+ patients were lower (n=9, dose=0,78±0,26g) than the doses used for JAK2- patients (n=12, dose=1,21+/-0,54g, p=0,041 T test). Allelic sample calibration curves showed an excellent correlation coefficient (r2>0.98) and a sensibility of 2%, allowing the calculation of AR in every previously JAK2+ tested sample. *Conclusions*. The frequency of JAK2+ patients found in PV and TE groups were almost similar to those described in literature. In ET, JAK2- samples was correlated to pourer response to Hydroxyurea, requiring higher doses to achieve more discrete platelet count reductions. The allelic ratio data, obtained from DNA, allowed a more detailed analysis of patients. This could be relevant in future attempts to early predict good and bad responders to Hydroxyurea-therapy.

ABSENCE OF REARRANGEMENTS OR ACTIVATING MUTATIONS IN THE IN THE RTK III AND IV FAMILY GENES IN BCR-ABL1 NEGATIVE AND JAK2V617F NEGATIVE CHRONIC MYELOPROLIFERATIVE NEOPLASMS (CMPNS)

P. Aranaz, C. Ormazábal, C. Hurtado, I. Erquiaga, M.J. Calasanz, M. García-Delgado, F.J. Novo, J.L. Vizmanos

Universidad de Navarra, PAMPLONA, Spain

BCR-ABL1 negative chronic myeloproliferative neoplasms (CMPNs) are a heterogeneous group of clonal haematological malignancies. Over the last years, some genetic alterations have been described to cause these diseases, most of them activating tyrosine kinase (TK) genes. Tyrosine kinases (TK) have an important role in cell growth and oncogenesis, as gain-of-function mutations can lead to the constitutive activation of the signalling pathways in which they are involved. In this study, we have analysed all genes from the families III (PDGFRA, PDGFRB, CSF1R, KIT and FLT3) and IV (FGFR1, FGFR2, FGFR3 and FGFR4) of RTKs. All of them code for receptors with tyrosine kinase activity and some of them have been found mutated in CMPNs and in other tumor types. We have used FISH to detect cryptic rearrangements and dHPLC to detect sequence mutations on samples from 44 BCR-ABL1 negative and V617FJAK2 negative CMPN patients. Both analyses have shown that these genes are no frequently mutated in these diseases, implying that molecular events or cryptic rearrangements causing these diseases, if they exist, must be located in other genes.

1496

FISH AND MUTATIONAL SCREENING OF THE ABL, SYK AND JAK TYROSINE KINASE FAMILY GENES IN BCR-ABL1 NEGATIVE AND JAK2V617F NEGATIVE CHRONIC MYELOPROLIFERATIVE NEOPLASMS (CMPNS)

C. Ormazábal, P. Aranaz, C. Hurtado, I. Erquiaga, M.J. Calasanz, M. García-Delgado, F.J. Novo, J.L. Vizmanos

University of Navarra, PAMPLONA, Spain

Chronic myeloproliferative neoplasms (CMPNs) are clonal disorders of the hematopoietic stem cells, characterized by abnormal proliferation and survival of one or more cells of the myeloid lineage. BCR-ABL1 negative CMPNs are a heterogeneous group of diseases for which the molecular pathogenesis is not well understood. Over the last years some genetic alterations have been described, most of them activating some tyrosine kinase genes playing a role similar to ABL1 in CML. Tyrosine kinases (TK) have an important role in cell growth and oncogenesis. Deregulation of TK genes (mainly due to translocations, amplifications or point mutations) can result in constitutive activation of the signalling pathways in which they are involved, causing the abnormal proliferation and survival that characterize these pathologies. In this study, we have analysed all genes from the families Jak (JAK1, JAK2, JAK3 and

TYK2), Abl (ABL1 and ABL2) and Syk (SYK and ZAP70) of TKs. All of them code for cytoplasmic tyrosine kinase proteins and some of them have been found mutated in CMPNs and in other tumor types. We have used FISH to detect cryptic rearrangements and dHPLC to detect sequence mutations on samples from 44 BCR-ABL1 negative and V617FJAK2 negative CMPN patients. Both analyses have shown that these genes are no frequently mutated in these diseases, implying that lesions in other genes must be involved in the pathogenesis of these diseases.

1497

QUANTIFICATION OF PRV1 GENE USING ABL AND GAPDH AS REFERENCE GENES - COMPARISON OF RESULTS OBTAINED IN GROUP OF 21 PATIENTS WITH POLYCYTHEMIA VERA

S. Czekalska, M. Zawada, I. Florek, T. Sacha, J. Wegrzyn, G. Wator, K. Stozek, J.J. Pietrzyk, A.B. Skotnicki

Jagiellonian University Collegium Medicum, KRAKÓW, Poland

Primary polycythemia results from an intrinsic defect in hematopoietic stem cell, which results in increased production of erythrocytes. The most common form of primary polycythemia is polycythemia vera (PV) - one of Ph-negative chronic myeloproliferative disorders (Ph-negative cMPD). The aim of the study was to compare results of RQ-PCR obtained from 21 patients with PV performed using GAPDH and ABL as reference genes. GAPDH was used according to Klippel S. et al (Blood 2003, 15 (102); 3569-74). The method with use of ABL was established in our laboratory. A group of 21 patients with Ph-negative cMPD at the moment of diagnosis and 5 healthy volunteers were investigated. For PRV1 gene quantification only patients with negative result of multiplex-RT-PCR for BCR/ABL were taken. Briefly: from peripheral blood white cells preserved in TriPure RNA were isolated, then the reverse transcription from 1000ng of RNA (Superscript II, Invitrogen) was done. The next step was the RQ-PCR reaction based on TaqMan Gene Expression Assay Hs 00360669_mL (PRV1, Applied Biosystems). Two reference genes GAPDH (primers and probe (JOE, TAMRA) based on Klippel S. et al) and ABL (primers and probe (FAM, TAMRA) based on Europe Against Cancer program) were used. All reactions were performed in duplicates using 7500 Applied Biosystems platform. Our results were analysed with 3 different thresholds: 0,04 for PRV1/0,2 for GAPDH (*according to Klippel S. et al.*), and 0,1 for PRV1/0,1 for ABL (according to European Leukemia Net standards). The results were expressed as ratio: Ct PRV1/Ct GAPDH and Ct PRV1/Ct ABL. For statistic analysis t-student test was used. We did not find any differences between PRV1 expression obtained with use of two different reference genes. However three different thresholds were used. In the group of patients with PV analyzed by Klippel S. et al the mean ratio is 1,04 (range 0,85-1,17), and in healthy volunteers is 1,31 (range 1,20-1,52). The results obtained in our patients are shown in Table.1

Table 1.

	PRV1/ABL	PRV1/GAPDH
Mean ratio in PV group (range)	0,96 ± 0,12 (0,59 – 1,02)	0,94 ± 0,11 (0,64 – 1,06)
Mean ratio in healthy group (range)	1,05 ± 0,02 (1,02 – 1,07)	1,03 ± 0,05 (1,00 – 1,05)

The thresholds detected by Klippel *et al*. are lower than in our method. In many patients diagnosed as PV according to WHO criteria PRV1 expression in bone marrow was at the lower level than 0,85. The discrepancy like this could cause the difficulties with proper allocation of patients to PV or non-PV group. Therefore it would be suggested that each laboratory should establish individual thresholds in control group and patients diagnosed as PV according to WHO clinical criteria. It is possible to quantify the expression of PRV1 using GAPDH or ABL as reference gene

1498

DISAPPEARANCE OF JAK2 EXON 12 MUTATION BY HYDROXYUREA TREATMENT

J. Rey,[1] M.J. Mozziconacci,[1] A. Noble,[2] P. Guillet,[2] Z. Azgui,[3] S. Harbi,[1] R. Devillier,[1] L. Benarous,[1] V. Salinas,[1] V. Ivanov,[1] D. Coso,[1] R. Bouabdallah[1]

[1]Paoli-Calmettes, MARSEILLE, France; [2]Hôpital Casteluccio, AJACCIO, France; [3]Hôpital Pitié Salpétrière, PARIS, France

Background. Management of polycythemia has been dramatically changed with the discovery of Jak2 mutation. Actually, a negative search for Jak2 mutations at diagnosis excluded the diagnosis of polycythemia vera. However, this situation is more complex for patients already treated by cytoreductive drugs, as it was reported that interferon α and hydroxyurea can diminish the exon 14 Jak2 mutation allele burden or eventually can obtain molecular complete remission. In this setting, a negative search for Jak2 mutations is not sufficient to eliminate the diagnosis of polycythemia vera but necessitates to reconsider the diagnosis. *Aims*. We report the first case of disappearance of exon 12 Jak2 mutation on hydroxyurea treatment. *Methods*. A 42 year-old man was referred to our center for confirmation of polycythemia vera. He was diagnosed before the Jak2 area with polycythemia with 6 500 000 erythrocytes, 18,5 g/dL hemoglobin and 58% hematocrite confirmed by red cell mass evaluation. Leucocytes and platelets were normal. No cause of secondary polycythemia was retrieved. He was treated with hydroxyurea. After the discovery of exon 14 Jak2 mutation, the patient was screened for this mutation. Exon 14 Jak2 screening was negative. After the discovery of exon 12 Jak2 mutation, the patient was screened for this second mutation but was negative. Moreover, it was decided to stop hydroxyurea treatment to reconsider the diagnosis of polycythemia vera. Four months after the cessation of hydroxyurea, polycythemia occurs again with 0,60 of hematocrit. After the reported effect of interferon and then hydroxyurea on Jak2 allele burden, the patient was again tested for the two Jak2 mutations. Exon 14 Jak2 mutation was negative but exon 12 mutation was positive. The diagnosis of polycythema vera was confirmed and hydroxyurea treatment was restarted. Results - Negative screening for Jak2 mutations in a patient with polycythemia at diagnosis is a major criteria against the diagnosis for polycythemia vera. More recently, it was reported that treatment as interferon α or hydroxyurea can diminish Jak2 exon 14 mutation allele burden and even gives negative results. So, a negative result in a polycythemia vera patient treated can not exclude the diagnosis. To our knowledge, disappearance of exon 12 mutation on hydroxyurea treatment has never been reported. *Conclusions*. Hydroxyurea treatment and probably interferon α can modulate exon 12 mutation allele burden, as for exon 14 mutation. A negative result in a treated patient may be interpreted with caution.

1499

JAK2 V617F, C-MPL W515L AND W515K MUTATIONS IN ROMANIAN PATIENTS WITH POLYCYTHEMIA VERA, ESSENTIAL THROMBOCYTHEMIA AND PRIMARY MYELOFIBROSIS

A.P. Trifa,[1] A. Cucuianu,[2] R.A. Popp,[1] D.M. Dima,[2] L. Urian,[2] M.S. Militaru,[1] L. Petrov,[2] I.V. Pop[1]

[1]University of Medicine and Pharmacy "Iuliu Hatieganu", CLUJ-NAPOCA, Romania; [2]"Ion Chiricuta" Cancer Institute, Department of Hematology, CLUJ-NAPOCA, Romania

Background. Polycythemia vera (PV), essential thrombocythemia (ET) and primary myelofibrosis (PMF) are typical myeloproliferative disorders (MPDs). A major breakthrough in the ethiopathogenesis of MPDs has been made with the discovery of a somatic mutation, Janus kinase 2 (JAK2) V617F, which shortly afterwards became a major diagnosis criterion, in most of PV cases and around half of ET and PMF cases. Moreover, a small proportion of ET and PMF cases were shown to harbour somatic mutations in myeloproliferative leukemia virus oncogene (c-MPL) gene. *Aims*.The purpose of this study was to investigate JAK2 V617F and c-MPL W515L and W515K mutations in a group of Romanian patients with PV, ET and PMF. *Design and Methods*. A total number of 99 patients were included in the study, comprising 59 PV, 35 ET and 5 PMF patients. The JAK2 V617F mutation was studied by two different approaches, a nested PCR-RFLP (Polymerase Chain Reaction -

Restriction Fragments Length Polymorphism) and a tetra-primer PCR technique, respectively. c-MPL W515L and W515K mutations were screened by allele-specific PCR approaches in ET and PMF patients. *Results.* JAK2 V617F mutation could be demonstrated in 48 PV patients (81%), 21 ET patients (60%) and 4 PMF patients (80%). Overall, the expansion of the JAK2 mutant clone tended to be higher in JAK2 positive PV and PMF patients than in JAK2 positive ET patients. Both the techniques used for studying JAK2 V617F mutation, nested PCR-RFLP and tetra-primer PCR, respectively, gave concordant results in all the patients. As for c-MPL mutations, no ET or PMF patient was found to harbour neither the W515L mutation, nor the W515K mutation. *Conclusions*. The distribution of JAK2 V617F mutation in our group is concordant with data reported in literature. The absence of c-MPL W515L/K mutations in our group is not so surprising, taking into consideration their low frequency reported in ET and PMF patients. We cannot rule out the possibility of other JAK2 or c-MPL mutations in patients negative for JAK2 V617F and c-MPL W515L/K, which we were not yet able to analyze. The techniques used in this study for studying JAK2 V617F and c-MPL W515L/K mutations are quite inexpensive and they provide sufficient sensitivity for diagnostic purposes. As new molecular markers are discovered in hematological malignancies, their investigation become part of the investigations protocol, as diagnostic and sometimes as prognostic markers.

COEXISTENCE OF POLYCITHEMYA VERA JAK2 V617F-POSITIVE AND MONOCLONAL GAMMOPATHY

A. Fiorini,[1] A. Carpaneto,[1] F. Celesti,[1] C. De Gregoris,[1] P. Falcucci,[1] G. Trapè,[1] G. Pessina,[2] M. Montanaro[1]

[1]Ospedale di Ronciglione, VITERBO, Italy; [2]Polo Biomedico Ospedale Viterbo, VITERBO, Italy

Background. Polycithemia vera (PV) is a clonal disease which originates from abnormal hematopoietic progenitor cells at the pluripotent stem cell level. The somatic mutation JAK2 V617F in exon 12 of the jak2 gene, with the constitutive activation of the gene, has been identified in about 81% (range, 65-97%) of patients with PV; in addition JAK2 V617F is not associated with Multiple Myeloma as recently showed. Concomitant cases of Monoclonal gammopathy (MG) with PV have been described in literature but gammopathies have been related to the precedent therapy for PV and JAK2 V617F was not performed. *Aims*. Here we report 2 cases of concomitant PV JAK2 V617F-positive and monoclonal gammopathy in which the MG has been diagnosed before or at the same time of PV. *Design and Methods*. The first one is about a 70-year old female who was referred to our institution because of elevated blood cell count and MG. Her blood test showed an increase in the number of white blood cells (WBC) and thrombocytosis of $12x10^9$/L and $0.7x10^{12}$/L, respectively, and hemoglobin of 178 g/L. Immunoelectophoresis showed 0.8 g/L of IgG/k monoclonal protein . Bence Jones (BJ) proteinuria was negative and renal function was normal. BM aspirates was consistent with PV and showed plasmacells (PC)<10% and eythroid iperplasia. Karyotype analysis revealed 46 XX. JAK2 V617F was identified in whole blood peripheral leucocytes with RT-PCR. PV was diagnosed according to WHO 2008 criteria. The second one is about a 67-year old male referred to our institution for MG. His blood test showed increased WBC, platelets and hemoglobin ($11x10^9$/L, $0.6x10^{12}$/L, 180 g/L respectively). He had 2 g/L of IgG/a monoclonal protein . BJ proteinuria was negative and renal function was normal. BM aspirates was consistent with PV and showed PC <10%. X-ray total body showed two osteolitic lesions in the skull. JAK2 V617F analyzed with RT-PCR from whole blood peripheral leucocytes was positive. Both patients were treated for PV with low dose aspirin and with periodic phlebotomy to reduce hematocrit to 47%. Laboratory blood test check for MG was performed every six months; a X-ray total body every year. *Results and conclusions*. Our case reports suggest that the coexistence of two different diseases from the same bone marrow milieu probably takes origin from different cell clones. In literature coexistence of PV and MG has been described but it has been associated to a precedent therapy for PV. Here the two diseases were diagnosed at the same time and the presence of JAK2 V617F mutation provides a molecular basis for the identification of PV-clone.

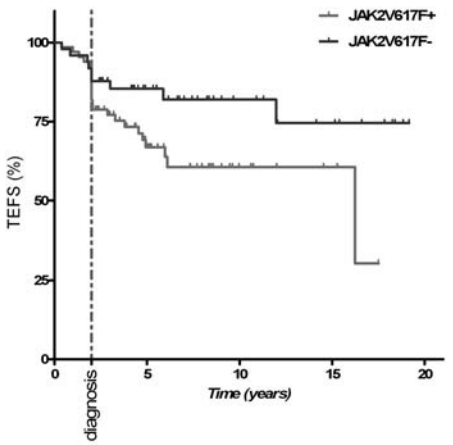
1501

JAK2V617F MUTATION IN PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA: INFLUENCE ON CLINICAL AND LABORATORY FEATURES AT DIAGNOSIS AND DURING FOLLOW UP

E.M. Elli, A. Belotti, M. Parma, F. Colnaghi, A. Colombo, E. Lanzi, P. Pioltelli, E.M. Pogliani

San Gerardo Hospital, MONZA, Italy

Background. Acquired mutation of JAK2V617F can be found in approximately 50-60% of Essential Thrombocytemia (ET). The impact of this mutation on its molecular pathogenesis and clinical phenotype is still debated AIMS: We investigated the frequency of JAK2 mutation and its possible impact and correlation with clinical and laboratory features at diagnosis and during follow-up in ET patients (pts) referred to our division between 1987 and 2008. *Design and Methods*. Allele-specific PCR for JAK2V617F mutational status was performed on genomic DNA from bone marrow cells or peripheral blood granulocytes in 115 ET (49 males, 66 females) pts. Clinical and laboratory features were evaluated at diagnosis and during follow-up, comparing mutated JAK2 ET pts versus pts harbouring wild-type (WT) gene. Data were processed using the Graph Pad PRISM 5 DEMO Software performing statistical non-parametric methods: univariate analysis was performed to evaluate differences in proportions by the chi-square and Fisher's exact tests for categorical nominal variables and the Mann-Whitney rank test for ordinal variables. Continuous variables have been categorized using median values. The log-rank (Mantel-Cox) test applied to Kaplan-Meyer method was employed to estimate thrombotic risk and thrombotic event-free-survival.



Thrombotic event free survival (TEFS) in JAK2V617F positive and negative patients

Figure 1.

Results. 66 ET pts (57,4%) were JAK2V617 positive. JAK2 mutated pts were older (median age 59 vs 48 years, p=0,0016) and presented at diagnosis significantly higher hemoglobin (Hb 14,3 g/dl vs 13,3 g/dl, p=0,0027), higher hematocrit (Ht 43% vs 39,8%, p<0,0001) and lower PLT count (PLT 725 vs 841 $x10^3$/L, p=0,005) respect to WT group. These PV-like features have also maintained during the course of disease, with statistical significance. No difference was observed in term of gender, white blood count, LDH, progression or entity of splenomegaly, and need of cytoreductive therapy between JAK2 mutated and WT pts. A highly significant increase of thrombotic complications was registered for JAK2 positive pts. Considering JAK2 WT ET as reference group, the relative risk (RR) of primary thrombotic event was 2,143 (95% CI: 1.053-4.360, p=0.035) for JAK2 mutated pts, with a TEFS lower than WT pts (as shown in Picture 1). Arterial events were more frequent than venous events without statistical difference between two ET groups. A trend of higher risk of recurrent thrombosis (p=0.056) was also shown for JAK2 mutated respect to WT pts. There was no difference about haemorragic complications, time and incidence of evolution in myelofibrosis between JAK2 mutated or WT pts. *Conclusions*. In our population, 57,4% ET pts displayed JAK2V617F mutation. This mutation divides pts into two distinct subtypes. JAK2 mutated pts present older age and laboratory features at diagnosis and during follow-up compatible with PV-like phenotype. Mutated pts also showed an increased risk of thrombosis, at diagnosis and during the course of disease, in terms of recurrent throm-

bosis, too. These observations suggest a more aggressive phenotype since the diagnosis in JAK2 mutated ET group. A possible biological continuum between JAK2 mutated ET and PV, or in general between JAK2 positive ET and JAK2 positive MPD may be supposed.

1502

EFFECT OF ANAGRELIDE ON PLATELET, COAGULANT AND ENDOTHELIAL FUNCTION IN PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA

R.R. Cacciola, E. Di Francesco, F. Pezzella, D. Tibullo, E. Cacciola

Institute of Hematolgy, CATANIA, Italy

Background. The large vessel thrombosis may complicate the essential thrombocyhemia (ET). Its pathogenesis is probably associated with platelet coagulant activation and this makes difficult its management. Anagrelide (ANA) is a platelet lowering drug that inhibits platelet aggregation. *Aims*. We investigated platelets and platelet factor 4 (PF4), prothrombin fragment 1+2 (F1+2) and thrombin-antithrombin complex (TAT), markers of platelet and coagulant activation, and tissue factor (TF) and von Willebrand factor (vWF), indicators of macrovascular damage in patients with ET. *Patients and Methods*. We recruited 19 patients with ET (12 males and 7 females, mean age 51 years) who fulfilled PVSG and WHO. All patients were on antiplatelets either aspirin (10 patients) or indobufen (7 patients) and ticlopidine (2 patients). Their mean duration of disease was 7 years. ANA was administered in dose of 0.5 mg/day, with increases of 0.5 mg/day every 7 days until the platelets decreased below $400x10^9$/L and with a average maintenance dosage of 2.1 mg/day. Platelets, PF4, F1+2, TAT, TF, vWF were measured before cytoreduction and to complete response defined as platelets < $400x10^9$/L. Platelets were measured by automated analyser. PF4, F1+2, TAT, TF and vWF were assayed by ELISA and immnunoturbidimetric assay, respectively. Results: Before ANA all patients had marked platelets ($1057\pm349x10^9$/L) and high PF4 (121±43 IU/mL vs 5.5±2.6 IU/mL) ($p<0.0001$), F1+2 (3.5±3.3 nmol/L vs 0.7±0.2 nmol/L) ($p<.0001$), TAT (28±32 µg/L vs 2.7±1 µg/L) ($p= 0.001$) and TF (247±184 pg/mL vs 4.8±2.5 pg/ml) ($p<0.0001$) and low vWF (22±8% vs 92±31%) ($p <.0001$). After ANA all patients had platelets <$400x10^9$/L (388 ± 66 x10^9/L) and normal PF4 (8.4±3.2 IU/mL) as well as F1+2 (1.1±0.8 nmol/L), TAT (2.4±1.1 µg/l), TF (8.3±0.4 pg/mL) and vWF (96±37%). A correlation was found between PF4 and F1+2 and TAT ($p<0.0001$ and $p=0.004$, respectively) and between PF4 and TF and vWF ($p<0.0001$ and $p=0.001$, respectively). Additionally, there was a correlation between F1+2 and TF and vWF ($p<0.0001$ and $p<.0001$, respectively) and TAT and vWF and TF ($p=0.001$ and $p= 0.023$, respectively). *Conclusions*. These findings suggest that the platelet coagulant activation is responsible for macrovascular damage and that ANA may repair the platelet coagulant endothelial injury and, hence, prevent the large vessel thrombosis.

1503

RAPID AND RELIABLE MUTATION SCREENING OF JAK2 EXONS 11-15 CODING SEQUENCE USING NON ISOTOPIC RNASE CLEAVAGE ASSAY (NIRCA)

K.C. Kambas,[1] I.A. Mitroulis,[1] I.P. Kourtzelis,[1]
A.K. Chrysanthopoulou,[1] M.G. Speletas,[2] K.D. Ritis[1]

[1]*General University Hospital Alexandroupolis, ALEXANDROUPOLIS, Greece;* [2]*Immunology and Histocompatibility Unit, University of Thessaly, LARISSA, Greece*

Background. The myeloproliferative disorders (MPD), polycythemia vera (PV), essential thrombocytosis (ET) and idiopathic myelofibrosis (IMF) exhibit gain-of-function V617 mutation of the Janus kinase (JAK) 2 gene (JAK2). Furthermore, 2 novel nucleotide exchanges in exon 14 and several exon 12 mutations of JAK2 have been identified in JAK2 V617F negative patients. In addition, there is low JAK2 V617F neutrophils allele burden in ET patents which can be omitted. *Aims*. In this study we report the development of a convenient and accurate method for screening of the coding region of the JAK2 gene which includes all potential mutations identified in exons 12 and 14 up to now and possible unidentified in the same regions. *Design and Methods*. Eight MPD patients (four PV, two ET and two IMF), who have been previously diagnosed to express JAK2 V617F mutation with allele specific PCR restriction enzyme analysis, four (two idiopathic erythrocytosis and two ET) negative in the same mutation and ten healthy individuals were cross-analyzed with NIRCA. RNA from peripheral granulocytes was isolated and PCR was performed using specific primers (containing a T7 promoter for upper primer and an SP6 one for the lower primer) spanning exons 11-15. These PCR products were analyzed using a NIRCA assay which is comprised by transcription, hybridization and digestion of these products. In transcription both strands of these products are transcribed along with wild type sample with the use of T7 and SP6 polymerases. These transcripts are hybridized in a fashion of sense and anti-sense patient strands mixed with complementary wild type strands. Wild type sense and anti-sense transcripts are hybridized in order to provide the control sample and the same procedure is repeated for the patient samples. Following hybridization, the products are digested using RNases in order to identify mutations by cleavage of mismatches. Then the digestion products are subject to agarose gel electrophoresis. *Results*. All eight patients positive to V617F mutation showed the same digestion pattern while digestion of all ten healthy individuals did not yield any fragments (results verified by direct sequencing). The same pattern of digestion was followed by a V617F negative ET patient, previously analyzed using restriction enzymes (direct sequencing verified low burden of V617F mutation). Different positive digestion pattern was also observed in two ET patients that were found negative in V617F mutation. Direct sequencing verified the presence of N542_E543del deletion in patient granulocytes. *Conclusions*. NIRCA is a rapid, highly sensitive and low cost technique that can be used in any laboratory. It has been proven to be accurate in the identification of even a low allele burden of JAK2 mutations in MPD patients and can be used for the simultaneous screening of the entire exon 11-15 JAK2 coding region with possible mutations while providing 100% sensitivity on negative results. As a result, its application could be used as a rapid screening test for the diagnosis of MPD patients since the digestion patterns are repeatable identifying particular mutations and direct sequencing can be avoided.

FIGURE 1. NIRCA digestion profiles in JAK-2 mutations.
Typical digestion profiles of A) healthy individuals, B) patients with V617F mutation, C) a patient with V617F mutation that showed false negative results with Baxter protocol and D) a patient with N542_E543del mutation. (ii) in B and D provides the corresponding sequencing for each digestion along with the wild type sequence (iii), while in C they are represented by (iii) and (iv) respectively. Lanes 1,2 and 3 in A(i), B(i), C(ii) and D(i) represent digestions, of the RNA duplex formed after hybridization of patient SP6 with wild type T7 opposable strands, with RNase 1, RNase T1 and a mix 1/1 of RNase 1 and RNase T1 respectively, while in C(i) the RNA duplex is formed after hybridization of patient T7 with patient SP6. Lane L corresponds to 100 base pair DNA marker (Fermentas). Digestion products are marked with arrows.

Background. The WHO 2008 classification of Philadelfia negative chronic mieloproliferative neoplasms (MPN), by exploiting the crucial role of bone marrow biopsy and JAK2 V617F mutation, lowered the platelet (PLT) count cut-off for ET diagnosis from 600 to 450x10^9/L. *Aims*. To validate the diagnostic impact of the updated WHO PLT cut-off in a large series of ET patients, by evaluating the main parameters of the clinical and biological phenotype at diagnosis. *Design and Methods*. The patients, enrolled in the Registro Italiano Trombocitemia (RIT) after a written informed consent was reached, were divided on the basis of PLT count (x10^9/L) at diagnosis in three groups (451-600, 601-1000, >1000) and were compared by considering gender and other characteristics at diagnosis as age, symptoms, thrombosis, haemorrhage, splenomegaly, WBC count, Hgb level, bone marrow cellularity and fibrosis, and JAK2 pattern. The prescription of antiplatelet drugs was also considered. *Results*. The patients with a PLT count (x10^9/L) at diagnosis range >450 resulted to be 1844, being the PLT count 451-600 (group I) in 258 cases (14%), 601-1000 (group II) in 1219 cases (66.1%), and >1000 (group III) in the remaining 367 cases (19.9%). By moving from group I to group II and to group III, the female:male ratio increased (1.50, 1.58, 1.80), the median age was 60, 62, 58 years, the disease-related symptoms increased (36.8%, 37.3%, 45.5%, p 0.01), the thrombotic events decreased (27.2%,18.4%,12.9%, p 0.0001), the haemorrhagic events were 1.2%, 3.9%, 4.1%, a splenomegaly was 26.4%,25%, 26.4%. A rate of WBC count >8.7 x10^9/L increasd (34.5%, 48.9%, 62%, p 0.000), the median value of Hgb (g/dL) was 14.4, 14.3, and 13.7, the bone marrow biopsy documented an increase (p 0.000) of hypercellularity (36%, 50.4%, 59.5%) and of a grade 1 fibrosis (21.3%, 27,7%, 40,6%). In 665 evaluated cases, the JAK2 V617F mutation rate decreased (64.3%, 56.1%, 47.3%, p=0.04). The use of antiplatelet drugs was prescribed without significant differences in the three groups. (69.4%, 70.9%, 65.7%) *Conclusions*.In this RIT study the ET patients with a PLT count at diagnosis in the range 451-600x10^9/L showed a clinical and biological phenotype globally similar to that of patients with higher PLT count, althougt same characteristics resulted differently distributed. In fact, as expected they had a lower incidence of disease-related symptoms, haemorrhage, leukocytosis, bone marrow ipercellularity and grade 1 fibrosis, while surprisingly they had a higher incidence of thrombosis and Jak2 V617F mutation.

1505

PREVALENCE OF JAK2V617F MUTATION IN WOMEN WITH UNEXPLAINED RECURRENT MISCARRIAGE

M.N. Lauw,[1] S.P. Kaandorp,[1] C.E. van der Schoot,[2] M. Goddijn,[1] F. van der Veen,[1] H.R. Koene,[3] B.J. Biemond,[1] S. Middeldorp[4]

[1]Academic Medical Center, AMSTERDAM, Netherlands; [2]Sanquin Research at CLB, AMSTERDAM, Netherlands; [3]St Antonius Hospital, NIEUWEGEIN, Netherlands; [4]Leiden University Medical Center, LEIDEN, Netherlands

Background. The JAK2V617F mutation is associated with the group of Philadelphia-chromosome negative myeloproliferative disorders (MPD), e.g. polycythemia vera and essential thrombocytemia. The risk of a first trimester miscarriage is increased in pregnant women with MPD. Furthermore, an approximately five-fold increased risk of sporadic pregnancy loss (first trimester miscarriage, second trimester miscarriage and stillbirth) - was recently described in healthy women carrying the JAK2V617F mutation.[1] *Aims. W*e hypothesised that the JAK2V617F mutation plays an etiologic role in unexplained recurrent miscarriage and we assessed its prevalence in a well-defined group of healthy women with unexplained recurrent miscarriage. *Design and Methods.* The presence of the JAK2V617F mutation was determined in a cohort of 147 women diagnosed with unexplained recurrent miscarriage in an academic recurrent miscarriage clinic. Recurrent miscarriage was defined as two or more miscarriages with an upper gestational age of 20 weeks. Recurrent miscarriage was classified as unexplained when chromosome abnormalities, of both patient and her partner, uterine anomalies, antiphospholipid antibody syndrome (lupus anticoagulant and anticardiolipin IgM/ IgG) and hyperhomocysteinemia (fasting levels < 16 mmol/L) were ruled out. To test for the presence of the JAK2V617F mutation we used an allele-specific real-time quantitative TaqMan PCR. Results Of 147 women with unexplained recurrent miscarriage, 141 DNA samples could be tested for the presence of the JAK2V617F mutation. In none (0%, 95%CI 0.0-2.7%) of the women with unexplained recurrent miscarriage the JAK2V617F mutation was found. The significant association between JAK2V617F mutation and the risk of miscarriage could not be reproduced in our cohort. Conclusions The prevalence of JAK2V617F mutation in a group of women with unexplained recurrent miscarriage is negligible. The significant association between JAK2V617F mutation and the risk of miscarriage[1] could not be reproduced in our cohort. Our results do not support a significant etiologic role for JAK2V617F mutation in women with unexplained recurrent miscarriage. Currently there is no evidence to test for JAK2V617F mutation in the diagnostic work-up in women with recurrent miscarriage.

PHARMACOKINETICS AND SAFETY OF ANAGRELIDE HYDROCHLORIDE IN YOUNG AND ELDERLY PATIENTS WITH ESSENTIAL THROMBOCYTHAEMIA

C. Freitag,[1] R. Coll,[1] S. Troy,[1] P. Martin,[1] C. Besses[2]

[1]Shire Pharmaceuticals Ltd., BASINGSTOKE, UK; [2]Hospital del Mar, BARCELONA, Spain

Background. Anagrelide hydrochloride is a megakaryocyte-selective agent, licensed in Europe for the reduction of elevated platelet counts in at-risk essential thrombocythaemia (ET) patients who are intolerant or resistant to their current therapy. *Aims*. The primary objective of this Phase II open-label, multicentre study was to assess the pharmacokinetic and pharmacodynamic profiles of anagrelide and its active metabolite, BCH24426, in young (18-50 years) and elderly (≥65 years) patients with ET. Assessment of the safety and tolerability of anagrelide were secondary objectives. *Design and Methods*. Patients who were receiving a stable dose of anagrelide (≥5 mg/day) for at least 4 weeks and provided informed consent were eligible for the study. For 3 days prior to pharmacokinetic evaluation, each patient evenly divided their standard total daily dose of anagrelide into a twice daily (BID) regimen. Serial blood samples were obtained for pharmacokinetic and pharmacodynamic analysis over a 12-hour dosing interval. Drug plasma concentrations were normalised to a common 1 mg BID regimen to account for dosing differences between subjects. Patients were routinely monitored for platelet count, blood pressure, heart rate and adverse events (AEs). Results: Twelve patients aged 18-50 years and 12 patients aged ≥65 years were enrolled in the study. Mean (± standard deviation) total daily doses were 2.09 (± 0.74 mg) and 1.42 (± 0.67 mg) in young and elderly patients, respectively. Compared with younger patients, the geometric mean dose-normalised Cmax (maximum observed plasma concentration) and AUCtau (area under the concentration-time curve over one dosing interval) in elderly patients were higher for anagrelide (Cmax: 3.63 vs 2.66 ng/mL; p=0.09, AUCtau: 10.3 vs 6.4 ng-h/mL; p=0.01) and lower for BCH24426 (Cmax: 4.19 vs 7.26 ng/mL; p=0.02, AUCtau: 17.4 vs 27.6 ng-h/mL; p=0.03). No significant difference was observed in geometric mean terminal half life (T1/2) of anagrelide in elderly and young patients (1.4 vs 1.3 hours, respectively; p=0.38). The geometric mean T1/2 of BCH24426 was significantly longer in elderly patients than young patients (3.5 vs 2.7 hours, respectively; p=0.01). There were no substantial changes in platelet count, blood pressure or heart rate between age groups. Six AEs were reported in three younger patients, all of which were mild-to-moderate in intensity. Headache was the most common AE. There were no deaths, serious AEs or AEs that led to withdrawal from the study, and no clinically significant abnormalities in electrocardiogram or cardiovascular function. Conclusions: Anagrelide and BCH24426 have equipotent anti-megakaryocyte activity. Therefore, despite different exposures to anagrelide and BCH24426 in elderly and younger patients, anti-megakaryocyte activity is expected to be similar. Safety findings were as expected and consistent with the pharmacological profile of anagrelide and underlying disease. The results of this study do not suggest a different anagrelide dosing paradigm (starting regimen or dose-titration steps) should be implemented to achieve individual, patient-optimised platelet control in young or elderly patients with ET, thus simplifying the therapeutic approach for the clinician.

1507

THE RISK OF RECURRENT THROMBOSIS IN PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA CARRYING HOMOZYGOUS OR HETEROZYGOUS JAK2 V617F MUTATION

V. De Stefano,[1] T. Za,[1] E. Rossi,[1] A.M. Vannucchi,[2] M. Ruggeri,[3] E. Elli,[4] C. Micò,[5] A. Tieghi,[6] R. Cacciola,[7] C. Santoro,[8] N. Vianelli,[9] P. Guglielmelli,[2] L. Pieri,[2] F. Seragnoli, University of Bologna, BOLOGNA, Italy

Background. Some evidence suggests that the JAK2 V617F mutation is associated with an increased risk of first thrombosis in patients with essential thrombocythemia (ET). Whether is a risk factor for recurrent thrombosis too is currently unknown. *Aims*. In order to investigate the impact of the JAK2 V617F mutation on the risk of recurrent thrombosis in patients with ET, we carried out a multicenter retrospective cohort study. *Design and Methods*. We recruited 143 patients with ET, with previous arterial (64.4%) or venous major thrombosis (34.8%) or both (0.8%). The total observation time after thrombosis was 922 pt-years (median 5.5). All patients had to be tested for the presence of the JAK2 V617F mutation in granulocytes by allele-specific polymerase chain reaction; 98 of them (68.5%) carried the mutation. Information about the patient's mutant allele burden was recorded in 47 mutated patients. Heterozygous (n=42) or homozygous (n=5) status was defined as a mutant allele burden < 50% or > 50%, respectively. The relative risk of recurrence was estimated as a hazard ratio (HR) using a Cox proportional hazards regression model. The HR was adjusted using recurrence as the dependent variable and selecting as covariates gender, age at the time of the initial thrombosis (>60 or <60 years), presence of one or more vascular risk factors, history of remote thromboses, type of first thrombosis (arterial or venous), presence of the JAK2 mutation, and type of treatment following thrombosis. Results: Thrombosis recurred in 43 patients (30%); after adjustment for sex, age, presence of vascular risk factors, and treatment after the first thrombosis, the presence of the JAK2 mutation did not predict recurrence (multivariable HR, 0.88, 95%CI 0.46-1.68). This finding was substantially unchanged after stratification of the patients according to the age at the time of the first thrombosis (<60 years or >60 years), the type of first thrombosis (arterial or venous), and administration of cytoreduction after the first thrombosis. Indeed, homozygotes for JAK2 V617F had an increased risk of recurrence in comparison with wild-type patients (HR 6.15, 95%CI 1.51-24.92); in respect to the heterozygous patients, the risk was increased but without reaching the statistical significance (HR 2.94, 95%CI 0.73-11.78). The heterozygous patients had a risk of recurrence quite similar to that of the wild-type patients (HR 0.99, 95%CI 0.45-2.14) Conclusion: The JAK2 V617F mutation is not a risk factor for recurrent thrombosis in patients with ET, unless the patient is homozygous for the gene.

1508

COMBINED USE OF THE PLATELET FUNCTION ANALYZER (PFA)-100 AND PLATELET AGGREGOMETRY IN THE DIFFERENTIATION OF ESSENTIAL THROMBOCYTHEMIA FROM REACTIVE THROMBOCYTOSIS

E. Tsantes,[1] G. Mantzios,[1] P. Tsirigotis,[2] A. Dimoula,[2] S. Bonovas,[3] A. Kardoulaki,[4] E. Mygiaki,[4] Z. Kartasis,[5] V. Giannopoulou,[2] J. Dervenoulas,[2] A. Travlou[4]

[1]Attikon' General Hospital, School of Medicine, University of Athens, Greece, ATHENS, Greece; [2]Second Department of Internal Medicine, Propaedeutic, 'Attikon' General Hospi, ATHENS, Greece; [3]Department of Epidemiological Surveillance and Intervention, Center for Disea, ATHENS, Greece; [4]Laboratory of Haematology and Blood Bank Unit, 'Attikon' General Hospital, ATHENS, Greece; [5]Department of Hematology, General Hospital of Chalkida, Greece, CHALKIDA, Greece

Background. The most crucial component of all diagnostic criteria for essential thrombocythemia (ET) has been the exclusion of reactive thrombocytosis (RT). *Aims*. Our goal was to evaluate the diagnostic performance of the PFA-100 collagen-epinephrine (CEPI) cartridge test and epinephrine-induced aggregometry individually, but mainly combined, in the differentiation of ET from RT. *Design and Methods*. Twenty-six patients with ET and 25 with RT were studied. Platelet function was analyzed by the PFA-100 using CEPI and collagen-ADP (CADP) cartridges, and by light transmission aggregometry with epinephrine and ADP. Haematological parameters, plasma von Willebrand factor antigen and activity levels were also assessed. *Results*. The sensitivity (Se), specificity (Sp), positive predictive value (PPV), and the negative predictive value (NPV) of PFA-100 CEPI vs epinephrine-induced aggregometry in the differentiation of ET from RT were estimated as follows: Se (%): 78.9 vs 84.6, Sp (%): 92.0 vs 96.0, PPV (%): 88.2 vs 95.7, NPV (%): 85.2 vs 85.7, respectively. When both of these methods were combined, a lower sensitivity of 68.4%, but a specificity of 100% was attained. The PPV observed with this double abnormal combination was 100% and the NPV 80.6%. Lastly, when we assessed the abnormality for either CEPI CT or epinephrine-induced aggregometry, the sensitivity was 100%, the specificity 88.0%, PPV 86.4% and NPV 100%. *Conclusions*. An abnormal combination was strongly suggestive of ET, while normal results with both methods excluded ET. If our results are replicated by further studies, these two methods could be used very effectively as adjunct markers in the differentiation between ET and RT.

1509

PLATELETS AND WHITE BLOOD CELLS (WBC) DO NOT INCREASE IN JAK2-WILD TYPE (WT) POLYCYTHEMIA VERA (PV) AFTER OBTAINING A NORMAL HEMATOCRIT (HT) WITH PHLEBOTOMIES

F. Tezza, M.L. Randi, M. Scapin, L. Faccio, E. Duner, F. Fabris

University of Padua, Medical School, PADUA, Italy

Background. Diagnostic tools in cases presenting with isolated erythrocytosis have been recently improved by the mutations of the janus-kinase 2 (JAK2), that identify more than 90% of patients with PV. This observation induced the recent modification of WHO diagnostic criteria for PV and now the presence of JAK2 mutation is a major diagnostic data for the disease. Nevertheless, PV represents a small proportion of patients with isolated erythrocytosis and other disorders display the same clinical phenotype. Other absolute erythrocytosis, both congenital or acquired, do not carry the JAK2 mutations. In the presence of an acquired absolute erythrocytosis, after the exclusion of secondary and familial causes, if no JAK2 mutation is found, the diagnosis may be of PV or idiopathic erythrocytosis (IE). The former is characterized by an increase of red blood cells without an identified cause and the patients usually undergo phlebotomies to avoid the thrombotic risk due to hyperviscosity.

Table 1.

	Group 1	Group 2	p
N° of patients	24	16	
Sex (M/F)	21 / 3	12 / 4	NS
Mean age at diagnosis (years)	66 ± 10	62 ±16	NS
Median follow-up (years)	5.85	4.41	NS
Platelets x 10^9/L	320 ± 123	281±129	NS
	552 ±178	316 ±154	0.001
WBC x 10^9/L	8,04 ±2,25	8,54 ±2,44	NS
	14,55 ±5,48	8,40 ±2,32	0.001

Material, methods and patients. We retrospectively evaluated 201 patients with PV diagnosed in agreement with the criteria in use at the first diagnosis and treated with phlebotomies to maintain Ht <48% in males and <45% in females. The present study comprehends 40 (19.9%) of these patients who had platelets and WBC within normal limits (respectively 150-450x10^9/L and 4.4-11x10^9/L) at the time of diagnosis. The patients were divided on the basis of platelets and/or WBC increase over the 25° percentile after Ht goal achievement. Group 1 is formed by 12 patients with both platelets and WBC, 10 patients with platelet and 2 with WBC increase. Patients of group 2 did not develop platelets or WBC modification with phlebotomies. We searched JAK2V617F mutation in DNA from granulocytes by allele specific PCR assay and exon 12 JAK2 mutations with sequencing. Our patients were thereafter stratified on the basis of presence of JAK2 mutations. Chi square and Student's t tests were used for statistical analysis. *Results*. 17 patients of group 1

and 4 of group 2 (p=0.01) were found to carry JAK2V617F mutation while no patient had exon 12 mutations. In respectively 18 and 12 patients with JAK2 mutation and in 6 and 2 JAK2-WT, platelet or WBC increased significantly (respectively p=0.001 and p=0.005) at Ht achievement. *Conclusions*. Our results suggest that phlebotomies do not increase platelet and WBC counts in PV patients that do not carry JAK2V617F mutation. Because dubious exist in considering JAK2-WT patients with PV as "true" PV, we can surmise that no increase in platelets and WBC occurs in IE rather than PV. Larger and prospectic studies are needed to confirm our observation.

1510

PREVALENCE OF ESSENTIAL THROMBOCYTHEMIA IN THE JAK2V617F ERA: A POPULATION BASED STUDY APPROACH IN A SPANISH COMMUNITARY HOSPITAL

A.V. Mena-Durán, J. Sanchis-Cervera, C. Sanchis-Piqueras

Hospital La Plana, VILLAREAL, Spain

Background. Essential thrombocythemia (ET) is an infrequent myeloproliferative disease lacking population based epidemiological data particularly after JAK2V617F mutation was described. Essential thrombocythemia diagnosis is still challenging and shares different features with other myeloproliferative diseases which make difficult population based studies. Prevalence data from Spain has not been published yet despite undergoing surveys. *Aims*. To calculate the prevalence of ET in an Spanish mixed urban-rural area of 189.877 inhabitants (Departamento 3, Agencia Valenciana de Salud, Spain). *Design and Methods*. From January 2007 until December 2008, a Laboratory Information System (Modulab Gold®, Izasa, Barcelona) was used to detect thrombocytosis ($750000x10^9$) in blood counts centralized in our laboratory. Thrombocytosis had to be confirmed after 15 days. Confirmed thrombocytosis patients were electronically notified to be reviewed at Hematology Dept. Thrombocytosis were classified as reactive if patients had a previous history of cancer, chronic inflammatory diseases, iron deficiency or splenectomy. A myeloproliferative disease was suspected in remaining patients and WHO diagnostic criteria were applied to proper diagnosis and classification of patients. In order to confirm ET diagnosis all patients underwent a bone marrow biopsy and PCR for JAK2V617F . ET prevalence was calculated from raw number of confirmed diagnosis in two years and expressed as N per 100,000. Results 540 patients had thrombocytosis. Non-reactive thrombocytosis was detected in 63 patients. 18 patients did not meet criteria for diagnosis of myeloproliferative disease. 4 patients were diagnosed of CML. 1 patient was diagnosed of PMF. 25 patients were diagnosed of PV and 26 patients were diagnosed of ET. JAK2V617F mutation was detected in 25% of myeloproliferative disease cases and 47% of ET cases. For ET we estimate a prevalence of 6,8 cases per 100,000. *Conclusions*. To our knowledge this is the first study to assess the prevalence of ET in a large Spanish population and it´s in agreement with previous data from other industrialized countries. Centralized Laboratory Information Systems are an interesting tool to develop population based epidemiological studies.

1511

MOLECULAR REMISSION ON LOW-DOSE NILOTINIB AFTER IMATINIB INTOLERANCE IN A PATIENT WITH FIP1L1-PDGFRA POSITIVE CHRONIC EOSINOPHILIC LEUKEMIA

D. Friess,[1] O. Hausmann,[2] E. Oppliger Leibundgut,[3] A. Reiter,[4] P. Keller[5]

[1]*University Hospital of Berne, BERNE, Switzerland;* [2]*Department of Allergology, Berne University Hospital, BERNE, Switzerland;* [3]*Department of Hematology, Berne University Hospital, BERNE, Switzerland;* [4]*III. Medizinische Universitätsklinik, Universität Heidelberg, MANNHEIM, Germany*

The FIP1L1-PDGFRA fusion gene results from a cytogenetically invisible interstitial deletion on chromosome 4q12. It is the most frequent genetic aberration in chronic eosinophilic leukaemia (CEL) and the vast majority of patients achieve complete molecular remissions on low-dose imatinib (50-100 mg/day). Adverse effects are rare, and therefore the optimal management of patients with unexpected toxicity or intolerance to imatinib are yet unknown. We here report on a 58-years old male patient with FIP1L1-PDGFRA-positive CEL with severe hepatotoxicity after rapid complete haematologic remission on imatinib 100 mg. The patient was switched to low-dose nilotinib and achieved rapid complete haematological and complete molecular remission. Initially, the patient presented with an eosinophil count between 5 to $7x10^9$/L. Allergic disease or parasitic infection were excluded. The bone marrow showed a 30% infiltration of eosinophils. The karyotype was normal, FISH revealed a deletion of CHIC2 in only 0.3% of cells. A FIP1L1-PDGFRA fusion gene was identified by nested RT-PCR. Complete haematological remission was achieved after one week on imatinib 100mg. After four weeks, hepatotoxicity occurred, accompanied by fever, abdominal discomfort and limb pain. When toxicity resolved, imatinib was restarted at 50 mg/day with rapid complete haematological response. Reappearance of hepatotoxicity led to definite discontinuation of imatinib treatment. No data exist on the clinical use of nilotinib or dasatinib in FIP1L1-PDGFRA-positive CEL. *in vitro* data have shown that both components effectively inhibit cell lines transformed by FIP1L1-PDGFRA. Dasatinib inhibits proliferation of EOL-1 cells with an IC_{50} of 0.5 to 1 nM, which is about the same range compared to imatinib. Nilotinib inhibits proliferation of Ba/F3 cells transformed by FIP1L1-PDGFRA with an IC_{50} of 23 nM, the corresponding IC50 for imatinib only being 3 nM. Because of the similar chemical structure, cross intolerance is expected with nilotinib rather than dasatinib and was shown in one out of four patients with CML who were switched from imatinib to nilotinib due to hepatotoxicity. Comparing the two drugs, the higher risk of cross intolerance for nilotinib was rated lower than the possible side effects related to the greater off-target activity of dasatinib. Although IC_{50} of nilotinib might suggest the use of even higher doses than in CML patients, a reduced dose of 200 mg b.i.d. was chosen due to history of hepatotoxicity. After start of nilotinib, eosinophil count normalized within one week. Although no adverse effects occurred, the patient requested a further dose reduction to nilotinib 200 mg/day. After eight months on nilotinib, the patient remains in ongoing complete haematological and complete molecular remission. We conclude that nilotinib is a well tolerated alternative treatment option in imatinib-intolerant FIP1L1-PDGFRA positive CEL and may potentially achieve similar rates of haematological and molecular remissions. This case demonstrates that responses can be achieved at lower doses than expected from *in vitro* data.

1512

DEPENDENCE OF CLINICOHISTOLOGICAL PARAMETERS FROM THE PRESENCE OF JAK2V617F MUTATION IN PATIENTS WITH PRIMARY MYELOFIBROSIS

M.A. Sokolova, E.A. Semenova, M.D. Sanatko, N.V. Tsvetaeva, M.V. Zvetkova, A.V. Misyurin, N.D. Khoroshko

Hematology Research Center of Russian Academy of Medical Sciences, MOSCOW, Russian Federation

Background. Among Philadelphia-negative chronic myeloproloferative disorders (CMPD): essential thrombocythemia, polycythemia vera and primary myelofibrosis - mutation of Jak2V617F tyrosine kinase occurs only in half of patients with primary myelofibrosis (PMF). Phenotypic similarity in the group of patients with PMF does not correlate with the presence of Jak2V617F mutation and require identification of main features for making diagnosis of PMF. *Aims*. To determine the frequency of Jak2V617F mutation in patients with PMF and impact of this mutation on clinical and histological characteristics in such patients. *Design and Methods*. The Jak2V617F mutation was detected by polymerase chain reaction. Morphological assessment of bone marrow biopsy was performed in 37 patients with Ph-negative CMPD (29 patients with PMF, 8 patients with post-PV myelofibrosis). *Results*. Patient's groups were formed according to the presence or absence of Jak2V617F mutation: 25 (68%) patients were Jak2V617F-positive and 12 (32%) patients were Jak2V617F-negative. The median age was 45-48 years in both groups. There were no differences in main clinical and hematological features in both groups. Group of patients with Jak2V617F-positive mutation had higher level of hemoglobin (137g/L versus 119 g/L), red blood cells (5, $1x10^{12}$/L versus 3, $4x10^{12}$/L), lactate dehydrogenase (984 versus 687 E/L). However, presence of Jak2V617F mutation predisposed to more frequent vascular complications, then in Jak2V617F-negative group of patients (48% versus 0%, p<0,001). Comparative analysis of histological parameters of bone marrow in this groups showed, that fibrosis is present in both groups and is more evident in Jak-negative group (67% versus 44%, p< 0, 02). Significant proliferation of the erythroid lineage was observed in Jak2-positive patients (44% versus 8% of patients). There were seen distinction in morphology of megakaryocytes, prevalence of enlarged forms occurred in Jak-positive group (36% versus 8%, p<0,001), and pleomorphic forms of megakaryocytes dominated in Jak-negative group (75% versus 40%, p<0, 01). The majority of Jak2V617F-positive patients with PMF had the same histological features of bone marrow like patients with polycythemia vera. Patients with PMF who had Jak2V617F mutation differed from patients without Jak2V617F

mutation and Jak2V617F-positive patients characterized by prognostic unfavorable bone marrow histology. *Conclusions*. We consider that presence of Jak2V617F mutation can be prognostic unfavorable factor for vascular complications and may have an effect on prognosis and clinical course. Histological differences in these two groups of patients can be explained by presence of other molecular markers or/and by definite stage of the disease.

1513

IRON STATUS PARAMETERS IN POLYCYTHEMIA VERA

J. Kwapisz, A. Slomka, E. Zekanowska

Nicolaus Copernicus in Torun, Collegium Medicum in Bydgoszcz, BYDGOSZCZ, Poland

Background. Polycythemia vera (PV) is classified as one of the myeloproliferative neoplasms. Several studies have shown that iron deficiency is common complication in PV patients. However still little is known about iron status in PV. There is no data in the last decade documenting iron metabolism in polycythemia vera despite the progress in laboratory techniques measuring iron status parameters. *Aims*. The objective of this study was to estimate concentrations of prohepcidin and other iron metabolism parameters in PV patients. *Design and Methods*. The study was performed in 56 PV patients (F/M 23/33) aged 38-84 years (65,6±10,5). The control group consisted of 20 healthy persons age and sex matched. The following parameters were determined in blood serum samples: prohepcidin, iron, unsaturated iron binding capacity (UIBC), transferrin saturation and soluble transferrin receptor (sTfR). Results: All patients with polycythemia vera showed significantly lower levels of prohepcidin (93,85 ng/mL [80,64; 108,00] vs 293,67 ng/mL [172,81; 353,25]; p<0,0000001) and higher levels of sTfR (2,14 µg/mL [1,31; 4,19] vs 1,48 µg/mL [1,07; 2,01]; p=0,02) compared to healthy controls. Almost 36% of the PV patients showed concentrations of ferritin below the normal range and significantly lower levels of serum iron (35 µg/dl [24; 90,5] vs 100,5 µg/dl [68,5; 121,5]; p=0,0001), transferrin saturation (8,22% [5,86; 23,25] vs 34,04% [25,74; 47,59]; p=0,000002) and significantly higher levels of sTfR (4,39 µg/mL [2,74; 6,11] vs 1,77 µg/mL [1,04; 2,27]; p=0,00003) and UIBC (353,70±73,91 µg/dl vs 177,36±65,92 µg/dl; p<0,0000001) in comparison with PV patients with normal ferritin values. In this group of patients prohepcidin concentrations (87,54 ng/mL [76,20; 98,05] vs 99,39 ng/mL [85,85; 113,05]; p=0,045) were significantly lower than in other patients. *Conclusions*. The results of our study confirm that many patients with polycythemia vera suffer on iron metabolism disorders. The lower serum levels of prohepcidin in patients with polycythemia vera may be the consequence of iron deficiency. We indicate that the lower levels of prohepcidin in patients with ferritin concentrations below the normal range are the result of organism compensation which increase iron absorption in the intestine.

Supported by grant 04/2008 UMK.

A NOVEL JAK2 MUTATION INVOLVING 14TH INTRON SPLICING REGION IN A PATIENT WITH ESSENTIAL THROMBOCYTHEMIA

X. Sun, Z. Xu, L. Xie, R. Lai, X. Zhu, W. Zhang, H. Yu

Jiangsu Provincial Hospital of Chinese Medicine, NANJING, China

Background. The discovery of the V617F point mutation of JAK2 has revolutionized the understanding of the pathogenesis of BCR-ABL-negative myeloproliferative neoplasms (MPNs) Further discoveries of JAK2 exon 12-15 and MPL mutations have extended the scope of the research in this field. However, a very small proportion of patients with polycythemia vera (PV) and 50% of patients with essential thrombocythemia (ET), as well as primary myelofibrosis, are negative for JAK2 or MPL mutations. This indicates that other forms of the mutations may exist. Recently, we analysed a patient with ET by routine methods for exon 14 and 12 detection. Aims To evaluate the optimal protocol in molecular diagnosis in patients with MPNs. *Design and Methods* The genomic DNA of mononuclear cells from heparin-treated bone marrow as well as he gastric tissue from paraffin embedding samples obtained from the patient was extracted using a DNA extraction kit, according to the manufacturer's instruction (Promega, Madison, WI, USA), and stored at -20'. JAK2 mutation with genomic DNA from this patient was studied by RFLP, AS-PCR, RT-PCR and direct sequencing. Results No JAK2 V617F mutations were detected by RFLP, AS-PCR, or RT-PCR analyses. A C/T mutation was detected by sequencing in intron 14 at the position 14 downstream of the exon 14 (see Figure 1) with bone marrow cells. Informatively, this mutation was not found in genomic DNA of the gastric tissue (Figure 2). *Conclusions*. The C-to-T mutation found in this study is localized in intron 14 with no JAK2 V617F mutation or mutations in exon 12 of JAK2. The mutation has not been reported. The change in intron 14 restricted to hematopoietic tissue demonstrates that this nucleotide change is not due to gene polymorphornisms, but might be a mutation that can cause disease. We hypotheses that mutation at the intron splicing region could cause the changes of the exon ligation, which infects the mature mRNA structure and function. Thus the normal inhibition effect of JH2 domain on the JH1 tyrosine kinase domain would be attenuated. Further examination of the effect of this nucleotide change in mutated JAK2 cell lines as well as animal models would be interesting.

ERADICATION OF MPL W515A MUTATION AFTER ALLOGENEIC STEM CELL TRANSPLANTATION IN A PATIENT WITH POST ESSENTIAL THROMBOCYTHEMIA MYELOFIBROSIS

E. Rumi,[1] F. Passamonti,[2] P. Bernasconi,[2] D. Pietra,[2] A. Brisci,[3] E. Arbustini,[4] L. Arcaini,[2] C. Elena,[2] E.P. Alessandrino,[2] M. Cazzola,[2] M. Lazzarino[2]

[1]Fondazione IRCCS Policlinico S. Matteo, PAVIA, Italy; [2]Division of Hematology Fondazione IRCCS Policlinico S. Matteo, PAVIA, Italy; [3]Genomic Unit for the Diagnosis of Human Pathologies,San Raffaele Institute, MILANO, Italy; [4]Department of Surgical Pathology Fondazione IRCCS Policlinico S. Matteo, PAVIA, Italy

Background. Myelofibrosis (MF) may occur as disease evolution in essential thrombocythemia (post-ET MF). Allogeneic hemopoietic stem cell transplantation (ASCT) is currently the only curative option for these patients, although associated with high rate of transplant-related mortality. Patients with post-ET MF may carry the JAK2 V617F mutation or more rarely mutations within the MPL gene. *Aims*. To evaluate the clinical course and minimal residual disease (MRD) in a patient with MPL-positive post-ET MF who received ASCT. *Design and Methods*. Diagnosis of post-ET MF was according to International Working Group on Myelofibrosis Research and Treatment (IWG-MRT) criteria. MRD was assessed by chimerism analysis using microsatellites evaluation and by MPL mutation analysis using high resolution melting (HRM) and sequencing.*Results*. The patient was a 49 year old male when he received diagnosis of post-ET MF. One year later, when he was referred to our Division, he showed post-ET MF with transfusion-dependent anemia (hemoglobin 7.1 g/dL), leukopenia (white blood cell 3.4x10^9/L) and splenomegaly. Circulating CD34$^+$ cells were 49x10^6/L, and lactate dehydrogenase was 1085 mU/mL. Bone marrow biopsy showed hypercellularity (90%), megakaryocytic hyperplasia with atypia, grade 2 myelofibrosis (EUNMET criteria), and 3% CD34$^+$ blasts. HRM and sequencing analyses on circulating granulocytes showed MPL W515A mutation. After failure of conventional treatments, he received ASCT from

matched-unrelated-donor with fully myeloablative conditioning (total body irradiation, cyclophosphamide and anti-thymocyte globulin). Peripheral CD34+ cells (8.9x10⁶/kg) were infused. Engraftment was on day +16 after transplantation. During the post-transplant period he experienced CMV reactivation, treated with gancyclovir. At day +100, a complete remission was documented according to IWG criteria: resolution of splenomegaly, normal peripheral blood counts and differential, normal bone marrow histology without fibrosis. Circulating CD34+ cells returned to normal (3.1x10⁶/L). Full donor chimerism was achieved. Eradication of MPL W515A mutation was demonstrated with HRM and sequencing analyses, defining a status of molecular remission (Figure). *Conclusions*. This is the first report of a patient with MPL-positive post-ET myelofibrosis who obtained the eradication of the MPL mutation with allogeneic hemopoietic stem cell transplantation.

ANALYSIS OF CLINICAL COMPLICATIONS IN ESSENTIAL THROMBOCYTEMIA: A RETROSPECTIVE STUDY OF 74 PATIENTS

A. Andriani,[1] N. Villivà,[1] C. Andrizzi,[2] G. Lizzani,[2] U. Recine[2]

[1]P.T.P. Nuovo Regina Margherita, ROME, Italy; [2]Hosp. Santo Spirito in Sassia, ROME, Italy

Background. Essential thrombocytemia (ET) is one of "myeloproliferative neoplasms" (MPN), characterized by an indolent clinical course. ET does not generally shorten life expectancy. Still, medical supervision of individuals with ET is important to prevent or treat complications, as the propensity to develop thrombohemorrhagic complications, myelofibrosis or secondary malignancies. *Design and Methods*. In this study, we retrospectively investigated long-term development of haematological and non-haematological second malignancies and thrombosis in 74 patients (male 26/ female 48) with ET. Our group followed 74 patients with diagnosis of ET from 1987 to 2008, with median follow-up of 72 months (range 1-144 months); median age was 70 years (range 23-90),. RESULTS In our series, we considered risk factors the preesistent presence of arterial hypertension, diabetes, smoking, and hypercholesterolemia. Of the 74 patients observed, we found the one cardiovascular risk factor in 24 pts (32%), two risk factors in 7 pts (9%) and three risk factors in 1 pts (1,3%). At the diagnosis we found 7 cases (9%) of primary malignancies: 3 breast (4%), 1 prostate (1.3%), 1 skin cancer (1.3%), 1 bladder (1.3%) and 1 endometrial (1.3%). After a median follow-up of 36 months from the start of treatment (range 0-144 months), 20 patients (27%) developed a clinical complication. In 11 of 20 patients (55%) a second non-haematological malignancy was documented (2 colon, 1 prostatic, 1 pancreas, 3 endometrial, 2 bladder, 1 breast and 1 large B-cell NHL. Nine patients (45%) developed vascular complications including: ischemic stroke (n=1, 11.1%), acute myocardial infarction (n=2, 22, 2%), deep vein thrombosis of the of the lowr extremities (n=5, 55, 5%). No clinical progression to myelofibrosis or leukaemia occurred. Of the 62 pts (83, 7%) who were treated with chemotherapy, 45 (72, 5%) received only hydroxyurea (HU), 3 pts (0, 48%) only anagrelide (ANA), 2 pts (0, 32%) only interferon (IF), 6 pts (0, 96%) HU followed by ANA, 6 pts (0, 96%) other combination chemotherapy. According to the type of complications, 8/11 pts (72%) with second malignancies were treated with only HU, 3/11 pts (27%) with more than one citotoxic agent; of the 9 patiens with vascular complications 5/9 pts (62%) received only HU, 3/9 more than 1 line of therapy and 1 no treatment. *Conclusions*. Our retrospective study shows that ET is a real chronic disease which affected patients having a long survival exceeding 144 months. In our group all patients who developed second malignancy or cardiovascular complication were in treatment with HU; no patients in clinical observation developed any complication.

1517

SAFETY AND EFFICACY OF PEGYLATED INTERFERON THERAPY FOR ESSENTIAL THROMBOCYTHEMIA DURING PREGNANCY

J. Rey,[1] C. D'Ercole,[2] S. Harbi,[1] R. Devillier,[1] L. Benarous,[1] V. Ivanov,[1] D. Coso,[1] D. Blaise,[1] R. Bouabdallah[1]

[1]Paoli-Calmettes, MARSEILLE, France; [2]Hôpital Nord, MARSEILLE, France

Background. Management of essential thrombocythemia during pregnancy remain a difficult challenge for both patients and doctors. Treatment may allow reducing the fetal complications without side effects for the fetus. Few data have been published on the safety of treatment for essential thrombocythemia during pregnancy. Classical Interferon α is considered the drug of choice in this context. *Aims*. We report the case of a woman with essential thrombocythemia who was treated with pegylated interferon during pregnancy. *Design and Methods*. A 25 year old woman was diagnosed with essential thrombocythemia. She was treated with hydroxyurea because of high platelet count. At 35 year-old, the patient wants to become pregnant and so hydroxyurea was stopped and aspirin was continued. Two months after hydroxyurea cessation, a rebound thrombocytosis was observed with 2 000 000 of platelets and biological acquired von Willebrand disease. So it was decided to introduce treatment with pegylated interferon α 2a at the dose of 90 µg/ week. Five months after the cessation of hydroxyurea and three months after beginning of pegylated interferon α 2a, the patient becomes pregnant. The patient has been under joint care of an obstretician experienced in the care of patients with high risk pregnancies. During treatment, the intrauterine development was closely monitored without abnormalities. The pregnancy was managed according to the European recommendations for pregnancy during essential thrombocythemia. Platelet count was maintained with pegylated interferon α below 600 000 during all the pregnancy. She delivered three weeks before term a healthy child. The child is now 1 year old and has a completely normal growth. *Results*. Little is know about the safety and efficacy of pegylated interferon α2a during pregnancy. Classical Interferon α is considered the drug of choice during pregnancy because it is not expected to cross the placenta barrier. However it must be administered generally three times a week and so it may be an inconvenient schedule during pregnancy. Pegylated interferon α2a is formulated by attaching polymers of ethylene glycol of large molecular weight to the native interferon α2a molecule and so a once-a-week schedule is sufficient. The passage of the placenta barrier has not been studied for pegylated interferon α but molecular weight is greater than classical interferon. *Conclusions*. Pegylated interferon α2a seems safe and might be a more convenient treatment option than classical interferon for pregnant women with essential thrombocythemia. More cases are necessary to confirm this data.

1518

LEUKEMIC TRANSFORMATION OF PHILADELPHIA CHROMOSOME-NEGATIVE CHRONIC MYELOPROLIFERATIVE DISEASE - ANALYSIS OF 10 CASES

A. Vidovic, G. Jankovic, D. Tomin, M. Gotic, I. Djunic, M. Perunicic, N. Kraguljac, V. Djordjevic, M. Colovic

Institute of Haematology, Clinical Center of Serbia, Belgrade, BELGRADE, Serbia

Introduction. Chronic myeloproliferative disease (CMPD) is a clonal proliferation arising from a hematopoietic progenitor of stem cell. Recently, the discovery of mutations on the genes for the Janus kinasa 2 (JAK2) and the trombopoietin (TPO) receptor and MPL gene in Philadelphia chromosome (Ph1)- negative MPD lead to the reassesment of classification of CMPD and provided new tools for diagnosis and treatment. On the other side, leukemic transformation of Ph1 negative CMPD, mainly polycythemia rubra vera (PRV), essential thrombocythemia (ET) and primary myelofibrosis (PMF) are unfrequent events with incidence about 2-20%. A little is knowen about mechanisms and factors that cause leukemic transformation of chronic MPD. *Aims*. To analize the course, therapy and survival of 10 patients with leukemic transformation of Ph1 negative CMPD. *Patients and methods*. We studied 10 patients (pts) median age of 60 years (range 50-73 years). Seven pts were diagnosed as PMF, one as ET and two as PRV. Cytogenetic analysis were performed on all pts in the chronic phase of disease and at the time of leukemic transformation. Flow cytometry or immunohystochemical analysis were used to confirm type of accutisation. We coment on therapy, response and survival of patients. *Results*. The median duration of chronic phase of MPD was 92 (range 32- 288 months). All pts developed transformation of MPD to acute leukemia: 8 pts to AML, FAB

M-2; and the last two to AML, FAB M-4. At the time of acutisation, mean values of blood counts were: hemoglobin 100g/l (range 78- 134g/l); WBC 14,5x10^9/l (range 2,9- 35,3x10^9/L) and platelets 199,2x10^9/L (range 20- 478x10^9/l/l). Evolution of cytogenetic abnormalities in kariotype were detected in four pts: 48,XY,+8, +16 in one patient; del (20q) in two pts and del (13q) in one. Normal kariotype was confirmed in last 6 pts. Four pts (two with PMF, one with ET and one with PRV) were treated with chemotherapy according to the standard protocol "3+7' (Doxorubycin and ARA-C). Complete remission was achived in 3 pts; and a partial remission in one patient. All patients with complete or partal remission hade normal kariotype at the time of accutisation. Palliative therapy was applied in 4 pts with PMF. Supportive therapy was applied in 2 pts due to advance age and high ECOG score. At the commencement of the study 6/10 pts were still alive, 3 pts in complete remission, lasting 24, 14 and 35 months, one in partial remission lasting 48 months, and two patients with stabile disease lasting 10 and 32 months. Four remaining pts died 2, 4, 5 and 6 months after acute transformation. *Conclusions*. Blastic transformation of Ph1-negative CMPD requires further studies in both pathogenetic and therapeutic sense. Our modest experience with a small number of patients confirms that complete hematological response is obtainable by conventional chemotherapy. This gives hope that pts within this spectrum could be successfully treated.

1519

THROMBOEMBOLIC AND HEMORRHAGIC COMPLICATIONS AND JAK2 V617F MUTATION POSITIVITY IN PHILADELPHIA NEGATIVE MYELOPROLIFERATIVE DISEASES

M. Unubol, I. Yavsoglu, G. Bozkurt, G. Kadikoylu, Z. Bolaman

Adnan Menderes University Medical Faculty, AYDIN, Turkey

Background. Thromboembolic and hemorrhagic complications are the leading cause for morbidity and mortality in myeloproliferative diseases (MPD) representing the initial presentation for 12-39% of patients subsequently diagnosed with polycyhemia vera (PV) and 11-25% for those given a diagnosis of essential thrombocythemia (ET). In recent years, there was relationships between JAK2 V617F mutation and the diagnosis and complications of MPD. *Aims*. To investigate the prevalance of thromboembolic and hemorrhagic complications and the correlation between these complications and JAK2 V617F mutation in MPD. *Design and Methods*. According to criteria, Philadelphia (Ph) negative MPD was diagnosed to one hundred-seven patients (51 males, mean age 64±14 years). There were ET in 60 (56%), PV in 25 (23%), primary myelofibrosis (PM) 19 (18%), and unclassified MPD in 3 (3%) patients. Thromboembolic and hemorrhagic complications were recorded. Survival duration was followed up. JAK2 V617F mutation was examined using by PCR. Ph chromose was investigated using by PCR and sitogenetic examinations. Results: Thromboembolic complications was detected in 45 (42%) patients with MPD. The most common complications were cerebrovascular events (19%) and myocardial infarction (12%). Hemorrhagic complications were found in 54 (51%) patients with MPD. The most common complications were skin (30%) and gastrointestinal (22%) bleeding. There was no difference for thromboembolic and hemorrhagic complications between subgroups of MPD (p>0.05). While leukemic transformation (1%) was seen in only one patient, no secondary myelofibrosis was detected. JAK2 V617F mutation was examined 68 (64%) of 107 patients. The prevalance of JAK2 V617F mutation was 70% in all patients. The prevalence of this mutation was 61% in ET, 80% in PM, 83% in PV, and 50% in unclassified MPD. However there was no difference for JAK2 V617F mutation positivity between subgroups of MPD (p>0.05). Mean and median survival durations of all the patients was 48±46 months (range 2-262 months) and 36 months, respectively. There was no difference for mean survival duration between subgroups of MPD (p>0.05). 24 (23%) patients died. The most common cause of death were thromboembolic events (42%). *Conclusions*. Thromboembolic and hemorrhagic complications were the most common causes of mortality in MPD. Although the prevalance of JAK2 V617F mutation in PV wass higher than other MPD, this prevalence was not statistically different. Moreover there was no correlation between JAK2 V617F mutation and these complications.

1520

COMPLICATIONS OF MYELOPROLIFERATIVE DISEASES

E. Simonovic,[1] L. Macukanovic Golubovic,[2] M. Stojkovic,[1] V. Colic[1]

[1]*General Hospital, LESKOVAC, Serbia;* [2]*Clinic of Hematology, NIS, Serbia*

Myeloproliferative diseases (MPD) belong to the group of clonic malignant diseases of parent cell hematopoiesis, characterized by abnormal increase of one or several blood lines with normal or nearly normal maturing of those cells, both in bone marrow and in extramedullary hemotopoietic organs.The objectuve of the paper is to confirm which are the most frequent diseases that occur as the complication of MPD. The investigation included 219 subjects of both sexes, between 17 and 83 years of age with the diagnosis of MPD. The patients were divided into five groups: A. Chronic myeloid leukemia (CML)-group; B. Polycythaemia vera (PV)-group; C. Idiopathic myelofibrosis (IMF)- group; D. Essential thrombocythaemia (ET)-group; E. Myeloproliferative disease that cannot be classified (MPS)-group. Among possible complications, we followed hypertension, presence of ulcus disease, coronary disease, thrombotic complications and neurological disorders. The methods of clinical examinations, endoscopies, exosonographies and computer-assisted tomographies have been used. Hypertension was described with the third of the subjects with MPD. It was the mostly expressive with the patients with PV (p<0,01). Presence of thrombotic complications was recorded in almost 20% of all subjects. In the group with ET, there were statistically remarkably more subjects with thrombotic complications than in other groups (p<0,05,p<0,001). Presence of coronary diseases was established with slightly more than 20% of patients. The most subjects were within the group with ET (p<0,001). Presence of ulcus disease was noticed with slightly less than the fifth of subjects. In groups with PV, ET and MPS, between 30 and 40% of subjects had ulcus disease (p<0,001). Neurological disorders were represented in nearly 20% of patients. The highest percentage of neurological disorders was established within the group with ET (52%), which is statistically remarkably more frequent in comparison with the group with PV (p<0,05) and IMF (p<0,01), and especially in comparison with CML (p<0,001). With our patients with PV we noticed significantly less frequency of neurological disorders than we could find in literary data. We proved that examined complications often follow myeloproliferative diseases and they are mostly represented with patients with ET, and then with patients with PV and MPS, but it is remarkably rare manifestation with patients with CML and IMF.

SKIN CHANGES AFTER LONG-TERM TREATMENT WITH HYDROXIUREA

D. Petranovic,[1] A. Duletic Nacinovic,[1] T. Valkovic,[1] T. Batinac,[1] I. Bunjevac,[1] K. Crnjar,[1] Z. Striskovic,[1] I. Host,[1] D.A. Petranovic[2]

[1]*Clinical Hospital Center Rijeka, RIJEKA, Croatia;* [2]*Poliklinika Medico, RIJEKA, Croatia*

Background. Hydroxyurea is a potent inhibitor of DNA synthesis and recently has been recognized to enhance carcinogenesis and various skin changes (ulcers, skin cancers, alopecia, lichenoid eruptions, nail pigmentation etc). *Aim*. To present our experience with hydroxyurea-related cutaneous changes. *Design and Methods*. We followed up patients with myeloproliferative disorders who were treated with hydroxiurea in Clinical Hospital Center of Rijeka, Croatia prospectively during five year period. *Results*. During five year 97 persons were treated for myeloproliferative disease with hydroxyurea . Five of them had unusual skin changes which we could not explained by any reason but long term treatment with hydroxiurea (range 6 months to 15 years). Most of them had multiple skin changes (i.e. multiple skin carcinomas, hand ulcers, melanonychia with skin necrosis in the same patient). Clinical findings, dermatologic evaluation , patohystology analysis, cytogenetics (bcr/abl, JAK2, fragile site for 3p14, p53 mutation), PDGF and PCR for retroviruses were evaluated. *Conclusions*. We emphasize that long term treatment with hydroxiurea could be associated with mucocutaneous side effects. Close dermatological follow up should be imperative during and even after many years after discontinuation of hydroxyurea therapy.

1522

CAN ESSENTIAL THROMBOCYTHEMIA BE CURED BY AUTOLOGOUS TRANSPLANT?

J. Rey,[1] V. Ivanov,[1] M.J. Mozziconacci,[1] I. Aubert,[2] R. Devillier,[1] S. Harbi1, L. Benarous,[1] V. Salinas,[1] D. Coso,[1] R. Bouabdallah[1]

[1]Paoli-Calmettes, MARSEILLE, France; [2]Hôpital Font-Pré, TOULON, France

Background. Essential thrombocythemia is the most begnin myeloproliferative disorder but follow-up can be complicated by thrombotic complications or haematological transformations as myelofibrosis or acute leukaemia. Actual management of essential thrombocythemia diminish thrombotic complications but no treatment can cure the disease. The discovery of Jak2 mutation has led to the development of Jak2 tyrosine kinase inhibitors which may affect positively the disease and benefit many patients. Allografting is reserved for patients with haematological evolution as myelofibrosis. Autologous transplant is not a standard procedure in myeloproliferative disorders, apart for few cases reported in the palliative treatment of myelofibrosis. Aims - We report the case of a woman with essential thrombocythemia who was treated for concomittant plasmocytoma with intensive chemotherapy and autologous transplant. *Design and Methods*. A 60 year-old woman was diagnosed with essential thrombocythemia after the observation of elevated platelet count. She was treated with hydroxyurea and aspirin. Thereafter, a diagnosis of costal plasmocytoma was made on a biopsy and treated chirurgically. Plasmocytomas recidive in costal and vertebrae. A treatment with bortezomib and dexamathasone was introduced with good results. Hydroxyurea treatment was stopped. Consolidation therapy consists of intensive chemotherapy with Melphalan 200 mg/m2 rescued by autologous transplant. This treatment led us to monitor evolution of platelet count and Jak2 mutation allelle burden after autologous transplant. Jak2 mutation was positive before transplant at 45-50%. Three months after autologous transplant, platelet count was normal. Jak2 mutation diminish to 15-30%. Six months after autologous transplant, platelet count was 550 000 and Jak2 mutation was in augmentation at 30-50%. *Results*. No treatment can cure essential thrombocythemia at that time. However, recent reports have showed that pegylated interferon α and at a lesser extent hydroxyurea could modulate Jak2 mutation allelle burden. Moreover, complete molecular remission with indectable Jak2 mutation detection could be obtained in some patients with interferon α or allografting. In contradiction, intensive chemotherapy with autologous transplant can not diminish Jak2 mutation allelle burden for long time in our patient. *Conclusions*. This exceptional observation of coexistence of plasmocytoma and essential thrombocythemia has led us to monitor Jak2 mutation allele burden after intensive chemotherapy and autologous transplant. Studies on cytapheresis cells are ongoing in order to detect Jak2 mutation on CD34 positive cells.

1523

^{18}F -FLT PET IN MYELOFIBROSIS. REPORT OF TWO CASES AND REVIEW LITERATURE

G. Giglio,[1] M.R. Grivet Fojaja,[2] B. Carabellese[2]

[1]Hematology Unit A.Cardarelli, CAMPOBASSO, Italy; [2]Nuclear Medicine A. Cardarelli Hospital, CAMPOBASSO, Italy

Actually few diagnostic procedures are available to determine the quantity of bone marrow cellularity and the numbers of cycling cells in patients with bone marrow disorders. Non invasive imaging of the bone marrow compartment may be helpful. The PET tracer 3'-fluoro-3'-deoxy-L-thymidine (18F-FLT) has been developed in recent times. 18F-FLT uptake is linked to the rate of DNA synthesis and increases with higher proliferation rates in many types of tumour. We have had the opportunity to perform the PET investigation in two patients with idiopathic hypecellulary myelofibrosis before medical treatment. Case report: Two patients, respectively 40 years old male and 68 years old woman were hospitalized for checks on splenomegaly, night sweats, bone pain and alteration of peripheral blood. The physical examination revealed splenomegaly in both without abdominal masses or lymphadenopathy. The remainder of the examination was normal. Laboratory studies showed the following: in woman patient lactic dehydrogenase 1477 IU/L, β2 microglobulin 2719 ng/ml, Ferritin 126.20 ng/ml, WBC 5.5x10^3/ul, HGB 10.8 g/dl, RBC 3.82x10^3/ul; PLT 283. X10^3/ul. The other laboratory results were normal. In male patient : WBC 7.14 x 10^ 3/ul, HGB 13.2 g/dl, PLT 508x10^3/ul, Lactic dehydrogenase 1408 IU/L, β 2 microglobulin 2034 ng/ml, γglobulin 0.76 g/dl. The other laboratory results were normal. A computed tomography scan of the abdomen disclosed splenomegaly in both ; no other abdominal masses or adenopathy were showed. A Positron Emission Tomography scan demonstrate markedly increased uptake throughout the bone marrow, without uptake of the spleen. The bone marrow biopsy made it possible to diagnose in both idiopathic myelofibrosis. Man patient was treated with anti-platelet drugs for thrombocytosis and woman patient with small doses of prednisolone and. vit. D3 with a good recovery of hemoglobin from 10 to 12.5 g/dl. *Discussion*. Idiopathic myelofibrosis is a chronic myeloproliferative disorder with neoplastic proliferation of myeloid stem cells, primarily in the spleen. As the disease progresses the marrow becomes hypocellular and fibrotic. Many patients develop osteosclerosis of the cortical bone. Marked extramedullary hematopoiesis results yielding massive enlargement of the spleen and moderate enlargement of the liver. Background uptake of 18F-FLT in bone marrow is common. ^{18}F-FLT PET might, for that reason, visualize the high cycling activity of hematopoietic cells in the bone marrow compartment. The feasibility of visualization and quantification of the activity of the bone marrow compartment with ^{18}F-FLT PET is so very important to discriminate diverse hematologic disorders. Reported in the literature are few work on the topic; an important increase in ^{18}F-FLT uptake was observed in all of the studied patients with myeloproliferative disorders. The findings on the F-18 FDG PET scan reflect the increased metabolism associated with the extramedullary hematopoiesis in the markedly enlarged liver and spleen, as well as peripheral bone marrow expansion. *Conclusions*. ^{18}F-FLT PET can be used to visualize the proliferative activity of the bone marrow compartment and may be helpful to distinguish separate hematologic disorders.

1524

JAK2VAL PHE 617 MUTATON IN A PEDIATRIC CASE WITH POLYCTHEMIA VERA

S. Aytac-Elmas, M. Cetin

Hacettepe University Faculty of Medicine Pediatric Hematology Department, ANKARA, Turkey

Background. Polycthemia vera (PV) is a clonal myeloperative disorder charactherized by abnormal increase of precursors in predominatly erythroid, myeloid and megacaryocytes series. It is very rare in childhood and account for only 0.1% of total PV patients. V617F mutation is very rare in children although constitute 90% of mutations in adult patients. Aim:We present clinical properties of youngest PV patients with V617F mutation in our clinic. *Case Report*. Ten year old female patients admitted to our clinic with complaints of pain on the lower extremities lasting a few days. She was referred to hematology clinic for his high level of blood counts. She was pleotoric, and on examination cervical lymphadenopathy 1X1cm and massive splenomegaly (4 cm below costal margine) were detected. Complete blood analysis were as follows Hb:18g/dl, Hematocrit: 55%, WBC: 14x10^9/L, RBC:5,7x10^{12}/L, Plt: 687 x10^9/L, blood smear was normochormic and normocytic and 79% PNL, 4% eosinophilia, 12% lymphocyte reported. Bone marrow aspiration was performed and increased megacaryocytes detected with a M/E rate 3/1. Cytogenetic analysis was 46XX. Ultrasonography confirmed splenomegaly and also showed increased renal echogenicity. Her O2 saturation was 96%. HbA2 was 2.9% and HbF: 0,6%. Erytrocyte mass index was 51,7 ml/kg (36 ml/kg) with Cr51 analysis. Leukocyte alkalen phosphatase level was normal and erytropoetin level was low (2 Mu/ml). Clinical and hematological findings met the criteria for the diagnosis of polycythemia vera. She was diagnosed as PV and low dose aspirin treatment was started. Phlebetomy was done 4 times for controlling hematocrit, red cell volume and progressed asympthomatic till 17 years old. She was readmitted to our clinic with abdominal pain and abdominal swelling. She has broken her routine controls and did not take aspirin treatment for one year. Her complete blood counts were as follows ; Hb: 17 g/dl; Hematocrit: 53%, WBC: 11x10^9/L, RBC: 6x10^{12}/L , and Plt: 634 x10^9/L. Abdominal computerized tomography was consistent with Budd-Chiari disease. Hydoxyurea and anticoagulant treatment were given. Peripheral blood analysis detected JAK2 exon 12 (n1849G>T; Val 617Phe) mutation. She is now asymptomatic and treated with aspirin, hydroxyurea and cumadin for 3 months. Majority of previously reported patients were 10-13 years at time of diagnosis. Our case was diagnosed at the age of 10 years old and she was well being until the age of 17 on which the complication Budd-Chiari occured. *Conclusions*. As pediatric cases with PV in the literature is very rare and diagnostic criteria is not well established as adult patients, JAK2 mutation can give a clue about the diagnosis for pediatric patients.

1525

APRIL SERUM LEVELS PREDICT TIME TO TREATMENT IN CHRONIC LYMPHOCYTIC LEUKEMIA

I. Nichele, C. Tecchio, A. Ambrosetti, R. Zanotti, D. Veneri, G. Pizzolo

University of Verona, VERONA, Italy

Background. In chronic lymphocityc leukemia (B-CLL) B lymphocytes gradually accumulate and survive due to apoptosis resistance. Since B-CLL lymphocytes rapidly die *in vitro*, it is postulated that molecular and cellular interactions occurring in tissue microenvironment support their survival *in vivo*. APRIL (a proliferation-inducing ligand), a TNF superfamily member involved in normal B cells survival and differentiation, is known to play an important role in protecting B-CLL cells against spontaneous apoptosis through paracrine and autocrine stimulation of their receptors. In B-CLL APRIL may be released both by microenvironment cells and by malignant lymphocytes themselves. Several studies suggest that APRIL is involved in other B cell derived malignancies, in autoimmune diseases and in cancer. *Aim.* to examine APRIL serum levels in B-CLL patients compared to healthy donors and to evaluate the correlation of soluble APRIL with clinical-biological parameters and survival. *Methods*. we retrospectively evaluated by ELISA serum samples from 83 B-CLL patients referred to our Institution from 1993 to 2008. Sera were collected at diagnosis and before any treatment upon patients consent. Sera from 25 age and sex matched healthy donors were used as control. The following clinical characteristics were considered: gender (51 male; 32 female); age (47 <65 years; 36 ≥65 years); classification according to Rai (73 stage 0-2; 10 stage 3-4) and Binet (56 stage A; 27 stage B-C); lymphocyte count (41<13000/m^3; 42 13000/m^3); development of autoimmune cytopenia (AIC) (34 with AIC, 49 without AIC). We also evaluated: ZAP-70 (24 negative; 50 positive) and CD38 expression (28 negative; 37 positive); IgV(H) mutation status (12 mutated; 26 unmutated); sCD23 (37<60 U/L; 24 ≥60 U/L), Thymidine Kinase (30<9.14 U/L; 31 9.14 U/L) and B2 microglobulin levels (25<2 mg/L; 47 ≥2 mg/L); cytogenetic analysis (23 with normal or favourable karyotype, 9 with unfavourable karyotype). *Results*. We found significantly higher levels of APRIL in the sera of B-CLL patients as compared to normal donors (17.37±3.773 vs 4.186±0,683 ng/ml; Mann-Whitney test, p<0.0001). The mean APRIL serum level was increased in patients with unfavorable karyotype as compared to those with favourable karyotype (17.22±7.629 vs 5.68±0.623 ng/ml, p=0.032). No other significant associations were found between APRIL levels and the other clinical and biological markers evaluated. To better evaluate the clinical relevance of APRIL, we divided patients according to median APRIL serum level (<7.08 ng/mL vs >7.08 ng/ml). Interestingly, patients with APRIL serum level below the median showed a significantly higher time to treatment as compared to patients with APRIL level above this value (34.40 months±5.45 vs 10.8 months±4.279) (p=0.021). On the other hand, the two groups of patients did not significantly differ regarding overall survival and other clinico-biological parameters. *Conclusions*. although based on a limited number of patients, our results suggest that APRIL is increased in B-CLL patients as compared to healthy donors. Furthermore APRIL levels above the median value significantly correlate with a shorter time to treatment.

1526

ZAP-70 EXPRESSION ASSESSED BY FLOW CYTOMETRY BECOMES A RELIABLE, REPRODUCIBLE AND PREDICTIVE MARKER FOR IGVH MUTATION STATUS IN CLL PATIENTS IF THE RATIO OF B- TO T-CELL FLUORESCENCE INTENSITY ('RATIOMETRIC METHOD') IS TAKEN INTO ACCOUNT

M. Solenthaler,[1] C. Schällibaum,[1] M. Horn,[2] P. Keller,[1] E. Oppliger Leibundgut[1]

[1]University Clinic for Hematology and Central Hematology Laboratory, Inselspital, BERN; [2]University Institute of Immunology, Inselspital, BERN, Switzerland

Background. ZAP-70 expression in B-CLL lymphocytes is a powerful prognostic marker and is strongly correlated to IgVH mutation status (IgVHms) as shown by gene expression profiling yielding concordance in 93%. However, methods assessing ZAP-70 expression by flow cytometry vary and results may differ considerably. Recently, a ratiometric analysis method based on comparison of ZAP-70 expression in B- and T-cells was described to circumvent intra-/interlaboratory variation, but cut-off values are not well established. *Aims*. Assessment of the performance of an in-house ZAP-70 analysis method by flow cytometry (FC) incorporating a ratiometric approach. *Design and Methods*. On previously acquired data, we compared retrospectively our 'standard' (healthy donor as an external control; cut-off >20% for positivity according to Rassenti *et al.*) with a 'ratiometric' (mean fluorescence intensity of B-cells / T-cells x 100 [%]) analysis method. If available, results were compared to IgVHms. ZAP-70 analysis was done by separation of mononuclear cells from EDTA anticoagulated blood by Ficoll density gradient, permeabilization by incubation within 80% ice ethanol for at least 24 hours, 3 color FC assay with ZAP-70-PE (Clone 1E7.2; Caltag Labortories), CD3-PerCP (BD) and CD19-APC (BD) and corresponding isotype controls on patient and control sample, respectively. Results: ZAP-70 measurements in the peripheral blood of 104 pts. with SLL/CLL were available. The Mean + 3 SD of ZAP-70 expression of 84 normal controls was 21% (B-cells) and 19.9% (B-/T-cells) with the standard and ratiometric method, respectively. 37 pt. samples were ZAP-70 pos., 64 ZAP-70 neg. and 3 yielded borderline results. In 75 pts. IgVHms was available: 28 pts. had unmutated IgVH and 47 mutated IgVH. 80% of the ZAP-70 results were concordant to IgVHms (8 false pos., 8 false neg.) with the standard, and 76% (5 false pos., 13 false neg.) with the ratiometric method using the same cut-off (20%). However, ROC curve analysis was better for the ratiometric than for the standard method (AUC 0.84 with a cut-off of 13.2% and 0.77 with a cut-off of 22%, respectively). Combining both methods (cut-off >20% for ZAP-70 positivity using standard or ratiometric method, cut-off ≤20% or ≤13.2% for ZAP-70 negativity using standard and ratiometric method, respectively, ratio = 1st priority) the concordance was 86% (4 false pos., 7 false neg.). 4 pts. had undergone ZAP-70 analysis at different time points with all results being concordant with the combined but not the standard method (2 pts. discordant). 11 samples were remeasured after a median of 161 (78-238) days and showed concordant results (Spearment's coefficient with standard and ratiometric method 0.74 (p=0.02) and 0.94 (p=0.003), respectively). *Conclusions*. The performance of ZAP-70 expression analysis by flow cytometry in CLL patients can be improved by combination of the 'standard method' with the ratio of the B- and T-cell expression ("ratiometric method"). This may be due to methodology and/or by concomitant but variably abnormal ZAP-70 expression in the T-cells of CLL patients with mutated IgVH compared to unmutated IgVH.

1527

EXPRESSION OF TLRs IN B-CLL: RELATIONSHIP WITH DISEASE ACTIVITY

W. Barcellini, F.G. Imperiali, A. Zaninoni, G. Reda, A. Cortelezzi, A. Zanella

Fondazione IRCCS Ospedale Maggiore Policlinico Mangiagalli e Regina Elena, MILAN, Italy

Background. Toll-like receptors (TLRs) are co-stimulatory molecules expressed on cell of the immune system and represent major agents of innate immunity and initiators of adaptive immunity. Main function of TLRs is to directly activate the immune system recognizing viral and microbial agents; moreover, TLRs are involved in the self-antigen recognition and could play a role in autoimmune phenomena. It is well established that B-chronic lymphocytic leukemia (B-CLL) is characterized by a variable clinical course, and by an increased incidence of autoimmune phenomena and immunodeficiency, which can greatly influence the disease outcome. Aims. To study the gene expression of TLRs in 25 patients with B-CLL (mean age+/-SD 72+/-12 years, range 42-90, 10 female and 15 male) and to relate it with the clinical course of the disease and the expression of prognostic factors (mutational status of Ig VH region, CD38 and ZAP70 expression, and cytogenetic alterations). *Design and Methods*. The gene expression of TLR4, TLR9, and TLR10 was evaluated in B cell from B-CLL patients and controls. Total RNA was extracted from B-CLL patients and controls (pool of 10 healthy donors), cDNA was synthesized, and real-time PCR was performed. For each real-time PCR reaction 50 ng of cDNA were mixed with 1.25 microl of TaqMan primer/probe set and 10.25 microl of TaqMan Universal Master Mix. Real-time PCR was performed with a model 7300 real-time PCR system (Applied Biosystems). The TLR4, TLR9, and TLR10 expression was normalized according to GAPDH as an internal control gene and it was expressed as percentage of control. *Results.* We found that TLR4 gene expression was lower in B-CLL patients compared to controls (23%±4.5%) while TLR9, and TLR10 gene expression was higher (4467%±773% and 2705% +/- 387% for TLR9 and TLR10 respectively). TLR4 gene expression was significantly lower in "progressive" B-CLL patients (n=15) compared with "indolent" B-CLL ones (n=10): 9.5%±2.7% vs 38.8%±7.9% (p<0.001). The 2 patients with autoimmune diseases (hemolytic anemia and Evan's syndrome) showed no characteristic TLRs gene expression pattern. At present no clear relationship was found between TLRs expression and CD38/ZAP70 levels. *Conclusions*. The reduced expression of TLR4, which is even more pronounced in "progressive" B-CLL patients, is consistent with the reduced ability to a proper immune response to Gram-negative bacterial lipopolysaccarides; the clinical significance (number, severity and outcome of infectious episodes and autoimmune phenomena) as well as the relationship with standard prognostic markers is under investigation in a larger number of patients.

1528

METHYLATION OF VON HIPPEL-LINDAU GENE IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

A. Vassou,[1] E. Hatzimichael,[2] A. Dasoula,[3] L. Benetatos,[3] K. Zaharopoulou,[2] L. Kefala,[3] K. Bourantas[2]

[1]Ioannina University Hospital, IOANNINA, Greece; [2]Haematogy Departement University Hospital Ioannina, IOANNINA, Greece; [3]University Hospital Ioannina, IOANNINA, Greece

Background. The Von Hippel-Lindau (VHL) is a tumor suppressor gene and its protein product, pVHL, is part of an E3 ubiquitin ligase complex that targets HIFα subunits for destruction in the presense of oxygen. Accordingly, pVHL defective tumor cells overproduce a variety of HIF-induced target genes, which have been implicated in metabolism, mitogenesis and angiogenesis. Aim. To investigate whether the inactivation of the VHL gene, through its promoter methylation, is present in CLL and if there is any correlation with clinical parameters and patient survival. *Design and Methods*. 41 CLL patients (36 male, 5 female) were studied. Genomic DNA was isolated from patient sera in 38 cases and from parrafin-embedded biopsies in 37. All samples were taken at diagnosis. The methylation status of the VHL promoter region was determined using methylation -specific polymerase chain reaction (MSP) with primers for methylated and unmethylated alleles for VHL. All samples previously subjected to bisulphite-modification, according to pre-established protocols. DNA from 10 individuals without malignancies served as negative controls. Human male genomic DNA universally methylated for all genes was used as positive control for methylated alleles. Results. Methylation of the VHL promoter was found in 7 of the 38 serum DNA samples (18%) and in 12 of 37 bone marrow DNA samples (32%). The presence of methylated DNA for VHL either in bone marrow or in serum was correlated significantly with advanced Rai stage (2 p=0.036) and high serum LDH (χ^2 p=0.022). At a median follow up of 61 months, 12/31 patients with serun unmethylated VHL died (mortality 39%) versus 4/7 of those with methylated VHL present in serum (mortality 58%). In contrast, 10/25 patients with bone marrow unmethylated VHL died (mortality 40%) versus 5/12 of those with bone marrow methylated VHL present (mortality 42%). The median survival of patients with serum unmethylated VHL was 80 months (95% CI 59-103) whereas that of patients with serum methylated VHL was 67 months (log-rank p=0.38). *Conclusions*. Methylation of the VHL promoter occurs in a fifth to a third of CLL patients and is associated with adverse clinicopathologic characteristics and inferior outcome. The promoter methylation status of the VHL gene in serum carries potential prognostic significance, probably due to predominant derivation of serum DNA from the neoplastic clone. Validation in larger cohorts is warranted.

1529

TNFRSF13B GENE EXPRESSION AND MOLECULAR ANALYSIS IN B-CELL CHRONIC LYMPHOPROLIFERATIVE DISORDERS

M. Speletas,[1] A. Mamara,[1] F. Kalala,[1] K. Liadaki,[1] N. Papadoulis,[2] A. Kioumi,[3] N. Giannakoulas,[1] S. Lafioniatis,[4] K. Loukidis,[5] P. Matsouka,[1] Z. Kartasis5, A. Germenis[1]

[1]University of Thessaly, LARISSA, Greece; [2]General Hospital of Larissa, LARISSA, Greece; [3]Papageorgiou General Hospital, THESSALONIKI, Greece; [4]General Hospital of Volos, VOLOS, Greece; [5]General Hospital of Chalkeida, CHALKIDA, Greece

Background. Mutations in the TNFRSF13B gene, encoding TACI, a tumor necrosis factor (TNF) superfamily member, have recently been implicated in the pathogenesis of common variable immunodeficiency. Expression of this gene, yet of unknown significance, has been detected in malignant lymphocytes of patients with chronic lymphoproliferative disorders (LPDs). *Aims*. Since certain genotypes of other TNF superfamily members have been implicated as contributing to the enhanced survival potential of malignant lymphocytes, this study was scheduled to investigate in LPDs the mutational status of the TNFRSF13B gene and its expression, in relation to the disease phenotype. Materials and *Design and Methods*: One-hundred and forty-five patients (M/F: 78/67, mean age: 67.9 years, range: 41-87) with LPDs (108 with B-cell chronic lymphocytic leukemia, B-CLL; 29 with low-grade non-Hodgkin lymphomas (NHL); 3 with diffuse large B-cell lymphoma, DLBCL; 5 with hairy cell leukemia, HCL) were enrolled in the study. Diagnoses were made by standard criteria. The expression levels of TACI were estimated by flow cytometry using an anti-CD267 monoclonal antibody (Abcam, clone: 1a1) in 102 LPD patients (81 with B-CLL and 21 with low-grade NHL). The two most common polymorphisms of TNFRSF13B (V220A and P251L) were detected by PCR-RFLP, using DNA extracted from peripheral blood or bone marrow. Thirty-seven individuals (M/F:19/18, mean age: 64.8 years, range: 47-87), free of disease, were also analyzed for TACI expression and TNFRSF13B polymorphisms and were considered as normal controls. Statistical analysis was performed using the SPSS statistical software. Results: Patients with B-CLL displayed significantly lower expression levels of TACI (mean±STDEV: 16.2±21.3%) compared to both patients with low-grade NHL (43.2±27.6%) and normal controls (40.6±20.6%) (p<0.001 and p<0.001, respectively). Moreover, the presence of TNFRSF13B-P251L was associated with a 2.8-fold increased probability for LPD development (allele frequencies 17.2% vs 6.8%, 95%CI: 1.05-7.87, p=0.039), while the allele frequency of TNFRSF13B-V220A did not significantly differ between patients and controls (3.1% vs 5.4%, p=0.338). Finally, no correlation of TACI expression or the presence of TNFRSF13B polymorphisms with autoimmune manifestations, the presence of hypogammaglobulinemia, or monoclonal gammapathy was observed. *Conclusions*. A positive association of TACI expression and TNFRSF13B-P251L polymorphism with LPD phenotype was observed and considering the development of new anti-TACI treatments, our findings might have significant therapeutic consequences.

INHERITED POLYMORPHISMS IN THE LIGAND OF CD38, THE CD31/PECAM-1 PROTEIN, ARE ASSOCIATED WITH PREDISPOSITION TO B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA

K. Jamroziak, Z. Szemraj, J. Szemraj, O. Grzybowska-Izydorczyk, E. Balcerczak, M. Mirowski, T. Robak

Medical University of Lodz, LODZ, Poland

The platelet endothelial adhesion molecule-1 (CD31/PECAM-1) is the ligand of CD38 signaling receptor, an important prognostic marker in B-cell chronic lymphocytic leukemia (B-CLL). B-CLL cells co-express variable levels of CD38 and CD31/PECAM-1, thus interactions within B-CLL clone and bone marrow microenvironment may influence natural history of B-CLL. Interestingly, the CD31/PECAM-1 gene is known to have functional single nucleotide polymorphisms (SNPs) that alter the protein structure,though little is known on the significance of these genetic variants in B-CLL. The objective of this hospital-based case control study was to compare allelic frequencies of three non-synonymous CD31/PECAM1 SNPs in 127 Caucasian B-CLL patients and 207 healthy individuals, and to analyze potential impact of these polymorphisms on clinical outcome of B-CLL. The genotyping of the 373C>G (Leu125Val), 1688G>A (Ser563Asn) and 2008A>G (Arg670Gly) SNPs was performed using PCR-based assays. We found that some CD31/PECAM-1 genotypes were significantly associated with the risk of B-CLL. The logistic regression analysis revealed an association between B-CLL and genotypes: 373 CG [odds ratio (OR) = 2.22; 95% confidence interval (95%CI) = 1.3-3.8, p=0.005], 373 GG (OR = 8.56; 95%CI = 4.3 - 17.0, p<0.0001) and 1688 AA (OR = 4.93, 95%CI = 2.6 - 9.4, p<0.0001). In contrast, none of the studied CD31/PECAM1 SNPs was found to influence survival of the B-CLL patients. In conclusion, our data suggest that inherited variants of CD31/PECAM1 protein may be associated with susceptibility to B-CLL in Caucasians. The mechanism of this association and its potential link with CD38 signaling need to be further elucidated.

Background. B-Chronic lymphocytic leukemia (B-CLL) is the commonest leukemia of adults populations in Western countries, characterized by highly heterogeneity at the clinical as well as at the molecular and cellular level. Chromosomal changes have been detected in the majority of B-CLL samples by use of interphase fluorescence *in situ* hybridization (I-FISH) and an association has been found between chromosomal abnormalities and clinical prognosis or disease progression. In clinical practice, FISH is performed, at diagnosis, for the most frequent chromosomal abnormalities such as 13q14, 11q22-q23, 17p13 deletions and trisomy 12. However, a new method has been described for the measurement of gene copy number: Multiplex Ligation-dependent Probe Amplification (MLPA). *Aims.* The purpose of this study was to performed MLPA assay in a panel of 33 B-CLL patients in early stage disease (Binet stage A) and to compare the results with FISH data. *Design and Methods*. The MLPA assay was performed for all samples in two independent reactions, one for each probe mix (SALSA Probe-Mix P037 and P038) according to the manufacturer's recommendations (MRC-Holland). This mixes contains 55 target sequences specific for different chromosome regions: 17p13 (8 probes), 13q14 (12 probes), ATM 11q23 (7 probes), 10q23 (2 probes), 2p24 (3 probes), 8q24 (3 probes), 6q25-26 (3 probes), 9p21 (2 probes) chr. 12 (10 probes) and chr. 19 (5 probes). Data were analyzed with Coffalyser Software (MRC-Holland) using DNA from ten healthy donors as controls. FISH study was performed on a panel of highly purified (>90%) peripheral mononuclear CD19+ cells. A set of commercially available probes (Vysis, Downers Grove, IL, USA) was used, as follows: del(11)(q22-23), ATM and centromeric probe for chromosome 11; +12, centromeric probe for chromosome 12; del(13)(q14), D13S325 and subtelomeric probe 13q34; del(17)(p13), p53 and centromeric probe for chromosome 17. A minimum of 100 interphase nuclei were evaluated per probe for each patient. *Results*. MLPA and FISH approaches detected 13q14 deletion in twenty (60%) patients, 4 of which showing biallelic deletion. Same results were obtained for four (12%) cases with trisomy 12. Deletions in TP53 were detected by MLPA in two of the three cases detected by FISH (3/33, 9%). Deletions in ATM were found by MLPA in four of the five B-CLLs detected using the FISH approach (5/33, 15%). In these two cases, detected only by FISH, the low percentage of cells carrying the alterations (< 30%) may hamper MLPA detection. Finally, in one additional case, FISH assay was not able to detect deletion at 11q22-23, instead identified by MLPA since a deletion could be too small for the FISH size probe. *Conclusions*. Our study showed a good correlation between the MLPA and FISH results (91%), as most of the alterations were detected by both techniques. MLPA and FISH showed a comparable sensitivity. However, MLPA unlike FISH has proven to be rapid, cost effective, relatively easy to perform and enabled the simultaneous analysis of many samples with automated data processing, so representing a useful technique for the analysis of genomic alterations in B-CLL.

1533

EPIGENETIC ALTERATION IN DLK1/MEG3 IMRPINTING GENES IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

A. Vassou,[1] A. Dasoula,[2] L. Benetatos,[2] E. Hatzimichael,[3] L. Kefala,[2] K. Zaharopoulou,[3] K. Bourantas[3]

[1]Ioannina University Hospital, IOANNINA, Greece; [2]University Hospital Ioannina, IOANNINA, Greece; [3]Haematogy Departement University Hospital Ioannina, IOANNINA, Greece

Background. DLK1 and MEG3 are reciprocally imprinted genes on human chromosome 14q32 . DLK1 is a paternally expressed gene and encodes a transmembrane protein that is involved in the Notch signaling pathway. The maternally expressed MEG3 (also known as GTL2) allele encodes non-conding RNA. DLK1 and MEG3 are coexpressed and respond in a reciprocal manner to loss of DNA methylation. Regulation of imprinted expression of DLK1 and MEG3 involves a differentially methylated region (DMR) that encopasses the MEG3 promoter. Imprinting status and epigenetic alterations of DLK1/MEG3 have been studied in Wilms, pituitary and brain tumors and lymphomas. *Aims*. To study the methylation status of DMR of MEG3 promoter in patients with CLL in order to detect epigenetic alterations of DLK1/MEG3 gene and investigate possible prognostic significance of these alterations. *Design and Methods*. 41 CLL patients (36 male, 5 female) were studied. Genomic DNA was isolated from patient sera in 38 cases and from paraffin-embedded biopsies in 37 cases. All samples were taken at diagnosis. DNA methylation pattern was determined by methylation-specific PCR of samples previously subjected to bisulphite-modification, according to standard protocols. The normal pattern consists of 2 bands, one corresponding to the methylated paternal allele, a 160bp PCR product and an unmethylated maternal allele, a 120bp PCR product. DNA from 10 individuals without malignancies served as negative controls. *Results*. Abnormal methylation pattern of the MEG3 DMR was observed in 8 of the 38 serum DNA samples (21%) and was significantly correlated with early Rai stage (0-I), nodular/interstitial bone marrow infiltration, late initiation of therapy (2 $p<0.05$). Abnormal methylation pattern of the MEG3 DMR was observed in 13 of 37 DNA bone marrow samples (35%) and was correlated significantly with late initiation of therapy (χ^2 $p<0.05$). At a median follow up of 61 months, 17/41 died. 14 out of 30 patients who had normal serum DNA methylation pattern died (47% mortality) in contrast to 2/8 patients with abnormal methylation pattern (25% mortality). The group with normal pattern of serum DNA methylation had a median survival of 67 months (95% CI 45-89) whereas the median survival of the group with abnormal pattern was not reached yet (log-rank $p=0.47$). 11 out of 24 patients who had normal bone marrow DNA methylation pattern died (46% mortality) in contrast to 4/13 patients with abnormal methylation pattern (31% mortality). The former group had a median survival of 83 months (95% CI 40-126) whereas the median survival of the latter was 80 months (95% CI 44-116) (log-rank $p=0.36$). *Conclusions*. Serum and bone marrow DNA hypermethylation of the promoter of the tumor suppressor gene MEG3 was seen in 21 and 35% of our CLL patients respectively and was associated with favourable clinicopathologic characteristics and outcome. This contradictory result, if validated, may be due to epigenetic inactivation of DLK1 or to unknown molecular cellular pathways that need further study.

1534

DIAGNOSTIC VALUE OF CD19 COUNT FOR B-CLL IN PATIENTS WTH ABNORMAL WBC'S IN A PRIMARY HEALTH CARE SETTING

G.D. te Raa,[1] K. Fischer,[2] W. Verweij,[3] D.H. Biesma[4]

[1]St Antonius Hospital, NIEUWEGEIN, Netherlands; [2]Department of Epidemiology, Julius Centre, UTRECHT, Netherlands; [3]Primary Care Laboratory, SALTRO, UTRECHT, Netherlands; [4]Department of Internal Medicine, UTRECHT, Netherlands

Background. B-cell chronic lymphocytic leukaemia (B-CLL) is often diagnosed by coincidence in patients with an increased absolute lymphocyte count (ALC). Immunophenotyping is advised for all patients with an increased ALC of unknown aetiology, however, this will result in high costs and unnecessary complete immunophenotypings, since a considerable number of patients with increased ALC has no B-CLL or other malignancy. On the other hand, early haematological consultation at diagnosis is becoming more important, since initiation of treatment of B-CLL is changing from a symptom-based strategy towards a strategy based on biological markers. In this context, an additional CD19 count might be a valuable laboratory test to reduce unnecessary complete immunophenotypings and to facilitate early haematological consultation of B-CLL patients. *Aims*. To investigate the value of a CD19 count in patients with an abnormal WBC to detect and exclude B-CLL in a primary care laboratory. *Design and Methods*. In the period from March 2001 until October 2006, a CD19 count was performed in all patients, living in a previously defined geographic area, aged ≥40 years with an abnormal White Blood Cell count (WBC), defined as ALC ≥6.0x10^9 cells/L, relative lymphocyte count (RLC) ≥60% or atypical lymphocytes (AL) ≥2+. Patients with positive EBV or CMV serology were excluded. CD19 counts were classified as normal (<1.0x10^9/L) or abnormal (≥1.0x10^9/L). In case of an abnormal test, referral to a haematologist was advised. A geographic area in which the contingency areas of the laboratory and the referral hospitals overlapped was based on postal codes in order to link patients in whom a CD19 count was performed to newly diagnosed B-CLL patients in the hospitals. In October 2007, all cases of B-CLL in this area were identified by a stepwise search-strategy with a survey among general practitioners, including two postal questionnaires and a telephone reminder and by consultation of three different hospital-based databases. All data were collected anonymously and CD19 count cases and B-CLL cases were cross-referenced by postal code and date of birth. Results: A CD19 count was performed in 543 patients of 199,108 (0.3%) patients in whom a WBC was performed; 229 (42%) were abnormal and 314 (58%) were normal. In total, 120 patients with a B-CLL were identified; 119 in the abnormal group en 1 in the normal group. This resulted in a sensitivity and Positive Predictive Value (PPV) of 99%(95%CI 97.9-99.7) and 52%(95%CI 47.6-56.2) respectively and specificity and Negative Predictive Value (NPV) of 74%(95%CI 70.1-77.7) and 100%(95%CI 98.7-100) respectively. This resulted in a Number Needed to Screen (NNS) of 1.9. The AUC and PPV for CD19 combined with ALC, 0.92(95% CI 0.90-0.94) and 52% respectively, were significantly higher than the AUC and PPV for ALC; 0.85(95% CI 0.81-0.88) and 34% respectively. In retrospect, 37% of patients with an increased ALC of ≥5.0x10^9/L could be avoided from further complete immunophenotyping due to a normal CD19 count. *Conclusions*. CD19 is a valuable laboratory test in the detection and exclusion of B-CLL. It facilitates the diagnostic follow-up of an abnormal WBC and reduces unnecessary referrals for complete immunophenotyping.

LENALIDOMIDE TREATMENT OF CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS HAS DIVERSE EFFECTS ON B-CELLS, BUT CONSISTENTLY CHANGES THE ACTIVATION STATE OF CD8+ T-CELLS, REDUCES REGULATORY T-CELLS AND INDUCES TH17 T-HELPER CELLS

D. Mertens

University Ulm, ULM, Germany

Background. Lenalidomide shows promising activity in patients with refractory chronic lymphocytic leukemia (CLL). However, lenalidomide has side effects, and the mechanism(s) of action is unclear, and the drug is likely affecting several cell populations and a variety of cellular pathways. Understanding the effects of lenalidomide in CLL in-vivo is important as severe side effects have been reported that are specific to CLL, and markers that would allow identification of patients prone to develop these side effects are required. In addition, understanding how lenalidomide exerts its function would also allow logical combination with other drugs effective in CLL. *Design and Methods*. In order to shed light on the in-vivo mode of action of lenalidomide, we collected samples from patients during the course of treatment with lenalidomide. In order to characterize its cellular and molecular effects in CLL in-vivo, sequential samples from patients undergoing therapy with lenalidomide were analyzed with FACS analysis. We performed an in-depth analysis not only of the activation of CLL cells, but also of changes in composition and activation of T-cell, NK cell and regulatory T-cell populations. *Results*. In contrast to previous findings, a tumor flare reaction was not correlated with an *in vivo* activation of CLL cells. Interestingly, the numbers of immunosuppressive regulatory T-cells consistently decreased upon treatment. This is in keeping with an immunostimulatory effect of lenalidomide, and consequently numbers of NK cells, $CD4^+$- and $CD8^+$ T-cells were increased in a subset of patients. Intriguingly, the population of pro-inflammatory $CD3^+CD4^+IL17^+$ Th17-cells expanded at the same time as CLL cell counts decreased. *Conclusions*. These findings support an immunostimulatory and pro-inflammatory mode of action of lenalidomide in CLL *in vivo* via suppression of regulatory T-cells and an induction of Th17-cells.

1536

IMPAIRED EXPRESSION OF CD3 γ, Δ, ε AND ζ GENES IN PERIPHERAL BLOOD T CELLS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

L. Huang,[1] S.H. Chen,[2] L.J. Yang,[2] X.F. Zha,[2] Y.Q. Li[2]

[1]Medicine, Nursing and Health Sciences Faculty, Monash University Clayton campus, MELBOURNE, Australia; [2]Medical College, Jinan Univesity, GUANGZHOU, China

Background. In leukemia patients, T-cell function has been suppressed with disease progress. This immune dysfunction may be due to the disorder of recent thymic output function, the abnormal expression of T cell receptor repertoire and, may in part, due to abnormal signal transduction, possibly through altered expression of CD3 genes. Recently, quantitative CD3 ζ chain associated protein kinase 70 kDa (Zap-70) is considered as a marker of IGHV mutational status and a powerful prognostic factor in B-cell chronic lymphocytic leukemia (B-CLL). *Aims*. The expression level of TCR signaling transduction factor CD3γ, δ, ε and ζ genes in T cells from patients with B-CLL were investigated. *Design and Methods*: Real-time RT-PCR with SYBR Green technique was used for detecting the expression level of CD3 γ, δ, ε and ζ genes in peripheral blood mononuclear cells (PBMCs) from 17 patients with B-CLL, and 17 healthy individuals served as control. The β2-microglobulin gene (β2M) was used as an endogenous reference. Relative mRNA expression level of genes was analyzed by using the 2Δ -Ct-100% method. *Results*. All of four CD3 genes could be detected in samples from healthy individuals, however, CD3 γ, ε and ζ genes were not detected in 2, 3 and 1 samples from B-CLL respectively. The expression level of CD3 γ, ε and ζ genes were significant decreased compared with healthy controls (p=0.002, p<0.001 and p=0.014, respectively). Although the expression level of CD3 delta gene was 1.18 times higher in B-CLL patients than that from controls, there was not significant different (p=0.054). The expression pattern of these four CD3 genes was compared, there was not significant different in the expression level in B-CLL patients, however, the expression level of CD3 delta in healthy controls was significant different compared with the other CD3 genes (p<0.0001). Additional, the expression level of all four CD3 genes was not significant different associated with age in B-CLL patients as well as in healthy controls. *Conclusions*. Decreased expression of CD3 genes might associate with the immune dysfunction in the patients, which was thought to be impaired

in activation and results in an increased susceptibility to apoptosis of T cells. The study might contribute to better understand the cellular immune features in B-CLL patients.

