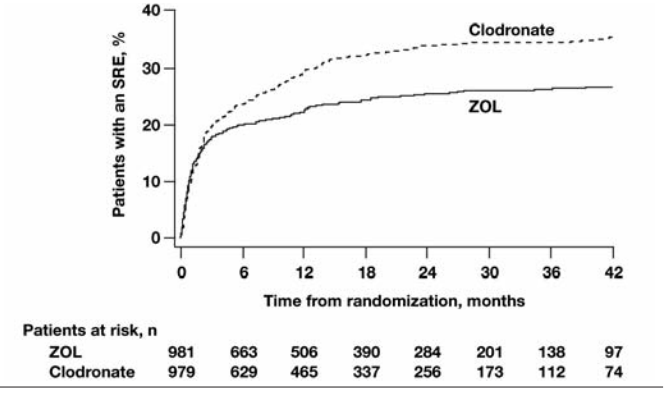
Background. In addition to prolonging survival, an important goal of MM management is the prevention of potentially debilitating sequelae including renal failure and SREs. Bisphosphonates can prevent SREs. However, the comparative SRE-preventing efficacies and renal safety profiles of ZOL and clodronate have not been evaluated in a large head-to-head randomized study in MM. Furthermore, ZOL was reported to improve survival versus no ZOL in a small study in patients with newly diagnosed MM (Aviles *et al.* Med Oncol 2007); therefore, effects on disease outcomes may also be possible. *Aims.* The MRC Myeloma IX study compared primary therapy regimens for patients with newly diagnosed MM. Randomization to ZOL and clodronate was included within each primary-therapy group to allow comparisons between disease outcomes, SREs, safety, and survival between these 2 agents. *Methods.* Newly diagnosed MM patients were randomized to intravenous ZOL (4 mg, dose-adjusted based on renal function) every 3-4 weeks or daily oral clodronate (1600 mg) plus antimyeloma therapy. A diagnosis of myeloma bone disease was not a study requirement; therefore, bisphosphonate use was off-label in some patients. Treatment continued at least until disease progression, and all patients were evaluated for disease outcomes, SREs, and safety before disease progression, and survival after disease progression or discontinuation of study medication. All patients provided written informed consent. Time to first SRE was assessed using the cumulative incidence function, and survival was estimated using the Kaplan-Meier method, adjusting for antimyeloma therapies. A Cox proportional hazards model was used to assess the hazard ratio (HR) and associated 95% confidence interval (CI) for SRE risk adjusting for the effects of antimyeloma therapies, minimization factors, treatment pathways, and prior SRE at baseline. ISRCTN68454111.



Figure

Results. A total of 1960 patients were evaluable, with a median follow-up of 3.7 years. Mean age for ZOL and clodronate groups was 65 years, IgG was the predominant subtype, and approximately 70% of patients in each group had bone disease. Most patients in each group did not experience an SRE. However, after the first 3 months, a smaller proportion of patients at each timepoint developed a first SRE in the ZOL versus clodronate groups (graph). Overall, ZOL significantly reduced the risk of first SREs by 26% versus clodronate in the adjusted Cox model (HR=0.74; 95%CI: 0.62, 0.87; P=.0004). SREs were more prevalent among patients with bone disease at baseline versus those without; ZOL reduced the risk of first SRE in both groups. ZOL significantly increased survival by 5.5 months compared with clodronate (median 50 versus 44.5 months, respectively; P=04). The survival benefit with ZOL remained statistically significant after adjustment for between-group differences in SREs (P=.04). Both bisphosphonates were generally well tolerated. There was no significant between-group difference in the rate of acute renal failure (60 [6.1%] patients with clodronate and 57 [5.8%] patients with ZOL). *Conclusions.* In MRC Myeloma IX, ZOL significantly delayed the onset of SREs and prolonged survival compared with clodronate in patients with newly diagnosed MM receiving antimyeloma therapy. Rates of renal failure were low overall and comparable between groups.

ZOLEDRONIC ACID (ZOL) SIGNIFICANTLY INCREASES PROGRESSION-FREE SURVIVAL (PFS) VERSUS CLODRONATE AND MAY IMPROVE RESPONSE RATES IN NEWLY DIAGNOSED MULTIPLE MYELOMA (MM): MRC MYELOMA IX TRIAL RESULTS

G Morgan,[1] F Davies,[2] W Gregory,[3] K Cocks,[3] S Bell,[3] A Szubert,[3] N Coy,[3] M Drayson,[4] A Feyler,[5] A Ashcroft,[6] R Owen,[7] G Jackson,[8] J Child[3]

[1]The Institute of Cancer Research, London, Surrey, UK; [2]Institute of Cancer Research, Royal Marsden Hospital, London, UK; [3]University of Leeds, Leeds, UK; [4]University of Birmingham, Birmingham, UK; [5]Mid-Yorkshire Hospitals NHS Trust, Wakefield, UK; [6]St. James' University Hospital, Leeds, UK; [7]University of Newcastle, Newcastle-upon-Tyne, UK

Background. There is no consensus on optimal treatment for patients with newly diagnosed MM. In addition to standard cytotoxic and antiangiogenesis therapies, bisphosphonates have recently shown anticancer effects beyond their skeletal-related event–preventing indication. Of note, in patients with breast cancer, ZOL reduced the risk of disease recurrence by 36% (P=.01) versus adjuvant endocrine therapy alone (Gnant, *et al*. N Engl J Med 2009). *Aims*. To compare the efficacy of various first-line treatment options for MM and to compare the effects of ZOL and clodronate. *Methods.* The MRC Myeloma IX study assigned newly diagnosed MM patients to either intensive or non-intensive induction therapy pathways based on current guidelines. Intensive pathway patients were randomized to 21-day cycles of either CVAD or CTD. After achieving best response, patients were treated with high-dose melphalan (200 mg/m^2) and stem-cell transplant. Non-intensive pathway patients were randomized to either MP or reduced-dose CTD, each of which was continued until best response. Responses were graded per modified-EGMT criteria. Each of the 4 treatment groups were randomized to intravenous ZOL (4 mg; adjusted for renal function) every 3-4 weeks or daily oral clodronate (1600 mg), which was continued at least until disease progression. After initial therapy, eligible patients were again randomized to either add daily thalidomide maintenance therapy or continue with only bisphosphonate therapy. All patients were evaluated for disease outcomes and safety. PFS was assessed by Kaplan-Meier analyses, and between-group hazard ratios (HR) were based on Cox models stratified by treatment pathway. All patients provided written informed consent. ISRCTN68454111. *Results*. A total of 1960 patients were evaluable, with a median follow-up of 3.7 years. Most patients had ISS stage ≤2, IgG was the predominant subtype, and approximately 70% of patients in each group had bone disease (bisphosphonate therapy was therefore off-label in 30% of patients). Overall, ZOL significantly prolonged median PFS by 2 months versus clodronate (19.5 versus 17.5 months; P<.05). PFS benefits were comparable in each treatment pathway. Complete or very-good-partial responses were achieved by significantly more patients treated with ZOL (85 [20.0%]) versus clodronate (60 [14.2%]) in the non-intensive pathway (P=.03), and a similar proportion of patients treated with ZOL (200 [36.0%]) and clodronate (193 [34.7%]) in the intensive pathway (P=.66). However, in both treatment pathways fewer ZOL- versus clodronate-treated patients developed new osteolytic bone lesions (non-intensive: 5.2% versus 9.9%, respectively; intensive: 4.3% versus 9.5%, respectively). There were also trends toward fewer disease- or treatment-related–deaths within the first 60 days on study (during induction therapy) for ZOL- versus clodronate-treated patients (intensive: 13 [2.3%] versus 18 [3.2%] respectively; non-intensive: 11 [2.6%] versus 23 [5.4%]. respectively). ZOL and clodronate were generally well tolerated, and confirmed osteonecrosis of the jaw was infrequent with both (ZOL, 3.6%; clodronate, 0.3%). *Conclusions*. In addition to its established indication for preventing skeletal-related events, ZOL significantly improved PFS and produced trends toward increased response rates to induction therapy versus clodronate in patients with newly diagnosed MM in MRC Myeloma IX. Therefore, ZOL may have clinically meaningful anticancer effects when combined with chemotherapy.

INACTIVATING MUTATIONS OF THE HISTONE METHYLTRANSFERASE EZH2 ARE ASSOCIATED WITH CHROMOSOME 7 ABNORMALITIES IN MYELOID DISORDERS

T Ernst,[1] A Chase,[1] J Score,[1] C Hidalgo-Curtis,[1] C Bryant,[1] A Jones,[1] K Waghorn,[1] K Zoi,[2] F Ross,[1] A Reiter,[3] A Hochhaus,[4] H Drexler,[5] A Duncombe,[6] F Cervantes,[7] D Oscier,[8] J Boultwood,[9] F Grand,[1] N Cross[1]

Medizinische Klinik, Universitätsmedizin Mannheim, Mannheim, Germany; [4]Klinik für Innere Medizin II, Universitätsklinikum Jena, Jena, Germany; [5]DSMZ-German Collection of Microorganisms and Cell Cultures, Braunschweig, Germany; [6]Dept. of Haematology, Southampton General Hospital, Southampton, UK; [7]Hematology Department, Hospital Clínic, IDIBAPs, University of Barcelona, Barcelona, Spain; [8]Dept. of Haematology, Royal Bournemouth Hospital, Bournemouth, UK; [9]LRF Molecular Haematology Unit, John Radcliffe Hospital, Oxford, UK

Abnormalities of chromosome 7q are common in myeloid malignancies but no specific target genes have been identified. Recently, we and others reported that 7q acquired uniparental disomy (aUPD) is seen in MDS/MPN and MDS but is uncommon in AML. To identify further cases with 7q aUPD, we performed genomewide single nucleotide polymorphism (SNP) analysis using Affymetrix SNP 6.0 arrays on 148 MDS/MPN cases. Sixty-three tracts of copy number neutral homozygous SNP calls >20 Mb were seen in 46 (31%) of cases, of which 12 involved 7q. The minimally affected region was 52 Mb spanning 7q22.3-7qter. Resequencing 15 genes excluded the involvement of tyrosine kinases and several other candidate genes. To search for microdeletions we designed a targeted high density comparative genomic hybridization array; analysis of 8 cases identified a 400kb deletion at 7q36.1 that encompassed C7orf33, CUL1 and EZH2. Sequencing revealed a frameshift mutation in the residual EZH2 allele of the deleted case, plus homozygous EZH2 mutations in 9/12 cases with 7q aUPD. To determine the prevalence of EZH2 variants, we scanned all exons in 518 cases with MPN, MDS/MPN or MDS. After excluding known polymorphisms, 39 additional heterozygous, hemizygous or homozygous variants were identified in 32 cases. Three patients had -7 on cytogenetic analysis, indicating that both aneuploidy and aUPD can lead to loss of the wild type EZH2 allele. To determine if EZH2 is more generally associated with chromosome 7 loss, we screened AML with -7/7q (n=54) but found no mutations. Of the 49 EZH2 variants, 26 were missense, 21 were predicted to result in premature chain termination mutations and 2 were in frame deletions. The truncating mutations were dispersed throughout the gene whereas the missense mutations mostly targeted evolutionarily highly conserved residues in domain II and the CXC/SET region. Analysis of T-cell DNA showed that 5 of 5 variants analyzed were acquired. Mutations were seen in diverse diseases but were most common in MDS/MPN (27/219; 12%) and primary or secondary myelofibrosis (4/30; 13%). Univariate analysis in MDS/MPN indicated that EZH2 mutations were associated with a poor prognosis compared to cases without mutations (overall survival: 39 months vs. 13 months [P=0.0006]; progression-free survival: 30 months vs. 17 months; [P=0.044]). EZH2 encodes the catalytic subunit of the Polycomb repressive complex 2 (PRC2), the highly conserved histone H3 lysine 27 methyltransferase that influences stem cell renewal by epigenetic repression of genes involved in cell fate decisions. The biallelic truncating mutations we identified were clearly inactivating. To test if this was also the case for missense variants, we infected Sf9 cells with baculoviruses expressing FLAG-tagged EZH2 mutants along with the PRC2 components EED and SUZ12. Following immunoprecipitation and H3K27 methyltransferase assays, all four CXC/SET domain mutants tested were found to abrogate or greatly reduce EZH2 catalytic activity. EZH2 has been reported previously to have oncogenic activity and its overexpression has been causally linked to differentiation blocks in epithelial tumors. Unexpectedly, the mutations we identified abrogated histone methyltransferase activity, suggesting that EZH2 acts as a tumor suppressor in myeloid malignancies.

ORAL DABIGATRAN VERSUS ENOXAPARIN FOR THROMBOPROPHYLAXIS AFTER PRIMARY TOTAL HIP ARTHROPLASTY: THE RE-NOVATE II RANDOMISED TRIAL

M Huo,[1] B Eriksson,[2] O Dahl,[3] A Kurth,[4] S Hantel,[5] K Hermansson,[6] J Schnee,[7] R Friedman[8]

[1]Unitversity of Texas Southwestern Medical Center, Dallas, USA; [2]University of Gothenburg, Mölndal, Sweden; [3]Elverum Central Hospital, Elverum, Norway; [4]Department of Orthopaedic Surgery, University Medical Centre, Mainz, Germany; [5]Medical Data Services, Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach an der Riss, Germany; [6]Medical Department, Boehringer Ingelheim AB, Stockholm, Sweden; [7]Boehringer Ingelheim Pharmaceuticals Inc, Ridgefield, Connecticut, USA; [8]Medical University of South Carolina and Charleston Orthopaedic Associates, South Carolina, USA

Background. Extended thromboprophylaxis after hip arthroplasty reduces the risk of venous thromboembolism (VTE). As oral dabigatran offers practical advantages over subcutaneous enoxaparin in the post-discharge setting, we compared the efficacy and safety of these treatments in this indication. *Methods.* In this double-blind, non-inferiority trial, 2055 patients undergoing total hip arthroplasty were randomized to treatment for 28 to 35 days with oral dabigatran, 220 mg once-daily, starting with a half-dose 1 to 4 hours after surgery, or subcutaneous enoxaparin 40 mg once-daily, starting the evening before surgery. The primary efficacy outcome was a composite of total VTE (venographic or symptomatic) and death from all-causes. The main secondary composite outcome was major VTE (proximal deep-vein thrombosis, nonfatal pulmonary embolism) plus VTE-related death. The main safety outcome was major bleeding during treatment. *Results.* The median treatment duration was 32 days. In total, 2013 were treated, of whom 1577 operated patients were included in the primary efficacy analysis. The primary efficacy outcome occurred in 7.7% (61 of 792) of the dabigatran group versus 8.8% (69 of 785) of the enoxaparin group, absolute risk difference -1.1% (95% confidence interval [CI], -3.8 to 1.6%); P<0.0001 for the pre-specified non-inferiority margin. The main secondary efficacy outcome occurred in 2.2% (18 of 805) of the dabigatran group versus 4.2% (33 of 794) of the enoxaparin group (absolute risk difference -1.9%, (95% CI,-3.6% to -0.2%; P=0.03). Major bleeding occurred in 1.4% of the dabigatran group and 0.9% of the enoxaparin group (P=0.40). The incidence of adverse events during treatment did not differ significantly between the groups. *Conclusions.* Extended prophylaxis with oral dabigatran 220 mg once-daily was as effective as subcutaneous enoxaparin 40 mg once-daily in reducing the risk of VTE after total hip arthroplasty. The risk of bleeding and safety profiles were similar.

DEREGULATION OF C/EBPG RESULTS IN DIFFERENTIATION ARREST IN ACUTE MYELOID LEUKEMIA

M Alberich Jorda,[1] B Wouters,[2] M Balastik,[1] C Koss,[2] D Hamer,[2] I Lowers,[2] H Zhang,[1] H Radomska,[1] M Ye,[1] P Zhang,[1] P Valk,[2] R Delwel,[2] D Tenen[3]

[1]Harvard Medical School, Boston, USA; [2]Erasmus University/Hematology, Rotterdam, Netherlands; [3]Harvard Medical School, Boston, USA, and Cancer Science Institute, University of Singapore, Singapore

CCAAT/enhancer-binding proteins (C/EBPs) are a family of transcription factors in which 6 core members have been identified: C/EBPA, C/EBPB, C/EBPG, C/EBPD, C/EBPE, and C/EBPZ. These transcription factors play important roles in differentiation and growth control in various tissues. In the hematopoietic system, C/EBPs, with the exception of C/EBPG, have been shown to regulate different stages of granulocytic development, and their aberrant expression has been observed in acute myeloid leukemia (AML). Although C/EBPG function has been partially described in the erythroid and lymphoid lineage, little is known about the role of this transcription factor during myelopoiesis or AML. In the present study, we investigated C/EBPG expression in 547 cases of *de novo* human AML and found that C/EBPG is highly upregulated in a specific subset of AML samples characterized by silencing of C/EBPA. Similarly, in C/EBPA conditional knockout mice, we found that ablation of C/EBPA in the LKS (lineage- c-kit+ Sca-1+) stem/progenitor cells caused an upregulation of C/EBPG. Reintroduction of C/EBPA into C/EBPA knockout LKS by retroviral infection resulted in C/EBPG downregulation, demonstrating a direct relation between C/EBPG expression and absence of C/EBPA. Supporting this hypothesis, DNA promoter microarrays (ChIP on Chip) showed that C/EBPA binds to the C/EBPG promoter, repressing C/EBPG expression. Next, to study the contribution of C/EBPG to the pathogenesis of AML we overexpressed C/EBPG in an *in vitro* differentiation model, and observed that sustained expression of this transcription factor induces a neutrophilic differentiation arrest. Similar neutrophilic arrest has been described in C/EBPA conditional knockout mice, resulting in their lack of mature neutrophils in the bone marrow and blood. Our observations that LKS from this mouse model have high levels of C/EBPG mRNA and that sustained C/EBPG expression blocks granulocytic differentiation led us to hypothesize that downregulation of C/EBPG is required for neutrophilic differentiation in stem/progenitor populations *in vivo*. To test this hypothesis, we designed several shRNA constructs specifically targeting C/EBPG, and examined the effect of knocking down CEBPG in the CEBPA knockout LKS. We observed that downregulation of C/EBPG expression in the C/EBPA deficient LKS was sufficient to completely restore granulocytic differentiation, as shown by *in vitro* cultures and bone marrow transplantation experiments. Altogether, we identify for the first time a role for C/EBPG in AML. Our results indicate that C/EBPG mediates the myeloid differentiation arrest induced by C/EBPA deficiency and suggest that targeting this transcription factor represents an alternative therapeutic strategy for AML.

A PHASE 3 STUDY TO DETERMINE THE EFFICACY AND SAFETY OF LENALIDOMIDE COMBINED WITH MELPHALAN AND PREDNISONE IN PATIENTS = 65 YEARS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA (NDMM)

A Palumbo,[1] M Dimopoulos,[2] M Delforge,[3] R Hajek,[4] M Kropff,[5] MT Petrucci,[6] Z Yu,[7] L Herbein,[7] J Mei,[7] C Jacques,[7] J Catalano[8]

[1]University of Torino, Torino, Italy; [2]Alexandra Hospital, University of Athens School of Medicine, Athens, Greece; [3]Myeloma Study Group, Belgian Hematological Society, Leuven, Belgium; [4]University Hospital Brno, Brno, Czech Republic; [5]University of Muenster, Muenster, Germany; [6]Sapienza University, Rome, Italy; [7]Celgene Corporation, Summit, NJ, USA; [8]Frankston Hospital, Frankston, Australia

Background. Lenalidomide is an oral IMiD® immunomodulatory agent with proven efficacy in MM patients. A phase 1/2 trial in elderly patients with NDMM demonstrated that treatment with lenalidomide in combination with melphalan and prednisone (MPR), elicited a high overall response rate (ORR) resulting in prolonged overall (OS) and progression-free survival (PFS) with acceptable toxicity (Palumbo. Clin Lymphoma Myeloma. 2009;9:145-150). *Aims.* A prospective, randomized phase 3 trial compared safety and efficacy of MPR followed by lenalidomide (MPR-R), MPR followed by placebo (MPR), and MP plus placebo followed by placebo (MP) in elderly patients with NDMM. *Methods.* 459 patients aged ≥65 years with NDMM were randomized to receive MPR-R, MPR, or MP. Patients received melphalan 0.18 mg/kg (D1-4), prednisone 2 mg/kg (D1-4), with or without lenalidomide 10 mg/day (D1-21) for nine 28-day cycles. M and R doses were simultaneously reduced for myelosuppression. Following 9 cycles of MPR, patients received continuous treatment with lenalidomide (10 mg/day; D1-21) or placebo until progression; MP patients received placebo until progression. The primary comparison was MPR-R vs MP. Data from a preplanned interim analysis at 50% of events (median follow-up of 9.4 months) are summarized here and the updated results with 70% of events will be presented at the meeting.

Table.

	MPR-R (n = 152)	MPR (n = 153)	MP (n = 154)	*P* Value (MPR-R vs MP)
ORR (CR+VGPR +PR)	77%	67%	49%	< .001
≥ VGPR PR	32% 45%	33% 34%	12% 37%	< .001 ---
Time to first response, months	1.9	1.9	2.8	< .001
PFS, months	Not reached	13.2	13.0	< .001
PR, partial response.				

Results. MPR-R resulted in a higher ORR, higher rates of complete response (CR) and very good partial response (VGPR), more rapid responses, and longer PFS compared with MP (Table). The secondary comparison of the trial (MPR-R vs MPR) demonstrated that continuous therapy with lenalidomide extended PFS compared to placebo (not reached and 13.2 months, respectively; P=.002). A landmark analysis of PFS in patients remaining on therapy following cycle 9 demonstrated that continuous treatment with lenalidomide versus placebo (regardless of the induction arm) resulted in a 75% reduced risk of disease progression (P<.001; HR: 0.245; 95% CI [0.126, 0.476]). MPR-R had a favorable safety profile with minimal cumulative toxicities; only 16% of patients discontinued due to adverse events (AEs). Grade 3/4 neutropenia, neutropenic fever, thrombocytopenia, and anemia occurred in 70%, 7%, 37%, and 23% of patients receiving MPR-R and 29%, 13%, and 17% of patients receiving MP; no grade 3/4 peripheral neuropathy was observed. Importantly, incidence of AEs after cycle 9 was very low, with only 1% patients experiencing grade 3/4 neutropenia and no thrombocytopenia. *Conclusions.* MPR-R elicited higher and more rapid respons-

es resulting in prolonged PFS. Additionally, lenalidomide taken continuously versus a fixed number of cycles significantly extended PFS with incidence of AEs comparable to placebo during the continuous therapy period. These data suggest that continuous use of lenalidomide is superior to regimens of limited duration and provides sustained disease control to patients with NDMM.

0567

MP VERSUS MPT FOR PREVIOUSLY UNTREATED ELDERLY PATIENTS WITH MULTIPLE MYELOMA: A META ANALYSIS OF SURVIVAL OF 1682 INDIVIDUAL PATIENT DATA FROM 6 RANDOMIZED CLINICAL TRIALS

A Waage,[1] A Palumbo,[2] C Hulin,[1] M Beksac,[3] P Fayers,[4] JY Mary,[5] S Bringhen,[2] P Sonneveld,[6] P Wijermans,[7] T Facon[8]

[1]Department of Hematology, Trondheim, Norway;, [2]Divisione di Ematologia dell'Università di Torino, Torino, Italy; [3]Ankara University, Ankara, Turkey; [4]University of Aberdeen, Aberdeen, UK; [5]INSERM U717, Paris, France; [6]Erasmus MC, Rotterdam, Netherlands; [7]Hospital Leyenburg, Haag, Netherlands; [8]Service des Maladies du Sang, Lille, France

Background. Randomized clinical trials including previously untreated patients who were uneligible for high dose treatment were initiated in Italy (GIMEMA 331 pts), France (IFM 321 and 229 pts), Netherlands/Belgium (HOVON 333 pts), Nordic countries (NMSG 357 pts) in 2000-02 and in Turkey (TMSG 114 pts) 2006. These groups in European Myeloma Network have agreed on a common analysis of their individual patient data. *Methods.* An electronic search for publications, abstracts and presentations about MP vs. MPT in multiple myeloma found no trial additional to the 6 presented here. The protocol for the common analyses was finalized after discussions with participants from all groups. All patients from the original studies have been entered into a common data base. Daily dose of thalidomide was 100 mg until relapse (Italy), 200-400 mg in patients below 65 years and 100 mg in patients above 65 years mg in 72 weeks (12 cycles) (France), 400 mg until plateau phase, maintenance 200 mg until relapse (Nordic), 200 mg until 4 weeks after last cycle (HOVON) and 100 mg during 48 weeks (8 cycles) (Turkey). Melphalan dose was 4 mg/sqm day 1-7 every 4 weeks in 6 cycles (Italy), 0,25 mg/kg day 1-4 every 6 weeks below 65 years and 0,20 mg/kg above 65 years in 12 cycles (France), 0,25 mg/kg day 1-4 in cycles every 6 weeks until plateau phase (Nordic), 0, 25 mg/kg day 1-5 every 4 weeks in at least 8 cycles (HOVON), 9 mg/sqm day 1-4 every 6 weeks in 8 cycles (Turkey). The French study in patients above 65 years and the Nordic study were blinded with placebo.

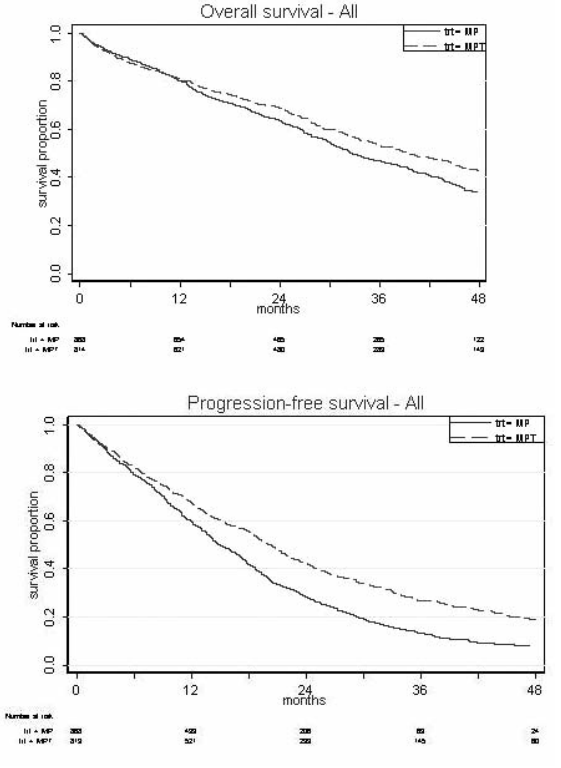

Figure.

Results. We analyzed 1682 patients, 868 in the MP arm and 814 in the MPT arm. Median OS was 32.7 (95% CI 30.4-36.5) months in the MP arm and 39.3 (35.6-39.0) months in the MPT arm. Median PFS was 14.9 (14.0-16.6) months in the MP arm and 20.4 (18.8-21.6) months in the MPT arm. Overall hazard ratio of MPT compared to MP was 0.82 (0.66-1.02) for OS and 0.67 (0.55-0.80) for PFS when a random effects model was used. Test of heterogeneity between the studies was statistically significant for OS (P=0.26) and for PFS (P=0.23). *Conclusions.* The meta analysis demonstrates a significant effect on progression free survival and a close to significant difference in OS when thalidomide is added to melphalan and prednisone in first line treatment to elderly patients with multiple myeloma.

0568

A PROSPECTIVE RANDOMIZED TRIAL OF BORTEZOMIB-MELPHALAN-PREDNISONE-THALIDOMIDE FOLLOWED BY CONTINUOUS BORTEZOMIB-THALIDOMIDE FOR INITIAL THERAPY OF MULTIPLE MYELOMA: EFFECT OF AGE AND CO-MORBIDITIES

A Palumbo,[1] S Bringhen,[1] D Rossi,[2] M Cavalli,[2] R Ria,[2] M Offidani,[2] C Nozzoli,[2] L Baldini,[2] L De Rosa,[2] G De Sabbata,[2] AM Liberati,[2] C Crippa,[2] F Ciambelli,[2] V Callea,[2] M Spriano,[2] F Ferrara,[2] F Elice,[2] M Galli,[2] J Peccatori,[2] L Catalano,[2] M Rizzo,[2] R Marasca,[2] F Pisani,[2] M Cavo,[2] M Petrucci,[2] P Musto,[2] P Omedè,[1] A Larocca,[1] G Gaidano,[2] M Boccadoro[1]

[1]A.O.U. San Giovanni Battista, Torino, Italy; [2]Italian Multiple Myeloma Network, Gimema, Italy

Background In elderly patients with newly diagnosed multiple myeloma (MM) bortezomib-melphalan-prednisone (VMP) and melphalan-prednisone-thalidomide (MPT) are now regarded as the new standards of care. *Aims.* To compare VMP-thalidomide followed by continuous bortezomib-thalidomide (VMPT-VT) with VMP alone as induction therapy. Primary end point was progression-free-survival (PFS). *Methods.* Between May, 2005 and January, 2009, 511 patients aged ≥ 65 years were randomized to receive VMPT-VT (N=254) or VMP (N=257). In the VMPT-VT arm patients received bortezomib 1.3 mg/m^2 days 1,4,8,11,22,25,29,32 in cycles 1-4 and days 1,8,22,29 in cycles 5-9; melphalan 9 mg/m^2 plus prednisone 60 mg/m^2 days 1-4 and thalidomide 50 mg days 1-42 for nine 6-week cycles, followed by VT therapy (bortezomib 1.3 mg/m^2 days 1, 15, thalidomide 50 mg/day). In the VMP arm patients received the same schedule without any further therapy. To evaluate if the treatment regimen could be further optimized by decreasing the toxicity while maintaining efficacy, in March 2007 the protocol was amended and both bortezomib schedules were reduced to once-weekly infusion.

Table.

	VMPT-VT (n = 250)	VMP (n = 253)	*P* Value (VMPT-VT vs VMP)
CR	38%	24%	<.001
≥ VGPR	59%	50%	.03
3-year PFS	56%	41%	.008
3-year OS	89%	87%	.77

Results. 503 patients were evaluable: 250 were assigned to receive VMPT-VT and 253 to VMP. Both arms were well balanced for baseline characteristics. Response rates were superior in the VMPT-VT group as compared to VMP: ≥VGPR rate of 59% vs 50% (P=.03) and CR of 38% vs 24% (P<.001), respectively. VT therapy was able to increase response rate in 11% of evaluable patients. After a median follow-up of 23.4 months, the 3-year PFS was 56% and 41% (P=.008), and the 3-year overall survival (OS) was 89% and 87% (P=.77) in the VMPT-VT group and in the VMP group, respectively. VMPT-VT induced a higher incidence of grade 3-4 neutropenia (38% vs 28%, P=.02) and cardiac complications (10% vs 5%, P=.04); the incidence of grade 3-4 peripheral neuropathy (PN) was 8% in VMPT and 5% in VMP (P=.19). During maintenance therapy with VT, the most relevant toxicity was PN (4%), other serious adverse events were less than 1.5%. 133 patients were older than 75

years, 65 in the VMPT-VT group and 68 in the VMP group. In patients ≥75 years of age, response rates and PFS were similar in VMPT-VT and VMP patients: ≥VGPR was 49% vs 41% (P=.35) and CR 31% vs 29% (P=.72), respectively; the 2-year PFS was 56% in the VMPT-VT and 53% in the VMP group (P=.49). In patients ≥75 years, the incidence of non-hematologic events (59% vs 31%, P=.001) cardiologic events (18% vs 4%, P=.01), and treatment discontinuation for toxicity (31% vs 16%, P=.04) were higher for VMPT-VT as compared to VMP. *Conclusion.* These results indicate that: 1. VMPT-VT was significantly superior to VMP; 2. cardiologic toxicity may reduce the efficacy of the VMPT-VT regimen in elderly frail patients.

IMMUNOPHENOTYPIC RESPONSES CAN BE ACHIEVED IN ELDERLY MULTIPLE MYELOMA PATIENS TREATED WITH NOVEL AGENTS

B Paiva,[1] M Vidriales,[2] J Martinez,[3] A Oriol,[4] E Redondo,[3] M Montalban,[3] M Mateos,[2] N Gutierrez,[2] L Lopez-Corral,[2] J Perez,[2] A Martin,[5] M Terol,[6] Y Gonzalez,[7] M Echebeste,[8] J Hernandez,[9] F De Arriba,[10] R De Paz,[11] J Blade,[12] J Lahuerta,[3] J San Miguel[2]

[1]Hospital Universitario Salamanca, Salamanca, Spain; [2]Hospital Universitario de Salamanca, Centro de Investigación del Cáncer, Salamanca, Spain; [3]Hospital 12 de Octubre, Madrid, Spain; [4]Hospital Universitari Germans Trias i Pujol, Badalona, Spain; [5]Hospital Virgen de la Concha, Zamora, Spain; [6]Hospital Clínico de Valencia, Valencia, Spain; [7]Hospital Josep Trueta, Girona, Spain; [8]Hospital de Donostia, San Sebastian, Spain; [9]Hospital General de Segovia, Segovia, Spain; [10]Hospital Morales Meseguer, Murcia, Spain; [11]Hospital Universitario La Paz, Madrid, Spain; [12]Hospital Clínic, IDIBAPS, Barcelona, Spain

Introduction: Recent data suggest that the immunophenotypic response is one of the most relevant prognostic factors in MM patients treated with conventional therapy plus ASCT. However, so far the value of MRD investigations in the context of novel agents had not been explored, especially in the elderly population. *Aims.* To assess the frequency and the prognostic value of the multiparameter flow cytometry (MFC) remission status after induction therapy in elderly newly diagnosed non-transplanted MM patients. *Methods.* A total of 153 patients were evaluable for this analysis. All of them uniformly treated according to the Spanish GEM05>65y protocol (two arms of six cycles of Bortezomib/Melphalan/Prednisone (n=79) or Bortezomib/Thalidomide/Prednisone (n=74) supplemented with maintenance therapy). The median follow-up was 24 months and the EBMT criteria were used for response evaluation. Patients were defined to be in immunophenotypic response when myelomatous plasma cells (MM-PCs) were undetectable by MFC or when less than one phenotypically aberrant PC was detected among 105 cells analyzed. *Results.* After 6 induction cycles, residual MM-PC were undetectable or present at a frequency bellow 10^{-5} in 34 out of the 153 cases analyzed (22%), and thus qualified as MFC responses (MFCr); this frequency being similar in the VMP and VTP induction arms (24% vs. 19%, P=.4). Median time to progression (TTP) in these patients has not been reached while in the remaining 131 cases (78%) was 31 months (P<.001). A trend for longer overall survival (OS) was also seen in patients with MFCr compared to the rest of the cases (P=.07). MFC also afforded prognostic information within the 48 patients who achieved complete remission (CR) by immunofixation (IFx). The 2-year TTP rates were 100% in patients achieving MFCr (n=25) versus 70% in those who didn´t achieved (n=23;P=.03), and the respective 2-year OS rates were 100% versus 80% (P=.06). Moreover, we found that the better the quality of the response the longer the TTP, with 2-year rates of 100%, 83%, 57% and 36% for MFCr, CR, nCR+PR and less than PR, respectively;P<.001. Discordant results between MFC and IFx response status were found in 23 patients (21%), 7 being IFx+/MFC- and 16 IFx-/MFC+. Strikingly, in all 7 cases IFx+/MFC- the M-component became negative by IFx in subsequent analysis, consistent with the long half-life of some immunoglobulins in patients achieving an optimal response by MFC. In contrast, IFx-/MFC+ cases showed a tendency to early reappearance of the M-component (6/16;38%). Finally, the multivariate model selected the immunophenotypic response as the most potent marker for predicting PFS (hazard ratio -HR=33.6; P=.04) followed by highly abnormal baseline sFLC ratio (<0.02 or >10;HR=4.1;P=.007) and high% of MM-PC in S-phase (>2%;HR=3.4;P=.01), whereas CR failed to reach significance (HR=2.8;P=.15). *Conclusions.* Our results show that patients with immunophenotypic response display a significantly longer PFS, clearly superior to that of patients in CR by IFx, and that the achievement of an immunophenotypic response should be a goal even in elderly MM patients (non-transplant candidates) in the era of novel agents, confirming that the better the quality of response the longer the survival.

0570

ACHIEVEMENT OF COMPLETE REMISSION IS A STRONG PROGNOSTIC FACTOR IN 895 ELDERLY MYELOMA PATIENTS TREATED WITH MELPHALAN-PREDNISONE BASED-REGIMENS: RESULTS OF 3 MULTICENTER ITALIAN TRIALS

F Gay,[1] A Larocca,[1] MT Petrucci,[2] P Musto,[2] AM Liberati,[2] V Callea,[2] R Ria,[2] T Caravita,[2] C Cangialosi,[2] M Grasso,[2] M Offidani,[2] P Pregno,[2] F Patriarca,[2] M Galli,[2] M Cavo,[2] L Catalano,[2] C Nozzoli,[2] T Guglielmelli,[2] R Zambello,[2] F Pisani,[2] V Montefusco,[2] F Rossini,[2] V De Stefano,[2] B Lupo,[1] F Di Raimondo,[2] G Gaidano,[2] M Boccadoro,[1] A Palumbo[1]

[1]A.O.U. San Giovanni Battista, Torino, Italy; [2]Italian Multiple Myeloma Network, Gimema, Italy

Background. several studies, mostly in the context of autologous stem cell transplantation, demonstrate that a better tumor reduction significantly correlates with longer survival or at least progression-free survival (PFS) in multiple myeloma (MM) patients. In elderly patients, treated with conventional chemotherapy, complete remission (CR) was a relatively rare event since new drugs has been added to standard melphalan and prednisone (MP). *Aims.* to validate the prognostic value of CR in a large group of elderly newly diagnosed MM patients treated with MP based-regimens. *Methods.* 895 patients with newly diagnosed MM, aged ≥ 65 years (or younger but considered not eligible for high-dose chemotherapy), enrolled in the GISMM-2001, RV-MM-PI-026 and MM0305 multicenter Italian trials were analyzed. Patients received MP (n=164), MP plus thalidomide (MPT, n=167), MP plus lenalidomide (MPR, n=53), MP plus bortezomib (VMP, n=257) or MP plus bortezomib and thalidomide (VMPT-VT, n=254). Median number of cycles administered was 6 (range 1-9). Best response assessment was available in 847 patients. *Results.* the best response was CR in 195 patients, very good partial response (VGPR) in 171 patients and partial response (PR) in 297 patients. After a median follow-up of 51 months, 4-year progression-free-survival (PFS) was 62% in patients who obtained CR, 28% in those who achieved VGPR and 28% in patients who achieved partial response (PR) only (P<0.0001). Four-year overall survival (OS) was significantly higher in patients obtaining CR compared to VGPR or PR (79% versus 52% versus 54%, P<0.0001). At a landmark analysis performed at 6 months after enrolment (n=644) PFS and OS were significantly better in patients who achieved CR compared to patients with VGPR or PR (P<0.0001). Subgroup analysis was performed according to age, International Staging System (ISS) stage and treatment regimen. The benefit of achieving CR on PFS was confirmed in patients younger than 75 years (P<0.0001) and older (P<0.0001); in patients with ISS stage I (P=0.018), stage II (P<0.0001) and stage III (P<0.0001) and in patients treated with bortezomib-based regimen (VMP, P=0.003) or immunomodulatory agents (MPT and MPR, P=0.002) or bortezomib plus immunomodulatory agents (VMPT-VT, P=0.0004). Similarly, CR achievement was correlated to a significant increase in OS in patients younger (P=0.001) and older than 75 years (P=0.015) and in patients with ISS stage II (P=0.003) and III (P=0.006). By subgroup analysis of treatment regimen, the impact of CR on OS was confirmed both for patients treated with MPT and MPR (P=0.019) and with VMPT-VT (P=0.019). *Conclusions.* in elderly MM patients treated with MP-based regimens, CR achievement is a strong prognostic factor regardless of age, ISS stage and treatment regimen.

Table.

	CR N=195	VGPR N=171	PR n=297	CR vs VGPR vs PR p value
4-year PFS	62%	28%	28%	p<0.0001
4-year OS	79%	52%	54%	p<0.0001

Aggressive non-Hodgkin's lymphoma

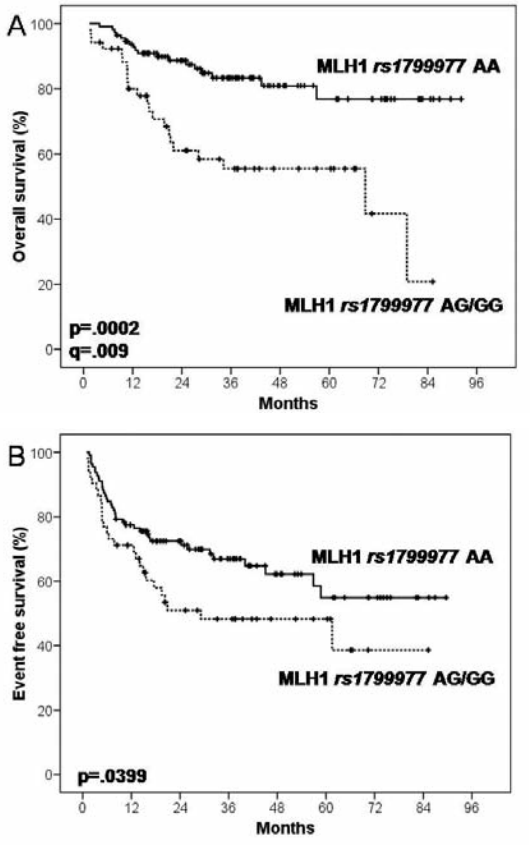
A GENETIC VARIANT OF MLH1, A GENE INVOLVED IN DNA MISMATCH REPAIR, IS AN INDEPENDENT PREDICTOR OF OVERALL SURVIVAL IN DIFFUSE LARGE B-CELL LYMPHOMA TREATED WITH R-CHOP

D Rossi,[1] S Rasi,[1] A Fabbri,[2] F Forconi,[2] A Bruscaggin,[1] A Di Rocco,[3] M Fangazio,[1] S Franceschetti,[1] L De Paoli,[1] R Bruna,[1] A Chiappella,[4] E Pogliani,[5] F Lauria,[2] U Vitolo,[4] S Hohaus,[6] M Martelli,[3] R Foà,[3] G Gaidano[1]

[1]Division of Hematology, Amedeo Avogadro University, Novara, Italy; [2]Division of Hematology and Bone Marrow Transplantation, University of Siena, Siena, Italy; [3]Division of Hematology, La Sapienza University, Rome, Italy; [4]Division of Hematology, AOU S. Giovanni Battista, Turin, Italy; [5]Division of Hematology, University of Milan Bicocca, Milan, Italy; [6]Institute of Hematology, Catholic University of the Sacred Heart, Rome, Italy

Background. Several drugs utilized in diffuse large B cell lymphoma (DLBCL) treatment rely on DNA damage for tumor killing. Host genetic variability in genes repairing DNA damage may affect response to drugs and prognosis. *Aims.* We verified the impact of DNA repair genes SNPs on prognosis of R-CHOP treated DLBCL. *Methods.* The study was based on 163 consecutive DLBCL treated with R-CHOP and provided with a prospectively collected dataset. At diagnosis, age >60 years was observed in 104/163 (63.8%) cases, ECOG PS >1 in 21/163 (12.9%), extranodal sites >1 in 41/163 (25.2%), Ann Arbor stage III-IV in 85/163 (52.1%), bulky in 46/163 (28.2%), LDH elevation in 75/163 (46.0%), IPI >2 in 55/163 (33.7%). Median follow-up was 48 months. Thirty-five SNPs from 18 genes were analyzed on patients' germline DNA. These included SNPs affecting: i) mismatch repair (MLH1rs1799977/rs1800734); ii) base excision repair (XRCC1rs1799782/rs25487, OGG1rs1052133); iii) nucleotide excision repair (ERCC1rs3212986, ERCC2rs1052555/ rs13181/rs1799793/ rs238406, ERCC4rs1800067/rs3136038, ERCC5rs17655, ERCC6rs2228528/rs2228529/rs3793784, XPArs1800975, XPCrs222799/ rs2228000/rs2607775/rs2228001); iv) double strand break repair (BRCA1rs49868507rs17999507rs799917, BRCA2rs144848, LIG4rs1805388, XRCC2rs3218536, XRCC3rs17997947rs861539, XRCC4rs1805377, XRCC6rs5751129/rs132788); and v) direct reversal (MGMTrs16906252/rs2308321/rs12917). Clinical endpoints were overall survival (OS) and event free survival (EFS). Informed consent was obtained.



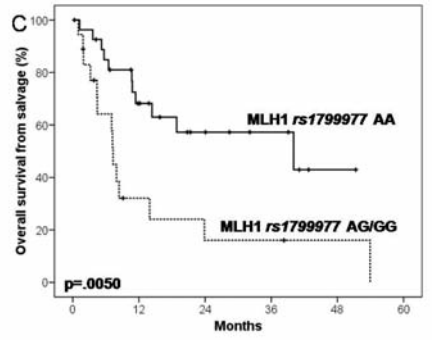


Figure.

Results. Univariate analysis controlled for multiple comparisons identified MLH1rs1799977 as the sole DNA repair SNP predicting OS in R-CHOP treated DLBCL. Patients carrying the MLH1rs1799977 AG/GG genotype displayed an increased risk of death (HR:3.23; 4-years OS: 55.5%) compared to AA carriers (4-years OS: 80.9%) (P=.0002; q=.009; Fig.1A). Multivariate analysis selected MLH1rs1799977 (HR:3.14; P=.0004) as an independent predictor of OS, along with IPI (HR:1.38; P=.0377) and bulky disease (HR:2.56; P=.0044). Accordingly, when combined to IPI, MLH1rs1799977 refined the clinical prognostication of DLBCL. The poor prognosis heralded by MLH1rs1799977 AG/GG genotype in DLBCL is due to first and second line treatment failure. Patients carrying the MLH1rs1799977 AG/GG genotype displayed an increased risk of failing R-CHOP (HR:1.66; 4-years EFS: 48.3%) compared to AA carriers (4-years EFS: 62.2%) (P=.0399; Fig.1B). Multivariate analysis identified MLH1rs1799977 (HR:1.66; P=.0498) as an independent predictor of EFS, along with IPI (HR:1.61; P<.0001) and bulky disease (HR:1.84; P=.0215). Also, patients carrying the MLH1rs1799977 AG/GG genotype displayed an increased risk of failing second line platinum-based regimens (HR: 3.04; 4-year OS from salvage: 16.0%) compared to AA carriers (4-year OS from salvage: 57.3%) (P=.0050; Figure 1C). By bivariate analysis, MLH1rs1799977 predicted OS from salvage independent of having (P=.0020) or having not (P=.0480) consolidated with SCT. *Conclusions.* MLH1rs1799977 is an independent predictor of survival in DLBCL treated with R-CHOP. The biologic plausibility of this association is supported by four lines evidence: i) MLH1rs1799977 is a nonsynonymous SNP causing the I219V amino acidic substitution on MLH1, a gene of the mismatch repair pathway; ii) in silico, MLH1rs1799977 is predicted to have deleterious consequences; iii) *in vitro*, the G variant allele of MLH1rs1799977 associates with reduced MLH1 protein expression; iv) loss of MLH1 in tumor cells is known to induce refractoriness to doxorubicin and platinum compounds. Consistently, DLBCL carriers of the MLH1rs1799977 AG/GG genotypes displayed poor OS possibly due to altered MLH1 expression.

0572

ROMIDEPSIN EXPERIENCE IN 317 PATIENTS WITH T-CELL LYMPHOMAS

B Coiffier,[1] S Horwitz,[2] S Whittaker,[3] B Pro,[4] T Robak,[5] A Samtsov,[6] Y Kim,[7] M Prince,[8] F Foss,[9] R Piekarz,[10] J Nichols,[11] S Bates[12]

[1]Hospices Civils de Lyon, Pierre Benite, France; [2]Memorial Sloan-Kettering Cancer Center, New York, USA; [3]Guys and St Thomas NHS Foundation Trust, London, UK; [4]M.D. Anderson Cancer Center, Lymphoma/Myeloma, Houston, USA; [5]Medical University of Lodz and Copernicus Memorial Hospital, Poland, Lodz, Poland; [6]Russian Federation Medical-Military Academy, Saint-Petersburg, Russian Federation; [7]Stanford Cancer Center, Stanford, USA; [8]Peter MacCallum Cancer Centre, Melbourne, Australia; [9]Yale Cancer Center, New Haven, USA; [10]National Cancer Institute, Rockville, USA; [11]Celgene Oncology, Cambridge, USA; [12]National Cancer Institute/National Institutes of Health, Bethesda, USA

Background. Romidepsin is a novel pan-histone deacetylase (HDAC) inhibitor recently approved for the treatment of cutaneous T-cell lymphoma (CTCL) in patients with one prior systemic therapy. *Aims.* Evaluate efficacy and safety of romidepsin in patients with CTCL and peripheral T-cell lymphoma (PTCL). *Methods.* 317 patients received single-agent romidepsin in 3 phase 2, multicenter, international studies: GPI-04-0001 enrolled patients with CTCL; GPI-06-0002 patients with PTCL; and NCI 1312 patients with CTCL or PTCL. The primary endpoint for the CTCL studies was overall response rate (ORR) assessed by a composite endpoint including skin, blood, lymph nodes, and viscera. The primary endpoint for PTCL studies was complete response (CR) rate. Duration of response (DOR) and safety were evaluated for all patients. *Results.* Both populations were heavily pretreated (median 2-4 prior therapies) and represented patients with advanced disease. Romidepsin was active in CTCL and PTCL with ORRs of 34% and 38%, CR rates of 6% and 15%, and median DOR of 13.7-15 months and 10 months, respectively. For CTCL, the most common treatment-related adverse events (AEs) for all cycles were nausea (67%; 3% ≥grade 3), fatigue (49%; 10% ≥grade 3), and vomiting (34%; 2% ≥grade 3). For PTCL, the most common were nausea (53%; 3% ≥grade 3), thrombocytopenia (44%; 21% ≥grade 3), and fatigue (43%; 7% ≥grade 3). Thrombocytopenia (all grades and ≥grade 3 events) and neutropenia (≥grade 3 events) occurred at a higher frequency in patients with PTCL compared with CTCL. These differences are likely related to reduced marrow reserves due to prior therapies and increased incidence of bone marrow involvement in PTCL. Discontinuation due to AE occurred in 28/167 (17%) and 28/150 (19%) CTCL and PTCL patients, respectively. *Conclusions.* These results represent one of the largest single-drug T-cell lymphoma data sets. Romidepsin treatment resulted in clinically meaningful and durable responses in CTCL and PTCL. Overall, the safety profile was similar across T-cell lymphomas. Romidepsin appears to be a promising new therapy for T-cell lymphoma patients.

ANTI-CD22 IMMUNOCONJUGATE INOTUZUMAB OZOGAMICIN (CMC-544) + RITUXIMAB: CLINICAL ACTIVITY IN PATIENTS WITH RELAPSED/REFRACTORY FOLLICULAR OR 'AGGRESSIVE' LYMPHOMA

G Verhoef,[1] N Dang,[2] M Smith,[3] F Offner,[4] P Johnson,[5] A Rohatiner,[6] J Kaufman,[7] E Gine,[8] B Coiffier,[9] M Czuczman,[10] J Foran,[11] S Durrant,[12] S Hua,[13] E Vandendries,[13] J Boni,[13] L Fayad[14]

[1]UZ Leuven, Leuven, Belgium; [2]University of Florida Shands Cancer Center, Gainesville, FL, USA; [3]Fox Chase Cancer Center, Philadelphia, PA, USA; [4]Ghent University, Gent, Belgium; [5]Cancer Research UK Centre, Southampton General Hospital, Southampton, UK; [6]Institute of Cancer (School of Medicine and Dentistry), University of London, London, UK; [7]The Emory Clinic, Atlanta, GA, USA; [8]Hematology Department, Hospital Clinic, Barcelona, Spain; [9]Hospices Civils de Lyon and Universite Claude Bernand, Lyon, France; [10]Roswell Park Cancer Institute, Buffalo, NY, USA; [11]University of Alabama at Birmingham, Birmingham, AL, USA; [12]Royal Brisbane and Women's Hospital, Brisbane, Queensland, Australia; [13]Pfizer, Cambridge, MA, USA; [14]University of Texas M.D Anderson Cancer Center, Houston, TX, USA

Background. Inotuzumab ozogamicin (CMC-544) is a humanized anti-CD22 antibody conjugated to calicheamicin, a potent cytotoxic agent. CD22 is expressed on the majority of B cell non-Hodgkin lymphomas (NHL). CMC-544 has demonstrated single agent efficacy and good tolerability in heavily pre-treated and refractory patients with NHL. *Aims.* To assess clinical activity of CMC-544 combined with rituximab in patients with NHL, including: relapsed follicular lymphoma (FL), relapsed diffuse large B cell lymphoma (DLBCL), and refractory 'aggressive' NHL. *Methods.* Part 1 dose-escalation phase determined the maximum tolerated dose (MTD) of CMC-544 combined with rituximab to be 1.8 mg/m^2 q4w. In part 2, eligible patients had CD20$^+$/CD22$^+$ B cell NHL and prior rituximab. Patients with relapsed FL and DLBCL had ≤2 prior therapies, but were not refractory to rituximab-containing therapy. Patients with rituximab-refractory 'aggressive' NHL could have DLBCL, mantle cell lymphoma, or transformed FL, with no limit on prior therapies. Patients received 375 mg/m^2 rituximab IV on Day 1, followed by 1.8 mg/m^2 CMC-544 on Day 2 of each 28-day cycle for up to 8 cycles in the absence of disease progression. Safety, efficacy (ie, objective response rate [ORR], overall survival [OS], progression-free survival [PFS]), and pharmacokinetics were evaluated. *Results.* The study enrolled 119 patients, including 110 treated with CMC-544 at the MTD of 1.8 mg/m^2. Median age was 66 years (range: 20-85); 60% were male; 35% had 1 prior chemotherapy/immunotherapy regimen, 46% had 2, and 18% had ≥3; 73% had stage III/IV disease; 40% had elevated lactate dehydrogenase; and 19% had bulky disease (>7.5 cm). Common drug-related treatment-emergent adverse events (TEAEs) included thrombocytopenia (46%), nausea (44%), fatigue (40%), and increased aspartate aminotransferase (33%). Drug-related serious TEAEs were reported for 12 (10%) patients. Median follow-up was 16.7, 10.9, and 3.1 months for patients with FL, recurrent DLBCL, and 'aggressive' NHL treated at the MTD, respectively. Patients with relapsed FL (n=38) had an ORR of 84%; patients with relapsed DLBCL (n=40) had an ORR of 80%. One-year OS and PFS rates were 97% and 80% (median PFS not reached), respectively, for patients with relapsed FL. One-year OS and PFS rates were 79% and 56% (median PFS: 15.1 months), respectively, for patients with recurrent DLBCL. Response to prior therapy appears to be a major prognostic factor. Patients with rituximab-refractory 'aggressive' NHL (n=28) had a lower ORR (18%), with a median PFS of only 1.7 months. Maximal serum CMC-544 concentration (measured by total calicheamicin) was comparable across cycles (61-71 ng/mL). However, exposure (AUC) increased with each subsequent cycle (Cycle 1: 4,700 ng/mL; Cycle 2: 8,600 ng/mL; Cycle 3: 9,558 ng/mL); half-life also increased after Cycle 1. *Summary/Conclusions.* The combination of inotuzumab ozogamicin (CMC-544) plus rituximab has a safety and pharmacokinetic profile similar to that previously reported for CMC-544 alone. The ORR and PFS results indicate promising efficacy in patients with relapsed FL and DLBCL. Patients with rituximab-refractory 'aggressive' NHL had a low ORR and median PFS, consistent with their expected poorer prognosis. These encouraging results in patients with relapsed NHL support continued clinical development of this regimen.

0574

LENALIDOMIDE MONOTHERAPY IS CLINICALLY ACTIVE IN PATIENTS WITH RELAPSED/REFRACTORY DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL): A POOLED ANALYSIS OF DATA FROM 2 PHASE II STUDIES (NHL-002/003)

M Czuczman,[1] J Vose,[2] PL Zinzani,[3] C Reeder,[4] R Buckstein,[5] C Haioun,[6] R Bouabdallah,[7] J Polikoff,[8] A Ervin-Haynes,[9] T Witzig[4]

[1]Roswell Park Cancer Institute, Buffalo, USA; [2]University of Nebraska, Omaha, USA; [3]Institute of Hematology and Medical Oncology, Bologna, Italy; [4]Mayo Clinic, Scottsdale, USA; [5]Toronto Sunnybrook Odette Cancer Center, Toronto, Canada; [6]Hôpital Henri Mondor, Créteil, France; [7]Institute Paoli-Calmettes Haematology, Marseille, France; [8]Kaiser Permanente Medical Group, San Diego, USA; [9]Celgene Corporation, Summit, USA

Background. DLBCL is the most frequently diagnosed type of aggressive non-Hodgkin's lymphoma (aNHL). Despite recent advances failure-free survival remains at ~50% (Habermann JCO 2006), and prognosis remains dismal for those not cured with either R-CHOP or autologous stem cell transplantation (SCT). Lenalidomide is an immunomodulatory agent that demonstrates considerable clinical activity in the treatment of B-cell hematologic malignancies. Two phase II trials, NHL-002 (49 patients; Wiernik JCO 2008) and a larger scale, international study NHL-003 (217 patients) have been conducted in patients with relapsed/refractory aNHL of various histologies treated with single-agent lenalidomide at the schedule of 25 mg days 1-21 in a 28-day cycle. Here, we present the subset analysis of patients with DLBCL from the NHL-003 study, as well as pooled data from both studies evaluating the clinical utility of lenalidomide in patients with relapsed/refractory DLBCL (off-label). *Aims.* To assess the clinical activity and tolerability profile of lenalidomide monotherapy in patients with relapsed/refractory DLBCL. *Methods.* In both studies, patients with relapsed/refractory aNHL (defined as DLBCL, mantle cell lymphoma, transformed lymphoma, and follicular lymphoma grade 3), with measurable disease (≥2 cm), and ≥1 prior treatment, provided informed consent and received oral lenalidomide 25 mg once daily on days 1-21 of every 28-day cycle. In NHL-002, treatment continued for ≤52 weeks, whereas in NHL-003 treatment continued until disease progression. Overall response rate was the primary endpoint; secondary endpoints included response duration, progression-free survival (PFS), and safety. Histology and response were as per investigator assessment. *Results.* 26 patients from NHL-002 and 108 patients from NHL-003 had a DLBCL histology and were included in this analysis. For the pooled population of 134 patients, the median age was 66 years (21-87), median time from diagnosis was 2.3 years (0.3-21.1), and 82 patients (61%) were male. Patients failed a median of 3 prior regimens (1-10), and 52 (39%) patients had prior SCT. Lenalidomide monotherapy induced responses in 35 patients (26%), which included 12 patients (9%) who achieved a complete response (CR)/unconfirmed CR (CRu). Responses were observed in 10 of 62 patients (16.1%) refractory to their last prior therapy and in 15 of 52 patients (28.8%) with SCT. At a median 4.6-month follow-up median response duration was 6.0 months. Patients with a CR/CRu after lenalidomide achieved a median response duration lasting 10.4 months. Consistent with other studies of lenalidomide most common grade 3 and 4 adverse events were reversible neutropenia (22.4% and 13.4%), thrombocytopenia (15.7% and 5.2%), and anemia (6% and 0.7%). *Conclusions.* This analysis of 134 patients pooled from 2 phase II studies shows that single-agent lenalidomide has clinical activity and can achieve durable responses in patients with relapsed/refractory DLBCL. Patients with a CR/CRu achieved particularly promising response durations. The data also suggest that among patients with DLBCL there may be sub-populations for whom lenalidomide may provide a particular benefit. Additional studies are underway to explore patient subsets that are more likely to respond to lenalidomide, and to evaluate lenalidomide in combination with other agents currently used to treat aNHL.

SUSTAINED SURVIVAL ADVANTAGE AFTER A MEDIAN FOLLOW-UP OF 5 YEARS FOR IMMUNO-CHEMOTHERAPY (R-MCP) VERSUS CHEMOTHERAPY ALONE (MCP) IN ADVANCED FOLLICULAR LYMPHOMA - UPDATE OF THE OSHO#39 TRIAL

M Herold,[1] G Maschmeyer,[2] V Lakner,[3] G Dölken,[4] G Ehninger,[5] M Hänel,[6] R Rohrberg,[3] A Hochhaus,[7] A Neubauer,[7] L Fischer,[8] U von Grünhagen,[3] S Hahnfeld,[3] F Hoffmann,[3] M Wuβling,[3] W Stein,[9] E Kettner,[10] D Hähling[11]

Franklin, Berlin, Germany; [9]Klinikum, Frankfurt/Oder, German; [10]Städtisches Klinikum, Magdeburg, Germany; [11]Helios Klinikum, Schwerin, Germany

Background. When we presented our results of R-MCP immunochemotherapy for follicular lymphoma at the 2006 ASH meeting, this was the first randomized phase III study ever demonstrating an overall survival advantage of immunochemotherapy over chemotherapy alone. Now we are now able to report much more mature data with a median follow up of 60 months. *Methods.* After informed consent previously untreated patients with advanced stage, symptomatic CD 20-positive indolent NHL and mantle cell lymphoma (n=358) were randomized to receive either MCP-chemotherapy (mitoxantrone 8 mg/m² d1+2, chlorambucil 3x3 mg/m² d 1-5, prednisolone 25 mg/m² d 1-5 x 8 q 4 weeks) or MCP + rituximab (375 mg/m² d -1) followed by interferon maintenance treatment (3 x 4.5 mioIU per week) for responding (CR, PR) patients. Here we report the 60 months follow up results of the follicular lymphoma patients (grade 1+2), who represented the majority of patients and for whom the sample size was calculated, so this is not a subgroup analysis. Study endpoints included overall and complete response rate (RR + CR), progression free survival (PFS), event free survival (EFS), time to next treatment (TTNT), overall survival (OS) and toxicities. *Results.* Concerning toxicities there was no striking difference. For the FL - ITT population the treatment results are as follows: R-MCP (n=105) MCP (n=96) p - value. Response rate 92,4% 75% .0009. Complete responses 49,5% 25% .0004. PFS median 86 mo. 35 mo. < .0001 .PFS 5 y 65% 33%. EFS median 86 mo. 27 mo. .0001. EFS 5 y 63% 30%. TTNT median n.r. 29 mo. <.0001. No retreatment at 5 y 55% 31%. OS median n.r. 108 mo. .0278. OS 5 y 86% 74%. (PFS=progression free survival, EFS=event free survival, TTNT= time to next treatment, OS=overall survival). *Conclusions.* Concerning all end points rituximab plus MCP remains to be significantly superior to MCP alone: after a median follow-up of now 5 years we can demonstrate that an improvement in induction treatment (CR-rate doubled) results in a highly significant advantage concerning survival parameters: PFS and EFS as well are doubled and OS is clinically and statistically superior too.

CELL OF ORIGIN INFLUENCES LEUKEMIA STEM CELL PHENOTYPE

V Krivtsov,[1] C Stubbs,[1] U Sinha,[1] J Wang,[1] L Bullinger,[1] L Kung,[2] A Armstrong[1]

[1]Children's Hospital, Boston, USA; [2]Dana Farber Cancer Institute, Boston, USA

MLL-fusion proteins can transform either hematopoietic stem cells (HSC) or granulocyte macrophage progenitors (GMP) into leukemia stem cells (LSC). We hypothesized that different cells of origin would generate LSC with different properties. First, we assessed kinetics of AML development through introduction of MLL-AF9 into HSC or GMP isolated from mice that express luciferase under control of the ubiquitin promoter. The expansion of leukemias was monitored using *in vivo* bioluminescent imaging at multiple time points after transplantation. We observed almost linear kinetics of accumulation of leukemic cells when AML was initiated from 3×10^3 Lin-Kit+sca1+ cells, and there was a 3 to 4-week delay in accumulation of leukemic cells when AML was initiated from GMP. To assess leukemic transformation of individual cells we transduced HSC and GMP with MLL-AF9 or control retroviruses, then sorted single-cells expressing MLL-AF9 (GFP+). Both the infected HSC and GMP could be serially replated for over 9 passages. Upon transplantation into syngeneic mice, 86.3% (n=22) of HSC:MLL-AF9 single cell derived clones (SCC) induced AML with a median latency of 61 days, while 33.3% of GMP:MLL-AF9 SCC induced AMLs with median latency of 100 days. Given the apparent increased aggressiveness of HSC-derived leukemias we assessed drug response. Treatment with Etoposide reduced the spleen weights in mice transplanted with HSC-derived AML to a lesser extent (28%) than in mice transplanted with GMP-derived AML (88%) suggesting the cell of origin influences drug response. Immunophenotype analysis of the resultant leukemias demonstrated that long-term repopulating HSC and GMP-derived leukemias were quite similar, with a GMP-like (LGMP) population enriched for LSC in both cases. Gene expression analysis demonstrated that globally the LGMP isolated from HSC derived AML and from GMP derived AML were similar to each other, but possessed specific gene expression programs reminiscent of their cell of origin (HSC or GMP). For example Evi1, Jun, Jund, and Fos oncogenes were highly expressed in HSC and the AML that arose from HSC, but were expressed at low levels in GMP or the AML that arose from GMP. The gene expression program that distinguished LGMP-HSC from LGMP-GMP was found to correlate with a gene expression program in human MLL-rearranged AML associated with a poor clinical outcome in three independent MLL-rearranged AML data sets. Computational modeling of activated signaling pathways predicted the Wnt/Ctnnb1 pathway is more active in LSC arising from HSC than those that arose from GMP. Additionally, Ctnnb1 target genes were expressed at higher levels in LSC originating from HSC, and Ctnnb1 reporter activity was higher in MLL-AF9 transformed HSC as compared to MLL-AF9 transformed GMP. Finally, western blotting analysis demonstrated higher levels of Ctnnb1 in LSC originating from HSC than those originating from GMP. Altogether, these data indicate that the cell of origin of AML can influence the genetic program of the fully developed LSC, and thus might account for some of the heterogeneity in human leukemias and their clinical outcome. Furthermore, suppression of Ctnnb1 might be a rational approach in AML.

DEVELOPMENT OF A MOUSE MODEL OF ONCOGENIC COOPERATION IN DS-AML AND IDENTIFICATION OF HUMAN CHROMOSOME 21 GENES THAT FACILITATE LEUKEMOGENESIS

S Malinge

Northwestern University, Chicago, USA

Background. Children with Down syndrome (DS) have a 500-fold increased risk of Acute Megakaryoblastic Leukemia (DS-AMKL). In addition to trisomy 21, DS-AMKL blasts typically harbor somatic mutations in the gene encoding GATA-1, an essential transcriptional regulator of erythroid and megakaryocytic differentiation. In every case, the GATA1 mutations lead to a block in expression of the full-length protein, but allow for translation of a shortened isoform named GATA-1s, which lacks the N-terminal transcriptional activation domain. Recent studies have shown that genetic abnormalities affecting JAK2, JAK3 and MPL, which lead to constitutive activation of JAK/STAT pathway, is another feature of AMKL. *Aims.* Whereas the impact of genetic mutations in GATA1, JAK2 and MPL is relatively well known, the specific effects of trisomy 21, the initiating event in DS leukemogenesis, is still under investigation. Here, we used two different models of DS-AMKL to identify specific genes on human chromosome 21 (Hsa21) that participate in leukemogenesis: human DS-AMKL cell lines and the Ts1Rhr mouse strain, which is trisomic for only 33 orthologs of Hsa21 genes. *Methods.* We comprehensively analyzed hematopoiesis in progressively more complex models of DS-AMKL: this included Ts1Rhr mice, Ts1Rhr/Gata-1s mutant mice, and recipients of Ts1Rhr/Gata-1s/ hematopoietic progenitors expressing MPL W515L. In parallel, we performed a shRNA screen in the CMY and CMK DS-AMKL cell lines to identify specific Hsa21 genes implicated in megakaryocyte proliferation, survival and/or differentiation. Genes identified in this screen were then evaluated for expression and activity in our *in vivo* model of DS-AMKL. *Results.* Ts1Rhr mice develop a progressive myeloproliferative disease characterized by a thrombocytosis, increased number of megakaryocytes, extramedullary hematopoiesis and alterations in the HSC/progenitor compartment. By breeding Ts1Rhr mice with Gata1s knock-in mice, we discovered that Gata-1s expression transiently cooperates with the trisomy to induce a prolonged thrombocytosis. However these double transgenic mice failed to develop AMKL. Next we overexpressed the MPL W515L mutant in Ts1Rhr/Gata-1s hematopoietic progenitors and transplanted these cells to lethally irradiated recipients. We observed rapid development of a fatal megakaryocytic disorder that was accompanied by profound marrow myelofibrosis and the presence of immature megakaryoblasts. Of note, expression of MPL W515L in either Ts1Rhr or Gata-1s alone failed to cause a similar disease. Thus, these 3 genetic events are necessary and sufficient for AMKL *in vivo*. Analysis of candidate genes that were selected from our human CMY and CMK cell line screening revealed that ERG, DYRK1A, CHAF1B and HLCS likely all play a role in etiology of DS-AMKL. *Summary*. Here we report that the partially trisomic Ts1Rhr mice display progressive alterations of the megakaryocytic compartment, that mutagenesis of Gata1 in the Ts1Rhr background exacerbates the phenotype, and that combining mutant Gata-1, trisomy for Hsa21 orthologs and an activating mutation of MPL leads to a fulminant megakaryocytic leukemia with myelofibrosis. Moreover, we identify four Hsa21 genes that are required for the phenotype of human megakaryocytic cell lines that also function in the murine AMKL model, emphasizing a likely role of those genes in predisposition to DS-AMKL.

0578

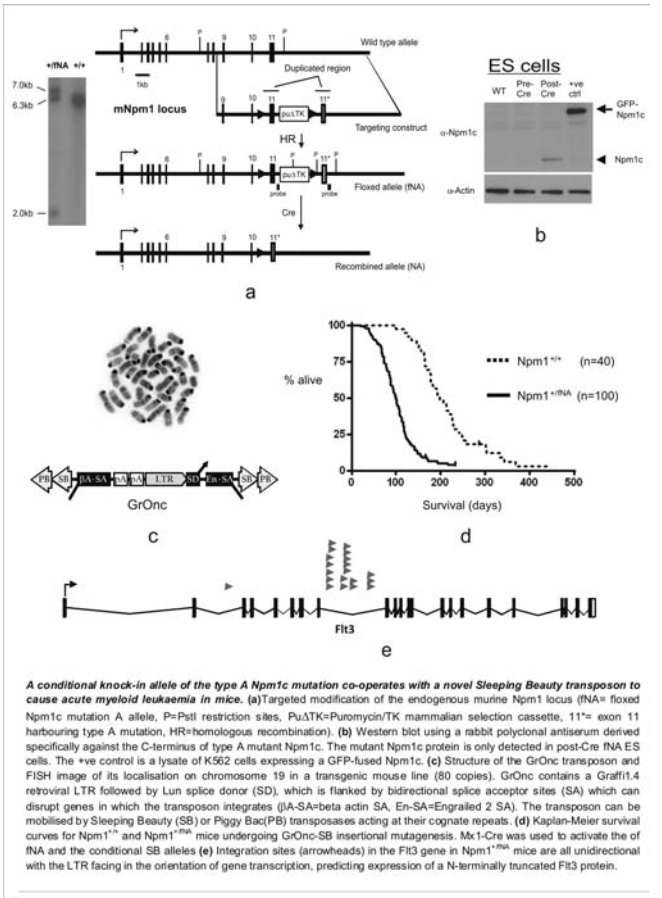
A CONDITIONAL KNOCK-IN ALLELE OF THE TYPE A CYTOPLASMIC NUCLEOPHOSMIN MUTATION COOPERATES WITH A NOVEL SLEEPING BEAUTY TRANSPOSON TO CAUSE ACUTE MYELOID LEUKAEMIA IN MICE

G Vassiliou,[1] J Cooper,[1] R Rad,[1] S Rice,[1] M Arends,[2] P Wright,[2] L Rad,[1] R Banerjee,[1] K Yusa,[1] P Ellis,[1] C Grove,[1] A Uren,[3] B Huntly,[4] D Adams,[1] J Li,[4] A Bradley[1]

[1]Wellcome Trust Sanger Institute, Cambridge, UK; [2]Department of Pathology, University of Cambridge, Cambridge, UK; [3]Netherlands Cancer Institute, Amsterdam, Netherlands; [4]Department of Haematology, University of Cambridge, Cambridge, UK

Mutations in the gene for nucleo-cytoplasmic shuttle protein Nucleophosmin (NPM1) are found in up to 60% of acute myeloid leukaemia (AML) with normal karyotype. Nearly all such mutations occur within the last exon of the NPM1 gene and are associated with aberrant localisation of NPM1 protein to the cytoplasm (NPM1c mutations). However, the mechanism through which NPM1 mutations cause AML remains unknown. To address this, we generated a conditional knock-in mouse model of type A mutation which represents 80% of all human NPM1 mutations. Our floxed allele (Npm1fNA) leaves the native Npm1 locus largely intact, yet enables the expression of mutant Npm1c after Cre-recombination (Figure 1a,b). Heterozygous germline activation of this allele by Cre was universally lethal before embryonic day 8 (Observed 0, Expected 34; P<0.00001). By contrast, heterozygous activation of the allele in the haematopoietic system through the action of Mx1-Cre was associated with an expansion in the bone marrow mature myeloid compartment and increased whole bone marrow serial re-plating ability in methylcellulose assays. Npm1+/fNA, Mx1-Cre double transgenic mice had a significantly increased incidence of acute myeloid and lymphoid leukaemias compared to single transgenic controls (20/43 vs 7/45, p =0.0024). However, Npm1+/fNA leukaemias developed after a median of 493 days (264-802) suggesting that additional mutations are required

for leukaemogenesis. In order to identify genes that can cooperate with Npm1c to cause AML we generated a transgenic mouse line carrying the novel transposon, GrOnc, that can be mobilised by Sleeping Beauty and PiggyBac transposases and can both activate and disrupt genes (Figure 1c). Using Mx1-Cre and a conditional Sleeping Beauty line we performed insertional mutagenesis screens in Npm1+/cNA and in Npm1+/+ mice. Npm1+/+ mice (n=40) developed lymphoid leukaemias/lymphomas after a median of 197 days. By contrast, in Npm1+/cNA mice (n=100), leukaemias were mainly myeloid and their onset was accelerated (median 99 days, P<0.0002). Initial analysis of transposon integration sites from 33 Npm1+/+ and 83 Npm1+/cNA mice, identified common integration sites (CISs) in known and novel cancer genes in both types of mice. Additionally, several CISs were unique to Npm1+/cNA mice including many in genes not previously described to cooperate with Npm1c. Amongst other genes we identified recurrent integrations in Flt3, mutations of which occur frequently in human Npm1c-positive AML, validating this approach and the significance of other loci hit in this screen. In summary, we have developed a novel knock-in mouse model of the type A Npm1c mutation which develops AML with features reminiscent of the human disease. Furthermore, using a novel transposon we have identified known and novel cancer genes that can cooperate with Npm1c to cause AML.