1537

APOPTOSIS INDUCED BY VERBENA OFFICINALIS OIL AND CITRAL IN PERIPHERAL BLOOD LYMPHOCYTES OF CHRONIC LYMPHOCYTIC LEUKEMIA

G. D'Arena,[1] M.M. Minervini,[1] L. De Martino,[2] B.M. Fusco,[2] S. Deaglio,[3] V. De Feo,[2] N. Cascavilla[1]

[1]Casa Sollievo della Sofferenza Hospital, SAN GIOVANNI ROTONDO, Italy; [2]Department of Pharmaceutical Sciences, University of Salerno, SALERNO, Italy; [3]Laboratory of Immunogenetics, University of Turin, TURIN, Italy

Background. Isoprenoids, a broad class of mevalonate-derived phytochemicals which are ubiquitous in the plant Kingdom, may suppress the proliferation of tumour cells as breast adenocarcinoma (MCF7), human leukemia (HL-60), and human colon adenocarcinoma (CaCo2). *Verbena officinalis L.* (verbenaceae), commonly known as vervain, is a medicinal plant which grows wild everywhere. Despite its pharmacological mechanisms of action is still unclear, V. Officinalis essential oil has several traditional medicinal uses and is almost completely constituted of isoprenoids compounds. *Aims*. To verify the CLL cells ability of udergoing apoptosis in the presence of the isoprenoid compounds deriving from Verbena Officinalis (Vervain) and their main component Citral. *Design and Methods*. We obtained the essential oil *V. Officinalis* from plants grown in the Garden of Medicinal Plants in the Campus of the State University of Salerno, Italy. The chemical composition of the volatile oil was achieved by GC and GC-MS methods. The essential oil and citral, its main constituent, were tested on 13 untreated patients (8 M, 5 F, median age 68 yrs) with B-cell chronic lymphocytic leukemia (CLL) and from 10 healthy donors (5 M, 5 F, median age 55 yrs). Mononuclear cells were isolated from peripheral blood samples by centrifugation of a Ficoll/Hypaque gradient and cultured at a cell concentration of $2,5x10^6$/mL in RPMI 1640 culture medium in a humidified incubator 5% CO2 at 37°C. Cells were incubated for up to 24 hours with vervain essential oil or citral at different concentrations. The proapoptotic effect of the compound was evaluated after three different times of incubation (4, 8 and 12 hours in dark conditions) by adding to cells annexin-V 5 microL, and propidium iodide 5 microL (Annexin V-FITC Apoptosis Detection kit 1, BD Pharmingen). FACSCanto flow cytometer (Becton Dickinson) was used to acquire and analyze samples. *Results*. Both vervain essential oil and pure citral induced a significant apoptosis in CLL samples with respect to controls ($p<0.0001$). Necrosis was also found to increase with time, reaching the maximum after 24 hours. The presence of del 17p13, was associated to a reduced ability to undergo apoptosis compared with other rearrangements or nomal karyotype. *Conclusions*. Our data agree with the literature in indicating natural compounds as possible precursors of new therapeutic agents.

1538

PROGNOSTIC VALUE OF DYNAMICS OF EXPRESSION OF COSTIMULATORY MOLECULES CD 80+, CD86+ AND THE LEVEL OF INTERLEUKIN-2 IN PATIENTS WITH B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA

N. Tretyak, A. Gordienko, T. Perekhrestenko, L. Issakova

State institution"Institute of hematology and transfusiology AMSU", KYIV, Ukraine

51 patients with B-CLL were studied with median age of 56.7±3.1. Among them 19 patients were on stage II-III according to Rai et al. and 32 of them - in remission phase. Treatment was given according to FC scheme. The expression of costimulatory molecules were measured with FACScan flow cytometer (BD) and the level of Interleukin-2 - with immuno-enzyme method. In patients with clinical expression phase of B-CLL we observed the decline of following molecules' amount: CD19+CD80+ tumor lymphocytes - 4.1 times, CD19+CD86+ - 3.2 times ($p<0.05$), CD4+ lymphocytes - 6.0 times ($p<0.01$), CD8+ - 4.7 times ($p<0.01$), CD3+ lymphocytes - 9.2 times ($p<0.001$), CD3+CD28+ - 7.8 times ($p<0.001$). During the remission phase we observed increased expression of CD19+ and CD3+ by lymphocytes of B7 family costimulatory molecules (CD80, CD86) and CD 28 ligand respectively. Interaction of these molecules leads to CD4+ synthesis by interleukin-2, which activates killer functions of CD8+ antigen-specific lymphocytes. Data analysis of expression of these molecular structures and their comparison to average value in the groups showed, that in patients with remission phase of B-CLL the amount of CD19+CD80+ were decreased by 32.4%, CD19+CD86+ B lymphocytes - by 2.2% ($p<0.05$). CD19+CD86+ lymphocytes were decreased by 1.6 times in 18.9% of patients ($p<0.05$). CD3+CD28+ were decreased by 1.8 times in 8.1% of patients ($p<0.05$). The dynamics of immunologic data showed that revealed changes in patients with B-CLL in remission phase were early predictors of disease recurrence, which clinically manifest 2-4 months later.

1539

IGVH MUTATIONAL STATUS AND GENE SEGMENTS USAGE IN A SPANISH GROUP OF 224 PATIENTS DIAGNOSED WITH B-CLL

J.A. Hernández

Hospital Infanta Leonor, MADRID, Spain

Background. The mutational status of IgVH gene identifies patients with different outcome in B-CLL. Thus, IgVH unmutated patients have poor prognosis. However, the information related with different IgVH gene segments usage and the patients characteristics and prognosis is controversial and the series are limited. *Aims*. i) To assess the frequency of the IgVH gene segments usage and the mutational status in a Spanish large cohort of patients with B-CLL. ii) To correlate the results with CD38 expression and cytogenetics. iii) To analyze the survival and the time to first therapy of the patients according to the IgVH gene segments usage and mutational status. *Patients and Methods*.Mutational status was performed in 224 patients diagnosed with B-CLL (152 male; ratio: 2.1). Median age was 63 years (range: 29-90). Most of cases (77%) were in Binet A stage while 46% showed CD38 expression. A total of 150 patients (67%) displayed cytogenetic aberrations analysed by FISH: 13q deletion was present in 47.5%, +12 in 14.3%, 11q- in 9.4%, IGH rearrangement in 5.8%, and 17p- in 4.5%. IgVH gene usage and mutational status were investigated by PCR and sequencing (Ghia P, et al. Leukemia 2007; 21:1-3). Unmutated cases were considered when a VH homology ≥98% was present. *Results*. A total of 125 patients (55.8%) presented mutated IgVH. The most frequent VH gene segments used were VH3 (49%), VH1 (24%), and VH4 (18%), while VH5 and VH7 were used in only 4% and <1%, respectively. We did not observe expression of VH2 or VH6 gene segments. VH1 family showed a predominance of non-mutated cases (68.5%), being VH1-69 the most frequent usage and strongly associated to non-mutated IgVH (86%, $p<0.0001$) with male preference. Most of patients of VH3 family were mutated cases ($p = 0.004$), mainly VH3-23 and VH3-74. By contrast, all VH3-11 ($n = 5$) were non-mutated cases ($p = 0.0016$). VH3-30 ($n = 22$) and VH3-23 ($n = 19$) were the VH-3 segments more used. It should be noted that VH3-21 only supposed 3.1% of patients in our study with 6/7 mutated cases. VH4 family was more frequent in females with more mutated cases ($p = 0.022$). All but one of cases with VH5 usage affected VH5-51. Interestingly, all VH5 patients were non-mutated ($p = 0.023$) and all of them were male. Mutated patients showed correlation with CD38- ($p<0.001$) and 13q- ($p=0.011$), while non-mutated cases correlated with 11q- ($p<0.0001$), 17p- ($p<0.0001$) and +12 ($p=0.004$). Three out of eight cases of VH5 segment showed 11q deletion ($p=0.025$), while all five cases of VH4-04 had 13q deletion ($p=0.023$). The median overall survival was longer in mutated patients (215 months vs 117 months, $p=0.027$). However, no differences in the overall survival were observed when the analysis was performed according to the IgVH usages. Furthermore, the median time to first therapy was also longer in mutated patients (227 months vs 29 months, $p<0.001$). Of note only 29 out of 107 VH3 patients required therapy ($p=0.016$) while six out of seven VH5 patients were treated during follow-up ($p=0.01$). A trend of VH3-21 patients to require early therapy was also observed ($p=0.07$). *Conclusions*. In patients diagnosed with B-CLL, the identification of IgVH gene segments could provide additional information related to the outcome. VH3-21 usage had a low incidence and VH5-51 identified a group of patients with a bad prognosis. Overall survival and therapy free interval were significative related with IgVH mutational status.

1540

CYTOCHROME C LEVELS MEASURED BY ELISA IN SERUM OF CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS AND IN LYSATE OF THEIR LYMPHOCYTES

O. Bairey,[1] R . Rosenberg,[1] Y. Zimra,[2] O. Shpilberg,[2] E. Rabizadeh[2]

[1]Hematology, PETAH TIQWA, Israel; [2]Hematology, Rabin Medical Center, PETAH TIQWA, Israel

Background. It has been reported that the levels of cytochrome c in serum can indicate the presence of *in vivo* apoptosis and can serve as a prognostic factor during cancer chemotherapy. This finding can help to determine the efficiency of chemotherapy in it beginnings. It has also been shown that cytochrome c levels in different hematological malignancies can correlate with aggressive disease or may be a prognostic marker. *Aims*. To determinate the levels of cytochrome c and bcl-2 in lymphoma patient's serum using ELISA method before and after initiating chemotherapy. To examine the levels of cytochrome c and bcl-2 in the serum and in lymphocyte's lysates taken from chronic lymphocytic leukemia (CLL) patients. To try to find a correlation between the level of those apoptotic factors and clinical and laboratory parameters and known prognostic factors. *Design and Methods*. This study included 7 non-Hodgkin's lymphoma (NHL) patients that received RCHOP chemotherapy and 51 untreated CLL patients (65% stage A, 21% stage B, 13% stage C, median follow-up time 79 months, mean age 84 years, 69% males). Informed consent was obtained from all patients. In NHL patients, blood was taken before and after therapy at different timepoints. We examined serums levels of cytochrome c and bcl-2 using ELISA method with kit from ''Bender Med systems'' company, Burlingame, CA, USA. In CLL patients we checked cytochrome c and bcl-2 levels in serum and in lymphocyte's lysates by the same method. In CLL patients these levels were compared with known prognostic factors. Results: In NHL patients we could not detect levels of cytochrome c, and bcl-2 by this method in the serum before or after treatment. In CLL patients we could not detect levels of cytochrome c and bcl-2 in serum, nor bcl-2 levels in lysates of CLL cells. The results of cytochrome c in lymphocyte's lysates were positive. Figure 1 shows the distribution of results. We have found a negative correlation between cytochrome-c levels in lymphocyte lysates and serum hemoglobin level (p=0.035) and a positive correlation between cytochrome c levels in lymphocyte lysates and WBC (p=0.014) and lymphocytes count (p=0.005). We did not find a correlation between cytochrome c levels in lymphocyte's and other clinical and laboratory parameters of the CLL patients.

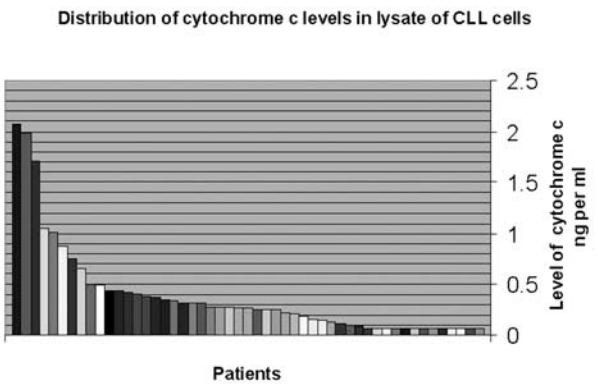

Figure.

Conclusions. Using this ELISA kit cytochrome c and bcl-2 could not be detected in serum of all patients including NHL and CLL. Therefore it was impossible to compare the levels before and after treatment and the study continued on lymphocyte's lysats from CLL patients. We find a negative correlation between cytochrome c levels in lymphocyte's lysates and hemoglobin levels and a positive correlation with WBC and lymphocytes count. We did not find a correlation between cytochrome c levels in lymphocyte's lysates and parameters that are known as prognostic factors in CLL patients, such as stage, β2 microglobulin and LDH.

1541

THE VALUE OF ULTRASTRUCTURAL CHARACTERIZATION IN DIFERENTIAL DIAGNOSIS OF HAIRY CELL LEUKEMIA (HCL), HAIRY CELL LEUKEMIA VARIANT (HCL-V), SPLENIC MARGINAL ZONE LYMPHOMA (SMZL) AND PROLINFOCYTIC LEUKEMIA (PL)

E. Luño,[1] C. Sanzo,[2] M. González,[2] F. Jonte,[2] E. Fanjul,[2] A. Rodríguez,[2] A. Martínez[2]

[1]Hospital Univesitario Central de Asturias, OVIEDO, Spain; [2]Hospital Universitario Central de Asturias, OVIEDO, Spain

Background. In the chronic lymphoproliferative disorders, although the information derived from immunophenotyping, is essential to define the type of the lymphoid population and it´s helpful to distinguish between the various conditions: the clinical, morphologic, cytochemical and histopathological features of these diseases are also important in order to establish a more precise diagnostic. Despite the HCL is a B proliferation, a peroxydase activity was found in the hairy cells. *Aims*. Analyze the more typical morphological and cytochemical ultrastructural characteristics of HCL, HCL-V, SMZL and PL to establish the ultrastructural criteria useful for diagnosis of uncertain cases. *Design and Methods.* Blood cells were obtained from patients with typical or suspicious HCL, 33 cases, 6 HCL-V, 31 SMZL, and 5 B-PL. The Roels and Breton-Gorius methods were applied for the peroxydase reaction. *Results*. With the Roels method the 75-94% of hairy cells showed peroxydase activity in the perinuclear envelope, ER cisternae and the ER surrounding the ribosome-lamellar complex (RLC). With the Breton-Gorius method, the hairy cells were negative or only slightly positive. In the HC variant cells, the peroxydase reaction was positive in all cases, in more than 71% of cells. Highlight that the intensity of the reaction was always slightly. In the cells of SMZL and PL only the mitochondria were reactive by the cytochrome. Morphological features: The most typical morphological features of HCL were: a) Markedly variable shape of nucleus and large cytoplasm with multiples organelles and the numerous, short and long projections, frequents "lake like" and pseudopods that showed the HC membranes in all the cases b) The RLCs were observed in 30/33 of the cases. They were found in 6-75% of hairy cell and some cellular fragments. RLCs are cylindrical cytoplasm structures constituted by spirals with rows of ribosomes spaced among the lamellae. HCL-V, an infrequent entity, could be identified not only for the peroxydase reaction present in all six cases but also for her typical central nucleus (2/3 cases), round or oval nucleus shape (85%) with medium-sized nucleoli and their short and long cytoplasm projections. Moreover 3/6 patients cells show a variable frequency of RLCs including a case with 60% RCLs. In the SMZL, 62% of cells were small size, normal or low nucleus/cytoplasm ratio, central or excentric round or oval nucleus, single nuclear pockets (43,5%), small nucleoli (29%), large cytoplasm with scarce organelles, RER circular (11/31), absent RLCs and short projections or wide base around of all plasmatic membrane or pseudopods (12/31). For the PL, the lymphoid cells showed medium size, high N/C ratio, round nucleus with scantily condensed chromatin, median-large sized, round nucleoli (63-83% cells) and small cytoplasm with scanty organelles, without RLC or projections. *Conclusions*. The peroxidase unfixed cells and morphological ultrastructural study have been useful to confirm uncertain HCL or HCL-V cases and to demonstrate that RLC is not exclusive of classic Hairy cell leukemia. For SMZL, a combination of ultrastructural methods and immunophenotyping combination allow to exclude HCL and to confirm the SMZL diagnosis. For PL, the ultrastructural study was characteristic.

1542

FAMILIAL AGGREGATION OF MALIGNANT HEMOPATHY AND AUTOIMMUNE DISEASES

M.L.A. Balea,[1] M. Dutescu,[2] D. Ilinca,[2] H. Bumbea[3]

[1]Clinical Hospital Colentina, BUCURESTI, Romania; [2]National Institute of Transfusional Hematology Prof. Dr. C.T.Nicolau, BUCHAREST, Romania; [3]Universitary Emergency Hospital Bucharest, BUCHAREST, Romania

We selected from the last 20 years case record a number of 34 subjects with malignant hemopathy and autoimmune diseases who were constituted in 15 familial groups. In four cases the 1st generation was represented by father and the 2nd generation by daughters. The diagnosed pathology was: 1. father: IgA λ Multiple Myeloma (MM) stage III, acute renal failure secondary to the hypercalcemia syndrome, and daughter: RAEB t complicated with Sweet syndrome; 2. father: DLBC Lymphoma, CD 20 + stage III B, and daughter: Follicular lymphoma grades 2 - CD20+; 3. father, son and daughter Chronic Lymphocytic Leukemia

(CLL); 4. father and daughter: Mixed cellularity Hodgkin's disease (MC - HD). One group where the 1st generation was represented by the mother with MC-HD, the 2nd generation represented by the daughter with micromolecular λ Multiple Myeloma and the 3rd generation by the niece with immunodeficiency IgA. One group where the 1st generation was represented by mother with diagnosis Polycythemia Vera and the 2nd generation was a son with diagnosis non-Hodgkin lymphoma. One familial group where the wife had Nodular Sclerosis Hodgkin's Disease (NS - HD) diagnosed in 2002 and husband was diagnosed in 2008 with MC - HD. One group where the 1st generation, the father, had IgA lambda MM, severe hyperviscosity syndrome, and the 2nd generation, daughter had Takayasu disease and the 3rd generation, grand daughter had SLE. The other 14 cases are grouped in 7 familial clusters with SLE, Systemic sclerosis, Cryoglobulinemia with vasculitis, Polymyositis, Juvenile rheumatoid arthritis. The group with hemopathy of the first generation the average diagnosis age was 69 (62-79) and the average age of the second generation was 41 (29-53) The analysis of this sample showed from a clinical point of view: a predominance of the father daughter sequence; an increase of suffering in the 2nd generation, meaning a maximal severity of the condition in the second generation and early onset, approximately three decades before the onset in parents. we also point out other observations: the result of the HLA evaluation class I and class II at brothers diagnosed with Chronic Lymphatic Leukemia, descendents of parents with CLL: DE sister, born in 1948, has blood group A, Rh+ and HLA class I: A2, 29; B44, 62; CW3 ;BW4; BW6 HLA class I: DR7, 16; DR51; DR53; DQ1,2, MG brother, born 1950, has blood group A, Rh+ and HLA class I: A2,2 ; B44,62; CW3; BW; BW6. HLA class II: DR7,16; DR51; DR53; DQ1,2. We highlight the identity HLA class I and II. Flow Cytometric Immunophenotyping shows: at the sister (DE): 80% of Lymphocyte population: [CD19 +, low; CD 20 neg.; CD 45 +; CD 23 +, low] at the brother (MG): 80% of Lymphocyte population: [CD 20+; CD 23+; CD5 +low, CD45+ high] We also observed: HLA B5 common in the group HD father-daughter; HLA A1, B8 common in the SLE familial group; HLA B8 common in the IgA MM - Takayatsy disease group; HLA DR3 common in the SLE/ Polymyositis family group. In the husband-wife group with HD, we only observed serology IgG + for EBV (negative for EBV- IgM, CMV, HTLV - I, VHB, VHC, Toxoplasmosis, HIV) *Conclusions*. an increase of suffering in the second generation meaning an earlier onset by approximately 25 years, predominant father-daughter transmission , genetic susceptibility suggested by the identity HLA class I and II in brothers with CLL without identical phenotype of lymphocyte population, we suggest as useful the deepening of the analysis of these type of subjects in a medical center with better technological endowment.

GENISTEIN-INDUCED APOPTOSIS ON MEC1 CELL LINE

T. Roman,[1] D. Hotnog1,[1] C. Maglas,[1] H. Bumbea[2]

[1]Center of Immunology, Inst.Stefan S. Nicolau, BUCHAREST, Romania; [2]Emergency Universitary Hospital, Carol Davila University of Medicine, BUCHAREST, Romania

Apoptosis is a physiological cell suicide program, critical for the development and maintenance of healthy tissues, therefore aberration of this process can de detrimental. B-cell chronic lymphocytic leukemia (B-CLL) is a neoplasic disorder characterized by defective apoptosis. In many cases the classical therapy failed and we must find new therapeutical strategies. One of this strategies being the use of biological active agents as genistein. Genistein is a nontoxic isoflavone with chemopreventive activity present in soy. During the past years soy consumption has been associated with lower cancer incidence. The aim of this study was to investigate the apoptosis-induced (at mitochondrial and caspase level) by genistein on MEC1 (cell line derived from B-chronic lymphocytic leukaemia). The genistein activity was putted in evidence by flowcytometry and western blot technique and our results indicate that MEC1 leukemia cell line is sensitive to the apoptotic effect of genistein in a dose-and time-dependent manner as well as a caspase dependent way. Genistein may prove to be a safe and effective anti-cancer therapeutic agent, either as a single agent and/or in combination with other therapies, therefore antileukemic activity of genistein merits further investigation.

1544

NEW DIAGNOSTIC MARKERS IN CHRONIC LYMPHOID LYMPHOCYTIC LEUKEMIA

F. Culurgioni,[1] S. Lilliu,[2] G. Pala,[1] D. Cardia,[1]A. Murgia,[1] M.G. Murtas,[1] E. Angelucci[1]

[1]Cancer Institute A.Businco, CAGLIARI; [2]ASL 8, CAGLIARI, Italy

Introduction. Chronic lymphocytic leukaemia (CLL) is a B-cell chronic lymphocytic leukemic condition occurring in a premature stage of maturation, when immunoglobuline types IgM and/or IgD on surface are scarcely expressed. Several epidemiological factors may contribute to its occurrence, including familiar predisposition, level of industrialization (higher in Western Countries), age (50-70 years), and gender (M/W 2: 1). For the study (of CLL) , clinical and laboratory parameters are used: LDH, b2 microglobulin, clinical stage, bone marrow infiltration type, lymphocytic doubling time as well as others biochemical parameters such as IgVH gene somatic mutations, chromosomal alterations (i.e. deletions on chromosomes 13, 11, and trisomy 12), and CD38 expression. Molecular markers include ZAP-70. CLLU1, the first gene-specific marker in Chronic lymphocytic leukaemia with elevating pattern of expression, which represents a predictive index of CLL risk. Additionally, MUM1 is a recent factor whose expression levels that prognosticates the form of CLLU1 with a favorable clinical course and long survival. Aims of the study: i) to characterize the molecular alterations, mutational states and gene rearrangements, associated with this disease; ii) to find biological markers of specific stages of the disease. These prognostics parameters should allow a more correct therapy and a better estimation of the prognosis for patients in the high risk category (Binet stage B-C). *Materials and methods*. 23 cases with a diagnosis of CLL were analyzed. The study was performed between 2006 and 2008 at the "A. Businco" Cancer Hospital in Cagliari, Sardinia, (Italy). Case age, 42-88 years (W/M 39% /61%, ratio M/F 2:1). DNA and total RNA from mononucleated cells obtained from bone marrow and peripheral blood were extracted. serum surveying, measurement of prognostic indicators by real time Polimerase Chain reaction, immunohistochemical and immunocytometrical analysis, and study of trascripts by sequence analisys were performed. *Results*. 30% of the patients showed an aggressive clinical course, while 70% of them had a good clinical course. The CD79b immunologic level resulted immeasurable or very weak in all cases (91%), except in two (9%) where it was high. CD38 was positive in 43% of the cases, while it remained negative in 57%. Mutational status of immunoglobuline IgVH and CD38 correlation: 5% were ZAP-70 +/ IgVH unmutated, 69% were ZAP-70 -/ IgVH mutated, with absence of correlation in 26% of cases. Histopathological analysis was performed using standard markers (CD5, CD79a, CD20, CD23) in order to differentiate between classic CLL and its variants. The mutation status of IgVH was performed by RT-PCR using 3 sets of primers specific for VHL, VHFs, and VHD families. IgVH extension molecular analysis show: 89% mutated, and 11% not mutated. For the IgVH carrying somatic mutations, we studied also the specific interested families: 19% VH1, 52% VH3, 29% VH4. VH3-21 family was absent (unique index negative prognosticates in IgVH with somatic mutation). ZAP-70 and CLLU1 has been performed through RT-PCR by ABI-PRISM 7000 and relative quantification expressed as (2Δ-CT). From real time evaluation : Positive ZAP-70: 26%, Negatives ZAP-70: 74%: CLLU1 and IgVH not any correlation Expression of MUM1 was high in all ZAP-70 negative cases . *Conclusions*. In the IgVH analysis we found discordant data with respect to the European guidelines, in particular the absence of VH3-21 expression family. The ZAP-70 values performed by molecular biology techniques remain the more important index of the IgVH mutational status. The high expression of MUM1 may be indicative of patients with favorable clinical course and longer survival expectancy. CLLU1, CD38, and ZAP-70 correlation have characterized groups of patients with a better or a worse prognosis. Because of the limited number of cases (23 patients diagnosed) analyzed, our results should in future be extended to investigate the prognostic factors, disease clinical stage study on mutational state of the IgVH, expression of the polymorphism of IL1B and IL6 genes, doubling time of the lymphocyte study CD38 and ZAP-70 quantitation expression.

1545

HIGH PREVALENCE OF CLONAL B-CELL DISEASE IN PATIENTS WITH LGL-LEUKEMIA

G.E. Tjønnfjord,[1] E. Schrumpf,[2] A. Tierens[1]

[1]Rikshospitalet, Oslo University Hospital, OSLO; [2]Faculty of Medicine, Univwersity of Oslo, OSLO, Norway

Background. When we recently reported on 52 patients with LGL-leukaemia, we serendipitously found a high prevalence of monoclonal gammopathy. This was in line with a recent report by Viny et al showing high prevalence B-cell dyscrasias in LGL-leukaemia. *Aims*. This prompted us to systematically address the issue of concomitant clonal B-cell disease including monoclonal gammopathy in an extended group of patients with LGL-leukaemia diagnosed at our hospital. *Design and Methods*. Between October 2001 and December 2008, 65 patients were diagnosed with LGL-leukaemia at Rikshospitalet, Oslo University Hospital. The median age was 59 years (range 26-86), and the cohort consisted of 30 men and 35 women. The medical records were retrospectively scrutinized to identify patients with monoclonal gammopathy and/or lymphoproliferative disease. *Results*. Results of protein electrophoresis of serum and/or urine were available in 59 patients. Monoclonal gammopathy was detected in 12 patients (20% of those assessed by electrophoresis). In six patients, the monoclonal gammopathy was diagnosed as monoclonal gammopathy of undetermined significance (MGUS). In the other six patients with monoclonal gammopathy, a lymphoproliferative disease was disclosed in the bone marrow by immunhistochemistry and/or flow cytometry (smoldering myeloma in two patients, indolent lymphomas in four patients). Three patients were diagnosed with chronic lymphoprolifetrative disease with no signs of monoclonal gammoapthy; CLL in two patients and follicular lymphoma in one patient. *Summary*. All together, in our cohort of 66 patients with LGL-leukaemia 15 patients (23%) were diagnosed with concomitant indolent clonal B-cell disease, which is considerably higher than expected. This is in line with data recently reported by Viny and coworkers. This finding may have some relevance to the pathogenesis of LGL-leukaemia.

1546

LUMILIXIMAB TREATMENT RESULTS IN INCREASES IN SERUM CD23 BUT NO MODULATION OF MEMBRANE CD23 IN RELAPSED CLL PATIENTS

S.G. Harris, J.V. Ranuio, A. Estrellado, S.G. Hughes, S. Tangri

Biogen Idec, SAN DIEGO, USA

Background. Lumiliximab (IDEC-152) is an anti-CD23 monoclonal antibody that binds to CD23, the low-affinity IgE receptor. CD23 is a trimeric molecule with both membrane-bound and serum forms. Membrane CD23 is a 45 kD glycoprotein expressed on B cells, monocytes /macrophages, eosinophils, platelets, and dendritic cells, with expression being increased on chronic lymphocytic leukemia (CLL) cells. Serum CD23 is produced via the cleavage of membrane CD23 into fragments by endogenous proteases, with the 25 kD fragment occurring at ng/mL concentrations in normal human serum. Increased levels of serum CD23 are found in patients with several disease states, including CLL. *Aims*. We report two trials that assessed the effects of lumiliximab treatment, alone (Ph I) or in combination (Ph I/II) with FCR (Fludarabine, Cyclophosphamide, and rituximab), on membrane and serum CD23 levels in relapsed CLL patients. Receptor occupancy levels in patients were also evaluated following weekly (monotherapy) or monthly (+ FCR) treatment with lumiliximab. In addition, potential correlations between the level of membrane CD23 expression and absolute lymphocyte count (ALC) decrease or clinical response were studied in both trials. *Design and Methods*. Serum CD23 levels were measured using a validated enzyme-linked immunosorbant assay. Two non-competitive CD23 antibodies (anti-CD23 PE and lumiliximab-FITC) were utilized in a flow cytometry assay to assess the receptor occupancy of lumiliximab on the surface of B-CLL cells, as well as membrane CD23 levels. Lymphocytes were gated on CD45 and SSC followed by gating on CD5+CD19+ cells to identify B-CLL cells. CLL cells were assessed for membrane CD23 by gating on CD23+CLL cells. The receptor occupancy (fraction of lumiliximab-bound CLL cells) was reported as the ratio of CD23+CLL cells divided by lumiliximab+CD23+CLL cells. Results Membrane CD23 levels remain relatively consistent following treatment with lumiliximab, both in a monotherapy and combination therapy setting. However, serum CD23 levels increased within several hours of dosing with either lumiliximab alone or in combination with FCR. The intensity of the serum CD23 increase varied from patient to patient, and was dose-dependant. Following initial increases in serum CD23, subsequent kinetics are dose and schedule dependant. CD23 receptor saturation with lumiliximab was maintained, and clinical activity was observed, despite the presence of high serum CD23 levels in both trials. Membrane CD23 levels did not appear to correlate to ALC decreases and clinical response. *Conclusions*. These analyses show that treatment of relapsed CLL patients with lumiliximab results in increases in serum CD23 levels in a dose- and schedule-dependant manner. These studies also found that lumiliximab treatment did not result in a reduction in membrane CD23 levels. As CD23 receptor saturation and a favorable response profile occurred in the presence of high circulating CD23 levels, these studies suggest that increased levels of serum CD23 do not negatively impact on clinical activity and do not appear to behave as an antigen sink. Furthermore, the level of membrane CD23 expression did not correlate with ALC decreases or clinical response to lumiliximab. These findings will be further evaluated in ongoing clinical trials.

1547

ERUFOSINE, A NOVEL ALKYLPHOSPHOCHOLINE, IN CHRONIC LYMPHOCYTIC LEUKEMIA: IN VITRO COMPARISON WITH BENDAMUSTINE AND FLUDARABINE

S. Konstantinov,[1] D. Josifov,[1] T. Alaikov,[2] V. Shivarov,[3] N. Stoyanov,[3] M. Guenova[3]

[1]Medical University of Sofia, SOFIA, Bulgaria; [2]University Hospital St.Anna, SOFIA, Bulgaria; [3]National Haematological Hospital, SOFIA, Bulgaria

Background. Alkylphosphocholines represent a new class of cytostatic drugs with a novel mode of action. Erucylphospho-N,N,N-trimethylpropylammonium (erufosine - ErPC3), the first compound of this class that can be administered intravenously, has recently been shown to be active against human tumor and leukemic cell lines and is currently undergoing clinical trials in leukemia patients. Erufosine has high activity against leukemic cells without affecting the normal hematopoiesis. The aim of the study was to evaluate *in vitro* the antileukemic potential of ErPC3 in chronic lymphocytic leukemia (CLL) compared to fludarabine and bendamustine, that are routinely used drugs for the treatment of CLL. *Design and Methods*. The cytoreductive activity of ErPC3, fludarabine, and bendamustine was evaluated in primary cell cultures of mononuclear cells isolated from peripheral blood from newly diagnosed patients with CLL using the MTT-dye reduction assay. The levels of bcl-2 and NF-kB proteins were measured by Western blot. *Results*. Erufosine showed clear concentration-dependent efficacy against CLL cells that exceeded in some cases the efficacy of the reference drugs fludarabine and bendamustine (IC50 values ranging from 12 to 30 μM). Subsets of cell cultures showed greater sensitivity towards fludarabine or bendamustine as estimated by the corresponding IC50 values. Immunoblot analyses revealed about 90% Bcl-2 and about 70% NF-κB positive samples. Bcl-2 protein expression showed a decrease after cytoreductive treatment. *Conclusions*. Erufosine is a promising agent for the treatment of lymphoproliferative disorders such as CLL because of its remarkable antitumor activity *in vitro* and its ability to intensify normal hematopoiesis.

The study was funded by the National Research Fund, Bulgarian Ministry of Education and Science(VU-L-309/07).

1548

FLUDARABINE AND CYCLOPHOSPHAMIDE (FC) VERSUS CYCLOPHOSPHAMIDE, VINCRISTINE AND PREDNISONE(CVP) AS FIRST LINE THERAPY IN CHRONIC LYMPHOCYTIC LEUKEMIA

H. Ionita,[1] I. Ionita,[1] L. Cheveresan,[1] M. Ionita,[1] M. Delamarian,[1] M. Racz[2]

[1]UMF Victor Babes, TIMISOARA; [2]City Hospital, RESITA, Romania

Background. The introduction of Fludarabine into the treatment of chronic lymphocytic leukemia (CLL) has improved the complete remission rate (CR), overall response rate (OR) and progression free-survival (PFS) compared with alkilator based regimens. Its synergistic action with cyclophosphamide has demonstrated semnificative advances as front line therapy in untreated CLL patients. *Aims*. To evaluate the response rate time, the disease progression and survival of the patients of FC (Arm A) vs CVP (Arm B) as first line CLL treatment. *Design and Methods*. Starting from I 2004 until I 2008, 87 untreated patients with CLL were enroled, diagnosed and treated in the Hematology Department from the western part of the country. The group was formed by 56 males and 31 females who were randomised into the two treatment arms approxi-

matelly 43 in each group. The diagnosis of CLL was established according to the criteria of International Workshop on CLL (IWCLL) 1989. The median age was 66,3 years, range (37-78), ECOG performance status 0-II with high risk category (RAI stage III-IV or RAI stage I-II if they have at least one of the followings: one or more of the disease related symptoms, progressive marrow failure, massive splenomegally or lymphadenopathy or progressive lymphocytosis). Arm A received: cyclophosphamide 250 mg/m^2 i.v. D1 to D3 and Fludarabine 25 mg/m^2 D1 to D3. Arm B received Cyclophosphamide 400 mg/m^2 i.v. D1 to D3, Vincristine 1,4 mg/m2 D1 and Prednisone 100 mg/m^2 D1 to D5. Cycles to be repeated every 21 days. Hematological toxicity was recorded according to NCI-WC for diagnosis and treatment and evaluation of response was done according to the NCI-WC response criteria. Were excluded from the study with stable or progressive disease after 3rd cycle. While PR and CR cases continued to 6 cycles of the same treatment. To confirm the repsonse to treatment, were performed Bone marrow biopsy and immunophenotyping. Results: 28 patients had stage IV, 34 patients had stage III and 25 patients had stage II. The median WBC was 93x10^9/L, the median lymphocyte count was 75x10^9/L, the median hemoglobin level was 8,3 gr/dl, the median platelet count was 110x10^9/L. Bone marrow biopsy showed difuse pattern in 84% and the median lymphocyte in the bone marrow was 90,5%. Complete clinical remission was reported in 29/44 patients in arm A (66%) compared to 9/43 in arm B (21%), p=0,15. Confirmed CR by bone marrow biopsy was reported in 14 patients in arm A (31,8%) and in only 4 cases in arm B (9,3%). Partial respons with nodules was reported in 10 patients (22,7%) in arm A and 5 cases (11,6%) in arm B. Median time to progression was 28 months in Arm A and 8 months in Arm B (p=0,03). In therms of hematological toxicity in Arm A 9 patients developed grade IV neutropenia and received G-CSF treatment while 2 patients developed severe anemia (grade III and IV) that required red blood cell transfusion. Two patients developed transient febrile neutropenia of unknown origin, which required hospitalization. Mild extra-hematological toxicity consisting of nausea and vomiting occured in 10 patients during the treatment in both Arm A and B. Treatment related mortality occured in 2,0% in FC Arm and 1,5% in CVP Arm. *Conclusions.* The overall response rate (ORR) was significantly higher in FC Arm in comparison with CVP Arm. Also the complete response rate of FC Arm was high compared with CVP Arm. The combination of FC is able to induce higher response rate at the level of bone marrow biopsy. The hematological end extrahematological side effect were mild and manageable. There was a statistically significant difference in time to disease progression in favor of FC regimen.

1549

PREDICTORS OF DEATH IN CRITICALLY ILL CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS

A. Xhaard, L. Epelboin, M. Darmon, J. Mayaux, V. Levy, M. Malphettes, B. Schlemmer, E. Azoulay

Hopital Saint-Louis, PARIS, France

For chronic lymphocytic leukemia (CLL), prognostic factors which are the most used by haematologists are the clinico-biological staging of Rai/Binet, along with newly identified cytogenetic and molecular markers. In that retrospective monocentric study, we sought to identify risk factors for in-hospital mortality in critically ill CLL patients. We studied 62 consecutive patients with CLL admitted to the medical intensive care unit (ICU) at Saint-Louis hospital, Paris, France, between 1991 and 2008. Binet staging was as follows: stage A, 21%, stage B, 16% and stage C, 58%. Five percent of the patients had a Richter disease. Before ICU admission, 15% of the patients had never received any treatment for CLL, 60% had already received at least one course of Fludarabine, 36% had received Rituximab and 35,5% had received prolonged steroid treatment. Thirteen percent of the patients were receiving anti-pneumococcal disease prophylaxis, 26% anti-herpes and varicella-zoster viruses prophylaxis and 30% anti-pneumocystis prophylaxis. Haematopoietic stem cell transplantation (autologous or allogeneic) had been performed in 8% of the patients. During the course of CLL, 36 patients (58%) had presented an infectious episode, including 9 patients with low immunoglobulin levels. The two major reasons for ICU admission were acute respiratory failure (75,8%) and sepsis (61,3%). Twenty-nine percent of the patients presented with shock. Median LOD (Logistic Organ Dysfunction) scores at day 1 and 3 were 5 (25%-75%, 0-20) and 4 (idem), respectively. Noninvasive mechanical ventilation was needed in 27,4% of the patients and 50% needed invasive mechanical ventilation or vasopressors throughout the ICU stay. ICU, in-hospital and 90-day mortalities were 35,4%, 45% and 58%, respectively. Univariate and multivariate logistic regression analyses were performed. By multivariate logistical regression analysis, we identified 3 variables independently associated with in-hospital mortality: (i) previous infection during CLL course, (ii) admission to the ICU for shock and (iii) low oxygen saturation at ICU admission. The risk for in-hospital mortality increased with an increasing number of these risk factors. In this study of CLL patients, ICU was necessary mainly for acute respiratory failure, primarily from infectious origin. Prognosis relied on severity of lung injury and on the presence of septic shock, rather than on the characteristics of the underlying malignancy. The high mortality in sepsis-related ICU admission in CLL patients suggests that infection prevention may translate into reduced ICU admission and associated mortality.

1550

WHAT DO WE KNOW ABOUT THE REAL INCIDENCE OF CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) AND WHERE AND HOW ARE THE PATIENTS WITH CLL TREATED?

A. Panovska, M. Doubek, Y. Brychtova, S. Pospisilova, J. Mayer

University Hospital Brno, BRNO, Czech Republic

Background. Currently, pathogenesis, modern prognostic factors, or modern therapy in CLL are frequently discussed, however, up-to-date data concerning the incidence and the management of CLL in "real life" are still missing. *Aims*. The aim of our study was to find out the actual epidemiological situation of CLL, and the diagnostic and therapeutic preferences of hematologists in the preselect area - the South Moravian Region. *Design and Methods*. We asked 18 specialized hematological departments to fill in our questionnaire in order to get exact information about epidemiology and treatment of CLL patients. All hematologists filled the questionnaires out. Acquired data were merged with our database. According to the Czech Bureau of Statistics, 1,127,718 inhabitants live in the South Moravian Region. *Results.* The total number of 540 patients (median age at the time of diagnosis: 65 years, range: 33-92; sex: 306 males, 234 females) who were followed up in the year 2008 were included in the analysis. Therefore, the incidence of CLL was 6.2 per 100,000, the prevalence 48 per 100,000. The Rai stage at diagnosis was as follows: 0 (n=274, 50%), I (n=173, 32%), II (n=36, 6.7%), III (n=25, 4.6%), IV (n=25, 4.6%). In 7 patients (1.3%) the Rai stage wasn't determined. Flowcytometry was carried out in 525 patients (97%), the others were diagnosed by a histological examination either of bone marrow or a lymph-node. Two hundred eighty-seven patients (53%) were followed up at the local hematological ambulances, 253 (47%) were treated at one main hematological center. The median follow-up was 56 months (range: 5-1262). Two hundred ninety-one patients (54%) were cytogenetically examined (del 17p, n=5; del 11q, n=18; +12, n=29; del 13q, n=111; normal karyotype, n=94, combined cytogenetic abnormalities, n=34). IgVH mutational status was examined in 305 (57%) patients (155 mutated, 134 unmutated, 16 polyclonal). ZAP-70 was examined in 191 (35%) patients (77 positive, 114 negative). The treatment of CLL was indicated in 194 patients (36%), 93 (17%) of them also underwent the second line treatment. As the first line treatment, 64 patients (33%) were given fludarabine-based regimen, 40 (20.6%) of them achieved complete remission (CR), 74 (38%) received chlorambucil with 12 (6%) CRs, 28 (14%) CHOP-like regimen with 8 (4%) CRs, 10 (5%) alemtuzumab with 6 CRs, 18 (9%) corticosteroids with 1 CR. Ninety-three patients (17%) underwent the second line treatment: fludarabine-based regimen (n=39, 42%) with19 CRs, chlorambucil (n=19, 20%) with 1 CR, CHOP-like regimen (n=8, 9%) with 1 CR, alemtuzumab (n=10, 10%) with 4 CRs, and corticoid-based treatment (n=17, 18%) with no CR. Thirty patients were treated within clinical trials. *Conclusions*. According to our analysis, fewer patients with CLL were surprisingly indicated to therapy than we expected. Although the treatment was indicated in the minority of patients, the modern prognostic factors were examined in almost all patients. It remains questionable if in *real life* the examination of the modern prognostic factors is necessary in all CLL patients.

Supported in part by the Czech Leukemia Study Group for Life, and in part by Research Grant MSM 0021622430.

FLUDARABINE REFRACTORY AND VERY ADVANCED CLL: VALUE OF RITUXIMAB MONOTHERAPY

S. Lepretre,[1] V. Leblond[2]

[1]*Centre Henri Becquerel, ROUEN, France;* [2]*Groupe Hospitalier Pitié Salpêtrière, PARIS, France*

Background. In chronic lymphocytic leukaemia (CLL) therapeutic

options are limited for heavily pretreated patients, or patients who have failed or relapsed shortly after treatment with fludarabine (F-refractory). Many patients with advanced stage CLL have compromised bone marrow capacity, and many are elderly with significant co-morbidities further limiting choice of therapy. Thus, there is a need for mild 'salvage' regimens that combine efficacy with reduced hematotoxicity. Rituximab has been widely explored as a single agent in CLL and has considerable advantages due to its manageable, predictable safety profile. Rituximab monotherapy is evaluated here in the context of heavily pretreated and F-refractory CLL. *Aims*. The objective of this literature survey was to conduct a comprehensive analysis of existing clinical data to evaluate reported efficacy of Rituximab in heavily pretreated and F-refractory CLL. A secondary objective was to evaluate reported efficacy of Rituximab in combination with novel, non-chemotherapy combinations. Methods A search of all electronic information including Medline databases, conference proceedings (ASH, EHA, ASCO) and trial registers was conducted. Extracted data included prior therapies, treatment regimen, dosing schedule, response rate, median follow-up time, progression free survival (PFS) and time to progression (TTP). *Results*. The total number of publications exploring utility of single agent Rituximab in heavily pretreated or F-refractory CLL was 21 and involved 292 patients. When administered at a dose of 375mg/m2 weekly for 4 weeks, Rituximab gave variable efficacy (ORR ranging from 0-38%) and limited durability of response (TTP ~ 4 months). Eight studies employed alternative Rituximab dosing regimens, including high dose (up to 2250 mg/m^2), dose dense (administered 3x/week) and prolonged dosing regimens. These modified dosing schedules were associated with improved ORR (ranging from 33 to 85%) and considerable improvements in durability compared to the standard (375 mg/m^2 weekly x 4) dosing regimen (TTP ranging from 6 to over 25 months). Where individual data on F-refractory patient sub-sets was reported, clinical responses were observed in 41-50% of patients. Three separate case studies report successful use of Rituximab in F-refractory CLL. Rituximab-non-chemotherapy combinations offer the potential for improved efficacy with acceptable toxicity. An emerging body of evidence supports utility of Rituximab in combination with high dose glucocorticoids, with five recent studies reporting ORRs of 78-93% in F- refractory CLL, and TTP ranging from 12-15 months. *Conclusions*. Rituximab monotherapy has utility in CLL patients for whom alternative therapies have been exhausted or are not advisable due to hematotoxicity. Intensified Rituximab monotherapy regimens have resulted in response rates of up to 85% in CLL patients, with ORRs of 41-50% in F-refractory subsets. Rituximab-non-chemotherapy combinations offer the potential for improved efficacy with acceptable toxicity and a combination that is demonstrating exciting synergistic efficacy as salvage for refractory patients is the Rituximab-glucocorticoid combination, with ORRs greater than 90% reported in F-refractory CLL. Thus, Rituximab as monotherapy or in combination with high dose glucocorticoids is an efficacious and well tolerated treatment option for patients with very advanced or F-refractory CLL. Together, these studies support utility of Rituximab in CLL patients that are unsuitable candidates for more cytotoxic regimens.

1552

SERUM LEVEL OF BFGF AND HIS CORRELATION WITH BIOLOGICAL PARAMETERS IN PATIENTS WITH B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA

E. Wasik-Szczepanek, A. Bojarska-Junak, A. Dmoszynska, D. Koczkodaj, M. Jarosz, M. Wach, J. Rolinski

Department of Haematology, LUBLIN, Poland

A lot of study indicate that angiogenesis may play important role in the pathogenesis of hematological malignancies, including B-cell chronic lymphocytic leukaemia (B-CLL). Angiogenesis is regulated by many substances with pro- and anti-angiogenic activity. Basic fibroblast growth factor (bFGF) is a pleiotropic cytokine that plays an important role in angiogenesis. bFGF can also act as a hematopoietic cytokine. It is found in megakariocytes and cells of the granulocyte lineage. Elevated levels of bFGF have been previously reported in cells derived from renal cell carcinoma, malignant melanoma. Some investigators have shown that clonal B cells from B-chronic lymphocytic leukemia are able to synthesize bFGF and a correlation between increased levels of bFGF and impaired prognosis. We investigated whether is an association between the concentration of bFGF and other biological parameters in untreated CLL patients. Two hundred sixty one patients (110 women, 151 men) with Rai stage 0-4 were studied. They were newly diagnosed according NCI criteria. Analysis of bFGF serum concentration, Zap-70, CD38 expression and detection of genomic aberrations (del 17p, del 11q, del 13q, trisomy 12) was performed. Serum bFGF levels were measured in 261 CLL patients with range from 2.49 to 556.09 pg/mL with a mean of 88.9703 (SD=132,92) pg/mL. The serum concentration of bFGF was higher in the CLL group (mean 90.1960 pg/mL, SD=134,15) when compared to the control group (mean 1.3837 pg/mL, SD=1.38) and that difference found to be significant (p<0.003). The mean bFGF concentration in ZAP-70 positive patients was 79.32 (SD=120.23) pg/mL and ZAP-70 negative patients was 103.72 (SD=152.43)pg/mL. Among CD38 positive patients mean concentration of bFGF was 102.03 (SD=160,48) pg/mL, and among CD38 negative patients was 87.40 (SD=126,16) pg/mL. However, differences between bFGF concentration in group of ZAP- 70 positive versus ZAP-70 negative patients, and CD38 positive patients versus CD38 negative patients were no statistically significant. There were no statistically significant differences in concentration of bFGF between gender groups and between four clinical stage groups. No statistically significant correlation was found between bFGF serum concentration level and patients sex, time to treatment, overall survival and genetics aberrations. Lack of relationship between CD38, ZAP-70, genomic aberrations and another clinical parameters show, that further investigation of the exact role of bFGF in CLL is warranted.

1553

AN ANALYSIS OF EXPRESSION OF MAJOR LYMPHOID ANTIGENS IN B-CLL IN PATIENTS WITH DIFFERENT STAGES OF DISEASE

V. Vilchevskaya, V.V. Tyutyunnik, N.S. Kovalenko, I.L. Ilyushenko, S.A. Tetura, H.I. Samsonova

V.K.Gusak Institute of Urgent and Recovery Surgery, Academy of Medical Science, DONETSK, Ukraine

The application of the immunophenotyping method for diagnosing chronic lymphoproliferative diseases allows not only to reveal the expression of major antigens but to assess the number of cues expressing these antigens. Currently there is no common opinion of a prognostic role of degree of «ANCHOR» antigens expression. The purpose of the study was the assessment of major lymphoid antigens (CD5, CD19, CD23) expression in patients with an established diagnosis of B-linear chronic lymphocytic leukemia (B-CLL) to reveal phenotypically heterogeneous groups of patients. Samples of bone marrow (BM) aspirate from 71 patients with B-CLL were studied. The diagnosis was made on the basis of standard clinical and laboratory criteria. The standard panel of monoclonal antibodies for CLL typing was utilized for immunophenotyping. Assessment of the results was made by flowing cytometer FACS Caliber (BD). B-linear belonging was determined by the presence of major B-antigens (CD19, CD20, CD22, CD23, HLA-DR). Belonging of cells to B-CLL was confirmed by the presence of specific co-expression CD5+\CD19+, CD5+\CD20+, the presence of antigen CD23, by clonality according to one of light chains (**K** or **λ**) and a negative reaction with FMC7 and CD10 antigens. Thus it was established that the number of cells with monoclonal CD5+ accumulation in B cells (CD19+) is different in patients with a clinically and morphologically established diagnosis B-CLL. We analyzed the degree of expression of antigens depending on the stage (according to Rai classification) of disease. We found the level of CD5+ and CD19+ cells is the highest (median 71%) for stage 1 and gradually lowers to stage III (median 48%), and at stage IV increases again (median 70%). The greatest number of cells with co-expression CD5+\CD19+ was observed in the subgroup with stage IV of disease (median 63%). While studying the expression of membrane antigen CD23 which is carried by lymphocytes in B-CLL, we also observed high values of the given antigen expression (max = 98%), but noted a decrease in CD23+ level (up to 6%) in some cases. Therefore, the greatest number of cells positive to CD23 antigen was in the subgroup with stage 1 (median 79%) and the least - with stage IV (median 51%). The given antigen was expressed by the same cells which were CD19+\CD5+. The cells with high values according to one antigen also expressed a considerable amount of other antigen molecules, indicating direct dependence. The obtained results give evidence that heterogeneity regarding the level of expression of *key* antigens is observed in group B-linear CLL. First stage disease patients demonstrated the highest amount of lymphocytes carrying major antigens B-CLL on the superficial membrane. The given values gradually decrease to stage III. At stage IV the amount of cells with co-expression CD5+/CD T9+ increases, and CD23 level continues to decrease. The study of phenotype in patients with different stages of B-CLL and follow-up of the patients with revealed differences in the phenotype will be continued. The aim of continuing the investigation is to determine the correlation of antigen changes in a clinicomorphologic picture.

1554

CAUSE OF DEATH IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKAEMIA (CLL): EFFECT OF AGE AND LYMPHOCYTE COUNT AT DIAGNOSIS

J. Moore,[1] T. Sooriyakumara,[1] A. Yong,[2] G. White,[1] J. Stanley,[2] J. Phillips[1]

[1]Wellington Hospital, WELLINGTON, New Zealand; [2]University of Otago, DUNEDIN, New Zealand

Background. Limited data is available on the cause of death in patients with CLL. CLL has been reported as the underlying or contributory cause of death in 52-69% of patients, secondary malignancies in 16-34% and non malignant causes in 32%.[1-3] This retrospective study analysed the causes of death in patients diagnosed with CLL in Wellington Hospital from 1992-2007. *Aims*. To see if CLL was the primary cause of death in our population and if age and lymphocyte count were independent prognostic factors for dying of CLL related causes.

Table.

Exposure variable	Odds Ratio	95% confidence limits Lower	Upper	*P* value
Sex (female:male)	0.615	0.246	1.538	0.299
Age at diagnosis (≥65 relative to <65)	0.210	0.078	0.571	0.002
Log2 of lymphocyte count (modelled as linear predictor)	1.47	1.05	2.47	0.026

Design and Methods. Patients with CLL were identified from laboratory diagnostic records. Information on age, gender, date of diagnosis, lymphocyte count was collected from clinical records. Date and cause of death was established from the New Zealand Health Information Service. All results reported are given for CLL-related relative to non-CLL related cause of death. Exposure variables included in the model were patient gender, patient age (under 65 years or 65 and older) and a log-transformed lymphocyte count (obtained at diagnosis). Cause of death was modelled using logistic regression. All analyses were performed using PROC LOGISTIC in SAS 9.1 (SAS Institute Inc, NC, USA). *Results*. 392 patients with CLL were identified and of these, 153 patients had died. Data on cause of death were available for 119 of the deceased patients with a lymphocyte count at diagnosis recorded in 108. CLL was the leading cause of death in 47% of patients, with non-malignant causes in 30% and secondary malignancy in 22%. Of the 108 patients included in the analysis, a total of 50 patients died of CLL-related causes (CLL or Richters Transformation) and 58 died of non-CLL related causes. From the 11 patients missing lymphocyte counts, 6 died from CLL-related causes. Table 1 reports the odds ratios associated with each of the variables in the model. As can be seen, patient gender did not significantly influence the likelihood of dying from CLL-related causes. Patients aged 65 or over at the time of diagnosis were less likely to have died from CLL-related causes than those patients aged less than 65 years. Furthermore, lymphocyte count at diagnosis was significantly related to the likelihood of dying from CLL -related causes: for each two fold increase in lymphocyte count, the odds of dying from a CLL related cause increased by a factor of 1.47 (95% confidence interval 1.05, 2.07). These risk factors were independent of each other. *Conclusions*. CLL accounted for nearly half of all deaths in our population. The risk of dying of CLL or related causes increased with younger age at presentation and increasing lymphocyte count at diagnosis.

IMMUNOHISTOCHEMICAL DETERMINATION OF ZAP-70 PROTEIN IN BONE MARROW BIOPSIES IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) PATIENTS

A. Vassou,[1] N. Simou,[2] E. Hatzimichael,[3] D. Bogdanos,[3] K. Zaharopoulou,[3] M. Efthimiou,[3] M. Bai,[2] K. Bourantas[3]

[1]Ioannina University Hospital, IOANNINA, Greece; [2]Pathology Departement University Hospital of Ioannina, IOANNINA, Greece; [3]Haematogy Departement University Hospital Ioannina, IOANNINA, Greece

Background. CLL is the most common type of leukemia in the western world, with a variable clinical course. The biology of CLL partly depends on the mutational status of the variable region of immunoglobulin heavy chain genes (IgVH), which defines two subgroups of tumors: mutated and unmutated. The expression of ZAP-70 protein is a surrogate marker of more aggressive unmutated cases. *Aims*. Our study aimed to assess the ZAP-70 immunohistochemical protein expression on bone marrow biopsies (BMBs) and examine possible associations with clinicopathologic characteristics and patient survival. *Design and Methods*. 37 BMBs of typical CLL patients were studied (32 male, 5 female) at diagnosis. 21 patients were stage Binet A, 12 stage B and 4 stage C. Immunohistochemistry (IHC) was performed in paraffin sections usinig streptavidin-biotin method. The applied antidody was mouse monoclonal 2F3.2 (Cell Marque). IHC profile also included CD3, CD20, CD5, CD23. A threshold of 25% of CLL cells expressing the ZAP70 protein was used as cut-off for classification of samples as negative (<25% cells positive) or positive (>25% of cells positive). We also evaluated percentage of positive cells along with intensity of staining (0+ absent, 1+ weak, 2+ moderate, 3+ strong staining) in a composite semi-quantitative ZAP70 score (range 0-300). To grade the staining intensity, T-cells were used as strongly positive controls. *Results*. 16/37 cases were negative (43%) and 21/37 (57%) were positive. All positive cases exhibited >50% staining cells . ZAP70 protein expression was associated with advanced age (χ^2 p=0.017), need for therapy (χ^2 p=0.002) and early initiation of therapy (χ^2 p=0.012). At a median follow up of 61 months, 4/16 patients with ZAP70 negative subtype died (mortality 25%), whereas 10/21 among those with ZAP70 expressing tumor died (mortality 48%). The median survival of patients with ZAP70 negative CLL was 90 months while that of patients with ZAP70 positive CLL was 80 months (log-rank p=0.07). When cell number and staining intensity were evaluated by means of the ZAP70 score, the median value of 150 was used to classify patients to ZAP70 negative or ZAP70 positive CLL subgroup. The difference in overall survival favouring the former group reached statistical significance (log-rank p=0.05). *Conclusions*. Immunohistochemistry for ZAP70 protein expression in bone marrow leukemic cells from paraffin-embedded biopsies is a convenient and reliable surrogate marker for aggressive biology of CLL and inferior patient outcome. Its association with adverse clinicopathological characteristics and molecular links to proven cellular pathways of cell kinetic and therapy resistance should be further studied.

1556

CHRONIC LYMPHOCYTIC LEUKAEMIA PATIENTS WITH V3-21 GENE REARRANGEMENT HAVE A HIGHLY VARIABLE CLINICAL OUTCOME DEPENDING ON MUTATIONAL STATUS AND CYTOGENETIC FEATURES

V. Prochazka,[1] R. Urbanova,[2] P. Turcsanyi,[2] T. Papajik,[1] R. Plachy,[3] H. Urbankova,[4] M. Jarosova,[1] K. Indrak[1]

[1]Teaching Hospital in Olomouc, OLOMOUC, Czech Republic; [2]Dept. of Hemato-oncology, Teaching Hospital, OLOMOUC, Czech Republic; [3]Molecular Genetics Lab, Dept. of Hemato-oncology, Teaching Hospital, OLOMOUC, Czech Republic; [4]Cytogenetics lab, Dept. of Hemato-oncology, Teaching Hospital, OLOMOUC, Czech Republic

Background. Mutational status of the immunoglobulin heavy chain variable region (IgVH) gene is a robust and independent predictive factor in patients with B-cell chronic lymphocytic leukaemia (B-CLL). Growing evidence suggests that patients with rare rearrangement of a specific variable region (V3-21) gene have a uniformly unfavourable clinical outcome irrespective of the IgVH mutational status. *Aim.* To analyze the haematological features, clinical behaviour and outcome of patients with V3-21 gene rearrangement. *Method*. IgVH mutational status was analyzed in 352 patients with B-CLL who met the NCI-WG diagnostic criteria. IgVH mutational status was analyzed using cDNA transcribed from B-CLL RNA for touch-down reverse transcription polymerase chain reaction (RT-PCR) with degenerate primers for VH1-7 families; IgVH were aligned to the nearest germline using the Ig BLAST database. A sequence homology cut-

off of 98% was used to define the IgVH mutational status. The V3-21 gene was clonally rearranged in 22/352 (6.25%) cases and mutated in 12/22 (55%) patients. FISH analysis was performed in 19/22 patients (86%); high-risk genetic abnormality (17p or 11q deletion) was detected in 8/19 (42%) cases. The median age at diagnosis was 66 years (36-76). Binet clinical stages were as follows: A 32%, B 36% and C 32%. Treatment was initiated in 18/22 patients (82%), with first-line therapy comprising chlorambucil (6/22), fludarabine-based regimen (7/22) or C(H)OP-like regimen (9/22). After a median follow-up of 54 months, 9/22 (41%) patients died. *Results*. Overall survival at 7 years (7y OS) reached 61% (95% CI 0.35-0.87); treatment-free survival at 2 years (2y TFS) was 39% (95% CI 0.16-0.61). Prolonged TFS was strongly associated with unmutated IgVH (log rank 0.004) and with the absence of high-risk cytogenetics (log rank 0.02). Patients without 17p or 11q deletion had longer survival (3y OS 90% vs 57%, log rank 0.02). Similarly, those with mutated IgVH showed a trend for favourable OS (7y OS 72% vs 40%, log rank 0.09). No correlation was found between 17p or 11q deletion and IgVH mutational status (χ^2 0.6). There was a trend for treatment initiation in patients with mutated IgVH and unfavourable cytogenetics (χ^2 0.1). *Summary*. Patients with V3-21 gene rearrangement do not share the same clinical outcome. Survival and treatment initiation are influenced by both unfavourable cytogenetics and unmutated IgVH status. Most patients with mutated IgVH are long- term survivors. Currently used standard cytogenetic and molecular cytogenetic methods do not lose their predictive role in the population of B-CLL patients with V3-21 gene rearrangement.

PERSISTENT UNEXPLAINED MILD LEUKOPENIA: HOW FAR A SEARCH SHOULD BE DONE

C. Megalakaki, M. Kotsopoulou, D. Maltezas, V. Chatziantoniou, A. Alexopoulos, M. Dadakaridou, S. Alexia, Chr. Mitsouli-Mentzikof

Heamatological clinic, Metaxa Anticancer Hospital, PIREAUS, Greece

Mild leucopenia is often encountered in everyday practice. In most cases it is transient, associated with smoldering viral illness or drug consumption. Persistent chronic leucopenia is usually associated with specific clinical situations but in a few cases there is no obvious explanation and there arises a question of how deep and vigorous a search should be done. In this paper we report the outcome of long follow-up of 32 patients with persistent and apparently unexplained mild leucopenia. 32 patients, 13 men, 19 women, aged 24-80 years, median 58 years presented with low (2.2-3.8x10^9/μL, mean 3.4x10^9/μL) white blood cell count (WBC) lasting more than one year. History, physical examination and the basic laboratory work-up failed to reveal the cause of the abnormality. Two to six months after the first visit all patients were re-examined with physical examination and laboratory testing including complete blood counts, biochemical and serological tests, ultrasound of the abdomen, immunophenotyping, bone marrow aspiration and biopsy and karyoryping. In most cases the findings were inconclusive and the diagnostic search was repeated every six months, until the resolution of the leucopenia or a diagnosis was reached. After follow-up of 2-6 years, median 2.4 years, in 5/32 pts the WBC was gradually restored. 4/32 patients developed autoimmune disease, 2 patients myelodysplastic syndrome, 1 chronic myelomonocytic leukemia and 10 lymphoproliferative disorders. In 11/32 pts no definite diagnosis is reached. The pts with lymphoproliferative disorders, 5 men, 5 women, aged 44-80 years, median 58 years presented the following: 3/10 hairy cell leukemia, 2/10 Waldestrom's macroglobinemia, 1 follicular lymphoma, 1 MGUS, 1 large granular lymphocytosis, 1 T- lymphocytosis with TCR rearrangement and in one pt a monoclonal lymphocyte infiltration of the bone marrow was found without further histological typing. The patient with the follicular lymphoma rapidly progressed to grade 3, stage IV and was treated appropriately. No other patient was treated. *Conclusions*. 30% of patients with persistent leucopenia eventually developed monoclonal lymphoid disorders The persistence of unexplained leucopenia may be the early sign of an emergent disease, particularly a low-grade lymphoproliferative disorder. An extended laboratory diagnostic work-up is absolutely warranted.

1558

THE EVALUATION OF EFFICACY AND TOXITY OF THE FIRST LINE THERAPY WITH FLUDARABINE COMBINED WITH CYCLOPHOSPHAMIDE (FC) VERSUS. 2-CHLORODEOXYADENOSINE WITH CYCLOPHOSPHAMIDE (CC) IN CHRONIC LYMPHOCYTIC B-CELL LEUKEMIA (CLL) SUBJECTS - THE OWN STUDY REPORT

B. Ceglarek

Institute of Hematology and Blood Transfusion, WARSAW, Poland

Background. Purine analogs are characterized with high effectiveness in CLL patients. The combined therapy FC/CC as the first line therapy can increase percentage of hematological response and improve quality of life and prolong survival. *Aims*. To evaluate the efficacy and safety of FC and CC therapy as first line therapy for CLL-B-1-4 grade Rai. *Design and Methods*. During 5 yr study 38 CLL-B patients (22 Male, 16 Female ; range 50 - 77 years) were randomized in the Department Of Hematology and Internal Diseases of the Institute of Hematology and Blood Transfusion to receive FC (Fludarabine-25 mg/m^2 i.v. 1-3 days and Cyclophosphamide 250 mg/m^2 i.v. 1-3 days) or CC (2-CdA-0,12 mg/kg/24h i.v. 1-3 days i.v. and Cyclophosphamide 250 mg/m^2 i.v. 1-3 days).The efficacy of therapy was performed after 3 and 6 cycles of therapy with FC / CC. Characteristics of CLL-B patients is in the Table 1.

Table 1. Number of evaluated patients 38(16F; 22M).

Age 50 - 77 years
FC 18 pts. CC
20 pts.
Number of received cycles 3-6
Time between 2 cycles 1-7 months (range 1.02 months)
Side Effects :8/38 (21%)
Leucopenia:
1oWHO after 2 cycles 2 pts.
1o WHO after 5 cycles 1pt.
2oWHO after 6 cycles 1pt.
2oWHO after 2 cycles 1pt.
Anemia after po 2 cycles 1pt.
Thorombocytopenia 4oWHO 1pt.
Electrolytes disorders 1pt.
Results are shown in the Table 2.

Table 2. Results FC (n=17/18) CC (n=18/20).

After 3 cycles :			
CR	04	02	
PR	10	14	
NR	03	02	
CR+PR	14 (77.8%)	16 (80.0%)	
Results	FC (n=13/18)	CC (n=16/20)	
After 6 cycles :			
CR	05	07	
PR	08	07	
NR	0	02	
CR+PR	13 (72.2%)	14 (70.0%)	
Deaths :	02	03	
PD	01	02	
Others	01	01	
Survival time since diagnosis (months)			8-84 months
(median 39.5 mo)	30-60 months		
(median 45.3 mo)			
Survival time since FC/CC therapy (months)			7-62 months
(median 31.8 mo)	11-59 months		
(median 40.1 mo)			

Conclusions. FC/CC combined chemotherapy induces the similar percentage hematological response (CR+PR) after 3, 6 cycles treatment. Side effects were performed in 21% of treated FC/CC CLL-B patients Overall survival time and survival time since diagnosis are longer in CC arm CLL-B patients.

1559

ALEMTUZUMAB IN FLUDARABINE-REFRACTORY CLL

H. Ionita,[1] L. Cheveresan,[1] I. Ionita,[1] M. Cheveresan[2]

[1]*UMF Victor Babes, TIMISOARA;* [2]*City Hospital, TIMISOARA, Romania*

Background. Chronic lymphocytic leukemia (CLL) patients treated with Fludarabine have good responses in 60-65% of the cases. Alemtuzumab was approved in 2001 for the treatment of patients with CLL previously treated with alkylating agents and fludarabine. *Aims*. The trial evaluated intravenous (i.v.) alemtuzumab (Campath) 3 x 30 mg weekly in fludarabine refractory CLL. *Design and Methods*. From October 2005 to October 2008, 27 patients were enrolled and received alemtuzumab. Median age was 58 (38-80) years, 70.37% were male, 74,07% were Binet C, and a median of 3 (1-6) prior lines had been given. Unfavorable genetics were frequent (51.85%). I.V. treatment was performed on an hospitalized patients basis in 81,48% and had to be temporarily interrupted in 7 patients due to neutropenia (2 pts.), anemia (1 patient), thrombocytopenia (1 patient), infections (3pts.), and was stopped early in 3 cases due to insufficient response (1 case) and infections (2 cases). Clinical and biologic parameters (age, sex, B-symptoms, stage, ECOG, number of prior lines, node size, hepato-spenomegaly, WBC, LDH, β2-MG) were evaluated for their prognostic role. Results: Toxicity during treatment period was mostly grade I/II apart from hematotoxicity. Grade neutropenia, thrombocytopenia, anemia occurred in 8 (29.63%) patients. Grade $^{3}/_{4}$ non-cytomegalovirus infection occurred in 5 patients (18,52%). CMV reactivation was observed in 18,52% (5 cases) total, all grade. The CMV episodes were successfully treated with anti-CMV therapy and there was one CMV-related death. After a median follow-up of 30 months, there were 19 (70,37%) deaths, 56% due to disease progression, 31% due to infection, and 13% not related to CLL. Overall response rate was 33.33% (CR 7,4%, PR 25,93%), median progression free survival time was 7.7 months, and median overall survival time was 19.1 months. OS was significantly inferior for age > 65 y (10.2 vs 26.0 mo, $p<0.001$), ECOG > 1(9.8 s 19.5 mo, $p=0.001$), and β2-MG >5 (11.5 vs 25.2 mo, $p=0.004$. The median OS since next therapy in these patients was 10.3 months. *Conclusions*. Alemtuzumab was well tolerated and determined good survival in 29,63% of the fludarabine refractory advanced phase CLL patients.

HYPOADIPONECTINEMIA IS ASSOCIATED WITH B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA RISK

M. Dalamaga,[1] A. Lekka,[2] B.H. Crotty,[3] J. Fargnoli,[3] M. Triantafilli,[2] K. Karmaniolas,[2] G. Sotiropoulos,[2], A. Dionyssiou-Asteriou,[1] C. Mantzoros[3]

[1]*Attikon General University Hospital, ATHENS, Greece;* [2]*NIMTS General Hospital, ATHENS, Greece;* [3]*Beth Israel Deaconess Medical Center, BOSTON, USA*

Background/Aim. Adiponectin, an adipocyte secreted hormone, is inversely related to risk for many malignancies associated with obesity and the metabolic syndrome, including leukemia. In this case-control study, we explored the role of total and high molecular weight (HMW) adiponectin, the presumed active form of adiponectin in the etiopathogenesis of B-cell chronic lymphocytic leukemia (B-CLL). We also explored their association with several established prognostic factors for B-CLL. *Design and Methods*. Blood samples were collected from 95 cases with incident B-CLL, and 95 hospital controls, admitted for non-neoplastic and non-infectious conditions, matched on gender, age and year/month of diagnosis (±1 month) between 2001 and 2007. Serum total adiponectin concentrations were determined by radioimmunoassay (LINCO Research Institute, St Charles, MO). Serum HMW adiponectin was measured using ELISA (ALPCO Diagnostics, Salem, NH). Moreover, serum lactate dehydrogenase (LDH), β2-microglobulin (BMG), lymphocyte morphology and the surface expression of CD38 in >30% of B-CLL lymphocytes were determined. Statistical analysis of the data was performed with SAS 9.1 for Windows XP. Results: Cases presented a higher body mass index (BMI) than controls ($p=0.008$). Significantly more cases than controls presented a family history of lymphohematopoietic cancer (LHC) ($p<0.01$). Total adiponectin was positively associated with HMW adiponectin ($p<0.01$) among all study subjects. Lower serum adiponectin levels were associated with higher risk of B-CLL by bivariate analysis and after adjusting for age, gender, weight, BMI and family history of LHC (OR: 0.96; 95% CI 0.92-1.00). No significantly different adiponectin and HMW adiponectin levels were found amid different stages of B-CLL according to the Binet classification. Only LDH was weakly but significantly positively correlated with total adiponectin and HMW adiponectin ($p<0.05$) among B-CLL cases. *Conclusions*. This study suggests that adiponectin may be weakly associated with B-CLL etiopathogenesis and could represent a potential marker of disease severity. Further studies are needed to confirm these associations and to explore the mechanisms underlying adiponectin's role in lymphopoiesis in general and B-CLL specifically.

THE RESULTS OF IFN-A AS FIRST-LINE THERAPY IN PATIENTS WITH HAIRY CELL LEUKEMIA

A.M. Gaman, G.D. Gaman

University of Medicine and Pharmacy Craiova, CRAIOVA, Romania

Hairy cell leukemia (HCL) is a chronic B-cell lymphoid leukemia characterized by pancytopenia, splenomegaly, myelofibrosis and the presence in peripheral blood, bone marrow and spleen of atypical lymphoid cell with hairy aspect. The purine nucleoside analogs represent the first-line therapy, often associated with immunosuppression and secondary malignancies. IFN-α is an alternative therapy with significant eficacy. *Aim of study*. to evaluate the eficacy of IFN-α as first-line treatment and if the maintenance therapy with IFN-a increased progression free survival in this disease. *Design and Methods*. We studied 29 patients with HCL hospitalized in Clinic of Hematology from Craiova (Romania) between 1997-2007 treated with IFN-α as first-line therapy 3MU/m^2 three times weekly for 12-24 months, devised by age, sex. We followed the presence of splenomegaly, hepatomegaly, complete blood counts, bone marrow infiltration with atypical lymphoid cell with cytoplasmic elongations at diagnosis. Results: the median age of HCL patients was 52 years with a high frequency at men (M/F = 3/1). A half of them had splenomegaly and 14% hepatomegaly at diagnosis. Median hemoglobin value was 10.9 g/dl , leukocytes 2.7x10°/L, absolute neutrophil counts 0.86 x10°/L, platelets 83 x10°/L; the median percentage of bone marrow infiltration with hairy cell was 72% at diagnosis. Three patients were splenectomized and 26 received IFN-a treatment at a dose of 3 MU three times weekly for 12-24 months. 14% of patients achieved complete response with negative bone marrow and 63% had a partial response. 49% of patients received maintenance therapy with IFN-α. 28% of patients never needed a second therapy and 35% were retreated with IFN-α. One patient developed a secondary neoplasia. The median follow-up was 52 months and the disease free survival in patients with maintenance therapy was 28 months. *Conclusions*. IFN-α has a significant eficacy in patients with HCL and the maintenance therapy seems to increase disease free survival.

HAIRY CELL LEUKEMIA IN YOUNG PATIENTS: RUSSIAN EXPERIENCE

A. Pivnik,[1] L.S. AlRady,[2] A.I. Vorobjev[2]

[1]*Pirogovs National Medico-surgical Center, MOSCOW, Russian Federation;* [2]*Hemalogical Research Center of Russian Academy of Medical Sciences, MOSCOW, Russian Federation*

From 1995 to 2007 we followed 160 pts (m/f 1.8/1) with verified hairy cell leukemia (HCL) aged 27 - 81 (median 49) yrs. 41 (26%) pts (m/f 2. 2/1) were from 27 to 40 (median 35) yrs of age. 27 (66%) pts (m/f 1. 7/1) had a typical form of HCL, 14 (34%) (m/f 3.7/1) - a variant form of HCL. Duration of the disease covered from 1 to 30 (median 5. 8) yrs. There were no substantial distinctions in frequency and degree of cytopenia, lymphocytosis, monocytopenia and splenomegaly between old and young groups. For certain there was more frequent for the young pts enlargement of abdominal lymph nodes (32% against 9% in old group). Marrow cytology, trephine biopsy histology, TRAP test were typical for all patients. Immunophenotype was performed in 30 (73%) pts. In 60% cases clone and in 40% cases clon k were found. Differences of immunophenotyping in young and old pts showed 25% frequency of variable phenotype (CD25-, CD23+, CD10+) in young pts. Splenectomy was performed in 15 (37%) young pts. Interferon -alfa in standart doses as initial therapy for 8-12 wks received 40 (98%) pts as treatment-prophylactics of agranulocytosis after subsequent Cladribine. Cladrib-

ine received 36 pts (88%). Complete remission from 1 to 9+ (median 5) yrs was achieved in 31 (86%) pts, partial remission- in 4 (11%). Relapses after one course of cladribine were observed at 1, 3 to 6 (median 3. 5) yrs in 11 (34%) pts aged to 40. In old pts it consisted of 12%. We consider HCL patients younger than 40 yrs at risk of early relapse after Cladribine and propose the supporting therapy with monoclonal antibody anti-CD20 or 22 once in 2-3 mos during the time to be established in near future.

1563

DOUBLE PRIMARY HEMATOLOGICAL MALIGNANCY: REPORT OF 21 CASES

C. Megalakaki,[1] I. Iakovidou,[2] A. Patrinou,[1] I. Triantafyllopoulou,[1] I. Lalaki,[1] D. Maltezas,[1] P. Repousis,[1] M. Kotsopoulou,[1] Chr. Mitsouli-Mentzikof[1]

[1]Heamatological clinic, Metaxa Anticancer Hospital, PIREAUS, Greece; [2]Department of pathology, Metaxa anticancer Hospital, PIREAUS, Greece

Nowadays there are many reports of patients with two primary malignant diseases, usually two solid tumors. In 2003 we reported 57 patients with one hematological malignancy and at least one second primary malignant neoplasm, including 9 cases of two primary hematological cancers, who were admitted in our clinic from 1995-2003. In the present paper we report those patients along with 12 new cases admitted from 2004-2008, that is a total of 21 patients with two apparently unrelated malignant hematological diseases. Patients with treatment-related malignancies or disease in transformation in a more aggressive subtype were excluded. 21 patients, 13 men, 8 women, aged 8-77, median age 61, presented the following malignancies: 12 chronic lymphocytic leukemia (CLL), 10 non Hodgkin lymphoma (NHL), 7 Hodgkin's lymphoma (HL), 5 myeloproliferative disease (MPD), 5 multiple myeloma (MM), 2 myelodysplastic syndrome (MDS), 1 acute leukemia. No patient had congenital immunodeficiency, exposure to toxic agents and/or irradiation or strong family history associated with malignancy. In three patients the diagnosis of two different diseases was done simultaneously (CLL and MM, CLL and CML, NHL and AML) while in 14 patients the second disease presented 1- 7 years following the first one and in 4 patients (all with cured HD) after 13-28 years. 9/21 had received no treatment for the first disease (CLL) at the time of the second diagnosis while 12 had received the appropriate treatment for the initial disease (NHL, HL, MPD, MDS). Of these, 5 were in long term complete remission, 2 with recently achieved remission, 3 were on hydroxyurea and 2 were transfusion-dependent. The clinical and laboratory features of the second disease did not present any particular difference from the usual pattern. Treatment was administered in 16/21. 3 patients were not able to receive full-dose chemotherapy, because of the previous treatments. 12 patients responded to therapy according to their prognostic risk factors while in 4 patients the second disease was unexpectedly aggressive. These patients had rather recently -less than two years- undergone treatment for the first disease. 13/21 are alive 0.5 - 11 years after the second malignancy. 8 patients died, 6 with progressive second disease in less than 2 years, one with acute leukemia while in complete remission for 3 years and one from breast cancer. Conclusions. The prevalence of two primary and apparently unrelated hematological malignancies seems to be rising. The epidemiology and clinical and laboratory features of the second neoplasms do not differ from those of the general population, CLL and NHL being the most frequently encountered hematological malignancies. Patients with successfully treated Hodgkin's lymphoma may present after a decade a second hematological neoplasm not necessarily treatment-related. Second neoplasms in long-term survivors or patients with low-grade malignancies should be treated appropriately as the prognosis seems independent of the first disease. However, when the second neoplasm arises less than two years from the treatment of the first one, the prognosis is much worse.

1564

LOWER SERUM LEPTIN LEVELS ARE RELATED TO B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA OCCURRENCE

M. Dalamaga,[1] A. Lekka,[2] B.H. Crotty,[3] J. Fargnoli,[3] M. Triantafilli,[2] K. Karmaniolas,[2] A. Dionyssiou-Asteriou,[1] C. Mantzoros[3]

[1]Attikon General University Hospital, ATHENS, Greece; [2]NIMTS General Hospital, ATHENS, Greece; [3]Beth Israel Deaconess Medical Center, BOSTON, USA

Background and Aims. Obesity is now considered to be a risk factor for many types of cancer, including leukemia and lymphoma. Leptin, an adipocyte secreted hormone, has also been proposed to have a role in hematopoiesis and was not studied in depth in B-cell chronic lymphocytic leukemia (B-CLL). In this case-control study, we attempted to investigate the contribution of serum leptin levels to the etiopathogenesis of B-CLL, taking also into account potential confounders including the family history of lymphohematopoietic cancer (LHC) and the body mass index (BMI). We also attempted to ascertain whether a relationship between prognostic markers and levels of leptin exists among patients with diagnosed B-CLL. *Design and Methods*. Blood samples were collected from 95 cases with incident B-CLL, and 95 hospital controls, admitted for non-neoplastic and non-infectious conditions, matched on gender, age and year/month of diagnosis (±1 month) between 2001 and 2007. Serum leptin concentrations were determined using ELISA (Diagnostic System Laboratories Inc., Webster, Texas). Furthermore, serum lactate dehydrogenase (LDH), β2-microglobulin (BMG), lymphocyte morphology and the surface expression of CD38 in >30% of B-CLL lymphocytes were assessed. Statistical analysis of the data was performed with SAS 9.1 for Windows XP. *Results*. Patients in the case group on average had a higher body mass index as compared with controls (27.8 vs. 26.7 kg/m2; $p<0.01$). Significantly more cases than controls presented with a family history of LHC (13 vs. 3 controls; $p<0.01$). Serum leptin was significantly lower in cases as compared with controls (10.03 vs. 13.89 ng/ml; $p=0.004$). Among controls, BMI was positively correlated with leptin levels ($p=0.04$). Lower leptin levels were associated with B-CLL risk in unadjusted analyses as well as after controlling for age, gender, date of diagnosis, family history of LHC and BMI (OR: 0.94, 95% CI 0.90-0.97; $p=0.01$). No significantly different serum leptin levels were found amid different stages of B-CLL according to the Binet classification. However, a weak but significant positive correlation between LDH and leptin was found (r=0.22, $p<0.05$), and between leptin and β-2-microglobulin (r=0.27, $p<0.01$). *Conclusions*. Leptin was found to be lower among cases as compared to controls, despite cases having a higher BMI. These results will need to be confirmed in an even larger study population, but if reproduced may suggest that leptin becomes dysregulated, or that other factors such as inflammatory cytokines secreted by lymphocytes suppress leptin expression at later stages of the disease process.

1565

HEPATITIS C VIRUS-POSITIVE CHRONIC LYMPHOCYTIC LEUKEMIA

G. D'Arena,[1] L. Laurenti,[2] S. Deaglio,[3] M.L. Vigliotti,[4] N. Cascavilla[1]

[1]"Casa Sollievo della Sofferenza" Hospital, SAN GIOVANNI ROTONDO, Italy; [2]Hematology Unit, Catholic University, ROME, Italy; [3]Laboratory of Immunogenetics, University of Turin, TURIN, Italy; [4]Hematology Unit, "S. Sebastiano" Hospital, CASERTA, Italy

Background. The association of hepatitis C virus (HCV) and B-cell chronic lymphocytic leukemia (CLL)/small lymphocytic lymphoma (SLL) is not well established. Some epidemiological studies tend to rule out such a relationship. Again, little is known about the clinic-biological features and outcome of HCV-positive patients with CLL. Aims. To evaluate clinico-biological features and outcome of HCV infected patients with CLL at diagnosis compared to HCV negative CLL patients. *Design and Methods*. We retrospectively evaluated clinico-hematological characteristics of 23 HCV-positive CLL patients compared with 189 HCV-negative CLL patients seen at our Institutions. *Results*. No differences were found with respect to sex distribution and age. The HCV genotype was known only in 4 patients: in 3 cases was found 2a/2c, in one case 1b. No difference was also found in the absolute lymphocyte count, hemoglobin level, platelet count, Rai and Binet clinical stage at diagnosis, lymphocyte doubling time. Mutational status of IgVH, CD38 expression, and ZAP-70 expression did not show differences among the two groups of patients. The major cytogenetic abnormalities, detected by means of FISH in 13 HCV-positive patients, showed 7 cases of normal karyotype,3 cases of trisomy 12, 2 cases of deletion 13q14, 1 case of deletion of 11q22.3 (ATM). Finally, overall survivals of HCV infected patients and HCV-negative patients did not show any significant difference ($p=0.1$). *Conclusions*. In conclusion, HCV-positive patients with B-cell CLL seem to not differ from other patients for presentation and clinical outcome as well. However, preliminary results need to be confirmed on a large cohort of patients.

1566

EFFICACY OF ALEMTUZUMAB TREATMENT ON REFRACTORY T-CELL LARGE GRANULAR LYMPHOCYTIC LEUKEMIA

I. L. San Román, N. Golbano, R. Herraez, D. De Miguel, B. Pinedo Albiz

University Hospital Guadalajara, GUADALAJARA, Spain

Background. Lymphoproliferative disorders of large granular lymphocytes are rare (<3% of all cases of small lymphocytic leukemias) and generally indolent, so that approximately half of patients may not need therapy. When needed, standard treatment includes immonusuppresive and/or chemotherapeutic agents. However, none of these have proven universally effective in achieving durable disease control, although data are limited by patient numbers. *Aims/Design and Methods*. We describe the disease course of a 76 year-old male patient with refractory T-cell large granular CD52 + lymphocytic leukaemia, who was totally dependent on blood transfusions after failing standard treatment (continuous cyclosporin A [CSA] and low-dose oral methotrexate [MTX]), and achieved long- term (30 months) disease control with alemtuzumab. Alemtuzumab was administered first intravenously (day 1, 3 mg; day 2, 10 mg, day 3: 30 mg, then 30 mg IV thrice weekly for 6 weeks, once weekly for 3 weeks), and then subcutaneously (30 mg every third week for 16 months, and 30 mg monthly thereafter, for 21 months). *Results*. The patient became independent on blood transfusions and is still in remission, 30 months after the initial dose, of which 9 months after treatment withdrawal. No adverse effects were observed. *Conclusions*. Although MTX and CSA are effective as first-line therapy of T-cell large granular lymphocytic leukemia, alemtuzumab probably deserves further investigation, particularly for refractory disease.

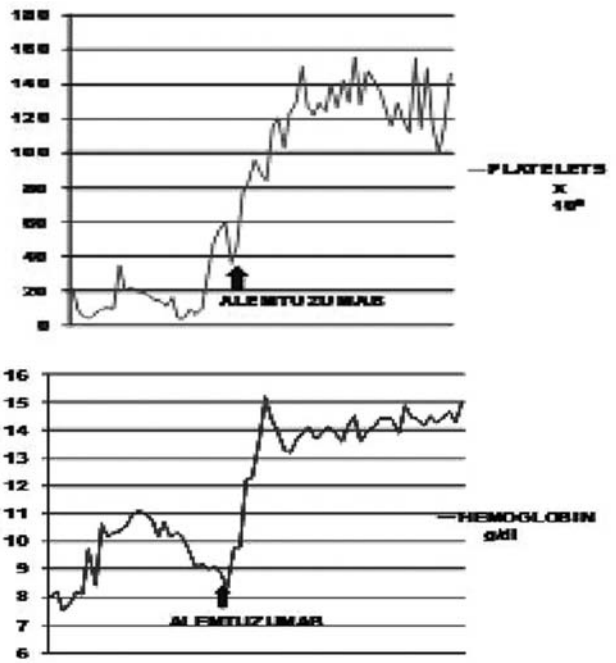

Figure.

CHANGE IN EXPRESSION PATTERN OF TCR-CD3 COMPLEX IN PATIENTS WITH MULTIPLE MYELOMA

Y.Q. Li,[1] S.H. Chen,[1] L.J. Yang1, B. Li,[1] C.A. Schmidt[2]

[1]Medical College, Jinan University, GUANGZHOU, China; [2]Dept. of Hematology and Oncology, Ernst-Moritz-Arndt University Greifswald, GREIFSWALD, Germany

Background. In hematological malignancy, cell-mediated immunity has been shown to be suppressed with advanced disease. This immune dysfunction may be due to decreased output of recent thymic emigrants, the abnormal expression of T cell receptor repertoire and, may in part, due to altered expression of TCR-CD3 complex. *Aims*. The distribution and clonality of TCR Vβ repertoire, the expression level of signaling transduction factor CD3 ζ, γ and ε genes in T cells from patients with multiple myeloma (MM) were investigated. *Design and Methods*. Specific family primers (24 VΔ subfamilies), RT-PCR and genescan technique were use to analyze the expression of TCR Vβ subfamily and the clonality of TCR VΔ T cells in 7 patients. Real-time RT-PCR with SYBR Green technique was used for detecting the expression level of CD3 ζ, γ and ε genes in peripheral blood mononuclear cells (PBMCs) from 22 patients with MM, and 17 cases healthy individuals served as control. The β2-microglobulin gene (β2M) was used as an endogenous reference. Relative mRNA expression level of genes was analyzed by using the 2Δ-Ct-100% method. *Results.* The pattern of TCR Vβ repertoire which is full expressed in healthy controls, was changed in patients. Only 5/24 Vβ subfamilies were detected in 2 MM cases, 6, 16,17, 20 and 22 Vβ subfamilies were found in 1 case respectively. The most frequent expressed Vβ subfamilies were Vβ1, Vβ9 and Vβ13 (7/7, 100%), and Vβ16 (6/7, 85.7%). Clonal expanded T cells could be identified in some subfamilies in all patient samples, while all of 24 Vβ subfamilies displayed polyclonality in healthy controls. The Vβ21 subfamily was expanded most frequently in patient samples. It could be identified in all five cases with Vγ21 expression. Vγ13 oligoclonal expansion was identified in 5/7 cases. The CD3 ζ and ε gene was expressed in all patients with MM, while CD3 γ was not detected in two cases. Compared with healthy controls, the relative mRNA expression level of CD3 γ in MM samples was significant decreased (p=0.001) and the expression of CD3 ε gene was significant increased (p<0.0001). Although the expression level of CD3 ζ is 2.23 times higher than that from healthy individuals, no significance was found compared to controls (p=0.059). We further compared the expression pattern of the three CD3 genes. There are no significant differences in the expression levels in healthy individuals. However, significant changes of ε>ζ>γ gene expression were observed in MM patient samples (p<0.0001). *Conclusions*. Skewing expression and dominant utilization of TCR Vβ repertoire may indicate T cell immunodeficiency, however frequent oligoclonal expanded TCR Vβ subfamily T cells may be also consequence of a host specific immune response to MM associated antigens. On the other hand, the altered expression of CD3 may be associated with the immune dysfunction. We here present precise data concerning changes in the variability of Vβ patterns and expression of TCR signal transduction molecules in samples from multiple myeloma patients compared to controls. This study will contribute to better understand the cellular immune features in MM patients.

1568

EPIGALLOCATECHIN-3-GALLATE FROM GREEN TEA INHIBITS MYELOMA CELL GROWTH, BUT ANTAGONIZES THE EFFECTS OF BORTEZOMIB

R. Burger, H. Czekalla, M. Staudinger, K. Richter, T. Ahrens, A. Günther, M. Gramatzki

Div. f. Stem Cell Transplantation and Immuotherapy, KIEL, Germany

Background. The tumorsuppressive, antiinflammatory, and antioxidant activity of the green tea polyphenol epigallocatechin-3-gallate (EGCG) is currently being investigated in a number of clinical studies including solid tumors and chronic lymphocytic leukemia. In multiple myeloma (MM), EGCG induces cell growth arrest and apoptotic cell death via binding to the 67-kDa laminin receptor-1 (Shammas et al., Blood 108, 2006). The molecular mechanisms on how EGCG exerts its effects, however, are manifold, and not fully understood. Aims: The aim of the study was to investigate the effects of EGCG on malignant plasma cells, alone and in combination with other drugs, and to delineate molecular mechanisms of action. *Design and Methods*. Six human myeloma cell lines including the IL-6 dependent INA-6 cell line were assessed for their sensitivity to EGCG in a colorimetric (MTS) based assay and by trypan blue exclusion. For primary patient tumor cells, DNA synthesis was measured by [^{3}H]-thymidine uptake. Induction of apoptosis was determined by flow cytometry upon annexin-V/7-AAD staining. Western blot analysis was performed to detect EGCG effects on intracellular signaling pathways using phospho-specific STAT3 and ERK1/2 antibodies. *Results*. EGCG inhibited the *in vitro* growth of myeloma cell lines as well as patient tumor cells in a dose-dependent manner at IC50 concentrations between 12.5 μM and 50 μM. Remarkably, concentrations as low as 1 μM were sufficient to significantly reduce INA-6 cell numbers in long-term cultures. Bone marrow stromal cells, IL-6, or overexpression of Mcl-1 and Bcl-xL did not protect from EGCG induced cytotoxicity. In INA-6 cells, EGCG dose-dependently inhibited IL-6 induced STAT3 phosphorylation, concomitant with induction of apoptosis. Interestingly, catalase, which blocks the formation of reactive

oxygen species (ROS) was not active in INA-6 cells, but abrogated the growth-inhibiting effect of EGCG in other myeloma cell lines. The combination of EGCG with doxorubicin, dexamethason, or rapamycin did not yield synergistic or additive effects. Surprisingly, growth inhibition by bortezomib was antagonized by EGCG at concentrations as low as 1 μM. This was observed in myeloma cell lines as well as in patient cells. *Conclusions*. EGCG inhibits malignant plasma cell growth by formation of ROS and abrogation of intracellular signalling pathways. Importantly, serum levels of pharmacologically active concentrations of EGCG are achievable. Using EGCG as dietary supplement, the antagonizing effect on bortezomib activity has to be considered, and may lead to choosing another therapeutic strategy. This work provides the rationale for additional studies to evaluate the optimal use of EGCG in plasma cell tumors.

1569

EFFECT OF COMMON ABCB1 SNPS ON OVERALL SURVIVAL IN PLASMA CELL MYELOMA

S. Drain,[1] M. Catherwood,[1] N. Orr,[2] L. Galligan,[1] C.F. Hodkinson,[1] M.B. Drake,[1] P.J. Kettle,[1] T.C. Morris,[1] H.D. Alexander[1]

[1]Belfast City Hospital, BELFAST, UK; [2]The Breakthrough Breast Cancer Research Centre, LONDON, UK

Background. Multi-drug resistance (MDR) is a significant factor in the successful management of malignancy. One major source of this resistance is the P-glycoprotein (P-gp) drug efflux pump. Three single nucleotide polymorphisms (SNPs) which form a common haplotype have been identified in ABCB1 which, alone or in combination, may alter activity of P-gp, resulting in alterations to the MDR phenotype. We have previously reported on a single SNP rs1045642, within a plasma cell myeloma (PCM) patient cohort,1 which suggested an overall survival (OS) advantage in patients heterozygous for rs1045642 (CT) when treated with P-gp substrates. However this data was not in concordance with previous findings in Italian2 and Dutch3 studies. Further work is therefore required to determine the impact of ABCB1 SNPs on the MDR phenotype. It remains unresolved whether rs1045642, or other SNPs in the region, are providing the primary effect on OS within PCM. *Aims*. This study was designed to elucidate the impact of ABCB1 SNPs, rs1128503 and rs2032582, on the OS of PCM patients, in with the context of our previous results on rs1045642. *Design and Methods*. Patients with a diagnosis of plasma cell dyscrasia (PCD) were studied [n=92]. SNP genotyping was performed using real time PCR and melting curve analysis with fluorescence resonance energy transfer (FRET) probes and primers designed specifically for each SNP. Treatment and OS data was available on the majority of PCM patients investigated. Survival analysis was performed on each SNP with Cox proportional hazards regression analysis using R. *Results*. Previously reported results from our group have demonstrated increased OS for rs1045642 heterozygotes (CT) (p=8.4x10^{-3}, HR=0.46 (0.24-0.85)).1 In the present study, rs2032582 was nominally associated with OS (p=5.3x10^{-2}), the TT group having a poorer OS. rs1128503 was not significantly associated with OS (p=0.2). *Conclusions*. Our results suggest that rs2032582 TT genotype results in a poorer outcome in PCM patients. This is in concordance with our earlier work which also suggests that rs1045642 TT genotype was associated with a poorer response in PCM. We hypothesise that beneficial therapeutic effect of increased drug retention within tumour cells in the presence of the TT genotype is negated by increased toxicity within normal tissues. In our study rs1128503 was not associated with OS. This may be a consequence of low linkage disequilibrium (LD) between this SNP and the others in our study population or it may suggest that it is rs2032582 and rs1045642 within the common haplotype that generate the most significant effect. Further work will examine the impact of haplotypes that include these SNPs on OS, in a larger patient cohort.

SERUM ENDOGLIN (CD105) LEVELS IN MULTIPLE MYELOMA PATIENTS IS A MARKER OF BONE MARROW ANGIOGENESIS AND DISEASE ACTIVITY

F.H. Passam,[1] G. Tsirakis,[1] K. Sfiridaki,[2] F. Psarakis,[2] M. Kaparou,[1] C. Pappa,[2] F.H. Passam,[1] D.S. Kyriakou,[3] M.G. Alexandrakis[1]

[1]University Hospital of Crete, HERAKLION, Greece; [2]Venizelion General Hospital, HERAKLION, Greece; [3]University Hospital of Larisa, LARISA, Greece

Background. Plasma cell growth in multiple myeloma (MM) has been shown to be dependent on endothelial cell proliferation and angiogenesis in the bone marrow (BM) microenvironment. *in vitro* proliferation of endothelial cells in the presence of multiple myeloma BM mononuclear cells forms endothelial cell colonies which express endoglin (*Dominici et al. 2001*). Endoglin (CD105) is a transmembrane glycoprotein expressed on activated vascular endothelial cells. Its vascular expression is limited to proliferating endothelial cells and has been found to be overexpressed in various solid tumours, with the level of expression correlating with clinical parameters such as decreased survival and the presence of metastases. Information regarding its role in MM is limited although vessel formation is a hallmark of myeloma disease. Aim The aim of the current study was to measure the serum levels of circulating endoglin in multiple myeloma patients to determine if it could be an accurate marker of the extent of angiogenesis and the severity of MM. *Design and Methods.* 46 multiple myeloma patients and 12 healthy controls were included in the study. These patients were staged according to the Durie Salmon staging system. Serum samples were obtained at initial diagnosis from all patients and from 18 patients who had reached plateau phase after standard chemotherapy. Bone marrow biopsies were obtained from all patients before initiation of treatment and were evaluated for the expression of proliferation marker Ki67 in the plasma cell compartment and microvessel density as determined by staining with an anti-CD31 antibody. Serum levels of endoglin and of the inflammatory marker IL-6 were determined by ELISA using commercially available kits. *Results*ì. Endoglin levels were significantly higher in the myeloma patient group in comparison to the control group (p<0.05 by Mann Whitney). Furthermore, endoglin showed a higher average±SD value with increasing stage of disease (p<0.05 by ANOVA,Student Newman Keuls) (9.0±3.5 ng/mL for stage I, 9.8±2.7 ng/mL for stage II and 13.9±5.8 ng/mL for stage III). Endoglin's levels in serum decreased significantly following effective chemotherapy reaching levels comparable to controls (pre versus posttreatment values were 13.2±6.1 ng/mL versus 7.9±2.7 ng/mL respectively). Endoglin showed a good correlation with the proliferation rate Ki67 of malignant plasma cells (r:0.43, p 0.005 Spearman's rho) and bone marrow microvessel density (r:0.33, p 0.05). It also showed a significant correlation with the levels of circulating IL-6 (r:0.39, p 0.01). *Conclusions*. It was interesting to find that endoglin circulates at levels which reflect bone marrow neovascularization as expressed by marrow MVD. Serum endoglin may be the product of increased expression in the bone marrow vasculature especially in relation to an inflammatory phenotype as it couples with increased levels of IL-6. Further studies under way will determine the relative expression of endoglin in bone marrow tissues. The study also supports serum endoglin as a surrogate marker of myeloma disease activity.

PERIPHERAL LEVELS OF OSTEOPONTIN PARALLEL DISEASE PROGRESSION IN PATIENTS WITH MULTIPLE MYELOMA

F.H. Passam,[1] G. Tsirakis,[1] K. Sfiridaki,[2] F. Psarakis,[2] P. Kanellou,[1] C. Pappa,[2] F.H. Passam,[1] D.S. Kyriakou,[3] M.G. Alexandrakis[1]

[1]University Hospital of Crete, HERAKLION, Greece; [2]Venizelion General Hospital, HERAKLION, Greece; [3]University Hospital of Larisa, LARISA, Greece

Background. Neoplastic plasma cell proliferation in multiple myeloma has a profound effect on bone turnover resulting in characteristic osteolysis. Many indices of bone metabolism such as pyridinoline products have been studied in MM showing increased activity of osteoclasts. Osteopontin is an osteoclast regulator produced by malignant plasma cells also involved in angiogenesis, Studies regarding the relevance of peripheral levels of osteopontin with disease activity have yielded contradicting results (*Saeki et al, 2001 and Kang et al, 2007*). *Aims*. The aim of the current study was to determine if circulating osteopontin can be used as a marker of bone disease activity in myeloma patients. *Design and Methods.* 37 multiple myeloma patients and 10 healthy controls were included in the study. These patients were staged according to the Durie Salmon staging system and bone disease was graded according to skeletal involvement on x-ray (grade O: no bone involvement, 1: one lytic lesion, 2: more than one lytic lesion, 3: bone fracture or vertebral col-

lapse). Serum samples were obtained at initial diagnosis from all patients and from 20 patients who had reached plateau phase after standard chemotherapy. Bone marrow biopsies were obtained from all patients before initiation of treatment and were evaluated for the extent of angiogenesis by staining bone marrow vessels with an anti-CD31 antibody. Serum levels of osteopontin and the angiogenic molecule VEGF were determined by ELISA using commercially available kits. Results Osteopontin levels increased significantly with increasing disease stage (median±SD 18.5±9.5 ng/mL in stage I, 37.8±11.2 ng/mL for stage II and 71.1±51.0 ng/mL for stage III). Osteopontin also increased significantly with increasing grade of bone destruction with the highest value in the subgroup of patients with grade 3 bone disease(139±67ng/ml). The levels of osteopontin in the control group were 71±65ng/ml) which was not significantly different than the myeloma group as a whole. Osteopontin levels in serum decreased significantly following effective chemotherapy in comparison to pre-treatment values in the subgroup examined. Pretreatment values of osteopontin correlated with the the angiogenesis indices bone marrow MVD (r:0.28, p:0.05) and serum VEGF (r:0.44, p:0.005). *Conclusions*, Osteopontin is a sensitive marker of bone disease activity in multiple myeloma. Its relation with angiogenic markers indicates the contribution of developed vasculature in the enhanced bone destruction seen in myeloma disease.

OLIGO ARRAY-BASED COMPARATIVE GENOMIC HYBRIDIZATION SHOWS A DIFFERENCE IN GENOMIC PROFILES OF MULTIPLE MYELOMA PATIENTS WITH AND WITHOUT CYTOGENETIC NEGATIVE PROGNOSTIC FACTORS

R. Zaoralova,[1] V. Vranova,[2] J. Smetana,[2] D. Kyjovska,[3] B. Sablikova,[4] R. Kupska,[5] R. Hajek,[2] P. Kuglik[2]

[1]Masaryk University, Faculty of Science, BRNO-BOHUNICE, Czech Republic; [2]Masaryk University, Faculty of Science, Department of experimental biology, BRNO, Czech Republic; [3]Masaryk University, Faculty of Medicine, Department of Internal Hematooncology, BRNO, Czech Republic; [4]The Faculty Hospital Brno, Clinic of Internal Medicine, Hematology and Oncology, BRNO, Czech Republic; [5]Masaryk University, Faculty of Medicine, University Research Centre, The Czech, BRNO, Czech Republic

Background. Multiple myeloma (MM) is an incurable disease caused by malignant transformation of the B-cell, its clone proliferation and accumulation in a bone marrow. Generally MM is characterized by high clinical and genetic heterogeneity. There is a set of confirmed prognostic factors for new diagnosed MM, but not all of them seem to have a similar impact for relapsed patients treated by new drugs (bortezomib, thalidomide, lenalidomide). *Aims*. The clinical implementation of array comparative genomic hybridization (array-CGH) analyses allow us to do a whole-genome screening and sensitive identification of new genetic markers important for diagnosis, classification and prediction of prognosis of MM. The main aim of our work was molecular diagnostic of multiple myeloma focused on detailed genomic profiling of this disease using array-CGH. Material and methods We performed high-resolution (44K Agilent) array-CGH on 19 samples from 18 MM patients with various cytogenetic findings examined previously by FISH. 8 patients had confirmed hyperdiploidy, 7 non-hyperdiploidy, 7 had gain of 1q21 and 4 of them had translocation t(4;14). 8 of the samples were DNA from bone marrow, 11 were DNA obtained from MACS separated cells. 4 samples were uninformative because of low percentage of myeloma cells in whole bone marrow samples. 11 of informative cases were relapsed MM treated by new drugs, 4 of them were newly diagnosed MM. *Results*. We have found 52 various deletions and 26 gains in our samples. According to the findings from array-CGH we confirmed previous FISH results in all informative cases. Besides that, we found another aberrations present in four or more samples, as losses of 8p, 16q, 1p13, 6q25, and gain of chromosome 19. In two patients we observed biallelic deletion in cytoband 11q22 including some potentionaly important genes. We observed a clear difference in genome profile between hyperdiploid (H, N=8) and non-hyperdiploid (NH, N=7) group of MM patients: in hyperdiploid samples, mostly whole-arm gains were present, and occurred repeatedly (19 regions, 10 in 3 or more patients in H group vs. 6 regions, one in 3 patients NH). For non-hyperdiploid samples, high numbers of smaller and unique deletions were the typical aberrations (more than 30 in NH vs. 17 in H). In all cases with FISH confirmed gain of 1q21, gain of all 1q arm was observed. Comparison of gain 1q positive and negative group showed a difference in number of sub-chromosomal deletions (42 in gain 1q cases vs. 17 in non-gains), but not in whole-arm gains (15 in gain 1q group, 16 in non-gains). *Conclusions*. The results show a difference between genomic profiles in patients with and without cytogenetic negative prognostic factors examined by FISH (gain 1q, non-hyperdiploidy). The analysis of repeating genetic changes, as well as analysis of differences in array-CGH patterns might lead to finding valuable prognostic or predictive markers especially for relapsed patients treated by new drugs, or to a better classification of stage and risk, providing the basis for improved clinical management and tailored treatment of MM.

TETRAC, A SMALL MOLECULE INTEGRIN LIGAND, COOPERATES WITH BORTEZOMIB AND ENHANCES CELLULAR RESPONSE IN MYELOMA CELLS: A NOVEL CHEMOSENSITIZING APPROACH

O. Ashur-Fabian,[1] A. Hercbergs,[2] M. Ellis[3]

[1]The Hematology Institute, Meir Medical Center, KFAR-SABA, Israel; [2]Radiation-Oncology department, Cleveland Clinic, CLEVELAND, USA; [3]Translational Hemato-Oncology, The Hematology Institute, Meir Medical Center, KFAR-SABA, Israel

Background. Multiple myeloma (MM) is a plasma cell (PC) neoplasia accounting for more than 10% of hematological malignancies. Proteasome inhibitors represent a novel class of anticancer agents that have potent anticancer activity in both preclinical and clinical settings. Bortezomib is the first proteasome inhibitor for cancer therapy and is currently an important drug for treatment of relapsed and refractory MM. Despite all treatment approaches, this disease remains challenging with increasing chemoresistance. For more than two decades, actions of thyroid hormone in a variety of cells have been described to be relevant to proliferation and angiogenesis. In the past few years, clinical studies suggested that the pharmacological induction of mild biochemical hypothyroidism significantly improves survival time and enhances response rates to chemotherapy and radiotherapy in patients with glioblastoma multiforme (GBM), one of the deadliest refractory forms of brain tumors. Recently it was reported that thyroid hormones (T4 and T3) affect proliferation and angiogenesis through αVβ3 integrin, a common cell surface receptor. Tetraiodothyroacetic acid (tetrac), an analog of T4, was shown to block the αVβ3 integrin receptor site, mimicking hypothyroidism in the cells. Interestingly, MM cells interact with the same αVβ3 integrin for their invasion, spreading, proliferation and protease secretion activities. *Aims*. [1] To block the αVβ3 integrin utilizing tetrac and examine the effects of tetrac treatment on myeloma cell survival and proliferation. [2] To test the additive/supra additive effects of tetrac on bortezomib treatment in multiple myeloma cell lines *Design and Methods*. Proliferation (WST-1), apoptosis/necrosis (Annexin/PI), cell cycle (PI), were measured following addition of tetrac (1-100 μM) alone or in combination with bortezomib (1-100 nM) in five different MM cell lines. Results: Positive preliminary results demonstrate that tetrac treatment significantly inhibited cell proliferation/survival and increased the number of apoptotic/necrotic cells. In addition, co-treatment with tetrac and several doses of bortezomib sensitizes cells response with a significant reduction in survival and increase in apoptosis and necrosis, in a synergistic/additive manner. *Summary*. As most MM patients still relapse, new drugs combinations are needed to overcome resistance. Our novel chemosensitizing approach using tetrac, may potentially demonstrate the importance of aVb3 blocking and may be a useful unique adjunct for MM therapy

DETERMINING THE NORMAL PLASMA CELL PROPORTIONS IN PLASMA CELL DYSCRASIAS BY FLOW CYTOMETRIC IMMUNOPHENOTYPING AND HIGHER CD27 AND LOWER CD56 AND CD28 EXPRESSION IN KOREAN PLASMA CELL DYSCRASIAS

S. Park, C.J. Park, H.S. Chi, S.S. Jang, J.S. Lee, K.H. Lee, J.H. Lee, C.W . Suh

University of Ulsan College of Medicine and Asan Medical Center, SEOUL, South-Korea

Background. Immunophenotyping of plasma cells (PCs) have been reported to be useful. The evaluation of immunophenotypic markers in neoplastic PCs could be easily applicable using flow cytometric methods, which have become widely available in Asian patients. Studies on plasma cell dyscrasias (PCDs) have been limited due to the relatively low incidence. However, with a slowly increasing occurrence, immunophe-

notyping of PCs becomes more valuable in diagnosing PCDs, identifying prognostic markers, and markers for minimal residual disease. AIMS : The purpose of our study was to determine the immunophenotypic characteristics of PCs to distinguish between neoplastic and reactive PCs in order to diagnose PCDs and determine the proportion of normal PCs among total PCs (nPC/tPC) in cases with PCDs. In addition, we compared the immunophenotypic expression patterns with previous studies to evaluate whether ethnic variances may exist. *Design and Methods*. A total of 52 patients that showed bone marrow plasmacytosis were included in the study. Immunophenotypic evaluation by 4-color flow cytometry was done using a combination of CD38/CD138/-/CD45, CD56/CD20/CD138/CD19, and CD27/CD28/ CD138/CD117. The CD38/CD138/-/CD45 panel was used to differentiate between reactive and neoplastic PCs. Of the 52 patients, 19 had a PCD including multiple myeloma (MM, n=16), plasma cell leukemia (n=1), smoldering MM (n=1), and monoclonal gammopathy of undetermined significance (MGUS, n=1). A reactive plasmacytosis (range, 1.5% to 31.4% of total nucleated cells) was observed in 33 patients with or without other underlying diseases such as lymphoma, leukemia, or myelodysplastic syndrome. *Results*. Neoplastic and reactive PCs were discriminated by determining the CD45 expression in CD138+ gated populations except one MM case which showed CD45+ expression. The CD138+ gated cells showed CD45+ expression in all patients with reactive plasmacytosis (n=33) whereas patients with PCDs (n=19) had a distinct CD45- population except the previously mentioned case. In PCD patients, the median percentage of normal PCs among all PCs (CD138+ cells) was 28.2% (range, 1.2 to 97.9%). Eleven patients with newly diagnosed MM had a median nPC/tPC was 19.8% (range, 1.9 to 94.0%) whereas 4 follow-up MM patients had a median nPC/tPC value of 65.2% (range, 13.6 to 91.0%). A nPC/tPC value of 97.9% was noted in the patient diagnosed with MGUS. The reactive PCs were positive for CD27 but lacked CD28 expression in all 33 patients. All but one of the patients showed CD27 expression (94.7%) whereas CD56 and CD28 expression was demonstrated in 6 patients (31.6%) and 1 patient (5.3%), respectively. *Conclusions*. We were able to differentiate neoplastic PCs with reactive PCs in most cases of PCDs. In cases of PCDs, a proportion of normal PCs were identified, which might correlate with therapeutic response and prognosis. The immunophenotyping results showed discrepancies with previous studies, such as higher CD27 expression and lower CD56 & CD28 expression. Larger studies in Asian populations is warranted to define the characteristics of neoplastic PCs that might somewhat differ from previous studies based on non-Asian populations.

MULTIPLE MYELOMA CELLS UNDERGO DIFFERENTIATION UPON EXPOSURE TO ROSIGLITAZONE AND ALL-TRANS RETINOIC ACID

H.W. Huang, D.P. Wu

Soochow University, SUZHOU, China

Background. Activation of PPARg by its ligands has shown differentiating effects in solid tumors. However, few reports addressed its role in myeloma cells. Aims In this study, we investigate the effects of rosiglitazone (RGZ) as well as combined with all trans-retinoic acid (ATRA) on human myeloma cell lines and primary CD138$^+$ myeloma cells. *Design and Methods. U266*, RPMI-8226 cells and primary myeloma cells purified with CD138 immunomagenetic beads were treated with different concentration of RGZ in the presence or absence of ATRA and various biological responses were studied by the methods of [3H] thymidine incorporation, cell cycle analysis, Annexin V-PI staining, Wright-Giemsa staining and measurement of light chain protein in the culture supernatants. *Results*. Our study demonstrated that exposure to PPARg ligand (rosiglitazone, RGZ) induced proliferation inhibition and cell cycle arrest in myeloma cells. A combination of RGZ with all-trans retinoic acid (ATRA) can enhance the growth inhibition effects of RGZ. Further study shows that RGZ treated myeloma cells displayed morphological characteristics of cell differentiation, and more evident signs of differentiation were observed when RGZ was combined with ATRA. These changes were confirmed by the detection of CD49e expression and light chain protein secretion. Similar results were also observed when primary CD138$^+$ cells were treated with RGZ and ATRA.*Conclusions*. We showed that RGZ can induce growth inhibition and cell cycle arrest in multiple myeloma cells, which may be caused by induction of cell differentiation. Concomitant RXRa activation by ATRA can enhance the effects of RGZ. Therefore, RGZ may have the potential to be used as a differentiation inductor for clinical patients and ATRA may be useful as a combination therapy for myeloma. Further studies are needed to be performed to elucidate the mechanisms of the myeloma cell differentiation induced by RGZ and ATRA.

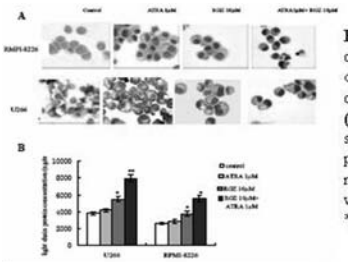

Figure 1 (A) Marked morphological changes of cell differentiation were observed in RGZ, RGZ+ATRA treated cells. Photographs are 400 magnification. **(B)** Exposure to 10 μM RGZ caused a significant increase of light chain proteins secretion in both cell lines. The most obvious change was observed when RGZ was combined with ATRA. $*p < 0.05$, $**p < 0.01$.

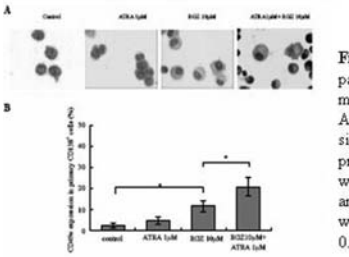

Figure 2 (A) Primary cells from myeloma patients also underwent morphological maturation after 48h exposure to RGZ and ATRA (400×). **(B)** ATRA caused no significant increase of CD49e expression in primary cells, while the CD49e expression was obviously up-regulated in RGZ group and the up-regulation was more significant when RGZ was combined with ATRA. $*p < 0.05$.

EXPRESSION OF PRAME, WT1 AND XIAP GENES IN MULTIPLE MYELOMA PATIENTS DURING HIGH DOSE CHEMOTHERAPY AND THERAPY OF PROTEOSOME INHIBITORS

T.V. Gaponova, A.V. Misyurin, L. Mendeleeva, E. Varlamova, E.N. Parovichnikova, V.G. Savchenko

National Research Center for Hematology, Moscow, Russia, MOSCOW, Russian Federation

Background. High dose chemotherapy and comprehensive drugs enable further improvement of the outcome of multiple myeloma (MM) patients. However, it is still necessary to determine prognostic factors that may influence treatment results and provide additional criteria for the precise selection of treatment approaches. A number of tumor associated genes is over-expressed in different malignancies including MM. These genes are believed to modulate cancer properties and should be taken into account during treatment. Their significance as prognostic factors require further investigation. *Aim.* To analyze the expression levels of PRAME, WT1 and XIAP genes in MM patients at diagnosis, during high dose chemotherapy and therapy of proteosome inhibitors, and to compare these data with clinical outcome. *Design and Methods.* Our study included 34 primary MM patients; all of them gave informed consent. The median age was 46 years (range 31-62). IgG MM was diagnosed in 28 cases, IgA MM in 2 and Light Chain MM in 4. 20 patients received initial treatment consisted of 3 cycles of VAD. 10 of them was given bortezomib 1.3 mg/m2 on days 1,4,8 and 11, and dexamethasone (dex) 40 mg daily on days 1-4 days (6-8 cycles) as the 2nd line therapy. In the other 14 primary MM patients VAD treatment was just started at the moment of our study and has not fulfilled yet. RQ PCR investigation of PRAME, WT1 and XIAP expression levels was performed before therapy (n=34), after VAD (n=20), after bortezomib (n=10). Results were normalized against expression of ABL gene which was used as internal control. *Results.* In primary MM patients: PRAME gene expression was found in 62% (n=21), WT1 in 20% (n=7) of patients, all of whom were exclusively PRAME-positive. In primary MM patients the XIAP gene expression was found in 100%. In the control group of healthy donors (n=8) PRAME gene expression was found in 50% (in 4 from 8), WT1 in 12% (in 1 from 8), XIAP in 62% (in 5 from 8). Median PRAME expression level in the group of MM patients was 0.3% and it dramatically exceeds not less than by 100 times the median PRAME expression in the group of healthy donors (0.003%). The level of PRAME expression in the MM group of patients was ranged from 0.001 to 132%, whereas in the donor's group it was never more than 2.5%. The PRAME hyperexpression (>2.5%+3SD) was found in 4 patients (11.7%). Median WT1 expression level was 0.01% in the case of MM patients and it was about 6 times higher than the median WT1 expression in the group of healthy donors (0.0017%). The range of WT1 expression in the group of MM patients was from 0.002 to 2.5%. Median XIAP expression level in the MM patient's group was more than 10 times as intensive if compare it with the case of healthy donors (28% vs. 2%). The minimal level of XIAP expression in MM patients was comparable with healthy donors,

but maximal level of its expression in MM patients reached 5382%, whilst in the donor's group it did not exceed 28%. The XIAP hyperexpression (> than healthy donor median 28%+3SD) was found in 27 patients (79%). It was found that PRAME, WT1 and XIAP expression did not correlate with tumor bulk and was independent of the levels of M-protein, β-2M and albumin. In the patients with high primary PRAME expression (>2.5%+3SD) the frequency of CR+PR was significantly lower than in PRAME-negative primary patients and in patients with low (<2.5%+3SD) primary PRAME expression (25% vs 75%) (p=0.06). Moreover, the higher was PRAME expression at the start of treatment, the less efficient and durable was response on the VAD treatment. The level of the XIAP gene expression significantly decreased during bortezomib treatment, in good responders nearly reaching the normal values according to healthy donor control. In the MM patients who achieved CR + PR after 4-6 courses of bortesomib + dex (n=6), expression of XIAP reduced from 11-325% (median 66%) to 1-123% (median 20%). On the contrary, in the MM patients with poor response after 4-6 courses of bortesomib + dex (n=4), we observed increased expression of XIAP from 16-127% (median 36%) to 22-528% (median 121%). The expression of PRAME significantly decreased after 3 VAD cycles to 0.001-20,7% (n=10), at the moment of auto-SCT it was 0.001 -6.1% (n=6) and after auto-SCT it was 0.004-4.9% (n=9). However, in the case of WT1, we observed that expression increased after 3 VAD cycles to 0.004-0.07% (n=5) and at the moment of auto-SCT it was 0.001-0.4% (n=6) and after auto-SCT - 0.0193-2.03% (n=7). It is worth mentioned that during the treatment in a small number of initially negative PRAME and WT1 gene patients, we demonstrated that these genes became activated. Thus, during the therapy we detected de novo activation of these genes expression up to low levels in 1 of 13 initially negative PRAME (6.1%) and in 8 of 26 initially negative WT1 (range of level 0.01-1.03%). Interestingly, the detection of de novo PRAME and WT1 gene expression did not correlate with disease status, which may be explained that period of observation was rather short. All these patients achieved still maintained CR+ VGPR. In one of the secondary positive patients (who acquired reappearance of PRAME and WT1) relapse occurred, with highly elevated expression of PRAME (104%), WT1 (0,62%) and XIAP (1264%). *Conclusions*. Expression of PRAME gene was found in 62% primary patients and the level of PRAME decreased according to tumor reduction which renders this gene to be a useful molecular marker of treatment efficiency. High expression level of PRAME turned out to be a factor of unfavorable prognosis of MM. Expression of WT1 was found in 20% of MM patients, all of whom were PRAME-positive. WT1 expression increased during treatment in a small group of pts. Some initially negative pts acquired PRAME and WT1 expression during treatment, but clinical relevance of it is not clear so far. In MM patients at diagnosis, the level of the XIAP expression is higher than in the normal control group. The decrease of the XIAP expression correlates with the chemotherapy and especially with the proteasome inhibitor treatment efficiency. XIAP expression comes to the normal values at the time of CR and PR achievement.

1577

CHANGES IN ACTIVATORY AND INHIBITORY NK RECEPTORS ASSOCIATED TO THE PROGRESSION OF MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE TO MULTIPLE MYELOMA: IMPLICATIONS FOR TUMOR EVASION OF T AND NK CELLS

P. Garrido Collado,[1] M. Bernal,[2] P. Jiménez,[2] R. Carretero,[2] M. Almagro,[2] P. López,[2] P. Navarro,[2] F. Garrido,[2] F. Ruiz-Cabello[2]

[1]Hospital universitario Virgen de las Nieves, GRANADA, Spain; [2]Hospital Universitario Virgen de las Nieves, GRANADA, Spain

Background. Monoclonal gammopathy of undetermined significance (MGUS) is characterized by the presence of a monoclonal (M) protein in persons without evidence of plasma cell neoplasia. MGUS was considered to be benign, however a 1% of patients per year evolve to symptomatic monoclonal gammapathy constituying a premalignant state for transformation to Multiple Mieloma (MM). The molecular basis of MGUS progression to a malignant monoclonal gammopathy remains poorly understood. AIMS In this study, we examined the immunogenic differences of plasma cells from patients of non-gammopathies and plasma cells from MGUS and myeloma. We studied continuous changes in MHC class I expression, MICA and CD95 during the malignant transformation and progression of plasma cells. *Design and Methods*. We studied bone marrow (BM) of patients with diagnosis of MGUS (n=6) or MM (n=6) based on estandar criteria and no treatment were receiving at the day of the immunophenotype analysis. We also select by flow cytometry and cytology 5 BM donors. Samples were analyzed by the FACSCanto cytometer and the FACSDiva software (BD Biosciences) was used for data analysis. Were processed by direct staining using the following monoclonal antibodies (mAb): anti-CD38, anti-CD138, anti-CD95, anti-HLA-ABC and anti MICA-MICB directly conjugated with fluorescein isothiocyanate (FITC), phycoerythrin (PE) and allophycocyanin (APC). Significance levels were determined by Student t test analysis. P values of 0.05 or less were considered significant. RESULTS We detected high levels of MHC class I expression in plasma cells from donors without monoclonal gammopathy, that are increased in MGUS and the highest levels of expression were detected in MM plasma cells. Malignant transformation in MM is associated to upregulation of MHC class I surface expression in plasmatic cells. While the activating NKG2D ligand MICA expression was the opposite: lower in MM, intermediate levels in MGUS and the highest expression in donor cells. The differences found were significant between plasma cells from donor and MGUS and between MGUS and MM cells .The expression of CD95 in MM varied considerably and appear associated with the induction of programmed cell death to anti-FAS mab. We also observed a significant reduction of expression of FAS in MM cells surface (p<0.001). Changes in these molecules expression could deeply affect the balance between activatory and inhibitory signals that regulates NK cells actitity. *Conclusions*. Our results show that the phenotype MHC class I bright, MICAdim/- , CD95 dim/- is clearly associated to progression of MGUS cells to myeloma. It is possible that, both innate and adaptative response maintains the tumor cells in an equilibrium state (MGUS) and evolve into MM only when the cells become edited promoting tumor escape from immunosurveillance. Additionally, our findings are also in agreement with previous reports that support the key role of NK cells in controlling myeloma progression.

1578

COMPARISON OF SERUM PROTEIN IMMUNOFIXATION ELECTROPHORESIS, SERUM FREE LIGHT CHAINS AND HEAVY/LIGHT CHAIN RATIOS FOR MONITORING IGA MULTIPLE MYELOMA PATIENTS

J. Harding,[1] C.D.E. Margetts,[1] N.J. Fourrier, M.T. Drayson,[2] G.P. Mead,[1] A.R. Bradwell[2]

[1]Binding Site Ltd, BIRMINGHAM, UK; [2]University of Birmingham, BIRMINGHAM, UK

Background. IgA multiple myeloma (MM) patients are difficult to monitor when the monoclonal band co-migrates with other proteins on serum protein electrophoresis (SPE) gels. While immunofixation (IFE) is more sensitive than SPE, it is not quantitative. If there are adequate concentrations of serum free light chains (FLC), they can be used to monitor responses to treatment but this leaves some pure IgA producing tumours that cannot be monitored properly. Recently, immunoassays that separately measure IgA-κ and IgA-λ molecules (targeting heavy chain/light chain conformational epitopes - HLC) have been described and IgA-κ/IgA-λ ratios can be derived in the same manner as FLCs. These assays can be used to characterise and monitor patients with IgA MM alongside conventional measurements. Aims To assess SPE, IFE, HLC and FLC ratios for analytical specificity and sensitivity when monitoring patients with IgA MM. *Design and Methods*. FLC, IgA-kappa and IgA-λ analyses were performed on a Siemens Dade-Behring BN'II nephelometer while SPE and IFE were performed on a SEBIA Hydrasys' electrophoresis system. 191 blood donor sera were used to produce normal ranges. 31 IgA MM patients (22 IgA-kappa and 9 IgA-lambda) were assessed through the course of their disease using between 3 and 45 (mean 14) time points per patient. Results By SPE and IFE, 12 patients achieved a partial response (PR), 18 patients achieved a complete response (CR) and 1 patient had no response recorded. 5 patients had no obvious paraprotein by SPE, while in a 5 further patients, the monoclonal band migrated with other proteins by SPE so accurate quantification was difficult. In all patients achieving a PR, FLC and HLC ratios remained abnormal. In 9 patients achieving a CR, FLC and/or HLC ratios were more sensitive than SPE and/or IFE. In 4 patients, changing FLC ratios or HLC ratios were discordant, indicated the presence of more than one tumour clone. In 3 patients, FLC ratios became increasingly abnormal whilst HLC ratios and SPE remained unchanged or decreased, indicating "free light chain escape." In 1 patient, the first relapse was predominately with IgA molecules whilst the terminal relapse was with both IgA and FLC molecules. *Conclusions*. Monoclonal IgA proteins can be difficult to identify and measure using electrophoretic techniques because of their co-migration with other molecules. We now report novel immunoassays that separately measure IgA-κ and IgA-λ. When applied to the study of patients with IgA MM, these assays can be more sensitive than SPE and IFE. Using these HLC assays alongside FLC tests provided greater clarity when monitoring changing monoclonal protein expression than electrophoretic techniques.

1579

COMPARISON OF HEAVY CHAIN/LIGHT CHAIN RATIOS WITH IMMUNOFIXATION ELECTROPHORESIS FOR THE DIAGNOSIS OF MONOCLONAL GAMMOPATHIES

C.D.E. Margetts,[1] J. Harding,[1] E. Koulieris,[2] N.J. Fourrier,[1] G.P. Mead,[1] M.C. Kyrtonis,[2] A.R. Bradwell[3]

[1]Binding Site Ltd, BIRMINGHAM, UK; [2]1st Department of Propedeutic Internal Medicine, Athens Medical School, ATHENS, Greece; [3]University of Birmingham, BIRMINGHAM, UK

Background. In screening for monoclonal gammopathies, immunofixation electrophoresis (IFE) is a reflex test for abnormal serum protein electrophoresis (SPE). However, identification of monoclonal proteins using IFE depends upon the observer. To provide better accuracy, immunoassays have been developed that separately measure immunoglobulin-κ (Ig-κ) and immunoglobulin-λ (Ig-λ) molecules based upon recognising specific epitopes between the heavy and light chains (HLC) of immunoglobulins. Ig-κ/Ig-λ ratios can be derived that can be of use in identifying intact immunoglobulin monoclonal proteins. Aims To compare IFE and HLC ratios for identifying patients with monoclonal gammopathies. *Design and Methods*. The immunoassays for HLCs were performed on a Siemens Dade-Behring BN'II analyser. IgA-κ/IgA-λ and IgG-κ/IgG-λ ratios were measured in 150 and 142 blood donor sera respectively to generate a normal range. The 95 percentiles were used for comparison with clinical samples. 98 patient presentation samples were studied. 90 with confirmed multiple myeloma (MM) (9 IgA-κ: 8 IgA-λ: 47 IgG-κ: 23 IgG-λ: 2 free κ: 1 free λ) and 8 with monoclonal gammopathies of undetermined significance (MGUS) (1 IgA-κ: 1IgA-λ: 6 IgG-κ). Monoclonal proteins were also assessed using IFE, SPE (Sebia hydrasysTM) and individual immunoglobulin measurements (Dade Behring) Results Median and 95%ile ranges for the normal sera were: IgG-κ 7.54 g/L (3.92-12.16), IgG-lambda 3.95 g/L (2.28-6.05), IgG-κ/IgG-λ 1.86 (1.13-3.27), IgA-κ 1.41g/L (0.54-2.42), IgA-λ 1.19 (0.50-2.16), IgA-κ/IgA-λ 1.17 (0.69-1.99). Summated IgG-κ + IgG-λ and IgA-κ + IgA-λ correlated well with total immunoglobulin measurements: r2=1.01 and r2=0.97 respectively (Passing Bablock correlation). Abnormal HLC ratios were identified in 17/17 IgA sera and 2/2 IgA MGUS sera. All patient sera with IgG MM, free light chain MM and IgG MGUS had normal IgA HLC ratios. Abnormal HLC ratios were identified in 69/70 IgG MM sera which had a positive IFE. There was a discordant result between HLC and IFE in one IgG MM sample that had a reported total IgG of 18g/L. This sample needs further investigation. 3/6 IgG MGUS samples were identified with abnormal HLC ratios. High levels of polyclonal IgG seen in MGUS and smouldering MM may obscure abnormal HLC ratios and bands in SPE but the clinical relevance is unknown. 15/17 IgA and all free light chain MM had normal IgG-κ/IgG-λ ratios. The two IgA MM sera with abnormal IgG-κ/IgG-λ ratios had less than 3g/L of total IgG. One sample had a ratio of 0.99 falling only marginally outside the normal range. The remaining sample had an abnormal IgG HLC ratio of 0.39 that may indicate a monoclonal protein not detected by IFE. *Conclusions*, 86/87 intact immunoglobulin MM sera and 5/8 MGUS sera had abnormal HLC ratios. The data indicates that HLC ratios could be used as a reflex test to abnormal SPE and the uncommon remaining unclassified sample could be tested by IFE. Such a testing algorithm would remove the subjective nature of IFE.

THE BISPHOSPHONATE IBANDRONAT REDUCES EXPRESSION OF RECEPTOR ACTIVATOR OF NUCLEAR-KB LIGAND IN BONE MARROW STROMAL CELLS DERIVED FROM MULTIPLE MYELOMA PATIENTS

M. Fernandez, P. Figueroa, J.P. Rodriguez, G. Alarcon

University of Chile, SANTIAGO, Chile

Background. Much of the morbidity and mortality associated with multiple myeloma is attributed to the severe osteolytic bone disease seen in patients with this disease. The receptor activator of nuclear factor-κB ligand (RANKL) and interleukin-1β are osteoclast activating factors which are abnormally expressed in bone marrow stromal cells and plasma cells of myeloma patients, respectively. *Aims*. In this study we assessed the effects of the biphosphonate ibandronate on RANKL mRNA steady state levels and protein production in bone marrow stromal cells obtained from multiple myeloma patients. Furthermore, we also evaluated the effect of ibandronate on the activation of MAPK signalling pathway induced by IL-1β. *Design and Methods*. Bone marrow mononucleated cells from 10 newly diagnosed multiple myeloma patients were separated by Ficoll-Hypaque density gradient centrifugation. Adherent cells were cultured and expanded in α-MEM supplemented with 10% fetal calf serum at 37°C in 5% CO2 humidified atmosphere. Cells were cultured in the presence of 5 mM ibandronate and/or 5 ng/mL IL-1β during selected times. At the end of the culture period mRNA for RANKL and protein levels were assayed by RT-PCR and western blot, respectively. Human bone marrow stromal cell line HS-5 was used to analyze the effect of IL-1β and ibandronate on the MAPK signalling pathway. All of the patients were stage III, classified according to the Durie-Salmon classification. Bone marrow samples used in this study were obtained from patients who provided a written informed consent according to Institutional Review Board Guidelines. *Results*. Ibandronate reduces RANKL mRNA and protein produced by bone marrow stromal cells. IL-1β increases the expression of RANKL mRNA and protein; nevertheless, this increase is neutralized by the presence of Ibandronate in the culture medium. Furthermore, IL-1β also significantly increases the ratio of pERK1,2/ERK1,2 on HS-5 cell line; although in the presence of ibandronate the ratio is similar to that of the control. *Summary and Conclusions*. In bone marrow stromal cells from newly diagnosed multiple myeloma patients, ibandronate may abrogate RANKL expression induced by interleukin-1β acting as an inhibitor of extracellular signal-regulated kinase.

Funds: FONDECYT # 1071114.

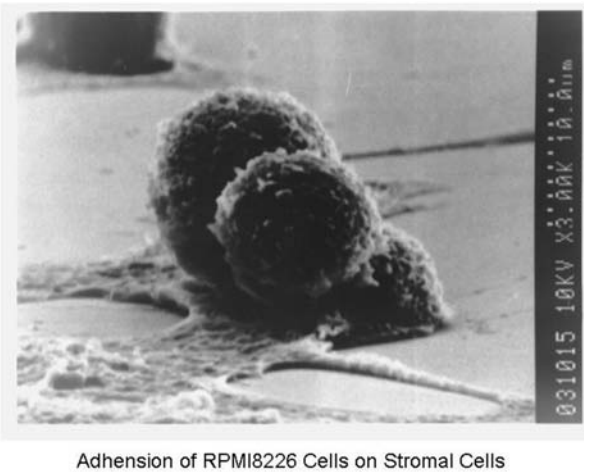
EFFECTS OF BONE MARROW FIBROBLASTOID STROMAL CELL ON THE PROLIFERATION AND SENSITIVITY TO CHEMOTHERAPY OF MULTIPLE MYELOMA CELL RPMI8226

Q.X. Bai, X.Q. Jin

Xi Jing Hospital, XI'AN, China

Background. Myeloma cells predominantly localize in bone marrow and rarely occur in peripheral blood and invade other organ, which is closely associated with the bone marrow microenvironment. More attention is paid to the effect of bone marrow stromal cells (BMSCs) on myeloma cells. We established co-culture system of normal human bone marrow fibroblastoid stromal cell lines HFCL cells with multiple myeloma cell lines RPMI 8226 cells (non-IL-6 dependent) and investigated the effects of HFCL cells on the proliferation and response to chemotherapeutic agents of RPMI8226 cells in the co-culture. *Aims*. To investigate the effects of HFCL cells on the proliferation and sensitivity to chemotherapy of RPMI8226 cells in the co-culture. *Design and Methods*. Setting up co-culture system of RPMI8226 cells with HFCL cells, and dividing into direct and indirect co-culture (transwell group). The adhesion ratio was determined by MTT colorimetric assay; the mitotic index (MI) of RPMI8226 cells was observed by Wright-Giemsa staining. Flow cytometer and Western Blot were used to study the changes of cell cycle and expression of proliferating cell nuclear antigen (PCNA), respectively. In cytotoxicity assays, cell viability was determined by MTT.



Adhension of RPMI8226 Cells on Stromal Cells

Figure 1. An electron microscope image.

Results. In co-culture experiment, the adhesion ratio of RPMI8226 after 1 hour was 29.4%. Growth curves show the proliferation of RPMI8226 cell in direct contact with HFCL cell was inhibited as compared with control, no obvious changes were observed in RPMI8226 cell separated by transwell inserts. After 72h co-culture, the percentage of G1, S phase of RPMI8226 cells in suspension was 33.6% , 52.1%(control group); the percentage of G1 phase of RPMI8226 cells in direct contact culture was

higher than that in transwell group (40.4% vs. 30.6%), and the percentage of S phase of RPMI8226 cells in direct contact culture was lower(40.8% vs. 49.1%) $p<0.01$. Moreover, the MI of RPMI8226 cell in transwell group was higher than that of direct contact group (1.4%±3.4%±3%±1.8%±1.6% *vs.* 1.2%±2.6%±2%±0.8%±0.4%) when cells co-cultured for 1 to 5 days. The expression of PCNA in RPMI8226 cell in transwell group was higher than direct contact group after 72h in co-culture. The dose-effect curves showed that HFCL cells diminished RPMI8226 cells death when exposure to mitoxantrone, vincristine, doxorubicin, topotecan after 72h co-culture in direct contact group. *Conclusion*. The HFCL cells could inhibit the proliferation and progression of cell cycle of RPMI8226 cells. Moreover HFCL cells could diminish the effects of chemotherapeutic agents on RPMI8226 cells in cell-cell contact co-culture.There might be cell adhesion mediated drug resistance beteen stromal cell and myeloma cell.

1582

FLOW CYTOMETRIC MINIMAL RESIDUAL DISEASE MONITORING IN MULTIPLE MYELOMA AFTER BONE MARROW ALLOGENIC TRANSPLANTATION

I. Safra

Pasteur Institut of Tunis, TUNIS, Tunisia

Background: Multiple myeloma is caracterised by an increased number of clonal plasma cells in bone marrow witch produce a monoclonal immunoglobulin. Intensive treatment of patients and stem cell infusion indication results in more complete remission, even free survival and overall survival than treatment with conventional chemotherapy.*Aims*. Flow cytometry (FCM) is applicated in order to investigate whether the number of residual tumour cells in multiple myeloma after bone marrow allogenic transplantation (BMT) can predict the duration of response. *Design and Methods.* FCM investigation was used to mesure tumour load in bone marrow at six months intervals post bone marrow graft in eleven patients. 40 bone marrow samples were analysed. 4 *Results*. FCM can detect malignant plasma cells in 36 samples from 40. The number of plasma cells range from 0.01 10-2 to 7 10-2. The results of minimal residual disease(MRD) after a median follow up of five years post BMT are presented in this table Course of MRD announce clinical relapse or stability of tumour load. *Conclusions*. FCM is a reproducible and simple method of detection of MRD in myeloma, both course of MRD and quantification of malignant palsma cells are important to predict prognosis.

Table.

Statut of disease	Complete remission	Partiel remission	Relapse
Number of patients	7	1	3
MRD	$< 0.5\ 10^{-2}$	$2<MRD<5\ 10^{-2}$	$>5\ 10^{-2}$

1583

DENDRITIC CELL COUNTS AND THEIR SUBSETS IN MULTIPLE MYELOMA PATIENTS BEFORE AND DURING TREATMENT

A. Karamoutsios, A. Petsiou, A. Chatzigianni, N. Kolaitis, K. Bourantas, G. Vartholomatos

University Hospital of Ioannina, IOANNINA, Greece

Background. Dendritic cells (DCs) are antigen-presenting cells that are pivotal for the initiation of the primary immune response by stimulating naïve resting T cells. After loading with relevant antigen, anti-tumor immunity can be induced in patients with multiple myeloma (MM). Thus, immunotherapeutic applications could be based on DCs attributes. Recent advances allow accurate quantification of peripheral blood myeloid and plasmacytoid DC populations (mDC and pDC, respectively). *Aims*. The quantitative determination of mDC and pDC subsets of DCs in peripheral blood of patients with multiple myeloma, before and after treatment using the technique of 3-colour fluorescence flow cytometry. *Design and Methods*. In this study we analysed the proportion of mDC and pDC subsets of DCs in peripheral blood of 17 patients with MM (5 newly diagnosed and 12 under treatment patients) compared to 9 healthy volunteers. Flowcytometric determination of relative and absolute cell counts in peripheral blood was based on the expression of surface antigens CD14+16 and CD85k (Beckman Coulter Monoclonal Antibodies). Depending on the expression of CD33 or CD123, we divided these cells into CD33+ dendritic cells (mDC) and CD123+ DC (pDC). The samples were analysed by BD FACS Calibur cytometer. *Results*. Flowcytometric analysis was performed by Cell Quest software and showed a sufficient reduction in both subsets compared to the healthy humans' average counts and a greater reduction in pDC subset. *Conclusions.* Although the study population was small to detect precise conclusions, we did observe a tendency of reduction in peripheral blood DCs of MM patients. Interestingly, the proportion of both DC subsets is remarkably reduced in under treatment patients compared to new diagnosed patients.

Table 1. Proportion of dendritic cells in peripheral blood.

	% mDC	CV (mDC)	% pDC	CV (pDC)
MM patients	0,254	0,130	0,160	0,124
Healthy Controls	0,481	0,199	0,548	0,224

A NEW METHOD FOR DIFFERENTIATION BETWEEN AMYLOIDOGENIC AND NON-AMYLOIDOGENIC HUMAN IMMUNOGLOBULIN LIGHT CHAINS USING RIGID FIBRILLAR NANOSTRUCTURES AS MARKERS

P. Spólnik,[1] L. Konieczny,[1] J. Rybarska,[1] B. Stopa,[1] B. Piekarska,[1] A. Jagusiak,[1] J. Spólnik[2]

[1]Collegium Medicum Jagiellonian University, CRACOW, Poland; [2]KMG Klinikum Wittstock, WITTSTOCK, Germany

A number of devastating human diseases, including the amyloidoses, originate from the aggregation of structurally unstable proteins. Progressive renal dysfunction caused by the deposition of partially unfolded monoclonal proteins is, apart from infection, the commonest cause of death in patients suffering from multiple myeloma. To obtain insight into the pathogenesis of amyloid and non-amyloid renal precipitate formation we prepared a new rapid method of assessing the aggregation processes *in vitro*. The solution of human immunoglobulin light chains obtained from urine of patients with multiple myeloma was added to Congo red dye which was maintained in an electric field for the arrangement of its rod-like supramolecular nanostructures. The scaffolding efficacy was created due to higher rigidity of used dye nanoparticles which resulted from stronger stacking of molecules at low pH because of decreased charge repulsion. In this environment many of the monoclonal proteins were deposited during complex formation between the assembled molecules. This precipitation was observed by light microscopy with polarization equipment and electron microscopy. The properties of the obtained aggregates differ between light chains. Among amorphous granular material some light chains were able to form fibrillar structures with typical amyloid properties. This rapid precipitation may also suggest that the process of amyloid formation, under these conditions, may bypass the nucleation step. Our study supports this new rapid and easy diagnostic technique, which allows control and formation of immunoglobulin light chain aggregates *in vitro*. Thus the amyloidogenic tendency of Ig monoclonal light chains in urine could easily be tested.

1585

CYTOGENETIC ABNORMALITIES IN 40 SLOVENIAN MULTIPLE MYELOMA PATIENTSK

Trdina, H. Podgornik, P. Cernelc

University Medical Center, LJUBLJANA, Slovenia

Background. Multiple myeloma is a plasma cell malignancy characterised by complex karyotypes that show both numerical and structural chromosomal alterations. The non-random recurrent nature of chromosome abnormalities in myeloma suggests a role for them in disease pathogenesis. Virtually all multiple myeloma patients are characterised by the occurrence of aneuploidy, and can be divided into two major groups; hyperdiploid group, associated with recurrent gains of some, if not all, of the non-random odd chromosomes 3, 5, 7, 9, 11, 15, 19 and 21; and non-hyperdiploid group, which includes the hypodiploid, pseudodiploid and near-tetraploid karyotypes. The most recurrent chromosomal rearrangements involve deletion of chromosome 13 (del(13)), deletion of chromosome 17 (del(17)) and chromosomal translocations juxtaposing the immunoglobulin heavy chain (IGH) regulatory regions at 14q32 with a wide spectrum of partner loci (11q13, 6p21, 4p16, 16q23 and 20q11) leading to dysregulation of CCND1, CCND2, FGFR3/MMSET, c-MAF and MAFB respectively. *Aims*. Recent publications suggest that multiple myeloma is also associated with amplifications of 1q, deletions of 1p and deletions of 6q. It was also suggested that amplifications of 1q are associated with progression and drug resistance. Moreover, it was suggested that deletions of 1p impart poor prognosis. Deletions of 6q are more frequent in hypodiploid multiple myeloma patients that is associated with poor prognosis. Amplifications of 15q represent chromosomal abnormality belonging to hyperdiploid multiple myeloma that is associated with more favourable prognosis. Therefore, we investigated following chromosomal abnormalities: amplifications of 1q, deletions of 1p, deletions of 6q and amplifications of 15q in patients, where occurrence of del(13)(q14.3), translocation t(4;14), translocation t(14;16) and del(17)(p13.1) has been already tested by fluorescence *in situ* hybridization (FISH). Additionally, conventional cytogenetics with G-banding method was previously performed for majority of patients. *Design and Methods*. Chromosomal abnormalities were tested by commercially available FISH DNA probes in 40 multiple myeloma patients. Within this group of patients, subpopulation of patients had an isolated del(13) and 10 patients had no chromosome abnormalities. Remaining patients were subdivided into groups with t(4;14), t(14;16), del(17)(p13.1) and complex chromosomal rearrangements. *Results*. We were not able to confirm the deletion of 1p in multiple myeloma patients. Amplification of 1q was detected in patients that had concomitant deletion of chromosome 13. Patients with detected deletion of 6q had no other chromosomal abnormality. Patients with detected amplification of 15q were equally distributed among the two groups. *Conclusions*. The results obtained in this study indicate that amplifications of 1q and deletion of chromosome 13 are highly associated. The prognostic significance of these abnormalities highlights the importance of cytogenetic results of multiple myeloma patients.

1586

EPIDEMIOLOGY OF PLASMA CELL DYSCRASIAS IN EGYPT: A SINGLE INSTITUTE EXPERIENCE

N. Kassem, R. Metwally, S.H. Lasheen

Kasr-el-Aini Oncology Centre, Cairo University, CAIRO, Egypt

Background. Plasma cell dyscrasias (PCD) are a group of diseases characterized by the proliferation of a plasma cell clone which produces a monoclonal protein (M- protein).The most common type is Multiple Myeloma (MM) followed by Waldenstroms macroglobulinaemia (WM) and Light chain disease (LCD). Hypocalcaemia, anemia, renal damage, increased susceptibility to bacterial & fungal infections, and impaired production of normal Immunoglobulins as well as diffuse osteoporosis are common clinical manifestations of MM (*Grethlein S, medicine_MM_2004*).Thus, plasma cell dyscrasias present in different fields of clinical practice, making it of great interest to study the epidemiology of this disease. *Aims*. In the present study, we described the epidemiological aspect of PCD presenting to our oncology unit of Cairo university hospitals during eight years period of time. *Design and Methods.* We retrospectively reviewed the medical records of patients diagnosed with MM, WM and LCD in our unit from January 2001 through February 2009. Results: The study included 203 newly diagnosed and untreated PCD patients, 125 Males / 78 Females, with a mean age 45years (range 28-70). 181 were affected by MM (89.1%), 13 by WM (6.5%) and 9 by LCD (4.4%). IgG myeloma was diagnosed in 132 (72.9%) patients, IgA myeloma in 49 (27.1%).K light chain in urine was found in 139 (68.4%) patients and λ in 64 (31.6%) .The International Staging System (ISS) using β2 micro globulin and albumin as staging parameters was applied to classify 115 patients out of 203; accordingly 41 patients were found to be in stage I, 71 in stage II and 3 in stage III. *Conclusions*. This descriptive study enabled us to identify the pattern of distribution of different PCD referred to our unit, drawing our attention to the increased incidence in females & to the younger age at presentation (down to28 and 32 years old).Further collaborative studies in association with other institutions will help establish the Egyptian configuration of PCD needed for prospective individualization of therapeutic guidelines.

1587

TARGETING ANGIOGENESIS VIA A C-MYC/HIF-1α-DEPENDENT PATHWAY IN MM

K. Podar,[1] J. Zhang,[1] G. Tonon,[1] C. Grabher,[1] S. Lababidi,[1] A. Zimmerhackl,[1] M.R. Raab,[1] S. Sonia,[2] Y. Zhou,[3] M.A. Cartron,[3] Y.T. Tai,[1] T. Hideshima,[1] D. Chauhan,[1] K.A. Anderson[1]

[1]Dana-Farber Cancer Institute, BOSTON, USA; [2]MGH, BOSTON, USA; [3]Myeloma Institute for Research and Therapy, University of Arkansas for Medical S, LITTLE ROCK, USA

Background. Bone marrow (BM) angiogenesis is associated with multiple myeloma (MM) progression. *Aims*. to identify potential pathophysiologic role of Hif-1α in MM cells under normoxic conditions. *Results and Methods*. Here we report high constitutive hypoxia-inducible factor-1*Design and Methods* (Hif-1α) expression in MM cells, which is associated with oncogenic c-Myc. A drug screen for anti-MM agents which decrease Hif-1 and c-Myc levels identified a variety of compounds including bortezomib, lenalidomide, enzastaurin, and adaphostin. Functionally, based on transient knockdowns and overexpression, our data delineate a c-Myc/Hif-1α-dependent pathway mediating VEGF production and secretion. The anti-angiogenic activity of our tool compound adaphostin was subsequently demonstrated in the zebrafish model and translated into a preclinical *in vitro* and *in vivo* model of MM in the BM milieu. *Conclusions*. Our data therefore identify Hif-1α as a novel molecular target in MM and add another facet to anti-MM drug activity.

1588

CYTOKINES BEHAVIOR IN MULTIPLE MYELOMA PATIENTS DURING ZOLEDRONIC ACID TREATMENT

A.O. Annibali,[1] M.T. Petrucci,[2] M.C. Tirindelli1, B. Giannetti,[1] R. Foà,[2] G. Avvisati[1]

[1]University "Campus Bio-Medico", ROME, Italy; [2]University " La Sapienza", ROME, Italy

Background. Multiple myeloma (MM) is characterized by uncoupling of bone resorption from bone formation which leads to the predominance of resorption. Bisphosphonates are chemical compounds which selectively concentrate at the interface of the active osteoclasts and the bone resorption surface where they inhibit osteoclast activity. Aim of this study was to demonstrate whether or not zoledronic acid could have an *in vivo* anti-angiogenetic property in MM as observed in solid tumors. *Design and Methods*. Serum samples from 29 (16 males and 13 females) consecutive MM patients with lytic bone lesions treated with 4 mg of zoledronic acid were tested for PDGF, VEGF, IL6, TNF α, and IGF-I any form of treatment. Basal cytokine levels were compared with the values observed after 1, 2, 7 and 21 days of treatment, using the Wilcoxon's test for nonparametric-dependent continuous variables. *Results*. A significant increase in IL-6 and TNF α was observed on days 1 and 2. As for VEGF, the levels of this cytokine did not change significantly from basal values during the entire period of observation except for day 7 (p=0.0005). Moreover, PDGF significantly decreased (p=0.005) after 2 days following zoledronic acid infusion, unexpectedly followed by a statistically significant increase of VEGF on day 7. Furthermore, these two cytokines remained mainly within the normal range throughout the entire period of study. *Conclusions*. in MM, treatment with Zoledronic acid has little activity on the angiogenetic cytokines VEGF and PDGF , therefore, the anti-myeloma effect of this drug may be operational through other mechanisms.

1589

INFLUENCE OF C-REACTIVE PROTEIN ON PROLIFERATION OF U266 CELLS

Y.P. Ma, Y.R. Yang, L.J. Huang, L.H. Yang

Second Affiliated Hospital of Shanxi Medical University, TAIYUAN, China

Background. C-reactive protein (CRP) is a nonspecific but sensitive marker of inflammation. Interleukin-6 (IL-6), IL-1, and tumor necrosis factor α induce the synthesis of CRP in hepatocytes.It may contribute to the pathogenesis of cardiovascular disorders,and can be upregulated in many malignancies,such as multiple myeloma. As report,when CRP accessing 80 mg/L, patient's condition make advancement quickly.But whether CRP could improve the MM cells proliferation directly is unknow.Aims: The influence of C-reactive protein on proliferation of U266 cells was investigated in this experiment.*Design and Methods*. The human multiple meyloma cell lines U266 were incubated with human CRP(0, 5, 10, 20 mg/L) for 24 hours,then analyzed by blood analyser for proliferation ratio.The effects of CRP in U266 cells in various concentrations on Survivin, Hsp90α mRNA expression were examined by RT-PCR. *Results*. The proliferation ratio increase compared to the control group ($p<0.05$), further more up regulated Survivin/Hsp90α at mRNA levels in proportion for increased CRP concentrations. There were significant correlations between Survivin and Hsp90α (r=0.737, $p<0.0001$) in incubated cells. *Conclusions*. These results demonstrate that CRP could encourage the proliferation of MM cells directly by upregulating the expression of Survivin and Hsp90 in MM cells. CRP could be regarded as a potential target for MM treatment.

1590

EVALUATION OF PROGNOSTIC STAGING SYSTEMS FOR MULTIPLE MYELOMA IN THE ERA OF BORTEZOMIB

N. Wee, D. Tan

Singapore General Hospital, SINGAPORE, Singapore

Background. Multiple myeloma (MM) has an indolent clinical course with marked variability in survival outcomes. Hence, a staging system with prognostic reliability is crucial in clinical practice. *Aims*. We sought to compare the overall survival (OS) of patients with MM managed in our institution according to the Durie-Salmon Staging System (DSSS) and International Staging System (ISS), overall, and with respect to the treatment eras before and after the introduction of bortezomib. *Design and Methods*. Retrospective analysis of demographic data, clinical features and OS of all MM patients diagnosed between 1997 and 2006 was conducted. The patients were staged according to the DSSS and ISS, and OS curves were estimated by the Kaplan-Meier method, and differences compared using the log-rank test. *Results*. The OS for all patients (N=222) was 5.2 years with a median age of 62 years. 63 of the patients (28.4%) received bortezomib as treatment for relapsed disease. According to DSSS, 23 (10%) were classified in stage I, 66 (30%) in stage II and 133 (60%) in stage III, with median OS not reached in stage I, 5 years in stage II and 4.1 years in stage III (p-trend=0.01). According to ISS, 45 (20%) were classified in stage I, 101 (46%) in stage II and 76 (34%) in stage III, with median OS of 8.7, 5 and 3.3 years respectively (p-trend<0.001). Compared to DSSS, the ISS was simpler, with a higher prognostic power and more statistically significant differences in survival outcomes. However, when the survival outcome was stratified by exposure to bortezomib, both DSSS and ISS were not able to prognosticate clinical outcome. *Conclusions*. We have validated the usefulness of the ISS in clinical practice. However with the advent of bortezomib, the ISS may be insufficient for prognostication and a separate system incorporating genetic biomarkers will be essential.

1591

PATIENT RESPONSE TO BORTEZOMIB IN RELAPSED/REFRACTORY MULTIPLE MYELOMA: INTERIM RESULTS FROM AN OBSERVATIONAL STUDY

K. Zervas,[1] E. Katodritou,[2] M. Delforge,[3] H. de Samblanx,[4] D. Sargin,[5] C. Hulin,[6] L. Ahlberg,[7] J. de la Rubia,[8] K. Abdulkadyrov,[9] R. Ganguly,[10] J. Diels,[10] R. Dhawan[10]

[1]Theageneion Anticancer Hospital of Thessaloniki, THESSALONIKI, Greece; [2]Department of Hematology Theagenion Cancer Center, THESSALONIKI, Greece; [3]University Hospital Leuven, LEUVEN, Belgium; [4]ZNA Middelheim, ANTWERP, Belgium; [5]Istanbul University, ISTANBUL, Turkey; [6]Centre Hospitalier Universitaire of Nancy-Brabois, NANCY, France; [7]Hematolog Kliniken Universitetssjukhuset, LINKOPING, Sweden; [8]La Fe Hospital, VALENCIA, Spain; [9]Russian Scientific Research Institute of Hematology and Transfusiology, SAINT-PETERSBURG, Russian Federation; [10]Johnson & Johnson Pharmaceutical Services, RARITAN, USA

Background. The Electronic VELCADE® Observational Study (eVOBS) is a non-interventional study of patients from Belgium, France, Greece, Russia, Spain, Sweden, and Turkey scheduled to receive bortezomib (VELCADE®) therapy for relapsed/refractory multiple myeloma. Data collection includes 1 year of retrospective data before and 3 years of prospective data after initiation of bortezomib. The study initiated in October 2006; this report includes interim response to treatment based on data collected from study start through 21 November 2008. Aims: In this study we assess the response rates of patients treated with bortezomib as well as other clinical parameters of importance for relapsed/refractory multiple myeloma. *Design and Methods*. Given the nature of the non-interventional study, no pre-specified response criteria were mandated to measure patient response; investigators applied several patient response criteria such as M-protein (38%), EBMT (35%), and SWOG (5%) and others (22%) and documented the patient response rates. In this analysis we report the response rate as reported by the study investigators. Response data are continuously being collected prospectively for 3 years. We also report time to response, time to progressive disease and time to next therapy by Kaplan-Meier survival analysis for all patients enrolled through November 2008, using an intent-to-treat approach. The current analysis excluded Spain and Russia due to time lag involved in data availability. *Results*. At baseline a total of 447 patients (58% male, median age 64.5 years) were evaluated. Bortezomib was initiated as 2nd-, 3rd-, and 4th-line therapy in 45%, 28%, and 17% of patients, respectively. 52% of patients received bortezomib in combination with other multiple myeloma agents. At 6 (12) months, 13.3% (17.6%) achieved complete response, 28.6%(32.5%) had at least near complete response, 66.1% (74.7%) with at least a partial response (median=91 days), and 77.7% (82.6%) had at least a minimal response (median=56 days). Within 6 (12) months, 24.1% (40.4%) of the patients progressed or died (median=296 days), 29.2% (83.3%) received alternative treatment (median=211 days) and 55.4% (88.3%) progressed or started subsequent therapy (median=192 days). *Conclusions*. The interim analysis of this current international, prospective, observational study provides preliminary evidence that bortezomib alone or in combination with other multiple myeloma agents used outside the context of a clinical trial improves overall response rates and thus is a reliable and effective option for relapsed/refractory multiple myeloma.

1592

BORTEZOMIB FOR THE TREATMENT OF MYELOMA - THE SCOTTISH EXPERIENCE

A.J.M. Broom, L. Soutar

Beatson West of Scotland Cancer Centre, GLASGOW, UK

Background. Bortezomib is a selective proteosome inhibitor used for the treatment of myeloma. Phase II and III trials demonstrated useful therapeutic effect; however its use was associated with a significant early discontinuation rate due to side effects. The Scottish Medicines Consortium (SMC) accepted its use within the Scottish National Health Service from October 2004 for patients who had already received two lines of therapy. Concerns about toxicity led the Scottish Haematology Society to institute a national audit of Bortezomib use between May and August 2008. *Aims*. The aim was to determine how Bortezomib was being used in Scotland: specifically, to determine the number of treatment courses patients are able to complete; to establish clinical effectiveness in the Scottish population; and to compare practice with treatment advice stipulated by the SMC. *Design and Methods.* A questionnaire was sent to all treating centres in Scotland to be completed retrospectively for up to ten patients who had completed Bortezomib treatment. *Results.* The audit was completed within a three month period with a 100% response rate. 136 completed forms from 18 centres were returned. 79% received Bortezomib in combination with Dexamethasone and 2% received Bortezomib in combination with other chemotherapy. 85% of patients received Bortezomib as third line treatment or greater. The median number of treatment cycles completed was 3 (range 0 to 8). The complete response rate was 12% and the partial response rate 44%. 44% of patients discontinued treatment early due to side-effects: neuropathy, fatigue and gastrointestinal symptoms were the most commonly cited. The median overall survival derived by Kaplain-Meier method was 18 months. The tolerability of Bortezomib in Scotland

was less than expected from the phase III APEX trial data. In this trial, 56% of patients completed at least five cycles of Bortezomib (27% in our audit). Similarly, in APEX 29% completed eight cycles (39% in the earlier phase II SUMMIT trial), in our population only 5%. Despite this, the Scottish overall response rate was superior (56% vs 38%). The differences in response could in part be due to higher concomitant corticosteroid use in Scotland. Our higher overall response rate did not translate to an improved median overall survival. 44% of Scottish patients discontinued Bortezomib early due to side effects compared to 37% in the APEX trial. Peripheral neuropathy was the single most frequent side-effect necessitating early discontinuation in both APEX and Scottish patients. However, the prevalence was much greater in Scotland - 29% vs 8%. This may be due to greater exposure to prior Thalidomide in Scottish patients. Additionally, as Scottish patients generally received more prior therapies than APEX patients, they may have been exposed to other neurotoxins. The combination of Bortezomib with corticosteroids may be associated with higher rates of autonomic neuropathy than single agent Bortezomib. *Summary and conclusions*. In conclusion, the Scottish "real life" experience is that Bortezomib is an effective treatment. It is associated with greater toxicities than seen in clinical trials - this may be a reflection that trial patients are not always representative of "all comers".

PROINFLAMMATORY CYTOKINES PROFILE IN THE PATHOGENESIS OF BONE DISEASE IN MULTIPLE MYELOMA

P. Giraldo,[1] J. Gervas,[1] R. Rubio-Escuin,[1] M. Pocovi,[2] P. Giraldo[1]

[1]Miguel Servet University Hospital, ZARAGOZA, Spain; [2]Biochemistry and Molecular and Celular Biology Department, ZARAGOZA, Spain

Background. Bone disease is one of the most frequent complications in Multiple Myeloma (MM), and as consequence produce irreversible and invaliding lesions. The pathogenesis of bone disease is not completely known. There are some publications about the influence of different cytokines in the bone remodelling, by break the balance between osteoclastic/osteoblastic activities. *Aims*. to study a cytokine panel in a series of MM patients and to compare the results between patients with overt bone disease and without. *Design and Methods*. Between June-December 2008, we have studied a total of 39 MM patients. (IgG 23(60%); IgA 10(25%), LChain: 4; IgD 1, IgG+IgA 1) Females: 23(60%). ISS(1: 60%, 2: 32%, 3:8%) and 25 healthy controls matched by gender and age. The cytokine assay was performed in plasma according Luminex®100 technology with the Millipore human cytokines Kit, the designed panel were: IL-4, IL6, IL-7, IL-10, IL-13, MIP-1a, MIP-1b, 'NF- α. Four different degrees of bone disease was established: Osteolisis 55%, vertebral collapse 35%, osteopenia 10%. The results of the cytokine panel were compared with the variables: immunochemical subtype, ISS stage, haemoglobine concentration and free light chain ratio and with response to therapy. Descriptive analysis and mean comparative chi2 test was performed. *Results*. In this series the cytokine profile more frequent had been over expression of IL-6, IL-10, MIP-1b. The comparative analysis of profiles and variables show that there are not significant differences according immunochemical subtypes. There are significant differences in IL-10(p=0.05), IL-13 (p=0.01) in patients with low ISS vs high ISS. There are differences according the bone disease degree IL-6 (p=0.04), IL-13 (p=0.02), TNF(p=0.03). Related to haemoglobine <11 g/dL vs >11 g/dL, abnormal vs normal free light chains ratio we not observe significant differences. When we compared complete response to therapy vs failure we observed significant differences in IL-7 p=0.03),IL-10 (p=0.04). *Comments*. In our experience Luminex®100 technology is a sensible and accurate technique useful to determine cytokine profile in plasma. A different significant cytokine profile was observed in patients with different degrees of bone affectation, ISS and therapy response. It is necessary to perform more studies with more patients in order to confirm these results.

This work has been partially sponsored by a grant from CIBERER

AN OBSERVATIONAL POST AUTHORIZATION STUDY ON THE USE OF BORTEZOMIB IN MULTIPLE MYELOMA PATIENTS IN THE NETHERLANDS: RESULTS OF AN INTERIM ANALYSIS

H. Lokhorst,[1] C. van der Heuls,[2] H. Roerdink,[3] O. De Weerdt[4]

[1]University Medical Centre Utrecht, UTRECHT, Netherlands; [2]Internal Medicine, St. Elisabeth Hospital, TILBURG, Netherlands; [3]TweeSteden Hospital, TILBURG, Netherlands; [4]Sint Antonius Hospital, NIEUWEGEIN, Netherlands

Background. Bortezomib (Velcade) is a novel agent in the treatment of patients with Multiple Myeloma (MM). Most data on efficacy and safety are from randomised controlled studies in selected groups of patients with MM. Aim of the study: To evaluate safety and efficacy of bortezomib in real-life daily practice as second and later line therapy in patients with MM. *Design and Methods*. In an observational, multicentre study, the efficacy and safety of treatment with bortezomib, (1.3 mg/m2 on day 1, 4, 8 and 11 with or without dexamethasone) was assessed in MM patients. All enrolled patients consented in the collection of their relevant medical data. An interim analysis was performed on data of patients enrolled from November 04 until November 06 (10^9 patients). *Results*. All results are given as median. The patients age was 67 yrs, Karnofsky Performance Score was 80%, time from initial diagnosis was 3.3 years, 62% of the patients had more than 2 previous treatment lines, 85% of the patients had disease stage III. Patients were treated with median 4 cycles (95% CI: 4.1 - 5.0) of bortezomib. Median time to initial response was 50 days and median time to best response category was 84 days. Of all patients 43.2% achieved a partial response or better (12.9% VGPR or better, 30.3% PR); 16 patients were not evaluable for response. The duration of response (DOR) was 6.3 months. Overall survival was 1.2 yrs and PFS 5.8 months. The treatment was generally well tolerated. Most common adverse events (all grades) in >15% of the patients were in order of decreasing frequency thrombocytopenia, nausea, diarrhoea, fatigue, (poly)neuropathy, constipation, malaise, anaemia, pyrexia, vomiting and anorexia. For responding patients treatment discontinuation due to an AE occurred in 46.8% of the patients. For the three most common AE's (polyneuropathy, fatigue/malaise, thrombocytopenia) resulting in discontinuation of the bortezomib treatment, the discontinuation was not preceded by a dose adjustment in almost half of the cases. In 9 patients (8.3%), Herpes zoster was reported. Twenty-two out of 10^9 patients were thalidomide naïve when starting bortezomib. 59.4% of these patients achieved a PR or better vs. 39% in thalidomide pre-treated patients, but thalidomide pre-treated patients had a longer time from initial diagnosis (3.5 vs 2.6 years) and had more previous treatment lines compared to thalidomide naïve patients (≥2 lines of previous therapy 97.7% vs 59.1% resp). *Conclusions*. Response Rates in this study were comparable to those in other community studies and higher than reported in previous clinical studies. Overall the treatment with bortezomib was well tolerated. However, it seems dose adjustment as a strategy to continue treatment and to increase the quality of response is still used insufficiently. Overall survival was as expected in this patient population. The thalidomide naïve group was yet too small to draw any conclusions on safety and efficacy as compared to the thalidomide pre-treated patients.

1595

FLUDARABINE BASED COMBINATION THERAPY IS HIGHLY ACTIVE AS PRIMARY OR SALVAGE TREATMENT IN PATIENTS WITH WALDENSTRÖM MACROGLOBULINEMIA

S. Peinert,[1] C. Tam,[2] M. Wolf1, D. Westerman,[1] H. Januszewicz,[1] J. Scarlett,[3] H.M. Prince,[1] J.F. Seymour[1]

[1]Peter MacCallum Cancer Centre, MELBOURNE, Australia; [2]St. Vincent's Health Melbourne, MELBOURNE, Australia; [3]Latrobe Regional Hospital, TRARALGON, Australia

Background. Treatment with single agent rituximab (R), alkylating agents or purine analogues is safe and moderately effective as primary treatment for patients (pts) with Waldenström Macroglobulinemia (WM). However, efficacy in relapsed/refractory WM is unsatisfactory. *Design and Methods*. We retrospectively analysed if combinations of fludarabine (F) with alkylators and/or R were safe and more effective. Results From 12/94 - 08/08, 25 courses of at least 2 cycles of intravenous F-combination therapy were administered to 22 pts with WM: FC (F 25 mg/m^2 d1-3, cyclophosphamide (C) 250 mg/m^2 d1-3; n=7); FCR (FC+R 375 mg/m^2 d1; n=14); FM (F+mitoxantrone (M) 10mg/m2 d1; n=3); FR, n=1). The median age of pts was 57yrs [range; 36-89], 18/22 (84%) male, 6 pts received F-combination as their primary treatment (24% of courses). The

19 pre-treated pts had a median number of 2 [1-7] prior treatments, prior F-exposure in 5 cases (20%), 9 pts (36%) were alkylator-refractory. The median time from diagnosis to F-based treatment was 23 Mo [0-153], baseline paraprotein (PP) 30g/L [7-64]. A total of 99 cycles were administered, median 4 [2-6] per pt. Treatment was generally well tolerated with 5% infusion reactions grade (G) 2, gastro-intestinal toxicity was mostly limited to G 1 or 2 (35% of cycles) with only one G3 episode, no renal toxicity or hepatic side effects > G 1. G 3 thrombocytopenia occurred in 5%, G ≥3 neutropenia and infections complicated 20% and 3% of cycles, respectively, none of which were life-threatening. However, 3 heavily pre-treated pts subsequently developed secondary AML/MDS (1 fatal) at 56, 61, and 91 Mo post-treatment. The overall response rate (RR) was 21/25 (84%) with a median PP reduction of 90% [30-100%]. One pt achieved a complete remission, 17/25 (68%) had a partial response, resulting in an objective RR of 72%, 3 responses (12%) were minor (PP-reduction of 25-<50%). The median times to response and maximum response (PP nadir) were 2.6 [0.7-7.3] Mo and 9.5 [0.9-47.5] Mo, respectively. The median event free survival (EFS) for all pts was 43.4 [0.9-113.6] Mo, the median overall survival (OS) was not reached. With a median follow-up of surviving pts of 59 Mo, the 5- and 10-year-actuarial survival rates were 85±8%, and 68±13%, respectively. With a median follow-up of 51 Mo [13-97], all 6 previously untreated pts remain alive and progression-free. The RR was independent of pre-treatment status whereas untreated pts had superior EFS but not OS compared to alkylator-refractory pts (p=0.01 and 0.29, respectively). Neither R administration nor the known adverse prognostic factors age >60 years or increased baseline β^2 microglobulin impacted on EFS or OS. Anemia (Hb <100 g/L) resulted in a trend for reduced EFS (43 Mo vs. not reached, p=0.05), but not OS (p=0.24). *Conclusions*. We conclude that F-combination therapy is highly active in patients with untreated as well as in those with alkylator-refractory WM, leading to high response rates and prolonged remissions. However, possible contribution to the cumulative risk of treatment-related MDS/AML in heavily pre-treated pts is a concern.

1596

ANTITUMOR ACTIVITY OF BORTEZOMIB RETREATMENT IN RELAPSED OR REFRACTORY MULTIPLE MYELOMA PATIENTS

N. Skvortsova,[1] T. Pospelova,[2] I. Nechunaeva,[3] S. Kovalchuk[2]

[1]The State Medical University, NOVOSIBIRSK, Russian Federation; [2]State Medical University, NOVOSIBIRSK, Russian Federation; [3]City Hematological Center, NOVOSIBIRSK, Russian Federation

Background. Bortezomib is a proteasome inhibitor with multiple effects on myeloma cell lines and primary myeloma cells. Bortezomib therapy has become an important part of the standard of care for patients with relapsed multiple myeloma, and preliminary clinical evidence suggests that bortezomib retreatment in patients previously treated with the drug may prolong disease control. *Aims*.The aim of this retrospective review of patients with multiple myeloma (MM) was to describe patterns of retreatment with bortezomib-based therapy and responses to retreatment. *Design and Methods*. Data were retrospectively extracted from the medical records of patients treated in Russia Novosibirsk hematologycal center, who were subsequently retreated off protocol with bortezomib-based therapy. Eligible patients had 60 or more days between treatments and > or = 4 bortezomib doses during initial treatment. Response categories included very good partial response (VGPR), > or = 90% M-protein decrease; partial response (PR), 50%-89% decrease; and less than PR (< PR), < 50% decrease, excluding progressive disease (PD). Results. Retreatment response data were available for 26 patients: 3 (12%) had VGPR, 6 (23%) had PR, 8 (31%) had < PR, 7 (27%) had PD, and 2 (7%) died. Thus, the overall response rate for bortezomib retreatment was 64%. During retreatment, 15 (58%) of 26 patients received bortezomib in combination with another antineoplastic agent, 11 (42%) bortezomib alone. Median time between bortezomib treatments was 7.9 months; 31% of patients received non-bortezomib therapy between treatments. Toxicity contributed to discontinuation in 27% of patients during retreatment; rates of neuropathy contributing to discontinuation were 15%, respectively. *Conclusions*. Thus, bortezomib retreatment appears to be safe and effective. Favorable observed response rates with bortezomib retreatment suggest that it may be a viable option for relapsed or refractory multiple myeloma, even in patients previously exposed to bortezomib.

1597

SERUM CONCENTRACION OF C-TERMINAL COLLAGEN TELOPEPTIDE AS AN OSTEOLYTIC LESIONS MARKER IN PATIENTS WITH MULTIPLE MYELOMA

I. Djunic,[1] I. Elezovic,[1] D. Tomin,[1] G. Jankovic,[1] D. Antic,[1] A. Vidovic,[1] J. Bila,[1] M. Marinkovic[2]

[1]Institute of Haematology, Clinical Center of Serbia, Belgrade, BELGRADE, Serbia; [2]Institute of Oncology and Radiology, BELGRADE, Serbia

Background.The degradation product of collagen type I, ICTP, represents a new biochemical parameter which reflects the changes in resorption properties of skeletal system. Affection of the skeleton is one of the most important characteristics of multiple myeloma (MM). Increased resorption of bone mass can exist even in patients where osteolytic changes cannot be found by means of conventional radiography. Aims: The aim of this study was to estimate the correlation between serum levels of C-terminal collagen telopeptide type I (ICTP) and osteolytic changes seen on the conventional skeleton radiography, that is, to estimate the relevance of ICTP as a marker of osteolytic activity and survival prognostic factor, as well as comparison with known clinical parameters of prognostic significance: β2-microglobuline (β2-MG) and C reactive protein (CRP), in patients with MM. *Design and Methods*. In this study were included 25 untreated patients with MM. Following findings were determined initially in all patients: blood count, total proteins, electrophoresis with immune electrophoresis of serum and urine proteins, urea, creatinine, calcium ions (Ca++), β2-MG, CRP, percentage of plasma cells in the bone marrow, and skeleton radiography. Serum level of ICTP was determined with competitive radioimmunoassay (RIA), through ICTP marked with radioactive iodine- I125, and rabbit's polyclonal antiserum as detection reagent. *Results*. A significant difference between patients with and without osteolysis was proved in ICTP (p=0.009), β2-MG (0.011), and CRP (p=0.044) values. In univariate analysis, significante osteolysis predictor was ICTP (p=0.021), β2-MG have been on border of significance (p=0.052), and CRP have not statistical significance (p=0.069), while significant survival predictor were: ICTP (p=0.001), β2-MG (p=0.009), and CRP (p<0.001). In multivariate analysis, ICTP was, compared with β2-MG i CRP, the most powerful osteolysis predictor (p=0.021), whereas CRP was the most powerful survival predictor (p<0.001). There were statistically significant positive correlation between osteolytic changes and level of anaemia (p=0.010), uraemia (p=0.033), increased values of creatinine (p=0.034) and increased values of Ca^{++} (p=0.045). There were statistically significant positive correlations between ICTP and urea values (p=0.038), and creatinine (p=0.015). *Conclusions*. Being highly significant predictor for osteolysis and survival, ICTP can be used for identification of patients with MM who had increased risk for developing osteolytic lesions, as well for identifying patients with poor prognosis in sense of survival. Patients with increased values of ICTP, and without verified osteolytic changes by means of conventional skeleton radiography, are indicated for more thorough diagnostic procedures, e. g. skeleton IMR (magnetic resonance imaging), for more precise detection of osteolysis.

1598

PATHOGENETIC RELATIONSHIP BETWEEN BONE LESIONS AND RENAL FAILURE IN MULTIPLE MYELOMA IS OF 'VITIOUS CIRCLE' TYPE

E. Goranov, S. Goranova - Marinova

University Hospital "Sv.Georgi" Plovdiv, PLOVDIV, Bulgaria

Background. Clinical manifestation and pathogenetic relationship between myeloma bone disease (MBD) and renal failure (RF) are not well- defined. *Aims*. To analyze the interactive influence of bone lesions and renal failure in multiple myeloma (MM) in clinical, pathogenetic and prognostic aspect. *Design and Methods*. 425 previously untreated patients with (223 male and 203 female) were studied for a period of 28 years (1980-2007). They were diagnosed at the University clinic of hematology, stage was defind according to Durie and Salmon system and were treated in a similar way. RF (creatinine clearance < 1,3 ml/sec) was assessed in incidence, grade and outcome after induction treatment. MBD (X-ray, CT scans) was graded according to the Merlini scale. Bone mineral density of L-spine was assessed by dual energy X-ray absorbtiometry (DXA) in anterior - posterior plan. Calciura, phosphaturia, creatininuria and the clearances of Ca, P and creatinine were determined simultaneneously. Median of survival (MS) was calculated by the method of Kaplan-Meier. Statistics were done with SPSSv13 (for Windows). *Results*. RF was found in 196 (46,1%) of the patients, most frequently in grade I (cr ≤353,0 μmol/l) - 62,7% and was completely

reversible after treatment in 91(46,4%). MBD was found in 353 (83,1%), most frequently in grade « 2» in 210 (49,1%) patients. Bone lesions had 94,4% of the patients with RF and 52,4% of the patients with MBD had RF. As MBD progressed, the incidence, grade and resistance of RF to treatment significantly increased. In patients with RF the mean Z-score showed osteoporosis (-2,32±0,40), and without RF - osteopenia (1,89±0,41). Calculating odds ratios patients with RF increase 5 times their risk to develop MBD. In 26,1% of the patients, hypercalciemia was found, in 41,1% - hypercalciuria>4.5mmol/24h, in 3,1% - hyperphosphatemia and in 26,8% - hyperphosphaturia>26.0 mmol/24h. In patients with BJ proteinuria and RF, although creatinine clearance is limited, Ca clearance (0,061±0,003 ml/sec) and Cca/Ccr ratio(0,108±0,013) are higher while tubule reabsorbtion of TRCa (89,23±1,59%) and TRP (60,16±5,34%) are reduced (p<0,05) because of proximal tubular impairment. MS of the whole group is 35 month; patients without RF and without MBD live 46 months, while patients with RF and MBD-21months *Conclusions*. The relationship between MBD and RF is based on the principle of the "vitious circle" which modulates their clinical manifestation, therapeutic outcome and prognostic significance. Influence of MBD on renal function. Hypercalciemia a) induces contraction, limits the glomerular filtration and results in RF. b) intensifies the co-precipitation of light chains and development of cast nephropathy, also resulting in RF, inhibits the adenylatcyclase activity in the tubule epithelium, induces resistance to antidiuretic hormone, resulting in polyuria + hypostenuria. 2.Influence of RF on MBD. The tandem of hypercalciuria + BJ proteinuria causes different tubular dysfunctions. When proximal tubular injury occurs, hypercalciuria and hyperphosphaturia are observed: Fanconi syndrome, light chain osteopenia /osteomalatia; intensive demineralization of the skeleton is induced and b) most probably renal osteodystrophy also plays role in advanced RF.

1599

EXTRAMEDULLARY RELAPSES IN PATIENTS WITH MULTIPLE MYELOMA

X. Papanikolaou,[1] D. Maltezas,[1] P. Repousis,[1] T. Tzenou,[2] K. Megalakaki,[1] S. Sahanas,[2] M. Agelopoulou,[2] T. Vasilakopoulos,[2] C. Mitsouli-Mentzikof,[1] G. Pangalis,[2] P. Panagiotidis,[2] M.-C. Kyrtsoni[2]

[1]S.A.H.P. Metaxa, PIRAEUS, Greece; [2]Laiko G.H., ATHENS, Greece

Background. Extramedullary relapses (ER) during the course of Multiple Myeloma (MM) is a truly rare finding , and is considered to carry a rather poor prognosis.This kind of MM relapse is best described after autologous or allogeneic transplantation or immunomodullatory treatment. Due to the rarity of this particular kind of relapse in MM, it has not yet been studied thoroughly. *Aims*. Purpose of this work is the presentation of the characteristics of the MM patients which had an ER. *Design and Methods.* These patients derived from a series of 406 patients which were diagnosed and followed during the last 11 years. *Results.* 14 patients (3,5% of total),8 men and 6 women with a median age of 67 years (49-76),presented with an ER during their disease course (4 liver,3 pleural effusions,2 CNS,1 lung,1 ureter and psoas muscle,1 base of the tongue).At the time of initial diagnosis of MM 43% of them were stage III , 22% were stage II and 35% were stage I according to ISS staging system, while the type of MM was IgG in 64%,IgA in 22% and non-secretory in 14% of the patients. 93% of them presented with pathologic bone fractures (7 patients) and/or bone plasmocytomas (9 patients). Serum LDH was abnormally high in 21% while for the rest of the population the percentage was 5,6% (p<0.01). Bone marrow plasma cell infiltration was <50% in 85% of patients. The median time from initial diagnosis till ER was 33 months(5-117).The mean number of therapies till ER was 2 (1-5).21% have had an autologous transplantation,43% had previously received thalidomide, 28% bortezomib, 14% lenalidomide prior to ER. During ER 28% of the patients had "B" symptoms,93% had an abnormally high LDH, while most of the patients still had a plasmacytic infiltration below 50%. 80% of patients with "B" symptoms had an ER located in the liver. The median survival after ER was 5 months and 71% of the patients died. *Conclusions*. ER is characterized by a very aggressive and treatment resistant behavior. Given the higher rate of elevated LDH and presence of plasmacytomas and extensive bone disease, it seems that patients with an ER relapse belong to a subcategory of MM with a more aggressive kind of biological behavior since the time of initial diagnosis.

INCIDENCE AND OUTCOME OF OSTEOLYTIC LESIONS IN THE JAW IN PATIENTS WITH MULTIPLE MYELOMA (MM)

M.J. Moreno,[1] F. De Arriba,[1] C. Jiménez,[1] R.E. Oñate,[1] M.C. Cabrerizo,[1] M. Canteras,[2] C. Castilla,[1] V. Vicente[1]

[1]Hospital Morales Meseguer, MURCIA, Spain; [2]Statistic Department. University of Murcia, MURCIA, Spain

The increase incidence of Osteonecrosis of the jaw (ONJ) in patients receiving intravenous bisphosphonates, and the higher prevalence in patients with MM, suggest a predisposition in these patients to suffer this complication. This fact justifies the interest in understanding the impact and outcome of the jaw bone lesions associated with MM. Aims: to analyze the incidence and location of lytic lesions in the jaw in patients with MM at diagnosis, and to analyze their progress after the induction treatment. *Design and Methods.* A retrospective study of patients diagnosed of MM was performed at diagnosis or during the 1st line treatment of MM without clinical o analytical data of progression. Additionally, 10 patients were reevaluated after completing the induction therapy. A single examiner made the visual inspection of oral cavity and the orthopantomography in all the patients. To set the location of the lesions, the jaw was divided into two halves (right and left) and, in turn, each half was divided into 10 anatomical regions (Rouvière). Statistical analysis was performed using SPSS program version 15.0. Results: 48 patients were included. The median age was 61 (range 30-73 years). 22 were male, 26 female The clinical characteristics of the group were: 1) Type of M protein: IgG: 48% (23), IgA: 25% (12), BJ 27% (13). 2) Skeletal survey with plain radiography: without osteolytic lesions 15% (7), < 4 affected regions 46% (22), > 4 affected regions 29% (14), and not available in 5 cases. 3) Durie-Salmon staging (DS): I 13% (6), II 31% (15) and III 56% (27), 4) ISS: I 27% (13), II 17% (8), III 39% (19), and not available in 8 cases. The jaw was affected at the diagnosis in 28 patients (58%), with no differences between right and left jaw. We identified a higher frequency of osteolytic lesions in 5 anatomic areas. We found no statistically significant differences when comparing the presence or absence of osteolytic lesions in the jaw with the type of M protein, skeletal survey with plain radiography, DS staging or ISS. The comparison of the initial study with the survey after completing the induction treatment was performed in 10 patients. The 1st study show that 90% of patients (9 / 10) had at least one osteolytic lesion of the jaw, with a total of 66 affected areas; At the 2nd revision jaw lesions were detected in at least one region in 7 patients (70%), with a total of 54 affected areas. Affected regions decreased in 5 cases (50%), remained stable in 3 cases (30%), while increased in 2 (20%). The inferential analysis (t-student for paired data and chi-square), showed no statistically significant differences between both evaluations. *Conclusions*. Osteolytic lesions in jaw are common in patients with MM, affecting more than half of patients at diagnosis. Our study suggests an improvement in osteolytic lesions of the jaw after induction treatment.

1601

BORTEZOMIB RETREATMENT IN RELAPSED OR REFRACTORY MULTIPLE MYELOMA: RESULTS IN A COHORT OF 52 PATIENTS

A. Canovas,[1] J.J. Alonso,[2] B. Barreiro[2]

[1]Cruces University Hospital. UPV, BARACALDO (VIZCAYA), Spain; [2]Osakidetza, BARACALDO. VIZACAYA, Spain

Background. Bortezomib is a drug with significant activity in relapsed or refractory multiple myeloma (MM) although there is limited experience in retreatment in the daily clinical practice. *Aims*. To evaluate bortezomib efficacy and safety as retreatment in non selected relapsed or refractory MM patients. *Design and Methods.* All the patients with MM followed in our department from June 2004 to January 2009 were retrospectively reviewed. The patients with relapsed or refractory disease after one or more therapeutic regimens that were treated with bortezomib (both as first and subsequent rescue therapy) were selected. Bortezomib was combined with other drugs (accordingly to the clinical features of each patient) when previous response was shorter than six months, minor or nonexistent. Efficacy was evaluated as response and time to symptomatic progression (TTP) and clinical features were assessed as prognostic variables. Complete response (CR) was defined as the disappearance of both monoclonal serum protein (tested by IF) and urinary component. Partial response (PR) was defined as a 50-99% monoclonal serum protein reduction and 90% reduction in urinary component. Minor response (MR) was defined as a reduction of 25-50% and non response (NR) as an inferior reduction or progression. Response was

assessed after at least two cycles of bortezomib unless clinical progression during treatment and retreatment occurred. Safety evaluations were coded using the WHO scale. Efficacy and safety of first rescue treatment with bortezomib was compared with subsequent retreatment. Statistical methods: descriptive, χ^2, Fisher exact test, Kaplan-Meier tables, log-rank test and Cox binary logistic regression. *Results*. Fifty two patients received first rescue treatment with bortezomib or bortezomib/dexametasone (B/D): mean age was 69.8 years (49-85), 44% had refractory MM and 56% relapsed MM. Median time from diagnosis was 2,6 years (0-15) and the median number of previous therapies was 2 (1-9), eighteen patients (35%)had undergone an ASCT. After a median time of 4.5 months (1.5-6.5), 46 patients were assessable for response. 19 had CR (41%), 13 PR (28%), 4 MR (9%) and 10 NR (22%). There was progression in 36 cases (78%) in a median follow up of 2.1 years in living patients, with median TTP of 9.5 months and median survival of 2.5 years. ISS was the only variable associated with response (1 versus 2-3) (p:0,02;OR=0,1; 95% C:I: 0,01-0,94). A longer TTP was significantly associated with relapsed versus refractory disease (13 months versus 7 months. p=0.03). As for subsequent rescue treatment, 16 patients received a second bortezomib therapy for relapsed or refractory MM (7 B/D, 2 B/D with infusional doxorubicin and 5 B/D with endovenous melfalan). Their median age was 73 years, the median number of previous therapies was 4 (2-10) and time from the first bortezomib course was 8 months (2-20). 13 patients were evaluable for response: 3 achieved CR and 4 PR and the median TTP was 7 months. In these patients no statistical difference was found between response and TTP in the first and second treatment with bortezomib, although the probability of response was greater in those who responded to the first treatment (p=0,07). Safety: We detected adverse events in 71% of patients in the first treatment and 69% in the second, without significant differences (thrombocytopenia: 17% versus 19%, peripheral neuropathy: 33% versus 19%, others: 40% versus 33%). Two patients in each group required discontinuation of treatment for toxicity. *Conclusions*. In our experience bortezomib is an active drug in relapsed or refractory MM both as first rescue treatment and as subsequent therapy without changes on its safety profile.

THROMBOPOIETIC CYTOKINES AND PLATELET COUNT IN MULTIPLE MYELOMA

Z.N. Özkurt,[1] M. Yagci,[1] K. Acar,[2] G.T. Sucak,[1] R. Haznedar[1]

[1]Gazi University Faculty of Medicine, ANKARA, Turkey; [2]Selçuk University Faculty of Medicine, KONYA, Turkey

Background. Platelet counts are frequently in normal range among patients with multiple myeloma (MM) despite the disease activity. Cytokines like interleukin-6 (IL-6) and IL-1a are both implicated in myeloma pathogenesis and megakaryopoiesis. *Aims*. We analyzed plasma levels of TPO, IL-1α, IL-11 and IL-6 levels in myeloma patients with various stage and activity. *Design and Methods*. Sixty eight patients with multiple myeloma [30 female and 38 male, median age 58 (40-79), 38 newly diagnosed, 15 in plateau, and 15 relaps and/or refractory patients] were incluted in the study. Twenty one healthy adult subjects [10 female and 11 male, median age 58 (41-71)] were studied as control group. Plasma TPO, IL-6, IL-1α, IL-11 levels were measured by ELISA. *Results*. Platelet counts were not different between control group and myeloma patients with various disease stage and activity. Platelet counts inversly correlated with TPO levels (r=-0.577; p<0.0001), and percent of bone marrow plasma cells in bone marrow aspiration (r=-0,268; p=0.06) and a positive corelation was detected with IL-6 (r=0.263; p=0.04) levels in MM patients. TPO and IL-6 levels were significantly correlated (r=0,305; p<0.001). TPO (p<0.001) and IL-6 (p<0.001) levels were higher in MM patients than healthy subjects, but IL-1β and IL-11 levels were not different. Disease activity has no effect on plasma cytokine levels. TPO levels were higher in stage III than stage I (p=0.05) and stage II (p=0.03) patients in newly diagnosed MM. Cytokine levels and platelet count were not different between stage A and B disease. *Conclusions*. In this study, IL-6, and TPO levels were higher in myeloma patients than healthy subjects. High TPO levels induced by IL-6, stimulate platelet production and may sustain normal platelet counts despite bone marrow infiltration by plasma cells.

1603

FERRITIN AS A PROGNOSTIC FACTOR OF MULTIPLE MYELOMA

J.S. Chung,[1] M.K. Song,[1] G.J. Cho,[1] Y.J Choi,[1] B.R. Kwon,[1] Y.M. Seol,[1] Y.D. Joo,[2] Y.S. Yang[3]

[1]Pusan National University Hospital, BUSAN, South-Korea; [2]Inje Baik Hospital, BUSAN, South-Korea; 3Busan Medical Center, BUSAN, South-Korea

Background. Serum ferrtin is a known marker of acute phase reactions and iron storage. A previous study showed that hematologic malignancies had significantly elevated serum ferritin levels. Another study suggested that ferritin may be a surrogate for more advanced disease and thus have an impact on relapse because elevated serum ferritin levels are associated with overall survival (OS) and relapse-free survival following autologous stem cell transplantation for lymphoma. *Aims*. This study was planned to examine serum ferritin levels in newly diagnosed MM patients to determine whether the level would be correlated with outcome and be an independent factor of survival in MM.

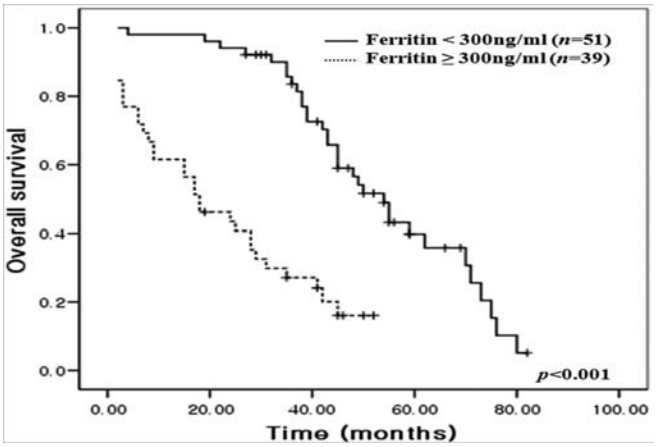

Figure 1. Overall survival according to serum ferritin level.

Design and Methods. Between 2001 and 2006, 121 consecutive patients with MM were evaluated at the Pusan National University Hospital. Ninty patients were eligible to partcipate in the study. The median follow-up duration was 35 months (range, 2-72 months). The international staging system was used for initial staging, Eighteen patients were stage I, 31 were stage II, and 41 were stage III. Twenty-seven patients underwent autologous stem cell transplantation (ASCT). The primary endpoint was to assess the impact on overall survival (OS) based on the serum ferritin level at the time of diagnosis in newly diagnosed MM patients. The secondary endpoint was to determine whether the serum ferritin level at the time of diagnosis was an independent prognostic factor for OS in MM patietns. *Results*.We studied 89 consecutive patients with multple myeloma at the time of diagnosis to determine the value of serum ferrtin levels in comparison with previous known prognostic factors. During a median follow-up of 35 months, we found that the OS in the elevated serum ferritin level group (≥300 ng/mL) was longer than the normal serum ferritin level group (< 300 ng/mL; p<0.001). Multivariate analysis showed that an elevated serum ferritin level was an independent prognostic factor of mortality in patients with multiple myeloma (RR=3.610, 95% CI=1.608-8.105, p=0.002). *Summary and Conclusions*. In conclusion, the serum ferritin level is expected to be a prognostic factor related to OS of the patients with multiple myeloma. A multicenter study is needed to evaluate the usefulness of the ferritin level.

1604

LONG-TERM FOLLOW-UP OF MULTIPLE MYELOMA PATIENTS TREATED BY VELCADE

M. Michallet, M. Sobh, Q.-H. Le, F. Barraco, F.E. Nicolini, C. Dumontet, Y. Chelghoum, X. Thomas, G. Cannas, E. Nicolas-Virelizier, N. Plesa, S. Ducastelle, J. Troncy

Edouard Herriot Hospital, LYON, France

We evaluated the immediate and long-term efficacy, tolerance, survival and time to progression of MM patients who received VELCADE

as induction and in those who relapsed or were refractory after standard therapies. 92 pts included, 62 M, 30 F. Median age = 60 years [35-79]. Patients= group1: 16(17%) pts who received Vel. as induction, group2: 58(63%) pts who received Vel. as 2nd line n=41 or 3rd line n=17, group 3: 18(12%) pts who received Vel. as ≥ 4th line. Median interval diagnosis-Velcade. initiation = 28.3 months (0.2-125). Median number of Vel. cycles in group 1, 2 and 3 were 4[2-9], 5[2-12] and 5[3-12] respectively with a standard dose of 1.3 mg/m^2. Peripheral neuropathy occurred in 61 pts(66%). The overall response rate was observed in 67(73%) pts [13 (14%)CR, 22 (24%)VGPR and 32 (35%)PR]. With a median follow-up of 23.4 months, the median overall survival (OS) for the whole population and for group 1 and 2 was not reached, and was 17 months for group 3. The probability of OS at 3 years for the whole population was 61%[50-73.5] and were: 80%[62-100], 66%[54-81] and 45%[25-82.5] for groups 1, 2 and 3 respectively. The probability of OS at 5 years for the whole population from MM diagnosis was 72.5%[63-84]. The median time to progression was 25.5 months for the whole population; it was not reached for group 1, were 25.5 and 13 months for group 2 and 3 respectively. The probability of progression-free survival (PFS) at 2 years was 51%[40-64,5] for the whole pop. and 66%[45-96], 52%[39-70] and 29%[12-71] for group 1, 2 and 3 respectively. We showed no significant difference in term of OS and PFS between the patients with del(13) [51%(31-83) and 42%(23-78)] and without del(13) [83%(68,5-99,6) and 58%(40-85,5)] (p=0.006). The multivariate analysis showed a significant negative impact of thalidomide HR=3.06 and a positive trend for short interval diag-Vel. We performed a study of MRD by free light chains analysis and the results will be presented.

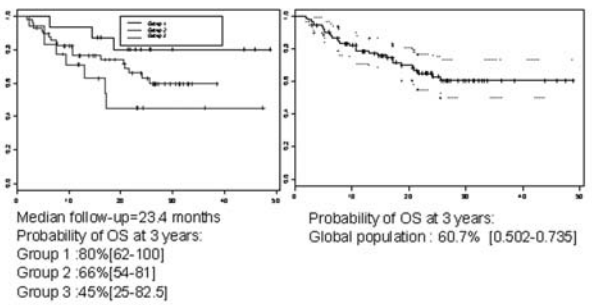

Figure.

THALIDOMIDE THROMBOPROPHYLAXIS: IS ASPIRIN COVER ADEQUATE TO PREVENT VENOUS THROMBO-EMBOLISM. A 2 CENTRE RETROSPECTIVE AUDIT

W. Laurie,[1] S. Hartley,[1] S. Narat,[1] T. Sugai[2]

[1]Worthing and Southlands NHS Trust, LONDON, UK; [2]Brighton and Sussex University Hospital, BRIGHTON, UK

Background. Thalidomide therapy has changed the landscape of myeloma treatment. One major side effect of Thalidomide is increased venous thrombo-embolism (VTE) when used in conjunction with Dexamethasone, with one meta-analysis showing an incidence of 15.7% if not on prophylaxis. This increased VTE risk is related to decreased thrombomodulin levels and an increased resistance to activated Protein C. No clear guidelines for thromboprophylaxis in Thalidomide treated patients exist. BCSH Guidelines note that although studies exist looking at Thromboprophylaxis including Aspirin, Low Molecular Weight Heparin (LMWH) and Warfarin, no consensus opinion has been reached. We have noted heterogeneity in our own prescribing practice. Historically we opted for no thromboprophylaxis or Aspirin 75mg OD, though recently a move has been made towards LMWH. In our clinical practice we suspected the number of VTE events in our population was higher than rates quoted and therefore decided to audit our practice. Aims Collect data on Thalidomide treated patients at Worthing and Southlands Hospital (WASH) and Brighton and Sussex University Hospital (BSUH). Determine incidence of VTE and compare against mode of thromboprophylaxis used. Alter prescribing practice if a clear advantage is found. *Design and Methods*. We retrospectively audited 71 patients who have received Thalidomide at WASH, a further 11 patients from BSUH were also included. Data was collected on patient demographics, diagnosis, past history of thrombosis, dosing and duration of thalidomide, thromboprophylaxis and subsequent VTE. *Results*. Age range: 54-89 Age mean: 73.6 Sex: 45♂, 37♀. *Diagnosis.* Myeloma (74), Mantle Cell (3), LPL with Amyloid (1), Primary Amyloid (1), Myelofibrosis (1), SLVL (1), MDS with Epistaxis (1) Prophylaxis used: LMWH (30), Aspirin (29), Nil (17), Warfarin (6) Events: P.E. (5), DVT (3), CRVO (1), CVA (1) Deaths: Unknown cause (8), Sudden death (2), Congestive cardiac failure (1) Events details: Event 1 - DVT on Aspirin Event 2 - DVT on LMWH Event 3 - CRVO on Aspirin Event 4 - DVT on Nil Event 5 - PE on Aspirin Event 6 - PE on Nil Event 7 - PE on Aspirin Event 8 - PE on Nil Event 9 - CVA on Warfarin Event 10 - PE on Aspirin. *Summary and Conclusions.* Incidence of VTE regardless of anticoagulation was 12.2%. Given the quoted VTE incidence of 15.7% with no prophylaxis, our population shows a higher than expected rate of events. We observed 10 VTE events, though this number may be higher if we consider the unexplained deaths. Of these, 2 patients have documented sudden deaths where the possibility of a fatal VTE is high. These patients however have not been included in our analysis. Of the 10 events only 1 patient was on LMWH prophylaxis and 1 on Warfarin. This suggests that no prophylaxis/Aspirin is inferior at preventing VTE compared to LMWH (or Warfarin). However no head to head studies comparing the different thromboprophylaxes have been undertaken. Given the difficulties maintaining Warfarin levels in patients receiving pulsed chemotherapy we recommend LMWH as thromboprophylaxis. We recognise for some individuals this may be unsuitable i.e. chronic renal failure, high bleeding risk or patients unable to tolerate/administer daily injections.

LOW-DOSE THALIDOMIDE THERAPY IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA

K.O. Kohei,[1] S. Ando,[2] S. Hasino,[1] H. Huse,[1] R. Morita,[1] M. Takahata,[1] M. Onozawa,[1] K. Kahata,[1] T. Kondo1, S. Ota,[1] T. Kawamura,[3] M. Kurosawa,[4] K. Aikawa,[4] T. Ogawa,[4] S. Suzuki,[4] S. Takahashi,[4] K. Izumiyama,[5] H. Iwasaki,[6] S. Ando,[2] M. Maemori,[2] H. Sakai,[2] M. Asaka[1]

[1]Hokkaido University Hospital, SAPPORO,HOKKAIDO, Japan; [2]Teine-Keijinnkai Hospital, SAPPORO, Japan; [3]Hakodate General Central Hospital, HAKODATE, Japan; [4]National Hospital Organization Hokkaido Cancer Center, SAPPORO, Japan; [5]Obihiro-Kosei General Hospital, OBIHIRO, Japan; [6]Sapporo-Kosei General Hospital, SAPPORO, Japan

Background. Multiple myeloma is a clonal disorder of plasma cells, accounting for 10% of hematological malignancies. The median overall survival has been improved by high-dose chemotherapy with autologous stem cell transplantation. However, treatment of relapsed patients after conventional and/or high-dose chemotherapy remains unsatisfactory. Treatment with thalidomide for patients with relapsed/refractory myeloma has been initiated in many countries. Some studies have shown that the response rate and survival were improved by a standard dose of thalidomide. However, treatment with thalidomide at a standard dose has also caused many adverse events involving the nervous, gastrointestinal and vascular systems. We conducted a retrospective chart review of 73 patients who had multiple myeloma in 6 facilities in Hokkaido, Japan. *Aims.* The aim of this study was to determine of the efficacy and safety of low-dose thalidomide (100-200 mg). *Design and Methods*. Between July 2003 and June 2008, 73 patients with relapsed/refractory multiple myeloma were treated with thalidomide in those facilities. Sixty-one of the 73 patients were evaluable. The diagnosis of multiple myeloma was made according to the Southwest Oncology Group (SWOG) criteria. The male/female ratio was 1.03 (31/30) and the median age was 69 yr (range, 48-90 yr). Immunoglobulin subtypes were as follows: IgG (n=30), IgA (n=19), IgD (n=1) and light chain (n=9). One patient had nonsecretory type. The staging of multiple myeloma was done according to the crassification of Durie and Salmon as follows: clinical stage I (n=8), II (n=16), III (n=37). Thirteen patients received stem cell transplantation (SCT). Most patients were administered thalidomide orally at maintenance and maximum doses of 100~200 mg/day. Only three patients were administered a maximum dose of 300~400 mg/day. *Results*. The overall response (nCR+PR+MR) rate was 39%.There was significant difference between age of responder and that of non responder (65.5±9.7 yr vs 71.4±9.3 yr, p=0.02). There was no significant difference when thalidomide was used alone or in combination with steroid and/or chemotherapy (p=0.56). The actuarial overall survival rates were 50.4% at 2 years and 25.0% at 5 years. Overall survival was longer for patients who received SCT than for patients who did not receive SCT (p=0.002). Frequent non-hematological events included constipation (39%), peripheral neuropathy (31%), edema or weight gain (18%), drowsiness (18%) and skin eruption (11%). Thrombosis (deep vein thrombosis: 2 patients, pulmonary embolism: one patient) was observed in only three cases (4.9%). Hematological adverse events

included leucopenia (6.6%), anemia (3.3%) and thrombocytopenia (3.3%). Grade 3 to 4 adverse events were observed in 18 patients. Frequency of adverse events was significantly lower than those in previous series used standard-dose thalidomide. *Summary and Conclusions*. Low-dose thalidomide therapy was as effective as standard-dose thalidomide in patients with refractory/relapsed multiple myeloma, and the incidences of adverse events were lower than these in the case standard-dose thalidomide.

1607

BONE MARROW SAMPLING USING A ROTARY POWERED DEVICE YIELDS EXCELLENT BIOPSY SPECIMENS IN AN ANIMAL MODEL

A. Brenner,[1] L. Miller,[2] T. Philbeck,[2] S. Hacker[1]

[1]*University of Texas Health Science Center, SAN ANTONIO, TEXAS, USA;* [2]*Vidacare Corporation, SAN ANTONIO, TEXAS, USA*

Background. The importance of bone marrow examination in the evaluation of hematopoietic and non-hematopoietic diseases is well established. The most common method of accessing the bone marrow for diagnosis and monitoring disease and treatment is the core, or trephine, biopsy of the bone within the medullary cavity. Recently a new FDA-cleared battery-powered bone marrow biopsy system was developed to allow operators to access the bone marrow space quickly and efficiently. *Aims*. Using a swine model, a study was designed to compare the quality of bone marrow biopsy core specimens using the new powered device to specimens obtained using a traditional manual device, with particular attention to the possibility of cellular damage resulting from a thermal effect caused by the rotation of the needle attached to the powered device. *Design and Methods*. The study was reviewed and approved by the University of Texas Health Science Center at San Antonio Institutional Animal Care and Use Committee (IACUC) prior to implementation. Three anesthetized mature pig were used for the study. The powered device (OnControl®, Vidacare Corporation, San Antonio, TX, USA) was comprised of two basic components: the battery-powered driver and the needle set with an 11 gauge x 4 inches (2.3mm x 102 mm) outer cannula. The manual device was an 11 gauge x 4 inches (2.3 mm x 102mm) T-Handle Jamshidi® bone marrow biopsy needle (Cardinal Health, Dublin, OH, USA). Following cut-down to the iliac crest by the veterinary staff, operators performed the bone marrow biopsy procedures. Core biopsy samples were measured for length, assessed for gross sample quality, fixed in preservative, and submitted to a pathologist blinded to the biopsy device for analysis. The primary endpoint of the study was quality of bone marrow core biopsy samples, and the secondary endpoint was biopsy sample length.

Figure 1. OnControl Rotary-Powered Bone Marrow Biopsy Device.

Results. Thirty-three bone marrow samples were obtained from three swine on two different dates, including 23 samples using the powered device (Powered) and 10 samples using the manual device (Manual). To date, pathology results have been received for 13 samples obtained from the first swine. Pathology reported no cellular damage or other significant artifact for any of the samples captured from either device. For eight Powered samples, pathology reported a mean length of 22.2±10.8mm. For five Manual samples, pathology reported a mean length of 12.7±6.8mm. *Summary and Conclusions.* In this study, preliminary results showed Manual and Powered biopsy samples were equivalent in specimen quality at the microscopic level and the samples by the Powered method were greater in quantity of sample obtained. The new Powered bone marrow biopsy system appeared to be capable of quickly and accurately capturing core biopsy samples of suitable length and quality for analysis, without significant artifact. The Powered device may reduce the time and effort required to obtain adequate bone marrow specimens; and thereby lessen the procedural pain experienced by patients. This should be confirmed in randomized, controlled clinical trials.

1608

AUTOLOGOUS STEM CELL TRANSPLANTATION AND MAINTENANCE TREATMENT IN MULTIPLE MYELOMA PATIENTS. A SINGLE CENTER EXPERIENCE

A. Bilalis, N. Soupos, A. Sioni, P. Stefanitsi, M. Tsirogianni, V. Zina, A. Pouli, S. Tsakanikas, K. Papanastasiou, M. Stamatelou

Saint Savvas Oncology Hospital, ATHENS, Greece

Background. During the last two decades autologous stem cell transplantation (ASCT), is the standard management for the younger patients with multiple myeloma (MM), followed by maintenance therapy (thalidomide or α-interferon). AIM: The purpose of this retrospective study was to evaluate the effect of ASCT in MM patients, in terms of event free survival (EFS) and overall survival, in correlation to thalidomide (THAL) and α-interferon (IFN) as regimens for maintenance treatment in the post transplant period. *Design and Methods*. one hundred twelve patients with MM undergone ASCT in our Department, since 1989 until 2007. Females are 53, males 59 with median age 53 years (30-65). At the diagnosis they were at stage (DS) IA=9, IIA=33, IIIA=49 and IIIB=21 patients. The subtype is IgG=69, IgA=31, IgD=3, free light chain=8 patients and one patient had non secretory myeloma. At the time before the ASCT, 37 patients are in CR, PR =51, VGPR=12, PD=5, SD=7 patients. Response was assessed by international uniform response criteria for multiple myeloma. Conditioning regimen for 101 patients was melphalan 200 mg/m^2 and for the rest Bu/Cy/VP-16. After ASCT 47 patients received IFN and 28 received THAL as maintenance treatment. The remaining 37 patients did not received any regimen as maintenance treatment. *Results*. After ASCT 63 patients (56%) are in CR, 36 in PR (32%), 8 in VGPR, 2 in SD and 3 patients developed PD. The transplantation related mortality (TRM) is 0.89%. The median value of OS is 84 months (16-192). The median value of EFS since ASCT for all the patients is 27 months (4-137). The EFS since ASCT for patients received IFN as maintenance is 38.5 months (5-111), for the patients received THAL the EFS is 23.5 (4-61) months (p<0.001) and for the patients who did not received maintenance therapy is 17 months (4-47). The ten years OS is 30.7% for all the patients. *Conclusions*. 1) ASCT is a safe procedure with very low TRM, 2) ASCT followed by maintenance treatment may offer long lasting remissions in a previously difficult responded disorder, 3) in our study group there is a slight superiority of IFN in EFS rate (this result maybe affected by differences between the groups of THAL and IFN), 4) the ten years OS in MM patients received ASCT and maintenance therapy is 30.7%.

1609

PERCUTANEOUS KYPHOPLASTY IN THE TREATMENT OF PATHOLOGICAL VERTEBRAL BODY FRACTURES IN MULTIPLE MYELOMA PATIENTS

L. Smardova, J. Neubauer, L. Pour, M. Vesela, M. Navratil, R. Chaloupka, Z. Adam, R. Hajek, V. Valek, J. Mayer

University Hospital and Faculty of Medicine, Masaryk University, BRNO, Czech Republic

Background. Percutaneous kyphoplasty is a minimal invasive procedure for stabilizing pathological vertebral compression fractures caused by osteoporosis or osteolytic tumours such as multiple myeloma and metastatic diseases of the spine. This technique involves the injection of thick viscous bone cement (poly-methyl-methacrylate) into the preformed cavity through special instruments. In this way rapid pain relieve and stabilizing of vertebral fractures can be achieved. *Aims.* Retrospective evaluation of clinical and radiographic outcome of percutaneous kyphoplasty in the treatment of vertebral fractures caused by multiple myeloma. *Design and Methods*. Between May 2005 and August 2008, fourteen consecutive kyphoplasty procedures were performed in 8 patients with multiple myeloma vertebral fractures. Median of patient age was 61 years (53-67). The kyphoplasty was performed in thoracic and lumbar spine location, under general anesthesia and continuous skiascopic control. For the evaluation of the analgetic effect a 10-point subjective visual analog scale (VAS) has been done during the period of 6 months. Further, plain X-ray pictures were taken before the surgery, 1 day after the surgery and 6 months after the surgery in order to measure the vertebral body height (anterior, mid-vertebral and posterior) and assess the restoration of the sagittal alignment. *Results.* The average pain

scores (VAS) decreased significantly ($p<0.01$) from 5,6 points (before the kyphoplasty treatment) to 2,5 points (after 3 months) and 1,2 points (after 6 months). Improvement of vertebral height was achieved in 12 of 14 fractured vertebral bodies (85,7%). A significant elevation ($p<0.05$) was observed only in the mid-vertebral body height, where a mean increase of 5 mm (pre- to postoperative value) was achieved. Requirement of analgetics decreased in all patients immediately after the procedure. Clinically asymptomatic peroperative cement leakage occurred in 4 cases (28,6%). During median of the follow-up of 20,5 months, we didn´t observed any late complication or secondary fracture. *Summary*. With respect to our results we can support the percutanous kyphoplasty as an effective and safe procedure for the treatment of painful pathological fractures of multiple myeloma patients.

1610

BORTEZOMIB IN COMBINATION WITH DEXAMETHASONE FOR THE TREATMENT OF ELDERLY PATIENTS AFFECTED BY REFRACTORY MULTIPLE MYELOMA

M.R. Villa, A. Lucania, M. Esposito, P. Della Cioppa, S. Improta, S. Russolillo, L. Mastrullo

ASL NA1 San Gennaro, NAPLES, Italy

Background. Multiple myeloma (MM) is a neoplastic disease especially affecting elder patients even if in recent years it has been also observed in younger patients. The use of the proteasome inhibitor bortezomib has been recently introduced in the treatment of relapsed and/or refractory MM. In fact, bortezomib has proven to be safe and effective in MM patients not only as monotherapy but also given in combination with cytotoxic agents. Bortezomib-based combination regimens have induced clinical benefits with manageable toxicities and may ultimately lead to improvement in the duration of response and survival of patients in the first-line setting. Aims. The objective of study was to evaluate the efficiency and safety of bortezomib in combination with dexamethasone for the treatment of elderly patients affected by relapsed/refractory MM. *Design and Methods*. In our institution we are following 33 elderly patients with stage II/III MM (18 F and 15 M, median age: 73 years, r.: 67-84 years). As first-line treatment all patients received Melphalan and Prednisone chemotherapy (10 out of 33 plus thalidomide). However, patients suspended chemotherapy after a maximum of 6 cycles of Melphalan and Prednisone (with or without thalidomide) for excessive toxicity even if they presented progression disease (PD) at the clinical re-staging performed with both serum marker evaluation and cytological examination of bone marrow blood. All the 33 patients underwent a treatment with bortezomib (1,3 mg/m^2 i.v. d. 1,4, 8, 11 every 21 days) together with dexamethasone (40 mg i.v. d. 1,4, 8, 11 every 21 days). *Results.* At a clinical re-staging performed after four courses from the beginning of bortezomib-dexamethasone combined administration a partial remission (reduction of M-component > 50-75%) was recorded in 28 out of 33 patients while the remaining was in steady disease (SD). Thereafter all patients received further four courses of therapy. At one month from the end of treatment 5 out of 33 patients achieved a complete remission (negative immunofixation) and the remaining showed a partial remission (PR). At the present, (month +24) nine patients show a progression disease, while four patients are in CR and the remaining in PR. *Conclusions*. Our results suggest that the combination of bortezomib and dexamethasone is effective and well tolerated in the treatment of refractory MM in elderly patients. Although there are several published data on the activity of the therapy based on the combination between bortezomib and dexamethasone, little is still known about the improvement in the duration of response and survival of elderly patients in the first or second line therapies.

1611

ALGORITHM FOR MONOCLONAL GAMMOPATHIES DIAGNOSIS. TO PROSPECTIVE STUDY OF INCIDENCE FROM OUR POPULATION

E. Esperanza, M.R. Sanchez-Navarro, C. Caffarena, J. Mora-Vallellano, M. Zafra-Ceres, C. Samaniego-Sanchez

Hospital Universitario San Cecilio, GRANADA, Spain

Background. A protocol with a flow diagram form has been designed for the study of Monoclonal Gammopathy (MG), it follows the diagnostic criteria developed by "The International Myeloma Working Group 2003" and uses standard laboratory methods. Review of the samples sent to their Laboratory for protein electrophoresis to over to a 3-year period, between January 1, 2006 and December 31, 2008. *Design and Methods*. The study includes: 1.Protein: quantification of total proteins, albumin, globulins, ratio albumin/globulin and inmunoglobulins in serum and urine. 2. Serum protein electrophoresis (SPE), identification of the M-component (MC) by Inmunotyping (IT) to determine the isotype of heavy and slight chain. 3.Measures in serum levels of free lambda and kappa immunoglobulin light chains (FLC). 4.Estimation renal function: urea, creatinine and glomerular filtration ratio (GFR) in serum. β-2 microglobulin, cystatin and slight chains in serum and urine. 5.Anemia study: complete hemogram and erythrocyte sedimentation rate. 6.Osteolysis activity: calcium, total alkaline phosphatase and, if appropriate, determination of the alkaline phosphatase bone isoenzyme. 7.Protein electrophoresis in urine, with or without previous concentration to determine the presence of MC. Inmunotyping and measures levels FLC in urine. Modular Analytics D/P Hitachi/Roche, Capillary Electrophoresis/Sebia, Nephelometric BNII/ Dade Berhing, Advia120/Bayer Cytometer, Hydragel Iso-ALP/Sebia Results Following this protocol in order to detect MG, we extracted huge amount of dates from to single sample. These dates were than available for the clinician on the same day. No additional analytical applications or to parameter repetitions were needed. Incidence: Total SPE 10500, MC 3,7%: Monoclonal Gammopathy of Undetermined Significance (MGUS) 54%, Multiple Myeloma 28%, Lynphoma 4%, Waldeström´s Macroglobulinemia 3%, Amyloidosis 2%, Chronic Lymphoid Leukemia 2%, Light Chain Disease 1%, Others 6% *Conclusions*. The importance of the Laboratory in the monoclonal gammopathy diagnosis is: 1) To search and eventually characterize the M-Component. 2) To complete a study whose protocol includes: MC concentration, grade of anemia, estimation and monitoring of renal function and evaluation and monitoring of bone osteoclastic activity. These latter analyses are relevant to exclude myeloma and to detect a possible progression of malignant disease in the case, more frequent, of MGUS. This algorithm allows for efficient diagnosis or exclusion of multiple myeloma.

ASSESSMENT OF DISPOSITIONAL OPTIMISM AND PERCEIVED STRESS RELATED TO A HEMATOLOGICAL DISEASE: MULTIPLE MYELOMA

M. Bastos Oreiro, M. Canales, A. Lopez de la Guia, R. De Paz Arias, M.J. Garcia Rodriguez, J. Barbero Gutierrez, L. Diaz Sayas, I. Muñoz, F. Hernandez Navarro

Hospital La Paz, MADRID, Spain

Background. Based on the observation of daily interactions with our patients, physicians and psychologists have noted a significant emotional distress in patients with multiple myeloma (MM), more evident than in other similar diseases. There are no data on literature assessing this important issue. With this in mind, we compared possible variables related with emotional distress in two hematological diseases, MM and chronic lymphocytic leukemia (LLC). *Aims*. To characterize the perceived experience in relation with the suffering of the disease and to identify the significance of the pain as aggravating factor of mod. *Design and Methods*. Patients where asked to answer a questionnaire on: 1) two pain scales, one related to the pain at the moment of the survey and the other one related to the pain in the last month, 2) two validated test, one about optimism (LOT-R)1 and the other one of perceived stress (PSS)2. Questionnaires where given to the patients at the outpatient clinic of MM of our center. Patients with chronic lymphocytic leukemia where used as controls. For statistical analysis SPSS 15.0 software was used. Chi-square test was used to compare qualitative variables and Mann-Whitney U-test was used to compare means between the two groups. Results Forty-one patients answered the questionnaire: 21 with MM and 20 with CLL. The mean age was 67 (MM: 65, range: 54-84; CLL: 70, range: 60-82, $p>0.05$). Fifteen percent of MM had more than 5 years of disease, 40% between 3 and 5 years, 40% between 1 and 3 years and 5% less than a year of disease. Of patients with LLC, 50% had more than 5 years of disease, 25% between 3 and 5, 20% between 1 and 3 and 5% had less than a year of disease. For the pain at the moment of the survey, MM patients had 3.75/10 points, whereas CLL had 0.5/10 ($p<0.0001$). With regard to the pain over the previous month, the mean value for MM was 4.5/10 and 0.75/10 for CLL ($p<0.0001$). The mean value of MM patients for optimism was 19.2/40 and for CLL patients was 25.9/40 ($p<0.0001$; statistic power: 96%). With regard to the stress perception, patients with MM had a mean of 19/28 points and patients with CLL, 15/28 points ($p=0.07$). *Conclusions*. Patients with MM show an important abnormality of variables that negatively influence the mod as well as the optimism and the perception of the stress (despite the fact that this variable was not significant, there was a clear tendency), probably related with pain that is difficult to control. Patients with MM show a pessimistic vision of their disease, with emphasis in the inability and frustration. We think that obtaining these of kind of objective data is of

paramount importance to the better understanding of our patients. In addition, it is necessary to emphasize the importance of the interdisciplinary management of the myeloma-related pain to improve the quality of life of these patients.

AGGRESSIVE THERAPEUTICS APPROACH INCLUDING IN HOME ASSISTANCE CHEMOTHERAPY IN MULTIPLE MYELOMA

A. Fiorini, M. Morucci, A. Carpaneto, F. Celesti, C. De Gregoris, P. Falcucci, V. Tini, G. Trapè, C. Mastini, M. Montanaro

Ospedale di Ronciglione, VITERBO, Italy

Background. Multiple Myeloma (MM), is a B-cell neoplastic disease characterized by bone marrow infiltration by malignant plasma cells which secrete monoclonal immunoglobulin fragments. Although several parameters such as β-2-microglobulin, serum creatinine, haemoglobin, calcium levels or cytogenetics abnormalities have been considered as predictive factors of the outcome of patients (pts) with MM, the molecular features of this disease remain still unclear. Consequently therapy for MM remains empiric. New agents have improved the possibility of obtaining disease response and better quality and duration of responses. Although response to therapy traditionally has not been considered a good predictor of long-term outcome, most recent studies suggest that response is a surrogate of improvement in survival. Aim:Here, we want to show that, despite relapse and therapy-toxicity, pts with MM must be always treated after relapse or in presence of progressive disease, and if possible also in home assistance (HA) chemotherapy, especially elderly ones, because survival increases in presence of PR, VGPR or SD rather than in presence of PD.*Design and Methods*. We report a retrospectively analysis of 181 pts (94 females/87 males, median age 58 ys) diagnosed with MM in our institution from 1980 to 2007. *Results*. Overall survival (OS) was influenced significantly by ISS (1 > 3 and 2 >3; and 1+2 >3), renal impairment (cr >1.5 mg/dl), β-2 microglobulin (>3.5 mg/dl), LCh-MM vs not LCh-MM, and haemoglobin <10 g/dl, autologous or allogeneic transplamtation ; bone lesion or fractures, isotype κ/λ, precedent MGUS and the presence of Amiloid AL didn't influence survival. Pts who achieved PR or VGPR after first line therapy (47%) had an OS longer than pts in progressive disease (PD) (31.5%) or stable disease (SD) (21.5%), as pts with PR + VGPR vs PD; also after second and third line therapy. OS of pts in HA chemotherapy was 13 months from the moment of enrollment in home assistance chemotherapy. We treated 35 pts in HA chemotherapy and the median survival (ms) was 52.2 months vs 36 months of pts not in HA chemotherapy, matched for the same characteristics. 18 pts of these are still alive (ms 65.7 months vs pts not in HA chemotherapy ms 47.5) but our data are still limited and the comparison between the two groups doesn't achieve statistical evidence(p=0.07). *Conclusions*. We can only suggest that pts with PD or relapse must be treated also in HA chemotherapy, if elderly, to achieve at least a SD.

1614

VERTEBROPLASTY IMPROVES QUALITY OF LIVE IN MYELOMA PATIENTS

D. Hofer, P. Ashton, W. Rennie, C.S. Chapman

Leicester UHL nhs trust, LEICESTER, UK

Background. Back pain is common in myeloma patients and the incidence was found to be 40-60% (1) and new patients may even present with vertebral collapse (2).Treatments for this include analgesia and or invasive orthopaedic surgery. A new and considerably less invasive intervention is percutaneous vertebroplasty (PV) (3). In PV acrylic bone cement is injected into the vertebral body by a percutaneous approach under X-ray guidance in order to stabilize the vertebra and ultimately to reduce pain. Whilst there are trials in osteoporosis ongoing (4) we are not aware of any studies published so far looking into quality of life (QOL) issues, the good pain control has been demonstrated in several other studies in myeloma patients (7,8,9), some with larger patient groups. *Aims*. to assess the effectiveness of PV for pain relief and QOL in myeloma patients. *Design and Methods*. We assessed QOL and effectiveness of pain control via the EQ-5D health questionaire. The EQ-5D, established in 1987, is a simple measure of health status comprising a visual analogue scale(VAS) and a descriptive system with the five dimensions mobility, self-care, usual activities, pain, anxiety/depression(5). This information was obtained by direct telephone contact or in presence of the patient at pre-assessment, 12-24 hours post procedure, 1 week post-procedure and at 1,2,6 and 12 months post-procedure. In addition we gathered the following information from the patients' clinical case notes: age at procedure, time from diagnosis to procedure, type of myeloma, number of previous chemotherapy regimens (including bone marrow transplant), time from referral to X-ray to procedure, reduction in analgesia after the procedure, complications from the procedure. Results: The number of patients who had PV is n=8, the mean age was 70.4 years (range from 60-85) and the time from diagnosis of myeloma to the procedure was 51.4 months mean (range 7-154 months). Four patients were IgA and four IgG myeloma, the mean number of previous treatment course was 2.75 with 4 patients having had a autograft and one had auto- and allograft. The mean time from referral to procedure was 3.8 months. Most important for our study: 63% of patients (n=5) subsequently were able to reduce their analgesia with 3 patients coming completely off any analgesia. There were no complications in any patient. The EQ-5D results showed an average VAS score of 59.0 prior to procedure (the average for healthy people in that age group ranges from 79.8 to 72.5 in the UK population(6)) and increased to 72.7 immediately after and to 79.0 at 1 week after the procedure. There is then a slight drop to 78.5, 77.8, 74.3 and 70.0 at 1month,2 months,6 months and 12 months (but there were only 3 patients in this group) respectively. The mobility index increased by one point in 4 of 8 and was sustained for 6 months. The self-care index did not change due to the procedure(but all our patients were outpatients anyway which may explain their relatively high degree of independence). The usual activities index showed improvement over time from an increase in 3 patients to 6 patients at 2 months but then declined again to 3 patients. The pain index improved in 5 patients and was sustained in 4 patients for up to 6 months, at 12 months still 2 of 3 patients felt an improvement in their pain score. The anxiety/depression showed improvement in 4 patients which was sustained up to 6 months and at 12 months still 3 of 3 patients showed improvement. *Conclusions*. PV showed the potential to reduce their objective analgesia requirement in more than 60% of our patients confirming other studies. Nobody however has bevore shown an improvement in Qol which we were able to demonstrate with the VAS score returning to normal for the respective age group as well as an improvement in their subjective health status regarding pain and anxiety/depression. This was sustained for at least 6 months. Our group is small with so far short follow-up: however with additional information on 8 more patients pending, these results will make PV results especially interesting from a pharmaco-economical and health-economical point.

PREDICTIVE VALUE OF SERUM FREE LIGHT CHAINS RATIO IN RELAPSED OF MULTIPLE MYELOMA AFTER AUTOLOGOUS TRANSPLANT

P. Giraldo, V. Recasens, R. Rubio-Escuin, A. Rubio-Martinez, T. Pascual, P. Giraldo

Miguel Servet University Hospital, ZARAGOZA, Spain

Background. The International Myeloma Working Group Uniform Response Criteria, included the normalization of serum free light chain ratio (FLC) as a criteria of stringent complete response. The quantitative assay Freelite®, is an easy and reproducible method to determine serum concentration of FLC, and could be a good biomarker to predict the early relapse in Multiple Myeloma patients in apparently complete response. *Aims*. To determine the predictive value of the abnormal ratio serum FLC in detect early relapsed in MM patients in complete response after autologous stem cell transplant. *Design and Methods*. Observational, analytical study performed in 27 MM patients included in an autologous stem cell transplant program in 2004-2008 in one center. All patients receiving induction therapy with alternant VBCMP/VBAD (x4), mobilization and collection of $CD34^+$ cells was performed after the second VBAD therapy and conditioning with high doses of Melphalan. The infussion of $CD34^+$ cells was performed with a mean of cells In all cases were recollected serum samples in days 0,+4, +7, +21, +30, +60 y +90 and stored frozen at -80ºC. We have analyzed serum FLC in a nephelometer system following the manufacturer instructions. We have compare the increase of FLC according M-component subtype, number of $CD34^+$ cells administered, time to immune reconstitution, administration of coadyuvant AM3-glycopeptical therapy, infections in early postrasplant period, maintenance therapy and time free relapsed survival. Descriptive statistical analysis, ANOVA comparative test and Kaplan-Meier survival study was performed. *Results*. 27 patients, 47.0% females, mean age 63.2 y (38-72), IgG(46.1%), IgA (15.4%), light chains (23.0%), non secretory (7.7%), mean CD34+ cells infused $5.39x10^6$/kg (2.24-18.8), time to immune reconstitution 15-17 days, ratio of κ to λ at baseline 57.0 (CI95% 0.8,20.3), after 4 days: 37.3(CI95% 0.1,3.2), +7: 1.85(CI95% 1,3), +21 2.37 (CI95% 0.4,2.0), +30 0.87 (CI95% 0.2,0.9), +60 0.4 (0.2, 2.1) and +90 1.26 (CI95% 0.3, 2.9). Mean relapsed free survival 27.6 m (CI95% 9,55), OS 59.0 m (CI95% 27,76), 7 patients have dead for progression. At day +21 correlation κ/λ ratio and RFS was observed. *Comments*. The early determination of the ratio free serum free light chains could be a good biomarker to predict RFS and OS in patients with Multiple Myeloma in complete response after autologous transplant.

1616

A CASE SERIES OF SIXTH NERVE PALSY ASSOCIATED WITH INTRACRANIAL PLASMACYTOMA.

J. Krawczyk,[1] T. Meenaghan,[1] M. Kelly,[2] N. Ansar,[1] T. Murphy,[1] B. MacDonagh,[1] G.M. Crotty,[2] A. Hayad,[1] M. Murray,[1] M. O'Dwyer,[1] P. Hayden[1]

[1]Galway University Hospital, GALWAY, Ireland; [2]Tullamore Regional Hospital, TULLAMORE, Ireland

Background. Multiple myeloma (MM) are rare causes of lesions of skull base and cavernous sinus. We present a series of four patients whose initial presentation included a VI cranial nerve (CN VI) palsy. Aims: We analyzed clinical presentation and outcome of patients with MM and CN VI palsy. *Results*. Over the period of 3 years we collected data of 4 patients with MM and CN VI palsy. Case 1: A 49 year old patient presented with a right CN VI palsy. CT and MRI brain revealed an enhancing soft tissue mass in the right side of the brain stem with extensive bony destruction with invasion of the right cavernous sinus and numerous osteolytic lesions and was diagnosed with MM. Patient had radiotherapy and 4 cycles of bortezomib and dexamethasone. Her CN VI palsy completely resolved. Stem cell collection and autologous stem cell transplant followed and patient is doing very well, her disease markers are stable. Case 2: A 64 year old lady with IgA myeloma completed 8 cycles of VMP while developed signs of CN VI palsy. MRI confirmed the presence of myeloma deposit in the left cavernous sinus associated with bone destruction. At that time she had stable that rapidly progressed. Patient had radiotherapy and afterwards was started on systemic therapy. She died shortly afterwards with a progressive disease and sepsis. Case 3: A 69 year old man had been admitted to regional hospital with double vision. He had multiple co-morbidities. MRI brain showed massive tumour of base of the scull. The bone marrow aspirate and skeletal survey were consistent with MM. Initially patient was treated with radiotherapy, however developed acute renal failure complicated by multiorgan failure and died in intensive care unit. Case 4: A 70 years old female with 2 years history of IgG MM presented with diplopia and progressive right CN VI palsy. Subsequently she developed right CN III palsy. First MRI of brain was not diagnostic. A repeated MRI revealed a cavernous sinus lesion. Initial treatment consistent of radiotherapy and dexamethasone and subsequently bortezomib. Due to complications she was changed to thalidomide. Due to progression patient died shortly. Discussion: In our series, three patients had a lesion of cavernous sinus. In one patient there was a direct extension of the skull lesion. The initial MRI was not diagnostic in one case. Two patients who developed CN VI palsy in the course of disease progressed rapidly and had a poor outcome. One patient who presented with *de novo* MM and CN was treated successfully with regimen containing bortezomib and stem cell transplant. As MM is a potentially treatable disease, it should be included in the differential diagnosis of cranial nerve palsies, especially among those who demonstrate a progressive course or multiple cranial neuropathies. MRI is a diagnostic modality of choice, however a negative result does not exclude the cavernous sinus lesion and the imaging should be repeated if clinically indicated. Therapeutic approach can incorporate local radiotherapy as well as systemic chemotherapy including bortezomib.