A conditional knock-in allele of the type A Npm1c mutation co-operates with a novel Sleeping Beauty transposon to cause acute myeloid leukaemia in mice. **(a)**Targeted modification of the endogenous murine Npm1 locus (fNA= floxed Npm1c mutation A allele, P=PstI restriction sites, PuΔTK=Puromycin/TK mammalian selection cassette, 11*= exon 11 harbouring type A mutation, HR=homologous recombination). **(b)** Western blot using a rabbit polyclonal antiserum derived specifically against the C-terminus of type A mutant Npm1c. The mutant Npm1c protein is only detected in post-Cre fNA ES cells. The +ve control is a lysate of K562 cells expressing a GFP-fused Npm1c. **(c)** Structure of the GrOnc transposon and FISH image of its localisation on chromosome 19 in a transgenic mouse line (80 copies). GrOnc contains a Graffi1.4 retroviral LTR followed by Lun splice donor (SD), which is flanked by bidirectional splice acceptor sites (SA) which can disrupt genes in which the transposon integrates (βA-SA=beta actin SA, En-SA=Engrailed 2 SA). The transposon can be mobilised by Sleeping Beauty (SB) or Piggy Bac(PB) transposases acting at their cognate repeats. **(d)** Kaplan-Meier survival curves for Npm1$^{+/+}$ and Npm1$^{+/fNA}$ mice undergoing GrOnc-SB insertional mutagenesis. Mx1-Cre was used to activate the of fNA and the conditional SB alleles **(e)** Integration sites (arrowheads) in the Flt3 gene in Npm1$^{+/fNA}$ mice are all unidirectional with the LTR facing in the orientation of gene transcription, predicting expression of a N-terminally truncated Flt3 protein.

Figure 1. Npm1c cooperates with Sleeping Beauty to cause AML.

MEIS1 CONTROLS SUSCEPTIBILITY TO MN1-INDUCED LEUKEMIC TRANSFORMATION

M Heuser,[1] H Yun,[1] B Argiropoulos,[2] E Yung,[2] F Kuchenbauer,[3] G Park,[2] C Lai,[2] M Leung,[2] G Lin,[2] I Hamwi,[1] N Thiessen,[2] G Robertson,[2] M Hirst,[2] M Marra,[2] A Ganser,[1] R Humphries[2]

[1]Hannover Medical School, Hannover, Germany; [2]British Columbia Cancer Agency, Vancouver, Canada; [3]University Hospital of Ulm, Ulm, Germany

Background. Leukemia stem cells have been identified in human acute myeloid leukemia and several mouse leukemia models by prospective isolation of phenotypically characterized cells. It has become clear that the phenotype of leukemia stem cells does not necessarily reflect the cell of origin in which the transforming events occurred. For several oncogenes it has been shown that a spectrum of hematopoietic stem and progenitor cells rather than a specific lineage can be transformed. *Aims.* We evaluated which normal hematopoietic cell might be the cell of origin in MN1-induced leukemias, and which genetic factors might influence permissiveness to transformation. *Methods.* We employed retroviral infection of single sorted hematopoietic progenitor cells, colony-forming cell (CFC) and mouse bone marrow transplantation assays, gene expression profiling, and chromatin-immunoprecipitation (ChIP) sequencing. We found that (1) common myeloid progenitors (CMP), but not granulocyte-macrophage progenitors (GMP) can be transformed by MN1, (2) GMP transformation can be achieved by cotransduction of MN1 and MEIS1, (3) MN1 and MEIS1 co-regulate a large set of putative direct target genes, and (4) transcriptional repression of MEIS1 target sites by a M33-MEIS1 fusion protein prevents MN1-induced transformation. *Results.* Retroviral infection of single cell-sorted common-myeloid (CMP) and granulocyte-macrophage progenitors (GMP) with MN1 demonstrated that CMPs (n=16) but not GMPs (n=11) could be transformed by MN1 as evidenced by the capacity to serially replate in CFC assays and to induce leukemia in mice (P<.001). Moreover, bulk infections of up to 4000 GMPs with MN1 did not transform these cells. To identify pathways explaining the differences in transformation susceptibility between CMPs and GMPs, we compared gene expression profiles of MN1 leukemias, normal CMPs, and normal GMPs. FLT3, MEIS1, and HOXA10 were upregulated in MN1 leukemias and CMPs, but downregulated in GMPs. None of these factors could transform GMPs *in vitro* when co-infected with a control gene. However, GMPs were readily transformed by co-infection of GMPs with MN1 and MEIS1, but not FLT3, as evidenced by the ability to undergo more than 10 serial replatings in CFC assays. To further elucidate the mechanism of MEIS1-dependent transformation susceptibility of GMPs, we employed next-generation sequencing of chromatin immunoprecipitates and gene expression profiling of MN1 and MEIS1 to identify shared chromatin targets and genes coregulated by MN1 and MEIS1. Sixteen percent of MN1 targets overlapped with MEIS1 targets. We thus hypothesized that the transforming potential of MN1 relies on the transcriptional activity of MEIS1, and evaluated the leukemogenic potential of MN1 when coexpressed with a dominant negative form of MEIS1. Strikingly, coexpression of M33-MEIS1 in MN1 expressing cells prevented leukemic outgrowth of double transduced cells *in vivo*. *Conclusions.* Our data identify transcriptional states that determine transformation susceptibility of hematopoietic progenitor cells, and highlight the interactions of oncogene and susceptible cell. The requirement of MEIS1 as a cooperating gene in many different leukemia models reported previously highlights the importance of developing novel therapeutic strategies which target MEIS1 in leukemia.

EXPRESSION OF THE CYTOPLASMIC NPM1 MUTANT (NPMC+) CAUSES THE EXPANSION OF HEMATOPOIETIC CELLS IN ZEBRAFISH

N Bolli,[1] E Payne,[1] A Johnston,[1] C Grabher,[2] B Falini,[3] J Kanki,[1] T Look[1]

[1]Dana-Farber Cancer Institute, Boston, USA; [2]Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany; [3]Istituto di Ematologia, Universita' di perugia, Perugia, Italy

Mutations in the human nucleophosmin (NPM1) gene are the most frequent genetic alteration in adult acute myeloid leukemia (AML) and result in aberrant translocation of this nucleolar phosphoprotein to cytoplasm (NPMc+). However, the underlying mechanisms leading to leukemogenesis remain unknown. To address this issue, we took advantage of the zebrafish model organism, which is characterized by rapid, external embryonic development and conserved primitive and definitive hematopoiesis. Perturbation of zebrafish hematopoiesis can be studied upon transient gene knock-down or overexpression through injection of antisense oligonucleotides (morpholinos) or mRNA, respectively. We found that zebrafish express two npm1 genes, both highly similar and orthologous to human NPM1, referred to as npm1a and npm1b. Both genes are ubiquitous and knock-down of each gene produces a reduction in myeloid cell numbers as shown by anti-mpx whole mount *in situ* hybridization (WISH). This effect is synergistic when both genes are knocked down, suggesting partial redundancy in their functions. Importantly, the reduction in myeloid cell number is specifically rescued by NPM1 expression, indicating functional conservation of NPM1 in zebrafish. When expressed in zebrafish, wild-type human NPM1 is nucleolar and NPMc$^+$ is cytoplasmic by confocal microscope analysis, as in human AML. Co-immunoprecipitation studies show that both forms of NPM1 interact with endogenous zebrafish Npm1a and Npm1b. Importantly, NPMc$^+$ dislocates both Npm1 proteins to the cytoplasm, as in human AML. Taken together, these data provide a strong rationale for testing the consequences of NPMc+ expression in the developing hematopoietic system of zebrafish embryos. WISH and FACS analysis in the Tg(pu.1:EGFP) transgenic line showed that the forced expression of NPMc$^+$ in zebrafish causes an increase in pu.1-positive primitive myeloid precursors at 19 hpf but not in mature mpx-positive and csf1r-positive myeloid cells at 24 hpf because of a p53-dependent apoptotic cell death response. In p53m/m embryos expressing NPMc+ no cleavage of caspase-3 is seen, and all three markers of primitive hematopoiesis show increased numbers of stained cells by WISH. We also investigated whether NPMc$^+$ expression results in perturbation of definitive hematopoiesis. To this end, we analyzed the number of hematopoietic stem cells (HSCs) in the ventral wall of the aorta, an hematopoietic site corresponding to the mouse Aorta Gonad Mesonephros, and the numbers of transient erythromieloid progenitors (EMPs) in the posterior blood island (PBI). Importantly, upon NPMc+ expression, increased numbers of c-myb-positive and cd41-positive cells were observed in the ventral wall of the aorta both in the presence and absence of a functional p53, suggesting that HSC number is increased. These results were confirmed by WISH, FACS and confocal analysis in the Tg(c-myb:EGFP) and in the Tg(cd41:EGFP) zebrafish lines. Furthermore, an expansion of EMPs was also noted, as shown by increased numbers of gata1$^+$/lmo2BRIGHT cell in the PBI by FACS and confocal microscope analysis. These results are highly relevant to human AML, where NPMc$^+$ is expressed in leukemia-initiating cells and in all myeloid lineages arising from the leukemic clone. The zebrafish model will thus provide an invaluable platform to dissect the developmental and cellular pathways affected by NPMc$^+$ expression.

Chronic myeloid leukemia - Biology

ISOLATION AND KILLING OF CANDIDATE CML STEM CELLS BY ANTIBODY TARGETING OF IL1RAP

M Järås,[1] P Johnels,[1] N Hansen,[1] H Ågerstam,[1] M Rissler,[1] C Lassen,[1] T Olofsson,[1] O Bjerrum,[2] J Richter,[1] T Fioretos[1]

[1]Lund University, Lund, Sweden; [2]University of Copenhagen, Copenhagen, Denmark

Therapeutic strategies aiming for a permanent cure of chronic myeloid leukemia (CML) will require full eradication of Philadelphia chromosome positive (Ph+) CML stem cells. One such strategy is an antibody-based therapy directly targeting CML stem cells, in which the antibody mode of action is independent of the known resistance mechanisms causing CML stem cells to be unresponsive to tyrosine kinase inhibitor treatment. The major limitations for such developments have so far been the lack of a cell surface receptor distinguishing Ph$^+$ from Ph- CML stem cells. Here we used gene expression profiling to identify Interleukin 1 Receptor Accessory Protein (IL1RAP) as upregulated in CML CD34$^+$ cells and also in cord blood (CB) CD34$^+$ cells as a consequence of retroviral BCR/ABL1 expression. In agreement with the microarray gene expression data, we confirmed by FACS analysis that the IL1RAP protein indeed becomes upregulated on the cell surface of CB CD34$^+$ cells following retroviral P210 BCR/ABL1 expression. In the CML CD34$^+$CD38$^-$ population, containing both Ph$^+$ and Ph$^-$ CML stem cells, two populations of cells were identified: one exhibiting low/absent IL1RAP expression, and the other having higher IL1RAP expression. The IL1RAP-positive cell fraction constituted between 75% and 95% of the CML CD34$^+$CD38$^-$ cells (n=5), representing about one cell in 1,300 mononuclear cells. The more rare CD34$^+$CD38$^-$IL1RAP$^-$ cells represented only about one cell in 11,000 mononuclear cells. To test whether IL1RAP expression distinguishes normal (Ph$^-$) and leukemic (Ph$^+$) cells within the CML CD34$^+$CD38$^-$ cell compartment, we established a new protocol for conducting FISH on small numbers of sorted cells. By using this method, referred to as Flow-drop-FISH, we sorted cells directly into drops on slides to investigate their Ph-chromosome status. Interestingly, we found that the CML CD34$^+$CD38$^-$IL1RAP$^+$ cells were Ph$^+$ (99.9±0.2% Ph$^+$, n=5), whereas CML CD34$^+$CD38-IL1RAP- cells were almost exclusively Ph- (97.1±3.4% Ph-, n=5). By performing long-term culture-initiating cell assays on the two cell populations, we found that Ph+ and Ph- candidate CML stem cells could be prospectively separated. To test whether antibody-dependent cell-mediated cytotoxicity (ADCC) could be achieved using IL1RAP as a target, we generated a polyclonal anti-IL1RAP antibody. By using this antibody, we were able to provide proof of concept that IL1RAP can be used as a target on CD34$^+$CD38$^-$ candidate CML stem cells to induce cell death through ADCC in an NK-cell dependent manner. In summary, this study thus identifies IL1RAP as the first cell surface biomarker distinguishing Ph$^+$ from Ph$^-$ candidate CML stem cells and opens up a new avenue for exploring diagnostic and therapeutic strategies in CML.

WHOLE-TRANSCRIPTOME SEQUENCING IN CHRONIC MYELOID LEUKEMIA AT DIAGNOSIS AND AT THE TIME OF PROGRESSION TO BLAST CRISIS REVEALS NOVEL GENE MUTATIONS

S Soverini,[1] A Poerio,[1] A Ferrarini,[2] I Iacobucci,[1] M Sazzini,[3] E Giacomelli,[2] L Xumerle,[2] S Colarossi,[1] A Gnani,[1] F Castagnetti,[1] F Palandri,[1] G Gugliotta,[1] M Amabile,[1] G Rosti,[1] M Baccarani,[1] M Delledonne,[2] G Martinelli[1]

[1]University of Bologna, Bologna, Italy; [2]Department of Biotechnology, University of Verona, Verona, Italy; [3]Department of Experimental and Evolutionary Biology, University of Bologna, Bologna, Italy

Background. Philadelphia-positive (Ph$^+$) chronic myeloid leukemia (CML) is generally regarded as a genetically heterogeneous disease and therapy with Bcr-Abl inhibitors results in high response rates. Nevertheless, resistance may develop, especially in high Sokal risk patients, and progression to BC still represents a major concern. *Aims.* To perform a qualitative and quantitative survey of the whole transcriptome of Ph$^+$ CML cells at diagnosis and at progression in order to shed further light on the biological bases underlying high risk, as well as on the determinants of BC. *Methods.* We used massively parallel sequencing on a Solexa

Illumina Genome Analyzer to scan the transcriptome of a CML patient at the time of diagnosis, at the time of remission (major molecular response) and at the time of progression from chronic phase (CP) to lymphoid blast crisis (BC). Both custom scripts and published algorithms were used for read alignment against the human reference genome, for single nucleotide variant (SNV) calling, for identification of alternative splicings and fusion transcripts, and for digital gene expression profiling. Sanger sequencing was used for validation and for further screening of a preliminary additional subset of 10 CP CML patients at diagnosis (4 low, 3 intermediate and 3 high Sokal risk) and 10 BC CML patients. *Results.* Comparison of the SNVs identified in the diagnosis and relapse samples with the SNVs detected in the remission sample - representing inherited sequence variants not specific for the Ph+ clone - allowed the identification of nine missense mutations at diagnosis affecting the coding sequence of AMPD3, SUCNR1, FANCD2, INCENP, BSPRY, ZWILCH, HEXDC, KIAA2018 and NUDT9 genes. Six of these mutations (FANCD2, INCENP, BSPRY, ZWILCH, HEXDC, NUDT9) were also detected in the Ph^+ clone re-emerged at the time of disease progression, together with six additional missense mutations affecting the coding sequence of IDH2, DECR1, C4Orf14, MRM1, PRKD2 and TCHP genes. Mutations of isocitrate dehydrogenase 1 and 2 enzyme isoforms (IDH1, IDH2), including the same R140Q found in our study, have recently been reported in in some *de novo* acute myeloid leukemias and in patients with leukemia evolved from a Philadelphia-negative (Ph-) chronic myeloproliferative disease, suggesting that they can be associated with leukemic progression to acute phase both in Ph- and in Ph+ neoplasms. AMPD3 (encoding adenosine monophosphate deaminase 3) and KIAA2018 (encoding a protein with predicted DNA binding and transcriptional regulation activity) genes were found to harbour the same point mutations in 1 out of the 3 additional high Sokal risk patients analyzed. Moreover, the same MRM1 (mitochondrial rRNA methyltransferase 1) mutation detected at the time of progression was found in 3/10 additional BC patient patients analyzed. Digital gene expression profiling and chimeric or alternatively spliced transcripts will also be presented. *Summary*. Our preliminary data highlighted putative key genes whose deregulation may be recurrent in a subset of CML patients and may be linked to disease pathogenesis or progression. Further investigations in a larger series of patients are ongoing.

HIGH-RESOLUTION GENOME-WIDE ANALYSIS OF COPY NUMBER ALTERATIONS/LOSS OF HETEROZIGOSITY IN CHRONIC MYELOID LEUKEMIA SHOWS THAT HIGH SOKAL RISK PATIENTS HAVE MULTIPLE LOSSES TARGETING DNA REPAIR GENES

S Soverini,[1] S Colarossi,[1] A Gnani,[1] A Astolfi,[2] S Formica,[2] F Castagnetti,[1] F Palandri,[1] G Gugliotta,[1] G Rosti,[1] A Poerio,[1] I Iacobucci,[1] M Amabile,[1] G Marzocchi,[1] S Luatti,[1] S Durante,[1] C Terragna,[1] N Testoni,[1] M Baccarani,[1] G Martinelli[1]

Background. Chronic myeloid leukemia (CML) patients (pts) display a certain degree of clinical heterogeneity that is documented by the varying levels of response to tyrosine kinase inhibitors and is best reflected by the Sokal risk score. Clinical differences must reflect a biological heterogeneity the bases of which are still poorly understood. *Aims.* To perform a genome-wide scan of newly diagnosed CML pts looking for submicroscopic genetic alterations and uniparental disomy targeting key cellular genes. *Methods.* We have used Human 6.0 SNP Arrays (Affymetrix) to perform high-resolution (<1 kb) karyotyping of DNA samples from 73 newly diagnosed chronic phase CML pts. *Results.* Of 189 genes known to be implicated in the cellular DNA repair pathways, 135 (71%) were found to map in regions affected by CNAs or copy-neutral LOH (uniparental disomy, UPD) in 44/73 (60%) pts. However, this was markedly more frequent in high and intermediate Sokal risk pts (20/27, 74% and 16/23, 69%, respectively) than in low Sokal risk pts (8/23, 33%), although neither the total number of detected regions of CNAs/UPD per sample nor the quality control parameters differed significantly across different risk categories. Regions of CNA involving DNA repair genes ranged from 105 Kb to 1.1 Mb and were either focal lesions involving a part or the whole single gene (17% of cases), or more extensive losses/gains including 2 to 84 genes. Monoallelic deletions were much more frequent than amplifications. Regions of UPD involving DNA repair genes were much larger and ranged from 980 kb to 32 Mb. The pathways and genes most frequently affected by CNAs or UPD were: a) Base Excision Repair: MUTYH (loss or UPD, 10 pts); PNKP (loss, 10 pts); NEIL1 (loss, 7 pts); b) Mismatch Repair: PMS2L5 (loss or UPD, 11 pts), MSH2 (loss, 8 pts), POLD1 (loss, 8 pts); c) Nucleotide Excision Repair: ERCC1 (loss, 11 pts), ERCC2 (loss, 10 pts), XAB2 (loss, 9 pts); d) Homologous Recombination: RAD51C (loss or UPD, 7 pts), RAD52 (loss, 7 pts); e) Non-Homologous End-Joining: DCLRE1C (Artemis; loss, 6 pts); REV7 (gain, 6 pts). For some genes (e.g., RAD52), the monoallelic deletion was found to translate into reduced mRNA expression, observation that was also independently confirmed in an additional group of high/intermediate versus low Sokal risk pts. In all the 44 pts, multiple pathways and multiple genes within the same pathway were affected, supporting the hypothesis that the lesions we detected might actually have consequences on DNA integrity despite the known partial functional redundancy of pathways and effectors. *Summary.* We have identified a series of alterations that might result in a perturbation of DNA repair systems in high Sokal risk CML pts. For many of the genes identified in this screen, activating or inactivating mutations are known to occur, and together with overexpression or haploinsufficiency, have been linked to a mutator phenotype in several malignant conditions. We are currently investigating whether this may be the case also in CML. Supported by European LeukemiaNet, AIL, AIRC, PRIN, Fondazione del Monte di Bologna e Ravenna.

DISSECTING MOLECULAR BASES OF HIGH SOKAL VERSUS LOW SOKAL RISK IN CHRONIC MYELOID LEUKEMIA PATIENTS BY GENE EXPRESSION PROFILES OF CD34+ CELLS AT DIAGNOSIS

C Terragna,[1] S Durante,[1] A Astolfi,[1] F Palandri,[1] F Castagnetti,[1] N Testoni,[1] I Iacobucci,[1] S Soverini,[1] M Amabile,[1] A Poerio,[1] G Alimena,[2] M Breccia,[2] F Pane,[3] G Saglio,[4] G Rosti,[1] M Baccarani,[1] G Martinelli[1]

Background. CML is a clonal myeloproliferative disease which typically presents in chronic phase (CP), in which malignant progenitor cells proliferate rapidly, still retaining their ability to differentiate, with the disease later evolving to accelerated phase/blast crisis. Even after the introduction of imatinib, the calculation of the Sokal and the Euro prognostic scores has remained essential in clinical practice, since allow to stratify CML patients at different evolutive risk at diagnosis, guiding therapeutic decisions. More recently, numerous research efforts, (which use high-throughput molecular approaches) are ongoing to gain a better understanding about the intrinsic heterogeneity of CML. *Aim.* Here we present data obtained from gene expression profiling (GEP) experiments aimed at the identification of genes and pathways able to discriminate between high vs. low Sokal risk patients at diagnosis and predict the disease course of CP-CML pts at the onset of the disease. *Patients and Methods.* Highly enriched $CD34^+$ cells from peripheral blood were obtained from 107 patients with untreated CML in CP and enrolled in GIMEMA CML WP protocols. Overall, 34 patients were included in the GEP analysis. GEP was performed using the Affymetrix HG-U133 Plus 2.0 platform. Raw data was normalized using the RMA algorithm and filtered. Genes associated with Sokal risk score were selected by a moderated t-statistic (Limma package, P threshold=0.05). *Results.* We showed that 576 genes were differentially expressed between high vs. low Sokal risk patients (P=0.05). Clustering of their expression profiles showed an homogeneous pattern in high Sokal risk patients, where up-regulated genes are mainly related to the glutathione metabolism, the "intrinsic"Wnt signaling (e.g. WNT6, 4E-BP1, ADCY9) and the response to hypoxia and oxidative stress (e.g. GSMT3, GSTT1, GPX1), whereas down-regulated genes are mainly involved in the negative regulation of "extrinsic"pathway of Wnt signaling (e.g. RBX1ligase, Tcf, CSKN1A and TCF7L2). In the second part of the study, the most significant genes were validated by Real-time PCR in a test set of CD34+ cell fraction obtained from 73 newly diagnosed patients. Moreover, the expression of the set of genes related to high or low Sokal risk score has been also evaluated on peripheral blood samples obtained from a different cohort of 100 newly diagnosed CML patients (30 high and 70 low Sokal risk), thus showing a similar pattern of expression of these genes. *Conclusions.* Overall, our data suggests that the expression at diagnosis of a particular array of genes might drive the evolutive risk of CML patients.

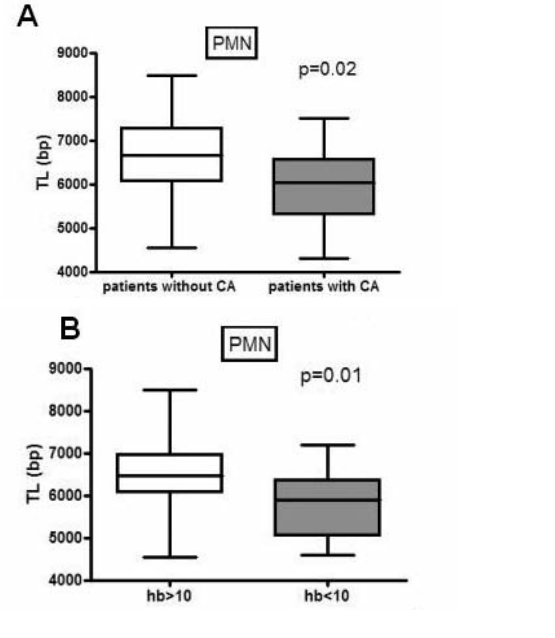
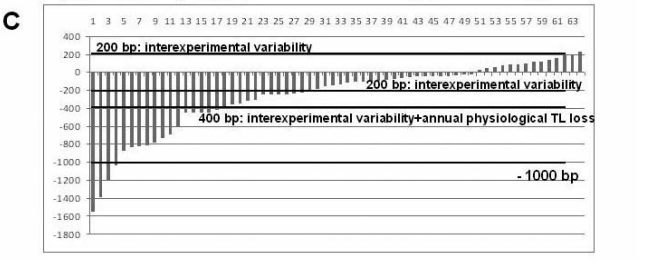
Background and Aims. Telomere attrition represents a useful marker of proliferative and oxidative stress and provide useful insights to monitor the genetic integrity of the hematopoietic compartment. This approach has been used to assess the genetic integrity of Ph-negative hematopoietic cells (HCs) repopulating the bone marrow after successful chronic myeloid leukemia (CML) treatment.





Patients and Methods. We investigated 81 CML patients with persistent (≥12 months) complete cytogenetic remission (CCR). Median age was 62 (23-88), M/F ratio was 1.5. Median time from diagnosis and CCR were 54 months (25-217) and 37 months (12-191) respectively. Fifteen patients had acquired cytogenetic abnormalities (CA) (del7: 4 patients, +8: 5 patients, del5q: 2 patients, del or +Y: 2 patients, other CA 2 patients). Telomere length (TL) analysis was performed by Southern Blotting on polymorphonucleates (PMN) and on monocyte-depleted PBMC (MD-PBMC) to monitor the myeloid and lymphoid compartments. Two age-matched control groups were used: a) 109 healthy subjects; b) 20 patients receiving imatinib for a gastrointestinal stromal tumor (GIST) (to investigate treatment-related effects on TL). Prospective follow-up monitoring of TL was performed on 64 patients (median time 11 months, range 6-20). *Results.* PMN (but not MD-PBMC) from CML patients showed a major erosion of their telomeric DNA (median loss 1294 bp P<0.001). Telomere attrition appeared to be CML-specific as GIST patients had a TL not significantly different from healthy subjects with a median TL of 7152 (P=1). A multivariate general linear model (GLM) was applied on CML patients and controls: CML and age were predictors of telomeric attrition (both P<0.001), while sex and GIST history had no significant impact (P=0.6 and 0.8 respectively). We then analyzed whether clinical and biological features of CML patients were predictive of telomere attrition. We found no association with sex, Sokal score, molecular remission or treatment schedule. Of note, we found increased telomere attrition and acquired CA compared to CML patients without CA (P<0.030, Figure 1A). When a multivariate model was applied to the CML series only age and CA were predictors of telomeric damage (P=0.013 and 0.001 respectively). When telomere shortening was correlated to hematopoietic function we found no association with WBC or platelets level. However we found an association between telomere shortening and severe anemia (Hb<10 gr/dL, P=0.003) (Figure 1B). TL was substantially stable overtime in the majority of patients. In none of the patients TL recovery overtime was observed. However in 16 (25%) patients a non-physiological telomeric loss was noticed (Figure 1C). *Conclusions.* I) Ph-negative HCs display severe telomeric loss, compared to healthy controls and CML-free subjects treated with imatinib; II) telomere erosion is more pronounced in patients with CA; III) an association between short telomeres and anemia was observed; IV) telomere loss is persistent and potentially worsening in a subset of cases. Our results suggest that Ph-negative hematopoiesis in CML patients has undergone significant genetic damage and warrants careful clinical monitoring.

UBIQUITINATION OF THE ERYTHROPOIETIN RECEPTOR IS NOT REQUIRED FOR EPO-INDUCED INTERNALIZATION BUT IS IMPORTANT FOR ENDO-LYSOSOMAL SORTING AND DOWN-REGULATION

J Huang, R Sulahian, G Bulut

University of Texas Southwestern Medical Center, Dallas, TX, USA

Background. Erythropoietin (Epo) is the primary cytokine controlling red blood cell production and its function is mediated through the Epo receptor (EpoR). Epo binding to the EpoR initiates signaling cascades that result in the survival, proliferation, and differentiation of erythroid progenitor cells. Following Epo binding, cell surface EpoRs are rapidly internalized and are subsequently degraded intracellularly. Down-regulation of the EpoR critically controls the amplitude and duration of Epo signaling. It was shown that EpoR is ubiquitinated upon Epo stimulation and the E3 ubiquitin ligase β-TrCP (β-transducin repeat-containing protein) inducibly binds the EpoR cytoplasmic domain upon stimulation. Mutation of the predicted β-TrCP recognition motif in the EpoR abolished β-TrCP binding and blocked EpoR ubiquitination and degradation. However, the exact process(es) in receptor down-regulation controlled by ubiquitination are not entirely understood. *Aims*. We aimed to examine the role of EpoR ubiquitination in receptor internalization, endosomal-lysosomal targeting and degradation. *Methods and Results*. We engineered a mutant receptor that is unable to be ubiquitinated, in which all five EpoR cytosolic lysines were replaced with arginines. Although this lysineless receptor (AllKR) was not ubiquitinated upon Epo stimulation, it internalized similarly to wild-type EpoR. In addition, fusion of (mono)ubiquitin to the wild-type EpoR cytoplasmic domain did not trigger receptor internalization. Therefore, EpoR ubiquitination is not necessary or sufficient for ligand-induced EpoR internalization. The fate of EpoRs upon Epo induction was examined by confocal immuno-fluorescence microscopy. 25 min post Epo treatment, HA-tagged wild-type EpoRs shifted from the plasma membrane to an internal compartment that co-localizes with the early endosomal marker, EEA1 (early endosome antigen 1). At 35 min post Epo stimulation, EpoR co-localized with the lysosomal-associated membrane protein 2 (LAMP2). In contrast, HA-tagged AllKRs co-localized with EEA1 25 min post Epo stimulation but were not efficiently sorted to the lysosome, as few receptors co-localized with LAMP2 35 min post Epo treatment. Consistently, Epo-induced degradation of AllKR was dramatically impaired. Therefore, EpoR ubiquitination is not required for internalization but is important for endo-lysosomal sorting and down-regulation. To identify the EpoR lysine residue(s) that are ubiquitinated upon Epo stimulation, we examined mutated receptors in which individual lysine was replaced with arginine. Ligand-induced degradation was defective in K428R, while other lysine mutants behaved normally. Importantly, receptor ubiquitination and normal degradation were restored in cells where K428 was re-established on the lysineless receptor, indicating that K428 may be the major target of ubiquitination. *Conclusion.* We show in this work that ubiquitination of the EpoR itself is not required for internalization but is important for endo-lysosomal sorting and receptor down-regulation upon stimulation.

A NOVEL APPROACH TO CELL-TARGETED COMPLEMENT INHIBITION IN PNH: THE HUMAN COMPLEMENT RECEPTOR 2/FACTOR H FUSION PROTEIN TT30 PREVENTS BOTH HEMOLYSIS AND UPSTREAM C3-OPSONIZATION OF PNH ERYTHROCYTES

C Pascariello,[1] C Selleri,[1] L Del Vecchio,[1] M Sica,[2] C Horvath,[3] M Holers,[3] L Luzzatto,[2] A Risitano[1]

[1]*Department of Biochemistry and Medical Biotechnologies, Federico II University, Naples, Italy;* [2]*Core Research Laboratory - Istituto Toscano Tumori, Florence, Italy;* [3]*Taligen Therapeutics, Cambridge, USA*

Background. In paroxysmal nocturnal hemoglobinuria (PNH) severe hemolytic anemia results from the fact that spontaneous complement alternative pathway (CAP)-activation fails to be controlled, because affected RBCs are deficient in CD55 and CD59. Eculizumab has proven highly effective in controlling MAC-mediated intravascular hemolysis (IVH); however, we have recently reported that its hematological benefit may be limited by the emergence of C3-mediated extravascular hemolysis (EVH). TT30 is a recombinant human fusion protein consisting of (a) the iC3b/C3d-binding region of C receptor 2 (CR2) and (b) the inhibitory domain of the CAP regulator factor H (fH). The resulting molecule is a novel CAP inhibitor, based on the notion that the CR2 component will localize the molecule specifically to target cells on which C-activation is taking place; whereas the fH component will help to control CAP activity.*Aims.* To investigate whether TT30 can protect PNH RBCs from hemolysis and can prevent their C3-fragments (C3frag)-opsonization after C-activation. *Methods.* We have incubated washed RBCs from PNH patients with ABO-matched sera from healthy volunteers, and activated the CAP by acidification. These conditions allow us to monitor not only the terminal C pathway responsible for hemolysis, but also the early C-activation responsible for C3frag-opsonization of RBCs. Both hemolysis and RBC C3frag-opsonization were serially measured by flow-cytometry. *Results.* We have studied RBCs from 9 untreated and 4 PNH patients on eculizumab. After 24h incubation in acidified normal serum, 74±16% of PNH RBCs from untreated patients were lysed; C-mediated hemolysis was confirmed by the presence of C3frag on RBC ghosts. Addition of TT30 produced a concentration-dependent inhibition of C mediated hemolysis; with 1 μM (65 μg/mL) TT30 hemolysis was reduced to 14±26% and with 3 μM TT30 it was reduced to 5±7%. Equimolar concentrations of human fH produced much less inhibition of hemolysis (about 50% lysis), supporting the notion that TT30 is cell-targeted. Of note, unlike with exposure to eculizumab, *in vivo* or *in vitro* (Sica, EHA 2010), surviving PNH RBCs did not show any C3frag-deposition on their surface. When incubated with ABO-matched normal sera, lysis of PNH RBCs from patients on eculizumab was comparable to that of RBCs from untreated patients; with 3 μM TT30 hemolysis was 31±8%. This reduced protection from hemolysis of RBCs from PNH patients on eculizumab could be attributed to increased susceptibility to lysis of C3frag+ RBCs. However, RBCs from treated patients that had survived 24h incubation in acidified serum with TT30 were protected from lysis even after serum removal and re-exposure to fresh acidified sera, for up to 24h: i.e., longer than those from untreated patients. This in turn could be explained by the fact that C3frag pre-loading *in vivo* is helping to target TT30, when added *in vitro*, to the RBC surface. *Conclusions*. Our experiments support the concept that TT30 targets C3frag on PNH RBCs to deliver surface-based fH activity: thus, by blocking the CAP and its amplification loop, TT30 inhibits both hemolysis and C3frag-opsonization of PNH RBCs. In principle, TT30 is a candidate agent to control both MAC-mediated IVH and C3-mediated EVH in patients with PNH.

THE BRAZILIAN HEREDITARY PERSISTENCE OF FETAL HEMOGLOBIN TYPE MUTATION REDUCES THE BINDING OF THE NF-E1/YY1 TRANSCRIPTION FACTOR AND MAY BE RESPONSIBLE FOR THE REACTIVATION OF THE GAMMA GLOBIN GENE

F Roversi,[1] A Cunha,[2] C Lanaro,[1] AF Brugnerotto,[1] DS Souza,[1] D Albuquerque,[1] F Costa[1]

[1]*UNICAMP, Campinas, Brazil;* [2]*UFSCAR, Sao Carlos, Brazil*

Non-deletional hereditary persistence of fetal hemoglobin (nHPFH) results in the continued expression of the gamma globin gene and production of hemoglobin (Hb) F in adults. High levels of HbF can ameliorate several manifestations of sickle cell disease and beta-thalassemia symptoms. Understanding the molecular mechanisms leading to reactivation or repression of gamma globin gene expression will lead to the development of new therapies to treat these patients. The Brazilian nHPFH type was identified in 1990 as a C→G mutation at position -195 of the A gamma globin promoter. In order to elucidate the mechanism mainly responsible for the Brazilian nHPFH phenotype, some studies have been carried out, but this mechanism remains unclear. The aim of this study was to identify transcription factors (TF) involved in the reactivation or repression of the A gamma globin gene in the Brazilian nHPFH type. Nuclear extracts from day 10 of primary human erythroblast cultures of Brazilian nHPFH type subjects and control subjects (C) were used to profile the activities of TFs using Protein-DNA Array technology. Using this array method, more than 20 TFs, whose DNA binding activities were modulated by the Brazilian nHPFH type, were identified. These TFs include NF-E1/YY1, HOX, Tat, Pax-1, TEF1, HIF-1 and HFH-3. To verify the array data with a secondary assay, nuclear extracts were used to conduct electrophoretic mobility shift assay (EMSA) with some TFs: NF-E1/YY1, Tat, HOX and TEF-1. The EMSA analysis validated the previous array *Results.* Interestingly, NF-E1/YY1, a transcription factor that represses epsilon and gamma globin, showed decreased activity in nuclear extracts of Brazilian nHPFH type subjects in the two methods used - DNA-protein array and EMSA. The consensus sites for NF-

E1/YY1 binding from various promoters have been found to share a CCAN core motif. The C→G mutation at -195 may disrupt this motif and causes decreased NF-E1/YY1 binding. This observation suggests that the -195 C→G substitution may abrogate NF-E1/YY1 in this promoter region, probably resulting in the reactivation of the A gamma globin gene. These results provide the first *in vitro* evidence for the probably molecular mechanism of reactivation of the A gamma globin gene in Brazilian type nHPFH.

OUTCOMES OF UNRELATED CORD BLOOD TRANSPLANT IN PATIENTS WITH HEMOGLOBINOPATHIES

A Ruggeri,[1] M Eapen,[2] A Scaradavou,[3] D Purtill,[1] M Cairo,[4] M Bhatia,[4] J Kurtzberg,[5] J Wagner,[6] A Fasth,[7] L Lo Nigro,[8] W Chaves,[1] M Walters,[9] E Gluckman,[1] V Rocha[1]

[1]Eurocord-Hopital Saint Louis, Paris, France; [2]Center for International Blood and Marrow Transplant Reasearch, Milwaukee, USA; [3]National Cord Blood Program, New York Blood Center, New York, USA; [4]Columbia University Medical Center, New York, USA; [5]Pediatric Hematology, Duke University Medical Center, Durham, USA; [6]Pediatric Hematology-Oncology and Blood and Marrow Transplantation, Minneapolis, USA; [7]Dep of Oncology, The Queen Silvia Children's Hospital, Goteborg, Sweden; [8]Oncoematologia pediatrica, Policlinico Catania, Catania, Italy; [9]Hildren's Hospital and Research, Oakland, USA

Allogeneic hematopoietic cell transplantation (HCT) from HLA-identical donors is curative in patients with hemoglobinopathies. In order to extend the availability of HCT, unrelated cord blood transplantation (UCBT) has been investigated. Between 1996 and 2009, 51 patients receiving a single UCBT for hemoglobinopathy were reported to the Eurocord and CIBMTR registries. Thirty-five had thalassemia major (Thal) and 16 had sickle cell disease (SCD). All Thal patients were transfusion-dependent with a median time from diagnosis to UCBT of 26 months. Twelve of 16 patients with SCD had a history of stroke or central nervous system involvment. Median age at UCBT was 3.9 years and 6.3 years for Thal and SCD, respectively, and median follow-up was 2 years. Cord units were matched at 6 of 6 (15%), 5 of 6 (34%) and 4 of 6 (51%) HLA loci (antigen-level for class 1, allele-level for class 2). Median infused cell dose was 4.9×10^7/kg (1.5-13). Forty patients received a myeloablative conditioning regimen (MAC) with busulfan (BU) and cyclophosphamide (n=33) or BU with other agents (n=6). Reduced intensity conditioning regimens (RIC) (n=10) were fludarabine-based with BU<8 mg/kg or melphalan<150 mg/m^2. Cumulative incidence (CI) of neutrophil recovery at 60 days was 72±6%, with 37 of 51 patients reaching neutrophil recovery at a median time of 22 days. UCBT performed after 2004 (84% vs 68%, P=0.005) were associated with improved neutrophil recovery. According to conditioning regimen used, 29 of 40 who received a MAC and 7 of 10 who had a RIC achieved neutrophil recovery. Day 100 chimerism analysis was available for 48 patients: 20 patients had complete donor chimerism, 4 mixed chimerism and 24 autologous recovery. Among 14 patients who did not achieve neutrophil recovery, 5 had available data on subsequent treatment. Two received an autologous back-up and one received a second UCBT which engrafted. CI of grade II-IV acute-graft versus-host disease (GVHD) was 23% and 9 patients had chronic GVHD (2 with extensive disease). The 2-year probability of overall survival was 72%. Thirty-eight patients (23 Thal, 15 SCD) are alive, 15 with full donor chimerism (8 Thal, 7 SCD). Of the 13 deaths, 5 occurred prior to day-100, mainly due to infections. No deaths due to GVHD were reported. Despite the small number of subjects, these results show a particularly high risk of graft failure after UCBT for hemoglobinopathy. Novel approaches modifying the conditioning regimen and/or increasing cell dose in prospective clinical trials are needed.

THE ROLE OF VLA-4 AND CX3CR1 ON RECRUITMENT OF T CELLS INTO BONE MARROW IN PATIENTS WITH APLASTIC ANEMIA

J Peng, R Ren, M Ma, Y Yu, X Xu, H Hou

Qilu Hospital, Jinan, China

Background. Aplastic anemia (AA) is a typical example of the human bone marrow failure syndromes. More and more evidence has proved acquired AA is a T-cell-mediated autoimmune disease. Peripheral blood cytopenia and bone marrow hypoplasia due to T-cell-mediated destruction and apoptosis of hematopoietic stem and progenitor cells is considered to be the essential pathogenesis of acquired AA. However, the transportation of T-cells into bone marrow has intimate relationship with the expression of adhesion molecules and chemokine receptors on T-cells. Recently, Bob Olsson and coworkers reported that elevated expression of VLA-4 and CX3CR1 was involved in recruitment of T-cells into bone marrow in patients with idiopathic thrombocytopenic purpura (ITP), which intiated us to investigate the expression of VLA-4 and CX3CR1 on T cells in acquired AA patients. *Aims.* This study was to analyze the role of VLA-4 and CX3CR1 on recruitment of T-cells into bone marrow in patients with acquired AA and povide new evidence for the immunologic mechanism of acquired AA. *Methods.* The expression of VLA-4 and CX3CR1 on T cells from peripheral blood and bone marrow was analyzed by flow cytometry in 27 AA patients (15 with severe aplastic anemia and 12 with moderate aplastic anemia) and 21 controls. Confocal scanning microscopic analysis of immunoflourescence was introduced to detect the expression of VLA-4 and CX3CR1 in paraffin-embedded bone marrow biopsies from 17 AA patients and 10 controls. *Results.* Both in peripheral blood and bone marrow, there was no statistically significant difference in the mean fluorescence intensity (MFI) or the percentage of VLA-4 on T-cells ($CD3^+$ T-cells, $CD3^+/CD4^+$ T-cells and $CD3^+/CD8^+$ T-cells) between acquired AA patients and controls. However, the percentages of $CX3CR1^+/CD3^+$ cells and $CX3CR1^+/CD3^+/CD8^+$ cells from peripheral blood as well as bone marrow were increased significantly in acquired AA patients compared with controls. This finding was confirmed by confocal scanning microscopic analysis of immunoflourescence of BM biopsies. *Conclusions.* Acquired AA, as an immune-mediated disease, is inseparable with accumulation and activation of oligoclonally expanded cytotoxic T-cells in bone marrow. Increased expression of certain adhesion molecules or chemokine receptors may contribute to the trafficking of T-cells from peripheral blood to bone marrow, and CX3CR1 is an important one of these molecules involved in T-cell homing in acquired AA.

THE ROLE OF MEIS1 IN PRIMITIVE AND DEFINITIVE HAEMATOPOIESIS AND VASCULAR PATTERNING DURING ZEBRAFISH DEVELOPMENT

A Cvejic,[1] J Serbanovic-Canic,[1] D Stemple,[2] W Ouwehand[1]

[1]*University of Cambridge, Cambridge, UK;* [2]*Sanger Institute, Cambridge, UK*

Background. Meis homeobox 1 (Meis1) is a three-amino-acid loop extension (TALE) homeodomain protein that was first identified as a common viral integration site in myeloid leukaemic cells of BXH-2 mice. It is considered as a critical effector, possibly downstream of Scl, that has a rate-limiting regulatory role in mixed lineage leukaemia (MLL) and limb development. In addition to its role in leukaemogenesis, several lines of evidence indicate a key role of meis1 in normal haematopoiesis. Along with *hoxa-9* and *pbx1* genes, *meis1* is transcribed in human CD34$^+$ haematopoietic stem cells (HSCs) and is down regulated following differentiation, except in the megakaryocytic lineage where transcript levels remain abundant. Mice lacking *meis1* are not viable and die early during development (E11.5-14.5) due to lack of megakaryocytes and extensive haemorrhaging, and while erythromyeloid lineages are present the number of colony-forming cells is severely reduced. Mutant fetal liver cells also fail to radioprotect lethally irradiated animals and they compete poorly in repopulation assays. In addition, *meis1* mutant mice display localised defects in vascular patterning with capillary network being mainly affected. *Aims.* Though much is known about the role of *meis1* in leukaemogenesis, its function in normal haematopoiesis, remains largely unclear. Here we characterise the role of the proto-oncogene, *meis1*, during zebrafish primitive and definitive haematopoiesis and vascular patterning. *Methods and Results.* Using antisense morpholino oligonucleotides (MO) to interrupt *meis1* expression we find that, although primitive macrophage development can occur unhampered, the posterior erythroid differentiation requires *meis1*, resulting in severe decrease in number of mature erythrocytes. Definitive haematopoiesis was also critically dependent on functional *meis1* signalling. MO injected embryos showed normal specification of haematopoietic stem cells (HSCs) mediated by c-myb expression. They failed, however, to seed the caudal haematopoietic tissue (CHT) and differentiate into the mature progeny, ultimately producing significantly fewer myeloid cells and completely lacking lymphoid cells and thrombocytes. In addition, *meis1* MO knockdown leads to dramatic single arteriovenous tube formation and impairment of caudal vein plexus development. In *meis1* MO injected embryos we observed a dramatic decrease in the expression of the arterial marker Ephrinb2a (Ephb2) and a concurrent ectopic expression of the venous marker *flt4*. From these observations we inferred that the loss of *meis1* function leads to a major disruption of the segregation of angioblasts and the associated vessels lumen formation. We also find that knockdown of *pbx1* results in a strikingly similar phenotype to that of *meis1* knockdown. *Summary.* Thus, these results implicate that meis1, jointly with pbx1, regulates both primitive and definitive haematopoiesis as well as vascular development.

C/EBPa INSTRUCTS EARLY THYMIC PROGENITORS TOWARDS CELLS WITH MYELOID AND DENDRITIC CELL POTENTIAL

A Wölfler,[1] J Haanstra,[2] M Valkhof,[2] E Vroegindeweij,[2] P van Strien,[2] A Danen-van Oorschot,[2] T Cupedo,[2] I Touw[2]

[1]*Medical University Graz, Graz, Austria;* [2]*Department of Hematology, Erasmus MC, Rotterdam, Netherlands*

Background. In contrast to the classic scheme of haematopoietic cell differentiation, which proposes a symmetrical early branch into lymphoid and myeloid lineages in the bone marrow, myeloid potential has recently been shown to be retained among some thymic progenitor cells. Within the progenitor compartment myeloid potential was predominantly confined to the earliest stage of T cell development, the DN1 (double-negative for CD4/CD8 and c-kit$^+$CD25$^-$) population, reduced in DN2 (c-kit$^+$CD25$^+$) and absent in DN3 (c-kit-CD25$^+$) cells. However, mechanisms responsible for retained myeloid potential as well as markers for such progenitors are not known. *Methods and Aims.* To delineate a role of C/EBPα, which is a crucial transcription factor in myeloid cell development and indispensable for granulocyte formation, in early thymic progenitors with retained myeloid potential, we used a recently developed mouse model expressing Cre recombinase under control of the endogenous *Cebpa* promoter and an inducible EYFP allele (Cebpa^{cre}/+ R26 EYFP mice). This model enabled us to track single cells that either express Cebpa or are the progeny of Cebpa-expressing cells and to evaluate their developmental potential. *Results.* The highest fraction of Cebpa/EYFP$^+$ cells was found within the DN1 population (22%), whereas the percentage of Cebpa/EYFP$^+$ cells gradually decreased during T cell differentiation resulting in the lowest fraction among the most mature single positive CD3$^+$ thymocytes (9%) suggesting either a proliferation disadvantage of Cebpa/EYFP$^+$ progenitor cells during T cell development or an alternative cellular fate of Cebpa/EYFP$^+$ progenitors. Indeed, Cebpa/EYFP$^+$ DN1/2 cells contained approximately 7 times higher numbers of myeloid colony-forming cells relative to EYFP- DN1/2 cells. Since thymic dendritic cells (DC) have been proposed to descend from DN1/2 cells, we also analyzed the distribution of Cebpa/EYFP in this cell population. About 20% of CD11cintB220$^+$ plasmacytoid DC expressed EYFP, whereas 50% of CD11chighB220$^-$ conventional DC were Cebpa/EYFP$^+$. Because Cebpa is not expressed during later stages of DC differentiation, these data imply that significant fractions of conventional and, to a lesser extent, plasmacytoid DC in the thymus are derived from Cebpa-expressing progenitors. Accordingly, sorted Cebpa/EYFP$^+$ DN1/2 cells displayed a higher potential to form dendritic cells *in vitro* as compared to EYFP$^-$ cells. Given the loss of Cebpa/EYFP$^+$ cells during T cell development *in vivo*, we then asked whether C/EBPα affects the expansion of DN1/2 cells in a T cell inducing environment. EYFP$^+$ and EYFP- DN1/2 cells expanded at comparable proliferation rates in fetal thymic organ cultures (FTOC), a result supported by competitive repopulation experiments. However, a significantly higher proportion of cells obtained from EYFP$^+$ DN1/2 cells remained double-negative (CD4$^-$CD8$^-$) after 3 weeks of culture, relative to the EYFP- DN1/2. These results suggest that although their ability to proliferate in FTOC is not affected, Cebpa/EYFP$^+$ DN1/2 cells are hampered in differentiation towards CD4$^+$CD8$^+$ thymocytes. *Conclusions.* Myeloid potential in DN1/2 progenitors is predominantly confined to cells, which express Cebpa or are the progeny of Cebpa-expressing cells. C/EBPα instructs these cells to develop toward clonogenic myeloid cells or DC and thus represents a marker for myeloid potential in early thymic progenitors.

Background. Mutations in *CEBPA*, a gene essential for myeloid differentiation, have been associated with a favorable prognosis in cytogenetically normal acute myeloid leukemia (CN-AML). Recent reports found this favorable impact restricted to double-mutated *CEBPA* (*CEBPA*-2mut), while single-mutated *CEBPA* (*CEBPA*-1mut) associated with a prognosis similar to that of *CEBPA* wild-type (*CEBPA*-wt). None of these studies focused on the clinical significance of *CEBPA* mutations in older [≥60 years (y)] CN-AML patients who generally have a poor outcome. *Aims.* To analyze the clinical impact of *CEBPA* mutations in the context of other molecular markers in older *de novo* CN-AML and provide biologic insights through gene- and microRNA-expression profiling. *Methods.* Pretherapy marrow or blood from 243 patients (60-83y) treated intensively on front-line cytarabine/daunorubicin-based CALGB protocols were analyzed centrally for *CEBPA* mutations and other molecular markers [*NPM1*, FLT3 (ie, *FLT3*-ITD, *FLT3*-TKD), *WT1, MLL, IDH1* and *IDH2* mutations and BAALC, ERG and MN1 expression]. Allelic discrimination of *CEBPA*-2mut was assessed by cloning the entire *CEBPA* coding sequence. Gene and microRNA expression were profiled by Affymetrix U133 plus 2.0 and OSU_CCC v4.0 arrays, respectively. *Results.* Twenty-nine (12%) patients harbored *CEBPA* mutations, including 9 with *CEBPA*-2mut, all of whom had bi-allelic *CEBPA* mutations and

were NPM1 wild-type (*NPM1*-wt). Compared with *CEBPA*-wt and *CEBPA*-1mut patients, *CEBPA*-2mut patients had lower platelet counts (P=.015 and P=.009, respectively) and were more often NPM1-wt (P=.003 and P=.045, respectively). No significant differences were observed for complete remission rates, disease-free survival (DFS) or overall survival (OS) among *CEBPA*-2mut, *CEBPA*-1mut, and *CEBPA*-wt patients. When restricting analyses to NPM1-wt patients (n=103), a large molecular subset of older CN-AML we previously reported to have a particularly poor prognosis, we still observed no outcome differences between *CEBPA*-1mut and *CEBPA*-wt patients. However, *CEBPA*-2mut patients tended to have a longer DFS (P=.06; 3y-rates 43% v 4%) and a significantly longer OS (P=.03; 3y-rates 33% v 6%) compared with the combined group of *CEBPA*-1mut (n=11) and *CEBPA*-wt patients (n=83). Expression profiling distinguished *CEBPA*-2mut from *CEBPA*-wt patients by a signature comprising 307 differentially expressed genes. This signature predicted *CEBPA*-2mut status with 99.5% cross-validated accuracy. Prominent signature features were up-regulation of *CEBPA* and the hematopoietic progenitor markers CD34, CD38, CD7 and CD96, and down-regulation of the leukemia-associated RUNX1, HOXA and HOXB genes. *CEBPA*-2mut could also be distinguished from *CEBPA*-1mut patients by a signature comprising 173 genes; as in the comparison with *CEBPA*-wt patients, CD7 was up-regulated and *RUNX1, HOXA,* and *HOXB* down-regulated in *CEBPA*-2mut patients. Based on this signature, *CEBPA*-2mut status was predicted with 85.7% cross-validated accuracy. Consistent with the HOX down-regulation, *CEBPA*-2mut compared to *CEBPA*-wt and to *CEBPA*-1mut patients had significant down-regulation of miR-10a, a microRNA embedded in the HOXB gene cluster. *CEBPA*-1mut patients were not as readily distinguishable from *CEBPA*-wt patients, with only 98 differentially expressed genes and cross-validated prediction accuracy of only 64.3% for *CEBPA*-1mut patients. *Conclusions.* In older *de novo* CN-AML, *CEBPA*-2mut associates with more favorable outcome within the prognostically adverse NPM1-wt subset. The gene and microRNA expression characteristics suggest that CEBPA-2mut represents a distinct genetic entity within CN-AML.

MICRORNA NETWORKS IN LEUKEMIA

R Garzon,[1] G Gamberroni,[2] R Visone,[1] Y Pekarsky,[1] M Galasso,[2] G Calin,[3] M Andreeff,[3] C Croce[1]

[1]The Ohio State university, Columbus, USA; [2]University of Ferrara, Ferarra, Italy; [3]MD Anderson Cancer Center, Houston, USA

Background and *Aims.* MicroRNAs (miRNAs) are small non-coding RNAs whose expression is de-regulated in human leukemias. Typically miRNAs have been studied by using the gene profiling approach: i.e. each miRNA has been studied for its single contribution to differential expression or, at the most, to a compact predictive signature. Here, we propose a paradigm shift to the study of miRNAs role in cancer by applying a "whole cell"systems biology approach. We have performed detailed analysis of coordinated miRNA activities and built miRNA gene networks by using large expression miRNA datasets obtained from chronic lymphocytic leukemias (CLL) and acute myeloid leukemia (AML) patients. *Methods.* The miRNA expression datasets were obtained using the OSU-CCC custom miRNA microarray version 2, 3 and 4 and all, except 326 AML cases were already used in publications by our group and deposited in public microarray databases. The microarray experiments, data normalization (quantiles) and filters used were performed as previously described in the papers cited below. Banjo was used for inferring the bayesian network and the MCL clustering algorhytm was used to extract (and visualize) coherent groups of nodes from the expression network. 'Hub"gene of an expression module was defined as a gene with strong intramodule connectivity, as measured by the sum of its pair-wise weighted correlation to all other genes in the same module. *Results.* First, we generated a single network reflecting the miRNome of AML. We assayed mature miRNAs in 598 AML samples (480 newly diagnosed and 109 relapsed patients). Cytogenetics and molecular information was available for 560 patients and follows this distribution: complex karyotype: 136 (24%), t(8;21) and inv16:12(2%), t(15;17):+8(1.4%), t(11q23):14(2.5%), other abnormality: 96(17%), cytogenetically normal: 302(53%), including FLT3-ITD(42/189), NPM1-mutation (103/220). Results from this analysis revealed a well connected network, except two miRNA families; miR-181 and miR-146 that were positioned in a separate cluster. Both miRNA families have been associated with NFκB (Marcucci G,et al NEJM 2008). On the main cluster, two miRNAs with known roles in myeloid leukemias; miR-328 and miR-29b acted as a hub in the AML. The oncogene miR-155 was located on the main cluster and in close association with miR-223, miR-92a, miR-25 and miR-32. Next, using the same approach described in AML, we assayed mature miRNAs in 254 CLL patients from 3 different datasets (Calin G, et al NEJM 2005; Calin G.et al Cancer Cell 2007 and Visone R,et al Blood 2009). In CLL we observed 3 separated clusters. The main cluster was dominated by miR-21 which acts as a hub. There was a direct association between miR-21 and the oncogenic miR-17-20-106a cluster. While the miR-29 was a hub in AML, it is a branch in CLL. Two isolated clusters were found: miR-23a and -b and the miR-15a/miR-16-1 cluster. *Conclusions.* In summary, the complexity of our expression database enabled us to perform detailed analysis of coordinated miRNA activities. We inferred, for the first time, genetic networks for miRNAs in human leukemias. Intriguingly, some prominent cancer associated miRNAs were separated from the coordinate control of the general transcriptional program.

ABERRATIONS OF MULTIPLE GENES REGULATING NF KAPPA B PATHWAY IN MALIGNANT LYMPHOMA

M Kato,[1] K Yoshida,[1] M Sanada,[1] I Kato,[2] Y Sato,[3] J Takita,[1] K Takeuchi,[4] R Kawahata,[1] A Niwa,[2] K Nakazaki,[1] J Nomoto,[5] T Igarashi,[1] M Kurokawa,[1] S Chiba,[6] S Mori,[7] Y Ishikawa,[4] K Okamoto,[5] K Tobinai,[5] H Nakagama,[5] T Nakahata,[2] T Yoshino,[3] Y Kobayashi,[5] S Ogawa[1]

[1]The University of Teikyo, Tokyo, Japan; [2]Kyoto University, Kyoto, Japan; [3]Okayama University, Okayama, Japan; [4]Japanese Foundation for Cancer Research, Tokyo, Japan; [5]National Cancer Center, Tokyo, Japan; [6]Tsukuba University, Ibaraki, Japan; [7]Teikyo University, Tokyo, Japan

Nucleo factor kappa B (NFκB) plays an important role in proliferation and development of lymphocyte. Aberrant activation of NFκB is a characteristic feature of several subsets of B-lineage malignant lymphomas. Previous reports revealed various genomic abnormalities in genes regulating NFκB pathway. Recently, our group showed that A20, a negative regulator of this pathway, is frequently inactivated in B-cell malignant lymphomas. However, the landscape of genomic aberrations in NF kappa B pathway genes has not fully understood. In this study, to clarify the genetic basis of the aberrant NFκB activation, we performed genome-wide analysis of copy number alterations as well as allelic imbalances of primary B-lineage lymphoma specimens using single nucleotide polymorphism genomic microarray. We also searched for possible mutations in multiple genes encoding positive and negative regulators of NFκB pathway, including CARD11, CYLD, IKK family genes and TRAF family genes and IκB family genes. This study included 238 primary lymphoma samples, including 64 samples of diffuse large B-cell lymphomas (DLBCL), 52 of follicular lymphomas (FL), 35 of mantle cell lymphomas (MCL), and 87 of mucosa-associated tissue (MALT) lymphomas. Through a genome-wide analysis, we identified that each histology type had a unique genomic signature, suggesting a distinctive underlying molecular pathogenesis for different histology types. As expected, genomic abnormalities in NFκB pathway associated genes were frequently detected. In total, more than 40% of analyzed samples had genomic abnormalities in genes on NFκB pathway. Fifty cases had loss of heterozygosity at A20 locus, 24 of which had mutation or deletion in the remaining A20 allele. Thirty-nine cases had copy number gains (8 cases of amplification is included) at REL locus, encoding one of NFκB components. Fourteen cases had gains/amplifications at TRAF6, positive regulator of NFκB pathway. In addition, mutations in CARD11 and IκBε were also detected in DLBCL and MALT. To also assess the role of uncontrolled signaling of NFκB pathway in lymphomagenesis, we re-expressed wild-type A20 in two lymphoma-derived cell lines without normal functional A20 alleles (KM-H2 and L1236, derived from Hodgkin lymphoma). In both cells, re-expression of wild-type A20 resulted in suppression of cell growth and induction of apoptosis, accompanied by down-regulation of NFκB activation. According to array-based expression analysis, the list of genes suppressed by A20 expression included various cytokines (ex. M-CSF and various chemokines), receptor for various stimuli (ex. CD40 and CD58) and proteins regulating NF kappa B pathway (ex. NFKB2, Bcl-x and IκBε). In conclusion, our study demonstrated that uncontrolled NFκB signaling caused by alterations of multiple genes is a common feature of B-lineage lymphomas.

A PEDIATRIC-INSPIRED INTENSIFIED THERAPY OF ADULTS T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA REVEALS THE FAVORABLE OUTCOME OF NOTCH1/FBXW7 MUTATIONS, BUT NOT OF LOW ERG/BAALC EXPRESSION: A GRAALL STUDY

R Ben Abdelali,[1] V Asnafi,[2] A Buzyn,[3] E Lengliné,[2] S Le noir,[3] N Ifrah,[4] E Macintyre,[2] H Dombret[5]

[1]Necker Hospital, Paris, France; [2]Hematology Department , Necker Hospital, Paris, France; [3]Hematology Department, Necker Hospital, Paris, France; [4]Hematology Department, Angers, France; [5]Hematology Department , Saint Louis Hospital, Paris, France

T-ALL corresponds to a heterogeneous group of acute leukemia which account for 10% of pediatric and 35% of Ph1-negative adult ALL. Several genetic abnormalities have been identified in T-ALL but therapeutic stratification still relies on clinical markers. The French study group (GRAALL) reported a highly significant improvement of adult T-ALL outcome using a pediatric-inspired intensified therapy, but relapses are still frequently fatal. Therefore identification of molecular risk factors that allow early and effective treatment stratification is needed. NOTCH1 and/or FBXW7 mutations (N/Fmut) lead to activation of NOTCH1 pathway in more than 70% of both pediatric and adult T-ALL and have been reported to be of favorable outcome in pediatric T-ALL but either it is also the case in adult T-ALL remain unclear. Low ERG and BAALC (E/Blow) transcript expression, initially described as of good prognosis in AML, was reported by the German GMALL group to predict also a highly favorable outcome in 41% of adult T-ALL. More recently, they showed that N/Fmut is associated to better EFS within the group of E/Blow patients but is not predictive of a better outcome in the overall cohort of adult T-ALL. Controversial N/Fmut prognosis impact in adult T-ALL is likely due to the small number of patients included in some previously studies and more importantly to the differences in therapy regimens. Herein, we investigated the prognosis impact of N/Fmut and E/Blow in a large cohort of 227 adult T-ALL enrolled in the LALA-94 (n=86) or GRAALL-03/05 (n=141) protocol. The incidence of N/Fmut (159/227=70%) was similar in both protocols. N/Fmut patients when compared to non-mutant, had a better pednisone response (62% vs 36%; P=.005), a higher rate of complete remission (CR) (96% vs 91%;P=.11) and a lower relapse rate (35% vs 53%;P=.02). N/Fmut had a better 3-years EFS (53% vs 37%;P=.002) and OS (61% vs 48%;P=.008). When LALA-94 and GRAALL-03/05 protocols were analyzed separately, N/Fmut retained their higher OS in LALA-94 (48% vs 42%;P=.03) but lost their significant higher EFS (35% vs 31%;P=.11). In contrast, the most recent GRAALL-03/05 trials, highlight the very good prognosis of N/Fmut (OS=72% vs 50%, EFS=69% vs 41%; P<.01). We next quantified E/B transcript expression in 193 patients of whom sufficient RNA was available. 44% (n=84) of patients were classiffied E/Blow as previously reported by Baldus et al. E/Blow patients had higher CR rate (97.5% vs 90.6%;P=.05) ,a trend toward a better EFS (58% vs 47%; P=.12), but not better OS (61%vs 59%; P=.3). E/Blow prognosis impact was further investigated within N/Fmut and non-mutated cases separately. There is no difference in outcome in the non-mutated group according to E/B expression level. In contrast, within N/Fmut , E/Blow demonstrated a trend to a better EFS (P=.19). Taken overall, our data demonstrate that N/Fmut, but not E/Blow, identify a major subgroup (70%) of adult T-ALL with a highly favorable outcome. This benefit is most striking with the pediatric inspired GRAALL-03/05 trials and could justify individual therapeutic stratification for T-ALL.

IKZF1 DELETIONS PREDICT RELAPSE IN UNIFORMLY TREATED PEDIATRIC PRECURSOR B-ALL

R Kuiper,[1] E Waanders,[1] V VanderVelden,[2] C VanderSchoot,[3] S VanReijmersdal,[1] R Venkatachalam,[1] B Scheijen,[4] E Sonneveld,[5] J VanDongen,[2] A Veerman,[6] F van Leeuwen,[4] A GeurtsvanKessel,[1] P Hoogerbrugge[4]

[1]Human Genetics, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [2]Erasmus MC, University Medical Centre Rotterdam, Rotterdam, Netherlands; [3]Department of Experimental Immunohematology, Sanquin Research and Landsteiner La, Amsterdam, Netherlands; [4]Pediatric Hemato-Oncology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [5]Dutch Childhood Oncology Group, The Hague, Netherlands; [6]Department of Paediatric Oncology, VU University Medical Centre, Amsterdam, Netherlands

Background. Relapse is the most common cause of treatment failure in pediatric acute lymphoblastic leukemia (ALL) and is difficult to predict in the majority of cases. *Aims.* To explore the prognostic impact of recurrent DNA copy number abnormalities on relapse in children diagnosed with precursor B-ALL. *Methods.* We performed genome-wide copy number profiling of 34 paired diagnosis-relapse samples, and validated the findings in an unselected cohort of 131 precursor B-ALL cases, enrolled in the dexamethasone-based Dutch Childhood Oncology Group (DCOG) treatment protocol ALL9. *Results.* We observed that diagnosis and relapse samples were genomically distinct in the majority of cases. Lesions detected at diagnosis were frequently absent at relapse, including those encompassing recurrent targets in precursor B-ALL such as PAX5, CDKN2A, and EBF1, which indicates that these lesions represent secondary events that may be absent in the relapse-prone therapy-resistant progenitor cell. In contrast, deletions and nonsense mutations in IKZF1, which encodes the lymphoid differentiation factor IKAROS, were frequently observed and found to be consistently preserved at the time of relapse. A targeted copy number screen in the unselected cohort revealed that IKZF1 deletions are significantly associated with poor relapse-free and overall survival rates. Similar results were obtained after separate analysis of the non-high-risk and high-risk groups within this treatment protocol, i.e., non-high-risk patients with IKZF1 deletions had a ~12-fold higher relative relapse risk compared to patients without IKZF1 deletions. Consequently, IKZF1 deletion status allowed the prospective identification of 53% of the relapse-prone patients within this sub-group. *Conclusions.* In pediatric precursor B-ALL patients treated according to the dexamethasone-based DCOG-protocol ALL9 the IKZF1 deletion status serves as one of the strongest predictors of relapse at the time of diagnosis and, as such, has a high potential for future risk stratification.

Background. In B-lineage acute lymphoblastic leukemia (ALL), persistence or relapse of minimal residual disease (MRD) is an independent poor prognostic factor and new treatments are needed. CD19 is the most frequently expressed B-cell differentiation antigen. It can be targeted by blinatumomab, a member of a novel class of T-cell engaging bispecific single-chain antibodies (BiTE antibodies). A Phase 2 study was conducted in collaboration with the German Multicenter Study Group on Adult Lymphoblastic Leukemia (GMALL) in order to determine the efficacy of blinatumomab in MRD-positive B-lineage ALL. *Methods.* Between May 2008 and November 2009, 21 patients with MRD persistence or relapse (MRD-level ≥ 10-4) after induction and consolidation therapy were treated with blinatumomab as a four-week continuous intravenous infusion at a dose of 15 µg/m²/d followed by a 2-week treatment-free period (1 cycle). Sixteen patients with Ph-negative (2 patients with MLL-AF4) and 5 patients with Ph-positive ALL were enrolled. MRD was assessed by quantitative reverse transcriptase-polymerase chain reaction for either rearrangements of immunoglobulin or T-cell-receptor genes, or specific genetic aberrations. *Results.* Sixteen out of 20 evaluable patients (13 out of 15 patients with Ph-negative and 3 out of 5 patients with Ph-positive ALL) became MRD-negative (MRD-level <10-4) after one cycle of blinatumomab regardless of the MRD level prior to study treatment. Nine patients were enrolled with high MRD load (> 10-2) prior to study treatment. All of these 9 patients became MRD-negative. Thirteen out of 16 patients with persistent MRD prior to study treatment and 3 out of 4 patients with MRD-relapse became MRD-negative. Nineteen patients are evaluable for duration of hematological relapse-free survival (median follow up 11 months, range from 3 to 20 months). One patient withdrew consent for follow-up. Fifteen patients remain in continuous hematological remission. Four non-transplanted patients experienced hematological relapse (3 responders and 1 non-responder). Ten responders are not transplanted after treatment with blinatumomab. Six out of these 10 non-transplanted responders are still MRD-negative without additional treatment. Six out of 7 non-transplanted responders with Ph-negative ALL are still MRD-negative without additional treatment. Eight patients (6 responders, 2 non-responders) underwent allogeneic HSCT after at least one cycle of blinatumomab (median 2 cycles) and all remain alive without hematologic relapse. Transient pyrexia (100%), chills (42.9%), headache (42.9%) were the most common clinical adverse events (AEs), which all resolved to baseline during treatment. Target-mediated Grade 3 or 4 lymphopenia (33.3%) and hypogammaglobulinemia (14.3%) were also observed, but without increased incidence of opportunistic infections. Grade 3 seizure, which was fully reversible within 1 day after drug discontinuation, was observed in 1 patient. There were no blinatumomab related deaths. *Conclusions.* Blinatumomab induces complete molecular remissions in patients with persistent and relapsed MRD independent from the extend of MRD-positivity and prolong leukemia-free survival with a favorable safety and tolerability profile. These molecular remissions might be durable without additional conventional maintenance chemotherapy.

0599

IMPACT OF ALLOGENEIC STEM CELL TRANSPLANTATION ON TYROSINE KINASE DOMAIN MUTATIONS AND MINIMAL RESIDUAL DISEASE LEVELS IN PATIENTS WITH PHILADELPHIA-CHROMOSOME-POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA

H Pfeifer,[1] S Wystub,[1] A Schmidt-Tanguy,[1] M Stadler,[2] J Dengler,[3] W Bethge,[4] T Lange,[5] J Meyer,[5] U Platzbecker,[6] B Wassmann,[1] P Brueck,[7] N Goekbuget,[1] H Serve,[1] D Hoelzer,[1] O Ottmann[1]

Persistance of BCR-ABL transcripts and detection of TKD mutations during TKI based treatment of Ph+ ALL are associated with a high risk of relapse. Allogeneic stem cell transplantation (alloSCT) is potentially curative, but the ability to eradicate the different BCR-ABL mutations associated with imatinib resistance is uncertain. Moreover, the clinical implications of high mrd levels prior to SCT on outcome after SCT remains to be defined. It was the aim of this analysis to determine the impact of allogeneic SCT on MRD levels and the prevalence of BCR-ABL mutations in patients with Ph+ALL treated with imatinib in combination with chemotherapy. Bone marrow (BM) and/or peripheral blood (PB) samples were collected pre-treatment (n=26), during IM-based combination therapy prior to SCT (n=361) and serially after SCT (n=1793) from a total of 66 pts. with newly diagnosed Ph+ALL (median age: 45 yrs.) who were enrolled in prospective GMALL trials of IM followed by SCT. Additionally, we examined a total of 536 samples from 27 Ph+ALL pts. (median age: 48 yrs.) who were enrolled in the early phase II trials of IM as salvage therapy and transplanted in PR, CR2 or with progressive disease. MRD were analysed in all samples by quantitative rtPCR with nested bcr-abl PCR to confirm PCR negativity. Mutational status was analysed by denaturing high-performance liquid chromatography (D-HPLC) plus cDNA sequencing in a subset of these samples prior to and serially after transplantation, respectively. A mutation was detected at any time prior to SCT in 10 of 66 pts. (15%) with *de novo* Ph+ALL who received IM-based front-line treatment and were evaluable by both DHPLC and ASO-PCR. Of these, 4 pts. relapsed with detection of the same mutation as prior to SCT, 5 patients remain in continuous molecular CR with a median follow up of 34 months, 1 patient died in CR. 53 pts. with *de novo* Ph+ALL were evaluable prior to allogeneic SCT in CR1: of 22 pts. who achieved MRD negativity prior to SCT, 4 experienced a hematologic (n=2) or molecular relapse (n=2)[20% overall recurrence rate]. Substantially higher rates of hematologic relapse (6/18; 33%) and molecular positivity (10/18, 56%) after SCT were observed in the 18 pts. who remained MRD pos. within 6 weeks prior to SCT. Nearly all (21/23) patients with relapsed or refractory Ph+ALL who received IM as salvage treatment remained MRD positive prior to SCT. Thirteen of these 21 pts. harboured a detectable TKD mutation. Analysis of MRD and mutational status after alloSCT was possible in 8 of the 13 pts. with an initial TKD mutation. Four pts. converted to MRD-negativity, while another 4 pts. relapsed with mutated BCR-ABL. In conclusion, a strategy encompassing TKI-based frontline treatment followed by allogeneic SCT results in long-term elimination of mutant clones in the majority of patients transplanted in CR1. A minority of patients remain at risk of relapsing with previously undetectable TKD mutations, particularly after SCT beyond CR1. Some of these mutations may be responsive to second generation ABL TK inhibitors.