1617

THERE IS NO PLACE LIKE HOME: A PILOT PROGRAM OF HOME ADMINISTRATION OF BORTEZOMIB AT GALWAY UNIVERSITY HOSPITAL

T. Meenaghan, J. Krawczyk, A. Hayat, M. O' Dwyer, P. Hayden

Galway University Hospital, GALWAY, Ireland

Introduction. Evidence shows that combinations of previously standard therapies with novel agents have improved outcomes for patients with multiple myeloma. Bortezomib is one of the novel therapies that is proven to improve overall response (OR), complete response (CR) rates and progression free survival. Routinely bortezomib is administered intravenously in the day ward facility, twice a week over a two week period with a ten day rest period. In the West of Ireland many patients need to travel long distances to the regional haematology day ward and as a result experience significant inconveniences. Aims: As bortezomib is increasingly used and has significant impact on capacity of haematology day-ward we decided to look for an alternative arrangement for the administration of bortezomib. The purpose of this was to increase the accessibility for the patients, reduce inconvenience related to treatment and ultimately improve the patients' quality of life. After two years of preparation we established a pilot scheme for the administration of bortezomib at home. *Design and Methods*. Organisation of the home administration of bortezomib: Home administration of bortezomib is coordinated by a consultant haematologist. Administration is delegated to an external company, which employs qualified nurses and provides complete evaluation of home conditions, and suitability for administration of bortezomib at home. Bortezomib is supplied from the hospital pharmacy. Patients who are identified as being suitable for the home administration of bortezomib attend the Haematology Day Ward on day 0. Clinical examination and evaluation of relevant laboratory results are carried out and chemotherapy is prescribed. The prescription is sent to pharmacy and the administering company. Patient receives information regarding possible side effects and therapy related risks. On the days of administration the nurse collects bortezomib and performs systematic clinical evaluation for side effects and detection of contraindications for the administration of bortezomib. In addition, on the day 8 of each cycle full blood count and biochemistry samples are collected. Relevant documentation of each administration is provided and results of laboratory tests are sent to the treating consultant haematologist. Patient is routinely evaluated on day 21 prior to next cycle of therapy or more frequently if clinically required. Results: To date 9 patients have been enrolled to the program and there has been 60 home administrations of bortezomib. All of them were successful. Two patients were withdrawn from the program due to non-myeloma related medical issues. No significant complications of therapy were observed. The feedback from patients is very satisfactory and encouraging as they find the service is convenient and benefits their quality of life. *Conclusions*. In our experience the program of home administration of bortezomib is safe and efficient in administration of a potent chemotherapeutic agent to more patients, who otherwise could potentially experience delays in accessing the treatment.

1618

MULTIPLE MYELOMA: EVALUATION ON THE KNOWLEDGE OF PRIMARY HEALTH ATTENTION DOCTORS IN RESPECT TO THE DISEASE

R.O Paula e Silva, R.M.D. Faria, N.C.D. Clementino, M.C.J.W. Côrtes, J.R. Faria

Universidade Federal de Minas Gerais, BELO HORIZONTE, Brazil

Background. Multiple Myeloma (MM) patients frequently show non-specific and high prevalence symptoms such as bone pain and anemia. These symptoms can be treated as distinct medical circumstances if the professional doesn't consider MM as an option for distinguishing diagnosis, leading to unnecessary interventions and delaying the correct diagnosis. Being the doctor who works in primary attention the one that generally first sees the patient, it is important that he recognizes the most common characteristics of this pathology, requests examinations for diagnostic confirmation and carries through the correct guiding. Aims:To verify the clinical knowledge on MM in general clinical doctors from the units of primary health attention in Belo-Horizonte, MG/Brazil. *Design and Methods*. Observational and transversal study of field research through the use of "best answer" multiple choice test to be answered by a doctor from each one of the 137 units of primary health attention in Belo-Horizonte from October to December, 2006. The applied instrument was composed of 5 questions that approached basic aspects in the diagnosis and handling of the patient suffering from MM. The descriptive analysis of the variables for characterization of the studied group was made through the distribution of frequency, medium and average. The knowledge on the disease was defined on the basis of the percentage of correct answers to the questionnaire, as well as the questions with higher rates of rightness and errors, delimiting the difficulties and the previous knowledge of the interviewed ones. The test of quisquare was used to compare the frequency of the categorical variables and the analysis of variance (ANOVA) with LSD correction for the continuous variables. *Results*. The time since graduation of the evaluated doctors varied from less than 1 year to 37 years (M=11,1/ D*p*=9,3). In relation to how long doctors had been working in primary attention, it varied from 1 month to 30 years (M=7,84/ D*p*=7,37). Most of them (61,5%) had some type of specialization, being The Medicine of Family and Communities (27,7%) the most frequent. In the evaluation on knowledge, most of the studied population (94,5%) correctly concluded that for an aged patient with anemia, the evaluation of chronic and neoplasics diseases is necessary. 61,4% of the evaluated doctors could not identify MM as the main diagnosis for an aged patient with characteristic osteolytic bone injuries in the x-ray.59,3% had not known how to diagnose hypercalcemia for a clinical case with classic manifestations of this metabolic clutter. 71,1% had not known the correct interpretation of eletrophoresis of serum proteins in MM. Only 37% had formulated hypothesis of MM for a typical clinical case. These results had not been influenced by the time since graduation, how long doctors had been working in primary attention or presence of specialization. *Conclusions*. The evaluated professionals had shown laboratorial and clinical unfamiliarity with MM; this unfamiliarity was homogeneous in all net of primary attention in Belo Horizonte, not being influenced by time since graduation, how long doctors had been working in primary attention or presence of specialization.

1619

SAFETY AND EFFICACY OF LIPOSOMAL DOXORUBICIN ADDED TO LOW DOSE BORTEZOMIB AND DEXAMETHASONE IN ADVANCED REL/REF MULTIPLE MYELOMA

S. Aquino, F. Ballerini, M. Miglino, M. Clavio, C. Ghiggi, M. Gobbi, L. Canepa

Clinica Ematologica, GENOVA, Italy

Background and Aims. Despite the significant improvement related to the introduction of new drugs, the treatment of relapsed multiple myeloma (MM) represents a challenge, especially in patients with a low performance status, due to age, concomitant diseases and toxicity due to previous chemotherapy. In order to improve outcome in this subset of patients and reduce the therapy related toxicity we planned a 3-drugs combination adding liposomal encapsulated doxorubicin to dexamethasone and low dose Bortezomib. Bortezomib and anthracyclins can reciprocally increase their efficacy, as already demonstrated *in vitro* and *in vivo*. In comparison with standard doxorubicin, liposomal and pegylated liposomal doxorubicin show comparable efficacy and lower cardiac toxicity. Furthermore liposomal doxorubicin is reported to reach higher concentrations in bone marrow and is not associated with severe palmar-plantar erythrodysesthesia (hand-foot syndrome) reported with the pegylated form. *Design and Methods*. Starting from July 2006 14 patients with poor performance status referred to our institution for relapsed MM were treated with bortezomib 1.0 mg/mq i.v. twice weekly for 2 weeks (days 1,4,8,11 of each cycle) in a 21 days cycle, oral dexamethasone 20 mg on the day and the day after bortezomib and liposomal doxorubicin (Myocet®) 50 mg/mq i.v. on day 4 (30 mg/m^2 for patients older than 75 yrs). Response was defined according to modified EBMT criteria (*Bladé et al, 1998*). Responsive patients continued treatment until a maximum of six cycles. After the completion of the schema Thalidomide 100 mg/die p.o.continously was added for patients who had not presented previous unacceptable toxicity.

Table 1. Patients characteristics.

Age (years), median		65 (55-79)
Relapsed		11 (79 %)
Refractory		3 (21%)
Durie-Salmon stage III		9 (64%)
Prior tratment		2 (1-6)
Treatment results:		2 CR (14%)
		1 nCR (7%)
		2 VGPR ((14%)
		7 PR (50%)
		2 SD (14%)
Toxicity: haematological	gr 1-2	2 (14%)
	gr 3-4	4 (29%)
Toxicity: neurological	gr 2	4 (29%)

Results. Clinical characteristics of the patients are described in Table 1. Hematological toxicity was present in 42% of the patient, whereas transient neurological toxicity developed in 4 patients (29%). No case of DVT or cardiac failure was recorded. Overall 12 out of 14 patients (86%) responded, with 2 CR, 1 nCR, 2 VGPR and 7 PR. All partial responses (PR) exhibited a >70% reduction in monoclonal component (MC) ; 2 patients showed SD. Despite the high response rate, PFS was very short for 8 out of 14 patients, who experienced disease progression in a median of ten weeks after completion of therapy. Four patients maintained response at 6+ (CR),8+ (VGPR), 8+ (VGPR) and 20 (CR) months. *Conclusions*. According to our experience the combination of Bortezomib, Dexamethasone and Myocet® is a very feasible treatment for relapsed MM in frail and heavily pretreated patients, showing a high overall response rate (86%). Hematological toxicity was manageable and extrahematological toxicity was negligible so that all patients were treated on an outpatient basis. Nevertheless a high proportion of responding patients (67%) experienced early progression of disease, despite the apparently satisfactory quality of response (6 PR with >70% MC reduction, 1 VGPR, 1 nCR). Conversely four patients (33%) experienced a durable and stable response. Whereas the early relapsing patients reached their best response after 4-6 cycles of therapy, all the long lasting responders had reached at least a VGPR (>90%) after only 2 cycles, suggesting that early acquisition of VGPR rather than quality of best response could predict progression free survival.

1620

DOUBLE AUTOLOGOUS STEM CELL TRANSPLANTATION IN POEMS SYNDROME

F. Saltarelli,[1] A. Moscetti,[1] M. Pacilli,[2] A. Ferrari,[2] G. Antonini,[3] S. Morino,[3] B. Monarca,[2] G. La Verde[1]

[1]UOS Discrasie Plasmacellulari e Amiloidosi, Az Sant'Andrea Università La Sapienza, ROMA, Italy; [2]UOC Ematologia,Az Sant'Andrea,Università La Sapienza II Facoltà, ROMA, Italy: [3]UOC Neurologia,Az Sant'Andrea,Università La Sapienza II Facoltà, ROMA, Italy

Background. POEMS syndrome is a rare multisystemic disease related to a plasma cell dyscrasia and characterized by the association of Polyneuropathy, Organomegaly, Endocrinopathy, M protein and Skin changes. POEMS is a potentially fatal disease and patients' quality of life deteriorates because of progressive neuropathy, massive peripheral edema and multiorgan failure. We described a case of POEMS syndrome treated with high dose chemotherapy and double autologous peripher-

al stem cell transplantation (PBSCT). *Design and Methods*. We observed a 30 years-old woman with POEMS syndrome associated with Castleman disease. She presented a severe and rapidly progressive sensorymotor polyneuropathy with inability to walk, monoclonal component IgA l, splenomegaly, melanosis and thrombocytosis. Results of bone marrow biopsy showed mild plasmacytosis (10%). She was previously treated with high dose intravenous immunoglobulin in the neurologic unit without any clinical benefit. The patient received cyclophosphamide 2 gr on day 1,3, dexamethasone 40 mg on days 1-4 for 2 cycles and G-CSF 5 mcg/kg/day was added for mobilization. Time from diagnosis to first transplantation was three months. At time of first PBSCT the patient showed a severe neurologic involvement (Modified Rankin Scale 4). Melphalan 140 mg per square meter of body surface area was administered intravenously as conditioning regimen followed on day 2 by reinjection of the cells collected by leucapheresis. The number of CD34+ cells infused was $7.1x10^6$/kg. All the procedures for PBSCT were well tolerated and the post-transplantation period was uneventful, except for an episode of neutropenic fever without bacteriological documentation that resolved under broad-spectrum antibiotics. Five months later, the patient underwent a second consolidation PBSCT using the same conditioning regimen. The same number of CD34+ cells were infused. Any complication occurred in the period after the transplantation procedure. *Results.* After the first PBSCT we observed slow but progressive improvement in neurological disease, skin changes and performance status. After the second PBSCT splenomegaly was resolved and laboratory analyses showed negativization of monoclonal component, absence of plamacytosis at bone marrow biopsy and absence of trombocithosis. After one year from transplantation, the patient could perform their daily activities autonomously and had gone back to their social and working life. *Conclusions*. To our knowledge, between 1998 and 2008, 42 patients with POEMS have been successfully treated with autologous bone marrow transplantation. The goal of PBSCT in POEMS syndrome is to achieve remission of both the haematological and the systemic manifestations. Our case confirms usefulness and safety of this procedure in this disease and supports the idea that PBSCT should be considered early during the disease course to obtain the best response.

1621

EFFICACY AND SAFETY OF LENALIDOMIDE IN COMBINATION WITH DEXAMETASONE IN RELAPSED OR REFRACTORY MULTIPLE MYELOMA

A. Canovas,[1] J.J. Alonso,[2] B. Barreiro[2]

[1]Cruces University Hospital. UPV, BARACALDO (VIZCAYA), Spain;; [2]Osakidetza, BARACALDO. VIZACAYA, Spain

Background. Lenalidomide is an active immunomodulatory agent recently approved for relapsed or refractory multiple myeloma (MM) in combination with dexametasone but there is yet little experience of its use outside of clinical trials. Aims: To evaluate the efficacy and safety of the combination lenalidomide-dexametasone (L/D) as rescue therapy in relapsed or refractory MM in unselected patients. *Design and Methods*. All the patients with MM followed in our department from the 1st January 2007 to the 31st January 2009 were retrospectively reviewed. The patients with relapsed or refractory disease after two or more therapeutic regimens that underwent treatment with L/D (25 mg of daily oral lenalidomide on days 1 to 21 of each 28-day cycle and 40 mg of weekly oral dexametasone) were selected. They all received anti-thrombotic prophylaxis with low molecular weight heparin. Treatment was continued until the occurrence of disease progression or unacceptable toxic effects. Efficacy was assessed by the response rate and time to progression (TTP). Complete response (CR) was defined as the disappearance of both monoclonal serum protein (tested by IF) and urinary component. Partial response (PR) was defined as a 50-99% monoclonal serum protein reduction and 90% reduction in urinary component. Minor response (MR) was defined as a reduction of 25-50% and non response (NR) as an inferior reduction or progression. Response was assessed after at least one L/D treatment course. Safety evaluations were coded using the WHO scale. Statistical methods: descriptive, χ^2, Fisher exact test, Kaplan-Meier tables, log-rank test and Cox binary logistic regression. Results. Seventeen patients were included, with a median age 76 years (47-80) and a median time from diagnosis of 3,1 years (0,3-14,5). The median number of prior therapies was 4 (2-13): 53% had previously undergone an ASCT, 100% had been treated with Bortezomib and 23% with thalidomide. The reason for therapy with L/D was relapse in 7 cases (41%) and refractoriness to prior therapy in 10 (59%). 16 patients were assessable for response: 2 had obtained CR, 12 PR (CR+PR: 87%) and 2 NR. Two patients with PR underwent a ASCT after 4 cycles of L/D, in one case and after mobilization with cyclophosphamide and filgrastim. The median TTP from the beginning of L/D was 10 months and median survival of 15 months; 7 patients are alive at end of study with a median observation of 8 months. Association of response, TTP and overall survival with clinical variables such as age (>76 years versus equal or minor 76), gender, reason for treatment, monoclonal component type, performance status and previous therapies was analysed. No statistically significant relationship was found in any case. Nevertheless there was a trend of a superior median TTP in patients with 4 or less prior lines of treatment (11 versus 4 months) and in the previously treated with thalidomide (11 versus 2.6 months). The most common toxicity was hematological with neutropenia or thrombocytopenia grade 3 or 4 in 6 patients (35%). It was more frequent in those with 4 or more prior lines of therapy (p=0.04) or prior ASCT (p=0,009). However age was not associated with hematological toxicity. There was a pulmonary embolism in one case, but therapy with L/D could be continued. On the other hand, therapy was discontinued due to facial angioedema in another case. No febrile neutropenia events were registered. G-CSF support was required in 5 patients. *Summary and Conclusions*. In our experience L/D has a remarkable efficacy in response rate and TTP in relapsed or refractory MM, even in elderly patients with several previous treatment lines (half of them with prior ASCT). Main adverse events were mostly hematological and controllable.

1622

AN IN VITRO CULTURE SYSTEM FOR HIGH-THROUGHPUT SCREENING OF ANTI-MYELOMA DRUG CANDIDATES

A. Duek, P.K. Filanovsky, L.. Basous, A. Berrebi, M. Shtalrid, F. Arditti

Kaplan Medical Center, REHOVOT, Israel

Background. Long-term cultures of MM cells are hard to establish in the absence of additives like cytokines or feeder cells that could alter the outcome of drug tests. Similarly, their engraftment in animal models has not been prominent. Hence, a high number of drug candidates with anti-myeloma potential are accumulating waiting to be tested. *Aims*. Establishment of primary BM cultures from MM patients in the absence of additives to improve our capacity to evaluate drug candidates in high-throughput assays leading to a more personalized medicine. *Design and Methods*. Bone marrow aspirates samples from 10 MM patients at different disease stages were cultured in complete medium (RPMI1640, 10% FCS, 1% pen-strep, non-essential amino acids, L-glutamine, and sodium pyruvate) in 75 cm^2 flasks following red cell blood lysis. Confluent cultures were trypsinized and expanded in larger flasks. Subsequently, adherent cells were tested for CD138 expression. In parallel, a cell drop was cytospined and stained by May-Grunwald Giemsa. *Results*. The bone marrow cells expanded *in vitro* generating confluent cultures of adherent cells after 3-4 wks. Subsequent trypsinization and replating of primary BM cells generated 3 weeks later a new layer of adherent cells. BM cells derived from patients at partial remission (PR) or relapse contained a large population (24% to 42%) of CD138 positive cells, whereas BM cells from patients in remission show only background levels of the plasma cell marker. Histology revealed the presence of plasmacytoid cells with typical eccentric nuclei and golgi halo in the BM cultures derived from patients in PR and relapse, but not from patients in remission, suggesting that the previous (before culture) disease state was conserved. *Conclusions*. This *in vitro* culture system will be useful for screening novel drug candidates in high-throughput assays and also will facilitate studies on several aspects of myelomagenesis.

1623

A PHASE I/II CLINICAL STUDY TO INVESTIGATE EFFICACY, SAFETY AND PHARMACOKINETICS OF LENALIDOMIDE WITH/WITHOUT DEXAMETHASONE IN JAPANESE PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA

S. Iida,[1] H. Nagai,[2] S. Okamoto,[3] T. Chou,[4] M. Takatoku,[5] T. Hotta

[1]Nagoya City University Hospital, NAGOYA, Japan; [2]National Hospital Organization Nagoya Medical Center, NAGOYA, Japan; [3]Department of Medicine, Keio University, TOKYO, Japan; [4]Niigata Cancer Center Hospital, NIIGATA, Japan; [5]Celgene KK, TOKYO, Japan

Lenalidomide is an immunomodulatory drug which has been approved in USA, EU, and other countries for the treatment of relapsed and refractory multiple myeloma (MM), but it has not yet been introduced into clinical practice in Japan. We conducted a multicenter phase I/II clinical study to investigate the maximum tolerable dose (MTD), efficacy, safety and pharmacokinetics of lenalidomide administered alone or in combination with dexamethasone (Dex) in Japanese patients

with MM. Fifteen patients with relapsed and/or refractory MM were enrolled. This study was composed of two stages, i.e., the MTD-determining stage and the subsequent treatment stage. In the MTD-determining stage, lenalidomide (10 mg or 25 mg) alone was administered once a day for 21 days to confirm the safety. In the treatment stage, lenalidomide was administered alone or in combination with Dex for 21 days in each 28-day cycle to investigate the efficacy, safety and pharmacokinetics. Coadministration of Dex was started after determining the MTD. In the MTD-determining stage, 3 patients were enrolled to the 10-mg single cohort and then 6 patients to the 25-mg single cohort. In the treatment stage, 6 patients were newly registered to the combination cohort. In the 10-mg cohort, no dose-limiting toxicity (DLT) was observed, and in the next 25-mg single cohort, grade 3 toxicity (hypoxia) was observed in one out of 6 patients. Based upon the observation, 25mg was chosen as the dose for next stage. Regarding the efficacy evaluation throughout the MTD stage and the treatment stage, all of the 6 patients who received the combination treatment showed good response; two of the 6 patients achieved complete response (CR), 4 patients achieved partial response (PR). One patient of the 10-mg single cohort achieved minimum response (MR). Three patients of the 25-mg single cohort achieved PR, and one patient did MR. In safety evaluation, hyperglycemia of grade 3 was noted in one patient of the combination cohort, but neither grade 4 adverse event nor thromboembolic event was observed. In pharmacokinetic evaluation, it was found that the pharmacokinetic profile of lenalidomide was similar between Japanese and Caucasian MM patients and it was also confirmed that coadministration of Dex did not have an significant impact on the pharmacokinetic profile of lenalidomide. In conclusion, this study demonstrated the MTD of lenalidomide to be 25 mg daily in Japanese as well as Caucasian MM patients and the combination therapy of lenalidomide with Dex could be sufficiently effective in the clinical practice. In addition, the adverse events associated with this treatment were well-known and manageable

THE USEFULNESS OF INTERPHASE FISH AT DIAGNOSIS OF MYELOMA IN ADDITION TO METAPHASE CYTOGENETICS

S.K. Park,[1] C. Kim,[1] H.J. Kim,[1] E.J. Lee,[1] D.S. Hong,[1] J.H. Won,[2] H.S. Park,[2] S.B. Bae,[3] S.C. Lee,[2] K.T. Lee,[3] Y.S. Jung[2]

[1]Soonchunhyang University Bucheon Hospital, BUCHEON, GYEONGGI, South-Korea; [2]Soonchunhyang University Hospital, SEOUL, South-Korea; [3]Soonchunhyang Chunan Hospital, CHUNAN, CHUNGNAM, South-Korea

Background. Multiple myeloma is characterized by the accumulation of malignant plasma cells within the bone marrow and regarded as incurable, but remissions may be induced with steroids, chemotherapy, thalidomide and stem cell transplants. The clinical heterogeneity of myeloma is dictated by the cytogenetic aberrations present in the clonal plasma cells. Fluorescence *in situ* hybridization (FISH) overcomes the limitations of standard cytogenetics and allows for the detection of numerical and structural chromosomal abnormalities in both metaphase spreads and interphase nuclei. *Design and Methods*. We evaluated the chromosome abnormalities in 34 MM patients using conventional cytogenetics and interphase FISH with 6 probes such as IGH/CCND1, IGH/FGFR3, IGH/MAF, DS13S319/LAMP1, IGH/BAP, and p53/CEP17. Results: Cytogenetic abnormalities were found in 24 (70.6%) of the 34 MM patients. 10 (29.4%) patients had abnormal metaphases by conventional cytogenetics. Interphase FISH results were abnormal in 21 (61.8%) patients and 11 (32.3%) patients had abnormal interphase FISH but normal metaphases. The evidence of the loss of D13S319 with or without loss of LAMP1 was found in 6 (17.6%) patients, and loss of p53±CEP17 for 2 patients, IGH-BAP for 9 (26.5%) patients, IGH/FGFR3 for 2 patients, and IGH/CCND1 for 7 (20.6%) patients, respectively. However, there were none positive for IGH/MAF. Chromosome 13 abnormalities and IGH rearrangement is correlated with poor clinical outcome. *Conclusions*. Interphase FISH can provide useful information to evaluate the presence of prognostic chromosome abnormalities in addition to metaphase cytogenetics. And it should be used in the routine evaluation of multiple myeloma.

1625

DIFFERENT PATTERN OF RELAPSE IN MULTIPLE MYELOMA (MM) PATIENTS TREATED WITH NOVEL AGENTS

G. Farina, S. Piano, G. Giordano, T. Grafone, C. Nicci, S. Storti

Università Cattolica Sacro Cuore, CAMPOBASSO, Italy

Background MM's malignancy of terminally differentiated antibody-secreting plasmacell, homes to and expands in the bone marrow(BM), where it causes a constellation of disease manifestation including BM suppression, osteolytic bone destruction and end organ damage. It's mostly confined to medullary sites and its predominant clinical manifestations are generally related to BM infiltration and destruction of bone. However extramedullary involvement is seen in some patients. During the main course of disease evolution, MM cells depend on BM microenviroment for their growth and survival. Reciprocal interactions between MM cells and BM mediate not only MM cell growth but also protect them against apoptosis and cause bone disease and angiogenesis. Newer therapies, such as thalidomide and bortezomib, capitalize on recent advances in our understanding of biology of MM, including molecular mechanisms by which MM cell-host BM interactions regulate tumor-cell growth, survival and drug resistance in the BM microenviroment. Thalidomide's orally bio-available glutamic acid derivative which inhibits production of TNF-α and angiogenic cytokines such as basic fibroblast growth factor (bFGF) and/or VEGF. Bortezomib's intracellular proteolytic system which regulates degradation of broad spectrum of intracellular proteins, including diverse regulators of cell proliferation (e.g., cyclin-dependent kinase inhibitor proteins) or apoptosis. Aims To describe different pattern of relapse in MM patients treated with thalidomide or bortezomib. *Design and Methods*. We treated, in 48 months, 37 MM patients. M/F was 19/18, median age was 65 (47-90). All patients showed advanced disease (III stage): 15/37(40%) with IgG/k type, 8/37(21%) IgG/l type, 4/37(10%) IgA/K and 5/37(13%) IgA/l type, 1/37(2%) IgD and 3/37(8%) micromolecular type. Patients treated with Thalidomide plus dexamethasone or MP regimen are 14/37(37%), with Bortezomib plus Dexamethasone or Caelyx-Dex regimen are 20/37(54%), with combination Thalidomide and Bortezomib plus dexamethasone or MP regimen are 3/37(8%). Results In our retrospective analysis we observed that 11/20(55%)MM patients treated with Bortezomib presented relapse. 3 of these patients(27%) had relapse with extramedullary but not BM and bone litic lesion involvement. Today 2/3(66%) patients are alive and salvage therapy ongoing. We also evidenced that 5/14(35%) patients treated with thalidomide showed relapse. Two of these patients(40%) had both BM and extramedullary involvement. Today these patients are died. All three patients treated with associated regimen are alive and in complete remission with median follow-up of 19 months (12-24). *Conclusions*. Prognosis and treatment of MM has evolved greatly over the past decade. Development and incorporation of new agents such as immuno-modulators and proteasoma inhibitors into therapy has improved outcomes and is helping patients enjoy longer periods of remission. Their combination are being evaluated to better manage in MM population as our few data confirmed. Despite of these, in follow-up of patients treated with Bortezomib, we suggest to evaluate possibility of extra-medullary disease even if BM biopsy and skeleton radiography are negative. Actually we don't know the pathogenetic mechanism. We speculate that with bortezomib, plasmacellular clone escape from drug control not microenvironment- related. Probably this control hold over in BM and bone compartment where bortezomib continue to inhibit binding of myeloma cells to BM stromal cells and BM triggered angiogenesis.

1626

MULTIPLE MYELOMA: NEW ATTAINMENTS IN RUSSIAN LABORATORY MEDICINE

E.B. Rusanova,[1] A.V. Kurtova,[2] N.V. Stepanova,[1] V.A. Shuvaev,[3] Y.E. Zueva,[1] G.N. Salogub[1]

[1]Saint-Petersburg State Medical University, SAINT-PETERSBURG, Russian Federation; [2]MDAnderson Cancer Center, HOUSTON, USA; [3]Russian Research Institute of Hematology and Blood Transfusiology, SAINT-PETERSBURG, Russian Federation

Background. Multiple myeloma (MM) is a group of hematological malignancies characterized by excessive numbers of abnormal plasma cells in the bone marrow and overproduction of monoclonal component (MC) or Bence-Jones protein (free monoclonal kappa or lambda light chains). Cytogenetic and molecular deletion of chromosome 13 is associated with poor prognosis of MM. Last years the appearance of new therapeutic agents provokes revisions in guidelines of laboratory diagnostics of MM. The aim of this study to describe peculiar biological properties of russian patients with MM. *Design and Methods*. 360 patients with median age 63 (44-83) years diagnosed with *de novo* MM were enrolled into this study. Microscopy of bone marrow smears, protein electrophoresis and serum/urine immunofixation (Paragon, Beckman Coulter, USA), serum immunoglobulins (IgA, IgM, IgG) (Immage, BC), serum/urine κ and λ light chains, β-2-microglobulin (Immage, BC),

molecular genetics (FISH) and immunophenotyping (IPT) of plasma cell by multiparametric flow cytometry (Cytomics FC500, BC) using a panel of monoclonal antibodies: CD45-FITC, CD38-FITC, CD138-PE, CD19-PC5, CD20-PE, CD56-PE, CD117-PC5 (BC) were performed. *Results*. MC IgG and κ chain is the most often MC and was identified in 48% cases, and IgG/λ and IgA/λ both 12%, IgA/κ 9%, IgM/κ 2%, IgA 5%, λ 5% and κ 7%. The karyotype was without cytogenetic abnormalities in the most cases (91%). There were detected trisomy 7 (3% of cases), del RB1 (3% of cases), del 14q (3% of cases). The del(13)/-13, t(4;14) and p53 by FISH were not identified in all cases. Immunophenotype profile D38+CD138+CD56+ and/or CD117+ was identified only in 51 cases. All cases with Bence-Jones myeloma demonstrated the absence of CD56 and/or CD117 expression on transformed plasma cells. *Conclusions*. In the era of growing progress in multiple myeloma treatment we need the modern laboratory tests with quality control endorsement. Our report describes peculiar biological properties of MM in the north-west region of Russia with cytogenetic data, flow cytometry phenotype of transformed plasma cells and the type of MC.

1627

BORTEZOMIB-INDUCED SEVERE HEPATOTOXICITY DURING PROGRESSIVE MULTIPLE MYELOMA: A MEDICAL CHALLENGE TREATED SUCCESSFULLY WITH LENALIDOMIDE

J. Garcia-Suárez, J.J. Gil-Fernández, Y. Martín, D. De Miguel, H. Magro, H. Guillén, M. Callejas, C. Burgaleta

Príncipe de Asturias University Hospital, ALCALÁ DE HENARES (MADRID), Spain

Background. Multiple myeloma (MM) remains incurable with conventional treatments, with a median survival duration of 3-5 years. Treatment with the proteasome inhibitor bortezomib or immunomodulatory drugs such as thalidomide and lenalidomide represent an important advance that improves outcomes for patients with MM, but their side effects remain a concern. A recent review of PubMed (February 20, 2009) revealed only one patient with MM who developed bortezomib-induced severe recurrent hepatitis (*Rosiñol et al. Arch Intern Med 2005;165: 464*). Aims: To present a second case of bortezomib-induced severe hepatotoxicity during progressive MM successfully rescued with lenalidomide. *Design and Methods*. A 60-year-old man was diagnosed as having stage IIIB IgA-κ MM with a high level of Bence Jones proteinuria (more than 2 g/day). An abdominal subcutaneous fat biopsy detected no amyloid. Electrocardiographic findings showed atrial fibrillation with a rapid ventricular rate, and echocardiographic findings disclosed a left ventricular ejection fraction of 68% without ventricular septal or left ventricular thickness. In addition to intensive supportive care and IV amiodarone, the patient was treated with bortezomib at 1.3 mg/m^2 on days 1, 4, 8, and 11, and dexamethasone 20 mg orally on the day of the first bortezomib injection and on the following day. Scleral icterus with a pattern of cholestatic injury appeared on day 7 (ASAT, 49 U/L; ALAT, 118 U/L; γGT, 217 U/L; Bilirubin, 26 micromol/L). Serology revealed no acute infection with hepatitis A, B, C, or E, cytomegalovirus, Epstein-Barr virus, adenovirus or toxoplasmosis. Tests for primary biliary cirrhosis and autoimmune hepatitis were negative. Caeruloplasmin, urinary copper excretion and alfa1-antitrypsin levels were normal. Ultrasonography of the liver and computed tomography of the abdomen showed moderate hepatomegaly (16 cm) but no bile duct dilation or thrombi in hepatic veins. IV amiodarone was discontinued on day 8; however, on subsequent days liver function continued to deteriorate. This finding suggested that amiodarone was not the cause of hepatic toxicity, and transjugular liver biopsy was performed on day 23. The biopsy showed marked ductopenia as confirmed by the absence of staining with immunohistochemical epithelial markers. At this point bortezomib-induced liver toxicity was strongly suspected, and bortezomib was discontinued. On day 28 the patient experienced symptomatic life-threatening atrial fibrillation refractory to diltiazem, and IV amiodarone was successfully restarted. Simultaneously, progression of MM was noted with worsening renal function, pancytopenia, and increasing serum M protein level (45 g/L) and free kappa-light chain Bence-Jones proteinuria (4.925 g/L). *Results*. Despite limited clinical experience with lenalidomide in severe liver dysfunction, we treated him with lenalidomide (10 mg/day p.o. on days 1-21), in combination with cyclophosphamide and dexamethasone (Morgan GJ et al 2007;37, 268). Treatment with IV amiodarone was continued. Within 1 week of beginning the lenalidomide-based regimen, renal failure resolved and thrombocytopenia improved; thus the dose of lenalidomide was increased to 25 mg/day, and enoxaparin 40 mg once daily was started as prophylaxis for venous thromboembolism. During treatment with the lenalidomide-based regimen, liver function recovered, and his liver function profile had returned to near normal values 50 days after bortezomib had been started. At the time of this writing, 9 months later, the patient has received 8 courses of lenalidomide-based treatment with a very good partial response, and liver function tests remain normal. *Conclusions*.This experience illustrates two important considerations. 1) Regular monitoring of the hepatic function indices during the therapy with bortezomib is therefore indispensable for the early detection of unpredictably severe hepatotoxicity 2) Dosing for lenalidomide in this situation can be difficult, but good clinical results are possible.

1628

RECOMMENDATIONS FOR USE OF FLC TESTS IN MONOCLONAL GAMMOPATHIES

V. Radovic

STADA Hemofarm AD, BELGRADE, Serbia

Background. Monoclonal gammopathies constitute a group of disorders characterized by the clonal proliferation of plasma cells. The M protein is a tumor marker specific for monoclonal gammopathies because it reflects the clonal production of immunoglobulin. Aims: The objective of this work was an estimate of the use of free light chain tests for diagnosis, screening, identification of clonality, follow up of disease and prognostic evaluation in monoclonal gammopathies. *Design and Methods*. The method of the analysis sums up the results of Guidelines for the diagnosis and management of monoclonal gammopathies. *Results*. According to NACB (National Academy of Clinical Biochemistry) and NCCN (National Comprehensive Cancer Network) recommendations, the tumor markers are: serum and/or urine protein electrophoresis, serume and/or urine immunofixation, serum and/or urine free light chains, serum viscosity and β2-microglobulin. UK and Nordic Guidelines for the diagnosis and management of multiple myeloma state that the "Free light chain assay has also recently been shown to be helpful in monitoring response in the majority of patients with an intact immunoglobulin paraprotein...". Serum free light chain automated immunoassays are more sensitive for the detection of monoclonal light-chain myeloma, nonsecretory myeloma and AL amyloidosis than traditional electophoretic and immunofixation methods. There is not a strong correlation between serum free light chain and measurement of urine free light chain (Bence Jones protein) by 24 h protein electrophoresis. Furthermore, serum FLC ration is an independent risk factor for malignant progression in MGUS patients. *Conclusions*. The determination of serum FLC and serum electrophoresis as first-line tests for investigating possible B-cell disorders gains additional diagnostic information.

1629

CLINICAL EFFICACY OF VELCADE (BORTEZOMIB) AND DEXAMETHASONE THERAPY IN PATIENTS WITH REFRACTORY OR RELAPSED MULTIPLE MYELOMA

I. Ionita,[1] M. Cheveresan,[2] D. Calamar,[1] C. Ionita,[1] D. Oros,[3] H. Ionita[1]

[1]UMF Victor Babes Timisoara, TIMISOARA, Romania; [2]City Clinical Hospital, TIMISOARA, Romania; [3]UMF VICTOR BABES Timisoara, TIMISOARA, Romania

Background. Recent studies demonstrated that the combination of Bortezomib and several chemotherapeutic agents may have significant activity in multiple myeloma (MM). The most used chemotherapeutic agents are Cyclophosphamide, Thalidomide and Dexamethasone. Aims: In this study we assessed the efficacy and safety of the Bortezomib-Dexamethasone combination for the patients with relapsed/ refractory myeloma. *Design and Methods*. 21 new MM patients were diagnosed and treated in the Hematology Department during a period of two years (2006-2008). The patients who received at least one previous regimen of treatment were enrolled. Bortezomib was given at 1,3 mg/m^2 or D 1, 4, 8, 11 (cycles of 21 days) and Dexamethasone 20 mg/m^2 i.v. or p.o. or D 1, 4, 8, 11(cycles of 21 days). Results: The group was formed out of 14 males and 7 females. The median age of patients was 61 years (range 45-69 years). Median number of previous treatment regimens was two (range 1-4). There was no complete remission obtained. 17 patients obtained partial remission, 3 patients did not respond, and 1 patient died due to the complications not related to the treatment. Median progression-free survival (PFS) was 11.3 months (range 9.3-15.7 months) and median overall survival (OS) from the onset of Velcade-Dexamethasone was 27.6 months (range 20.3-34.2 months).Grade $^3/_4$ toxicities included thrombocytopenia (28.57%), neutropenia (14.28%), peripheral sensory neuropathy (42.85%). There was no treatment-related deaths. *Conclu-*

sions. Velcade-Dexamethasone therapy for patients with relapsed/ refractory MM is highly effective. The side effects such as peripheral neuropathy should be considered. Hematological toxicity did not require treatment disruption. It is necessary to use Velcade in association with other chemotherapeutical regiments like - ciclofosfamide, adriamcin, thalidomide for higher therapeutical efficiency in these patients.

1630

SURVIVAL PROBABILITIES IN PATIENTS WITH MULTIPLE MYELOMA TREATED AT THE CLINIC OF HEMATOLOGY IN SKOPJE

S. Stankovic

University Clinic of Hematology, SKOPJE, Macedonia

Introduction. Multiple myeloma (MM) is a cancer formed by malignant plasma cells. It's an incurable but treatable disease. The treatment of MM has changed considerably over the past decade. Conventional therapy with MP containing agents was the standard treatment option for many years until myeloablative doses of Melphalan supported by an infusion of autologous hematopoetic stem cells were implemented in the treatment protocols. *Aims.* The aim of this study is to present the effects of treatment of MM patients at the Clinic of Hematology in Skopje in the past 15 years. Retrospectively we analyzed data from 112 patients treated with conventional therapy with MP-containing protocols compared to a group of 17 patients treated with high-dose therapy and autologous stem-cell transplantation. *Design and Methods*. 112 patients with MM (M-68; F-44; median age 59 years, range 36-80) were treated with conventional therapy with MP containing protocols, mostly according to VMCP (Vincristine, Melphalan, Cyclophosphamide, Prednisolon) protocol. 17 patients with MM (M-9; F-8; median age 53years, range 43-64) were prepared for treatment with high doses Melphalan and autologous hematopoetic stem cell transplantation. For the induction of remission VAD (Vincristine, Adriamycin, Dexamethason) protocol (4 cycles) was applied. Non-responders (4 patients) received Thalidomide+Dexamethason as a second line therapy for 5 month period and one patient received Bortezomib as a third line therapy. High-dose regimen consisted of Melphalan in doses of 200 mg/m^2. The Kaplan-Meier method was used to estimate survival probabilities. *Results*. Following the conventional therapy remission was obtained in 61% of patients (19% achieved a complete and 42% partial remission after 12 months of treatment). The median survival was 18 months including the patients with an early fatal outcome (25%) who died during the first 2 months after the confirmation of diagnosis. The 5-year survival rate was achieved in 30% of patients. In the high-dose group median survival after transplantation was 56 months, disease-free survival was 22 months; 5-year survival rate was achieved in 50% of patients. *Conclusions*. Our study has shown that the high-dose chemotherapy with autologous stem cell transplantation improves the response rate, event-free survival and overall survival in myeloma over that obtained with conventional chemotherapy.

1631

PATIENT SUFFERING FROM POEMS SYNDROME TREATED WITH LENALIDOMIDE PLUS DEXAMETHASONE

G. Ramirez, A. Campos, A. Rosell, M.P. Queipo de Llano, R. García-Sánchez, R. García-Delgado, I. Caparrós, A. Delgado, S. del Castillo

Hospital Virgen de la Victoria, MÁLAGA, Spain

Background. POEMS syndrome (Polyneuropathy, Organomegaly, Endocrinopathy, M protein and Skin changes) is also known as osteoclastic myeloma, PEP (polyneuropathy, endocrinopathy and plasma-cell dyscrasia), Crow-Fukase or Takatsuki syndromes. It is a paraneoplastic disorder of unknown etiology although cytokines (VEFG, IL-6, IL-1α) play an important role. No randomized clinical trials are available to provide evidence on the appropriate treatment for this syndrome and the strongest evidence on outcomes come from retrospective analyses. These reports covered alkylators, stem cell transplantation, thalidomide, corticosteroids, radiotherapy and skeletal targeted radiotherapy. In 2005, when asymptomatic and free of organomegaly, a 55-year-old man was diagnosed with chronic myeloproliferative syndrome and essential thrombocythemia in our center. Presence of an IgA monoclonal band was detected. A sensation of fatigue was initially described in the legs during 2006, with progression to the arms. Sensitive-motor polyneuropathy was diagnosed and immunoglobulin-based therapy initiated. The patient was refractory to treatment and respiratory distress was noted. He tested negative for Bcr-abl and Jak2. Amyloidosis was ruled out. Difficulty walking, dyspnea, generalized erythroderma and sclerotic lesions in the hands, without organomegaly, aroused suspicion of POEMS syndrome in 2008. Complementary test confirmed POEMS syndrome with neurological affectation, monoclonal gammopathy and endocrinopathy. *Aims.* We report treatment with lenalidomide (Len) plus dexamethasone (Dex) of a 55-year-old man suffering from POEMS syndrome. *Design and Methods*. Len 25 mg was administered on days 1 to 21 of a 28 days cycle, in combination with low doses of Dex (40 mg/weekly). The patient was closely monitored for efficacy and safety purposes. We present a descriptive analysis of the clinical status of the patient in both pre-treatment and on-treatment periods. Results: Baseline laboratory tests: platelets 976000 mm^3, TSH 13.6 mUI/mL, testosterone 1.51 ng/mL, IgA 1010 mg/mL, light chain lambda 496 mg/dL, VEGF 4339 pg/mL. A agglomerate of lymph nodes was identified by ultrasound in the left inguinal region and the bifurcation of the left common iliac artery. The biopsy of a lymph node showed the plasmocytic form of Castleman disease. Nocturnal respiratory polygraphy showed desaturation and hypoventilation during sleep, with phrenic paresis with severe restrictive respiratory failure. Sclerotic bone lesions were identified in the right femur and in the L5 vertebrae. When Len+dex treatment was applied, low molecular weight heparine (LMWH) was used until the patient was able to walk. A respiratory rehabilitation program was implemented. After 4 cycles of len+dex, substantial clinical improvement was noted: respiratory improvement, walk without cane. LMWH was substituted by ASA 100 mg. Laboratory tests: normalization of hormone levels, platelets 273000, light IgA 788 ng/mL, lambda chain 293 mg/dL, M component not quantified by migration to β region, VEGF 1015 pg/mL. *Conclusions*. Treatment with Len+dex is a feasible and effective option to treat POEMS syndrome. The treatment is well tolerated. More data from prospective were awaited.

1632

EFFICACY AND SAFETY OF LENALIDOMIDE IN THE TREATMENT OF MULTIPLE MYELOMA WITH RENAL INSUFFICIENCY

L. Bernal, E. Bonafonte, I. Izquierdo, A. Aules, M. Malo, M. Olave, G. Azaceta, M. Gutierrez

Hospital Clinico Lozano Blesa, ZARAGOZA, Spain

Background and aims. Renal impairment in multiple myeloma (MM) is associated to poor prognosis and worse survival. Standard treatments based on chemotherapy are associated to high toxicity. The apparition of new drugs has improved the evolution of these patients. There is more experience with bortezomib, as its metabolism is independent of renal function. On the other hand, lenalidomide is metabolised by the kidney, so it is necessary to perform dose adjustment. We present four patients treated with lenalidomide. *Design and Methods*. Patient 1: 52-year old man diagnosed of a MM IgG κ IIIA with chains in urine 13 g/24 h. After treatment with one cycle of VBMCP and bortezomib, he developed a tumor lysis syndrome, and renal insufficiency that required dialysis. He continued with bortezomib. After 15 cycles he obtained a PR. For that reason he started lenalidomide (15 mg/3 days a week/21 days) plus dexamethasone, obtaining a CR, without side effects. Patient 2: 66-year old man diagnosed of a MM IgG κ with chains in urine >25 g/24 h, and creatinine 2.2 mg/dL. After treatment with VAD, without obtaining any response, he started lenalidomide (15 mg/48 h/21 days) plus dexamethasone, with a creatinine of 3.1 mg/dL and a creatinine clearance of 25 mL/min. After 4th cycle, the renal function improved, and the dose was increased to 15 mg/day. The treatment was well tolerated, and after 10 cycles he shows an important improvement of his renal function (Creat 1.4 mg/dL), and a PR of the MM. Patient 3: 78-year old man diagnosed of a MM IgG κ IIIB with important elimination of chains in urine, and mild renal insufficiency (Creat: 3.1 mg/dL). He was treated with four cycles of VAD, without obtaining any response, and his renal function decreased. With an elimination of chains in urine of 15 g/24 h, he started bortezomib plus dexamethasone without any response after 3 cycles. For that reason he started lenalidomide (15 mg/48 h/21 days) plus dexamethasone, with a Creat of 6.9 mg/dL and a Creat clearance of 9 mL/min. After 5 cycles, he presents a PR and a significant improvement of the renal function (Creat 4.4 mg/dL). Patient 4: 63-year old man diagnosed of a MM IgA lambda IIIA, with a femur pathologic fracture. He was treated with four cycles of VAD, obtaining a VGPR, and therefore an autologous transplantation was performed, achieving a CR. Years later, he relapsed with an orbitary plasmacytoma and evidence of serum M-protein, so he started bortezomib plus dexamethasone. After 8 cycles, however the plasmacytoma disappeared, M-protein persisted. He also presented diarrhea as a side effect. Months later, his analysis showed renal insufficiency (Creat 2.2 mg/dL; Creat clearance: 32 mL/min) and proteinuria (1 g/24 h), with an M-protein of 2.5 g/L. He

started lenalidomide plus dexamethasone. After two cycles he showed CR. *Summary*. In our experience, lenalidomide in MM patients with renal insufficiency is effective, well tolerated, and with low profile of toxicity.

1633

ORAL VORINOSTAT COMBINED WITH LENALIDOMIDE AND DEXAMETHASONE IN A PATIENT WITH REFRACTORY END-STAGE MULTIPLE MYELOMA - A CASE STUDY

D. Siegel, K Olivo

Hackensack University Medical Center, HACKENSACK, USA

Background. While bortezomib, thalidomide, and lenalidomide have provided survival advantages for patients with multiple myeloma (MM), morbidity and mortality associated with MM remains high. Currently, there is a need for new treatment strategies for patients with relapsed and refractory MM who have exhausted current treatment options. Vorinostat is a potent oral inhibitor of Class I and II histone deacetylases and is approved in the US for treatment of cutaneous manifestations of advanced T-cell lymphoma in patients with progressive, persistent or recurrent disease on or following two systemic therapies. Vorinostat synergistically enhances the activity of bortezomib in patients with advanced MM and enhances responses to thalidomide analogs in preclinical studies. *Aims*. We present a case study of a heavily pretreated 73-year-old male patient with end-stage IgA MM who received clinical benefit from combined vorinostat, lenalidomide, and dexamethasone (VLD). *Design and Methods*. The patient was diagnosed with end-stage IgA MM in January 2005. Prior to diagnosis of MM, he had been diagnosed with myeloproliferative disorder (polycythemia vera) and presented at the time of MM diagnosis with myelofibrosis with severe splenomegaly; both of these latter conditions responded to treatment with lenalidomide therapy. Following diagnosis of MM, the patient had failed a bone marrow transplant and numerous previous systemic therapies, such as steroid and biologic agents including 1 year of lenalidomide and dexamethasone combination therapy and >1 year of treatment with bortezomib combined with lenalidomide. In May 2008, >3 years after the initial MM diagnosis, the patient commenced VLD combination therapy. Vorinostat (300 mg, orally) was administered on Days 1-7 and 15-21 of a 28-day cycle, with lenalidomide (10 mg, orally) on Days 1-21 and dexamethasone (40 mg, orally) on Days 1, 8, 15, and 22.

Table 1.

Patient treatment history for MM		
Systemic therapy	Best response	Reason for discontinuation
Thalidomide Dexamethasone	Stable disease	Poor tolerability
Lenalidomide Dexamethasone	Minor response/stable disease with a reduced dose of lenalidomide	Poor tolerability/relapse (reduced dose of lenalidomide)
Bortezomib Lenalidomide Dexamethasone	None	Lack of response
Bortezomib Lenalidomide Liposomal doxorubicin Corticosteroids	Stable disease	Poor tolerability and patient refusal to continue
Vorinostat Lenalidomide Dexamethasone	Very good partial remission	Treatment ongoing

Results. In the second cycle, vorinostat was reduced to 200 mg/day due to development of Grade 3 transient high fevers, which resolved spontaneously. The patient also experienced diarrhea during treatment cycle 1 and the following low-grade adverse events in treatment cycle 2: fevers, weakness, diarrhea, and other gastrointestinal-related events. IgA levels were 2230 mg/dL (cancerous) at diagnosis; VLD therapy reduced IgA levels to 248 mg/dL after one cycle (28 days) and to 194 mg/dL (within normal range) following two treatment cycles (56 days). Other immunoglobulin levels (depressed by the cancerous IgA) increased to normal ranges; IgG increased from 276 mg/dL to 346 mg/dL and 490 mg/dL following treatment cycles 1 and 2, respectively; IgM levels increased from 2 mg/dL to 19 mg/dL and 30 mg/dL after treatment cycles 1 and 2, respectively; M-protein levels in the urine reduced from 3721 mg/24 h to <60 mg/24h after VLD. The patient is currently completing his third treatment cycle and continues to respond to VLD. To date, he has shown a very good partial remission for one treatment cycle (see table). *Conclusions*. For this patient with refractory end-stage MM, oral VLD was well tolerated and conferred substantial clinical benefit, reversing disease progression and normalizing immunoglobulin levels in the blood.

1634

LOW DOSE LENALIDOMIDE WITH LOW DOSE DEXAMETHASONE IN PREVIOUSLY TREATED PATIENTS WITH MULTIPLE MYELOMA OLDER THAN 75 YEARS REQUIRING TREATMENT

A. Ruedas,[1] M.A. Moreno,[2] P. Guisado,[3] I. Barbolla,[1] C. Montalban[1]

[1]Hospital Ramón y Cajal, MADRID, Spain; [2]Hospital Ramon y Cajal, MADRID, Spain; [3]Hosptal Ramón y Cajal, MADRID, Spain

Background. The management of very old patients with active Multiple Myeloma (MM) who have received previous treatments but require further (although in most cases palliative) therapy is very difficult, due to the presence of concomitant diseases, decreased bone marrow reserve, systemic toxicity, relatively decreased renal function and general problems due to old age. Aims. As in this setting the tolerability of standard doses of dexamethasone (DEX), chemotherapy or IMiDs is a concern, we used low doses of lenalidomide and low doses of DEX and we present the preliminary results. *Design and Methods*. Four patients aged over 75 years with pretreated MM and progressive disease were treated with flexible low doses of lenalidomide along with low doses of DEX. Lenalidomide was initially given at a dose of 10 mg daily for 21 days and DEX 20-40 mg (20,20,32 and 40 mg, median 28 mg) for days 1 to 4, every 28 days. The dose of lenalidomide was maintained, when tolerated, up to 6-8 cycles, but moderately increased or reduced according to response and toxicity. Patients received prophylaxis with LMWH and omeprazol. CSF or red cell transfusions were used when needed. Patient risk was stratified following the Salmon and Durie (SD) score and the International Staging System (ISS). Response was assessed with the IMWG criteria. All patients signed an informed consent. Results. Median age was 83 years (range 75 to 90). Previous treatments were cyclophosphamide/prednisone (n=3), melphalan/prednisone (n=1) and DEX (n=1). Three patients had received 1 and another one 2 previous treatment modalities. Median creatinine level was 1.19 mg/dl (0.75 to1.63) and median hemoglobin level 9.8gr/dl (range 9.1 to10.9). 3 pts had IgGα and another IgGα. Median IgG serum level was 3.352 mg/dl (868 to 4990). 3 pts had SD stage IIA and another IA. 3 pts. had IIA and another IA ISS stage. Patients received 2, 6, 6 and 7 cycles, respectively. In one patient treatment was stopped due to toxicity and in another patient lenalidomide was reduced to 5 mg after 2 cycles and maintained for 4 additional cycles. In another one the doses was modified to 20 mg and then to 15 mg. Overall response occurred in all 4 patients (100%): 2 patients achieved Partial Remission (PR) and the remaining 2 achieved significant, but lesser that 50%, reduction of the M-component (Stable Disease), one of them after increasing the dose of lenalidomide. Of note, both PR were achieved after 3 cycles. Expectable and manageable grade II-III bone marrow toxicity occurred in 3 patients. *Conclusions*. Treatment with low doses of lenalidomide and low doses of DEX is an active and tolerable option to be considered in previously treated elderly patients with MM requiring treatment. Low lenalidomide doses can be flexibly modified depending of the quality of the response and toxicity. Longer follow up is needed to evaluate the duration of the response.

1635

ADVANTAGE OF SERUM MEASUREMENTS FREE LIGHT CHAIN IN PLASMA CELLS DISCORDERS

V.R. Radovic

Stada Hemofarm AD, BELGRADE, Serbia

Background. Accurate detection and quantitation of monoclonal immunoglobulins (Ig) is important for diagnosis and management of monoclonal gammopathies (MG). In particular, monoclonal Ig can be used for screening, monitoring cause and treatment of disease, and for monitoring progression in monoclonal gammopathy of unknown significance (MGUS). *Aims*. The objective of this work was an estimate advantage of serum measurements free light chain (FLCs) tests for diagnosis, screening, identification of clonality, follow up of disease and prognostic evaluation in plasma cells disorders (PCD). *Design and Methods*. The method of the analysis sums up the results of Guidelines for the diagnosis and management of PCD. *Results*. According to Guidelines Work-

ing Group of UK Myeloma Forum and Guidelines on the diagnosis and management of AL amyloidosis state that the "FLC assay has also recently been shown to be helpful in monitoring response in the majority of patients with an intact Ig paraprotein...". Approximately 30% of MG patients (including patients with light chain myeloma (LLMM), primary AL amyloidosis, nonsecretory myeloma (NSMM), and light chain deposition disease (LCDD)) produce FLC as the only monoclonal component, and as many as 96% of patients with intact Ig myeloma produce levels of FLC that can be quantitated in serum. A new, latex-enhanced, immunoassay provides ultrasensitive detection and quantification of FLC in serum (1 mg/L compared with 150-500 mg/L by IFE and 500-2000 mg/L by PE). This assay is able to detect FLC earlier than PE in patients with NSMM and amyloidosis. Serum FLC are also better for monitoring patients with LCDD. *Conclusions*. Serum FLC concentrations increase as urine FLC concentrations increase, but relate better to the changing tumor mass than urine measurements.

SYSTEMIC CAPILLARY LEAK SYNDROME DIAGNOSED BY IMPEDANCE CARDIOGRAPHY IN PATIENT WITH MULTIPLE MYELOMA

J. Halka, P. Krzesinski, R. Wierzbowski, O. Matysiak

Military Hospital Warsaw, WARSAW, Poland

Systemic capillary leak syndrome (SCLS) is rare disorder with a high mortality rate, characterized by rapidly developing diffuse swelling, weight gain and hypotension, hemoconcentration and hypoproteinemia. SCLS are cardinal features of acute lung injury and the acute respiratory distress syndrome , a severe illness associated with mortality of 30-50%. This syndrome is caused by sudden, reversible capillary hyperpermeability with a rapid extravasation of plasma from the intravascular to the intestinal space. Even though SCLS has been suggested to be pathogenic mechanism for the pulmonary toxicity of various drug, such as gemcitabine, retinoids, sirolimus, interferon-α and rare other cytostatic medicines, for example anthracyclin antibiotics. The pathogenesis of SLS is still unclear, but there's recently been a report showing this syndrome in association with monoclonal gammopathy This syndrome can be a fatal disease because cardiovascular collapse can occur in the initial capillary leak phase. This disease could lead to death if the blood pressure is not increased during the initial leak phase. Although theophylline, diuretics, terbutaline, steroids, calcium antagonist Ginkgo biloba extract and plasmapheresis have been suggested as medication ,none of them have been proven to be effective. Considering that this disease is self-limiting, conservative treatment in the acute phase is believed to be very important. We describe a case of SCLS after anthracyclin antibiotics (doxorubicyne) administration in a 71 -years- old male with multiple myeloma IgA kappa stadium III A Durie-Salmon treated a combination of doxorubicyne , vincristine and prednisone (VAD pattern). Two days after chemotherapy (VAD) administration the patient presented worsening dyspnea, diffuse swelling, weight gain and hypotension. Venticular dysfunction, superior vena cava compression or thrombosis or lung infiltrates were excluded by echocardiography and thorax spiral CT scan. The detection of doxorubicin -induced SCLS supports the hypothesis that SCLS could be pathogenic way of doxorubicin pulmonary toxicity. We diagnosed SCLS by means of impedance cardiography (NiccomoTMICG monitor) (ICG). This is a easy to use and safety diagnostic method. Intravenous administration of Furosemid and high dose steroid (Methylperednisoloni) was promptly given , with complete symptom recovery within third days. The next treatment cycle was given on time , without antracyclin antibiotics (doxorubicyne)- VCMP pattern. He wasn't suffer for sever dyspnea , diffuse swelling and hypotension. The impedance cardiography after chemotherapy (52 days) showed normal distribution of fluid between the intravascular space and the interstitial space. Conclucsion: SCLS is rare disorder with a high mortality rate, characterized by rapidly developing diffuse swelling, weight gain and hypotension, hemoconcentration and hypoproteinemia. SCLS are cardinal features of acute lung injury and the acute respiratory distress syndrome , a severe illness associated with mortality of 30-50%. In diagnosis of SCLS the technique was designed of measuring and monitoring the basic haemodynamic parameters in patients by means of impedance cardiography (ICG), also known as 'impedance plethysmography of the chest', 'electrical bioimpedance of the chest' or 'reocardiography'. The method makes it possible to denote stroke volume and cardiac output. It also enables the factors to be assessed that influence the following: preload (measurement of thoracic fluid content), afterload (measurement of systemic vascular resistance), the systemic vascular resistance index, contractibility (measurement of the acceleration index), the velocity index, the pre-ejection period, left ventricular ejection time, systolic time ratio and heart rate. The measurements also provide haemodynamic information during the treatment of patients with cancer to make a swift diagnosis of the cause of complaints such as dyspnoea and hypotonia.

1637

QUANTITATIVE CT PERFUSION MEASUREMENTS IN HODGKIN LYMPHOMA AND COMPARISON WITH 18-FLUORO-DEOXYGLUCOSE POSITRON EMISSION TOMOGRAPHY (FDG-PET): PRELIMINARY EXPERIENCE

A.F. Fabbri, M.A. Mazzei, I. Chitarrelli, P. Sacco, G. Fontanelli, L. Volterrani, F. Mazzei, F. Lauria

Azienda Ospedaliera Universitaria Senese, University of Siena, SIENA, Italy

Background.Structural CT criteria such as nodal size and appearance have a poor correlation with the vitality of a lymphoma mass, particularly in Hodgkin Lymphoma. However, differences in vascularity between tumors and normal surrounding tissues offer potential for more precise imaging. Many tumor capillary beds have a higher vessel density than normal, with a larger flow of blood per unit volume, or perfusion; moreover, these capillary beds also have increased permeability. CT-perfusion is an exciting CT technology that allows functional evaluation of tissue vascularity. *Aims*. This study investigates the potential for functional CT-perfusion and permeability measurements in distinguishing between active, recurrent disease and residual scar tissue, also in comparison with 18-Fluoro-deoxyglucose positron emission tomography (FDG-PET) that recently become widely used in the management of patients with malignant lymphomas, providing unique metabolic information about tissue vitality and prognosis of patients. *Design and Methods*. 21 patients with Hodgkin lymphoma underwent imaging with both modalities, CT perfusion with 64-detector scanner (VCT, GE Healthcare, contrast material 100 ml, 4 mL/sec) and FDG-PET at staging, early assessment and restaging (n=2), or at early assessment and restaging (n=10) and only at restaging (n=9). All 35 CT perfusion studies were conducted on the most significant lymphoadenopathy and analyzed by using commercially available software (CT Perfusion 3 - Body tumour protocol; GE Healthcare Technologies); blood volume (BV), bloodflow (BF), mean transit time (MTT) and permeability surface (PS) were measured. Results: thirty out of 35 (86%) CT-perfusion and FDG -PET scan resulted concordant. In particular, all examination were positive at staging, while FDG-PET was positive and TC-perfusion negative in a case at early assessment and the two techniques resulted different in four cases at restaging, in which FDG-PET was negative but TC-perfusion was doubt/positive. Conclusions: CT-perfusion like FDG-PET offers the advantage of functional tissue characterization that is largely independent of morphologic criteria. It can represent a potential alternative non-invasive method in evaluating response to treatment in early assessment of Hodgkin lymphoma and in distinguishing between active, recurrent disease and residual scar tissue after therapy. Further and larger studies are needed to confirm these preliminary data and to extend the prognostic value of FDG-PET to TC-perfusion, particularly when used in the early assessment of response to treatment.

1638

CARDIOPULMONARY TOXICITY OF DIFFERENT CHEMO-RADIOTHERAPIC REGIMENS FOR HODKGIN'S DISEASE

F. Villani, A. Busia, V. Bonfante, S. Viviani

Fondazione IRCCS Istituto Nazionale Tumori, MILANO, Italy

The combination of mediastinal radiotherapy (RT) and polichemotherapy regimens (CT) can produce late toxic pulmonary and cardiac effects which remain often at subclinical level. The majority of studies has been directed to the evaluation of cardiopulmonary function at rest using conventional procedures (spirometry, determination of lung transfer factor for CO, echocardiography) but only minimal research has been directed to evaluate cardiopulmonary function and reserve during exercise. The aim of the present investigation was to compare the late lung and cardiac toxicity of three chemotherapic regimens followed by RT and particularly ABVD (doxorubicin, bleomycin, vinblastine and dacarbazine), VEBEP (vincristine, epi-doxorubicin, cyclophosphamide, etoposide and prednisone) and MOPP-ABVD (mechloretamine, vincristine, procarbazine and prednisone). Therefore we investigated 147 patients suffering from Hodgkin's disease after a follow up of at least 5 years from the completion of CT-RT. Seventy eight have been submitted to ABVD-RT, 36 to VEBEP-RT and 33 to MOPP-ABVD-RT. Patients were submitted to spirometry, determination of lung transfer factor for CO, 2D-Doppler Echocardiography at rest, cardiopulmonary exercise test on cycloergometer and determination of cardiac output by a non invasive method. Patients of the three groups showed tolerance to exercise, and oxygen consumption significantly lower than the predicted values : by this point of view no statistically significant difference were found between the three groups. Patients treated with VEPEB and MOPP-ABVD showed a lower ejection fraction at rest than ABVD patients and moreover patients treated with VEBEP showed a cardiac output per oxygen uptake lower than that observed in the ABVD and MOPP-ABVD groups. These data confirm that the combination of mediastinal radiotherapy and the more common used polichemotherapy regimens produce late pulmonary and cardiac toxic effects which remain at subclinical level. The lower exercise capacity seems to be due to a combination of decreased cardiac performance and impairment of ventilation. The VEBEP regimens seems to be slightly more toxic for the heart probably because of the higher cumulative dose of anthracyclines.

1639

THE ROLE OF PET-FDG BEFORE AUTOLOGOUS STEM CELL TRANSPLANTATION IN ADVANCED HODGKIN'S LYMPHOMA

A. Pulsoni, E. Cavalieri, S. Capria, F. Torelli, G. Annechini, F. De Angelis, A. Matturro, L. Santini, G. Meloni, R. Foà

Sapienza University of Roma, ROME, Italy

Background. PET-FDG (PET) has assumed in recent years a relevant role in the management of patients with Hodgkin's lymphoma (HL). In advanced stage HL, PET performed after two courses of ABVD chemotherapy has demonstrated a very high negative predictive value (NPV) and positive predictive value (PPV) and is presently considered the most relevant available prognostic factor in correlation with outcome. *Aims*. To investigate the prognostic role of PET performed before autologous stem cell transplantation (ASCT) in resistant or relapsed HL. *Design and Methods*. From May 2005 to November 2008, 19 patients with resistant or relapsed HL underwent a salvage chemotherapy program consisting of 3 or 4 courses of IEV or IGEV chemotherapy with peripheral blood stem cell collection followed by BEAM conditioned ASCT. Seven patients were consolidated with the BEACOPP regimen (2 to 4 courses) before transplantation. Median age was 30 years (22 - 46); 9 were males. At the time of enrolment, B symptoms were present in 1 patient and bulky and/or extranodal disease was recorded in 5 patients; the International Prognostic Score (IPS) was >2 in 6 patients. Nine patients were resistant to first-line chemotherapy, 7 were in first relapse (in 2 cases occurred earlier than 12 months), 3 were in second or subsequent relapse. *Results*. Pre-transplant PET evaluation was negative in 11 cases: of these, 7 are currently in continuous complete remission (CCR) after a median follow-up of 23 months (range 9 - 32), while 4 have relapsed after 5, 12, 20 and 31 months from transplant, respectively. Among the 8 patients autografted after a positive PET, 6 relapsed after a median follow-up of 15 months (range 7 - 28). The NPV of pre-transplant PET was 63.6%; the PPV was 75.0%. The prognostic value of the following parameters at the time of enrolment was evaluated: presence of bulky and/or extranodal disease, number of previous chemotherapy lines, chemoresistance/chemosensitivity to pre-transplant therapy evaluated by CT scan; no statistically significant correlation with the outcome was recorded. *Summary and conclusions*. Our preliminary results show that in resistant or relapsing HL a positive pre-transplant PET predicts progression or relapse in 75% of patients. A negative PET predicts long-term disease control in two thirds of patients. Pre-transplant PET does not have the same high predictive value as interim PET performed during first induction; other prognostic factors need to be considered, although none of those examined showed a statistically significant role. These data need to be further confirmed on a larger number of patients.

1640

ABVD CAN BE SAFELY ADMINISTERED REGARDLESS OF ABSOLUTE NEUTROPHIL COUNT AND WITHOUT G-CSF SUPPORT IN HODGKIN'S LYMPHOMA PATIENTS

R. Crocchiolo,[1] S. Gov,[1] M. Bruno Ventre,[1] A. Assanelli,[1] G. Dognini,[2] P. Ghia,[1] F. Ciceri,[1] A.J.M. Ferreri[1]

[1]San Raffaele Scientific Institute, MILAN, Italy; [2]Ospedale "Treviglio-Caravaggio", TREVIGLIO, Italy

Background. Dose intensity of chemotherapy is an important factor for complete remission and long-term survival of patients (pts) affected by Hodgkin's lymphoma (HL); it has been recently reported a significant higher incidence of bleomycin-induced lung toxicity and mortality with concomitant use of G-CSF in bleomycin-containing schemes. For these reasons in July 2007 we started to administer ABVD regimen without G-CSF support and regardless of absolute neutrophil count (ANC) before each treatment administration. *Aims*. Here we report the safety outcome of 22 consecutive patients with newly diagnosed HL treated with ABVD regimen at our Institution. *Design and Methods*. Patients received ABVD between July 2007 and February 2009 for stage I-II (17 pts, 77%) and stage III-IV (5 pts, 23%) HL. Median age was 35 years old (range 16-63), ratio M/F = 10/12. A total of 97 cycles were administered so far and three pts are under ABVD treatment at present. *Results.* Mean ABVD dose-intensity was 97.6% and mean cycle duration was 28.6 days (see table); 39% of chemotherapeutic treatment were given with a ANC $<1.0x10^9$/L and 17% with an ANC $<0.5x10^9$/L. Antibacterial prophylaxis was given in five occasions. One grade 3 febrile neutropenia, one grade 3 neurological toxicity and one event of bronchiolitis obliterans organizing pneumonia (BOOP) were observed. No bleomycin-related lung toxicity neither other relevant side effects were recorded. At present, all pts are alive and those who completed treatment are in complete remission (n= 18), at a median follow-up of 12 months (range 6-19) for these latter. One patient with persistent disease after four cycles of ABVD was shifted to MOPP regimen. *Conclusions*. we conclude that ABVD may be safely administered at adequate dose intensity without G-CSF support and regardless of ANC.

	Cycle 1	Cycle 2	Cycle 3	Cycle 4	Cycle 5	Cycle 6
N. pts	22	21	21	19	7	7
Mean cycle duration (days)	29.3	29.3	28.0	29.5	28.0	28.0
ABVD dose	100%	100%	100%	100%	100%	100%
Dose intensity	95.5%	95.5%	100%	94.9%	100%	100%

Table 1. Patients and treatment deliveries.

1641

COMBINED VBM (VINBLASTINE, BLEOMYCIN, METHOTREXATE) CHEMOTHERAPY AND INVOLVED FIELD (IF) RADIOTHERAPY (RT) IN EARLY STAGE HODGKIN'S LYMPHOMA (HL): A SINGLE CENTRE EXPERIENCE

E. Cocorocchio, S. Bassi, M. Negri, F.A. Peccatori, L.L. Travaini, G. Piperno, L. Preda, G. Pruneri, A. Vanazzi, A. Alietti, G. Martinelli

European Institute of Oncology, MILAN, Italy

Background. Early stage HL patients (pts) may benefit from a short course of chemotherapy, usually ABVD, combined with IF RT. 18FDG-PET scan in HL performed before therapy is helpful to identify early stage disease pts that can benefit of a more conservative approach. AIMS: To verify efficacy of the four courses of VBM with IF RT on good prognosis early stage HL pts. *Design and Methods*. From May 2001 to February 2008, 37 treatment naïve Hodgkin's lymphoma pts (21 male, 16 female) were treated with four courses of VBM (D1, D8: Vinblastine 6 mg/sm, Bleomycin 10 mg/sm, Methotrexate 30 mg/sm, repeated every 28 days) followed by IF RT. Median age was 37 years (range 16-73). All

pts were staged with CT scan, bone marrow biopsy and blood exams. Histology was classical HL in 28 pts and lymphocyte predominant in 9 pts. Pts were all stage I-IIA (no bulky disease), no more than three sites involved, performance status 0-1 and ESR < 50. IF radiotherapy was performed one month after the last chemotherapy cycle; median dose administered was 30Gy (range 26-30.4) 18FDG-PET were performed at staging to identify a low risk pts group and repeated after chemotherapy and RT. *Results*. Chemotherapy was usually well tolerated. Eight pts experienced G3-4 neutropenia while the main non-haematological toxicities recorded were G3 transaminitis in two pts and G1-2 neurological (constipation/abdominal pain) in 14 pts. With chemotherapy 30 pts achieved a complete remission (CR), 5 pts a partial remission (PR); one patient progressed after chemotherapy and before RT and one patient, not in clinical response after two cycles of VBM, received hybrid salvage chemotherapy. In 5 cases PET was positive at the end of CT, becoming negative after RT in 4 cases. 35/37 (94%) pts completed the whole program, all achieving CR. With a median follow-up of 54 months (range: 6-90), all pts are alive. Two pts relapsed after 8 and 48 months the end of therapy and underwent high dose chemotherapy with autologous stem cell transplant, achieving CR. *Conclusions*. 18FDG-PET scan before treatment effectively helps to identify low risk early stage HL, allowing a more careful selection of pts suitable of less aggressive therapy. In our experience four cycles of VBM chemotherapy combined with IF RT is an effective program. This schedule, without alkylating or anthracycline agents, avoids alopecia and may decrease the risk of hematological and cardiac toxicity.

SUBJECTIVE OUTCOME (QUALITY OF LIFE) IN LONG-TERM SURVIVORS OF HODGKIN´S LYMPHOMA (HL): A CROSS-SECTIONAL STUDY OF PATIENTS TREATED 1995 TO 2003 WITHIN THE GHSG TRIALS IN THE CZECH REPUBLIC

K. Klaskova,[1] J. Markova,[1] E. Dragomirecka,[3] J.P. Prasko,[3] L. Zikavska,[2] Z. Kral,[4] L. Smardova,[4] T. Kozak,[2] H.H. Flechtner[5]

[1]University Hospital Kralovske Vinohrady, PRAGUE, Czech Republic; [2]Dpt of Clinical Hematology Univ Hospital Kralovske Vihohrady, Charles University, PRAGUE, Czech Republic; [3]Prague Psychiatric Center, Charles University, PRAGUE, Czech Republic;[4]Internal Department of Hematooncology, University Hospital of Masaryk University, BRNO, Czech Republic; [5]Clinic for Child & Adolescent Psychiatry, Otto-von-Guericke University, MAGDEBURG, Germany

Background. We investigated the current quality of life (QoL) in long-term survivors of HL treated within the German Hodgkin Study Group (GHSG) trials between 1995 and 2003 in the Czech Republic. Aims: To describe patients (pts) QoL after cure and returning to normal life during the years (yrs) after end of treatment in a cross-sectional design. *Design and Methods*. EORTC QLQ C-30, MFI-20, subjective retrospective evaluation of treatment and a life situation questionnaire (LSQ) wer used for the assessement of the pts' situation after end of treatment. An authorised Czech version of the questionnaires was sent to 172 pts who were disease free and were followed-up for four and more yrs. Results: 142 (82,5%) pts replied. Median age at time of assessment was 33 yrs, median follow-up 5.5 yrs (range 4-12 yrs). Regarding the QoL functional and fatigue scales, pts report a mixed pattern of responses but indicate quite severe limitations in their perceived QoL during later years of follow-up. Emotional functioning and global QoL recovers fully only in 50% of pts 4-12 years after end of treatment and about 25% report constant severe strain. General fatigue remains high with 45% of pts reporting "high fatigue" levels but only 15-30% of pts report high levels of reduced motivation and activity. In physical functioning 70% recover fully and only 6% report very low functioning. In general, women report lower QoL and higher symptom scores over time than men. Study arms and study generations showed no substantial influence on QoL. Compared to the German study population the Czech patients report lower QoL and higher levels of fatigue. *Conclusions*. QoL data from the reintegration process of pts into normal life during the years of follow-up reveal substantial strain and limitations of QoL, particularly in subsets of patients and in specific areas of QoL. Longitudinal QoL assessment within the GHSG trials is ongoing also for Czech pts and will add the QoL course of recovery to the current cross-sectional data. Other factors not yet clearly identified seem to play a more important role for the QoL outcome than e.g. stage and treatment in these patients. Cultural differences in QoL outcome between Czech and German patients were noticed.

COMPARISON OF EARLY FAVORABLE STAGE HODGKIN'S LYMPHOMA TREATMENTS: A SINGLE INSTITUTION REVIEW

S. Alomary,[1] R. Samant,[2] E. Alsaeed,[3] B. Al-Jasir,[4] I. Bence-Bruckler,[2] P. Cross,[2] P. Genest,[2] L. Huebsch[2]

[1]Princess Nora Oncology Center, JEDDAH, Saudi Arabia; [2]The Ottawa Hospital Cancer Center, OTTAWA, Canada; [3]King Fahad Medical City, RIYADH, Saudi Arabia; [4]King Abdulaziz Medical City Westren region, JEDDAH, Saudi Arabia

Background. This study was conducted to compare outcomes of patients receiving combined modality chemotherapy and radiation (CMT) versus other approaches for early stage Hodgkin's lymphoma (HL). *Design and Methods*. A review of patients with non-bulky early stage (IA/IIA) HL treated between 1984 and 2002 was performed to determine the treatment approaches used and the outcomes obtained. Results: There were 173 adult patients with newly diagnosed early stage Hodgkin's lymphoma, with 51% men and 49% women and a median age of 33 years (17-82). Treatment was as follows: extended field radiotherapy alone (EFRT) 49%; chemotherapy alone (CTA) 14%; and CMT 37%. Among CMT patients, 36% received abbreviated ABVD chemotherapy (3-4 cycles) followed by involved-field radiotherapy (IFRT). With a median follow-up of 8.3 years, the estimated 10-year RFS and OS for the entire cohort were 78% and 85% respectively. The 10-year RFS and OS for the various groups were as follows: 69% and 81% for EFRT; 78% and 84% for CTA; and 87% and 89% for CMT. The 10-year RFS was significantly higher ($p<0.05$) among CMT patients. The use of EFRT has diminished from approximately 90% in the 1980's to virtually no use at present, while the use of CTA and CMT has increased significantly ($p<0.01$). *Conclusions*. Early stage Hodgkin's lymphoma treatment has changed dramatically over the past 2 decades, and our results support the superiority and continued use of CMT, specifically abbreviated course chemotherapy and IFRT as an appropriate treatment approach.

DETECTION OF EBV DNA IN PATIENTS WITH HODGKIN LYMPHOMA IN THE CZECH REPUBLIC: FREQUENCY, QUANTITY IN PLASMA, WHOLE BLOOD AND LYMPH NODE

P. Hubacek,[1] M. Spacek,[2] K. Kamaradova,[1] M. Zajac1,[1] E. Kabickova,[1] H. Mottl,[1] J. Markova,[2] T. Kozak[2]

[1]2nd Medical Faculty of Charles University and Motol University Hospital, PRAGUE, Czech Republic; [2]University Hospital Kralovske Vinohrady and 3rd Medical Faculty of Charles Univ., PRAGUE, Czech Republic

Background. Presence of latent EBV genome is detected in 30-50% of patients with Hodgkin lymphoma (HL). According to recent works aggressiveness of disease correlates with amount of free EBV DNA present in plasma. Our aim was to investigate the frequency and quantity of EBV-DNA in our patients. *Design and Methods*. In total we have obtained 603 samples of plasma and whole blood from 173 adult patients (161 newly diagnosed, 7 in progression of disease, 5 with relapse of disease) and 22 newly diagnosed paediatric patients with HL. Samples were obtained before start of treatment, after cycles of chemotherapy and

radiotherapy and during outpatient controls. Moreover, in 8 EBV positive patients, we have obtained also samples of lymph node tissue. DNA was extracted using Qiagen Blood Mini Kits (whole blood and plasma) and Roche High Pure PCR Template Prep. Kit (tissue samples). Presents of EBV was tested using real-time PCR technology and samples were normalised to 100 000 human genome equivalents obtained by quantification of albumin gene in the sample (whole blood and tissue) or as copies per 1 mL (plasma). *Results*. EBV was detected in 38 samples of whole blood and 30 of plasma from 13 patients (11 adults) which represents frequency of 6.7% among our patients. Mean of detected quantity was 5400/mL in plasma (600-126600) and 34.9 normalised EBV copies in whole blood (1.1-6815.7). In 10 patients was positive in initial sample only and the disappearance of EBV in peripheral blood correlated with good response to treatment. In the samples from tissues, mean of normalised EBV quantity was $10^9$662 (22-785714), which represents in general the ratio of 1 EBV genome in every cell. *Conclusions*. The observed frequency of EBV positive patients in our cohort is much lower than so far published data. The good correlation between the reaction to treatment and vanishing of detectable EBV confirmed the possibility of using quantitative detection as biological marker of the disease activity in such patients. Moreover the normalization to human genome equivalents showed to be useful in testing of the tissue samples in patients with HL.

ADVANCED HODGKIN'S DISEASE: PROGNOSTIC FEATURES IN THE EXTREMES

O. Karanfilski, A. Stojanovic, T. Sotirova, S. Trajkova, S. Trpkovska-Terzieva, S. Stankovic, A. Latifi, D. Dukovski

University Clinic for Hematology, SKOPJE, Macedonia

Upon our previous observation that patients with both clinical stage IIIB and IV Hodgkin's disease (HD) follow an almost identical survival curve, we underwent this study in order to define similarities in their characteristics and determine the parameters which could possibly influence their outcome. In a longer than twenty-five period, out of the total number of observed patients with HD, 172 manifested extremely unfavorable clinical stages at disease presentation. Their actuarial survival is understandably quite poor, reaching 42% at the 10-year mark, and somewhat over 32% at the 20-year observation point. Univariate statistical analyses, performed separately on each stage subgroup, as well as in the subpopulation as a whole, pointed out several parameters that manifested prognostic significance regarding the vital statistics, some marginal and fewer true. Four of these are International Prognostic Index (IPI) parameters, but only one manifests true prognostic significance. Not surprisingly, knowing that the original IPI scoring system had established its validity on patients mostly with early stage disease, some of the prognostic factors incorporated in the IPI, showed no significance at all. Since the whole studied subpopulation already fulfills one criterion among the adverse prognostic factors, it is also understandable that the majority of these patients had an unfavorable IPI score (>=3) also: 70.93% of the subpopulation, mostly attributable to the 93.51% of the stage IV patients. Multivariant statistical analysis left only one of the IPI parameters with significant prognostic influence: abnormal WBC levels (p= 0.020061). However, it also revealed the prognostic significance that the diagnostic and treatment periods carry for the vital statistics of these patients. Development of the disease, the diagnostic period, when the patient is lacking treatment, in a period of more than three months, carries a significant negative prognosis (p= 0.045212). Among the management parameters, meticulous fulfillment of treatment administration in terms of dosage, accounts for significantly more favorable prognosis (p= 0.033629). The analysis shows a x2 value of 12.2728 for three degrees of freedom (p= 0.00651). Although representing an extremely delicate and tenacious population in terms of management, we need to keep in mind that disease characteristics have already classified such patients as prognostically unfavorable. Not being in the position to alter those parameters, we still need to instigate our efforts, skills and knowledge in two domains, in order to reverse the odds and accomplish more favorable prognosis for these patients: quick, precise diagnostic procedures and proper, meticulous, relentless, more aggressive treatment.

PROGRESSIVE MUSCLE ATROPHY AND WEAKNESS AFTER TREATMENT BY MANTLE FIELD RADIOTHERAPY IN PATIENTS WITH HODGKIN'S LYMPHOMA

E.M. van Leeuwen-Segarceanu,[1] L.D.A. Dorresteijn,[2] S. Pillen,[2] O.J.M. Vogels,[3] N. van Alfen[2]

[1]St. Antonius Hospital, NIEUWEGEIN, Netherlands; [2]Donders Center for Neuroscience, RU Nijmegen Medical Center, NIJMEGEN, Netherlands; [3]St Antonius Hospital, NIEUWEGEIN, Netherlands

Background. There are still Hodgkin's lymphoma (HL) patients alive who were diagnosed and treated as early as the 1970's or 1980's. With longer follow-up it has become apparent that these patients carry a risk for treatment-related side effects that may not manifest until many years after their initial treatment. Well-known late treatment-related complications are cardiovascular disease and second malignancies. However, patients treated by so-called *mantle* field irradiation can also develop symptomatic muscle atrophy and weakness in the treated area. This can result in neck pain and weakness which may be particularly disabling. These neuromuscular complications as long-term sequelae to local radiotherapy have so far received little attention in the literature. Aims. To describe the damage to the muscles and the pathophysiological mechanism of muscle atrophy and weakness after mantle field irradiation for HL. *Design and Methods*. We investigated 9 patients (ages 33-61 years) treated by mantle field irradiation between 1969 and 1998 (mean follow-up 26,6 years). Irradiation was in most cases delivered in a total dose of 40 Gy and 2 Gy/fraction. The patients are part of a larger cohort of HL survivors who are currently screened at our institution for late sequelae of cancer treatment. They were selected because on clinical examination they manifested weakness of the neck flexors, which was graded 2-4 on the Medical Research Council (MRC) scale (range 0 = no muscle movement to 5 = normal power). We also performed detailed clinical history, dynamometry, ultrasonography of the sternocleidomastoid, biceps and antebrachial flexor muscles and needle electromyography of the affected muscles. Results. All but two patients had neck complaints, mostly pain and muscle weakness, with the two most affected patients presenting a 'dropped head syndrome' (Figure 1).

Figure 1.

Dynamometric studies show that there was neck weakness in 7 out of 9 patients, defined as results below the p5 of the normal population. The neck flexors were more often damaged (in 6 patients) than the neck extensors (in 4 patients). On muscle ultrasonography 7 patients met the criteria for abnormal echo-intensity in one or more of the investigated muscles. Abnormal echo intensity of the sternocleidomastoid muscles was seen in only 2 patients. However, the sternocleidomastoid was severely atrophic in 8 of the 9 patients. Needle electromyography of the muscles situated in the radiation field showed mostly myopathic changes, while muscles situated outside the radiation field appeared to have mostly neuropathic damage, suggesting affection of the nerve roots and brachial plexus in the radiation field. *Conclusions*. (i). Patients previously treated by mantle field radiation can develop severe atrophy and weakness of the muscles situated in the radiation field. (ii). Muscles sit-

uated outside the mantle field show mostly neurogenic damage. (iii). The discrepancy between echo intensity and atrophy suggests that muscle damage is most likely caused by an extrinsic factor such as progressive microvascular fibrosis, which is also presumed to cause nerve damage to the radiated field. (iv). Our findings have implications for patient management: both patients and caregivers need to be counseled about the possible neuromuscular sequelae of mantle field radiation.

1647

AUTOLOGOUS STEM-CELL TRANSPLANTATION IN REFRACTORY OR RELAPSE HODGKIN'S LYMPHOMA: MONOCENTRIC STUDY OF 85 PATIENTS

R. Devillier, J. Rey, S. Harbi, L. Benarous, V. Salinas, D. Coso, V. Ivanov, J.M. Schiano de Collela, N. Vey, A. Charbonnier, P. Ladaique, B. Chetaille, J.A. Gastaut, C. Chabannon, D. Blaise, L. Xerri, A.M. Stoppa, R. Bouabdallah

Paoli-Calmettes, MARSEILLE, France

Background. Autologous stem-cell transplantation (ASCT) is a common option for first relapse or refractory Hodgkin's lymphoma (HL). However there are few reports with sufficient number of patients and follow-up. The respective place of autologous transplant versus allogeneic transplant is under investigation. *Aims*. To study the efficacy and tolerability of intensive chemotherapy with single or tandem autologous transplant in the setting of HL after failure of first line treatment. *Design and Methods*. We retrospectively analyzed a series of 85 patients with first relapse or refractory HL seen at our institution over a 10-year period, between 1997 and 2007. Patients who relapse were classified in two prognostic groups: poor-risk (two or three risk factors among relapse before 12 months, stage III or IV at relapse, and relapse within previously irradiated sites) and good/intermediate-risk (0 or one risk factor). *Results*. There were 85 patients, with a median age at 29 years. Most patients received first line treatment with ABVD (68%). 42 patients (49%) had primary refractory disease, and 43 patients relapse after first line therapy (51%). Poor-risk and good/intermediate-risk included respectively 20 (48%) and 22 (52%) patients. After high-dose chemotherapy (HDC), 41 patients achieve complete response (CR) or near complete response (nCR), 37 patients were in partial response, stable or progressive disease. 47 patients received single ASCT, 26 patients received tandem ASCT and 11 patients received ASCT and allogenic stem-cell transplantation. The global 5 year overall survival (OS) and disease free survival (DFS) was 76% and 81% respectively. We didn't find any difference on OS and DFS in unvaried analysis for single or tandem ASCT, neither for relapse risk groups. *Conclusions*. We globally find results reported in the literature for global OS and DFS but no difference was shown for prognostic factors or treatment. A recent prospective study of 245 patients with HL has shown the superiority of tandem ASCT versus single ASCT for poor-risk patients without good response to salvage chemotherapy. Despite encouraging results of HL treatment, refractory disease stays a real problem and treatment of these patients need to be improved. Reduced intensity conditioning allogenic stem cell transplantation could be an alternative for young patients relapsing.

1648

RETROSPECTIVE ANALYSIS OF EARLY STAGE HODGKIN'S LYMPHOMA TREATED WITH CHEMOTHERAPY WITH OR WITHOUT RADIOTHERAPY

A. Giordano,[1] F. Gaudio,[2] T. Perrone,[2] C. De Risi,[2] A. Spina,[2] P. Curci,[2] R. Miccolis,[2] S. Scardino,[2] M. Sorino,[3] P. Colonna,[3] P. Pedote,[4] G. Specchia,[2] V. Liso[2]

[1]University of Bari, BARI, Italy; [2]Hematology, BARI, Italy; [3]Cardiology, BARI, Italy; [4]Radiology, BARI, Italy

The treatment for Hodgkin's Lymphoma (HL) has evolved over the past several years. Combined modality therapy including ABVD followed by involved field irradiation represents the current standard of care for patients with early stage HL. Long term toxicities are the major concern in survivors of early stage disease. Current approaches attempt to preserve the high remission rate achieved, while reducing treatment-related acute and late toxicities. *Aims*. To compare the outcome of early stage HL treated with chemotherapy with or without radiotherapy, we reviewed clinical features, therapy, and long term outcome of 79 patients treated at our institution from 1999 to 2005. *Design and Methods*. 44 patients (pts) were treated with 4-6 cycles of ABVD plus involved field radiotherapy (CT+RT group) and 35 pts were treated with chemotherapy alone, consisting of 3-6 cycles of the ABVD regimen (CT group). Median pts age was 36 years, 53% were males, 72% presented B symptoms and 75% had clinical stage II. The histology was nodular sclerosis in 82% patients. Patients with bulky disease were excluded from the analysis. The two therapeutic groups were statistically comparable for clinical features and median follow-up (60 and 62 months for the CT and CT + RT group. respectively). Results In the CT+RT group 88% achieved CR and 12% PR after first line therapy whereas in the CT group 83% achieved CR and 17% PR. High dose chemotherapy was employed as salvage therapy for 5 partial responders in the CT and 4 in the CT + RT group. One relapse occurred in the CT+RT group at 12 months after first-line therapy. At a median follow-up of 60 months the disease-free survival was 88% in the CT group and 89% in the CT+RT group (p: n. s.). In the CT+RT group 3 patients (6.8%) developed long term toxicities (one case of Chronic Restrictive Pulmonary Disease, one case of hypothyroidism and one of thyroid cancer at 41, 49 and 53 months of follow-up, respectively) whereas one patient (2.8%) in the CT group developed a late toxic event consisting in cardio-myopathy at 20 months of follow-up (p=ns). *Summary and Conclusions*. Our retrospective analysis shows that a high response rate was achieved both with chemotherapy alone and with chemoradiotherapy; no difference was observed in terms of relapse rate in the two groups. Nevertheless, we observed a higher incidence of long term toxicities in the group treated with the addition of radiotherapy. Multicentric studies and additional cases are required to assess the role of radiotherapy in early stage Hodgkin's lymphoma therapy. A better definition of prognostic factors at presentation and the predictive value of interim fluoro-2-deoxy-D-glucose-positron emission tomography scans may be useful to individualize therapy, improve the remission rate and minimize toxicity.

1649

OUTCOME OF FEMALE PATIENTS AGED 45 YEARS OR YOUNGER TREATED FOR HODGKIN LYMPHOMA: SINGLE INSTITUTIONAL EXPERIENCE

S. Falorio, F. Fioritoni, G. La Barba, G. Fioritoni, F. Angrilli

Civic Hospital, PESCARA, Italy

Background. In 1998, Hasenclever score identified seven prognostic factors (serum albumin level, hemoglobin level, sex, age, stage IV disease, leukocytosis, lymphocytopenia) that predict the success rate of conventional treatment in patients with locally extensive or advanced stage Hodgkin lymphoma (HL). In particular, younger persons (< 45 years) and women tend to have better outcomes than older individuals and males. *Aims*. To retrospectively evaluate clinical characteristics at diagnosis and outcome of female patients with HL aged 45 years or younger treated in our institution. *Design and Methods*. From January 1991 to August 2008, we diagnosed and treated 121 HL female patients with a median age of 25 years (8-45). Nodular Sclerosis was the most common histological subtype (84%). Forty-nine (49%) patients were in clinical stage (CS) I-IIA including 13 with bulky disease, 62 (51%) were in CS IIB-IV including 20 with bulky disease. According to the GISL criteria, patients were stratified in three prognostic groups: Early Favourable HL (EFHL) (CS I-IIA without risk factors, 18 patients), Early Unfavourable HL (EUHL) (CS I-IIA with bulky disease and/or subdiaphragmatic disease, ESR higher than 40, extranodal involvement, hilar involvement and more than three involved lymph node areas, 41 patients) and Advanced HL (ADHL) (CS IIB-IV, 62 patients). Early HL patients received combined treatment including 4-6 courses of ABVD/ABVD-like regimens and involved field radiotherapy (14,4-36 Gy). ADHL patients were treated with 6 courses of ABVD or COPP/ABV or COPPEBVCAD or BEACOPP, and radiotherapy on residual masses. Overall, 46 patients were submitted to radiotherapy. Refractory/relapsed patients received salvage treatment with 3-6 courses of iphosphamide-based regimens (IGEV, IEP) and ASCT. *Results.* One hundred seventeen patients completed therapy while 4 are receiving treatment today. One hundred eight patients obtained complete remission (91%) and 9 patients were unresponsive (9%). Seven patients (2 with EUHL and 5 with ADHL) relapsed after a median time of 23 months (12-131) from diagnosis. Overall, after a median follow-up of 72 months (5-208) Overall Survival (OS) and Time To Treatment Failure (TTTF) are 97% and 83%, respectively (EFHL: OS and TTTF 100%; EUHL: OS 100%, TTTF 86%; ADHL: OS 95%, TTTF 80%). In the group of the 16 relapsed/refractory patients OS is 79%, and only 3 of them died after salvage treatment because of progressive disease. In regards to the treatment- related secondary cancers we recorded 2 non-Hodgkin lymphomas and 1 breast cancer and all 3 patients are alive so far. *Discussion.* Our results confirm that young female patients affected by HL have an excellent outcome both in early and advanced stages. Considering that

the late treatment-related toxicities represent a major concern for HL survivors, we think that an overtreatment should be avoided especially in early stage HL patients. Therefore, in order to offer individually tailored treatment, prospective studies on PET/CT-guided treatment strategies are underway worldwide

1650

DISEASE CHARACTERISTICS AND TREATMENT APPROACH AS PREDICTIVE FACTORS IN HODGKIN'S DISEASE

O. Karanfilski, A. Stojanovic, T. Sotirova, S. Trpkovska-Terzieva, S. Trajkova, A. Latifi, D. Dukovski

University Clinic for Hematology, SKOPJE, Macedonia

Labeling Hodgkin's disease (HD) as one of the curable neoplastic diseases, motivates hematologists to define the basis on which this contemporary medical achievement is accomplished. Our study is a contributing attempt in this direction. At our Clinic we have been managing more than 500 HD patients over a 25-year period. We have studied the prognostic impact that disease onset manifestations, mostly included in the IPI scoring system, but alongside with and across different treatment approaches, and the impact that both have on the disease course and its outcome. Of a total of 473 HD evaluable patients, 119 were with clinical stages 1-2A, and were analyzed regardless of the disease mass (bulk). Evaluable advanced stage patients, with clinical stages 2B-4, also irrespective of tumor mass size, were 348 of them. Multivariate statistical analyses show that of the seven IPI parameters, only the scoring system backbone still retains its prognostic significance: Hb and Alb levels. Patient's gender, and a modified range for age and clinical stage of the disease, also remain important factors. Selective statistics reveal that this importance is valid mostly due to factor's impact on advanced stages of HD, whereas the prognosis of early stage HD patients does not seem to be affected by these parameters. The values for the chi-square tests are 45.9023 and 24.5866 for 3 degrees of freedom (gender, Hb, Alb) for the whole population and the advanced disease subset respectively, and the p-values are highly significant (0.00000 and 0.00002), when the analysis is performed on standard IPI values. Modified values achieve even higher significance and incorporate more parameters. Following our assessment that onset manifestations do not have statistical influence on the outcome of early stage disease patients, we extended the analysis to the post-diagnostic period. Analyzing different types of treatment engaged, as well as similar approaches, it is clearly evident that these patients benefit from treatment modalities containing the gold standard and the increasingly competitive newer chemotherapy regimen: ABVD and BEACOPP. Interestingly enough, and possibly due to the low number of entries, combined modality treatment did not show significant advantage over chemotherapy alone in these early stage patients. On the other hand, advanced stage disease course could not be significantly altered by employing even more aggressive treatment approaches. Rough grouping of the originally and contemporarily treated subsets, show an evident difference of 25-40% in overall survival (p<0.001). Both observations clearly imply that rapid diagnosis, diminishing the possibility of disease advancement, and utilization of contemporary and aggressive treatment options in the first instance, speculating that the appreciated effect is mostly attributable to the potential of doxorubicin and very possibly etoposide, are the milestones on which the successful story of HD management has been created and confirmed.

1651

HYPER-IGE (JOB'S) SYNDROME IN AN ADULT PATIENT PREVIOUSLY DIAGNOSED OF LYMPHOCYTE PREDOMINANT HODGKIN'S LYMPHOMA: IMPORTANCE OF DISTINGUISHING SYMPTHOMATIC JOB'S SYNDROME FROM ACTIVE HODGKIN'S LYMPHOMA

J.J. Gil Fernandez, J. García-Suárez, Y. Martin, E. Magro, M. Callejas, M. Lopez-Rubio, M.A. Calero, T. Pascual, C. Burgaleta

Hospital Universitario Principe de Asturias, MADRID, Spain

Background. Hyper-Immunoglobulin E, IgE (HIES) or Job's syndrome is a rare primary immunodeficiency disorder characterized by clinical triad of recurrent staphylococcal abscesses, cyst-forming pneumonia and an elevated serum IgE level of > 2000 IU/ml. Most cases are sporadic; however, multiplex families displaying autosomal dominant (AD) and autosomal recessive (AR) inheritance have been described. The etiology of HIES is still unresolved. Therapy for HIES is directed at prevention and management of infections by using sustained systemic antibiotics and antifungals along with topical therapy for eczema and drainage of abscesses. Anti-staphylococcal antibiotic prophylaxis is useful. Interferons, immunoglobulin supplementation, or low-dose cyclosporine A, have been reported to benefit selected patients, but they are not generally indicated. There has been described an increased risk of development of different types of lymphoma in these patient's population. The exact mechanism of this increased risk is not fully understood but some similarities to the pathogenetic model of AIDS-related lymphoma have been established. *Aims*. In the vast majority of cases the Job's syndrome has been diagnosed previously to the lymphoid neoplasia. A high index of suspicion for lymphoma should be given in patients with HIE syndrome who present with lymph node enlargement. We report an adult patient previously diagnosed of lymphocyte predominant Hodgkin's lymphoma successfully treated with immunochemotherapy who developed a sympthomatic HIES mimicking active Hodgkin´s lymphoma. *Case Report*. A 70 years-old male patient was diagnosed of a CD20-positive lymphocyte-predominant Hodgkin´s lymphoma, Ann-Arbor stage II-A, non-bulky, supradiafragmatic. He was treated according to its age and localized stage with 3 cycles of ABVD plus Rituximab (3 doses), achieving a complete remission (CR) confirmed by a negative TAC-PET study. In the follow-up, although radiological studies were normal, the patient developed symptoms and biological signs mimicking active Hodgkin´s disease (malaise with generalized pruritus and a continuosly elevation of reactants of acute phase: ESR>15 mm; Reactive Protein C > 5 mg/l; fibrinogen > 400 mg/dL; blood eosinophilia > 500/mm^3). A complete searching of a systemic disorder and dermatologic and allergologic studies were all negative for a specific process. Because of maintained markedly increased IgE (> 5,000 Ui/mL) with chronic dermatitis, repeated respiratory infections and persistent pruritus, a Hyper-Immunoglobulin E, IgE (HIES) or Job's syndrome was suspected. At the time of this writing the patient has not started any treatment for HIES. *Conclusions.* In order to avoid unnecesary treatments of chemotherapy or radiotherapy in Hodgkin's lymphoma patients in continous CR, HIES should be considered in the differential diagnosis of patients with persistent pruritus and markedly increased IgE.

1652

CHANGES IN CLINICOPATHOLOGICAL FEATURES IN HODGKIN-LYMPHOMA

A. Illes, L. Gergely, L. Varoczy, Zs. Simon, Zs. Miltenyi

University of Debrecen, DEBRECEN, Hungary

Background. Hodgkin-lymphoma (HL) is an uncommon malignant tumour of the lymphatic system. Nowadays more reports show changing of the disease's epidemiology. *Aims*. Examination the characteristics of our HL patients retrospectively. *Design and Methods*. We examined 439 HL patients, who were treated between 1980.01.01 and 2008.12.31. *Results*. In the first period (1980-89) were 177 patients, 1990-99 (second period) were 147 patients, and between 2000-08 (thrisd period) were 115 patients. We observed a reduced male-to-female ratio (I. period: 1,42, II. period: 1,45, III. period: 1,04). The mean age was 40,1 years, 35,9 years, and 36,8 years (I. v. II. v. III. period). Comparing the distribution of HL cases diagnosed at 3 different time periods, we detected decreased frequency of the mixed cellularity subtype (43.5%, 58.5% v. 42.6% p<0.0098), and an increased frequency of the nodular sclerosis subtype (24.85%, 27,2% *vs.* 34,78% p<0.1734). We diagnosed more early stage patients (33.33%, 30.6% v. 59.12% p<0.0001), than advanced stage (66.67%, 69.38% *vs.* 40% p<0.0001). Five-years overall survival were 68.4%, 73,3%, and 91%. *Conclusions*. The comparsion of HL cases from the same geographic are during different time period provides an opportunity to observe the changing of clinicopathological features of HL.

1653

AUDIT OF ABVD CHEMOTHERAPY FOR HODGKIN LYMPHOMA PATIENTS REGARDLESS OF THE ABSOLUTE NEUTROPHIL COUNT AND WITHOUT G-CSF; NO TREATMENT DELAYS AND OPTIMAL DOSE INTENSITY

R. Stewart, J. Allan, M. Drummond, R. Soutar

Beatson West of Scotland Cancer Centre, GLASGOW, UK

Background. Historically delivery of the standard Hodgkins lymphoma chemotherapy regimen "ABVD" has been supported with G-CSF and patients experiencing myelosuppression were given chemotherapy treatment delays which affected dose intensity. *Aims.* To review local practice, we investigated whether delivery of ABVD, administered regardless of the absolute neutrophil count, and without routine supportive G-CSF, caused patients to experience treatment delays due to either myelosuppression or sepsis. Dose intensity in the patient cohort was examined

as this has previously been shown to be important in survival. *Design and Methods*. 22 patients were identified and patient notes and pharmacy ("Chemocare") records audited. Dose intensity scores were calculated as per published formulae. *Results*. Of the 22 patients 18 had completed chemotherapy while 4 were on ongoing treatment. The total number of administration days of ABVD was 206 (103 cycles of ABVD). 3 patients had dose omissions of Bleomycin or Vinblastine due to non haematological side effects. 17 patients (77%) experienced at least one episode of grade III or grade IV neutropenia (neutrophils $<1.0x10^9$ L), 12 (55%) experienced at least one episode of grade IV neutropenia (neutrophils $<0.5x10^9$ L) on scheduled administration days . Of 206 administrations 81 (39%) were given with an absolute neutrophil count of $< 1.0x10^9$ L. 3 patients required admission with neutropenic sepsis with only 1 of these patients encountering a subsequent delay in ABVD administration. Of the 18 patients who have completed treatment median dose intensity was 1 (mean 1.0). *Conclusions*. In an unselected population, ABVD administration irrespective of the absolute neutrophil count allowed treatment to be given safely without significant delays caused by neutropenia, thrombocytopenia or sepsis. There is no need for routine growth factor support or dose alteration to maintain dose intensity.

1654

BCL-6 PREDICTS IMPROVED PROGNOSIS IN HODGKIN LYMPHOMA. TRUE OR FALSE?

D. Antic, D. Tomin, M. Petrovic, S. Jankovic, B. Mihaljevic

Clinical Center Serbia, BELGRADE, Serbia

Introduction. In several past years researches in the field of the biology of Hodgkin lymphoma (HL) were very extensive. Several clinical and laboratory feature have been used to compose a prognostic model, the International Prognostic Score (IPS), which is able to predict failure-free survival (FFS) and overall survival (OS). However, this model usually fails to identify patients with very low or very high chances of cure, who might benefit from therapies tailored to their predicted risks. Therefore, attention has turned to the possible identification of biological features that could be added to the IPS in order to better predict clinical outcome. Aim: The aim of this study was to evaluate whether the expressed p53, pRb, bcl-6, EBV and Ki67, combined with IPS, could be important predictive factors for more accurate outcome in patients with HL. *Design and Methods*. Between October 2001 and June 2003, 40 de novo patients with a confirmed diagnosis of Hodgkin lymphoma were studied. Immunhistochemistry was performed on formalin-fixed paraffin-embedded tissue from diagnostic biopsies, with prediluted monoclonal antibodies against p53, pRb, bcl-6, EBV and Ki67. Positively staining H/RS cells were counted and expressed as ratio of total observed H/RS cells. Negative staining was recorded as 0%, and further positivity was graded from 1-100%, depending on the proportion of the positive cells. Results: Group of 40 patients with HL consisted of 60% males and 40% females were analysed, with mean age at the diagnosis 30.2 years (range 15-68 years). A vast majority of patients (85%) had nodular sclerosis histological subtype of HL, 62.2% of the patients were in an advanced clinical stage (III and IV) of HL, and 57.5% had involvement of the mediastinum. Half of the patients had low IPS (0,1,2). Baseline treatment was ABVD while patients with additional risk factors such as large mediastinal mass or three or more involved lymph node areas treated with escalated BEACOPP. Five years OS and FFS were 70.8 and 60.1 months, respectively. In univariate analyses, only bcl-6 positivity (expression bcl-6 > 20%) had a significant effect on OS (77.1 months in bcl-6-positive patients vs 44.4 months in bcl-6-negative patients; $p<0.01$) and FFS (63.9 vs 38.2 months; $p=0.017$). Correlation between the expression of the oncogenes and the response to therapy was not found. As observed previously,the value of IPS was a significant indicator of survival before relapse/death. *Conclusions*. Cell cycle regulatory molecules including p53, pRb, bcl-6, EBV and Ki67, had different levels of expression in patients with HL, but we found that only bcl-6 had influence on the outcomes. Full assessment of the prognostic role of the biological features in patients with HL required studies with larger number of cases and longer observation time.

1655

BONE NECROSIS IN A PATIENT WITH HODGKIN LYMPHOMA AFTER TREATMENT WITH PEGFILGRASTIM AND SHORT COURSE OF STEROIDS

M. Quitt, M. Ballan

Carmel Medical Center, HAIFA, Israel

Background. Osteonecrosis, also known as aseptic necrosis or ischemic necrosis of the bone is a pathological process that has been associated with numerous conditions and therapeutic interventions. The mechanisms by which this disorder develops are not fully understood. However, compromise of the bone vasculature leading to death of bone appears to be common to most proposed etiologies. The male to female ratio is 8 to 1. Prolonged treatment with glucocorticosteroids is one of the frequently reported causes of this disorder. *Case report*. We present a 28 year old patient diagnosed with nodular sclerosis Hodgkin lymphoma who developed an osteonecrosis immediately after the first cycle of treatment. He had an advanced stage disease with poor prognostic factors (IPI=5). His past history was uneventful and physical examination revealed a massive cervical lymphadenopathy. CT scan showed also bulky mediastinal lymph nodes with evidence of jugular vein thrombosis. Bone marrow (BM) biopsy at presentation showed a normocellular BM with no evidence of malignancy. Enoxaparin and escalated BEACOPP chemotherapy were started. The therapy included 100 mg of oral prednisone per day for 10 days. 48 hours post completion of the first cycle of escalated BEACOPP the patient received a subcutaneous injection of pegylated G-CSF (Pegfilgrastim). The WBC count on the day of Pegfilgrastim treatment was $2,980/mm^3$ the next day the patient developed severe rest groin pain that radiated to the thighs and buttocks. 48 hours after the treatment with Pegfilgrastim his WBC count reached $52,360/mm^3$. The bone X- ray as well as the Technetium-99 bone scan and CT scan showed signs of necrosis of the bone which involved the head of the femur, both femurs and the pelvis. MRI scan showed a hypervascular granulation tissue which is regarded as pathognomonic sign of this disease. A bone biopsy was obtained during a procedure of core decompression and confirmed the diagnosis of bone necrosis. At the same time, a repeated BM biopsy showed a normocellular BM with no evidence of necrosis. A broad workup excluded the presence of hypercoagulable state such as antiphospholipid antibodies, inherited or acquired thrombophilia, sickle cell or Gaucher disease .The patient completed 5 cycles of ABVD and involved field radiotherapy and one year post completion of chemotherapy is in complete remission. He remains with severe pain and there is radiographic evidence of persistent bilateral osteonecrosis of the pelvis and head of the femur. *Conclusions*. Bone pain is a common side effect of treatment with G-CSF; however, we are not aware of any previous reports of bone necrosis due to use of this drug. Our patient received only a very short course of steroids during the first cycle of the treatment. Therefore, it is unlikely that this treatment alone was responsible for the bone necrosis. We assume that the combination of his very high WBC count together with the use of steroids contributed to metabolic, mechanical and ischemic changes that compromised the blood supply to the bone and caused the osteonecrosis in our patient.

1656

THE 'BATTLE' FOR THE GOLD STANDARD IN HODGKIN'S DISEASE: EVIDENCE FOR SUPERIORITY OF ABVD IN THE PRE-BEACOPP ERA

O. Karanfilski, A. Stojanovic, T. Sotirova, M. Pavkovic,
S. Trpkovska-Terzieva, S. Trajkova, A. Latifi, D. Dukovski

University Clinic for Hematology, SKOPJE, Macedonia

Different treatment approaches, regarding chemotherapy and radiotherapy, were available and utilized over different time periods for patients with Hodgkin's disease (HD). Even today, different centers and schools have adopted different treatment modalities as standard. Efforts are directed towards tailoring the optimal treatment method for each patient, or at least for different risk stages. Nevertheless, in the segment of chemotherapy, most researchers still accept the ABVD regimen as the present and valid 'gold' standard for treating all stages and types of HD, in combination or without adjuvant radiotherapy. In a single-center study, on a population of more than 500 HD patients, treated at our Clinic over a longer than 25-year period, we attempted to define points where ABVD has shown superiority over earlier chemotherapy option(s), the sustainability of prognostic models for HD patients when analyzed separately according to treatment protocol, as well as the benefit it implies, evaluated by patient longevity and quality of life. Univari-

ant statistical analyses were performed on a number of patient characteristics, disease manifestations and treatment modalities and their outcomes, and compared in patients grouped according to treatment protocol, meaning also according to the period when they were observed and/or treated at our Clinic. Special attention was placed on the subgroup of HD patients in whom the ABVD chemotherapy protocol was the principal one. Multivariate analyses were performed in order to define whether known predictive factors, certainly the ones incorporated in the IPI, and others, sustain prognostic significance within the 'newer' subpopulation of HD patients, treated initially with the present gold chemotherapy standard. The most obvious advantage of ABVD treated patients was observed in the field of life expectancy. Overall survival was above 85% at 10 years, reaching its plateau shortly after year 2, as opposed to a near 55% for MOPP-based treated patients. EFS followed this line of conclusions. Chance for relapse was also markedly low. Patients treated with the hybrid MOPP/ABV(D) were not valuable for the analyses, since when this treatment option first became available, it was widely used for poor risk HD patients, thus diminishing their chances for a privileged outcome. In the segment of univariate statistical analyses, most of the parameters maintained their prognostic significance, although with slightly higher p-values. This applies to the IPI parameters also, both with the original settings, as well as under our dichotomization criteria (slightly altered points derived from population and disease characteristics). Nevertheless, in multivariate analyses, ABVD treated patients manifest no outcome affection by the known predictive parameters, except for a couple: one patient characteristic - age, and one disease manifestation - symptom presence. Therefore, HD patients treated with ABVD chemotherapy as their underlying regimen, still remain with significantly greater outcome expectations and very high reliability for achieving definite disease control. In that process not many patient characteristics, nor disease manifestations can influence their favorable prognosis, which is why this chemotherapy protocol is applicable to patients with different age and gender, with disease of different type or extent, with comparably similar favorable effect. The evidently lower incidence of undesired late effects is also a fact deserving respect and a confidence vote.

OBSERVATIONS WITH INTERIM PET/CT IN HODGKIN-AND DIFFUSE LARGE B-CELL LYMPHOMAS

Zs. Miltenyi,[1] Zs. Simon,[1] A. Illes,[2] L. Varoczy,[1] L. Gergely[1]

[1]University of Debrecen, DEBRECEN, Hungary; [2]3rd Department of Internal Medicine, DEBRECEN, Hungary

Background. Complete remission and recovery have been achieved in the majority of lymphoma patients owing to development of diagnositcs, modern treatment strategies, and risk-adapted therapy. 18FDG-PET/CT has role in the correct determination of stage, prognostic factors and early recognition of relapsed in Hodgkin's lymphoma (HL) and diffuse large B cell lymphomas (DLBCL). Positive or negative interim PET/CT had stronger connect with prognosis of the disease than prognostic factors, that we knew. *Design and Methods*. We examined 50 patients (32 HL and 18 DLBCL) in the CHEAP (chemotherapy effectiveness assessed by PET) study, after 2. or 3. cycle of the chemotherapy from June 2008. Assessment of the examen based on SUV and we compared this with the pretreatment PET/CT. We detected complete metabolic remission or minimal residual uptake in 80% of the patients. We continued the treatment of these patients. Interim PET/CT was positive in 20% of the cases, we changed the therapy (one patients had high-dose therapy and autolog stem cell transplantation). *Conclusions*. Interim PET/CT is useful for lymphoma patients. But there are some questions that we don't know the answers yet. Shall we do PET/CT after complete the therapy, if interim PET/CT was negative? Shall we change the therapy (cycle, dose or another therapeutic options) if we seen minimal residual uptake on interim PET/CT? Shall we reduced therapy (cycle or dose) if interim PET/CT negative?

1658

GEMCITABINE (GEMZAR) AS A SALVAGE THERAPY AT RELAPSED AND REFRACTORY HODGKIN' S LYMPHOMA

V. Violeta, S. Jankovic, B. Andjelic, M. Bogunovic, M. Petrovic, B. Mihaljevic

Clinical Center Serbia, BELGRADE, Serbia

Background. Most patients with Hodgkin's lymphoma (HL) can be cured with initial chemotherapy. Effective salvage treatment is needed at about 20-30% patients who had refractory and relapsed disease. The purpose of this study was to analyzed the efficacy and the toxic profile of gemcitabine in patients with relapsed and refractory Hodgkin' s lymphoma. *Design and Methods*. This study included ten patients with Hodgkin' lymphoma diagnosed between January 2001 and April 2007 at the Institute of heamtology CCS, Belgrade. Demographic caracteristics were as follow: male/female ratio was 7:3 (70%:30%); the median age was 43 years (range, 20-76). All patients had advanced disease: 4 pts had CS II B M+, 2 pts had CS III B, 4 pts had CS IV B); International Prognostic Scor < 3 had 4/10 patients. Six patients were refractory to initial therapy. Six patients with mediastinal bulky form of disease were initially treated with BEACOPP regimens and 4 pts received ABVD. Seven patients received involved field radiotherapy. Gemcitabine was administered at a starting dose of 1250 mg/m^2 on das 1, 8 and 15 every 3 weeks in combinations with steroids (dexamethasone). All patients had received at least 2 cycles of gemcitabine (range, 2-6). The median follow-up period was six months. *Results*. Overall response rate was 30% with 1 patient achieving complete remission (CR) and 2 patients partial remission (PR). Hematological toxicity grade 3-4 occurred in 5 patients leading to dose reduction. No other non-hemathological toxicites were observed. Seven patients discontinued treatment because of dissease progression. The median time to treatment failure was 4,5 months. The longest responder has been in CR for over 40 months. *Conclusions*. Gemcitabine is an effective drug with low toxicity profile in patients with refractory and relapsed Hodgkin' s lymphoma. Dose and schedule may be modifided in the future to optimize responses. Further trials using gemcitabine in combination with other chemotherapy are needed.

1659

THE PROGNOSTIC PROFILE AND THE OUTCOME OF PATIENTS WITH EXTRANODAL HODGKIN'S LYMPHOMA

L. Jakovic,[1] B. Mihaljevic,[1] M. Perunicic Jovanovic,[1] A. Bogdanovic,[1] V. Bumbasirevic[2]

[1]Clinical Center of Serbia/Institute of Hematology, BELGRADE, Serbia; [2]Institute of Histology and Embryology, School of Medicine University of Belgrade, BELGRADE, Serbia

Background. Hodgkin's lymphoma (HL), much more than non Hodgkin's Lymphoma (NHL) is predominantly a nodal disease with extranodal involvement being uncommon. Although the treatment of patients (pts) with HL at any stage of presentation is highly successful, a significant minority of pts fails primary therapy. Distinguishing further prognostic factors might contribute to initially better selection of pts for more intensive treatment. *Aims*. To analyze the prognostic value of extranodal involvement in advanced HL pts in order to determine optimal initial prognostic model which could follow more adequate therapeutical modality. *Design and Methods*. In a cohort of 89 pts with advanced HL (CS IIB-IV) treated with ABVD regimen from 1997- 2004, we examined subgroup of 31 pts with extranodal disease for prognostic profile, at diagnosis. The median follow-up was 7 years (yrs). Their significance was evaluated according to the response to treatment and survival period. It was correlated with International Prognostic Score (IPS), bulky mass, >3 sites involvement, ESR>50 as well as molecular parameters Ki67, Bcl2 and BAX. *Results*. The distribution of extranodal disease was: 18 patients had bone marrow infiltration, the spleen in 5 patients, the lungs in 4 patients, the liver in 4 pts. The IPS> 3 had 25 pts and 15 of them had bone marrow infiltration. The EN localisation had adverse effect on OS7y (45% vs 78% for pts without EN, p=0.005) and also on EFS (log rank p<0.05). There was a positive correlation between IPS>3 and EN disease p=.001, as well as bone marrow involvement p=.003. Both pts with EN localization and pts with bone marrow infiltration had high proliferative index (Ki67>50%) p=0.019, p=0.004 respectively. There was no significant correlation with other examined features. Cox's multivariate model did not revealed EN disease as a significant independent prognostic factor (p>0.05). *Conclusions*. Extranodal HL patients with high IPS and high proliferative index are at higher risk of treatment failure and might be eligible for more effective treatment approach.