THE NOVEL CALICHEAMICIN-CONJUGATED CD22 ANTIBODY INOTUZUMAB OZOGAMICIN (CMC-544) EFFECTIVELY KILLS PRIMARY PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA CELLS

F de Vries,[1] C Zwaan,[2] M de Bie,[3] J Voerman,[3] M den Boer,[2] J van Dongen,[3] P Kelly,[4] V van der Velden[3]

[1]Erasmus MC, Rotterdam, Netherlands; [2]Dept of Pediatric Oncology/Hematology, Sophia Children's Hospital/Erasmus MC, Rotterdam, Netherlands; [3]Dept. of Immunology, Erasmus MC, Rotterdam, Netherlands; [4]Wyeth Pharmaceuticals, Cambridge, USA

Background. Although conventional treatment with chemotherapy results in 80% survival in children with acute lymphoblastic leukemia (ALL), long-term side effects are frequently observed. Inotuzumab ozogamicin (CMC-544), consisting of a humanized CD22 antibody coupled to the anti-tumor antibiotic calicheamicin, specifically binds to CD22 antigens expressed on immature and mature B cells. It has recently been shown that CMC-544 is effective in patients with B-cell lymphomas and in ALL cell lines. *Aim.* To study the effectiveness of CMC-544 in primary B-cell precursor (BCP)-ALL cells *in vitro* and to analyze which parameters determine its efficacy. *Methods*. Freshly isolated or thawed BCP-ALL cells from 19 patients (15 at diagnosis, 4 at relapse) were tested for their sensitivity to CMC-544 and calicheamicin by quantitative flowcytometric measurement of viable ALL cells after 0 to 96 hours of incubation. CD22 antigen saturation, internalization of CMC-544, and renewed CD22 antigen expression were determined by flowcytometric analysis. *Results.* CMC-544 induced dose-dependent cell kill in the majority of primary BCP-ALL cells, although IC_{50} values varied substantially (median 5.4 ng/mL, range 0.1-1000 ng/mL at 48h). One patient hardly responded to CMC-544, and three patients showed a delayed response. BCP-ALL cells were at least 100 times more sensitive to CMC-544 than normal CD22- lymphocytes of the same patients and AML cells. BCP-ALL cells were highly sensitive to free calicheamicin compared to primary AML cells (median IC_{50} values at 48h: 0.21 and 1021 ng/mL, respectively). The sensitivity of BCP-ALL cells to CMC-544 was strongly related to their sensitivity to calicheamicin (R2=0.76; P<0.0001). In addition, the efficacy of CMC-544 was associated with CMC-544 internalization, and, to a lesser extent, to renewed membrane expression of CD22 antigens. No direct relation between CD22 expression levels and efficacy of CMC-544 was found, probably due to the predominant contribution of calicheamicin sensitivity to CMC-544-induced cell kill. Nevertheless, CD22low ALL patients were generally less sensitive for CMC-544 than for calicheamicin, whereas CD22high BCP-ALL cells showed comparable sensitivity for both CMC-544 and calicheamicin. Furthermore, preliminary experiments showed that in a CD22low ALL cell line the percentage of lysis after 48 hours was much lower after incubation with CMC-544 for one hour compared to continuous incubation with CMC-544, whereas this was less evident in a CD22high cell line. Additional studies in ALL cell lines showed that the cytotoxic effect of CMC-544 was mediated via induction of double-strand DNA breaks, resulting in a G2/M cell cycle arrest, and subsequent apoptosis. *Summary/Conclusions.* CMC-544 is a highly efficient and specific new drug for killing BCP-ALL cells. Since BCP-ALL cells are far more sensitive to calicheamicin than primary AML cells, they are less dependent on intracellular accumulation of calicheamicin by a repetitive loop of saturation-internalization-and renewed expression, which was required to achieve efficient Mylotarg-induced cell death in AML cells. However, high CD22 expression levels and efficient internalization of CMC-544 accelerate reaching an intracellular calicheamicin threshold level required for induction of cell death. These new data will have consequences for the design of clinical trials to test the efficacy of CMC-544 in BCP-ALL patients.

THE ROLE OF THE IAP LIVIN IN MEGAKARYOCYTES DIFFERENTIATION AND THROMBOPOIESIS

I Abd-Elrahman,[1] I Deutsch,[2] S Kay,[2] N Noyman,[3] R Perlman,[4] D Ben-Yehuda[4]

[1]Hadassah-Hebrew University Medical Center, Jerusalem, Israel; [2]The Hematology Institute, Tel Aviv Medical Center, Tel Aviv, Israel; [3]Department of Pathology , Hadassah-Hebrew University Medical Center, Jerusalem, Israel; [4]Division of Hematology Hadassah-Hebrew University Medical Center, Jerusalem, Israel

Background. The exact mechanism of platelet production is poorly understood. A relationship between activation of the apoptotic cell machinery and the formation of pro-platelets has been established. In this study we show that Livin plays a role in this process. Livin is a member of the Inhibitor of Apoptosis Proteins (IAP) family of intracellular anti-apoptotic proteins that acts by binding and inhibiting caspases. We found that Livin is unique among the IAP members as upon strong apoptotic stimuli it is specifically cleaved by caspases to produce a truncated protein (tLivin) with a paradoxical pro-apoptotic activity. *Methods.* In this work we studied Livin expression in normal bone marrow (BM) and in BM from patients with hematological diseases using immunohistochemistry (IH) staining. An *in vitro* model was established to evaluate the potential role of Livin in thrombopoiesis. The human BCR-ABL positive cell line, LAMA-84, was induced by a phorbol ester (PMA) to differentiate to MK. The effect of PMA on megakaryocytic differentiation of LAMA-84 cells was investigated both by morphological changes and by the expression of CD41 and CD71. Increased cell size, ploidy and DNA synthesis, all markers of MK differentiation, were detected by flow cytometry (FACS). *Results.* Livin protein was clearly detected in MK in normal mature BM (by IH staining) and is expressed in platelets. Livin expression was also demonstrated in MK of patients with various hematological diseases such as ITP, MDS, Hodgkin's disease, ET and PV. Differentiation was characterized by up regulation of the MK marker CD41 from 6% to >60% and down regulation of the erythroid cell marker CD71 from 97-70%. Upon differentiation induced by PMA, LAMA-84 cells formed pro-platelets and produced functional platelets capable of aggregation. This differentiation of LAMA-84 cells into the MK was accompanied by Livin protein expression. In contrast to Livin, the anti-apoptotic proteins Bcl-2, XIAP and Survivin levels decreased upon MK differentiation. Moreover, when we derived single clones from the LAMA-84 cell line and induced differentiation of these clones with PMA, only clones that expressed Livin upon differentiation produced functional platelets that aggregated in response to stimulators. At the terminal stage of differentiation and platelets production, we observed a drastic decrease in the anti-apoptotic full length form of Livin and accumulation of the pro-apoptotic tLivin concomitant with increased caspase 3 activity and apoptosis. *Summary/Conclusions.* We established an *in vitro* model to investigate the role of Livin in thrombopoiesis. LAMA-84 cells differentiate into megakaryocytic lineage and produce functional platelet like particles. The IAP Livin is upregulated upon MK differentiation and is then cleaved to pro-apotic tLivin at the end of this process. We suggest that Livin plays a role in thrombopoiesis by regulating the apoptotic cell machinery in MK.

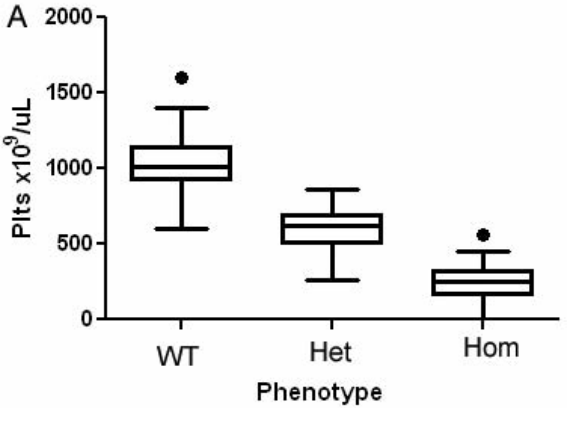
0602

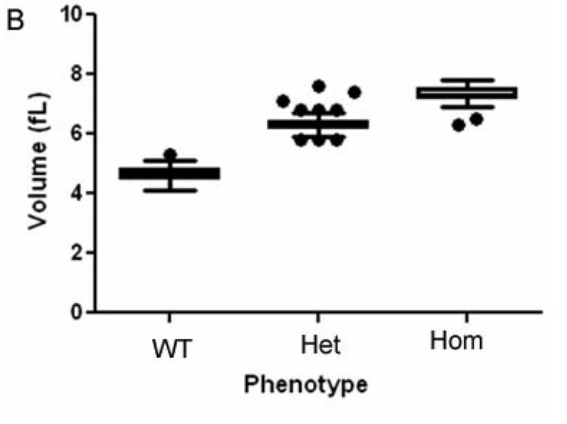
AN ENU-DERIVED MOUSE MODEL OF MYH9-RELATED DISEASE IDENTIFIED BY MASSIVELY MULTIPLE PARALLEL SEQUENCING

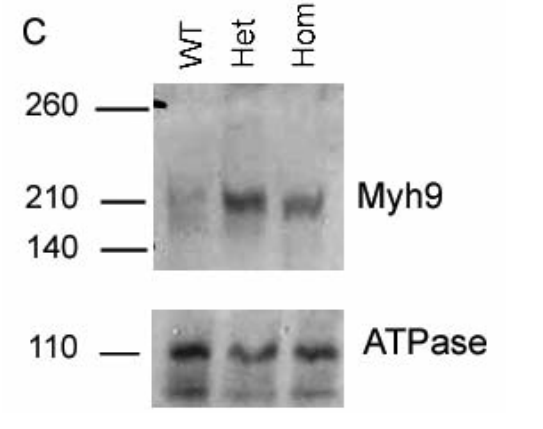
E Berndl,[1] N Anderson,[1] Z Milenkovic,[2] J McPherson,[3] D Barber,[4] W Stanford[1]

[1]*Univeristy of Toronto, Toronto, Canada;* [2]*Centre for Modeling Human Disease, Toronto, Canada;* [3]*Ontario Institute for Cancer Research, Toronto, Canada;* [4]*Medical Biophysics, Ontario Cancer Institute, Toronto, Canada*

Background and *Aims.* To produce models of human hematopoiesis, we induced random point mutations using N-ethyl-N-nitrosourea (ENU) mutagenesis in 129S1/SVImJ (129) male mice, which were bred to C57BL/6J (B6) females. Offspring were monitored for deviations in peripheral blood composition and backcrossed to B6 mice to determine heritability and positionally clone the mutated gene. The mutant strain 7238 presented with macrothrombocytopenia, as the peripheral blood of unaffected mice averaged a platelet concentration of 1031±169×10^9 plt/μL and a mean platelet volume (MPV) of 4.7±0.2fL; heterozygous mice, 599±126×10^9 plt/μL and 6.3±0.3fL; and homozygous mice, 245±109×10^9 plt/μL and MPV of 7.3±0.2fL (Figure 1A and B).







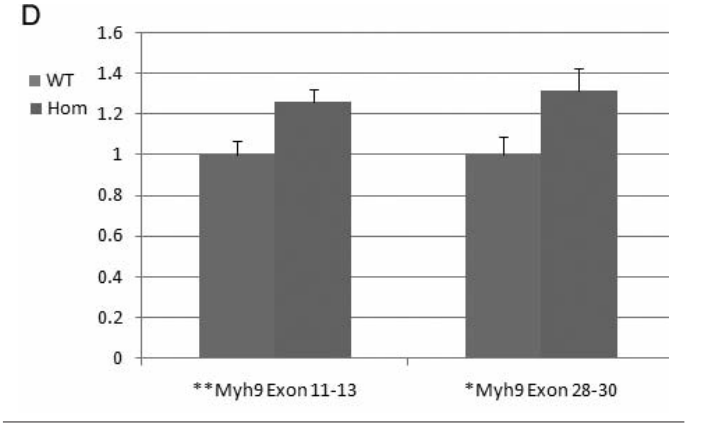


Figure 1. Phenotyping data for the Myh9Q1443L mouse line.

Methods. We used array-based sequence selection followed by massively multiple parallel sequencing to identify potential mutations within our 4.25Mb region of interest, located on chromosome 15. We designed a custom NimbleGen array for covering the 4.25Mb interval using overlapping 25-mers unique within the interval. Genomic DNA was sheared to ~200bp and hybridized to the array. Following washing, the DNA was denatured and sheared to 25-50bp, and linkers were ligated. These sequences were bound to the Illumina lawn, amplified in place, and concurrently sequenced *in situ* using temporarily terminated, fluorescently labeled dNTPs, and assembled using the B6 mouse sequence as a reference. Illumina sequencing identified 19 potential mutations located within the exon and border regions of 7238. Of these, the only non-synonymous coding is in exon 30 of Myh9. Sanger sequencing of both the 129 and B6 parental lines has shown that this site is not a novel single nucleotide polymorphism (SNP), and that Q1443L is an ENU-induced mutation. Genotyping of offspring has shown that this mutation is indicative of the observed macrothrombocytopenia phenotype. Further, we are sequencing the parental strains for the remaining 18 potential mutations; we have currently demonstrated that eleven of these sites are novel B6/129 SNPs. Therefore, the 7238 strain is relabeled Myh9Q1443L, and is a model of MYH9-related disease (MYH9-RD). *Results.* Human MYH9-RD is characterized by macrothrombocytopenia and various combinations of neutrophil inclusions, increased bleeding and bruising, cataracts, nephritis, and sensorineural deafness. The tail bleed assay demonstrated while both the wild type and Myh9Q1443L/+ mice had similar clotting times (75±36s and 98±79s, respectively, P=0.17), the Myh9Q1443L/ Q1443L mice take significantly longer (319±276s, P<0.005). We have also shown that the expression level of Myh9 protein and transcript is consistent between genotypes (Figure 1C, D). Experiments are underway - including neutrophil studies, urine analysis and auditory brainstem response studies - to determine which clinical presentations of MYH9-RD are characteristic of the Myh9Q1443L mouse model. Data from these studies will be presented. *Conclusions.* Upon completion of these experiments, we will have produced and characterized the first mouse model capable of modeling multiple aspects of MYH9-RD. This model will therefore be a valuable tool to better understand the function of MYH9 in various tissues, and potentially lead to treatments aimed at lessening the clinical symptoms of this disorder.

Background. Primary immune thrombocytopenia (ITP) is characterised by an immune-mediated destruction of platelets and impaired platelet production. Glucocorticoids, including dexamethasone, are the recommended first-line therapy for newly diagnosed ITP patients. Several studies have shown that rituximab induces an increase in platelet count in up to 60% of patients with refractory ITP. *Aims.* This study provides the interim data from an on-going national multicenter study comparing rituximab in combination with dexamethasone vs dexamethasone as monotherapy in treatment of newly diagnosed ITP patients. *Methods.* Patients are enrolled at 10 Danish haematology departments according to predefined criteria. All patients have given written informed consent prior to enrolment. Patients are ≥ 18 years of age with confirmed ITP and platelet counts ≤ 25×10^9/L or ≤ 50×10^9/L in the presence of bleeding symptoms. Eligible patients are randomised 1:1 by use of pre-coded envelopes to receive either dexamethasone (40 mg daily for 4 consecutive days repeated every 1-4 weeks for a total of up to 6 treatment cycles) as monotherapy or in combination with rituximab(375 mg/m^2 repeated once weekly for a total of 4 weeks. Pre-medication includes paracetamol and antihistamine to reduce infusion-related discomfort). Primary endpoint is sustained complete response (CR, platelets ≥100×10^9/L) or partial response (PR, platelets ≥ 50×10^9/L) at 6 months follow-up. Secondary end-points include relapse-free time periods and rates of splenectomy. Adverse effects are reported and graded by the individual clinician. Response rates, frequency of splenectomy and adverse effects were analysed by the Fisher exact test. Relapse-free survival was calculated using the Kaplan-Meier method.

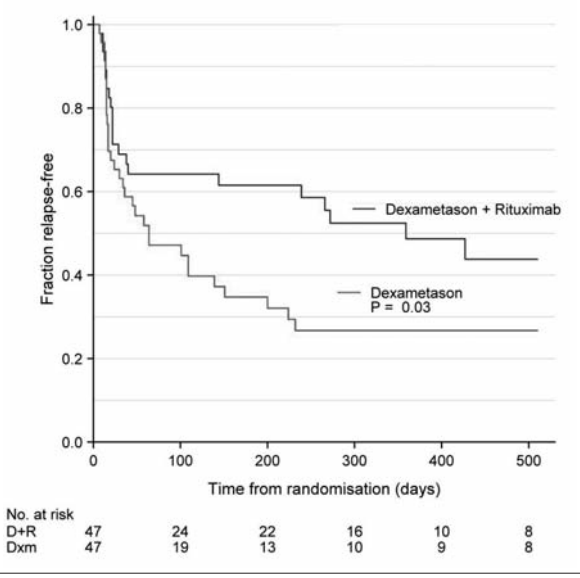

Figure 1. Kaplan-Meier plot of relapse-free survival.

Results. 116 patients were assessed for eligibility, 13 patients were excluded according to predefined criteria and 9 patients were excluded from these interim analyses due to lack of data. 94 patients were included in the efficacy and toxicity analysis (median age 51 years, range 18-84, 59% women). Sustained response (CR or PR) at 6-months follow up was achieved in 55% of patients in the rituximab group and 34% of patients in the dexamethasone monotherapy group (P=0.1). Fraction of relapse-free patients during the course of the study (up to 500 days) was significantly higher in the rituximab+dexamethasone group than in the dexamethasone group (P=0.03, Figure 1) There was no significant difference in splenectomy-rates between the two groups (2 patients in the dexamethasone group, 5 patients in the rituximab+dexamethasone group, P=0.3). Adverse effects were mild to moderate, grade 1-2 adverse effects were reported in 85% of patients in the dexamethasone group and 74% in the rituximab+dexamethasone group (P=0.32). Grade 3 adverse effects were reported in 4 patients in the dexamethasone group and 9 patients in the rituximab+dexamethasone group, 3 of these patients had 2 events (P=0.32). *Conclusion.* Initial treatment of newly diagnosed ITP patients with rituximab in combination with dexamethasone induced a sustained response in 55%, and gave rise to significantly longer relapse-free survival than in patients treated with dexamethasone alone.

0604

RESULTS OF BONE MARROW EXAMINATIONS IN PATIENTS WITH CHRONIC IDIOPATHIC (IMMUNE) THROMBOCYTOPENIC PURPURA TREATED WITH ELTROMBOPAG FOR MORE THAN ONE YEAR

J Bussel,[1] M Saleh,[2] O Meyer,[3] H Frederiksen,[4] D Johnni,[5] M Aivado,[5] A Brainsky[5]

[1]Weill Medical College of Cornell University, New York, USA; [2]Georgia Cancer Specialists, Atlanta, USA; [3]Odense University Hospital, Odense, Denmark; [4]Institute of Transfusion Medicine, Charité,, Berlin, Germany; [5]GlaxoSmithKline, Collegeville, USA

Background. Increased reticulin fibers can be found in bone marrow of patients with neoplasms and autoimmune diseases, and can lead to a condition similar to primary idiopathic myelofibrosis ([MF]; Frisch Haematol [Budap] 1982; Aharon Lupus 1997; Mufti J Supp Onc 2007). In healthy individuals, grade 1 reticulin has been reported in 27%-70% of bone marrow biopsies, while grade 2 reticulin has been reported in 4%-20% (Hultdin Med Onc 2007; Beckman Arch Path Int Med 1990; Bauermeister Am J Clin Path 1971). Bone marrow biopsies are not routinely performed in patients with chronic idiopathic (immune) thrombocytopenic purpura (ITP). Based on limited data published prior to the introduction of thrombopoietin receptor agonists, grade 1-2 bone marrow reticulin was reported in up to 67% of patients with ITP (Mufti 2007). Theoretically, stimulation of megakaryocytes with thrombopoietin receptor agonists may increase the risk of bone marrow fibrosis. Reticulin deposition, peripheral erythroblasts, tear drop cells, and blasts were reported in patients with chronic ITP treated with romiplostim (Kuter Blood 2009). Eltrombopag is the first oral, nonpeptide thrombopoietin receptor agonist licensed for the treatment of chronic ITP. EXTEND is an ongoing, long-term open-label ITP study in which patients who completed previous eltrombopag trials receive eltrombopag at a starting dose of 50 mg. *Aims.* To determine whether eltrombopag treatment is associated with a clinically significant increase in bone marrow reticulin and collagen *Methods.* In EXTEND, a bone marrow biopsy is requested annually while on treatment. Complete blood counts and white blood cell (WBC) differentials are performed at each visit. If immature or dysplastic cells are identified, a peripheral blood smear is performed. If abnormal cells are confirmed, a bone marrow biopsy is indicated; a bone marrow biopsy can be performed any time at the investigator's discretion. Reticulin is quantified using the modified MF scale (Thiele Haematologica 2005). *Results.* As of February 1, 2010, 135 patients treated for a median of 12 months at the time of the procedure (range: 1-32 months) had bone marrow biopsies evaluated for reticulin/collagen. The summary of the reticulin and collagen findings from on-treatment biopsies is presented in the Table. None of the 135 patients experienced a reticulin grade of MF-3; 3 had collagen. Of the 11 patients with a reticulin grade of MF-2, none showed clinical signs or symptoms that would indicate bone marrow dysfunction (ie, abnormal WBC differential or peripheral blood smear). Eleven of the 135 patients had a second on-treatment biopsy after ≥24 months. Compared to the first on-treatment biopsy, 8/11 patients had no change in reticulin grade, 1/11 experienced an increase of MF-1 to MF-2; and 2/11 experienced a decrease in reticulin grade (MF-2 to MF-0 and MF-1 to MF-0). No biopsy was prompted by clinical symptoms or a blood smear suggestive of

MF. *Conclusions.* In this, by far the largest series, patients treated for ≥1 year with eltrombopag had no evidence of clinically relevant increases in bone marrow fibers. Pretreatment bone marrow biopsies need to be considered in future studies.

Table.

Parameter	Patients With On-Treatment Bone Marrow Biopsies* N=135
Evaluable samples examined for reticulin/collagen, N[a]	146
MF grade 0 (or "no", "no significant increase", "no evidence of fibrosis")	87
MF grade 1 (or focal mild)	48
Collagen reported	1[b]
MF grade 2	11[b, c]
No collagen reported	9
Collagen reported	2[b]
MF grade 3	0
*Median duration of eltrombopag treatment, months: 12(1–32) for MF grades 0 and 1; 15(12–24) for MF grade 2.	

MF, myelofibrosis.

a. 11 patients had 2 samples (after 12 and 24 months of treatment).
b. No symptoms potentially related to bone marrow dysfunction.
c. 2/11 patients had reticulin in pretreatment bone marrow biopsies, considered to have increased on study. Pretreatment biopsies were unavailable for the vast majority of patients.

0605

THE EFFECT OF DESMOPRESSIN (DDAVP) ON PLATELET FUNCTION: SELECTIVE AND MARKED ENHANCEMENT OF PLATELET PROCOAGULANT ACTIVITY

L Alberio, T Conte, M Pavicic, M Reusser, M Stutz, C Thürlemann, P Keller, G Colucci

Inselspital University Hospital, Bern, Switzerland

Background. Desmopressin (DDAVP) is clinically efficacious in patients with disorders of the platelet function. This effect might be mediated by the release of von Willebrand factor (VWF) from endothelial cells. However, the documented efficacy of DDAVP in patients with Bernard-Soulier suggests that other mechanisms may be involved. *Aim.* To evaluate the effect of *in vivo* DDAVP administration on platelet function, in particular on aggregatory and procoagulant properties. *Methods.* We performed platelet aggregation (PA) and flow cytometry in 31 patients with disorders of the platelet function who received a test dose of DDAVP (0.3 mcg/kg body weight). Following platelet characteristics were studied (at baseline and 2-4 hours after DDAVP): 1) PA induced by ADP, collagen, arachidonic acid and ristocetin. 2) Surface expression of glycoprotein (GP) Ib and GPIIb-IIIa. 3) Content of delta-granules and their secretion induced by thrombin (T). 4) Secretion of alpha-granules and GPIIb-IIIa activation by graded concentrations of ADP, convulxin (CVX, a specific agonist of the collagen receptor GPVI) or T. 5) Generation of procoagulant COAT platelets induced by CVX and T. 6) Platelet-dependent thrombin generation (TG) assessed by an in house modification of the Hemker's method. *Results.* Agonist-induced PA was unchanged after DDAVP-infusion. Surface GPIb and GPIIb-IIIa did not significantly change. Delta-granules content and their T-induced secretion remained unchanged. Secretion of alpha-granules and GPIIb-IIIa activation by ADP significantly decreased by 40% and 18% respectively; both end-points induced by CVX decreased by 15% and 6%; both end-points induced by T decreased by 12% and 7%. Of note: 5) Percentage of COAT platelets significantly increased by 27%, and 6) Platelet-dependent TG significantly increased by 30%. *Conclusions.* We show that *in vivo* administration of DDAVP selectively and markedly enhances the ability to form COAT platelets and increases platelet-dependent TG, while it does not improve platelet aggregation. This is the first report showing that the beneficial haemostatic effect of DDAVP is not limited to an increase in large VWF multimers. An enhancement of platelet procoagulant activity appears to be an additional and -at least in platelet disorders- possibly more important mechanism of DDAVP's action.

POSTER SESSION II

Acute lymphoblastic leukemia - Clinical

0606

MICRORNA EXPRESSION IN PEDIATRIC PRECURSOR-B ACUTE LYMPHOBLASTIC LEUKEMIA: BIOLOGY, CLASSIFICATION AND PROGNOSIS

T Lammens, B De Moerloose, J van Baelen, J van der Meulen, P Mestdagh, B Verhasselt, J Philippé, F Speleman, Y Benoit

University Hospital Ghent, Ghent, Belgium

Background. B-lineage acute lymphoblastic leukemia (ALL) consists of ~80% of childhood ALL cases and is characterized by different genetic subgroups based on specific recurrent genetic abnormalities, bearing prognostic and therapeutic implications. MicroRNAs (miRNAs) are a class of small endogenously expressed repressor RNAs that play key roles in many cellular pathways. Recently, miRNA expression patterns have been linked to cancer subtypes as well as to disease outcome. *Aims.* In this study, we aimed to define whether different genetic subgroups in pediatric precursor-B ALL are characterized by a distinct miRNA expression signature. Furthermore, we assessed whether miRNA profiling might provide useful information for better classification and risk stratification and additionally, might contribute to our understanding of the underlying disease biology. *Methods.* A total of 693 miRNAs were profiled using automated high-throughput quantitative stem-loop RT-PCR in a cohort of 48 average risk (AR1) pediatric precursor B-cell ALL patients treated according to EORTC protocols 58881 and 58951. The cohort included cases with normal karyotype (N=6), hyperdiploid karyotype (N=12), TEL-AML1 (N=20), E2A-PBX1 (N=3) and complex rearrangements (N=7). The miRNA profiles of mononuclear cells from 13 normal bone marrow samples served as control. Moreover, a microRNA expression map of four FACS-sorted B-cell subsets was generated. The ethical committee approved the study and informed consent was obtained from the patients and/or their parents. *Results.* MiRNA profiling of the sorted B-cell subsets revealed that 97 out of 693 miRNAs were significantly expressed to more or less extent in one or more B-cell subsets. In more detail, we found that 16 miRNAs are exclusively expressed in one stage of early B-cell development, whereas the remaining showed periodic activity during B-cell maturation. Further, Significance Analysis of Microarray (SAM) revealed a 36 miRNA signature (FDR = 5%), able to distinguish between the different genetic subgroups (TEL-AML1, E2A-PBX1 and Hyperdiploidy) after unsupervised hierarchical clustering. Using Prediction Analysis for Microarrays (PAM, using cross-validation), we identified a specific and sensitive minimal classifier of 12 miRNAs for the above mentioned pre-B ALL subtypes. Adding the 'complex' sample profiles revealed that many of them clustered together with the E2A-PBX1 subgroup, suggesting a common molecular background. Target prediction of differentially expressed miRNAs revealed an overrepresentation of genes involved in cell cycle, MAPK signaling, WNT signaling and TGF-β signaling. Finally, preliminary results suggest that miRNA expression differences observed at diagnosis could give useful information on the probability of relapse. The outcome signatures are currently being validated in a larger, independent cohort. *Conclusions.* This study shows that cytogenetic subgroups in pre-B ALL are characterized by a specific miRNA expression signature. The generation of a minimal classifier within the AR1 group will allow addressing the 'normal' and 'complex' samples into a better defined subgroup. Correlation of our findings to the expression of deregulated miRNAs in normal B-cell subsets will point us to the miRNAs with true oncogenic potential and allows delineating a subset for further functional studies. After stringent validation, the preliminary outcome signature might guide us to a better understanding and handling of the possibility to relapse.

0607

CLINICO-BIOLOGIC CHARACTERIZATION OF 5203 ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS ENROLLED IN THE ITALIAN AIEOP AND GIMEMA PROTOCOLS, STRATIFIED IN AGE-COHORTS FROM SMALL CHILDREN TO YOUNG ELDERLY

S Chiaretti,[1] A Vitale,[2] SM Orlando,[3] P Fazi,[3] D Silvestri,[4] MG Valsecchi,[4] L Elia,[2] A Guarini,[2] G Cazzaniga,[5] A Biondi,[5] G Basso,[6] R Foà[2]

[1]Sapienza University of Rome, Rome, Italy; [2]Dept. of Cellular Biotechnologies and Hematology, Sapienza University, Rome, Italy; [3]GIMEMA Data Center, Rome, Italy; [4]Medical Statistics Unit, Università Milano Bicocca, Monza, Italy; [5]Centro Ricerca Tettamanti, Clinica Pediatrica Università Milano Bicocca, Monza, Italy; [6]Pediatric Hemato-Oncology, University of Padua, Padua, Italy

Background. Acute lymphoblatic leukemia (ALL) shows marked differences in clinical outcome between children and adults. Several factors account for this different scenario, including the variable incidence of molecular aberrations. It is likely that other factors differ between the two cohorts. Overall, there is limited information on the distribution of the clinico-biologic variables in the various age-cohorts, ranging from small children to young elderly. *Aims.* To define the clinico-biologic profile of newly-diagnosed ALL patients, stratified in 9 age-cohorts: 1-5, 5-10, 10-14, 14-18, 18-25, 25-30, 30-40, 40-50, 50-60 years. *Methods.* Overall, 5203 patients were evaluated: 3754 children enrolled in the AIEOP protocols and 1449 adults recruited in the GIMEMA protocols. Clinical features included WBC (>50×10^9/L) and Plt (<100×10^9/L) counts, Hb levels (<10 g/dL), liver, spleen, mediastinum enlargement and CNS involvement. Biological features comprised immunophenotypic and molecular analyses. Differences among groups were evaluated using non-parametric tests (Chi-squared and Fisher-Exact test). *Results.* There were 2890 males and 2313 females (M/F=1.25).The highest incidence was recorded in the age-cohorts 1-5 and 5-10 (36.6% and 21.4%, respectively), with a progressive decrease from 10 to 30 years and an increase from 30 years onwards. Gender distribution highlighted a lower incidence of females: this phenomenon was remarkable between 14-50 years and disappeared in the 50-60 age-cohort (P<.0001). Hyperleukocytosis was less frequent in the age-cohorts 1-5 and 5-10 (P<.0001); spleen, liver and mediastinum enlargement were present in 28.8%, 19.5% and 7% of cases, respectively: there was a constant decrease of organ involvement in older patients (P=0.0276, P<.0001, P<.0001). CNS involvement was recorded in 2.1% of cases, most frequently between 1-14 years. A T-lineage affiliation was rarer among the 1-5 and 5-10 age-cohorts (5.1%, and 15.7%, respectively), increased in patients between 10 and 40 years (average=25%), and decreased in the elderly (40-50=11.9%, 50-60=12.2%). There was a significant association between gender and immunophenotype, T-ALL being more frequent in males (P<.0001) up to the 4th decade. A B-lineage derivation was found in 85.8% of patients: an increased incidence of pro-B ALL, sustained by ALL1/AF4 positivity, was recorded in the age-cohorts from 10 to 50 years. Molecular screening highlighted a progressive increase in BCR/ABL$^+$ cases (P<.0001), detected in 52.7% of B-lineage cases in the 6th decade, and in ALL1/AF4+ cases with age (P<.0001) and a constant decrease in ETV6/RUNX1+ cases (P<.0001), whereas E2A/PBX1+ cases showed a consistent distribution among age-cohorts.

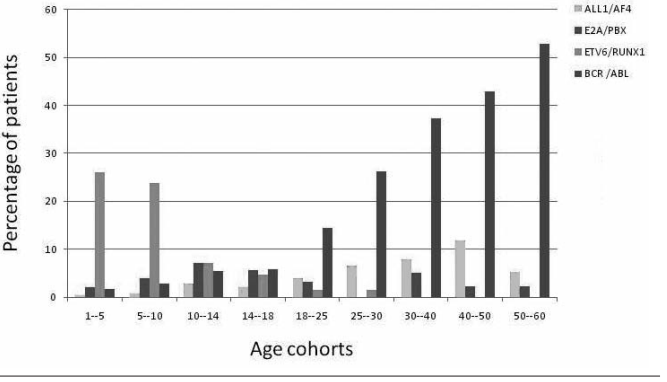

Figure 1. Molecular aberrations incidence among age-cohorts

Conclusions. Stratification in 9 age-cohorts confirms a high incidence of ALL in small children and shows a lower occurrence of ALL in females, particularly significant between 14-50 years, suggestive of a protective effect of fertility. Organ involvement declines with age, pos-

sibly reflecting a progressive, physiological atrophy, that may result in a lesser efficient immunologic control of the disease, ultimately translating in a worse outcome Finally, we conclusively quantify the decrease of ETV6/RUNX1 and progressive increase of ALL1/AF4 and BCR/ABL with age. This results in an increase with age of unfavorable prognostic markers that may be managed by targeted therapies, bearing in mind that in the 50-60 age-cohort BCR/ABL positivity accounts for over 50% of B-lineage cases.

0608

IDENTIFICATION OF A FAVORABLE PROGNOSIS GROUP OF ADULT B-LINEAGE ACUTE LYMPHOBLASTIC LEUKEMIA WITHOUT MOLECULAR ABERRATIONS BY COMBINING GENE EXPRESSION AND SINGLE NUCLEOTIDE POLYMORPHISM ARRAYS

S Chiaretti,[1] M Messina,[2] I Iacobucci,[3] S Tavolaro,[2] A Piciocchi,[4] L Elia,[2] A Vitale,[2] A Negulici,[2] M Vignetti,[4] D Weinstock,[5] A Yoda,[5] A Guarini,[2] G Martinelli,[3] R Foà[2]

Seràgnoli, University of Bologna, Bologna, Italy; [4]GIMEMA Data Center, Rome, Italy; [5]Dept. of Medical Oncology, Dana-Farber Cancer Institute, Boston, USA

Background. In B-lineage acute lymphoblastic leukemia (B-ALL) several rearrangements (BCR/ABL, MLL/AF4, E2A/PBX1) have been identified and have a prognostic impact. However, roughly 50% of cases lack major genetic aberrations visible by conventional karyotyping; for these patients the therapeutic approach is largely empiric, resulting in over or undertreatment. In B-ALL, the introduction of new advanced technologies, i.e. Single Nucleotide Polymorphism (SNP) analysis and Gene Expression Profiling (GEP), have greatly the improved discovery of novel recurrent lesions and the identification of novel prognostic subsets, especially in the pediatric setting. *Aims.* To highlight recurrent genomic aberrations in adult B-ALL, we performed SNP array analysis on a cohort of newly diagnosed cases lacking known molecular rearrangements and we integrated these data with GEP results and clinico-biologic features. *Methods.* For SNP analysis, 38 B-ALL samples without major molecular rearrangements were genotyped with the GeneChip® Human Mapping 250K NspI array (Affymetrix). Analyses were performed using the Partek Genomic Suite 6.4 and dChip softwares. Copy number aberrations were scored using the Hidden Markov Model and the segmentation approach. For GEP experiments, we evaluated the same samples and an additional cohort of 33 patients using HGU133 Plus 2.0 arrays (Affymetrix). Statistical analysis, performed using the dChip software, was based on unsupervised and supervised approaches; DAVID software was used for functional annotation analysis. Overall survival (OS), disease-free survival (DFS) and event-free survival (EFS) were estimated using the Kaplan-Meier product limit method and compared in univariate analysis using the Log-Rank test. All analyses were run in SAS. *Results.* Sixty-eight percent of cases displayed alterations larger than 1.5 Mb, the most frequent being deletions of 9p (32%), 20q (16%), 12p (16%), 7p (13%) and gains of chromosome 21 (21%). In a large proportion of patients (88%), small alterations (<1.5 Mb) were documented, the most common involving IKZF1 (58%) and CDKN2A/2B (39%), whose deletions produced a gene dosage effect. Deletion of the IFNA cluster genes, often associated with loss of MLLT3, was also frequent (32%). GEP analysis, namely unsupervised clustering, revealed the presence of several subsets (Cluster I-V). Remarkably, when these data were integrated with SNP results, an association between Clusters and specific large alterations was observed (P=0.05). Correlation with clinical variables and outcome was highly revealing: Cluster II, lacking by SNP analysis large alterations, was characterized by a lower white blood cell (WBC) count at presentation (19.1×10^9/L *vs.* 52.2×10^9/L, mean of all other Clusters), a better EFS (P=0.0015) and DFS (P=0.0003). By Linear Discriminant Analysis, additional cases falling in the above mentioned Clusters were identified and statistical analysis of clinical data confirmed that patients included in Cluster II experience a better outcome. Moreover, functional annotation clustering performed on ANOVA result highlighted an enrichment in mitochondrial genes (BH: 7.8E-1) in Cluster II specific genes. *Conclusions.* In summary, most adult B-ALL cases without major genetic abnormalities harbor copy number alterations when examined by refined techniques. Moreover, the integration of GEP and SNP data is highly informative, allowing to identify a subset of patients with a very favorable outcome.

EFFECTS OF GLUCOCORTICOID RECEPTOR GENE N363S POLYMORPHISM ON THE STEROID - INDUCED TOXICITIES DURING THE PEDIATRIC ALL THERAPY

O Eipel,[1] M Hegyi,[2] A Ponyi,[2] D Török,[2] K Csordás,[2] D Erdélyi,[2] M Csóka,[2] K Németh,[2] G Kovács[2]

[1]Semmelweis University, Budapest, Hungary; [2,2]nd Department of Pediatrics Semmelweis University, Budapest, Hungary

Introduction. Glucocorticoidreceptor (GR) gene polymorphisms are reported to be associated with increased glucocorticoid (GC) sensitivity. For that reason GR gene polymorphisms may modify the severity of the adverse effects of glucocorticoids during the chemotherapy of children with acute lymphoid leukemia (ALL). *Aim.* In our study we aimed to investigate whether any relation could be marked between the N363S GR gene polymorphism and acute glucocorticoid-induced side effects in children with ALL during their chemotherapy. *Patients and Methods.* In this retrospective study 346 pediatric patients with ALL were involved. DNA was extracted from peripherial blood taken in heamatologic remission. N363S polymorphism was determined by allele-specific PCR. Most common glucocorticoid toxicities were investigated such as hepatotoxicity, glucose metabolism abnormalities, encephalopathy, elevated blood pressure. *Results.* 32 of the 346 pediatric patients found to be heterozygous carriers (9.2%). N363S polymorphism was found to be related to hepatotoxicity and glucose metabolism abnormalities. Patient with the 363S variant had a significant higher risk for hepatotoxicity than the non carriers (31.2% *vs.* 11.1%, P=0.004). Also glucose metabolism abnormalities occurred more often among carriers than non carriers (18.7% *vs.* 3.7%, P=0.001). In our study there was no significant association between the patients with and without the polymorphism regarding the occurrence of encephalopathy (8.6% *vs.* 6.25%, P=1.0) or hypertension (28.1% *vs.* 18.1% P=0.171). The numbers of patients with at least one toxicity (65.6% *vs.* 34.1%, P=0.001) were significantly higher in the groups of carriers. Our results were similar regarding patients having at least two (21.9% *vs.* 6.7% P=0.009), or at least three (9.4% *vs.*1.3% P=0.02) glucocorticoid-induced toxicities. Their numbers were significant elevated among the 363S-carriers. *Conclusion.* Patients with N363S polymorphism may prone to have more and also more sever glucocorticoid-induced side effects during the chemotherapy. These results suggest the prospective opportunity of an individual dosing of chemotherapeutic drugs.

ONE YEAR REINDUCTIONS WITH VINCRISTINE, ASPARAGINASE AND PREDNISONE AS POST-REMISSION THERAPY IMPROVES OUTCOME IN CHILDREN WITH INTERMEDIATE RISK (IR) ACUTE LYMPHOBLASTIC LEUKEMIA (ALL)

A Oriol,[1] P Bastida,[2] O García,[2] C Calvo,[2] JM Perez-Hurtado,[2] ME González-Valentin,[2] JL Fuster,[2] I Egurbide,[2] V Martin-Reina,[2] A Molines,[2] J Lassaletta,[2] M Sanz,[2] M Tormo,[2] M Carnero,[2] JJ Ortega,[2] JM Ribera[1]

[1]ICO-Hospital Germans Trias i Pujol, Barcelona, Spain; [2]On behalf of the PETHEMA Group, Spain, Spain

Background. The ALL89 PETHEMA trial proved that delayed consolidation had a favorable influence on the outcome of children with IR-ALL.The subsequent ALL96 trial incorporated reinductions with vincristine, asparaginase and prednisone (VAP) during the first year of maintenance therapy to consolidations of the previous protocol. *Aims.* We compared both cohorts of children to evaluate the benefit of such approach in children with newly diagnosed ALL of low (LR) and intermediate risk (IR) in first complete remission (CR1). *Methods.* Children aged 1 to 18 years were classified as LR if they were 1 to9 years of age and the WBC at diagnosis was $<50\times10^9$/L and as IR if their age was >9 to 18 years or the WBC was $>50\times10^9$/L. High-risk patients [i.e. children with ALL carrying the t(9;22) or t(4;11) translocations or with WBC > 200×10^9/L] were excluded from analysis. The ALL89 trial assigned 213 with LR (N=111) or IR (N=102) ALL in CR1 to receive early or early and late consolidation cycles followed by 2 years of maintenance treatment with oral mercaptopurine and weekly intramuscular methotrexate. Children (86 IR and 233 LR) achieving CR in the ALL96 trial received similar early and delayed consolidations plus monthly vincristine (2 mg IV), asparaginase (20000 UI/sq meter IV) and prednisone (60 mg/sq meter PO x 7 days) reinductions (VAP) during the first year of maintenance treatment. The primary end point of the historical comparison was disease-

free survival (DFS). *Results.* Median follow-up of children in CR1 was 6 years. Patients in both trials were comparable in demographic and ALL characteristics. 109 children (75 LR and 34 IR) in the ALL89 trial were assigned to receive early consolidation only (Cohort 1 - C1) and 104 (36 LR and 68 IR) to receive early and delayed consolidation (Cohort 2 -C2). 281 children (79 LR and 202 IR) in the ALL96 trial received a median of 7 (range 3-7) reinductions with VAP after both consolidations (Cohort 3 - C3). 46 LR patients relapsed (24 in C1, 9 in C2 and 13 in C3). The 5-year DFS rates were 67% (95%CI 58-76), 74% (95%CI 62-86) and 84% (95%CI 77-93) for C1, C2 and C3 respetively. The hazard ratios for patients in the C2 and C3 groups were 0.77 (95%CI 0.36-1.65, P=NS) and 0.45 (95%CI 0.22-0.93, P=0.031). 80 IR patients relapsed (18 in C1, 27 in C2 and 25 in C3). The 5-year DFS rates were 46% (95%CI 31-61), 57% (95%CI 46-68) and 80% (95%CI 75-86) The hazard ratios for patients in the C2 and C3 groups were 0.77 (95%CI 0.42-1.39, P=NS) and 0.29 (95%CI 0.16-0.52, P<0.001) respectively. Two children (1 in the C2 and 1 in the C3 group) died in CR1 due to consolidation or reinduction related toxicity. *Conclusions.* VAP reinductions significantly reduced the relapse rate and improved the DFS of children with LR and IR ALL in CR1. The major benefit was obtained in IR ALL.

EFFICACY AND CLINICAL OUTCOME OF PHILADELPHIA (PH) POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) PATIENTS TREATED WITH SECOND GENERATION TYROSINE KINASE INHIBITORS (TKIS): THE BOLOGNA EXPERIENCE

C Papayannidis, I Iacobucci, S Soverini, S Paolini, C Clissa, S Parisi, MC Abbenante, S Colarossi, A Gnani, A Lonetti, A Ferrari, N Testoni, M Amabile, E Ottaviani, A Curti, V Guadagnuolo, M Baccarani, G Martinelli

Institute of Hematology Seràgnoli, Bologna, Italy

Background. Approximately 30% of adult ALL patients are characterized by the presence of the Philadelphia (Ph) chromosome, which derives from a reciprocal translocation t(9;22)(q34;q11) and results in a chimeric BCR-ABL oncogene. The prognosis for this subset of patients treated with standard therapies, including multi-agent chemotherapy, imatinib, and allogeneic stem cell transplantation, is still dismal, due to a high risk of relapse. Dasatinib and nilotinib are second generation TKIs developed to overcome resistance to imatinib in relapsed Ph^+ leukemias. Here, we sought to determine the efficacy of these agents in patients with relapsed Ph^+ ALL. *Methods.* We retrospectively evaluated the single-center experience of dasatinib, nilotinib, and experimental third-generation TKIs administered as second or subsequent lines of therapy. We evaluated the efficacy of these agents in 25 adult patients with relapsed Ph^+ ALL. All patients were previously treated with imatinib. *Results.* The median age at time of diagnosis was 50 years (range, 18-74 years). Seventeen patients were male and 8 were female. Ten patients presented with a BCR-ABL P190 fusion protein and corresponding fusion transcript, and the remaining patients exhibited BCR-ABL P210. Nineteen patients received dasatinib, 2 patients nilotinib, and the remaining 4 patients were treated with third-generation TKIs. Fourteen patients (56%) were in first relapse, and 7 (28%), 3 (12%) and 1 (4%) were in second, third, and fourth relapse, respectively. A mutational analysis was performed twice in all the patients: before administering TKIs (9 patients with wild type BCR-ABL, 16 with mutated BCR-ABL, including T315I) and at the time of subsequent relapse. Gene expression profiling, SNPArray (6.0 Affymetrix chip), and Ikaros deletions were also analyzed. Thirteen out of 25 patients (52%) achieved a hematologic response (HR) (11 patients treated with dasatinib, 1 patient with nilotinib, and 1 patient with a third-generation experimental TKI). Ten patients also achieved a cytogenetic response (CyR) and 6 patients a molecular response (MolR). With a median follow up of 10.8 months (range, 2-29 months), median duration of HR, CyR, and MolR was 117 days (range, 14-385 days); progression free survival was 162 days with dasatinib and 91 days with nilotinib. Overall survival was 25.8 months. Interestingly, in 6 out of 9 patients with wild-type BCR-ABL treated with dasatinib, the mutational analysis showed the emergence of T315I or F317I mutation at the time of relapse. *Conclusions.* Second- and third-generation TKIs represent a valid approach in treating patients with relapsed Ph^+ adult ALL. The subsequent relapse in Ph^+ ALL patients is often associated with the emergence of mutations conferring resistance to TKIs. *Acknowledgments*. ASPARAGINASE LEVELS, ANTIBODIES AND SILENT INACTIVATION IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

V Mondelaers,[1] M Dewulf,[2] B Wuyts,[1] B de Cuyper,[2] Y Benoit,[1] B De Moerloose[1]

[1]Ghent University Hospital, Ghent, Belgium; [2]Ghent University, Ghent, Belgium

Introduction. Asparaginase is a cornerstone in the treatment for childhood acute lymphoblastic leukemia (ALL). Depletion of circulating asparagine by asparaginase results in selective apoptosis of leukemic cells who require large amounts of this circulating amino acid for their cell growth. Asparaginase of bacterial origin, like E. coli asparaginase (Paronal®), induces anti-asparaginase neutralising antibodies in a large proportion of the population. This results in allergic reactions or silent inactivation, characterized by circulating antibodies and rapid clearance of the enzyme and probably impairment of the outcome by inappropriate efficacy of this potent anti-leukemic drug. *Aim of the study.* Monitoring of asparaginase levels in children with ALL, detection of antibodies and identification of silent inactivators, in order to elucidate their impact on the outcome of these patients. *Materials and Methods.* Between May 2004 and August 2008, we collected serum samples of 104 patients with *de novo* ALL who received asparaginase according to the EORTC 58951 protocol. Asparaginase enzymatic activity was measured by photometry at 450nm after reaction with Nessler's reagent. Quantitative detection of human anti-E. coli asparaginase antibodies was performed by using a direct ELISA format. Asparaginase activity >100 U/L was considered to be sufficient for complete depletion of asparaginase in the serum. *Results.* 51 (49%) of the 104 patients developed an allergic reaction to Paronal®, 26 of them were boys, 25 girls. 4 were treated according to the very low risk group, 27 according to average risk group (AR) 1, 10 according to AR group 2 and 4 received a very high risk protocol. The majority of the allergic reactions were classified as grade 2 and 3 according to the WHO classification; we did not observe grade 4 allergic reactions. Allergy could occur in all treatment phases (induction: 27%, consolidation: 20%, maintenance: 8%), with predominance during reinduction (45%). 26 patients were switched to Erwinia asparaginase (Erwinase®),18 to pegylated E. Coli asparaginase (Oncaspar®). Allergic patients presented significantly higher asparaginase antibodies at the time of clinical allergic reaction, compared to non-allergic patients (mean: 5,9 105 µg/L *vs.* 2,5 103 µg/L). In most allergic cases high antibody levels correlated with low asparaginase activity. Four allergic patients presented asparaginase activity >400U/L and low antibody titers. Presumably their allergic reaction was triggered by a compound of Paronal® instead of the E. Coli asparaginase itself. On the contrary we observed 3 non-allergic patients with low asparaginase activity and high antibody levels (>105 µg/L), so called silent inactivation. Currently, these 3 patients remain in complete remission. *Conclusions*. These results show that monitoring of asparaginase levels and antibody titers during treatment of children with ALL is feasible. Unexpected observations as silent inactivation and absence of antibodies after allergic reaction show the additional value of these measurements. A prospective multicenter study will unravel the importance of these asparaginase levels, antibodies and silent inactivation in the clinical course and outcome of patients treated with asparaginase for childhood ALL and will determine cross-reactivity of antibodies after switching products. Consecutive measurement of asparagine and glutamine depletion will give insight in the ideal cut-off for asparaginase activity.

ARE PEDIATRIC LEUKEMIA SURVIVORS AT RISK OF DEVELOPING A METABOLIC SYNDROME IN ADULTHOOD?

C Oudin,[1] A Bégu,[2] M Simeoni,[3] B Play,[1] P Bordigoni,[4] A Contet,[4] N Sirvent,[5] H Chambost,[1] P Auquier,[6] G Michel[1]

[1]Hopital Timone enfants, Marseille, France; [2]Hopital Timone, Marseille, France; [3]Faculté de Médecine de marseille, Marseille, France; [4]Hopital d'Enfants de Brabois, Nancy, France; [5]Universitary Hospital L'Archet, Nice, France; [6]Faculté de Médecine de Marseille, Marseille, France

Background. long term survivors of childhood acute leukaemia are exposed to life threatening conditions during their adult life. A higher risk of cardio vascular diseases has formerly been pointed out in this population. *Aims.* to evaluate the prevalence of metabolic syndrome (MS), as defined by the National Cholesterol Evaluation Program Adult Treatment Panel III (NCEP-ATP III) and its components in the "L.E.A"(for Leucémie de l'Enfant et de l'Adolescent") French cohort. We then tried to define risk factors associated with the development of the

MS. *Methods.* this prospective study evaluates incidence and risk factors for MS in young adult leukemia survivors included in the « L.E.A » program, a French multicentric program, built in order to evaluate the long term health status, the quality of life and socio-economical status of childhood leukaemia survivors treated since 1980. During the years 2007 and 2008, assessment of MS and its components was systematically offered to all adults with a new L.E.A. health status evaluation. Metabolic syndrome was defined according to the 2005 revised NCEP ATPIII definition. Informed consent was obtained from all participants. *Results.* Out of 184 patients included in the study (mean age: 22.7 years, mean follow-up: 14.5 years), the overall frequency of the MS was 9.24% (CI: 5.47; 14.38), respectively 8.42 and 10.11%, for men and women. In a multivariate analysis, we found that a higher frequency of MS was significantly associated with total body irradiation (TBI) conditioning regimen before haematopoietic stem cell transplantation (OR: 3.88, CI: 1.13-13.32, P=0.03) compared with non TBI exposed subjects. The use of TBI was associated with a higher rate of dyslipemia (hypertriglyceridaemia, OR: 4.47, CI: 1.6-12, P=0.01, and low HDL-cholesterol, OR: 2.55, CI: 1.1-5.7, P=0.02) and elevated fasting glucose (OR: 6.11, CI: 1.11-33.47, P=0.04). By contrast, we did not find any impact of TBI on waist circumference or blood pressure. The use of cranial irradiation was not a significant risk factor, contrasting with several studies previously reported. Interestingly, MS was associated in univariate analysis with other late endocrine complications of childhood leukaemia: MS was more frequent among patients suffering from hypogonadism (23.53% *vs.* 6.00%, P=0.001), and hypothyroidism (23.53% *vs.* 7.78% out of patients without hypothyroidism, P=0.06). There was no significant association between MS and growth deficiency. *Conclusions.* MS is frequent among childhood leukaemia survivors. We have shown for the first time that TBI is a major factor involved in the genesis of the MS. The mechanisms by which these results could be explained remain to be explored.

0614

CLOFARABINE IN CLINICAL PRACTICE: THE UNITED KINGDOM EXPERIENCE IN PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA

D O'Connor,[1] K Sibson,[2] M Caswell,[3] P Connor,[4] M Cummins,[5] C Mitchell,[6] J Motwani,[1] M Taj,[7] A Vora,[8] R Wynn,[9] P Kearns[1]

[1]Birmingham Children's Hospital, Birmingham, UK; [2]Great Ormond Street Hospital for Children, London, UK; [3]Alderhey Children's Hospital, Liverpool, UK; [4]Children's Hospital for Wales, Cardiff, UK; [5]Bristol Royal Children's Hospital, Bristol, UK; [6]John Radcliffe Hospital, Oxford, UK; [7]The Royal Marsden Hospital, London, UK; [8]Sheffield Children's Hospital, Sheffield, UK; [9]Royal Manchester Children's Hospital, Manchester, UK

Background. Clofarabine, a second-generation purine nucleoside analogue is licensed for the treatment of multiply relapsed pediatric acute lymphoblastic leukemia (ALL). Early phase trials suggest it is effective and well tolerated when combined with other cytotoxic drugs. Combination regimes are increasingly prescribed for the treatment of resistant cases. *Aims.* This study aims to draw together the United Kingdom (UK) experience of clofarabine use for the treatment of pediatric ALL. *Methods.* All UK centers that had used clofarabine for the treatment of pediatric ALL outside the context of a clinical trial were approached to offer participation in the study. *Results*. Of the 11 centers identified, 9 provided information on 23 patients who had received clofarabine. Median age was 6 years, including 5 infants. The group included 18 B-lineage leukemias, 4 T-lineage leukemias and 1 mixed lineage leukemia. Six patients had adverse cytogenetics (5 MLL rearrangements, 1 t(9:22). Patients had received a median of 2 prior treatments (Range 1-4) and 5 patients had undergone previous hematopoietic stem cell transplantation (HSCT). Five patients received single agent clofarabine, whilst 18 received combination treatment with cyclophosphamide and etoposide using a range of schedules. Clofarabine, both as a single agent and in combination regimes, was well tolerated with no treatment related deaths. Most frequent adverse events were febrile neutropenia (65%), mucositis (26%) and diarrhea (17%). Several severe infections occurred including 2 invasive fungal infections and 2 viral infections (CMV reactivation and astrovirus diarrhea). Overall response rate (ORR) was 61%; 12 achieved complete remission (CR) and 2 partial remission (PR). ORR was higher in combination regimens compared with single agent use (67% *vs.* 40%). Responses were seen in both B- and T- lineage leukemias; ORR 61% (9CR, 2PR) and 75% (3CR) respectively. There were responses in patients with adverse cytogenetics, including MLL rearrangements and t(9:22). Responses were seen in all age groups including those less than one year of age (ORR 60%, 3CR). Response rate was inversely proportional to the number of prior treatments, with the highest ORR in those who had only received 1 prior treatment (ORR 86% 6 CR). Of the 12 patients who achieved a CR, 11 went on to receive HSCT. There were 2 deaths due to transplant related mortality. Of the remaining 9 patients, 2 have relapsed, whilst 7 remain in remission with a median follow up of 12 months. *Summary/Conclusions.* Clofarabine is being increasingly used in clinical practice in the UK in the treatment of pediatric refractory ALL, Our data suggest that it is most effective when given in combination with other cytotoxics and in first relapse and can lead to durable remissions. This study reports on the use of clofarabine in infants and shows good response rates. In contrast to previous studies, these data demonstrate a high response rate in T-lineage ALL. The associated incidence of fungal and viral infections would support the use of appropriate prophylaxis

0615

UTILITY OF SINGLE TUBE, SIX COLOUR FLOW MEASUREMENT OF MRD IN CHILDHOOD B-CELL PRECURSOR ALL DURING THE FIRST MONTH OF TREATMENT ON UKALL 2003

T Milne,[1] C Chang,[2] S Inglott,[1] J Moppett,[1] N Griffin,[1] D Webb,[1] P Ancliff,[1] P Virgo,[2] N Goulden[2]

[1]Great Ormond Street Hospital, London, UK; [2]Southmead Hospital, Bristol, UK

Background. Clearance of minimal residual disease (MRD) as assessed by PCR of antigen receptor genes is now established as the strongest independent prognostic factor in children receiving identical treatment for ALL. Flow cytometric measurement of MRD is quicker and cheaper than PCR but concerns remain over applicability, change in antigen density and relative insensitivity, particularly when four colour approaches are used. We have examined which of three 6 colour combinations provides optimal applicability stability and sensitivity for use in a single tube method. *Aims.* 1) assess utility of CD58, CD34 and CD123 when added to a common 5 marker combination CD19, CD20, CD38, CD45, CD10. 2) compare utility of the CD58 six colour tube with a re-gated four colour format (CD19/CD45/CD20/CD38), chosen to be minimally affected by steroid therapy. *Methods.* Diagnostic marrow from 52 unselected children treated consecutively for BCP ALL was screened for leukaemia associated immunophenotypes (LAIPs) defined as "empty spaces"in normal controls. LAIPS were then used to measure MRD in marrow at Day8, Day15 and Day28 of ALL 2003. Analysis was performed on a FACS Canto II using BD FACSDiva software. A minimum of 70,000 events were analysed to define a LAIP at diagnosis and 500,000 analysed at follow-up (Figure 1) .

Diagram 1: The sequential gating strategy for the 6-colour panel. Using normal bone marrow as an example, optimal separation of B cells (P1) is achieved using Side Scatter *vs.* CD19 gating. Immature B cells (P2) are separated from mature B cells (P3) using CD45 *vs.* CD19 gating. The P2 cluster was then gated for the 3 leukaemia-associated immunophenotypes (LAIPs). The P4 gates highlight the relative positions that the MRD clusters should fall into for each LAIP, termed 'MRD space'. The mature B cells (P3) are also gated for each LAIP for confirmation of maturity.

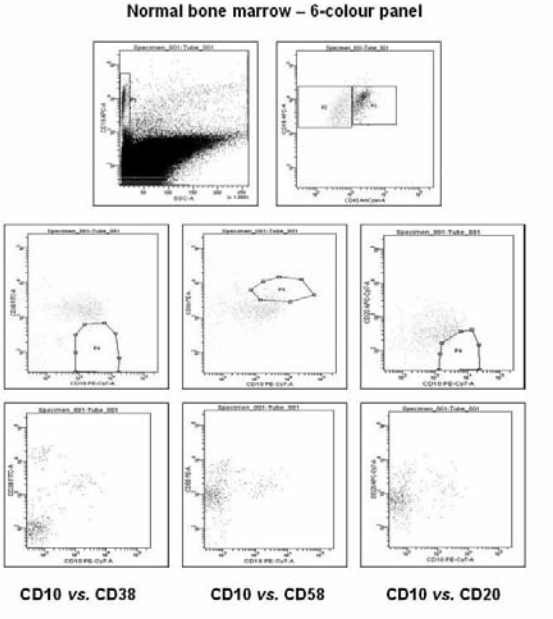

Diagram 2: The sequential gating strategy for the 4-colour panel. Using normal bone marrow as an example, optimal separation of B cells (P2) is achieved using Forward *vs.* Side Scatter, then Side Scatter *vs.* CD19 gating. The P2 cluster was then gated against the 3 LAIPs. The P3 gates highlight the relative positions that the MRD clusters should fall into for each LAIP, termed 'MRD space'.

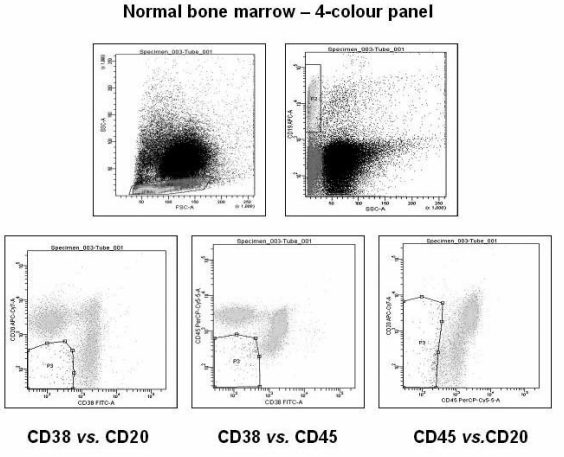

Figure 1.

Results. Applicability at diagnosis. The three six colour combinations were applicable to all patients tested - a diagnostic LAIP was defined in 52/52 screened with the CD58 combination, 36/36 screened with the CD34 combination and 31/31 screened with CD123 combination. Concordance of MRD results during the first month of treatment. 93 samples from 37 patients were analysed by multiple 6 colour marker sets (77 from 31 patients were analysed by all three). 54 of these samples were MRD positive (> 0.01%). All results were concordant between markers (<0.5 log difference). Changes in antigen density with treatment in more than 25% of cases. CD58 (41% of patients), CD34 (42%), CD10 (48%) became dimmer and CD45 (25%) became brighter. CD19 was not affected by treatment in any patient. Comparison of results of six and four colour strategies. 45 cases were screened by re-gating with 4 colours. No LAIP was defined at diagnosis in 9. In the remaining 36 cases, results of 4 and 6 colour analysis of 84 samples from 27 patients were concordant all time points (<0.5 log difference). Discordant results were seen in 22 samples from 9 patients - of particular note 8 of 9 patients had positive 4 colour results but negative six colour analysis at day 28, suggesting that four colour analysis may be cofounded by lymphoid regeneration. *Summary/Conclusions.* A single six colour combination CD19/CD45/CD20/CD38/CD10/CD58 is a widely applicable, stable marker of MRD early in therapy for BCP ALL. There is no gain in applicability from inclusion of tubes containing either CD34 or 123. Applicability, sensitivity and specificity are superior to four colour flow. At €12 the consumable cost of this single tube method is 50 times less than that of PCR of antigen receptor genes.

0616

CLINICAL OUTCOME AND MONITORING OF MINIMAL RESIDUAL DISEASE (MRD) IN PATIENTS WITH THE MLL-ENL GENETICALLY DEFINED ACUTE LYMPHOBLASTIC LEUKEMIA SUBTYPE

G Cimino,[1] L Elia,[2] S Grammatico,[2] A Rago,[3] L Moleti,[2] M Luciani,[4] A Biondi,[5] MR Caraci,[6] G Gaidano,[7] L Santoro,[8] R Fanin,[9] F Paoloni,[10] M Vignetti,[2] R Foà,[2] F Mandelli[10]

Background. MLL-ENL fusion represents one of the most frequent abnormalities of ALL with the mixed-lineage leukemia (MLL) gene alteration. Because of the rarity and prevalence of this alteration in infants, the outcome of MLL-ENL positive ALL in patients of the other age groups is not firmly established. *Aims.* To better define the clinical-biologic characteristics of this leukemic subtype, we analyzed 12 MLL-ENL positive ALL patients (4 children and 8 adults), consecutively diagnosed between April 1999 and June 2009. *Methods.* At diagnosis MLL-ENL was detected by a multiplex RT-PCR, while we used the same individual primers and conditions as the multiplex system for the MLL-ENL RT-PCR monitoring of MRD, at a sensitive level of 10^{-4}. Ig/TCR gene rearrangements were detected at diagnosis and patient specific primers were designed to obtain at least two sensitive markers (^{3} 1×10^{-4}) and used to PCR-MRD. *Results.* The MLL-ENL fusion was identified in 4 (2.6%), 8 (0.6%) and 0 (0 %) of the 150 pediatric, 1215 adult and 70 elderly ALL tested patients, respectively. Four were females, 8 males. Median age was 26 years (range: 0.2-59 years). Eight patients had a WBC count $>50\times10^9$/L (median WBC = 74.5×10^9/L; range 2.9 - 707.0×10^9/L). A T-immunophenotype was detected in 3 of the 10 evaluable cases, while the 7 remaining had a B-precursor ALL (pro-B = 3; pre-pre B = 3 and pre-B = 1). Eleven out of twelve patients (92%) achieved CR; one died of infection. At 48 months 73.3% of patients is projected to be survivor and 66.7% to be event free survivor. At response evaluation, two of the 11 CR patients tested MLL-ENL negative and six positive. However, the MLL-ENL status did not correlate with outcome. In fact, the three relapses occurred in both the two RT-PCR negative cases and in one of the 6 positive patients, while the remaining 5 RT-PCR positive cases were in CR at 8, 9, 3, 3 and 5 years, respectively. In addition, MLL-ENL expression, not preceding a relapse, was detected several times during the follow-up of 5 long-survivors. In 4 cases (three children and 1 adult) therapeutic response was also determined by the parallel assessment of Ig/TCR markers. All the 4 cases remained MLL-ENL positive, but the 3 children achieved a Ig/TCR negativity, becoming long-survivors at 8, 9 and 6 years, respectively. The adult persisted Ig/TCR positive and underwent an allogeneic HSCT that induced a long-term continuous CR lasting for 5 years. Once again this case showed the MLL-ENL expression for several times during the follow-up. *Summary/Conclusions.* Present data suggests that: 1) the MLL-ENL fusion identifies a rare genetically determined leukemic entity with an extremely favourable prognosis also in adult ALL; 2) the inconsistency between the clinical cure and the presence of detectable MLL-ENL transcript, both at therapeutic response evaluation and during follow-up of long-term CR patients. This latter finding suggests the presence of a MLL-ENL-expressing "pre-leukemia" stem cells, similar to what demonstrated for the AML1-ETO positive leukemia setting.

0617

OUTCOME OF CHILDREN (NON-INFANT) WITH T(4;11) POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA TREATED WITH AIEOP-LLA 2000-R2006 PROTOCOLS

L Lo Nigro,[1] MG Valsecchi,[2] G Cazzaniga,[3] C Rizzari,[4] D Silvestri,[2] M Luciani,[5] E Barisone,[6] C Messina,[7] N Santoro,[8] G Masera,[4] G Basso,[9] M Aricò,[10] A Biondi,[4] V Conter[11]

[1]Azienda Policlinico University of Catania, Catania, Italy; [2]University of Milano, Milano, Italy; [3]Fondazione Tettamanti Ospedale Nuovo SanGerardo, Monza Milano, Italy; [4]Ospedale Nuovo SanGerardo, Monza Milano, Italy; [5]Ospedale Bambin Gesù, Roma, Italy; [6]Ospedale Regina Margherita, Torino, Italy; [7]Istituto G Gaslini, Genova, Italy; [8]Azienda Universitaria Policlinico, Bari, Italy; [9]University of Padova, Padova, Italy; [10]Ospedale Meyer, Firenze, Italy; [11]Ospedali Riuniti di Bergamo, Bergamo, Italy

Background. Nowadays children with ALL can be cured in more than 80% of cases. Unfortunately this rate is much lower in patients bearing specific chromosomal translocations as t(9;22) and t(4;11). The latter one is detected in 1-3% of children with ALL. However 60% of infants with ALL showed the t(4;11) translocation and a poor outcome. Conversely children with more than one year of age and bearing the same chromosomal aberration are fewer than infants and has a better outcome (Pui 2002). It is still unclear the role of chemotherapy and of hematopoietic stem cell transplantation (HSCT) in children older than one year of age with t(4;11) positive ALL. *Aim.* To evaluate response to AIEOP LLA 2000-R2006 protocol strategy in children older than one year of age (non infants) with ALL bearing t(4;11) translocation. *Materials and Methods.* Non-infants with t(4;11) positive ALL treated in AIEOP ALL 2000 and in ongoing R2006 protocols were analyzed. Patients stratification was based on prednisone response (at day 8 with blast count less than 1000/mmc), resistance (day 33) and detection of

minimal residual disease (MRD) performed at day 33 and at day 78. Children with t(4;11) were allocated to high risk treatment and eligible to a matched familiar donor (MFD) HSCT and to a matched unrelated donor (MUD) if prednisone poor responder (PPR). *Results.* We here present results of 20 children with t(4;11) positive ALL diagnosed and treated with AIEOP strategy between September 2000 and December 2007. The median age was 8 years. Eleven cases were male. The central nervous system (CNS) was involved in 2 cases. One child died before starting treatment and another one during induction (early death for infection). Six out 19 cases resulted PPR (31.5%). MRD analyses showed these results. 6 cases as HR; 11 cases as MR (4 patients were studied with one marker); one case had no evaluable markers. Relapse occurred in 8 cases (42%): 4 after front-line treatment (1 presented as AML); 4 after MFD-HSCT (1 singenic). Death occurred in 8 children who entered in the protocol: one during induction; two transplant related; five cases died of disease after relapse. Ten cases are alive in complete remission: 6 after front-line treatment; 2 after MFD HSCT; 4 after MUD HSCT. Event free and Overall survival rates at 2 years are 46.7% (SE 11.8) and 54.7% (SE 12.1), respectively. *Conclusions.* Our experience confirm that children older than one year of age with a t(4;11) positive ALL have showed an expected better outcome than infants. Moreover, However relapse rate is high, although they underwent a HSCT in first remission or showed an MRD profile as MR. Extended biological studies are needed to identify new target for a tailored-treatment in order to eradicate the disease and facilitate results of HSCT.

0618

PRESENTATION AND OUTCOME OF CHILDREN WITH DOWN SYNDROME AND ACUTE LYMPHOBLASTIC LEUKEMIA IN THE EORTC CHILDREN'S LEUKEMIA GROUP PROTOCOL 58951

V Mondelaers,[1] B De Moerloose,[1] S Suciu,[2] A Ferster,[3] P Lutz,[4] A Uyttebroeck,[5] D Plantaz,[6] L Norton,[7] N Sirvent,[8] A Robert,[9] P Philippet,[10] F Mazingue,[11] K Yakouben,[12] M Munzer,[13] F Millot,[14] P Rohrlich,[15] L Baila,[2] Y Bertrand,[16] Y Benoit[1]

[1]Ghent University Hospital, Ghent, Belgium; [2]EORTC Headquarters, Brussels, Belgium; [3]Hude, Brussels, Belgium; [4]Hautepierre, Stasbourg, France; [5]University Hospital Gasthuisberg, Leuven, Belgium; [6]CHR La Tronche, Grenoble, France; [7]Escolar San Joao Hospital, Porto, Portugal; [8]Fondation Lenval, Nice, France; [9]Children's Hospital, Toulouse, France; [10]CHC Espérance, Montegnée-Liège, Belgium; [11]CHR, Lille, France; [12]Robert Debré Hospital, Paris, France; [13]American Hospital, Reims, France; [14]J Bernard Hospital, Poitiers, France; [15]CHU, Besançon, France; [16]Debrousse Hospital, Lyon, France

Background. Children with Down syndrome (DS) are at increased risk of developing acute lymphoblastic leukemia (ALL). Previous studies indicate a worse outcome for children with DS-ALL when compared to similarly treated children with ALL without DS (non-DS). This poorer outcome is most likely due to a lower rate of remission induction and more treatment-related toxicities. Objectives. Examination of the characteristics and outcome of DS-ALL-patients and comparison of their survival with non-DS-ALL-children. *Methods.* Exhaustive retrospective analysis of the presenting features, treatment and outcome in DS-patients with ALL treated with the EORTC Children's Leukemia Group protocol 58951. An informed consent was obtained for all patients. Results. 35 DS-ALL-patients and 1554 non-DS-patients with B-cell precursor ALL were compared. There were no T-cell ALL cases amongst DS-patients and no DS-ALL-infants. DS-patients had less often splenomegaly, higher hemoglobin and lower platelet counts. There were no adverse prognostic translocations, i.e. t(9;22) and t(4;11); and favorable cytogenetic aberrations, i.e. hyperdiploidy with >50 chromosomes and t(12;21) were less often present in the DS-cohort. DS-patients received less methotrexate and they were not included in the high risk groups (AR2 and VHR). DS-patients had inferior 5-year EFS (73.7% *vs*. 84.1%, P=0.043) and 5-year OS (81.9% *vs.* 91.5%, P=0.007), as compared to non-DS-patients. This worse outcome resulted from an increased induction failure rate (5.7% *vs.* 0.1%), mainly due to infectious deaths, and higher relapse rate (17.1% *vs.* 11%). Children with DS more often displayed severe treatment-related toxicities, especially mucositis in all treatment phases and hyperglycemia in the corticosteroid and asparaginase containing blocks. There was a tendency towards more infectious episodes in the DS group. Conclusions. Inclusion of children with DS in phase III study protocols has increased overtime and survival has improved. However, the outcome of children with DS and ALL remains worse than in ALL patients without DS because of higher risk of induction failure, mainly due to infectious deaths, and relapse. These findings indicate that we have to face the difficult challenge to increase the efficiency of the treatment with that of preventing the severe toxicities to which this particular population is oversensitive.

0619

COMPARING EMOTIONAL/BEHAVIORAL PROBLEMS BETWEEN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA AND HEALTHY PEERS

S Nazari, S Sadeghi Koupaei

Shahid beheshti university of medical sciences, Tehran, Iran

Background. Survival rate for so many childhood malignancies has improved during the last decade by the introduction of new treatment modalities and chemotherapeutic agents.1 For childhood Acute lymphoblastic Leukemia (ALL), which is considered as one of the prevalent malignancies in children (~%26 of overall malignancies), the long-term survival rate has reached to more than 80%in 1-10 years old children and a majority of them are actually cured.2 However, despite this great achievement, the impact and burden of such malignancies on the psychosocial qualities of these children are not well emphasized and has remained a problem, which may even seem more challenging in future. Despite great achievements in treating acute lymphoblastic leukemia in children, its burden on the psychosocial status of patients is not well understood yet. *Aims.* This study aims to determine the effect of childhood ALL on emotion, behavior and attention of patients in comparison with normal peers. *Methods.* We enrolled one hundred 6-12 years old children with ALL and 100 healthy peers as control, matched for age and gender. Mean age in the case and control group were 8.97±1.74 and 8.74±1.74, respectively. We used the Child Behavior Checklist (CBCL) from Achenbach System of empirically Based Assessment (ASEBA) to evaluate the study group. The questionnaires were completed by the child's caregiver under direct supervision of a psychologist. *Results.* There were no significant differences between the groups for age, gender and level of study at school, but this was not true for the caregivers relation and father's and mother's educational level. There existed no significant difference for school performance, but ALL group had a significant failure in group activity and social relations. Total competence was also meaningfully disturbed for ALL cases. Thought problems, attention problems, aggressive behavior, externalization, attention deficit/hyperactivity, conduct and oppositional defiant problems were more prevalent in normal children. Somatic problems were more common in ALL children. *Conclusions.* Our findings suggest that less behavioral and emotional problem among ALL children is due to better support and care from parents. Unique findings of this study emphasize the importance of more research on the psychosocial status of children with cancer.

0620

EFFICACY AND FEASIBILITY OF NELARABINE SAVAGE THERAPY IN ADULT RELAPSED OR REFRACTORY T CELL ACUTE LYMPHOBLASTIC LEUKEMIA (T-ALL) OR LYMPHOBLASTIC LYMPHOMA (T-LBL): A SINGLE-CENTER EXPERIENCE

C Papayannidis, I Iacobucci, MC Abbenante, S Paolini, S Parisi, A Lonetti, V Guadagnuolo, A Ferrari, E Ottaviani, N Testoni, A Curti, C Clissa, M Baccarani, G Martinelli

Institute of Hematology Seràgnoli, Bologna, Italy

Background. T-ALL represents 15% of childhood and 25% of adult ALL. Despite a cure rate of almost 80% in children and adolescents, adult ALL remains a difficult disease to cure, due to a high risk of relapse. Effective treatment of relapsed acute T-ALL is limited with a low CR rate, a high treatment-related mortality, and a very low prolonged disease-free survival. Nelarabine is a pro-drug of ara-G, approved by the FDA for the treatment of T-ALL and T-LBL that have not responded to or has relapsed after treatment with at least 2 chemotherapy regimens. Similar to other nucleoside analogues, Nelarabine acts by inhibiting DNA synthesis and inducing apoptosis in malignant cells. *Aims.* of the study. To evaluate safety profile and efficacy of Nelarabine treatment as savage therapy in 9 adult relapsed or refractory T-ALL or T-LBL. *Patients and Methods.* After obtaining an informed consent, nine patients (median age 31 years, range 19-37, M/F= 9/0) affected by T-ALL (N=6) and T-LBL (N=3) received a savage therapy with Nelarabine (median cycle=1, range 1-3). Nelarabine was administered at standard adult dosage (1500 mg/sqm on days 1, 3 and 5, every 21). Seven patients were relapsed after two previous chemtotherapy regimens, including allogeneic bone marrow transplantation; the remaining two patients were primary resistant to standard induction treatment. *Results.* Five out of nine patients obtained a complete morphological remission (4 T-ALL patients and 1 T-LBL patient), whereas

a partial remission was documented in two cases, with an overall response rate of 78%. Median duration of complete response was 6 weeks (range 3-6 weeks). Nelarabine was well tolerated, and no significant adverse events were registered. Extra-hematological neurological toxicity, not clearly related to the drug, occurred in two cases, determining, in one patient a complete and irreversible paraplegia, and in the second one a condition of mental confusion (grade III), which resolved after few days. Conclusions. In our experience Nelarabine was successfully administered in such a high risk patients population. The drug showed a relevant efficacy and a good safety profile. Acknowledgments. This work was supported by European LeukemiaNet, AIL, AIRC, Fondazione Del Monte di Bologna e Ravenna, FIRB 2006, PRIN 2008, Ateneo RFO grants, Project of integreted program (PIO), Programma di Ricerca Regione - Università 2007 - 2009

0621

SAFETY AND TOLERABILITY OF INTRATHECAL LIPOSOMAL CYTARABINE AS CNS PROPHYLAXIS IN PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA

P Neumeister,[1] H Schmidt,[1] W Linkesch,[1] M Pfeilstöcker,[2] A Rohn[1]

[1]Department of Hematology, Graz, Austria; [2]3Medical Department, Hanusch Hospital, Vienna, Austria

Background. Central nervous system (CNS) recurrence in acute lymphoblastic leukaemia (ALL) occurs in up to 15% of patients and depends on the intensity of front line systemic and CNS directed therapy and subtype of ALL. Meningeal recurrence -which is generally associated with a systemic relapse- not only adds significant morbidity for the individual patient but is also frequently associated with poor outcome. Liposomal Cytarabine (DepoCyte) is a sustained release formulation of Ara-C with a more homogeneous distribution throughout the neuroaxis and a prolonged half life maintaining cytotoxic concentrations in the CSF for more than 14 days. *Aims.* The purpose of our study was to evaluate the efficacy and safety of a slow-release liposomal formulation of cytarabine for intrathecal (IT) meningeal prophylaxis in patients suffering from ALL. *Patients and Results.* From 7/2004 to 2/2010 31 patients aged 20 to 68 years (median= 35) were preventively treated with a total of 75 (range: 1-6) single doses containing 50 mg of liposomal cytarabine on a compassionate use basis. Diagnoses consisted of BCR-ABL positive Pro-B-ALL (n=6), c-ALL/Burkitt lymphoma (n=2), T-ALL (n= 11), and Pro-B-ALL (n=12). All patients were treated according to the risk adapted German Multicenter Protocol/ GMALL 07/2003 including 24 Gy irradiation to the neurocranium as constituent component of CNS directed therapy. Six patients expressed the bcr-abl fusion oncoprotein and were concomitantly treated with imatinib mesylate as outlined in the study protocol. All patients received dexamethason for 3-5 days in order to prevent chemical arachnoiditis. Except for headache grade 2 in one patient no specific toxicity attributable to IT liposomal cytarabine application was noted. So far, after a median observation period of 12 months (range:1-63) 14 patients died, 10 of disease recurrence, two of GVHD after allogeneic related or unrelated stem cell transplantation, one of pulmonary artery embolism, and one of sepsis. 17 patients are in complete (n=15) or partial (n=2) remission, one after successful salvage therapy of first relapse and 8 after myeloablative allogeneic stem cell transplantation. Only one patient experienced a combined medullary - leptomeningeal disease recurrence 6 months after primary diagnosis and finally succumbed to his disease. None of the surviving ALL patients developed neurological symptoms or long term neurological side effects. *Conclusions.* IT liposomal cytarabine therapy at a dose of 50 mg with concomitant dexamethasone appears to be feasible and well tolerated. However, since all patients received concurrent systemic chemotherapy and CNS directed irradiation the efficacy of liposomal cytarabine cannot be assessed separately. Ongoing studies will further define the exact schedule for IT prophylaxis in adult patients with ALL.

0622

NO BLASTS AT DAY 8 IS BETTER THAN MORE IN CORTICO-SENSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA

M Medhaffar,[1] I Frikha,[1] S Hdiji,[1] C Kallel,[2] N Ajmi,[1] H Bellaaj,[1] O Kassar,[1] H Eleuch,[3] H Sennana,[4] J Gargouri,[3] A Saad,[4] M Elloumi[1]

[1]Hematologie Clinique, Sfax, Tunisia; [2]Hematologic Laboratory, Sfax, Tunisia; [3]Centre Régionale de Transfusion Sanguine, Sfax, Tunisia; [4]Laboratoire Cytogénétique, Sousse, Tunisia

Background. Acute lymphoblastic leukemia (ALL) had a good prognostic in children and young adults. However, some parameters were predictive of a worse outcome. We analysed in this study the impact of persistent blasts at day 8 of pre-phase in cortico-sensitives patients with ALL. *Patients and Methods.* Between January 2000 and December 2007, we retrospectively analysed the data of 134 children and young adults treated according the EORTC 58951 protocol. Cortico-sensitivity was considered if peripheral blast count is less than 1000/mm^3 at day 8 of prephase. The group of cortico-sensitives ALL was subdivided on two subgroups: the first with no blasts at day 8 and the second with more. We analysed the impact of cortico-sensitivity on overall survive (OS), event free survive (EFS) and disease free survive (DFS). *Results.* One hundred one child and 33 young adults were treated according to the EORTC 58951 protocol. Median age was 11 years (1 to 28 years). Sex ratio was 1.73.The patients were stratified in low risk (3 patients), average risk (96 patients) and high risk (35 patients). One hundred eleven patients (83%) were cortico-sensitive and eighty six patients had no blast (77% of cortico-sensitive patients) at day 8 of pre-phase. Complete response was obtained in 87% with no difference in different groups of cortico-sensitivity. At 68 months of follow-up, OS, EFS and DFS were respectively 65%, 60% and 75% for cortico-sensitive ALL and 22%, 25% and 49% for cortico-resistant ALL, the difference was significant with respectively P=0.002, P=0.04 and P=0.09. In cortico-sensitive patients, DFS was higher in the subgroup with no blasts: 82% *vs.* 57% (P=0.01), but no difference concerning OS (69% *vs.* 46%, P=0.46) and EFS (63% *vs.* 48% P=0.36). *Conclusions.* Cortico-sensitivity is a one of several parameters that predict good outcome in ALL. Moreover, our study showed that no blasts in peripheral blood smear at day 8 of prephase can be considered a good first marker of early blastic clearance and good outcome. Larger studies were needed to confirm this result.

0623

MRD STATUS AT THE END OF ALL-MB 2008 PROTOCOL REMISSION INDUCTION COULD BE PREDICTED BY EARLY BLAST REDUCTION

A Popov,[1] G Tsaur,[2] T Verzhbitskaya,[2] E Tokareva,[1] O Streneva,[2] O Khlebnikova,[1] A Solodovnikov,[3] E Shorikov,[1] L Saveliev,[3] L Fechina[1]

[1]Regional Children's Hospital, Ekaterinburg, Russian Federation; [2]Research Institute of Cell Technologies, Ekaterinburg, Russian Federation; [3]Ural State Medical Academy, Ekaterinburg, Russian Federation

Background. Minimal residual disease (MRD) status after remission induction is a strong prognostic factor in childhood acute lymphoblastic leukemia (ALL). Aim. To evaluate predictive impact of different clinical and laboratory parameters on MRD status after remission induction of ALL-MB 2008 protocol in children with ALL. *Methods.* From March 2008 to December 2009 56 ALL patients were enrolled onto ALL-MB 2008 trial in our institution. Among them 54 patients were included in present study based on availability of end-induction (day 36) MRD data. Study design was partially based on previously published data for AIEOP-BFM-ALL 2000 protocol [R. Ratei *et al.*, Leukemia, 2008]. MRD on day 15 (MRDd15) and day 36 (MRDd36) was assessed by 6-9-color flow cytometry (FC). MRDd36 results were categorized as "positive"or "negative". Predictive impact of initial parameters such as age, gender, CNS involvement, spleen size, initial WBC count, immunophenotype, presence of ETV6-RUNX1 fusion gene was analyzed. We also investigated predictive value of early response parameters such as absolute blast count in peripheral blood on day 8 (BCPBd8), blast percentage in bone marrow on day 15 (BPBMd15) both assessed by cytology and MRDd15. ROC curve analysis was performed, areas under curves (AUC) were compared and threshold levels (TL) were defined. Variables were categorized as "high"and "low"in respect to TL. Univariate and multivariate odds ratios (OR) with 95% confidential intervals (CI) were estimated in multiple logistic regression model with a step-by-step identification of significant parameters. Positive and negative predictive values (PPV, NPV), sensitivity, specificity and overall correct prediction (OCP) were calculated. *Results and discussion.* Among all initial parameters difference between day 36 MRD-positive and MRD-negative patients was observed only for age (P=0.03). Hence age was added to early response parameters for ROC curve analysis. By AUC comparison MRDd15 (AUC=0.85) differed significantly from BPBMd15 (AUC=0.72, P=0.049), age (AUC=0.68, P=0.02) and BCPBd8 (AUC=0.64, P=0.004). TLs were defined as 0.160% for MRDd15, 0.5% for BPBMd15, 3 years for age and 38 blasts/_l for BCPBd8. Patients with high MRDd15, BPBMd15, BCPBd8 and older than 3 years have significantly higher chance to be MRD-positive after remission induction. MRDd15 and age remained significantly contributing variables (P=0.003 and P=0.040 respectively) to the regression model with an overall correct prediction rate of 77.36%. Diagnostic performance tests are shown in table. Thus among all analyzed parameters high MRD level on day

15 is the strongest predictor of MRD-positivity after remission induction in our series of childhood ALL patients treated by ALL-MB 2008 protocol. Despite insignificant difference between day 36 MRD-positive and MRD-negative patients (P=0.056) BCPBd8 showed appropriate OCP, better than age and BPBMd15. Conclusion. MRD status in childhood ALL after remission induction of ALL-MB 2008 protocol could be predicted by early blast reduction parameters and age while MRD level on day 15 is the strongest single predictor.

Table 1. Diagnostic performance tests.

	OR	95% CI	p	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)	OCP (%)

HIGH DOSE METHOTREXATE TREATMENTS IN CHILDHOOD LEUKEMIA - COMPARISON OF BFM 1995 AND 2002 PROTOCOLS

K Csordas,[1] O Eipel,[1] M Zubreczki-Hegyi,[1] M Csoka,[1] E Pap,[2] J Kralovanszky,[2] G Kovács[1]

[1]2nd Department of Pediatrics, Semmelweis University, Budapest, Hungary; [2]National Institute of Oncology, Budapest, Hungary

Methotrexat (MTX) is a widely used antifolate cytostatic agent for the treatment of different childhood malignancies, however the exact dose and mode of application is not clearly defined. The aim of our study was to compare high dose MTX treatments by analysing the pharmacokinetic parameters and toxicity after the therapies. We investigated children with acute lymphoblastic leukemia (ALL) treated according to the ALL-BFM-1995 and 2002 protocol at the 2nd Department of Paediatrics at Semmelweis University between 1998-2006. *Patients and Methods.* 43 children were treated with 5 g/m^2/24 h MTX and 39 children with 2 g/m^2/24 h MTX according to the protocols. The mean age of the patients was 7.1 years (0.5-16.7). Totally 283 MTX infusions were analysed. Serum MTX and 7-OH-MTX levels were measured with HPLC at 24, 36, 48 hours, while the MTX concentration in the CSF was determined at 24 hours after the start of MTX infusion. Considering the toxicity of the treatments we measured the serum ALAT, ASAT, bilirubin, creatinine, protein levels before therapy and one day, two days and one week after treatment. *Results.* Mean MTX level at 24. hours and 7-OH-MTX level at 36. hours were significantly lower after 2 g/m^2 courses than after 5 g/m^2 courses (MTX2: 29.7+/-17.4 μmol/L; MTX5: 89.5+/-55.0 μmol/l; 7-OH-MTX: 4.1+/-1.7 μmol/L and 7.6+/-5.2 μmol/L; P<0.05). In more than 50% of the cases with 2 g/m^2 MTX serum levels were below 30 μmol/L (therapeutic level). Comparing CSF MTX concentrations we did not find significant difference between the two doses (after 2g/m^2: 15.1+/-41.7 μmol/l; after 5g/m^2: 23.3+/-41.5 μmol/l). In children who received 5 g/m^2 MTX significantly more cases of hepatotoxicity, trombocytopenia, mucositis occurred, however these side effects were mild and reversible. 7-OH-MTX levels showed closer correlation with the toxicity parameters than MTX (P=0.0004). *Conclusion.* 5 g/m^2 MTX resulted more reliable therapeutic serum levels with slightly more toxicity. 7-OH-MTX measurements might be more useful than MTX levels to detect toxicity. However, further randomised studies are necessary to determine the optimal dose of MTX.

MRD - BASED RISK STRATIFICATION IN CHILDHOOD B-ALL USING RQ-PCR OF IMMUNOGLOBULIN (IG) AND T-CELL RECEPTOR (TCR) GENE REARRANGEMENTS - A SINGLE CENTER EXPERIENCE

M Martins,[1] X Duarte,[2] M Chagas,[2] F Pereira,[2] A Parreira,[3] M Gomes Da Silva,[4] P Gameiro[4]

[1]Instituto Portugues de Oncologia Francisco Gentil, Lisbon, Portugal; [2]Serviço Pediatria, IPOLFG, Lisboa, Portugal; [3]Departamento de Hematologia, IPOLFG, Lisboa, Portugal; [4]Laboratório de Hemato-Oncologia, IPOLFG, Lisboa, Portugal

Background. Several studies have shown that MRD quantification using RQ-PCR for detection of Ig/TCR gene rearrangements has prognostic value in childhood ALL. Different clinical trials already incorporate MRD-based risk stratification. *Aims.* We report RQ-PCR-based MRD results obtained on d32 of induction therapy in 71 childhood B-ALL patients (pts) treated according to the DFCI ALL-05 protocol. We compared the sensitivity levels and RQ-PCR-based MRD data obtained by cloning the Ig/TCR rearrangements into plasmids (according to DFCI-ALL-05 protocol) and using the EuroMRD guidelines. *Methods.* Bone marrow (BM) samples were obtained at diagnosis from 71 childhood B-ALL pts (30 females, 41 males, median age 5.7, 1.1 to 16.4 yo) from March 2007 to December 2009. Risk group stratification according to age, WBC, immunophenotype, CNS leukemia and cytogenetic at diagnosis showed 55/71 (77%) standard, 15/71 (21%) high and 1/71 (1%) pts at very high risk of relapse. Intensified therapy was administered to patients in the very high-risk group or with MRD>0.001 at d32 BM sample. Clonal Ig/TCR gene rearrangements were identified according to the BIOMED-1/2 strategies. After sequencing (ABI 3130) at least one allele-specific oligonucleotide (ASO) was designed for each patient. Experimental set-up of RQ-PCR (7900-HT) and interpretation of MRD data was done according to the EuroMRD guidelines and based in standard curves obtained from serial dilutions of diagnostic clonal DNA. Standard curves obtained from plasmid dilutions containing the target DNA were compared to curves obtained from serial dilutions of diagnostic clonal DNA using 10 Ig/TCR rearrangements: VH2-JH1, VH4-JH2, VH3-JH4, VH4-JH4, VH3-JH5, VH2-JH6, Vk7-Kde, Vg5-Jg1.3/2.3, Vb30-Jb2, Vd2-Dd3. *Results.* In 71 patients, 254 rearrangements were sequenced and 129 used as ASOs: 88 IGH, 18 incomplete TCRD, 8 TCRB, 8 IGK and 7 TCRG rearrangements. The majority (122/129) of targets had a sensitivity ≥10^{-4}; in 2/129 the sensitivity was <10^{-3} precluding its use. In 57% (74/129) a quantitative range (QR, reproducible sensitivity) of at least 10-4 was obtained. Globally, MRD-based stratification was feasible in 67/71 patients: 1/71 had resistant disease, 1 had no BM sample at d32 and 2/71 had no sensitive target. In 43/67 pts, MRD was quantified with two (34 pts) or three (7 pts) targets. At d32, 32/67 (48%) patients had undetectable MRD, 21/67 (31%) had positive non-quantifiable disease, 6/67 (9%) had MRD levels <0,001 and 12% (8/67) had MRD level >0.001 and were re-stratified into the very high-risk group. RQ-PCR-based MRD levels obtained with standard curves generated for ten different targets and using either plasmid or clonal diagnostic DNA dilutions showed highly concordant results (P<0,05, Pearson correlation r=0,894). All targets had a sensitivity of 10^{-4}, according to EuroMRD guidelines. Using the DFCI-05 protocol strategy 9/10 targets reached a sensitivity of 10^{-4}. *Conclusions.* Our RQ-PCR strategy based on the EuroMRD guidelines allowed therapy intensification in 8/67 (12%) B-ALL pediatric patients treated according to the DFCI-ALL-05 protocol. The use of a more simple RQ-PCR method based in serial dilutions of clonal diagnostic DNA, minimizing the risk of PCR contamination enables a highly sensitive, reproducible and fast MRD quantification in precursor-B- ALL patients.

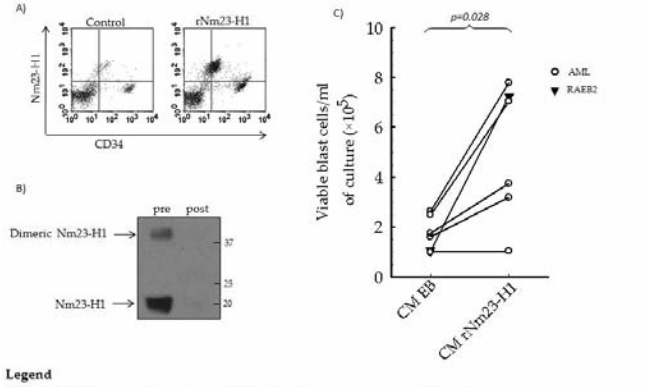
NM23-H1 PROMOTES AML CELL SURVIVAL VIA CROSS TALK BETWEEN THE MORE IMMATURE AND MATURE COMPONENTS OF THE CLONE

A Lilly, R Hayden, F Khanim, M Drayson, C Bunce

University of Birmingham, Birmingham, UK

Background. Nm23-H1 protein is elevated in the serum of AML patients, and its levels correlate with the white cell count at diagnosis and, therefore, prognosis. Recent data from Okabe-Kado and colleagues (2009) suggests that this association is causal and that Nm23-H1 acts as an AML survival factor. However, the role of Nm23-H1 in exacerbating the tumour burden in AML is poorly understood. *Aim.* The aim of this study was to delineate whether the effect of Nm23-H1 on AML cells is mediated via actions against the immature cells or their more mature progeny. *Methods.* Primary AML cells from 18 patients were cultured with and without 2 μg/mL rNm23-H1 in serum-free conditions. Analysis of cell surface Nm23-H1 binding, as determined by flow cytometry, revealed preferential binding to the more mature component of the clone. Cells from 5 AML patients and 1 RAEB2 patient were consequently sorted in to immature ($CD34^{+ve}$ and/or $CD117^{+ve}$) and more mature ($CD34^{-ve}$ and/or $CD117^{-ve}$) fractions. The $CD34^{-ve}/CD117^{-ve}$ cells were treated with 2 μg/mL rNm23-H1 for 20 hours, after which the resulting conditioned medium was depleted of rNm23-H1 using nickel resin. Subsequently, the $CD34^{+ve}/CD117^{+ve}$ cells, which had been stored at 4°C overnight, were cultured in this conditioned medium, and cell survival was analysed after 2 days in culture. Nm23-H1 induced cytokine release from the $CD34^{-ve}/CD117^{-ve}$ cells was investigated using a luminex assay. *Results*. rNm23-H1 enhanced the survival of those AMLs that bound rNm23-H1 at the cell surface (n=11), whilst there was little effect on AMLs which did not detectably bind rNm23-H1 (n=7). The population of cells which bound rNm23-H1 were $CD34^{lo}/CD34^{-ve}$ and $CD11b^{+ve}$, indicating that the survival effect on the more immature cells was indirect. In 5 out of 6 cases, the survival of immature $CD34^{+ve}/CD117^{+ve}$ blast cells was enhanced by medium conditioned by rNm23-H1 stimulated $CD34^{-ve}/CD117^{-ve}$ cells, but not by medium conditioned by non stimulated $CD34^{-ve}/CD117^{-ve}$ cells. Analysis of the $CD34^{-ve}/CD117^{-ve}$ cell conditioned medium demonstrated that rNm23-H1 stimulated the release of multiple cytokines including IL1β, IL6, MCP-1, IL8, and VEGF. This effect was not the result of LPS contamination of rNm23-H1 as the addition of the LPS inhibitor polymyxin B to cultures had no effect on induced cytokine release.



Legend

A) Nm23-H1 binds a population of $CD34^{lo}/CD34^{-ve}$ cells to mediate AML cell survival
B) Nm23-H1 western blot of $CD34^{-ve}/CD117^{-ve}$ conditioned media pre and post rNm23-H1 depletion
C) Medium conditioned by rNm23-H1 stimulated $CD34^{-ve}/CD117^{-ve}$ cells enhances the survival of immature $CD34^{-ve}/CD117^{-ve}$ blast cells (CM EB: conditioned medium from elution buffer control treated $CD34^{-ve}/CD117^{-ve}$ cells, CM rNm23-H1: conditioned medium from rNm23-H1 $CD34^{-ve}/CD117^{-ve}$ cells)

Figure 1.

Conclusion. It has been previously shown that Nm23-H1 is highly expressed in normal immature $CD34^{+ve}$ haemopoietic cells, and that its expression decreases during haemopoietic maturation (Willems *et al.,* 1998). Thus it is likely that the elevated serum Nm23-H1 levels found in AML patients derive from the more immature components of the clone. Collectively our findings indicate that the released Nm23-H1 is sensed by the more mature malignant cells, improving their survival, and stimulating a reciprocal cytokine mediated survival signal directed at the immature cells. This novel feedback mechanism reveals that the action of Nm23-H1 in promoting AML cell survival and clonal expansion is more complex than expected. Following the demonstration that Nm23-H1 inhibits myeloid cell differentiation (Okabe-Kado *et al., 1995*), we hypothesise that this mechanism may reflect the subversion of a previously unidentified process of quorum sensing during normal haemopoiesis.

A NOVEL NUP98/RARG REARRANGEMENT IN AN ACUTE MYELOID LEUKEMIA RESEMBLING PROMYELOCITIC PHENOTYPE

E Such, J Cervera, A Valencia, M Ibañez, B Costan, I Gómez, ML Perez-Sirvent, L Senent, I Luna, E Barragan, M Sanz

University Hospital La Fe, Valencia, Spain

Background. The NUP98 gene at 11p15 is known to be fused to more than twenty other partner genes in various hematologic malignancies. The common in all NUP98 chimeras is a transcript consisting of the 5' part of NUP98 and the 3' portion of the partner gene. Despite the high homology sequence (90%) of the RARA gene with the other members of the retinoid acid receptor family (RARB and RARG), rearrangements involving these last two genes have not been reported in human leukemias. *Aims.* To determine the genes involved in a novel t(11;12) translocation in a patient with an AML morphologically resembling an APL. Case History. A 35-year-old male referred to our department because of asthenia, mucosal bleeding, ecchymoses and fever. Blood tests showed anemia (hemoglobin 6 g/dL) and thrombocytopenia (platelet count 8×10^9/L) and white blood cell counts (12×10^9/L) with 82% blasts. Morphological and immunophenotype picture in bone marrow resembled the hypergranular subtype of acute promyelocytic leukemia (M3) of the French-American-British Classification, but lacking the PML/RARA rearrangement on molecular analysis or the t(15;17) in karyotype and FISH. The karyotype showed, however, a translocation t(11;12)(p15;q13). The patient underwent treatment with PETHEMA AML 2007 protocol based on a 3+7 schedule of chemotherapy for induction and consolidation followed by an autologous peripheral blood transplant. Six months after transplant, the patient remains alive in complete remission. *Methods.* Array-CGH fine mapping of minor or cryptic genomic imbalance was performed in bone marrow sample. Labelled DNA was hybridized with Human Genome CGH Microarray 244K (Agilent p/n G4423B-014693) containing 236,000+ coding and noncoding human sequences represented. DNA control sample extracted for the patient's lymphocytes was used as reference in match hybridizations. Arrays were scanned in an Agilent Microarray Scanner (Agilent G2565BA) and data extracted using Agilent Feature Extraction Software 9.5.3.1. The NUP98-RARG mRNA was determined on random hexamer reverse transcribed cDNA using primers to NUP98 5'-GGGCTTGGTGCAGGATTTGG-3') with the reverse RARG (exon 7: 5'-GCTGACCCTGAACCGGACCCA-3'). These primers were also used to amplify the genomic breakpoint. *Results.* We found a 1.0Mb microdeletion in 11p15 affecting NUP98 gene and 2.5Mb microdelection in 12q13 affecting RARG gene. The other entire genomic regions presented a normal copy of the DNA. To confirm the NUP98-RARG fusion, an 881bp product was specifically amplified from patient cDNA but not from the control cDNA. The genomic breakpoint product was co-amplified in the same reaction and sequenced. The NUP98-RARG fusion mRNA was predicted to encode a 862 amino acid protein of 97 KDa, that retains the N-terminal region motif of the nuclear export of poly(A)+ RNA and nuclear pore complex (NPC) structure from NUP98 fused to the entire tyrosine kinase domain of RARG. *Conclusion.* We report a novel rearrangement involving the subunit gamma of the retinoid acid receptor (RARG) and the nuclear pore complex protein NUP98, a known promiscuous gene frequently involved in AML and myelodysplastic syndromes. The morphological and immunophenotypic features resembled those in hypergranular subtype of APL.

HEMATOGONES : A NEW PROGNOSTIC FACTOR IN ACUTE MYELOBLASTIC LEUKEMIA

S Chantepie,[1] V Salaün,[1] JJ Parienti,[1] F Truquet,[1] M Macro,[1] S Cheze,[1] JP Vilque,[2] O Reman[1]

[1]Centre Hospitalier Universitaire, Caen, France; [2]Centre Francois Baclesse, Caen, France

Despite the identification of several baseline prognostic factors, the outcome of patients with acute myeloid leukemia (AML) is still heterogeneous. New prognostic parameters are needed to assess the risk of relapse, in particular in patients without aberrant leukemia associated phenotypes (LAPs) and in absence of fusion genes derived from chromosome translocations. Hematogones (HGs) are normal B-lymphocytes precursors described in healthy subject, increasing in several hematological and non-hematological disease and in marrow regenerative state following chemotherapy. We investigate, by flow-cytometry, the prognostic impact of HGs on leukemia free (LFS) and overall survival (OS) in 120 patients with AML in first complete remission (CR). In univariate analysis, leucocytosis, favourable cytogenetic and HGs>0,1% were associated with improved LFS and OS. Patients with positive marrow HGs in first CR have significant higher LFS (29.2 *vs.* 11.7 months : P=0.0011) and OS (31.7 *vs.* 21 months: P<0.03) than patients without. Furthermore predictive value of HGs for a better LFS is still significant, when adjusted for cytogenetics and leucocytosis in a multivariate analysis (P<0.047). The presence of HGs in first CR with a cut-off of 0.1% can be a useful tool to predict relapse and survival in acute myeloblastic leukemia.

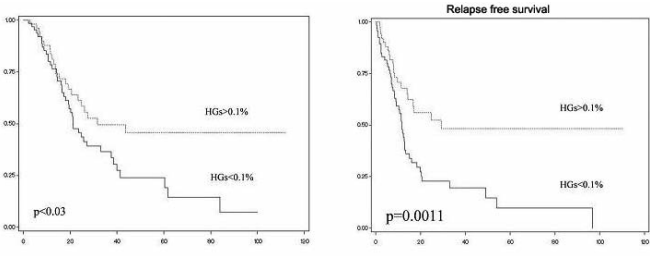

Figure 1. OS and LFS according to HGs status.

FMR1NB IS THE FIRST CANCER-TESTIS ANTIGEN EXPRESSED ON THE SURFACE OF MALIGNANT CELLS

T Luetkens, Y Cao, K Bartels, S Meyer, C Bokemeyer, D Atanackovic

University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background. Cancer-testis (CT) antigens represent ideal candidates for tumor-specific therapy due to their exceptional tissue restriction. Unfortunately, most CT antigens are inaccessible to immediate targeted therapies due to their predominantly intracellular localization. CT antigen FMR1NB might represent a promising exception as prediction algorithms indicate a putative transmembrane topology. *Aims.* The aims of our study were the conclusive determination of the subcellular localisation of FMR1NB and to assess the possibility to target this protein on the cell surface using specific antibodies. *Methods.* We screened acute (AML) and chronic (CML) myeloid leukemia samples as well as healthy tissues for the expression of FMR1NB. Mammalian cell lines were transfected with FLAG- or GFP-tagged FMR1NB expression constructs. We evaluated the subcellular localization of FMR1NB by fractionation and confocal microscopy. Epitopes of commercial anti-FMR1NB antibodies were characterized by ELISA using overlapping peptides, and localization and expression of the protein in AML cells was evaluated by immunofluorescence stainings and Western Blot. *Results.* FMR1NB mRNA was expressed in AML cell lines and patient samples and confirmed by western blot on the protein level. Specificity was confirmed by the lack of FMR1NB expression in healthy tissues. Confocal fluorescence microscopy of GFP chimeras in mammalian cell lines, immunofluorescence staining of AML cell lines, and subcellular fractionation strongly support a membraneous localization of FMR1NB including the plasmamembrane. In contrast to results of structural prediction software our characterization of epitopes recognized by polyclonal anti-FMR1NB antibodies and the subsequent immunostaining of intact transfected and native AML cells suggest an extracellular amino-terminus of FMR1NB. Flow cytometric analysis of AML and CML cell lines as well as AML patient samples and healthy donors further confirmed a strong and specific expression of FMR1NB on leukemia samples. *Conclusions.* FMR1NB mRNA is specifically expressed in AML cells and the resulting protein localizes to the membrane compartment including the plasma membrane. A putative extracellular domain of over 100aa length of the protein can be detected using FMR1NB-specific antibodies. The membrane localization of FMR1NB is a rare exception within the CT antigen family and our data suggest that it represents an ideal target for the diagnosis and therapy of myeloid leukemias.

FUNCTIONAL DEREGULATION OF NF-κB AND ABNORMAL TNFα RESPONSE IN ACUTE PROMYELOCYTIC LEUKEMIA

M Mathew,[1] M Sukhai,[2] N Schuh,[2] Y Xuan,[2] M Minden,[2] S Kamel-Reid[2]

[1]Ontario Cancer Institute, Toronto, Canada; [2]University Health Network, Toronto, Canada

Background. Acute promyelocytic leukemia (APL) accounts for approximately 10% of acute myelogenous leukemia (AML) cases, and is characterized by accumulation of abnormal promyelocytes in patient bone marrow and peripheral blood. APL is associated with balanced chromosomal translocations involving retinoic acid receptor alpha (RARA), giving rise to fusion oncoproteins referred to as X-RARA. *Aims.* As deregulation of retinoid signaling is insufficient for leukemia development, our studies aim to determine other signaling pathways involved in APL by assessing the gene expression profiles and cell biology of X-RARA. Methods and *Results.* We previously determined, using gene expression microarray analysis, common downstream targets of the variant APL fusion proteins NPM- and NuMA-RARA. We observed an over-representation of NF-κB target genes within this dataset. In these cells, a number of NF-κB target genes were commonly over-expressed. A subset of commonly deregulated genes were validated in our APL cell lines and 23 primary APL patient samples by real-time quantitative RT-PCR (RQ-PCR). 13/16 genes that were tested were significantly altered in APL compared to normal BM (n=11) P<0.05. The majority of these deregulated genes showed a progressive trend towards normal expression levels in post-treated samples. These data indicate defects in NF-κB-mediated gene expression in APL pathogenesis. We next examined NF-κB activity by assessing the expression levels of NF-κB target genes by quantitative real-time RT-PCR, in the presence and absence of TNFα. We observed that there was sustained activation of NF-_B in cells expressing NPM-RARA, as evidenced by the increased expression of NF-κB transcriptional target genes after induction by TNFα. This was also evident by sustained increases in levels of phospho-p65/NF-κB in U937-NPM-RARA cells after TNFα treatment. Western analysis of protein derived from U937-NPM-RARA and NB4 cells demonstrated over-expression of NF-κB (p65) protein, as well as its transcriptional target IκBα. The increased pool of NF-κB localized to both the cytoplasm and the nucleus in U937-NPM-RARA cells as visualized by immunofluorescent confocal microscopy. Having observed deregulated expression of downstream targets of TNFα, we sought to examine the ability of X-RARA to confer resistance to TNFα-mediated apoptosis. Our results in colony formation assays indicated that NPM-RARA expressing cells formed significantly more colonies, in the presence of 0-100 ng/mL TNFα, in a dose-dependent manner, compared to U937 control cells. Summary/*Conclusions.* These data suggested a greater ability on the part of NPM-RARA+ cells to survive and proliferate in the presence of TNFα. Our data provides the first evidence of the functional deregulation of the NF-κB-mediated signaling pathway and the TNFα response in cells expressing the variant APL fusion proteins.

0631

INCREASED RISK OF ACUTE MYELOID LEUKEMIA IN PATIENTS WITH CYP1A1 POLYMORPHISMS

F Pelloso,[1] I Silva,[1] N Souza,[1] M Yamamoto,[1] C Botelho,[2] ML Chauffaille[1]

[1]UNIFESP-EPM, Sao Paulo, Brazil; [2]The Programa Estadual de Proteção à Gestante MS, Campo Grande, Brazil

Background Acute Myeloid Leukemia (AML) is a heterogeneous group of genetically diverse hematopoietic malignancies arising from blood cell progenitors developing in the myeloid pathway or from primitive stem cells with multilineage potential. Till current knowledge it seems the development of AML probably arises through a combination of genetic

susceptibility and environmental factors most of which are not yet fully understood. Thus, very little is known related to inherited factors (genetic susceptibility of AML) that contribute to DNA damage or poor detoxification of carcinogens and chemical compounds. From experimental data DNA damage in the haematopoietic precursor cell is the essential pre requisite for the development of AML. DNA damage can be induced directly by chemical mutagens, partially metabolized carcinogens that bind directly to DNA forming DNA adducts. Chemical compounds are metabolized by a two phase detoxifying system. CYP1A1 is a a cytochrome P-450 phase-1 superfamily enzyme involved in the bioactivation of environmental pollutants (byproducts of fuel burning, lubricant oils, fossil fuel combustion, coal, vehicle exhaust, tar and cigarette smoke). The four CYP1A1 polymorphisms are: CYP1A1*2A, CYP1A1*2C, CYP1A1*3 and CYP1A1*4. Phase-2 metabolism polymorphisms (del{GSTM1} and del{GSTT1}) result in loss of enzymatic activity. The genetic component of AML etiology is likely to be polygenic and the identification of further candidate genes is essential for future studies and assessment of AML risk-related genes. Aims We determined the frequencies of carcinogen metabolism gene polymorphisms (CYP1A1, del{GSTM1} and del{GSTT1}) in a case control-study (control group and AML patients in Sao Paulo, Brazil) based on polymorphism analysis. Methods We studied 58 consecutively AML patients (29 males and 29 females, median age: 62 years, range 18 - 91 years) and 174 age and sex-matched control group (CG, 90 males and 84 females, median age: 50 years range 19-74 years). To verify if any of those genetic polymorphisms could pose a risk for AML there had been calculated three sex and age controls for each AML patient (alpha =0.05% (bicaudal), statistical power 80% beta=0.20) with an estimated odds ratio (OR) equal or less than 2. Hardy-Weinberg equilibrium was also calculated. CYP1A1 polymorphisms (CYP1A1*2A, CYP1A1*2C, CYP1A1*3 and CYP1A1*4) were assessed by a PCR-RFLP assay (Cascorbi *et al.*, 1996). Polymorphisms were categorized as wild-type, heterozygous or mutant. Del{GSTM1} and del{GSTT1} were studied using a PCR assay (Gattás *et al.*, 2000). Beta-globin gene was amplified as an internal control. Results. There were 51 *de novo* AML and 7 secondary AML. CYP1A1*2A and CYP1A1*2C polymorphisms were much more frequent in CG than AML P<0.001 and in contrast, CYP1A1*3 and CYP1A1*4 polymorphisms frequencies were significantly more frequent in AML than CG P<0.001. There were no differences found in del{GSTM1} neither del{GSTT1} between AML (P=0.999 and P=0.539). The OR for AML patients with CYP1A1*3 genotype was 2.36 (95% CI 1.2 - 4.5) and 2.38 for CYP1A1*4 (95% CI 0.8 - 6.8). Adjusted OR (for sex and age) was 2.63 for CYP1A1*3 (95% CI 1.4 - 5.1) and 2.66 for CYP1A1*4 (95% CI 0.9 - 7.8). In the multivariate analysis CYP1A1*3 polymorphism was a risk factor for AML with an OR for 3.99 (CI 1.9-8.6 95%) (Table). On the other hand CYP1A1*2A and CYP1A1*2C heterozygous polymorphisms presented a protective genotype AML risk (OR 0.54, 95% CI 0.1 - 0.6 and OR 0.23 0.1-0.5 respectively, for CYP1A1*2A and CYP1A1*2C). Conclusions. To the best of our knowledge this is one of the few studies assessing the risk of AML in individuals with xenobiotic metabolism polymorphisms. Our data supports that inherited absence of this carcinogen detoxification pathway may be an important determinant of AML. To the best of our knowledge this is the first study to show that CYP1A1*3 heterozygous genotypes increase the risk of AML. Biological effects of this genotype in AML are still unknown and require further investigation.

Table. Estiamated relative risk of AML, crude and adjusted odds radio by univariate and multivariate analysis.

Univariate analysis		Crude OR (95% CI)	Adjusted OR (95% CI)
*CYP1A1*2A*	Wild type	1.00	1.00
	Heterozygous	0.21 (0.1 – 0.4)	0.20 (0.1 – 0.4)
	Mutated	0.13 (0.0 – 1.1)	0.14 (0.0 – 1.1)
*CYP1A1*2C*	Wild type	1.00	1.00
	Heterozygous	0.23 (0.1 – 0.4)	0.19 (0.1 – 0.4)
*CYP1A1*3*	Wild type	1.00	1.00
	Heterozygous	2.36 (1.2 – 4.5)	2.63 (1.4 – 5.1)
	Mutated	0.39 (0.0 – 3.2)	0.44 (0.1 – 3.7)
*CYP1A1 *4*	Wild type	1.00	1.00
	Heterozygous	1.31 (0.7 – 2.6)	1.31 (0.7 – 2.6)
	Mutated	2.38 (0.8 – 6.8)	2.66 (0.9 – 7.8)
GSTM1	Present	1.00	1.00
	Null	1.00 (0.5 – 1.8)	0.95 (0.5 – 1.7)
GSTT1	Present	1.00	1.00
	Null	1.27 (0.6 – 2.8)	1.37 (0.6 – 3.0)
Multivariate analysis			**Adjusted OR** (95% CI)
*CYP1A1*2A*	Wild type		1.00
	Heterozygous		0.28 (0.1 – 0.6)
	Mutated		0.54 (0.1 – 5.3)
*CYP1A1*2C*	Wild type		1.00
	Heterozygous		0.23 (0.1 – 0.5)
*CYP1A1*3*	Wild type		1.00
	Heterozygous		3.99 (1.9 – 8.6)

BROAD COPY NEUTRAL-LOSS OF HETEROZYGOSITY REGIONS AND RARE RECURRING COPY NUMBER ABNORMALITIES IN KARYOTYPICALLY NORMAL ACUTE MYELOID LEUKEMIA GENOMES

A Romano,[1] V Barresi,[2] N Musso,[2] C Capizzi,[2] C Consoli,[1] MP Martelli,[3] G Palumbo,[1] F Di Raimondo,[1] F Condorelli[2]

[1]Ospedale Ferrarotto, Università di Catania, Catania, Italy; [2]Laboratorio sui Sistemi Complessi, Scuola Superiore di Catania, Catania, Italy; [3]Istituto di Ematologia, Policlinico Monteluce, Perugia, Italy

Background. Approximately 40-50% of AML are karyotypically normal (KN-AML) and prognostically heterogeneous, showing various molecular alterations. Recent advances in genome-wide analysis of submicroscopic DNA segment copy number variations (CNVs) may allow the identification of novel molecular tumor-associated abnormalities (somatic copy number abnormalities, CNA). However, CNVs are also present physiologically in the normal population (germline CNVs) and can represent potential predisposition factors in disease. Loss of heterozygozity (LOH) is an allelic imbalance in polymorphic loci, resulting from genomic losses or gains leading to unequal ratios of parental alleles. *Aims.* To test the ability of the last generation of Affymetrix single nucleotide polymorphism (SNP)/CNV platform (SNP Array 6.0) to distinguish somatic tumour-associated CNAs and LOHs from germline CNVs and LOHs and to identify possible recurring genomic abnormalities. *Methods.* 19 patients have been studied, 9 females, 10 males (median age 42 years, range 25-70) using bone marrow aspirates collected at diagnosis (Dx) and at the first complete remission (R), defined as karyotypically-normal on the basis of standard metaphase cytogenetics (MC). We re-analysed them using the SNP Array 6.0 Assay kit (Affymetrix, Santa Clara, CA) and HapMap 270 DNA as reference to detect SNP and LOH. Signal intensity was analysed using Genotyping Console Version 3.0.1. We obtained quality control (QC) call rates in excess of 90% in all cases and MAPD <0.4. In 11 cases we obtained a bone marrow sample at the remission phase of comparable high quality, used to obtain a first estimate of tumor-associated CNAs. All Dx segments not overlapping for more that 30% of their size the corresponding R segments were included in a list of somatic CNAs. For each sample algorithms implemented in the GTC software provided a list of all gains or losses (DNA segments spanning multiple consecutive markers showing an increase or a decrease in copy number in comparison to a reference normal population). The number of tumor-associated CNAs were determined after comparison of matched Dx/R samples using stringent conditions able to reduce the number of false positive CNAs. Results. With the exception of a single outlier case, we observed few recurring CNAs per sample (Table 1). However, a high prevalence of CNAs in the KN-AML population was detected, thus providing new hints towards identification of cooperating mutations. In particular, our results point to the region 3p14.1-p12.3 as a target for the identification of driver mutations in AML. An extensive search of all tumour-associated CN-LOH regions > 1 Mb revealed only 3 broad regions (terminal 12Mb of 22q, terminal 27Mb of 1p and the whole chromosome 21) in three patients out of 19 (16%). All CN-LOH segments lower than 10 Mb were not tumour-associated, as shown by their presence in corresponding matched R samples. CN-LOH of the whole chromosome 21 was responsible for homozygosity of a missense mutation (R80C) of RUNX1/AML1. Conclusion. Our study confirms that a relative submicroscopic copy number stability, with low recurrence of specific CNAs and broad CN-LOH regions, characterises KN-AML.

Table 1.

# Somatic losses	0	1	2	≥3
Observed in % of KN-AML patients (n=19)	27%	27%	18%	27%
# Somatic gains	**0**	**1**	**2**	**≥3**
Observed in % of KN-AML patients (n=19)	37%	18%	18%	27%

ANALYSIS OF THE CELLULAR TARGET OF SECONDARY MUTATIONS IN C/EBPA-ASSOCIATED ACUTE MYELOID LEUKEMIA

AK Frank, B Schuster, B Fossum, T Porse

BRIC, Copenhagen N, Denmark

Acute Myeloid Leukemia (AML) is a poor prognosis-associated malig-

nant condition in the hematopoietic system characterized by rapid accumulation of abnormal myeloid progenitor cells in the hematopoietic as well as extra-hematopoietic organs. Development of AML occurs by a multistep process, involving several genetic and/or epigenetic events. This is especially relevant in patients with pre-clinical stages of disease, and patients in remission, who eventually undergo relapse. These two groups of patients host pre-leukemic populations carrying the initial mutations, but lacking the final mutations leading to a fully transformed phenotype. Like the hematopoietic stem cell in normal hematopoiesis, only a sub-population of the leukemia (hereafter referred to as the Leukemia Initiating Cells (LICs)) possesses the self-renewal capacity necessary for maintaining the leukemic population. The transcription factor C/EBPalpha is crucial for late differentiation events in numerous physiological processes, including myeloid differentiation (C Nerlov 2004, M.B Schuster 2006 , H. Leroy 2005). Therefore, it is not surprising that CEBPA mutations occur in about 9 % of all AML cases (C. Nerlov 2004). Since identical CEBPA mutations are almost uniformely present at initial diagnosis and relapse (L-Y Shih 2006), these mutations are early events in leukemogenesis and hence must be present in pre-leukemic stages of disease development as well as in patients in remission before relapse. In this study, we used transgenic mice carrying one of the most common Cebpa mutations (hereafter termed Lp30) known from AML-patients. Homozygousity for this mutation results in a myeloid differentiation-block, downstream of Granulocyte Macrophage Progenitors (GMPs). This phenotype progresses into AML with full penetrance (P. Kirstetter 2008). Since the LICs in leukemic animals resemble committed myeloid progenitors, we hypothesize that the potential to acquire a malignant phenotype resides within committed myeloid progenitors (i.e. GMPs) of pre-leukemic animals and can be delineated by expression profiling of these cells. A logical extension of this hypothesis is that GMPs constitute targets for secondary mutations. As a negative control, we used another Cebpa mutation termed the Basic Region Mutation 2 (BRM2). Similar to Lp30, BRM2-homozygousity results differentiation-block, downstream of GMPs (B.T Porse 2005), albeit only with a limited progression into AML. Gene expression profiling revealed that certain molecular pathways were differentially regulated in Lp30-GMPs *vs.* BRM2-GMPs. Specifically pathways involved in signal transduction, lymphoid differentiation, cell motility and leukemic transformation were upregulated.To identify Lp30-GMPs as the direct target of secondary mutations, we compared BRM2-GMPs and Lp30-GMPs in terms of differentiation potential, self-renewal capacity and immortalization. We found that while both Lp30-GMPs and BRM2-GMPs displayed similarly impaired *in vitro* differentiation potentials, only Lp30-GMPs spontaneously immortalized into cells displaying morphologies and surface marker profiles resembling myeloid progenitors, as well as efficient short-term homing capacity. No AML was observed in recipients transplanted with these cells - probably reflecting the limitations of the *in vitro* conditions used. However, the correlation between leukemogenic potential of Lp30-mice and the ability of GMPs from these mice to immortalize suggests that this population might constitute the target for secondary mutations.

0634

PHARMACOLOGICAL TARGETING OF THE PI3K-AKT/PKB-MTOR PATHWAY ALTERS LOCAL ANGIOREGULATION IN ACUTE MYELOGENOUS LEUKEMIA

H Reikvam, K Hatfield, E Ersvær, A Ryningen, Ø Bruserud

Institute of Internal Medicine, University of Bergen, Bergen, Norway

Background. Acute myeloid leukemia (AML) is a heterogeneous malignancy characterized by clonal proliferation of immature myeloid cells in the bone marrow. Even though the AML cell biology has been extensively characterized, this has not translated into any major improvements in overall disease-free survival. New therapeutic agents that are more efficient and better tolerated than today's treatment are therefore needed. Bone marrow angiogenesis is involved in leukemogenesis and affect AML cells' chemosensitivity, and its regulation is mediated by the balance between pro- and antiangiogenic mediators that are constitutively released by either AML or stromal bone marrow cells. One possible approach to target angioregulation could be to modulate the constitutive AML cell release of regulatory cytokines through inhibition of intracellular signaling pathways. Among the emerging therapeutic alternatives in AML are agents acting on intracellular signalling pathways involved in regulation of cellular proliferation and viability. Two of these pathways involve phosphatidylinositol 3-kinase (PI3K) and mammalian target of rapamycin (mTOR), and these pathways are connected via the serine/threonine kinase Akt/Protein kinase B (PKB). The Akt/PKB is a client protein of heat shock protein 90 (HSP90) and modulates several substrates important for leukemogenesis, including the transcription factor nuclear factor-κB (NF-κB). *Aims.* To characterize effects of pharmacological targeting of the intracellular PI3K-Akt/PKB-mTor pathway on cell viability, apoptosis, proliferation and the constitutive release of pro- and antiangiogenic factors by primary human AML cells. *Methods.* Six pharmacological intervention were tested; (i) non-specific mTOR inhibitor rapamycin (1μM), (ii) specific inhibitor of mTORC1 temsirolimus (0,1μM), (iii) class I PI3K inhibitor GDC-0941 (1μM), (iv) class III PI3K and autophagy inhibitor 3-methyladenine (3-MA) (1mM), (v) HSP90 inhibitor 17-dimethylaminoethylamino-17-demethoxygeldanamycin (17-DMAG) (1μM) and (vi) proteasome and NF-kB inhibitor bortezomib (0,1μM). These concentrations had a maximal effect on AML cell proliferation. Primary human AML cells from 60 unselected patients were cultured under highly standardized *in vitro* conditions before evaluation of proliferation (3H-thymidine incorporation), cell viability (flowcytomertic analyses with AnnexinV-propidiumiodide staining) and cytokine release (ELISA). *Results.* AML cells derived from various patients differed in their release of angioregulatory mediators and the response to pharmacological agents. The various inhibitors of the PI3K/Akt/mTOR pathway showed antiproliferative effects for a large subset of patients, but an unexpected growth enhancement was seen for a subset of patients, especially when testing temsirolimus and 3-MA. Rapamycin, temsirolimus and 3-MA had only minor effects on cell viability, while GDC-0941, 17-DMAG and bortezomib decreased the viability. All drugs inhibited the release of at least four angioregulatory cytokines (Table 1), and these effects could not be explained by altered AML cell viability. The inhibition was strong especially for Ang-1 and HGF that were significantly decreased by all agents. The mTOR inhibitors rapamycin and temsirolimus often showed weaker effects than the other drugs. Summary/*Conclusions.* Pharmacological agents that affect the PI3K-Akt-mTOR pathway alter proliferation and constitutive release of angioregulatory cytokines by primary human AML cells. Such effects may inhibit bone marrow angiogenesis and hence increase AML cells susceptibility to conventional chemotherapy.

Table 1. The effect of pharmacological agents on proliferation and cytokine release by AML cells (p<0.05 indicated by↓ p<0.001 indicated by↓↓)

	Number of patients with detectable proliferation or cytokine release (median level in controls)	Rapamycin	Temsirolimus	GDC-0941	3-MA	17-DMAG	Bortezomib

MYELOPEROXIDASE EXPRESSION AS A POTENTIAL DETERMINANT OF PARTHENOLIDE-INDUCED APOPTOSIS IN LEUKEMIA BULK AND LEUKEMIA STEM CELLS

JW Cheong, YR Kim, JI Eom, SJ Kim, JS Kim, YH Min

Yonsei University College of Medicine, Seoul, South-Korea

Background. Since parthenolide (PTL) is an effective anti-leukemic agent, identifying molecular markers predicting response to PTL is important. Myeloperoxidase (MPO) may be an important determinant of leukemia cell sensitivity to oxidative stress-mediated apoptosis. *Aim.* To evaluate whether the PTL-induced apoptosis is critically modulated by MPO molecule in leukemia cells. *Methods.* We evaluated the role of MPO in determining the sensitivity of leukemia cells to PTL-induced apoptosis. *Results.* PTL-induced apoptosis via reactive oxygen species (ROS) generation acts to a greater extent in the MPO-high leukemia cell lines, as compared to MPO-low cell lines. Pretreatment of MPO-high

leukemia cells with MPO inhibitor, ABAH or ScAc, abrogated PTL-induced apoptosis, indicating that MPO molecule is critically involved in PTL-induced apoptosis. PTL-induced apoptosis was accompanied by downregulation of NF-κB, Bcl-xL, Mcl-1, XIAP, and survivin, and selectively observed in primary acute myeloid leukemia (AML) cells expressing higher level of MPO (≥ 50%), while sparing both AML cells with lower MPO and normal hematopoietic stem cells (HSC). PTL-induced apoptosis rate in the $CD34^+CD38^-$ cell fraction was greater in MPO-high AML cells, as compared to MPO-low AML ($P<0.01$) and normal CD34+ HSC ($P<0.01$) cells. NOD/SCID xenograft leukemia model revealed that PTL preferentially targets the AML $CD34^+CD38^-$ population. Summary/*Conclusions.* Our data suggest that MPO plays a crucial role in determining the susceptibility of leukemia cells to PTL-induced apoptosis. PTL can be considered a promising LSC-targeted therapy for AML with high level of MPO.

MULTI-COLOR FLOW CYTOMETRIC MEASUREMENT FOR QUANTIFICATION AND IMMUNOPHENOTYPING OF LEUKEMIC STEM CELLS IN ACUTE LEUKEMIA

K Hwang, CJ Park, HS Chi, S Jang, SJ Park, JH Lee, KH Lee, DY Kim

Asan Medical Center, Seoul, South-Korea

Background. Leukemic stem cells are root of clonal growth in acute leukemia and responsible for growth and proliferation of leukemic blasts. They could remain as minimal residual disease after chemotherapy and cause relapse. Leukemic stem cells are defined as $CD34^+/CD38^-$ populations among leukemic blasts and often express CD123, CD44, CD96, CLL-1 and CD184 (CXCR4) which are rarely expressed on normal hematopoietic stem cells, and being studied as the targets of anti-leukemic therapy. *Aims.* We measured the proportions of leukemic stem cells and identified immunophenotypes of leukemic stem cells with clinical and laboratory findings of acute leukemia. *Methods.* Bone marrow aspirate of 75 patients who were newly diagnosed or relapsed as acute leukemia were measured for detection of leukemic stem cells from March to September 2009. At first, $CD45^+$dim or negative and low sideward scatter area in which leukemic blasts exist was gated on a FACSCanto flow cytometer (BectonDickinson, San Jose, CA, USA), and then proportion of $CD34^+/CD38^-$ leukemic stem cells among leukemic blasts were measured. After then proportions of $CD123^+$, $CD44^+$ and $CD184^+$ leukemic stem cells were obtained. The proportions and immunophenotypes of leukemic stem cells were compared with patients' WBC count, bone marrow blast proportion, morphologic features of blasts and molecular genetic or cytogenetic findings and clinical courses which were reviewed from electronic medical record. *Results.* Median leukemic stem cell proportion among leukemic blasts was 3.1% (0.0-63.4%) in all 75 patients with acute leukemia (54 acute myeloid leukemia (AML), 17 acute B-lineage lymphoblastic leukemia (B-ALL) and 4 acute T-lineage lymphoblastic leukemia (T-ALL)) at the time of diagnosis. B-ALL patients showed higher leukemic stem cell proportions (median 20.2%, 0.0-63.4%) than AML (median 2.5%, 0.0-54.7%) and T-ALL patients (median 0.2%, 0.0-0.8%) ($P=0.008$). CD123 was tend to be highly expressed on leukemic stem cells in AML and B-ALL ($P=0.050$), CD44 was highly expressed on leukemic stem cells in AML and T-ALL ($P<0.001$). There was a negative correlation between leukemic stem cell proportion and WBC count ($P=0.039$). But proportions of leukemic stem cells were not correlated with proportions of bone marrow blasts ($P=0.586$). There were no differences in proportions and immunophentypes of leukemic stem cells according to the molecular genetic or cytogenetic findings. Comparing complete remission (CR) group and non-CR group after chemotherapy, proportions of leukemic stem cells were significantly low in CR group with AML. Otherwise, there were no significant relationships between characteristics of leukemic stem cells and relapse rate. Summary/*Conclusions.* We were able to measure the proportions of leukemic stem cells among leukemic blasts fast and simply by using multi-color flow cytometry. The proportions of leukemic stem cells are different according to the diagnosis of acute leukemia, CD123 and CD44, being studied as the targets of anti-leukemic therapy are also differently expressed among leukemic stem cells. The lower proportions of leukemic stem cells in AML patients with complete remission state indicated that measurement of the proportion of leukemic stem cells might be helpful to predict the prognosis of AML.

0637

GEFITINIB ENHANCES ARSENIC TRIOXIDE (AS2O3)-INDUCED DIFFERENTIATION OF ACUTE PROMYELOCYTIC LEUKEMIA CELL LINE

H Kim,[1] EK Noh,[1] JH Baek,[1] JH Park,[1] SJ Cha,[1] JH Won,[2] YJ Min[1]

[1]Ulsan University Hospital, University of Ulsan College of Medicine, Ulsan, South-Korea; [2]Soon Chun Hyang University College of Medicine, Seoul, South-Korea

Gefitinib (Iressa, ZD1839), a selective epidermal growth factor receptor tyrosine kinase inhibitor, inhibits growth, invasion and colony formation of various cancer cells. However, little is known about the effect of combination of gefitinib and arsenic trioxide (ATO) on differentiation of acute promyelocytic leukemia (APL). Therefore, we investigated whether gefitinib had any role in the ATO-induced differentiation of NB4 cells (APL cell line). As shown in Figure 1, gefitinib (10 μM) significantly enhanced ATO-induced differentiation of NB4 cells.

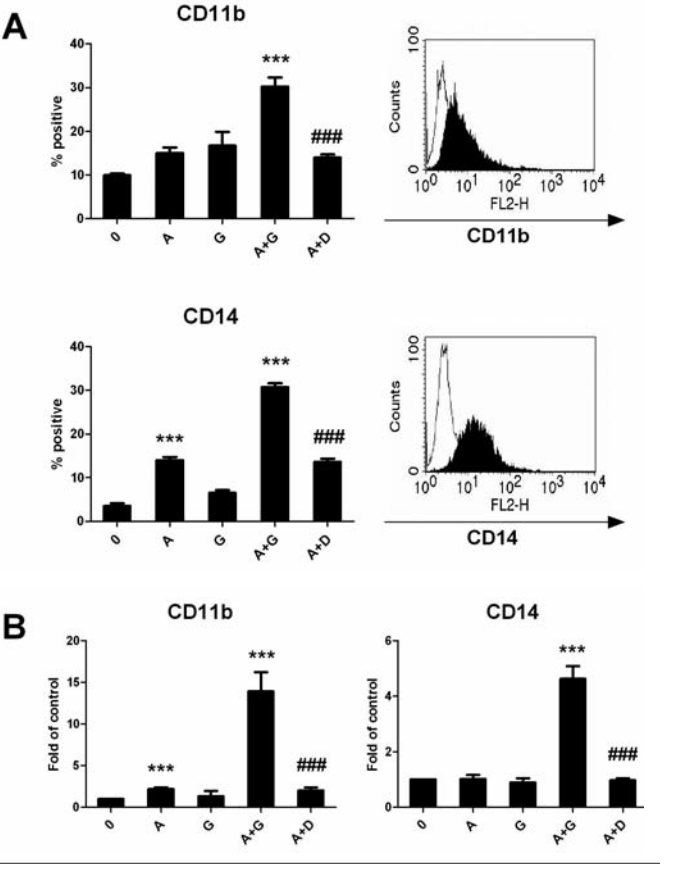

Figure 1. Synergy effects of gefitinib and ATO.

Induction of differentiation was assessed by measuring the expression of myeloid marker proteins including CD11b and CD14 using flow cytometric analysis. Treatment of NB4 cells with arsenic trioxide (0.6 μM) alone for 3 days resulted in 15% CD11b-positive cells and 14% CD14-positive cells, whereas gefitinib alone (10 μM) had no effect on the expression of differentiation markers such as CD11b and CD14 of NB4 cells. However, NB4 cells in ATO combined with gefitinib showed significantly enhanced expression of CD11b and CD14 by 3 and 8.8-fold, respectively (30.3% CD11b-positive cells and 30.8% CD14-positive cells). Moreover, we also measured the mRNA levels of CD11b and CD14 using QRT-PCR. The results revealed that expression of CD11b and CD14 increased 13.9-fold and 4.6-fold in response to augmentation of gefitinib in ATO-treated NB4 cells. The ATO (0.6 μM) with DMSO was used as a negative control to compare with the combination of ATO and gefitinib. The expression of differentiation markers and QRT-PCR of the arsenic trioxide with DMSO were similar to those of ATO alone. These results indicated that gefitinib played an important role on the enhancement of ATO-induced differentiation of NB4 cells. Moreover, the ERK pathway was necessary for the enhancement of gefitinib in ATO-induced differentiation, measured by CD11b and CD14 expression on NB4 cells. Therefore, our data indicated that

gefitinib can play a potential role as an adjunctive differentiation agent in APL.Mitogen-activated protein kinase (MAPK) and ERK were reported to play an important role on AML differentiation.[14] We assessed whether ERK or p38 MAPK pathway was related to gefitinib-enhanced differentiation of NB4 cells treated with ATO. We pretreated NB4 cells with 20 and 15 μM of PD98059 (an ERK inhibitor) and SB203580 (a p38 MAPK inhibitor) for 1 hr, and then stimulated the cells with 10 μM gefitinib in ATO-treated NB4 cells. Cells were collected and myeloid cell surface marker CD11b and CD14 expression were measured using flow cytometric analysis. CD11b and CD14 expression, or macrophage-like cells differentiation increased after exposure to gefitinib in ATO-treated NB4 cells. However, PD98059 treatment led to significant reduction of CD11b and CD14 expression in gefitinib-enhanced NB4 cells. Also, SB203580 pretreatment alone showed no significant effect on the CD11b expression when compared with a control group, whereas it significantly suppressed CD14 expression in gefitinib and ATO-treated NB4 cells. Therefore, the results indicated that the ERK pathway is essentially required for gefitinib enhancement of ATO-induced differentiation of NB4 cells. And p38 MAPK pathway is partially related to the gefitinib/ATO-induced differentiation of NB4 cells.

0638

DOWN-REGULATION OF NR4A3 IS ASSOCIATED WITH DIFFERENTIATION IMPAIRMENT DURING MYELOID LEUKEMOGENESIS

SJ Wu, YY Kuo, WC Chou, JL Tang, HF Tien

National Taiwan University Hospital, Taipei, Taiwan

Background. Acute myeloid leukemia (AML) is a relentless hematological malignancy characterized by overproduction of hematopoietic precursor cells with impaired differentiation. Increasing evidences suggest that the development of AML is a multistep process that requires collaboration of at least two classes of genetic aberrations: class I aberrations confer a proliferation advantage to hematopoietic cells, whereas the class II aberrations serve primarily to impair hematopoietic differentiation. Orphan receptors Nr4A1 and Nr4A3 have been implicated to be homeostatic regulators of proliferation, apoptosis and differentiation. Recently it was reported that abrogation of these two proteins in mice led to development of AML. Besides, down-regulation of both genes was a common feature in leukemic blasts from AML patients, irrespective of karyotypes. These findings suggest that silencing of both genes plays a critical role in myeloid leukemogenesis. *Aims.* Nr4A1 has been proposed to contribute to cell apoptosis; suppression of its expression is supposed to be correlated with survival advantages (class I aberration). Nonetheless the function of Nr4A3 in myeloid leukemogenesis remains unclear. We hypothesize that suppression of Nr4A3 may impair the hematopoietic differentiation (class II aberration). *Methods.* K562 cells were treated with 12-O-Tetradecanoylphorbol-13-acetate(TPA) to induce megakaryocytic differentiation. NB4 cells were treated with all-trans-retinoic acid(ATRA) to induce granulocytic differentiation. The Nr4A3 expression levels were determined before and after differentiation induction in these two cell lines. The effect of Nr4A3 on leukemic cells differentiation was also investigated by Nr4A3 knock-down using siRNA. For clinical validation, the Nr4A3 expression in archived bone marrow (BM) samples from a cohort of chronic myelocytic leukemia (CML) patients in various disease phases and leukemia cells from peripheral blood of a patient with fresh acute promyelocytic leukemia (APL) treated with ATRA was analyzed by quantitative real-time PCR (Q-PCR). The expression of megakaryocytic differentiation marker PDGF was determined by Q-PCR, and that of granulocytic differentiation marker CD11b was determined by flowcytometry. Transfection of Nr4A3 siRNA was done by electroporation. Results. Differentiation of K562 and NB4 cells were successfully induced by TPA and ATRA, respectively, as shown by morphological appearance and PGDF and CD11b expression. The induction of differentiation also led to obviously increased Nr4A3 expression in both cell lines. Transfection of siRNA into K562 cells not only knocked down Nr4A3 expression after TPA treatment but also suppressed K562 differentiation demonstrated by decreased PDGF expression. These data suggested that Nr4A3 expression is necessary for leukemic cell differentiation *in vitro*. In CML patients' bone marrow cells, Nr4A3 expression did not decrease when the disease was in chronic phase, but it was significantly decreased when the disease progressed to acute blastic phase. In peripheral blood cells of an APL patient, Nr4A3 expression was low before ATRA treatment but was elevated after 2 days of ATRA treatment. These clinical findings are compatible with the hypothesis that Nr4A3 expression levels are associated with leukemic cell differentiation status. *Summary/Conclusions.* Down-regulation of Nr4A3 is associated with differentiation impairment during myeloid leukemogenesis. Induction of Nr4A3 expression could be a target of differentiating therapy for AML.

0639

IN VITRO AND *IN VIVO* EFFECT OF AN ORAL IRON CHELATOR DEFERASIROX IN MYELOID LEUKEMIA CELLS

CW Choi,[1] JL Kim,[2] HN Kang,[2] MH Kang,[2] YA Yoo[2]

[1]Korea University Guro Hospital, Seoul, South-Korea; [2]Graduate School of Medicine, Korea University College of Medicine, Seoul, South-Korea

Background. Iron is an essential component for cell proliferation and viability, and it has been reported that iron depletion by chelator inhibits the proliferation of cancer cells, including hepatoma, neuroblastoma and leukemia. Among the different kind of iron chelators, deferoxamine is the most widely studied molecule as an antitumor agent. Deferasirox (DFS) is a new oral iron chelator and there are few reports regarding *in vitro* and *in vivo* effect on myeloid leukemia cells. *Aims.* This study was undertaken to evaluate the *in vitro* and *in vivo* effect of DFS in myeloid leukemia cells and to define the involved molecular mechanism. *Methods.* The effect of deferasirox on two human leukemic cell lines (HL-60 and KG-1) was determined by cell proliferation (MTT assay), cell cycle analysis, and apoptosis assay. MTT assay was done with various concentrations (5, 10, and 50 μM) of DFS for 24, 48, or 72 h. Apoptosis was evaluated by flow cytometry with use of Annexin V and propidium iodide (PI) and by caspase activation assay. Western blotting was used to investigate the involved signal(s) in apoptotic pathways. Tumor xenografts in nude mice (n=14 for each cell line) were used to evaluate the *in vivo* effect of DFS. All *in vitro* experiments were repeated at least three times. *Results.* MTT assay showed that DFS had antiproliferative effect on both myeloid leukemia cell lines and this cytotoxicity was a dose- and time-dependent manner. Cell cycle analysis revealed that subG1 fraction was increased dose-dependently. To determine whether the cytotoxicity induced by DFS was due to apoptosis in HL-60 and KG-1, we measured the fraction of early apoptosis [Annexin V(+)/PI(-)] and caspase-3 and -9 activities. The percentage of Annexin V(+)/PI(-) cells was increased significantly and caspase-3 and -9 activities were also increased by colorimetric assay. Western blot analysis revealed that expression of cleaved PARP, caspase-3, and -9 was increased, indicating involvement of caspase-3/-9 pathway in DFS-induced apoptosis. For *in vivo* experiments, we injected 5×10^6 (HL-60) and 1×10^7 (KG-1) cells into nude mice, respectively. Treatment group (DFS 20 mg/kg) showed statistically significant decrease in tumor mass compared with control group. Summary/*Conclusions.* This study demonstrated that a new oral iron-chelating agent DFS had apoptotic effect on myeloid leukemia cells, and apoptosis was dependent on caspase-3/caspase-9 pathway. DFS might be beneficial for iron-overloaded patients with myeloid leukemia, not only from iron chelation but also from reduction of leukemia cells.