FAMILIAL CD3+ T LARGE GRANULAR LYMPHOCYTE (T-LGL) PROLIFERATION PRESENTING WITH CYTOPENIAS: HISTOPATHOLOGICAL, FUNCTIONAL AND MOLECULAR STUDIES

E. Stalika,[1] N. Stavroyianni,[1] A. Anagnostopoulos,[1] H. Papadaki,[2] T. Papadaki,[3] K. Stamatopoulos[1]

[1]George Papanikolaou General Hospital, THESSALONIKI, Greece; [2]University of Crete Medical School, HERAKLION, Greece; [3]Evangelismos Hospital, ATHENS, Greece

CD3+ T-LGL proliferations often present with cytopenias (especially neutropenia) and splenomegaly. We report results from detailed analysis of two relatives (father and son) with CD3+ T-LGL proliferation. Case 1 (father): thrombocytopenia, splenomegaly, positive test for anti-nuclear antibodies at the age of 55 (1999). Partial response to corticosteroids. 2002: splenectomy (initial pathology assessment «non-specific findings»), mild persistent neutropenia ever since. Case 2 (son): pancytopenia since the age of 17 (1993). Routine laboratory investigations (including bone marrow aspiration and biopsy): non-diagnostic. 2002: pancytopenia, splenomegaly, splenectomy. Partial recovery of hematologic values, persistent thrombocytopenia since 2003. Strikingly similar results were obtained for both cases on detailed laboratory investigations. (1) Flow cytometry (repeated tests 2003-2006): inverted CD4/CD8 ratio, increased CD3+CD8+CD57+ cells (father>30%, son: 18-22%). (2) Antineutrophil antibodies (GIFT, GAT assays): positive. (3) Molecular testing for elastase mutations: negative. (4) Bone marrow biopsy: 10-15% interstitial T (CD3+CD20-) lymphocytic infiltration (CD8>CD4), increased cellularity, hyperplasia of all series with concomitant dysplastic changes. (4) Spleen biopsy: (i) white pulp: hyperplasia of both the B zone (mantle/ marginal zone, CD20+CD3-) and the T zone (CD20-CD3+, CD4+>CD8+) (ii) red pulp: moderate CD3+CD20- T lymphocytic infiltration (CD8+>CD4+) of the splenic cords and sinusoids. The most important difference between father and son concerned the patterns of T cell receptor β (TRBV) rearrangements. (1) Father: monoclonal TRBV rearrangement amidst a polyclonal background. TRBV gene repertoire: 34 identical TRBV12-3/TRBD2/TRBJ2-6 rearrangements (major subclone) and 16 identical TRBV7-2/TRBD1/TRBJ1-2 rearrangements (minor subclone) from three timepoints over a 6-year period among a total of 147 subcloned sequences. (2) Son: polyclonal TRBV rearrangement. TRBV gene repertoire: heterogeneous. In conclusion, the results from TRBV repertoire analysis support a role for antigen in lymphomagenesis, in the sense that persistent antigenic drive may initially lead to polyclonal proliferation and, under certain circumstances (genetic predisposition?), evolve to clonal disease (T-LGL leukemia). Furthermore, the findings reported here indicate that TCR antigen specificity may determine the clinical presentation by specifically recognizing and destroying distinct hematopoietic lineages.

1660a

FOLLICULAR LYMPHOMA: INCIDENCE, PROGNOSTIC FACTORS AND OVERALL SURVIVAL IN 78 PATIENTS FOLLOWED FOR 7 YEARS(2002-2008) FROM A SINGLE INSTITUTION

C. Saguna, M. Closca, O. Ciocan, A. Colita, A. Ciobanu, N. Berbec, R. Manolache, E. Coles, A.R. Lupu

Coltea Hospital, Bucharest, Romania

Background. Follicular lymphoma(FL) represents approximately 25% of all adult nonHodgkin's lymhomas in Western countries, usually characterised by an indolent course and a median survival of 10 years. *Aim.* : to identify the prognostic factors that influence overall survival (OS) in patients with follicular lymphomas. *Methods*. We report here our experience with 78 patients treated in our institution since 2002.These 78 patients represent above 2% of the patients with B cell lymhoproliferative disorders seen in our institution.We evaluated the predictive value of pretreatment clinical features:age, sex,Ann Arbor stage,Bsymptoms,ECOG performance status, presence of bulky disease, bone marrow involvement and number of extranodal sites.Patients were evaluated by physical examination,including LDH,beta-2-microglobulin, bone marrow biopsy and radiologic studies(chest x-ray, CT scans).Therapy strategies ranges from single-agent therapy,combination therapy,Interferon,combinations chemotherapy/targeted monoclonal antibody to radioimunotherapy, local radiation therapy. Nine patients with follicular grade 1 lymphoma,Ann Arbor stage I did not require therapy at a median of of 4 years. Fiftyeight patients were BCL2 positive and harbor t(14;18). *Results.*The median age of patients was 62.Men and women are affected equally. According to the WHO classification, 32 % of patients were with grade I FL,24% with grade II FL and 44% of patients were with grade III FL. The survival was 72% at 5 years.Among extranodal sites of disease, bone marrow was the most common in our series .Features associated with shorter survival included advanced stage-especially IV, extranodal and bone marrow involvement,age>60. Serum beta 2 microglobuline was also strongly correlated with survival:76% of those with beta2 microglobuline lower than 3 were alive at 5 years.The most patients had high serum LDH levels, but lower than 1000U/L and a good performance status(0-1).Chemotherapy /targeted monoclonal antibody combination improved responses compared with chemotherapy alone. The best survival was related to the patients treated with Interferferon. There was no correlation between presence of BCL2 and clinical outcome of disease. *Conclusions.* The incidence of follicular lymphoma in our institution is lower that it was reported in literature. Similar results were reported in other institutes from Romania so it seems that the incidence of follicular lymphoma in our country could be lower than Western countries.Presence of t(14;18) is similar to frequency in Western countries but is not of prognostic significance.

SERUM LEVELS OF TH1 AND TH2 CHEMOKINES IN CUTANEOUS T CELL LYMPHOMAS (CTCL)

A. Campanati,[1] S. Rupoli,[2] G. Goteri,[3] L. Canafoglia,[2] F. Marchegiani,[4] A. Costagliola,[3] P. Picardi,[2] T. Biscotti,[3] M. Cardelli,[4] L. Rosamaria,[5] S. Mulattieri,[2] F. Olivieri,[6] G. Ganzetti,[7] S. Pulini,[8] A.M. Offidani,[7] P. Leoni[2]

[1]Polytechnic Marche University, ANCONA, Italy; [2]Clinic of Hematology, Polytechnic Marche University, ANCONA, Italy; [3]Institute of Pathology, Polytechnic Marche University, ANCONA, Italy; [4]Immunology Center, Italian National Research Center on Aging (I.N.R.C.A), ANCONA, Italy;[5]Italian National Research Center on Aging (I.N.R.C.A.), ANCONA, Italy; [6]Dep. Molecular Pathology, Innovative Therapies, Polytechnic Marche University, ANCONA, Italy; [7]Dermatological Clinic Medicine and Biostatistic Department of Polytechnic Marche, ANCONA, Italy; [8]Department of Hematology, "Spirito Santo" Hospital, PESCARA, Italy

Background and aims. Interferon-inducible protein-10 (IP10)/CXCL10, monokine induced by interferon-α (MIG)/CXCL9, thymus and activation-regulated chemokine (TARC)/CCL17 and CTACK/CCL27, represent Th1 and Th2 chemokines that regulate skin selective T lymphocyte trafficking and recruitment in inflammatory and neoplastic disorders. In Cutaneous T Cell Lymphomas (CTCL), which derive from CD4+ memory Th2 cells, they have been considered critical both for pathogenesis and progression from early to advanced stages, although few and conflicting results are available in literature. The aim of our study was to determine the serum release of these four chemokines in 24 CTCL patients at different stages and to compare their levels with those of a population of healthy donors in order to identify a potential clinical significance; moreover, we intended to assess whether the combination of PUVA and interferon-α2b (PUVA/IFNα2b) in early CTCL affects the balance of serum levels of Th1 and Th2 chemokines and may have clinical importance. *Design and Methods*. Serum samples were collected from 24 CTCL patients at the time of the diagnosis (17 mycosis fungoides/MF-15 early and 2 advanced; 7 Sézary Syndrome) and from 20 healthy donors age- and gender-matched used as controls. In 15 MF patients who obtained a clinical complete remission after PUVA\IFNα2β combination therapy, serum samples were also collected and examined after the end of the treatment. Quantikine kits (R&D Systems, Minneapolis, USA) were used for the ELISA assays, performed according to the manifacturer's instructions, and optical densities were determined using a VICTOR2 Multilabel Counter fluorescence plate reader (Perkin-Elmer, Torrance, CA, USA). *Results*. In all CTCL patients serum CCL27 levels were similar to those of healthy controls, whereas for the other chemokines we observed a statistically significant increase of serum CCL17 and CXCL10 levels in advanced CTCL compared to early MF (6/9 vs 2/15, Fisher's exact test, p=0.021). We also found increased levels of CXCL9 in 5/9 advanced CTCL and in 4/15 early MF (p=NS, between the two groups of CTCL patients). Treatment with PUVA plus interferon-α2b did not substantially change the serum levels of any of these chemokines. *Conclusions*. Although we and others have previously observed enhanced CCL27 expression by keratinocytes in MF cutaneous lesions, suggestive for a possible role of this molecule in lymphocyte skin-homing (1,2), we were not able to confirm an elevation in serum, as indicated by others (2). We therefore propose that CCL27 might be considered a cutaneous, but not a serum marker of disease activity. On the other hand, we found a significant elevation of serum

levels of the other three chemokines (CCL17, CXCL10 and CXCL9) in less than 40% CTCL patients, thus limiting the clinical utility of these proteins as specific disease-markers. However, abnormally high serum levels of CCL17 and CXCL10 tend to be associated to more advanced clinical stages of disease, and they can be retained as potential prognostic markers. Finally, while Interferon-γ and UVB were reported to affect the serum levels of Th1 and Th2 chemokines in CTCL (3-6), in our experience PUVA and interferon-α2b failed to show similar effects, despite achieving complete remission in early MF stages. In this subset of patients, evidence of clinical utility of serum chemokine determination in monitoring the disease during therapy is still lacking.

1662

MANTLE CELL LYMPHOMA: ONE OR MORE ENTITIES?

K. Dimosthenous,[1] V. Bikos,[2] E. Pouliou,[1] S. Afentaki,[1] A. Michailidou,[3] A. Zomas,[4] G. Kokkini,[3] A. Fassas,[5] A. Anagnostopoulos,[5] K. Stamatopoulos,[5] T. Papadaki[1]

[1]Evangelismos Hospital, ATHENS, Greece; [2]Democritus University of Thrace, ALEXANDROUPOLIS, Greece; [3]Sismanogleion Hospital, ATHENS, Greece; [4]Attikon Hospital, ATHENS, Greece; [5]G. Papanicolaou Hospital, THESSALONIKI, Greece

Mantle cell lymphoma (MCL) is pathogenetically linked to the reciprocal translocation t(11;14), and is considered to derive from the neoplastic transformation of the "naïve" lymphocyte residing in the mantle zone (MZ). Nevertheless, the differences between the phenotypic profile of MCL and its proposed normal counterpart (mantle zone lymphocyte) raise significant questions regarding its ontogeny. We present results of a combined morphologic, immunohistochemical and genotypic analysis of 30 MCL cases. The study group consisted of 24 nodal and 6 extranodal MCLs. Morphologically, 17 cases were ascribed to the "common" variety, 5 of which exhibited "monocytoid" and 1 "plasmacytoid" differentiation. The growth pattern was as follows: (1) diffuse: 7/30, (2) mantle zone differentiation (MZDif): 8/30 (3) "vaguely" nodular: 3/30, (4) nodular+diffuse: 10/30, (5) nodular+diffuse+MZDif: 2/30. The immunohistochemical study (on paraffin sections) revealed the following profiles: (1) CD20+, CD79a+, BCL-2+, Cyclin D1+, CD23-, CD10-, BCL-6-, DBA.44-, CD3-: 30/30, (2) CD5+: 28/30, (3) CD43+: 26/30. The cellular proliferation index ranged from 6-96% (median: 20%). Kappa or lambda light chain isotype expression was observed in 10/27 and 17/27 cases, respectively. The breakdown of cases based on the heavy chain isotype was as follows: (1) IgM: 20/28, (2) IgM, D: 7/28, (3) IgG: 1/28. CD27 positivity was observed in 13/25 cases, 8 of which exhibited lambda light chain clonal restriction. Molecular analysis of immunoglobulin heavy chain (IGH) gene rearrangements identified one case carrying rearranged IGHV genes with <98% germline nucleotide identity ("mutated"), 7 cases carrying IGHV genes with 98-99.7% identity ("borderline mutated") and 4 cases with unmutated IGHV genes (100% identity). Six of seven CD27 positive cases with available molecular data were found to carry "borderline mutated" or "unmutated" IGHV genes. In addition, 3/7 IgD+ cases were positive for CD27. In conclusion, the results of this study document the significant phenotypic and genetic heterogeneity of the MCL and suggest the existence of "subtypes" defined on the basis of: (1) the mutational status of IGHV genes ("unmutated" versus "borderline mutated" and rarely "mutated"), (2) the functional profile of the malignant cells ("naïve" versus "activated"/"antigen-experienced"). CD27 positivity in a subset of cases and biased expression of lambda light chain isotype could be construed as evidence for antigen contact and receptor editing, respectively. Finally, in light of the aforementioned results, the mantle zone, "naïve" lymphocyte, cannot be established as the cell of origin of the MCL, at least in a significant proportion of cases.

1663

PROTEIN KINASE Cβ (PKCB) INHIBITOR ENZASTAURIN HCL (LY 317615) IN MANTLE CELL LYMPHOMA

G. Hutter,[1] M. Rieken,[2] Y. Zimmermann,[1] E.M. Hartman,[3] V. Jurinovic,[4] A. Rosenwald,[3] M. Weinkauf,[1] A. Pastore,[1] W. Hiddemann,[1] M. Dreyling[1]

[1]University Hospital Munich, Grosshadern, MUNICH, Germany; [2]Helmholtz Center Munich, Germany, MUNICH, Germany; [3]Institute of Pathology, University of Wuerzburg, Germany, WUERZBURG, Germany; [4]Institute of Medical Informatics, Biometry and Epidemiology, LMU, MUNICH, Germany

Introduction. The protein kinase C (PKC) family of enzymes are serine/threonine kinases essential to the cell signal cascades effecting cellular growth, proliferation and apoptosis. Previous studies in diffuse large B-cell lymphoma suggest that PKC β activity enhances B-cell proliferation and survival. Accordingly PKC β overexpression correlates with poor clinical prognosis in this lymphoma subtype. The pivotal role of PKC β in neoplastic transformation renders it a potential therapeutic target in the therapy of hematologic malignancies. However, the effect of PKC β inhibition in mantle cell lymphoma (MCL) has not yet been reported. *Aims*. To access the effect of PKC ß inhibition in mantle cell lymphoma on cell proliferation, mRNA- and protein expression to define genetic predictors of sensitivity to PKC β inhibition in mantle cell lymphoma. *Design and Methods*. Five MCL cell lines (HBL-2, GRANTA 519, Jeko-1, Z138, Rec-1), two hematological control cell lines (Jurkat, Karpas 422) and patient samples were cultured in the presence of LY 317615 (PKC ß inhibitor). Cell proliferation and viability was assessed by cell counts and WST-1 proliferation assay. Analysis of cell cycle profile and apoptosis was performed by flow cytometry (PI and Annexin V FITC staining). mRNA expression was measured by microarray and real time PCR after 4h and 8h in cell lines. Protein expression was analysed by western blot. *Results*. Treatment of the cell lines with LY 317615 lead to inhibition of cell proliferation and accumulation of cells in the G2, M phase in susceptible cell lines (Hbl-2, Jeko-1), whereas cell cycle profile remained unaltered in the refractory cell lines (Rec-1). Enzastaurin induced CCND1 and BCl2 mRNA downregulation as well as reduced protein levels. A significant downregulation of the global mRNA expression could be observed in susceptible to enzastaurin cell lines (Jeko -1 and Granta 519 ($p<2.2x10^{-16}$) after 8h of treatment, but upregulation in Rec-1 (p=0,0005618). Further mRNA expression analysis are ongoing to determine differentially expressed mRNAs as predictors of enzastaurin sensitivity. *Conclusions*. PKCβ inhibition by LY 317615 inhibits cell growth and induces cell cycle alterations and apoptosis in MCL cell lines. Differences in mRNA expression in susceptible to refractory to enzastaurin cell lines were observed. The characterization of differentially expressed mRNAs as predictors of enzastaurin sensitivity will be useful for a targeted application of combination partners for the treatment of MCL.

EPIGALLOCATECHIN-3-GALLATE INDUCES GROWTH INHIBITION INDEPENDENT OF THE 67 KDA LAMININ RECEPTOR IN LEUKEMIC CELLS

M. Hazawa,[1] K. Takahashi,[2] I. Kashiwakira[2]

[1]Hirosaki University Graduate School, HIROSAKI, Japan; [2]Hirosaki University Graduate School of Health Sciences, HIROSAKI, Japan

Background. Epigallocatechin-3-gallate (EGCg) is the major catechin present in green tea which has attracted much attention because of its various pharmacological effects. Especially, many reports showed that EGCg has anti-tumor properties related to induction growth arrest and/or apoptosis via reactive oxygen species, mitogen-activated protein kinase (MAPK), epidermal growth factor receptor and etc. However, EGCg has been shown to produce hydrogen peroxide rather than induce an EGCg-direct action under certain cell culture conditions. Recently, 67 kDa laminin receptor (67LR) was identified as a cell surface receptor that mediates the direct anti-cancer action of EGCg. The expression level of 67LR strongly correlates with the risk of tumor invasion and metastasis. *Aims*. This study investigated the anti-tumor effects of EGCg against myeloid leukemic cell lines UT-7 and K562, and lymphoid leukemic cell line Raji by examining the relationship between EGCg sensitivity and 67LR expression levels. *Design and Methods*. Each cell was cultured with various EGCg doses (1 nM - 10 μM) for 1 to 10 days to clarify the sensitivity to EGCg. After incubation, the cells were harvested from the culture and the number of viable cells was determined by the trypan blue exclusion method. In the analysis of the expression level of 67LR on the

cell surface and cytosol, each cell was analyzed using a flow cytometer. *Results*. The number of Raji cells decreased in a dose- and time-dependent manner under the treatment with EGCg. A significant growth arrest against Raji cells was observed with the treatment with 1 - 10 μM EGCg. Treatments of 10 μM EGCg induced over 70% growth inhibition at day 5, and treatments of 1 μM EGCg induced 50% growth inhibition in Raji cells at 10 days. On the other hand, UT-7 and K562 cells were resistant to EGCg at several concentrations tested here. However, the expression level of 67LR on the cell surface by a flow cytometric analysis showed the highest expression in UT-7 cells which are most resistant to EGCg-induced growth inhibition (mean fluorescence intensity (MFI): 56.7). Furthermore, no difference was observed in the expression of 67LR on the cell surface among K562 cells and Raji cells (MFI: 3.7, 4.3 respectively). Although Raji cells are most sensitive to EGCg treatments, it presents little 67LR on the cell surface. These results suggest that EGCg-induced growth inhibition is induced independence of the 67LR mediated pathway. *Conclusions*. The growth inhibition against Raji cells was induced at 1 μM EGCg treatments suggesting an adequate concentration for induction the direct effects of EGCg through 67LR. This study implies the possibility that other signaling pathways therefore exist induced by EGCg independent of 67LR in lymphoid leukemic cells.

FOXP3+ T REGULATORY CELLS EXHIBIT EFFECTOR PHENOTYPE IN PATIENTS WITH B-CELL MALIGNANCIES

A. Lindqvist,[1] H. Christiansson,[1] M. Mangsbo,[1] H. Tötterman,[1] B. Simonsson,[2] U. Olsson-Strömberg,[2] G. Enblad,[2] S.I. Loskog[1]

[1]Uppsala University, UPPSALA, Sweden; [2]Uppsala University Hospital, UPPSALA, Sweden

Background. Recent reports have indicated that infiltration of Foxp3+ T-regulatory cells (Tregs) in the tumor area can be associated with better overall survival of patients with B-cell malignancies, which is in contrast to patients with solid tumors. Since the tumor in lymphoma patients is a cell of the immune system it is possible that Treg cells may have a suppressive role in tumor progression. *Aims*. In this study, we have investigated the phenotype and function of Tregs in patients with B-cell malignancies. *Design and Methods*. Peripheral blood was collected from patients with B-cell malignancies and evaluated for the presence of CD3+CD4+Foxp3+ cells. These cells were further characterized by investigating their expression of IL-7R (CD127), IL-2R (CD25), FasL and CD107a, as well as evaluating their biological function *in vitro*. Results Tregs were significantly increased in patients with B-CLL while not in patients with B-cell lymphoma compared to healthy, age-matched controls. However, all patients displayed higher expression of the degranulation marker CD107a, indicating perforin/granzyme release, on their Tregs. No difference in FasL expression was found. Interestingly, patients that did not respond to treatment had fewer effector Tregs than controls. Further, a flow cytometry-based cytotoxic assay indicated that patient Tregs were more efficient in killing autologous B-cells than Tregs from healthy donors. *Conclusions*. Patients with B-cell malignancies have circulating Tregs that exhibit effector phenotype and these cells may participate in the control of tumor cell progression.

ANALYSIS OF NEOPLASTIC LYMPHOCYTES IN PERIPHERAL BLOOD OF PATIENTS WITH B NON HODGKIN LYMPHOMA WITHOUT LYMPHOCYTOSIS

M.T. Orero,[1] R. Collado,[1] S. Beltrán,[1] I. Oliver,[1] A. Del Rey,[1] J. Hueso,[2] A. Miguel,[1] F. Ibáñez,[3] F. Carbonell[4]

[1]Consorcio Hospital General, VALENCIA, Spain; [2]Hospital de Alcoy, ALCOY, Spain; [3]Hospital de Requena, REQUENA, Spain; [4]Consorcio Hospital General. Universidad de Valencia, VALENCIA, Spain

Background. Several studies in non Hodgkin lymphomas include peripheral blood involvement as a prognostic factor. Although a high leucocyte count probably reflects peripheral blood involvement, it may also occur without lymphocytosis. In order to detect these cases, we must employ methods more sensitive than morphology. Aim: To study the presence of neoplastic lymphocytes in peripheral blood of patients with B non Hodgkin lymphoma (B-NHL) without lymphocytosis. *Design and Methods*. : We applied a standardized four-color cytometry assay to peripheral blood from 42 patients with B-NHL at diagnosis without lymphocytosis (lymphocytes <4x10^9/L): 8 lymphoplasmacytic lymphoma (LPL), 4 splenic marginal zone lymphoma (SMZL), 1 nodal marginal zone B-cell lymphoma (NMZL), 15 follicular lymphoma (FL), 5 mantle cell lymphoma (MCL), 4 diffuse large B-cell lymphoma (DLBCL), 2 Burkitt lymphoma (BL), 2 MALT lymphoma (ML) and 1 cutaneous B lymphoma (CBL). Samples were stained using a mixture of the following directly conjugated monoclonal antibodies: CD45, CD3, CD4, CD8, CD19, CD5, CD10, λ and κ. A total of 0.5 - 1x10^6 events from each sample were adquired using a BD FACSCalibur flow cytometer with CellQuest software and analyzed with Paint-a-gate software (BD). Results: The median lymphocyte count was 1.9x10^9/L (range, 0.6-4x10^9/L). Light chain restriction and inmunophenotypic aberrations were observed in 18 samples (42.8%) with a median neoplastic lymphocyte count of 0.47x10^9/L (range, 0.01-1.43x10^9/L). Among these altered cases, 8 were predominantly disseminated lymphomas (3 SMZL and 5 LPL), 4 MCL, 4 FL and 2 DLBCL. Peripheral blood involvement by morphology was observed in only 7 samples (16.6%) with a median neoplastic lymhocyte count of 0.56x10^9/L (range, 0.07-1.05x10^9/L). In the other 11 cases (26.2%), the morphologic study was negative and their neoplastic lymphocyte values were lower (median: 0.29x10^9/L, range: 0.01-1.43x10^9/L). *Conclusions*. Flow cytometry allows us to easily identify and quantify circulating neoplastic lymphocytes in an important proportion of B-NHL without lymphocytosis and morphologic evidence. The probably prognostic value of blood involvement analyzed by this methodology should be studied in the future.

1667

DOWNEXPRESSION OF TCR-ζ CHAIN IN PATIENTS WITH B-CELL NON-HODGKIN'S LYMPHOMAS

S.H. Chen, J.X. Li, L.J. Yang, C.L. Lin, Y.Q. Li

Medical College, Jinan Univesity, GUANGZHOU, China

Background. In patients with hematological malignance, cell-mediated immunity is often suppressed, being most profound in those advanced disease. The immune dysfunction, may be due to the disorder of recent thymic output function, the abnormal expression of T cell receptor repertoire and, may in part, due to altered expression of TCR ζ chain, which is an important component of the TCR. *Aims*. To analysis the expression level of signaling transduction factor TCR ζ chain gene in T cells from patients with B-cell non-Hodgkin's lymphomas (B-NHL). *Design and Methods*. Real-time RT-PCR with SYBR Green echnique was used for detecting the expression level of TCR ζ chain gene in peripheral blood mononuclear cells (PBMCs) of 17 patients with B-NHL, and 17 cases healthy adults served as controls. The β2-microglobulin gene (β2M) was used as an endogenous reference. Relative mRNA expression level of TCR ζ chain gene was analyzed by using the 2Δ-Ct-100% method. *Results*. TCR ζ chain gene was expressed in all patients with B-NHL. Compared with healthy control, the relative mRNA expression level of TCR ζ chain gene could be found significantly decreased (p=0.000). All samples from healthy individuals expressed normal level of TCR ζ chain gene, which is 3.26 times higher than that from B-NHL patients. There was no significant correlation between the expression level of TCR ζ chain gene and age in patients with B-NHL. *Conclusions*. The down expression of TCR ζ chain gene could be identified in peripheral blood of patients with B-NHL, which might play a role in cell-mediated immunodeficiency in most of B-NHL patients.

NEW MOLECULAR MARKERS IN DIAGNOSIS OF SPLENIC LYMPHOMAS

M. Closca-Gheorghiu, G. Ofiteru, A.R. Lupu, C. Saguna, O. Ciocan, A. Colita, A. Ciobanu, C. Mitrescu, E. Coles

Coltea Hospital, BUCHAREST, Romania

Background. Since the initial description of splenic malignant lymphomas, an increasing number of publications have dealt with multiple aspects of diagnosis, molecular pathogenesis and treatment. The diagnosis has been until very recently based on the pathological study of the spleen with the conjunction of the clinical features, although the integration of the morphology in bone marrow and peripheral blood with the immunophenotype and molecular characteristics of the tumour makes a more accurate diagnosis now possible. Therefore the classification, the diagnosis and therapeutic management of these patients have been frequently controversial and inadequate. Molecular studies of these lymphomas are starting to reveal new diagnostic and prognostic markers, and identify new potentially useful therapeutic targets. In this context, new cytogenetic and molecular findings were added to existent data (API2-MALT1 - t(11;18)(q21;q21), del 7q, changes in the expression of the p53 protein, over expression of cyclins, etc). *Aims*. The main

objective of this research study was agreeing on the main diagnostic, staging and therapeutic guidelines for patients with splenic lymphomas. *Design and Methods*. With the aim of characterizing these lymphomas more comprehensively, and of identifying new diagnostic and prognostic markers, we performed cDNA microarray expression profiling and tissue microarray (TMA) immunohistochemical studies in a relatively large series of splenic lymphomas. *Results*. Clinical presentation with lymphadenopathies and B-symptoms was mainly associated with the diagnosis of mantle cell lymphoma, whereas splenomegaly was suggestive of marginal zone splenic lymphomas. In our study group 44% patients were diagnosed at an early clinical stage with still conserved hematopoiesis, 32% of them, being diagnosed following a routine hemoleucogramm. Time-to-event analysis, involving Kaplan-Meier, log-rank test, and Cox models, served to identify markers influencing disease-related overall survival (DOS) and progression-free interval (PFI). The estimates of the hazard ratios (HRs) along its 95% confidence interval (95% CI) were computed via the Cox model. Patients were considered to have progressive disease on the basis of progression to a more advanced stage, or the enlargement or new appearance of lymph nodes, development of systemic symptoms, large B-cell lymphoma progression, or death attributable to the lymphoma. Concerning molecular markers we had studied, API2-MALT1 was correlated with prognosis in MALT lymphomas, overexpressions of cyclins was correlated with poor prognosis in mantle cell lymphomas and in some marginal splenic lymphomas and aberrant expression of the p53 protein with lymphoplasmocytoid lymphomas. *Conclusions*. We were trying to create a specific guideline for diagnosis criterias, differential diagnosis, staging, prognostic factors, treatment and response criteria. The guidelines proposed here are intended to contribute to the standardization of the diagnosis and treatment of these patients, and should facilitate the future development of clinical trials that could define more precisely predictive markers for histological progression or lack of response, and evaluate new drugs or treatments.

HYPERMUTATION OF THE BCL6 GENE IN PRIMARY MEDIASTINAL LYMPHOMA AND OTHER TYPES OF DIFFUSE LARGE B CELL LYMPHOMA

S. Trajkova,[1] A. Stojanovic,[1] I. Panovska-Stavridis,[1] G. Petrusevska,[2] O. Karanfilski,[1] A. Pivkova,[1] B. Georgievski,[1] S. Stankovic,[1] T. Sotirova,[1] S. Trpkovska,[1] M. Pavkovik,[1] A. Ljatifi,[1] D. Dukovski,[1] L. Cevreska[1]

[1]Universyti Clinik for Hematology, SKOPJE, Macedonia; [2]Institute for Pathology, SKOPJE, Macedonia

Beckground. Somatic hypermutation of the BCL6 gene and its expression in lymphoma represent specific marker of the germinal center. Thus, analysis of the BCL6 may aid in explanation of the relationship between primary mediastinal (PMBL) and other types of diffuse large B cell lymphoma (DLBCL). These subgroups of lymphoma arise from different stages of B-cell diferention and differ in their ability to be cured by chemotherapy. *Design and Methods*. Forty (40) patients with NHL were included in the study. Twenty (20) pts with PMBL and 20 pts with other types with DLBCL were analyzed for BCL6 status by immunohistochemistry. All samples were analyzed using an antibody panel characterizing PMBL and DLBCL (anti-cytokeratin 5, anti-CD20, anti - BCL6 antibody, anti - BCL2 antibody, anti - MUM1 antibody). *Results.* The average age of pts with PMBL was 30, 65 years, and average age for pts with DLBCL was 47 years, 18 cases from PMBL group showed BCL6 immunohistochemical expression, and 10 cases (50%) from DLBCL group showed BCL6 immunohistochemical expression. Overall survival(OS) was 46,65 months for pts with PMBL respectively 76,2 months for pts from DLBCL group, Event free survival(EFS) was 46,15 months for pts with PMBL and 76,2 months for pts from DLBCL group, Duration of remission(DoR) was 43,6 months for pts with PMBL and 76,75 months for pts with DLBCL *Conclusions*. The consistent expression of BCL6 protein should be considered of germinal center origin.PMBL originate from an already defined sub-population of B - cells which are different from those leading to other types of DLBCL.

1670

PROGNOSTIC VALUE OF THE SOLUBLE INTERLEUKIN-2 RECEPTOR IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA: RESULTS FROM A RETROSPECTIVE ANALYSIS

Z. Kubová,[1] T. Papajík,[2] V. Procházka,[3] J. Pavlík,[4] K. Indrák[3]

[1]University Hospital Olomouc, OLOMOUC, Czech Republic; [2]Department of Hemato-oncology, Universtity Hospital Olomouc, OLOMOUC, Czech Republic; [3]Department of Hemato-oncology, University Hospital Olomouc, OLOMOUC, Czech Republic; [4]Institute of Biostatistics and Analyses, Masaryk University, BRNO, Czech Republic

Background. Interleukin-2 (IL2) is a signalling molecule of the immune system which acts by binding to the interleukin-2 receptor (IL-2R). The IL-2R is a heterotrimeric membrane protein complex consisting of three distinct subunits, the α chain (IL-2Rα, CD25), the β chain (IL-2Rβ, CD122), and the γ chain (IL2-Rγ, CD132). Release of the IL-2Rβ extracellular domain gives rise to the soluble interleukin-2 receptor (sIL-2R). Concentration of the sIL-2R increases under various pathological conditions. Aims: It has been shown that increased concentration of the sIL-2R is a predictive indicator of poor prognosis in patients with diffuse large B-cell lymphoma (DLBCL) treated with chemotherapy alone. The question is whether its predicting value is maintained in the era of rituximab. *Design and Methods*. Pretreatment serum levels of the sIL-2R were measured by enzyme-linked immunosorbent assay (ELISA) in 162 patients with *de novo* DLBCL treated with anthracycline-based chemotherapy alone (N=60) or rituximab combined with chemotherapy (N=102). Univariate progression-free survival (PFS) and overall survival (OS) analyses were performed according to the cut-off serum level set at 116 pmol/l (<116 pmol/l N=92/57% vs. ≥116 pmol/l N=70/43%), and the first-line treatment (chemotherapy alone vs. rituximab combined with chemotherapy). The median follow-up for OS and PFS was 29.7 and 30.4 months, respectively. *Results*. Three-year OS was significantly better in patients with low serum levels of the sIL-2R than in those with high sIL2-R levels, regardless of whether chemotherapy was used alone or in combination with rituximab (OS 84.4% vs. 70%, p=0.005). In the chemotherapy alone group, patients with high serum levels of the sIL-2R had significantly worse three-year OS and PFS when compared with those with low serum levels of the sIL-2R (OS 47.7% vs. 80%, p=0.003, PFS 68.4% vs. 81.5%, p=0.034). But in the rituximab group, no differences related to serum levels of the sIL-2R were shown (sIL-2R ≥116 vs. <116: OS 84.8% vs. 88.5%, p=0.222, PFS 85.1% vs. 87.2%, p=0.765). *Conclusions*. Our results showed that pretreatment serum level of the sIL-2R is significantly related to outcome in DLBCL patients treated with anthracycline -based chemotherapy, but has not maintained its prognostic value in the rituximab era. Significance of the sIL-2R should be re-evaluated in large prospective trials with longer follow-up. It is appropriate to evaluate the significance of the sIL-2R with different cut-off levels.

TREATMENT OF DIFFUSE LARGE B-CELL LYMPHOMA: CHEMOTHERAPY WITH RITUXIMAB IMPROVED PROGNOSIS IN ALL AGE GROUPS

T. Papajik,[1] V. Prochazka,[2] Z. Kubova,[2] L. Raida,[2] E. Faber,[2] J. Vondrakova,[2] L. Kucerova,[2] M. Myslivecek,[2] T. Pavlik,[3] K. Indrak[2]

[1]University Hospital, OLOMOUC, Czech Republic; [2]Palacky University Hospital, OLOMOUC, Czech Republic; [3]Masaryk University, BRNO, Czech Republic

Background. Diffuse large B-cell lymphoma (DLBCL) is the most common non-Hodgkin's lymphoma, accounting for approximately one third of all new diagnoses. Anthracycline-based combined therapy has been the standard treatment for more than 25 years. The addition of rituximab (R) to chemotherapy (Chemo) has significantly improved outcome in older and low-risk younger DLBCL patients and some data have suggested that the administration of rituximab-supplemented intensive chemotherapy may improve prognosis of poor-risk younger patients. Aims: To prove the efficacy of a treatment for adults with DLBCL in the pre-rituximab and rituximab era. *Design and Methods*. From 1995 to 2007, 290 pts. with newly diagnosed DLBCL were treated with curative intent at the Hemato-oncology Dpt. Olomouc. Patients younger than 65 years were divided into low-risk, intermediate-risk and high-risk group and treated with standard CHOP-like, intensified PACEBO-like and intensive sequential chemotherapy (+/- rituximab). Patients older than 65 years were treated with CHOP-like regimen (+/- rituximab) if they had no

major comorbidity. Results: 3-year overall survival (OS) were 84% in R-Chemo group and 59% in chemotherapy without (p<0.001). 3-year progression-free survival (PFS) were 85% in R-Chemo group and 64% in chemotherapy without (p=0.002). R-Chemo significantly improved OS and PFS in pts. younger and older than 65 years (OS: 90% vs 71%, and 69% vs 37%; p<0.001), (PFS: 87% vs 68%, and 78% vs 53%; p=0.09). R-Chemo also improved 3-year OS in aa-IPI 2-3 in comparison with Chemo (91% vs 45%; p<0.001), the OS in aa-IPI 0-1 wasn´t different (90% vs 89%; p=0,76). In R-Chemo group there were also significantly lower number of relapses/progressions (9% vs 30%; p<0.001) and exitus (13% vs 46%; p<0.001). In multivariate analysis, age, tumor size, lymphocyte count, IPI and therapy with R was identified as independent prognostic factor related to OS. *Conclusions*. Prognostically stratified therapy in younger patients and the addition of rituximab in all age groups markedly improved PFS and OS for DLBCL.

Background. Primary hepatic lymphomas are rare while secondary liver involvement by systemic lymphoma is relatively common. However, except for hepatosplenic T-cell lymphoma, the incidence and the clinical relevance of secondary liver involvement by different lymphoma subtypes, that primarily arise in the spleen, have not been so far evaluated. In particular, splenic marginal zone lymphoma (SMZL) is disease usually characterized by isolated splenomegaly and bone marrow infiltration. At now, it is not ascertained the incidence of liver involvement in SMZL, also considering the high seroprevalence of HCV in this lymphoma subtype. AIM To analyze splenectomies performed in pts affected by lymphomas and to evaluate the incidence and features of liver involvement by lymphoma in wedge liver biopsies, when available. *Design and Methods*. We analyzed 45 pts with lymphoma who underwent a laparotomic splenectomy from 2001 to 2008: 19 SMZL, 15 primary splenic DLBCL [12 centroblastic (CB) and 3 T-cell histiocyte rich large B-cell lymphoma (TCHRBCL)], 1 secondary splenic DLBCL (a TCHRBCL case evolution of lymphocyte-predominance HL); 8 classic HL (most secondary), 1 lymphoplasmocytic lymphoma, 1 hepatosplenic T-cell lymphoma. A concurrent wedge biopsy of the liver was available for all pts except for 5 (4 SMZL, 1 DLBCL-CB). *Results*. Liver involvement was detected in 18 pts: 11/15 pts (73%) with SMZL, 4/15 (26%) primary splenic DLBCL (2 CB and 2 TCHRBCL), 3/8 (37%) HL, 1 hepatosplenic T-cell lymphoma. In SMZL a portal pattern of liver involvement was detected in 10/11 pts; in 7 pts it was associated to sinusoidal pattern, and in 2 pts to a nodular/lobular pattern; in a single case the lymphoma infiltrate was confined to hepatic sinusoids. Bile duct lympho-epithelial lesions were detected in 6 cases, cholestatic changes in 5, ductopenia in 2 and hepatitic changes in 4. No case showed progression to DLBCL in hepatic infiltrates. HCV serology was positive in 5/15 (33%) SMZL. Three HCV+ cases showed liver involvement by lymphoma and were HCV-RNA (2a/2c in 2 pts and 1b in 1 patient); in all these cases pattern of liver infiltration was portal; 1 of them has a double pattern of infiltration: portal and sinusoidal. The remaining 8 pts with SMZL involving the liver were HCV-. Phenotype was CD20+, CD79a+, CD5-, CD10-, bcl-6-, cyclin D1- in 15/15, bcl2+ in 14/15 and CD23- in 14/15 SMZL. Among the 12 cases of primary splenic DLBCL-CB, 7 were HCV+; 6 cases showed a germinal center (GC) phenotype, whereas 6 had a non-GC phenotype. Liver involvement was detected in 2 HCV- pts, with a nodular to diffuse pattern. Liver localization was found in 2/3 cases of HCV-TCHRBCL (portal and nodular/lobular pattern). Both DLBCL-CB and TCHRCBCL with liver involvement showed a non-GC phenotype. *Conclusion*s. Our data demonstrate that SMZL is characterized by a high incidence of liver involvement with a frequent portal and sinusoidal pattern. Interestingly, detection of hepatic localization by SMZL seems to be irrespective to HCV status infection and appears as an intrinsic feature of this lymphoma subtype.

1673

OUTCOME WITH LONG-TERM L-ASPARAGINASE THERAPY OF ADOLESCENTS AND YOUNG ADULTS (AYA) WITH PRECURSOR B AND T LYMPHOBLASTIC LYMPHOMA: PRELIMINARY RESULTS

S. Kulikova, S.V. Semochkin, M.M. Bobkova, E.G. Arshanskaya, A.G. Rumiantsev

Federal Clinical Center for Pediatric Hematology, Oncology and Immunology, MOSCOW, Russian Federation

Background. Lymphoblastic lymphoma (LBL) is a relatively rare subtype (3-5%) of adult non-Hodgkin's lymphoma. LBL represents a distinctive lymphoma entity with cytological and morphological features similar to those of acute lymphoblastic leukemia (ALL). At present, generally precursor B and T LBL has been treated with intensive ALL -similar chemotherapy. At the same time in a number of shows that high-dose methotrexate and early intensification useful in the treatment of leukemia is not useful in lymphoma (Abromowitch M., ASH 2008). The greatest amount of data obtained in studies in children. Optimal treatment of lymphoma treatment for adolescents and young adults (AYA) with LBL is still not clear. *Aims*. Thus, the purpose of this retrospective study was to investigate treatment outcomes for adolescents and young adults (AYA) with LBL treated with long-term L-asparaginase versus BFM-similar therapy. *Design and Methods*. 18 patients (pts) were enrolled from July 1998 to December 2007. 6 (33%) pts were treated on the protocol NHL-BFM 90 for non-B NHL and 11 (67%) pts to treat pediatric protocols ALL-MB 91 and 2002. In these protocols the pts receive four drug induction with dexametasone 6 mg/m^2 daily for 36 days, daunorubicin 45 mg/m^2 for 2 doses, vincristine 2 mg weekly for 5 doses and and intrathecal (IT) cytarabine and IT methotrexate and IT prednisolone weekly for 6 doses. Consolidation therapy included L-asparaginase in a constant dose of 10000 ME/m^2 weekly for 18 doses and 6-merkaptopurine 50 mg/m^2 (100%) daily and methotrexate 30 mg/m^2 (100%) weekly with weekly doses adjusted according to white blood cell count. Central nervous system (CNS) irradiation is performed only for pts with CNS involvement at diagnosis. Maintenance was carried out up to 24 months. The protocol NHL-BFM 90 called for the purpose of comparison as an effective standard therapy. Results: The patients were male predominent - 14 (78%) pts. 16 (89%) pts have a T-cell immunophenotype. The median age at time of presentation was 21.1 (range 15-42) years. The presenting sites of primary disease included mediastinal mass in 14 (78%) cases. The bone marrow was involved (< 20% blasts) in 8 (44%) pts. CNS involvements were found in 4 (22%) pts. 7 (39%) pts previously received from 1 to 7 (median - 4,5) lines of therapy, such as one with B-NHL: 2 - NHL-BFM 90; 5 - ALL-MB 91/2002. 11 (61%) pts did not have a history of other therapy. 5/7 (71%) pts are in complete remission (CR) on the protocol NHL-BFM 90 vs. 11 (100%) pts - ALL-MB 91/2002. 1/7 (14%) pt had not responded (NHL-BFM 90). 2/11 (18%) pts relapsed after ALL-MB 91/2002. After therapy protocol NHL-BFM 90 relapse was not. 6-years event free survival (6y-EFS) has 71% vs. 67% (median of observation 2.4 years, p>0.05), and 6-years overall survival (6y-OS) has 71 vs. 83% (p>0.05) respectively. *Conclusions*. The results of therapy of 2 protocols for adolescents and AYA with LBL are comparable. Long-term L-asparaginase consolidation is alternative to high-dose methotrexate. Previous failed B-NHL-like therapy is not an absolute disadvantage further treatment.

1674

FACTORS PREDICTIVE FOR SURVIVAL AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION IN LYMPHOMA AND MYELOMA. A SINGLE INSTITUTION 11 YEAR EXPERIENCE

L. Poplawska, J. Romejko-Jarosinska, A. Borawska, B. Ostrowska, E. Wojciechowska-Lampka, M. Osowiecki, K. Domanska-Czyz, A. Dabrowska-Iwanicka, M. Swierkowska-Czeneszew, W. Michalski, E.K. Machaj, Z. Pojda, J. Meder, J. Walewski

Maria Sklodowska-Curie Memorial Institute and Cancer Centre, WARSZAWA, Poland

Background. Autologous stem cell transplantation (ASCT) is a generally accepted therapy for multiple myeloma and recurrent lymphoma but subsequent disease progression is a major cause of treatment failure. In a survey of factors predictive for poor outcome, we retrospectively analyzed survival of all patients transplanted at our institution over the period of 11 years. Purpose: To evaluate factors predictive for overall (OS) and progression free survival (PFS) for all patients treated with ASCT at a single institution over 11 years. *Design and Methods*. Between

1997 and 2008 we performed 415 procedures in 406 patients (pts). The indication for ASCT was multiple myeloma responsive to front-line treatment or recurrent/refractory Hodgkin (HL) and non-Hodgkin (NHL) lymphoma after cytoreductive therapy in fit pts. Few very high-risk NHL pts received ASCT in a first remission. The source of stem cells was peripheral blood in 87% and bone marrow or both - in 13% of pts. The median CD34+ cell dose was $2.9x10^6$/kg and the median mononuclear cell (MNC) dose was $1.2x10^8$/kg. A diagnosis was Hodgkin lymphoma (HL) in 45%, diffuse large B-cell lymphoma (DLBCL) in 18%, multiple myeloma (MM) in 16%, mantle cell lymphoma (MCL) in 9%, and other lymphoma - in 12% of pts. Mean pts age was 39 years and male to female ratio was 1.3. The conditioning regimen was BEAM in 58%, Melphalan 200 in 16%, and BuCyV - in 10% of pts. TBI was used in <2% of pts. *Results*. Five year OS for all patients was 61% and PFS was 54%. Treatment related mortality was 3%. In multivariate analysis by Cox model, the following factors were significant predictors for OS: age with 60 years cut-off, quality of remission: first (CR1) or subsequent complete remission and partial remission versus relapsed/refractory disease, and disease diagnosis. Patients younger than 60 years, first or subsequent remission, and diagnosis of HL or MM had a favorable OS. Five year OS for pts of age <60 and ≥60 was 63% and 36%, respectively. Hazard ratio (HR) over 5 years post-ASCT was 35 times higher for relapsed/refractory lymphoma than for pts in CR1 (p<0.001). HR for NHL was 2 times higher than for HL or MM (p=0.001). Factors predictive for PFS were: age, quality of remission, CD34+ cell dose/kg and MNC cell dose/kg. Age older than 60 years, relapsed/refractory disease, lower CD34+ cell/kg and higher MNC/kg dose adversely affected PFS. *Conclusions*. These data indicate acceptable safety and substantial efficacy of ASCT in high-risk lymphoma and myeloma patients. However, more active conditioning regimens and better quality graft preparations are clearly needed. Adverse effect of higher MNC dose on PFS is intriguing and needs a further investigation.

1675

CLINICAL VALUE OF SERIAL CTNI AND QTC MEASUREMENTS AND ITS CORRELATION WITH DOPPLER ECHOCARDIOGRAPHY IN THE ASSESSMENT OF CARDIOTOXICITY OF PATIENTS TREATED FOR AGGRESSIVE NON HODGKIN LYMPHOMA

M. Salah-Eldin,[1] E. Daoud,[2] E. Azmy,[2] I. Abdel Alla,[2] Y. Saleh[2]

[1]Mansoura Oncology center, MANSOURA, Egypt; [2]Faculty of Medicine, MANSOURA, Egypt

Background. Anthracycline-based chemotherapy is a key point of the treatment of patients with aggressive non-Hodgkin's lymphoma. However, cardiac toxicity remains a key problem in clinical practice. Currently, various methods including electrocardiogram, biochemical markers and Doppler echocardiography have been used to detect anthracycline induced cardiotoxicity. *Aims*. The aim of our study is to determine the clinical need of serial measurement of QTc, serum cardiac troponin I (cTnI) and Doppler echocardiography (conventional and TDI) in detection of early doxorubicin induced cardiac toxicity in patients with aggressive non-Hodgkin's lymphoma. Also, to study the correlation between these various methods of monitoring of cardiac toxicity. *Design and Methods*. Forty-two patients who had a diagnosis of aggressive non-Hodgkin's Lymphoma (NHL), and had been scheduled to receive doxorubicin-based chemotherapy (CHOP) were included in this study (mean age, 46.9±13.01, 26 males and 16 females). In all patients, echocardiography, cTnI, and clinical evaluation were performed before (baseline), after the second, last cycles of chemotherapy, and then 6 months later. *Results*. Serial echocardiographic evaluation of patients treated by doxorubicin-based chemotherapy (CHOP) for aggressive NHL revealed changes in the diastolic LV function early after anthracycline therapy (decrease of E peak velocity and TDI E/A ratio). At the final evaluation, diastolic changes were more pronounced and associated with alteration of the systolic function (LV ejection fraction, FS, and Sa). We observed that TDI could detect indices of diastolic dysfunction prior to alteration in conventional Doppler. cTnI levels measured after the second cycle, and after completion of therapy were significantly higher, compared with those measured at baseline (p<0.001). QTc interval was progressively increased on serial evaluation. cTnI levels and QTc interval measurements were found closely correlated with systolic parameters of both conventional and TDI (EF, FS and Sa) (p<0.05). *Conclusions*. Serial Doppler echocardiographic evaluation and QTc measurment has to be done in patients with aggressive NHL receiving doxorubicin, before, during and even after therapy completion. In our population cTnI was elevated early after therapy, and it can be considered a sensitive and reliable marker of myocardial damage after doxorubicin therapy.

BEAM OR BUCYE HIGH-DOSE CHEMOTHERAPY FOLLOWED BY AUTOLOGOUS STEM CELL TRANSPLANTATION IN NON-HODGKIN'S LYMPHOMA PATIENTS

C. Suh, J.E. Kim, B.S. Sohn, D.H. Yoon, D.H. Lee, S.W. Kim, J.S. Lee, S. Kim

Asan Medical Center, University of Ulsan College of Medicine, SEOOUL, South-Korea

Background. Effective but less toxic combinations of high-dose regimen is needed considering that expected toxicity of intensive regimens makes almost 50% of all non-Hodgkin' s lymphoma (NHL) patients with old age and poor performance ineligible for autologous stem cell transplantation (ASCT). Aims: The objective of this study was to compare the efficacy and toxicity of two high-dose regimens for ASCT in patients with NHL: BEAM (BCNU, etoposide, cytarabine, and melphalan) and BuCyE (Busulfan, cyclophosphamide, and etoposide). *Design and Methods*. We analysed 65 NHL patients, who underwent high-dose chemotherapy with BEAM (N=43) or BuCyE (N=22), followed by ASCT, at the Asan Medical Center. BEAM was used from February 2002 to October 2005, and BuCyE was used from November 2005 to April 2008. *Results*. Median age was 46 years (range: 15-68), and baseline characteristics, such as gender, International Prognostic Index (IPI), age adjusted IPI, stage and status of disease at ASCT, and median number of infused CD 34+cells/kg were well balanced between groups. The incidence of mucositis, nausea/vomiting, diarrhea and bleeding, and the number of events clinically important infections during ASCT did not differ between groups. Median follow-up for survivors was 49.3 months in the BEAM group and 21.5 months in the BuCyE group. Median overall survival (OS) was 30.6 months (95% confidence interval [CI], 8.19-53.0 months) and 22.6 months (95% CI, 12.1-33.1 months) and median event-free survival (EFS) was 16.1 months (95% CI, 0.0-53.6 months) and 11.2 months (95% CI, 0.0-22.5 months) in the BEAM and BuCyE group, respectively. There were no significant differences in OS (p=0.636) and EFS (p=0.575) between the two groups. *Conclusions*. In our analysis, BuCyE appeared to be not inferior to BEAM for survival. And we found that regimen-related toxicities did not differ significantly between the two groups.

CONSOLIDATION EFFICACY OF 90Y-IBRITUOMAB TIUXETAN AFTER RESCUE THERAPY IN PATIENTS WITH FOLLICULAR LYMPHOMA

M. Capponi,[1] L. Flenghi,[1] I. Sabalich,[2] B. Palumbo,[2] P. Minga,[1] F. Falcinelli[1]

[1]Istituto di Ematologia, PERUGIA, Italy; [2]Sezione Di Medicina Nucleare, Universita' Di Perugia, PERUGIA, Italy

Background. Therapy with 90Y-Ibrituomab tiuxetan is efficacious and is usually administered after obtaining FDA or EMEA authorization to patients with follicular lymphoma or those in relapse or refractory to rituximab. To date, very few patients have received 90Y-Ibrituomab tiuxetan to consolidate rescue therapy after chemo- or radio- therapy following, in some cases, autologous bone marrow transplantation (ABMT). Aims: To establish the efficacy of 90Y-Ibrituomab tiuxetan consolidation therapy in patients in relapse and its safety in ABMT recipients. *Design and Methods*. We administered 90Y-Ibrituomab tiuxetan to consolidate rescue in relapsed patients with follicular lymphoma after rituximab therapy and after ABMT for a total of 19 patients (13 M, 6F, age range 43-75 years, median age 58 years). All patiets had previously received immunochemotherapy with rituximab and 15 had received at least two lines of chemotherapy. Bone marrow was normal in all except for 1 patient with molecular evidence of involvement. Neutrophil counts were >1500 mmc; platelet counts were >100,000 mmc. Response to therapy was classified as complete response (CR), near complete response (nCR), partial response (PR), no response (NR), disease progression (DP). Response was assessed by clinical examination and a PET-CT scan before and 16 weeks after 90Y-Ibrituomab tiuxetan infusion in order to minimise post-chemotherapy inflammatory changes. *Results*. Before 90Y-Ibrituomab tiuxetan infusion, 10 patients had achieved nCR, 7 PR and 2 NR. At a median follow-up of 13.7 months (range 1-25 months) 18/19 patients survive. One died of disease progression. At 4 months after 90Y-Ibrituomab tiuxetan infusion response in 14 evaluable patients was CR in the 10 (pre-infusion: 7 nCR,3 PR). One relapsed after 24 months. The 5 patients who received 90Y-Ibrituomab tiuxetan infusion after ABMT sustained CR. Two patients achieved PR (Pre-infusion both PR) but disease progressed after 5 and 7 months, respectively. Three patients did not respond (Pre- infusion: 2 NR, 1 PR). In 2 there was rapid DP. Both had a

bulky mass of >5 cm and were in Stage IVB when diagnosed. One died (see above). Safety profile: Three patients developed Grade 3 neutropenia; 14 needed granulocyte growth factor support; 3 developed Grade IV thrombocytopenia, resolved with transfusions. All patients had a good haematological recostitution after 12 weeks. No patient developed severe extra-haematological toxicity or required hospitalization. *Conclusions*. Eighteen of our 19 patients survive with a good quality of life. Patients who were refractory to previous treatments did not respond to 90Y-Ibrituomab tiuxetan infusion either. This approach emerged efficacious and safe as consolidation therapy when these very high risk patients were in nCR or PR before infusion. 90Y-Ibrituomab tiuxetan infusion is also safe after ABMT.

In memory of Prof Antonio Tabilio, close friend and colleague, eminent physician and scientist.

CEREBROSPINAL FLUID PLEOCYTOSIS AS A DIAGNOSTIC CHALLENGE - DISCRIMINATING REACTIVE FROM MALIGNANT CELLS USING FLOW CYTOMETRY

M. Schmid, C. Schöpflin, M. Bommer

University Hospital of Ulm, ULM, Germany

The spread of cancer cells into the compartment of the central nervous system (CNS) is a rare complication in solid tumours with an incidence of 5-15% but more common in leukemia and lymphoma with an estimated incidence of up to 20%. Diagnosis of CNS involvement is important for the prognosis and essential for the treatment of choice. Diagnosis of CNS involvement by malignant tumor cells is based upon neuroradiology such as magnetic resonance imaging (MRI) and morphologic examination of the CSF. Especially in patients with diffuse leptomenigeal disease the diagnosis based solely on cytological examination of the CSF is often inadequate. Due to the therapeutic and prognostic importance of CNS involvement for patients with solid tumours as well as lymphoma or leukemia, additional diagnostic methods are required. The aim of this study was to compare morphology and flow cytometry in the diagnosis of lepromeningeals disease in patients with haematological malignancies. Between 1996 and 2008, we performed morphologic and flow cytometric examination of CSF-samples from patients with various malignancies being suspicious of CNS involvement. All patients (n = 126) were treated according to standard protocols. All patients were suspected to suffer from meningeosis carcinomatosa or lymphomatosa most of them were suffering from leukemia or lymphoma. Depending on the suspected diagnosis, a particular marker panel was used. According to the final clinical diagnosis, three groups of patients can be separated: 1.) Patients with inflammatory diseases and non hematopoietic cancer (n = 31), 2.) patients with acute leukemia (25), and 3.) patients with lymphoproliferative disease (n = 71). FACS analysis confirmed the diagnosis in 47/53 (89%) samples. Six samples were diagnosed as non-malignant by FACS analysis (four patients with known diffuse large B-cell lymphoma, two patients with non-hematopoietic cancer). Seventy-four samples were judge morphologically as reactive/normal or non-diagnostic. Using FACS analysis six out of these 74 samples (8%) were categorized as malignant (c-ALL [n=1], B-CLL [n=2], AML [n=2] and DLBCL [n=1]), sixty-eight samples (92%) were classified as non-malignant. Thirty-one patients underwent CSF analysis due to clinical or radiological changes suspicious for meningeosis carcinnomatosa or lymphomatosa but had no evidence of a pre-existing malignant tumor. Twenty-six samples were judged morphologically to be reactive, two were non-diagnostic. FACS analysis confirmed all twenty-eight samples to be reactive. Two samples morphologically obviously stated as leptomeningeal infiltration by carcinoma, exhibited only T-cell marker expression and were found to be reactive by FACS. Eighty-three samples from patients with known lymphoproliferative disorders were analyzed. Fourty-three samples were classified as malignant by FACS, whereas two of the samples had been judged as reactive by morphology. Two samples were non-diagnostic by morphology and could be classified correctly as malignant using FACS. In conclusion, we conducted CSF analysis in patients which did not have known underlying malignancy but had clinical signs and/or imaging findings suspicious for hematopoietic malignancy. We also propose distinct marker panels in order to differentiate between malignant CSF lymphocytosis and reactive B- or T-lymphocytes.

1679

MINIMAL RESIDUAL DISEASE MONITORING IN MANTLE CELL LYMPHOMA (MCL) USING FIVE COLOUR FLOW CYTOMETRY

J.T. Revell, C. Boakes, S. Sepstrup, M.B. Rassam

Kent Oncology Centre, KENT, UK

MCL accounts for 5% of Non- Hodgkin's lymphoma. The disease is incurable with conventional chemotherapy; only 8% of patients are alive 10 years after diagnosis with a median survival of 3 to 4 years. Minimal residual disease (MRD) is common and contributes to relapse. MCL cells have a characteristic antigen profile of CD5+, CD20+, FMC7$^+$, CD19$^+$, CD10$^-$, CD23$^-$ with strong light chain expression. Aberrant immunophenotypes can occur, such as lack of CD5 expression and weak expression of CD23. Infiltration of the bone marrow (BM) and spillage into peripheral blood (PB) is common. In Complete Remission (CR) up to 1010 malignant cells can remain in PB or BM. MRD monitoring is a powerful prognostic factor, to predict relapse and in assessment of treatment efficacy. Achievement of MRD negative CR can be the first step to curing many haematological malignancies. *Aims*. To design a five colour flow cytometric panel specific for the diagnosis of MCL and to identify the sensitivity and specificity of the method using dilution studies. *Patients.* PB samples from eight MCL patients were analysed along with a bone marrow (BM) sample from one. PB samples from nine CLL patients and two HCL patients were used as controls. *Design and Methods*. The Beckman Coulter FC500 analyser was used with a two tube, five colour antibody panel (CD5, CD19, CD20, CD3, CD23 and κ and λ). Prism analysis enabled quantification of lymphocytes percentages according to patterns of expression. The percentage of cells positive for each antigen profile were reported for each sample to show that the method is specific. The MCL PB samples were serially diluted with normal PB based on the lymphocyte count of each, up to one mantle cell in 200,000 normal lymphocytes. The percentage of cells positive for the MCL antigens was reported for each of the dilutions. Analysis was to determine whether the results obtained correlate with the dilution factor according to the percentage positive cells obtained from the neat tube. *Results*. MCL patients had an average of 45.2% MCL lymphocytes compared with 3.7% in the non-MCL group and 2.6% in the normal control. CLL patients had an average of 51.7% CLL lymphocytes compared to 2.3% in the non-CLL LPD group and 2.1% in the normal control. Prism analysis enabled us to report the lymphocytes that were CD20$^+$, CD19$^+$, CD5$^+$, CD3$^-$, CD23$^-$ and λ and κ positive as MCL cells. The percentage of cells designated MCL cells did not correlate significantly with those showing clonal light chain expression (r = 0.77). 6 out of the 11 dilution studies produced results that were consistent with the dilution factor. Three samples were shown to be MRD negative by the method and indeed these patients were in confirmed clinical and cytological remission. *Discussion.* Prism analysis did not allow proper integration of the information from 2 tubes to quantify the type of light chain expression on cells classed as MCL cells by the first tube. A seven colour panel could be developed including the antibodies of tube 1 together with κ and λ, to show the specific light chain expression. We underestimated reporting the intensity of antigen expression per cell which may have made the method less robust. In, addition, the dilution with normal blood confounded the MRD issue by including background MCL like cells in healthy samples. Beads are required to obtain absolute counts by flow cytometry and their use may have improved the accuracy of the dilution studies.

1680

RITUXIMAB PLUS PEGYLATED LIPOSOMAL DOXORUBICIN IN COMBINATION WITH CYCLOPHOSPHAMIDE: A FIRST LINE THERAPEUTIC OPTION FOR VERY ELDERLY OR UNFIT PATIENTS WITH AGGRESSIVE NON HODGKIN LYMPHOMA

E. Capochiani,[1] S. Cupini,[2] M. Barletta,[2] L. Landi,[2] A. Falcone[2]

[1]Haematology Section, LIVORNO; [2]Oncology Department, LIVORNO, Italy

Background. The standard treatment for patients with aggressive B-cell lymphoma, in particular diffuse large-B-cell lymphoma [DLBCL), is cyclophosphamide, doxorubicin, vincristine and prednisone [CHOP) plus rituximab, a chimeric monoclonal antibody against the CD20 antigen. However, some very elderly patients are not fit enough to tolerate CHOP or they have a comorbidity that exclude antracyclin in the regimen. The overall survival in this subset of patients is very poor. Pegylated liposomal doxorubicin is associated with a lower risk of cardiotoxocity than conventional formulations of doxorubicin, allowing the use of higher cumulative doses The aim of this single institution study was

to investigate the outcome of pegylated liposomial plus cyclophosphamide (Cae-CY) and rituximab (R) regimen in patients >/= 75 years old, with diagnosis of DLBCL and cardiological comorbidity. *Design and Methods*. In this study, 22 patients aged over 75 years (median 79, range 75-91 years) with aggressive non-Hodgkin's lymphoma (NHL) (age adjusted International Prognostic Index (IPI): IPI-2 (25%); IPI-3 (35%); IPI-4 (40%)) received pegylated liposomal doxorubicin (25 mg/m^2/day 1), cyclophosphamide (300 mg/m^2 day 1) and rituximab (375 mg/mq^2 day 2), q28. *Results*. 20 patients completed 6 treatment cycles and were evaluable for efficacy and safety. A complete response was achieved in 14 (70%) patients and a partial response in 2 (10%) patients. 4 patients showed stable disease or progressive disease (20%). With a median follow-up of 18 months, the median time to progression was 12 months. The major toxicity was haematologic: grade 2 leukocytopenia occurred in 6 patients, grade 3 thrombocytopenia in 5 patients, but no grade IV toxicity occurred. There were no episodes of clinicaliy significant bleeding. Three patients developed febrile neutropenia. No significant decrease in LVEF or clinical evidence of congestive heart failure was observed during the treatment or in follow-up. Pegylated liposomal doxorubicin plus cyclophosphamide is an effective and weII tolerated regimen for the treatment of aggressive NHL in elderly or unfit patients.

1681

INHIBITORY EFFECT OF PEGINTERFERON ALFA-2A ON EBV REACTIVATION AND TUMOR RECURRENCE FOLLOWING CHEMOTHERAPY IN PATIENTS WITH EBV-ASSOCIATED EXTRANODAL NK/T CELL LYMPHOMA

S.G. Cho, K.S. Park, J.H. Lim, B.O. Choi, B.S. Cho, Y.J. Kim, K.S. Eom, H.J. Kim, S. Lee, C.K. Min, J.W. Lee, W.S. Min, J.W. Park, C.C. Kim

The Catholic University of Korea, SEOUL, South-Korea

Background. Extranodal NK/T-cell lymphoma, nasal type responds poorly to intensive chemotherapy regimens or has a significant relapse rate in spite of low IPI and loco-regional staging. Poor clinical outcome may result from EBV reactivation during chemotherapy since this unique subtype is closely associated with EBV latency. Some *in vitro* data suggested that various chemotherapy agents, including gemcitabine, doxorubicin, cis-platinum, and 5-fluorouracil, induced lytic EBV gene transcription in latently infected EBV positive cell lines. The presence of the EBV genome within tumor cells raised the possibility of developing therapeutic strategies directed at viral targets. *Aims*. The primary objectives of this prospective, single center, nonrandomized phase II trial are the evaluation of efficacy by determination of progression-free survival after concurrent administration of peginterferon α-2a (PEGASYS®, provided by Roche Korea) and chemoradiotherapy in patients with extranodal NK/T cell lymphoma. In addition, we evaluated the efficacy of peginterferon alfa-2a maintenance therapy for 3 years. *Design and Methods*. All seven patients with newly diagnosed CD56+ EBV+ extranodal NK/T-cell lymphoma were enrolled onto a prospective clinical trial. Step 1; PEGASYS® 180 mcg was administered once weekly on D1, D8 of ProMACE-CytaBOM. 1, 2 cycles. Step 2; PEGASYS® 180 mcg will be administered once weekly on D1, D8, D15, D22 of involved-filed irradiation 3600 cGy (180 cGy x 20, for 4 weeks). Step 3; PEGASYS® 180 mcg will be administered once weekly on D1, D8 of ProMACE-CytaBOM. 3, 4 cycles. Step 4; PEGASYS® 180 mcg will be administered every two weeks after hematologic recovery of high-dose therapy and autologous PBSCT for 3 years. In case of advanced stage and non-nasal lesion, Step 2 was omitted and ProMACE-CytaBOM was extended to 6 cycles. EBV DNA copy based on real-time PCR was monitored. *Results*. Of all 7 patients, 6 patients achieved complete response and 1 patient was dead due to pneumonia during 2nd cycle of chemotherapy. With a median follow-up of 37.5 months (12-44 months), the 3-year PFS were 67%. Of 6 assessable patients, five patients extended to peginterferon α-2a maintenance therapy and four patients showed PFS. Among two relapsed patients, one patient refused a peginterferon alfa-2a maintenance therapy. Titer of EBV DNA copy in whole blood was markedly decreased compared with the titer on initial diagnosis. The main toxicities of peginterferon α-2a were mild flu-like symptoms. *Summary and Conclusions*. This pilot study suggests that peginterferon α-2a may effectively inhibit EBV reactivation and lymphoma relapse. It warrants that larger prospective studies are needed to define the therapeutic role of peginterferon α-2a concurrent administration during induction therapy and maintenance therapy in EBV-associated extranodal NK/T-cell lymphoma.

1682

INFECTION RISK RELATED VARIABLES IN FIRST LINE CHEMOTHERAPY OF INTERMEDIATE GRADE NON HODGKIN LYMPHOMA IN A SERIES OF 199 PATIENTS

J.J. Alonso,[1] A. Cánovas,[2] J.G. Barreiro[2]

[1]Hospital de Cruces, BILBAO; [2]Hospital de Cruces.UPV, BARACALDO.VIZCAYA, Spain

Background. Lymphoma patients are exposed to infection as a consequence of both the disease itself and the immunosuppression due to the chemotherapy. Evaluating this risk in each patient has been deemed necessary in order to prescribe treatments such as colony-stimulating factors(CSF) or antibiotic prophylaxis. The predictive variables of this risk may depend on the population of patients considered. Aims: To asses clinical and analytical variables at diagnosis in a series of unselected patients with non-Hodgkin lymphoma(NHL), which are related to infection risk in the course of first line chemotherapy. *Design and Methods*. Prospective observational study of all intermediate grade NHL in first line standard chemotherapy at a University Hospital Internal Medicine Lymphoma Unit, from 1996-January until 2007-June.The patients were followed since chemotherapy beginning until three weeks after last cycle. CHOP or alike chemotherapy was administered incorporating Rituximab in B NHL since its approval. Blood counts were scheduled next to expected nadir and until neutrophils count was upper than 500/µL. Filgrastim according to ASCO guidelines and ciprofloxacin prophylaxis was prescribed. The recommendations of IDSA guidelines were followed in febrile neutropenia(FN) and other infectious events. Infectious episodes requiring antimicrobial treatment were considered and classified as microbiologically (MD) or clinically documented(CD) or fever of unknown origin(FUO). We asses the predictive value regarding FN and other infections of the following variables taken at diagnosis: age, sex, B symptoms, performance status(WHO), albumin, β2microglobulin, immunoglobulins, type of lymphoma, bone marrow involvement and IPI. Statistical methods: descriptive, chi2, Student t, Kaplan-Meier survival tables, log rank test, multivariate logistic binary and proportional hazard regression model. *Results*. 199 patients were included, 51% male, 61.6 years(15-88) mean age;24(12%) mantle cell lymphoma, 148(74%) LBCL (10 with AIDS) and 27(14%) peripheral T lymphoma. CSF (filgrastim) was delivered in 62% of patients(12% in primary prophylaxis, secondarily in 47% and as treatment of FN in 3%).We detected 408 episodes of grade IV neutropenia in 141 patients(71%) and 184 infectious events(12 deadly;6%) in 97 (49%), 79 of them FN in 53 patients(27%).FN occurred only in the first cycle in 17% of patients and only later in 72%. MD infections were observed in 51%, CD in 10% and 39% were FUO.Gram negative bacilli were more frequent(26%) than Gram positive cocci(13%) and other agents(12%), but in BSI(n:30) the frequency was similar(14 and 16 respectively).There were no significant difference in the distribution of grade IV neutropenia, FN, type or ethiology of infection among the subtypes of NHL. In the assessment of variables related to the first or any episode of FN were significant: B symptoms (p:0.02), unfavourable IPI (p=0.004) and PS (p=0.0002); in multivariate analysis only PS remained significant in respect to the first episode of FN(HR:1.8, 95%CI:1.3-2.3;p:0.0003E-1)or anyone(OR:1.8; 95%CI:1.3-2.5;p:0.0003E-1.In relation to risk of infection were significant B symptoms (p:0.0001), PS (p<0.0001), unfavourable IPI (p=0.0001) and UNL β2microglobulin (p=0.003); in multivariate analysis only PS remained significant (OR:3.1;95%CI: 1.7-5.5 p:0.0002E-3). *Conclusions*. PS recorded at diagnosis seems a valuable predictor of FN and infectious events throughout the course of first line chemotherapy in our series of intermediate grade NHL patients, probably reflecting both the aggressiveness of the tumor and the patient comorbidity.

1683

SALVAGE CHEMOTHERAPY WITH NON-PEGYLATED LIPOSOMAL DOXORUBICIN (ADRIAMYCIN), FLUDARABINE, OXALIPLATIN AND CYTARABINE (AFOXA) IN POOR-RISK B CELL NON-HODGKIN'S LYMPHOMA

A. Thiel,[1] S. Bennemann,[1] F. Kroschinsky,[2] J. Birkmann,[3] U. Kreibich,[4] R. Herbst,[1] M. Wilhelm,[3] G. Ehninger,[2] M. Haenel[1]

[1]Clinic of Internal Medicine III, CHEMNITZ, Germany; [2]Medical Clinic I, University Hospital, DRESDEN, Germany; [3]Medical Clinic 5, Klinikum Nuernberg, NUERNBERG, Germany; [4]Clinic of Internal Medicine II, Klinikum Zwickau, ZWICKAU, Germany

The aim of the present phase I/II study was to evaluate the feasibility and toxicity of the combination of non-pegylated liposomal doxoru-

bicin, fludarabine, oxaliplatin and cytarabine (AFOXA) in patients (pts.) with prognostically unfavourable recurrent and refractory B cell non-Hodgkin's-lymphoma (NHL). Between 02/2005 and 01/2009 a total of 25 pts. (12 male, 13 female) with diffuse large B cell lymphoma (n=14), mantle cell lymphoma (n = 6) and follicular lymphoma (n=5) were treated according to the AFOXA protocol. Pts. (median age 59, range 42 - 70) with primary refractory disease (n=19) and second (n=5) or third (n =1) relapse were enrolled. The intensive pretreatment contained a median of 7 (range 1 - 18) cycles of chemotherapy. 21/25 pts. were pretreated with the anti-CD20 monoclonal antibody Rituximab. The AFOXA regimen consisted of non-pegylated liposomal doxorubicin (25 mg/m^2, days 1 + 3), fludarabine (25 mg/m^2, days 1 - 4), oxaliplatin (escalating doses of 100 or 130 mg/m^2, day 5) and cytarabine (escalating doses of 1000 or 1250 or 1500 mg/m^2, day 5). In the phase I part of the study (n=12) the maximal tolerable dose (MTD) was determined for oxaliplatin and cytarabine according to World Health Organization Common Toxicity Criteria (CTC). The primary objective of the subsequent phase II part of the study, which uses the determined MTD, is efficacy. *Results*. In the phase I part we established the MTD for oxaliplatin with 130 mg/m^2 and for cytarabine with 1000 mg/m2. Out of 25 pts.; 16 pts. were treated with the established MTD. 5 pts. (31%) achieved complete remission (CR or CRu) and 2 pts. (13%) partial remission, with an overall response (OR) rate of 44%. A successful peripheral blood stem cell harvest through mobilization with the AFOXA regimen was possible in 7 pts. (44%). *Conclusions*. AFOXA is a feasible salvage protocol for patients with poor-risk recurrent or refractory NHL. The observed toxicity (MTD) seems to be acceptable considering the unfavourable prognosis and intensive pretreatment. The efficacy will be evaluated in the ongoing phase II study.

1684

NON-HODGKIN LYMPHOMA (NHL) IN ACQUIRED IMMUNODEFICIENCY SYNDROME (AIDS) IN POST-HAART ERA: ELEVEN YEARS OF EXPERIENCE OF A PORTUGUESE CENTRE

T. Melo,[1] S. Silva,[2] H. Gomes,[2] R. Coelho,[2] C. Abreu,[2] C. Alves,[2] M. Gandra,[3] A. Sarmento,[2] J. Guimarães,[3] J. Andrade[3]

[1]Hospital S. João, PORTO, Portugal; [2]Infecciology Department, Hospital de S. João, PORTO, Portugal; [3]Hematology Department, Hospital de S. João, PORTO, Portugal

NHL is a common cause of HIV-related mortality, presenting with an aggressive clinical behaviour and being a therapeutic challenge. The prognosis has improved with the availability of highly active antiretroviral therapy (HAART) and the survival of many of these patients is actually comparable to HIV -negative NHL patients. We evaluated clinical records of patients with HIV-related NHL admitted in our Hospital between January 1997 and July 2008, according to clinical features, treatment, response rate and survival. We diagnosed 60 HIV-related NHL: 48 as systemic NHL, 11 as primary central nervous system lymphoma (PCNSL) and 1 as primary effusion lymphoma. Before diagnosis of lymphoma, 45 of the patients were naïve to HAART (45/58; 78%). The median age of the patients (37M; 11F) with systemic NHL was 43.5 (27-63). It was the first AIDS defining illness in 67% of patients. Regarding WHO classification, 30 (65%) of 46 patients were classified as diffuse large B cell lymphoma (DLBCL) and 9 (19%) as Burkitt/Burkitt-like and the remaining 7 as other histologic subtypes. Severe immunossupression at diagnosis was a common finding (median CD4 cell count of 143/mm^3). Of 46 patients with evaluable plasma viremia at diagnosis, only one had undetectable viral load (<50/mm^3). Extranodal manifestation was present in 93% of the patients (more frequent in bone marrow, gastrointestinal tract, liver and CNS); advanced stage disease with a median of IV (Ann Arbor stage) was observed in 85% and an elevated LDH in 77%. Two patients were treated outside our Hospital, 12 received only palliative treatment and curative chemotherapy (m-BACOD, CHOP, da-EPOCH, Hyper-C-VAD and LMB-96) was initiated in 34 (4 currently on treatment, 20 died of resistance/progression, 8 alive disease-free and 2 relapses). The median overall survival was 180 days (233 days in patients with an intention to cure approach) and 42% were alive at 12 months and also at 4 years. Median age of the patients (10M; 1F) with PCNSL was 34 (23-41). The median CD4 cell count was 13/mm^3. None of them had undetectable viral load. Palliative treatment was adopted in 7 patients while 4 were on an intention to cure basis. Median overall survival was 32 days, with 2 alive and disease free at 41 and 69 months. Although diagnosed in the "post- HAART era", a high proportion of our patients were not receiving HAART in spite of presence of severe immunossupression. A high number of patients, in our series, only received palliative treatment (19/60, 32%). When an intention to cure option was chosen, early mortality was very high, and overall prognosis for HIV-NHL was worse than for HIV-negative patients; however, when complete remission was achieved, the disease had a closer behaviour to HIV-negative population. The results obtained in our population, stress the need to provide an adequate antiretroviral therapy as soon as indicated, thus permitting a curative approach in a higher number of patients with NHL.

1685

INTEGRATED 18F-FDG PET/CT MAY PREDICT THE OUTCOME OF PATIENTS WITH T-CELL LYMPHOMAS

V. Prochazka,[1] T. Papajik,[1] Z. Kubova,[1] K. Indrak1, L. Kucerova,[2] E. Buriankova,[3] M. Myslivecek[3]

[1]Teaching Hospital in Olomouc, OLOMOUC, Czech Republic; [2]Dept. of Pathology, Teching Hospital, OLOMOUC, Czech Republic; [3]PET/CT centre, Dept. of Nuclear Medicine, OLOMOUC, Czech Republic

18F-fluorodeoxyglucose positron emission tomography (PET) is a highly sensitive method for imaging of aggressive B-cell and Hodgkin's lymphomas. A recently developed integrated PET/computed tomography (CT) system combines a PET camera with a CT scanner in a single session, providing both anatomical and functional imaging at the same position. Achieving PET negativity (complete metabolic response, CMR) after therapy has a strong prognostic impact. Yet the use and predictive power of PET/CT imaging in T-cell lymphomas is still poorly studied. Aim: To evaluate the predictive role of achieving CMR using integrated FDG PET/CT restaging in an unselected population of patients with newly diagnosed T-cell lymphoma. Method: We studied a cohort of 20 patients with T-cell lymphomas who had PET-avid T-cell lymphoma at the time of diagnosis. Histological subtypes were as follows: peripheral T-cell lymphoma, unspecified (PTCL NOS, n=11), anaplastic large cell lymphoma (ALCL, ALK-1-positive, n=1, ALK-1-negative, n=5), enteropathy-associated T-cell lymphoma (EATL, n=2), angioimmunoblastic lymphoma (AIL, n=1), Sézary syndrome (SS, n=1). All biopsies were reviewed by a university centre haematopathologist and the final diagnosis was made according to the WHO classification (2001). The median age at diagnosis was 63 years (30-78), most patients had advanced Ann Arbor stages (15 patients, 75%), IPI score ≥3 had 60% of the patients. All patients were examined with integrated PET/CT (Siemens Biograph Sensation 16) at the time of diagnosis and after first-line therapy. The PET scan was defined as positive if higher than mediastinal or background activity was observed. The CT scans were assessed according to the International Workshop Criteria (Cheson, 1999). Results: After first-line therapy, CMR was achieved in 8 patients (40%), whereas 12 (60%) remained PET-positive. Treatment response (CT) was as follows: complete remission or complete remission unconfirmed (CR/CRu) n=8 (PET-negative n=7, PET- positive n=1), partial remission (PR) n=4 (PET-negative n=1, PET-positive n=3), stable disease (SD) n=3 and progressive disease (PD) n=5 (all SD and PD cases PET-positive). At the time of follow-up, only 1 (12.5%) of the 8 PET-negative patients died and 2 (25%) relapsed or progressed. Of the 12 PET-positive patients, 8 (66.6%) died and 6 (50%) relapsed or progressed. The overall survival (OS) at 2 years reached 46% (95% CI 0.16-0.75); progression-free survival (PFS) was 17%(95% CI 0.00-0.45). While the 2-year OS in the PET-negative subgroup was 67% (95% CI 0.13-1.00), it dropped to 30% (95% CI 0.00-0.62) in the PET-positive subgroup (log rank 0.033). *Summary*. The overall prognosis of patients with T-cell lymphomas is still poor. Our pilot data show that PET positivity after first-line therapy is frequently associated with chemoresistant, rapidly progressive disease and extremely low survival. On the other hand, patients with PET-negative CR have a chance of longer survival. The value of interim PET/CT assessment as a method for early identification of poor responders should be further clarified. CLINICAL OUTCOME AFTER BEAM AUTOLOGOUS SCT IN RELAPSED B-CELL NHL: EFFECTS OF THE ADDITION OF RITUXIMAB AND/OR ZEVALIN

M.L. De Rooij, O. Visser, M.J. Wondergem, J.M. Zijlstra, P.C. Huijgens

VU Medical Center, AMSTERDAM, Netherlands

Background. Since more than 25 years, autologous stem cell transplantation (ASCT) with BEAM conditioning is a commonly used treatment for patients with relapsed or refractory B-cell non Hodgkin lymphoma (NHL). In recent years, the monoclonal antibody anti-CD20 (rituximab)

and 90-Y labeled anti-CD20 (ibritumomab tiuxetan, Zevalin®) were added to (re)induction therapy and conditioning respectively. *Aims*. Evaluation of clinical outcome of patients with relapsed or refractory B cell NHL, treated with chemotherapy with or without rituximab followed by BEAM with or without Zevalin® and autologous stem cell transplantation (ASCT). *Design and Methods*. In this single center, retrospective analysis we reviewed extensively the clinical records of 200 patients with diffuse large B cell NHL (n=122), folliculair B cell NHL (n=37), transformed B cell (n=31) and other B cell NHL types (n=10), treated with ASCT between November 1984 and January 2009 (Mantle Cell NHL excluded). We defined three groups: patients treated with ASCT preceded by BEAM conditioning (1) without rituximab in reinduction chemotherapy (R- BEAM, n=134), (2) treated with rituximab in reinduction chemotherapy (R+ BEAM, n=48) and (3) treated with rituximab in reinduction and Zevalin-BEAM as conditioning regimen (RZ+ BEAM, n=18). Statistical analysis was performed using SPSS 16.0, Log Rank (Mantel-Cox) test. Event free survival (EFS) is defined as follow-up time in months until disease progression or relapse, and death of any cause. Overall survival (OS) is defined as follow-up time in months until death of any cause. *Results*. The median age was 47 (range 17-64) years and 85 (42.5%) were females. The R- BEAM group differs from the R+ BEAM- and RZ+ BEAM group regarding two variables: the R- BEAM group contains significantly more follicular and less transformed NHL (p=0.03) and there are significantly more patients who received more than 1 treatment before the BEAM therapy (p=0.026) as compared to R+ BEAM and RZ+ BEAM. All other individual parameters, including IPI score, are balanced in the three groups. The maximum follow-up of currently alive patients is 287, 85 and 33 months for patients in the R- BEAM, R+ BEAM and RZ+ BEAM group, respectively. Regarding EFS and OS, there is no significant difference between the R- and R+ BEAM treated group (p=0.303 and 0.657 respectively). Comparing the RZ+ BEAM and R+ BEAM groups, there is also no significant difference in EFS and OS (p=0.079 and 0.212). *Summary and Conclusions*. The addition of rituximab to reinduction chemotherapy did not improve clinical outcome in patients who proceeded to BEAM ASCT, most likely reflecting lymphoma characteristics: patients relapsing after immunochemotherapy. The addition of Zevalin to BEAM in patients who proceeded to BEAM ASCT after rituximab containing reinduction may improve results.

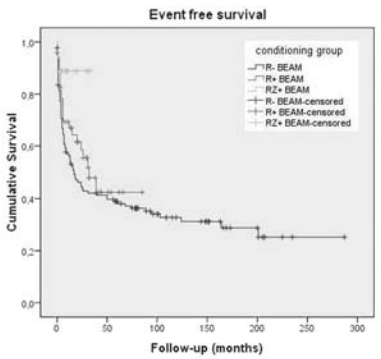

Figure.

135 CASES OF AIDS-RELATED LYMPHOMAS: RUSSIAN EXPERIENCE

A. Pivnik

Pirogovs National Medico-surgical Center, MOSCOW, Russian Federation

During 2000-2008 we observed 135 pts. with AIDS-related lymphomas. 96% of them were intravenous drug users; 80% were co-infected with HCV or/and HBV. 106 pts were diagnosed with stage III-IV lymphomas: males - 69, females-37. Median age - 35 yrs (range 22- 68). Median of CD4 counts at presentation was 300 cells/ mL (range 10 - 550); median of viral load - 50000 copies/mL (range 4000 - 7500000). 30% of pts received HAART. Histological and immunohistochemical diagnoses: diffuse large B- cell lymphoma in 60 cases (56%) with primary localization: gastric lymphoma - 3 pts, intestinal - 3, uterine - 2, ovarian -2, thyroid -1, testicular -1. Burkitt lymphoma in 26 cases (24%), plasmoblastic lymphoma - 3 (2,8%), lymphoplasmoblastic lymphoma of oral cavity - 4 (3,7%), Castleman's lymphoma - 1 (0,9%), primary CNS lymphoma - 3 (2,8%), follicular lymphoma - 3 pts over 50 yrs old (2,6%), T-cell lymphoma - 6 (6,6%). 31 pts (29%) died before treatment and in 15 cases (14%) lymphoma was diagnosed initially only at postmortem examination. Remaining 71 pts received chemotherapy: CHOP (6 with DaunoXome), CHOPE, A-B blocks NHL-BFM - 95, A-C blocks BL-2004 (E. Zvonkov et al.) with CNS prophylactics and +\- MabThera. Treatment mortality achieved 26,4% (28 pts) with signs of lymphoma progression at autopsies. Complete remissions were reached in 22 cases out of 71 (31%), overall survival- 58% from 6 to 60 mos of follow-up, disease-free survival (pts in CR followed until relapse) - 85%, 18 pts are at therapy with good response. Post treatment median CD4 count was 200 (range 150-550) and viral load median 20000(range 500-60000). Hodgkin's lymphoma was established in 29 cases: nodular sclerosis in 14 cases (48%), type1 - 34% (10 pts) and type 2 - 13,8% (4 pts); mixed cellularity- 31% (9 pts), lymphoid predominance- 10,5% (3 pts) and lymphoid depletion - 10,5%(3 pts). Abundance of EBV antigens was noted in majority of cases. Males - 15, females -14. Median age 28 yrs (range 23-54). HAART received 10% of pts. Median CD4 count was 550 cells /mL (range 350 -1200), median viral load - 30000 HIV RNA copies/mL (range 1000 -100000). 9 pts (31%) did not receive chemotherapy because of the poorest performance status at admission. 20 pts received chemotherapy: ABVD, BEACOPP2 (escalated), DHAP, DEXA-Beam +\- radiotherapy. Complete remission was achieved in 60% (12 pts), overall survival- 75% and disease-free survival - 100% from 6 to 48 mos. 8 pts are at therapy and at HAART with good response. Post treatment median CD4 count was 700 (ran ge 250- 900), median viral load 12000 (range 500 to 20000). AIDS pts with aggressive lymphomas may receive diagnostic and treatment approaches results of which are comparable with general population. They must have an opportunity to get standard hematological treatment all over the country. Late admittance and low results of overall therapy are caused by patient's personal psychosocial pattern which is worsened by drugs and HCV/HIV cortical damage.

1688

PULMONARY MARGINAL ZONE B-CELL LYMPHOMA; CLINICAL MANIFESTATION AND TREATMENT OUTCOME

S.Y. Oh,[1] W. Kim,[2] S. Kim,[2] C. Suh,[3] H.C. Kwon,[1] J.H. Won,[4] I.G. Hwang,[5] M.K. Kim,[6] S.I. Lee,[7] Y.S. Chae,[8] D.H. Yang,[9] G.W. Lee[10]

[1]Dong-A University College of Medicine, BUSAN, South-Korea; [2]Samsung Medical Center, SEOUL, South-Korea; [3]Asan Medical Center, SEOUL, South-Korea; [4]Soon Chun Hyang University, SEOUL, South-Korea; [5]Chung-Ang University Young San Hospital, SEOUL, South-Korea; [6]Yeungnam University College of Medicine, DAEGU, South-Korea; [7]Dankook University College of Medicine, CHEONAN, South Africa; [8]Kyungpook National University Hospital, DAEGU, South-Korea; [9]Chonnam National University Hwasun Hospital, JEOLLANAM-DO, South-Korea; [10]Gyeongsang National University, JINJU, South-Korea

Background. Pulmonary marginal zone B-cell lymphoma of the MALT type (P-MZL) is a relatively uncommon form of lymphoma. Due to its rarity, the natural history of an optimal treatment modality for this disease has yet to be well established. Aim: we performed a retrospective analysis of the clinical features and treatment outcomes of P-MZL . *Design and Methods*. From 1991 to 2008, a total of 39 patients with biopsy proven P-MZL were analyzed retrospectively. *Results*. The median age of our subjects was 57 (range: 24-79) years. This study involved 20 males (51%) and 19 females (49%). 18 patients (46%) initially were diagnosed without any symptom. Video-assisted thoracic surgery (VATS) was used for diagnosis in 16 patients (41%). The most common site involved was the RUL and RML (8 patients, 20.5%, respectively). 26 patients (67%) were involved single lobe. Two or more lobes involvement was observed in 13 patients (33%). Lung lesions were bilateral in 6 patients (15%). 4 patients had synchronous involvement of extra-pulmonary MZL. Consolidation was the most frequent pattern of parenchymal lesions observed in 27 patients. Overall, 37 of 39 patients were treated with surgery (n=20), chemotherapy (n=14), or radiotherapy (n=3). 31 patients achieved complete or partial remissions. The median time to progression (TTP) was 58 (95% CI: 34.2-82) months. Only one patient expired during follow-up. Synchronous extra-pulmonary MZL was determined to be a poor prognostic factor for TTP. TTP was no difference between operation group and chemotherapy group. *Conclusions*. P-MZL trends to be an indolent disease - characterized by prolonged survival with frequent relapses, similarly to other MALT-type site MZL. To conserve lung function and reduce risk of operation, chemotherapy should be considered for first treatment option of P-MZL.

1689

SAFETY AND EFFICACY OF R-CHOP14 REGIMEN REDUCING GRANULOCYTE COLONY-STIMULATING FACTORS (G-CSF) VIALS

B. Puccini, L. Rigacci, R. Alterini, I. Donnini, V. Carrai, F. Bernardi, A. Bosi

Azienda Ospedaliera Careggi, FLORENCE, Italy

Background. Rituximab plus CHOP14 is increasingly used in the treatment of diffuse large B cell lymphoma (DLBCL). Some recent studies lead to the conclusions that intensified R-CHOP could be considered the standard of care for young patients with good prognosis DLBCL and the new standard for elderly patients with DLBCL (MInT trial and RICOVER 60 trial). Dose dense therapy is feasible with GCS-F support which is recommended for10 days. *Design and Methods*. Starting from 2002 we have treated young patients with IPI:0-1 and elderly patients all affected by DLBCL. We prospectively decided to use 7 vials of G-CSF (from +5 to +11) in first ten patients and in absence of infections or delays the following patients were treated with 5 vials (from +7 to +11). Moreover if patients reached a number of leucocytes over 20.000/mm^3 we reduced again the number of vials until three per cycles. We have included 60 pts with DLBCL and 5 with follicular lymphoma grade IIIb, median age was 61 years (range 34-79), 60% had an high-intermediate or high IPI. CHOP was administered every 14 days, preceded on day 1 by rituximab and followed by 7 (in the first ten patients), 5 or 3 days (3 vials in 40% of patients) of G-CSF (filgastrim). Haematological toxicity and feasibility was calculated over 381 cycles administered. *Results*. We have used 1526 GCS-F vials, 5 vials (range 2-7) for cycle and a median of 24 vials (range 10-35) for every pts. The programmed therapy was completed in 62 out 65 pts (96%); three pts swichted to a different scheduling (R-CHOP21). Twelve cycles (3%) have been delayed in 10 pts for severe adverse events. Neutropenia grade 3-4 developed in 2.3% of cycles, febrile episodes in 1.2% of cycles, thrombocytopenia grade 3 or 4 in 1.2% of cycles and hospedalization in 1% of pts. Of the 381 cycles considered, the median nadir of leucocyte was 3850 x10^9/L (range 400-8400), the median nadir of haemoglobin was 11.3 gr/dl (range 5.8-15.7) and the median nadir of platelets was 135000 (range 43000-328000). The complete remission rate was 87% and after a median period of 23 months overall survival was 81%. *Conclusions*. In conclusion in our experience, dose dense chemotherapy (R-CHOP14) supported by G-CSF has been well tolerated by patients, including the elderly. We confirm that the reduction from 10 to 5 or 3 GCS-F vials has not determined an increase of neutropenia, febrile episodes, delays in the treatment and hospedalizations confirming and high rate of response to therapy. Thus R-CHOP14 can be performed with a lower number of G-CSF vials with a clear clinical and biological advantage for the patients and an economical advantage reducing supportive therapy cost.

1690

IMPORTANCE OF FLOWCYTOMETRIC ANALYSIS OF CEREBROSPINAL FLUID FOR DIAGNOSIS OF CNS LESION IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES

R. Urbanova

University Hospital, OLOMOUC, Czech Republic

Background. Diagnostics of CNS lesion in hematological malignancies is based on flowcytometric, cytological and biochemical examinations of cerebrospinal fluid, imaging methods given their unspecific findings have supportive significance. *Methods and samples*. In years 2003-2007 we examined 257 samples of cerebrospinal fluid from 164 patients with hematological malignancies. These samples were obtained from patients with clinical symptoms, unsymptomatic patients with diagnosis of acute leukemia (preventive examinations) and high-risk patients with non-Hodgkin's lymphoma (NHL). Objectives: Samples of patients with positive flowcytometric findings were analyzed in detail and all methods of cerebrospinal fluid examinations were compared with the results of imaging examinations. *Results*. In 33 examinations of 21 patients (i.e., 7 patients with acute B-lymphoblastic leukemia, 2 patients with acute T-lymphoblastic leukemia, 4 patients with acute myeloid leukemia, 4 patients with diffuse large B cell non-Hodgkin's lymphoma, 1 patient with peripheral T-cell non-Hodgkin's lymphoma, 1 patient with primary lymphoma CNS, 1 patient with mantle cell lymphoma and 1 patient with B-chronic lymphatic leukemia) positive findings were examined by flowcytometric, morfological or biochemical analysis. In 17 cases all methods of analysis were used, in 12 cases (71%) compliance in positivity of cerebrospinal fluid examination was observed. Flowcytometric analysis proved to be a more sensitive method in 3 examinations of 2 patients. In one case in neurologically symptomatic patient with diffuse large B-cell non-Hodgkin´s lymphoma biochemical analysis of cerebrospinal fluid was always positive (3 times), while flowcytometric analysis was positive only in the third examination. Clinical symptoms of CNS afflictions were observed in 13 patients (62%). 12 patients underwent imaging examinations (MRI or CT scan of brain and spinal cord), in 4 cases findings were negative, in 8 cases unspecific positive findings appeared. Overall survival (OS) for patients with CNS hematological malignity remains low, from our sample of 21 patients 19 patients died, median OS from a hematological diagnosis was 15 months. *Conclusions*. Results of our observations unambiguously confirm the necessity of repetitious and complex examinations of all obtained samples of cerebrospinal fluid and imaging examinations especially for patients with clinical suspicion of CNS afflictions.

Supported by MSM 6198959205.

THE COMPARISON BETWEEN CONVENTIONAL PROCEDURES AND 18F-FLUORO-DEOXYGLUCOSE POSITRON EMISSION TOMOGRAPHY IN RESPONSE ASSESSMENTS OF PATIENTS WITH T-CELL NON-HODGKIN'S LYMPHOMA AFTER TRANSPLANTATION

C. Suh, B.S. Sohn, D.H. Yoon, S. Kim, D.H. Lee, S.W. Kim, J.S. Lee

Asan Medical Center, University of Ulsan College of Medicine, SEOOUL, South-Korea

Background. Although there had been numerous studies about the usefulness of 18F-fluoro-deoxyglucose positron emission tomography (FDG-PET) for predicting patients' outcomes following autologous stem cell transplantation (ASCT), there had been little reports for T-cell non-Hodgkin's Lymphoma (NHL). Aims: We retrospectively re-evaluated whether post-ASCT PET study had an additional benefit in post-treatment response assessments in T-cell NHLs. *Design and Methods*. Twenty-one patients with T-cell NHLs performed post-ASCT PET study and conventional procedures with computed tomography (CT). The results of post-ASCT PET study were compared with those of CT, and the usefulness of FDG-PET study for response assessments and predicting patients' outcomes, including event-free survival (EFS) and overall survival (OS) were evaluated. *Results*. After the comparisons of response assessments between CT image and PET study, 14 of 21 patients (66.7%) showed concordant results on both CT images and PET study. In these 14 patients, 5 patients showed CR on CT and negative PET result, and 9 patient showed Not-CR on CT and positive PET results (six patients showed matched lesions at both imaging modalities and three patients showed partially matched lesions). 7 of 21 patients (33.3%) showed discordant results. In these 7 patients, 4 patients showed positive PET result which suggested new pathologic lesions which was not reported on CT (two cases of extranodal involvements and two cases of nodal involvements), and 3 patients showed remaining pathologic lesions on CT which was negative PET result. In CT images, 9 patients acquired CR after ASCT. However, 4 of 9 patients (44.4%) showed an early relapse or progression within 4.2 months after ASCT. In patients who did not acquire CR, 3 of 12 patients (25%) have shown disease free status after ASCT with minimum duration of 26.3 months. In PET study, 8 patients acquired negative PET result. However, 2 of 8 patients (25.0%) showed early relapse or progression within 2.0 months after ASCT. In patients who acquired positive PET result, 2 of 13 patients (15.4%) have shown disease free status after ASCT with minimal follow-up of 24.5 months. Overall, there were 7 patients (33.3%) whose response assessments on CT did not correlate with prognosis and 4 patients (19.0%) on PET study. According to CT images alone, the 2-year EFS rate or OS rate in patients who acquired CR did not showed statistical differences compared with patients who did not acquired CR (p>0.05). According to PET results, the 2-year EFS rate was 60.0 ±18.2% in patients with negative PET result and 15.4±10.0% in patients with positive PET result (p=0.026). The 2-year OS rate was 70.0 ±18.2% and 23.1±11.7%, respectively (p=0.062). *Conclusions*. Post-ASCT PET study shows substantial improvement in response assessments, thus in estimating patient's survival after ASCT in T-cell NHLs. Although routine PET study in T-cell NHLs is not recommended, it seems to have a benefit in the prediction of patients' prognosis after ASCT as it does in B-cell NHL.

1692

INTENSIFIED THERAPY PROGRAM FOLLOWED BY HIGH-DOSE THERAPY AND AUTOLOGOUS STEM CELL TRANSPLANTATION AS FIRST-LINE TREATMENT FOR PERIPHERAL T-CELL LYMPHOMA: PRELIMINARY RESULTS OF A PROSPECTIVE STUDY

R.E. Russo,[1] O. Annibali,[2] S. Capria,[1] A. Di Rocco,[1] E. Finolezzi,[1] G. Avvisati,[2] G. Meloni,[1] R. Foà1, M. Martelli[1]

[1]Hematology - University Sapienza, ROME, Italy; [2]Hematology-University Campus Bio-medico, ROME, Italy

Background. Patients (pts) with mature peripheral T-cell lymphoma (PTCL) are known to have a poor prognosis when receiving standard conventional chemotherapy. Therefore, many physicians consider high dose chemotherapy (HDT) followed by autologous stem cell transplantation (ASCT) a standard therapy for these pts. *Aims.* To evaluate the effectiveness and safety of an intensified first-line chemotherapy approach including a conventional MACOP-B regimen followed by alternated IVE/DHAP and HDT-ASCT as consolidation therapy in newly diagnosed pts with PTCL. *Design and Methods*. Between September 2006 and December 2008, 10 adult pts with newly diagnosed PTCL, aged less than 65 years and eligible for intensive treatment, were treated with 12 courses of standard MACOP-B followed by one course of IVE (ifosfamide, etoposide, epirubicin), alternated with one course DHAP (dexamethasone, cytosine-arabinoside, platinum). Stem cells were harvested after IVE and pts who achieved a complete response (CR) were consolidated with a myeloablative HDT-ASCT using BEAM as conditioning chemotherapy regimen. Pts with primary cutaneous, immature lymphoblastic lymphoma or with anaplastic large cell kinase (ALK) positive or negative patients were not included. Histological subtypes were peripheral T-cell lymphoma unspecified (PTCLu) in 9 pts and enteropathy associated T-cell lymphoma (EATL) in the remaining patient. The median age at diagnosis was 46 years (35-64), 7/10 were males, 7/10 pts had advanced (III-IV) stage disease. B symptoms were present in 5/10 pts, 5/10 had high LDH levels, 1/10 a bulky mass and 3/10 presented an extranodal involvement. According to the age-adjusted IPI, 5 pts had an IPI score of 0-1 and 5 a score of 2-3. *Results*. To date, 6/10 pts have completed the full program, while 4 pts are still on therapy. After the MACOP-B regimen, 5/7 pts (71%), achieved a CR/Cru and 2/7 (29%) a partial response (PR). Six pts received the planned intensification therapy; of these, 5 (83%) witnessed a CR/Cru and underwent an ASCT, while 1 (17%) progressed during the IVE regimen. After a median follow-up of 12 months, 2 pts have relapsed at 17 and 13 months from the ASCT and have died of disease progression despite salvage therapy. The patient who progressed during intensification therapy is still alive with lymphoma. There were no treatment-related deaths and all pts experienced mild or moderate toxicities compatible with the planned procedure. The 2-year OS and PFS are 60% and 41%, respectively. *Conclusions*. These preliminary results indicate that an intensified first-line chemotherapy program with HDT-ASCT is effective and safe, and may lead to a potential cure of pts with PTCL. Further prospective studies on larger series of pts are warranted to better define the curative impact of this intensive therapeutic approach for PTCL.

RADIOIMMUNOTHERAPY IN FOLLICULAR NON-HODGKINS LYMPHOMA: TIME TREATMENT AND PREVIOUS THERAPEUTHIC APPROACHES EFFECTS

N. Cascavilla,[1] M. Scaramuzzi,[2] A. La Sala,[3] G. D'Arena,[3] S. Mantuano,[3] A.M. Carella,[3] M.M. Greco,[3] E. Merla,[3] A. Iacobazzi,[4] F. Dicembrino,[5] A.M. Varraso,[5] S. Capalbo,[6] A. Guarini,[4] V. Frusciante[5]

[1]Hematology, "Casa Sollievo Della Sofferenza" Hospital IRCCS, SAN GIOVANNI ROTONDO, Italy; [2]Surgery, Casa Sollievo Della Sofferenza" Hospital IRCCS, SAN GIOVANNI ROTONDO, Italy; [3]Hematology, "Casa Sollievo della Sofferenza" Hospital IRCCS, SAN GIOVANNI ROTONDO, Italy; [4]Hematology, National Cancer Institute, BARI, Italy; [5]Nuclear Medicine,"Casa Sollievo della Sofferenza" Hospital IRCCS, SAN GIOVANNI ROTONDO, Italy; [6]Hematology, Ospedali Riuniti, FOGGIA, Italy

Background. Radioimmunotherapy (RIT) is a novel modality of treatment option for non-Hodgkin lymphoma (NHL). Zevalin radiolabeled with yttrium 90 consists of ibritumomab, a murine anti-CD20 monoclonal antibody, conjugated to the metal chelator tiuxetan for retention of the β emitter (90)Y. Eoncouraging results have been reached until now, even though due to the different settings of patients (pts) that have been treated, they are extremily heterogeneous. Most recent experiences have shown better results when the treatment was started in an early phase of the diesease, where it was chemosensitive and pts were still not pluritreated. Aims: The aim of our study is to verify the RIT therapeutic efficacy, safety and toxicity in pts affected by follicular Non-Hodgkins lymphoma (FL). Pts were stratified according to diagnosis time, disease status and to the quality and quantity of previous therapeuthic approaches received. *Design and Methods*. Since December 2005 to date, 20 pts have been treated with RIT (male/female 10/10; mean age 57 years - range 45-73), who were affected by FL in different phases of the disease: 1 patient at the moment of the diagnosis (I group); 7 pts in partial remission (PR) after first line therapy (II group); 5 relapsed pts after a line of treatment (III group); 4 refractory/relapsed pts after 2 or more lines of treatment (IV group); 3 refractory/relapsed pts after multiple lines of treatment including autologus stem cell transplantation (ASCT) (V group). All pts received the classic scheduled combination of Rituximab 250 mg/mq on days 1 and 8; second Rituximab dose was followed by Zevalin at the dose of 15 MBq/kg (maximum infusion dose was of 1200 MBq). All pts received Cotrimoxazole, Itraconazole and Acyclovir as anti-infective prophylaxis. *Results*. Totally 17 complete hematological remission (85%) were observed and they were distributed as follows: 1 (100%) in the 1st group; 7 (100%) in the 2nd group; 5 (100%) in the 3rd group; 2 (50%) in the 4th group and 2 (66%) in the 5th group. In 8 pts molecular responses were also documented. Out of the 17 pts in complete remission, 6 relapsed between +5 and +20 months from RIT. RIT was well tolerated by all patients and a WHO grade 3/4 hematological toxicity was observed in 8 pts (40%). At the bone marrow aspiration, 1 patient who underwent RIT after post ASCT relapse, showed a secondary myelodysplastic syndrome. *Conclusions*. Treatment with RIT has been, in the whole, well tolerated. Hematologic and molecular responses were satisfactory in terms of long lasting remission. Hematologic toxicity was acceptable. There were no documented infections and no hospitalization was necessary after RIT. Our experience has shown that RIT efficacy was directly proportional to the precociousness and was inversely proportional to the previous therapeuthic approaches received.

1694

IMMUNOLOGICAL PROFILE LINKED CLINICAL APPEARANCE AND OUTCOME IN ADVANCED STAGE MANTLE CELL LYMPHOMA

M. Todorovic,[1] B. Mihaljevic,[1] B. Balint,[2] N. Kraguljac,[1] B. Andjelic,[1] B. Perunicic,[1] O. Markovic,[1] M. Petrovic[1]

[1]Clinical Center of Serbia, BELGRADE, Serbia; [2]Institut for Medical Research, BELGRADE, Serbia

Background. Mantle cell lymphoma (MCL) is uncommon B-cell malignancy with distinct molecular genetics characterized by t(11;14) involving cyclin D1 gene over-expression and typical pathological characteristics. *Aims*. to evaluate immunophenotypic profile and clinical characteristics in with advanced stage MCL as well as their influence on patients overall survival (OS).*Design and Methods*. Bone marrow (BM) and/or peripheral blood (PB) derived cell flow cytometric analyses for following antigens (Ag) were performed: HLA-DR, CD19, CD20, CD22, CD23, CD25, CD10, SmIg, kappa, lambda, CD79b, CD38, FMC7, CD3, CD2, and CD5. Cut-off for Ag expression was accepted positivity > 30%. Pathohistology and immunohistochemical testings were performed in BM an lymph node biopsies. The used monoclonal antibody specifies were: CD5, CD20, CD23, CD10, CD79b, and cyclin D1. Cell morphology in PB and BM smears (MGG staining) was analyzed. According to cell morphology, small cell, typical cell and blastoid variant cell categories were determined. *Results*. A total of 50 patients diagnosed between 1996 and 2007 were evaluated. There was 16 patients in IV CS, while 34 patients had leukemic phase at presentation. Among patients, 46 were treated with CHOP, 2 with FND, and 2 with Hyper-CVAD as initial treatment option. Typical immunophenotype was presented in all cases: CD5+,CD23-, Cyclin D1+. Pathohystological type of BM infiltration was diffuse (74% of patients) and in remainder nodular. Morphological analysis of lymphoma cells showed typical MCL morphology in 36, small cells in 5 and blastoid variant in 9 cases. Patients with blastic MCL variant had higher CD23 expression, compared to typical MCL (19 vs. 5; $p<0.01$), although CD23 Ag was negative (< 30%) in all patients. Hematological parameters showed median Hb 112g/L, Plt $105x10^9$/Ll, WBC $25x10^9$/L. Extranodal involvement (26%) included pleural effusions, bowel, sinus and palpebral infiltration. Among patients, 5 of them achieved complete and 20 partial remission. Median OS was 24 months, and there were no significant OS-differences between CS IV and leukemic phase patients. Survival analyses showed that negative prognostic influence had high IPI ($p< 0.01$), MIPI ($p<0.001$), presence of extranodal localization ($p<0.01$), and diffuse type of BM involvement ($p<0.01$).

Using Cox regression according to OS, MIPI had independent prognostic value (p<0.001). *Conclusions*. In the advanced MCL, had higher MIPI, IPI, diffuse BM infiltration, extranodal disease localization had negative influence on survival. Immunotypization showed elevated, but still negative CD23 expression in blastoid vs. small cell MCL. Accordingly, CD23 could be used as prognostic marker in the blastoid variant as a form of transformed aggressive MCL.

1695

PHASE II PILOT STUDY OF TANDEM CONSOLIDATION USING 90Y-IBRITUMOMAB TIUXETAN (ZEVALIN) AND HIGH-DOSE THERAPY WITH AUTOLOGOUS PERIPHERAL BLOOD STEM CELL TRANSPLANTATION IN HIGH-RISK PATIENTS IN PRIMARY REMISSION WITH DIFFUSE LARGE B-CELL LYMPHOMA

S.G. Cho, J.H. Kim, B.S. Cho, K.S. Eom, Y.J. Kim, H.J. Kim, S. Lee, C.K. Min, J.W. Lee, W.S. Min, C.C. Kim

The Catholic University of Korea, SEOUL, South-Korea

Background. Intense consolidation therapy or successive High-dose therapy (HDT) during the early period of diagnosis intended to increase the dose-intensity effects have been performed in aggressive diffuse large B-cell lymphoma (DLBCL), but the range of the effect was thought to be narrow considering the large amount of effort and treatment-related toxicity. Radioimmunotherapy such as Zevalin can overcome the refractoriness of rituximab in low-grade lymphoma and thus a superior response is also expected in diffuse aggressive lymphoma. Tandem stem cell transplantation using HDT is performed in patients with resistant or refractory lymphoma. This offers the chance of a cure in these patients with a poor prognosis, although there are associated risks. In this study, we expect to improve the treatment of diffuse aggressive lymphomas using tandem consolidation therapy consisting of initial consolidation therapy using Zevalin and second consolidation with HDT and PBSC support 3-4 months after Zevalin administration. We expect that Zevalin will have the potential to minimize the tumor burden without cross-resistance to R-CHOP and the risk of HDT-related toxicity and prolong the initial remission durtation. *Aims*. The objective of this study is the evaluation of the efficacy of tandem consoliadation with Zevalin and HDT with autologous PBSCT in high-risk patients in primary remission with DLBCL. *Design and Methods*. Eleven eligible patients (median age 54, 27-75 yr) with high-risk DLBCL (international prognostic index 4/5) were enrolled in this study and received 6-8 cycles of R-CHOP as a front-line chemotherapy. PBSC mobilization was performed after 1-2 course of ICE (ifosfamide, carboplatin, etoposide) or IVAM (ifosfamide, VP-16, ara-C, methotrexate). The administered dose of Zevalin did not exceed the absolute maximum allowable dose of 32.0 mCi (1184 MBq); 0.4 mCi/kg (14.8 MBq/kg) for patients with a normal platelet count, and 0.3 mCi/kg (11.1 MBq/kg) with a platelet count of 100,000 149,000 cells/mm3. The second consolidation (HDT and PBSCT) was performed 3-4 months after 1st Consolidation using Zevalin. Results: All patients received Zevalin therapy but 3 patient did not perform PBSCT as the 2nd consolidation because of PD (n=2) and inevitable use of cryopreserved PBSCs. Among 11 patients (CR=8, PR=3) in primary remission, 6 patients (CR=3, PR=3) had already showed relapse/PD before PBSCT. PBSCT did not affect their aggressive course. Clinical outcome of another 5 CR patients were as follows; DFS (n=2; 23 mo & 33 mo), RIST after relapse (n=2), death due to relapse (n=1). *Conclusions*. In the period of R-CHOP considered as the standard therapy for DLBCL, our pilot study revealed that the 1st consolidation using Zevalin did not provide some beneficial effects on the 2nd consolidation of HDT and PBSCT in primary remission patients with high-risk DLBCL.

FLOW CYTOMETRY IN THE DIAGNOSIS OF DIFFUSE LARGE B CELL LYMPHOMA - AN ALL WALES LYMPHOMA PANEL EXPERIENCE

K. Karunanithi, B. Hewamana, H. Poynton, J. Couzens, D. Dojcinov

University Hospital of Wales, CARDIFF, UK

Background. The diagnosis of diffuse Large B Cell Lymphoma (DLBL) is often difficult by flow cytometric analysis. Normal flow cytometric pattern is often seen in large cell lymphoma and Hodgkin lymphoma. Diagnostic correlation with histology by flow cytometry is poorly reported. *Aims*. The aim of the study is to evaluate the efficiency of flow cytometry in the diagnosis of Diffuse Large B cell Lymphoma in comparison with histological diagnosis. *Design and Methods*. The study cohort included all the lymphoid material studied by All Wales Lymphoma Panel (AWLP) between December 2002 and December 2007. It will be distributed around the diagnostic laboratories for further investigations such as flow cytometry, cytogenetics, fluorescent *in situ* hybridization (FISH) and polymerase chain reaction (PCR). We selected samples which underwent flow cytometry as part of the work up from Dec 2002 to December 2007. These were compared with histological and immune histochemistry diagnosis. *Results.* We identified 75 cases of diffuse Large B cell lymphoma diagnosed through All Wales Lymphoma Panel which had flow cytometry as part of the diagnostic work up. Flow cytometry was interpretable in 62 (82%) cases Failed cases (n=13) had no correlation with biopsy type (excision-8, Needle core-4, Resection-1) or site of biopsy (Lymphoid mass-9, tonsil, testes, spleen, and small bowell-1). This was mainly due to poor viability of samples (12 out of 13) and lack of cells (1/13). Failure had no correlation to the Sub type of DLBL (GC-6, Non-GC-6, and Indeterminate-1) There was varying success in identifying the clonality. κ or λ clonal B cells were identified in 42 (56%) cases. Flow cytometry failed identify any clonal B cells in 9 cases. 11 cases showed unusual clonality. Three (4%) cases had no kappa or lambda on the gated B cells while eight (10%) had streaky pattern indicated by taking both κ and λ fluorochromes. There was no correlation with type of DLBL (GC-4, Non-GC-4, and Indeterminate-1). *Summary and Conclusions*. Flow cytometry is successful in diagnosing DLBL in 70% of the incidence and failure was mainly due to poor viability of cells in the sample. Furthermore three patterns of Light chain restriction were identified in this study. We suggest that flow cytometry can be employed in the diagnosis of DBCL but further studies in to different patterns of clonal expression are warranted.

1697

OUTCOMES IN PATIENTS WITH PRIMARY GASTRIC DIFFUSE LARGE B-CELL LYMPHOMA AFTER RITUXIMAB, CYCLOPHOSPHAMIDE, DOXORUBICIN, VINCRISTINE AND PREDNISOLONE (R-CHOP) CHEMOTHERAPY

C. Suh, B.S. Sohn, D.H. Yoon, S. Kim, D.H. Lee, S.W. Kim, J.R. Huh, J.S. Lee

Asan Medical Center, University of Ulsan College of Medicine, SEOOUL, South-Korea

Background. Gastrointestinal lymphoma is the most common form of extranodal lymphoma, and the most common involved site is the stomach with histological subtype of diffuse large B-cell lymphoma (DLBCL). Rituximab plus anthracycline-based chemotherapy is the treatment of choice, and the role of radiation therapy and surgery are controversial. *Aims*. The aim of this study was to investigate the patient's outcomes after rituximab, cyclophosphamide, doxorubicin, vincristine and prednisolone (R-CHOP) treatment in primary gastric DLBCL in a single center. *Design and Methods*. We searched AMC Registry for Non-Hodgkin's Lymphoma and found 26 patients with primary DLBCL, who received R-CHOP as first-line chemotherapy. Ten of 26 patients had localized disease. Remaining patients had disseminated disease. R-CHOP was repeated every 21 days in all patients. *Results*. Overall, complete response (CR) was observed in 20 of 26 patients (76.9%). Three-year event free survival (EFS) and overall survival (OS) was 76.5% and 75.0%, respectively. After analyses of 10 patients with localized disease, we found that these patients had received a total 38 cycles, with a median of 3 cycles per patient. Of 10 patients, one patient had 2 cycles of R-CHOP, four had 3 cycles, and one had 4 cycles, all 6 patients above followed by consolidation radiotherapy. Remaining one patient and four patients had 5 cycles and 6 cycles of R-CHOP, respectively. In patients with localized disease, CR was observed in 10 of 10 patients (100%), and both 3-year EFS and OS was 100% (10 of 10 patients). In analyses with 16 patients with disseminated disease, 16 patients had received a total 91 cycles, with a median of 6 cycles per patient. In these patients, two patients had radiation therapy after R-CHOP, one patient had CR before consolidation radiation therapy, and another had partial response before radiation therapy. CR after R-CHOP treatment was observed in 10 of 16 patients (62.5%), partial response in 3 patients, stable disease in 1 patient, and progressive disease in 1 patient. Three-year EFS and OS was 61.1% and 57.8% in patients with disseminated disease. *Conclusions*. R-CHOP regimen showed a promising result in primary gastric DLBCL. Combination with rituximab in CHOP regimen showed excellent prognosis especially in patients with localized disease. In localized disease, CR was 100%, 3-year EFS and OS was 100%. In disseminated disease, CR was 62.5%, 3-year EFS and OS was 61.1% and 57.8%.

1698

CLINICOPATHOLOGIC CHARACTERISTICS OF THE T(14;19)(Q32;Q13)-POSITIV SPLENIC MARGINAL ZONE LYMPHOMA

H. Julhakyan,[1] T. Obukhova,[2] A. Kremenetskaya,[2] E. Zvonkov,[2] I. Kaplanskaya,[2] A. Vorobiev[2]

[1]Hematology research center, MOSCOW, Russian Federation; [2]Hematological Research Center, MOSCOW, Russian Federation

Background. Splenic marginal zone lymphoma (SMZL) is well recognized B-cell neoplasm. Which characterized with splenomegaly, lymphocytosis, involvement of bone marrow, sometimes with M-component. Immunologically characterized with typical phenotype of marginal zone. The most frequent findings in SMZL are involvement of chromosomes 1, 3, 7(usually deleted in 7q) and 8. The t(14;19)(q32;q13) is rare cytogenetic abnormality with rearrangement bcl-3 that has been reported in B-cell lymphomas and leukemia. *Aims*.To describe the clinical, morphological, immunophenotypic findings in SMZL associated with t(14;19)(q32;q13). *Design and Methods*. In Hematological Research Centre, Moscow between January 2005 and February 2009 identified three cases SMZL with t(14;19)(q32;q13). In all patients (males with median age 58 years (from 51-67)) debut of lymphoma with B-symptoms, high level of lactate dehydrogenase (LDH), hepatosplenomegaly and only with splenic hilar lymphadenopaty. The median hemoglobin was 110 g/l (range 92-122 g/l). All patients had normal count of leucocytes with an absolute lymphocytosis (median lymphocytes count 72,3 x 10^9 g/l, range 58-83x10^9/L) and thrombocytopenia. Morphological examination of peripheral blood and bone marrow lymphocytes showed that all lymphocytes are atypical with wide cytoplasm, nuclear indentation. In all cases bone marrow involvement was nodular and composed of heterogeneous mixture cells, majority medium sized. The results of immunophenotypic analysis were expression of mature B-cells antigens and absence CD10-, CD23-, CD5-, CD43-, CyclinD1-. In debut two patients were get chemotherapy (CHOP-regimen) However there were progression - enlargement of spleen size and decreased of thrombocytes counts. All patients undergo to splenectomy. Median weight of spleen was 2083 g (range 1800-2850 g). Splenic section generally show massive nodular pattern (involvement of the white and red pulp) associated with diffuse invasion of the sinuses. In all cases discovered high Ki-67. There were occur progression after splenectomy during 3-6 months which is characterized with increase of leucocytes counts (range 45,4 - 101,8x10^9 /l), high level of LDH, appearance of peripheral and visceral lymph nodes. Consideration of increasing leucocytes count and presence of lymphadenopathy in all patients were used alkylating agents (in one patient - chlorambucil and in two - cyclophosphamide). Results: There were normal peripheral blood index and level of LDH, absence of lymphadenopathy in all cases after 4-6 months of treatment with alkylating agents. Median observation was 13+ months (range 15-18 months). All patients were alive. *Conclusions*. t(14;19)(q32;q13)-positive SMZL is distinct variantof SMZL which characterized with high Ki-67, transient progression on chemotherapy and after splenectomy and high efficiency of alkylating agents.

1699

MYELOID PRECURSOR THERAPY IN LYMPHOMA PATIENTS

Zs. Miltenyi,[1] A. Illes,[2] Zs. Simon,[1] L. Gergely,[1] L. Varoczy,[1] E. Payer[1]

[1]University of Debrecen, DEBRECEN, Hungary; [2]3rd Department of Internal Medicine, DEBRECEN, Hungary

Background. Myeloid growth factors help to prevent and cure neutropenic events in malignant lymphoma patients treated by chemotherapeutical regimens. Administering either filgrastim or pegfilgrastim, treatment schedule can be kept well and less dose reductions are needed, which results in better survival rates. *Aims*. The aim of this study was to examine the indications and the outcome of myeloid precursor therapy among our malignant lymphoma patients. *Design and Methods*. Between 2003 and 2007, 249 malignant lymphoma patients received 1655 cycles of different polychemotherapies. Myeloid growth factor therapy was administered in 138 cases by 65 patients, which meant 8.33% of all treatment cycles and 26.1% of all patients, respectively. As for the indications, prevention was more common than intervention (71.7% vs. 28.3%). By preventive usage of growths factors, two third of threatening neutropenic events could be avoided. Side effects were uncommon and mild: grade I-II toxicity was observed in 31% of all treatments. Analyzing the risk factors for febrile neutropenia among patients who received myeloid growth factor therapy compared to those who did not, we found the incidence of comorbidities, hypoalbuminaemia, advanced stage disease and agressive chemotherapies significantly different in the two groups. Interestingly, there was no significant difference between the median age and the incidence of low body surface area. *Conclusions*. Our observations support that myeloid precursor therapy is an effective and safe tool to prevent or treat neutropenia in high-risk malignant lymphoma patients.

1700

IMPROVEMENT OF THE OUTCOME OF DLBC AND FOLLICULAR LYMPHOMAS IN VENEZUELAN PATIENTS TREATED WITH R-CHOP

A. Müller,[1] M. Morales,[1] M.A. Torres,[2] G. Acquatella,[1] E. Tovar,[1] A. Soyano,[3] A.E. Soyano,[4] M. Di Stefano,[5] M. Villegas[1]

[1]Institute of Hematology and Oncology, CARACAS, Venezuela; [1]Clínica Santa Sofía, CARACAS, Venezuela; [3]Venezuelan Institute for Scientific Research, CARACAS, Venezuela; [4]Clínica Ávila, CARACAS, Venezuela; [5]Hospital Clínicas Caracas, CARACAS, Venezuela

A study of patients with lymphoma studied and treated at the Oncology and Hematology Institute (THE LYMPHOMA GROUP) in Caracas, and at other Public and Private Clinics in Venezuela was performed. *Design and Methods*. 1117 patients with lymphoma were studied during the period 1996-2008. The diagnosis of lymphoma was established by lymph node and tissue biopsies (depending of the case), histopathology and inmunohistochemistry studies, and complemented with X rays and TACs. Results: Most of the patients had non-Hodgkin lymphomas (NHL, 727 cases, 65.1%); the Hodgkin lymphomas represented 34.9% (HL, 390 cases), distributed as follows: Nodular Sclerosis (62.6%), Mixed Cellularity (27.7%), Lymphocyte Predominance (4.3%), patients with Lymphocyte Depletion (5.4%). The average age and gender of the patients were Nodular Sclerosis: 32.45 years old (18-65), 129 females and 115 males, Mixed Cellularity: 22.3 years (18-56), 37 females and 72 males, Lymphocyte Predominance 22.6 years old (18-67), 6 females and 11 males, Lymphocyte Depletion 22 years old (20-42) 15 males and 6 females. Stadio I: 5.5%, II: 44%, III: 31.1%, IV: 19.4%. These patients were treated with different protocols according to the year they were treated: MOPP, ABVD, STANDFORD V, HYBRIDO, COPP/ABVD, COPP/EBVD, and since 2004 with BEACOPP. Non Hodgkin Lymphomas (NHL) were distributed as follows: diffuse large B cell (36,4%), follicular (24,1%), MALT lymphoma (10%), Peripheral T cell (5,5%), Mantle Cell lymphoma (3%); 20,8% of the patients had another type of lymphoma such as mycosis fungoides, immunoblastic, anaplastic, Lymphoblastic, Burkitt or Cutaneous B cell lymphoma. Of the Follicular NHL 45% had high FLIPP, while 60% of the DLBC lymphoma had intermediate high IPI score with high risk prognostic factors and only 15% of cases had low risk lymphoma. They were treated with CHOP, CHOP Bleo, MACOB B, ATT, HyperCvad, CHOP MTX and since 2004 with R-CHOP. The R-CHOP as induction in Follicular NHL *de novo* and Rituximab as maintenance produced 46% CR and 56% PR. The CR increased to 77% after two years of Rituximab maintenance during four years observation period. The CR for DLBC lymphoma was 68%. An improvement in the outcome of our lymphoma patients has occurred when we compared the percentage of relapse in different years. *Conclusions*. 1117 Venezuelan patients with lymphoma were studied: 34.9% Hodgkin and 65.1% non Hodgkin lymphomas. The most common subtype of HL was nodular sclerosis (62.6%), being more common in female and young adults. The mixed cellularity HL represented 27.7%, while the lymphocyte predominance and lymphocyte depletion types were only 6,8% and 8,7%, respectively. The most common NHL was the DLBC lymphoma, followed by the follicular lymphoma. The Venezuelan population are integrated by a mixture of different ethnic group: Indians, Caucasians and Blacks but it seems that HL in these patients follows the same pattern reported in other populations. The outcome of Follicular and DLBC lymphoma patients improved using R-CHOP.

1701

A PHASE II TRIAL OF GEMCITABINE, IFOSFAMIDE, DEXAMATHASONE, AND OXALIPLATIN (GIDOX) FOR PATIENTS WITH REFRACTORY OR RELAPSED NON-HODGKIN'S LYMPHOMA

B.B. Park,[1] W.S. Kim,[2] H.S. Eom,[3] J.S. Kim,[4] S.J. Oh,[5] I.G. Hwang,[6] C. Suh[7]

[1]Hanyang University College of Medicine, SEOUL, South-Korea; [2]Samsung Medical Center,Sungkyunkwan University School of Medicine, SEOUL, South-Korea; [3]Research Institute and Hospital, National Cancer Center, GOYANG, South-Korea; [4]Yonsei University College of Medicine, SEOUL, South-Korea; [5]Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, SEOUL, South-Korea; [6]Chung-Ang University, School of Medicine, SEOUL, South-Korea; [7]Asan Medical Center, University of Ulsan College of Medicine, SEOUL, South-Korea

Background. Gemcitabine combined with cisplatin has been known as an effective regimen for lymphoma treatment in salvage setting. However, this regimen has the modest response with severe nephrotoxcity and neurotoxicity, especially to heavily treated patients. *Aims*. We investigated the response rate and toxicity of gemcitabine, ifosfamide, dexamethasone, and oxaliplatin (GIDOx) for recurrent or refractory aggressive B-cell non-Hodgkin lymphoma (NHL), looking for the more effective and less toxic therapy.*Design and Methods*. Patients with recurrent or refractory diffuse large B-cell NHL or mantle cell lymphoma, measurable disease, and more than one previous chemotherapy regimen were eligible. Treatment consisted of gemcitabine 1000 mg/m^2 intravenously (i.v.) on Days 1 and 8, ifosfamide 2000 mg/m^2 i.v. on Day 1, dexamethasone 40 mg orally on Days 1-4, and oxaliplatin 130mg/m2 i.v. on Day 2, every 21 days. The primary end point was a response after three cycles. Patients could then proceed to stem cell transplantation (SCT) or receive up to six treatment cycles. *Results*. Twenty-seven eligible patients were evaluable for toxicity and response. The median age of the patients was 54 years (range, 18-75 years) and most had diffuse large-cell lymphoma. After 3 cycles, there were 4 complete responses (CR; 15%) and 10 partial responses (PR; 37%). There was an overall response rate (RR) of 52%. The RR after completion of all protocol chemotherapy including SCT was 44% (10 CR, 2 PR). In total 88 cycles of GIDOx, grade 3 and 4 neutropenia occurred in 33% and 16% of cycles, respectively. Grade 3 and 4 thrombocytopenia occurred in 14% and 16% of cycles, respectively. Tow patients (2%) experienced febrile neutropenia. Seven patients (26%) proceeded to SCT. *Conclusions*. GIDOx is an active salvage regimen in aggressive B-cell NHL and can be administered with acceptable toxicity.

1702

TREATMENT WITH ALEMTUZUMAB IN T CUTANEOUS LYMPHOMAS

G.D. Gaman, A.M. Gaman

University of Medicine and Pharmacy Craiova, CRAIOVA, Romania

Background. Mycosis fungoides (MF) and Sézary syndrome (SS) are the most frequent T cutaneous lymphomas, characterised by acumulation of CD4 + T cells in the skin. The results obtained through classic chemotherapy or new treatment (PUVA therapy, interferons, retinoids, rexinoids) are mediocre. The recent studies propose the treatment with anti-CD 52 monoclonal antibody therapy in these cases. *Design and Methods*. We studied 11 patients with T cutaneous lymphomas (9 cases of mycosis fungoides and 2 of Sézary syndrome), treated with classic chemotherapy (CHOP regimens) and PUVA therapy as first line treatment, obtaining only short and ephemeral remissions. All patients were then treated with Alemtuzumab, 30 mg x 3 / weekly, subcutaneous administration, for 3 months. *Results.* The results were 8 complete remissions and 3 partial remissions ; 1 of the patients with partial remission died because of a complication which had no relationship with the initial disease. Treatments wasn't associated with local adverse reactions or the reactivation of CMV infection. *Conclusions*. The good results obtained recommended this treatment for all patients suffering from T cutaneous lymphomas, refractory or relapsed after the classic therapy.

1703

HIGH AND PROLONGED RESPONSE RATE WITH LOW TOXICITY PROFILE WITH RITUXIMAB IN COMBINATION WITH CHLORAMBUCIL IN UNTREATED FOLLICULAR LYMPHOMA PATIENTS

S. Bassi, F. Gigli, S. Sammassimo, P. Bertazzoni, M.T. Lionetti, C. Rabascio, L. Nassi, A. Calleri, L. Calabrese, E. Cocorocchio, D. Laszlo, F.A. Peccatori, G. Martinelli

European Institute of Oncology, MILAN, Italy

Background. The use of Rituximab in combination with chemotherapy it is now standard practise as first-line treatment in patient with follicular lymphoma (FL), because the association has demonstrated significantly improved progression-free survival, complete response rate compared to chemotherapy alone. Despite the progress made in treatment, a great majority of patients still relapse, so treatment options that extend the duration of remission with a low toxicity profile are warranted. *Design and Methods*. Between December 2001 and April 2008 33 patients not eligible for clinical trials were treated at our institution with a combination of Rituximab plus Chlorambucil (Chl). Sixteen were men and the median age at diagnosis was 55 years old. Seventy percent of patients presented grade 1 and 2 FL, while just 5 patients had grade 3 lymphoma. Twenty-one patients had advanced stage of FL and the majorities (82%) were asymptomatic. In terms of prognostic index 19 patients were low risk FLIPI score. The schedule included an induction phase of 4 weekly administrations of monoclonal antibody at standard dose during 6 continuously weeks of Chl at the dose of 6 mg/m^2/daily. After restaging between the 10-12th week from the beginning of treatment, the patients underwent the maintenance phase with Rituximab once a month and 15 day of Chl at the same dosage each month for 4 consecutive months. *Results*. After the induction the ORR was 97% with 11 patients in complete response (CR). At the end of treatment 97% of patients responded and 29 (88%) achieved a CR. One patient showed a stable disease and underwent to intensification and high-dose chemotherapy. In terms of molecular response the 14 patients positive for the BCL-2 rearrangement at diagnosis, after the treatment 9 of the 10 valuable patients were negative. All patients but one concluded the treatment scheduled. One patient discontinued the therapy because of grade 3 hepatic toxicity. None reduced the dosage of Chl during induction (mean dose 10mg/daily), while in the 2nd phase 14 patients reduced the daily dose (mean dose 8,5 mg/daily) mainly at 1st or before the 3rd maintenance because of haematologic toxicity (neutropenia grade 2 6 pts, grade 3 5 pts and platelets <10x^9/L in 3 cases). One case of thorax HZV has been reported. No late toxicity has been observed. With a median observation time from diagnosis of 62 months (range 8-88 months) 24 patients (72%) maintain a CR. Eight patients experienced relapse, included 5 in CR with a median TTF of 25 months (7-37 months). Up to now 2 patients died and just one because of progressive disease. *Conclusions*. Our experience confirmed that the immuno-chemotherapy is able to improve the outcome of follicular lymphoma patients with high and prolonged responses (72% of CR with a median 5 years observation in our study). Despite other chemotherapy regimens, our schedule of Rituximab in combination with Chlorambucil resulted safety and feasible mainly for the patient, who experienced a very low and easy-manageable toxicity profile.

1704

IMPACT OF MODERN CHEMOTHERAPY IN OUTCOME OF NON-HODGKIN LYMPHOMA IN CHILDREN

M.D. Dragomir, E. Gruber, C. Comsa

Institute of Oncology, BUCHAREST, Romania

Background. The aim of our study was to evaluate the epidemiologic and pathological features of non-Hodgkin lymphoma(NHL) in children, as well as comparative treatment results according to the type of the therapeutic regimes employed : modern protocols-type BFM versus classical regimes.*Design and Methods*. A retrospective review of 135 patients (pts) treated and followed-up in the Institute of Oncology- pediatric oncology department, Bucharest between 1990 -2005 was performed. Eligibility criteria required: pathologic diagnosis of the subtype of non-Hodgkin lymphoma, staging according to the international accepted standards, chemotherapy +/-radiotherapy depending on the stage and histological type and follow-up of at least 3 years after the completion of therapy. Until 1995 the chemotherapy consisted of protocols type CHOP, COPP, COP, CVP; starting with 1996, more aggressive regimes-type BFM, LSA2-L2 were applied. Results: The data we obtained showed a predominance in males (65%) and in the 10-14 year old group

(36%). Most of the pts were diagnosed in stage III -IV (89%). The distribution of the histological types: NHL type B (39.6%), NHL nonB (45.5%), anaplastic NHL with large cells (5.9%). NHL low-grade (8.9%). An 100% survival rate was registered in NHL with large cells and NHL with low-grade, irrespective of stage. The curable stages (I, II) survival rate was of 100% in NHL type B and of 80% in NHL non-B. In advanced stages the survival rates were higher in stage III of NHL type B (65%) versus type non-B (44%) and in stage IV of NHL non-B (33%) versus type B (18%). Global survival was of maximum 100% in NHL low-grade and of minimum 45% in NHL nonB. Modern aggressive protocols type BFM induced higher survival rates in comparison with classical regimes : 68% versus 48%. *Conclusions*. The most frequent histological types were B and non-B NHL, 91% of cases were diagnosed in advanced stages, and significant efficiency of modern aggressive protocols was registered in our study.

1705

EFFICACY AND SAFETY OF 90Y-IBRITUMOMAB TIUXETAN (ZEVALIN) IN MABTERA/INMUNOTHERAPY PRETREATED NON FOLLICULAR B CELL LYMPHOMA PATIENTS

R. Raquel

MDanderson Internacional España, MADRID, Spain

Background. 90Y-ibritumomab tiuxetan (Zevalin) was EMEA approved for mabtera pretreated, refractory or relapsed, Folicular Lymphoma patients. However there are currently several clinical trials evaluating radioimmunotherapy in other subtypes of lymphoma and clinical situations. *Aims*. We present observations from our clinical experience with a retrospective study to evaluate safety/effective of Zevalin as salvage or consolidation in 14 mabtera/inmunotherapy pretreated non follicular B cell lymphoma patients. *Design and Methods*. Between october/2007-december/2008, 14 mabtera pretreated B cell NHL patients received Zevalin. Five patients as consolidation after mabtera+chemotherapy (1 or 2 lines), 9 patients as salvage therapy (2-5 previous lines), of those, 2 received Zevalin with BEAM, followed by autologous SCT, and 7 in monotherapy. Zevalin dose was platelet count adapted, over $150x10^9$/L received 0.4 mCi/kg zevalin, 0.3 mCi/kg, if less. For each patient, clinical examinations and imaging studies (18F-FDG PET/CT before therapy and at 12 wk after RIT) were used to document response to therapy using the revised International Workshop Criteria (IWC). Primary endpoints were overall response rate (ORR), CR rate and primary safety variable were the incidence of hematological or critical toxicities. *Results*. Patients main characteristics at diagnosis (n=14): median age (range) was 75 years (36-88); 79% were olders than 60 years. Male/female: 10/4. Ann arbor stage classification: I:0/II:3/III:4/IV:7; 79% were advanced stage. "B" symptoms: n/y 12/2. Bone marrow involvement n/y: 4/14 (28.5%). Bulky disease none. ECOG over 2 (43%). Only 2 patient present a IPI 0-1. Histological subtypes: mantle 3 (2 variant blastoid), marginal 1. Large B cell 5, ot hers 5. Average previous lines was 2.7. ORR was 64%, CR was 50%: 4 of 7 patients how achieved CR, received RIT as consolidation and 3 as salvage therapy. 5 patients received zevalin as consolidation therapy. Present day all are alive, 4 in CR. 9 patients received zevalin as salvage therapy after 2-5 chemotherapy lines. 3 are still in CR. 2 patients are alive on treatment; 4 patients have died (Z-BEAM-TASPE:1) all cases with NHL progression. The median PFS of the 14 patients who received RTI was 6 months with follow-up time of 12.0 months (range 4-26 months). All the patients presented hematologic toxicity with grade 3/4 of neutropenia, thrombocytopenia or anemia in 8 (57%), 8 (57%) and 3 (14%) respectively. We have observed in 4 patients a diagnosis of second neoplasia after RIT: 3 skin cancers and one patient with bladder cancer. *Conclusions*. RIT with 90Y-Ibritumomab Tiuxetan is a safe and effective approach for patients affected by NHL and heavily pretreated with Rituximab + chemotherapy.

1706

CLINICOBIOLOGICAL FEATURES, OUTCOME AND PROGNOSTIC FACTORS OF 104 PATIENTS WITH EARLY-STAGE (ANN ARBOR I-II) DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL): EXPERIENCE IN A SINGLE INSTITUTION

S. Mercadal,[1] E. González-Barca,[1] E. Domingo-Doménech,[1] F. Climent,[2] J. Sarrà,[1] A. Oliveira,[1] V. Clapés,[1] V. Romagosa,[2] A. Fernández de Sevilla[1]

[1]Hospital Duran y Reynals, BARCELONA, Spain; [2]Hospital Bellvitge, L'HOSPITALET, BARCELONA, Spain

Background. DLBCL is the most frequent non Hodgkin lymphoma. It presents as a localized disease in 30% of cases. *Aims*. To analyze the main clinicobiologic features, response to treatment and outcome of patients with early stage DLBCL. *Design and Methods*. Patients with Ann Arbor stage I-II DLBCL diagnosed in a single institution during a 17-year period were identified in a data base. Clinicobiological features, treatment, response and survival were analyzed. Multivariate analysis of the variables predicting response was performed using a logistic regression model. Survival curves were constructed by Kaplan Meier´s method. Multivariate analysis for survival was performed using the Cox model. *Results*. One hundred and four patients were identified. Forty-six (44%) were males, median age was 56 years. The characteristics of the disease at diagnosis were as follows: stage I, 44 patients (42%); bulky disease, 40 (38%); primarily extranodal disease, 45 (43%); ECOG 0-1, 69 (67%); B symptoms, 16 (15%); elevated LDH, 91 (88%) and elevated β2 microglobulin, 41/80 (51%). IPI subgroups were: low risk, 49 (47%); low-intermediate risk, 37 (36%) and high-intermediate risk 18 (17%). One hundred patients (96%) were treated with CHOP/CHOP-like chemotherapy, 33 (32%) of them with rituximab and 61 (58%) followed by extended field radiotherapy. Eighty-six patients (82%) achieved complete remission (CR), 9 (9%) partial remission, and 9 (9%) failed. Five year event free survival (EFS) and overall survival (OS) were 68% and 71% respectively. Thirty-three patients died during follow-up, most of them due to disease progression. Three patients died due to neoplasms in CR: gastric adenocarcinoma, pancreatic adenocarcinoma and acute myeloblastic leukemia. A multivariate analysis was performed, including the main significant variables identified in the univariate analysis (age < 60 years, bulky disease, performance status, IPI, β2 microglobulin, rituximab and complementary radiotherapy). Bulky disease (p=0.04) and elevated β2 microglobulin (p=0.001) had prognostic value to predict poor response. Age > 60 years (p=0.04) and elevated β2 microglobulin (p=0.035) significantly predicted poor EFS. IPI (p=0.007) and β2 microglobulin (p=0.0086) were the most important factors predicting OS. No differences were found in terms of response, OS and EFS regarding treatment with rituximab. *Summary*. Early-stage DLBCL presented as an extranodal disease in almost half of the patients. Almost half of the patients presented bulky disease. Elevated β2 microglobulin predicted poor outcome either for response as for OS and EFS. The exact rule of treatment with rituximab in this subset of patients has yet to be determined in a prospective clinical trial.

1707

PRIMARY CNS LYMPHOMA - THE OUTCOME AFTER THE THERAPY WITH DEANGELIS COMBINED MODALITY TREATMENT - SERBIAN LYMPHOMA STUDY GROUP EXPERIENCE

B. Andjelic, B. Mihaljevic, M. Sretenovic, S. Jankovic, A. Sretenovic, N. Colovic, R. Jancic-Nedeljkov, I. Elezovic, M. Petrovic

Institute of Hematology Clinical Center of Serbia, BELGRADE, Serbia

Background. Primary central nervous system lymphomas (PCNSL) are aggressive malignancies, having one of the worst prognoses among lymphomas. The best and generally accepted treatment modality for PCNSL has not yet been identified. AIM. This study was performed to assesses the therapeutic outcome and late side effects of combined modality treatment (CMT) presented by DeAngelis et al. We tried to determine the possible prognostic value of clinical and laboratory parameters in patients (pts) with PCNSL. *Design and Methods*. 16 pts diagnosed with PCNSL between 1994 and 2008 received CMT. The diagnosis was obtained by biopsy of the tumor, all the pts had diffuse large B-lymphoma. The CMT was consisted of methotrexate (Mtx) 1g/m2 i.v. at day 1 and 8, Mtx i.t. 12mgx6, 40 Gy whole brain radiotherapy + 14,4 Gy to the tumor site, and 2 courses of Ara-Cx2d i.v. Before the start of treatment CT scans and bone marrow biopsy were performed to exclude any other lymphoma involvement. In all pts on the admission, complete laboratory work up (including LDH) and ECOG performance status were determined. *Results*. The median age was 53 (range 27-66), 11 pts were male and 5 female. In the whole group nine pts (56%) achieved remission: complete remission (CR)-3 pts (19%) and partial remission (PR) had 6 pts (37%). Seven pts (44%) didn't respond to therapy and died within 6 months after the diagnosis was established. Median overal survival for the whole group of pts was 9 months and by now 22 months in patients who responded to treatment (6 pts are still alive). One pt died in first relapse occurred 4 months after completing CMT, before starting "selvage" therapy. Two patients in first relapse (first after 17 months, the second after 27 months) were retreated with CMT without radiotherapy and achieved remissions lasting 38 and 7 months, both of them died within 17 months after second relapse and were treated with cyclophosphamide, Mtx and procarbazine combination. The elevated

LDH level was present in half of pts both in responders and non-responders group. Eight pts had ECOG ≥3 (three pts older than 60 yrs) and only 2 of them responded to CMT. In the CMT responders group, two patients developed severely symptomatic and one mildly symptomatic leukoencephalopathy. *Conclusion*. According to our experience, treatment with combined regimen led to a marked prolongation of survival in patients who responded to therapy. Having in mind that the risk of late side effects exists and that the response rate was 56%, further investigations seems to be necessary for finding appropriate, more efficious and less toxic treatment for PCNSL. According to our experience, high ECOG and older age may be predictive for poor prognosis of these patients.

1708

GOOD OUTCOME OF PRIMARY MEDIASTINAL B CELL LYMPHOMA (PMBCL) IN PATIENTS TREATED WITH RITUXIMAB-CHOP PLUS RADIOTHERAPY

S. Falorio, F. Fioritoni, G. La Barba, G. Fioritoni, F. Angrilli

Civic Hospital, PESCARA, Italy

Background. The optimal treatment of PMBCL is not well-defined today. In retrospective studies third generation chemotherapy regimens, namely MACOP-B or VACOP-B, plus radiotherapy (RT) achieved better results in comparison with conventional CHOP. Moreover, the impact of the addition of rituximab (R) to CHOP in the treatment of PMBCL is still debated. *Aims*. To retrospectively evaluate clinical characteristics at diagnosis and outcome of patients with PMBCL treated with R-CHOP in our institution. *Design and Methods*. Between 3/2003 and 8/2008, 19 untreated patients with PMBCL have been admitted in our institution. Disease evaluation was performed with whole-body computed tomography at diagnosis, after 3-4 courses of chemotherapy and at the conclusion of treatment. Patients who obtained at least a partial remission (PR) at first restaging completed planned therapy, while patients who failed to achieve complete remission (CR) or had progressive disease (PD) started high dose sequential chemotherapy (HDSC) followed by autologous stem cell transplantation (ASCT). The planned treatment consisted of 6 courses of R-CHOP21 in aaIPI=0 or 8 courses of R-CHOP14 in age-adjusted-IPI (aaIPI) >0, plus involved field (IF) RT (25-36 Gy). Final restaging included PET/CT (4 months after RT or 2 months after ASCT) in all complete responder patients. Patients received G-CSF or peg-G-CSF in order to maintain dose-intensity of planned treatment, and trimetoprim-sulfametaxazole, acyclovir and nistatine as infections prophylaxis. Retrospectively, we evaluated the response rate, overall survival (OS) and disease-free survival (DFS). *Results*. Four patients were male and 15 female, with a median age of 32 years (15-54). Stage II was present in 15 patients and stage III-IV in 4. Fourteen patients had B symptoms; aaIPI was 0 in 3 cases and 1-2 in 16 cases. Bulky disease was reported in 16 cases. Today 18 patients completed treatment and are evaluable. At early restaging, 17 patients (94%) showed at least a PR. After completion of R-CHOP plus IFRT, 14 (82%) of the 17 PR patients obtained a CR, 2 (12%) remained in PR, and 1 patient (6%) had PD. Three of the 4 patients who received HDSC plus ASCT (1 after first restaging and 3 after treatment conclusion) obtained CR, while 1 patient died 20 months after initial diagnosis because of PD. After a median follow-up of 35 months (6-70), OS is 92%. We observed no relapse so far. Consequently, DFS of the 17 patients who achieved CR is 100%. All patients maintained planned dose-intensity. No cases of serious infections were recorded. In summary, the addition of rituximab to CHOP plus IFRT seems to be feasible, safe and effective in inducing durable CR in a high proportion of our small cohort of patients with PMBCL. Large, prospective studies are needed to further confirm our encouraging results.

1709

A PHASE II STUDY OF GEMCITABINE IN PATIENTS WITH ADVANCED STAGE MARGINAL ZONE B-CELL LYMPHOMA

Y. Oh,[1] D. Lee,[2] W. Kim,[3] S. Kim,[3] S. Kim,[1] B. Ryoo,[4] H. Kang,[4] Y. Choi,[5] J. Chung,[5] H. Kim,[6] C. Suh[2]

[1]Dong-A University College of Medicine, BUSAN, South-Korea; [2]Asan Medical Center, SEOUL, South-Korea; [3]Samsung Medical Center, SEOUL, South-Korea; [4]Korea Cancer Center Hospital, SEOUL, South-Korea; [5]Pusan National University, BUSAN, South-Korea; [6]Hallym University College of Medicine, SEOUL, South-Korea

Background. Therapeutic approaches for marginal zone B-cell lymphoma (MZL) are still evolving. Localized MZL responds favorably to local treatment such as surgery and/or local radiation therapy. However, MZL presents as a disseminated disease in one-third of the cases at the diagnosis. Moreover, relapses involving distant sites after local therapy have been reported. Therefore, the search for effective forms of systemic therapy is an important issue. *Aims*. We conducted this multi-center, phase II trial to investigate the efficacy and safety of gemcitabine single chemotherapy in patients with stage III/IV MZBCL. *Design and Methods*. Patients received gemcitabine 1250 mg/m^2 on day1 and 8 each cycle. The treatment was repeated every 3 weeks and continued for 6 cycles until disease progression, withdrawal due to toxicity, or withdrawal of consent. *Results*. Between Sep 2006 and Sep2008, a total of 16 patients were enrolled with informed consent at this trial from 6 institutes in Korea. Among these patients, 4 patients were dropped out without evaluation. The median age of the evaluated 12 (9 males, 3 females) patients is 62 (range 25-73) years. Seven patients (58%) had extranodal sites involvement. All of patients had received previous treatment about MZL. The patients received a total of 69 cycles of gemcitabine chemotherapy (range 3 - 6 [median 6] cycles/person). There were 2 PR (17%), 9 SD (75%), and 1 PD (8%). There were 8/69 cycles (12%) of grade 3/4 neutropenia. Non-hematologic toxicities were mild and tolerable. There were 5 cycles (8%) of delayed chemotherapy (median 1 week) because of neutropenia. Dose reduction was needed in 12 cycles. But, there was no treatment-related death. The median TTP was 10.2 months (95% CI, 5.3-15.1). As the response rate in stage I did not justify progressing to stage II (≥8/15), this study had to be discontinued in accordance with the established protocols. *Conclusions*. Gemcitabine as a single agent, in this dosage and schedule, has minimal clinical activity in relapsed or refractory MZL

1710

DOSE-ADJUSTED R-EDOCH-14 SUPPORTED BY PEGFILGRASTRIM OR FILGRASTRIM IN PATIENTS WITH HIGH-RISK DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL): FEASIBILITY AND PRELIMINARY EFFICACY

J. García-Suárez, J.J. Gil-Fernández, Y. Martín, M. Callejas, H. Magro, M. López-Rubio, M.A. Calero, C. Burgaleta

Príncipe de Asturias University Hospital, ALCALÁ DE HENARES (MADRID), Spain

Background. Poor prognosis DLBCL represents 50% of all DLBCL with overall cure rates ranging from 50-60% with modern dose-dense immunochemotherapy regimens such as R-CHOP14. Using an alternative strategy, as infusional and dose-adjusted R-EPOCH, we have shown an 83% of complete responses (CR), with an estimated 5-year overall survival (OS) rate of 75% (*García-Suárez et al. Br J Haematol 2007, 136:276*). Despite this improvement in outcome, the search for new treatment strategies should continue. Therefore, compared with prior R-EPOCH we decided to investigate whether the introduction of dexamethasone (40 mg IV on days 1-5) in place of prednisone (based upon data which demonstrated that the former was associated with enhanced CNS penetration) and the reduction of treatment intervals from 3 to 2 weeks would be feasible and might improve the outcome in this group of patients. *Aims*. To evaluate the feasibility and clinical activity of DA-R-EDOCH-14 as upfront therapy in patients newly diagnosed of poor prognosis DLBCL. *Design and Methods*. Herein,8 consecutive patients (median age 61 years; range 46-73) of an ongoing observational prospective study in newly diagnosed patients with DLBCL and an age-adjusted IPI ≥2 are reported (aaIPI=2 in 25% and aaIPI=3 in 75%). Other patient´s characteristics were: stage IV (100%), high LDH (100%), > 1 extranodal site involvement (50%), ECOG ≥2 (87.5%), bone marrow involvement (25%), and bulky disease (25%). Dose adjusted R-EDOCH-14 was administered every 14 days if feasible for 6-8 cycles, supported by pegfilgrastrim on day 5 in a single per cycle sc dose of 6 mg or filgrastrim with a 6-day schedule from day 6 to 11 at a dosage of 5 µg/kg/d. The type of G-CSF administered was at the discretion of the treating physician (6 patients received pegfilgrastrim and 2 patients filgrastrim). Complete blood counts were monitored at least twice weekly. Toxicity was calculated over 53 cycles administered; feasibilitiy was calculated over 44, since the first cycle in each patient was not susceptible to delay or dose-reduction. *Results*. Of the 44 cycles considered, 31 (70.5%) were delivered on time. Four (50%) patients required dose escalations to achieve an ANC nadir, with 30% of cycles having at least 120% of the entry-dose level. The average RDI was 110% for etoposide, doxorubicin and cyclophosphamide. Grade 4 neutropenia, thrombocytopenia and anaemia were recorded in 70%, 7.6% and 22% of cycles and occurred in 100%, 22% and 44% of the patients, respectively; The median duration of grade 4 neutropenia was 2 days (range: 0-5).The inci-

dence of grade 4 neutropenia in the pegfilgrastrim and filgrastrim cycles was 73% and 66%, respectively. In addition, the mean duration of grade 4 neutropenia was also similar with both G-CSF formulations (2.1 and 2.3 days, respectively). ANC nadir was invariably observed around day 10 to12 of treatment. Only 9 cycles (17% of total) were complicated by neutropenic fever occurring in 4 patients (50% of patients). Severe non-haematological toxicities were registered in 8 cycles (15% of cycles), involving 4 patients (50% of patients). There were no toxicity-related deaths. Out of 7 evaluated patients for efficacy after 10 months follow-up (range: 5-24+), 6 patients (85.7%) achieved CR. *Conclusions*. This ongoing study supports that dose adjusted R-EDOCH-14 is a feasible regimen with no increased toxicity compared with the 3-weekly dose-adjusted R-EPOCH standard regimen. Despite the small number of patients and cycles, our data suggest a comparable neutrophil support with pegfilgrastrim or a 6-day filgrastrim schedule. The CR rate seems very promising even our cohort of patients represent a group with particularly unfavourable outcome.

1711

FALSE POSITIVE PET FINDINGS IN LYMPHOMA MANAGEMENT

J.M. Arguiñano, M.A. Goñi, M.C. Mateos, M.A. Ardaiz, M. Echeveste, M.V. Aznar, Y. Burguete, M. Redondo, I. Ezpeleta, M.J. Paloma, M.A. Labaca, F.J. Oyarzabal

Hospital Virgen del Camino, PAMPLONA, Spain

Background. Positron Emission Tomography (PET) imaging has become a useful tool in assessing lymphoma at diagnosis, during and after therapy. Standard uptake value (SUV) measurement is thought to improve accuracy, even though there is no clear cutting value to differentiate malignant from non-malignant lesions. PET's strongest point is a high negative predictive value; thus a negative PET scan at the end of therapy predicts a very low risk for relapse. Unfortunately positive predictive value is not so high and false positive results remain a major drawback of the technique. At our institution we perform a PET scan at the end of therapy in those patients with lymphoma known to be consistently PET positive (Hodgkin and aggressive non-Hodgkin lymphoma). Additionally a PET scan is obtained in patients with doubtful lymphoma locations at initial staging.

Table 1

	Demographics	Histology at diagnosis	Time from end of therapy to PET imaging	SUV Max	Location	Biopsy result	Follow up
# 1	Female 39 yr	DLBCL	3 weeks	14,8	Retroperitoneum	Fibrosis	63 months
# 2	Female 63 yr	DLBCL	7 weeks	5,36	Lung and hiliar nodes	Mycobacterial infection (culture)	3 months
# 3	Female 30	Hodgkin	10 months	2,69	Mediastinum	Fibrosis	10 months
# 4	Female 72 yr	Non malignant	Initial diagnostic workup	11,1	Tonsil	Tonsil inflammation	8 months
# 5	Female 31 yr	DLBCL	6 weeks	5,2	Illium bone	Bone remodelling	15 months

Case series. We present a series of five patients where PET scans have been considered positive for lymphoma considering SUV values as well as clinical data. In all cases final diagnosis was a nonmalignant process. Biopsy procedures were performed in all cases but one, where microbiological cultures settled final diagnosis. Follow up has been very close and no lymphoma relapse has been detected. Results are detailed in Table 1. *Conclusions*. Despite using SUV values, false positive results are not uncommon in PET imaging for the management of lymphoma. There are cases in which fibrosis, inflammation or infection can resemble malignancy. In this scenario, a new biopsy is essential, thus arising the problem of access to residual nodes or lesions. Although PET improves accuracy in lymphoma management, its use can launch new issues such as the need for biopsy in PET positive images.

1712

CHOLESTEROL AND APOLIPOPROTEINS IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES: A PRELIMINARY REPORT

J. Dzietczenia,[1] A. Chachaj,[2] A. Skoczynska,[1] B. Kreczynska,[1] T. Wróbel,[1] G. Mazur,[1] K. Kuliczkowski,[1] R. Andrzejak[1]

[1]*Wroclaw Medical University, WROCLAW, Poland:* [2]*Wroclaw Medical University, WROCLAW, Poland*

Background. Abnormal plasma lipid levels was observed at diagnosis in patients with various types of cancer, including hematological malignancies. Relationship between low baseline level of cholesterol and poor prognosis in cancer patients is well-established. There are few data regarding possible links between plasma cholesterol or apolipoproteins levels and pathophysiological consequences of tumor growth such as inflammation or activation of coagulation system in patients with hematological malignancies. *Aims*. The aim of the study was to assess plasma cholesterol and apolipoproteins levels and their relationships with laboratory parameters of tumor burden, inflammation status and coagulation/fibrinolysis status in men with newly diagnosed hematological malignancies. *Design and Methods*. The study population included 80 men. Hematological group consisted of 33 de novo diagnosed patients (mean age: 53,85±13,18). There were 15 patients with non-Hodgkin lymphoma (NHL) in stage IV and 1 patient with Hodgkin's lymphoma (HL) in stage II acc. to Ann Arbor Staging System, 15 patients with chronic lymphocytic leukemia (CLL) in stage II (1 patient), III (4 patients) and IV (10 patients) acc. to Rai Staging System, 2 patients with multiple myeloma (MM) in stage II and III of disease acc. to International Staging System. Control group consisted of 47 aged-matched healthy men (mean age: 49,06±10,00]). Nephrotic syndrome, severe renal failure (GFR<40 mL/min/1,73 m^2), hypo- or hyperthyroidism, familial hypercholesterolemia and use of any medication that could affect lipid metabolism were the exclusion criteria of the patients and controls. The following parameters were determined in fasting blood samples obtained from all eligible hematological and control subjects: total cholesterol (TC), low-density lipoprotein-cholesterol (LDL), high-density lipoprotein-cholesterol (HDL-C) and its subfractions (HDL2 and HDL3), triglycerides (TG), apolipoproteins A1 and B (ApoA1, ApoB). Additionally, laboratory parameters reflecting tumor burden (activity of lactate dehydrogenase [LDH]), inflammation status (C-reactive protein [CRP]) and coagulation/fibrinolysis status (D-dimer and fibrinogen) were performed in every hematological patient. In hematological group the blood samples were taken prior to the initiation of chemotherapy. RESULTS: Statistically significant differences between the groups included reduced TC (155,61±43,42 mg/dl in hematological group vs 171,77±27,98 mg/dl in controls; p=0,048), HDL-C (32,57±11,57 mg/dl vs 43,73±8,88 mg/dl; p<0,001), HDL3 (25,89±9,56 mg/dl vs 34,87±7,97 mg/dl; p<0,001), ApoA1 (0,95±0,31 g/l vs 1,44±0,27 g/l; p<0,001) and ApoB (0,98±0,35 g/l vs 1,14±0,27 g/l; p=0,033) levels. ApoA1/ApoB ratio was higher in hematological than in control group (1,20±0,85 vs 0,80±0,18; p=0,003). Plasma levels of LDL, HDL2 and triglycerides did not differed between the groups (p>0,05). There were negative relations between ApoA1 level and LDH activity (r=-0,51; p=0,08) and ApoA1 and CRP levels (r=-0,52; p=0,015). TG correlated with D-dimer and fibrinogen levels (respectively: r=0,38; p=0,031 and r=0,35; p=0,047). *Conclusions*. The study confirms that hematological malignancies are associated with alterations in plasma total cholesterol, its HDL fractions and apolipoproteins levels. Relationships between ApoA1 or triglycerides levels and parameters of tumor burden, inflammation or coagulation/fibrinolysis status require further investigations.

1713

INCIDENCE AND SURVIVAL OF PRIMARY EXTRANODAL LYMPHOMA IN ZARAGOZA (SPAIN)

P. Giraldo,[1] E. Franco-García,[2] R. Alvarez,[1] G. Garcia-Carpintero,[3] M. Pascual,[1] C. Martos[3]

[1]*Miguel Servet University Hospital, ZARAGOZA, Spain;* [2]*Royo Villanova Hospital, ZARAGOZA, Spain;* [3]*Health Department. Aragon Government, ZARAGOZA, Spain*

Background. There are a few studies in order to estimate the differences in incidence and survival of primary extranodal Lymphoma (PEL) compared with nodal. In Zaragoza (Spain) a population-based Cancer Registry (ZPCR) that includes all non-haematological and haematological (HMs) incident cases, is conducted since 1960. *Aims*. To review all cases diagnosed of lymphoma during the period 1992-2004. 2. To estimate the incidence of PEL in the ZPCR registered cases during this period. 3.

To calculate the survival of PEL compared with nodal lymphoma. *Design and Methods*. We had reviewed lymphoma cases occurred in patients residing in Zaragoza(Spain) during the period 1992-2004 that selected from ZPCR. All cases were reviewed in order to confirm the primary location and the morphology classification according to REAL classification. The population at risk was 9.255.818 person-years. The crude (CIR) and age standardized incidence rate (ASR) were calculated, using the European population as standard. Kaplan-Maier method was applied to calculate median survival time and their 95% confidence intervals, as well as 5-year survival. The end of follow-up was 31 Dec 2007 and log-Rank was used to compare survival curves. Results. Among all 4,570 HMs, a total of 1,987 (43.4%) were NHL (CIR: 19x105 person-year), 331 (16.6%) of them were classified as PEL, yielding an ASR of 2.7x105 person-year (males: 183 cases (55.2%), mean age: 59.2 years, ASR: 3.1x105 person-year and females 148 cases (44.7%), mean age: 66.8 years ASR: 2.4x105 person-year. According to topography the most frequent sites were digestive tract (50.4%), skin (19.8%), gland tissue (10.0%), oral cavity-pharynx (7.9%), lung (2.9%), CNS (2.4%), orbit (2.1%) and others (4.5%). The median survival for PEL was 6.61 years (95%CI: 3.7-9.5) and for nodal Lymphomas 5.01 years (95%CI: 4.1-5.9). The 5-year relative survival was 53.5% and 50% respectively. There are not significant differences between extranodal/nodal groups, different locations and gender. The differences in survival were related to histological subtypes. Theses results were similar to those found in the EU, according EUROCARE data. *Conclusions*. The occurrence of PEL according to gender and mean age is similar to nodal NHL. No significant differences in survival were observed between nodal and extranodal NHL, probably the survival is more conditioned by the histology than the location or gender.

Funding: This work has been partially supported by a grant from FEHHA.

1714

HEPATITIS C INFECTION AND NON HODGKIN LYMPHOMA IN 37 EGYPTIAN PATIENTS: A SINGLE INSTITUTE EXPERIENCE

N. Kassem,[1] E. Hamada,[2] S.H. Lasheen,[1] R. Metwally[1]

[1]Kasr-el-Aini Oncology Centre, Cairo University, CAIRO, Egypt; [2]Kasr-el-Aini Oncology Centre, Cairo university, CAIRO, Egypt

Background. Hepatitis C virus (HCV) infection has recently been recognized as a potential cause of developing B-cell lymphoproliferative disorders. Several studies have reported a significantly higher prevalence of HCV in patients with NHL (i.e. 20% in Italy, 6.4% in other European countries,14% in Japan and 11% in USA). HCV is endemic in EGYPT, according to the WHO (*Z. Mesban & A.Wakil; HCV in Egypt _2003*), HCV has been declared a global health problem with approximately 3% of the world's population infected with HCV- Egypt is considered to contain the highest prevalence of HCV in the world, the national prevalence rate of HCV antibodies positivity was estimated by the Egyptian Ministry of Health & Population (MOHP) in 1999 to be 18.9%, with genotype 4 representing over 90% of the cases in Egypt. Aim: Defining the epidemiological aspect of HCV infection in newly diagnosed untreated NHL Egyptian patients with special emphasis on the relationship between HCV infection & NHL, raising the possibility of combining antiviral therapy (Interferon/ribavirin) with lymphoma treatment protocols in HCV +ve NHL patients to achieve better therapeutic outcomes. *Design and Methods*. Sera collected from patients recently diagnosed with NHL presented to our institute between December 2008 through February 2009, 37 patients were screened for the presence of HCV antibodies with commercially available serologic tests. Reverse transcription-PCR was carried out in 6 cases for quantitation of HCV-RNA. Results: Thirty seven patients were included in our study; 24 Males and 13 Females with a mean age of 42 (range 18-65).Twenty six patients (70.3%) were high grade NHL and 11(29.7%) low grade NHL. HCV positive patients were 15(40.5%) and 22(59.5%)were HCV negative. Quantitative RT-PCR was performed for 6 HCV positive patients out of 15 and they were all in the low to moderate viraemia range (1x104_5x105 IU/mL). *Conclusions*. In our study inspite of the limited number of patients results suggest the presence of a correlation between HCV & NHL, but we are still screening patients coming to our institute to establish a statistically significant correlation.

1715

RITUXIMAB AND MALABSORPTION SYNDROME INTESTINAL IN PATIENTS WITH NON-HODGKIN LYMPHOMA. ONE COMPLICATION NOT PREVIOUSLY DESCRIBED

E. Romero Fernandez, M.J. Sanjurjo, R. de Paz, P. Baltasar, A. Lopez de la Guia, M. Canales, F. Hernandez- Navarro

Hospital la Paz, MADRID, Spain

Background. The combination with R to induction chemotherapy improves the overall survival (OS) in patients with non-Hodgkin lymphoma of B lineage (LNHB) and their use in the maintenance treatment of patients with follicular lymphoma improves progression-free survival (PFS). We have observed the occurrence of diarrhea after treatment with rituximab in patients Aims: Assess the development of intestinal malabsorption syndrome in patients treated with R and analyze factors that promote. *Design and Methods*. We reviewed the medical records of 5 patients with NHL treated with R subsequently developed malabsorption syndrome consisting of chronic diarrhea esteatorreica, significant weight loss, abdominal distension, borborigmos, edema and muscle atrophy *Results*. Of the 5 patients (3M and 2H) who developed intestinal malabsorption syndrome, two were follicular lymphoma who were still in remission maintenance therapy with R: 375 mg/m2 dose, 4 doses every 6 months for 2 years. The other three patients (2 NHLDLC and 1 orbital MALT NHL) had received rituximab as part of chemotherapy protocol for remission induction. Three had received FluCy-R diagnosis as the induction protocol. The other two received R-CHOP14 diagnosis. In addition, all were in remission of lymphoproliferative disease. Four patients were ex-smokers and an active smoker. The analytical parameters: hypoalbuminemia, hypoproteinemia, hypocalcemia, hypocholesterolemia, deficiency of folic acid / B12, fat-soluble vitamins and prealbumin. In the radiological study with barium shows acceleration of intestinal transit.Antitransglutaminasa antibodies and antigliadin antiendomysium antibodies unchanged. Parasites in stool and repeatedly negative stool.CMV antigenemia negative. Endoscopic and pathological studies rule out inflammatory bowel disease, colitis and CMV lymphomatous infiltration *Conclusions*. In our series there is a plausible time sequence between the administration of R and the subsequent development of intestinal malabsorption syndrome. Discontinuation of treatment with R produced a significant symptomatic improvement in patients. The use of fludarabine regimens and dose density (R-CHOP14) as part of the induction scheme could encourage the development of malabsorption syndrome in patients treated with R. However, further studies are needed to confirm these findings

1716

POSITRON EMISSION TOMOGRAPHY FINDINGS IN PATIENTS WITH LYMPHOMA-ASSOCIATED HEMOPHAGOCYTIC SYNDROME

C.R. Yiu, D. Tan, C. Phipps

Singapore General Hospital, SINGAPORE, Singapore

Introduction. Haemophagocytic syndrome (HPS) is a clinicopathological entity characterized by systemic proliferation of histiocytes, fever, cytopenia, liver dysfunction, hepatosplenomegaly and often coagulopathy. It is often associated with infection, autoimmune diseases and haematological malignancies, particularly non-Hodgkin's lymphoma. Lymphomas manifesting initially with HPS often pose a diagnostic challenge as the majority of cases have no significant lymphadenopathy for early histological diagnosis. There is paucity of data on specific features of Positron Emission Tomography (PET) in patients with lymphoma-associated HPS (LHPS). *Case Report*. Herein, we describe 3 cases of LHPS and their characteristic PET scan features. These 3 patients had pyrexia of unknown origin and pancytopenia. Extensive workup did not reveal any infection or autoimmune aetiology. The Computed Tomography (CT) findings of all 3 patients were largely unremarkable for significant disease. Their PET scans however showed extensive and diffuse fluorodeoxyglucose (FDG) uptakes in bone marrow of the axial skeleton with little involvement in lymph nodes. Bone marrow biopsies showed evidence of haemophagocytosis in all 3 cases, but only 2 of the marrow trephines confirmed the diagnosis of large B cell lymphoma and peripheral T-cell lymphoma (unspecified). The third case of anaplastic large cell lymphoma was diagnosed by biopsy of a FDG-avid supraclavicular node. *Discussion*. Patients with LHPS often present with fever of unknown origin, associated with cytopenia and liver dysfunction. Lymphadenopathy may be absent or minimal. Histological diagnosis of the lymphoma is often delayed due to its atypical presentation. Bone marrow biopsy is required to confirm the presence of haemophagocytosis

and to detect any lymphomatous infiltration. CT scan may not be sufficient for appreciation of the full extent of the disease. Our 3 cases illustrate the usefulness of PET scan which shows distinctive features of extensive lymphomatous involvement in LHPS, which may otherwise be missed on conventional CT scan.

1717

THE EVALUATION OF EFFICACY AND RELIABILITY OF BIOMED-2 CLONALITY ASSAY IN DIFFERENTIAL DIAGNOSIS OF LYMPHOPROLIFERATIVE DISEASES IN 37 CASES: SINGLE CENTER EXPERIENCE

N. Selvi, D. Aygunes, N. Ozsan, B. Kosova, G. Saydam, S. Cagirgan, M. Tombuloglu, N. Topcuoglu, M. Hekimgil

Ege University Hospital, BORNOVA IZMIR, Turkey

Background. The differential diagnosis of lymphoproliferative disorders has been based on immuno-histochemical findings in specimens. Recent studies have indicated requirement of further analysis, especially for unique cases. Molecular techniques such as clonality assay have been implemented into the diagnosis and follow-up of lymphoid malignancies. AIMS:The aim of this study was retrospective evaluation of 37 cases that were diagnosed as lymphoproliferative disease and assessed for T-and/or B-cell clonality using BIOMED-2. *Design and Methods*. 37 cases were evaluated by Pathology and Medical Biology Departments of our institution between October 2007 and January 2009. The surgically excised samples were sent directly to the Pathology unit and after primary evaluation; samples of cases which need to have molecular confirmation for diagnosis were transferred to Medical Biology unit for clonality assay by using BIOMED-2 primers for either B- or T-cell clonality. Clonality assay was performed according to kit manual and instructions provided by kit. Of 37 patients, 14 were female and 23 were male. The median age was 34.44 years. The source of samples were as follows; 2 blood aspirations, 3 bone marrow aspirations, 1 cerebrospinal fluid, 4 fresh tissue samples (3 lymph nodes, 1 gastroendoscopic biopsy) and 27 paraffin-embedded tissue blocks (13 lymph nodes, 4 bone marrows, 3 gastroendoscopic biopsy, 1 skin, 1 bladder wall, 1 parotis, 1 tonsil, 1 retro-orbital mass, 1 brain biopsy). 20 samples were evaluated for T-cell clonality, 15 for B-cell clonality and 2 for both T-cell and B-cell clonality. *Results* Results are provided in Table 1.

Table 1. The results and the diagnosis of the cases.

Clonality assay	Pre-diagnosis	Confirmation
B-cell	Marginal zone lymphoma	5/7
	Diffuse large B-cell lymphoma	2/2
	Lymphomatoid granulomatosis	2/2
	Follicular lymphoma	1/1
	Nodular lymphocyte predominant Hodgkin lymphoma	0/1
	B-cell acute lymphoblastic leukemia lymphoma	1/1
	B-cell leukemia lymphoma	1/1
T-cell	Peripheral T-cell lymphoma (PTCL)	4/9
	NK/T-cell lymphoma	0/1
	T-cell acute lymphoblastic leukemia lymphoma	1/1
	T-cell chronic lymphocytic leukemia	1/1
	Lymph node infiltration of Mycosis Fungoides	1/1
	Hodgkin lymphoma	1/1
	Dermatopathic lymphadenopathy	1/1
	Reactive lymphoid infiltrate	1/1
	Kikuchi lymphadenopathy	2/2
	Infiltration of CSF by PTCL	0/1
	Hypereosinophilic syndrome ± PTCL	0/1
B- and T-cell	PTCL	0/1
	T-cell rich B-cell lymphoma	1/1

The diagnosis was changed after clonality assessment in 20% of cases by B-cell analysis, in 35% of cases by T-cell analysis, overall 30% of all cases studied. *Conclusions*. Our results have shown that clonality assay by BIOMED-2 multiplex PCR tubes provide a powerful strategy for the differential diagnosis of T- and B-cell malignancies and is essential for the diagnosis of certain cases.

1718

CLINICAL PROFILE OF PATIENTS WITH PRIMARY GASTRIC LYMPHOMA, AND EVALUATION THE R-CHOP REGIMEN. A RETROSPECTIVE STUDY

S. Bougherira, F. Grifi, H. Hamdane

Faculty of medicine, ANNABA, Algeria

Background. In recent years, it has been reported that addition of rituximab of chemotherapy has improved outcomes in several types of non Hodgkin lymphoma (NHL) without significant addition of toxicity. There are many controversies regarding the treatment for primary gastric lymphoma (PGL). The aim was to analyze the clinico-pathologic characteristics of patients with PGL and evaluate the treatment of this disease. *Design and Methods*. This retrospective study enrolled 15 patients with PGL, diagnosed between January 2005 and September 2008. All patients clinical, biochemical, radiological and endoscopic features were evaluated. The histological diagnosis was established by endoscopic biopsies. All patients were treated with chemotherapy with or without surgery, but none of them have received radiotherapy. Results. The mean age was 42 years (range 19 - 68 years), with male predominance. The most common symptom was abdominal pain in 50%, followed by abdominal mass and weakness. Duration of symptoms varied from 15 days to six months. Histological subtypes were Diffuse Large B Cell (DLBC) in 46%, marginal zone B cell NHL of Mucosa Associated Lymphoid Tissue (MALT) in 46% and B small cell in 8%. *Helicobacter Pylori* infection was seen in the majority of MALT type NHL. The surgery was performed to five patients with stag IE PGL. All patients received chemotherapy whose the gold standard was CHOP which is associated to Rituximab. No major toxicities related, response was evaluated by repeat endoscopy after completion of 4 and 6 or 8 cycles. Patients with MALT as histopathology received HP treatment. Fourteen patiets are alive with a median foolow up 30 months (range 04- 54 mo). *Conclusions*. These preliminary data indicate that the R-CHOP regimen was well tolerated and may be effective producing complete remission.

1719

TREATMENT OF PERIPHERAL T-CELL LYMPHOMA UNSPECIFIED SINGLE CENTRE EXPIRIENCE

G. Marjanovic, I. Tijanic

Department of Hematology, NIS, Serbia

Background. The optimal treatment strategy for patients with Peripheral T-cell Lymphoma-Unspecified (PTCL-U) remains controversial. *Design and Methods*. Herein we have retrospectively analyzed 24 cases fulfilling the criteria defined by the WHO classification. All patients were diagnosed and treated at Clinic of Hematology CC Nis, from January 1991 until December 2008, with median follow up of 15 months (range 3-96). Majority of patients 20 (83,3%) received yclophosphamide/doxorubicine/vincristine/prednisone therapy (CHOP). Alemtuzumab combined with CHOP was administered in one case 1 (4, 16%) and high dose therapy regimen "LALA 94" used in acute lymphoblastic leukemia was given in another case (4, 16%). Dose intensified doxorubicin, cyclophosphamide, vindesine, bleomycine and prednisone (ACVBP) plus intensified consolidation was given to 3 patients (12,5%). *Results*. During the first 24 months of follow up, cumulative probability survival was 54, 3%. Factors significantly associated with reduced survival in multivariate analysis were elevated LDH (p=0,027) and complete response vs. no response vs. partial response to therapy (p=0, 0016). There was no difference in remission induction between CHOP and ACVBP groups (2=0.34). Prognostic model PIT was successful in identifying risk group patients (p= 0,030), while simplified two-class PIT seemed to be superior over simplified two class IPI. (p=0, 003179 versus p=0, 017) There was no difference in overall survival among patients treated with CHOP alone and those receiving more aggressive regimens (p= 0,651). Possible explanation might be in high treatment associated mortality given the fact that more aggressive approach was chosen for patients with unfavorable prognosis. *Conclusions*. Aggressive chemotherapy still remains controversial in high risk PTCL-U.

1720

HEPATOSPLENIC γδ T-CELL LYMPHOMA IN A HIV-INFECTED PATIENT: REPORT OF AN EXCEPTIONAL ASSOCIATION WITH EMPHASIS ON CYTOMORPHOLOGICAL FEATURES

L. Morabito, J.M. Raya, I. Ceballos, T. Martin, H. Alvarez-Argüelles, L.M. Gonzalez-del-Castillo, M.R. Aleman, M. Llanos, N. Batista, M.L. Brito, L. Hernández-Nieto

Hospital Universitario de Canarias, LA LAGUNA, Spain

Background. Non-Hodgkin lymphoma (NHL) is the most common AIDS-defining malignancy and most cases are high-grade, aggressive subtypes. Lymphomas occurring more frequently are Burkitt-type, diffuse large B-cell, primary effusion, and plasmablastic lymphomas. T-cell lymphoma comprises only 3% of all AIDS lymphoma, and we have not specifically found, in the revised bibliography, the appearance of hepatosplenic T-cell lymphoma in AIDS patients. *Aims*. We describe a case of hepatosplenic γδ T-cell lymphoma in a HIV-infected patient, an extremely exceptional association. *Design and Methods.* After 13 years from diagnosis of HIV infection, a 37-year-old patient with an irregular compliance to antiretroviral therapy was studied because of fever, dyspnea, abdominal pain, marked hepatosplenomegaly, and a blood count showing WBC $0.5x10^9$/L, haemoglobin 70 g/L, and platelet $78x10^9$/L. At this moment, CD4+ T-cell were $41/mm^3$ and plasma viral load 497 copies/mL. Bone marrow biopsy showed a medium-sized, CD3+ lymphoid cell infiltration with a predominantly intrasinusoidal pattern. With the suspect of hepatoesplenic T-cell lymphoma, splenectomy was performed and pathological analysis showed distended and infiltrated sinusoids by a monotonous population of atypical, CD3+ neoplastic lymphoid cells. A diagnosis of hepatosplenic T-cell lymphoma, stage IVB, was established. Early at postsurgery period, leukocytosis (WBC $24,7x10^9$/L) with a significant lymphocytosis ($19.8x10^9$/L) was detected in blood count, with atypical lymphoid cells at light microscopy (small to medium-sized with non-granular basophilic cytoplasm, irregular nuclei, and a visible, mostly sole, nucleolus). Phenotypic analysis showed T-cells 95,2% and B-cells 3,3%, and two types of T-cells were detected: a majority malignant subset (75%) positive for CD3, CD2, CD7, CD56, CD16, and TCRγδ (negative for CD4, CD8, CD5, CD1a, CD57, CD25, CD11c, and TCRγδ), and a minority subpopulation (18,3%) of normal T-cells (CD3+CD4+ 4,3% and CD3+CD8+ 14,2%). An initial good response to chemotherapy (CHOP) was obtained but, as expected, the course was aggressive and relapse occurred five months later, again as leukemic-phase disease. The patient died after six months from diagnosis. Figures showing morphology and immunophenotypical analysis of peripheral disease expression, and bone marrow and splenic pathological features, are presented. *Conclusions*. The WHO classification of tumours of lymphoid tissues does not mention the blood as site of involvement of hepatosplenic T-cell lymphoma, not even as unusual. In addition, hepatosplenic T-cell lymphoma has not been reported among the rare cases of peripheral T-cell lymphoma occurring in HIV-infected patients. As cited by other authors, we must be awarded that in the antiretroviral therapy era, non-AIDS-defining malignancies account for more morbidity and mortality than AIDS-defining malignancies. For the best of our knowledge, this is the first reported case of a hepatosplenic T-cell lymphoma in a HIV-infected patient.

1721

PEGFILGRASTIM TO SUPPORT R-CHOP Q14 CHEMOTHERAPY IN THE PATIENTS (PTS) WITH AGGRESSIVE B-CELL NON-HODGKIN'S LYMPHOMA (NHL)

E. Capochiani,[1] S. Cupini,[2] S. Bursi,[2] L. Landi,[2] L. Coltelli,[2] N. Giuntini,[2] M. Barletta,[2] G.G. Baldi,[2] I. Stasi,[2] A. Falcone[2]

[1]Haematology Section, LIVORNO, Italy; [2]Oncology Department, LIVORNO, Italy

Background. CHOP chemotherapy administered every 21 days has been the standard regimen for treatment of aggressive NHL for many years. Recent studies have shown improvements in both complete remission and survival following addition of Rituximab to CHOP 21 (*Coffier et al., NEJM 2002*) and following reduction of the cycle length of standard 21 day CHOP to 14 days (*Pfreundschuh et al., Blood 2004*). Previous studies with CHOP 14 have demonstrated the need of filgrastim to allow the administration of chemotherapy at planned dose and on time in this setting. *Design and Methods*. This study evaluates the feasibility of the combination of CHOP plus Rituximab (375 mg/mq) repeated every 2 weeks (CHOP-R 14) supported with a single administration pegfilgrastim (6 mg, on day 2) up to six cycles in pts with aggressive B-cell NHL. *Results*. Up today 21 pts have been enrolled. Patients' characteristics are: median age 65.5 years (46-73), sex 9M/12F, ECOG PS 0(16), 1(4), 2(1), B symptoms 39%, stage I(1), II(7), III(6), IV(7), extranodal location 5 (24%). Overall 95% of pts received full dose chemotherapy on schedule for all planned cycles (range 4-7). Chemotherapy was delayed and dose reduced in 10% and 5% of pts respectively. Main grade 3-4 adverse events per pts were: neutropenia 29%, febrile neutropenia 10%, thrombocytopenia 10%, anemia 24%. One pts died because of treatment related sepsis. Responses at the end of treatment (21 evaluable pts) were: complete 62%, partial 33%. Up today the median follow up is 12,6 months, median PFS is 25,6 months and OS have not been reached. *Conclusions*. These results indicate that the delivery on schedule of dose-dense CHOP-R 14 to pts with previously untreated aggressive B-cell NHL is safe and active with once per cycle pegfilgrastim support.

1722

PROGNOSTIC PROFILE IN THE PATIENTS WITH BALT (BRONCHUS- ASSOCIATED LYMPHOID TISSUE) LYMPHOMA

V. Violeta, A. Bogdanovic, S. Jankovic, B. Andjelic, A. Sretenovic, B. Mihaljevic

Clinical Center Serbia, BELGRADE, Serbia

Background. Bronchus-associated lymphoid tissue (BALT) lymphoma is a rare subtype of low grade B cell marginal zone non Hodgkin's lymphoma. BALT represents 10% of all MALT lymphoma, 3-4% of all extranodal lymphomas and 0,5-1% of all malignans of the lung. The purpose of this study was to analyzed the prognostic profile in the patients with BALT lymphoma. *Design and Methods*. This study included seven patients who had BALT lymphoma diagnosed between January 2001 and April 2008 at the Institute of hematology CCS, Belgrade. Demographic characteristics were as follow: male/female ratio was 2:5 (28,57%:71,43%); the median age was 64 years (range, 37-73). On presentation, five patients (71,43%) had nonspecific respiratory symptoms and all of them had B symptoms. Patients were seronegative for human imunodeficiency viruses (HIV and hepatotropic viruses HCV and HBsAg). Three patients had Sjogren's syndrome, reumatoid arthritis and pulmonary tuberculosis, respectively. The diagnosis was based on open lung at one and transbronchial biopsy at 6 pts. Patohistological findings suggested lymphoma of marginal zone B cell lymphoma, and immunohistological profile confirmed the diagnosis: CD20+/CD10'/CD5'/CyclinD1'/ CD23'/IgM' with Ki-67< 20%. According to the Ferraro staging system, four patients (57,14%) had localized disease (stage I E-II E) and three had stage III E. Bulky tumor mass had two patients. Four patients (57,14%) had ECOG performance status (PS) 0 and three patients had a PS 1. Six patients (71,43%) received chemotherapy consisting of chlorambucil alone (doses was 10 mg p.o. during ten days monthly up to 6 cycles). One patient underwent surgical resection, followed with chlorambucil. Results: A complete response with initial therapy was achieved in two patients (28,57%) and a partial response was obtained in five patients. All the patients were alive during the median follow-up period of 39 months (range 6-82 months). During the follow up period two patients relapsed into the other extranodal localization, but achived stable PR after CHOP regimen and they are regularlly followed up. *Conclusions*. BALT lymphoma tends to be localised disease at the time of diagnosis, responds well to surgical treatment or mono chemotherapy with chlorambucil and has a favourable prognosis.

1723

PRIMARY T-CELL ANAPLASTIC LYMPHOMA ASSOCIATED TO A BREAST IMPLANT: CASE REPORT

P. Mora, A.C. Melo, G.L.S. Amorim, A.A. Scheliga

Oncologistas Associados, RIO DE JANEIRO, Brazil

Background. Breast Non-Hodgkin lymphomas are rare, with approximately 0.04-0.5% of all malignant breast tumors, and the vast majority are B-cell lymphomas. In contrast, T-cell phenotype has been rarely reported and some of these lymphomas are associated to breast implants. The neoplastic cells with T-cell phenotype are $CD30^+$, express cytotoxic granule-associated proteins, EMA and clusterin, and are anaplastic lymphoma kinase-1-negative. *Design and Methods*. We present a case of a woman who recently changed silicone breast prostheses, with a fast growing mass along one implant. *Results*. A 56-year-old white female patient had a recent history of plastic surgery to change old breast

implants, with a normal mammogram one month before the procedure. Nearly two months after the surgery, she noticed a firm nodule in right breast, located at superior limit of the implant. The MRI described a lobulated nodule with 36 x 33 x 24 mm, with early peripheral enhancement, classified as BIRADS V. A right mastectomy with sentinel lymph-node mapping was carried out. The cryosection suggested sarcoma histology. Further pathological analysis (H&E stain) showed undifferentiated carcinoma, with negative axilar lymph node, and the immunohistochemical staining was performed. The neoplastic cells express CD30, CD45, granzyme B, clusterin, CD43 (weak) and TIA-1. They do not express ALK, CD3, CD2, CD5, CD7, CD20, CD15, ER/PR, AE1/AE3, OSCAR, p63, keratin 903, S-100 or EMA. The morpoholgy and immunoperoxidase stains support a diagnosis of anaplastic large cell lymphoma, T-cell phenotype, ALK negative. A postoperative chest and abdominal scan was performed and showed no other sites of disease. She had no laboratory abnormalities and her HIV and HTLV testing were negative. *Conclusions*. This case is unique for its unusual presentation; similar cases have been reported in the literature. Although an increased risk of breast lymphomas in patients with silicone prostheses has been speculated, no studies have been conducted so far.

1724

PEDIATRIC EXTRANODAL NK/T-CELL LYMPHOMA, NASAL TYPE

T. Valiev, A. Kovrigina, N. Sholokhova, N. Tupitcin, G.L. Memtkevich

Paediatric Oncology and Hematology Research Institute, MOSCOW, Russian Federation

Background. Extranodal, nasal-type NK/T-cell lymphoma (ENK/TL) cells express a cytotoxic T-cell or NK-cell phenotype, including CD56 and TIA-1. Nasal-type NK/T-cell lymphomas arise from extranasal sites such as the skin and are often associated with Epstein-Barr virus (EBV) infection. Asian adults are affected most commonly. Very few pediatric cases are reported in the literature, of which only 5 presented with cutaneous involvement. In the current study, we report a case of primary orbital NK/T-cell lymphoma, nasal type with successful chemotherapy treatment. *Aims.* Estimate clinical, morphological and immunological features of pediatric ENK/TL. *Results*. A 13-year-old European boy presented with a 1-month history of right-side exophthalmos in September 2002. His physical examination was significant for right ophtalmoptosis, ophthalmoxerosis, decrement in visual acuity. A computed tomography (CT) scan of the head revealed tumor mass with homogenous structure, sharp contours in a cavity of right orbita (65x23x35mm). Tumor dislocated bulb of right eye, pushed aside optic nerve and bulbar muscles. The tumor was gallium-avid. A CT scan of the left orbita, chest and abdomen revealed no tumor mass. The total serum lactate dehydrogenase activity was normal as a standard peripheral blood test and cerebral fluid. A bone marrow aspiration showed normal cellularity and no tumor involvement was detected by light microscopy. A biopsy of the right orbital tumor mass demonstrated a circumscribed mass of intermediate-sized lymphoid cells, located near the vessels. Tumor cells by immunohistochemical staining for CD57, CD45 and TIA-1 were positive, for CD2, CD3, CD5, CD7, CD10, CD19, neuroblastoma antigens were negative. The stain for EBV latent membrane protein was strongly positive. Flow cytometric analysis demonstrated intense expression of CD56 and weak expression of CD45. The tumor cells were negative for CD4, TCRγ/δ, TCRγ/δ. The patient received treatment on the non-B-NHL-BFM-90 Programme. After 1 phase of I protocol, CT scan revealed a significant decrease in tumor size: 33x10x20mm. ophtalmoptosis decreased, sense of vision improved. After an initial partial response the treatment was continued on HR1-ALL-BFM90M Protocol. After the first course the tumor size was 14x13x70mm., eyesight recovered, ophtalmoptosis disappeared. After HR2 and HR3 courses - 8x4x6mm; therefore the patient was treated with fractioned involved field radiation (36 Gy total). One month after radiation therapy the tumor size was 7x3x6mm, which was estimated as a fibrosis. The last CT scan was on June 2008, the size of fibrosis mass was 7x4x6mm. So at the present moment our patient is a 19-year-old boy, who is alive in a first common remission of extranodal NK-cell lymphoma, nasal type.

1725

IS OBESITY A RISK FACTOR FOR NONHODGKIN MALIGNANT LYMPHOMAS?

A. Mihaila,[1] E.C. Rezi,[2] R. Isaila,[2] G. Boca,[2] R. Mihaila,[3] M. Deac[1]

[1]Lucian Blaga University, SIBIU, Romania; [2]County Clinical Hospital, SIBIU, Romania; [3]Public Health Authority, SIBIU, Romania

Background. Sedentary life and hypercaloric diet is favoring the weight gain and obesity. In present, there are discussions regarding the pathways among which obesity is involved in oncogenesis. *Aims*. Our aim was to study if there is any correlation between the body mass index (BMI) and non-Hodgkin malignant lymphomas. *Design and Methods*. We have studied a group formed by all the 56 patients with non-Hodgkin malignant lymphomas who were in the evidence of the Hematology Department from the County Clinical Hospital from Sibiu in 2008 (group A) and a group of 64 consecutive patients with non-malignant diseases, who were hospitalized in the Second Medical Department of the same hospital in the first half of February 2008 (group B). At the two studied groups, we have analyzed: age, height, weight, BMI, blood pressure or the presence of arterial hypertension diagnosis, glycemia or the diabetes mellitus diagnosis, triglycerides, cholesterol levels or the diagnosis of dyslipidemia. We have compared the results of the two studied groups and we have statistically analyzed them using the t Student test. *Results*. The average age of the patients from group A was 64.82±11.04 years, which did not differ significantly from the one in group B. The BMI was significantly higher in group A (26.29±3.5 kg/m^2), comparing with group B (23.82±2.75 kg/m^2) (p=0.032). Arterial hypertension was significantly more frequent in group A comparing with group B (p=0.041). The number of components of the metabolic syndrome was significantly higher in group A comparing with group B (p<0.0001). There were no significant differences between the two groups regarding the levels of glicaemia, cholesterol or triglycerides. *Summary*. In our group of patients with non-Hodgkin malignant lymphomas, BMI, arterial hypertension and the number of components of the metabolic syndrome were significantly higher comparing with the ones of the patients with non-malignant diseases, fact which sustains the idea that overweight and obesity could constitute a risk factor for non-Hodgkin malignant lymphomas. It will be useful to investigate, by multicentric studies, on a higher number of patients, this association, and the possible role of weight loss on the risk and evolution of malignant hemopathies.

1726

EFFICACY AND TOLERABILITY OF LIPOSOMAL DOXORUBICINE IN CARDIOPATHIC PATIENT WITH NON HODGKIN LYMPHOMA

A. Lucania,[1] P. Della Cioppa,[1] M.R. Villa,[1] M. Esposito,[1] S. Improta,[1] G. Nitrato Izzo,[1] M. Mallardo,[2] L. Mastrullo[1]

[1]ASL NA1 San Gennaro, NAPLES, Italy; [2]ASL NA1 San Gennaro U.O.C. Cardiologia, NAPLES, Italy

Background. R-CHOP protocol is the gold standard treatment for Non Hodgkin's Lymphoma and doxorubicine is the drug with the higher antitumoural activity. However, disease (cardiotoxicity, drug-resistence, etc.) and patient characteristics (advanced age, comorbidity) limit the use of that protocol. In frail patients the use of liposomal anthracycline instead of classic one may reduce cardiotoxicity even though manteining the same antitumoral efficacy (i.e. R-COMP regimen). *Aims*. We investigated the use of liposomal doxorubicin in patients affected by NHL with associated cardiopathy. *Design and Methods*. From 2003 to 2008, in our Haematology Unit ASL NA-1 we treated 24 patients affected by NHL. All patients were affected by heart diseases (heart failure, atrial fibrillation, etc.). All the patients underwent echocardiographic evalutation of left ventricular ejection fraction (LVEF%) before starting treatment, during treatment and 3, 6, 12, 18, 24 months after the end of therapy. Patients' characteristics were: 16 male and 8 female; median age 69 years (range: 66-80); istology: 14 Diffuse Large B Cell Lymphoma (DLBCL), 4 cutaneous NHL; 3 Mantle Cell Lymphoma (MCL) and 4 Follicular (G3) Lymphoma. At diagnosis LVEF was less than 50% (35-45%) in all patients. *Results*. One month after the last cycle all patients were subjected to a disease re-staging: 85% of patients were in CR, 12% in PR, 3% in progression disease or resistance. Nobody had a reduction of LVEF; interestingly, 2 out of 24 patients showed an improvement of LVEF. Overall survival (+24 months) was 85%. *Conclusions*. We confirm the efficacy of R-COMP regimen in the treatment of NHL. Moreover, the use of liposomal anthracycline allows the treatment of cardiopathic patients with aggressive lymphoma. Further studies are warranted to confirm the safety and effectiveness of polichemotherapy with liposomal anthracycline in NHL frail patients.

1727

AUTOIMMUNE HEMOLYTIC ANEMIA AS A RISK FACTOR OF POOR OUTCOME IN PATIENTS WITH SPLENIC MARGINAL ZONE LYMPHOMA

A. Fodor,[1] M.Z. Molnar,[2] L. Krenacs,[3] E. Bagdi,[3] J. Csomor,[4] A. Matolcsy,[4] J. Demeter[5]

[1]Semmelweis University, BUDAPEST, Hungary; [2]Department of Transplantation and Surgery, Semmelweis University, BUDAPEST, Hungary; [3]Laboratory of Tumor Pathology and Molecular Diagnostics, SZEGED, Hungary; [4]1st Department of Pathology and Experimental Cancer Research, Semmelweis Univer, BUDAPEST, HungaryP; [5]1st Department of Internal Medicine, Semmelweis University, BUDAPEST, Hungary

Background. Splenic marginal zone lymphoma is a rare disease, accounting for 1% of all lymphomas. The main disease features are splenomegaly, lymphocytosis and cytopenias often related to hypersplenism. Autoimmune phenomena are present in 9 to 20% of patients. SMZL generally has an indolent clinical course with a median survival of 10 years, and a 5-year survival rate of 70%. *Design and Methods*. We reviewed our single center experience of 13 patients with SMZL, where long term (at least three years) follow-up data are available. Results: Based on the prognostic model developed by Integruppo Italiano Linfomi 31% (4/13) of our patients had good, 38% (5/13) had intermediate and 31% (4/13) had a poor prognosis. The presence of two out of three prognostic factors (anemia, elevated LDH, low serum albumin) assignes the patient into the high risk category. In patients with anemia and an elevated LDH due to hemolysis, the outcome seems to be especially poor. Three out of 13 (23%) cases were complicated by autoimmune hemolytic anemia. All patients with AIHA died 7-28 months after the diagnosis. The mean follow-up time of those nine patients (69%) who are still alive is longer than 5 years (42-106 months). SMZL patients with AIHA had significantly (p<0.001) worse survival than those without AIHA. *Conclusions*. The main finding of our study is that the presence of AIHA is an adverse prognostic factor in SMZL.

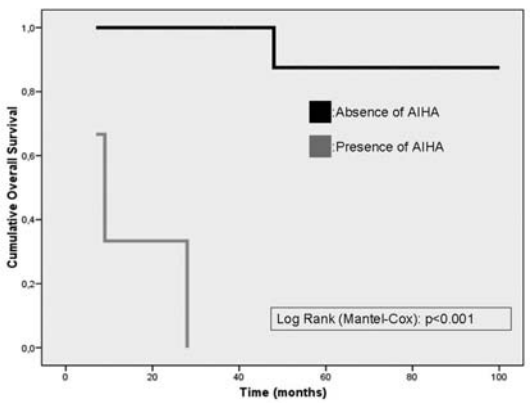

Figure 1. Presence of AIHA and survival in our patients.

1728

CORRELATION OF PRETREATMENT VALUES OF S - VEGF AND PLATELET LEVELS IN DIFFUSE LARGE B CELL LYMPHOMA PATIENTS

N. Milanovic1,[1] D. Ristic,[1] S. Matkovic,[1] S. Jelic,[1] M. Petrovic[2]

[1]Institute of Oncology and Radiology of Serbia, BELGRADE, Serbia; [2]Institute of Hematology, BELGRADE, Serbia

Background. Level of S - VEGF above median value is an early poor prognostic indicator for CRR and OS in diffuse large B cell lymphoma patients (*Pedersen et. al. 2005*). Platelets are the main source of VEGF in cancer patients with *dynamic equilibrium* of VEGF amount in platelets and circulation (*Gunsilius et al. 2000*). Platelet level above normal is accompanied with high pretreatment values of S - VEGF but without any influence on lymphoma patients survival (*Salven et. al., 2000*). *Aims*. To define possible correlation between pretreatment values of S - VEGF with platelet levels and relations to response rate and overall survival. *Design and Methods*. Serum samples of 50 DLBCL patients were collected at out institution between February 2006. and July 2007. and tested by ELISA S - VEGF Amersham Biotrak. Patients were under surveillance for a study since August 2008.g. Two S - VEGF categories were established: under or above median m S - VEGF - cat 1. and cat 2., with correspondent values of platelets below and above normal level (450 000). Groups were tested for complete response rate (CRR) and median overall survival (OS). *Results* - Patients were divided according to VEGF categories and categories with normal and elevated platelets (Tables 1 and 2).

Table 1. VEGF category range number pts.

cat 1. < 111,68 pg/ml	15,0 - 109,8 pg/mL	25
cat 2. > 111,68 pg/mL	111,3 - 1009,5 pg/mL	25

Table 2. Platelet category range number pts.

platelet level < 450 000	105 000 - 435 000	35
platelet level > 450 000	453 000 - 726 000	11

***NA = 4.**

Relations between s - VEGF categories and platelets levels below and above normal were:

Table 3. Category platelet level < 450 000 platelet level > 450 000.

cat 1. < 111,68 pg/ml	21 (84%)	2 (8%) *
cat 2. > 111,68 pg/ml	14 (70%)	9 (36%) **

*** NA = 2 (8%) ** NA = 2 ((%), (Fisher Exact test: p = 0,035)**

Two separate categories of patients were formed by s - VEGF and platelets levels. Those categories were compared on complete response (CR) vs. no complete response (no CR) (Table 4)

Table 4. Category CR no CR.

cat 1. <111,68 pg/mL and platelet level < 450 000	17 (80,95%)	4 (19,05%)
cat 2. > 111,68 pg/mL and platelet level >450 000	5 (35,71%)	9 (64,29%)

(Fisher Exact test: p = 0,019)

and by median overall survival (mOS) (Table 5).

Table 5. Category m OS 95%CI number pts.

cat 1. <111,68 pg/mL and platelet level < 450 000	inf * inf-inf	21
cat 2. >111,68 pg/mL and platelet level > 450 000	13 8-inf	9

(inf * - not reached)

(Log-Rank test: X -2 = 4,7; df = 1; p = 0,031)

Conclusions. Patients with low serum level of VEGF and normal number of platelets and high serum level of VEGF and elevated number of platelets are two distinct categories of diffuse large B cell lymphoma patients. There is statistically better complete response rate (CRR) and longer median overall survival (m OS) in category of patients with low serum VEGF level and normal number of platelets.

1729

EVIDENCE OF GVL EFFECT IN NK/T CELL/NASAL TYPE LYMPHOMA: A CASE REPORT

M. Cimminiello,[1] I. Attolico,[1] N. Filardi,[1] M. Pizzuti,[1] M. Poggiaspalla,[1] D. Vertone,[1] G. Morlino,[1] T. Pierri,[2] R. Chiacchio,[3] V. Lalinga,[3] G. Nacci,[4] A. Olivieri[1]

[1]U.O. Hematology, POTENZA, Italy; [2]Servizio Trasfusionale, POTENZA, Italy; [3]U.O. di Anatomia Patologia, POTENZA, Italy; [4]U.O. Neuroradiologia, POTENZA, Italy

Mature T/natural killer lymphoma/leukemias (T/NK L) represent 5-15% of all non-Hodgkin lymphoma. Prognosis is poor, with 5-year survival less than 30% (except for anaplastic lymphoma) and there is no consensus about therapy. Autologous stem cell transplantation (ASCT) might be an option in these patients. Conventional allogeneic stem cell transplant might be considered in some high-risk patients. We report a 60 years old man who came to our observation on February 2007 complaining of fever, nasal obstruction and multiple subcutaneous nodular lesions; head CT scan revealed a large rynopharingeal mass, involving ethmoidal and maxillar sinus; biopsy of the mass showed findings of extranodal T cell/NK nasal type lymphoma. Total body CT scan and bone marrow biopsy were normal; EBV was negative. Patient received 3 courses of CHOP, with Campath 1H at day 1 (C-CHOP), with a partial response. Second line therapy was Hyper-Cydam was stopped because of a second lymphoma progression; patie nt underwent allogeneic transplant from compatible, conditioning regimen was Thiotepa, Fludarabine and Cytoxan; GVHD prophylaxis was made with Cyclosporine and Methotrexate; patient received Peripheral Blood Stem Cells. During the aplastic phase there was CMV reactivation; engraftment was rapid and complete. No acute GVHD was present when the patient was discharged. One month after transplant all cutaneous lesions had disappeared, rinopharingeal mass persisted, albeit slightly reduced; chimerism showed a full donor pattern. Cyclosporine was quickly reduced and patient developed a grade III acute GVHD, (skin rash and diarrhea) requiring steroids. A CTscan performed 8 weeks, after GVHD onset, showed a consistent reduction of rynopharingeal mass. We observed several flares of intestinal GVHD, requiring steroids; the last CT scan, 7months after transplant, documented complete disappearance of rynopharingeal mass, without other signs of Lymphoma. Up to now the patient is alive and i n Continuous CR, with sporadic intestinal GVH flares, responding to intermittent steroid administration..Our experience shows that even in a patient with extranodal disease, refractory to 3 lines of chemotherapy, RIC transplantation achieved a dramatic response and the rapid withdrawal of immunosuppression after transplant was followed by complete disappearance of lymphoma, contemporaneous with the acute GVH onset, strongly arguing for a potent GVL effect also in this particular setting of patients.

1730

EFFICACY AND SAFETY OF INTRATHECAL LIPOSOMAL CYTARABINE IN COMBINATION WITH METHOTREXATE AND STEROIDS FOR THE TREATMENT AND PROPHYLAXIS OF LEUKEMIC AND LYMPHOMATOUS MENINGITIS: A SINGLE INSTITUTION EXPERIENCE.

E. Vigna,[1] M. Gentile,[1] C. Mazzone,[1] E. Lucia,[1] L. Morabito,[2] R. Morelli,[1] M.G. Bisconte,[1] C. Gentile,[1] F. Morabito[1]

[1]U.O. Ematologia Ospedale Civile dell'Annunziata di Cosenza, Italy., COSENZA, Italy; [2]Hematology Department, Hospital Universitario de Canarias, La Laguna, Tenerife, TENERIFE, Spain

Background. Intrathecal (IT) chemotherapy is an important component of the prophylaxis or treatment of hematologic malignancies in the central nervous system (CNS), especially in patients with acute lymphoblastic leukemia and aggressive lymphomas. The three commonest IT drugs are methotrexate, cytosine arabinoside (Ara-C), and corticosteroids. Liposomal cytarabine (Depocyte) is a sustained-release formulation of cytarabine developed for intrathecal administration, ensuring prolonged cytotoxic drug concentrations of cytarabine in cerebrospinal fluid. Liposomal cytarabine permits to decrease frequency of lumbar punctures, without loss of efficacy, because intrathecal levels of the drug remain cytotoxic for up to 14 days. *Aims*. With the aim to evaluate the safety and efficacy of treatment and prophylaxis schedule with methotrexate, liposomal cytarabine and methyl-prednisolone. *Design and Methods*. From October 2007, 6 patients affected by aggressive lymphomas (HG NHL) (5 cases) and acute lymphoblastic leukemia (ALL) (1 case) underwent CNS prophylaxis with methotrexate 12 mg, liposomal cytarabine 50 mg and methyl-prednisolone 40 mg IT every 15 days in our Institution. Moreover 2 patients (HG NHL 1 pt and ALL 1 pt) have been treated with same schedule for neoplastic meningitis. The clinical and hematological features of the patients were: 6 males, 2 females; median age 60 yrs (range: 32-73). *Results*. After a median follow-up of 9 a total of 80 lumbar punctures have been administered. In any case a III-IV WHO grade toxicity has been observed. All 6 patients undergone prophilaxis did not show the occurrence of neoplastic meningitis. The remaining 2 patients treated for neoplastic meningitis showed a complete clearance of blasts after a median of 3 lumbar punctures and are still in remission. *Conclusions*. In conclusion, although the relatively low number of cases, simultaneous IT administration of methotrexate, Liposomal cytarabine and corticosteroids was well tolerated and appeared to be particularly effective in the prophylaxis for aggressive lymphomas patients and acute lymphoblastic leukemia patients, who achieved long term remission. Certainly, confirmation in a larger cohort of patients is now warranted

1731

PRIMARY B-CELL CUTANEOUS LYMPHOMA - A SINGLE INSTITUTION EXPERIENCE

A. Colita,[1] A.R. Lupu,[1] C. Saguna,[1] G. Barca,[1] O. Ciocan,[1] M. Closca,[1] A. Ciobanu,[1] A.M. Ivanescu,[1] M. Oprea,[1] S. Angelescu,[1] D. Barbu,[1] C. Dobrea[2]

[1]Coltea Hospital, BUCHAREST, Romania; [2]Fundeni Clinical Institute, BUCHAREST, Romania

Background. Primary cutaneous B cell lymphomas (PCBCL) represent a rare form of non-Hodgkin's lymphoma (NHL). The new WHO-EORTC classification for cutaneous lymphomas distinguishes 3 main types of PCBCL: primary cutaneous marginal zone B-cell lymphoma (PCMZL), primary cutaneous follicle center lymphoma (PCFCL), and primary cutaneous diffuse large B-cell lymphoma, leg type (PCDLBCL,LT). PCBCL have good overall prognosis with a high response rate to therapy but with almost half of cases relapsing al least once. PCDLBCL,LT has poorer prognosis than the other two types of PCBCL. There is no standard treatment but several studies have shown long term survival with surgery, radiation, chemotherapy and/or immunotherapy. Most institutions use radiation therapy as the main modality after excisional biopsy. *Aims*. To analyze the clinical features and therapy outcome in patients from our Hematology Department. *Design and Methods*. we diagnozed 5 cases during the last 5 years (3 males, 2 female) with ages ranging from 24 - 79 (median 61 years); 1 case was PCMZL, 3 cases with PCFCL and 1 case of PCDLBCL with multifocal, extended cutaneous and subcutaneous involvement. Initial evaluation was made by physical examination, blood counts, biochemistry, chest radiograph, computed tomographic scan of chest and abdomen, bone marrow biopsy. Neither of the cases had bone marrow involvement; in the case of diffuse B cell cutaneous lymphoma, we noted moderate splenomegaly preceding the NHL in the context of chronic C virus hepatitis. The follow-up ranged from 4 to 62 month (median 8 month). Results: The initial therapy consisted in excision and local radiotherapy (20Gy) in 1 case of marginal zone lymphoma (PCMZL) and 1 case of follicular lymphoma (PCFCL) with single lesion, limited disease. In 1 case of limited PCFCL, only excision was performed. All cases are in complete remision after a median follow-up of 6 month. The third case of follicular cutaneous lymphoma was diagnosed 2 years after the onset of the first lesion. At diagnosis, he had several lesions limited to the left supraclavicular area so that the initial treatment consisted in 4 ×CHOP chemotherapy followed by complete remision. He relapsed after 1,5 years at the same site but also with regional lymphadenopathy and received 6 R-CHOP courses with the achievement of a second remision (still lasting after 18 month). The case with diffuse lymphoma, aged 79, presented at diagnosis with extended cutaneous involvement and subcutaneous extension of the lower anterior thoracic region and of the upper anterior abdomen. After 4 CEOP courses we observed the remision of cutaneous lesions and of subcutaneous infiltrates. *Summary*. PCBCL are rare lymphomas. Generally, at onset the disease is limited with single lesions; excision +/- local radiotherapy is followed by remission. In the case of extended, multifocal disease we reported relapse in the first 2 years involving also the regional lymphnodes with good response to immuno-chemotherapy. According to the WHO-EORTC classification which divides PCBCL into two main groups, with PCDLBCL,LT having poor prognosis, we treated our case with systemic chemotherapy despite the advanced age - with favorable outcome.

1732

AN UNUSUAL CASE OF PRIMARY RENAL LYMPHOMA DISSEMINATING TO BONES

A. Arcari, D. Vallisa, P. Bernuzzi, C. Bosi, A. Lazzaro, C. Moroni, E. Trabacchi

Piacenza Civil Hospital, PIACENZA, Italy

Background. Diffuse large B cell lymphoma (DLBCL) represents approximately 30% of all non-Hodgkin's lymphoma (NHL) and is characterized by a relatively frequent extranodal involvement. A simultaneous multifocal extranodal involvement is quite rare. Most of these cases arise in the gastrointestinal tract (stomach and/or bowel), with or without other extranodal disease localizations such as lung or bone. A renal involvement can be demonstrated during widespread diffusion of advanced-stage NHL. Among all cases of NHL with a renal involvement at diagnosis, only a minority has a renal localized origin without distant lymph nodes and meets the criteria for primary renal lymphoma. This is a very rare entity, often with an aggressive clinical course and a rapid subsequent dissemination. *Results*. We described here an unusual case of extranodal DLBCL diagnosed as a renal mass associated with multiple osteolytic lesions. A 50-year-old man presented with a 3-month history of left flank pain and an episode of gross hematuria. Computed tomography (CT) of the abdomen revealed a large tumor mass of the left kidney, without locoregional or distant lymph node involvement. A radical nephrectomy was performed under a preliminary diagnosis of renal cell carcinoma, but histological examination of the kidney revealed a diffuse large B cell NHL. Clinical staging was then completed by a CT scan of thorax and neck and bone marrow biopsy, with negative results. Because of the occurrence of right knee pain, a magnetic resonance imaging (MRI) was also performed, showing a large osteolytic lesion of femoral epiphysis. A US-guided fine needle aspiration biopsy showed a NHL infiltration. A subsequent total body fluorodeoxyglucose-positron emission tomography (FDG-PET) confirmed multiple bone lesions of right femur, ischium, and jaw. Considering the high risk presentation of this case (advanced stage with multiple extranodal involvement and abnormal LDH), we choose an intensified immunochemotherapy with the R-CHOP 14 scheme. The patient received also bisphosphonate infusions, with great clinical benefit. A complete restaging after the fourth cycle showed a good partial response (FDG-PET was slightly positive only at right knee). The patient underwent other four cycle of R-CHOP 14, achieving a final complete haematological remission. *Conclusions*. This is a case of aggressive B cell NHL probably arising in the kidney (principal mass detected at diagnosis) and rapidly spreading to bones. Also in this poor-risk presentation, an intensified immunochemotherapy allowed a complete clinical remission.

1733

CENTRAL NERVOUS SYSTEM MANIFESTATION OF PRIMARY EFFUSION LYMPHOMA IN A HIV-NEGATIVE PATIENT

S. Doerr,[1] B. Kurzidim,[2] M. Hildebrandt,[2] S. Stein,[3] W.D. Ludwig[2]

[1]Rössle Klinik im HKBB, BERLIN, Germany; [2]Helios Klinikum Berlin, Robert-Roessle-Clinic, BERLIN, Germany; [3]Institute for Pathology, Campus Benjamin Franklin, Charité University Medicine B, BERLIN, Germany

Background. Primary effusion lymphoma (PEL) is a rare neoplasm of large B cells that usually presents as a serous effusion without detectable tumor mass. It is associated with Human Herpes Virus (HHV)-8 infection and occurs virtually exclusively in the setting of immunodeficiency. PEL accounts for 4% of all HIV-associated Non-Hodgkin lymphomas and for less than 1% of all NHL in HIV negative patients. Establishing the diagnosis of PEL requires HHV 8 presence. *Case report*. A 67 year-old Caucasian woman presented with a two months history of dyspnoea, fever and cough with bloody expectoration. CT scans revealed a pulmonary mass, massive pleural effusion, and a pararenal mass on the left side. The histological and cytological workup of effusion and solid pulmonary mass showed pleomorph cells expressing leucocyte antigen (LCA) but no cytoceratins. Immunocytochemistry was strongly positive for CD45 and VS38, slightly positive for CD138, and negative for CD38. B or T cell- markers, markers for a lymphatic source of the tissue (incl. CD79a, CD30, CD43, CD2), light chain restriction, or clonal IgH/ TCR γ rearrangement were not detected. The staining for HHV 8 was strongly positive. Laboratory workup revealed a leucocytosis, lymphopenia with a shifted CD4/CD8 ratio, and a hypercortisolism. Based on the morphology, pattern of surface markers and HHV8 positivity the diagnosis of a primary effusion lymphoma (PEL) was established. Screening for human immunodeficiency virus (HIV) was negative. After 7 cycles of chemotherapy according to the CHOP-14 regimen a partial remission was achieved. However after three month a massive progression of disease required salvage chemotherapy. ICE regimen (ifosphamide carboplatin, etoposide) was used for stem cell mobilization and followed by one course high dose chemotherapy according to BEAM regimen (BCNU, etoposide, cytarabinoside, melphalan) and autologous stem-cell transplantation. The therapy was well tolerated and the CT scan showed a partial remission. Two month later the patient noticed a progressive bilateral visual loss. Cranial CT scan showed bilateral occipital contrast enhancing lesions. Chest CT scans revealed a massive progression of both thoracic tumor mass and effusion. Extended blood and cerebrospinal fluid (CSF) workup including microbiological and serological investigations was unremarkable. Since cerebral manifestation of PEL has never been proven an opportunistic infection of the central nervous system (CNS) was taken into consideration. When the patient's condition deteriorated to blindness and severe dementia a stereotactic brain biopsy confirmed a CNS manifestation of PEL. The patient refused any further treatment and died six weeks later. *Conclusions*. In summary, we here report the first histologically confirmed CNS manifestation of PEL in a HIV negative patient. A biopsy-proven CNS manifestation has not been reported so far. We emphasize, that normal CSF studies do not exclude CNS involvement and suggest that in PEL patients presenting with symptoms or signs suggestive for a CNS dysfunction, cerebral manifestation of PEL should be taken into consideration.

1734

TREATMENT OF DEEP VENOUS THROMBOSIS WITH LOW MOLECULAR WEIGHT HEPARIN IN PEDIATRIC CANCER PATIENTS:SAFETY AND EFFICACY DATA

K. Tousovska,[1] O. Zapletal,[1] J. Skotakova,[1] J. Bukac,[2] J. Sterba[1]

[1]University Hospital, HRADEC KRALOVE, Czech Republic; [2]Faculty of Medicine, Charles University, HRADEC KRALOVE, Czech Republic

Background. There are very little data regarding treatment of venous thromboembolism in children undergoing chemotherapy. *Aims*. We designed this study to unify treatment of venous thromboembolism in oncology pediatric patients at our department. At the same time we wanted to evaluate safety and efficacy of the newly designed treatment schedule. *Design and Methods*. Data from the pediatric oncology patients with deep venous thrombosis (DVT) treated at the Dept.of Pediatric Oncology, Brno, were collected prospectively over a 2-year period (January 1, 2006 - December 31, 2007). All patients received low molecular weight heparin (LMWH) at the intitial dose of 1.2 -1.5 mg /kg body weight twice daily subcutaneously (s.c.) for the first 7 - 10 days. Afterwards, the dose was lowered to 1.5 mg / kg s.c. once daily. We kept this dose unchanged for a minimum of 3 months.For the first 6 weeks of treatment the platelets were maintained ≥20x10^9/l with no LMWH withdrawal. For the rest of the treatment, LMWH was interrupted once platelets reached 20x10x10^9/l. *Results.* A total of 33 patients were followed for a median of 6 months. DVT was symptomatic in 15/33 patients (46%) and asymptomatic in 18/33(54%) patients. Complete thrombus resolution occurred in 22/33(67%) patients, partial or no recanalization was achieved in 11/33(33%) patients. Eight patients (8/33;24%) were diagnosed with posthrombotic syndrome (PTS). The risk of PTS was significantly higher for patients with symptomatic DVT compared to those with asymptomatic DVT . Neither patency rates nor the risk of PTS showed a positive correlation with the achievement of therapeutic anti Xa activity. Thrombocytopenia <20x10^9/l occurred at least once during LMWH treatment in 30/33(91%) patients. None of the patients experienced severe bleeding whereas mild bleeding episodes were observed in 5/33(15%)patients. *Conclusions*. Our treatment schedule has proved to be both safe and reasonably efficient in treating of DVT in children undergoing chemotherapy. Further studies on larger patients groups are warranted.

1735

INTRODUCING A USEFUL MONOCLONAL ANTIBODY FOR THROMBOLYTIC THERAPY

A. Maleki,[1] M. Akrami,[2] M. Mirshahi[2]

[1]Social Security Organization, KERMANSHAH, Iran; [2]Tarbiat Modares University, TEHRAN, Iran

Background. Human plasminogen is a single-chain glycoprotein of 92 kDa, consisting of 791 amino acid residues and contains five kringles. Several monoclonal antibodies (mAb) against specific parts of the human plasminogen molecule have been developed. *Design and Methods*. In this

study, we investigated the effects of an anti-human plasminogen monoclonal antibody, A1D12 on Glu-plasminogen activation in presence of u-PA, t-PA and streptokinase. The kinetic activation of Glu-plasminogen by it`s activators (u-PA, streptokinase and t-PA) in presence of A1D12 following the effects of the antibody and its comparative ligands on conformational changes of two plasminogen forms by fluorescence and circular dichroism spectroscopy were investigated. Enhancing of β-structure percentage of Glu-plasminogen in presence of A1D12 according to CD-spectra study was coinciding with higher fluorescence intensity in Glu-plasminogen-FITC than Lys-plasminogen-FITC by A1D12 inducing. *Results*. A high similarity between EACA and A1D12 in inducing of Glu-plasminogen conformational changes was concluded. The kinetic analysis of the time course of Glu-plasminogen activation at varying concentrations of S-2251 showed that the A1D12 increased catalytic efficiency of Glu-plasminogen activation by all plasminogen activators without changing in KM values significantly. Thermal inactivation studies also confirmed the conformational change results. We suggested that the binding of A1D12 from F(ab) region to N-terminal epitope of Glu-plasminogen following conformational changes to a more open structure enhanced catalytic efficiency of activation reactions. *Conclusions*. It may be useful to apply clinically monoclonal antibody A1D12 for the therapy of some thromboembolic events by humanizing the F(ab) region of the antibody.

1736

ORAL ANTICOAGULANT THERAPY WITH ACENOCUMAROL IN ELDERLY PATIENTS OLDER THAN 85 YEARS: COMPARATIVE ANALYSIS WITH ANTICOAGULATED PATIENTS BETWEEN 60 AND 70 YEARS OF AGE

P. Machado, T. Martin, L.M. Perez, J.M. Raya, L. Morabito, L.M. Gonzalez-del-Castillo, M.L. Brito, J.M. Rodríguez-Martín, L. Hernández-Nieto

Hospital Universitario de Canarias, LA LAGUNA, Spain

Background. It has been postulated that oral anticoagulant therapy (OAT) in elderly patients is associated with a higher hemorrhagic risk due to three main reasons: the concurrence of another diseases, possible pharmacological interactions and a poor ambulatory control (mostly secondary to a dependence on other persons and a poor understanding of treatment). *Aims*. To analyse OAT in a wide group of patients older than 85, and to compare this series with a control group from 60 to 70 years of age. *Design and Methods*. We have retrospectively studied a group of 58 patients who began OAT over 85 years old (median 88.6 years, range 86-95) and a group of 91 patients that began the treatment when they were between 60 and 70 years of age (median 63.3 years, range 60-70), the latter group randomly chosen from our database. Taking into account that there were not carriers of prosthetic heart valves in the group of patients older than 85, we only included patients with indications to maintain INR between 2.0 to 3.0 in both groups. The most frequent indications in the group over 85 years were isolated atrial fibrillation (75%) or associated with ischemic ictus (9%) or coronary cardiopathy (8%); in the 60-70 years old group, isolated atrial fibrillation accounted for 57% of patients, and 10% associated with ictus, being miocardiopathy the third main indication (9%). As valuable variables, we included in both groups the time of follow-up under OAT (F, in months), the number of analytic measurements in the same time (NAM), the NAM/months of follow-up ratio, the median INR value, the acenocumarol weekly dosage (total mg/week), the percentage of INR values within therapeutic range, and the presence of hemorrhagic or thrombotic events during OAT. The statistical analysis included Student´s t and Jonckhere-Terpstra´s tests.

Table 1

Variable	Group 60-70 years (n= 91)	Group > 85 years (n=58)	p value
Patients with isolated atrial fibrillation (%)	57	71	0.09
Follow-up (F, months)	24.7 ± 12.2	21.6 ± 12.4	0.14
NAM / F – Ratio	1.08 ± 0.23	1.09 ± 0.22	0.78
Median INR value	2.57 ± 0.34	2.48 ± 0.35	0.12
Weekly average dosage (mg)	17.07 ± 7.65	12.47 ± 4.89	<0.001
INR within therapeutic range (%)	56 ± 15	48 ± 17	0.003
Major hemorrhagic events	1	3	0.16
Thrombotic events	None	None	0.30

Results. Main findings are expressed in the following table (percentage or median and standard deviation). *Conclusions*. In our experience, anticoagulated patients older than 85 years of age do not need analytic controls more frequently than those between 60 and 70, although the percentage of INR values within therapeutic range is significantly lower in these elderly patients. As described by other authors, required dosage of acenocumarol to obtain a correct anticoagulation level is lower in patients older than 85. In this preliminary study we find that incidence of hemorrhagic or thrombotic events is similar in both groups, but further studies with a larger number of patients are required to confirm these findings.

1737

PREVALENCE OF ANTIPHOSPHOLIPID ANTIBODIES IN PATIENTS WITH ANTI-THYROID ANTIBODIES

M. Skoura, C. Lougovoi, M. Mavrolia, S. Konstantinou, E. Deilakis, C. Karakoida, E. Merkouri, P. Paraskevopoulou

Hematology, Biochemical, Microbiology Lab of Konstantopoulionia, ATHENS, Greece

Background. Anti-thyroid antibodies are pathogenic in the development of autoimmune thyroid disease. Antiphospholipid antibodies (APLA) are a family of immunoglobulins that may be responsible for venous and arterial thromboses. *Aims.* We have studied the prevalence of antiphospholipid antibodies in patients with autoimmune thyroid disease. Method 70 patients (50 women and 20 men) with antithyroid antibodies (anti-TG, anti-TPO) were examined for antiphospholipid antibodies: ACA (IgG,IgM), β2GPI (IgG, IgM), and anti-Prothrombin. The median age was 50,5 years(31-70) and only 5 of them (7,4%) had a history of atrial fibrillation. Also these patients were immunologically tested (CRP,RA-test,C3,C4 and ANA). The anti-TG, anti-TPO and thyroid hormones T3,T4.FT3,FT4 were measured with ADVIA Centaur XP Immunoassay of Siemens. ACA (IgG,IgM), β2GPI (IgG, IgM), and anti-Prothrombin were measured with Elisa (Genesis Biodiagnostics). All the immunological tests were performed with Nephelometry (plasma protein determination) in BN Prospec analyzer of Dade Behring. ANA were detected with indirect immunefluorescence. *Result*s (Table 1) 18,5% of patients with thyroid antibodies had also antiphospholipid antibodies, 2 of them IgG subtype of ACA , 4 IgM subtype of ACA and 1 both IgG and IgM. In addition 1 had IgG subtype of β-2GPI and 2 IgM subtype of β-2GPI .2 patients had anti-prothrombine antibodies. One of the patients had clinical evidence of antiphospholidid syndrome. All measurements of APLA were found to be borderline or slightly elevated. 21 patients (30%) demonstrated high CRP levels and only 5 (7,1%) low C3 concentration. ANA were found slightly positive in 8 patients(11,4%) with no evidence of a clinical syndrome. *Conclusions.* Our study proves an increased prevalence of antiphospholipid antibodies in patients with thyroid antibodies of 18,5%.We have to prolong the follow up of these patients in order to determine the clinical significance of APLA while in cases of strongly elevated APLA we have to check the patients for thrombophilia in order to prevent a thrombotic event.

Table 1.

Anti-TG and anti-TPO increased		n: 70	%	
ACA increased	IgG	3	4,2	Total 18,5 %
	IgM	5	7,1	
β-2GPI increased	IgG	1	1,4	
	IgM	2	2,8	
anti-Prothrombin increased		2	2,8	
CRP >3 mg/l		21	30	
RA-test >15IU/ml		0	0	
C3 <0,9g/l		5	7,1	
C4 <0,1g/l		0	0	
ANA		8	11,4	

1738

ECONOMIC ASSESSMENT OF SIDE EFFECTS OF NEW ANTICOAGULANTS

J. Peris, L. Pasto, E. Pina, E. Rossello, P. Domenech

Hospital de Bellvitge, BARCELONA, Spain

Background. Long term anticoagulation is currently made with vitamin K antagonists (VKA). When patients on treatment with VKA require to be reversed, vitamin K is frequently given. In a few hours coagulation tests become normalized. If immediate correction is required for critical bleeding or urgent surgery, prothrombin complex concentrated (PCC) administration is usually needed. In the near future, probably the new oral anticoagulants, direct thrombin inhibitors or factor Xa inhibitors, will replace the VKA. These drugs do not have a specific antidote, but their short half-life (dabigatran 12-14 hours; rivaroxaban 7-11 hours) suggest that only in cases of extreme emergency its effect will need to be immediately reversed. Although there is little evidence about, it seems that the most effective treatment would be to administer recombinant activated factor VII (rVIIa). Based on data from studies with ximelagatran, we believe that major bleeding episodes in anticoagulated population with new drugs will not differ significantly from the current incidence. We assume that the indication to administrate rVIIa in our area will be close enough to the current PCC use. *Aims*. We try to assess the economic impact that this change in strategy will lead, entailing the use of rVIIa rather than PCC. *Design and Methods*. Our hospital has a reference population of approximately 1300000 inhabitants. We directly control about 3500 patients on VKA treatment and about 2500 are being managed in primary care. We have compiled all patients on treatment with VKA that required administration of PCC in 2008 because of critic bleeding or the need of urgent invasive procedures. *Results.* During this year, 39 patients on VKA received PCC: 20 because of urgent surgery, 15 because of critical spontaneous bleeding and 4 because of major bleeding after trauma. 22 (56.4%) patients were taking acenocumarol and 17 (43.6%) warfarin; 11 (28.2%) patients had an excessive level of anticoagulation and 28 (71.8%) were in the therapeutic range. The cost of the medium dose of PCC used in our patients (1500 F IX IU) is 579 , and the cost of the recommended rVIIa dose (90 mg/kg) calculated for a standard weight is 3225 . This will r epresent an increase of 2646 per patient treated. Given the fact that in our area about 6000 patients are being anticoagulated, this means that the expected change in anticoagulant drug treatment will cause an increase of 17,199 per 1,000 patients per year invested in immediate reversion strategies. Conclusions: The recommendation of administrate rFVIIa in patients treated with new anticoagulant drugs that need to be immediately reversed may cause an increase in costs of 17,199/1000 patients treated per year.

1739

THE IMPACT OF THE GENETIC POLYMORPHISM G455 ON FIBRINOGEN B-CHAIN GENE IN PATIENTS WITH CORONARY ARTERY DISEASE AND HEALTHY INDIVIDUALS: EFFECTS ON INFLAMMATORY AND THROMBOTIC PROCESS

I. Bossinakou, A. Vlachopoulou, N. Papageorgiou, M. Kozanitou, D. Tousoulis, E. Andronopoulou, Z. Pallantza, E Bossinakou

Hippocratio General Hospital, ATHENS, Greece

Background. The genetic polymorphism G455A on fibrinogen b-chain gene has been associated with the risk of coronary artery disease (CAD). However, it is not clear if it is associate with inflammatory and thrombotic process in patients with coronary artery disease. In the present study we examined the impact of this polymorphism on low-grade inflammation and thrombotic process in patients with CAD and healthy individuals. *Design and Methods*. The study population consisted of 191 CAD patients and 52 healthy individuals (controls). The G455A polymorphism was estimated by PCR and suitable restriction enzymes. Serum levels of C-reactive protein (CRP) and fibrinogen were measured by nephelometric methods. In addition, D-dimers levels were measure by standard coagulometry techniques. Results: The genotypes contribution was GG: 48.2%, AG: 40.3%, AA: 11.5% for CAD and GG: 50.0%, AG: 34.6%, AA: 15.3% for healthy individuals. Fibrinogen levels were much higher in CAD than controls for the G455A polymorphism (448.1±130.3 vs 382.5±103.8 mg/dl, $p<0.001$). Among patients with CAD AA patients had significantly higher levels of fibrinogen only than GA patients (AA: 517.5±144.0, GA: 434.0±132.2, GG: 443.0±121.0 mg/dl $p<0.05$ for AA vs GA). In controls, there was no difference across the genotypes (GG: 335.1±174.6, GA: 448.3±581.1, AA: 278.6±105.2 mg/dl, p=NS for all). For AA and GG patients with CAD there were significant higher levels of fibrinogen than AA and GG controls (517.5±144.0 vs 278.6±105.2 mg/dl, $p<0.01$ and 443.0±121.0 vs 335.1±174.6 mg/dl, $p<0.05$ respectively). Interestingly, AG controls had significant higher fibrinogen levels than CAD (448.3±581.1 vs 433.7±132.2 mg/dl, $p<0.05$). Patients with CAD had significantly higher levels of D-dimers than controls for the G455A polymorphism (566.2±664.1 vs 357.8±333.1 mg/L, $p<0.01$). Coronary artery disease patients with AA and GG genotypes had significantly higher levels of D-dimers than controls, while there was no difference for AG genotype (551.7±321.5 vs 278.7±105.2 $p<0.05$, 616.4±817.4 vs 335.1±174.6 $p<0.05$ and 511.4±526.7 vs 448.3±581.1 mg/L p=NS). Despite the fact that CRP levels were higher in CAD than controls for the G455A polymorphism, this difference was not significant (2.8±4.0 vs 2.4±3.0 mg/L, p=NS). *Conclusions*. The genetic polymorphism G455A on fibrinogen b-chain gene strongly affects fibrinogen levels and merely thrombotic process in patients with CAD. However, it does not have an impact on inflammatory process. These findings indicate that mechanisms independently to inflammation, but associated to thrombosis may be involved in the expression of this polymorphism.