0640

IMPACT OF MOLECULAR MARKERS ON THE OUTCOME OF ACUTE MYELOID LEUKEMIA WITH INTERMEDIATE-RISK CYTOGENETICS

M Hoyos,[1] S Brunet,[2] M Tormo,[2] JM Ribera,[2] J Nomdedéu,[2] J Esteve,[2] A Llorente,[2] D Gallardo,[2] MP Queipo de Llano,[2] R Duarte,[2] I Heras,[2] J Besalduch,[2] J Bargay,[2] JM Martí,[2] C Pedro,[2] J Gonzalez,[2] L Font,[2] M Pratcorona,[2] A Oriol,[2] J Sierra[2]

[1]Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; [2]On behalf of CETLAM Cooperative Group, Barcelona, Spain

Chromosomic alterations help to classify Acute Myeloid Leukemia (AML) in prognostic groups. The intermediate group (IG) described by the Medical Research Council (MRC), with overall survival (OS) of 35-40% at 5 years, is heterogeneous and includes patients with normal karyotype (NK) (50%) and others with cytogenetic abnormalities not associated to favorable or bad prognosis. Several studies have shown that the prognosis in the IG is more accurately defined by molecular characterization including mutations in NPM1, FLT3-ITD and CEBPA, as well as expression of new genes such as the BAALC, EVI1, MN1 and ERG. Objective. To analyze the impact on outcome clinical and biological features, including the above mentioned molecular markers, in AML patients belonging to the IG who achieved a complete remission (CR). *Patients and Methods.* 197 patients with available samples for gene studies and treated under the CETLAM AML-03 protocol were included in the study. Parameters analyzed were complete CR rate, and disease free survival (DFS), Kaplan Meier analysis of time-dependent variables, and

Cox regression for multivariable studies. *Results.* The median age of the series was 53 years (range 20-73); 8% of the patients died during induction chemotherapy, 81% achieved complete remission, and 11% showed refractoriness to treatment. In the multivariate analysis, the presence of NPM1 or CEBPA mutations without FLT3-ITD was associated to increased CR rate (95% *vs.* 75%, P= 0.001). OS of the cohort at 4 years was 41±4,6%, DFS 44±4.6% and relapse probability (REL) 52±5%. Adverse prognostic factors for the OS in the multivariate analysis were age over 50 years (>50y *vs.* <=50y P<0.001, odd ratio [OR]: 2.5 CI95%: 1.6-3.9), and the absence of a favorable genotype (NPM1+,or CEBPA+/FLT3-ITD-)(P<0.001,OR:4, CI95%:2.2-7.5). Regarding DFS, the adverse prognostic factors were age over 50 years (p:0.023, OR: 1.7, CI95%:1.1-2.8), a white blood cell count (WBC) over 100×10^9/L (>=100 *vs.* <100, P:0.050, OR:1.7, CI95%:1-3) and the absence of a favorable genotype (P:0.003, OR:2.3, CI95%1.3-4). For REL, the independent adverse factors were, older age (>50y) (P:0.036, OR:1.7, CI95%:1-2.9), the absence of a favorable genotype (P:0.003, OR:2.6, CI95%:1.3-4.8), and the over-expression of BAALC gene (P:0.011, OR:2.6 CI95%:1.2-5.1). *Conclusions.* In AML with intermediate cytogenetic risk, the over-expression of BAALC was an adverse prognostic factor for relapse rate. Regarding DFS and OS, the well established prognostic factors such as age, leukocyte count and NPM1, CEBPA and FLT3 status were confirmed in this series. The results presented here, confirmed the need to adjust therapeutic decisions based in clinical and biological features.

0641

ANTI-LEUKEMIC EFFECT OF SODIUM METAARSENITE (KML001) IN ACUTE MYLOGENOUS LEUKEMIA WITH BREAKING-DOWN THE RESISTANCE OF CYTOSINE ARABINOSIDE

Y Lee,[1] SS Yoon,[2] ES Kim,[2] K Kim[3]

[1]Han Yang University Hospital, Seoul, South-Korea; [2]Cancer Research Institute Seoul National Unviersity, Seoul, South-Korea; [3]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, South-Korea

Background. Arsenic compounds have been used in traditional medicine for several centuries. Especially, arsenic trioxide (As_2O_3) has proven effective in the treatment of acute promyelocytic leukemia (AML M3 subtype). A drawback of arsenic trioxide is that it is administered intravenously, and not effective in the treatment of acute mylogenous leukemia (AML) except AML M3 subtype. Sodium metaarsenite ($NaAs_2O_3$: code name KML001) is an orally bioavailable arsenic compound with potential anti-cancer activity. However, the effect of KML001 has not been well studied in AML. *Aims.* Firstly, to determine the anti-leukemic effect of KML001 in AML, and to compare the efficacy with arsenic trioxide, secondarily, to investigate the mechanism of anti-leukemic effect of KML001. *Methods.* Eleven AML cell lines were used in this study including Ara-C (cytosine arabinoside) resistant HL-60 (HL-60R) cells. AML blasts were isolated from 4 AML patients (2 M1 and 2 M2 subtypes) after obtaining informed consents. Cellular inhibition was measured by MTT assay. Expression of molecules was done by western blot. Analysis of cell cycle was used by flow cytometry. Transcriptional expression of catalytic subunit of telomerase, hTERT, was done by real-time PCR. *Results.* KML001 inhibited the cellular proliferation in all AML cell lines and primary AML blasts as well as HL-60R cells in a dose-dependent manner with IC_{50} of 5×10^{-8}M. While KML001 effectively inhibited cellular proliferation of HL-60 cells (IC_{50}; 5×10^{-8}M) as well as HL-60R cells (IC_{50}; 1×10^{-8}M), and its anti-leukemic effect was almost same as Ara-C (IC_{50}; 5×10^{-8}M), Ara-C did not inhibit cellular proliferation in HL-60R as expected. Furthermore, arsenic trioxide was not effective in primary AML blasts and AML cell lines including HL-60 R cells. KML001 (1×10^{-7}M) was induced G1 cell cycle arrest which was associated with decreased expression of cyclin D1, cyclin E1, CDK1 (cdc2p34), CDK4, and CDK6. While KML001 increased the p21 and p27 levels, and enhanced their bindings with CDK4 in HL-60 cells, the expression of p21 and p27 bound CDK2 was observed in HL-60R cells. Apoptotic molecules of Bcl-2, proform of caspase-3 and caspase-9 were decreased, in contrast, expression of PARP was increased in HL-60 and HL-60R cells treated with KML001. Real-time PCR with RNA extracted from KML001-treated HL-60 and HL-60R cells showed a significant reduction of catalytic subunit of telomerase, hTERT, at 12 hr. When treated KML001, DNA damage molecule (γ-H2AX) in HL-60 and HL-60R cells was increased. In addition, KML001 inhibited the activation of STAT1, 3, 5, NF-κB (p65 and p50 subunits), pAKT and PI3K in a time-dependent manner. On the other hand, activated PTEN was up-regulated.Summary/*Conclusions.* KML001, sodium metaarsenite, demonstrated anti-leukemic effect via various mechanisms including cell cycle arrest, induction of apoptosis, and inhibition of JAK/STAT and PI3K pathways. Especially, KML001 might target telomerase with DNA damage. Furthermore, it is probable that KML001 may overcome the resistance of chemotherapeutic agents. Collectively, KML001 may be a candidate agent for the treatment of *de novo*, refractory and relapsed AML.

FLOW-CYTOMETRIC MULTIPLEX IMMUNOBEAD ASSAY FOR THE DETECTION OF CBFβ-MYH11 AND AML1-ETO FUSION PROTEINS IN ACUTE MYELOID LEUKEMIA

E Dekking,[1] V Velden,[1] N Boeckx,[2] E Sonneveld,[3] J Flores-Montero,[4] S Boettcher,[5] M Comans-Bitter,[1] J van Dongen[1]

[1]ErasmusMC, Rotterdam, Netherlands; [2]Universitair ziekenhuis De Gasthuisberg, Leuven, Belgium; [3]Dutch Children Oncology Group, The Hague, Netherlands; [4]University of Salamanca, Salamanca, Spain; [5]University of Kiel, Kiel, Germany

The prognostic classification of acute myeloid leukemias (AML) is generally based on the presence or absence of specific genetic aberrations-particularly fusion genes-that are detected by karyotyping, FISH or PCR. These techniques are laborious and demand specialized laboratories. Therefore fast and easy research-based cytometric bead array (CBA) assays (BD Biosciences) are being developed for detection of fusion proteins in cell lysates of leukemic cells that contain these well-defined fusion gene aberrations. Here we present data of a multiplex AML "core-factor"CBA which detects the AML1-ETO and CBFβ-MYH11 "core-factor"fusion proteins. AML patients harboring either of those fusion proteins comprise a biologically distinct and prognostically favorable subgroup of patients who often achieve long-lasting complete remissions. Therefore accurate identification of CBFβ-MYH11/ inv(16) and AML1-ETO/ t(8;21) positive cases is essential. Monoclonal antibodies were generated against the fusion proteins (both N- and C-terminus). Based on the recognized epitopes, the antibodies should recognize all variants of the CBFβ-MYH11 fusion proteins which result from translocations in the different breakpoint cluster regions. In the CBA, catcher antibodies were coupled to separate CBA beads and the detector antibodies with fluorochrome-labeling. A specific signal in the flow cytometer is only detectable when the relevant fusion protein is present in the analyzed sample. Since wild-type proteins are not recognized by the antibody couples, no signal should be obtained when samples are analyzed that do not contain the fusion protein. To limit the number of cells required for analysis, the two assays were combined into a multiplex so-called "AML core-factor"CBA. The multiplex assay appeared specific (cell lines that express other fusion proteins were not detected) and sensitive since it detects at least 10-15 % of fusion protein positive leukemic cells diluted in normal PB-MNCs or WBC's. The suitability of the multiplex AML core-factor CBA was tested in five EuroFlow laboratories: 63 myeloid and monocytic AML samples were analysed (blood and bone marrow).The presence or absence of CBFB-MYH11 or AML1-ETO transcripts in the specimens was determined by RQ-PCR analysis according to the EAC program. The performance of the CBA was assessed by parallel analysis of well-defined positive and negative control samples. The multiplex AML assay had full concordance with the RQ-PCR results (18/18 positive and 45/45 negative) with identification of all AML1-ETO (5/5) and CBFβ-MYH11 (13/13) positive patients. The multiplex AML core-factor CBA is suitable for accurate and simultaneous detection of CBFβ-MYH11 and AML1-ETO containing samples. The assay is specific and can be performed within 4-5 hours in a routine diagnostic setting, without the need of special equipment other than a flow cytometer. The novel CBA will enable fast and easy classification of AML patients that express CBFβ-MYH11 and AML1-ETO fusion proteins. These patients can be included at an early stage in the right treatment protocols, much faster than by use of current molecular techniques. The CBA can be run in parallel to routine immunophenotyping and is particularly attractive for clinical settings without direct access to molecular diagnostics.

GENE EXPRESSION ANALYSIS IN AML CELL LINE MV4-11 FOLLOWING TREATMENT WITH THE ANTI-CANCER APTAMER AS1411

S Sederovich,[1] A Ajami,[2] B Doran,[1] F McLaughlin,[1] D Jones[1]

[1]Antisoma Research Limited, Welwyn Garden City, UK; [2]Antisoma Inc, Cambridge, MA, USA

Background. AS1411 is a 26-base DNA aptamer which is shortly due to enter a phase IIb clinical trial in acute myeloid leukaemia (AML). In

an initial phase II trial in AML, combination of AS1411 with cytarabine produced an increased response rate compared to cytarabine alone, and AS1411 was well tolerated. When cells in culture are exposed to AS1411, a cytostatic effect is observed initially, followed by cell death after 72 to 96 hours. Several mechanisms have been described by which AS1411 exerts these effects; we performed a gene expression microarray analysis to evaluate which cellular pathways and functions were modulated by AS1411 treatment. We also sought to identify biomarkers for drug activity which could be translated to use in the clinic in the forthcoming phase IIb trial. *Results.* The AML cell line MV4-11 was exposed to AS1411 at two concentrations; these approximated concentrations observed in patient plasma following two different doses of AS1411 in the prior phase II trial. mRNA was isolated from cells at 24 and 72 hours, time points associated with cytostatic and cytotoxic effects, respectively. Controls at time zero and in the absence of drug were also analysed. The Affymetrix plus 2™ arrays were processed and the raw data were normalised according to the Rosetta Resolver model. The gene lists for each time point (4 replicates) were then clustered non-hierarchically and distributed into pathways using MetaCore™. Gene clusters were separately generated to identify specific genes which were up- or down-regulated at different doses and different time points. These were then compared to identify those that were regulated by a common pathway. Pathways and regulatory networks that were either up- or down-regulated after exposure to AS1411 included nuclear import/export, nucleotide biosynthesis/metabolism, DNA damage response and pathways related to cell cycle control and cell death (including genes in the p53 signalling pathway). While some of these activities had been shown previously to be modified upon AS1411 exposure, other findings are novel. A number of genes showed marked changes in expression following AS1411 exposure; these are undergoing validation by quantitative PCR as potential biomarkers. They include upregulated genes TP53i3 and p21 (p53 signalling pathway), RDM1 (DNA damage), YPEL3 and DAPK1 (proliferation and apoptosis) as well as individual genes such as GNG7. Several genes, including INO80C, exhibited a marked dose dependent down regulation. *Conclusions.* This work demonstrates that a number of cellular activities are modulated by AS1411, and provides important information for the future clinical development of AS1411, including pointers to the selection of biomarkers for analysis of blood and bone marrow samples from patients in the forthcoming phase IIb study in AML.

ANKYRIN REPEAT AND KH DOMAIN CONTAINING 1 (ANKHD1), A NEW SCAFFOLDING PROTEIN, REDUCES APOPTOSIS AND IS MODULATED IN LEUKEMIC CELLS

P Rodrigues,[1] S Saad,[1] F Traina,[1] P Severino,[2] F Costa,[1] C Moreira-Filho[2]

[1]Unicamp, Campinas, Brazil; [2]Albert Einstein, São Paulo, Brazil

Background. Ankyrin repeat and KH domain containing 1 (ANKHD1) is the human homolog of the Drosophila melanogaster Mask (Multiple ankyrin repeat and single KH domain protein), a protein involved in photoreceptor differentiation, cell survival and proliferation. ANKHD1 associates with SHP2 in neoplastic cells and all its isoforms are upregulated during hematopoietic cell differentiation. ANKHD1 knockdown of in Hela cell lines was associated with increasing of apoptosis levels and caspase activation However, the exact contribution of ANKHD1 in leukemogenesis is still unknown. *Aims.* The aim of this study was to analyze the gene expression profile in ANKHD1-depleted cells, compared to control cells. We also evaluated apoptosis levels in leukemia cell line submitted to ANKHD1 overxpression and ANKHD1 expression after treatment with immunomodulator drugs. *Methods.* Analysis of gene expression profile of ANKHD1-depleted cells was performed using a microarray approach (codelink,GE technologies) in siRNA-treated cells, analyzed by Ingenuity Pathway Analysis. Using real-time quantitative polymerase chain reaction (qRT-PCR), ANKHD1 expression was analysed in bone marrow mononuclear cells (BMNC) of patients with acute leukemia (AL) at the time of diagnosis or in BMNC from healthy donors. A total of 38 adult cases diagnosed with acute leukemia at the Hematology and Hemotherapy Center of the State University of Campinas were studied, including 7 ALL, 1 biphenotypic acute leukemia and 30 AML (1 M0, 5 M1, 6 M2, 3 M3, 10 M4, 3 M5, 1 M6, 1 M7) based on the French-American-British (FAB) classification and normal bone marrow donors (n=11).The hyperxpression was done by AMAXA®nucleofector® electroporation and apoptosis levels were measured in percent of annexin 5(Molecular probes) positive cells under and without the action of camptothecin apoptosis induction. Leukemia cell lines were treated with Interferon α or Thalidomide for 18 and 16 hours respectively and ANKHD1 expression was analyzed by qRT-PCR. Statistical analysis was performed by Mann-Whitney test. *Results.* BMF, a pro-apoptotic "BH3-only protein"of the BCL2 family, was upregulated in ANKHD1-depleted cells in microarray analysis. qRT showed a reduced expression of ANKHD1 transcripts and an upregulation of BMF in leukemia primary samples ($P<0.0001$ and $P<0.001$ respectively), corroborating our microarray *Results.* ANKHD1mRNA was upregulated in leukemia cell lines under Interferon α or Thalidomide treatment. Finally, ANKHD1 hyperexpression protects leukemic cell from apoptosis induction by camptothecin. *Conclusions.* The high levels of BMF expression is associated with bad prognosis in leukemia. Our results show that dowregulation of ANKHD1 is associated with high levels of BMF in primary leukemic samples and ANKHD1 overexpression induced decreasing in apoptosis. These results indicate that ANKHD1 is likely a novel scaffolding protein involved in apoptosis signaling and/or cellular proliferation processes and could be involved in leukemogenesis.

Background. A combination of all-trans retinoic acid (ATRA) and chemotherapy (CT) has improved the clinical outcome of APL. However, considerable numbers of patients still relapse after an initial response. Although prognostic factors for APL have been studied, the prognostic impact and clinical characteristics of ACAs in APL remains controversial. The results differ among previous papers (De Botton *et al.*, Hernandez *et al.*, Schlenk *et al.*). Recently, Cervera *et al.* found in the largest study that ACAs were associated with lower relapse-free survival in univariate analysis. *Aims.* Large prospective studies with longer follow-up are needed to evaluate whether ACAs have an impact on the efficacy of treatment with ATRA and CT. We analyzed the prognostic importance of ACAs in 10 years' follow-up of a large prospective study. *Methods.* Among 302 patients with newly diagnosed APL enrolled in this study (Asou *et al.*, 2007), 225 patients were assessable. The patients had been continuously registered from May 1997 to June 2002. Informed consent was obtained before registration. Clinical outcomes were updated on January, 2009, and the median follow up period is 7.3 years. Clinical characteristics were analyzed in relation to ACAs. In addition, CR rate, relapse rate (RR), OS and disease-free survival (DFS) were assessed in APL patients with or without ACAs. *Results.* ACAs were observed in 67 patients (29.7%). Trisomy 8 was found in 21 cases (31%). Other ACAs were found involving chromosome 15 and 17 in twelve (18%), chromosome 9 in seven (11%), chromosome 7 in six (9%), chromosome 6 in four (6%). No clinical or biological differences were found between patients with or without ACAs, except for the frequency of M3v, which was significantly lower in those with ACAs (P=0.04). The CR rates in patients with or without ACAs were 97% and 95%, respectively (P=0.72). DFS and OS were not different between the two groups at 10 years (68% *vs.* 71%, P=0.59; 91% *vs.* 84%, P=0.18; respectively). The cumulative incidence of relapse was not different between the two groups (26% *vs.* 22%, P=0.51). The cumulative incidence of early death at 50 days in the patients with or without ACAs was 2% and 6%, which was not significantly different (P=0.16). Additionally, the clinical outcomes were analyzed among subgroups of patients with ACAs. DFS and OS were not significantly different between ACAs patients with or without trisomy 8 (70% *vs.* 67%, P=0.58; 95% *vs.* 89% , P=0.37; respectively). Other abnormalities including chromosome-7, -9, -15 and -17 did not influence outcomes. *Conclusions.* The prognostic impact of ACAs has not been elucidated in this study. One of the reasons in the experimental difficulty is the clinical outcome of APL has been considerably improved due to the introduction of ATRA. It might become more difficult to determine significant prognostic factors in the study of APL. However, we should continue to conclude it in larger prospective studies after the introduction of more specific molecular-targeted agents, such as arsenic trioxide and gemtuzumab ozogamicin.

C-KIT MUTATION IS A SIGNIFICANT PROGNOSTIC FACTOR OF T(8;21) AML: IMPORTANCE OF HIGHLY SENSITIVE Q-PROBE METHOD

S Wakita

Nippon medical school, Tokyo, Japan

Background and *Aims.* t(8;21) AML is thought to have a better prognosis than other AMLs. Nevertheless, only approximately 50% of patients were alive at 5 years. This suggests that some patients have more aggressive leukemic phenotypes and indicates the need for predictive marker of relapse. Recently, several groups reported that c-kit mutation defined an unfavorable subgroup in t(8;21) AMLs. However the rate of c-kit mutation has been reported to be approximately 20% at diagnosis of core binding factor leukemias. In the present study, we analyzed samples collected at diagnosis to investigate the role of c-kit mutations and FLT3-ITD in t(8;21) AML. *Methods.* We analyzed c-kit mutation and FLT3-ITD among t(8;21) AML patients diagnosed between 1991-2009 at the Nippon Medical School Hospital. Exon 8 and 17 of c-kit were analyzed by direct sequencing method and Q-Probe system (ARKRAY Inc. Kyoto, Japan). Q-Probe method was a highly sensitive mutation screening system using mutation specific guanine quenching probe (Leukemia Res 32;1462-1467,2008). FLT3-ITD was analyzed by PCR amplification. *Results.* 26 patients were enrolled. All of them successfully achieved CR, but 15 patients (57.7%) relapsed. Using direct sequencing method, c-kit mutations were found in 5 patients out of 26 patients (D816V: 3 patients, N822K: 2 patients). Next we analyzed to detect small amount of mutations by Q-Probe method and D816V in 1 patient and N822K in 6 patients were newly found at diagnosis in the patients negative by direct sequencing method. Totally, c-kit mutations were found in 12 patients out of 26 patients at diagnosis (46.2%, D816V: 4 patients, N822K: 8 patients) using Q-Probe method. To evaluate the importance of c-kit mutations as a predictive factor of relapse, we analyzed the cumulative incidence of relapse (CIR) of these patients using Kaplan-Meier method. Relapse rate of all cases was 57.7% and median time to relapse was 16 months. In direct sequencing method, the CIR at 2 years tended to be higher for patients with c-kit mutations, but there was no significant difference (P=0.3970, wild type 54.9% *vs.* c-kit mutation 80.0%). On the other hand, when we analyzed using Q-Probe method, the CIR at 2 years was significantly higher for patients with c-kit mutations with the p value of 0.0193 (wild type 41.2% *vs.* c-kit mutation 81.8%). We detected FLT3-ITD in 2 patients at diagnosis, then we analyzed the CIR accordingly to the presence of c-kit mutation or FLT3-ITD. The CIR at 2 years was much higher for patients with c-kit mutation (Q-Probe method)/FLT3-ITD than the patients without mutations (P=0.0069, wild type 35.5% *vs.* c-kit/FLT3-ITD 83.3%). As for the position of c-kit mutations, the function of D816V was thought to be closely related to the relapse of t(8;21) AML. *Conclusions.* In this study, we showed that c-kit mutation was a significant poor prognostic factor for t(8;21) AML. And we also revealed the importance of using highly sensitive Q-Probe method. It will be necessary to consider therapeutic strategy including up-front stem cell transplantation and/or tyrosine kinase inhibitors for t(8;21) AML patients with c-kit/FLT3-ITD mutations.

0647

PREDICTIVE VALUE OF AN IN VITRO BIOLUMINESCENT ASSAY FOR RAPID ASSESSMENT OF RESPONSE TO CYTARABINE AND FLUDARABINE IN PATIENTS WITH ACUTE LEUKAEMIA

E Anderson,[1] V Salisbury,[1] M Conway,[1] A Smith,[2] A Martin,[3] M Ruddock,[3] J Lamont,[3] H Alloush,[1] P Mehta,[4] J Smith[5]

[1]University of the West of England, Bristol, UK; [2]Royal Marsden NHS Foundation Trust, London, UK; [3]Randox Laboratories Ltd, Belfast, UK; [4]Bristol Haematology and Oncology Centre, Bristol, UK; [5]Frimley Park NHS Foundation Trust, Frimley, UK

Cytarabine (Ara-C) is the mainstay of treatment for acute non lymphoblastic leukaemia (ANLL). Currently there is no rapid, inexpensive test to assess patient sensitivity to Ara-C or combination chemotherapy prior to treatment. Over 30% of patients with ANLL fail to respond to Ara-C with potential causes of resistance including decreased hENT-

1 transporter activity and over expression of cytidine deaminase (cdd). We have previously reported a bioluminescent 8-hour assay which assesses Ara-CTP levels in leukaemic cell lines and patient samples independently of the cause of patient resistance (Anderson *et al.,* Blood 2009; 114(22): p643). In theory any agent capable of potentiating generation of Ara-CTP from Ara-C can also be tested on the biosensor system. Here we present results using the 8-hour assay for combination therapy screening, as tested on seven ANLL cell lines and an initial cohort of seven patients with ANLL, dosed with Ara-C alone or in conjunction with the purine analogue fludarabine and granulocyte-colony stimulating factor (G-CSF). The 8-hour assay was optimised for combination therapy using a range of pre-incubation periods based on the protocol for *in vitro* dosing proposed by Ahlman *et al*. (Leukaemia 2001; 15(1): 69-73). The optimal dosing schedule required 4 hours pre-incubation with fludarabine (5 μM) followed by the 8-hour protocol previously described (Anderson *et al.,* Blood 2009; 114(22): p643). Where appropriate G-CSF (5 ng/mL) was dosed 24 hours prior to treatment with fludarabine and/or Ara-C (FLA). The Ara-C concentration used *in vitro* was 25 μM which is equivalent to 2 g/m^2 in the clinical setting. ANLL samples were sourced at presentation from patients with blast burdens of >80% in bone marrow. The *in vitro* FLA dosing schedule was initially tested on seven ANLL cell lines with known response to Ara-C (CCRF-CEM, K562, MV4-11, HEL, KG-1a, HL-60 and THP-1) and these results were correlated with a commercially available 3-day cytotoxicity assay (CellTiterGlo™, Promega). A significant response to FLA dosing was observed for K562, THP-1 and MV4-11 cell lines, which are highly resistant to Ara-C using the 8-hour assay. These results were corroborated by the 3-day cytotoxicity assay. For the patient cohort the distribution of FAB sub-types was M4 (30%), M2 (14%), secondary AML (14%), M0 (14%), biphenotypic AML (14%) and Ph+ ALL (14%). Patient ages ranged from 27 to 71 (median 53 years) and included five peripheral blood and three bone marrow samples. In four samples the 8-hour assay showed a significant improvement in blast cell sensitivity to combination treatment compared with Ara-C alone ($P<0.05$ in all cases). Confirmation of the predictive capacity of the 8-hour assay was observed in two of these patients: one was initially resistant to daunorubicin/Ara-C, and achieved remission with FLAG-Idarubicin; the second also successfully achieved remission with FLAG-Idarubicin. This bioluminescent assay system offers a valuable tool in predicting response in patients receiving Ara-C or fludarabine/Ara-C. This may be of importance in patients demonstrating chemoresistance, at presentation and at relapse.

0648

SAFETY AND EFFICACY OF ALL-TRANS RETINOIC ACID (ATRA) AND ARSENIC TRIOXIDE (ATO) COMBINATION THERAPY IN ACUTE PROMYELOCYTIC LEUKEMIA

A Arora, P Malhotra, R Das, S Varma, V Suri, N Varma

PGIMER, Chandigarh, Ahmedabad, India

Introduction. Acute Promyelocytic Leukemia (APL) is considered as one of the curable malignancy. The standard therapy consists of all-trans Retinoic Acid (ATRA) along with an anthracycline with or without cytarabine. The relapse/resistance rates have been in the range of 20-30%. Almost similar success and relapse rates have been seen with single agent Arsenic Trioxide (ATO). Combination of ATRA with ATO as first line therapy is an attractive treatment option in APL. Both drugs have distinct action on degradation of PML-RAR alpha and thus act synergistically. *Methods.* All newly diagnosed patients with APL were given the option of combined therapy with ATRA and ATO after informed consent. This protocol was also used in those patients who had poor performance status and did not give consent for standard chemotherapy. The diagnosis of APL was made by bone marrow examination and PML-RAR alpha detection by RT-PCR. ATRA was used in the dose of 25 mg/m^2 and ATO in the dose of 0.15 mg/kg/day until complete hematological remission. Consolidation therapy consisted of ATRA for 6 weeks and 28 injections of ATO (5 days/week). All patients received three consolidation therapies each after a gap of one month. Subsequently after documentation of molecular remission, patients were put on maintenance chemotherapy consisting of intermittent ATRA 15 days every 3 monthly, 6-mercaptopurine 50 mg/m^2 daily and methotrexate 20 mg/m^2 weekly for 2-years. RT-PCR for PML RAR alpha was done after successful induction, after completion of consolidation and yearly during maintenance therapy. *Results.* From January 2005 till December 2009, 25 patients (13 males, 12 females) were offered combined therapy with ATRA and ATO. The median age of the patients was 33 years (range 13-48 years). The presenting complaints were low-grade fever and fatigue with median symptom duration of 30 days (range 5-90 days). Baseline median hemoglobin value was 7 gm/dl (range 6-12.4 gm/dL). White cell count of more than 10,000/μl was found in 12 patients (48%) and 21 patients (88%) had platelet count of less than 40,000/μL. Coagulopathy was present in 22 patients (85%). Hematological remission was achieved in 23 patients (92%) with median time to remission of 35 days (15-49 days). ATRA syndrome developed in 9 patients (36%). Two patients developed cardiac toxicity in the form of prolongation of QTc interval. Four patients died during therapy (two deaths during induction therapy, one after successful induction and one during maintenance therapy). One patient relapsed during maintenance phase. Two patients abandoned the treatment while in molecular remission. Remaining 18 patients are in molecular remission at a median follow-up duration of 17 months (range 3-57 months). *Conclusions.* Combination of ATRA and ATO produces high rates of successful induction in APL. The therapy is well tolerated without any major side effects and requires further evaluation in a randomized trial.

0649

IN ADULT ACUTE MYELOID LEUKAEMIA (AML) ALL RISK SUBSETS BENEFIT FROM A SEQUENTIAL HIGH-DOSE PROGRAMME AS EARLY RESCUE OF FIRST INDUCTION FAILURE: A REPORT FROM NORTHERN ITALY LEUKAEMIA GROUP (NILG)

T Intermesoli,[1] G Rossi,[2] E Pogliani,[3] F Marmont,[4] I Cavattoni,[5] V Cassibba,[5] A Scattolin,[5] M Musso,[6] D Mattei,[7] C Minotto,[5] F Ciceri,[8] L Campiotti,[9] P Corradini,[10] E Borlenghi,[2] G Ruggeri,[2] E Terruzzi,[3] L Verga,[3] E Audisio,[4] P Fabris,[5] T Chisesi,[5] U Giussani,[11] O Spinelli,[12] P Zanghì,[12] E Oldani,[12] T Barbui,[12] A Rambaldi,[12] R Bassan[12]

Circolo Fondazione Macchi, Varese, Italy; [10]Hematology Istituto Nazionale Tumori, Milano, Italy; [11]Cytogenetic Unit OO.RR, Bergamo, Italy; [12]Hematology OO.RR., Bergamo, Italy

Background. In adult AML the complete remission (CR) rate following standard induction therapy varies according to incidence of risk factors. Because obtaining a CR is a primary determinant of survival, the analysis of induction outcome in function of risk group and specific treatment elements is essential to optimize induction results and eventually improve survival. *Aims.* To analyse (1) the failure rate to a standard induction regimen and (2) the salvage rate after a sequential high-dose programme in different risk subsets of adult AML, as defined by cytogenetics and selected additional risk factors. *Methods.* In prospective study NILG-AML 01/00, CR induction therapy consisted of standard ICE chemotherapy with idarubicin 12 mg/m^2/d dd 1-3, etoposide 100 mg/m^2/d dd 1-5, cytarabine 100 mg/m^2/bd dd 1-7, G-CSF from d 8. Refractory cases were to receive a sequential high-dose regimen with idarubicin 17.5 mg/m^2/d dd 1 and 8, cytarabine 3 g/m^2/bd dd 2, 3, 9, and 10, G-CSF from d 11 (s-HAI). Patients were stratified according to cytogenetics and additional risk factors (WBC count >50×10^9/L, FAB class M0/6/7, hepato/splenomegaly, MDS-related/secondary AML, FLT3/ITD mutation). Cytogenetic risk groups were favourable with t(8;21), inv(16); normal with 46 XX/XY; unfavourable with -5/del(5q), -7, abn(11q23), abn 3q/9q/11q/20q/21q/17p, iso(17q), t(3;5), t(6;9), t(9;22), complex with >3 unrelated clonal anomalies; and intermediate with other aberrations or unknown karyotype. Results. Between 2000-07, 581 patients were enrolled (age range 19-68 years, median 52). The distribution of cytogenetic abnormalities and the association with other risk factors is shown in the table. Overall incidence of hyperleukocytosis was 24%, adverse FAB class 10.2%, MDS/secondary AML 15%, hepato/splenomegaly 20%, and FLT3/ITD+ 27%. Following ICE induction, 22% of the patients had refractory AML. As expected, this figure varied greatly from favourable to unfavourable cytogenetic risk class (8% to 36.6%), with a nonsignificant trend to worse results conferred by additional risk factors in each cytogenetic risk group (cumulative resistance 24.3% *vs.* 18.7% without, P=0.1). Following s-HAI in 95/129 ICE-refractory patients (73.6%), the risk class effect was no longer detectable as demonstrated by the high cumulative CR rate (n=54, 56.8%), that was unrelated to cytogenetic risk subset and/or associated risk factors (Table). Conclusions. The integrated clinical and cytogenetic risk model identified patients at higher risk of resistance to standard ICE induction therapy. More than half of these cases were effectively rescued by s-HAI, regardless of cytogenetics or clinical risk class.

This documents the potential relevance of a combined risk classification and points to the inadequacy of conventional first-line therapy in HR subsets.

Table 1.

		cycle 1 (ICE)		cycle 2 (s-HAI)	
Cytogenetic risk class	Additional risk factors	No. treated	Refractory, no. (%)	Refractory treated, no.	Complete remission, no. (%)
Favourable	Absent	30	3 (10)	2	2 (100)
	Present	20	1 (5)	1	1 (100)
Normal	Absent	94	13 (14)	9	5 (55.5)

TREATMENT-RELATED AML AND AML EVOLVING FROM MDS: SIMILAR OUTCOMES FOLLOWING TREATMENT WITH AMONAFIDE + CYTARABINE

M Sekeres,[1] S Allen,[2] S Mohan,[1] A Lundberg,[3] H Erba[4]

[1]Cleveland Clinic Taussig Cancer Institute, Cleveland, USA; [2]North Shore LIJ Health System, Manhasset, NY, USA; [3]Antisoma Inc, Cambridge, MA, USA; [4]Univ of Michigan Health Syst, Ann Arbor, MI, USA

Background. Secondary AML (sAML) is a well recognized poor prognostic factor in AML. sAML is a heterogeneous group of diseases, including both AML evolving from myelodysplastic syndromes (MDS, MDS→AML) and AML following chemotherapy for another malignancy, treatment-related AML (tAML). These two subtypes of poor risk AML have similar outcomes when treated with standard anthracycline-based chemotherapy, supporting their inclusion into the same clinical category. It is unknown whether this classification is valid when using experimental antileukemic agents. We therefore examined the outcomes of MDS→AML *vs.* tAML, following amonafide-based therapy. *Methods.* Patients (pts) received amonafide 600 mg/m^2/day IV days 1-5 and cytarabine 200 mg/m^2/day IV continuous infusion days 1-7. Post-remission therapy (PRT) included hematopoietic stem cell transplant (HSCT; n=10) or cytarabine (intermediate-dose, n=13; or high-dose, n=7). The primary endpoint was CR/CRi; secondary endpoints were safety, DOR and OS. Cytogenetic classifications were based on modified SWOG-ECOG criteria. *Results.* 88 pts with sAML were treated. 45 (51.1%) had tAML (including 5 pts with MDS→AML and tAML), and 48 (53.4%) had MDS→AML. Baseline characteristics were as follows: tAML: 12 (27%) male, age 60 yrs (23-87), 35 (78%) ECOG 0-1, 37 (86%) unfavorable cytogenetics; MDS→AML: 29 (67%) male, age 66 yrs (24-81), 37 (86%) ECOG 0-1, 15 (35%) unfavorable cytogenetics. 37 pts (42%) achieved CR+CRi. CR+CRi rate was 18/45 (40%) for tAML pts and 19/43 (44.2%) for those with MDS→AML (P=0.691). PRT was given to 16/18 tAML pts (89%, HSCT 5, HiDAC 4, IDAC 7), and 14/19 MDS→AML pts (74%, HSCT 5, HiDAC 3, IDAC 6). Median DOR: 512 days for tAML, 164 days for MDS_AML (P=0.026) Median OS: 209 days tAML, 183 days MDS→AML (P=0.091). *Conclusions.* tAML and MDS→AML are diseases with similar outcomes in response rate and overall survival following amonafide therapy, further supporting their inclusion together into a broad category of sAML, though duration of remission appears shorter for MDS→AML . These data validate sAML as an appropriate grouping when considering treatment options for these poor-risk patients.

WT1 MUTATION IN 470 ADULT PATIENTS WITH ACUTE MYELOID LEUKEMIA-STABILITY DURING DISEASE EVOLUTION AND IMPLICATION OF ITS INCORPORATION INTO A SURVIVAL SCORING SYSTEM

HA Hou,[1] TC Huang,[2] LI Lin,[2] CY Chen,[2] WC Chou,[2] JL Tang,[2] MH Tseng,[2] CF Huang,[2] YC Chiang,[2] FY Lee,[2] MC Liu,[2] M Yao,[2] SY Huang,[2] BS Ko,[2] SC Hsu,[2] SJ Wu,[2] W Tsay,[2] YC Chen,[2] HF Tien[2]

[1]National Taiwan University Hospital, Taipei, Taiwan; [2]NTUH, Taipei, Taiwan

Background and *Aim.* The impact of WT1 mutations in acute myeloid leukemia (AML) is not completely settled. We aimed to determine the clinical implication of WT1 mutation and its stability during the clinical course. *Methods* and Materials. From November 1995 to March 2007, a total of 470 adult patients ≥15 years who were newly diagnosed as having *de novo* non-M3 AML at National Taiwan University Hospital (NTUH) were enrolled. Mutation analysis of WT1 exons 7 and 9 was performed by genomic DNA polymerase chain reaction (PCR) and was correlated with other gene mutations and clinical features. Results. WT1 mutations were identified in 6.8% of total patients and 8.3% of younger patients with normal karyotype (CN-AML). The WT1 mutation was closely associated with younger age (P=0.0008), FAB M6 subtype (P=0.006), and t(7;11)(p15;p15) (P=0.0025). Multivariate analysis demonstrated that WT1 mutation was an independent poor prognostic factor for overall survival and relapse-free survival among total patients and CN-AML group. A scoring system incorporating WT1 mutation with FLT3/ITD, NPM1 and CEBPA mutations into survival analysis was proved to be very useful to stratify CN-AML patients into different prognostic groups (P<0.001). Sequential analyses were performed on 133 patients. WT1 mutations disappeared at complete remission in all WT1-mutated patients studied. At relapse, three of the 16 WT1-mutated patients who had paired samples lost the mutation and two acquired additional mutations, while three of 110 WT1-wild patients acquired novel mutations. *Conclusions.* WT1 mutations are correlated with poor prognosis in AML patients. The mutation status may be changed in some patients during AML progression.

0652

BIPHENOTYPIC ACUTE LEUKAEMIA: TREATMENT WITH ALL-TYPE REGIME MAY OFFER A BETTER OUTCOME

F Lim, GC Wong

Singapore General Hospital, Singapore, Singapore

Background. Biphenotypic acute leukemia (BAL) is an uncommon disease and accounts for 4% of acute leukaemias. There is no standard treatment. *Aims.* We present an overview of the clinical and biological characteristics, response to treatment and outcome of BAL in a single institution over 8 years. *Methods.* BAL patients were identified through a search of the Leukemia Registry (a computerized database approved by the Ethics committee). Informed consent was waived by EC. The characteristics and clinical profile of patients diagnosed with BAL according to European Group for the Immunological Characterisation of Leukemias (EGIL) Classification were studied. Results. BAL was diagnosed in 22 patients (12 males and 10 females) amongst 442 acute leukemia cases between 1998 and 2006. BAL accounted for 5% of acute leukemias. Median age was 42 years. Eight patients co-expressed B-lymphoid/myeloid antigens while 14 patients co-expressed T-lymphoid/myeloid antigens. No patient demonstrated trilineage differentiation. Cytogenetic analysis revealed normal karyotypes in 6 patients (27.3%) and abnormal karyotypes in 16 patients (72.3%). Four patients carried the Philadelphia chromosome (Ph) t (9; 22), while 2 patients had karyotype involving chromosome 11. Two patients received ALL type induction therapy, while 17 patients received combined ALL and AML type induction therapy. Complete remission (CR) was achieved in both patients (100%) that received ALL type induction therapy over a mean period of 1.5months. One patient is alive after 10 months from diagnosis and has received allogenic bone marrow transplant. In the group that received combined ALL and AML type induction therapy, CR was achieved in 8 patients (47.1%) over a mean period of 1.4 months, however, 4 patients relapsed after a mean period of 6.8 months and died. The remaining 4 patients in CR received allogenic bone marrow transplant. Two patients are alive after a mean period of 78.5 months from diagnosis while 2 died after a mean period of 8.5months from CR. Summary/Conclusions. In this study, the incidence of T-lymphoid/myeloid leukemia was 63.6% while that of B-lymphoid/myeloid leukemia was 36.4%. Cytogenetic analysis revealed a high incidence of chromosomal abnormalities; 18.2% displayed the Ph chromosome while 9.1% had chromosome 11 abnormalities. Both are poor prognostic markers where 5 patients died and only 1 patient with the Ph chromosome is still alive after 10 months, having received ALL type induction therapy, imatinib and allogenic bone marrow transplant. Induction therapy with ALL type regime resulted in a disease free survival (DFS) greater than 6 months in both patients. Of the 4 patients that remained in CR after combined induction therapy, 50% died within 6 months, while 50% were still alive after a mean period of 78.5 months. No firm recommendations can be made regarding remission induction therapy as numbers are small. Patients receiving ALL type induction therapy seemed to fared better. At our centre, newly diagnosed BAL patients are now treated with ALL type induction therapy. For treatment protocols to be established in this rare disease, multi-center studies are required.

0653

OUTCOME OF THERAPY-RELATED ACUTE MYELOGENOUS LEUKEMIA AND MYELODISPLASTIC SYNDROMES RECEIVING ALLOGENEIC TRANSPLANTATION: THE IMPACT OF PERFORMANCE STATUS, CYTOGENETICS AND PREVIOUS TREATMENTS

F Spina,[1] PE Alessandrino,[2] L Farina,[1] R Milani,[1] F Bonifazi,[3] M Bernardi,[4] R Luksch,[5] F Fagioli,[6] P Corradini[1]

[1]Fondazione IRCCS Istituto Nazionale dei Tumori, Università degli Studi di Milano, Milano, Italy; [2]Ematologia - Centro Trapianti Midollo, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy; [3]Ematologia, Istituto L. e A Seragnoli, Policlinico S. Orsola Malpighi, Bologna, Italy; [4]Ematologia - Trapianto di Midollo Osseo, Fondazione San Raffaele del Monte Tabor, Milano, Italy; [5]Pediatria-Fondazione IRCCS Istituto Nazionale dei Tumori, Milano, Italy; [6]Oncoematologia-Centro Trapianti, Ospedale Infantile Regina Margherita, Torino, Italy

Backgroud. Allogeneic stem cell transplantation (alloSCT) can cure few patients with therapy-related myelodisplastic syndromes (tMDS) and acute myelogenous leukemia (tAML). Disease- and transplant-related mortality remain very high despite the use of less intensive conditionings. *Aims.* This retrospective study evaluated which characteristics may affect the survival outcome of tMDS/tAML patients receiving alloSCT. *Methods.* All the 28 patients with tAML (86%) or tMDS (14%) allografted in 4 Italian centers between 1998 and 2009 were considered eligible. Statistic methods included Kaplan-Meier analysis of overall (OS) and progression free survival (PFS), and Cumulative Incidence analysis of non-relapse mortality (NRM) and relapse incidence (RI). Patients' median age was 49 years (range 21-65), previous neoplasia was Hodgkin's and non-Hodgkin's lymphoma (54% and 29%, respectively), and non-hematologic cancer (17%). Treatment of previous cancer included chemotherapy (31%), radiotherapy (14%) or both (55%), 36% of patients received >2 lines of therapy before the onset of tMDS/tAML. t-AML (86% of patients) or tMDS (14%) was diagnosed at a median time of 86 months (range 13-253) from previous cancer. Twenty-four patients (86%) had cytogenetic analysis available, 33% of them had intermediate-risk and 67% high-risk cytogenetics according to Medical Research Council AML 10 Trial definitions. Twenty-three patients (82%) received induction, 20 (71%) consolidation chemotherapy. At transplant, 40% of patients was in CR1, 3% in CR2, 14% in PR and 25% in PD, 18% of patients received upfront alloSCT due to low blast percentage. Median time from tMDS/tAML diagnosis to alloSCT was 5.7 months (range 0-25). At transplant, 9 patients (32%) had a Karnofsky Performance Status (KPS)<=80%. Patients underwent reduced intensity (RIC, 39%) or myeloablative (61%) alloSCT from HLA identical (32%) or mismatched siblings (3%), unrelated (54%) or haploidentical donors (11%). Results. Twelve patients (43%) are alive at last follow-up, 7 (25%) died of disease, 9 (32%) died of NRM. Median follow-up of surviving patients was 528 days (55-1704). One- and 2-years OS was 50% and 36%, 1- and 2-years PFS was 42% and 38%. RI was 28% at both 1 and 2 years, NRM was 18% at 100 days, 30% at 1 year and 35% at 2 years. OS and PFS were significantly affected by KPS<=80% (P=0.008 and P<0.001, respectively) and high-risk cytogenetics (P=0.03 and P=0.01). RI was reduced by KPS>80% (P=0.02), chemo-responsive disease (trend, P=0.05) and intermediate-risk cytogenetics (trend, P=0.08). Treatment of previous neoplasia with >2 lines of therapy was correlated with a worse NRM (P=0.005) and a worse OS (trend, P=0.05), whereas the type of treatment (radiotherapy+chemotherapy *vs.* chemotherapy *vs.* radiotherapy) did not affect survival, NRM and RI. NRM was increased in patients who had infectious complications after induction (P=0.009) or received consolidation therapy (P=0.03), and in patients allografted >180days after tMDS/tAML (trend, P=0.05). The type of conditioning (RIC *vs.* myeloablative) did not affect survival, NRM and RI. Conclusions. In conclusion, some tMDS/tAML patients undergoing alloSCT can survive leukemia-free at 2-years. Patients' selection should be based on the assessment of KPS, cytogenetics and treatment history before alloSCT. Prospective trials are awaited in order to confirm these results.

0654

TREATMENT OF ACUTE MYELOID LEUKEMIA IN OLDERS WITH AN OUTPATIENT FLAG-IDA PROTOCOL

Z Díez Gallarreta,[1] G Pérez Vázquez,[1] C Montes-Gaisán,[1] A Bermúdez,[1] A Cuesta,[1] L Yáñez,[1] M López-Duarte,[1] M Colorado,[1] A Insunza,[1] M Gutiérrez,[2] P Sanroma,[1] E Conde,[1] J Baro,[1] C Richard,[1] A Iriondo[1]

[1]Hospital Universitario Marqués de Valdecilla, Santander, Spain; [2]Hospital Sierrallana, Torrelavega, Spain

State of the art. Acute myeloid leukemia (AML) is associated with poor prognosis in older patients and there is no a truly adequate treatment. Results of standard chemotherapy are dismal. Adverse biology and poor tolerability by their poor performance status and their significant comorbidities are the causes for bad results. Thus, new treatment options are necessary. We present the results of a new chemotherapy outpatient protocol in older patients (>65 years) with AML. Study design. Patients were assigned to receive: G-CSF (subcutaneous, 300 ug days -1 to 5), Fludarabine (oral, 40 mg/m^2 days 1 to 5), Cytarabine (subcutaneous 20 mg/m^2 days 1 to 5) and Idarrubicin (oral, 15 mg/m^2 days 1 to 3) as induction (1-2 cycles) and consolidation (2 cycles) therapy. Inclusion criteria were age >65 and significant associated comorbidity. If possible, they were followed as outpatients. Patients characteristics. Between 2006 and 2009, 30 patients with a median age of 78 years (66-91 years) were enrolled. Twenty-nine (97%) showed significant associated comorbidity [heart disease (58%) or lung disease (26%)]. ECOG score was 0-1 in 26 patients. There were 25 AML [(15 *de novo* and 10 secondary to myelodysplastic syndrome (MDS)] and 4 RAEB-2. Overall, 20% of patients had an unfavourable karyotype and 53% an intermediate karyotype. Median WBC was 4550/uL (range: 500-192000). *Results.* Treatment was well tolerated and followed in outpatient management in 73%. Twenty-six patients (86%) received a unique induction cycle and four needed to receive two cycles. Overall response rate was 57% [complete response (CR) in 50% and partial response (PR) in 7%]; 33% were refractory. The median to neutrophil recovery (>500 PMN) was 22 days for responders. Two patients died in induction. Fourteen patients got to receive consolidation therapy. A total of 62 cycles were administered. During induction cycles 40% required temporary hospital admission due to febrile neutropenia/pneumonia (9 patients), bleeding (2 patients) or bradyarrythmia (1 patient). Hospital admission was not necessary in any patient during consolidation cycles. Twenty-one patients died (17 by leukemia progression and 4 by treatment-related complications). Nine patients remained in CR (2 underwent an RIC allogeneic SCT in first CR). Overall survival at 40 months is 30%. Adverse factors related with survival were unfavourable karyotype, secondary AML and refractoriness to treatment. *Conclusions.* FLAG-IDA protocol in older patients with AML is well tolerated and is an excellent therapeutic option with a significantly higher survival in responders. Moreover, it offers the advantage of outpatient management, improving quality of life.

0655

MONOSOMY KARYOTYPE IN ACUTE MYELOID LEUKEMIA PREDICTS ADVERSE TREATMENT OUTCOME WITH LOW COMPLETE REMISSION RATE AND WORSE EVENT-FREE AND OVERALL SURVIVAL, AND ASSOCIATES WITH HIGH FUNCTIONAL ACTIVITY OF P-GLYCOPROTEIN, MDR1

K Dong Hwan,[1] HK Ahn,[1] YW Won,[2] JH Jang,[1] K Kim,[1] HJ Kim,[1] SH Kim,[1] CW Jung[1]

[1]Samsung Medical Center, Seoul, South-Korea; [2]National Center Center, Goyang, South-Korea

Background. It has been revealed that monosomy karyotype (MK), defined as 1) two or more distinct autosomal chromosome monosomies or 2) one single autosomal monosomy in the presence of structural abnormalities, identifies the highly unfavorable cytogenetic risk group of patients with acute myeloid leukemia (Breems, J Clin Oncol 2008), but lacking validation data. *Aims.* The current study aimed to validate the unfavorable impact of MK not only on overall survival (OS) but also on complete remission (CR) rate and event free survival (EFS) in AML patients. *Methods* and patients. A total of 370 consecutive AML (excluding APL) patients with available cytogenetic data who received treatment between 1995 and 2008 at the Samsung Medical Center, Seoul, Korea were included in this retrospective study, among whom 169 patients (45.7%) showed normal karyotype; 65 patients (17.6%),

core binding factor (CBF) positive AML; and 136 patients (36.7%), non-CBF AML, respectively. Karyotypes were scored according to their structural abnormalities, monosomy, trisomy, deletion and marker chromosome. The CR rate, EFS and OS were compared according to the presence of each cytogenetic abnormality. In addition, multidrug resistance (MDR) functional assay (P-glycoprotein assay) was performed and MDR functional activity was calculated by verapamil-inhibited rhodamine-123 efflux activity minus uninhibited rhodamine-123 efflux activity, and positivity was determined as equal to or over 5% MDR activity. *Results.* Among treated non-CBF AML group with any kind of cytogenetic abnormalities (n=136), 95 patients (69.9%) had structural cytogenetic abnormalities, 29 pts (21.3%), autosomal monosomy, 18 pts (13.2%), sex chromosome abnormalities, 59 pts (43.4%), autosomal trisomy, 41 pts (30.1%), deletion of part of a chromosome, 18 pts (13.2%), addition and 18 pts (13.2%), marker chromosome(s). MK was noted in 23 patients (16.9%), and complex karyotype (≥3 abnormalities) were found in 40 pts (29.%), -5 in 5 pts (3.7%), -7 in 12 pts (8.8%), del(5q) in 4 pts (2.9%), del(7q) in 8 pts (5.9%), inv(3) or t(3;3) in 4 pts (2.9%), t(6;9) in 5 pts (3.7%), and t(9;22) in 2 pts (1.5%). In univariate analyses, MK group was revealed to be associated with shorter OS and (median 10 *vs.* 31months, P=0.044) EFS duration (median 1.3 *vs.* 1.3 months, P=0.002), and a lower CR rate (70.8% *vs.* 34.8%, P=0.002). In a multivariate analysis, MK was associated with lower CR rate (HR of non-CR 0.33, 95% C.I. 0.12-0.93, P=0.036). MK has been defined as a single monosomy with structural abnormalities or multiple monosomies in a previous study. However, there were no significant difference in survival and CR rate between a single monosomy with (n=9) or without(n=6) structural abnormalities (OS, 23 *vs.* 8 months; P=0.349; EFS, 1 *vs.* 9months; P=0.078; CR rate 33% *vs.* 56%; P=0.608). The group with single autosomal monosomy showed a trend of better survival (n=15, median OS 23 months, EFS 1month) than multiple autosomal monosomy group (n=14, OS 6months, EFS 1month), but it was not significantly different (P=0.322, P=0.221). The functional MDR activity was measured in 40 patients, and positive MDR activity was found to be significantly associated with the presence of MK (87.5% *vs.* 33.3%, P=.013). In addition, the functional MDR activity was significantly higher in MK+ group (n=8, 45.9±17.8%, mean±S.E.) than in MK- group (n=32, 4.3 ±2.7%, P=0.005 by Mann-Whitney U-test). *Conclusion.* The current study demonstrated that the AML patients harboring MK showed a poor outcome in terms of lower CR rate and worse EFS/OS in an independent cohort of Korean AML patients, and that MK karyotype was associated with high MDR functional activity of leukemic blasts.

0656

ALLOGENEIC HAEMOPOIETIC STEM-CELL TRANSPLANTATION USING A NON T-CELL DEPLETE REDUCED INTENSITY CONDITIONING PROTOCOL FOR ACUTE MYELOID LEUKAEMIA & MYELODYSPLASIA: A 10-YEAR SINGLE CENTRE EXPERIENCE

D Mannari, P Jasani, F Macdougall, D Taussig, J Cavenagh

St. Bartholomew's Hospital, London, UK

Background. Over the last decade a number of reduced intensity conditioning (RIC) protocols have been developed, for treatment of patients with acute myeloid leukaemia (AML) and myelodysplasia (MDS). RIC haemopoietic stem cell transplants (HSCT) utilise the power of the graft *vs.* leukaemia effect and result in a lower transplanted-related mortality than standard myeloablative HSCTs. These protocols can be categorised into T-cell deplete (TCD) and non-TCD. The use of T-cell depletion results in less chronic graft *vs.* host disease (GvHD) but, in view of the impaired immune reconstitution, results in an increased risk of infections, particularly CMV re-activation, and potentially increased relapse risk. *Aims & Methods*. A retrospective analysis was performed on the outcomes of the RIC transplant programme at St. Bartholomew's Hospital between April 1999 and July 2009. Fifty consecutive patients, for whom a conventional transplant was deemed inappropriate, received a non-TCD RIC allogeneic (HSCT) for treatment of AML and MDS. The median age of the patients was 53 years. Thirty-eight patients were diagnosed with AML and 12 with MDS. Patients received fludarabine 25 mg/m^2 for 5 days (day -6 to day -2) and cyclophosphomide 1g/m^2 for 2 days (day -3 to day -2) as the conditioning schedule. Results. Median follow up of surviving patients was 42 months. The 5-year predicted overall survival (O/S) and event-free survival (EFS) was 56% and 52% respectively and the non-relapse mortality (NRM) was 6%. Acute and chronic GvHD incidence was 14% and 41% respectively. Occurrence of chronic GvHD was predictive of improved outcome, with 5-year O/S and EFS of 84% and 86% compared to 20% and 31% for those with and without chronic GvHD. Furthermore, 88% of patients with chronic GVHD were off immunesupression at 2 years follow up. Disease relapse occurred in 46% of patients that also included 3 cases of late extramedullary relapse. Systemic relapse occurred early and all within 1-year of follow up. However, due to the low toxicity of the conditioning protocol, a cohort of patients was able to undergo a further RIC transplant procedure. Summary. In conclusion, we present long-term follow-up data on a single centre experience of a non-TCD RIC allogeneic allograft regimen for patients with AML and MDS. This protocol is associated with a very low NRM, low levels of acute GvHD and good overall survival rates. Chronic GvHD, although more frequent than in TCD allograft procedures, is associated with a profound GVL effect and predictive of long term overall survival.

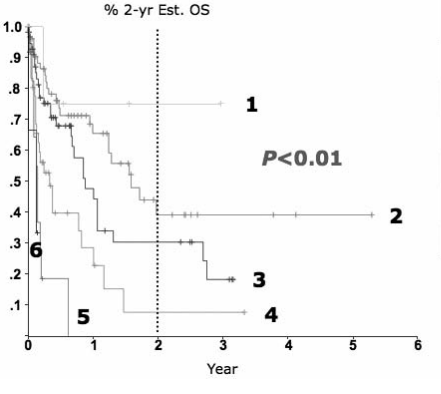
Background. Acute myelogenous leukemia (AML) is mainly a disease of older adults. Benefit of standard cytotoxic therapy for elderly patients remains debated because of excessive toxicity and short response duration. So, an organized and multi-disciplinary approach has to be required for these population, and especially, identification of subgroups who might benefit from chemotherapy is important. *Aims.* 1, to understand clinical characteristics of elderly patients with AML in Korea. 2, to analyze clinical outcomes, including response to chemotherapy. 3, to identify factors predicting responses to specific treatment. 4, to establish composite prognostic scoring system for determining personalized treatment strategy in elderly AML. *Methods.*From 17 institutes in Korea, 614 elderly (>60 yo) AML patients were enrolled and evaluated retrospectively by CRF collection.



KAMWP Elderly AML model	
Score	%2-yr Est. OS
1	75.0
2	39.1
3	30.2
4	7.6
5~6	0

Figure 1. KAMDS score.

Results. The mean age was 68.9 (60~101) and male to female ratio was 1:28:1. Twelve percents of patients had preceded hematologic diseases.

M2 and M4 by FAB classification were most common subtypes. Unfavorable cytogenetics were documented in 24% of patients. Remission induction chemotherapy was performed for 63% of patients and complete remission rate was 60.7%. Three year overall survival rate was significantly higher in treated patients (30.7% *vs.* 6.9%, P<0.0001), and relatively younger (60<<75) patients and patients with lower ECOG score showed higher survival rate. We made new prognosis scoring system using age, ECOG, initial WBC count, cytogenetics and myelofibrosis. By this scoring system, 2 year overall survival rate of elderly patients were significantly differentiated (Figure). Summary/*Conclusions.* Our novel scoring system using 5 factors in this study may be feasible and optimal for elderly patients. Furthermore, this scoring system need to be validated with prospective studies with larger number of patients and different races.

DAY 15 BONE MARROW DRIVEN DOUBLE INDUCTION IN YOUNG ADULT PATIENTS WITH ACUTE MYELOID LEUKEMIA: FEASIBILITY, TOXICITY AND THERAPEUTIC RESULTS

F Ferrara,[1] T Izzo,[1] C Criscuolo,[1] C Riccardi,[1] R D'Elia,[1] M Desimone,[2] C Carolina[1]

[1]Hematology and stem cell tranpslantation unit, Naples, Italy; [2]Hematology and Stem Cell Tranpslantation Unit, Naples, Italy

Background. The strategy named double induction (DI) in patients with acute myeloid leukemia (AML) consists of two courses of chemotherapy irrespective of the degree of cytoreduction in the bone marrow after the first course, with the second course starting on day 21 or on day 11 to 12 unless severe complications prohibit its application. *Aims.* To describe disease characteristics and treatment results from a series of 33 patients with AML, in whom day 15 (D15) morphological and immunophenotypic examination of bone marrow revealed persistence of more than 10% blast cells and therefore candidate to receive double induction with an additional course of chemotherapy. *Methods.* The median age was 50 years (16-66). All patients receive as induction the ICE regimen [idarubicin 10 mg/ sqm on days 1, 3 and 5; cytarabine (ARA-C) 100 mg/sqm as continuous infusion (c.i.) on days 1-7; etoposide 100 mg/sqm on days 1-4]. As second induction, we administered the combination of fludarabine (F), intermediate dose cytarabine (ARA-C) and G-SF. More in detail, F was given at 30mg/m2/day as 30 min intravenous perfusion and ARA-C 2 g/m^2/day 3 hour and half after the end of F from day 1 to 5. G-CSF at 300 mg was concomitantly given from day 1 up to CR achievement. *Results.* The median blast count at D15 was 30 (15-90). Overall, 30 out of 33 patients were judged as eligible to receive DI. Reasons for exclusion in three patients included in all cases active pulmonary infection (bacterial in two and fungal in one patient) in the context of severe pancytopenia. Of note, all patients were severely neutropenic at day 15 (< 0.5×10^9/L). According to cytogenetic examination, 19 patients (63%) had unfavorable karyotype and 11 (37%) showed diploid karyotype; 6 of these had FLT3/ITD mutation, while NPM1 mutation was found in 1 patient in association with FLT3/ITD. Overall, CR was achieved in 20/30 patients (67%), while 8 patients (27%) were classified as refractory, and 2 died of infectious complications while severely cytopenic (6%). Of interest, all refractory patients had unfavorable cytogenetics. The median number of days from start of DI to neutrophils > 0.5×10^9/L and platelets > 20×10^9/L was 22 and 30, respectively. Patients received a median of 13 packed red cells (range: 10-18) and 19 platelet units (range: 13-26). All patients achieving CR were programmed to receive allogeneic stem cell transplantation (allo-SCT), which was actually performed in 11 patients. On the contrary, allo-BMT was not performed in 9 patients because of early relapse in 6 patients, refusal in 2 and loss to follow-up in 1. Summary and *Conclusions.* Our study suggest that D15 driven DI represents a feasible and effective therapeutic strategy in young adult AML patients. Although inducing more relevant hematologic toxicity and longer hospitalization than conventional induction, DI improves therapeutic results and do not compromise feasibility of allo-SCT. Finally, as compared to conventional DI, day 15 driven DI offers the potential to avoid unnecessary toxicity in a consistent proportion of patients.

ATRA AND ANTHRACYCLINE BASED CHEMOTHERAPY IN CHILDHOOD ACUTE PROMYELOCYTIC LEUKEMIA (APL): 10 YEAR EXPERIENCE WITH TWO SUCCESSIVE PROTOCOLS IN 20 PATIENTS

R Jeddi, H Ghédira, Y Ben Abdennebi, L Aissaoui, R Ben Amor, K Kacem, W Bouteraâ, R Ben Lakhal, H Ben Abid, Z Belhadjali, B Meddeb

Aziza Othmana University Hospital, Tunis, Tunisia

Background. The combination of ATRA and intensive chemotherapy is very effective in childhood APL, a rare disease. Reports on childhood APL from developing countries are scarce. We report results of a 10 year experience in management of childhood APL and compare them with results obtained with adult APL in the same period. *Methods.* 65 genetically confirmed APL, either by t (15, 17) and/or PML/RARA, were treated with two consecutive protocols: 24 (36.9 %) with The European APL 93 (1998-2004) and 41 (63.1%) with the Spanish LPA 99 protocol (from 2004). Twenty (30.7%) were aged less than 20 years. In the same period 45 adults were treated with APL93 (n=18) and LPA99 (n=27) trials. *Results.* The 20 children included 11 girls and 9 boys; median age was 12 years (range, 4-19 years). Fever as initial symptom was more frequent among children (16/20) than adults (17/45) (P=0.002). 13 children (65%) had classical APL and 7 (35%) had variant APL, compared to 39 (87%) and 6 (13%), respectively, in adults (P=0.044). Additional cytogenetic abnormalities were observed in 3 children and 14 adults (P=0.14). According to Sanz'score 1 (5%) child had low risk, 11 (55%) intermediate and 8 (40%) high risk (compared to 7%, 60% and 33%, respectively of adults: P=0.6). During induction course differentiation syndrome (DS) diagnosed according to Frankel's criteria (Ann Intern Med 1992; 117: 292-6) was less often observed in children (1/20) than adults (13/45) (P=0.031, RR=0.21). The CR rate was 95% (19/20) in children and 80 % (36/45) in adults (P= 0.13). Two children relapsed and died during salvage therapy, 1 patient died in CR from infection during the third consolidation course and the last patient, aged 8 years, died from cardiac failure 15 months after CR (without any other cause of cardiac disease, and with a cumulative dose of idarubicin of 90 mg/m^2 and mitoxantrone of 50 mg/m^2) leading to a 4 year EFS of 78.9% compared with 88.9% in adults (P=0.44). With a median follow-up of 4 years, OS was 75% in children *vs.* 77.8 % in adults (P=0.94). Age (P=0.9), sex (P=0.19) and baseline WBC (P=0.29) had no impact on survival in children. *Conclusion.* We found comparable outcome in children and adult APL. Of note was the significantly lower incidence of differentiation syndrome in children (compared to adults) and the fact that one patient treated died from cardiac failure attributed to anthracyclines, a possibly emerging problem with high cumulative doses of anthracyclines in childhood APL.

0660

ROLE OF AGE AND CYTOGENETIC DATA IN THE OUTCOME OF FIT ELDERLY AML PATIENTS

T Vo,[1] S Benghiat,[2] M Vaes,[2] V DeWilde,[2] B Dessart,[3] S Vandenbosshe,[2] Y Libert,[2] P Lewalle,[2] B Cantinaux,[4] N Meuleman,[2] D Bron[5]

[1]Inst. J. Bordet (ULB), BRUSSELS, Belgium; [2]IJBordet, Brussels, Belgium; [3]Hop Erasme, Brussels, Belgium; [4]Hop St Pierre, Brussels, Belgium; [5]IJBordet (ULB), Brussels, Belgium

Background. Acute Myeloid Leukemia (AML) is most common in the elderly and the patients are often thought to be unfit for chemotherapy. Patients with poor prognostic karyotype are even not recommended for treatment outside clinical protocols. In this context prognostic factors are important tools for clinical judgement, decision making and patient information. Objectives. We retrospectively reviewed whether this assessment is validated in our AML population older than 60 yo. Population and methods. 82 AML patients, 60 yo and older, were referred to our centre between 1987 and December 2009. Patients requiring treatment were treated according to the EORTC (LAM 13 and LAM 17) protocols for patients above 60 years old. AMLs were classified according to the old FAB classification. Cytogenetic data were obtained by routine karyotype and additional FISH analysis since 1995. Complete remission was defined by morphology and flow cytometry on bone marrow smear. Karyotypes were stratified according to good and intermediate 1 *vs.* intermediate 2 and poor prognosis (ELN recommendation). Statistical analyses using age and Karyotype were performed for the following outcomes: complete remission (CR), overall survival, median survival and disease-free survival. *Results.* 76 files were evaluable for cytogenetic data and outcome. Median age was 70 (60-

86) years old. Because we are a referral tumour centre, all the patients had a PS <3 and no geriatric syndrome (falls, dementia, incontinence). The median follow up time was 40 (1-180) months. Overall survival for the whole population was 17% at 180 months with a median survival of 7 months. Median survivals of patients below 70 years old was significantly better (P<0.0001) than patients above 70 years old (38 *vs.* 7 months). Whatever the age, median survival was significantly better for patients in CR after the induction (48 *vs.* 6 months) and presenting with a favourable Karyotype (35 *vs.* 9 months) . Taking into account the cytogenetic data and age, the median survival of AML patients below 70 yo with a favourable Karyotype was 64 months with 40% of CCR, very similar to the younger population. Conclusion. in our series of fit elderly AML patients, we confirm that cytogenetic data have a major impact of OS and CCR in patients between 60 and 70 years old. For patients above 70 years old, median survival remains unsatisfactory and these patients should be offered new alternative treatment approaches.

0661

THE IMPACT OF CD117 (C- KIT GENE EXPRESSION) ON APOPTOSIS AND SURVIVAL IN ADULT ACUTE MYELOID LEUKEMIA(AML) PATIENTS

I Asfour,[1] S El-Kourashy,[2] S Youssef,[1] M Ayoub,[2] S Refaat,[1] W El-Salakawy[2]

[1]Ain-Shams University,, Cairo, Egypt; [2]Ain-Shams University, Cairo, Egypt

Introduction. The proto-oncogene c-kit encodes a trans-membrane receptor belongs to class III receptor tyrosine kinase family involved in development of hemopoietic cells and leukemogenesis supporting apoptosis resistance in leukemia blasts. The aim of this study is to evaluate CD 117 expression together with the apoptosis of the myeloid blast cells in adult patients with AML and correlating them with other prognostic parameters and treatment outcome. Patients and *Methods.* forty seven patients with newly diagnosed AML were included. Clinical examination and laboratory investigations including bone marrow aspiration for morphological examination, immunophenotyping and cytogenetic assay were done.CD117 and apoptosis (annexin V)quantification by flowcytometry were done before and after the induction therapy. Results.The median age of patients was 44±15years.15/47≈32% had unfavorable cytogenetics,16/47 ≈34% had favorable cytogenetics and the rest were intermediate risk.CD 117 was positive in 20/47 ≈43% before induction, patients with +ve CD 117 were significantly older than patients with -ve CD 117(49±15 *vs.*40±13 years respectively p value=0.02). At presentation, the percent of apoptotic blasts was lower in CD 117 +ve patients (24%) than CD117-ve patients (30 %) but the difference was not significant. There was no significant correlation between CD117 positive blasts (% and or mean fluorescence index MFI) and apoptotic blasts (% and or MFI) neither at presentation nor after treatment. Highly significant negative correlation was found between CD117 +ve blasts and CD57 (natural killer cells) before and after treatment, with a significant positive correlation between CD117 MFI and the number of infection episodes during induction and follow up period. CD 117 MFI at presentation was significantly inversely correlated to overall survival with p value 0.04. The percent of apoptotic blasts at presentation positively correlated with overall survival p value 0.02. *Conclusion.* c-kit gene expression detected by CD117 phenotype and lesser apoptotic blasts at presentation harbor a worse prognosis for AML patients. Targeting c-kit gene is a promising potential in therapy of c-kit positive AML elderly patients.

ABERRANT GENE EXPRESSION PROFILE OF ADULT DE NOVO ACUTE MYELOID LEUKEMIA WITH T(8;21)

LG Liu,[1] J Chen,[2] I Irons,[3] TP Xu,[4] J Luo,[4] W Gao,[4] YH Xie,[4] YT Lu,[4] LM Zhao,[4] DP Lu,[5] A Kimura[6]

[1]Shanghai fifth people's hospital, Fudan university, Shanghai, China; [2]Hematological department, Shanghai fifth people's hospital, Fudan university, Shanghai, China; [3]JCML, Fudan University, Shanghai, China; [4]Hematological Department, Shanghai Fifth People's Hospital, Fudan University, Shanghai, China; [5]Shanghai Fifth People's Hospital, Fudan University, Shanghai, China; [6]Department of Hematology/Oncology, RIRBM, Hiroshima University, Hiroshima, Japan

Background. Acute myeloid leukemia (AML) with t(8;21) was usually considered as a favorable subtype leukemia. However, it is highly heterogeneous in clinical practice. A lot of parameters including clinical features, cytogenetics and immunophenotypes were investigated, nevertheless, their clinical significance were still paradoxical. Aberrant gene expressions such as c-kit mutations have been considered as the poor prognostic factors in t(8;21) AML. Recently, more aberrant gene expressions including JAK2, FLT3 and TET2 have significant prognostic values in myeloid malignancies. *Aims.* To investigate the prognostic significance of JAK2, FLT3, c-kit and TET2 mutations in AML patients with t(8;21). Methods. The information including clinical features, cytogenetics, immunophenotypes, treatments and overall survivals were collected. JAK2, FLT3, c-kit and TET2 mutations were analyzed according to the published literatures. *Results.* Fifty-nine AML patients with t(8;21) were enrolled in the study. The mutant cases of c-Kit, tet2 and FLT3 were 20(20/59, 33.9%), 8(8/59, 13.6%) and 3(3/59, 5%), respectively. No JAK2 mutation was detected in this group. The overall survival rate at 5 years in patients with c-Kit, tet2 and FLT3 mutations was inferior to the non-mutant patients. The lose of sex chromosome, additional chromosome alternations and CD56 expression in the group were unrelated to the patients prognosis. *Summary/Conclusions*. c-Kit, TET2 and FLT3 mutations were the adverse prognostic factors in AML with t(8;21), and allogenetic stem cell transplantation might improve the prognosis of these patients.

0663

RESULTS AND TOXICITY PROFILE IN ADULT AML PATIENTS TREATED IN FOUR CONSECUTIVE RUSSIAN MULTICENTER CLINICAL TRIALS

P Parovichnikova, V Savchenko, G Kliasova, V Isaev, A Sokolov, S Kulikov

National Reaserch Center for Hematology, Moscow, Russian Federation

Background. Since late 1980s results in adult AML (16-60 yy) excluding patients with APL did not change dramatically, constituting 30-40% of 5-years overall survival in the selected for clinical trials cohort of patients, but the intensification of treatment protocols within this period of time was substantial. Each dose escalation and drug combination approach is followed by increased toxicity - severe myelosupression, increased transfusions support and rising rate of infections, thus potentially decreasing the tolerability of treatment. *Aim and Methods.* We evaluated the efficacy and toxicity profile of the treatment protocols of 4 consecutive Russian multicenter clinical trials since Jan 1992 till Dec 2009, comprising 1137 pts with AML (median age - 39 y (16-60yy)) from 32 hematological centers. Pts with APL treated in first two trials and those lost from follow-up were excluded, so the outcome of 899 AML pts was analysed. The results of four trial are depicted in Table 1.

Table 1.