1740

THE IMPACT OF THE GENETIC POLYMORPHISM G58A OF FIBRINOGEN A-CHAIN GENE ON LOW-GRADE INFLAMMATORY STATUS IN PATIENTS WITH CORONARY ARTERY DISEASE

I. Bossinakou, M. Kozanitou, N. Papageorgiou, A. Vlachopoulou, D. Tousoulis, E. Andronopoulou, Z. Pallantza, C Stefanadis C, E Bossinakou

Hippocratio General Hospital, ATHENS, Greece

Background. Fibrinogen levels are associated with the presence of coronary artery disease (CAD) and inflammation is an important component of coronary atherosclerosis. The impact of a genetic polymorphism on fibrinogen a-chain gene, the G58A on low-grade inflammation in patients with CAD remains unknown. In the present study we examined the potential effect of this polymorphism on low-grade inflammatory state in patients with CAD. *Design and Methods*. The study population consisted of 179 subjects angiographically documented for CAD. The G58A polymorphism was detected by PCR and suitable restriction enzymes. Serum levels of C-reactive protein (CRP) and fibrinogen were measured by immunonephelometric methods. In addition, levels of sCD40-ligand (cd40L) were determined by enzyme-linked immunosorbent assay (Elisa). *Results.* The genotype distribution was GG: 39.7% AG: 40.2% and AA: 20.1%. Despite of the fact that AA patients had higher levels of fibrinogen, this difference did not reach any statistical significance (AA: 477.5±123.1, AG: 449.0±119.3 and GG: 452.4±146.3 mg/dl, p=NS across genotypes). Similarly, there was no significant difference in CRP or CD40L among GG (2.6±2.5mg/L and 2.4±1.6 μg/mL), GA (3.2±5.5mg/L and 3.0±2.0_g/mL) and AA (3.1±2.7 and 2.7±1.3 mg/L) p=NS for all. *Conclusions*. Our study showed that the G58A polymorphism on fibrinogen a-chain gene does not affect sCD40L and C-reactive protein in patients with coronary artery disease. These findings indicate that other mechanisms rather than inflammatory process may be involved in the expression of this polymorphism.

1741

LEVELS OF VON WILLEBRAND FACTOR ON ADMISSION CAN DISCRIMINATE PATIENTS WITH ACUTE CORONARY SYNDROME FROM A GROUP OF PATIENTS WITH CHEST PAIN

T. Assimakopoulou,[1] N. Tragomalos,[1] M. Stamouli,[2] P. Petraki,[1] K. Makris,[1] C. Demponeras,[1] P. Lianidou[1]

[1]KAT Hospital, KIFISSIA, ATHENS, Greece; [2]Metaxa Hospital, PIRAEUS, Greece

Background. Several studies have indicated that elevated plasma concentration of some proteins including von Willebrand Factor (vWF), fibrinogen and D-Dimers are associated, as independent risk factors, with coronary artery disease (CAD). This association becomes much stronger in patients with acute coronary syndrome (ACS), due to the role of vWF, fibrinogen and D-Dimers in the process of thrombus formation and degradation, leading to myocardial ischemia. vWF participates in this process by supporting platelet adhesion to the subendothelial matrix of injured vessel walls. Fibrinogen and D-Dimers levels are increased in this acute phase of coronary syndrome as acute-phase reactant proteins. *Aims*. The aim of this study was to evaluate the vWF, fibrinogen and D-Dimers measurement for the discrimination of patients with ACS from

patients with acute chest pain of non-cardiac etiology. *Design and Methods*. Forty-four (44) patients (30 males/14 females) who presented within six hours after the onset of chest pain were included in this study. Blood samples were obtained on admission and 24 hours after the onset of chest pain under standardized conditions. Fibrinogen, D-Dimers and vWF activity were measured on Siemens-BCS coagulation system. Using clinical evaluation (ECG) and laboratory results (troponin I-TnI) patients were divided into three groups. Group I included patients with non-cardiac etiology chest pain (ECG and TnI-negative), group II patients with unstable angina (ECG-positive and TnI-negative) and group III patients with myocardial infarction (MI) (ECG and TnI-positive). Sixteen healthy males served as controls. *Results.* The table summarizes our results. The following must be noted a)vWF values on admission are statistically significantly higher in patients with MI than in patients with unstable angina and values in patients with unstable angina are also significantly higher than in patients with chest pain of non-cardiac etiology as well as controls (p<0.001) b)fibrinogen and D-Dimers values on admission are not significantly higher in patients with ACS (group I and group II) than in patients with chest pain of non-cardiac etiology and controls (t-test, p=ns). *Conclusions*. There are several studies that have demonstrated that vWF increase is an independent predictor of short term adverse clinical outcome in patients with ACS. The results of this study show that vWF levels could be used for the discrimination of patients with myocardial infarction and unstable angina from a group of patients with chest pain.

Table 1.

	Group I		Group II		Group III		Control	P anova

JUMPING TO MICROPARTICLES, A STRESS STUDY

M.C. Trappenburg, D.J. van Westerloo, M. van Schilfgaarde, A. Leyte, W.E. Terpstra

Onze Lieve Vrouwe Gasthuis, AMSTERDAM, Netherlands

Background. Microparticles (MP) are small cell derived membrane vesicles. Circulating MP may originate from blood or endothelial cells and display specific cell surface proteins that indicate their cellular origin. Many mediators as shear stress and cytokines may induce cells to release MP as has been shown in e.g. arteriosclerosis and sepsis. MP are both cause and consequence of vascular changes, and play a role in thrombosis and hemostasis. *Aims*. The bungeejump study was designed to elucidate the effects of an acute stress response induced by a bungee jump on the immune system and coagulation, and the role of the β-receptor herein. In the present side-study we investigated the influence of the bungeejump on the levels of circulating MP and their origin, in relation to several coagulation parameters. *Design and Methods*. 20 healthy young men performed a bungeejump from a 70 metres high crane. Ten of these volunteers had been taking propranolol (three times 40 mg a day) for three days prior to the jump. Blood samples were drawn 2 hours before the jump, just before and right after, and 2 hours after the jump. We used previously described methods for MP analysis by flowcytometry. *Results*. Right after the jump there was a significant increase (p<0.001) in total MP in all volunteers. In the control group this increase was mainly due to a significant increase in MP expressing monocyte markers and a moderate increase in MP expressing platelet and leukocyte markers. In contrast, volunteers taking propranolol showed a moderate increase of MP expressing monocyte markers, but an impressive increase of MP expressing platelet or leukocyte markers. After two hours, the MP levels in all volunteers had returned to baseline. Higher levels of von Willebrand Factor (vWF) and factor VIII were observed directly after the jump by volunteers not taking propranolol. *Conclusions*. Bungeejumping by healthy volunteers temporarily increased numbers of circulating platelet, leukocyte en monocyte derived MP as well as levels of vWF and factor VIII, indicating a short transient hypercoagulable state due to the jump. Interestingly, whereas use of propranolol effectively blocked the increase in vWF and factor VIII as expected, it led to a massive unexpected increase in leukocyte and platelet derived MP. The β receptor may therefore be involved in suppressing MP formation by leukocyte and platelets.

1743

ARE THROMBIN ACTIVATABLE FIBRINOLYSIS INHIBITOR (TAFI) LEVELS, TAFI GENE POLYMORPHISMS AND CLOT LYSIS TIME RISK FACTORS FOR PREECLAMPSIA AND INTRAUTERINE FETAL GROWTH RESTRICTION?

J.C. Reverter,[1] M.A. Martinez,[2] J. Monteagudo,[2] J. Pijoan,[1] C. Freire,[2] F. Carmona,[2] J. Balasch,[1] D. Tassies[2]

[1]Hospital Clinic Barcelona, BARCELONA, Spain; [2]Hospital Clinic, BARCELONA, Spain

Background. The aim of the study was to evaluate TAFI levels, TAFI gene polymorphisms and clot lysis time (CLT) in complicated pregnancies with severe preeclampsia (PE) and/or severe intrauterine foetal growth restriction (IUFGR), and to compare them with healthy pregnancies. *Design and Methods*. 129 pregnant women who delivered at 26 or more weeks of gestation were prospectively recruited. The study group (Group 1) included 63 pregnant patients with severe PE and/or severe IUFGR. The control group (Group 2) included 66 healthy pregnant patients. TAFI antigen was determined by ELISA, and CLT as previously reported (Lisman T et al. Hepatology 2002;35:616-21). TAFI and CLT were determined in patients of Group 1 at the time of diagnosis of severe PE and/or IUFGR at the third trimester and 10 weeks after delivery (basal period) and, in Group 2 during each trimester of gestation and 10 weeks after delivery. Polymorphisms of TAFI gene, Ala 147Thr and +1542C/G, were determined by PCR. *Results*. A progressive increase in TAFI antigen levels and CLT was observed during normal pregnancy, which returned to basal levels after delivery. Significant higher TAFI levels and longer CLT were found in the basal period in Group 1 compared to Group 2 (TAFI antigen Group 1/ Group 2: 10.63 mug/mL /9.54 mug/mL (p<0.05); CLT Group 1/Group 2: 78.64 minutes /68.09 minutes (p<0.05)). There were no differences in TAFI gene allele distribution between the two groups. *Conclusions*. Increased basal TAFI and CLT may constitute biological predictors of the risk of severe PE and/or severe IUFGR during pregnancy.

Supported in part by grant from FIS 05/0026, 02/0711 and 05/0204 from the Fondo de Investigaciones Sanitarias, Instituto de Salud Carlos III, Spain. MA.Martinez was recipient of a grant from the Hospital Clínic of Barcelona.

1744

PREDISPOSING PREVENTABLE FACTORS IN PATIENTS WITH BLEEDING DUE TO WARFARIN USAGE: EVALUATION OF 114 PATIENTS

E. Beyan,[1] C. Beyan,[2] S. Acar Vaizoglu[3]

[1]Numune Education and Research Hospital, ANKARA, Turkey; [2]Gulhane Military Medical Academy, ANKARA, Turkey; [3]Hacettepe University Faculty of Medicine, ANKARA, Turkey

Background. Warfarin, which is derivative of coumarin, is a commonly used anticoagulant drug for myocardial infarction, ischemic stroke, venous thrombosis, after heart valve replacement and atrial fibrillation both for prevention and treatment. However, warfarin has a narrow treatment range and the dose of the drug greatly differs among individuals. Insufficient dose might not prevent thrombosis while overdose may enhance hemorrhage risk. *Aims*. The aim of our study is to evaluate the predisposing preventable factors among patients with bleeding due to warfarin usage. *Design and Methods*. This study was performed on 114 cases who admitted to emergency service for complaint of bleeding due to warfarin usage. The sociodemographic characteristics, information on warfarin usage and their bleeding history are collected by a structured questionnaire form. The mean age of the patients was 66.65±13.57 years (mean±standard deviation, 27-89 years, 82 cases 60 years and over) and 61 (53.5%) of them were females. Results. At the time of admission 42 cases (36.8%) had melena, 31 (27.2%) hematuria, 29 (%25.4) ecchymosis, 25 (21.9%) epistaxis, 13 (11.4%) hematemesis, seven hemoptysis, five hematoma, five vaginal bleeding, three bleeding

from the current lesion, two hematochezia, two intracranial bleeding, one late bleeding after tooth extraction, one gingival bleeding and one case had subconjunctival bleeding. The mean of the time between the onset of the bleeding and admission to the hospital was 2.9±3.4 days. The mean dose of warfarin being used at the time of admission was 31.2±10.8 mg/week (8.7-70.0 mg; median 35.0 mg). The mean of the period from the onset of the warfarin usage to the time of bleeding was 31.6±49.0 months (1-228 months; median 10.5 months). 35 cases (30.7%) experienced bleeding during the first month, while 50 cases had bleeding (43.8%) within the six months. Only 37 cases were being controlled regularly. The mean number of the drugs being used other than warfarin was 4.8±2.5 drugs. Forty-eight cases were using aspirin, 28 non-steroidal anti-inflammatory drugs other than aspirin and 18 cases were using various antibiotics. Forty-eight of the patients knew that they had to use this drug under the regular follow-up of a physician and 43 knew that during monitoring a laboratory test had to be done while using the drug named as warfarin. Only 39 patients knew that this drug may cause bleeding. It was also surprising that only nine of the patients knew that there may be drug interaction and one knew that this drug may be affected from the dietary factors. *Summary and Conclusions*. As a result, our patients who admitted to the emergency service with bleeding have a big gap of knowledge which invited bleeding. Most of the patients were using drugs which are known to interact with warfarin metabolism while using warfarin. Developing a training program for the related specialists and general practitioners who follow-up such patients may have an effect on decreasing the morbidity and mortality caused by warfarin induced hemorrhages.

PREVALENCE OF FACTOR V LEIDEN, PROTHROMBIN G20210A AND MTHFR C677T MUTATIONS IN DEEP VENOUS THROMBOSIS PATIENTS FROM WESTERN IRAN

Z. Rahimi,[1] H. Mozafari,[1] K. Mansouri,[1] A. Shahriari,[1] M. Aznab,[1] M. Rezaei,[1] K. Ali-Moghadam[2]

[1]Kermanshah University of Medical Sciences, KERMANSHAH, Iran; [2]Tehran University of Medical Sciences, TEHRAN, Iran

Background and Aims. Inherited disorders related to hemostatic system are known as risk factors for thromboembolic events (TE) such as myocardial infarction, stroke, pulmonary embolism, pregnancy complications, and especially recurrent deep vein thrombosis (DVT). The present study was aimed to investigate the prevalence of factor V Leiden G1691A, prothrombin G20210A and MTHFR C677T in DVT patients and their possible association with DVT in Western Iran. Patients and *Design and Methods*. Seventy two DVT patients with the mean age of 40.4±13.6 years including 37 females and 35 males and 100 age and sex matched healthy individuals from Kermanshah Province of Iran with ethnic background of Kurd were studied for factor V Leiden G1691A, prothrombin G20210A and MTHFR C677T by PCR-RFLP method using Mnl I, Hind III and Hinf I restriction enzymes, respectively. Results. Prevalence of factor V Leiden was 12.5% in patients and 2% in control group. A significant association was found between factor V Leiden mutation and DVT with odds ratios (OR) of 7.0 (95% confidence intervals [CI] 1.46-33.46, p=0.018). The prevalence of prothrombin G20210A variant in patients and control individuals were 4.16% and 1.0% respectively. . The prevalence of MTHFR C677T was found to be 38.9% and 44% in patients and control group, respectively. Around 18.9% of women were Oral contraceptive pill users. In 17.5% of patients there was a history of DVT in the family. Around 23% of patients had a history of prior venous thromboembolism. Venous thrombosis in legs was the most frequent clinical manifestation (n=67), corresponding to 93.1% of the TE, followed by pulmonary thromboembolism (6.9%) *Conclusions*. Our study for the first time have determined the prevalence of inherited thrombophilia in a homogenous ethnic group of DVT patients and suggests that factor V Leiden, and not the prothrombin gene mutation is a risk factor for DVT in Western Iran.

PLASMA PROTEIN Z LEVELS IN NEONATES WITH RESPIRATORY DISTRESS SYNDROME

M. Sedky,[1] S. El-Sahrigy,[2] S. Bakr,[3] S. Emam[3]

[1]Children Cancer Hospital Egypt, CAIRO, Egypt; [2]National Research Center, GUIZA, Egypt; [3]Ain Shams University, CAIRO, Egypt

Background. Respiratory distress syndrome (RDS) is one of the most common lung disorders in preterm neonate. Fibrin deposition has been demonstrated in the pulmonary microcirculation and small airways in RDS suggesting the activation of the coagulation system with a special role of protein C (PTC) and protein S. Recently, protein Z (PTZ) -a vitamin k dependent protein-, was added to these factors. *Aims*. Our aim is to primarily evaluate Protein Z and Protein C levels in healthy preterm and full term newborns and compare their serum levels with those newborns suffering from RDS. Second is to assess their serum levels after recovery. *Design and Methods*. 60 newborn infants, recruited from the neonatal unit Aïn Shams University, Cairo, Egypt were enrolled in the study and divided into 3 groups: Group (I) of those 20 preterm with RDS, Group (II) of 20 healthy full term control newborns and Group (III) of 20 healthy preterm control newborns. Protein Z and C were measured by ELISA. Results: Lower levels of protein Z was obtained in RDS group compared to preterm controls whose levels were by their role, significantly lower than in full-term controls. A significant increase in protein Z levels in RDS' group was noticed after their recovery from RDS, where it reached near normal levels compared to full-term controls. In RDS, no significant correlation existed between protein Z levels and routine laboratory investigations except for a significant negative correlation with platelets. Regarding protein C, no significant difference was seen in RDS group before and after recovery. *Conclusions*. Premature newborns suffering from RDS showed lower serum protein Z levels than either normal preterm or full-term newborns with further increase in its pattern to reach near normal after recovery. We recommend serial measures of PTZ in premature RDS for follow up of their condition.

1747

FIBRINOGEN AND POLYMORPHISM V34L OF FACTOR XIII GENE IN PATIENTS WITH ACUTE CORONARY SYNDROME (ACS)

R. Gutiérrez-Tous, M Viloria, R. Fe, A. Valdivielso, R. Gil, C. Almeida, A. Fernandez-Palacin, I. Sainz

University Hospital Valme, SEVILLE, Spain

Background. The Factor XIII of the blood coagulation activated for the Thrombin, remains the Fibrin clot. The common polymorphism V34L of Factor XIII is localized in the subunit A, only to tree aminoacides of the zone of clivaje for Thrombin and certain would may to be implied in the stability of clot. The L allele frequency was significantly lower in patients group with Myocardial infarction compared to control group; this difference was extremely significant in patients younger than 50 years old. Those findings support the hypothesis that V34L polymorphism in FXIII gene has a protective effect against myocardial infarction (1). In a recent Meta-analysis with 5346 patients with ACS and 7053 controls (2), shows that the beneficial effect of the polymorphism might be smaller than the effect estimates obtained, because the analysis raised the possibility of publication bias. Data published in the literature suggest that gene-gene and gene-environmental interactions might significantly influence the protective effect of FXIII V34L polymorphism. Those authors (3) found that 34Leu homozygous patients form fibrin clots with lower permeability than 34Val homozygotes at low fibrinogen concentrations, but that the permeability was similar for both genotypes at intermediate fibrinogen levels and even higher for the 34 Leu homozygotes at high fibrinogen. *Design and Methods*. 1°. To determinate the prevalence of genotype of polymorphism V34L Factor XIII gene in patients with Acute Coronary Syndrome (ACS) 2°. The prevalence of genotype LL of polymorphism Factor XIII gene in the group of patients and the prevalence of control group will be compare for to determinate the protector factor (OR) of allele L. 3°. To value the meaning of Fibrinogen in relation to polymorphism V34L of Factor XIII gene in the patients with ACS. Patients: A group of 84 patients non older, surviving of an event of acute coronary syndrome; the diagnosis was based on the cardiology criteria's (descent of ST and /or Troponin >1). Controls: A group of 407 subjects voluntary healthy, blood donors of similar age and sex; before a physician informed them and they had authorized the recruitment in the study. All controls were free of any history of venous or arterial thrombosis. The detection of polymorphism Factor XIII V34L by Polymerase Chain Reaction (PCR), in liquid phase, in real time, adapted and automated in a LightCycler (Roche Diagnostic) thermal cycler will be made. To compare the percentages of allele L homozygote in every group of patients and controls, by Chi-square test will be made. The significative results in these proof of hypothesis with confidence interval 95% for odds ratio (OR) we will employ. *Results*. In the group of patients 80,2% are men and 19,8 women, medium age is 50 (24-74) years; in control group 66,6% are men and 33,4% women, medium age is 39 (22-73) years. A prevalence of allele L homozygote of polymorphism V34L of Factor XIII gene of 1,4% in the patients and 4,5% in the controls has been found. The difference is not significative but a tenden-

cy with protector effect is showed. In relation to levels of Fibrinogen in the patients of ACS, we had seen that in those with allele L the median is 350 mg (218-460) minor that the patients not carrier allele L 380 mg (189-740). *Conclusions*. A protective effect for ACS of the allele L of polymorphism V34L of Factor XIII gene has been showed in relation to fibrinogen levels. To study greater number of patients for a definitive result is necessary.

COAGULATION PARAMETERS IN PEDIATRIC SOLID TUMORS

U. R. El-Safy,[1] M.A. Heshmam,[1] J. Teruya,[2] N. Khalifa,[3] M. A. Aly[1]

[1]Pediatric and [2]Clinical Pathology Departments, Faculty of Medicine, ZAGAZIG Ubiversity; [3]Pediatric and Pathology Departments, TEXAS CHILDREN'S HOSPITAL

Background. Association of prothrombotic markers with thrombosis in pediatric oncology patients is conflicting. There is little agreement about the most useful tool for defining coagulability on cancer. This study was done to measure parameters of hypercoagulation panel and to generate estimated prevalence of prothrombotic factors in pediatric patients with newly diagnosed malignancies excluding leukemia and to compare these results with those of healthy controls. *Design and Methods*. Patients with newly diagnosed solid tumors, brain tumors and lymphoma and age/sex matched healthy children undergoing elective surgery as controls were enrolled in this study. We measured fibrinogen, D-dimer, prothrombin time, activated partial thromboplastin time, antithrombin, protein C, protein S, homocysteine, Lipoprotein (a) and factor VIII were also performed in all patients and controls. The specimens from the enrolled patients were collected prior to the start of chemotherapy and in the setting of >2 weeks after surgical intervention for tumor resection. Results: In this descriptive cross-sectional study of 40 patients, 16 had solid tumors, 14 brain tumors and 10 lymphomas. [Mean age 8.2 years; 25 males]. Forty age/sex-matched controls were enrolled. Of these 40 cancer patients, abnormal hypercoagulation panel results were detected in (55%). Four patients had low functional protein S, 2 had high homocystine levels and 12 had high lipoprotein (a) levels. In contrast to healthy subjects, children with cancer had significantly higher D-dimer, factor VIII and fibrinogen [$p<0.05$]. At the time of this report, no patients experienced clinically documented thrombotic events. *Conclusions*. Children with newly diagnosed solid tumors have a high prevalence of prothrombotic markers, when compared to age/sex-matched controls. Positive D-dimer, high factor VIII, fibrinogen levels were the commonly found thrombosis risk factors in pediatric patients with solid tumors.

1749

INCREASED IL-1B, IL-6 AND TNF-A LEVELS IN PEDIATRIC MALIGNANCY ASSOCIATED WITH HYPERCOAGULABLE STATE IN THROMBOELASTOGRAPHY PROFILES

Aly Aldeen Mo,[1] R. Edwards,[2] D. Cooper,[2] I. Tjia,[3] M. Hesham,[1] U. Elsafy,[1] M. Badr,[1] L. Bomgaars,[3] A. Pappo,[3] M. Chintagumpala,[3] J. Teruya[3]

[1]Zagazig University, ZAGAZIG, Egypt; [2]Texas Children's Hospital, HOUSTON, USA; [3]Texas Children's Hospital and Baylor College of Medicine, HOUSTON, USA

Background. Multiple factors contribute to the activation of coagulation and thrombotic diathesis. Prothrombotic markers and their association with thrombosis in pediatric solid tumor patients are not well defined. The host response to malignancy including the acute phase reaction, paraprotein production, inflammation, necrosis and hemodynamic disorders contribute to thrombotic risk. Tumor cells have the ability to activate the coagulation system through the release of inflammatory cytokines, such as IL-1α, IL-6, IL-8, and TNF-α, and physical interaction between tumor cells and blood or vascular cells. Inflammation might represent important role for mediating thrombosis. Thromboelastography (TEG) allows the assessment of patient's global hemostatic function. A hyper- or hypocoagulable state can be easily visualized using TEG. *Aims*. We hypothesize that newly diagnosed pediatric patients with malignant tumor have abnormal TEG profiles and higher prevalence of prothrombotic markers such as elevated cytokine levels when compared to age and sex matched normal controls. *Design and Methods*. Specimens from the enrolled patients were collected prior to the start of chemotherapy. In the occurrence of surgical intervention, specimens were collected two weeks after tumor resection. Otherwise healthy children undergoing elective surgery were enrolled in the control group. In both groups, TEG parameters, reaction time (R), angle (α), maximum amplitude (MA), lysis 30 minutes (LY30), G value (G), and coagulation index (CI), and cytokine levels, IL-1α, IL-6, IL-8, and TNF-α, were measured in these newly diagnosed pediatric cancer patients and control groups. Results: In this descriptive cross-sectional study of 40 patients (25 males and 15 females), 16 (40%) with solid tumor, 14 (35%) with brain tumor, and 10 (25%) with lymphoma, with mean age of 8.4 years (2 to 17 years). Forty age and sex matched healthy children undergoing elective surgery such as hernia repair were enrolled as controls. Abnormal hypercoagulable TEG profiles were found in eight patients. Moreover, cancer patient's TEG MA, CI, and G values were significantly higher than the control group ($p<0.001$). IL-1α, IL-6, and TNF-α levels were also significantly higher in cancer patient group ($p<0.001$). There was no statistical difference in TEG parameters and these cytokine levels between patients with and without surgery prior to receiving chemotherapy. At the time of cohort, no patients experienced clinically documented thrombotic events. *Conclusions*. The significant differences of TEG profiles and cytokine levels between children with newly diagnosed malignant tumor and age and sex matched controls may indicate an increased risk of thrombosis in children with malignancies. This may indicate that the pathogenesis of cancer-associated thrombosis is substantially influenced by inflammatory cytokines. Further studies are needed to assess utility of using TEG and cytokine levels as a clinical tool to predict who is at risk of thrombosis.

Table.

	Patient n=21	Patient Post-surgery n=19	All Patients n=40	Control n=40	p-value*
Age (years, range)	9.6 (2-17)	7.0 (2-15)	8.4 (2-17)	8.1 (3-15)

EVALUATION OF A NEW QUANTITATIVE HIGHLY SENSITIVE D-DIMER ASSAY IN HOSPITALIZED PATIENTS

A. Perdiou, A. Kousoulakou, G. Papadopoulou, G. Leveta, A. Trigka, G. Altouvas, A. Giannouli, K. Statherou, M. Andromida, V. Tsoukanas

Tzaneio General Hospital, PEIRAIUS, Greece

Background. D-dimer measurement is widely applied in the diagnostic work-up of venous thromboembolic disease, especially for the exclusion of deep vein thrombosis (DVT) and pulmonary embolism (PE). D-dimer Innovance is a new microparticle-enhanced immunoassay using monoclonal antibody and has been evaluated only in outpatients. Aims: To evaluate the levels of D-dimer Innovance in hospitalized patients. *Design and Methods*. We investigated the causes of elevated D-dimers in 425 patients with no symptoms or clinical signs of DVT or PE during their hospitalization. Pregnant women were excluded from the study. Patients samples were measured simultaneously on Dade Behring coagulation analyzer BCS XP (cutt-of: 0,5 mg/L). ; *Results*. From 425 samples assayed, elevated values were observed in 257 (60,47%). 70 (27,77%) of them were repetitions. Elevated levels were observed in the following situations, *Conclusions*. Innovance D-dimer is a highly sensitive assay and this increases the diagnostic value of its normal levels. However, this test has low specificity because elevated levels are observed in all diseases and conditions with activation of fibrinolytic system. Assessment of high levels requires attention, especially in patients with high D-dimer

values due to coexisting diseases. The use of D-dimer testing represents an efficient and safe screening tool for the exclusion of thromboembolic events in combination with a well-validated clinical pretest probability score. Further experience with this test when used in routine clinical practice in hospitalized patients should be obtained.

Table.

Disease	No of patients	Range of values (mg/l)
Bleeding	25	0,73-35,20
Infection	62	0,68-16,00

CLINICAL EXPERIENCE IN COMBINED ANTI-PLATELET PLUS ANTICOAGULANT THERAPY IN PATIENTS WITH VALVULAR AND NON VALVULAR ATRIAL FIBRILLATION

M. Malo, S. Valle, I. Izquierdo, A. Aules, E. Bonafonte, P. Serrano, O. Gavin, R. Cornudella

Hospital Clinico Lozano Blesa, ZARAGOZA, Spain

Background. Atrial fibrillation (AF) is the most prevalent arrhythmia in anticoagulated patients and it is also a strong independent risk factor for systemic embolism and stroke. From 1989 the role of anticoagulation for preventing stroke in this arrhythmia became established. AIMS: Following the 2004 NASPEAF trial: 'Comparative effects of antiplatelet, anticoagulant, or combined therapy in patients with valvular and nonvalvular atrial fibrillation", we have tried to assess the efficacy and safety of the combination of antiplatelet teraphy (trifusal) and moderate-intensity anticoagulation therapy (INR: 1'5-2'5) with acenocoumarol in patients with AF linked to recognized risk factors or mitral stenosis. *Design and Methods*. We selected 54 patients (33 men and 21 women) in acenocoumarol and triflusal combined therapy, dividing them in two groups: an intermediate-risk group including patients > 60 years age and a risk factor: hypertension, diabetes, heart failure, hyperlipidaemia (21 men and 14 women); and the high-risk group including patients with nonvalvular plus prior embolism, and patients with mitral stenosis with and without prior embolism (12 men and 7 women). The follow-up took place between 01/01/07 and 27/01/09. *Results*. Primary events: one case of deep venous thrombosis in a man from the intermediate-risk group who also had a minor rectal bleeding; one event of embolism stroke (TIA) in a high risk group female patient and another TIA of cardiac etiology in a man from the intermediate risk group who also suffered rectal bleeding and abdominal hematoma. All events occurred with INR in normal levels. Secondary events: 11 minor bleedings: one patient had subconjunctival bleeding and a limited hematoma. Another patient presented eye bleeding. Both patients were taking triflusal 300 mg/day. Another man from the intermediate risk group had spontaneous hematomas and one man from the high-risk group showed another subconjunctival hemorrhage. We also registered gingival bleeding in a man of the intermediate risk group and one epistaxis in a woman of the same group and in another patient who also had suffered a spontaneous hematoma event. Regarding the intermediate bleeding events, we registered two rectal bleeding cases in two men of the intermediate risk group and two patients presented hematuria, both from intermediate risk group, a man and a woman with INR: 2'57. We recorded a severe bleeding episode: an anemia due to great traumatic hematoma in the right thigh (the patient needed a blood transfusion due to hemoglobin: 7'1 and INR: 9'48). *Conclusions*. In our experience, combined antiplatelet and moderate-intensity anticoagulation therapy does not increase the risk of bleeding events. It seems an effective therapy, as the amount of thrombotic events is according to other previous studies using the same type of patients and treatment. In conclusion, the addition of antiplatelet therapy to acenocoumarol teraphy to reduce the anticoagulation intensity is effective in AF patients stratified by risk of stroke, and does it without increasing bleeding risk.

1752

PREVALENCE OF HYPERHOMOCYSTEINEMIA IN TUNISIAN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

R. Ellouze, S. Mahjoub, L. Kallel, H. Kallel, H. Bacouche, A. Filali, N. Ben Romdhane

Hôpital la Rabta, TUNIS, Tunisia

Background. Patients with inflammatory bowel disease (IBD) have an increased risk for thromboembolic events. Moreover, a hypercoagulable state has been hypothesized as a contributing factor in the pathogenesis of IBD. Recently, a growing amount of interest has focused on mild to moderate hyperhomocysteinemia as a risk factor for thromboembolic disease. Aims: We aimed to evaluate the levels of homocysteine and the prevalence of hyperhomocysteinemia in patients with IBD and to investigate the contribution of vitamin status in determining increased level of plasma total Homocysteinemie. *Design and Methods*. We studied 100 IBD Tunisian patients: 81 with Crohn's disease (CD) and 19 with ulcerative colitis (UC), of whom 4 patients had a history of venous thrombosis. Plasma homocystein concentration was determined by fluorescence polarization immunoassay with Axsym analyzer. The following parameters were analysed: age, sex clinical activity, length-extent and type of disease (CD or UC), plasma homocystein concentration, folates and vitamin B12. *Results*. The mean age of the population studied is 35.6 years, sex ratio female/male=1.12. Hyperhomocysteinemia was defined as homocystein level 14 µmol/l. Four cases with thromboembolic event were found (only in the patients with CD), but no one had hyperhomocysteinemia. The mean level of homocystein was 11.77 µmol/l. The prevalence of high homocystein concentration was 21% (11 male and 10 female) all of them had a CD. Only 2 patients had folate deficiency (there was no statistically significant correlation between folate and homocysteine plasma levels, p=0.19), but 7 patients had vitamin B12 deficiency (p=0.01). No correlation was found between homocysteine levels and either disease activity, smoking sex or involvement of the terminal ileum. *Conclusions*. Our study suggests that hyperhomocysteinemia is a common phenomenon in CD, and is associated with vitamin B12 deficiency, but no correlation is found between plasma level of homocysteinemia and thromboembolic complication in IBD Tunisian patients.

1753

INFLUENCE OF INFLAMMATION ON ATHEROSCLEROSIS DEVELOPMENT IN MAINTENANCE HEMODIALYSIS PATIENTS

A. Novkovic, D. Celeketic, Z. Cvetkovic, G. Perunicic-Pekovic, Z. Petrovic, A. Ivanovic

Clinical Hospital Zemun, BELGRADE, Serbia

Background. Inflammation in maintenance hemodialysis (MHD) patients (pts) contributes to atherosclerosis development besides traditional atherothrombotic factors. *Aims*. Aim of the study is to show the influence of inflammation on atherosclerosis development. *Design and Methods*. The population of 42 MHD pts was divided in 3 groups according to tertiles of C reactive protein (CRP) values (cut points 1.87 and 5.32) as inflammation marker with first group consists of 16 pts with lowest CRP tertile, second group consist of 12 pts with median CRP tertile and third group consists of 14 pts with highest CRP tertile. We compared ultrasonographic parameters of early atherosclerosis: lumen diameter(LD), intima media thicknes (IMT) and cross-sectional calculated intima media area (cIMA) using formula 3,14x[(LD/2+IMT)2-(LD/2)2] for both right and left common carotid arthery (RCCA and LCCA) as well mean values for both carotide artheries using Kruskal-Wallis test. Afterwards we tested inter-group differences using Mann-Whithney test. *Results*. We found significant differences between three groups in RCCA LD (7.40+/-0.82 vs 7.80+/-1.58 vs 8.95+/-1.37; p=0.017), LCCA LD (7.38+/-0.83 vs 8.05+/-1.46 vs 9.11+/-1.45; p=0.009), LCCA IMT (0.77+/-0.16 vs 0.78+/-0.13 vs 0.91+/-0.31; p=0.045), mean LD (7.40+/-0.88 vs 8.01+/-1.51 vs 9.03+/-1.40; p=0.011) mean IMT (0.76+/-0.12 vs 0.78+/-0.18 vs 0.89+/-0.30; p=0.05) nad mean cIMA (19.82+/-5.20 vs 20.50+/-9.87 vs 29.58+/-12.37; p=0.049). There was significant differences between first and third group in RCCA LD (p=0.002), LCCA LD (p=0.001), LCCA IMT (p=0.031), mean LD (p=0.001), mean IMT

(p=0.025) and mean cIMA (p=0.013). *Conclusions*. Pts with highest CRP values have highest ultrasonographic parameters of early atherosclerosis. Inflammation is significant factor for atherosclerosis development besides traditional atherothrombotic factors.

1754

PROCOAGULANT ACTIVITY OF CIRCULATING MICROPARTICLES IN HEMODIALYSIS PATIENTS

M. Simkovic, P. Sadílek, J. Mali, S. Dusilová-Sulková, F. Vrbacky, M. Pecka

University Hospital and Medical School, HRADEC KRALOVE, Czech Republic

Background. End-stage renal disease is associated with high prevalence of endothelial dysfunction and subsequent cardiovascular disease. Elevated count of microparticles, recently discovered biomarker of endothelial dysfunction, was observed in patients under hemodialysis. However, data concerning count and activity of circulating microparticles in patients on hemodialysis are limited. *Aims.* To quantify procoagulant activity of microparticles in plasma of patients immediately before hemodialysis procedure. To compare it to healthy controls and plasma level of soluble P-selectin and fibrinogen levels, as markers of inflammation and atherosclerotic cardiovascular complications. *Design and Methods*. We analysed the procoagulant activity of microparticles in plasma of stable patients (n=57) with various nephropathies (n=23 with diabetic nephropathy) undergoing long-term hemodialysis treatment procedure and healthy volunteers (n=20) by thrombin-generating functional assay. Patients with end-stage renal disease had arteriovenous fistula and all samples were drawn immediately before the hemodialysis session. Plasma levels of soluble P-selectin were analysed by enzyme immunoassay. C-reactive protein levels were assessed, as a marker of inflammation and infection. The procoagulant activity of circulating microparticles expressed as concentration of phosphatidyl serine equivalents was modestly but significantly lower in hemodialysis patients (n=57) than in the healthy controls (n=20) (3.98±1.89 vs. 5.30±1.65 nmol/l; p<0.05). On the contrary, the plasma level of soluble P-selectin was significantly higher in patients than healthy controls (55.2±18.1 vs. 40.3±8.2 ng/ml; p<0.001). Patients with end-stage renal disease, as expected, had significantly higher concentrations of plasma fibrinogen (4.37±0.99 vs. 3.27±0.67 g/l). *Conclusions*. Our pilot results suggest that circulating procoagulant microparticles counts are not increased immediately before a hemodialysis session. Larger cohorts and the effect of hemodialysis procedure on the levels of microparticles will be assessed by this promising functional method in following study.

THROMBOTIC EVENTS OF COBALAMINE DEFICIENCY

M. Bradai

Institue of Medicine, BLIDA, Algeria

Background. Diseases related to Cobalamine deficiency (CblD) or to congenital abnormalities of Cbl usually revealed by a macrocytic megaloblastic anemia. However CblD can be risk factor for vascular disease (VD). Hyperhomocysteinemia is sensitive and early indicator of CblD. There is relationship between it moderate elevation and the occurrence of both arterial and venous disease (*M. Catane. Hyperhomocysteinemia: A risk factor for arterial and venous thrombotic disease. Inter J Clin Res, 1997, 27: 139-144*). *Aims*. In this study we describe observations of patients with CblD revealed or associated with VD events, we aimed to establish incidence and prognosis of VD events in patients with a diagnosis of B12 deficiency. *Design and Methods*. We performed a retrospective study of all patients with Vit B12 deficiency between 1994 and December 2008. Diagnosis revealed by anemia and or macrocytosis megaloblastic, B12 dosage and therapeutic tests. Homocysteine levels performed just in 3 patients. Diagnosis of thrombosis was confirmed by ultrasoundgraphy, in others cases we need ECG, ophtalmoscopy, angiography and cerebral scanning. *Results*. 575 patients with Cbl deficiency were recruited. Among this cohort 9 (1.6%) had VD and thrombosis. The average age was 45years (18 - 67y), 6M/3F, 3 had deep vein thrombosis of extremities, 1acute ischemic stroke occurred without any context, 1 myocardial infraction, 1 had large vessel thrombosis with both arterial and venous thrombosis (mesenteric and portal vein thrombosis arterial cerebral thrombosis), 1 central vein retina thrombosis, 2 sibling patients with congenital Trancobalamin (TCII) deficiency had severe retinopathy. 3patients had history of an inadequate intake of folic acid or vitamin B12. Haemoglobin level was between 5 to 11,5 g/dL, MGV: 80 to 127 fl, Leucocytes:3,2 to 5,7/µL, platelets 115 to 210.00/µL, serum B12 level was : 87±26pg/ml. Average homocysteinemia performed in 3 patients was 55 µmol/l (N<15). Triglyceridemia, Cholesterol, HDL quotient were normal. Serum Folates and others prothrombotic factors (Protein C, S AT III) were normal. Birmer's disease was confirmed in 2 patients. Medium Interval between first symptoms and diagnosis was 18 months. Evolution: All patients received B12 therapy (1000 to 5.000 micgr /2days), and 4 patients were treated with fractioned heparin, switched to vitamin K antagonist (INR 2-3) during 6 to 12 months, 2 patients received clopidogrel sole. We observed 2 deaths after 3 and 7 days of diagnosis: 1after embolism pulmonary complicated DVT, 1 cardiogenic shock in patient with myocardial infraction. Neurological sequels observed in two patients (hemiplegia and leucoencephalopathy). Total Blindness noted in one patient after TVCR. Decrease of visual acuity in 2patients with TC deficiency related to proliferative retinopathy despite specific treatment. *Conclusions*. Our Study confirms the previously vascular disease reported the independent risk of thrombosis and associated mortality in patients with Cbl deficiency. A high index of suspicion should be maintained for early anticoagulant treatment. The prognostic value need to bee evaluated in properly designed studies.

THE STIMULATING EFFECT OF ANTI-PLASMINOGEN MONOCLONAL ANTIBODY (A1D12) ON CLOT LYSIS AND ANGIOGENESIS.

K. Mansouri, M.C. Mirshahi, A. Maleki, H.R. Mohammadimothlagh

Medical Biology Research Center, KERMANSHAH, Iran

Background. Plasminogen is a single chain 92-KD glycoprotein consisting of 791 amino acid. This proenzyme that has a central role in fibrinolyrtic system can activate through various activators (Pas) to its active form plasmin and perfoem its vital function that is fibrin clot lysis. Furthermore the fibrinolyrtic system plays a major role in angiogenesis. The fibrinolyrtic system activation control cell migration and invasion (that is essential step in angiogenesis) by plasmin-mediated matrix proteolysis. In addition to this, plasmin regulates tumor growth and metastasis by the activation of matrix metalloproteases (MMPs) and growth factors. Monoclonal antibodies, as biological tools play a important role in basic researches. *Aim*. In this study we evaluated the activation of fibrinolyrtic system and angiogenesis process in the presence of antiplasminogen monoclonal antibodies.Methds: In the first step the effects of antibodie on the activation of fibrinolyrtic system with PAs were evaluated in several methods including macroscopic observation, quantitative measurement of DD/E fragments by D-dimer assay and activation of plasminogen by S-2251 synthetic substrate (ELIZA method). In subsequent we studied the effect of antibodie on angiogenesis process in an *in vitro* model. *Results*. Results showed that A1D12 which is against to N-terminal domain of Glu-plasminogen, in addition to activation of fibrinolyrtic system in presence of plasminogen activators can activate *in vitro* angiogenesis process. *Conclusions*. Plasmin directly participates in angiogenesis by direct fibrin and other matrix components degradation, and indirectly by activating matrix degrading metalloproteinase and angiogenic growth factors such as TGF-α, HGF, VEGF and bFGF. During the last decade, angiogenic research has focused on identification and detection of angiogenesis inhibitors and stimulators and their potential value in treating angiogenesis related diseases. Plasmin activating system is a potential target for this reason .According to the results of *in vitro* A1D12 accelerates this process in a dose dependent manner

1757

MAJOR CARDIOVASCULAR DISEASE IN A CHILD WITH ANTITHROMBIN DEFICIENCY - HEPARIN BINDING DEFECT

B. Chowdhury, J.A. Cutler

St Thomas' Hospital, LONDON, UK

Background. We present an unusually severe case of cardiovascular disease in a child presumed secondary to Kawasaki's disease. This child was noted to be heparin resistant in the setting of coronary artery by-pass surgery and was therefore presumed to have acquired antithrombin deficiency. Surprisingly he was subsequently found to have an inherited antithrombin deficiency with a heparin binding defect (HBS). *Design and methods and Results*. Genetic analysis of this childs SERPINC1 (GenBank X68793.1, MIM#107300) gene revealed a heterozygous C>T substitution at nucleotide c.218 within exon 2. This predicts the replacement of the native proline with a leucine at amino acid 41 of the mature protein, and was first described as Antithrombin Basel. This corresponds to codon 73

using HGVS nomenclature where +1 is the initiating Methionine. Pro41Leu is a well described mutation, with 18 reports on the current update of the Antithrombin mutation database. Pro 41Leu is characterised as a HBS defect, leading to Type II HBS Antithrombin deficiency. *Summary and Conclusions*. Childhood thrombosis is rare.The vast majority of events occur as a complication of therapy for serious underlying disease and over recent years the incidence has been noted to be increasing. Patients who are heterozygous for Antithrombin deficiency HBS variants do not exhibit an increased tendency to thrombosis although the incidence of venous thrombosis is approaching 100% in homozygotes. There have been no reports of Pro41Leu in a child of this age, and almost all reports have been in asymptomatic patients. Interestingly studies on almost 10,000 healthy blood donors in Scotland and a further 2500 in Canada failed to detect a single individual with this variant. The lack of correlation with the clinical presentation leads to difficulties in estimating the true prevalence of this mutation and whether anticoagulation is deemed necessary and for what duration. This childs anticoagulation was extended to six months therapy with a VKA (warfarin) in light of the genetic findings. The question remains as whether this is adequate therapy or not.

1758

ORAL ANTICOAGULANT THERAPY (OAT) IN PEDIATRIC PATIENTS

J.M. Sanchez Ramirez, C. Pascual Izquierdo, A. Rodriguez Huerta, C. Muñoz Novas, M. Infante, F. Carretero Lopez, G. Perez Rus, M. Ballesteros, A. Gomez Pineda, J.L. Díez-Martín

Gregorio Marañon Hospital, MADRID, Spain

Introduction. The use of antithrombotic agents in pediatric patients has significantly increased in recent years, due to developments in pediatric cardiology. *Design and Methods*. We performed a retrospective review of the pediatric patients treated with OAT (acenocumarol) at our hospital, from Feb-1995 to Jan-2009. There were 86 children (age 0-18 years, 49M/37F); 22 children (26%) initiated OAT before the age of 1 year. The indications for OAT were as follows: - Prosthetic heart valve: 6 cases. - Primary thromboprophylaxis: 13 cases; atrial flutter (1), Kawasaki disease (5), dilated cardiomyopathy (4), and associated with cardiac stent (3). - Treatment of Thrombotic events: 29 cases; venous thrombosis with risk factors (22 cases, including 10 cases catheter related thrombosis), spontaneous venous thrombosis (2), and arterial thrombosis (5). - Fontan surgery, 38 cases. In all cases, the initial dose of acenocumarol was 0.2 mg/kg, except in the Fontan cases that was 0.1 mg/kg. RESULTS: The mean follow-up was 10.5 months (1-157). We observed a high proportion of controls outside the target INR range in all groups, most under therapeutic INR. There were however few complications: only 4 cases of mild epistaxis and 2 cases of thromboembolic events, one in a child with dilated cardiomyopathy, and the other one in a child with congenital heart disease in thrombotic events group. Both recovered successfully. *Conclusions*. In our experience, OAT in pediatric patients is safe and effective; a high proportion of children have controls outside the target INR, most below it, what suggests acenocumarol underdosing due to an unjustified fear of bleeding complications.

Table.

	Prosthetic heart valves		Thrombotic disease prophylaxis		Thrombotic events		Fontan surgery
Months	<12	>12	<12	>12	<12	>12	>12
N	4	2	2	11	16	13	38
Mean age of onset	7,5 m	10 y	5,5 m	7 y	8 m	7 y	6 y
INR range	2,5-3,5		2-3		2-3		2-3
Mean follow-up (months)	44 (3-157)		9 (2-49)		6 (1-39)		8 (1-64)
INR above range	13,37% (0%-29,41%)		34,11% (0%-77,78%)		15,08% (0%-66,67%)		11,61% (0%-33,33%)
INR below range	45,2% (25%-57,14%)		35,27% (5,26%-50%)		44,37% (0-100%)		41,7% (0%-100%)
Thrombosis/ hemorrhages	2 mild epistaxis		1 cardiac embolism		1 stroke		2 mild epistaxis

COULD WHOLE BLOOD THROMBOELASTOMETRY DISCOVER HYPERCOAGULABLE STATE IN PATIENTS AFTER AN EPISODE OF IDIOPATHIC VENOUS THROMBOEMBOLISM?

E. Wojtasinska,[4] Z. Turowiecka,[2] K. Zawilska,[2] K. Ciepluch,[2] A. Skubiszak,[3] A. Lehmann-Kopydlowska,[4] J. Kurosz,[4] J. Jaworski,[4] M. Michalak,[5] A. Regdos[4]

[1]Hemostasis Laboratory, POZNAN, Poland; [2]Hemostasis Laboratory, University of Medical Sciences, POZNAN, Poland; [3]J.Strus Hospital, POZNAN, Poland; [4]J. Strus Hospital, POZNAN, Poland; [5]Department of Statistics, University of Medical Sciences, POZNAN, Poland

Background. The recurrence rate after the first episode of idiopathic venous thromboembolism (VTE) is high. Hypercoagulability and reduced fibrinolytic capacity, which might predispose to recurrences of VTE are difficult to assess in assays employed in routine care. The whole blood rotation thromboelastometry (TEM) evaluates the clot formation initiation, development and lysis. This method seems suitable to discover hypercoagulable state. *Aims*. The aim of the study was to find out if patients at least 6 months after the first episode of VTE present hypercoagulable state in thromboelastometry profiles and to investigate a relation between thromboelastometric determinations and plasma concentration of D-dimer and fibrinogen. Elevated D-dimer is widely known as a predicting factor for venous thrombosis reccurence. *Design and Methods*. The study group consisted of 24 patients at least 6 months after the first episode of idiopathic VTE, aged 19-71 (median 31): 16 women (67%) and 8 men (34%). 8 healthy volunteers were enrolled to the control group. All patients from the study group had secondary antithrombotic prophylaxis with vitamin K antagonist (INR 2,0 - 3,0). One week before blood sampling vitamin K antagonist was replaced by enoxaparine s.c. (50% of therapeutic dose). Thromboelastometric evaluation, D-dimer and fibrinogen concentration measurements were performed in both groups. *Results*. A. Patients after VTE showed markedly increased values of ex-TEM Coagulation Time-CT (73.7s vs 59.3s; $p<0.0002$), ex-TEM Clot Formation Time-CFT (90.7s vs 71.1s ; $p=0.0347$) and ex-TEM a angle (72.04° vs 75.5°; $p=0.0464$) when compared to results of the control group. B. There was significantly higher concentration of fibrinogen in the study group in comparison with controls (5.07 vs 2.87 g µL; $p=0.0002$). C. There were no statistically significant correlations between thromboelastometry values and the plasma concentration of D-dimer. *Conclusions*. In patients after the first episode of idiopathic venous thromboembolism thromboelastometric determinations show features of hypercoagulability, which should be evaluated as risk factors for recurrent VTE, but do not correlate with D-dimer level. Elevated concentration of fibrinogen in patients might contribute to these modifications of thromboelastometric parameters.

1760

UPPER-EXTREMITY DEEP VENOUS THROMBOSIS: CLINICAL CHARACTERISTICS AND RISK FACTORS

N. Fernandez-Mosteirin, B. Soria, N. Fernandez-Mosteirin, N. Padron, N. Salvador-Osuna, A. Godoy, F. Sevil, M. Guillen, M. Torres, M. Abio, A. Iborra, C. Sierra, J.F. Lucia, D. Rubio-Felix

Miguel Servet Universitary Hospital, ZARAGOZA, Spain

Background. Deep venous thrombosis of the upper extremity (UEDVT) is an unusual event ranging from 1% to 4% of all cases of deep vein thrombosis. Limited data concerning the contribution of hypercoagulable status in the pathogenesis of this disease are avaliable. *Aims*. To evaluate the characteristics of patients who developed UEDVT and to determine the prevalence of inherited and acquired thrombophilic risk factors and incidence of rethrombosis. *Design and methods*. We reviewed the clinical files evaluating demographic and clinical parameters, and inherited and acquired thrombophilic risk factors of all patients who developed UEDVT and required oral anticoagulation in our center from May 2002 to May 2008. Laboratory investigations were performed in absence of anticoagulant therapy for at least one month. The following parameters were evaluated: Antithrombin, protein C and S, homocysteine, anticardiolipin antibodies, lupus anticoagulant and thrombophilic mutations. Statistical analysis was performed with SPSS 15.0. Results: 42 patients showed UEDVT: 17 female (40.5%), 25 male (59.5%). Median age 51.04 yr (6-92). 4 patients (9.5%) had familiar history of thrombosis . 14 patients (33.3%) had idiopathic thrombosis and the remaining 28 patients (66.7%) showed acquired risks factors of thrombosis (cancer or central venous catheter). Local anatomic abnormalities were found

in 7 patients (16.9%) . 20 patients (47.6%) had thrombosis in one localization while 22 (52.4%) have more than one area afected. Localizations were: 15 axillar-subclavian, 10 yugular, 6 subclavian, 4 brachiocefalic, 2 axillary-subclavian-yugular, 1 axillary-subclavian-cefalic, 1 axillary-subclavian-brachiocefalic, 1 yugular-carotidean, 1 brachiocefalic-cava and 1 yugular bulb, transverse and sigmoid sinuses. Diagnosis was stablished by ultrasound in 17 patients (40.5%), contrast venography in 3 patients (7.1%), computerized tomography in 3 patients (7.1%), ultrasound and venography in 4 patients (9.5%), ultrasound and computed tomography in 13 patients (31%) and 2 patients (4.8%) by the three procedures. 14 patiens (33.3%), had not acquired risk factors, 8 patients (19%) had history of cancer , 9 patients (21.4%) had cancer and central venous catheter, 3 patients (7.1%) had central venous catheter, 2 patients (4,8%) had pacemarker and cancer, 2 patients (4.8%) were under oral contraceptive therapy and the last 2 patients had recidivant pathology of shoulder and middle ear infections. About hypercoagulable status: 6 patients (14,3%) showed low level of protein C, protein S and homocysteine levels were normal in all patients and antiphospholipid antibodies were positive in 8 patients (19%). Thromobophilic mutations were shown as follows: 10 patients (23.8%) Heterozygous MTHFR, 2 patients (4.8%) doble heterozygous prothrombin and MTHFR, 1 patient (2.4%) doble heterozygous FV Leiden and MTHFR, 1 patient (2.4%) homozygous FV Leiden and heterozygous MTHFR, 2 patients (4.8%) homozygous MTHFR and 1 patient (2.4%) triple heterozygous. Patients were divided in 2 groups, idiopathic or non idiopathic thrombosis to analize differerencies about gender, age, thrombosis localization, anatomic abnormalities, diagnosis by ultrasound, tomoghaphy or venography, and hypercoagulable status. No statistical differences were found between the 2 groups except localization of thombosis which seems to be more extensive in idiopathic thrombosis group (p=0.04). Rethrombosis was observed in 7 patients (26.7%) as pulmonary thromboembolism. *Conclusions*. 1) The presence of central venous catheter does not influence the risk for other thromboembolic events like pulmonary embolism, being in our serie similar to previously reported in the literature. 2) Neoplastic status is teh most prevalent event as risk factor in our cases. 3) The antecedents of idiopathic thrombosis are correlated in our experience with more extensive disease. 4) In spite of the relatively high incidence of genetic hypercoagulable status, no statistical differences were observed between idiopathic or non idiopathic thrombosis.

1761

SPLANCHNIC VEIN THROMBOSIS AS THE FIRST CLINICAL FEATURE OF MYELOPROLIFERATIVE DISEASE

M. Zawilska, M. Jamrozek-Jedlinska, M. Grzywacz

J.Strus Hospital, POZNAN, Poland

Myeloproliferative diseases (MPDs) represent the commonest cause of splanchnic vein thrombosis. The resulting hypersplenism and haemodilution decrease the accuracy of blood counts and splenomegaly for MPD diagnosis. We present 7 cases (5 women, 2 men, aged 22-47 years) admitted for thrombophilia testing because of idiopathic portal or hepatic vein thrombosis. Inherited thrombophilia including: antithrombin-, protein C-, protein S deficiency, factor V Leiden or protrombin gene G20210A mutation was excluded in 6 cases. In one patient a hereditary heterozygotic deficiency of protein C was discovered. 4 cases presented with antiphospholipid antibodies and primary diagnosis of antiphospholipid syndrome was established. Splenomegaly was of no value in differential diagnosis, as it could result from hepatic or portal vein thrombosis. Histopathology of bone marrow revealed megakariocyte hyperplasia and fibrosis (+1) in 6 patients. Molecular testing was positive for JAK 2V617F mutation in 6 cases, suggesting myeloproliferative disease as the primary cause of thrombosis. Additionally paroxysmal nocturnal haemoglobinuria (NNH) has been diagnosed in one case. Conclusion: In patients with splanchnic vein thrombosis diagnosis of underlying clinically "latent" MPD could be established with JAK2 analysis. This test could replace bone marrow investigations as initial diagnostic test for MPD. Aniphospholipid antibodies were the most frequent associated prothrombotic factor in our group of patients.

1762

PROTEIN C, PROTEIN S AND ANTITHROMBIN III PLASMA LEVELS IN ACUTE LEUKEMIA IN CHILDREN

L. Sherief,[1] M. Badr,[4] T. Hassan,[4] N. Kamal,[2] S. Esh[4]

[1]Zagazig University, ZAGAZIG, Egypt; [2]Cairo University, CAIRO, Egypt

Background. Acute leukemia is the most common childhood malignancy. The occurrence of various coagulation abnormalities in acute leukemia is well established. Hemorrhage is the most common haemostatic disorder in patients with acute leukemia. Thrombosis is a rarer complication.However, the epidemiology and the exact pathogenesis of this entity are complex and have not yet been clearly defined. Aims: We aim to evaluate the plasma levels of the natural anticoagulant panel {protein C (PC), protein S (PS) and antithrombin β (ATβ)} and their role as predisposing factors for hemorrhagic and thrombotic complications of acute leukemia in children. *Design and Methods*. The study was carried out on 40 patients with acute leukemia (24 with ALL and 16 with ANLL) at Pediatric Hematology and Oncology Unit in Zagazig University Hospital. All patients were subjected to full medical history and examination, routine work-up for acute leukemia and estimation of Protein C, Protein S and Antithrombin β plasma levels at diagnosis and during treatment. *Results*. It was found that the level of ATβ was significantly lower at diagnosis in both ALL and ANLL (p<0.01) with a significant increase in its level during remission in ANLL patients (p<0.05). As regards PC, there was a significant decrease in PC level in both ALL and ANLL patients compared to controls (p<0.01 & p<0.05) respectively, while no statistically significant differences were detected regarding PS in all patient groups. *Conclusions*. Our results indicate that apart from thrombocytopenia, low levels of ATβ and PC and alteration in fibrinolysis and coagulation may be responsible for the hemorrhagic and thrombotic complications observed with acute leukemia in children.

1763

INVESTIGATIONS OF THROMBIN GENERATION TESTS IN WARFARIN-TAKING PATIENTS

E. Papakonstantinou, E. Yfantis, A. Skourbouti, P. Georgoutsou, A. Lavda, K. Paraskevopoulos, E. Paximadakis, C.D. Olympios, C. Manti

Thriassion General Hospital, ATHENS, Greece

Background. Thrombin generation tests measure the total thrombin formed and are potentially superior when compared with the currently used coagulation tests in monitoring the hypercoagulation or hypocoagulation state of patients. We used chromogenic method on the fully automated Behring Coagulation System (BCS) to measure the thrombin generation in patients under warfarin therapy with different international normalized ratios (INRs) to evaluate their coagulation state. AIM: The investigation of the relationship of endogenous thrombin potential (ETP) parameters between controls and patients under stable warfarin therapy. *Design and Methods*. We studied 30 control blood samples and 39 blood samples from patients who had been taking warfarin for more than 3 months since underwent valve replacement or suffered from atrial fibrillation. INR and thrombin generation parameters were performed in all samples.The INR values varied from 1.5 to 3.8. We used the chromogenic method on the fully automated Behring Coagulation System (BCS) for the measurement of thrombin generation parameters. RESULTS: Table Comparison of the two groups showed statistical significant differences p< 0.0001 for all parameters. The ETP and the Cmax showed a strong inverse correlation with the INR (n=20; r= -0.632 and -0.709 respectively). *Summary and Conclusions*. The range of ETP values is rather width at the investigated INR range. Patients at therapeutic INR range may have low ETP values and high risk of bleeding or high ETP values and thrombotic risk.Although the INR is a good surrogate, ETP measurement might be more accurate in estimating anticoagulation potential. Therefore, ETP might offer better differentiation between those who bleed more easily and those who develop thrombosis despite "therapeutic" anticoagulation. For clinical validation of these findings a prospective clinical trial is warranted.

Table.

IRINOTECAN AND INCREASED TRIGLYCERIDES LEVEL IN PARANEOPLASTIC DEEP VENOUS THROMBOSIS(DVT): A STRANGE LINK IN AN OLD PROBLEM

G. Giordano, G. Farina, R. Tambaro, S. Piano, S. Papini, B. Zappacosta, S. Storti

Research Center "J.Paul II" Catholic University Campobasso, CAMPOBASSO, Italy

Background. DVT is present in about 3-15% of cancer patient. Paraneoplastic thrombosis pathogenesis is multifactorial. Chemotherapy is frequently involved in DVT genesis as proinflammatory/prothrombothic factor. Ther are few data about incidence of DVT in patients treated with Irinotecan. *Aims*. Aim of our study is to define if thrombotic risk in patient treated with Irinotecan is increased and eventually through wich mechanism probably Irinotecan acts in DVT genesis. With this purpose we considered in our patient complement fraction C3 and C4 and immune circulating complex (ICC) because they activate macrophage and platelets and increase tissue factor level. Moreover we recognize also total cholesterol and triglycerides level, because they are linked with factor VII activation. *Design and Methods*. We considered C3, C4, ICC, cholesterol and triglycerides level, dose density and chemotherapeutic agents used in 116 patients with solid neoplasm (62colon, 26lung, 18gastric,) and without anticoagulant prophilaxis. Median age was 68.5 years (R 57-83). M/F ratio was 66/40. The threshold value of third quartile was chosen as risk cut-off (C3: 130mg/dl; C4: 32mg/dl; ICC: 2.9 mcg/ml; total cholesterol: 205mg/dl; triglycerides 120mg/dl). The statistical analysis was conducted with Yates corrected chi square test, Fisher's exat test, Odds Ratio (OR), realtive risk (RR). Results 24 patients (20%) showed DVT. Patients treated with Irinotecan were 42. DVT occurred in 14 of these patients (32%) and in 10 of 74 patients treated without Irinotecan (14%) with a Yates corrected chi square test of 4.6 (p 0.03), a Fisher's exact test with p0.03, an OR of 2.98 (95%CI 1.2-7.3) and a RR of 2.35 (95%CI 1.1-4.8). CRP and ESR at Pearson's test were not related with C3, C4, ICC, total cholesterol and triglycerides levels. All patients treated with Irinotecan had advanced stage colon cancer. High levels of triglycerides (>120mg/dl) were present in 17 out of 42 patients treated with Irinotecan (40%) and in 17 out of 74 patients treated without Irinotecan (23%) with a Yates corrected chi square test of 3.1 (p 0.07), a Fisher's exact test with p0.05, an OR of 2.2 (95%CI 1-5) and a RR of 1.7 (95%CI 1-3). *Conclusions.* Althoug patients receiveing Irinotecan and developing DVT were those with advanced stage colon cancer, influence of chemotherapy in DVT genesis in our study cannot be excluded. Probably Irinotecan contributes to DVT increasing triglycerides levels. In fact increased levels of triglycerides are linked *in vivo* with factor VII activation. This relief suggest also that other risk factors and other drugs (i.e. hypolypemizant drugs) might be used in paraneoplastic DVT prevention. Nevertheless these data need confirmation on a larger cohort of patients.

1765

SERUM THROMBOMODULIN LEVEL IN CHILDREN WITH β THALASSAEMIA MAJOR

H. Hassab, B. El Domiaty, W. ElGendy, A. Abd El Mohsen, Sh. Hassan

Faculty of Medicine Alexandria University, ALEXANDRIA, Egypt

Background. In recent years, it is suspected that vascular endothelial cells may have some role in vascular compications noted in thalassemic patients. Activated or injured endothelial cells release their protein constituents mainly thrombomodulin into the circulation. Thrombomodulin is considered the most important indicator of vascular endothelial injury. *Aims*. to study serum thrombomodulin level in children with β-thalassemia major and its relation to the duration of disease and extent of iron overload. *Subjects*: The present study was carried out on 35 patients with β-thalassemia major. They were divided according to the age into two groups. Group I: included 15 young children aged less than 10 years. Their mean age was 6.4 years, and their mean disease duration was 5.5 years. Group II: included 20 older children and adolescents aged from 10 to 20 years. Their mean age was 16.5 years and their mean disease duration was 15.6 years. Ten apparently healthy children of matching age and sex served as control group. *Design and Methods*. Estimation of serum levels of Thrombomodulin (TM) by ELISA. Echocardiography, two-dimensional, M-mode, and Doppler studies. *Results*. Cardiomegaly was found in 7 (35%) patients of group II. Pulmonary hypertension was encountered only in 4 (20%) patients of group II. Thromboembolic manifestations (femoral deep vein thrombosis) were found in only 1 (5%) thalassaemic patient in group II. The serum TM level was significantly higher in both groups, in comparison with controls (F=10.36, $p<0.001$). No significant difference was found between both thalassaemic groups (t=0.421, $p=0.673$). Moreover, no significant difference was found between TM levels in splenectomized and non-splenectomized cases (t=0.62, $p=0.541$). TM levels of both thalassemic groups showed no significant correlation with serum ferritin level (r=-0.02, $p=0.914$). A significantly higher mean value of right ventricular wall thickness was encountered in group II thalassaemic patient as compared to group I (t=2.57, $p=0.019$). *Conclusions*. increased serum TM level in our polytransfused thalassaemic patients reflects a state of endothelial cell activation and/or injury in these patients. The statistically significant negative correlation between serum TM level and pulmonary acceleration time (r=-0.45, $p=0.047$), may point to the possible role of pulmonary vascular endothelium injury as a contributory factor in the pathogenesis of pulmonary hypertension in our thalassaemic patients.

1766

PROGNOSTIC VALUE OF VON WILLEBRAND FACTOR AND FIBRINOGEN LEVELS IN ADVANCED GASTRIC CANCER PATIENTS

A. Godoy,[1] R. Pazo,[2] N. Fernandez-Mosteirin,[3] J. Lao,[2] R. Garcia-Foncillas,[4] J.F. Lucia,[3] D. Rubio[3]

[1]Hospital Universitario Miguel Servet, ZARAGOZA, Spain; [2]Servicio de Oncología Médica, Miguel Servet University Hospital, ZARAGOZA, Spain; [3]Servicio de Hematologia. Miguel Servet University Hospital, ZARAGOZA, Spain; [4]Departamento de Bioestadistica. Universidad de Zaragoza, ZARAGOZA, Spain

Background. Activation of clotting and fibrinolysis systems are thought to be involved in tumor angiogenesis, tumor-platelet adhesion and tumor-endothelial cell adhesion. Von Willebrand factor (vWf), an adhessive ligand with platelets, is elevated in advanced disseminated malignancies and it is involved in the metastatic process. *Aims*. To correlate coagulation markers levels in plasma of advanced gastric cancer (GC) patients (pts) undergoing palliative chemotherapy (CMT) with response to treatment and time to progression (TTP). *Design and Methods*. 41 pts with locally advanced or metastatic GC, diagnosed between january and december 2008, and 20 healthy controls were enrolled in the study. Blood samples were taken before (basal time) and after platinum-fluoropirimidine-based CMT. We measured plasma levels of vWf, vWf activity-ristocetin cofactor test (vWf: Rcof) (BCS coagulometer), vWf Antigen (vWf:Ag), factor VIII activity test, D-Dimer (DD), Plasminogen, Thrombin Time (TT), Fibrinogen and Reptilase time (ACL-TOP coagulometer) and plasma GC tumor markers (CEA and CA19.9). Results.- Median age of pts was 64 (range 38-89). All pts but one received at least one cycle of CMT, with a median of 3 cycles (range 0-10). Median basal ECOG was 1 (range 0-3). After a median follow-up of 9 months the median TTP was 4 months and the median overall survival (OS) 8 months. At basal time were found elevated levels of vWf:Ag (median 210%; range 121,1-492,2%), DD (median 530 mgr/L; range 49-17489) and Fibrinogen (median 5,4 gr/L; range 2,78-7,67) when compared with healthy controls. Basal time plasma levels of vWf:Ag were significantly correlated with basal CA19.9 levels ($p< 0.05$). Higher basal Fibrinogen levels predicted worse response to treatment ($p= 0.02$) and shorter TTP ($p= 0.012$); however basal time levels of vWf:Ag and DD were not correlated with CMT response, TTP or OS. Higher vWf:Rcof levels after 3 cycles of CMT were correlated with worse treatment response ($p= 0.019$) and shorter TTP ($p< 0.05$). *Conclusions*. vWF:Rcof levels during CMT and basal levels of Fibrinogen might both predict response to treatment and TTP in advanced GC pts.

1767

SUCCESSFUL PREVENTION OF ATTACKS WITH STANOZOLOL IN A CHILD WITH SEVERE CRYOFIBRINOGENEMIA

S. Unal, F. Kara, D. Orhan, M. Tuncer, F. Gumruk

Hacettepe University, ANKARA, Turkey

Background. Cryofibrinogenemia is a rarely symptomatic disorder that is underestimated due to the rarity of the symptomatic form of the disease; however it may sometimes cause multiple thromboembolism in the skin, lung and myocardium and cause deleterious effects leading to significant morbidity and mortality. The pathological manifestations associated with cryofibrinogenaemia have been treated with plasmapheresis and fibrinolytic drugs such as streptokinase, streptodornase and/or urokinase. *Aims*. Stanozolol, an androgenic steroid with fibri-

nolytic properties. is a safe and effective drug for the long-term management of hereditary angioedema and there is data on its use in childhood cases in this indication. There is also literature data on good results with stanozolol in adult patients with symptomatic cryofibrinogenemia, however data on its use in childhood cases with this indication is limited. *Design and Methods*. Herein, we report an eleven year-old male presented with complaints of red painful swelling of the tips of his right hand's third digit and his left hand's three digits. He had been having similar attacks on acral areas like finger tips, auricles, nose tip since he was 18 months-old. This attacks mostly occur after exposure to cold like playing with snowball. He was admitted to many other clinics before and was treated with many drugs like calcium channel blockers, asetil salisilic acid, intravenous pentoxyfilin, dextran infusion and methylprednisolone, but none of these measures could stop tissue loss and his left hand's fourth and fifth digits were amputated (Figure 1). Laboratory tests revealed slightly elevated fibrinogen and high α1 antitrypsin levels. On protein electrophoresis serum α 2 band was found as increased. Cryoglobulin was negative but cryofibrinogen test was positive in qualitative assay. The tests that are made to exclude secondary cryofibrinogenemia causes including collagen vascular diseases revealed ANA positivity (1/160 nucleolar pattern) and mildly increased anti dsDNA levels. Antiphosholipid and cardiolipin antibodies were negative. Hypercoagulability tests were normal. The skin biopsy taken from knee was consistent with thrombogenic vasculopathy showing PAS positive fibrin thrombi inside vascular lumen and on the wall which was positive with fibrinogen and C3 on immunohistochemistry stains. He was diagnosed to have cryofibrinogenemia and stanozolol (2 mg/day, po) prophylaxis was initiated with the concent of the family. The patient had no attacks in the winter under stanozolol, besides some of the new forming lesions at the onset of stanozolol healed without sequela. The patient developed no side effects related to stanozolol and being closely monitored. *Summary and Conclusions.* Cryofibrinogenemia is a difficult disease for patients and physicians in its symptomatic form. Stanozolol seems to be promising and safe with this indication in pediatric cases. The symptomatic form is rare in childhood and early prophylaxis with stanozolol may prevent morbidities like amputations of digits.

THROMBOPROPHYLAXIS DURING PREGNANCY-A RETROSPECTIVE STUDY IN A DISTRICT GENERAL HOSPITAL

J. Blundell,[1] M. Derias,[2] F. Duncan-Millar[2]

[1]Royal Cornwall hospital, TRURO, UK; [2]Peninsula Medical School, TRURO, UK

Background. Venous thromboembolic (VTE) disease is the most common cause of maternal death in the United Kingdom. The Royal College of Obstetricians and gynaecologists (RCOG) have produced guidelines (2004) on thromboprophylaxis during pregnancy. Aims To see if these how these guidelines were being followed at the Royal Cornwall hospital and to see if they were effective at preventing VTE. *Design and Methods*. Twenty one patients who had received thromboprophylaxis during pregnancy were selected at random from the haematology database. Information was obtained from hospital and laboratory records. This included, age, pre-pregnancy weight, timing of prophylaxis, risk factors, details of previous VTE, drug and dose used and thrombophillia status. *Results*. The mean age was 31 years (21-40) and all had previous VTE. The mean pre-pregnancy weight was 83kg (47-120kg); weight was not documented in 10 patients. Eighteen were started on prophylactic dose antenatal low molecular weight heparin (LMWH) dalteparin in the second trimester. One patient had severe skin reaction to several preparations and was changed to danaparoid post partum. Three patients had only post partum LMWH prophylaxis. Two patients had thrombotic events despite prophylaxis, one lady had Klippel-Trenaunay syndrome, immobility and hyperemesis, the other had a prolonged labour and caesarean section. All ladies had 6 weeks post natal thromboprophylaxis. Thrombophillia testing was performed in 14. Three results were positive (heterozygote for factorV Leiden). *Conclusions.* All women had a history appropriate to recommend use of thromboprophylaxis. Although guidelines suggest starting prophylaxis as early in pregnancy as practical, individual women expressed personal views on the timing of antenatal prophylaxis and in the absence of a strong evidence base this should be taken into consideration. The guidelines recommend thrombophillia screening; thrombophillia results did not influence the management of any of our patients and we question its value in the management of this patient group. It was difficult to extract information from the hospital notes; particularly the pre-pregnancy weight was unavailable in many notes. With increasing obesity more women will be over 100kg at booking, not only is this risk factor for VTE but anti-Xa levels should be measured to monitor effectiveness of LMWH in this patient group-clearer documentation is essential. The 2 patients who had VTE despite prophylaxis were complex but a more consistent multi disciplinary approach may have ensured their VTE risk was reassessed as the pregnancy progressed and their LMWH dose reconsidered

1769

ENDOGENOUS THROMBIN POTENTIAL (ETP) IN PATIENTS WITH AN ACUTE MYOCARDIAL INFRACTION

E. Papakonstantinou, E. Yfantis, S. Chaniotaki, A. Skourbouti, J. Rodis, E. Paximadakis, K. Safioleas, C.D. Olympios, C. Manti

Thriassion General Hospital, ATHENS, Greece

Background. The ETP test, recently, was added to the conventional coagulation tests, such as prothrombin time (PT) and activated partial thromboplastin time (APTT), for the investigation of coagulation function. ETP has been shown useful to detect an hypercoagulable state in individuals at risk of venous thrombosis. *Aims*. To investigate ETP parameters in acute myocardial infraction on admission and 4days later. *Design and Method*s. 12 patients with AMI were included. Blood was sampled on admission and after 4 days when all patients received heparin/LMWH, acetylsalicylic acid and/or clopidogrel. ETP parameters was measured by the chromogenic method on the fully automated Behring Coagulation System (BCS). *Results and Conclusions*. ETP and Cmax were decreased and tlag and tmax were prolonged when patients were on anticoagulant therapy. These results are not statistically significants. That might be explained by the key role of antiplatelet drugs in AMI which do not affect ETP. ETP is sensitive to antithrombotic medication but the number of patients was very small thus for clinical validation of these findings a prospective clinical trial is warranted.

Table.

		SD	P
ETP admission	365.2	73.2	**0.118**
ETP 4days	319.3	113.2	
Cmax admission	132.8	37	**0.201**
Cmax 4days	114.5	40.3	
Tlag admission	32.7	12.4	**0.277**
Tlag 4days	55.6	68.8	
Tmax admission	66.3	18.3	**0.276**
Tmax 4days	100.2	103.7

ESTIMATION OF THROMBIN PRODUCTION IN DIFFERENT SUBJECTS

P.E. Makris, M.P. Makris

Aristotle University of Thessaloniki, THESSALONIKI, Greece

Background. During the decade of 90s new methods, of global impact, for the evaluation of the activation of blood coagulation appeared and mainly after the presentation of Hemker and Beguin method. We thought of a newer and simpler method using the already existing aggregometer (Chrono-log, P.I.C.A). Our method is based in thrombin production using platelet rich plasma (PRP) in which CaCl2 is added. *Aims*. The aim of our study is the presentation of possible new test and checks it in normal subjects, and patients in different pathologic situations. Material: We applied our method in 114 subjects (30 normal subjects (NP) with mean age 37,9±9,4 to estimate the mean values and SD, 16 haemophiliacs, 36 patients under LMWH, 56 patients under antiplatelet drugs -48 under Aspirin and 8 under Plavix-, and 6 patients under anti-vitamin K treatment). *Principe of method*. The addition of CaCl2 in PRP activates it and produces coagulum. *Design and Methods*. In 450 μL of PRP we add 250 μL CaCl2 (0.025 mm) in a plastic tube of aggregometer (Chrono-log P.I.C.A). We also tested the reproducibility of the method by repeating the test 12 times in the same normal subjects CV for the area under curve 5,9%, and for the lag time was 13%. The results presented in table I. For normal subjects for example the mean lag time of GTT was 161,3±63,4sec while in haemophiliacs was 573.2±218.7sec (with a t-test statistically very significant, $p<0.001$). The advantages of our method besides the fact that it is without cost is: The mean values of lag time in these categories differ accordingly; witch is statistically significant and proves their diagnostic value.

Table. Mean value and t-test.

categories	X ± SD	p
NP vs hemophiliacs	161,3±63,4 vs 573,2±218,7	<0,000168
NP vs thrombophiliacs	161,3±63,4 vs 298,2±122,7	<0,0235
NP vs antiplatelets	161,3±63,4 vs 320,9 ±55,8	<0,020
NP vs LMHW	161,3±63,4 vs 349,6±144,3	<0,01

1771

USE OF TISSUE PLASMINOGEN ACTIVATOR(R-TPA) IN 6 CHILDREN, CASES SERIES

A. Gunes Meral, O. Bostan, B. Baytan, E. Semizel

Uludag University Faculty of Medicine, BURSA, Turkey

The information about the thromboembolic events, the optimal treatment choice, the dose and duration of antithrombotic therapy in children are limited. More clinical data are required. Recombinant tissue plasminogen activator (r-tPA) is increasingly used in pediatric thrombosis. We retrospectively analyzed the clinical course of 6 children (mean age: 6.1±3.4) with venous thrombosis (n:1) and intracardiac thrombosis (n:5). The children were treated with r-tPA. The dose ranged between 0.2-0.4mg/kg/h infused for 3 to 4 hours. This dose was repeated between 2 to 7 times till the thrombolysis was achieved. Treatment side effects were closely monitored. Plasma D-dimer, fibrinogen levels, prothrombin time and activated partial thromboplastin time were measured prior to each r-tPA administration. If they were prolonged, fresh frozen plasma was given in order to maintain normal hemostasis. Complete clote lysis was achieved in all cases. None of them had severe bleeding except mild recurrent epistaxis occurring in 2 cases. In conclusion, r-tPA is an effective and safe therapy under close haemostatic control in children.

1772

CLINICAL MANIFESTATIONS AND HEMOSTASIS LABORATORY ABNORMALITIES IN ADULT β THALASSEMIAS WITH HIGH LEVEL OF ANTIPHOSPHOLIPID ANTIBODIES

T.D. Atmakusuma

University of Indonesia, JAKARTA TIMUR, Indonesia

Background. A total number of 41 adult Adult β Thalassemias (87.81% were Thalassemia β/HbE, age ranged between 19 to 61 years old) with a high level of antiphospholipid antibodies (ACA IgG, ACA IgM, and anti β2 GP1 IgG), had been enrolled into a study on the clinical manifestations related to the blood circulation disturbances and the hemostasis laboratory abnormalities. No data has been reported about these findings. *Aims*. The questions were: (1) What clinical manifestations and how frequent the blood circulation disturbances developed in those 41 study subjects. (2) What kind hemostasis abormalities developed in those 41 study subjects. *Design and Methods*. Descriptive data of clinical manifestations of blood circulation disturbances as well as hemostasis laboratory abnormalities have been collected in those 41 study subjects of Indonesian populations. Laboratory examinations were conducted in Jakarta and compared to 41 people of control normal group. *Results.* Of 41 study subjects, 31 patients (75.61%) had head complains (cephalgia, migrain, vertigo), 24 patients (58.54%) experienced lower extremities disturbances (pain, edema and paresthesia), 22 patients (53,66%) demostrated chest complains (shortness of breath, chest pain, etc), 14 patiens (34,15%) developed tinnitus or visus problems, 9 patients (21,95%) developed bleeding (epistaxis, purpura, bleeding of the gum)), and 5 patients (12.20%) showed fetal loss syndrome (miscarriage, perinatal death). Of 41 study subjects, mean of VCAM-1 was 2101.339±1120.403 ng/ML (higher than control normal group, $p<0.001$), TAT complex 4.779±15.019 ng/mL (higher than control, $p<0.001$)) F1+2 prothrombin 1.168±1,657 nmol/L) (higher than control, $p=0,001$), D-dimer 539.415±1051.799 ng/mL (higher than control, $p<0.001$), AT III 75.448±19.360% (lower than control, $p<0.05$), Protein C 69.075±98.616% (lower than control, $p<0.001$), Protein S 72,225±18,883% (lower than control, $p<0.001$), PAI-1 3.395±5.328 iu/mL (compared to control $p > 0.05$), fibrinogen 207.666±95.707 (lower than control, $p<0,01$). Platelet aggregation revealed 31 of 41 patient (75.61%) had hyporeactive aggregation, normoreactive in 6 patients (14.63%), hyperreactive in 3 patients (7.31%), sticky platelet in 1 patient. *Conclusions*. Compared to thalassemia patients or patient with anti-phospholipid syndrome (APS) in general Adult β Thalassemias with a higher level of ACA IgG, ACA IgM, anti β GP1 IgG showed similiraties, except in the latest group showed hyporeactive platelet aggregation, low F1+2 prothrombine, and no differerences of PAI-1 compared to control normal group.

1773

PLASMA COAGULATION TESTING AND GENETIC THROMBOPHILIA MUTATIONS CAN PREVENT THE IDIOPATIC RECURRENT ABORTIONS IN HEALTHY FERTILE WOMEN

M. Musso,[1] R. Musso,[2] D. Cultrera,[3] A. Cipolla,[2] R.M. Rosso,[2] C. Grazia,[2] G. Giulia,[2] B. Ximenes,[2] M.G. Ferro[2]

[1]Dision of Hematology, CATANIA, Italy; [2]Hematology Division and Thalassemia Unit, Haemophilia & Thrombosis Centre, CATANIA, Italy; [3]Division of Hematology, CATANIA, Italy

Background. A hypercoagulation state is frequently reported in apparently health women with adverse pregnancy outcomes. In this scenario to many tests and too much conflicting data are until now described.In this regard several facors have been considered:increased venous stasis,high circulating plasma levels of FI,II,VII,VIII,IX,X,XI,XIII,misinterpreting temporary decrease in Protein C (PC), Protein S (PS) and antithrombin III (ATIII) as these rare inherited deficiencies,enhanced platelet activation,raised fibrin generation/deposition,latent or manifest vascular endothelium suffering/damage,immunological competence changes,increased complement activation,abnormal cytokines' release and up-expression or under-regulation of several cellular membrane receptors. Recently the genetic thrombohilia mutations have been invoked as causative agents for idiopathic recurrent abortions (ARI) as well as for repeated fetal losses (RFL),intrauterine growth retardation (IUGR), recurrent placenta abruption, early onset preeclampsia and oligohydramnios(so called maternal thrombophilias). Aims.To define the prerequisites for the genetic thrombophilias as adjunctive factors in women with ARI,RFL and/or maternal thrombophilias.To establish a suitable tests' ordering pattern. *Design and Methods*. 94 consecutive

apparently healthy fertile women,age ranging 16-52 years,with body mass index in normal average were considered.ARI from 2 to 9 and/or RFL at 2nd-3rd of pregnancy were referred in each subject.No infections,nor endocrinopathies,nor anatomic uterine malformations were documented.15/94 have had one birth in the list of their ARI and/or RFL.18/94 had venous tromboembolism episodes(>2)in juvenile age.Plama coagulation routine tests,LAC,PAI-1 and D-dimer were assayed.Anticardiolipin(ACA IgG-IgM),anti-phospholipid(APA IgG-IgM),anti-b2-glycoprotein-I(A-b2GP-I),anti-gliadine(AGA)antibodies and plasma homocysteine amount were determined.Genetic thrombophilia mutations(n=13) were performed by Reverse Dot Blo-Real Time PCR. Results.In 83/94 females a hypercoagulation pronesess and/or several thrombophilia mutations were seen: ATIII deficit(n=2),PC reduction(n=3),PS deficiency(n=57),LAC positivity(n=21),APA(n=21),A-b2GP-I(n=18),AGA(n=14),increased PAI-1(n=19),elevated(> 1200 mg/Lt) D-dimer(n= 46).Prothrombin mutation(n=29 etherozygousity and n=5 homozygous state),FV Leiden(Q506 n=19 etherozygous and n=4 homozygous condition),FV R2 aplotype(n=11 etherozygous state and n=2 homozygousity), combined FII and FV Leiden (n=9),MTHFR(C677T n=49 etherozygous and 21 homozygous state,A1298C n=21 etherozygous and n=13 homozygous, combined aplotypes n=18).Hyperhomocisteine (21-155 nmol/Lt) was found in 27/94 women. *Conclusions*.The pathogenetic mechanisms of ARI,RFL,IUGR and of so called maternal thrombophilias in apparently healthy fertile women remain of biggest concern. Predisposing/primary-secondary causes have to be considered. In this area, a wide hypercoagulation and heterogenous inherited thrombophilias are documented because of the patients' etherogeneity as well as laboratory variability.Furthermore,disparate perspectives of obstetrician,hematologist,reumatologist,internist persist until now in this scenario.Individual methodological laboratory approaches and an accurate clinical evaluation must be considered. The reasoned screening for hypercoagulability,the genetic thrombophilia profile and the immunological competence changes in conjuction with the sonography scanning pictures can define the etiopathogenesis of ARI,RFL,IUGR and the maternal thrombophilias to establish the therapeutical strategy.

1774

ENDOGENOUS THROMBIN POTENTIAL (ETP) AND COAGULATION MARKERS IN PATIENTS WITH AN ACUTE MYOCARDIAL INFRACTION ON ADMISSION

E. Papakonstantinou, S. Chaniotaki, P. Georgoutsou, A. Lavda, I. Tsakalis, E. Paximadakis, P. Safioleas, C.D. Olympios, C. Manti

Thriassion General Hospital, ATHENS, Greece

Background. The ETP test, recently, was added to the conventional coagulation tests, such as prothrombin time (PT) and activated partial thromboplastin time (APTT), for the investigation of coagulation function. ETP has been shown useful to detect an hypercoagulable state in individuals at risk of venous thrombosis. AIM: To investigate ETP parameters in acute myocardial infraction (AMI) and other coagulation markers in patients and controls. *Design and Methods*. 31 patients with AMI and 30 controls were included. Blood was sampled on admission. ETP parameters was measured by the chromogenic method on the fully automated Behring Coagulation System (BCS). Other markers were D-dimer and fibrinogen. RESULTS: 87.1% was male. Patients and controls had normal PT and aPTT. Table 1.

Table 1.

	CONTROLS		PATIENTS		
	median	sd	median	sd	p
tlagsec	19.3	2.6	41.4	28.4	**0.0001**
tmax sec	54.3	4.4	86.2	61.9	**0.007**
CmaxmA/min	123.5	6	124.2	35.1	0.916
ETPmA	394.7	29.5	352.6	70.5	**0.002**
FIBmg/dl	403.9	110.3	511.6	174.6	**0.008**
DDmg/l	0.27	0.15	1.22	2.2	**0.022**

Conclusions. Although AMI is an hypercoagulable state, ETP in AMI is comparable to the values of ETP in controls. ETP appears to take a rather width range of values in AMI. ETP reflects hypercoagulability in AMI similar to fibrinogen and d-dimers. For clinical validation of these findings a prospective clinical trial is warranted.

1775

SNEDDON SYNDROME IN A CHILD

N. Ozdemir,[1] T. Celkan,[2] S. Uysal,[3] S.P. Keskin,[3] O. Unver,[3] C. Islak,[4] O. Kizilkilic[4]

[1]Cerrahpasa Medical Faculty, ISTANBUL, Turkey; [2]Pediatric Hematology Dept., ISTANBUL, Turkey; [3]Pediatric Neurology Dept., ISTANBUL, Turkey [4]Neuroradiology Dept., ISTANBUL, Turkey

Background. Sneddon Syndrome is a rare disorder characterized by generalized livedo reticularis, multiple cerebrovascular events and ischemic stroke particularly in the territory of middle cerebral artery. This syndrome mainly affects women in early adult life and is very rare in childhood. *Aims*. We present a 4-year-old girl with Sneddon Syndrome. Case: A 4-year-old girl was admitted to our hospital with sudden onset of left sided weakness, right central facial paralysis. No fever , infection or arthralgia was described. She had livedo reticularis on physical examination and had a history of right sided optic atrophy. Her family history revealed two relatives diagnosed as Behçet's disease. There was no family history of trombosis, stroke or myocardial infarction. Her laboratory studies including clotting and thrombophilia screen were all normal. Her echocardiogram was normal. Magnetic resonance imaging revealed infarction in right anterior cerebral artery territory, which was on subacute phase, as well as right carotid artery signal void loss which is consistent with occlusion. Her skin biopsy was normal. The diagnosis is made by clinical and radiological findings. *Conclusions*. Sneddon Syndrome was first described by Champion in 1960 and Sneddon reported 6 cases with livedo reticularis, multiple cerebrovascular incidents of limited and benign nature. Sneddon syndrome is a rare syndrome with an incidence of 4 per million. The pathogenesis of this syndrome is unclear and different mechanisms such as thrombophilic, autoimmune or inflammatory vascular processes are considere. Sneddon Syndrome is rarely seen in children. Her skin biopsy was normal; there are reported cases with normal skin biopsies. The diagnosis of Sneddon Syndrome should be considered in presence of livedo reticularis and multiple cerebrovascular incidents.

1776

PATIENT INR RESPOND ON TREATMENT WITH OAT

J.V. Jovanoska, J.I. Jovanoski

General Hospital, PRILEP, Macedonia

Background. To present the response to OAT of the patients in the Department of transfusiology Prilep. *Design and Methods*. 496 patients were treated with OAT (Oral anti coagulant therapy) during a period of 1 year. (Prothrombic Time) PT INR was measured once to twice a monthly. Mainly were treated with OAT patients with DVT(Deep vein Thrombosis), 245, (49%), DVT and PE(pulmonary Embolism) 47(9,4%), PAD 42(8,4%), cardiac and vascular implants 24+14 (7,6%), arrhythmias 29 (5,8%), prosthetic heart valve 18 (3,6%), by pass 17 (3,4%), CVI Cerebra vascular insult) 18 (3,5%), St post IMA(infarcts myocardial acute) 12, 8 thrombophilia patients (ATIII, FV Leiden, Protein C, MTHFR mutations) and other diagnosis 22 patients. *Results.* During period of 1 year, from 1-01-2008 till 31-12-2008, 6070 analysis were performed and PT INR measured were fro interval INR 0,9-1,4 = 2066 (34%); PT INR 1,5-1,7 1486 (24%); PT INR 1,8-2,0= 1078 (18%); PT INR 2,1-2,5 =882 (14,5%); PT INR 2,6 - 3,5 =420 (6,9%); PT INR 3,6-5 =97 (1,6%); PT INR > 5 =29 (1%). In the interval of 1,8 to 3,5 =2380 (39,4%). This shows that a high% have no satisfactory answer on treatment. We recognized that many patients do not complied to the treatment appropriately, mainly because the drug were not available on the pharmacy, or they do not have a money to by it. Some of them by only one pack of the drug, and take it one or two week, and when the control is performed they have not taka a tablets for more than a week. Some doesn't believe that they need to take tablets, so they just come to check their "thrombus" or perform a "trombotest", to check their thrombosis. But some of them take a high dose of drug, but they do not respond to the therapy. *Discusion*. There is a need to improve a patient education and patient compliance to the treatment. Better communication between Department and family (matical) doctors and other specialist involved in treatment (multidisciplinary approach) is needed. Screening patients for thrombophilia is also a need.

1777

MARKERS OF ENDOTHELIAL ACTIVATION IN THE PREDICTION OF SUBSEQUENT DEVELOPMENT OF PREECLAMPSIA

J. Prochazkova,[1] L. Slavik,[1] J. Ulehlova,[1] M. Prochazka,[1] R. Pilka,[1] I. Dhaifalah,[1] A. Mechurova,[2] Z. Kubova[1]

[1]University Hospital Olomouc, OLOMOUC, Czech Republic; [2]Institute for The Care of Mother and Child, PRAGUE, Czech Republic

Background. The hypertension and preeclampsia in pregnancy are multisystemic diseases characterized by hypertension, proteinuria and generalized systemic vasoconstriction.The ischaemia of the fetoplacental unit cause the release of specific factors into maternal vessels and subsequent activation of the endothelium and vasoconstriction . There is a rush development of the laboratory tests and a new markers of the endothelial activation have been found. Eg. t-PA, PAI-1, vWF, EPCR, thrombomodulin and endothelial microparticules with procoagulant activity. The aim of the study: To detect of above mentioned markers of endothelial activation in healthy pregnant women compared to those with pregnancy complicated by hypertension, diabetes mellitus and preeclampsia. The work hypothesis: We suppose that plasma specimens of the women with preeclampsia and diabetes mellitus will contatin a higher levels of endothelial activation markers compared to healthy pregnant. *Design and Methods*. All included patient have to assign an informed constent. The blood samlping will be taken by the routine way at the time of the first blood pregnancy sampling the end of the first trimester. The second specimen will be taken between 24.- 28. weeks of gestation. The following tests will be performed: t-PA - ELISA, PAI-1 - ELISA, vWF.Ag - EIA (immunologic detection by imunoturbidimetry), ePCR - ELISA , MMP-2,9 - ELISA (fluorogenic detection), endothelial microparticules - Flow cytometry. *Results*. The levels of vWf Ag and vW activity are significantly different (p=0,02 resp. 0,01) in group patietns with diabetes in comparison with control group. The levels of TRM are significantly different (p=0,03) in group patiens with hypertension as well as in group patietns with diabetes (p=0,02) in comparison with control group. The levels of ePCR are significantly different (p=0,04) in group patiens with hypertension as well as in group patietns with diabetes (p=0,01) in comparison with control group. The levels of tPA and PAI are not significantly different in group patiens with hypertension as well as in group patietns with diabetes in comparison with control group. *Conclusions*. As expected, there were stat. significant differences in the diabetes group in the case of vWf Ag, vWact., thrombomodulin and ePCR. Significant difference was found in the hypertension group compared to controls in ePCR. Whereas EMP, MMP-9 were not different in all groups.

STUDY ON THE MOLECULAR PATHOGENESIS OF HEMOPHILIA B

L.H. Yang

Shanxi Medical University of China, TAIYUAN, China

Background. The hemophilia B (HB), which is caused by the mutations in the factor β gene, is known as an X-linked recessive disease and occurs in about 1:30000 male live births. Clinical characteristics of this disease were the family history, spontaneous or injured bleeding and hemarthrosis. At present, due to lacking of the eradicative therapy, the gene diagnosis and detection of the carriers, which is an effective method to prevent the infant patients to be born, block the transmission of harmful gene and improve the population quality, should be actively carrying out. Aims The aim of this study is to diagnosis the propositi and carriers in the gene level and explore the molecule pathogenesy of HB. *Design and Methods*. The 3 unrelated HB families gave informed consent to be included in the study. The genome DNA were collected from each propositus and the family member. The polymorphisms of the 6 STR loci were detected by polymerase chain reaction with multiple reaction system and the fluorescently-labeled primers. For the propositi and doubtful carriers, all regions of the Fγ gene, including all exons and the flanking sequences, were amplified by PCR using the primer sequences which were devised with Primer 5. The products of PCR were sequenced by the dideoxy chain termination using ABI 3700 sequencer, the trial effect was compared with normal sequences using Chromas for finding the mutations. Results The 9 doubtful carriers were found through the allele analysis. But confirmed by the direct sequencing, the doubtful carriers of the first and third family did not have the same gene defects as the propositi, we considered that the gene defects were spontaneous mutations. To the second family's carrier, the heterozygous mutation was found in the corresponding locus of the propositus, it illustrated that the gene defect of the propositus was transmitted from his mother. 3 missense mutations were identified in the Fγ gene of the propositi when compared with normal sequence. G22119A was identified in exon 6 of the first family's propositus, it existed in the shearing situs of the flanking sequences, affected the normal physiologic function of F_. G7932C (Glu8Asp) was identified in exon 2 of the second family's propositus, it impacted Fγ binding with phospholipid. T32685C (Cys336Arg) was identified in exon 8 of the third family's propositus, it affected possibly the synthesis and secretion of Fγ intracellular. *Conclusions*. 1. The defect of the Fγ gene is the molecular pathogenesy of HB. 2. Combination analysis of multiple STR loci could be an effective and simple method for indirect diagnosis of the carriers in the HB family. However, there is possible to misdiagnose with the genetic linkage analysis for the families without the family history of HB. 3. Gene sequencing is one of the straightest and rigorousest method for the diagnosis of HB.

A NEW CASE OF DYSFIBRINOGENEMIA Aα 13 GLY/GLU

R. Kotlín,[1] Z. Reicheltová,[1] M. Mal,[2] J. Suttnar,[1] T. Riedel3, P. Salaj,[1] V. Pohlreichová,[1] V. Geierová,[1] J.E. Dyr[1]

[1]Institute of Hematology and Blood Transfusion, PRAHA, Czech Republic; [2]Department of Cardiology, University Hospital Motol, PRAHA, Czech Republic; [3]Institute of Macromolecular Chemistry, Academy of Sciences of the Czech Republic, PRAHA, Czech Republic

Background. Fibrinogen is a 340 kDa glycoprotein which is composed of six polypeptide chains. It plays a crucial role in blood coagulation. Serine protease thrombin cleaves fibrinogen to fibrin monomer and releases N-terminal parts of Aα and Bβ chains, termed fibrinopeptide A and fibrinopeptide B, respectively. Hereditary dysfibrinogenemia is a disease wherein an inherited abnormality in the fibrinogen molecule results in defective fibrin clot formation. *Aims.* The aim of our study was to characterize a case of a gene defect causing dysfibrinogenemia in a patient with abnormal coagulation test results. *Design and Methods*. Fibrin polymerization and fibrinolysis were measured by turbidimetrical method. Kinetics of fibrinopeptide release was measured by HPLC method according to Suttnar *et al.*[1] Gene sequencing was performed by dideoxysequencing method. Scanning electron microscopy (SEM) was performed on VEGA Plus TS 5135 electron microscope as described earlier.[2,3] *Results*. The patient - 36 year old woman had prolonged thrombin time (39.3 s) and low Clauss fibrinogen level (0.85 g/l). Fibrin polymerization was impaired and measurement of fibrinopeptide release showed higher rate of released fibrinopeptide B. The patient bears a heterozygous point mutation in exon 2 of FGA causing substitution of Aα 13 Gly to Glu. SEM revealed thicker fibres than control. *Conclusions*. The patient was found to bear a heterozygous point mutation in the fibrinogen Aα chain. Gly 13 is necessary for right fibrinopeptide A release by thrombin. Substitution Aα 13Glu was found to inhibit thrombin catalyzed fibrinopeptide A release. The mutation leads to impaired fibrinopeptide release and polymerization, abnormal fibrin clot and pathologic coagulation.

LEVELS AND EFFECT OF ADRENOMEDULLIN ON ENDOTOXIN-INDUCED DISSEMINATED INTRAVASCULAR COAGULATION IN RABBITS

M. Karakukcu, T. Patiroglu, M.A. Ozdemir, C. Karakukcu, Y.A. Torun

Erciyes Universty, KAYSERI, Turkey

Background. Disseminated intravascular coagulation (DIC) known as consumptive coagulopathy is an acquired hemostasis dysfunction, char-

acterized by systemic intravascular activation of coagulation, leading to widespread fibrin deposition in the circulation and impaired fibrinolysis. Adrenomedullin (ADM) is a peptide consisting of 52 amino acids and is secreted from vascular endothelial cells and adrenal medulla. There are only a few studies about the effects of ADM on coagulation and platelets which is secreted from endothelial cells. *Aims*. To develop an experimental animal model for the DIC, to assay ADM levels in rabbits with DIC and to investigate the probable effects of ADM in management of DIC. *Design and Methods*. Four groups (Control, DIC, Heparin, ADM) each consisting of 8 New Zeland rabbits were formed randomly. A standard DIC model was developed in DIC group by infusion of endotoxin from Escherichia coli. Than the effect of standard dose heparin infusion and 0.05 µg/kg/minute ADM infusion were evaluated in this model and therapy results were compared with statistical methods. *Results*. Mean platelet count was 101.130±66.038/mm^3, prothrombin time (PT) was 19.8±2.1 sec, activated partial thromboplastin time (aPTT) was 236.9±40.3 sec, fibrinogen level was 158.0±83.9 mg/dl, activity of antithrombin was 90.0±8.3%, and activity of protein C was 28.8±17.9% on sixth hour in DIC group. These results were in accordance with DIC findings and were significantly different from the findings of control group (p<0.05). In DIC group beginning, second and sixth hour mean ADM levels were 7.09±1.63, 8.10±1.55, 9.35±0.76 ng/dl, respectively. ADM levels on second and sixth were significantly higher than control group (p<0.05). Heparin and ADM groups were not significantly different for DIC group with therapy. *Conclusions*. A DIC model that can be use by alternative therapies was developed successfully. ADM levels were found elevated during the progress of DIC. Heparin and ADM were not effective in DIC therapy. New substances are thought to use in this therapy model in the future.

SIGNIFICANT VARIATION IN ENDOGENOUS THROMBIN POTENTIAL (ETP) IN WARFARIN-TAKING PATIENTS

E. Papakonstantinou, E. Yfantis, S. Chaniotaki, P. Georgoutsou, A. Skourbouti, G Makavos, E. Paximadakis, C.D. Olympios, C. Manti

Thriassion General Hospital, ATHENS, Greece

Background. The ETP test, recently, was added to the conventional coagulation tests, such as prothrombin time (PT) and activated partial thromboplastin time (APTT), for the investigation of coagulation function. The International Normalised Ratio (INR) derived from the PT is sensitive only to factor VII,X,V,II and I. In contrast, the ETP is sensitive to all the coagulation factors. We speculate that the same INR may not accurately reflect ETP in all patients and that ETP might be useful in monitoring warfarin anticoagulation. *Aims*. The investigation of correlation of ETP and INR in patients under stable warfarin therapy. *Design and Methods*. We studied 20 chronic atrial fibrillation patients who were stable on warfarin. Their INR was between 2.0-3.0. We performed the chromogenic method on the fully automated Behring Coagulation System (BCS) and determined the ETP (mA) and the peak amount of thrombin generation (Cmax,mA/min). We also determined the D-dimers and the fibrinogen. RESULTS: The ETP and the Cmax showed a strong inverse correlation with the INR (n=20; r= -0.611 and -0.515 respectively). There was a wide range of ETPs at this INR range (47.33-222.27 mA, median 149.0755mA). There was no correlation between the fibrinogen and ETP/Cmax. However, d-dimer show a significant correlation with ETP r=0.702. The correlation with the INR is weaker with d-dimers r= -0.393. *Conclusions.* Although the INR is a good surrogate, ETP measurement might be more accurate in estimating anticoagulation potential. Patients at therapeutic INR range may have low ETP values and high risk of bleeding or high ETP values and thrombotic risk.. Therefore, ETP might offer better differentiation between those who bleed more easily and those who develop thrombosis despite "therapeutic" anticoagulation. The correlation with d-dimer merits further investigation especially in respect to developing a predictive model for thrombosis prevention.

IMMUNOTOLERANCE INDUCTION WITH VON WILLEBRAND FACTOR/FACTOR VIII CONCENTRATES IN PATIENTS AT HIGH RISK OF FAILURE

A. Gringeri,[1] N.P. Ewing,[2] M. Heisel Kurth,[3] W.K. Hoots,[4] C. Negrier[5]

[1]*University of Milan, MILAN, Italy;* [2]*Hemophilia and Sickle Cell Programs, City of Hope, DUARTE CA, USA;* [3]*Children's Hospitals and Clinics of Minnesota, MINNEAPOLIS, USA;* [4]*University of Texas Houston Health Science Center, HOUSTON TX, USA;* [5]*Centre de Référence de l'Hémophilie, Hopital E. Herriot, LYON, France*

Background. Inhibitor eradication with immune tolerance induction (ITI) is the best long-term therapeutic approach in haemophilia A patients with inhibitors. Several parameters are known that are correlated with success of ITI, such as the young age, a historical peak titer below 200 BU, inhibitor titer at ITI start below 10 BU. One that has more recently been proposed is the type of FVIII concentrate. Recent clinical findings indicate that plasma-derived factor VIII (FVIII) products containing von Willebrand factor (VWF/FVIII) could have an impact in ITI success rate, even in poor prognosis patients. *Design and Methods*. Two key prospective clinical studies have been designed to confirm the previous results supporting the use of VWF/FVIII in ITI: the RESIST experienced (RESISTexp) and the RESIST naïve (RESISTnaïve). RESISTexp is a prospective, nonrandomized study designed to assess rescue treatment with VWF/FVIII at high dosage (200 IU/kg daily) in patients who failed a previous ITI attempt with any dose of a VWF-free FVIII concentrate (plasma-derived or recombinant). RESISTnaïve is a prospective, controlled, randomized, open-label study comparing two types of FVIII concentrates (non-VWF-containing and VWF/FVIII) in their ability to induce tolerance in high responding haemophilia A patients, with no previous ITI attempt and with poor prognosis for success. Both types of concentrates will be administered at high dosage (200 IU/kg daily). Enrolment criteria are: severe haemophilia A (FVIII < 1%), any age, high responding inhibitors (peak inhibitor levels > 5 BU), any inhibitor level at study enrolment, and at least one of the following risk factors for ITI failure: (a) peak inhibitor titer > 200 BU, (b) titer at ITI start > 10 BU, (c) age > 7 years, (d) time between inhibitor occurrence and ITI > 2 years. Patients undergoing concomitant immunosuppressive treatment are not eligible for either study. Primary end point is the success in achieving ITI defined as: complete or partial, according to the complete disappearance of inhibitors with normal FVIII recovery and half-life or the presence of low titer inhibitors below 5 BU with low recovery and/or half-life. Secondary endpoints are: ITI maintenance, time to success, safety/compliance to treatment and cost of care. *Conclusions*. The results of RESIST studies will be crucial in understanding the role of VWF/FVIII in ITI outcome and will contribute to providing effective treatment for the devastating complication of FVIII antibody development in haemophilia A patients.

1783

A SYSTEMATIC REVIEW OF DISSEMINATED INTRAVASCULAR COAGULOPATHY ASSOCIATED WITH PROSTATE CANCER

A. Laber, J.J. Jarboe

University of Louisville, LOUISVILLE, USA

There are over 2 million men living in the United States with the diagnosis of prostate cancer (PC). Disseminated intravascular coagulation (DIC) is a catastrophic deregulation of coagulation that results in an overwhelming significant and sometimes fatal clinical syndrome. There are case reports of DIC in association with PC in the medical literature, but no rigorous study has been done. *Aims*. In this study we review the medical literature on DIC associated with PC to analyze the incidence, patient characteristics, clinical presentation, laboratory evaluation, diagnosis, treatment and outcomes of this syndrome. Methods: Published articles were screened through a MEDLINE search using the keywords "prostate cancer" and "disseminated intravascular coagulation" or "coagulopathy", and references from journal articles and books. Any English language article reporting any number of patients with DIC associated with PC was included for data extraction. Since most of the literature comprised of case reports and small series of patients, the heterogeneity of studies was too broad to allow any formal statistical calculation. The data was synthesized using descriptive methodology. Results: Several decades' worth of case reports and small series suggest that DIC associated with PC may not be as rare as previously thought. There is a noticeable distinction between more recent case reports and those prior to the mid-1990s; this might be related to aggressive screening for PC and early diagnosis. Older cases often have reported DIC as the first

manifestation of very advanced prostate cancer that either resulted in death or responded to castration. More recent reports have been of patients with known metastatic PC, who experienced the complication of DIC as their cancer progressed into castration-resistant PC that sometimes responded to chemotherapy. Treatment of DIC in the PC patient is challenging. The importance of treating the underlying PC has been highlighted in almost every article encountered during this review. Aminocaproic acid, an anti-fibrinolytic agent that works via inhibition of plasminogen activator, has been used successfully in some acute cases of DIC associated with PC. DIC in PC patients have been reported after surgical procedures, but improved surgical techniques have almost eliminated this complication. *Conclusions*. This study provides important information about a very serious complication of PC. Increased awareness of the potential development of DIC in patients with PC would allow aggressive medical intervention to prevent its devastating consequences.

1784

RAPID REVERSAL OF ORAL ANTICOAGULATION WITH WARFARIN BY A PROTHROMBIN COMPLEX CONCENTRATE AT DOSES OF 15IU/KG AND 30 IU/KG: EFFICACY AND SAFETY IN 36 PATIENTS

J. Bowers

South Eastern Trust, BELFAST, UK

Background. Rapid anticoagulant reversal for patients on oral anticoagulants is required for spontaneous life or organ threatening haemorrhage and for emergency surgery. Prothrombin complex concentrates (PCC) are now accepted as the quickest and most effective way to do this. The BCSH guidelines on warfarin recommend a dose of 50iu/kg but the optimal dose is uncertain due to lack of clinical and laboratory data 2. In this study we evaluated the efficacy in 36 patients requiring immediate reversal of their oral anticoagulant with 15iu/kg if INR <4 and 30 iu/kg if >4, using the PCC Octaplex. *Design and Methods*. Patients considered for immediate reversal of warfarin were discussed with the on-call consultant haematologist. A dose of PCC was recommended and a repeat INR and factor assay sample was requested for within an hour of treatment. All patients received 5mg IV Vit K. All 36 patients had repeat INR and 10 of these patients also had factors II, VII, IX, X analysed. The haemostasis laboratory uses a Sysmex analyser with Dode Behring reagents. The lab participates satisfactorily in the UK National External Quality Assessment Scheme (UK NEQAS). A retrospective inspection of the notes for arterial or venous thromboembolic disease during their hospital stay, clinical outcome and original need for warfarinisation was made. *Results*. Factor IIThe median (range) pre-treatment Factor II was 0.23 iu/mL (0.02-0.43) and post-treatment levels were 0.65 iu/mL (0.53-0.99). Factor VII The median (range) pre-treatment Factor VII was 0.18 iu/mL (0.01-0.49) and post-treatment levels were 0.39 (0.26-0.85). Factor XI The median (range) pre-treatment Factor IX was 0.25 (0.05-0.64) and post-treatment levels were 0.49 (0.31-0.92). Factor XThe median (range) pre-treatment Factor X was 0.065 (0.01-0.3) and post-treatment was 0.465 (0.23-0.76). INR The median (range) pre INR was 3.9 (2 - >10) and median post INR was 1.5 (1 - 2.8). INR ≤1.5 was achieved in 23 patients. Of the remaining patients only 3 had INR's >2. *Summary.* We present 36 patients who have had their INR reversed rapidly by dose controlled octaplex. No thromboembolic events were described. Ongoing bleeding in one patient may have contributed to one mortality. Of the 10 patients who had pre INR's of >10, only two had post INR of >1.5, and none had haemorrhagic deaths. The lack of thromboembolism and paucity of ongoing haemorrhage with overall reasonable reversal of anticoagulant effect could be supporting evidence that this is sufficient PCC to restore thrombo generation and reduce the risk of a hypercoagulable state with the higher doses (50iu/kg) normally recommended.

THE AUTOMATED ENDOGENOUS THROMBIN POTENTIAL (ETP) TEST TO REFLECT COAGULATION CHANGES IN PATIENTS WITH CIRRHOSIS OF THE LIVER

E. Papakonstantinou,[1] E. Yfantis,[1] S. Chaniotaki,[1] A. Skourbouti,[1] T. Loukas,[1] I. Rapti,[2] E. Dimou,[2] C. Manti,[1] S. Hadziyannis[2]

[1]Thriassion General Hospital, ATHENS, Greece; [2]Henry Dunant Hospital, ATHENS, Greece

Background. The role played by coagulation defects in the occurrence of bleeding in cirrhosis is still unclear. This is partly due to the lack of tests that truly reflect the balance of procoagulant and anticoagulant factors *in vivo*. Conventional coagulation tests (PT/INR and aPTT) seem unable to predict the severity of bleeding problems in patients with cirrhosis of the liver possibly because they do not adequately reflect the balance between procoagulant and anticoagulant clotting factors. Recently a test has become available to routinely measure the endogenous thrombin generation potential (ETP) by Dade Behring (Marburg, Germany). AIM: Comparison of ETP parameters and other coagulation markers - Antithrombin III, protein C, protein S, lupus anticoagulant, plasminogen, a2-antiplasmin, APCR, homocystein- between controls and patients with liver cirrhosis. *Design and Methods*. 18 samples, of consecutive patients with histologically confirmed liver cirrhosis, and 30 samples of controls were investigated for ETP parameters and other coagulation markers - ATIII, protein C, protein S, lupus anticoagulant, plasminogen, a2-antiplasmin, APCR, homocystein-. We used the chromogenic method on the fully automated Behring Coagulation System (BCS) for the measurement of thrombin generation parameters. RESULTS: 6 patients had alcoholic cirrhosis, 6 HCV, 2 PBC and 4 cirrhosis of unknown origin. The patients with alcoholic cirrhosis had prolonged times and decreased Cmax and ETP compared to HCV cirrhosis. (tlag 22.65 vs 18.8, tmax 54.6 vs 55.5, Cmax 89.2 vs 99.6, ETP 268.6 vs 299.1, these observations were not statistical significants). *Conclusions*. The reduction of procoagulant factors in patients with cirrhosis is compensated by the reduction of anticoagulant factors thus leaving the coagulation balance with minor changes. ETP might be normal in cirrhosis. For clinical validation of these findings, a prospective clinical trial is warranted where the results of ETP must be related to the occurrence of bleeding, to a much larger number of patients.

Table 1.

Parameters	Patients	Controls	P Value
Antithrombin III	64.2 (23-98.9)	100 (79-122)	0.0001
protein C	62.2 (17-139)	105 (78-135)	0.0001
protein S	71.3 (24.6-89.2)	110 (66-157)	0.0001
lupus anticoagulant	1.05 (1-2)	1.1 (1-1.2)	0.2
plasminogen	77.6 (38-118.6)	107(79-132)	0.0001
a2-antiplasmin	79.16 (46-110)	105 (82-115)	0.0001
APCR	0.77 (0.64-0.91)	0.9 (0.65-1.02)	0.0001
homocystein	8.7 (1.3-14.7)	10 (7-13)	0.043
tlag	21.9 (12.7-51.1)	19.3 (12.5-26.37)	0.146
tmax	63.7 (40.3-116.2)	54.3 (45.5-62.1)	0.017
Cmax	93.7 (60.5-146.9)	123.5 (112.7-134.6)	0.0001
ETP	301.4 (202.3-472,7)	394.7 (322.7-451.1)	0.0001

TRANSCATHETER ARTERIAL EMBOLIZATION OF CONCURRENT SPONTANEOUS HEMATOMAS OF THE RECTUS AND OBLIQUE LEFT ABDOMINAL MUSCLES IN A MODERATE HAEMOPHILIA B PATIENT

M.D. Musso,[1] D. Cultrera,[1] M. Musso,[3] A. Cipolla,[1] G. Giulia,[1] C. Grazia,[1] R.M. Rosso,[1] F.G. Ferro,[1] B. Ximenes[1]

[1]Hematology Division and Thalassemia Unit, Haemophilia & Thrombosis Centre, CATANIA, Italy; [2]Division of Hematology, Ospedale Ferrarotto, CATANIA, Italy; [3]Hematology Specialization School,University of Catania, CATANIA, Italy

Background. Cumulated evidence had proven that the substitution

therapy in haemophilia population according the prophylaxis regimens as well as the prompt infusion of concentrates had markedly reduced the occurrence of spontaneous muscle hematomas or their inevitable sequelae in terms of disability and/or signs of abdominal compartment syndrome or pseudotumor' late development. *Aims.* However, the incidence of life-threatening spontaneous or post-traumatic muscle hematomas of the anterior and/or posterior abdominal walls remain to be feared even in moderate haemophilia which commonly are less infused. Generally, the treatment is conservative and intensive by replacement therapy because of the difficulty of revealing or controlling the bleeding arterial vessel(s) surgically. Furthermore, in these cases the haemorrhage is often multifocal and involves complex collateral pathways. *Design and Methods*. We here report our recent observation of vaste concurrent spontaneous hematomas of the rectus and oblique left muscles of the anterior abdominal wall in a moderate hemophilia B patient 52 years old. By computed tomography(TC) an active and massive bleeding was documented from the epigastric artery with extravasation along the left retroperitoneum as far as the pelvic region. Despite the several infusions of FIX concentrates (AimaFIX® Kedrion) 19,000 IU/3 days, the epigastric artery haemorrhage lasted worrying. So, we considered to perform endovascular selective embolization by transcatheter arterial embolization (TAE)via transfemoral access to treat these muscle hematomas, as well as it has recently been done in non-hemophilia subjects i.e. in patients undergoing anticoagulation (*Basile A. et al. Cardiovascular and Interventional Radiology. 2004; 27:659-662*). In our case we used microcoils agreeing with the theory of Sharafuddin *et al.* (*J Vasc Interv Radiol 2001; 12:1231-1234*). Thus, because a part of the standard advantages (radiopacity, accuracy, and safer development), coils and microcoils are able to pack the entire length of the major supplying vessel(s), preventing retrograde filling from collaterals with selective arterial embolization. *Results*. TAE was technically successful. No active bleeding was detected by angiography after the procedure. *Conclusion/Summary*. No reports we found in the literature regarding TAE to treat muscle abdominis hematomas in haemophilia B patients. In our case the persistent and massive bleeding signs at CT as well as the unstable hemodynamic conditions of the patient indicated the use of angiography and the subsequent successful embolization to stop the severe haemorrhage and to prevent their inevitable sequelae. From this rare observation the embolization is effective and safe to control bleeding in these haemophiliac otherwise problematic cases where the conservative treatment seems to be insufficient and surgery can fail.

1787

THE PREVALENCE OF VON WILLEBRAND DISEASE IN WOMEN WITH MENORRHAGIA

C.H. Ho

Sultan Qaboos University, MUSCAT, Oman

Background. Menorrhagia is one of the important clinical manifestations of von Willebrand disease (vWD), however, it is easily neglected by the general practitioners that vWD could be a cause of menorrhagia. Aims: We conducted a study in patients with unknown cause of menorrhagia, in order to find the prevalence of vWD in this group of patients. *Design and Methods*. After first check-up by gynecologists to rule out the gynecologic causes of menorrhagis, 94 women with unknown cause of menorrhagia were enrolled into the present study. Bleeding time (BT), aspirin BT, prothrombin time (PT), activated partial thromboplastin time (APTT), complete blood count (CBC), liver and renal functions, von Willebrand factor antigen (vWF:Ag), ristocetin cofactor activity (RCoA), factor VIII assay (FVIII:C) and ristocetin-induced platelet agglutination (RIPA) were detected in these women, their results are compared and analyzed. Results: 4 patients (4.3%) with low vWF:Ag (<50%) were detected, low RCoA (<50%) noted in 2 of them. RCoA/vWF:Ag <0.5 was found in 2 patients. Aspirin BT was not found to be better than BT. The best test for detecting vWD in this study is vWF:Ag. *Conclusions*. About 8.6% of the menorrhagic patients would have vWD, although the percentage is not high, the clinicians should be alert of this disease in patients with unknown cause of menorrhagia.

1788

CYP2C9 , VKORC1 AND CALU GENOTYPE FREQUENCIES IN THE NATIVE OMANI POPULATION

V. Pathare,[1] A. Al Zadjali,[1] S. Alkindi,[1] S. Al Farsi,[1] N. Huneini,[1] J. Dennison,[1] L. Misquith,[1] R. Krishnamoorthy[2]

[1]Sultan Qaboos University, MUSCAT, Oman; [2]INSERM 763, Hopital Robert Debre, PARIS, France

Background. The utility of pre-prescription CYP2C9 and VKORC1 genotyping and the proposed pharmacogenomic algorithms have not yet been established in prospective randomized clinical trials. However, hereditary pharmacokinetic(CYP2C9) and pharmacodynamic(VKORC1) factors account for more that 50-60% inter individual variability of warfarin response.

Table.

Deviations from Hardy-Weinberg proportions with over representation of minor alleles

	Observed Genotype fequency	Calculated Genotype frequency	Chi Square P value
CYP2C9*1/*1	88.8	87.6	0.78[NS]
CYP2C9*2/*2	1.6	0.4	0.014[SIG]
CYP2C9*1/*2	9.6	11.98	0.0001[SIG]
CYP2C9*1/*3	10.4	10.28	0.81[NS]
CYP2C9*3/*3	0.8	0.36	0.001[SIG]
VKORC1*1/*1	43.41	41.9	0.17[NS]

Aims. To establish the CYP2C9, VKORC1 and CALU genotype frequencies in the native Omani population which consists of an admixture of African and Asian ethnicities. *Design and Methods*. In 240 Omani subjects(volunteer blood donors) we assessed CYP2C9 genotypes(*1,*2 &*3), VKORC1 haplotypes (*1[A] v/s NonA], Calumenin (CALU) Arg4Gln(rs2290228) and a29809g polymorphisms. Genomic DNA was isolated using the semi-automated 6100 nucleic acid extractor. CYP2C9, VKORC1 and CALU genotypes were defined by direct sequencing using primers designed by Primer Express software (ABI 3100 Genetic analyzer). *Results*. Observed allele frequencies for CYP2C9*1(wild type), CYP2C9*2& CYP2C9*3 were 88.8, 0.16 and 0.08 respectively in this population. Allele frequencies for VKORC1*1 (wild type) was 43.4. Allele frequencies for CALU Arg4Arg(wild type) 76.27 whereas for the a29809a(wild type) it was 41.53. Genotype data was tested for deviation from Hardy-Weinberg proportions using weighted least square estimates of allele frequencies and chi-square goodness-of-fit tests and showed significant over representation of the minor alleles. *Conclusions*. This study establishes the population allele frequencies of main genetic variables associated with pharmacokinetic(CYP2C9) and pharmacodynamic(VKORC1) variable responsible for inter individual variations in warfarin dosing. The increased practice and prevalence of consanguinity in the local culture and customs are probably responsible for the significant deviations from the Hardy-Weinberg proportions indicating nonrandom mating.

1789

PRIMARY OR SECOND ATTEMPT OF IMMUNE TOLERANCE INDUCTION IN PATIENTS WITH HEMOPHILIA A WITH INHIBITORS WITH A FACTOR VIII/ VON WILLEBRAND FACTOR HUMAN COMPLEX (FANHDI®). RETROSPECTIVE DATA COLLECTION STUDY FROM 14 SPANISH CENTERS

V. Jimenez-Yuste,[1] J.A. Aznar[2]

[1]Hospital Univeristario La Paz, MADRID, Spain; [2]Hospital La Fe, VALENCIA, Spain

Background. The prevalence of inhibitor development in Hemophilia A (HA) patients is as high as 33%. Currently, inhibitor eradication with immune tolerance induction (ITI) is the best long-term therapeutic alternative. Due to the number of parameters potentially related to the ITI

success, as well as to the inherent complexity of the ITI procedure, therapeutic optimization is a priority. Several parameters are known to be potential ITI outcome predictors such as the type of administered FVIII concentrate. Recent experimental and clinical findings indicate that plasma-derived FVIII products (pd-FVIII) containing von Willebrand factor (VWF/FVIII) could have an impact in ITI success rate, even in poor prognosis patients. *Aims*. Evaluate the rates of success, partial success, and failure among severe hemophilia A patients with inhibitors, who received a plasma-derived FVIII product (Fanhdi®) as a part of either a primary or rescue ITI protocol. *Design and Methods*. This is a multi-center, observational, retrospective chart review study of patients with severe Hemophilia A and factor VIII inhibitors who have been treated with Fanhdi® as part of their ITI treatment. The study will evaluate the ITI outcomes of around 14 centres and approximately 30 Fanhdi® patients with a known outcome of complete succcess, partial success or treatment failure. Patient population are diagnosed with congenital HA (FVIII < 2%) submitted to immunotolerance protocol with high purify FVIII/VWF concentrates (Fanhdi®) and who have completed primary ITI or are still ongoing (naïve patients) or who have had previously undergone at least one ITI procedure and failed, partially or totally (according to the criteria of the physician carrying out the ITI process). *Conclusions.* The results of this retrospective study will add valuable information in clarifying the role of VWF/FVIII in the success of primary or salvage ITI.

1790

HAEMOSTATIC ABNORMALITIES IN TREATMENT-NAIVE TYPE 1 GAUCHER PATIENTS

M. Mitrovic-Vasiljevic,[1] N. Suvajdzic,[1] I. Elezovic,[1] P. Miljic,[1] Z. Sumarac,[2] D. Janic,[3] M. Djordjevic,[4] M. Petakov,[5] P. Rodic,[3] I. Djunic,[1] T. Nikolic[6]

[1]Institute of hematology CCS, BELGRADE, Serbia; [2]Institute of Medical Biochemstry, BELGRADE, Serbia; [3]University Children Hospital, BELGRADE, Serbia; [4]Medical and Child Health Care Institute"Dr Vukan Cupic", BELGRADE, Serbia; [5]Institue of Endocrinology, Diabetes and Disease of Metabolism, BELGRADE, Serbia; [6]Institute of radiology, BELGRADE, Serbia

Background. Gaucher disease (GD) is the most common lysosomal storage disorder, caused by glucocerebrosidase deficiency. Gaucher patients may suffer from bleeding, which is usually attributed to thrombocytopenia; however, excessive bleeding has also been observed in patients with normal platelet count. It is postulated that coagulation factor deficiencies and platelet dysfunction might also contribute to bleeding tendency in GD patients. *Aim.* The aim of this study was to investigate platelet function and coagulation factors in Serbian, type 1 Gaucher patients who had not been treated with enzyme replacement therapy. *Design and Methods*. The study was carried out on 31 Serbian treatment-naive type 1 Gaucher patients (M/F 17/14; median age 49; splenectomized 9/31). Complete blood counts, prothrombin time (PT) and activated partial thromboplastin time (aPTT) were assessed according to standard methods. Coagulation factor activity was measured using commercial kits. Platelet aggregation was performed by a standard technique, using citrated platelet rich plasma, on a whole-blood aggregometer (Chrono-Log Corporation, Havertown, model 560, PA, USE). Results: Bleeding episodes were registered in 10/31 patients. Mean platelet count was $150x10^9$/L (range: 46-428); 22/31 patients had platelet count < $150x10^9$/L and 3/22 < $50x10^9$/L. Platelet count inversely correlated with spleen volume ($p<0.05$). PT and PTT were prolonged in 16/31 and in 13/31 of patients respectively. The most frequent clotting factor deficiencies (either isolated or combined) were: FV (9/31), vWF (5/31), FVIII (3/31), FX (3/31), FXI (4/31), and FXII (5/31). Platelet aggregation abnormalities were registered in 19/31 patients. Abnormal aggregation in response to 1 and ≥2 agents was registered in 13 and 6 patients, respectively. Patients with bleeding episodes had significantly lower platelet counts, higher plasma chitotriosidase levels (a specific marker of storage glucocerebroside) and greater spleen volumes compared to the non-bleeding patients ($p<0.01$). There was no significant difference in the clotting factor concentrations and platelet function between the bleeding and non-bleeding phenotype. None of the splenectomized patients had bleeding episodes. In addition, the non-splenectomized patients had significantly lower platelet count ($94x10^9$/L vs. $286x10^9$/L) and reduced response to collagen (0.55 vs. 0.79) compared to the splenectomized ones. Spleen volume inversely correlated with a reduced aggregation response to collagen, adenosine diphosphate in lower concentrations (5µg/ml), and arachidonic acid. *Conclusions*. GD type 1 is associated with decreased levels of coagulation factors and abnormal platelet function, which is a contributory factor in increased risk of bleeding.

1791

OFF LABEL USE OF RECOMBINANT FACTOR VIIA IN THE HAEMATOLOGY WARD

V. Rajic, L. Popovic, A. Savic, I. Savic, M. Urosevic, B. Zeravica, D. Agic, N. Vlaisavljevic, I. Percic

Clinical Centre of Vojvodina, NOVI SAD, Serbia

Recombinant factor VIIa (rFVIIa) has proven effective in treating bleeding in patients with haemophilia and inhibitor. Use of rFVIIa in other clinical conditions, like in patients with intractable bleeding and other serious haematological disorders, has not been studied in larger cohort of patients. The aim of this retrospective study is to investigate conditions and efficacy of rFVIIa in haematological patients with severe bleeding. The study included all off-label patients since 2005, which were treated in the Clinic of haematology Novi Sad. In the assessment of efficacy, our scoring system which combines clinical and laboratory, radiological or endoscopic data, was used. There were 18 patients (9 with acute leukemia, 3 with nonHodgkin lymphoma, 1 with chronic lymhocytic leukemia, 2 with aplastic anaemia, 1 with paroxysmal nocturnal haemoglobinuria, 1 with vonWillebrand disease and 1 with adult-onset Still disease). The most of them, 9 patients (50%) had severe gastrointestinal bleeding, 4 (22%) had soft-tissue haemathomas (neck, diffuse skin or perianal), 3 (17%) had intracranial bleeding and 2 (11%) respiratory tract bleeding. When the usual dose of rFVIIa (80-100 µg/kgBM) had been used, good efficacy was registered in more then 80% of patients. Low dose regimen (40 µg/kgBM or less) was associated with treatment failure. Although almost all patients received platelet transfusions, rFVIIa has been effective, even in severely thrombocytopenic patients. Conclusion- In our small group of haematological patients with severe haemorrhagic diathesis, rFVIIa proved effective, if given in usual dose and with platelet transfusions.

1792

FACTOR V DEFICIENCY AND CROHN'S DISEASE - A CASE REPORT.

J. Krawczyk, B. Ni Mhaille, M. Sweeney, B. Cleary, M. Murray

Galway University Hospital, GALWAY, Ireland

Background. Factor V deficiency is a rare inherited coagulopathy. Clinical presentation include ecchymoses, mucosal bleeding and blood loss. Factor V deficiency is caused by a large number of genetic abnormalities. The deficiency is a rare bleeding disorder whose genetic bases have been characterized in only a limited number of cases. The inheritance of factor V deficiency is autosomal recessive, with varying expressivity in the heterozygote; however, other modes of inheritance have been described. Heterozygotes have lower levels of factor V but probably never bleed abnormally. Consanguinity has been observed in families with factor V deficiency. Heterozygous deficiency states are generally unrecognized because of a lack of significant clotting time prolongation or bleeding risk. Presentation: A 23 year old gentleman with inflammatory bowel disease presented with pancytopenia. Initial full blood count showed haemoglobin 4.3g/dl, MCV 111.7, white cell count of 0.5, absolute neutrophil count of 0.3 and platelets of 125. He was diagnosed with Crohn's disease at the age of 14. His treatment included mesalazine 800mg TID and azathioprine 75mg od. He didn't have a blood count done for 18 months prior presentation with pancytopenia. Bone marrow biopsy showed a markedly hypoplastic marrow with reduced haematopoiesis and no evidence of infiltrate or malignancy. He did not have any symptoms or signs of coagulopathy at the time of presentation or in the past. He required treatment for neutropenic sepsis including intensive care facilities. He recovered well on intravenous tazobactam / gentamycine and G-CSF. He also required multiple red cell transfusion. He was found to have a prolonged prothrombin time, INR and APTT despite treatment with Vitamin K. A low factor V was noted (7%) and this was present on repeat studies following the recovery of his marrow and quiescence of his disease. All other factors investigated were normal (II VIII X IX XI XII). However, despite a low factor V level, the patient remained asymptomatic and did not required any intervention. Patient received routine vaccinations in line with current guidelines. Currently he is doing very well, his full blood count has recovered and patient does not require any haematological interventions. *Discussion*: Factor V deficiency is a rare coagulation abnormality and is associated with hemorrhagic complications of varying severity. Only a limited number of cases are reported in the medical literature. There are no report of an association with inflammatory bowel disease and factor V deficiency so far. Interestingly our patient never had any symptoms related to factor V deficiency and never required any treatment for it.

1793

SUCCESSFUL USE OF VINCRISTINE IN THE MANAGEMENT OF KASABACH-MERRITT PHENOMENON

D. Canatan, M. Aydin, A. Kuybulu, H. Duman, H.P. Anil, A. Boyaci, T. Koca

Suleyman Demirel University, ISPARTA, Turkey

Kasabach-Merritt Phenomenon (KMP) is a life threatening clinical picture characterized by thrombocytopenia, consumption coagulopathy with a low fibrinogen level and microangiopathic hemolytic anemia.in the presence of a rapidly enlarging vascular lesion. Affected infants may manifest high output cardiac failure as a result of increased blood flow through the vascular lesions. It can be lethal; the estimated overall mortality rate ranges from 10-37%. Kaposiform hemangioendothelioma is the responsible lesion most of the time, Retroperitoneal involvement is significant determinant of the mortality. Early treatment is important to prevent fatal bleeding.MRI and ultrasonography are both effective tools for determining the extension of the lesion hence the prognosis and and for assessing their response to therapy.We would like to present a 2 month old boy with KMS, successfully treated with vincristine therapy. *Case report.* A 2-month old boy with Kaposiform Hemangioendothelioma of the lumbosacral region invading the retroperitoneum was admitted with Kasabach-Merritt Phenomenon After corticosteroid and interferon treatments failed with progression of the disease to a life threatening condition, vincristine monotreatment granted a rapid rise in platelet counts, fibrinogen levels and a resolution in the enlargement of the lesion. Once a week induction treatment for a month was followed by once a month maintenance for 2 months. The remission was maintained and no adverse effects were observed during the treatment. The patient did not relapse 2 months after vincristine was stopped. *Conclusion*. This case and review of the literature point to vincristine as a first line treatment and suggest that multidrug regimens with additional drugs should be hold for bleeding emergencies.

1794

FERRITIN SERUM LEVELS IN BLOOD DONORS POPULATION

V.T. Tsagkari,[1] M.M. Mavrolia,[2] C. Palogiannidis,[1] I. Margara,[1] M. Skoura,[1] E. Moustaferi,[1] C. Veneti,[1] P. Paraskevopoulou,[1] N. Vgontza[1]

[1]Blood Bank , Hematology lab. Konstantopoulio GHNIonia, ATHENS, Greece; [2]Blood Bank and Hematology lab Konstantopoulio GHNIonia, ATHENS, Greece

Aims. The aim of this study is to determine the serum ferritin levels in a population of blood donors especially of those who donate blood two or three times per year. The evaluation of iron stores and the application of protocols concerning the frequency of ferritin serum measurement. *Design and Methods*.Were examined 280 blood donors ,156 men (aged 20-65 median age 40) and 124 women (aged 20-65 median age 37,4) . They were subdivided into two groups : Group A (n:185) consisted of regular blood donors with a frequency of blood donation of 2-3 times per year and Group B consisted of occasional blood donors who donate blood for a friend or relative.

Table.

Ferritine ng/ml	Regular Blood donors (n=185) 122 M+63W		Occasional Blood donors(n=95) 34M+61W	
>70	17	9.1%	40	42.1%
40-70	19	10.2%	4	4.2 %
30-40	33	17.8%	6	6.3%
20-30	35	18.9%	14	14,7%
<20	81	43.7%	31	32.6%

All of them filled out the blood donor form and were examined for serum ferritine levels. The determination of ferritin was done with reagents Beckman Coulter Access Ferritin in the analyzer Access . The expected normal values of ferritin : 25-320 ng/mL. *Results.* In Group A only 9.1% were found with ferritin levels > 70 ng/mL , for 46.9% the ferritin was 20-70 ng/mL and for 43.7% the ferritin level was found extremely low < 20 ng/mL meaning empty iron stores. In Group B , 42.1% were found with ferritin levels > 70 ng/ml, for 25.2% the ferritin was 20-70 ng/mL and for 32.6% the ferritin level was found < 20 ng/ml. *Conclusions*. It is obvious that the percentage of regular blood donors with ferritin levels <20 ng/mL is very high(43.7) and for this we have to take greater for them because their offer is significant. The regular blood donors have lower ferritin levels than the occasional blood donors regarding the times of blood donation per year. The determination of ferritin levels in all regular blood donors has been programmed for once every six months . If the ferritin is < 20 ng/mL, it is proposed : limitating the donation, treatment with ferrum and re-examination before the next donation.

1795

THE EFFECT OF PENTOXIFYLINE ON THROMBOCYTE FUNCTIONS, DURING THE CARDIOPULMONER BYPASS AND CORONER ARTER SURGERY

S. Ayaz, S. Yilmaz, K. Cagli

T Yuksek Ihtisas Hospital, ANKARA, Turkey

Background and Aims. Cardiopulmoner bypass (CPB) surgery caused endotelial injury and tissue edema because of the pathophysiologic reactions on thrombocyte functions. The aim of this study was to investigate the effect of using intraoperative pentoxifylline on the clinic findings and thrombocyte function. *Design and Methods*. Twenty patients were randomly selected among patients undergoing coronary bypass surgery. The effect of pentoxifylline on the thrombocyte number, platelet factor 4(PF4), mean platelet volume (MPV)and blood film were determined. The results were examined during the four periods of CPB surgery (1st period was anesthesia induction period-T1, 2nd period was after 30 minutes of surgery-T2, 3rd and 4th periods were after six and twentyfour hours of surgery-T3,T4) 100 mg pentoxifylline in% 0.9 isotonic was given in 180 minutes during the anesthesia induction with the warm cardioplegy .% 0.9 isotonic was given as placebo to 10 other patients. PLT and MPV were determined in automatic blood counters(CoulterLH 750, UK), PF4 levels were studied by ELISA (Stago, France).Blood film examination was done by the haematology doctor. *Results*. Platelet number was showed no statistically difference between two groups in T4 period, but in the group which pentoxifylline used, the platelet number was lower than other groups. In both group PF4 levels were found increased, but in T3 period the PF4 levels in patients were statistically higher than controls. MPV showed no difference between the groups. *Conclusions*. We concluded that, pentoxifylline could inhibite the thrombocyte activation particularly which was started during CPB surgery. But this effect wasn't enough to decrease complications such as hemorrhage and the ned of transfusion .

1796

SUCCESSFUL BURKITT'S LYMPHOMA TREATMENT DESPITE HPA-1A ALLOIMMUNIZATION

M. Ardaiz, J.M. Arguiñano, M.C. Mateos, M.V. Aznar, M.A. Goñi, Y. Burguete, M. Echeveste, M.J. Paloma, A.M. Redondo, I. Ezpeleta, M.A. Labaca, F.J. Oyarzabal

Hospital Virgen del Camino, PAMPLONA, Spain

Background. Some hematologic malignancies, such as Burkitt's lymphoma, must be treated with very intensive chemotherapy, thus requiring exhaustive transfusional support. Problems in finding compatible blood or platelets might hinder therapy administration. HPA1a antigen is part of most people's platelets; anti HPA-1a antibodies can arise in negative individuals after pregnancy or transfusion, causing post transfusional purpura or neonatal alloinmune thrombocytopenia in newborns. Once antibodies appear, blood or platelets must be transfused from HPA-1a negative donors although some alternative strategies must be used. Case report: We present a case of a 28 year old female patient with HPA-1a antibodies that caused prior neonatal alloinmune thrombocytopenia. She was diagnosed of Burkitt's lymphoma at stage IV A. Initial staging showed retroperitoneal masses extending to pancreas, stomach and left ovary. Additionally a right breast mass was confirmed to be involved by lymphoma. Bone marrow biopsy and cerebrospinal fluid were free of disease. Intensive chemotherapy was initiated according to Burkimab-08 Pethema protocol. This included high dose methotrexate, cyclophosphamide and cytarabine, so profound cytopenias were expected, therefore requiring intensive blood and platelet support. In order to minimize transfusion requirements erythropoietin was administered at maximum dose (30000 IU of Epoetin β twice weekly)

as well as parenteral iron therapy and antifibrinolytic drugs to avoid bleeding associated with thrombocytopenia. All chemotherapy was administered timely and complete remission was obtained quickly. Blood components transfused during therapy were as follows: -Two blood units from HPA1a positive donors, previously washed -Four blood units from HPA1a negative donors -Two platelet pheresis units from one HPA1a negative donor (same as one blood unit) Haematologic recovery after transfusion were as expected and no adverse reactions occurred during or following transfusion. *Conclusions*. Despite being a drawback, HPA-1a antibody has not precluded intensive chemotherapy administration. Washed blood components are an alternative to HPA-1a negative donor transfusion. Other support therapies such as erythropoietin and antifibrinolytics are of valuable help.

1797

BLOOD DONATION AND BLOOD TRANSFUSION IN SPAIN (1997 - 2007): POSSIBLE EFFECTS OF UNIVERSAL LEUKOREDUCTION?

J.A. García-Erce,[1] A. Pereira,[2] A. Campos,[3] M. Muñoz[4]

[1]SALUD, ZARAGOZA, Spain; [2]Servicio de Hematología y Hemoterapia. Hospital Clinic, BARCELONA, Spain; [3]Servicio Hematología. Hospital Clínico "Vírgen de la Victoria"., MÁLAGA, Spain; [4]GIEMSA. Medicina Transfusional. Universidad Málaga, MÁLAGA, Spain

Background. As epidemiological information is useful in planning the production and assessing the efficiency of product use, we reviewed the Spanish data on population, blood donation and blood component transfusion from 1997 to 2007, and the possible influence universal leukoreduction (ULR) on them.

Table.

Per 1000 population per year	Before ULR mean ± SD	After ULR mean ± SD	Difference Mean (95% CI)	P
RBCT (units)				
•Overall	30.1 ± 0.6	32.5 ± 0.5	2.5 (1.63 – 3.28)	0.001
•< 65 years	14.4 ± 0.3	15.7 ± 0.2	1.3 (0.81 – 1.68)	0.001
•≥ 65 years*	108.5 ± 2.4	115.0 ± 3.1	6.5 (2.41– 10.61)	0.006
Platelets (doses)**	2.7 ± 0.1	2.9 ± 0.2	0.2 (0.03 – 0.36)	0.024
FFP (units)***	5.3 ± 0.1	5.6 ± 0.3	0.3 (0.01 – 0.60)	0.045

Design and Methods. Data of the Spanish population were obtained from the National Institute of Statistics, and data blood donation and blood component transfusion from the Spanish Ministry of Health and Consume. Results. Along the study period, the Spanish population increased by 5.6 millions (14.4%), and blood donation by 28.1%, although red blood cell obtained increased only by 21.5% whereas red blood cell transfusion (RBCT) increased by 28.3%. However, RBCT rate was significantly higher after the implementation of ULR (2002 - 2006) when compared to the pre-ULR period (1997 - 2001) (Difference = 2.54 units/1000 population/year; 95%CI 1.81 - 3.27; $p<0.001$) (Table 1). No clinically relevant differences were observed for platelet or plasma transfusion. *Conclusions*. The increase observed in RBCT index after implementation of ULR may have been due to a reduction of the haemoglobin content in the RBC units. Therefore, our data on blood use seems to add to the case against ULR, which has led to an incremental cost at unknown and likely low benefits for the patient.

1798

LOW PREVALENCE OF ANTIBODIES TO HUMAN T-LYMPHOTROPIC VIRUS TYPE I AND II IN VOLUNTEER BLOOD DONORS IN A DEFINED AREA OF NORTHERN GREECE

A. Ioakimidou,[1] A. Karantani,[1] A. Mihailidou,[1] S. Georgousi,[1] A. Chatzimihailidou,[1] N. Malisiovas[2]

[1]Giannitsa General Hospital, GIANNITSA, Greece; [2]Malisiovas Nikolaos, THESSALONIKI, Greece

Background. TLV I/II infection is aetiologically associated with adult T-cell leukemia/lymphoma and HTLV-associated myelopathy/tropical spastic paraparesis. Blood donors are systematically screened for antibodies to human T-cell lymphotropic viruses type I and II (HTLV-I and HTLV-II) in Greece since 1995. AIMS:The aim of our study is to evaluate retrospectively the prevalence of HTLV I/II infection among the healthy blood donors of the area of Giannitsa of Northern Greece. *Design and Methods*. During the last eleven years (from September 1997 to September 2008) sera from 28254 consecutive blood donors were initially screened for anti-HTLV I/II antibodies using a comercially available immunoassay (sandwich ELISA- MUREX HTLV I+II®, Abbot, Germany). The reactive samples were further examined by a Western blot (WB) assay (HTLV BLOT 2.4, MP Diagnostics,) which detects specific IgG antibodies against HTLV-I and HTLV-II viruses, as a confirmatory test. RESULTS: Totally, only 6 serum samples were found to be reactive for anti-HTLV I/II antibodies by the ELISA, whereas only one was confirmed as positive by the WB assay. Thus, the prevalence of HTLV I/II infection among blood donors of our area is very low (0.00003%). *Conclusions* The practically zero prevalence of HTLV I/II infection among healthy blood donors of our area, during an eleven-year period of time, clearly demonstrates that this province of Northern Greece is not an endemic area for HTLV I/II. This result is consistent with the findings of other surveys conducted in different areas of Greece and poses the question of the necessity of routine screening for anti- HTLV I/II antibodies of the blood donors in Greece.

1799

DECLINING TENDENCY OF HUMAN T-CELL LEUKEMIA VIRUS TYPE I CARRIER RATES AMONG BLOOD DONORS IN MASHHAD, IRAN

D. Sayadpour Zanjani

Iranian blood transfusion organization, MASHHAD, Iran

Background. Human T-cell leukemia virus type I (HTLV-I) is a blood-transmissble retrovirus unevenly distributed around the world. Recently North East Iran, particularly the region of Mashhad, has been recognized as a new endemic region with 2-3% of the population and 0.7% of the blood donors infected with HTLV-I .Since 1996, all donated blood samples in the blood transfusion center of Mashhad, Iran, are routinely screened for HTLV-I. Aims: We studied the results of screening blood donors of Mashhad for antibodies to HTLV-I to understand the prevalence of this infecion during 3 years. *Design and Methods*. We evaluated and reported the results of screening 232,648 blood donors in Mashhad for antibodies to HTLV-I, from January 2004 to December 2006 which were taken from data sheets. *Results*. The donors were 90% male (n=211,265) and 10% female (n=21,383), with a mean age of 30 years (range: 18-65). The number of blood donations was 73489, 77502 and 81657 in the years of 2004, 2005 and 2006, respectively. Anti-HTLV-I antibody was performed by using ELISA. The positive samples were confirmed by Western blot (WB) test. Among the 232,648 blood donors analyzed, 1054 (0.45%) were repeatedly reactive by ELISA and confirmed by WB testing. The numbers of HTLV-I seropositive blood samples were 365, 343 and 346 in 2004, 2005 and 2006, respectively with a prevalence of 0.5%, 0.44% and 0.42% in these years. One hundred sixty three out of 1054 seropositive donors were females (15%) and 891 were males (85%). The prevalence of HTLV-I infection in males and females was 0.42% and 0.76% respectively. *Conclusions*. This decline in HTLV-I prevalence in Mashhad, from 0.77% in 1999 to 0.42% in 2006, could be attributed to better strategies for donor screening, sufficient education to the population about the routes of transmission and modes of protection, and other unknown reasons which need more studies to be determined.

1800

THE ROLE OF THERAPEUTIC APHERESIS IN THE TREATMENT OF IMMUNE-MEDIATED DISORDERS

A. Rafajlovski,[1] G. Ostojic,[1] M. Todorovic,[2] B. Balint1, M. Jevtic[1]

[1]Military Medical Academy, BELGRADE, Serbia; [2]University Clinical Center, BELGRADE, Serbia

Background. Therapeutic plasma exchange (TPE) is an apheresis procedure which guarantees high-level blood purification when removed plasma is replaced with normal plasma or saline and/or albumin. The basic goal of TPE is to reduce the patient`s load with pathogen(s), i.e. autoantibodies, cytokines, and other immune mediators and modulators to levels that will allow improvement and/or to supply an essential substance that is absent from patient`s plasma. *Aims*. To investigate of clinical efficacy of TPE, in combination with drug therapy, on the course and overall aucome of different immune-mediated disorders. *Design and Methods*. As the part of the management program, TPE (combined with anti-inflammatory and immunosuppressive agents) was applied in the treatment of patients with different immune-mediated disorders: myasthenia gravis, acute polyradiculoneuropathy, polymiositis, systemic lupus erythematousus, syndrome Goodpasture, progressive glomerulonephritis, hypersensitive vasculitis, lupus like syndrome, C1q-deficiency, cold agglutinin disease, autoimmune neutropenia, autoimmune trombocythopenia and autoimmune hemolytic anemia. TPE-procedures were performed by Cobe Spectra every other day, occasionally daily. The volume of exchanged plasma was: 1.0-1.5 patient's plasma volume (2.95 L in average) during one TPE-procedure and 3-5 patient's circulating plasma volume (21.4 L in average) during the whole treatment. The replacement fluids used were 5% and 20% albumin and physiological saline solution. *Results.* The use of TPE resulted with significant positive effect on clinical findings and some "para-clinical" events in patients with different immune-mediated disorders. In this group of patients disappearance or reversal of some symptoms and findings was obtained. To be precise, immune-complex removal, modulation of immune-mediators, correction of cellular immunity, improved circulation in targeted organs, renal function restitution, disappearance of arthralgia, viscosity reduction, disappearance of purpura and skin ulcer healing or complete clinical remission were observed. *Summary and conclusions*. TPE-procedures were effective, but not associated with long-term remission of disorders. The efficacy of TPE-treatment depends on the nature and stage of the basic disease, of adequate selection of patients and of timely applied apheresis procedures.

1801

ANALYSIS OF TURBID PLASMA DONATIONS

A. Castrillo,[1] C. Arcas,[1] B. Chomon,[2] J. Cabrera[1]

[1]Galician Transfusion Center, SANTIAGO DE COMPOSTELA, Spain; [2]Complejo Hospitalario Universitario, SANTIAGO DE COMPOSTELA, Spain

Plasma units are used for transfusion and for manufacturing of plasma derived products. Turbid plasma units like "milky white" are refused and destroyed. We investigated some donors characteristics. Material and *Design and Methods*. In our routine work, plasma unit is defined as turbid by visual inspection. The total incidence due to this problem last year was 4.1% from whole blood donation (113.724 WB donation) and 1.65% from single donation (7.996 SD donation). Between April and August 2008, plasma samples from WB (n=20) and from SD (n=20) with evident "milky" appearance were frozen. Samples of plasma and serum were analyzed in both donations but in case of apheresis platelet supernatant was analyzed too. Chemistries for triglyceride (TG) and cholesterol (Ch) levels were determined by enzymatic method, LPLasa-POD and CHOD-PAP respectively, supplied by Dade Behrring SA. The reference values for adults are triglyceride <150 mg/dL (<1.7 mmol/L) and cholesterol <200 mg/dL (<5.2 mmol/L). *Results*. The values are shown in media, range and median (see table below) We observed high triglyceride level with a normal cholesterol level in samples from serum and plasma. The TG level in supernatant platelet is irrelevant because the platelet concentrate is stored in additive solution, therefore the residual plasma was approximately 32%. Donations provided by men were more often turbid than those provided by women, in the report 37 men and 3 women. In our experience the total incidence had not relation to donation month but was related to dietetic habits. In this study, 52% of donors gave a turbid plasma more than three times of their previous donations. Therefore it is important that the donor of a "milky unit" is advised not to eat fatty food before their next donation. *Conclusions*. The incidence of turbid plasma donation depends on donor characteristics such as gender, nutritional factors and individual metabolic factors. We need to establish some procedures in order to decrease the amount of wasted plasma units, this could include donor questionnaire concerning dislipemic history, dietetic recommendation, and perhaps to promote and to facilitate plasmapheresis donation in young female donors to produce plasma derived products.

Table.

Age	Weight Kg	TG serum	TG plasma	Ch serum	Ch plasma
40.6 (27-63) 40.5	87 (70-107) 86.5	774 (252-2760) 658	660.5 (258-2160) 538	168 (88-246) 165	134 (81-179) 133.5

WAA APHERESIS REGISTER - RESULTS IN CZECH REPUBLIC

M. Blaha,[1] J. Ptak,[2] M. Blazek,[1] M. Lanska,[1] R. Prochazkova,[1] V. Ceeova,[1] I. Fatorova,[1] J. Maly[1]

[1]IInd Internal Clinic, Charles University, HRADEC KRALOVE, Czech Republic; [2]Department of Transfusiology, Regional Hospital, FRYDEK-MISTEK, Czech Republic

Background. Therapeutic aphereses are important contribution of transfusion medicine to the therapy of some serious diseases. They are performed in 7 centres in Czech Republic. Two of them have been registered their procedures in WAA register. One centre (I) is located in Moravia (Ostrava/Frydek) and the other (II) in Bohemia (Hradec Králové). We give a report on this activities. *Design and Methods*. WAA is a webb-based registry. So far 205 patients (672 procedures) have been included. A median of 3,3 treatments have been performed (1-26). Main indications: haematological and lipid apheresis, stem cell collection (autologous, less from donors) and neurological. Both centres are including their procedures regularly. Results: The reason of apheresis was therapeutic in 83% and retrieval of blood components in 17%. Blood access: mainly peripheral vessels (90%), central catheter through subclavia route or femoralis vein (9%) and AV fistula (in 1% only). Anticoagulant was ACD-A mainly. Replacement fluid was mainly by albumin. Advers events were registered in centre I in 3, 1%, in centre II in 5, 6% of procedures. They were clinically not relevant and no death occurred due to treatment. The connection with the leading centre in Sweden was without problems. The administrator was able to collect data to the end of each year or for the separate centres upon request. The actual version of WAA register is "user friendly", data submission are accompanied by a clear help. To enter data of one performed procedure usually lasts about 2-3 minutes. We can summarize that there were no significant differences between the centre I and II. *Conclusions*. Analyses of data in WAA register enables improvement of quality of apheresis. To learn more about various indications for apheresis as well as learn about the risks and to reduce adverse events, the use of WAA register is helpful as a quality assurance measure.

Supported by the grant of IGA MH CZ NR/9181-3.

PREVALENCE OF HEPATITIS C VIRUS (HCV) IN PATIENTS POLYTRANSFUSED

F.E. Ellakhdi,[1] H. Driouchi,[2]A. Khalikane,[3] S. Benchekroun,[4] N. Benchemsi[5]

[1]Chu ibn Rochd, CASABLANCA, Morocco; [2]Departement of Hematology 20Août CHU Casablanca, CASABLANCA, Morocco; [3]Regional Center for Blood Transfusion Casablanca, CASABLANCA, Morocco; [4]Department of Hematology [2]0Août CHU Casablanca, CASABLANCA MOROCCO, Morocco; [5]Laboratory Hematology CHU Ibn Rochd Casablanca, CASABLANCA MOROCCO, Morocco

Background. The incidence of HCV transmission through transfusion is estimated 1/700 000. The aim of this work is to assess the prevalence in patients polytransfused followed in the department of hematology and oncology pediatric from CHU Ibn Rochd for various hematological affections and after the introduction of the regional blood transfusion of Casablanca (CRTS) a new screening test to the combined search of the Ag-Ac HVC. *Design and Methods*. Patients candidates for polytransfusion are taken before any transfusion. They must be seronegative. The levies are renewed every 2 months to detect any seroconversion. Results: From May 2007 to Mars 2008, 100 patients were collected. All patients are HCV-negative with a follow up of 10 months for 36 of them. Discussion: Before the introduction of screening for hepatitis C among blood donors, the prevalence of HCV in patients polytransfused was 26.6%. This percentage was significantly reduced to 7% after the screening started in July 1994 to reach 1.6% with reagents of the 3rd generation introduced in 2003. *Conclusions*. The risk of transmission of HCV in the blood transfusion has become very small due to the constant improvement of the recruitment and selection of donors, and the progress being made in screening techniques which became with high performance.

1804

B12 AND FOLATE ACID SERUM LEVELS IN BLOOD DONORS POPULATION

M. Mavrolia,[1] V. Tsagkari,[1] I. Margara,[2] M. Skoura,[1] C. Palogiannidis,[1] C. Selidou,[1] E. Deilakis,[2] C. Veneti,[2] P. Paraskevopoulou[2]

[1]Blood Bank and Hematology lab. Konstantopoulio GHNIonia, ATHENS, Greece; [2]Blood Bank and Hematology lab Konstantopoulio GHNIonia, ATHENS, Greece

Background. The aim of this study is to determine the serum B12 and Folate levels in a population of blood donors. For the evaluation of these levels, the nutritional abilities and the alcool consumption of the blood donors were used. Method : 280 blood donors were tested ,156 men (aged 20-65 median age 40) and 124 women (aged 20-65 median age 37,4). They were subdivided into two groups : Group A (n:156) consisted of male blood donors and Group B (n: 124) consisted of female blood donors. All of them filled out the blood donor form and a questionnaire concerning their nutritional abilities (how many times per week they eat meat,fruit,vegetables) and how often and how much alcool they drink every week. The determination of B12 and Folate was done with reagents Beckman Coulter Access Ferritin in the analyzer Access. The expected normal values of B12: 145-914 pg/mL and Folate 2-17ng/ml. Results: In Group A , B12 was found from 100 pg/mL to 715 pg/mL with mean value 298,8 and Folate from 1,4 ng/mL to 10,8 ng/mL with mean value 4,01 In Group B , B12 was found from 119 pg/mL to 565 pg/mL with mean value 269,68 and Folate was found from 1,7 ng/mL to 17,5 ng/mL with mean value 4,33 . The study of the questionnaire results yielded the following conclusions How often do you eat Vegetables/fruits? -rarely : 80 men, 57 women -occasionally : 50 men ,26 women -often : 26 men,41 women -How often do you eat meat? -90% of participants (both men and women) eat meat 4-5 times weekly. -How often do you consume alcool ? -Never : 47 women, 12 men -Often :21 women, 68 men -Rarely : 56 women,76 men. *Conclusions*. The serum levels of B12 and Folate in both Groups are in normal values. Although we believe that Folate levels are quite low. For this reason we advise all blood donors to increase their consumption of folate rich vegetables/fruits.

1805

THE RECORD OF FERROPENIA AMIDST BLOOD DONATING PEOPLES

Patiakas,[1] N. Barbantonakis,[2] A. Tsina[3]

[1]General Hospital of Kastoria, THESSALONIKI, Greece; [2]General Hospital of Rethymno, RETHYMNO, CRETE, Greece; [3]General Hospital of Karpenisi, KARPENISI, Greece

Background and Aims. To study the frequency of ferropenia to regular and occasional blood doners, to reveal those with poor ferum storage and treat them with supplement therapy. *Design and Methods*. We studied 480 blood doners (314 men and 166 women). From those 305 were regular ones (at least 2 times a year), 156 were first timers, while 19 were occasional blood doners (had donated blood in the past, but less than 5 times in total). Ferritin values were calculated with the Elisa technique (MEIA ABBOTT). Ferropenia values were considered to be: ferritin <20 ng/mL for men and ferritin <10 ng/mL for women. *Results*. As you can see at the table. *Conclusions*. (i) Ferropenia among women is much more frequent than men. (ii) Regular blood doners present clearly greater ferropenia than occasional blood doners. (iii) It is therefore needed besides heamatocrit and hemoglobin measurment to have also the ferritin value periodicaly checked, especially in women.

Table.

BLOOD DONERS: 480	MEN	ferritin< 20 ng/ml	WOMEN	ferritin< 10 ng/ml
REGULAR: 305	211	38 (18%)	94	34 (36,1%)
FIRST TIMERS: 156	89	3 (3,4%)	67	12 (17,9%)
OCCASIONAL: 19	14	1 (7,1%)	5	1 (20%)

Mean Ferritin Value			
	MEN	REGULAR	56,9 ng/ml
		FIRST TIMERS	85,3 ng/ml
	WOMEN	REGULAR	17,1 ng/ml
		FIRST TIMERS	30,2 ng/ml

STUDING THE EFFECT OF PRESTORAGE WASHING (FOR LEUKOREDUCTION) ON THE FUNCTION OF PLATELETS IN PLT BAGS WHICH HAVE KEPT FOR 7 DAYS

A.A. Kiani,[1] A. Abdi,[2] S. Shirkhani,[1] K. Kashi,[1] M.R. Mehrabi,[3] N. Negravi[4]

[1]Lorestan University of Medical Sciences, KHORAM ABAD, Iran; [2]Blood Transfusion Center, KHORAM ABAD, Iran; [3]Azad Eslami University, BROUJERD, Iran; [4]Padideh Institute, SOSANGERD, Iran

Background. The presence of WBCs in platelet component may induce some problems such as alloimmunization against HLA, CMV transmission, febrile non-hemolytic transfusion reactions (FNHTRs) in the patients (recipients). During platelets storage in laboratory, their function may be affected by such factors as cytokine and metabolite release from WBCs and, probably, decrease in pH. Because of these factors PLT shelflife has been limited to at most 5days (depending upon the bag type) in room temperature. *Aims*. The main purpose of caring out this research is washing PLT component for leukoreduction which may help to abate the above concerns. *Design and Methods*. This study was on an experimental basis and carried out on the PLT components of random blood donors which were organized into two groups: test (washed products, 20) and control (unwashed products, 10). At the end of day 7 of storage all the PLT units were primarily assessed for any bacterial or fungal growth through culture, then WBC count was carried out on the components in two groups. Finally, in order to evaluate platelet function, samples were analyzed in an aggregometer with four agonists, arachidonic acid, ADP, collagen and ristocetin. The obtained data were assessed by t-test. *Results*. Statistical analysis indicated that PLT washing had no significant effect on the number of platelets but had caused WBC reduction in washed components ($p<0.01$). This analysis also showed that there was a significant difference in PLT average reaction with arachidonic acid ($p<0.01$) and collagen ($p<0.05$) in two groups, but there appeared no significant difference between PLT average reaction with ADP and ristocetin agonists in two groups ($P>0.05$). *Conclusions*. PLT washing causes WBC reduction in platelet component and fortunately doesn't have any undesirable on this product, so this protocol may be recommended for increasing PLT shelflife, from 5days to 7days.

1807

QUANTITATIVE DETERMINATION OF NEUTROPHIL VOLUME DISTRIBUTION WIDTH: A NEW AUTOMATED HEMATOLOGIC PARAMETER FOR ACUTE INFECTION

E. Papakonstantinou, E. Yfantis, P. Georgoutsou, A. Skourbouti, A. Lavda, P. Giannopoulou, I. Grafakos, K. Safioleas, C. Manti

Thriassion General Hospital, ATHENS, Greece

Background. Review of peripheral blood smears can yield important diagnostic information through the identification of the morphologic changes characteristically seen in reactive neutrophils during infection. This approach, however, is labor-intensive and time-consuming because it requires manual examination. Furthermore, the results are subjective because they depend on human interpretation, and only a few hundred cells can be analyzed for any given sample.The Coulter LH 780 hematology analyzer (Beckman Coulter, Fullerton, CA, USA) has the ability to measure specific parameters of neutrophil populations like mean and standard deviation (SD) of cell volume (MVI,SDVI), conductivity (MCI,SDCI), and light scatter (MSI, SDSI). These so-called positional parameters (PP) can detect morphologic changes in neutrophil population and can be an additional indicator for diagnosing acute infection. AIMS: To investigate the value of the neutrophil SDVI, generated by VCS technology of the Coulter LH 780 hematology analyzer, as an additional predictor of acute infection. *Design and Methods*. Absolute neutrophils count, and SDVI data from 328 patients with positive blood cultures and from 54 age-matched healthy control subjects were prospectively analyzed. We then studied whether changes in SDVI correlated with patients absolute neutrophil counts (less or greater than 6600/μL). The PP was obtained by the Coulter LH 750 hematology analyzer. Comparisons between means were performed by analysis of variance. Comparison between 2 means was performed by using the Student t test. A P value less than 0,05 was considered significant. *Results*. A significant increase in the SDVI was observed in the bacteremic patients compared with the controls (27,78 vs 20, 63, $p<0.001$). Such increase was observed even in patients with absolute neutrophil counts less than 6600/ ^{t}L) (25,46 vs 20,63, $p<0.001$). The more dramatic increases were seen in patients with neutrophilia (28.65 vs 20,63, $p<0.001$).

Table.

	Control	Patients	<6600	>6600	P
Number	54	328	89	239	
SDVI mean	20.63	27.78	25.46	28.65	<0,001

Conclusions. 1) The SDVI increases in acute infection 2) Using an SDVI cutoff of 23, as in bibliography, seems that SDVI is a good predictor of acute infection 3) The SDVI increase correlated significantly with neutrophilia but was observed even in patients with neutrophil counts less than 6600/ μL. 4) As a quantitive parameter, the SDVI has potential use as an additional indicator for diagnosing acute infection.

1808

EFFECTIVENESS OF POSACONAZOLE IN ANTIFUNGAL PROFILAXIS IN THE ANLL AND ALLO BMT TREATMENT

V. Pavone,[1] R. De Francesco,[2] C. Del Casale,[2] G. Greco,[2] L. Leo,[3] G. Lobreglio,[3] A. Mele,[2] A. Messa,[2] G. Pasanisi,[3] A. Rana,[2] B. Rossini,[2] S. Sibilla[2]

[1]U.O. Ematologia e Trapianto, TRICASE, Italy; [2]O.U.Haematology, TRICASE, Italy; [3]Med. Lab., TRICASE, Italy

Background. The risk of IFI in onco-haematological patients with ANLL and patients subjected to allo-BMT is >30% with respect to intensive chemiotherapy regimen, to >10 days neutropenia, to mucositis onset and to GVHD. The antifungal prophylaxis is important to control such infections. Studies by Cornely (ASH 2005) and Ulmann (ICAAC Washington 2005) documented the effectiveness of prophylaxis with posaconazole. *Aims*. to evaluate the positive effect of prophylaxis with posaconazolo in ANLL and allo-BMT treated patients. *Design and Methods*. 24 cases were subjected to prophylaxis with posaconazole, 14 of them were treated with induction protocol for ANLL (Fab subtype : 2 Mo-5 M1- 3 M2- 1 M5a- 3M5b) and 10 were subjected to HSC allotransplant (2 ANLL-3 NHL- 2 MM- 2 HL- 1 CLL). Average age of patients : 44 yrs (range 19-78). Among additional risk factors, 4 patients showed fungal colonization at the admission, 12 received previous chemiotherapy treatment, 3 was treated with ASCT and 6 received immunosuppressive therapy. The prophylaxis with posaconazole was carried out in 24 cases (200 mg three times daily on a full stomach) since the first day of chemiotherapy up to > 500 ANC. At the admission, all patients underwent to haemoculture on peripheral blood and CVC, culture test on faeces and urine and buffers in the various sites. At the fever onset, that is, on alternate days, haemoculture on peripheral blood and CVC as well as evaluations of PCR, Procalcitonin, Galactomannan (GM) and DNA for Gram + and Gram -, bacteria and fungi. On the 1st day of fever, chest X-Rays were carried out, followed by high-definition chest CT after 72 hours of persistent hyperpyrexia. *Results*. The prophylaxis lasted 18 days on average (range 5-30 days). The treatment was discontinued due to >500 ANC in 12 cases, to intolerance in 8 cases and to fungal infections shift therapy in 4 cases. 20 patients showed hyperpyrexia. 3 cases of fungal infections have been documented (12.5%) : 1 with Krusei Candida on peripheral blood and Candida Glabrata on coproculture, 1 with *Candida albicans* on DNA peripheral blood, 1 case with *Candida albicans* on expectoration and probable invasive *Aspergillosis* documented by GM index 0.6 and HR CT (high-risk patient subjected to allo-BMT showing 4th-degree hepatic GVHD). *Conclusions*. In our experience, prophilaxis with posaconazole has revealed positive effects in the onset of IFI (12.5%) with acceptable tolerability.

Table. Prophylaxis with posaconazole.

PROPHILAXIS WITH POSACONAZOLE	
DIAGNOSIS	ANLL 14 (ANLL FOLLOWING MDS 3) ALLO ESC 10 (ANLL 2- NHL3- MM2- HL 2- CLL1)

RENAL AFFECTION IN CHILDHOOD MALIGNANCY: IMPACT OF ANTICANCER DRUG MANAGEMENT

M. Badr, M. Hesham, H. Abdel Rahman, M. Besheer, T. Hassan, A. Zidan

Zagazig University, ZAGAZIG, Egypt

Background. Malignant disease can damage the kidneys by different mechanisms, e.g. infiltration of the kidneys, obstruction of urinary pathways or the syndrome of acute tumor lysis after progressive cytotoxic treatment. Moreover, there may be even direct renal damage caused by cytotoxic treatment. Renal impairment can results in altered excretion and metabolism of chemotherapeutic agents. Despite the recent advance in understanding the mechanism of anticancer drug nephrotoxicity, prevention still relies on drug dosage decrease and active screening for renal abnormalities as part of the usual biological work up in patient treated with anticancer drugs. *Aims*. We aimed to assess the effects of antineoplastic chemotherapy on kidney function when these drugs are used either alone or in combination with each other. *Design and Methods*. The study was carried out on 40 newly diagnosed malignant patients at Pediatric Hematology and Oncology Unit in Zagazig University Hospital from December 2007 till October 2008, their age ranged from 6 months to 14 years (24 males and 16 females). All patients were subjected to complete history taking and examination, laboratory investigations; especially BUN, serum creatinine, electrolytes (Na, K, Mg and Ca), blood glucose, arterial blood gases and creatinine clearance, and radiological evaluation of the kidneys at diagnosis and after three and six months of chemotherapy. *Results*. In our study the most commonly used anticancer drug was methotrexate (67.5%), followed by vincristin and cyclophosphamide (62.5%). Our results revealed that there was significant increase in BUN (p= 0.013), and significant decrease in creatinine clearance (p=0.002) after 6 months of chemotherapy especially solid tumors. The most common renal complication in our patients was hematuria (42.5%) followed by hypertension (17.5%). CRI was reported in 17.5% in our patients while ARF was reported in 15%. Serum phosphorus and uric acid were increased in a highly significant statistical fashion in all stages, (p=0.001), while there was no significant statistical difference regarding serum Na, Mg and K before and after chemotherapy. Among our patients ARF was the most common cause of death (57.1%). *Conclusions*. Renal affection should be focus of interest during treatment and follow up of childhood malignancies. Protocols of treatment of these patients especially those with solid tumors should be evaluated for their potential nephrotoxic effects. Good preparation of these patients, anticipation of nephrotoxic side effects and modification and substitution of these nephrotoxic agents if possible with less or none nephrotoxic ones are crucial factors.

1810

MEAN NEUTROPHIL VOLUME AS A NEW A NEW AUTOMATED HEMATOLOGIC PARAMETER FOR ACUTE INFECTION

E. Papakonstantinou, S. Chaniotaki, A. Skourbouti, P. Georgoutsou, A. Lavda, P. Giannopoulou, P. Safioleas, I. Grafakos, C. Manti

Thriassion General Hospital, ATHENS, Greece

Background. Review of peripheral blood smears can yield important diagnostic information through the identification of the morphologic changes characteristically seen in reactive neutrophils during infection. This approach, however, is labor-intensive and time-consuming because it requires manual examination. Furthermore, the results are subjective because they depend on human interpretation, and only a few hundred cells can be analyzed for any given sample. The Coulter LH 780 hematology analyzer (Beckman Coulter, Fullerton, CA, USA) has the ability to measure specific parameters of neutrophil populations like mean and standard deviation (SD) of cell volume (MVI,SDVI), conductivity (MCI,SDCI), and light scatter (MSI, SDSI). These so-called positional parameters (PP) can detect morphologic changes in neutrophil population and can be an additional indicator for diagnosing acute infection. AIMS: To investigate the value of the neutrophil MVI, generated by VCS technology of the Coulter LH 780 hematology analyzer, as an additional predictor of acute infection. *Design and Methods*. Total white blood cell count, percentage of neutrophils, and positional parameters data from 328 patients with positive blood cultures and from 54 age-matched healthy control subjects were prospectively analyzed. We then studied whether changes in MVI correlated with the type of microorganism. Positive cultures were subdivided to gram (+) or gram (-) microorganism. The PP was obtained by the Coulter LH 750 hematology analyzer (Beckman Coulter, Fullerton, CA). Comparisons between means were performed by analysis of variance. Comparison between 2 means was performed by using the Student t test. A P value less than 0,05 was considered significant.,*Summary and conclusions.* 1) The MVI increases in acute infection, while MSI decreases. 2) Using an MVI cutoff of 150, as in bibliography, seems that MVI is a good predictor of acute infection. 3) The MVI increase correlated significantly both with gram(+) and gram (-) microorganisms but it was greater at gram(-) microorganisms (p=0.085). 4) As a quantitive parameter, the MVI has potential use as an additional indicator for the diagnosis of acute infection.

Table.

	Control	Patients	P	Gram+	Gram-	P
Number	54	328		108	186

EPIDEMIOLOGY OF BLOOD ISOLATES FROM DEPARTMENT OF HEMATOLOGY AT THE CHU IBN ROCHD CASABLANCA MOROCCO BETWEEN 2003 AND 2007

F.E. Ellakhdi,[1] L. Ibrahimi,[2] H. Belabbes,[2] K. Zerouali,[2] N. Elmdaghri[2]

[1]Chu ibn Rochd, CASABLANCA, Morocco;2Laboratory of Microbiology, CASABLANCA, Morocco

Background. Bacterial ecology of the department of hematology at the CHU Ibn Rochd is important to know, to better guide the choice of antibiotic in 1st intention in the management of febrile patients. *Design and Methods*. We chose to exploit the results of blood cultures performed in this department from the database of the Microbiology Laboratory CHU Ibn Rochd Casablanca over five years (2003 to 2007). *Results.* During this period, we analyzed 4787 blood cultures performed in 2216 patients, an average of 957.4 blood / year and 2.2 balloons blood / patient. 751 blood cultures were positive (34%). Among the seeds frequently isolated (duplicates excluded), we find the *Staphylococcus* coagulase negative with 48%, followed by *Pseudomonas aeruginosa* (7%), Staphylococcus aureus (6%), *Escherichia coli* (6%), Klebsiella pneumoniae (4%) and *Acinetobacter spp* (2%). Of all the strains isolated, 39% of E. coli and 29% of *K.pneumoniae* are producing BLSE, 15% of *S.aureus* were resistant to Meticilline while *P.aeruginosa* and *Acinetobacter* are resistant to Imipenem with respectively 22% and 5%. *Conclusions*. These results which will be discussed in the light of the literature show the importance and the need to rationalize the use of antibiotics to control the spread of multiresistant strains.

1812

INFECTTIOUS COMPLICATIONS IN 81 CONSECUTIVE ADULT PATIENTS UNDERGOING INDUCTION CHEMOTHERAPY FOR ACUTE MYELOID LEUKEMIA

E. Audisio, A. Busca, S. D'Ardia, F.G. De Rosa, M. Falda, G. Limerutti, F. Marmont, A. Piceghello, U. Vitolo

Aso San Giovanni Battista, TORINO, Italy

Patients with Acute Myeloid Leukemia (AML) undergoing chemotherapy are at high risk for infections particularly during the induction phase. The records of 81 consecutive adult patients (pts) (mean age 49 years) with AML treated homogeneously with an induction chemotherapy with Idarubicin, Etoposide and Cytarabine (ICE) were analysed. All patients were treated in an air-conditioned facility without HEPA protection. Twelve pts (14.8%) had no infections. Neutropenic

fever was observed in 69 pts (85.2%). Twenty-seven ptss (33.4%) had fever without neither isolates nor clinical or instrumental signs of infection. They were therefore definded as Fever of Unknown Origin (FUO). Ten pts (12.4%) had fever with clinical or instrumental signs of infection and were defined as Clinically Documented Infections (CDI). In 23 pts (28.4%) isolates of infectious agents were obtained and therefore they were defined as Microbiologically Documented Infections (MDI). "Possible" invasive fungal infection (IFI) were observed in 2 pts (2.4%), "probable" IFI in 3 pts (3.7%) and "proven" IFI was documented in 4 pts (4.9%). In febrile episodes, a pneumonia was documented in 19 pts (27.5%), neutropenic enterocolitis in 8 pts (11.6%), perianal abscesses in 2 pts (2.8%), vulvovaginitis in 2 pts (2.8%) and cholecystitis in 1 pt (1.4%). In one patient a Central Venous Catheter (CVC) infection was documented. A Severe Inflammatory Response Syndrome (SIRS) was observed in 5 febrile pts (7.2%). Blood cultures were performed on occasion of the first febrile spike: in 44 pts (66.6%) the blood cultures were negative, in 22 pts (33.4%) a pathogen was found in at least two blood culture samples (17 Gram+, 5 Gram-, 3 candida). More isolates were found on infected sites swabs or tissue specimen cultures (1 fusarium, 3 p. aeruginosa, 2 s. epidermidis, 1 MRSA, 1 bacteroides ovatus,). S. maltophilia was isolated in 3 pts from sputum throat. L. pneumophila antigen was detected in the urine in two cases. Empiric antibiotic therapy was started with anti-pseudomonal penicillins in 42 pts (60.8%), with carbapenem in 16 pts (23.2%), with 3rd generation cephalosporins plus aminoglycoside in 11 pts (16.0%). Glycopeptides were added in 31 cases and antifungals (liposomal amphotericin, echinocandins or voriconazole) in 33 pts. Fever resolved with treatment in 34 pts (49.3%); 5 pts (7.2%) died because of infectious complications. Fever resolved with granulocyte recovery in 30 pts (43.5%). The predominance of Gram+ bacterial infections was confirmed in the present series. The incidence of probable and proven IFI (8.6%) was clinically relevant. A new HEPA filtered facility is now available for induction therapy of AML patients and therefore a reduction in fungal infections may be expected.

1813

WEST NILE VIRUS INFECTION IN A PATIENT WITH ACUTE GRAFT-VERSUS-HOST DISEASE

F. Arpaci,[1] T. Cetin,[2] A. Kubar,[3] M. Ozturk,[1] O. Kuzhan,[1] S. Komurcu,[1] B. Ozturk,[1] S. Ataergin,[1] A. Ozet[1]

[1]Gulhane Medical Faculty Oncology Dept., ANKARA, Turkey; [2]Gulhane Medical Faculty Hematology Dept., ANKARA, Turkey; [3]Gulhane Medical Faculty Virology Dept., ANKARA, Turkey

Background. West Nile virus (WNV) is generally transmitted by an infected mosquito. Some of the cases are infected by transfused blood products. No symptom is seen in approximately 80% of infected cases. In 20%, this microorganism causes mainly fever, neurological, gastrointestinal, respiratory symptoms. These symptoms are generally more severe and progressive in elderly or immunocompromised patients. Viremia persists for less than 12 days in an immunocompetent host, but may last much longer in immunosuppressed patients. *Design and Methods*. We describe a 40 year-old patient who underwent nonmyeloablative bone marrow transplantation for acute myelogenous leukemia. On posttransplant day 51 he was admitted with complaints of high fever (39oC), diarrhea, and diffuse skin rash. After 3 days, his liver enzymes increased mildly. Skin biopsy, but not liver and colon biopsies, was consistent with acute graft-versus-host disease (GVHD). His complaints due to acute GVHD relieved with immunosuppressive agents. On day +80, a second attack of fever together with headache and sudden onset of severe weakness of limbs happened. His CSF, blood, urinalysis and imaging studies were not remarkable for bacteria, CMV, EBV, HSV, toxoplasma, fungal infections, leukemic relapse and other neoplastic cells. He became pancytopenic. Three units erythrocyte and two units platelet concentrates were transfused in the posttransplant period. Diagnosis was made by a positive result of a reverse-transcriptase polymerase chain reaction for WNV on blood sample. Symptoms of the patient relieved gradually with supportive measures by day +110. There seems no complication so far. *Summary and Conclusions*. WNV is a severe infection with nonspecific findings. Therefore, differential diagnosis with another infections or GVHD may be difficult. Since it may be fatal in transplanted patients, this infectious agent should be kept in mind and all blood products which will be transfused to transplanted patients should be screened for WNV.

1814

AMINOGLYCOSIDE-FREE INTERVENTIONAL ANTIBIOSIS IN PATIENTS UNDERGOING HAEMOPOIETIC STEM CELL TRANSPLANTATION

W.H. Krüger, T. Kiefer, G. Daeschlein, I. Steinmetz, A. Kramer, G. Dölken

University-Hospital Greifswald, GREIFSWALD, Germany

Background and aims. The position of aminoglycosides within interventional antibiosis in the early phase after stem cell has not been clarified so far despite their use can induce serious renal impairment. Data from conventional haematological patients suggests that they can either be omitted or replaced by other drugs. *Design and Methods*. To investigate this question early-infection data from 152 patients undergoing 195 allogeneic and autologous stem cell transplantations were investigated. Prophylaxis and treatment of infections followed international standard, however, aminoglycosides were omitted when ever possible. Results: The overall-incidence of infections was 77,9% (152/195) and 67 patients suffered from more than one episode. Fever of unknown origin and bacteriaemia/septicaemia dominated the spectrum of infections. Spectrum of isolated pathogens showed no increase of Gram-negative rods. The overall-response to interventional regimen consisting of β-lactam or carbapenem plus glycopeptides was 47.7%. Aminoglycosides were given in three patients in the late course of disease. Overall mortality was 15/195 (7.7%) and clearly related to infection in nine cases mostly due to mould infection. A comparison with previous publications gave no hint for inferiority of 'aminoglycoside-free' antibiosis. *Conclusions*. In conclusion, the present analysis supports the policy to omit aminoglycosides in the therapy of early infections in patients undergoing stem cell transplantation to avoid additional nephrotoxicity.

1815

ALLOPORINOL, CHAMOMILE AND NORMAL SALINE MOUTHWASHES FOR PREVENTION OF CHEMOTHERAPY-INDUCED STOMATITIS

R. Shabanloei,[1] F. Ahmadi,[2] J. Vaez Gharamaleki,[1] K. Ansarin,[3] E. Hajizadeh,[4] R. Dolatkhah,[1] M. Golchin[1]

[1]Hematology and Oncology Research Center, TABRIZ, Iran; [2]Medical Sciences Faculty, Tarbiat Modares University, TEHRAN, Iran; [3]Tuberculosis & Lung Research Center, Tabriz University of Medical Sciences, TABRIZ, Iran; [4]Biostatistician Department, Tarbiat Modares University, TEHRAN, Iran

Background. Stomatitis is a common side effect in patients receiving chemotherapy. It is alters survival because of the risk of infection and has a significant impact on quality of life causing treatment delays, nutritional deficiencies and increasing cost of care. *Aims*. The aim of this study was to determine and compare efficacy of allopurinol, chamomile and normal saline mouthwashes in prevention of chemotherapy-induced stomatitis. *Design and Methods*. A randomized, double-blind clinical trial was conducted on 83 patients receiving chemotherapy . The cases were selected from Shahid Ghazi Oncology Service patients undergoing chemotherapy for various malignancies. They were randomly divided into three groups and received allopurinol (group 1), chamomile (group2) or normal saline (group 3) . ANOVA and 2test have been used for data analyzing. *Results*. Significant differences were obtained between allopurinol, chamomile and normal saline groups in scores of severity of stomatitis (p=0.017), stomatitis pain (p=0.027) and persistence of stomatitis. No significant differences noted among the mean stomatitis (p=0.59) and stomatitis pain (0.071) severity scores between group 1 and 2. *Conclusions*. These findings indicate equal efficacy of allopurinol and chamomile in prevention of chemotherapy-induced stomatitis compared to Normal Saline control group. Considering the cost and easy accessibility of chamomile and potential therapeutic applicability in reduction of the severity of chemotherapy-induced, it's implied.

1816

EPIDEMIOLOGY OF BLOODSTREAM INFECTIONS IN HEMATOLOGY-ONCOLOGY PATIENTS

S. Delimpasi

Evangelismos Hospital, ATHENS, Greece

Background. Bloodstream infections (BSIs) are directly responsible for a prolonged hospital stay and, in critically ill patients, are associated with high healthcare costs and significant mortality. *Aims*. To describe the clinical and microbiological characteristics and to determine the incidence density and predictors of BSIs in patients with hematologic malignancies *Design and Methods*. Standardized Surveillance system based on the Cen-

ters for Disease Control and Prevention's National Nosocomial Infections Surveillance system. *Results.* The incidence rate of BSIs was 16,7%. The incidence density of bloodstream infections was 7,4 per 1,000 patient-days (21,9 per 1,000 patient-days at risk). Most of patients with BSI had acute myeloid leukemia (75%). The origin of the BSI was unknown in 70,6% of the episodes and was associated with known sites in 11,8%. The most common isolates were E Coli (17,6%) and K Pneumoniae (17,6%). Most of BSI was monomicrobial (88,2%). Multivariate analysis showed length of stay (p=0.017), duration of neutropenia (p=0.017) and acute myeloid leukemia (p=0.017) as independent predictors of BSIs. *Conclusions.* The incidence density of BSI was high. Risk factors of BSIs are associated with severity of patients and could not modify by all staff members.

1817

HEMATOLOGICAL MODIFICATIONS IN PATIENTS WITH IMPORTED MALARIA FROM WESTERN ROMANIA

R. Neghina, A.M. Neghina, I. Marincu, R. Moldovan, I. Iacobiciu

Victor Babes University of Medicine, TIMISOARA, Romania

Background. Imported cases of malaria are occasionally diagnosed in Romania and their hematological modifications are difficultly managed due to complicate mechanisms and low therapeutic response. Anemia in malaria is multifactorial due to accelerated destruction of red cells, bone marrow dysfunction, shortened red cell survival and increased splenic clearance. It is used as an indicator of the impact of malaria control in intervention trials, monitoring and evaluation. Thrombocytopenia is commonly seen in severe *Plasmodium falciparum* malaria due to increased consumption of the platelets in the periphery, especially in the spleen. The hallmark of P. falciparum malaria is the sequestration of infected erythrocytes within the capillaries and postcapillary venules from different organs. *Aims*. To highlight the malaria clinical cases with their life threatening hematological modifications and to emphasize the importance of their adequate and fast correction in patients' survival. *Design and Methods*. Overview of the medical charts of patients diagnosed with malaria who required advanced medical attention due to the hematological modifications detected. Patients were hospitalized at Victor Babes Hospital of Infectious Diseases from Timisoara, Romania during the period 2001-2007. Clinical and laboratory features of the cases were analyzed. Results: Hematological modifications were observed in six patients diagnosed with P. falciparum (malignant tertian) malaria. The clinical pattern of these patients included: fever and shivers (all six patients), hepatomegaly (five patients), icterus (three patients) and splenomegaly (two patients). Regarding the laboratory tests, anemia was found in five patients, thrombocytopenia in two patients, leucocytopenia in one patient and leucocytosis in one patient. *Plasmodium falciparum* was found in thin and thick blood smears in all cases. The values of the routine hematological laboratory tests are shown in Table 1.

Table 1. Routine hematological laboratory tests.

Patient	Gender	Follow-up	Erythrocytes (/mm³)	Hemoglobin (g/dl)	Leucocytes (/mm³)	Thrombocytes (/mm³)
1	♂	fatality	3 250 000	4.8	normal	18 000
2	♂	survival	2 980 000	9.8	normal	normal
3	♂	survival	normal	normal	normal	89 000
4	♂	survival	2 630 000	9.4	2 800	normal
5	♀	survival	3 360 000	9.7	normal	normal
6	♂	survival	3 800 000	9.8	12 000	normal

Conclusions. Generally, hemoglobin levels of less than 7 g/dl must be a warning for impending crisis and a decrease of less than 5 g/dl is an indicator for transfusion of packed cells. In case of a single patient from our study a hemoglobin value of 4.8 g/dl was detected, leading to his death. Giemsa-stained thin and thick smears taken from this patient indicated a massive parasitemia (affecting over 60% of the erythrocytes). Anemia and fever tended to increase the cardiac output and this combination worsened the status of five patients from our study. In cases with severe parasitemia and profound hemolysis repeated transfusions were administered.

1818

MUCOR CIRCINELLOIDES INFECTION IN AN AUTOLOGOUS BONE MARROW TRANSPLANTATION RECIPIENT

J. Vázquez-Álvarez

Hospital Xeral-Cíes de Vigo, VIGO, Spain

Background. Invasive fungal infection (IFI) is a severe complication in bone marrow transplant recipients. In last decades, Candida was the main etiology of IFI in bone marrow transplant (BMT) recipients. Nowadays Aspergillus has became the main fungus in haematologist patients although other less frequent moulds can be also found. These infections are likely to become increasingly recognized even though the occurrence after BMT has only been described sporadically. Aim: In this work, we report a 59-year-old patient who developed a post-transplant zygomicosis due to Mucorales circinelloides. *Design and Methods*. The patient was diagnosed with Mantel cells lymphoma EIVB IPI 3 treated with 5 Mega-CHOP and 2 R-IFE and achieved an apparent CR. Autologous transplantation was performed after conditioning with total body irradiation and cytarabine treatment. After hospital delivery, he was treated with fluconazole and levofloxacin because of oropharyngeal candidiasis and flu, thorax radiology was normal. On day +91 he came to the hospital because of right intercostal metameric zoster, without fever but without resolution of oropharingeal candidiasis and flu. Thorax radiology showed an alveolar consolidation at right upper pulmonary lobe and started ceftazidima, aciclovir and itraconazole. On day +97 we found bilateral homogeneous ground glass opacity on the right upper pulmonary lobe with minimum bilateral pleural effusion in a CT. He had many fever episodes that make us to add linezolid and soltrin and change acyclovir and itraconazole for foscarnet, caspofungina and voriconazol. A bronchoscopy was carried out with macroscopic inespecific results. A new CT was worse. On day +105 the patient was moved to intensive care department because of respiratory instability. All the microbiological tests required, including fungal and viral antigenemias and cultures, were negatives. On day +106 we asked for parasites cultures and added doxiciclina and albendazol to the treatment. The patient presented acute renal failure and needed continuous hemofiltration, but finally the patient died. An autopsy was carried out with the diagnosis of invasive fungal infection (respiratory and gastrointestinal tracts). Tissue samples were sent to a microbiology laboratory in order to make a PCR. Results: The diagnosis was not achieved by means of different cultures, imaging or histopathology methods carried out before the death of the patient. The histopathology is an important aid although because of the fact that the morphology of hyphae is microscopically similar in a lot of moulds, a differential diagnosis became a difficult task. In this case Mucor Circinelloides Zygomicetos was only isolated using the mould DNA sequentiation by PCR. *Conclusions*. DNA sequentiation by PCR is potentially helpful for detection and identification of fungal infections in BMT recipients. It increases detection sensitivity and decreases time for results, a difference that can has a significant positive impact on patient care.

1819

UNUSUAL CAUSE OF DIARRHOEA AFTER UNRELATED HAEMATOPOIETIC STEM CELL TRANSPLANTATION FOR RELAPSED FOLLICULAR LYMPHOMA

E. Sebastián Pérez,[1] J. Alonso Rodríguez,[1] L. López Corral,[1] T. González,[1] T. Caballero Velázquez,[1] J. Martín Sánchez,[2] L. Vazquez,[1] J. San Miguel,[1] T.F Flores,[1] A. Rodríguez,[1] A. Blanco,[3] I. Fuentes,[3] G. Mcdonald,[4] D. Caballero Barrigón[1]

[1]Hospital Universitario de Salamanca, SALAMANCA, Spain; [2]Hospital Universitario de Salamanca, SALAMANCA, Spain; [3]Instituto Carlos III, MADRID, Spain; [4]American Society of Hematology, WASHINGTON, USA

We submit the case of a 46 years-old woman diagnosed of a stage IVA grade 2, FLIPI 1, follicular lymphoma. She received four lines, including autologous haematopoietic stem cell transplant (auto-HSCT). She underwent a reduced intensity conditioning, peripheral blood haematopoietic stem cell transplantation, from an ABO identical unrelated donor with one HLA mismatched, five years after initial diagnosis. At day + 100 she had a DLBCL transformation in an inguinal lymph node EBV negative, reaching complete remission after reducing inmunossupression and anti-CD20. On day + 190 after comitial crisis, cerebral abcess were detected on CT scan and RM, suggestive of toxoplasmosis which was resolved after antibiotics. From day 180 postHSCT she has two episodes of diarrhoea being diagnosed after gastric biopsy of late onset acute graft-ver-

sus-host-disease (aGvHD) that reached complete response with topical steroids. Microbiologic screening was negative. On month 16, watery diarrhoea reappeared with increasing stool volume, body weight loss, nausea and abdominal pain. Gastric endoscopy with biopsy take showed again GVHD, so second and subsequent line treatment for GvHD was initiated without response. A third gastric endoscopy was taken, suggesting GvHD versus infection. Colestasis appeared accompanying the former clinical symptoms. Abdominal ultrasonography, CT and MRI scans showed a dilated choledocus, an enlarged gall-bladder wall, and an obstructed common bile duct with a highlighted billiary system. Sphyncterothomy and Kherr tube placing relieved pain, and billiary fluid samples were taken. Spherical structures in crypts compatible with Cryptosporidium were revealed showing apoptotic bodies, crypt destruction, inflammatory infiltrate, and growing of coccidian organisms in crypt lumen in the Giemsa stain. All three gastric biopsy were reviewed and showed Cryptosporidium growth with varying degrees of accompanying GvHD immunofluorescence (IF) was positive in all gastric, duodenal and billes samples for Cryptosporidium as well as PCR testing (Cryptosporidium parvum) Therapeutical approach: Paromomycin and reduction of immunosupressive drugs. Clinical course: The patient got a better general performance, but minimal to mild diarrhoea persisted in an oscillating course. Five months after diagnosis, diarrhoea became acute again and fever reappeared. Cryptosporidium specific PCR was positive in new samples and the patient began Nitazoxanide therapy. After this treatment diarrhoea disappeared and patient gained 10 kilograms. Comments: Persistent diarrhoea unresponsive to immunosuppressive treatment after HSCT should lead to screening for uncommon microorganisms if no treatment response is achieved with conventional antibacterial, antifungal or antiviral agents . Cryptosporidiosis is typical of severely immunodepressed patients. The main clinical onset is with watery diarrhoea, which might be confounded with lower-tract intestinal GvHD. Very few post HSCT crytosporidiasis cases with this infection have been reported. Immunosupression withdrawal when possible should be the mainstay of treatment, at the risk of worsening pre-existing GvHD

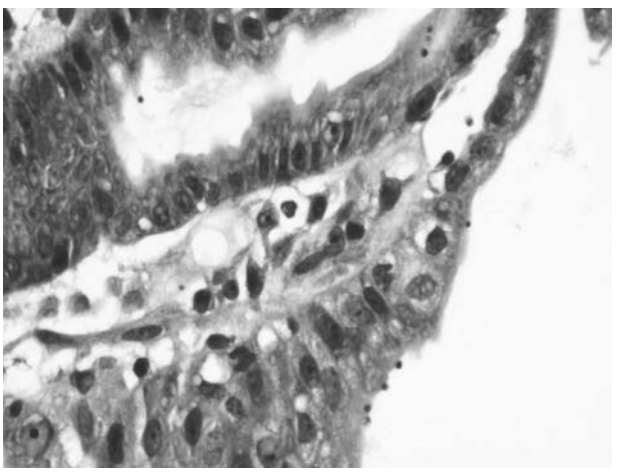

Figure.

PERSISTENT ABSOLUTE MONOCYTOSIS AND SPLENOMEGALY: THE IMPORTANCE OF EXCLUDING A NON-HEMATOLOGICAL ORIGIN

M. Callejas Charavía, J.J. Gil Fernandez, J. Garcia Suarez, Y. Martin, M.A. Calero, M. Lopez Rubio, E. Magro, T. Pascual, C. Burgaleta

Hospital Principe de Asturias, ALCALA DE HENARES, MADRID, Spain

Background. Persistent absolute monocytosis is sometimes the first and unique hematological abnormality in the peripheral blood (PB) in a variety of chronic infectious, inflammatatory diseases and neoplastic disorders. In patients with splenomegaly, malignant conditions must be excluded (e.g. lymphoma or myeloproliferative/ myelodysplastic disorders). A guided medical history and complementary studies are necessary to reach a correct diagnosis. *Aims.* To describe our experience in the follow-up of a patient with chronic monocytosis and mild splenomegaly under the suspiction of a chronic myelomonocytic leukemia (CMML) in which a positive serological evidence of brucella sp gave us the chance for a specific therapy. Case Report A 57 years-old healthy male, was studied in the haematological deparment because of persistent monocytosis (> 1000/mm^3), thrombocytopenia (122x10^9/L) but normal hemoglobin value > 140 gr/L. A mild palpable splenomegaly was observed by physical examination and abdominal studies (ultrasounds and CT Scan). The patient was totally asymptomatic without history of fever, arthralgias or weight loss. He had always lived in town, denied contact with animals but admitted occasional ingestion of dairy products without sanitary guarantee. The bone marrow (BM) aspiration and trephine biopsy only disclosed unspecific displastic changes. BM cariotype was normal (46 XY). Complete autoimmunity studies, serologies for common virusses and tumoral markers were all normal. A diagnostic of possible myelodysplasia of CMML type was established and the patient was follow-up, without observing any clinical or biological changes. Under suspiction of a non-hematological origin of both monocytosis and splenomegaly, a Rose Bengal slide agglutination test was performed which resulted positive. The standard tube agglutination titres and coombs test were both positive (1/ 320 and 1/640 respectively) and confirmed in another later serum sample. A spine X-Ray ruled out infectious spondylodiscitis; echocardiogram was normal and repeated blood cultures were all negative. It was indicated treatment with intramuscular streptomycin during three weeks and oral doxycycline and rifampicine for three months. At the time of these writing, the patient is still asymptomatic with no modification of PB abnormalities and with persistent asymptomatic splenomegaly. *Conclusions*. It's concluded for this study that screening tests for diagnosis of Brucellosis should be performed early in patients who live in endemic areas and presenting with chronic monocytosis. These laboratory findings could avoid an unnecessary bone marrow biopsy.

1821

INFORMATION AND PREOCCUPATION IN OUTPATIENTS WITH NON-ONCOHEMATOLOGICAL PATHOLOGIES AT ARRIVAL AT THE HEMATOLOGY EXTERNAL CONSULTATION

J.N. Rodríguez, A. Palma, E. Martín, M.V. Moreno, A. Chacón, M.J. Romero, K. Gómez, J.A. Quesada, A. Amian, J.C. Diéguez, A. Fernández-Jurado

Hospital "Juan Ramón Jiménez", HUELVA, Spain

Background. Haematology is frequently considered by the patients as a medical speciality that deals with the diagnostic and treatment of very serious diseases, this circumstance causes in them a variable degree of distress. *Aims*.- We have studied a group of outpatients with non-oncohematological pathologies sent to our external consultation to evaluate their knowledge about the reason for consultation, the existence or not of preoccupation and its degree at arrival. *Design and Methods*. We have conducted a prospective study including those consecutive patients who were sent to our external consultation between June 2008 and January 2009. First we designed an inquiry and with it all patients were interviewed. This inquiry included the following data: age, sex, origin (hospital, urban or rural health centres), reason for consultation, knowledge of the reason of consultation (yes, partially, no), existence or not of preoccupation and when present its degree (low, moderate, high). The interview was performed to the parents in those patients aged below 14 years. *Results*. One hundred and twenty eight consecutive patients were interviewed, 81 female (63.3%) and 47 males (36.7%), mean age 48,3 years (1-87). Eighty four were referred from hospital (65.6%), 28 (21,9%) from urban health centres and 16 (12,5%) from rural health centres. Hospital medical specialities that sent these patients to our consultation were: Internal Medicine 50 (59,5%), Gastroenterology 7 (8.3%), Anaesthesiology 6 (7.1%), rest ≤5 patients (≤6%). The causes for consultation were: anaemia 69 (53,9%) cases, thrombocytopenia 16 (12.5%), alterations in white blood cells distribution 9 (7%), alterations in coagulation tests 7 (5.5%), others ≤5 patients (≤3.9%). Only 57 (44.5%) patients knew the subject of consultation while 23 (18%) only knew it partially and 48 (37.5%) did not know it at all. Seventy (54,7%) patients referred to come worried at our consultation. The degree of preoccupation in these patients was low in 18 (25,7%), medium in 34 (48.6%), and high in another 18 (25.7%). When analyzing the knowledge of the subject of consultation and the existence of preoccupation we found almost significant statistical differences (0.10) (more patients referred preoccupation when they had no or partial information). Comparing the results of our interviews to parents of paediatric patients (n=16) with those of the rest of adults we have found no statistical differences in the knowledge of the subject of consultation nor in the existence or not of preoccupation but there were almost significant differences (p=0.06) with respect to the degree of preoccupation (all parents who came worried presented a medium or high degree). *Conclusions*. In our area, most of the patients with non-oncological problems sent to the external consultation of

Haematology refer at arrival a low or no information about the subject of consultation, most of them refer to come worried as well being the degree of this preoccupation medium-high. This circumstance is specially noted in parents of paediatric patients. We believe is essential to improve information of patients to reduce their stress.

1822

PSYCHOMETRIC PROPERTIES OF THE MULTIDIMENSIONAL FATIGUE INVENTORY IN BRAZILIAN HODGKIN LYMPHOMA SURVIVORS

M.D. Baptista,[1] A. Soares,[1] A. Scheliga,[2] E. Brabo,[1] I. Biasoli,[1] T. Vieites1, T. Hofmeister,[1] E.F. Cardoso,[1] W. Pulcheri,[1] G. Werneck,[1] N. Spector[1]

[1]Federal University of Rio de Janeiro, RIO DE JANEIRO, Brazil; [2]Instituto Nacional de Câncer, RIO DE JANEIRO, Brazil

Background. Cancer-related fatigue is the most common symptom among Hodgkin lymphoma survivors. *Aims*. To describe the validation steps of the Brazilian Portuguese version of the Multidimensional Fatigue Inventory (MFI). *Design and Methods*. The validation was done in two steps. The questionnaire was first translated from English to Brazilian Portuguese with the "forward-backward" procedure. The internal consistency, construct validity and convergent validity were then evaluated. The MFI was administered along with a general fatigue question and the informed consent form. Data from five different institutions were collected on 122 Hodgkin lymphoma survivors, with a median follow-up of 6.8 years from diagnosis. *Results*. The overall Cronbach alfa for the 20 itens was 0.85, and the Cronbach alfa of each of the five dimensions ranged from 0.83 to 0.75. Interitem correlations of each dimension ranged from 0.24 to 0.74, with almost all values higher than 0.4. There was a significant correlation between the MFI and the "General Fatigue" question, with a value of 0.75 for the "General Fatigue" dimension and 0.70 for the "Physical Fatigue" dimension. The factor analysis yielded a 5 factor solution that explained 75% of the variance. The first factor corresponded to the original "General Fatigue" and "Physical Fatigue" dimensions. The fifth factor identified, however, consisted of three isolated questions from different dimensions that need to be reappraised. *Summary*. The Brazilian MFI showed a satisfactory psychometric performance, and is a valid research tool for measuring cancer related fatigue, allowing different dimensions of fatigue to be assessed. General and physical fatigue were grouped together, as has been previously reported. The three questions grouped as a fifth factor require reformulation and revalidation.

THE CURRENT OPINION OF THE MEDICAL STAFF AND OF PATIENTS FROM SOUTHERN TRANSYLVANIA REGARDING THE BONE MARROW DONATION

A. Mihaila,[1] E.C. Rezi,[2] A. Catana,[2] O. Flucus,[2] M. Deac,[1] R. Mihaila[3]

[1]Lucian Blaga University, SIBIU, Romania; [2]County Clinical Hospital, SIBIU, Romania; 3Public Health Authority, SIBIU, Romania

Background. The bringing into existence of new bone marrow or peripheral stem cells banks and of the registers for the donors are essential for finding donors which are compatibles, without whom there could not be realized important stages of therapeutic consolidation at many patients with malignant haemopathies. *Aims*. We established this study in order to see the attitude of the medical staff and of the patients concerning the bone marrow donation. *Design and Methods*. We have realized a transversal study an a group of 252 subjects, among whom 168 were hospitalized patients (group A) and 84 were medical staff of the same hospital (group B), who have agreed to answer at a questionnaire with 17 questions regarding the bone marrow donation. We have analyzed the rates of the answers, their significations and we have drawn useful conclusions for medical practice. *Results*. The medium age of the studied group was 43.92±17.49 years. The gender repartition was 66.93% women and 33.07% men. While 74% from the questioned medical staff consider that bone marrow transplant takes sometimes to the curing of the patients with leukemia, 64% of the patients consider that after the transplant the healing is sure. 93% from the medical staff knows that, after the transplant there are possible complications related to the transplant and 71% of the patients are aware of this thing. If they were be proposed to become donors, only 60%, respectively 61% of the groups A, respectively B, will agree, while, if they personally will need a bone marrow transplantation, 100%, respectively 87% will adopt this opportunity. If they will be diagnosed with a malignant disease, and they will be in the situation of choosing between the classical treatment and the bone marrow transplantation, only 53% from group A and 79% from group B will choose the transplantation. Almost all from the 2 groups agree to donate bone marrow or peripheral stem cells if a family member would have acute leukemia, and they will be compatibles. Despite this thing, if the patient would be from another country of the European Union, only 54%, respectively 67% will accept to donate, and if the patient will be from an Asiatic country, the percentages would decrease at 47%, respectively 58%. The majority will agree that donation should be anonymous (78%, respectively 70%), and a charitable gesture (84%, respectively 88%). Almost all agree that there should be made a bone marrow donor's register, and that there should be more specialists and biologists involved in this programs. The majority also consider that the state and the European Union should involve more, financially, for this purpose. Only 68% of the patients and 85% of the medical staff are aware of the advantages of the peripheral stem cells donation, in contrast with the bone marrow. Almost 90% of all would agree to explain to their acquaintanceship that becoming a donor is a noble gesture. The differences between the 2 groups were not statistically significant. *Conclusions*. Many of the questioned subjects are insufficiently informed about the risks and benefits of the bone marrow transplantation, this being well reflected in their attitude regarding the donation and the acceptance of the graft. The majority agrees that there should be made a donor's register in Transylvania and they are willing to plead for the bone marrow donation.

1825

SKELETAL MANIFESTATIONS IN CHILDREN WITH DIFFERENT HEMATOLOGICAL DISEASES AND HEMATOLOGICAL MALIGNANCIES AT ZAGAZIG UNIVERSITY HOSPITAL [RETROSPECTIVE STUDY FROM 1998 TO 2008]

U. El Safy, T. Hassan, M. Besheer, R. El Behedy, K. El Gerby, M.H. Morad

Zagazig University, ZAGAZIG, Egypt

Background. Pediatric patients with hematoncological diseases are at risk for the development of numerous skeletal complications. In β thalassemia, skeletal manifestations occur frequently due to anatomic proximity of bones and joints to the active centers of hematopoiesis.These include fractures, premature epiphyseal fusions and thalassemic osteoarthropathy. Leukemia is the most common cancer in children and may affect virtually all organ systems. Skeletal abnormalities have been described in association with ALL, including juxtametaphyseal lucent bands or 'leukemic lines' in long bones, osteoporosis, periostal reaction, reactive sclerosis, lytic defects and vertebral compression fractures. In sickle cell anemia, the manifestations include intramedullary and extramedullary effects of increased hematopoiesis; sickle cell-related infarction and resultant abnormalities in the growth of bone; infection; and soft-tissue involvement. *Aims*. We aimed to evaluate the prevalence of skeletal manifestations in children with different hematological diseases and hematological malignancies and also to identify their nature, underlying factors, severity and Sequalae. *Design and Methods*. A retrospective analysis was conducted on a cohort of 500 randomly selected files of children at outpatient clinic of Pediatric hematology and oncology in Zagazig university hospital from 1998 to 2008. Two hundred patients with thalassemia major, one hundred patients with hemophilia, fifty patients with chronic ITP, thirty patients with thalassemia intermedia , Thirty cases with sickle cell disease, twenty cases with bone marrow failure, sixty cases with hematological malignancies and ten cases with gaucher disease. All available medical records were reviewed and data were collected with interest in collecting the following: medical history, physical examination, full laboratory and radiographic investigations, protocols of treatment, follow up data during treatment and after stopping it. Special concern was done for skeletal manifestations at initial presentation, during treatment as well as after stop of treatment. *Results*. Amongst 500 cases of our patients, Bone pain was the commonest complaint [59% of all patients].At initial presentation in leukemia [66%], during follow up in sickle cell anemia [72%] and ITP [40%]. The skeletal dysplasia was the least common presentation in our patients [5%], all of them with hereditary bone marrow failures [Fanconi anemia and Blackfan diamond syndrome].Arthritis occurred in 20% of all cases. *Conclusions*. Skeletal manifestations are highly prevalent in children with different hematological diseases and hematological malignancies. Bone diseases should be focus of interest during treatment and follow up of these patients.

1826

PARAMETERS AFFECTING COMPLIANCE OF THALASSAEMIA PATIENTS ON IRON CHELATION THERAPY STUDIED BY HAMILTON'S RATING SCALE FOR DEPRESSION

S. Fragatou,[1] I. Tsourveloudis,[1] M. Fragatou,[2] P. Paterakis[2]

[1]G.A.H. "G.Gennimatas", ATHENS, Greece; [2]Dromokaition Mental Hospital, ATHENS, Greece

Background. Compliance with iron chelation therapy in multitransfused thalassaemics is the predisposing factor for extended survival and improving quality of life. Although depression was found to affect compliance with Desferrioxamine (DFO), Deferiprone (DFP) or both, some depressed patients complied very well with the chelation regimen. Objective: To investigate the parameters of Hamilton rating scale (HAM-D) for depression potentially affecting compliance with different chelators in thalassaemia patients. *Design and Methods*. 45 thalassaemics were enrolled in the study, 19 males, 25 females, mean age 39 years. According to the chelation therapy patients divided into 4 groups. Group I: 9p on Deferasirox, Group II: 14p on DFO, Group III: 11p on DFP , Group IV: 11p on combination therapy with DFO and DFP. Every patient was privately interviewed and depression level was determined by Hamilton depression rating scale (HAM-RS) consisting of 24 parameters. HAM-D score >= 20 indicates depression. Compliance was estimated by compliance index. *Results*. Patients with HAM-D score >= 20 were found in overall groups. However depressed patients of groups I, II, III and IV had excellent compliance with chelation therapy in a ratio of 100%, 40%,50% and 22.2% respectively. Patients with increased rating in parameters 1,10,11,12,13 and 15 indicating depressed mood, anxiety and hypochondriasis showed poor compliance with chelation therapy. Although increased rating of the rest parameters leads to HAM-D score >=20, compliance was not affected. *Conclusions*. This study showed that depression generally affects compliance. However the prominent psychological parameters affecting compliance were depressed mood, psychic and somatic anxiety as well as hypochondriasis.

1827

MIDLINE CATHETERS AS ALTERNATIVE VASCULAR DEVICES IN PEDIATRIC THALASSEMIC PATIENTS WAITING FOR BONE MARROW TRANSPLANTATION

A. Roveda, P. Sodani, C. Gallucci, K. Paciaroni, G. De Angelis, C. Alfieri, A. Isgro, M. Marziali, J. Gaziev, P. Polchi, G. Lurarelli

MIH Foundation-Policlinico tor Vergata, ROME, Italy

Background. Thalassemia requires chronic long-life transfusions to treat the anemia caused by enhanced red blood cell destruction due to the disease. Midline catheters are emerging as a good alternative vascular devices, to ensure the best clinical practice, management and care also for pediatric patients waiting for bone marrow transplantation, that, to date, represents the only radical cure for thalassemia. *Design and Methods*. All patients in pre-transplant period who needed transfusion, intravenous drugs administration and blood samples collections were evaluated. Patients below 8 years old and with an inadequate basilic vein were excluded. From February to August 2008, patients on which it has been tried to insert a Midline catheter were 10: eight thalassemic and two microdrepanocytosis. Of these, two (1 microdrepanocytosis and 1 thalassemic) were excluded for the developing of an hematoma on the site of the insertion, and they have been submitted to a central vascular access in the surgical unit. None of the patients had piastrinopenia or clotting alterations before the insertion, and none of the patient was in a neutropenic condition. *Results*. For the 100% of the patients, the basilic vein was the best choice and none of them had any problem during the insertion. Midline catheters were used for maximum 48 days, with one episode of early removal (after 13 days) due to vein thrombosis, nevertheless antithrombotic treatment for previously splenectomy. Currently, two patients bring on this new type of catheter due to their pre-transplant treatment, three left the department because the end of treatments, and three switched to a tunnellized central access because started conditioning regimen and, due to their small size, they could not receive a peripherally inserted central access. *Conclusions*. In our experience, we can affirm that the use of these devices can carry on advantages to improve care, management and quality of life of the patients, supposing evidences could come from easy availability of ultrasound technique, easy possibility to perform the insertion bed-side, respecting all warnings in terms of patient's and operator's security, and easy acquisition of the specific required know-how, with the aim to reduce waiting time for the insertion. The only limit we faced is age, because children younger than 8 years old do not comply for the procedure, making mandatory the use of tunnellized central access. For correspondance: a.roveda@fondazioneime.org

1828

QUALITY OF LIFE IN BRAZILIAN PATIENTS WITH SICKLE CELL DISEASE: PRELIMINARY RELIABILITY REPORT OF THE SF-36 SURVEY

M.M. Loureiro, I. Biasoli, A. Viana, A.R. Soares, R.L. Baptista, E. Brabo, W. Pulcheri, G. Werneck, N. Spector

Federal University of Rio de Janeiro, RIO DE JANEIRO, Brazil

Background. Sickle cell disease (SCD) is one of the most common genetic disorders in Brazil and deeply compromises the quality of life (QOL) of those who are afflicted. We have evaluated the reliability of the Short Form 36 survey (SF-36) in our patients with sickle cell disease. *Design and Methods*. A validated Brazilian Portuguese version of the SF-36 was administered to patients with sickle cell disease in the outpatient clinic of the University Hospital. The domains evaluated by the SF-36 questionnaire cover physical function, physical and emotional role function, bodily pain, vitality, social function, mental health, and general health. Reliability (internal consistency) of all scales and of each domain were evaluated with the Cronbach's α coefficient. We also assessed whether gender and genotype had any influence on the SF-36 subscale results. The Mann Whitney test was used to compare the scale and subscales between two groups. *Results*. Eighty-eight patients responded the SF-36. The median age was 23 years (13-60), 57% were female, and 80% were black. Genotypes were SS (78.4%), Sb thalassemia (11.4%) and SC (10.2%). The internal consistency of items in the SF-36 scale was 0.85, and the internal consistency of domains were 0.85 (physical function), 0.81 (physical role function), 0.82 (emotional role function), 0.85 (bodily pain), 0.79 (vitality), 0.60 (social function), 0.85 (mental health) and 0.78 (general health). SS patientes and women have significantly lower scales (481 vs. 572; p=0.028, and 463 vs. 550; p=0.015 respectively) and lower subscales on all domains. When SS patients were compared to non-SS patients, the subscales were significantly lower in social function (68 vs. 84; p=0.014), bodily pain (58 vs. 74; p=0.021), physical function (58 vs. 71; 0.026) and general health (44 vs. 62; p=0.030). In women, subscales were significantly lower in social function (66 vs. 79; p=0.011), mental health (60 vs. 77; p=0.005), physical function (54 vs. 69; p=0,04) and vitality (54 vs. 67; p=0.035). *Conclusions*. This prelimary report suggests that the Brazilian Portuguese version of the SF-36 has a good internal consistency in patients with sickle cell disease. Patients with the SS genotype and females appear to have a worse QOL.

1829

ASSESSMENT OF QUALITY OF LIFE IN IRANIAN CHILDREN AND ADOLESCENTS WITH SEVERE HEMOPHILIA A AND B BY HAEMO-QOL QUESTIONNAIRE,A SINGLE INSTITUTE REPORT(SARVAR CLINIC, MASHHAD, IRAN)

Z. Badiei, Z. Memarzadeh, M. Khajedaloei, H. Farhangi

Mashhad University of Medical Sciences, MASHHAD, Iran

Background. Assessment of quantitative parameters is easier than qualitative ones.But it should not be forgotten that it is important to know quality of life (QOL) as a qualitative parameter in medicine to evaluate and if necessary to improve the patients care. Severe hemophilia A and B can lead to recurrent bleeding in joints, detoriate joints functions and significantly affect the QOL. *Aims*. The aim of this study is to evaluate the quality of life in children (8-12 y) and adolecens (13-16 y) with severe hemophilia A and B, by standard Hamo-Qol questionnaire. *Design and Methods*. 20 registerd patients with severe hemophilia A or B in two age groups (8-12 y and 13-16 y) and their parents were asked to fill out the standard Haemo-Qol questionnaire.This questionnaire was translated to persian language by authors ,pediatric psychologist and an epidemiologist (all together). According to patients self-report and parent-report and on the base of scoring list of standard Haemo-Qol questionnaire the QOL was assessed for each case. Results: In group A (8-12y) according to self-reports they had lower QOL in friends subscale [mean 62/50 (SD: 30/83)] and supports subscale [mean 62/50 (SD:26/27). Parents report showed that their children had lower QOL in friend subscale [mean 74/11(SD:23/78)] and physical health [mean 61/22 (SD:19/82)]. In group B (13-16 y) according to self-reports they had lower QOL in supports subscale [mean

51/28(SD:10/20)] and family subscale [mean 50 (SD:20/05)]. Parents report showed that their children had lower QOL in family subscale [mean 66/85(SD:13/85)] . In both age groups in comparison with patients self-reports, parents think that their children have lower QOL. *Conclusions*. According to results it seems that most of our patients and their parents experience a bad QOL. Further efforts are necessary to examine other aspects of QOL in these patients. And considering therapies that reduce bleeding events, like prophylaxis treatment, warrant more attention.

1830

A PHYSIOTHERAPEUTIC APPROACH TO REDUCE FATIGUE IN PEDIATRIC ONCOLOGY

J. Jung,[1] T. Klingebiel,[2] K. Siegler[2]

[1]Socialpediatric Center, FRANKFURT/MAIN, Germany; [2]Goethe University Frankfurt, Pediatric Oncology, FRANKFURT/MAIN, Germany

Background. 2007 we closed the gap between the presence of Cancer-related-fatigue (CRF) and the missing of an adequate assessment in Germany. Now we use the first german version of the PedsQL 3.0 Multidimensional Fatigue Scale to measure CRF in pediatric oncology. Aims: Now, after we made sure, that this most bothersome side effect is present in children, we`re searching for a strategy to reduce this phenomenon. According to the efforts made with adults, we developed a training program. We start this sports-program after bone-narrow- or stem-cell transplantation as a standard concept. *Design and Methods*. Additional to the PedsQL questionnaire we want to demonstrate the increase of physical strength (or feeling of well-being). Therefore we evaluate handcraft once a week, doing a lactate-measurement and examine the QoL with a questionnaire. *Results*: First impressions of the children will be demonstrated and a review of the last 6 months will be given.

ANALYSIS OF A DAY-HOSPITAL THROUGH CALCULATION OF ITS PERFORMANCE INDICATORS

M. Subira, R. Lopez, M. Constans, A. Lopez, M. Bosch, M. Trullas, C. Ramon, R. Guitart, C. Ruiz, N. Garcia, R. Salinas

Althaia, Xarxa Assistencial de Manresa, MANRESA, Spain

Background. The day-hospital (DH) is one of the main alternatives to conventional hospitalization. The optimal use of its resources improves hospital management with reduction of hospital admissions and economic cost. *Aims*. To analyze the efficiency and the efficacy of a medical DH through calculation of its performance indicators (PI) and asses whether changes in organizational model improves the PI. *Design and Methods*. The DH is open from 7:30 am to 17 pm, from Monday to Friday and has 22 treatment places. Three nurses work in the DH with an overlapped schedule, so that from 7.30 am to 10 am there are available 270 minutes of nurse, from 10 am to 12 pm: 360 minutes and from 12 pm to 17 pm: 720 minutes. We have collected, during 61 consecutive days of 2007, the data of all patients (Pts) attended and all procedures performed. Also, we have collected the time spent by the nurse in performing a procedure and the time of place occupation for each procedure. *Results*. 1.286 scheduled Pts and 229 (15%) urgent Pts were attended. The scheduled Pts generated 1.352 procedures. 61% of procedures were of medium duration (between 1 - 2 h), 23% were of long duration (> 2 h) and 16% were of short duration (< 1 h). The nursing occupancy rate (NOR) was highly variable among days with a median of 76% (range 51 - 116%). The place occupancy rate (POR) was 24% with a turnover rate of 1.1. Also, the scheduled Pts and procedures generated different minutes of activity throughout the day, being from 7:30 am to 10 am when there is highly activity. Moreover, the NOR and the POR varies throughout the day, being 137% and 45% from 7:30 am to 10 am, 78% and 37% from 10 am to 12 pm and 45% and 11% from 12 pm to 17 pm, respectively. If we change the nursing work schedule and the time that the DH remains open the NOR increases to 90% and the POR to 32%. *Conclusions*. The DH studied has a low efficacy and efficiency. The analysis of its PI suggests mismanagement in the scheduling of patients and procedures as well as poor management of nursing work schedule. The activity is highly variable throughout the day and there is less time of nurse during the hours of the day with major activity in the DH. These disparities can cause a reduction of equity and quality of care. To optimize the resources of the DH, we propose the implementation of a reengineering organizational process.

1833

EVALUATION OF A NEW POINT OF CARE AUTOMATED COMPLETE BLOOD COUNT (CBC) ANALYZER IN NEWBORN BABIES

A.V. Mena-Durán, J. Sanchis-Cervera, C. Sanchis-Piqueras

Hospital La Plana, VILLAREAL, Spain

Background. Hemoglobin, WBC counts and differentials are currently performed on complex and very expansive hardware in central laboratories not available in certain settings. Chempaq XBC®(Chempaq A/S, Denmark) is a rapid and easy point of care (POC) device with low volume samples requirement that can benefit certain patients with special clinical characteristics like newborn babies particularly in outreach facilities. This device needs a low volume sample that is analysed in a disposable cassette. Leukocytes, lymphocytes, monocytes and granulocytes are counted and their size is determined by impedance in a cell. Hemoglobin is measured photometrically at two wavelengths. Aims. To evaluate the precision, accuracy and linearity of the new POC device Chempaq XBC® for hemoglobin, leukocyte counts and 3-part differentials compared with an established laboratory based analyzer: Advia® 2120 (Bayer AG, Germany) in a cohort of 100 consecutive newborn babies. *Design and Methods*. A fresh 20 uL venous blood sample was drawn from each individual and simultaneously tested for hemoglobin (g/dL), leukocyte counts and 3-part differentials ($x10^9$/L) in the POC device and the established laboratory analyzer. Linear regression techniques were used to compare results. *Conclusions*. Chempaq XBC® is a reliable POC analyzer that provides accurate results for Hb, WBC and 3-part differentials for newborn babies which is clinically relevant for certain clinical settings where complex and costly central laboratory analyzers are not available.

Table 1. Linear regression for Chempaq XBC vs Advia

Assay	Slope	Y-Int	r
Hb (g/dL)	0.87	1.47	0.96
WBC ($x10^9$/L)	0.97	-0.15	0.99
Neutrophils ($x10^9$/L)	0.88	1.25	0.93
Lymphocytes ($x10^9$/L)	0.91	1.62	0.81
Monocytes ($x10^9$/L)	0.63	0.20	0.71

1834

MOBILIZATION WITH CHEMOTHERAPY COMPARED TO G-CSF ALONE: AN ANALYSIS OF RESOURCE USE AND COST IN AUTOLOGOUS STEM CELL TRANSPLANT PATIENTS

C. Dembek,[1] E.M. Pelletier,[2] P.J. Smith[2]

[1]Genzyme Corporation, CAMBRIDGE, USA; [2]IMS Consulting, WATERTOWN, MA, USA

Background. The most common mobilization regimens for autologous stem cell transplant (ASCT) are granulocyte-colony stimulating factor (G-CSF) alone or in combination with chemotherapy. Chemotherapy plus G-CSF has been shown to mobilize more cells than G-CSF alone but often at the expense of costly side effects. *Aims*. The purpose of this study was to evaluate resource use and cost during mobilization for patients mobilized with chemotherapy plus G-CSF vs. G-CSF alone. *Design and Methods*. Patients 18 years of age or older with evidence of ASCT between January 1, 2000 and December 31, 2006 were identified from a nationally-representative database of private payer medical and pharmacy claims. Patients had to receive apheresis within 60 days prior to ASCT and have a history of multiple myeloma, non-Hodgkin's lymphoma, or Hodgkin's disease; patients also were required to be continuously enrolled in one health plan for at least 90 days pre-ASCT and have no evidence of a prior ASCT. Using claims data, patients were classified into one of two mobilization regimens: G-CSF alone or chemotherapy with G-CSF.

Total resource use and direct medical costs were calculated from the time of administration of the mobilization regimen to the first apheresis day; paid claims were used as a proxy for costs and expressed in 2006 US$. *Results.* 235 ASCT patients were identified; 172 (73%) were mobilized with G-CSF alone and 63 (27%) with chemotherapy and G-CSF. Total mobilization costs were 27% higher among patients mobilized with chemotherapy versus those mobilized with G-CSF alone ($39,686 *vs.* $31,251, p=0.020). Patients mobilized with chemotherapy had higher inpatient hospital costs ($8,225 vs. $5,854, p=0.056), more use of growth factor ($9,217 *vs.* $6,948, p=0.003), and higher pharmacy costs ($5,343 *vs.* $1,484, p<0.001) than patients mobilized with G-CSF alone. Rituximab comprised 48% of pharmacy costs in the chemotherapy and G-CSF group, while the remaining costs were due to chemotherapy drugs, MESNA, and anti-emetics. *Conclusions*. ASCT patients mobilized with chemotherapy had higher total mobilization costs than patients mobilized with G-CSF alone. This significant difference in costs was due to more costly hospitalizations and greater use of G-CSF and other pharmaceuticals in patients mobilized with chemotherapy.

Table 1.

	Chemotherapy and G-CSF	G-CSF Alone	% Difference	*P*-value
Total Mobilization Costs	**$39,686 (31,188)**	**$31,251 (31,750)**	**27%**	**0.020**
Inpatient	$8,225 (19,214)	$5,854 (18,312)	41%	0.056
Outpatient	$16,901 (17,085)	$16,965 (19,772)	0%	0.971
Pharmacy	$14,560 (12,067)	$8,432 (13,502)	73%	<0.001
G-CSF	$9,217 (7,069)	$6,948 (10,514)	33%	0.003
Rituximab	$2,547 (6,228)	$332 (1,625)	667%	<0.001
Other retail pharmacy	$2,797 (2,923)	$1,152 (2,644)	143%	<0.001

ELECTRONIC HEALTH (EHR) FOR HEMATOLOGY AND ONCOLOGY PATIENTS

E. Shklovskiy-Kordi, V. Zingerman, G. Gabeeva, A. Savenkova

National Center for Hematology, MOSCOW, Russian Federation

Background. In 2008 ASCO developed 'Practical Guide for Selecting and Implementing Electronic Health Records' *www.cancer.net/ASCO/Practice+Resources*. It not only marks recognition of the necessity of the EHR, but also the importance of their specialization. Analysis of disease progression and treatment outcomes requires large amounts of time-sensitive data and causal connections. Most of these data exist in electronic form, but there are few instruments that allow extraction information from different data bases, compression, and collection on the single screen. *Design and Methods*. A National Standard «The Electronic Health Record», has been operating in Russia since 2008. It is similar with ASCO EHR Guide in many respects. We have developed this Standard based on the experience acquired by creation and implementation an EHR system for the National Center for Hematology. This system allows integrated data presentations on a uniform axis of time and direct access to all information concerning the patient. This approach is important for an estimation of correlations in dynamic changes in clinical parameters. The system has been already working more than 10 years. Now we have 400 physician-users and about 2 million of personal medical records on over 30 thousands patients treated in our center. The system has decreased a number of medical errors, proved to be an effective tool of clinical decision support, and allowed economizing time and resources. In the National Standard we have put in pawn recommendations to use new Internet technologies. The new system unites Internet-based life-long personal health records of patients with all clinical and administrative instruments of data presentation and processing. The Internet system promises to be cost-efficient in the field of remote consultation and telemedicine, but its efficiency will depend on a degree of standardization for different medical institutions. *Conclusions*. The world community of hematologists and oncologists and there patients will greatly benefit (efficiency of therapy, telemedicine, referrals and recruiting patients for clinical trails) from uniform approaches to EHR.

1836

BEHAVIOUR OF HOMOCYSTEINE PLASMATIC IN LONGEVOUS PATIENTS

M.J. Malem

Laboratorio ¨Claudio Malem and partners¨, GENERAL ALVEAR, Argentina

Introduction 158 male longevous patients were studied. They were all residents in old people´s homes and abandoned by their relatives. At the start of this case study the patients showed general neglect, not only about personal hygiene, but also about the building and fittings and they had difficulty in moving about. As regard the blood values, they were badly altered, showing severe anemia, macrocitocis accompanied with severe trombocitocis, also the homocysteine plasmatic was rather high. In the first place it was decided to move the old people to another home where they could have better hygienic and building conditions. The nourishing diet was also radically changed leaving out the former one which consisted of carbohydrates the seven days of the week and changing it for the ingestion of protein, vegetables and diary products nutriments. *Design and Methods*. During the first 40 days they were helped with folic acid to raise the hemoglobin level which was between 7 and 8,20 g/dl and with a minimum dose of acenocoumarol to prevent thrombosis events. At the next blood control it was clear sighted that slowly and gradually the blood values were encouragingly changing and basically the homocysteine plasmatic value which fell almost at a normal value. That´s why it was decided to suspend the folic acid but not the acenocoumarol, which was used for a time to allow the new diet to perform the corresponding supply. *Results*. After 90 days, when the corresponding hematological blood control was done, the patients had achieved normal analytical values: the homocysteine plasmatic had fallen to normal values, the hemoglobin values were between 12 and 13 g/dL accompanied with normocitic elements and values of count of thrombocytes between 300000 to 400000 x mm^3. *Conclusions.* These patients, by means of the diet and a period when they had folic acid, recovered their health, vitality and basically their rights to enjoy completely a better quality of life, thus achieving psycho-social stability. The authors provided free attention as regards treatment, medicine supplies, control and following of every part of the treatment, taking the place of the State in the care of the people´s health.

1837

DAPTOMICIN VS TEICOPLANIN, WITH OR WITHOUT IV CALCIUM CHLORIDE SUPPORT, IN POST CHEMOTHERAPY FEBRILE NEUTROPENIA: MONOCENTRIC PHARMACOECONOMIC PROSPECTIC RANDOMIZED STUDY

G. Giordano, S. Piano, M.P. Petrilli, G. Farina, G. Sticca, C. Di Falco, S. Storti

Research Center "J.Paul II" Catholic University Campobasso, CAMPOBASSO, Italy

Background. Daptomicin is a bactericidal antibiotic highly effective in gram positive infection. *in vitro* experiments seem to show that calcium ione might henance bactericidal activity of Daptomicin. Moreover it's well known that empirical use of glycopeptides in febrile neutropenia is of scarce utility. Data regarding use of Daptomicin in febrile neutropenia, in terms of safety, feasibility, clinical efficacy and pharmacoeconomy are actually lacking. *Aims.* Aim of this study is to evaluate efficacy of Daptomicin respect to Teicoplanin in febrile neutropenia in terms of: -days of fever, -days of hospitalization, -cost of antibiotic and supportive therapy per day of hospitalization, -days of fever in patients receiving Daptomicin and Teicoplanin if supported or not with intravenous calcium. *Design and Methods*. This is a monocentric, prospectic randomized study. Patients with post chemotherapy febrile neutropenia were randomized to receive empiric therapy with Piperacillin-Tazobactam 4.5 g tid iv, Amikacin 15 mg/kg/day iv and Teicoplanin 6 mg/kg/day iv (arm A) or Daptomicin 6 mg/kg/day iv (arm B). In each arm, patients were randomized 1:1 to receive iv support of Calcium Chloride up to achieve 10 mEq/l of blood calcium. Daily costs of antibiotic and supportive therapy for each patient was calculed dividing the global cost of entire period of hospitalization for the days of hospitalization. In 8 months 34 patients were enrolled. 32

patients were evaluable (16 in each arm). In arm A all patients were male. Median age was 44 years (R 30-72). 7 patients had NHL, 8 AML and 1 received autologous bone marrow transplantation. In arm B M/F was 11/5. Median age was 54 years (R 30-75). 9 patients had NHL and 7 AML. *Results*. In arm A median of days of fever was 10.5 days (R 6-12) and median of hospitalization was 35.5 days (R 10-40). Median cost of antibiotic and supportive therapy was 750 euros/day (R 329-1250). No differences in days of fever were noted between patient supported with calcium or not (10.5 days in two groups). In arm B median of days of fever was 10.5 days (R 4-17) and median of hospitalization was 24 days (R 19-27). Median cost of antibiotic and supportive therapy was 453 euros/day (R 178-807). Patient supported with calcium showed 5.5 days of fever (R 4-7) vs 15.5 days (R 14-17) in patients not supported. No adverse effects in patients receiving daptomicin were registered. *Conclusions*. Daptomicin seems to be safe and feasible in patients with post chemotherapy febrile neutropenia. Data regarding days of fever, hospitalization, cost of antibiotic and supportive therapy per day of hospitalization are difficult to evaluate because of eterogeneity in two treatment groups. In arm B the group receiving calcium showed similar characteristics than other group. This suggest that calcium support might really potentiate *in vivo* Daptomicin efficacy, shortening number of days of fever. These data need confirmation in a larger cohort of patients.