Trials AML-92 AML-95 AML-01.01 AML-06.06

Outcome	(n=185)	(n=251)	(n=354)	(n=109)
CR,%	63,4	61	65	78
CR after c.N1 %	51,9	48,6	55,4*	51
DR,%	15,1	21,9	34,1*	3
ED, %	21,5	17,1	10,5*	19
Platelet transfusions, doses	27	54	59	81
Death in CR,%	18,1	15,3	10	13
Fulfilled protocol, % pts	no data	no data	75%	25%
5 years OS / DFS, %	25/35	25/28	25,5/25	38/22 (3y)

**Parameters were evaluated only after the 1st induction course*

Within 4 trials CR rate after the 1st course was identical, after the 2nd induction - substantially increased in the last trial due to HDARA-C. The early death rate was high in all trials. The main death reason were infections. Infections were registered in 95% of pts during induction. During the analysed period pneumonias were diagnosed in 43,6%-52% pts, not differeing much among trials. The rate of sepsis and enterocolitis decreased from 29-46.5% to 19%, and 27-40.8% to 17,5%. In the last trial the incidence of invasive aspergillosis was 4,7% after the 1st induction and 6% - after the 2nd induction courses. Hemorrhage as one of the death's reasons deacreased from 35% to 24,4% due to the increasing plateletes support from 27 to 81 doses within two induction courses. The death rate in CR also decreased from 18,1% to 10-13%, but tolerability of the whole treatment and compliance worsened comparing AML-01.01 and AML-06.06. Only $^1/_4$ of pts in the last trial completed prescribed treatment due to poor tolerability of two HAM and 2 HDARA-

C as consolidation. The very intensive protocol AML-06.06 did increase CR rate, but worsened the comliance and survival results. In a multivariant analysis among common risk factors (age, cytogenetics) the number of randomised by each hematological center pts (<>10 pts for the trial) became significant factor of prognosis - less experience worser results. We conclude that RLSG treatment protocols should be balanced by toxicity profile and experience of the centers, and that the most important factor for improving results is the inclusion of pts into clinical trials.

0664

RESPONSE TO DIFFERENT TREATMENT SCHEDULES IN PATIENTS FAILING TO 400 MG OF IMATINIB. RESULTS FROM THE CML SPANISH REGISTRY (RELMC)

LF Casado Montero,[1] I Massagué,[2] P Giraldo,[3] M Pérez-Encinas,[4] R De Paz,[5] ML Paciello,[6] R Forés,[7] S Osorio,[8] MJ Requena,[9] L Palomera,[10] MJ Peñarrubia,[11] I Palomares,[12] B Maestro,[12] C Calle,[13] JL Steegmann[14]

Background. The Spanish CLM Registry (RELMC) is a multicentric, hospital-based cancer registry which aim is to describe the actual treatment received by patients with CML in Spain, their outcomes, and the variables that influence treatment choices. There is no common treatment protocol. *Aim.* To study the best final cytogenetic, as well as the major and complete molecular response in 223 newly diagnosed CML patients treated with Imatinib as first line treatment that change treatment due to inadequate response to the initial treatment. During their evolution, the patients included in the Registry have received several lines of treatment: 1. Im400. 159 patients received Imatinib 400 only Im400-HDIm: 27Patients received Imatinib 400, followed by high dose Imatinib (600 or 800). 2. Im400-HDIm-2GTKI: 9 Patients received Imatinib 400, followed by high dose Imatinib (600 or 800), followed by 2nd generation TKI. 3. HDIm: 11 Patients received high dose Imatinib only. 4. Im400-2GTKI: 17 Patients received Imatinib 400, followed by 2nd generation TKI. Patients and *Results.* Two-hundred and twenty three newly diagnosed CML patients have been analyzed. A summary of response rates and cumulative incidence are included in Table 1.

			NS	NS	NS

Follow-up of the different groups: Complete cytogenetic response: with regards to the best response, the CCyR rate was lower in patients with Im400-HDIm-2GTKI (44%) and patients with Im 400-2GTKI (50%). In the other groups, the rate was 80% (Im400) 1), 84.6% (Im400-HDIm) and 78% (HDIm) Pearson Chi-Square 12,867(a); P=0,012. The CCyR cumulative incidence was also lower in patients with Im400-HDIm-2GTKI and Im 400-2GTKI in comparison with the other groups, although second line response was faster in patients who changed to 2GTKI after Im400. Major molecular response: concerning the best response, the MMR rate was lower in patients with Im400-HDIm-2GTKI (0%) and patients with Im 400-2GTKI (19%). In the other groups, the rate was 52% (Im400) 1), 56% (Im400-HDIm) and 73% (HDIm) Pearson Chi-Square 17,405(a)P=0,002. The MMR cumulative incidence was higher in the HDIm group, lower in those treated with Im400-HDIm-2GTKI, and intermediate and similar in the other three groups. Complete molecular response: regarding best response, the CMR rate was lower in patients with Im400-HDIm-2GTKI (0%) and patients with Im400-2GTKI (23%). In the other groups, the rate was 48% (Im400) 1), 44% (Im400-HDIm) and 72% (HDIm) Pearson Chi-Square 17,405(a) P=0,002. The CMR cumulative incidence was higher in the HDIm group, and nil in those treated with Im400-HDIm-2GTKI. *Conclusions.* A High response rate (genetic and molecular) was seen in the majority of patient treated with imatinib. Patients treated with upfront HD appeared to have a faster molecular response. High-risk Hasford patients showed a worse outcome, independently of treatment chosen.

Background. DLBCL patients at poor prognosis had a dismal prognosis; investigational approaches in the context of clinical trials were experienced. *Aims.* A pooled analysis was conducted to test the role of high-dose chemotherapy (HDC) and autologous stem-cell transplant (ASCT), Rituximab, dose-dense MegaCEOP *vs.* third generation MACOP-B chemotherapy and involved-field radiotherapy (IF-RT) in first line treatment in young DLBCL at poor prognosis. Patients and *Methods.* 309 untreated patients <61 years were enrolled from 1986 to 2006 into four consecutive Italian multicenter trials; 42 into a phase II study and treated with MACOP-B chemotherapy (Vitolo U, J Clin Oncol 1992); 40 into a phase II trial with 8 weekly MACOP-B as induction therapy, followed by HDC with 2 courses of MAD and BEAM and ASCT (Vitolo U, J Clin Oncol 1997); 107 into a phase III randomized trial, 48 treated with high dose sequential (HDS) chemotherapy with ASCT and 59 with 6 be-weekly infusions of MegaCEOP, respectively (Vitolo U, Haematol 2005); 120 into a phase II trial with an induction phase with dose-dense chemoimmunotherapy Rituximab-MegaCEOP for 4 cycles followed by HDC and ASCT (Vitolo U, Haematol 2009). IF-RT was performed at the end of treatment as consolidation of bulky disease or residual disease. A Cox proportional hazard model was performed for Overall Survival (OS) and Progression-Free Survival (PFS) to estimate the Hazard Risks (HR) of the four treatment variables (with/without Rituximab, HDC+ASCT, new regimens *vs.* third generation regimen MACOP-B, radiotherapy yes/no), adjusted by age adjusted-International Prognostic Index (aa-IPI), age and sex.

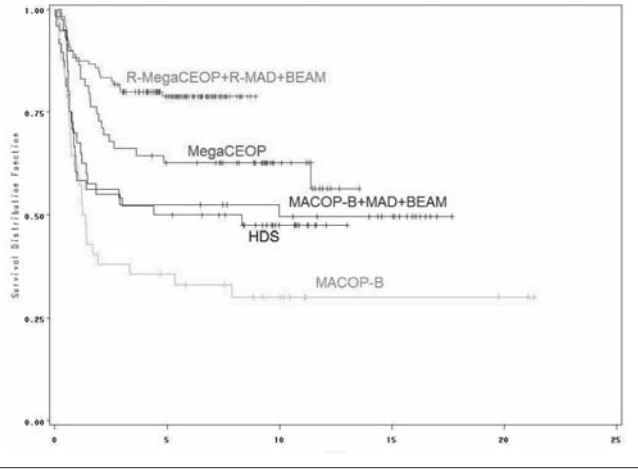

Figure 1.

Results. Clinical characteristics were: median age 44 (15-60) years; Performance Status >2 59%, 31% had BM involvement, 53% bulky disease, 84% LDH >normal, 12/19/69% stage II/III/IV respectively; according to aa-IPI 51% were at Intermediate-High and 39% at High risk. Rituximab was performed in 120 patients; IF-RT in 108; new generation regimens in 227 and MACOP-B in 82. As intention to treat, ASCT was scheduled for 208 patients; 171 patients (82%) did it, 39 did not because of: progression disease in 22, toxicity in 9 and poor mobilization in 6. Response rate in all 309 patients was: complete response 69%, partial 7%, no response 18% and 6% toxic deaths. With a median follow-up of 10 years, 10-year OS and 10-year PFS were: 59% (95%CI: 53-65) and 48% (95%CI: 41-55). OS for schemes was reported in Figure 1. Secondary haematological malignancies or solid tumour were observed in only three patients. The Cox's multivariable model showed an improvement of the outcome with the use of Rituximab (HR=0.36, 95% CI=0.21-0.63, P .0003) and IF-RT (HR=0.42, 95% CI: 0.27-0.66, P.0002), while no clear benefit was represented by new regimens (HR=0.86, 95%CI: 0.57-1.31, P.482) and HDC (HR=0.94, 95%CI: 0.62-1.41, P .751). *Conclusions.* with the limit of a retrospective analysis, the use of Rituximab and the IF-RT seems to represent an important role in the treatment of young patients with untreated DLBCL at poor prognosis. Randomized trials are ongoing to evaluate the real impact of HDC+ASCT supplemented with Rituximab compared to standard or dose-dense chemoimmunotherapy.

Background. Diffuse large B-cell lymphoma (DLBCL) is most frequent subtype of NHL in many European countries. Large trials on elderly DLBCL patients are infrequent and if, predominantly the fit patients participate in these trials. We have initiated Czech Lymphoma Project to describe the clinical and laboratory findings in unselected cohort of patients. *Aim.* To evaluate the treatment modalities, clinical outcome and prognostic factors in elderly patients with DLBCL. *Methods.* DLBCL forms 43% of newly diagnosed NHL per year in the Czech Republic. The median age is 63 years and 59% of patients are 60 years old or older. We analyzed data of 1,425 patients with confirmed DLBCL older than 59 years and diagnosed before 31/12/2008. Those with CNS involvement were excluded. Histology was reviewed in 92.7% of cases. The median age at diagnosis was 70 years (60-94); Ann Arbor stages were as follows: I (21.4%), II (26.5%), III (16.7%), IV (35.4%). Extranodal disease was present in 66.3% of cases. IPI and age-adjusted IPI (aaIPI) scores were: low (L) 23% and 22%, low-intermediate (LI) 26% and 30%, intermediate-high (IH) 25% and 27%, high (H) 26% and 21%, respectively. First-line treatment was initiated in 86.7%. The most frequent treatment modality was an anthracycline-containing (CHOP) regimen (78%) with a median of 6 cycles. An intensive chemotherapy was administered to only 2.3% of patients. Rituximab was added to chemotherapy in 58% (a median of 6 doses) and radiotherapy in 25% of patients. The treatment response was assessable in 1,076 (87.1%) of the treated patients. PET scan was used in 139 cases.

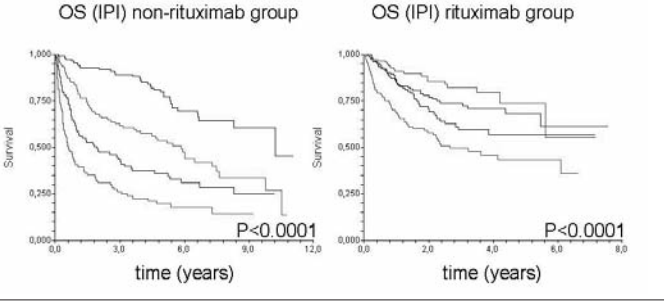

Figure 1.

Results. Generally, complete remission (CR), unconfirmed CR, partial remission and stable disease were achieved in 66.3%, 9.9%, 12.5% and 2.5%, respectively. Only 8.8% of patients progressed on therapy. The ORR reached 88.7%. PET-negative CR was achieved in 114 (82%) of 139 assessable cases. After a median follow-up of 2.7 years, 574 patients (40.3%) are alive without relapse, 313 (22%) relapsed or progressed and 517 (36.3%) died. The overall survival at 3 years (3y OS) reached 59.6% (95% CI 0.57-0.63); the event-free survival at 3 years (3y EFS) was 50% (95% CI 0.47-0.53). The 3y OS stratified by IPI and aaIPI: (L) 85%/ 84%, (LI) 67%/67%, (IH) 50%/50%, (H) 37%/32%. The 3y EFS according to IPI and aaIPI: (L) 76%/76%, (LI) 58%/57%, (IH) 39%/39%, (H) 28%/24%. Rituximab improved both 3y OS (55% *vs.* 65%, P<0.0001) and 3y EFS (44% *vs.* 59%, P<0.0001). OS improvement was seen in all risk groups except low-risk patients. PET negativity after treatment predicts longer OS and EFS (P=0.0011 and P=0.0005, respectively). Multivariate analysis identified nonCR status, age≥70, PS≥2 (ECOG), LDH and rituximab application as independent predictors of OS. Similarly, nonCR status, age≥70, IH/H aaIPI score, LDH and rituximab application independently predict EFS. Summary. Current treatment modalities lead to long-term remission in 2/3 of elderly DLBCL patients. Survival of high-risk patients remains poor. Rituximab significantly reduces the risk of death and disease progression especially in IH/H IPI subgroups. PET negativity is an essential prerequisite for long-term CR. Acknowledgements. IGA NR/9502-3.

LYMPHOCYTOPENIA MAY ADD TO THE PREDICTION ACHIEVED BY THE REVISED INTERNATIONAL PROGNOSTIC INDEX (R-IPI) IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) TREATED WITH RITUXIMAB-CHOP (R-CHOP)

Introduction. Low absolute lymphocyte counts (ALC), generally <1.0×10^9/L, have been recently considered as an adverse prognostic factor in DLBCL, both prior and after the introduction of Rituximab. However, published experience in the Rituximab era is limited to very few moderately sized series (approximately 100 patients each). Therefore, the prognostic significance of lymphocytopenia in patients with DLBCL treated with R-CHOP deserves further investigation. *Aim.* To determine the frequency of lymphocytopenia and to evaluate its correlation with other baseline features and the outcome of patients with DLBCL treated with R-CHOP. A predefined cutoff of 0.84×10^9/L was used to define severe lymphocytopenia, as proposed by Cox MC *et al.* (Leuk Lymphoma 2008; 49: 1745-51). Patients and *Methods.* Among 482 patients with DLBCL, who were treated with R-CHOP or similar anthracycline-based combinations in the participating centers, the ALC was available in 399. Gender and the 5 individual components of the IPI, as well as the R-IPI, were recorded at baseline, and failure free survival (FFS) (including early toxic deaths as events) and overall survival (OS) were determined as endpoints for the outcome. *Results.* The median age of the patients was 65 years (18-91), and 57% were males. According to the R-IPI, 20% of patients were classified as Very Good Risk (VG), 47% as Good Risk (G), and 33% as Poor Risk (P). The median ALC was 1.504×10^9/L; 21% of the patients had an ALC <1.0×10^9/L and 14% had severe lymphocytopenia according to the predefined cutoff of 0.84×10^9/L. The ALC was significantly correlated with advanced stage, elevated LDH, age >60 yrs and higher R-IPI, but not with poor performance status (marginal association), multiple extranodal involvement or gender. Severe lymphocytopenia was associated with inferior 3-yr FFS (79% *vs.* 67%, P=0.002) and 3-yr OS (83% *vs.* 73%, P=0.005). The R-IPI was also highly discriminative for both FFS and OS. In multivariate analysis, severe lymphocytopenia added independent prognostic information to R-IPI for both FFS and OS with hazard ratios in the order of 2.0. The presence of severe lymphocytopenia identified an even worse subgroup including19% of the poor risk R-IPI patients with 3-yr FFS and OS of 38% and 49% *vs.* 57% and 62% for the remaining poor risk R-IPI patients without severe lymphocytopenia. On the contrary, severe lymphocytopenia had not any prognostic impact in Very Good and Good risk patients according to the R-IPI. *Conclusions.* A severe depression of ALC (<0.84×10^9/L) was present in 14% of DLBCL patients, being associated with several other adverse prognostic factors. The presence of severe lymphocytopenia provides prognostic information independent from that obtained by the R-IPI and classifies patients with Poor risk R-IPI into two subgroups with different outcomes. Our results reinforce the view that lymphocytopenia might be incorporated in prognostic models for DLBCL in the R-CHOP era.

PROGNOSTIC SIGNIFICANCE OF INTERIM 18F-FDG PET/CT FOR TREATMENT OF DIFFUSE LARGE B CELL LYMPHOMA IN POST-RITUXIMAB ERA

DH Yang, JJ Min, SY Bae, JS Ahn, YK Kim, HS Bom, IJ Chung, HJ Kim, JJ Lee

Chonnam National University Hwasun Hospital, Jeollanam-do, South-Korea

FDG-PET/CT, a functional imaging modality used for staging and monitoring response to treatment of malignant lymphoma, has a higher sensitivity and specificity than conventional imaging. We prospectively investigated that PET/CT may provide additional prognostic information in interim response assessment prior to completion of chemotherapy in diffuse large B cell lymphoma (DLBCL). Patients and *Method.* 153 newly diagnosed patients with diffuse large B cell lymphoma were enrolled from Aug. 2004 to July 2009 in single institution. PET/CT analysis was performed at the time of diagnosis and after the 3rd or 4th R-CHOP chemotherapy. The clinical stage and response of the patients were assessed according to revised response criteria for aggressive lymphomas (Cheson, J Clin Oncol, 2007). The limited-stage patients were treated with four cycles of R-CHOP chemotherapy and followed by involved field radiation therapy (IFRT). The advanced-stage (III/IV) patients were treated with eight cycles of chemotherapy. However, the advanced-stage patients who were older than sixty-five, if they had a complete response (CR) by interim analysis were treated with only six cycles. *Results.* Median age was 60 years (range: 17 - 85). Sixty-four patients (41.8%) presented in advanced stages and 26 (17.4%) had bulky mass (≥10 cm). The International Prognostic Index was 47.1% of low risk, 19.6% of low-intermediate, 17.6% of intermediate-high and 15.7% of high risk. 110 patients (71.9%) achieved CR, 37 patients (24.2%) achieved PR, 4 patients (2.6%) showed stable or progressive disease and 2 patients (1.3%) was non-measurable by interim revised IWC. 111 patients (72.5%) had a negative, while 40 (26.1%) remained positive by interim PET/CT. Five patients (3.3%) revealed false positive-FDG and one false negative-FDG by tissue biopsy. After following median 30.8 months, 3-year overall (OS) and progression free survival (PFS) rate was 74.2±3.9% and 71.0±3.9%, respectively. The relapse rate was significantly different between FDG-positive (60.0%) and FDG-negative (12.6%) (P=0.000). Figures showed the Kaplan-Meier estimates of OS and PFS depending on the interim PET/CT. *Conclusions.* Interim PET/CT analysis was a significantly predictive value of disease progression and survival of DLBCL after R-CHP chemotherapy. The patients with PR or positive according to interim IWC and PET/CT analysis should be considered for an intensive therapeutic plan.

IMPROVEMENT OF OUTCOME IN DIFFUSE LARGE B-CELL LYMPHOMA AFTER INTRODUCTION OF RITUXIMAB IN COMBINATION WITH CHEMOTHERAPY. EVALUATION IN DAILY PRACTICE IN A COHORT OF 410 PATIENTS TREATED AT A SINGLE INSTITUTION BETWEEN 1996 AND 2008

H Ghesquieres, C Ferlay, O Derbel, I Dominsoru, P Rey, T Gargi, C Chassagne-Clement, B Favier, P Biron, JY Blay, C Sebban

Centre Leon Berard, Lyon, France

Background. Rituximab (R) in combination with chemotherapy (CT) has dramatically improved the prognosis of patients with Diffuse Large B-Cell Lymphoma (DLBCL). Good results have been observed in clinical trials or in the context of curative care in population-based analyses. *Aims.* Whether this therapeutic effect is observed in daily practice without any selection for patient age, type of associated CT or curative/palliative intent at diagnosis needs to be controlled. We proposed to perform this analysis in an unselected population of DLBCL patients. *Methods.* From 1996 to 2008, 410 patients with DLBCL received first-line therapy at our institution. The median age of the patients was 64 years (range, 19-96). Treatment consisted of CHOP-like CT (218 patients, 53%), high-dose CHOP CT (129 patients, 31%), other CT with anthracyclin (49 patients, 12%) or without anthracyclin (10 patients, 3%), radiotherapy and surgery in 4 patients (1%). Rituximab was associated to CT for 267 patients: respectively 17 and 250 before and after approval of rituximab for DLBCL in March 2002. *Results.* With a median follow-up of 60.2 months (95%CI [52.2-62.5]), the 5-year overall survival (OS) of the cohort is 67% (CI95% [62-72]). At last evaluation, 27 patients (7%) had died of toxicity after first-line therapy, 81 of progressive disease (20%) and 24 of other causes (6%). Amont these last patients, eight died of solid neoplasia and one of myelodysplasia. The 5-year Event-Free Survival (EFS) of the cohort, calculated from the date of diagnosis to the first occurrence of events (relapse, disease progression, or death of any cause), was 61% (CI95% [56-66]). Comparison of OS between patients treated with or without R showed that patients receiving R had a better outcome, with a 5-year OS of 72% (CI95% [66 - 78]) compared to 59% (CI95% [51 -67]) for patients not treated with R (P<0.001). EFS was also improved with a 5-year EFS of respectively 66% (CI95% [59 - 72]) and 53 % (CI95% [45 - 61]) (P<0.01) for patients treated with and without R combined to CT. Evaluation by age groups showed that this effect was observed for patients older than 60: 5-year OS was 65% (CI95% [56 - 74]) and 41% (CI95% [31 - 53]) (P<0.01) for patients treated and not treated with CT combined with R, respectively. In our cohort, the influence of R was not observed for patients younger than 60: 5-year OS and EFS were 82% (CI95% [70 - 89]) and 75% (CI95% [63 - 84]) for patients treated without R and 81% (CI95% [72 - 88]) and 77% (CI95% [68-84]) for patients with R (P=0.99 for OS; P=0.79 for EFS). *Conclusions.* This study confirmed the improvement of DLBCL prognosis by R in a context of daily practice without the selection bias of clinical trials. However this effect was observed for elderly patients but not for younger patients who were treated in our institution mainly by dose-dense chemotherapy (70%). The prognostic impact of R will be also presented by age-adjusted IPI, type of CT and treatment response.

0671

SERUM SORUBLE CD27 LEVEL DETERMINES CLINICAL OUTCOME IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA IN RITUXIMAB ERA

N Goto,[1] H Tsurumi,[2] N Kanemura,[2] S Kasahara,[2] T Hara,[2] Y Kito,[3] T Takami,[3] H Moriwaki,[2] H Nakamura[2]

[1]Gifu University Graduate School of Medic, Gifu, Japan; [2]First Department of Internal Medicine, Gifu University Graduate School of Medici, Gifu, Japan; [3]Department of Immunopathology, Gifu University Graduate School of Medicine, Gifu, Japan

Purpose. Diffuse large B-cell lymphoma (DLBCL) is a heterogeneous entity, with patients exhibiting a wide range of outcomes. The introduction of rituximab to CHOP (R-CHOP) has significantly altered improvement in survival. This raises concern regarding the utility of previously identified prognostic factors. Before rituximub era, some investigators have suggested that serum levels of some cytokines and their soluble receptors might reflect tumor growth and host tumor responses. CD27 belongs to tumor necrosis factor - receptor family, especially express on lymphcytes, and CD27 expression of variable intensity was detected on almost all immature and mature malignant B cells, and also the highest levels of serum soluble CD27(sCD27) were reported in chronic lymphocystic leukemia and low-grade non-Hodgkin's lymphoma. We have previously assessed that sCD27 was strong prognostic factor in patients with DLBCL who received CHOP without rituximab . The aim of the present study is to re-assess the prognostic significance of serum sCD27 in DLBCL treated with rituximab. In addtion we assessed sCD27 with subtype DLBCL, GCB type and non-GCB type, and we analyzed CD27 stain of tumor tissue in immunohistochemistry at the diagnosis. Materials and *Methods.* Consecutive 143 previously untreated patients with DLBCL prospectively participated in this study between 2002 and 2008. The patients were treated with 6-8 cycles of R-CHOP. Serum sCD27 was determined by ELISA, and we classified subgroups of DLBCL according to Hans *et al.*, and additionally we analyzed CD27 stain of tumor tissues. *Results.* In all patients with DLBCL, the median of serum sCD27 level was 157.61 ng/mL (range 1.6 - 1488 ng/mL). Various poor prognostic features, such as poor PS, many extranodal sites, advanced disease (CS III/IV), increased LDH and elderly people were strongly associated with high serum CD27 levels. The median serum sCD27 levels of the different IPI risk groups were as follows: 42.6 ng/mL for the L risk; 106 ng/mL for the LI risk; 218.1 ng/mL for the HI risk; 405.2 ng/mL for the H risk, respectively (P<0.0001). A similar result was provided in rivised IPI (42.6 ng/mL for the very good risk; 68.8 ng/mL for the good risk; 326.5 ng/mL for the poor risk, respectively P<0.0001). In addition, the serum sCD27 correlated with LDH, CRP (LDH: r=0.47, P<0.0001; CRP r=0.58, P<0.0001). Patients with high sCD27 (200 ng/mL and over) at onset had significantly lower overall survival rates (4-year: 54.4%), than those with low sCD27 (4-year: 73.5 %), respectively (P<0.0005). and there were no difference with median serum sCD27 levels in GCB and non-GCB subgroups, but CD27 positive cells were observed in GCB types more than in non-GCB types (GCB: 30%, non GCB: 6.78%; P=0.0007), and patients with CD27 positive tumor in GCB type had poorer prognoses than those of CD27 negative. *Conclusion.* These results suggest that, in even rituximab era, a high serum CD27 level predicts a poor prognosis of DLBCL and may be a useful biomarker for selecting appropriate treatment. Upfront high dose chemotherapy might be well indicated for DLBCL patients with high serum sCD27.

0672

CYTOGENETIC ANALYSIS OF BONE MARROW WITH INVOLVEMENT OF DIFFUSE LARGE B-CELL LYMPHOMA IN KOREA

SY Kim, CJ She, HK Kim, HI Cho, YK Cheon, DW Kim, SA Im, TY Kim, SS Yoon, YJ Bang, S Park, DS Heo, BK Kim, DS Lee

Seoul National University College of Medicine, Seoul, South-Korea

Background. Bone marrow (BM) evaluation is essential in routine staging of diffuse large B-cell lymphoma (DLBCL), because bone marrow involvement (BMI) affect both prognosis and treatment strategies. Cytogenetic studies have been used increasingly with the expending knowledge on genetic characteristics of DLBCL, however, little information is available on the clinical utility of cytogenetic studies in BM specimens for detection of BMI and cytogenetic characteristics of DLBCL with BMI and its clinical impact. *Aims.* The aim of this study was to assess the diagnostic utility of cytogenetic studies in comparison with morphologic findings in BM specimens from DLBCL patients and to characterize features and to determine the prognostic impact of chromosomal abnormalities in DLBCL with BMI. *Methods.* We analyzed results of histologic findings and karyotypes using the conventional G-banding technique on BM aspirates obtained for staging or follow-up purpose from 503 patients who diagnosed DLBCL from 1996 to 2009 in Seoul National University Hospital. In 148 patients, interphase fluorescent *in situ* hybridization (FISH) were also performed using commercially available probes including an IGH dual color break-apart rearrangement probe, a p16/CEP 9 dual color probe, and a BCL6 dual color break-apart rearrangement probe (all from Vysis). *Results.* 137 (27.2%) cases showed BMI of DLBCL cells by histological examination. Chromosomal aberrations were detected in 90 (17.9%) cases among 503 patients and 68/137 (49.6%) cases with BMI showed abnormal karyotypes. Meanwhile, 22/366 cases (6.0%) with no evidence of BMI by histologic examination showed abnormal karyotypes. Of 148 patients for whom FISH results were available, 44.0% (33/75) of cases with histologic BMI showed abnormal FISH results, while 1 patient among 73 patients with no evidence of BMI showed abnormal FISH *Results.* When compared with G-banding, 13/34 (38.2%) cases with abnormal FISH results showed normal karyotypes by G-banding. Among 90 patients with abnormal karyotypes with G-banding, complex karyotypes were observed in 59 cases (65.6%), hyperdiploidy in 15 cases (16.7%) and translocations in 46 patients (51.1%). Abnormalities affected chromo-

somes 1 (43.3%, 39/90), followed by Chromosome 3 (35.6%, 32/90), Chromosome 14 (34.4%, 31/90), Chromosome 6 (28.9%, 26/90), and Chromosome 18 (28.9%, 26/90) in descending order of frequency. The most commonly observed specific abnormalities were: rearrangements involving 14q32 (23.3%), 8q24 (13.3%), 19q13 (13.3%), 3q27 (11.1%), 11q23 (11.1%), 1p25-p36 (8.9%), 18q21-q23 (8.9%), and 19p13 (8.9%); deletions of 6q12-q25 (14.4%), 1p21-p32 (12.2%), and 7q22-q34 (8.9%); duplications of 1q21q42 (8.9%); chromosomal gain of 18 (14.4%), 7 (11.1%), and 3 (8.9%); chromosomal loss of 13 (8.9%). The prognostic analysis of patients with BMI showed that patients with complex karyotypes were significantly decreased overall survival than patients with normal karyotypes (9.0 *vs.* 51.1 months, P<0.001). However, 17 patients with minor chromosomal abnormalities with G-banding did not affect survival (P=0.575). *Conclusions.* In addition to histologic examination, conventional cytogenetic study with G-banding technique and FISH analysis could be useful tools in detecting BMI. Complex karyotype was an adverse prognostic factor, and further analysis of larger series of patients with DLBCL with BMI may clarify the prognostic stratification by cytogenetic results.

Table 1. Frequent chromosomal abnormalities in 90 patients with abnormal karyotypes.

Chromosome	No. of abnormal cases	Rearrangement (no. cases)	Deletion (no. cases)	Duplication (no. cases)	Gain (no. cases)	Loss (no. cases)
X	16				+X (5)	−X (4)

USE OF STATINS AND PROGNOSIS IN PATIENTS WITH CD20-POSITIVE 'DE NOVO' DIFFUSE LARGE B CELL LYMPHOMA (DLBCL) TREATED WITH RITUXIMAB CONTAINING REGIMENS

J Madsen,[1] R Nielsen,[2] M Engebjerg,[2] H Sørensen,[2] A Bukh,[3] F D'Amore[4]

[1]Aalborg Sygehus, Århus Universitetshospital, Aalborg, Denmark; [2]Department of Clinical Epidemiology, Aarhus/Aalborg, Denmark; [3]Department of Hematology, Aalborg Sygehus, Århus University, Aalborg, Denmark; [4]Department of Hematology, Aarhus, Denmark

Background. Statins may interfere with anticancer treatment by different promoting or inhibiting mechanisms. A recent study reported a better event-free survival in follicular lymphoma patients treated with statins as compared to non-users. So far, no data on the possible prognostic impact of statin use in '*de novo*' DLBCL have been reported. There is some evidence that statins may reduce the effect of Rituximab treatment by changing the expression of CD20 molecules on the surface of B-cells. However, so far, no studies have examined whether this may have a impact on treatment outcome in CD20 positive DLBCL patients using statins. *Aims.* To investigate whether the use of statins was associated with the clinical outcome of patients with CD20-positive '*de novo*' DLBCL treated with Rituximab containing regimens. *Methods.* We constructed a historical cohort based on the population-based Danish lymphoma registry LYFO and included patients with CD20-positive '*de novo*' DLBCL treated with Rituximab containing regimens diagnosed before 01.01.2008 at the haematological departments of Aarhus and Aalborg . Demographic and clinico-pathological characteristics were obtained from the LYFO database. Data on the use of statins, comorbidities and death were obtained from the prescription databases of the Central Denmark Region and the North Denmark Region, the Danish National Registry of Patients and the Danish Civil Registration System. We used regression analysis to compute adjusted mortality and event ratios within 30 months from diagnosis. The analysis was adjusted for age, IPI and comorbidity. *Results.* A total of 280 patients were analysed. Of these, 11 (3.9%) were excluded due to missing clinical data. Of the remaining 269 patients, 39 (14.5%) were statin users. Overall survival (OS) and event-free survival (EFS) proportions at 30 months after diagnosis were similar between statins users and nonusers (OS: 32.5% *vs.* 29.2% and EFS: 35% *vs.* 34.6%, respectively). Age and comorbidity showed a significant difference between the two groups. In the statin-treated group 12,5% of the patients were under 60 years of age (mean age 70 years) and 70% had a history of comorbidity, whereas corresponding values among non-users were 35% (mean age 64.3 years) and 41.3%, (P<0.01 and P<0.001) respectively . As a result of this the adjusted mortality ratios for OS and EFS comparing statin users with nonusers were: 0.76 (0.38-1.53) and 0.69 (0.35-1.37), respectively. *Conclusions.* Our data do not support the hypothesis, that statin use inhibits Rituximab activity. Further studies are warranted to investigate whether the use of statins may have impact on treatment outcome in selected subsets of patients with DLBCL and when evaluated over a longer follow-up period.

TOLERANCE OF R-CHOP-21 FOR DIFFUSE LARGE B-CELL LYMPHOMA IN AN UNSELECTED POPULATION AND IMPACT OF DOSE REDUCTION ON OUTCOME

T Todd,[1] M Karanth,[2] D Jackson,[3] M Furtado,[1] J Danielson,[4] P Kerr[1]

[1]Royal Devon and Exeter Hospital, Exeter, UK; [2]West Suffolk Hospital, Bury St Edmunds, UK; [3]Lismore Base Hospital, Lismore, Australia; [4]North Devon District Hospital, Barnstaple, UK

Background. 6-8 cycles of R-CHOP-21 is widely regarded as standard initial therapy for advanced diffuse large cell lymphoma (DLCL) with studies demonstrating high response rates and durable remissions even in those over sixty. However, there is very little published data on R-CHOP-21 tolerance in unselected patients or the impact of dose reduction on outcome. *Aims.* To establish the proportion of unselected patients in routine practice deemed able to receive full dose R-CHOP-21 for advanced DLCL and the impact of dose reduction on response rates, response duration and survival. *Methods.* All patients with stage 3 or 4 *de novo* DLCL (including follicular lymphoma grade 3b) commencing therapy between 1st Sept 2005 and 31st November 2009 were identified by computerised records searches at three centres with similar patient populations and supportive care protocols. Patients with known pre-existing low grade lymphoma, prior chemo- or radiotherapy for a haematological disorder or HIV were excluded. Patient records were reviewed for relevant data and staging and response re-determined. Overall and progression free survival were calculated from date of first chemotherapy.

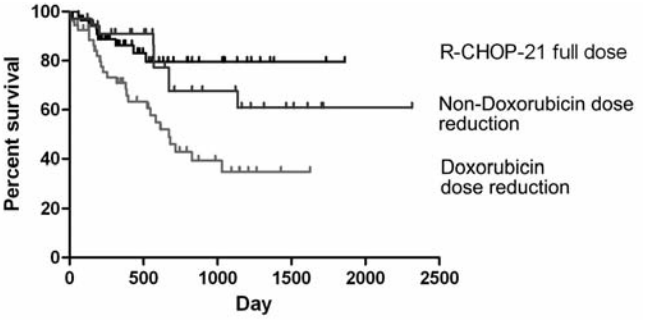

Figure 1. Overall Survival Curves for R-CHOP-21.

Results. 170 patients were identified. 14 received R-CHOP-14, 2 received other regimens, records were unavailable for 1, all these were excluded from further analysis. Of the remaining 153, 60 completed 6 cycles of full dose R-CHOP-21 (Rituximab 375 mg/m^2, Cyclophos-

phamide 750 mg/m^2, Vincristine 1.4 mg/m^2, maximum dose 2 mg, and prednisolone 100mg for 5 days) and 90 had some dose and/ or cycle number reduction. Treatment cessation for death or progressive disease during full dose therapy (3 patients) was not considered dose reduction. Doxorubicin dose was reduced in 54 (median 33% of full 6 cycle dose), cyclophosphamide in 37 (median 80% full dose), vincristine in 59 (median 50% full dose), Rituximab in 7 (range 50-83% full dose). 15 had ≤5 cycles with reduced dose per cycle of at least one agent (median 4 cycles). The commonest reasons for dose reduction were age (55%), neuropathy (14%) and poor tolerance (14%). There was no difference in IPI (median 3) or ECOG performance status (median 1) between those receiving full dose or not. Median age was higher in dose and/ or cycle reduction patients than full dose (78 *vs.* 65 years). Median IPI, performance status and age did not differ between doxorubicin dose reduction patients and those receiving only other drug reductions. Median follow up was 21 months. Overall survival, progression free survival and response rates were determined for full dose and reduction of each drug. Reduction in ≥1 of vincristine, cyclophosphamide, rituximab did not produce significant reduction in response rates or survival. Reduction in doxorubicin produced lower median overall survival (21 months *vs.* not reached, P=0.0022, Figure1) and overall response rates (97% *vs.* 82%, P=0.0025, Fisher's exact test). Summary/ Conclusions. Outside clinical trials, a substantial proportion (59%) of patients with advanced DLCL are deemed unfit to receive R-CHOP-21 at full dose. Reduction in agents other than doxorubicin has no significant impact on response rates or overall survival and, where dose reduction is necessary, is preferable to doxorubicin attenuation.

SINGLE NUCLEOTIDE POLYMORPHISMS IN FCGRIIA AND FCGRIIIA MAY AFFECT RESPONSE RATE BUT NOT SURVIVAL IN NEWLY DIAGNOSED DLBCL PATIENTS TREATED WITH RITUXIMAB AND CHOP CHEMOTHERAPY

A Fabisiewicz, E Paszkiewicz-Kozik, M Osowiecki, J Romejko-Jarosinska, J Walewski, J Siedlecki

The Maria Sklodowska-Curie Memorial Institute and Oncology Center, Warsaw, Poland

Background. Single nucleotide polymorphisms (SNPs) of Fcγ receptors (FcγRs): FcγIIA and FcγRIIIa in effector cells may predict response rate and clinical outcome in B-cell lymphoma patients (pts) treated with immunochemotherapy. However, reports on the prevalence of FCGR2A and FCGR3A genes SNPs and their influence on overall survival (OS) and progression free survival (PFS) in pts with diffuse large B-cell lymphoma (DLBCL) are inconsistent. *Aims.* To evaluate the frequency of FCGR2A-131H/R and FCGR3A-158V/F polymorphisms in DLBCL pts treated with R-CHOP and possible relation between SNPs and characteristics of pts, response rate, frequency of neutropenia, OS and PFS. *Methods.* Newly diagnosed DLBCL pts subsequently treated with R-CHOP between 2004 and 2007 at our institution were studied retrospectively. Peripheral blood was taken during R-CHOP therapy. Genotyping was performed on DNA obtained from peripheral blood using TaqMan SNP Genotyping Assays (Appliedbiosystems, USA) and confirmed by sequencing. Response to treatment and endpoints were determined by 1999 Cheson criteria. Statistics was done with SPSS 12.0. *Results.* Patient characteristics: n=87, median age (range): 57 (25-81), male/female: 41/46, Ann Arbor stage III-IV: 74%, LDH>normal: 48%, E sites: 59%, IPI score 0-2: 76% of pts. Median (range) number of R-CHOP cycles was 6 (4-8). During a median observation time of 40 months, 21 pts (44%) had disease progression with a median time to progression of 9 months. There were 17 deaths. SNP distribution was: H/H-31%, H/R-46%, and R/R-23% for FCGR2A, and V/V-17%, V/F-40%, and F/F-43% for FCGR3A. There were no significant differences in SNPs distribution by age, sex, Ann Arbor stage, LDH level, IPI, or primary site of DLBCL. A higher CR rate was observed in FCGR2A H/H (74%) and H/R (75%) alleles compared with R/R (55%; P=0.046). FCGR3A V/V allele was associated with more than 7-fold higher probability of CR (P=0.046, OR 7.492, 95%CI 1.039-54.028). Other predictive factors for CR were: ECOG PS - 0 (P=0, OR 18,705, 95%CI 4.369-80.06), IPI <3 (P=0.03 OR 6.587, 95%CI 1.206-35.993), and age>60 (P=0.014, OR 10.076, 95%CI 1.59-63.835). Neither FCGR2A nor FCGR3A allele were significantly related to OS and PFS. Normal LDH level was predictive for longer OS (P=0.021 HR 0.338, 95%CI 0.134-0.852), and IPI score<3 - for longer PFS (P=.02 HR 0.284, 95%CI 0.23-0.618). FCGR2A and FCGR3A polymorphisms had no significant influence on degree of neutropenia after R-CHOP. *Conclusion.* Our results indicate that FCGRs polymorphisms: FCGR2A: H/H and H/R, and FCGR3A: V/V were statistically significantly related to high CR rate but were not predictive for OS and PFS in DLBCL pts treated with R-CHOP, suggesting other mechanisms of elimination of lymphoma cells than ADCC via FcgRIIA and FcgRIIIA receptors.

0676

REDUCTION OF IMMUNE SUPPRESSION PLUS R/CHOP CHEMO-IMMUNOTHERAPY IN DLBCL PTLD SUBTYPE: LONG TERM ANALYSIS OF EFFICACY AND RENAL SAFETY DATA IN A SINGLE INSTITUTION STUDY

A Fields,[1] P Kotoucek,[1] B Wilkins,[1] S Crichton,[2] M Moonim,[1] J van der Walt,[1] D Goldsmith,[1] A Fields[1]

[1]Guys and St Thomas` Hospital, London, UK; [2]Kings College, London, UK

Background. A feared complication of solid organ transplantation is the development of post transplant lymphoproliferative disorder (PTLD). There is little consensus to the optimal treatment of PTLD, but general treatment principles include first the reduction of immune suppression. If this fails it is recommended to add in immunotherapy in the form of single agent rituximab. Recent data suggest the overall survival of PTLD utilising rituximab as a single agent is 76% at one year. (Choquet *et al.* Blood 2005). However for the more aggressive end of the spectrum i.e. Monomorphic PTLD such as DLBCL, it may be necessary to combine Rituxmab plus chemotherapy to achieve rapid disease control. There are few long term data on the safety and efficacy of R/CHOP in the management of DLBCL in terms of outcome both for disease and renal related morbidity / mortality. *Aims.* The aim of our study was to analyse the outcome data (for both disease and renal morbidity / mortality) in our series of patients. *Methods.* From our series of 49 patients diagnosed with PTLD, 11/49 patients first received reduction of immune suppression (RI) followed by administration of R/CHOP analysed on an intention to treat basis. The presence of latent EBV infection was determined by EBER *in situ* hybridization, and expression of EBV-LMP1 was detected by immunohistochemistry. Immunosuppressive protocols at our institution comprised prednisolone, Azathioprine or MMF, and Cyclosporin or Tacrolimus, all with Basiliximab induction from 2001 onwards. Routine depleting antibody therapy was not given at induction. *Results.* All patients had histological evidence of diffuse large B cell lymphoma (DLBCL) on the basis of morphology and immuno-histochemistry. EBV EBER *in situ* analysis was available in 8/11 patients of which 2/8 were positive. All patients first had reduction of immunesuppression (RI) and received R/CHOP. 4/11 were female; median age 48.5 years (range 27-55 years) and 7/11 were male; median age range 40 years (range 22-56 years). Development of PTLD occurred at a median of 10 years (range 1-20 years) of which 1/11was early (<12 months) and 10/11 were late (> 12 months). Median age at transplant was 38 years. Renal morbidity observed included 3 episodes of cellular rejection in 2 patients resulting in the loss of one allograft at 1.75 years but no functional change in the others. 4 patients returned to dialysis having lost their renal allograft function due either to rejection or to continued decline in already prejudiced allograft function. 10/11 patients entered CR after 6 cycles of R/CHOP. At a median follow up of 48 months (range 4-98) 3 year progression free survival was 81% and the 3 year overall survival 71%. 3/11 patients have died 1 of relapse, 1 of progressive disease and the other of myocardial infract (whilst in remission). *Conclusions.* These data show that a high proportion of PTLD patients with aggressive histology (DLBCL) can be successfully treated with RI and R/CHOP chemo-immunotherapy with an acceptable patient and renal allograft toxicity profile. 6/11 patients have been in CR for greater than 5 years treated with RI and subsequent R/CHOP chemo-immunotherapy.

ONLINE REGISTRY OF DIFFUSE LARGE B-CELL LYMPHOMA IN SOUTH KOREA

CS Kim,[1] JS Kim,[2] CW Suh,[3] WS Kim,[4] HG Yi,[1] JY Kwak,[5] SM Bang,[6] YS Kim,[7] YD Joo,[8] YH Min,[2] M Lee,[9] SS Yoon,[10] JH Won[1],[1] S Park,[10] HC Kim[12]

[1]Inha University Hospital, Incheon, South-Korea; [2]Yonsei University Severance Hospital, Seoul, South-Korea; [3]Asan Medical Center, Seoul, South-Korea; [4]Samsung Medical Center, Seoul, South-Korea; [5]Chonbuk University Hospital, Jeonju, South-Korea; [6]Seoul National University Bundang Hospital, Sungnam, South-Korea; [7]Kosin University Gospel Hospital, Pusan, South-Korea; [8]Inje University Pusan Paik Hospital, Pusan, South-Korea; [9]Konkuk University Medical Center, Seoul, South-Korea; [10]Seoul National University Hospital, Seoul, South-Korea; [11]Soonchunghyang Hospital, Seoul, South-Korea; [12]Ajou University Hospital, Suwon, South-Korea

Background. There has been few nation-wide data regarding diffuse large B cell lymphoma (DLBCL) the most prevalent subtype of non-Hodgkin's lymphoma in South Korea. *Aims.* This study was aimed at survey on clinical spectrum of DLBCL in terms of incidence, prevalence in age, clinical characteristic, stage, and international prognostic index (IPI) as well as treatment outcomes. *Methods.* In 2007-2008, thirteen university hospitals evenly distributed in Korean peninsula participated in online registry of DLBCL at www.lymphoma.or.kr provided by Korean Society of Haematology Lymphoma Working Party and filed a total of 1,649 cases of DLBCL experienced in 1990-2008. The data was collected and analyzed by one institution. *Results.* Data showed steadily increasing annual incidence of DLBCL with slight male predominance (M:F=943:706) as well as linear correlation between age and incidence until the peak at ages of 65-70. Histologic transformation or combination with low grade was found in 33 cases (2%). Patients' performance was 1 or less on ECOG scale in 1,385 (84%). DLBCL presented among 977 cases in which primary site was identifiable, as primary nodular disease in 458 (47%) or extanodular disease in 519 (53%) with origins from stomach in 456 (12%), GI tract other than stomach in 57 (11%), CNS in 73 (14%), and bone in 10 (2%). Rare types of DLBCL included mediastinal lymphoma (n=10), intravascular lymphoma (n=4), pyothorax associated lymphoma (n=2), plasmablastic lymphoma (n=2), and primary effusion lymphoma (n=1). Among 1,446 patients in whom staging workup was completely filed, DLBCL presented at early disease in 63% (405 in stage I and 501 in stage II) or advanced disease in 37% (261 in stage III and 279 in stage IV). B symptoms accompanied in 189 (13%) and tumour deposit in marrow was documented in 78 (5%). Grouping according to IPI score found 795 (55%) in 0/1, 376 (26%) in 2, 188 (13%) in 3, and 87 (6%) in 4/5. Age adjusted IPI score was 0 in 506 (35%), 1 in 607 (42%), 2 in 275 (19%), 3 in 58 (4%). HBsAg was positive in 113 of 813 patients (14%), anti-HCV positive in 17 of 810 (2%), anti-HIV positive in 3 of 750 (0.4%). Treatment including CHOP or R-CHOP therapy with or without radiotherapy was carried out in 1544 (94%). No measures were taken for various reasons or measures taken were unidentifiable in 105 (6%). Among those who had been treated, 993 (64%) were alive, free of disease in 80% of them, 417 were dead (27%), disease free in 13% of them, and 144 (9%) were lost to follow-up, disease free in 23% of them. Age < 60, stage on diagnosis, IPI score regardless age adjusted or not, and addition of rituximab to CHOP therapy, were shown to have given statistically meaningful impact on survival duration in all. Summary/*Conclusions.* The epidemiology, clinical spectrum, and biological behaviour of DLBCL in Korea are similar to those of western countries, and the incidence is continuously increasing.

0678

CLINICAL OUTCOMES AND PROGNOSTIC FACTORS IN PATIENTS WITH BREAST DIFFUSE LARGE B CELL LYMPHOMA; CONSORTIUM FOR IMPROVING SURVIVAL OF LYMPHOMA (CISL) STUDY

Background. The breast is a rare extranodal site of non-Hodgkin lymphoma, and primary breast lymphoma (PBL) has been arbitrarily defined as disease localized to one or both breasts with or without regional lymph nodes involvement. *Aims.* The aim of this study was to evaluate the clinical outcomes in patients with diffuse large B cell lymphoma (DLBCL) and breast involvement, and to find the criteria of PBL reflecting the outcome and prognosis. *Methods.* We retrospectively analyzed data from 68 patients, newly diagnosed with DLBCL and breast involvement at 16 Korean institutions between January 1994 and June 2009. Results. The median age at diagnosis was 48 years (range, 20-83 years) and all patients were female. Forty-three (63.2%) patients were PBL according to previous arbitrary criteria, sixteen (23.5%) patients were classified as high-intermediate to high risk according to the international prognostic index (IPI). According to the number of involved extranodal disease, the patients with one extranodal disease in the breast (OEND) with or without nodal disease were 49 (72.1%), and those with multiple extranodal disease (MEND) were 19 (27.9%). Sixty-seven (98.5%) patients were treated with systemic chemotherapy, 66 (97.1%) treated with anthracycline-based regimens. Fifty-five (80.9%) patients were treated with four or more than four cycles of systemic chemotherapy with or without any local treatment modalities such as surgery or radiotherapy. Any surgery or radiotherapy to the breasts was performed in 23 (33.8%) and 21 (30.9%) patients, respectively. Among 23 patients treated with surgery, modified radical mastectomy was performed in 13 (56.5%) patients. Forty-two (61.8%) patients were received chemoimmunotherapy with rituximab. During median follow-up of 41.5 months (range, 2.4-186.0 months), estimated 5-year progression-free survival (PFS) and overall survival (OS) were 53.7% (95% Confidence Interval [CI], 46.1-61.3) and 60.3% (95% CI, 53.1-67.5), respectively. The 5-year PFS and OS was significantly higher for patients with the OEND group than those with the MEND group (5-year PFS, 64.9% [95% CI, 56.0-73.8] *vs.* 27.5% [16.1-38.9], P=0.001; 5-year OS, 74.3% [66.7-81.9] *vs.* 24.5% [11.5-37.5], P<0.001). In univariate analysis, Ann Arbor stage III or IV (P=0.010), ECOG performance status of 2 or 3 (P=0.015), elevated levels of LDH (P=0.049), high-intermediate to high IPI (P=0.001), SBL group according to previous criteria (P=0.008), the MEND group (P<0.001), and fewer than four cycles of systemic chemotherapy (P<0.001) were significantly associated with lower OS. In multivariate analysis, MEND (hazard ratio [HR], 3.61; 95% CI, 1.07-12.2) and fewer than four cycles of systemic chemotherapy with or without local treatments (HR, 4.47; 95% CI, 1.54-12.96) were independent prognostic factors for worse OS. Twenty-five (36.8%) patients experienced progression, and the cumulative incidence of progression in multiple extranodal sites or other than breasts and central nervous system was significantly different between the OEND group and the MEND group (5-year cumulative incidence, 9.7% [4.3-15.1] *vs.* 49.0% [33.9-64.1], P=0.001). Conclusions. Our results show that the patients included in OEND group, reflecting different treatment outcome, prognosis and pattern of progression, should be considered as PBL in the future trial. Further studies are warranted to validate our suggested criteria.

0679

THE TREATMENT MODIFICATION DOES NOT SEEM TO CHANGE THE DLBCL PATIENT´S OUTCOME WHEN CORRELATED WITH EARLY PET RESULTS

M Trneny,[1] R Pytlik,[1] M Hnatkova,[1] I Vasova,[2] D Belada,[2] K Kubackova,[3] T Kozak,[4] O Belohlavek,[5] J Pirnos,[6] M Lysy,[7] M Hamouzova,[1] J Salkova,[1] M Trnkova[1]

[1]Charles University Genaral Hospital, Praha, Czech Republic; [2]University Hospital, Brno, Czech Republic; [3]University Hospital Motol, Praha, Czech Republic; [4]University Hospital Kralovske Vinohrady, Praha, Czech Republic; [5]Hospital Homolka, Praha, Czech Republic; [6]Hospital, Ceske Budejovice, Czech Republic; [7]Masaryk Hospital, Usti n Labem, Czech Republic

Background. It has been demonstrated that early PET examination can have prognostic impact in DLBCL. There is however only scarce data on the treatment modification based on early PET results. We present the retrospective analysis of the treatment modification in correlation with early PET results and its impact on patient´s outcome. Patients and *Methods.* The inclusion criteria were confirmed DLBCL, curative treatment and early PET (after 2nd or 3rd) cycle. The PET was not intended for treatment change, but the treating physician knew the results. Patients were recruited out of consecutively treated patients in one center (n 102) (dg IV/2000-IV/2009) and out of prospective phase II trial (ASH 2007, abstr 21, n 51). PET was interpreted as positive or negative. As a treatment modification was considered unplanned unplanned additional therapy or significant reduction of planned treatment. The endpoints were the PFS and OS according to the consensus definition (2007). *Results.* The median age of pts was 53 y (18-80), median follow up was 28 months, the aaIPI distribution was as follows: low 17 (11.1%), low-intermed 19 (12.4%), intermed-igh 67 (43.8%), high 50 (32.7%). All patients except 14 (9,2%) received rituximab. Seventy one (46.4%) pts were scheduled to intensive treatment protocol R-MegaCHOP/ESHAP/BEAM (Trneny, ASH 2007), 6 pts (3.9%) to CHOP followed by ASCT, 73 pts (47.8%) to CHOP regimen, and 3 ot other anthracyclin regimens. The early PET was negative in 104 pts (68%) and positive in 49 pts (32%). The 3 y PFS was 87.7% for PET neg and 56.1% for PET pos resp. (P 0.001) and 3y OS 91.9% and 68.6% resp. (p 0.001). 29 (80.2%) pts out of 36 previously PET pos pts who were examined at the end became PET negative. There was nonsignficant trend for better PFS (p 0.09) and for better OS (P 0.06) for PET neg-neg patients compared to the pos-neg patients. Compared to the preplanned therapy no change was in 107 cases (69.9%), the therapy was decreased in 20 cases (13.1%), and additional therapy was used in 26 cases (17%). The reduction of therapy consisted out of skipping of ASCT (10 cases), RT (6 cases) and significant chemotherapy reduction (4 cases), the additional therapy consisted out of RT (19 cases), ASCT (7 cases) and maintenance therapy (10 cases). The 3 y probability of early PET neg patients with unchanged and decreased treatment resp. were for PFS 87.7% *vs.* 100% resp. (p ns) and for OS 91.7% *vs.* 100% (p ns). The 3y probability of early PET pos pts with unchanged *vs.* additional treatment resp. was for PFS 57.7% *vs.* 66.7% resp. (P ns) and for OS 70.2% *vs.* 77.2% (P ns). *Conclusions.* We have confirmed prognostic value of early PET on outcome in this highly IPI poor prognostic group of pts (HI and H 76.5%). The reduction of treatment in early PET negative pts seems to have no adverse effect on outcome, on the other hand the additional treatment does not seem to improve the outcome of early PET positive patients.

THE OUTCOME OF DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) PATIENTS TREATED WITH R-CHOP IS NOT PREDICTED BY INTERIM EVALUATION OF 18-FDG-POSITRON EMISSION TOMOGRAPHY/COMPUTED TOMOGRAPHY (PET)

P Pregno,[1] A Chiappella,[1] M Bellò,[2] G Bisi,[2] C Boccomini,[1] B Botto,[1] G Castellano,[2] C Ciochetto,[1] S Ferrero,[3] C Frairia,[1] S Franceschetti,[4] M Ladetto,[3] M Menga,[2] M Nicolosi,[1] R Passera,[2] B Puccini,[5] L Rigacci,[5] F Salvi,[6] U Vitolo[1]

[1]Hematology, [2]San Giovanni Battista Hospital and University, Torino, Italy; [2]Nuclear Medicine, San Giovanni Battista Hospital and University, Torino, Italy; [3]Division of Hematology, University, Torino, Italy; [4]Hematology, University of Piemonte Orientale Amedeo Avogadro, Novara, Italy; [5]Hematology, Careggi Hospital, Firenze, Italy; [6]Hematology, Santi Antonio e Biagio e Cesare Arrigo Hospital, Alessandria, Italy

Background. In DLBCL patients PET evaluation has a defined role to assess the final response, but the predictive value of interim PET is contradictory. Standardized criteria of interpretation of Interim PET have not been well established yet and the visual analysis of PET results by dichotomous evaluation as positive or negative is difficult to apply. Aim of study. to determine the predictive value of interim (I-PET) and final PET (F-PET) on Progression Free Survival (PFS) in DLBCL patients treated with R-CHOP. Patients and *Methods.* From April 2004 to December 2008, 82 newly diagnosed DLBCL patients treated in five Hematology Departments were included. Clinical features were as follows: median age 56 years (19-81); 42 males and 40 females, 29 stage I-II and 53 stage III-IV; 47 L/LI and 35 I/IH IPI score. All patients were treated according to the planned therapy, not modified by I-PET results, with 6-8 R-CHOP. IF-RT was planned to areas of bulky disease and given to 13 patients. All patients had PET scan performed at the diagnosis, during treatment (I-PET) and at the end of therapy (F-PET). All PET results were centrally reviewed and defined as positive or negative by visual dichotomous response criteria according to the First Consensus Conference (Deauville 2009). *Results.* All patients were evaluable for response. I-PET was performed after two R-CHOP in 46 pts, after three in 13 and after four in 23. At the end of therapy 73 pts (89%) achieved a CR and nine (11%) were non responders. Fifty-five patients (67%) were negative and 27 (33%) positive at the I-PET; 69 pts (84%) were negative and 13 (16%) positive at the F-PET. 15/27 (56%) I-PET positive patients became F-PET negative at the end of the therapy. The concordance between clinical CR and F-PET negativity was 99%: one CR pt was false F-PET positive due to parothid carcinoma. The prognostic impact of PET results on the outcome was evaluated. With a median FU of 18 months, Progression-free survival (PFS) was 80%. PFS did not correlate with I-PET results, 18-months PFS rates were: 84% in I-PET negative patients and 74%in I-PET positive patients (p .198) (Figure 1A). Conversely F-PET strongly predicted PFS (p .015): 84% in F-PET negative patients and 61% in F-PET positive patients. (Figure 1B). A further analysis for progression was performed to adjust the effect of I-PET analysis for other known risk factors (age ≥60, stage, PS, IPI, LDH, bulky, number of extranodal sites, Bone Marrow involvement): only LDH (p .005) and IPI 0-2 *vs.* 3-5 (p .001) were confirmed as independent predictors for progression. The use of G-CSF during treatment did not influenced I-PET results. *Conclusions.* Our results indicate that in DLBCL patients treated with R-CHOP a positive interim PET did not predict a worse outcome. Conversely, final PET results strongly correlate with PFS. A longer follow up is necessary to validate our data. Prospective larger studies and standarditation of criteria for interim PET are needed to assess the prognostic value of interim PET in DLBCL patients.

AGGRESSIVE CRANIOFACIAL LYMPHOMA IN THE PRE-RITXUIMAB AND RITUXIMAB ERA

N Murawski, C Zwick, B Glass, S Zeynalova, J Fleckenstein, C Rübe, M Ziepert, B Kämpf, V Pöschel, M Loeffler, N Schmitz, M Pfreundschuh

DSHNHL, Homburg, Germany

Background. Among 4165 patients treated in the NHL-B1, NHL-B2, High-CHOEP, Mega-CHOEP, RICOVER-60 and MInT trials of the German High Grade Non-Hodgkin Lymphoma Study Group (DSHNHL), 316 patients had craniofacial involvement by their lymphoma. *Aims.* To analyze clinical characteristics and response to therapy of 316 patients with craniofacial lymphomas treated with CHOP-like chemotherapy with and without rituximab. *Methods.* A retrospective analysis was performed to compare characteristics and treatment outcome of patients with craniofacial lymphoma to all the other patients of these trials. *Results.* Of the 316 patients, 32 had orbital, 101 paranasal sinus, 44 main nasal cav-

ity, 109 mouth, 28 tongue and 57 salivary gland involvement. Patients with craniofacial lymphoma presented with a significantly lower LDH, better performance status, lower Ann Arbor Stage and less bulky disease compared to the entire population (elevated LDH: 16.8% *vs.* 35.9%, P=<0.001; ECOG >1: 2.8% *vs.* 10.1%, P=<0.001; stage III/IV: 28.2% *vs.* 40.7%, P=<0.001; bulky disease: 14.9% *vs.* 39.3%, P=<0.001). 3-year event free survival (70.4% *vs.* 60.5%, P=<0.001) and 3-year overall survival (81.2% *vs.* 75.6%; P=0.044) were better in patients with craniofacial involvement compared to the entire population of these trials. Multivariate analysis confirmed all IPI-relevant risk factors as significant and independent. With respect to different treatment strategies, the addition of rituximab to CHOP-14 in the RICOVER-60 trial reduced the relative risk to 0.6 for EFS and 0.5 for OS. This is clinically very relevant, but not significant due to the limited number of patients. In contrast, additive radiotherapy to the craniofacial involvement for patients in CR/CRu or PR at the end chemo- or immunochemotherapy, which was given to 178 patients had no influence on the outcome of these patients compared to patients not receiving additive radiotherapy (n=68). The relative risk for EFS was 1.0 (P=0.863) and 1.5 (P=0.315) for OS in patients receiving additional radiotherapy compared to patients receiving systemic therapy only. *Conclusions.* Patients with craniofacial lymphoma present with favorable prognostic parameters and treatment results are better in this population compared to the whole population of patients with aggressive lymphomas. Our results do not support the addition of radiotherapy to systemic therapy in these patients.

0682

FOLLOW UP WITH 18-FDG PET/CT IN AGGRESSIVE LYMPHOMAS IN FIRST PET-NEGATIVE COMPLETE REMISSION

T El-Galaly, V. Prakash, J Madsen, M Boegsted, A Bukh

Aalborg University Hospital, Aalborg, Denmark

Background. The use of 18-FDG-PET/CT (PET/CT) is well established as a primary investigation, interim scan and post-therapy evaluation of aggressive non-Hodgkin's lymphomas. However, there has been little focus on its value for disease surveillance. *Aims.* To evaluate use of PET/CT scans during follow-up in asymptomatic patients successfully treated with first-line therapy for aggressive non-Hodgkin's lymphoma (NHL). *Methods.* We retrospectively analyzed patients with aggressive NHL treated at our institution from 2006 to 2009. Patients were eligible if they achieved a PET/CT based complete remission (CR) on primary treatment and if PET/CT was used approximately every 6 month during the first two years of follow-up. Only PET/CTs performed in patients with no clinical or biochemical signs of relapse were included, whereas PET/CTs performed in patients with suspected lymphoma relapse were not analyzed. PET/CTs were described as true positive, false positive, true negative and false negative on a basis of PET/CT result combined with biopsy results, subsequent imaging or clinical course. For each positive scan, maximum standardized uptake value (SUVmax) was determined. *Results.* Of a total of 80 patients in CR after first-line therapy for aggressive NHL during the time period, 52 were eligible (43 Diffuse Large B-cell lymphoma, two Burkitt Lymphoma, one grade III Follicular Lymphoma and six T-cell Lymphomas). Median age was 61 years and median follow up 18 months. Each patient had between one and four PET/CTs giving a total number of 138 PET/CT's. In four cases relapses were detected by PET/CT in patients regarded CR at clinical evaluation. In one case the relapse was clearly visible on PET but with only discrete changes on CT. Four PET/CTs (3%) were true positive and 119 PET/CTs (86%) were true negative. The numbers of false positive and negative PET/CT's were 15 (11%) and 0 respectively (Figure 1).

	6 month	12 month	18 month	24 month
Total number of PET/CTs	52	42	29	15
False negative	0	0	0	0
True positive	1	1	1	1
False positive	4	5	5	1
True negative	47	36	23	13

Figure 1. PET/CT results at six month intervals after end of therapy.

Specificity was 89% and sensitivity 100%. The predictive value of a positive and negative PET/CT was 21% and 100% respectively. The median SUVmax in false positive PET/CTs was 6.3 (range 2.1-12.8) and for true positive 10.2 (range 5.8-14). *Conclusions.* The most important conclusion is that a negative PET/CT strongly indicated absence of lymphoma. However the significant number of false positive PET/CTs consequently leads to patient anxiety and unnecessary biopsies. High SUVmax was seen more often in lymphoma but with an overlap to non-lymphoma lesions. Given the low number of unsuspected relapses found by PET/CT compared to the total number of PET/CTs performed, a question of poor cost effectiveness could be raised as PET/CT is an expensive procedure compared with CT. In only one case, did the PET procedure of the PET/CT play an important role in detecting relapse.

0683

PROGNOSTIC VALUE OF CEREBROSPINAL FLUID FLOW CYTOMETRY ANALYSIS IN AGGRESSIVE NHL PATIENTS AT HIGH RISK FOR LEPTOMENINGEAL DISEASE: FCM+ MAY PREDICT AN HIGH RISK OF CNS RELAPSE

G Benevolo,[1] P Pioltelli,[2] M Spina,[2] C Boccomini,[2] A Stacchini,[2] A Evangelista,[2] L Godio,[2] F Mannelli,[2] S Franceschetti,[2] M Cantonetti,[2] A Di Rocco,[2] L Depaoli,[2] V Pavone,[2] N Di Renzo,[2] A Ferreri,[2] M Arras,[2] E Pogliani,[2] U Vitolo[2]

[1]Hematology ,[2] Turin, Italy; [2]N the behalf of Intergruppo Italiano Linfomi, Turin, Italy

Background. In aggressive NHL intrathecal prophylaxis (IT-P) reduces the incidence of CNS relapse but may increased the toxicity of systemic chemotherapy. The identification of patients subgroups for whom IT-P may benefit is therefore important. Flow cytometry (FCM) assessment of cerebrospinal fluid (CSF) has recently been known to increase the proportion of positive cases with leptomeningeal disease in comparison to conventional cytologic examination (CC). However it's still unknown its prognostic value. *Aims.* The primary aim of this prospective, multicenter trial was to compare CC *vs.* FCM in a large cohort of NHL patients at high risk for LD. The secondary aim was to assessed the impact of FCM^+ on PFS and OS. *Methods.* Patients, with no evidence or signs of neurological disease, were enrolled if they were diffuse large B-cell lymphoma (DLBCL) with IPI 2-3, elevated LDH along with at least two extranodal sites or with bone marrow, testis, palate or paravertebral involvement; Burkitt lymphoma (BL); blastoid variant of mantle-cell lymphoma (B-MCL); B-cell precursor lymphoblastic lymphoma (B-LL); HIV^+ patients. Pts received IT-P standard with MTX +/- cytarabin except for liposomial cytarabin in BL. PFS was defined as the time from diagnosis to any type of progression or death from any cause and compared by the log-rank test.

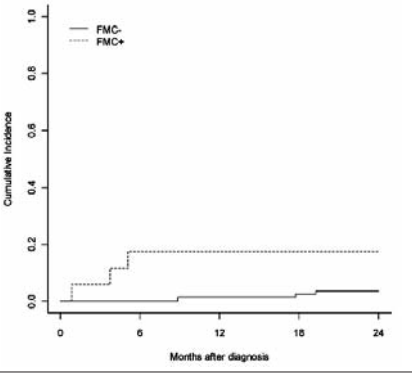

Figure 1. Cumulative incidence of CNS progression by FMC test result, accounting for competing events (death for any cause).

Results. From August 2004 to June 2008, 145 patients were enrolled by 12 centres. Clinical characteristics were: 96 males, median age 55 years (IQR:43-63); 111 patients (76%) with DLBCL, 22 pts (15%) with BL, seven pts (5%) with B-MCL and five pts (3%) with B-LL. Twenty-seven patients (19%) were HIV^+. FCM was able to detect a clonal population in 17 out of 145 patients (12%) whereas CC detected abnormal cells only among 7 pts (5%) (P=0.0002). Therefore, 10 patients (7%) were discordant: FCM^+/CC^-. From date of diagnosis, overall median follow up of survivors was 26 months. We observed 39 (30%) systemic progressions, 6 (5%) CNS progressions and 32 (25%) deaths. Among the 17 pts FCM positive, we observed 10 (59%) systemic progression,

three (18%) CNS progression (in two cases the disease of CNS was isolated whereas one pts presented a CNS progression along with systemic progression) and eight (47%) deaths (6 PD, 2 missing). PFS at 1 year was 71.2% (95%CI:62.1-78.5) in the whole group of patients. The progression risk was significantly higher in patients FCM^+/CC^+ compared with patients FCM^-/CC^- (P=0.003). An higher but not significant risk of progression was found in FCM^+/CC^- with respect to patients FCM^-/CC^-. At 24 months the cumulative incidence of CNS progression by FMC test result, accounting for competing events, was statistically higher in FCM^+ respect to FCM^- patients (18% *vs.* 4%)(P=0.010). *Conclusion.* FCM assessment of CSF is more sensitive than CC for detection of LD, but it's clinical relevance is still to be clearly defined. Our preliminary data suggest that patients FCM^+/CC^+ have an higher risk of progression compared with those FCM^-/CC^-, whereas discordant cases seem to have an intermediate prognosis. Moreover, pts FCM^+ seems to have an higher risk of CNS relapse in comparison to patients FCM^-.

0684

RITUXIMAB SERUM LEVELS DURING INDUCTION AND MAINTENANCE TREATMENT ARE DIFFERENT IN MEN AND WOMEN

M Fridrik,[1] U Jaeger,[2] G Hopfinger,[3] C Mannhalter,[2] G Mitterbauer,[2] W Oberaigner,[4] R Greil[2]

[1]AKH-Linz, Linz, Austria; [2]Medical University, Vienna, Austria; [3]Hanusch Hospital, Viennna, Austria; [4]Institut für Klinische Epidemiologie der TILAG, Innsbruck, Austria

Introduction. Rituximab is one of the pivotal substances in the treatment of B-cell lymphoma. Little is known regarding rituximab serum levels. Materials and *Methods.* We conducted a prospective multicenter trial in patients with previously untreated follicular lymphoma stage III or IV, which required therapy. Primary endpoint was conversion of BCL2/IgH PCR positivity to negativity. One of the secondary endpoints was serum rituximab level. Induction therapy (R-FM) consisted of 6 cycles of rituximab 375 mg/qm i.v. day 1, mitoxantrone 10 mg/qm i.v. day 1, fludarabine 25 mg/qm i.v. days 2-4 recycling every 28 days for 6 cycles. Patients not progressing during induction therapy received maintenance rituximab 375 mg/qm every 8 weeks for 12 doses which was an off label use. All patients signed a written informed consent.

Table 1.

female		N = 9			N = 8			N = 7			N = 4		
male		N = 7			N = 5			N = 6			N = 5		

Results. Twenty-seven patients were entered in the study. Median age was 55 years, (range 32-73 years). Rituximab serum concentrations were measured before and after rituximab infusion during induction and maintenance. Rituximab serum levels during induction and maintenance treatment were significant higher in female than in male patients (Table 1). Induction R-FM resulted in 11 (91.7%) and 6 (54.5%) complete remissions, 3 (27.3%) and 0 partial remissions in female and male patients, respectively (P=.142). Event free survival after 36 months was .823 and .671 for female and male patients, respectively (P=0.33). Overall survival after 36 month was 1.0 and .71 for female and male patients, respectively (P=.06). Discussion. A rituximab dose of 375 mg/qm achieves significant higher serum levels in female than in male patients. These higher levels did not result in significant higher remission rates, event free survival or overall survival. There are several explanations for these findings. Patient numbers may be too small; observation period could be too short to find a difference that really exists. Rituximab levels in male are high enough and higher levels do not add something to the effect of the therapy.

0685

DOSE-DENSE THERAPY WITH NON-PEGYLATED LIPOSOMAL DOXORUBICIN (R-COMP 14 *VS.* 21) IS FEASIBLE AND EFFECTIVE FOR ELDERLY PATIENTS WITH NEWLY DIAGNOSED AGGRESIVE B-CELL NON-HODGKIN LYMPHOMA

G Visani,[1] F Merli,[2] F Angrilli,[3] F Ferrara,[4] F Ilariucci,[2] S Falorio,[3] G Fioritoni,[3] F Alesiani,[2] M Brunori,[1] F Pollio,[4] M Celentano,[4] D Cangini,[5] S Ronconi,[5] M Catarini,[6] G Giglio,[3] D Vallisa,[3] A Arcari,[3] D Bernardi,[5] R Paolini,[2] B Guiducci,[1] S Barulli,[1] M Lucesole,[1] M Rocchi,[7] F Loscocco,[1] F D'Adamo,[1] A Isidori[1]

[1]Hematology and Stem Cell Transplant Center, Pesaro, Italy; [2]Oncohematology, Reggio Emilia, Italy; [3]Hematology, Pescara, Italy; [4]Division of Hematology and Stem Cell Transplantation Unit, Cardarelli Hospital,, Napoli, Italy; [5]Oncology, Forli', Italy; [6]Internal Medicine, Macerata, Italy; [7]Insitute of Biomathematics, Urbino University, Urbino, Italy

Background. The optimal treatment for elderly patients with non-Hodgkin's lymphoma (NHL) is still a matter of debate. The favourable toxicity profile of nonpegylated liposomal doxorubicin (Myocet™) makes its use particularly appealing for frail and elderly NHL patients. *Aims.* To evaluate the toxicity and the efficacy of nonpegylated liposomal doxorubicin when substituted for conventional doxorubicin in the CHOP 14 or 21 regimen for the treatment of elderly patients with newly diagnosed B-cell NHL. *Methods.* 69 patients with B cell NHL at diagnosis were split in 2 groups according to the Multidimensional Geriatric Assessment (MDGA). Patients with an Activities of Daily Living (ADL) = 6 received dose-dense R-COMP every 2 weeks (33 patients), whereas patients with an ADL < 6 received R-COMP every 3 weeks (39 patients). The median age was 70 years (range: 65-79) in the R-COMP 14 group and 75 years (range: 64-89) in the R-COMP 21. At baseline 23/33 (70%) patients had stage IV disease in the R-COMP 14 group, whereas 19/39 (49%) in the R-COMP 21. Median performance status and median number of comorbities were comparable between the 2 groups. Eighteen out of 33 (55%) patients had an intermediate or high risk International Prognostic Index score in the R-COMP 14 group, compared to 18/39 (46%) in the R-COMP 21. The median left ventricular ejection fraction (LVEF) before starting chemotherapy was comparable between the two groups (59% *vs.* 60%). *Results.* A total of 397 cycles of chemotherapy were administered (179 R-COMP 14 and 218 R-COMP 21). Grade 3/4 neutropenia occurred in 12% and 24% of cycles in the R-COMP 14 and 21 groups respectively, with an incidence of febrile neutropenia of 2% and 7% respectively. The relative dose intensity for the regimens was 93% for the R-COMP 14 group and 90% for the R-COMP 21 group, respectively. Regarding cardiotoxicity, only 2/33 patients presented a grade II-IV WHO toxicity in the R-COMP 14 group, whereas 5/39 in the R-COMP 21 group. All patients are evaluable for response. In the R-COMP 14 group, 23/33 patients (70%) obtained a CR, 8/33 (24%) achieved a PR, and 2/33 (6%) did not respond to therapy. In the R-COMP 21 group, 28/39 patients (72%) obtained a CR, 8/39 (21%) achieved a PR, and 3/39 (7%) did not respond to therapy. With a median follow-up of 10 months (range 2-20) and 10 (range 2-27) as of January 2010, 25/33 patients (76%) and 31/39 (79%) are alive and disease free in the R-COMP 14 and in the R-COMP 21 group, respectively. *Conclusions.* The stratification of patients according to the MDGA allows elderly and fit patients with aggressive B-cell NHL with poor prognosis (high IPI score) to receive dose dense chemotherapy which might favourably impact on response rate and survival. Due to the fact that the trial was design to demonstrate the superiority of the dose-dense regimen in terms of disease-free survival at 3 years, a longer follow-up is warranted to better define the impact of the R-COMP 14 regimen on the outcome of elderly patients with aggressive NHL.

0686

LENALIDOMIDE HAS CLINICAL ACTIVITY AND INDUCES DURABLE RESPONSES IN PATIENTS WITH TRANSFORMED LYMPHOMA: SUBSET ANALYSIS OF AN INTERNATIONAL PHASE 2 STUDY (NHL-003) IN AGGRESSIVE NON-HODGKIN'S LYMPHOMA

PL Zinzani,[1] T Witzig,[2] J Vose,[3] C Reeder,[2] R Buckstein,[4] J Polikoff,[5] J Li,[6] D Piertronigro,[6] A Ervin-Haynes,[6] M Czuczman[7]

[1]University of Bologna, Bologna, Italy; [2]Mayo Clinic, Rochester, USA; [3]University of Nebraska, Omaha, USA; [4]Sunnybrook Odette Cancer Center, Toronto, Canada; [5]Kaiser Permanente Medical Group, San Diego, USA; [6]Celgene Corporation, Summit, USA; [7]Roswell Park Cancer Institute, Buffalo, USA

Background. The heterogeneity among patients who transform from an indolent to an aggressive non-Hodgkin's lymphoma (aNHL) has led to a reported median survival ranging from 2.5 to 22 months. At a median follow-up of 9 years after initial diagnosis there appears to be a transformation risk of ~30% at 10 years (Al-Tourah JCO 2008). A retrospective analysis of 600 patients with aNHL showed that the 10-year overall survival was significantly longer for non-transformed patients (75%) *vs.* transformed patients (36%; P<0.001). Despite the aggressive nature of transformed NHL there are few prospective studies available to guide therapeutic decision for this patient population. The few trials that include patients with transformed lymphoma (TL) show limited activity with treatments used for other NHLs. Lenalidomide is an immunomodulatory agent that also exhibits tumoricidal activity in *in vitro* models of both aggressive and indolent NHL. Here we report on a subset of patients with TL, who were enrolled in a large international phase 2 trial of lenalidomide monotherapy in the setting of relapsed/refractory aNHL (off-label). *Aims.* To determine the clinical benefit and safety of single-agent lenalidomide in patients with relapsed/refractory TL. *Methods.* As part of the inclusion criteria for this multicenter, single-arm, open-label study, patients were required to be ≥18 years old, have a good performance status, have had ≥1 prior therapy, and ≥1 measurable lesion of ≥2 cm. Patients provided informed consent. Oral lenalidomide 25 mg/day was given on days 1-21 of a 28-day cycle, and continued until disease progression or unacceptable toxicity. Response rate was the primary endpoint, and secondary endpoints included response duration, time to progression, progression-free survival (PFS), and safety. Pathology assessment and efficacy evaluation were as per investigator assessment. *Results.* 217 patients enrolled in the study and received lenalidomide. Of these, 33 patients (15%) had TL; 23 had transformed follicular lymphoma (tFL), 7 had transformed chronic lymphocytic leukemia/ small lymphocytic leukemia (tCLL/SLL), and 3 were other or unknown. For patients with TL, the median age was 66 years (42-84), 58% of patients had stage IV disease, patients had a median of 4 (1-12) prior therapies, and 24% had received prior stem cell transplantation. Responses were observed in 45% of patients with TL, which included 21% complete response (CR)/CR unconfirmed. Responses to lenalidomide were noted in 13 of 23 (57%) patients with tFL and 0 of 7 patients with tCLL/SLL. The median PFS was 5.4 months and at a 5.6-month median follow-up the median response duration was 12.8 months. Reversible myelosuppression was the most common grade 3 or 4 adverse event. The occurrence of neutropenia (33% grade 3; 15% grade 4) and thrombocytopenia (12% grade 3; 3% grade 4) was consistent with results observed in other studies of lenalidomide in NHL. *Conclusions.* This study demonstrates that lenalidomide monotherapy has promising clinical activity and can achieve durable responses in pretreated patients with TL. The variation in responses to lenalidomide for patients with tFL and tCLL/SLL suggests that the original histology may be a factor in the response to treatment.

SINGLE-AGENT LENALIDOMIDE FOR THE TREATMENT OF RELAPSED OR REFRACTORY AGGRESSIVE LYMPHOMA PATIENTS

B Puccini, I Chitarrelli, G Antognoli, A Fabbri, L Rigacci, MP Lenoci, F Lauria, A Bosi

Hematology Department, Florence, Italy

Background. Aggressive lymphoma comprises a heterogeneous group of B-cell malignancies, each characterized by a unique histology and molecular markers. Although initial therapy can be effective, up to 40% of patients with DLBCL either fail to respond or relapse after initial therapy (Habermann TM *et al.* JCO 2006), and relapses are likely among patients with MCL. For such patients survival outcomes are particularly poor with few effective treatment options available. Lenalidomide is an immunomodulatory agent, which also exerts both antiproliferative and tumoricidal effects. In relapsed or refractory aggressive lymphoma this therapy proved to be a good treatment option with a ORR of 35%, which included 12% of patients with a complete response (CR), and a median duration of response (DR) lasting 10.4 months (Wiernik *et al.*, JCO 2008). *Aims.* In this prospective study we evaluate the safety and efficacy of lenalidomide oral monotherapy in patients with relapsed or refractory aggressive lymphoma. Mhetods. Patients were required to have relapsed or refractory aggressive lymphoma after ≥2 prior therapies. We treated with oral lenalidomide 25 mg once daily on days 1 to 21, every 28 days, for 52 weeks, until disease progression or intolerance. The primary end point was the ORR, feasibility and the safety. Response was evaluated after 4 cycles or progression of disease. *Results.* Starting from October 2008 we have treated 22 patients with a median age of 66 years (range 53-75). The histotype were: 14 diffuse large B-cell lymphoma (64%), 4 mantle cell lymphoma (18%), 2 follicular lymphoma (9%), 1 PTCL (4.5%) and 1 Hodgkin lymphoma (4.5%). Median time from diagnosis was 3 years (range 1-13) and patients received a median of 4 prior therapies (range 2-7); 13 patients (59%) were refractory to their last treatment, 8 (36%) patients were in partial remission and one patient (5%) was in complete remission. All patients but two used Rituximab. The patients performed a median of 2 cycles (range 1-8); two of them (9%) reduced dose of lenalidomide to 10 mg due to neutropenia grade IV. Five patients (23%) delayed treatment, 4 for neutropenia grade 3-4 and 1 due to herpes zooster reactivation. Seventeen patients were evaluable for response, five patients did not reached the fourth cycle. Three patients obtained a CR/CRu (17,5%), 3 a PR (17,5%) with an ORR of 35%. The most common grade 3-4 hematological adverse events were: neutropenia (32%), anemia (4.5%) and thrombocytopenia (4,5%). The extrahematological toxicities were: hypercalcemia (1), herpes zooster (1) and renal failure (1). Hypercalcemia was associated with progressive disease after fourth cycles. The median time duration to response was 1,5 months (range 0,5- 3,5 months). *Conclusion.* single agent lenalidomide appears to be active in heavily pretreated relapsed or refractory aggressive lymphoma with an ORR of 35%. Monotherapy lenalidomide was well tolerated in this group of patients; haematological toxicity represent the predominant adverse event, manageable with use of stimulating factors or delaying therapy.

RIVAROXABAN CALIBRATOR AND CONTROL SETS MEASURING RIVAROXABAN PLASMA CONCENTRATIONS USING THE PROTHROMBIN TIME

M Samama,[1] JL Martinoli,[2] C Guinet,[3] Y Gourmelin,[2] L Le Flem,[3] E Perzborn,[4] T Spiro[5]

[1]Hôtel Dieu University Hospital, Paris cedex 0,[4] France; [2]Diagnostica-Stago SA, Gennevilliers, France; [3]Biomnis, Ivry-sur-Seine, France; [4]Bayer Schering Pharma AG, Wuppertal, Germany; [5]Bayer HealthCare Pharmaceuticals Inc., Montville, New Jersey, USA. On behalf of the Rivaroxaban Prothrombin Time Field Trial Laboratories

Background. Rivaroxaban is an oral, direct Factor Xa inhibitor which is marketed in more than 60 countries for the prevention of venous thromboembolism and is under development for the prevention and treatment of arterial and venous thromboembolic diseases. No routine coagulation monitoring is required, but the rivaroxaban plasma concentration might be needed in some cases, i.e. severe overdose or compliance. Variation in the response sensitivity of prothrombin time (PT) reagents to rivaroxaban is well described in the literature and the international normalized ration correction of results can not be used to correct for this variability. *Aims.* This multicentre study evaluated rivaroxaban calibrators and the PT for the measurement of rivaroxaban plasma concentrations. The interlaboratory precision of the measurement of rivaroxaban plasma concentrations (ng/mL) was also evaluated. *Methods.* 20 centres were provided with a set of rivaroxaban calibrators (0, 41, 219 and 430 ng/mL) and a set of unknown rivaroxaban pooled human plasma controls (19, 160 and 643 ng/mL). The evaluation was carried out over 10 consecutive days by each laboratory using its own PT reagent as well as STA® Neoplastine CI Plus, Diagnostica Stago. A rivaroxaban calibration curve was produced daily. The day-to-day precision was evaluated by testing in duplicate three plasma controls. The control was diluted and re-tested if the level was above the highest concentration of the calibration curve. *Results.* A large interlaboratory variation (in seconds) was shown for the controls when local PT reagents were used, and their coefficient of variation (CV) was 14 to 30%; but the results were more consistent when using the same PT reagent with a CV of <6% (with undiluted samples). Expressed in ng/mL, a smaller interlaboratory variation was observed (CV ranging from 2% for the highest to 7.5% for the lowest). In addition, the CV for the 41 ng/mL calibrator with the central reagent was 4.4%, and the results were reliable for concentrations >40 ng/mL and up to 600 ng/mL. Summary/*Conclusions.* Rivaroxaban measurements may be of assistance when determination of its plasma concentrations is required. The results indicate that the PT expressed in seconds cannot be used to measure rivaroxaban activity in plasma due to the large variation in the sensitivity of different reagents to rivaroxaban; Rivaroxaban concentrations can be measured with acceptable precision by using a rivaroxaban calibration curve with reliable estimation for concentrations >40 ng/mL using both local PT reagents and STA Neoplastine CT Plus. Further validation of these methods in plasma samples obtained from patients with specific clinical events such as hemorrhage, recurrent thromboembolism or suspected overdose.

0689

G-CSF ALONE OR IN COMBINATION WITH CHEMOTHERAPY DOES NOT MOBILIZE ENDOTHELIAL PROGENITOR CELLS INTO PERIPHERAL BLOOD

R Campanelli,[1] M Della Porta,[2] E Bonetti,[1] M Massa,[1] A Tenore,[1] V Rosti,[1] M Castagno,[1] L Vanelli,[1] EP Alessandrino,[1] G Barosi,[1] M Cazzola[2]

[1]Fondazione IRCCS Policlinico San Matteo, Pavia, Italy; [2]Fondazione IRCCS Policlinico San Matteo and University of Pavia Medical School, Pavia, Italy

Background. Increasing interest has been devoted to circulating Endothelial Progenitor Cells (EPCs) because of their possible use as a therapeutic tool in the treatment of vascular lesions of ischemic tissues or as a target for anti-neoplastic therapy. Several drugs can increase the number of EPCs into the peripheral blood (PB); however, there is insufficient data concerning the frequency of EPCs during hematopoietic stem/progenitor cells mobilization and leukapheresis procedures for transplantation purposes. *Aims.* To investigate EPC mobilization and collection both in patients and in healthy donors (HD) undergoing different regimen of $CD34^+$ cell mobilization for autologous or allogeneic transplantation, respectively. *Methods.* We studied 19 patients with hematological malignancies treated with chemotherapy and G-CSF (5 μg/Kg), and 18 healthy donors (HD) treated with G-CSF alone (5 μg/Kg), as mobilizing regimens. Twenty-four healthy non-mobilized adults (CTRLs) were included in the study. The informed consent was obtained from all the subjects. EPCs were detected the day of mobilization, both in the PB and in the leukapheresis samples. By flow cytometry, we evaluated $CD34^+CD45^-$ cells, including EPCs but also mature endothelial cells (ECs), and the subset of $CD34^+CD45^-$ cells co-expressing the CD133 and VEGFR-2 antigens ($CD34^+CD133^+VEGFR2^+CD45^-$), representing a population of putative EPCs. Results are expressed as median percentage (range) of electronically gated $CD34^+$ cells. We assessed the number of Endothelial Colony Forming Cells (ECFCs) grown *in vitro* according to Ingram *et al.* (Blood 2004;104:2752). Results are expressed as median number (range) of ECFC/107 mononuclear cells. *Results.* The percentage of $CD34^+CD45^-$ cells in the PB of HDs (10.9%, 1.1-25.3) was higher (P<0.0002) than that of patients mobilized with cyclophosphamide and G-CSF (0.6%, 0.1-7.3), and comparable to that of CTRLs (13.8%, 0-54.7). A significant difference between the HDs and patients was confirmed in leukapheresis samples (P=0.006). The percentage of $CD34^+CD133^+$ $VEGFR2^+CD45^-$ cells was increased in the PB of HDs receiving G-CSF (13.2%, 0-36.9) with respect to that found in the PB of patients receiving cyclophosphamide and G-CSF (0.0%, 0-25.9), and to that of CTRLs (0.0%, 0-83.4) but the difference was not statistically significant. Similar results were obtained in the leukapheresis samples (*data not shown*). The functional analysis of EPCs showed that the frequency of ECFCs, progenitors faithfully belonging to the endothelial lineage, was comparable both in the PB and in the leukapheresis of either groups, with a median value of 0/107 cells (0-1.47). These frequencies were not statistically different from that found in the PB of the CTRLs (0/107 cells, 0-0.5). Summary. Our results indicate that the frequency of $CD34^+CD45^-$ cells, including both EPCs and mature ECs, is significantly higher in subjects receiving G-CSF than in those receiving cyclophosphamide and G-CSF, and comparable to that of CTRLs. However, a more specific phenotypic and functional characterization of EPCs showed no significant difference within the two pharmacological treatments and CTRLs, suggesting that the increase of $CD34^+CD45^-$ cells in HD compared to patients is mainly due to mature ECs. These findings suggest that the mobilization of EPCs into the PB is regulated by pathways different from those involved in hematopoietic stem/progenitor cells.

LUPUS ANTICOAGULANT TESTING IS UNINTERPRETABLE IN PATIENTS RECEIVING RIVAROXABAN THERAPY FOR VENOUS THROMBOEMBOLISM TREATMENT

Z Kaplan,[1] J Butler,[2] E Malan,[2] E Gan,[2] H Tran[1]

[1]The Alfred Hospital and Monash Medical Centre, Melbourne, Australia; [2]Monash Medical Centre, Melbourne, Australia

Background. Rivaroxaban a direct factor Xa inhibitor, is a member of an emerging class of anticougulants being evaluated in the treatment of venous thromboembolic (VTE) disease. Testing for a lupus anticoagulant (LA) is central in the clinicopathologic diagnosis of the antiphospholipid syndrome and thus is often employed to help guide the duration of anticoagulation following a VTE event. There is however, a paucity of literature regarding the effect of rivaroxaban on the coagulation based assays employed in identifying a LA. *Aim.* To evaluate the utility of LA testing in patients being treated with rivaroxaban for VTE. *Methods.* We identified 22 patients randomised to receive rivaroxaban on the EINSTEIN VTE trial on whom lupus anticoagulant testing was performed. The EINSTEIN trail is a randomised open label trial evaluating the efficacy and safety of rivaroxaban compared with warfarin in the treatment of acute symptomatic deep vein thrombosis or pulmonary embolism. Testing was performed while patients were taking a dose of 20 mg of rivaroxaban daily. Blood samples were taken within 12 hours of the last dose of rivaroxaban, but at no defined time interval from the last dose. Testing for a LA was performed using 3 screening assays and a confirmatory assay. The screening assays comprised a kaolin clotting time (KCT), dilute thromboplastin time (DTT) (Dade INNOVIN) at 1:100 and 1:200 dilutions and a dilute russell viper venom test (DRVVT) (Life Diagnostics). A confirmatory test to demonstrate phospholipid dependence of the inhibitor was performed using Stago Staclot LA™ (Bayer Diagnostics) assay. *Results.* Twenty-two patients were identi-

fied. The DRVVT was prolonged in 20/22 patients (range:1.1-3.4 mean: 2.33±1.5 2SD) (normal ratio:1.0-1.2). The DRVVT failed to correct upon performing a 50:50 mix with normal plasma in all but 1 patient with an initially elevated ratio. Similarly, the DTT at 1:100 and 1:200 dilutions also appeared to be sensitive to the presence of rivaroxaban evidenced by an increased ratio in 13/20 and 16/22 patients respectively (DTT 1:100 range:1.0-2.0 mean:1.21±0.45 2SD; DTT1;200 range:0.9-2.9 mean:1.46±0.82 2SD) (normal ratio:1.0-1.2). Conversely, the KCT was the least sensitive of the lupus anticoagulant screening tests to the presence of rivaroxaban, being normal in 20/22 patients. The Staclot LA™ confirmatory test for phospholipids dependence of a potential lupus inhibitor was performed in 13 patients and failed to demonstrate phospholipid correction in all patients tested. *Conclusion.* LA testing often plays an integral role in determining the duration of anticoagulation in patients with unprovoked VTE. LA testing using currently available laboratory screening tests whilst the patient is receiving rivaroxaban are uninterpretable. To confirm whether the patient has a LA, testing must be repeated when rivaroxaban has been ceased.

GENETIC VARIABILITY OF THE G58A POLYMORPHISM ON FIBRINOGEN A-CHAIN GENE IN ADVANCED ATHEROSCLEROSIS: EFFECTS ON FIBRINOGEN, D-DIMERS AND PLASMINOGEN LEVELS

Z Pallantza

Hippokration Hospital,Athens,Greece, Athens, Greece

Background. Evidence suggest that the G58A polymorphism on fibrinogen a-chain gene is associated with increased fibrinogen levels in healthy individuals. However, it is still unclear, whether this polymorphism is associated with coagulation/thrombosis in patients with coronary artery disease (CAD). In the present study we examined the impact of this polymorphism on fibrinogen levels, D-dimers levels and plasminogen levels. *Methods.* The study population consisted of 395 subjects, 246 of which angiographically documented for CAD. The G58A polymorphism was detected by polymerase chain reaction (PCR) and appropriate restriction enzymes. Fibrinogen levels were measured by immunonephelometry, while plasminogen and D-dimers levels were measured by standard coagulometry techniques. *Results.* The genotype distribution was GG: 37.8%, GA: 39.4% and AA: 22.8% for patients with CAD, while GG: 33.5%, GA: 44.3% and AA: 22.2% for controls. Patients with CAD had significantly higher fibrinogen levels (mg/dL) than controls (434.7±132.7 *vs.* 384.7±103.7, P=0.0002). However, in patients with CAD fibrinogen levels were not significant higher for 58AA homozygotes *vs.* 58G carriers (453.6±131.4 *vs.* 441.1±140.6, P=NS), while similar difference occurred in controls (AA: 385.2±129.4 *vs.* GG+GA: 392.6±103.0, P=NS). Moreover, D-dimers levels (mg/L) were significantly higher in CAD patients than controls (409.7±188.2 *vs.* 332.8±199.4, P<0.0001). In addition, there was a significant difference for 58G carriers *vs.* 58AA homozygotes for CAD patients (506.4±418.8 *vs.* 662.2±627.1, P<0.05), but not for controls (AA: 415.6±289.6 *vs.* GG+GA: 355.9±276.5, P=NS). Finally, CAD patients and controls had no significant difference in plasminogen levels (u/mL) (119.8±79.1 *vs.* 113.9±22.9, P=NS). Patients with CAD had no difference in plasminogen for 58AA homozygotes *vs.* 58G carriers (110.2±20.6 *vs.* 112.2±17.2, P=NS), while no significant difference was observed for controls (AA: 112.3±16.7 *vs.* GG+GA: 114.3±23.5, P=NS). *Conclusions.* Our findings indicate that the G58A polymorphism on fibrinogen a-chain gene affects D-dimers levels in patients with coronary artery disease. These findings provide a possible mechanism by which this polymorphism may affect thrombotic process/coagulation independently of fibrinogen levels and may have important clinical implications.

0692

LACK OF ASSOCIATION BETWEEN PLASMINOGEN ACTIVATOR INHIBITOR -1 4G/5G GENE PROMOTER POLYMORPHISM AND PAI-1 PLASMA LEVELS IN PATIENTS WITH ISCHEMIC STROKE

T Gadelha,[1] A Paula Sabino,[2] D Dias Ribeiro,[3] C Pereira Domingueti,[4] M Silva dos Santos,[4] T Gadelha,[5] MG Carvalho,[4] AP Fernandes[4]

[1]Federal University of Rio de Janeiro, Rio de Janeiro, Brazil; [2]Federal University of São João Del Rei, São João Del Rei, Brazil; [3]Faculty of Pharmacy, Minas Gerais, Belo Horizonte, Brazil; [4]Faculty of Pharmacy of the Federal University of Minas Gerais, Belo Horizonte, Brazil; [5]Department of Internal Medicine. Hospital Universitario Clementito Fraga Filho, Rio de Janeiro, Brazil

Background and purpose. The insertion/deletion 4G/5G polymorphism at 675 pb, located before the initial transcriptional site at the promoter region of the plasminogen activator inhibitor - 1 (PAI-1) gene, has been associated with arterial disease. In this study, we investigated the frequency of this PAI-1 polymorphism and its association with PAI-1 and C-reactive protein (CRP) levels in young survival patients of Ischemic Stroke (IS). *Methods.* The plasma levels of PAI-1 and CRP and the frequency of 4G/5G polymorphism were analyzed in a group of 127 Brazilian patients that presented IS and in 201 healthy and unrelated control subjects. *Results.* The levels of CRP (P<0.001) and PAI-1 (P<0.001) were significantly higher in patients when compared with control group. However, after adjustments for sex, age, smoking and hypertension using a multivariate regression model, only PAI-1 plasma levels were independently associated with risk of IS (OR 3.40; 95% CI 1.49 - 7.74; P=0.001). The 4G/4G genotype was significantly more frequent among control subjects as compared to patients (OR 0.41; 95% CI 0.24 - 0.68; P<0.001). Furthermore, no significant correlations were detected among the PAI-1 polymorphism and PAI-1 plasma levels. *Conclusion.* The data obtained suggest that, although increased PAI-1 plasma levels are associated with development of IS in Brazilian young patients, they are not influenced by the 4G/5G PAI-1 polymorphism.

0693

QUANTITATIVE PLASMA D-DIMER LEVELS AMONG PATIENTS SUSPECTED FOR PULMONARY EMBOLISM AND DEEP VENOUS THROMBOSES

M Ghumro, A Al-lami, S Altaf, C Sieber, J Keidan

QEH Kings Lynn UK, Kings Lynn, UK

Background. D-dimer tests are used in various diagnostic strategies to exclude pulmonary embolism and deep venous thromboses.However,their role as an exclusionary first-line test is still uncertain,mainly because accuracy of the test varies according to the assay and the studied population. Objective. To validate the observation that a low positive D-dimer level has a high negative predictive value for thromboembolic events diagnosis. Design and setting. A blinded retrospective study was conducted in all patients who had D-dimer values between 255-500ng/mL. The results of subsequent diagnostic radiological studies were then assessed for positive results. The notes for confirmed cases were then reviewed for Well's clinical probability scoring. All quantitative serum D-dimer measurements were performed using Latex agglutination tubidimetric immunoassay method with a fully automated coagulation analyzer. The diagnostic radiological investigations were Computed Tomography Pulmonary Angiography (CTPA), V/Q scans and Ultrasound Doppler studies. *Results.* 434 D-dimer values were included in the study. 371 were being investigated for pulmonary embolism whilst 63 were for deep venous thrombosis. Seven patients were radiologically proven to have pulmonary embolism i.e. negative predictive value of 98.12%, 95% confidence interval [CI], 96.1-99.2%. Four positive D-dimer values had positive radiological studies for DVT i.e. negative predictive value of 98.95% ,95% confidence interval [CI], 84.5% to 98.2%. Hence, the overall negative predictive value for thromboembolic events for the studied range of D-dimer values is 97.47% (95% confidence interval [CI], 95.5-98.7%. The well's clinical probability scoring for the patients with confirmed PE ranged from 3 to 7.5 (six patients with intermediate probability and one patient with high probability). *Conclusion.* The results of this study confirms that a d-dimer value <500 ng/mL used as a first diagnostic step in ruling out the diagnoses of pulmonary embolism and deep venous thromboses is a safe clinical practice when the pre-test clinical probability is low or intermediate. In patients with low clinical probability for thromboembolism and a D-dimer value of less than 500ng/mL the merit for further diagnostic radiological investigation remains to be seen.

0694

CHANGES IN PLASMA LEVELS OF ADAMTS 13 IN PATIENTS WITH VENOUS THROMBOEMBOLISM

B Karakaya, A Tombak, M Serin, E Tiftik, A Yalcin

Mersin University Medical Faculty, Mersin, Turkey

Background. Venous thromboembolism is a significant reason of morbidity and mortality. Hereditary and acquired risk factors are accused. However, in the studies being made for its etiology, number of patients with unidentified reason is substantially high. ADAMTS 13 (a disintegrin and metalloprotease with thrombospondin type 1 repeats) is a metalloprotease that splits von Willebrand factor (vWF) multimers in the plasma. Existence of large vWF multimers in plasma due to absence of ADAMTS 13 is the major factor in the pathogenesis of thrombotic thrombocytopenic purpura. The absence of ADAMTS 13 is also shown in also certain diseases where there is increased tendency to thrombosis (ischemic stroke, ischemic hearth disease etc.). *Aims.* The aim of this study is to determine the relation between thrombosis and ADAMTS 13, vWF antigen levels those detected in the plasma of patients with venous thromboembolism. *Methods.* Thirty patients with venous thrombosis and pulmonary embolia with 30 healthy individuals of the same age and sex were participated in our study. Diabetic, icteric patients, patients whose serum samples were lipemic, who had physical or surgical trauma, who have used drugs that influence thrombocyte functions, patients with acute coronary syndrome, kidney failure, liver disease, malignancy, collagenous tissue diseases and pregnants were excluded from our study. The plasma levels of ADAMTS 13 and vWF antigen of the patients and control group were determined quantitatively by ELISA. *Results.* The median value for ADAMTS 13 in patient group was 280 ng/mL (min-max: 70-1120 ng/mL) and 665 ng/mL (min-max: 350-2500 ng/mL) in control group (reference: 610-850 ng/mL). This result was found statistically significant (P<0.0001). The median value for vWF antigen in patient group was 1728±616 mu/mL and this was also found statistically significant (P<0.001) when compared with the control group whose median value was 1037±496 mu/mL (reference: 100-1000 mu/mL). Summary/*Conclusions.* Significantly lower levels of ADAMTS 13 and significantly higher levels of vWF antigen suggest that these changes can be the result of this pathogenic process, instead of being an etiological factor in venous thromboembolism. If the levels of ADAMTS 13 and vWF antigen are normal after the treatment of thromboembolism, this will make our theory stronger.

0695

THE IMPACT OF THE G455A POLYMORPHISM ON FIBRINOGEN B-CHAIN GENE ON THE COAGULATION CASCADE IN PATIENTS WITH ESTABLISHED CORONARY ARTERY DISEASE

Z Pallantza,[1] K Hatzigeorgiou,[2] C Stefanadis[2]

[1]Hippokration Hospital,Athens,Greece, Athens, Greece; [2]Hippokration Hospital, Athens, Greece

Background. The G455A polymorphism on fibrinogen b-chain gene has been associated with increased fibrinogen levels in healthy individuals. However, the impact of this polymorphism on coagulation markers such as factor V (fV), factor X (fX) and thrombin remains unknown. In the present study we examined the impact of this polymorphism on the aforementioned markers in patients with stable coronary artery disease (CAD). *Methods.* The study population consisted of 398 subjects, 253 of which angiographically documented for CAD. The G455A polymorphism was detected by polymerase chain reaction (PCR) and appropriate restriction enzymes. Factor X, f(V) and thrombin time were measured by standard coagulometry techniques. *Results.* The genotype distribution was GG: 51.4%, GA: 37.9% and AA: 10.7% for patients with CAD, while GG: 54.5%, GA: 35.8% and AA: 9.7% for controls. No significant difference was observed in thrombin time (sec) for CAD patients *vs.* controls (18.7±1.5 *vs.* 18.5±1.7, P=NS), while this difference remained for 455G carriers *vs.* 455AA homozygotes in CAD (18.8±3.1 *vs.* 19.8±12.0, P=NS) and controls (19.6±1.9 *vs.* 18.8±2.1, P=NS). In addition, fV (%) was significantly higher in CAD patients than controls (121.7±28.4 *vs.* 108.01±23.7, P=0.0011), while no difference was observed for 455G carriers *vs.* 455AA homozygotes both in CAD patients (122.2±29.5 *vs.* 131.55±28.6, P=NS) and controls (107.61±23.2 *vs.* 111.4±24.7, P=NS). No significant difference was observed in fX (%) for CAD *vs.* controls (94.0±35.4 *vs.* 91.9±14.2, P=NS) and 455G carriers *vs.* 455AA homozygotes in controls (92.2±14.2 *vs.* 94.6±11.8, P=NS). Interestingly, in CAD patients 455AA homozygotes had significantly higher fX compared to 455G carriers (103.6±21.1 *vs.* 89.3±23.8, P<0.05). *Conclusions.* Our findings suggest that the G455A polymorphism on fibrinogen b-chain gene affects plasma levels of factor X in patients with stable coronary artery disease. These findings provide new insights in the associations between genetic variability of fibrinogen genes and thrombotic state.

0696

THE ROLE OF THE G455A POLYMORPHISM ON FIBRINOGEN B-CHAIN GENE IN ADVANCED ATHEROSCLEROSIS: EFFECTS ON FIBRINOGEN, D-DIMERS AND PLASMINOGEN LEVELS

Z Pallantza,[1] K Hatzigeorgiou,[2] A Alexaki,[2] L Plavoukou[2]

[1]Hippokration Hospital,Athens,Greece, Athens, Greece; [2]Hippokration Hospital, Athens, Greece

Background. Genetic polymorphism G455A on fibrinogen b-chain gene has been associated with increased fibrinogen levels in healthy individuals. However, the impact of this polymorphism on the coagulation cascade in patients with coronary artery disease (CAD) is unknown. In the present study we examined the impact of this polymorphism on fibrinogen levels, D-dimers levels and plasminogen levels. *Methods.* The study population consisted of 398 subjects, 253 of which angiographically documented for CAD. The G455A polymorphism was detected by polymerase chain reaction (PCR) and appropriate restriction enzymes. Fibrinogen levels were measured by immunonephelometry, while plasminogen and D-dimers levels were measured by standard coagulometry techniques. *Results.* The genotype distribution was GG: 51.4%, GA: 37.9% and AA: 10.7% for patients with CAD, while GG: 54.5%, GA: 35.8% and AA: 9.7% for controls. Patients with CAD had significantly higher fibrinogen levels (mg/dL) than controls (434.7±132.7 *vs.* 384.7±103.7, P=0.0002). In addition, in patients with CAD fibrinogen levels were importantly higher in the 455AA homozygotes *vs.* 455G carriers (561.6±127.3 *vs.* 442.6±132.2, P<0.0001), while no similar difference occurred in controls (420.9±143.9 AA *vs.* 380.6±98.5 GG+GA, P=NS). Moreover, D-dimers levels (mg/L) were significantly higher in CAD patients than controls (415.02±201.9 *vs.* 332.8±199.4, P<0.0001). However, no significant difference was observed for 455G carriers *vs.* 455AA homozygotes for both CAD patients (394.8±189.6 *vs.* 489.6±318.4, P=NS) and controls (368.1±286.9 *vs.* 406.9±258.2, P=NS). Finally, CAD patients and controls had no significant difference in plasminogen levels (u/mL) (119.2±79.7 *vs.* 113.9±22.9, P=NS). Although, CAD 455AA homozygotes had higher plasminogen levels compared to 455G carriers (116.9±10.6 *vs.* 109.5±17.2, P=NS) this difference did not reach any statistical significance, while similar results were observed in controls for 455AA homozygotes *vs.* 455G carriers (116.7±15.9 *vs.* 113.6±23.7, P=NS). *Conclusions.* Our findings showed that genetic polymorphism G455A on fibrinogen b-chain gene strongly affects fibrinogen levels. However, this polymorphism fails to affect D-dimers levels as well as plasminogen levels in patients with stable coronary artery disease.

0697

COMPOSITION AND SIGNIFICANCE OF SPLENIC GAMNA GANDY BODIES IN SICKLE CELL ANAEMIA

A Piccin,[1] H Rizkalla,[2] O Smith,[3] C Mc Mahon,[3] C Furlan,[4] M Mc Dermott[5]

[1]San Maurizio Regional Hospital, Bolzano, Italy; [2]Pathology Dept, Our Lady's Children's Hospital, Dublin, Ireland; [3]Haematology Dept, Our Lady's Children's Hospital, Dublin, Ireland; [4]Centro Universitario Grandi Apparecchiature Scientifiche, Padua University, Italy; [5]Pathology Dept, Dublin, Ireland

Background. Children with sickle cell anaemia (SCA) may undergo acute splenic sequestration (ASS). Splenectomy (SP) is usually performed after two clinically significant ASS in an attempt to reduce the incidence of further events but its efficacy remains controversial. Histological studies of spleens have on occasion revealed the presence of granuloma-like nodules, known as Gamna-Gandy bodies (GGB). Moreover, amorphous inclusions have been seen in GGB, however their significance is unknown. *Aims.* To identify the nature and the significance of GGB in SCA. *Methods.* The medical case records and histological-samples of consecutive SCA children treated with open SP between 2001-2007 at Our Lady's Children's Hospital, Dublin were reviewed. Seventeen patients were identified, in all cases histological-samples were made available. Crises pre- and post-SP were recorded. GGB were also studied by scanning electron microscopy (SEM) and X ray fluorescence in energy dispersive spectroscopy mode (XRF-EDS). An extensive

literature search on GGB was performed. Original articles from the early studies (1905) in several languages were provided through a library specialising in antique medical articles. Results. GGB were identified in 7 (41%) of our patients, amorphous inclusions of different sizes were always seen in GGB. Patients age correlated significantly with GGB presence (P=0.0025). Chest crisis were strongly associated with GBB before and after SP (P=0.00). SEM analysis on high magnification demonstrated the crystalline nature of GGB inclusions and the chemical composition: carbon (C) 47.1%; oxygen (O2) 29.7%; phosphorus (P) 9.0%; potassium (K^+) 0.4%; calcium (Ca2+) 6.4%; iron (Fe^{2+}) 7.4%. Using SEM at low-magnification, a crystal-formation gradient was observed, arising from the red pulp (RP) to the white pulp (WP), with maximal expression in the WP in GGB proximity. The early pathological descriptions of GGB were reviewed together with the new spectrographic finding. *Summary/Conclusions.* This study demonstrates that GGB-crystals formations in SCA are derived from RCC breakdown when periarterial haemorrhage occurs and will be less expressed in the RP, in contrast with delicate sinusoidal haemosiderin, which is a result of chronic haemolysis. We also demonstrated that GGB presence is age-dependent, in keeping with the first morphological studies of the beginning of the century. Moreover a strong relationship between the presence of GGB and chest crises pre or post SP was seen. Recent studies shown that post SP, patients on hydroxyurea (HU) are less likely to develop further crises. Taken together these considerations suggest that post SP, particularly when GGB are seen, patients may benefit from prophylactic HU treatment. Larger studies are now warranted to support these findings.

THE PROTEIN C ASN2ILE SUBSTITUTION CAUSES MARKED DISCREPANCY BETWEEN PROTEIN C ACTIVITY CLOTTING ASSAYS

S Siddiq,[1] C Morse,[1] J Nightingale,[2] O Tunstall,[3] P Cooper,[4] A Mumford[5]

[1]University Hospitals Bristol NHS Foundation Trust, Bristol, UK; [2]East Kent Hospitals NHS Foundation Trust, Canterbury, UK; [3]Bristol Royal Hospital for children, Bristol, UK; [4]Sheffield Haemophilia and Thrombosis Centre, Sheffield, UK; [5]Bristol Heart Institute, Bristol University, Bristol, UK

Background. Laboratory measurement of protein C (PC) may be required to detect PC deficiency in individuals with premature or familial thrombosis and infants with purpura fulminans. Commercially available assays include ELISA PC antigen assays and PC activity assays in which snake-venom extracts are used to first generate activated PC (APC) in test plasma. APC activity is then measured using chromogenic or clotting end-point assays. Current consensus guidelines recommend that both chromogenic and clotting assays are performed to identify all functional PC variants. We have previously reported a kindred in which co-inheritance of the independent PROC mutations c.669C>A (predictive of Ser181Arg) and c.131C>T (predictive of Asn2Ile) caused a severe PC deficiency phenotype. The Ser181Arg PC variant was associated with a simple quantitative (type I) PC deficiency. However, PC with the Asn2Ile substitution in the PC Gla domain ω loop was dysfunctional and in heterologous cells, disrupted APC/PC binding to the endothelial protein C receptor and phosphoipid (PL). *Aims.* To characterise the Asn2Ile PC variant using commercially available PC assays. *Methods.* We obtained venous blood samples from the following family members with informed consent; II-3 (asymptomatic heterozygote for PC Ser181Arg); II-4 (asymptomatic heterozygote for PC Asn2Ile) and III-1 (purpura fulminans and compound heterozygous for PC Asn2Ile + Ser181Arg). PC antigen was measured using ELISA. PC activity was measured using 3 chromogenic assays (Berichrom Protein C, Stachrom Protein C and an in-house method using Protac® PC activator and the S2366 chromogenic substrate) and 3 clotting assays (Staclot Protein C, ProClot and CRYOcheck Clot C). Results. II-3 (Ser181Arg) showed concordant reductions of PC with the PC antigen assay and PC activity measured using chromogenic and clotting assays confirming a type I defect (Table). II-4 (Asn2Ile) showed normal PC antigen and PC activity with the chromogenic assays. PC activity was also normal with the ProClot clotting assay and close to the lower limit of the laboratory reference range with the CRYOcheck Clot C clotting assay. However, PC activity was clearly reduced using the Staclot Protein C clotting assay (Table) revealing a partial type IIb PC deficiency. III-1 (Ser181Arg+Asn2Ile) showed a partial reduction in PC antigen and PC activity measured using the chromogenic, ProClot and CRYOcheck Clot C clotting assays, suggestive of a partial type I PC deficiency. However, PC activity measured with the Staclot Protein C clotting assay was markedly reduced in keeping with the severe PC deficiency phenotype (Table). Summary and Conclusions. In PC activity clotting endpoint assays, APC is required to bind PL to exert an anticoagulant effect. Therefore, reduced PL binding caused by the Asn2Ile PC substitution is expected to manifest as reduced PC activity. Differences in PL concentration or duration of incubation with APC in the different clotting assays may account for the differences we have observed in assay performance. These data illustrate that a wider range of PC assays may be necessary to identify all functional PC variants.

Table 1. PC assay results for the study kindred.

CAN VERY HIGH VALUE OF D-DIMER PREDICT THE PRESENCE OF THROMBOEMBOLIC DISORDERS?

CH Ho, D Gravell

Sultan Qaboos University, Muscat, Oman

Background. D-dimer quantitative test is mainly used to rule out the presence of thromboembolic diseases (TED) when the result is below the cutoff point. *Aims.* To see if very high D-dimer value (100 times above the cutoff point) can exclusively indicate the presence of TED. *Methods.* D-dimer was detected by the method of quantitative immunoturbidimetric assay (Innovance* D-Dimer, Siemens Healthcare Diagnostics Products GmbH, Marburg, Germany). The normal value is 0.2-0.7 mg/L FEU (Fibrinogen Equivalent Units). The cutoff point to rule out TED is set at 0.5 mg/L FEU or less. During the year of 2009, 1053 D-dimer tests were performed in our hospital. We analyzed the results of these 1053 samples, mainly to find out the causes of very high D-dimer. *Results.* The mean value of D-dimer in the 1053 tests was 8.56 (SD 30.87) mg/L FEU, with range from <0.19 to 563.2 mg/L FEU and the medium was 2.1 mg/L FEU. Of them, 28 samples (2.7% of total tests) from 21 patients were found to have very high D-dimer value: >50 mg/L FEU, ranging from 51.0 to 563.2 mg/L FEU. We analyzed these 21 patients to see the underlying diseases which causing the very high D-dimer. Of the 21 patients, 9 (43%) were proved to have TED, 1 had suspected TED, but not proved by CT angiogram, 3 had massive gastrointestinal (GI) or abdominal bleeding, 2 patients had cardiac arrest with samples taken immediately after recovery from cardiopulmonary resuscitation (CPR), 1 had postpartum HEELP syndrome, 1 had hyperfibrinolysis, 1 had ALL on chemotherapy, 1 had multiple traumatic injury caused by traffic accident, 1 was after thrombolytic therapy, and 1 had sickle cell disease with acute chest syndrome with sample taken just before the patient's death. *Conclusions.* Although TED was the most

frequently seen disorders in patients with very high D-dimer value, very high D-dimer was not necessary exclusively the marker of TED. Other disorders such as massive GI or abdominal bleeding, status post CPR, multiple traumatic injuries, hyperfibrinolysis and HEELP syndrome can also have very high D-dimer.

SUCCESSFUL REMOVAL OF DABIGATRAN IN FLOWING BLOOD WITH AN ACTIVATED CHARCOAL HEMOPERFUSION COLUMN IN AN IN VITRO TEST SYSTEM

J Van Ryn,[1] M Neubauer,[2] R Flieg,[2] B Krause,[2] M Storr,[2] N Hauel,[1] H Priepke,[1] A Clemens[3]

[1]Boehringer Ingelheim Pharma GmbH & Co KG, Biberach, Germany; [2]Gambro Dialysatoren GmbH, Hechingen, Germany; [3]Boehringer Ingelheim Pharma GmbH, Ingelheim, Germany

Dabigatran etexilate is an oral direct thrombin inhibitor approved for prevention of VTE in patients after orthopedic surgery, and has shown efficacy and safety in prevention of stroke in patients with atrial fibrillation and in VTE treatment. A general limitation of anticoagulant use, particularly with chronic treatment, is the lack of a rapidly acting antidote to reverse its effects in emergency situations of overdose or uncontrolled bleeding. Dabigatran has a low plasma protein binding and thus can be dialysed. In addition, it could potentially be removed from patient blood by charcoal hemoperfusion. This was tested *in vitro* using the Adsorba™ cartridge, which contains specially activated carbon that allows hemoperfusion treatment and is clinically available for use in drug and toxin intoxifications. Dabigatran was added to 5L bovine whole blood (anticoagulated with sodium citrate) to achieve supratherapeutic concentrations (1000 ng/mL) and was pumped through a tubing system (flow rate increased every 2 hrs, between 150-350 mL/min) across a Gambro Adsorba™ cartridge (n=3 experiments). Blood pre and post Adsorba™cartridge was serially sampled at 15-30 min intervals over 6 hours. Plasma was obtained by centrifugation and frozen. Dabigatran was measured using standard LC-MS/MS methods. To test the effect of dabigatran on clotting in bovine blood an *in vitro* standard curve was also performed using routine clotting tests, thrombin time, activated partial thromboplastin time and ecarin clotting time. Initial circulating dabigatran levels in bovine blood were 1140±40 ng/mL. As blood was pumped across the Adsorba cartridge, circulating dabigatran was almost completely removed, i.e. at 15 min dabigatran pre filter levels were 710 ng/mL, this was reduced 16-fold to 42 ng/mL post filter (Fig1). Accordingly, dabigatran plasma levels in the 5 L volume decreased exponentially resulting in a ~85 % reduction when 1.8 plasma volumes were treated after 60 min and a more than 95% reduction when 3.6 plasma volumes were treated after 120 min. Dabigatran also prolonged clotting in bovine blood in a concentration-dependent manner. These data demonstrate that dabigatran can be removed from whole blood *in vitro*, by adsorption across an activated charcoal column (Adsorba™ Cartridge). Thus this may be a potential method to remove dabigatran rapidly in blood in emergency situations; however, further testing is required *in vivo* before this can be recommended for the clinic.

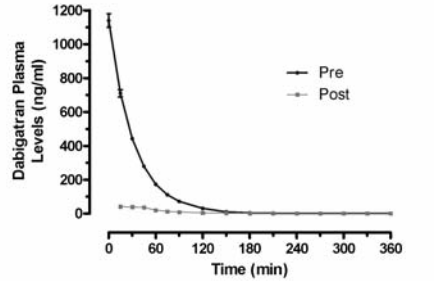

Figure 1. Mean +/- SEM, n=3 experiments.

NATIONAL REGISTRY OF THROMBOPHILIC STATES IN SLOVAK REPUBLIC

P Kubisz, J Stasko, I Plamenova, L Bartosova, J Chudej, M Dobrotova, K Gregorova

Jessenius Faculaty of Medicine, Comenius University, Martin, Slovakia

Background. Thrombophilic states (TS) are inherited or acquired hemostatic disorders associated with increased risk of thrombosis. Their most important clinical manifestation is venous thromboembolism (VTE). *Aims.* Primary goal of our project was to find out prevalence of the most frequent inherited TS in families of patients with thrombosis in Slovakia using National Registry of Thrombophilia States (NRTS). *Methods.* Patients from all regions of Slovakia with history of thrombosis and their relatives were examined for TS including FV Leiden and prothrombin mutation, protein C (PC), protein S (PS) and antithrombin (AT) defects, sticky platelets syndrome (SPS), hyperhomocysteinemia, etc. All patients were informed and agreed to participate at the database of NRTS. *Results.* There was confirmed the presence of TS in 2912 subjects of NRTS. The most frequent TS was FV Leiden mutation with prevalence of 42%, PS defect was found in 13%, prothrombin G20210A mutation in 10%, SPS in 9%, PC and AT defects in 5%. VTE was proved in 52% of TS (45% venous thrombosis and 7% combination of VT and pulmonary embolism), arterial thrombosis was present in 5% and other complication in 3% of patients. 600 patients with unexplained cause of thrombosis were examined for SPS, which was confirmed in 150 patients (25%). Summary/*Conclusions.* Our results from NRTS suggest that TS are common causes of thrombosis in Slovak population. The most frequent TS in families of patients with thrombosis are FV Leiden mutation (42%) and PS defect (13%). Interesting finding seems high prevalence of SPS in patients with unexlained thrombosis (25%). This work was supported by grants VEGA 1/0067/08, 1/0018/10 and by the European Regional Development Fund (ERDF) Project "Center of Excellence for Perinatological Research".

THROMBIN GENERATION POTENTIAL OF ACUTE PROMYELOCYTIC LEUKEMIA (APL) CELLS TREATED WITH ARSENIC TRIOXIDE (ATO) AND ALL-TRANS RETINOIC ACID (ATRA)

M Marchetti, E Diani, L Russo, D Balducci, A Falanga

Ospedali Riuniti di Bergamo, Bergamo, Italy

Background. Therapeutic approaches based on ATRA in combination with ATO are effective in curing APL and reuce chemotherapy-associated long-term complications in these patients. In addition, ATRA and ATO improve the APL life-threatening coagulopathy and affect APL cell procoagulant activity. *Aims.* In this study we evaluated, for the first time, the effect of ATRA and ATO, and of their combination, on the global APL cell (NB4) hemostatic potential as evaluated by the calibrated automated thrombogram (CAT). *Methods.* NB4 cells were incubated with either 0.1 μM ATO, 1 μM ATRA, their combination, or the vehicle (control). After 24h incubation, the NB4-TG potential was evaluated by the CAT assay in both normal pooled plasma (NPP) and factor VII-deficient plasma (FVII-DP). In parallel the levels of procoagulants [tissue factor (TF) and cancer procoagulant (CP)], anticoagulant (thrombomodulin, TM) and markers of differentiation, proliferation, apoptosis/necrosis were evaluated. *Results.* ATRA and ATRA/ATO treatment significantly reduce the TG of NB4 cells in both NPP and FVII-DP, whereas ATO only gives a slight reduction. TG potential of NB4 cells was significantly lower in FVII-DP than in NPP, confirming a major role for TF-like procoagulant activity. The residual TG activity in FVII-DP stands for the presence of FVII-independent procoagulants (i.e. CP, phospholipids). While all the treatments determined a decrease in TF and CP levels, and mainly in ATRA-treated cells, a parallel increase of TM was observed in ATRA or ATRA/ATO treated cells. Significant correlations were found between the different TG parameters and the levels of TF and CP, the rate of cell proliferation and differentiation. Summary/*Conclusions.* The pharmacological modulation of APL cell hemostatic potential by ATRA and ATO can be characterized by the CAT assay . It might possibly help to define the role *in vivo* of different TG phenotypes in the outcome of the APL-associated coagulopathy and in the patient prognosis.

0703

PROTHROMBIN ACTIVITY AND ANTIGEN IN CARRIERS OF PROTHROMBIN G20210A MUTATION

F Torelli, MG Mazzucconi, E Baldacci, F Biondo, A Cafolla, A Chistolini, F Dragoni, A Leporace, P Pignoloni, R Foà

Ematologia, Rome, Italy

Background. Patients with prothrombin G20210A mutation have higher plasma prothrombin levels than subjects with a normal genotype.The relationship of the prothrombin (Factor II) activity (FII:C) with the related antigen (FII:Ag) is poorly understood and it is unclear if the high levels of FII:Ag are correlated with high FII:C levels in subjects with

G20210A mutation. *Aims.* Aim of our study is the evaluation of the FII:C, FII:Ag and prothrombin fragments 1+2 (F1+2) in patients with prothrombin G20210A mutation as compared to a normal population. *Methods.* Subjects of our study were patients with a personal or family history of venous/arterial thromboembolic events and with G20210A mutation. Subjects without personal or family history of venous/arterial thromboembolic events and without G20210A mutation, matched for age and sex, were the control population. In patients and controls, the presence of all other markers of congenital and acquired thrombophilia were excluded. Normal ranges of FII:C and of FII:Ag were 60 -120 U/dl, and 50-150 U/dl, respectively. Normal range of F1+2 was 0.4 - 1.1 nmol/L. *Results.* We studied 63 subjects with prothrombin G20210A mutation, all cases were in the heterozygous status (Group A). Sixty-three healthy subjects without the mutation, were the control group (Group B). In Group A, the mean value of FII:C was 122.6 U/dL (SD = 18.90), the mean value of FII:Ag was 141.8 U/dL (SD= 48.20) and of F1+2 was 0.55 nmol/L (SD=0.11). In Group B the mean value of FII: C was 105.7 U/dL (SD = 12), the mean value of FII: Ag 98.6 U/dL (SD= 22) and of F1+2 was 0.59 nmol/L (SD=0.14). In Group A, the mean ratio between values of activity and antigen was 0.92 (SD=0.20) and in Group B it was 1.11 (SD=0.20). In Group A 34/63 (54%) patients showed almost one previous thromboembolic event; we compared patients with and without previous thromboembolic events: mean values of FII:C were 124.9 U/dL (SD=17) and 119.8 U/dL (SD=20.80), respectively and mean values of FII:Ag were 142.2 U/dL (SD=50.90) and 141.4 U/dL (SD=45.70), respectively; mean values of F1+2 were 0.56 nmol/L (SD=0.11), and 0.54 nmol/L (SD=0.10), respectively. Mean ratios between activity and antigen in patients with and without thrombotic events were 0.95 (SD=0.22) and 0.89 (SD=0.17), respectively. *Conclusions.* In comparison with Group B, subjects of Group A showed either higher levels of FII:Ag (P<0.000) and of FII:C (P=0<000), or a lower ratio between FII:C and FII:Ag (P<0.000). In patients of Group A with and without previous thromboembolic events, no differences concerning levels of FII:C (P=0.720), FIIAg (P=0.664), and F1+2 (P=0.097) were recorded. These data suggest that the G20210A mutation induces a procoagulant effect, but high levels of FII:Ag seem to play a greater role in comparison to the activity. In G20210A mutation carriers, we did not find any correlation between the levels of FII:C and of FII:Ag with the occurrence of thrombotic events.

0703a

GENDER BIAS OF CARDIOVASCULAR RISK IN CAUCASIAN TYPE II DIABETICS: A HAEMOSTATIC EXPLANATION?

W Quirke

Mid-Western Regional Hospital, Limerick, Ireland

Background. Cardiovascular disease (CVD) is the largest single cause of death in patients with diabetes, particularly in females.[1] The excess cardiovascular morbidity and mortality among female diabetics in developed countries has not been fully explained by conventional risk factors such as smoking, hypertension and high serum cholesterol.[2] Prospective studies in the general population have identified various haemostatic markers for the subsequent development or progression of large vessel atherosclerosis.[3,4] Evidence of increased thrombotic tendency through haemostatic parameters in a gender-specific fashion could have aetiological, preventive, and therapeutic implications in type II diabetics. *Aims.* This study examines specific parameters of the coagulation and fibrinolytic system in Irish Caucasian type II diabetics to examine their possible contribution to the increased CVD risk in diabetic females. *Methods.* A sample of 113 Irish caucasian (60 male and 53 female) type II diabetics attending the Mid-Western Regional Hospital Limerick submitted signed consent according to the protocol approved by the ethics research committee. Body Mass Index (kg/m^2), blood pressure, blood phenotype, current medications, evidence of positive family history of diabetes and any previous cardiovascular event(s) were recorded. Clinical CVD was defined as coronary heart disease, stroke, or peripheral vascular disease. Haemostatic parameters examined included Factor VII (commercial deficient FVII plasma), Factor VIII (commercial deficient FVIII plasma), von Willebrand factor (immunoturbidometric method), fibrinogen (Clauss), Thrombin Activatible Fibrinolytic Inhibitor (chromogenic method) and Plasminogen Activator Inhibitor -1 antigen (ELISA). Statistical analysis was performed using SPSS Version 16.0. A value of P<0.05 was considered to indicate a statistically significant difference. Haemostatic variables found to be significantly different between the genders were adjusted using multivariate analysis (ANOVA) for age, BMI, smoking habit, HbA1c, cholesterol, clinical CVD, hypertension, and family history of diabetes. Results. The only significant difference observed in clinical and biochemical variables was that more males were current smokers (P=0.001). Female diabetics had significantly higher unadjusted FVII levels (P=0.011) than their male counterparts (Table 1). However, following adjustment for clinical and biochemical variables, FVII was no longer significantly different between genders but significantly different between cholesterol levels (P=0.007), smoking (P=0.039) and clinical CVD (P=0.035) plus interactions between the smoking/family history of diabetes groups (P=0.043) and smoking/CVD/family history of diabetes groups (P=0.023). Unadjusted fibrinogen levels were significantly higher in females (P=0.001). However, this difference in fibrinogen according to gender was corrected without finding a single significant determinant. Although this study found significantly higher unadjusted TAFI levels in females than males (P=0.022), this difference was significantly related to total cholesterol levels (P=0.046) and was not predicted by gender. Conclusions. As the prevalence of type II diabetes continues to increase worldwide, there is an enhanced need for effective disease management. This study identifies specific traditional cardiovascular risk factors in females which may be associated with atherosclerosis through modifications of the plasma levels of certain haemostatic factors (FVII, fibrinogen and TAFI) and that haemostatic parameters do not independently contribute to the gender bias in CVD risk. Our findings provide additional support for control of lifestyle risk factors for cardiovascular health in female diabetics.

Table 1. Gender comparison of haemostatic parameters.

Parameter	Males (n=60)	Females (n=53)	*P*
FVII, %	106.8 [25.9]	118.9 [23.6]	0.011
FVIII, %	189 [141-228.5]	170 [132-214]	NS
vWF, %	136.5 [46.8]	134.9 [46.2]	NS
Fibrinogen, g/l	3.54 [0.67]	4.01 [0.76]	0.001
PAI-1 antigen, ng/ml	46.6 [13.3]	45.3 [13.9]	NS
TAFI, %	109.8 [22.5]	119.3 [20.9]	0.022

HbA1c, total cholesterol, FVIII reported as median with interquartile range. FVII, vWF, Fibrinogen, PAI-1 and TAFI reported as mean ± standard deviation. FVII differences between genders dependent on cholesterol levels (*P*=0.007), smoking (*P*=0.039), clinical CVD (*P*=0.035), smoking/family history of diabetes groups (*P*=0.043) and smoking/CVD/family history of diabetes groups (*P*=0.023). The fibrinogen difference had no single significant determinant. The TAFI difference was significantly related to total cholesterol levels (*P*=0.046) and not predicted by gender.

BIOCHEMICAL MARKERS OF BONE TURNOVER USED TO EVALUATE AND COMPARE DUAL ENERGY X-RAY ABSORPTIOMETRY (DXA) AND QUANTITATIVE ULTRASONOGRAPHY (QUS) IN BOYS WITH HAEMOPHILIA

A Christoforidis,[1] M Economou,[1] E Papadopoulou,[1] E Kazantzidou,[2] E Farmaki,[1] V Tzimouli,[1] I Tsatra,[1] N Gompakis,[1] M Athanassiou-Metaxa[1]

[1]*1st Paediatric Department, Aristotle University, Thessaloniki, Greece;* [2]*Radiology Department, Ippokration Hospital, Thessaloniki, Greece*

Background. Recent studies indicate a high prevalence of impaired bone properties in adult patients with haemophilia. Even among boys, decreased BMD values have been constantly reported and attributed to a multifactorial pathogenesis that mainly includes immobilization and increased bone turnover mediated by the secretion of pre-inflammatory cytokines due to haemophilic arthropathy. *Aims.* The aim of this study was to assess biochemical markers of bone turnover in boys with haemophilia, to investigate the pathogenesis of impaired bone quality and to compare two densitometric methods [Dual energy X-ray Absorptiometry (DXA) and Quantitative UltraSonography (QUS)]. *Methods.* Twenty-six boys with a mean decimal age of 12.08±4.44 years were included in the study. In every patient and in 13 controls serum levels of soluble receptor activator of nuclear factor κB ligand (sRANK-L), osteoprotegerin (OPG) and osteocalcin (OC) were measured. Additionally, all patients had a DXA scan performed at lumbar spine and were evaluated with QUS at radius and at tibia. Finally, joint evaluation was performed using the Hemophilia Joint Health Score (HJHS). *Results.* Boys with haemophilia had significantly higher serum levels of sRANK-L (21.04±4.78 *vs.* 18.58±2.28 ng/mL, P=0.038) and of OC (5.35±2.29 *vs.* 3.09±0.61 ng/mL, P=0.002) and significantly decreased levels of OPG (15.78±2.53 *vs.* 23.79±4.39 pg/mL, P<0.001) compared to controls. Only 2 out of 26 patients (7.7%) had Bone Mineral Density (BMD) Z-scores <-2, whereas another 4 patients (15.4%) had BMD Z-scores between -1 and -2. QUS values in both radius and tibia were generally within the normal limits as only one patient had radius and other two had tibia QUS Z-scores <-2. No agreement was recorded between QUS and DXA in identifying patients at risk for osteoporosis (k = 0.275, P=0.063) and no correlations were observed between lumbar BMD and QUS measured either at radius or tibia. QUS Z-scores at tibia were significantly correlated to HJH Scores (r=-0.450, P=0.040), whereas lumbar BMD Z-scores were significantly correlated to BMI Z-scores (r=0.500, P=0.009). Finally, multivariate analyses showed that levels of sRANK-L and OC are the most important predictors of SOS values at tibia, whereas for lumbar BMD values BMI values has the highest predictive value. Symmary/*Conclusions.* An increased osteoclastic activity followed by a compensatory osteoblastic function was indicated by biochemical markers of bone turnover, although no impaired bone properties, measured either by DXA or QUS were recorded in boys with haemophilia. No agreement was recorded between the two densitometric methods, whereas biochemical markers and HJH Score seemed to correlate more reasonably to QUS parameters measured at tibia.

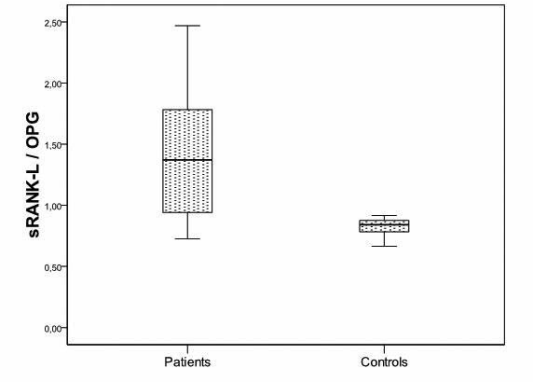

Figure 1. Significantly higher sRANK-L/OPG ratio in patients.

Background. Type 3 von Willebrand disease (VWD3) is a severe autosomal recessive inherited bleeding disorder caused by a virtually complete absence of von Willebrand Factor (VWF). Usually patients are homozygous or compound heterozygous for null alleles due to nonsense mutations, small insertions/deletions, splice site defects and, more rarely, large gene deletions. Nevertheless, several missense mutations have been reported. *Aims.* To better understand the molecular defects of VWD3, we have genetically analyzed 10 patients previously diagnosed with VWD3. *Methods.* Molecular defects of VWF were evaluated by DNA direct sequencing, High Resolution Melting (HRM) analysis and duplex PCR. Moreover, we performed *in vitro* expression studies of the missense mutations, to confirm their link with the disease. Mutant and wild-type (WT) expression vectors were used for transient transfection, alone and together (hybrids), in COS-7 cells. Conditioned media and cell lysates were collected and recombinant VWFs (rVWFs) were quantified by VWF: Ag and evaluated for multimeric structure. *Results.* Twenty-six exons were analyzed by direct sequencing whereas, the remaining twenty-five were evaluated by both HRM and sequencing analysis. Direct sequencing (see table) revealed eleven mutations (shown in italics); HRM analysis detected two defects (shown in bold) and one large deletion was identified by duplex PCR. Nine out of thirteen identified mutations were novel (*), which are 5% of VWD3 previously reported mutations. Four patients were found to carry mutations in the homozygous state, but only two of them were found to be born from a consanguineous marriage. The large deletion involving exons 1-3, recently reported as the most frequent in the Hungarian population, was found in two patients. Expression studies of missense mutations (C2184S, C2212R and C2325S) showed a strongly reduced secretion of mutant proteins, with only dimers being visualized using multimer analysis. Hybrids rVWFs showed mildly reduced secretion and a full set of multimers. Higher VWF: Ag levels were detected in cell lysates of mutants and hybrids rVWFs in comparison to the WT. *Conclusions.* HRM analysis, used for the first time in the molecular diagnosis of VWD3, shows a reduced ability in detecting mutations on VWF. The presence of many polymorphic sites in the VWF coding region has, so far, limited the use of this technique to twenty-five exons of the gene only. The three detected missense mutations were confirmed to be disease related by expression studies. All of them involve a cysteine residue, important in the correct folding/processing/secretion of the neo-synthesized VWF. Further analysis should be performed on the two partially characterized patients to evaluate intronic mutations or heterozygous large deletions, whereas, mRNA analysis should be carried out to confirm the candidate splice site mutations identified.

HLA GENOTYPING IN CHILDREN WITH SEVERE HAEMOPHILIA A AND RELATION TO INHIBITORS DEVELOPMENT

H Pergantou,[1] O Moraloglou,[2] K Spanou,[2] Z Kapsimali,[3] I Varela,[2] N Constantinidou,[2] H Platokouki[3]

[1]Aghia Sophia Children's Hospital, Athens, Greece; [2]Department of Immunology-Histocompatibility, Aghia Sophia Children's Hospital, Athens, Greece; [3]Haemophilia Centre/Haemostasis Unit, Aghia Sophia Children's Hospital, Athens, Greece

Background. Alloantibodies (inhibitors) against FVIII in severely haemophilia A (HA) affected patients (20-30%) represent a major complication of treatment, affecting patient's care, by rendering FVIII substitution therapy ineffective. Inhibitors development seems to be multifactorial and is based on complex immunological factors. Genetic factors, such as the type of FVIII gene mutation and immune response genes, e.g major histocompability complex, influence the risk of inhibitor formation. *Aim/Materials/Methods.* To investigate a possible correlation between FVIII gene intron-22 inversion and HLA factors with the risk for inhibitors development, we performed Long Range PCR for detection of intron-22 inversion and PCR-SSP and PCR-SSO for genotyping of HLA A, B, Cw, DRB1 and DQB1 alleles in 38 children with severe HA, exclusively treated with recombinant products (PUPs). X2 test and Fischer's exact test were used for statistical analysis. *Results.* On the whole, 19 patients had developed inhibitors (Group I) 13 of them high responding, while 19 had not (Group II). There were no statistically increased intron-22 inversion frequencies in the inhibitor positive group: 17/38 (44.7%) children were found positive for intron-22 inversion and nine of them were positive for inhibitors (high titre: 7, low titre: 2). Comparing frequencies of HLA alleles between Group I and Group II, statistical significant differences were found in the following genotypes promoting inhibitors development: DRB1*0101(P=0.016) and DQB1*0501 (P=0.017, OR=10.5) while a trend revealed regarding alleles DRB1*01 (P=0.08), DRB1*1302 (P=0.071), and DQB1*0601 (P=0.075). On the other hand, the following HLA alleles seemed to confirm protection from inhibitors development: HLA-B*18 (P=0.056), DRB1*11 (P=0.009, OR=6.1), DQB1*03 (P=0.004, OR=7.8) and DQB1*0301 (P=0.009, OR=6.1). *Conclusion.* The HLA genotyping in our study shares in common findings with other studies in Caucasian haemophilic population. Nevertheless, some differences observed between the present and some previously reported HLA associations in HA patients with inhibitors could be attributed to the varying ethnic immunogenetic profile. The biological significance of HLA associations in clinical application has to be prospectively confirmed, in order to prevent inhibitor development by modifying treatment strategies.

INTRA-ETHNIC AND FAMILY STUDIES OF THE INHERITANCE OF GENE MUTATIONS IN GLANZMANN THROMBASTHENIA USING AN EMERGING METHOD: HIGH RESOLUTION MELTING CURVE ANALYSIS

A. Nurden, X Pillois, M Fiore, H Fernandes, P Nurden

CRPP/PTIP, Pessac, France

Background. High Resolution Melting (HRM) curve analysis is a new, homogeneous, closed-tube, post-PCR method, permitting the identification of genetic variations in PCR amplicons. It uses a generic DNA fluorescent dye at high, saturating, concentration with homogeneous staining of dsDNA, without inhibiting the PCR reaction. Samples can be discriminated according to their sequence, length, GC content or strand complementarity. Our investigations have focused on Glanzmann thrombasthenia (GT), an autosomal recessive bleeding disorder caused by quantitative and/or qualitative deficiencies of the αIIbβ3 integrin encoded by the ITGA2B (30 exons) and ITGB3 (15 exons) genes. Classically, GT patients are homozygous or compound heterozygous for nonsense or missense mutations, small insertions or deletions and splice site defects that occur across both genes. Current screening for GT is expensive and slow; for most new families it requires sequencing of all exons and their splice sites. *Aims.* To test the relevance and the accuracy of HRM in genetic diagnosis for four known molecular variations of GT, in two different contexts: ethnic and familial inheritance. *Patients and Methods.* Studied were DNA samples from nine French families (25 subjects), including members of seven families from a gypsy ethnic group. Mutations screened, were the c.1544+1G>A transversion in intron 15 of ITGA2B, also called the 'Gypsy' mutation, leading to abnormal RNA splicing, a truncated protein and absent αIIbβ3 in platelets; a c.685T>C transition in exon 5 (ITGB3), leading to a Leu196Pro substitution and a functionally defective integrin; c.724C>T in exon 5 (ITGB3) giving a stop codon (Arg216X); and c.1871G>A in exon 11 (ITGB3) giving a Cys598Tyr substitution and a partially activated integrin. Conditions were established for HRM analysis on a ROCHE Light Cycler 480 apparatus, and all results were confirmed by direct sequencing. A control DNA sample was included in all experiments; it was also mixed with patient samples to reveal potential hetero-duplex complexes. *Results.* HRM analysis was successfully performed for all subjects. For families of gypsy origin, it identified 8 homozygous subjects, 5 heterozygous and 6 without the intron 15 c.1544+1G>A transversion on either chromosome. Heterozygosity for the c.685T>C transition in exon 5 of the ITGB3 gene previously detected in a patient with variant GT, was confirmed by HRM in all three members of his family. In contrast, a second c.1871G>A transition in exon 11, and was only present in the propositus who was therefore a compound heterozgote. This co-inheritance of qualitative inhibitory (β3 Leu196Pro) and partially activating (β3 Cys598Tyr) substitutions is unique in GT. A third unrelated GT patient also possessed the latter mutation, but was compound heterozygote with a separate exon 5 mutation giving a stop codon. HRM analysis permitted the rapid screening of all mutations including the presence of different exon 5 transitions. It also allowed SNP comparison between the two genes in different families. *Conclusions.* HRM provides an accurate and inexpensive same-day tool for studies on mutation inheritance and genetic diagnosis in GT. It detects the penetration of known mutations within families and will speed up prenatal diagnosis of defined GT genotypes.

ANALYSIS OF PERIPHERAL BLOOD CD4$^+$CD25$^+$T CELLS IN PATIENTS WITH ACQUIRED HEMOPHILIA A: IT HAS CORRELATION TO THE CLINICAL SEVERITY AND TREATMENT EFFICACY?

CC Zheng, JS Wu, KY Ding

Anhui Provincial Hospital, Anhui Medical University, Hefei, China

Background. Immunoregulatory CD4$^+$CD25$^+$ T cells play an important role in the induction and maintenance of peripheral self-tolerance. These professional regulatory cells prevent the activation and proliferation of potentially autoreactive T cells that have escaped thymic deletion. Therefore, we believed that CD4$^+$CD25$^+$ T cells possibly play an important role in acquired hemophilia A (AHA). *Aims.* The aim of this study was to explore the profile and function of CD4$^+$CD25$^+$ regulatory T cells in AHA patients, and to explore the correlation between the level of CD4$^+$CD25$^+$ regulatory T cells and clinical situations. *Methods.* We measured the count of CD4$^+$CD25$^+$ T cells in 10 patients diagnosed as AHA from January 2002 to December 2008 in our hemophilia center. Treg cell numbers were analyzed by flow cytometric analysis in peripheral blood mononuclear cells collected from patients with AHA or healthy donors. According to the titer of inhibitor, we divided these patients into two groups: low responders (≤5 Bethesda units, n=4) and high responders (>5 Bethesda Unit, n=6). Three low responders and all high responders were treated with immunosuppressive therapy such as prednisone (1 mg/kg/d) and/ or cyclophosphamide (200 mg/d), three high responders patients also received high-dose intravenous immunoglobulin (IV IG, 0.4g/kg/d, 5 days). We evaluated the CD4$^+$CD25$^+$ T cells dynamic changes in low responders, high responders and patients obtained partial remission (PR) and complete remission (CR). *Results.* Mean factor VIII level was 5.13 IU/dl (0.16-27.34IU/dl), mean titer of inhibitor was 17 BU (0.85- 65 BU). The percentage of CD4$^+$CD25$^+$ T cells was significantly lower in AHA patients in the active phase or non-remission state (4.23±1.35%). However, the percentage of those cells increased in the patients at the remission phase, including CR and PR (10.96±3.24%), especially after immunosuppressive treatment, which was similar to healthy subjects (13.63±4.56%). CD4$^+$CD25$^+$ T cells counts in high responders (2.75±0.56%) were lower than low responders (6.45±2.05%). But after treatment, all patients'CD4+CD25+ T cells increased, seven patients (all low responders and three high responders) obtained CR with CD4$^+$CD25$^+$ T cells of 12.16±4.11%, three high responders obtained PR with CD4$^+$CD25$^+$ T cells of 8.92±2.96%. *Conclusions.* These results suggested that decreased number of CD4$^+$CD25$^+$ T cells in AHA patients without effective treatment. The number of CD4$^+$CD25$^+$ cells closely correlated with the factor VIII level and inhibitor titer, and would be increased when immunosuppressive treatment was effective. CD4$^+$CD25$^+$ T cells might be one of mechanisms that cause immune regulation dysfunction in AHA, and the count of CD4$^+$CD25$^+$ T cells is considered to possibly be related to the severity of AHA.

0709

SEROPREVALENCE OF HEPATITIS A VIRUS IN EGYPTIAN CHILDREN AND ADOLESCENTS WITH HEMOPHILIA A: SAFETY AND IMMUNOGENICITY OF SUBCUTANEOUS HEPATITIS A VACCINE

A Tantawy, I AlGohary, S Abdel Ghani, S El Hadary

Faculty of Medicine,Ain Shams University,Cairo,Egypt, Cairo, Egypt

Background. Hepatitis A is a highly contagious infectious liver disease prevalent in Egypt , however hepatitis A vaccine is not routine compulsory vaccine. Transmission of hepatitis A virus (HAV) is primarily via the faeco-oral route; however hemophiliacs are at risk of transmission through clotting factor concentrate, particularly products inactivated by solvent-detergent purification. *Aim.* The aim of this study was to evaluate the seroprevalence of hepatitis A in non vaccinated Egyptian children and adolescents with hemophilia A as well as the safety and immunogenicity of subcutaneous hepatitis A vaccine in hemophilia patients. *Methods.* 182 male children and adolescents (aged 2-18 years) were studied,including 82 patients with moderate and severe hemophilia A (mean age 9.49±4.26 years) and 100 healthy controls (mean age 8.67±3.97 years). All did not receive prior hepatitis A vaccination and had no clinical history suggestive of hepatitis . After informed consent was taken from patients or their guardians, screening for anti-HAV antibody (IgG and IgM) was done by microparticle enzyme immunoassay using Abbott AxSYM analyzer. Seronegative patients received hepatitis A vaccine (HAVRIX,GlaxoSmithKline) at a dose of 720 Elisa Units at 0 and 6 months, given subcutaneous in hemophiliacs (without prophylactic factor replacement) and intramuscular for controls.Seroconversion rate was assessed in vaccinated children 2 months after the second vaccine dose by anti-HAV antibody IgG. Anti-HAV IgM was assessed at month 7 to exclude acquired hepatitis A infection in vaccinated children. *Results.* Seroprevalence of HAV antibody was 87.6% among hemophilia patients and 90% among the control group. Seronegative children(mean age 4.4±3.71 years) were significantly younger than seropositive children (mean age 10.2±3.86 years), P<0.01. Hepatitis A vaccine was given to 10 non immune hemophilia patients (SC) and 10 controls (IM). The vaccine was well tolerated by both groups with minor local side effects including pain in 40% and erythema in 20% of hemophiliacs *vs.* 20% for pain and erythema in the control group. No swelling or bruising was reported. As regards immunogenicity, all patients and controls developed seroconversion 2 months after the second dose ; there was no significant difference between both groups as regards the titre of anti- HAV IgG (351.4±65.0IU/L for hemophiliacs and 367.0±132.3IU/L for controls), P>0.05. *Conclusion.* Hepatitis A virus infection occurs early in life in Egyptian children , necessitating hepatitis A vaccination in early life especially in highly vulnerable patients as hemophiliacs.The vaccine is safe and effective when given subcutaneously in children with hemophilia.

0710

A NOVEL WHOLE PLATELET ELISA FOR THE DIAGNOSIS OF GLANZMANNS THROMBASTHENIA

D Shetty, V Lobo, B Kulkarni, K Ghosh

National Institute of Immunohaematology, Mumbai, India

Glanzmann's thrombasthenia is a rare autosomal recessive bleeding disorder, caused by a quantitative or qualitative defect of the platelet glycoprotein GPIIb-IIIa receptors with bleeding due to defective platelet haemostatic plug formation. There are various methods which are used for diagnosis of Glanzmann's thrombasthenia. Some of the methods are clot retraction, flow cytometry analysis, platelet aggregation studies, mutation analysis, dot blot analysis. These methods have their own advantages and disadvantages and these methods have their own flaws in detection of heterozygotes in Glanzmann's thrombasthenia. In this study, we describe an experiment of standardization of enzyme linked immunosorbent assay (ELISA) for detection of index cases as also heterozygotes in Glanzmann's thrombasthenia and then diagnosis of known and unknown heterozygotes in Glanzmann's thrombasthenia. The principle of sandwich ELISA was used as the final protocol during standardization of the above technique. The receptor glycoprotein GPIb/IIIa present on the surface of platelets acted as 'target antigens'.Fresh blood samples were obtained from the patients as well as from the controls and platelets isolated by using PGE1 and coated on to the wells. On the first day, 100 μL of 1:100 Anti CD36 dilutions was added to each micro titre well and then this plate was properly covered with a lid and incubated overnight at 40 C. On the second day the platelets are isolated and then resuspended in the RCD buffer and the count adjusted to 70,000/μL using the coulter counter. Subsequently the dilutions of the neat concentration of the platelets are carried out, the incubated plate is then flicked to remove excess of anti-CD36, and 100μl of each dilution of the platelet is added to the wells and incubated overnight at 40 C. On the third day, the wells were washed once using PBS-Tween20 and 100 μL of 1:100 echistatin conjugated with alkaline phosphatase was added to each well and then incubated for an hour at room temperature. After an hour the wells were washed once and 100μl of substrate is added and incubated at room temperature in dark for an hour. The OD was checked at 405 nm using an ELISA plate reader.The present study is the first ever to diagnose Glanzmann's thrombasthenia and the heterozygotes in GT using a whole platelet ELISA technique. From this standardized protocol, we were able to diagnose 8 known heterozygotes 2 unknown heterozygotes for GT. 30 controls were used for this study. The diagnosis of a heterozygote carrier of GT or variant type II GT can be made with a high probability using this ELISA.

HIGH PREVALENCE OF ARGININE HOT SPOT MUTATIONS IN INDIAN SEVERE VWD PATIENTS

P Kasatkar, S Shetty, K Ghosh

National Institute of Immunohaematology, Mumbai, India

Von Willebrand disease (VWD) is the most frequent inherited bleeding disorder caused by qualitative and or quantitative abnormalities of the von Willebrand factor (VWF). Mutation detection in VWF gene is quite challenging due to its large size (180 Kb), heterogeneous nature of mutations and the presence of a partial unprocessed pseudogene in chromosome 22 with 97% homology. In this study we adopted an initial strategy for screening for 11 CGA Arginine codons of the VWF gene in 78 unrelated severe VWD patients from all over India. 15 nonsense mutations were detected in exon 8, 9, 18, 28, 31, 43 and 45 by PCR-RFLP technique. Direct mutation detection by RFLP analysis in hot spot regions is the most simple, less time consuming and cost effective method especially in VWF gene which comprises of 52 exons and screening for mutation in type 3 VWD is difficult since mutations are not confined to the specific regions as in case of other VWD subtypes. We could detect 11 homozygous (1 each in exon 9,18, 28 and 45, 2 in exon 8, 43 and 3 homozygous in exon 31) and 4 (1 in exon 10, 18 31 and 45) heterozygous mutations by this relatively simple technique and thus report high prevalence (21%) of arginine hot spot mutations in Indian population. The study is significant in that most of the diagnoses are being based on the indirect method of gene tracking analysis which has limitations like noninformativeness of the markers, need for the index case and so on. Direct mutation detection by simple PCR RFLP technique can give an accurate diagnosis in approximately around 1/5 of the severe VWD cases without going for the more extensive and expensive mutation screening and sequencing techniques.

0712

LIVER TRANSIENT ELASTOGRAPHY (FIBROSCANNING) IS USEFUL IN THE ASSESSMENT OF LIVER FIBROSIS IN HEPATITIS C INFECTED PATIENTS WITH INHERITED BLEEDING DISORDERS

E Nikolousis, T Dunkley, D Mutimer, T Dudley, J Wilde

University Hospital Birmingham, Birmingham, UK

The accurate assessment of the degree of hepatic fibrosis is crucial for treatment decisions and prognosis in patients with inherited bleeding disorders infected with Hepatitis C (HCV). Transient elastography (fibroscanning) has recently been developed as a non-invasive alternative to liver biopsy. The technique assesses liver stiffness, a reflection of the degree of hepatic fibrosis. The introduction of fibroscanning has encouraged patients who have previously had concerns over the safety of liver biopsy to request active HCV management. 34 hepatitis C-infected haemophilia patients (33M, 1F) with a median age of 43 years (range 26-70) were assessed by fibroscan. Diagnoses: Haemophilia A(29), Haemophilia B(2), von Willebrand's disease (2, 1 type 2A, 1 type 3).12 patients were coinfected with HIV. 23 patients had not previously undergone HCV treatment. 10 of 11 patients who had previously received treatment with ribavirin and PEG interferon had persistent HCV infection. The breakdown of scores in the patients was as follows: score <7.0 (no or very mild fibrosis - Metavir classification F0-F1) n = 13, score 7.0 to 9.5 (significant fibrosis F2) n = 10, score >9.5 to 12.5 (severe fibrosis F3) n = 3, score >12.5 (cirrhosis F4) n=4. A fibroscan score was unobtainable in four patients because of a high BMI. Therefore encouragingly 43% of this cohort had fibroscan scores consistent with no or very mild fibrosis at least 30 years from acquisition of HCV

infection. Fibroscanning is a non-invasive alternative to liver biopsy in the assessment of HCV associated fibrosis in patients with hereditary bleeding disorders. The fibroscan score provides valuable information in the management of this patient group enabling decisions to be made such as whether or not to embark on eradication therapy or to await the new anti HCV medications.

0713

PROTHROMBIN MUMBAI: NOVEL CYS90PRO MUTATION IN A FAMILY

B Kulkarni,[1] S Kanakia,[2] S Shetty,[1] K Ghosh[1]

[1]National Institute of Immunohaematology, Mumbai, India; [2]Advanced Blood & Cancer Disorders, Lilavati Hospital, Mumbai, India

Coagulation factor II (F2) is proteolytically cleaved to form thrombin in the first step of the coagulation cascade which ultimately results in the stemming of blood loss. F2 also plays a role in maintaining vascular integrity during development and postnatal life. Mutations in F2 leads to various forms of thrombosis and dysprothrombinemia. Thrombin, which cleaves bonds after Arg and Lys, converts fibrinogen to fibrin and activates factors V, VII, VIII, XIII, and, in complex with thrombomodulin, protein C. We report here a novel mutation in Human Prothrombin (Factor II) gene in a family originating in Nepal. A four and half months old female child, born of non-consanguinous marriage to a 25 years old lady, was referred as a case of bleeding disorder with history suggestive of acute intracranial haemorrhage. At 21 hrs of life she developed hematemesis and was treated with Vit K for 3 days. Baby developed bleeding from umbilical stump for which surgical ligation was done and FFP and Vit K was given by the treating clinicians. FXIII clot stability test was normal. At 3 months of life, baby developed Intracranial bleed. CT brain showed Rt SDH with marked mass effect and Rt. occipital lobe hematoma. Prothrombin Time (PT) was 27/14.5, APTT was 40/23-35, Thrombin Time (TT) was 18/15 and Fibrinogen was 222gm/dl (normal). Factor II (Prothrombin) was found to be <1% on assay, with other factors within normal limits. DNA sequencing of all 14 exons of Factor II gene showed a G>C homozygous variation in exon 4, which caused a Cys90Ser mutation. Both the parents showed a heterozygous G>GC change. Bioinformatics tools such as the Panther classification system (Protein ANalysis THrough Evolutionary Relationships), Polyphen (Polymorphism phenotyping) and SIFT (Sorting Intolerant from Tolerant) suggested that this is a deleterious variation and has not been reported in Ensembl genome browser to detect reported nucleotide variations. Clustal W multiple sequence alignment analysis was done to look for the conservation status of the residues across mice to primates and humans. It showed that Cys90 is highly conserved across these species. Uniprot consortium shows that residue Cys90 lies just outside the Gla (gamma-carboxy-glutamate) domain and is involved in a disulfide bond with Cys103. The severe clinical manifestations that the baby had correlate well with the mutation detected and the deleterious effects it is predicted to cause. This family has been subsequently counseled for a possible antenatal diagnosis for the next pregnancy.

0714

DIRECT DETECTION OF HEMOPHILIA B F9 GENE MUTATION WITH MULTIPLEX PCR AND CONFORMATION SENSITIVE GEL ELECTROPHORESIS

YK Yoo,[1] SG Park,[2] SG Kim,[3] EJ Choi,[4] HJ Kim[5]

[1]Korea Hemophilia Foundation, Seoul, South-Korea; [2]Department of Pediatrics, Ulsan Medical College, Ulsan, South-Korea; [3]Department of Pediatrics, Inha Medical College, Incheon, South-Korea; [4]Department of Pediatrics, Daegu Catholic School of Medicine, Daegu, South-Korea; [5]Department of Laboratory Medicine & Genetics, Samsung Medical Center, Seoul, South-Korea

Background. The F9 gene is known to be the causative gene for hemophilia B, but unfortunately the detection rate for restriction fragment length polymorphism (RFLP) -based linkage analysis is only 55.6%. Direct DNA sequencing can detect 98% of mutations, but this alternative procedure is very costly. *Aims.* Here we conducted multiplex PCR-conformation sensitive gel electrophoresis (CSGE) screened DNA sequencing for the F9 gene and compared the results with direct sequencing in terms of accuracy, cost, simplicity and time consumption. *Methods.* A total of 27 unrelated hemophilia B patients was enrolled. Direct DNA sequencing was performed for 27 patients by a separate institute, and multiplex PCR-CSGE screened sequencing in our laboratory. Results of the direct DNA sequencing were used as a reference and the results of the multiplex PCR-CSGE screened sequencing were compared with them. For the patients whose mutation was not detected by the 2 methods, multiplex ligation-dependent probe amplification (MLPA) was conducted. *Results.* With direct sequencing, the mutations could be identified from 26 patients (96.3%), whereas for multiplex PCR-CSGE screened sequencing, the mutations could be detected of 23 patients (85.2%). One patient's mutation was identified by MLPA. A total of 21 different mutations was found among the 27 patients. Multiplex PCR-CSGE could reduce the cost of detection by 55.7% compared with direct DNA sequencing, but this technique was more labor-intensive and time-consuming as it required an extra day. Summary. Multiplex PCR-CSGE screened DNA sequencing detected 88.9% of mutations and reduced costs by 55.7% compared with direct DNA sequencing. But it was more labor-intensive and time-consuming.

GENOTYPIC AND PHENOTYPIC CHARACTERIZATION OF FACTOR VII DEFICIENCY PATIENTS FROM NORTH-EAST HUNGARY

Z Bereczky,[1] C Kiss,[2] G Pfliegler,[3] I Szegedi,[2] Z Boda,[4] L Muszbek[5]
Are equal opportunity first authors

[1]University of Debrecen, Medical and Health Science Center, Debrecen, Hungary; [2]Pediatric Hematology-Oncology, University of Debrecen, MHSC, Debrecen, Hungary; [3]Division of Rare Diseases, University of Debrecen, MHSC,, Debrecen, Hungary; [4]Division of Hemostaseology, University of Debrecen, MHSC, Debrecen, Hungary; [5]Clinical Research Center, University of Debrecen, MHSC, Debrecen, Hungary

Background. Congenital Factor VII (FVII) deficiency is one of the most frequent disorders among rare coagulopathies. The molecular genetic background is heterogenous; no so-called mutation hot spot can be identified within the gene of FVII (F7). No report has been available so far on the mutation profile of Hungarian patients. *Aims.* The aim of the study was to give an overview on the spectrum of mutations of F7 and on genotype-phenotype associations in Hungary. *Methods.* We analyzed 14 unrelated patients with FVII deficiency and their family members living in North-East Hungary for mutations in F7 by direct DNA sequencing of the coding region of the gene including exon-intron boundaries. Clinical symptoms, hemostasis laboratory results and treatment modalities were recorded and related to molecular genetic findings. *Results.* A total of 7 different mutations (6 point mutations and 1 small deletion) were identified, of which 2 were novel (p.E7G and p.C368F). The p.E7G mutation affects one of the glutamic acid residues involved in the gamma-carboxylation process suggesting functional defect of FVII. The p.C368F mutation locates in the catalytic domain where Cys368 forms a disulfide bridge with Cys340. The amino acid exchange to Phe368 suggests the disruption of this disulfide bridge and misfolding of the protein. Patients with severe laboratory phenotype (FVII activity < 1%) were homozygotes or compound heterozygotes. Patients or family members with heterozygous mutations exhibited mild symptoms or were silent carriers. Combined coagulopathy was found in two families, where besides FVII deficiency heterozygous factor X deficiency was also diagnosed. *Conclusion.* The genetic background of FVII deficiency is heterogenous even in the presented small cohort of patients from North-East Hungary. Most of the patients carried more than one causative mutation. In some patients a weak correlation could be demonstrated between the severity of bleeding symptoms, laboratory phenotype and the underlying genetic alterations.

IDENTIFICATION OF FUNCTIONAL DOMAINS AND NOVEL BINDING PARTNERS OF STIM PROTEINS

N Saitoh,[1] K Oritani,[1] K Saito,[2] T Yokota,[1] M Ichii,[1] T Sudo,[1] N Fujita,[1] M Okada,[3] Y Kanakura[1]

[1]Graduate School of Medicine, Osaka University, Suita, Osaka, Japan; [2]DNA-chip Development Center for Infectious Diseases, Osaka University, Suita, Osaka, Japan; [3]Research Institute for Microbial Diseases, Osaka University, Suita, Osaka, Japan

Background. Store-operated $Ca2^+$ entry, which is triggerd by the depletion of endplasmic reticulum (ER) $Ca2^+$ stores, is essential for the refill of $Ca2^+$ in ER and the cytokine/hormone-induced sustained increase of intracellular $Ca2^+$. In immune cells, stromal interaction molecule (STIM) proteins, which are unique sensors of ER $Ca2^+$ changes, have been believed to initiate store-operated $Ca2^+$ entry and to play pivotal roles in various cellular events, such as gene expression, cell activation, and differentiation. Indeed, the destruction of both STIM1 and STIM2 genes leads to the impairment of regulatory T-cell development. In addition, patients with homozygous nonsense mutations in STIM genes show phenotypes of immunodeficiency and/or autoimmunity. Thus, there is accumulating evidence that STIM proteins are involved in immune systems. Although expanding information is available for biochemical and physiological properties of STIM proteins, little is known about the domain functions of STIMs and their association molecules, which could help us understand not only why STIMs can display their specific functions but also what molecules control their localization and protein content in cells. AIMS Aims of this study are to clarify domain functions of STIM1 and to identify STIM1- associated molecules. Methods/Results. We constructed a series of deletion mutants of STIM1; STIM1(EX, EX+TM, EX+TM+CC, Full), where "EX" means extracellular domain, "TM"means transmembrane domain, "CC"means coiled-coil domains, and "Full"means full length of STIM1. First we examined protein trafficking of each mutant. After surface proteins on each transfectant were labeled with biotin, the cell lysates were analyzed with western blot using HRP-streptavidin. STIM1(EX+TM) was massively expressed on the cell surface, while surface-expressed STIM1(EX+TM+CC) and STIM1(Full) were only faintly detected. In addition, analysis with confocal microscopy revealed that only STIM1 mutants containing the coiled-coil domains, STIM1(EX+TM+CC) and STIM1(Full), aggressively accumulated in ER. Then we evaluated protein stability of each STIM1 mutant with 35S-methionine pulse-chase experiments. Estimated half life of STIM1(Full) was approximately 19 hours, similar to that of STIM1(EX+TM+CC). However, STIM1(EX+TM) disappeared more rapidly. Therefore, the coiled-coil domains of STIM1 is likely to yield its ER-retention and protein stability. To identify STIM1 associated molecules comprehensively, we performed co-immunoprecipitation experiments combined with mass spectrometry. After 293T cells were transfected with STIM1(Full)-FLAG, the cell lysates from each transfectant were subjected to immunoprecipitation with anti-FLAG antibody. After visualization of the immunoprecipitated proteins in the gel with silver staining, several specific bands were detected. Each specific band was subjected to mass spectrometry analysis. This screening identified calnexin, an ER-resident chaperone as a novel STIM-associated protein. The association was also confirmed with co-immunoprecipitation experiments. Importantly, the interaction between STIM1 and calnexin was independent on N-glycosylation, which calnexin generally recognizes. Therefore, STIM1 is likely to bind to calnexin in a specific manner. Summary/Conclusions. Our data suggest that the coiled-coil domains of STIM1 is involved in its ER-retention and protein stability and that calnexin is a novel STIM1-associated molecule. These findings might be useful to discuss unique characteristics of STIM1 proteins.

A CELL-DEATH-DEFYING FACTOR, ANAMORSIN, CONTRIBUTES CELL GROWTH THROUGH INACTIVATION OF P38 MAPK

Y Saito,[1] H Shibayama,[1] H Tanaka,[1] A Tanimura,[1] I Matsumura,[1] Y Kanakura[2]

[1]Osaka university Graduate School of Medicine, Suita,Osaka, Japan; [2]Osaka University Graduate School of Medicine, Suita, Osaka, Japan

Background. Anamorsin (also called CIAPIN-1) is a cell-death-defying factor, which was originally isolated as a molecule that conferred resistance to apoptosis induced by growth factor starvation. Anamorsin is ubiquitously expressed in various organs, including hematopoietic tissues like bone marrow, spleen, and thymus. Anamorsin-deficient mice die in late gestation. Anamorsin-deficient embryos are anemic and the size of the embryos is very small. It is thought that anamorsin plays a crucial role in hematopoiesis during late and/or terminal stages of differentiation. Anamorsin does not show any homology to known apoptosis and cell growth regulatory molecules such as Bcl-2 family, caspase family, or signal transduction molecules.(J Exp Med 199: 581-592, 2004) However, the precise biological effects of anamorsin remained unclear. *Methods and Results*. In an attempt to clarify the biological effects of anamorsin, we here tried to determine the signaling pathways by using murine embryonic fibroblast (MEF) cells produced from E-14.5 anamorsin-deficient or wild type embryos. The proliferation of anamorsin-deficient MEF cells was quite reduced compared with the wild type MEF cells. It is found that the phosphorylation status of ERK1/2, NFκB, and AKT were similar both in anamorsin-deficient MEF cells and wild type MEF cells, while p38 MAPK was more phosphorylated in anamorsin-deficient MEF cells than wild type MEF cells. P38 MAPK was also more phosphorylated in the stimulation of PMA, the PKC activator. Furthermore, the expression of cyclin D1, the target molecule of p38 MAPK, was down-regulated in the anamorsin-deficient MEF cells. The p38 MAPK inhibitor, SB203580, up-regulated the expression of cyclin D1 and partially restored the proliferation of the anamorsin-deficient MEF cells. Based on these data, it was thought that p38 MAPK activation reduced the cyclin D1 expression, thereby, resulting in the growth retardation of the anamorsin-deficient MEF cells. Conclusion. P38 MAPK, the stress activated MAPK, has been known to link to cell differentiation, growth inhibition and apoptosis, and also to be essential for survival in response to various stimuli. Moreover, p38 MAPK can contribute to the induction of G1/S and G2/M cell cycle check point. The growth of the anamorsin-deficient mice is quite retarded, and the hematopoiesis of the mice is also impaired. Our study suggests that p38 MAPK might play important roles in the cell proliferation, survival, and differentiation of the anamorsin-deficient cells.

MESENCHYMAL STROMAL CELLS INDUCE A CD4+CD25HI REGULATORY T-CELLS WITH HIGHER LEVELS OF CD73/ECTO-5-NUCLEOTIDASE THAN NATURALLY EMERGING CD4 CD4+CD25HI REGULATORY T-CELLS

F Saldanha-Araujo,[1] R Panepucci,[1] F Ferreira,[2] A Araujo,[1] M Orellana,[1] C Menezes,[1] P Palma,[1] R Queiroz,[2] D Covas,[1] M Zago[1]

[1]INCTC-Fundherp, FMRP-USP, Ribeirão Preto, Brazil; [2]FCFRP-USP, Ribeirão Preto, Brazil

Background. Mesenchymal stromal cells (MSCs) exert an immune regulatory function and suppress T-cell proliferation *in vitro* and *in vivo*, but at present, the mechanisms underlying this property are not completely known. One of the ways by which MSCs may modulate immune responses is by the induction of regulatory T cells (Treg). Generation of adenosine by CD73 mediates the imunosupressive capacity of naturally emerging Treg. Adenosine exerts several physiological effects though the interaction with four adenosine receptors. Moreover, adenosine levels are controlled by its convertion to inosine by the enzyme Adenosine Deaminase (ADA). Furthermore, biding of ADA to CD26 is capable of reducing the local concentration of adenosine and protects T cells from suppression. Several studies clearly show the role of adenosine as a T-cell immune modulator, mainly by activation of A2A receptor (AR A2A). Besides, AR A2A signalizing induces IL-10 production, an important immunoregulatory cytokine. *Aims.* To evaluate the involvement of adenosine signaling components in the immunomodulation promoted by MSCs. *Methods.* Peripheral blood $CD3^+$ T cells from 3 individuals were activated by anti-CD3/CD28 beads, cultured for 5 days either in the presence or in the absence of MSC (5:1). Following this period, $CD4^+$ cells were immunomagnetically purified and evaluated by RT-PCR for the expression of ADA, AR A2A and IL-10. In addition, periph-

eral blood CD3+ T cells from other 3 individuals were similarly activated and cultured. Following a 5 day period, ADA activity and adenosine levels were analyzed in culture medium by colorimetric assay and high performance liquid chromatography (HPLC), respectively. Percentage of CD26+ and CD73+ cells was accessed by flow cytometry on T cells cultivated or not with MSC. *Results.* As expected, proliferation of T cells co-cultured with MSC was significantly inhibited (BrdU incorporation assay). In line, T cells co-cultured with MSC showed higher level of AR A2A and IL-10, and lower level of ADA than lymphocytes cultured alone. Moreover, ADA activity was higher in culture medium from T-cells cultivated with MSCs and despite that, the extracellular levels of adenosine were higher in T-cells cultivated with MSCs compared to T cells cultivated alone (although not statistically significant). The percentage of CD26 in CD4 T-cells co-cultured with MSC was lower than in T-cells cultivated alone, indicating low local ADA concentration, thus favoring adenosine suppressive function. Interestingly, Tregs (induced by MSCs or naturally emerging after activation in the absence of MSC) displayed high levels of CD26, probably as a protective mechanism to locally counteract their suppression by adenosine. Finally, the percentage of CD4+ T-cells expressing CD73 increased significantly upon co-culture, indicating a shift toward adenosine production. Moreover, the percentage of CD73+ cells was higher among Treg induced by MSC than among naturally emerging Treg. *Conclusions.* We demonstrate for the first time that MSCs downmodulates the expression of CD26 in effector CD4+ T-cells, while inducing the generation of Treg with higher proportions of cells co-expressing CD73 or CD26, indicating an important role of adenosine signaling in the immunosupression mediated by MSC.

CALPAIN IS INVOLVED IN PTP1B MODULATION BY ERYTHROPOIETIN IN TF-1 AND DIFFERENTIATED UT-7 CELLS

MA Callero, D Vota, M Chamorro, D Vittori, A Nesse

Buenos Aires University, Buenos Aires, Argentina

Background. The central role played by tyrosine phosphorylation of erythropoietin receptor (EpoR) in cell activation by erythropoietin (Epo) has focused attention on protein tyrosine phosphatases (PTPs) as candidates implicated in the pathogenesis of the resistance to therapy with human recombinant Epo. Prototypic member of the PTP family is PTP1B, a widely expressed non-receptor PTP located both in cytosol and endoplasmic reticulum membrane, which has been implicated in the regulation of signaling pathways involving tyrosine phosphorylation induced by growth factors, cytokines and hormones. In previous reports we have shown that PTP1B expression, activity and phosphorylation are reciprocally modulated by Epo in undifferentiated UT-7 cell line. However, no information is available with respect to the modulation of this phosphatase in non-Epo depending cells or at late stages of erythroid differentiation. *Aim.* To characterize the relationship between Epo and PTP1B expression and to investigate a probable link between changes in PTP1B and intracellular calcium levels modulated by Epo. *Methods.* The TF-1 human cell line was used as a model of cells that can be grown with GM-CSF or Epo while the Epo-dependent UT-7 cells were induced to erythroid differentiation with hemin. Controls: TF-1 cells cultured in the presence of GM ad undifferentiated UT-7 cells cultured with Epo. Epo was added to Epo/serum-deprived cells for 18 h and after different periods, cells were lysed and total proteins and RNA were obtained to be analyzed by Western blotting and Real Time PCR, respectively. Immunoprecipitates with anti-PTP1B were subjected to a PTP1B activity assay using p-nitrophenylphosphate as substrate. Experiments with ionophore A23187 and calpeptin were performed to determine calpain involvement in PTP1B modulation by Epo. Flow cytometry was used to quantify calcium response to Epo. *Results.* A significantly increased level of PTP1B mRNA was observed in TF-1 and differentiated UT-7 cells either permanently maintained with Epo or Epo-stimulated for 24 h ($P<0.05$, n=4). This increment correlated with the highest level of PTP1B activity under the same conditions. Besides, an additional 46 kDa PTP1B isoform was observed in TF-1 cells and in hemoglobinized UT-7 cells cultured in the presence of Epo. After subcellular fractionation, this protein was found to be attached to the membrane fraction as the 50 kDa PTP1B isoform. Cell pre-treatment with calcium ionophore showed that a calcium-dependent protease was involved in the PTP1B cleavage. The addition of calpeptin to the experiments prevented PTP1B degradation, demonstrating that calpain was responsible for this Epo modulation. Flow cytometry analyses showed an Epo-induced intracellular calcium increase which was maintained after 60 min-Epo stimulation in TF-1 and differentiated UT-7 cells but not in UT-7 control undifferentiated cells. *Conclusions.* Results demonstrated an Epo-induced cleavage of PTP1B, resulting in a 46 kDa isoform attached to cell membrane which is associated with increased PTP1B enzymatic activity. Calpain was found to be responsible for this differential cleavage being the protein activation presumably a consequence of the intracellular calcium concentration change induced by Epo. These findings suggest a novel pathway of Epo - induced PTP1B regulation involving calcium, an already well known intracellular mediator.

RERVERSE SIGNALING B CELL-ASSOCIATED B7-H1 INDUCES CLASS SWITCHING TO IGG1 AND IGG3

I Choi,[1] Y Jeon,[1] H Jeong,[1] S Yang,[2] K Jung,[1] D Hwang[1]

[1]Inje University College of Medicine, Busan, South-Korea; [2]Inje University Paik Hospital, Busan, South-Korea

Background. B7-H1 (CD274), a B7 family ligand, delivers an inhibitory signal to its counter-receptor PD-1 and as-yet-unidentified receptor(s), leading to negative T cell immunity. Recent studies suggest that B7-H1 also receives a signal from its counter-receptor, rendering B7-H1+ cancer cells resistant to cytotoxic T cell killing activity and inducing proliferation and subsequent apoptosis of B7-H1+ T cells. Aim. We investigated the role of reverse signaling through B cell-associated B7-H1 (B-B7-H1) in proliferation, apoptosis, and immunoglobulin class switching of B cells. *Methods*. B7-H1+ tonsillar B cells were separated from B7-H1- B cells, and then were grown in 96 well plate coated with control Ig or anti-B7-H1 in the presence of anti-CD40 and IL-4. Total RNA was isolated from each B cell population and then subjected to RT-PCR for AID gene and , germline IH-CH transcripts of and mature VHDJH-CH transcripts. In some experiments, culture supernatant was harvested and subjected to ELISA for Ig isotypes. For examination of apoptosis of B cells cross-linked with anti-B7-H1, tonsillar B cells were incubated in 96 well plate plate coated with control Ig or anti-B7-H1 in the presence of anti-CD40 and IL-4, and then subjected to Annexin-V staining. *Results.* With plate-coated anti-B7-H1, B7-H1+ B cells exhibited upregulation of activation-induced cytidine deaminase (AID) gene transcription and class switch recombination from Cm to Cg1 and Cg3. B-B7-H1-mediated IgG productivity was positively correlated with the percentage of B7-H1+ B cells among the CD19+ B cells. B-B7-H1 cross-linking also induced apoptosis-promoting genes such as FasL, Bad, and Bid, but not anti-apoptotic Bcl-2, and lead to increased apoptosis in B7-H1+ B cells compared with B7-H1- B cells. In contrast to T cell-associated B7-H1, the engagement of B-B7-H1 was not responsible for B cell proliferation. *Conclusions.* These results indicate that reverse signaling through B-B7-H1 induced class switching to IgG1 and IgG3 and apoptosis, but was not involved in B cell proliferation.

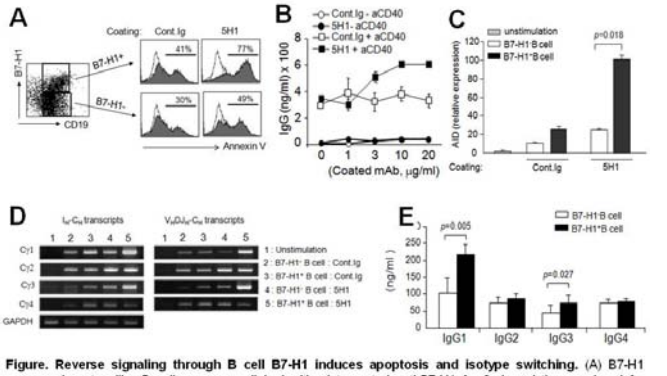

Figure. Reverse signaling through B cell B7-H1 induces apoptosis and isotype switching. (A) B7-H1 expressed on tonsillar B cells was cross-linked with plate-coated anti-B7-H1 for 3 d, and then analyzed for apoptosis with Annexin V staining. (B) Tonsillar B cells were treated as in (B) for 10 d in the presence of anti-CD40 and IL-4, and then ELISA was performed for IgG production from B cells. (C, D) B7-H1+ B cells were separated from B7-H1- B cells by MACS sorting procedure, and then treated as in (B) for 3 d. Total RNA was purified for RT-PCR for AID gene, germline I_H-C_H transcripts of and mature V_HDJ_H-C_H transcripts. (F) ELISA analysis of Ig isotypes in various B cell preparations engaged with control Ig- or 5H1-coated microbeads for 10 d.

IMATINIB-INDUCED APOPTOSIS; A POSSIBLE LINK TO TOPOISOMERASE ENZYME INHIBITION

Y Baran,[1] Z Zencir,[2] Z Cakir,[1] E Ozturk,[3] Z Topcu[4]

[1]Izmir Institute of Technology, Faculty of Science, Dept. of Mol. Biol. & Genetics, Urla Izmir, Turkey; [2]Ege University, Faculty of Sciences,, Izmir, Turkey; [3]Ege University, Faculty of Sciences, Department of Biology, Izmir, Turkey; [4]Ege University, Faculty of Pharmacy,Department of Pharmaceutical Biotechnology, Izmir, Turkey

Background. Chronic myeloid leukemia (CML) is a hematological malignancy resulting from a chromosomal translocation between long arms of 9. and 22. chromosomes that generates BCR/ABL fusion protein. Imatinib, a specific BCR/ABL inhibitor, is commonly used for the treatment of CML. Recent studies showed that imatinib has cytotoxic and apoptotic effects on BCR/ABL negative cancers. We have previously reported that imatinib induces apoptosis by increasing intracellular concentrations of apoptotic ceramides via generation and accumulation of ceramides through upregulating ceramide synthase genes and downregulating anti-apoptotic sphingosine kinase-1 gene. We have recent evidences indicating that imatinib induces autophagy, programmed cell death-II, by increasing the expression levels of Atg5, Atg6, and LC-3 genes in a dose-dependent manner (unpublished data). However, the mechanisms of imatinib induced apoptosis in BCR/ABL negative cancers is yet to be clarified. Numerous natural products and synthetic compounds having anti-cancer potential were shown to exert their functions via interfering with normal DNA topoisomerase functions. *Aims.* In this study, we examined the effects of imatinib on tumor cell killing and topoisomerase I and topoisomerase II enzyme activities. *Methods.* The human K562 cells were grown in RPMI1640 medium containing 10% FBS and 1% penicilline-streptomycine. Cytotoxicity analyses of imatinib were conducted by XTT cell proliferation assay. Changes in caspase-3 enzyme activity were determined using the caspase-3 colorimetric assay. The mitochondrial membrane potential (MMP) was measured using JC-1 MMP detection kit. Topoisomerase I plasmid supercoil relaxation assays and topoisomerase II decatenation assays were conducted in response to imatinib. *Results.* The results revealed that imatinib induces apoptosis and inhibits cell proliferation in a dose-dependent manner. We biochemically addressed plasmid DNA nicking and DNA catenation that rely on the ability of topoisomerase I to relax sc DNA and topoisomerase II to decatenate minicircle DNA substrates, respectively. The interference by imatinib was monitored as faster-migrating substrate band in plasmid relaxation method. Importantly, the results demosntrated that imatinib inhibited topoisomerase I and topoisomerase II enzymes activities in a dose-dependent manner *in vitro*, suggesting a possible link in the mechanism of imatinib-induced tumor cell-killing. *Conclusion.* Taken together, this is the first study proposing a potential link between apoptotic induction and topoisomerase interference by imatinib. The results of this study may help in understanding of how imatinib induces apoptosis and inhibits cellular proliferation in both BCR/ABL negative and positive cancers and strengthens its application potential.

0722

COMPARISON OF NEUROPROTECTIVE AND ERYTHROPOIETIC EFFECTS OF ERYTHROPOIETIN AND CARBAMYLATED-ERYTHROPOIETIN IN DIFFERENT CELL SYSTEMS

M Chamorro,[1] D Vittori,[2] D Vota,[2] S Wenker,[2] A Nesse[2]

[1]Universidad de Buenos Aires, Facultad de Ciencias Exactas y Naturales, Ciudad de Buenos Aires, Argentina; [2]Universidad de Buenos Aires, FCEN. CONICET, Ciudad de Buenos Aires, Argentina

Background. In addition to its well-known hematopoietic effects, erythropoietin (Epo) also has neuroprotective properties. However, hematopoietic side effects are unwanted for neuroprotection, underlining the need for Epo-like compounds with more selective neuroprotective action. One such compound extensively assayed is the chemically modified Epo-derivative carbamylated erythropoietin (cEpo), which in experimental assays cEpo has demonstrated non-hematopoietic tissue protection without significant erythropoietic effect. However, less is known about cellular mechanisms of action. *Aims.* To compare the neuroprotective action between Epo and cEpo and to distinguish their effects upon erythropoietic cells. *Methods.* Cell viability/proliferation was analyzed by the MTT assay and apoptosis by fluorescent microscopy after Hoechst staining. Models: Cells of neuronal origin: SH-SY5Y cells were cultured in E-MEM:Ham-FBS. Cells of ability to erythroid differentiation: a) Epo-dependent UT-7 cells were cultured in IMDM-FBS with Epo, b) Epo-independent K562 cells were grown in RPMI-1640-FBS and differentiated to erythroid lineage with hemin, and c) physiological colony forming units-erythroid (CFU-E) from Balb/c mice were evaluated by bone marrow cell cultures in methylcellulose-medium. After 48 h, 2,7-diaminofluorene reaction was performed and hemoglobinized colonies were counted. *Results.* Epo and cEpo acted in similar way (no significant differences) to prevent apoptosis induced by either staurosporine (STP) or TNF-α in SH-SY5Y cells (Control 8±1.5%; STP 44±5.2%; Epo-STP 12±2.2%; cEpo-STP 12±1.7%; TNF 32±1.7%; Epo-TNF 9±0.9%; cEpo-TNF 10±2.9%; n=4). Moreover, assays in the presence of inhibitors showed that cell activation by Epo and cEpo involves similar signaling pathways mediated by PI3K and Jak2. Instead, Epo but not cEpo overcame apoptosis induced by TNF-alpha in erythroid differentiated K562 cells (Control 8±2.3%; TNF 17±2.7%; Epo-TNF 8±1.0%; cEpo-TNF 18±1.5%, Epo-TNF *vs.* Epo $P<0.05$, n=4). Different from Epo, cEpo did not prevent apoptosis in cultures of UT-7 cells (Without Epo 39±5.8%; Epo 4±0.3%; cEpo 34±6.2%, n=4). Besides, Epo but not cEpo acted as growth factor in the development of mice CFU-E (Figure). To investigate probable competition between Epo and its carbamylated derivative, cEpo dose-response analysis were performed in the presence of Epo. Results showed that CFU-E growth in the presence of equal amounts of Epo and cEpo (20 ng) did not change the effect of Epo alone. Interestingly, higher amounts of cEpo (200 ng) inhibited the effect of Epo (20 ng) when both compounds were added simultaneously to cultures, but this inhibitory effect disappeared when cEpo was added 60 min after cellular stimulation by Epo (Figure: * Significant differences *vs.* [Without Epo] or [cEpo] or [Epo+cEpox10], $P<0.001$, n=10). *Conclusions.* This work adds new information about the neuroprotective and non-erythropoietic functions of cEpo. Similar mechanisms of action as anti-apoptotic factors in neuronal cells may be suggested for both compounds. However, results showing that the interference of high level of cEpo only occurred at early stages during the interaction of Epo with its erythroid target cell arose for the first time the possibility that cEpo block or modulate the activation of the Epo receptor. This finding may become crucial because it has been reported that relatively high doses of cEpo are needed to act as a neuroprotective factor.

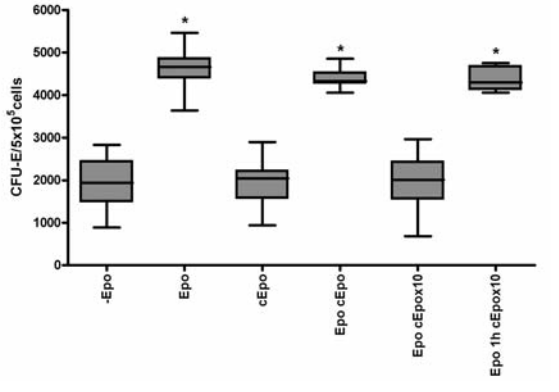

Figure 1. Effect of Epo and cEpo on CFU-E development.

KIR GENOTYPING OF ITALIAN PAROXYSMAL NOCTURNAL HAEMOGLOBINURIA PATIENTS

F Alfinito,[1] E Cosentini,[2] M Serra,[3] P Bruno,[2] L Gargiulo,[4] V Luongo,[2] S Lastraioli,[4] R Della Pepa,[2] G Ciardiello,[2] A Risitano,[2] R Notaro,[3] G Ruggiero,[2] G Terrazzano[5]

[1]University of Naples, Napoli, Italy; [2]Università di Napoli Federico II, Napoli, Italy; [3]Istituto Toscano Tumori, Florence, Italy; [4]Istituto Nazionale per la Ricerca sul Cancro, Genoa, Italy; [5]Università della Basilicata, Potenza, Italy

Background. Paroxysmal Nocturnal Haemoglobinuria (PNH) is a very rare haematopoieis disorder characterised by the expansion of a stem cell bearing a somatic mutation in the phosphatidyl-inositol glycan-A (PIG-A) gene, which is involved in the biosynthesis of the glycosyl-phosphatidyl-inositol (GPI) anchor. Haemolytic anaemia, thrombophilia and cytopenia characterise this disease. A number of data suggest the inability of PIG-A mutation to account alone for the clonal dominance of the

GPI-defective clone and for the development of PNH. In this context, the occurrence of immune-mediated mechanisms have been hypothesized. *Aims.* Our previous data (Hum Immunol 2008, 69:202-6) revealed the association of PNH with the HLA class I haplotype B*1402, Cw*0802 as well as with the extended Mediterranean haplotype A*33, B*1402, Cw*0802, DRB1*0102. NK cells are critical components of the innate immune response. They may also drive, shape and regulate the activity of the adaptive immune compartment. Killer-cell Immunoglobulin like Receptors (KIR) represent, with their known HLA ligands, a key component in the regulation of NK response. To analyse the biological mechanisms underlying PNH pathogenesis we are addressing the analysis of KIR genotype, whose role in the regulation of immune response and self-tolerance has been established. *Methods.* KIR distribution in 53 patients affected by PNH (estimated to represent almost the half of all Italian PNH patients) and in 64 controls of the same ethnical origin was analysed by PCR-SSP typing. In order to increase the number of controls bearing the HLA class I haplotype (B*1402,Cw*0802), 14 normal donors bearing such HLA haplotype have been selected and additionally enrolled in the study. Association has been tested by two-tailed Fisher's exact test with software InStat 3.0 (GraphPad Software Inc., San Diego, California, USA). Results. No significant associations with the KIR haplotype A or B as well as with specific KIR alleles has been observed. Independent segregation of HLA (6p21) and KIR (19q13.4) genes raises the possibility that any given individual may express KIR molecules from which no ligand is present or vice versa. The analysis of KIR-HLA matching in PNH patients, as compared with controls, showed significant differences only in the 3DL1/Bw4 matching. Indeed, a significant decrease in 3DL1/Bw4 mis-matching has been appreciated in the B*1402,Cw0802 subgroup (3DL1 without Bw4 was observed in 50% of controls as compared with 8.33% of PNH patients; P<0.05). When considering the occurrence of weak interactions, as represented by the presence of T80 Bw4 alleles, such observation become more consistent (72.22% in controls *vs.* 19.66% in PNH patients; P<0.01). In addition, a significant decrease in genotypes showing 3-4 activating genes (46.67% *vs.* 21.95%; P<0.01) accompanied by an increase in the frequency of genotypes showing 1-2 activating genes (35% *vs.* 56.09%) has been observed in B*1402,Cw0802- PNH patients, as compared with controls. Conclusions. This study suggests that a genotype showing higher NK activation threshold (less activating genes together with more effective 3DL1/Bw4 inhibitory pathway) characterises our cohort of PNH patients. This association may provide new insights into the autoimmune pathogenesis of PNH.

EXPRESSION ANALYSIS OF 84 GENES INVOLVED IN DIFFERENT SIGNALLING PATHWAYS OF CANCER IN CHRONIC MYELOID LEUKEMIA CELLS IN RESPONSE TO NILOTINIB

Y Baran,[1] A Camgoz,[2] G Can[3]

[1]Izmir Institute of Technology, Faculty of Science, Dept.of Mol.Biol. & Genetics, Urla Izmir, Turkey; [2]Izmir Institute of Technology, Faculty of Science,Dept.of Mol.Biol. & Genetics, Izmir, Turkey; [3]Izmir Institute of Technology, Fac.of Science,Dept.of Mol.Biol.& Genetics, IZMIR, Turkey

Background. Chronic myeloid leukemia (CML) is a hematological malignancy arising from a reciprocal translocation between long arms of chromosomes 9 and 22. The resulting BCR/ABL fusion protein is a strong oncogenic protein that regulates cell growth and proliferation, apoptosis and senescence, migration and adhesion. Imatinib was the first tyrosine kinase inhibitor for the treatment of CML. Although there were significant hematologic and cytogenetic responses to imatinib, resistance cases were observed in patients during treatments and this was the major drawback of imatinib treatment. After identification of the mechanisms of imatinib resistance, a more effective anticancer agent, nilotinib, was developed and started to be used for the treatment of Philadelphia chromosome positive hematological malignancies. *Aims.* In this study, we aimed to examine the molecular mechanisms of nilotinib-induced cell death in addition to inhibition of BCR/ABL in K562 chronic myeloid leukemia cells. *Methods.* Antiproliferative effects of nilotinib were determined by XTT cell proliferation assay. Increasing concentration of Nilotinib (20 and 50 nM) were applied to K562 cells. After 72 hours incubation, total RNAs were isolated and converted to cDNA. Changes in expression levels of 84 genes involved in apoptosis, cell cycle, senescence, adhesion, invasion, metastasis, angiogenesis, transcription factors, and signal transduction molecules were examined by PCR array. *Results.* There were 40 and 55% decreases in proliferation of K562 cells in response to 20 and 50 nM nilotinib, respectively, as compared to untreated controls. Gene expression results revealed that 50 nM nilotinib application resulted in more than 4-fold increases/decreases in expression levels of 41/6 genes as compared to untreated controls and normalized to housekeeping genes. On the other hand, lower concentration of nilotinib, 20 nM, increased/inhibited expression levels of 2/22 genes more than 2-fold comparing to untreated controls and normalized to housekeeping genes. Nilotinib induced expression levels of apoptotic (Bax, Serpin5B, GZMA, TNF, TNFRSF25, APAF1) cell cycle controlling (CDK2, CDKN2A, MDM2), and inhibitor of metastasis (TIMP1, TIMP3) genes and decreased expression levels of growth inducing (AKT1, IGF1, MYC, NFKB, MAP2K1, PLAU), antiapoptotic (SNCG, SYK), metastatic (MMP1, MMP2, ITGB5, ITGA3) and angiogenic (IL-8, ANGPT2) genes. The highest increases were observed in apoptotic TNF and GZMA genes while the highest decreases were observed in growth inducing MAP2K1 and PLAU genes. Summary/Conclusion. In this study, we demonstrated the molecular mechanisms of nilotinib induced cell death in addition to inhibition of oncogenic BCR/ABL protein. More importantly, we have also showed for the first time that nilotinib also has the potential to inhibit metastasis and angiogenesis through manipulating metastatic and angiogenic genes.

0725

IMMUNOGLOBULIN TREATMENT IMPROVES RECONSTITUTION OF B CELL COMPARTMENT AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION

L Justo, A Afonso, A Queirós, C Fesel, M Cabral, A Pires, C João

Instituto Portugues de Oncologia de Lisboa, Francisco Gentil, Lisboa, Portugal

Background. Early recovery of lymphocytes after stem cell transplantation is critical for a better survival and deficient B-cell functional recovery is due to decreased T-cell help and intrinsic B-cell defects. Studies after stem cell transplantation (SCT) demonstrated a delayed recovery of *in vivo* B-cell production of immunoglobulins. One way to improve reconstitution may be trough stimulation with molecules promoting lymphocyte development and function, as it is the case for natural antibodies. *Aims.* Evaluation of the effect of polyclonal immunoglobulin infusion or its fragments in promoting immune reconstitution after autologous stem cell transplantation (ASCT) in a lymphopenic *in vivo* model. *ethods.* Balb/c mice recipients, conditioned with lethal radiation, were distributed into four groups to test different weekly treatments: mouse polyclonal immunoglobulins (IgG), its derivatives Fab or Fc (250 μg/mouse/week), or saline (control). Evolution of peripheral immune reconstitution was monitored weekly up to 13 weeks (w) after ASCT. Age and sex-matched healthy Balb/c mice were used for normal references. Quantitation of B cells was performed by flow cytometry; serum levels of immunoglobulins and B-cell Activating Factor (BAFF) were measured by ELISA. Seric IgM reactivity against membrane protein extracts (*E. coli*) was assessed by quantitative immunoblot. Results were compared using SigmaPlot11.0 and IgorPro statistical softwares. *Results.* Recovery of B cell numbers was similar among groups. However, serum immunoglobulin recovering was significantly improved in treated groups. At 9w after ASCT, Ig-treated groups significantly increased IgM concentrations compared to control (P=0.002), most clearly for Fc and Fab treatments. Regarding recovery of serum IgG, all treated groups reconstituted better than control, at later time points. Fc-treated mice increased significantly comparing to control after 9w of follow up (FU) (P<0.001), surpassing normal values (n=10, md=695 ug/mL serum [25-75%]=[455-875]; maximum at 9-13w for Fc-group (n=6): 711 [466-1,188]; control (n=7): 143 [103-232]). All groups showed high BAFF serum levels at the first weeks of FU, not differing from normal (n=10, 7,419pg/mL [7,261-7,906]). During reconstitution, BAFF levels decreased in all groups similarly, being well below normal (P≤0.001) at the end of FU. Peripheral blood B cell counts and serum BAFF levels showed a significant negative correlation in Ig-treated mice (r=-0.845, P<0.001, 2-5w). At the first weeks, a positive correlation was also found between B cells and IgM (dominated by polyclonal-IgG: r=0.497, P=0.006) and B cells and IgG (dominated by Fab: r=0.511, P=0.013). Soon after ASCT, all groups exhibited low IgM reactivity, but treated groups showed a significantly faster recovery of IgM reactivity (OD measurements) after the 7th w comparing to control (polyclonal-IgG, n=12, P=0.0005; Fab, n=10, P=0.002; Fc, n=7, P=0.002), achieving significant higher values of IgM diversity compared to control. The control group seemed to recover only from the 10th w on. *Conclusions.* Our results suggest that treatment with polyclonal immunoglobulin (natural antibodies) during immunological recovery after ASCT promotes a better and more competent recovery of the B cell compartment.

CLINICAL SIGNIFICANCE OF CLONALITY AND EPSTEIN-BARR VIRUS INFECTION IN ADULT PATIENTS WITH HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS

JS Ahn,[1] SY Rew,[1] DH Yang,[1] MG Shin,[1] HR Kim,[1] D Cho,[1] SH Kim,[1] SY Bae,[1] SR Lee,[2] YK Kim,[1] HJ Kim,[1] JJ Lee[1]

[1]*Chonnam National University Hwasun Hosipital, Jeollanam-do, South-Korea;* [2]*Korea University Medical Center, Seoul, South-Korea*

Background. In adults, hemophagocytic lymphohistiocytosis (HLH) is often associated with a variety of infections, malignant neoplasms, drugs, autoimmune diseases, and various immunodeficiencies. Unfortunately, it is difficult to make a diagnosis of lymphoma-associated HLH because fatal conditions delayed to perform the tissue biopsy and it took a long time to confirm diagnosis. A lack of histological proof of lymphoma can delay the choice of appropriate treatment for lymphoma-associated HLH at the initial stage. So, we hypothesized that early diagnosis may be supported by molecular study of the EBV genome and the clonal rearrangement of immunoglobulin (IG) and T cell receptor (TCR) genes. *Aimes*. We assessed the clinical significance of T or B cell clonality and Epstein-Barr virus (EBV) infection in adult patients with hemophagocytic lymphohistiocytosis (HLH) to identify factors related to prognosis. *Methods*. A total of 30 adult patients with diagnosed HLH were included in the study. In all patients, EBV-DNA in peripheral blood was examined by quantitative real-time polymerase chain reaction and bone marrow cells were examined for clonal rearrangement of T cell receptor gamma (TCRG) and immunoglobulin heavy chain (IGH) genes. Twenty of 30 cases were treated with systemic immunotherapy or immunochemotherapy and four cases were treated with combination chemotherapies of lymphoma regimen initially. Four patients received conservative therapy only, and 2 patients were transferred to other hospitals. *Results.* With a median follow-up of 4.6 months (range, 0.1-93.1 months), the median overall survival was 6.9 months and the estimated overall survival rate at 1 year was 47.6±9.7%. When we analyzed the factors affecting survival, none of the clinical features or laboratory findings was found to affect survival except for excess viral load of EBV-DNA. Patients with ≥ 1000/mL copies of EBV-DNA showed poor overall survival compared with those with low EBV-DNA load (P=0.010) (Figure 1).TCRG clones were detected in 10 patients (33.3%) and IGH clones were detected in 8 patients (26.7%). However, the clonality of TCRG(P=0.273) and IGH (P=0.182) did not have any prognostic role in survival rate at patients with HLH. *Conclusions.* Our results suggest that TCRG and IGH rearrangement do not have any clinical significance in adult patients with HLH but that high viral load of EBV-DNA may be a risk factor for poor outcomes. In HLH, high viral load of EBV-DNA should thus suggest a prompt approach with aggressive therapeutic interventions.

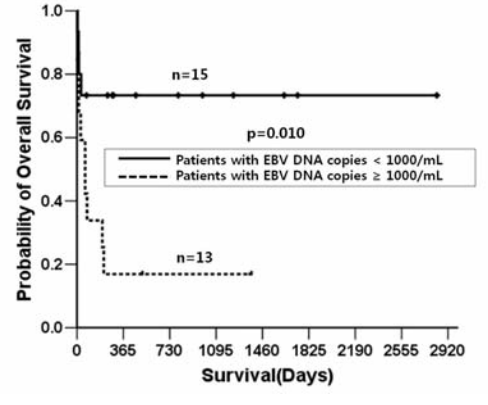

Figure 1. Overall survival according to EBV-DNA viral load.

A NATIONWIDE SURVEY OF PAROXYSMAL NOCTURNAL HAEMOGLOBINURIA IN FINLAND

E Kairemo, H Jarva, S Meri

Haartman Institute, Helsinki, Finland

Background. Paroxysmal nocturnal haemoglobinuria (PNH) is an acquired syndrome characterised by intravascular hemolysis, venous thrombosis and bone marrow abnormality because of a deficiency of glycophosphoinositol-anchored (GPI) proteins from a subset of bone marrow-derived cells. The diagnosis is made by flow cytometry of GPI-anchored complement inhibitors CD59 and CD55 on blood cells. In Finland the diagnostics has been centralised to the Helsinki University Central Laboratory (HUSLAB) since 1992. *Aims.* Our aim is to conduct a nationwide survey on PNH in Finland. During a study still ongoing we have investigated the natural history of the disease, age and sex distribution, triggering factors, incidence, prevalence, co-morbidity, fate during pregnancy, therapy outcome, possible prognostic factors and life expectancy. A particular attention has been paid on spontaneous remissions, thrombotic events and the co-existence of aplastic anemia. *Methods.* As a starting point we have used laboratory databases of diagnosed cases. RBCs have been divided into three groups (I,II,III) based on the level of CD59 expression. Additional laboratory parameters included haemoglobin, haematocrit, lactate dehydrogenase, haptoglobin, erythrocytes, leucocytes, thrombocytes, inflammation markers (e.g. CRP), bone marrow analysis and urine haemoglobin. Clinical data was collected from patients' records and an additional questionnaire was filled in together with the patients' clinicians. This data included the symptoms and conditions attributable to PNH; haemoglobinuria, thrombotic events, infections, fatigue, renal failure, pulmonary hypertension, abdominal pain, dysphagia, dyspnoea, erectile dysfunction, anaemia and co-existence of aplastic anaemia, myelodysplastic syndrome and acute myeloid leukemia. All patients participated with written informed consent. *Results.* So far 71 patients, 38 female and 33 male, were been found from Finland with a population of 5.2 millions. From the cases studied the prevalence of PNH was calculated approximately as 1:100 000. The mean age at diagnosis is 44 years, range 5-76 years. Clinical data has until now been obtained from 28 patients. Nearly half of the patients were diagnosed also with aplastic anemia and about one third had had a thrombotic event. Abdominal pain had occurred in 21% of patients and 3/28 of the patients had Budd-Chiari syndrome. From 4 patients who underwent allogeneic stem cell transplantation 3 are in remission. Myelodysplastic syndrome, erectile dysfunction, kidney failure and spontaneous abortion each occurred in 2/28 patients. *Conclusions.* Further clinical data is being collected and placed in a nationwide registry to serve both academic research and clinical practice. Since PNH is a very rare disease, the results of this study will help both in the clinical decision making and standardization of the treatment as well as in the development of new therapies. The progress and prognosis of the disease are highly variable. Considering the rarity of the disease, centralised treatment should be considered.

0728

MECHANISMS INVOLVED IN PREMATURE SELF-DESTRUCTION OF RED BLOOD CELLS UNDER DIFFERENT ERYPTOSIS STIMULI

D Vota,[1] M Callero,[1] M Chamorro,[2] R Crisp,[2] A Nesse,[1] D Vittori[1]

[1]*Universidad de Buenos Aires. CONICET, Ciudad de Buenos Aires, Argentina;* [2]*Universidad de Buenos Aires, Ciudad de Buenos Aires, Argentina*

Background. Recently, it has been reported that under certain circumstances erythrocytes (RBCs) can suffer premature self-destruction showing cell changes that mimic features of apoptosis in nucleated cells. Although much information about this process called eryptosis is available, the mechanisms are not yet well known. Aim. Based on the hypothesis that oxidative stress and increased intracellular calcium induce eryptosis through different pathways, the aim of this work was to study the mechanisms involved in this process under these two models of eryptosis. *Methods.* RBCs from healthy donors were obtained following informed consent. Cells were exposed to different eryptosis stimuli in buffer HEPES at 37°C for different periods. Morphological changes were observed by scanning electron microscopy. Flow cytometry assays were performed to detect Anexin V binding and to measure GSH, ROS, intracellular calcium, and band 3 levels. Membrane protein phosphorylation and nitrosylation were analyzed by SDS-PAGE and Western blotting. *Results.* The presence of either H_2O_2+$NaNO_2$ or Ca ionophore A23187 (CaI) induced membrane phosphatidylserine translocation (Control 1.8±0.6%; H_2O_2+$NaNO_2$ 71.6±27.3%; CaI 96.2±3.1%; H_2O_2+$NaNO_2$ *vs.* C P<0.05; CaI *vs.* C P<0.01, n=5). Interestingly, both treatments caused different morphological changes. Spherocytes with microvesiculation or stomatocytes were the characteristic cell shapes of CaI- or H_2O_2+$NaNO_2$-induced eryptosis, respectively. Significantly higher ROS and lower GSH levels with respect to untreated cells were observed in the presence of H_2O_2+$NaNO_2$ (P<0.05, n=3), whereas they remained unchanged under CaI exposure. In contrast with CaI treatment, no change in intracellular calcium levels was observed in the presence of H_2O_2+$NaNO_2$ (expressed as Gm of fluorescence intensity: C 53.3±6.7; H_2O_2+$NaNO_2$ 44.9±5.5; CaI 136.1±68.5; CaI *vs.* C P<0.01, n=4). Even though these results suggested that calpain activation may play an essential role to induce eryptosis, we did not detect a reduction of Anexin V positive cells in the presence of Calpain Inhibitor I under either H_2O_2+$NaNO_2$ or CaI incubation. Membrane protein analysis showed a strong reduction of band 3 after exposure to CaI (Flow cytometry, Gm: C 100.0±23.0; CaI 27.4±7.1; P<0.05, n=3) whereas post-translational modifications, such as nitrosylation of membrane proteins and band 3 phosphorylation were caused by cell incubation with H_2O_2+$NaNO_2$. Parallel assays to detect protein phosphorylation in cells pre-treated with staurosporine (kinase inhibitor) or sodium o-vanadate (phosphatase inhibitor) suggest higher involvement of kinase activation in eryptosis induced by H_2O_2+$NaNO_2$. *Conclusions.* RBCs exposed to oxidative stress or CaI suffered self-destruction detected by increase of Anexin V binding, although different pathways are involved in the mechanisms of eryptosis depending on the stimuli. On the one hand, an increase in calcium influx appears to specially affect membrane proteins such as band 3, possibly due to membrane vesiculation. On the other hand, oxidative stress not only reduces the amount of cellular protective anti-oxidative compounds, but also produces membrane protein modifications probably leading to alteration of their properties. Based on the present results we can suggest that the anemia observed under several diseases associated with chronic inflammation might be produced not only by erythroid progenitor dysfunction but also by direct effects of pro-eryptotic factors on erythrocytes.

HIGH AVIDITY PRAME SPECIFIC T-CELLS DERIVED FROM A PATIENT AFTER HLA MISMATCHED STEM CELL TRANSPLANTATION, POTENTIALLY USEFUL FOR THERAPEUTIC TCR GENE TRANSFER STRATEGIES

M Heemskerk, A Amir, D van der Steen, R Hagedoorn, M Griffioen, J Falkenburg, M Heemskerk

LUMC, Leiden, Netherlands

Adoptive immunotherapy with T-cells can effectively treat patients with hematological malignancies, EBV-associated malignancies and metastatic melanoma. Application of this therapy for these tumors is broadening by recent progress in genetic engineering of T-cells with genes encoding T cell receptors (TCR) specific for antigens expressed by these malignancies. TCRs with specificity for non-polymorphic tumor-associated self-antigens that are shared between various tumors are promising candidates. However, the isolation of high avidity T-cells that are specific for non-polymorphic tumor associated self-antigens is difficult, because of self-tolerance. During thymic selection T-cells exhibiting high avidity for self-antigens presented by self-HLA are deleted, and this most probably explains why most T-cells characterized to date directed against non-polymorphic tumor associated self-antigens exhibit low to intermediate avidity. After HLA mismatched stem cell transplantation, however, donor T-cells which have been educated in the donor have not encountered the allogeneic HLA molecules from the patient. Consequently, these T-cells can exhibit high avidity for tumor associated self-antigens presented by allogeneic patient specific HLA molecules. In this study we investigated whether high avidity T-cells directed against non-polymorphic tumor associated antigens restricted by allo-HLA could be selected from patients transplanted with HLA mismatched stem cell grafts. From one patient after HLA-A2 mismatched SCT at the time of graft *vs.* host disease we isolated T-cells specific for a peptide (SLL) of the tumor antigen PRAME (preferentially expressed antigen on melanomas) presented in HLA-A2. To determine whether the T-cells were solely PRAME-SLL peptide specific, T-cells were tested against T2 cells loaded with multiple HPLC fractions of peptides eluted from HLA-A2. The clone showed specific recognition of only one HPLC fraction, and by two additional HPLC fractionations and mass spectrometry we demonstrated that the SLL peptide was the only peptide that was recognized. In addition, by transfection of PRAME into HLA-A2 positive COS cells we demonstrated that endogenously processed PRAME was recognized. Peptide titration showed that the clone exhibited high avidity for the PRAME peptide (IC_{50}:50pM). HLA-A2 transduced K562 cells, known to highly express PRAME, were strongly recognized as well as a large fraction of tumors, including melanomas (90%), renal cell carcinomas (66%), non-small cell lung carcinomas (50%), and acute myeloid leukemia (AML) (50%). Since these T-cells exerted high avidity for PRAME we investigated whether HLA-A2+ non-malignant cells were recognized. The T-cells showed no reactivity against fibroblasts, keratinocytes, bronchus epithelial cells, hepatocytes, billiair duct epithelial cells, colon epithelial cells and mesenchymal stem cells. Also (activated) B-cells, (activated) T-cells, monocytes and $CD34^+$ cells were not recognized by the T-cells. However, the T-cells demonstrated reactivity against mature monocyte derived DC's and low reactivity against kidney epithelial cells. PRAME RNA expression levels of the tested target cells, determined by quantitative RT-PCR, demonstrated that the level of recognition correlated with PRAME expression. Based on these results we demonstrate single peptide specificity of allo-HLA reactive PRAME specific T-cells, high reactivity against numerous tumors and limited on-target toxicity. This PRAME specific TCR is a potential interesting tool for adoptive T-cell therapy using TCR gene modified T-cells.

NATURALLY OCCURING HLA-G EXPRESSING CELLS IN PERIPHERAL BLOOD OF HEALTHY INDIVIDUALS WITH IMMUNOREGULATORY PROPERTIES

I Lazana, A Zoudiari, D Kokkinou, M Themeli, E Lagadinou, N Zoumbos, A Spyridonidis

University Hospital Of Patras, Patras, Greece

Introduction. HLA-G is a nonclassic MHC class I with unique features that functions as an immunomodulatory molecule. HLA-G was initial-

ly found on trophoblasts, where it contributes to tolerance at the materno-fetal interface. HLA-G has been shown to regulate the rejection process after solid organ transplantation but its role in allogeneic hematopoietic cell transplantation (HCT) is unknown. Objectives. The aim of this study was to detect and characterize naturally occurring HLA-G$^+$ cells (HLA-Gnat) in peripheral blood and their possible immunomodulatory properties. Furthermore we investigated the effect of the demethylating agent 5-aza-2'-deoxycytidine (5-AC) on HLA-G expression and the generation of HLA-G induced cells (HLA-Gind). *Methods.* Peripheral blood mononuclear cells (PBMC) were obtained from 22 volunteer donors and were analyzed by FACS for the presence of HLAG$^+$ (MEM-G/9 MoAb) cells, both in whole PBMC and in specific cell subsets. Moreover, we isolated HLA-G$^+$ cells by FACS sorting (Vantage, BD) and analyzed their tolerogenic properties by using them as third party cells in mixed lymphocyte cultures (MLC). The lymphoproliferative response in the cultures was measured using the CFSE cell proliferation assay. The immunmodulatory effect of HLA-G was calculated in comparison to lymphocyte proliferation in control cultures without addition of HLA-G$^+$ cells. Furthermore, inhibition assays were performed with target cells that have been incubated with the anti-HLA-G1 87G moAb or an irrelevant isotypic control Ab. PBMCs and HLA-G neg cell lines (HaCaT, K562) were treated with 5-AC for 3 days, at final concentrations of 1 μM, 2.5 μM, 5 μM, 10 μM and 100 μM. HLA-G cell surface expression was determined with the MEM-G/09 mAb. *Results.* The mean percentage of HLA-G$^+$ cells in whole PBMC was 4.4% with a Specific Fluorescent Index (SFI) of 1.2. The mean percentage of HLA-G$^+$ cells was significantly higher in CD14$^+$ (23.2%) than in CD3$^+$ cells (1.4%), P=0.0002. Inversely, we isolated by FACS sorting HLA-G$^+$ cells from PBMC and found that 93% of them were CD14$^+$. CD14$^+$/HLAG$^+$ cells showed significant lower expression of HLA-DR (SFI 81.3) as compared to CD14$^+$/HLAG- cells (SFI 186), P<0.001. When FACS sorted CD14$^+$/HLAG$^+$ cells were added as third party cells in MLC we observed a dose dependent suppression of lymphoproliferation. Concentrations >1/1 of responder/HLA-G$^+$ cells showed significant suppression of the allo-response by 52% over the control, P=0.0012. The HLA-G mediated inhibition of lymphocyte proliferation could be reversed by masking HLA-G1 with blocking 87G moAb. HLA-G neg cell lines and CD3$^+$/HLAG- cells were found to express membrane HLA-G upon their *ex vivo* exposure to 5-aza-2'-deoxycytidine (HLA-Gind) in a dose dependent way (0.32% in the absence of 5-AC *vs.* 68% after treatment with100 μM 5-AC). *Conclusions.* Our results reveal the existence and the capacity to isolate HLA-G$^+$ cells with immunosuppressive function from PB of healthy individuals. Naturally occurring HLAG+ monocytic cells (and maybe also HLA-G$^+$ induced T-cells) suggest a promising strategy for adoptive cell immunosuppressive therapy after HCT.

0731

CYTOKINE INDUCED KILLER (CIK) CELLS FOR CELL THERAPY OF ACUTE MYELOID LEUKEMIA (AML): IMPROVEMENT OF IMMUNE ACTIVITY BY EXPRESSION OF CD33-SPECIFIC CHIMERIC RECEPTORS (CAR)

V Marin,[1] I Pizzitola,[1] V Agostoni,[1] M Pule,[2] R Rousseau,[3] A Lawson,[4] H Finney,[4] A Biondi,[1] E Biagi[1]

[1]Centro Ricerca M.Tettamanti, Monza, Italy; [2]UCL, London, UK; [3]CLB, Lyon, France; [4]UCB Celltech, Slough, UK

Background. CIK cells are ex vivo expanded effector cells with potent antitumoral activity.We demonstrated that CIK cells' infusion in AML patients relapsing after allogeneic transplant is well tolerated, but limited clinical responses were observed. *Aims.* to improve anti-leukemic CIK functions. *Methods.* CIK cells were genetically modified with SFG-retroviral vectors coding for anti-CD33-zeta or anti-CD28-OX40-zeta CAR and their ability to kill leukemic targets was analysed either by 4h-51Cr-release assays and long-term co-culture on stromal cells. CD33-specific proliferation was assessed by 3H-thymidine incorporation and cytokine release by flow cytometry. *Results.* anti-CD33-zeta or anti-CD28-OX40-zeta CAR expressing CIK cells (average CAR expression, 65%) acquired potent cytotoxicity against several AML targets: after 4-hour incubation we observed, at effector: target (E:T) ratio of 5:1, a mean lysis of the HL-60 cell line of 79% and 75%, for anti-CD33-zeta and anti-CD33-CD28-OX40-zeta cells respectively (P<0.005 *vs.* untransduced CIK cells). Analogous lytic efficiency was registered against the KG-1 cell line, known to be resistant to Gentuzumab-Ozogamicin, and primary AML blasts, with cytotoxicity >50%, contrarily from non transduced CIK cells, that showed <10% lysis against both targets (P<0.005). The strong anti-leukemic activity of manipulated CIK cells was confirmed in long-term killing experiments, where leukemic cells were co-coltured with CIK cells for 6 days on human stromal layer without exogenous IL-2 at an E:T ratio of 1:200.In these assays, anti-CD33-CD28-OX40-zeta CIK cells eliminated almost all leukemic cells, with 16% mean residual primary AML cells compared to 91% (P≤0.005) of untransduced CIK cells. Anti-CD33-zeta CIK cells showed analogous but lower efficiency, with 31% mean residual primary AML (P≤0.05). Moreover, a prominent CD33-specific proliferative activity was observed, with a mean proliferation index of 2.2 after HL-60-mediated stimulation and 2.4 after primary AML cells-mediated stimulation in anti-CD33-zeta transduced cells compared to 0.9 (P≤0.005) and 1.4 (P≤0.05) for un-transduced CIK cells. Expression of the anti-CD33-CD28-OX40-zeta CAR on CIK cells resulted in a higher expansion rate, with a mean proliferation index of 4.4 (P≤0.005) after HL-60-mediated stimulation and 3.7 (P≤0.005) after primary AML cells-mediated stimulation. In addition, when stimulated with irradiated HL-60, anti-CD33-zeta and anti-CD33-CD28OX40-zeta CAR-transduced CIK cells secreted 11-fold and 10-fold higher amount of IFN-gamma (P≤0.005 for anti-CD33-zeta and anti-CD33-CD28-OX40-zeta), 120-fold and 180-fold more TNF-alfa (P≤0.005 for anti-CD33-zeta and for anti-CD33-CD28-OX40-zeta), 250-fold and 600-fold more TNF-beta (P≤0.005 for anti-CD33-zeta and for anti-CD33-CD28-OX40-zeta), 1400-fold and 3800-fold more IL-2 (P≤0.05 for anti-CD33-zeta and for anti-CD33-CD28-OX40-zeta) compared to unmanipulated cells. Importantly, anti-CD33-CAR expressing CIK cells showed a transitory toxicity against normal hematopoietic CD34$^+$ progenitors, with a reduced, but consistent number of clonogenic progenitors recovered in colony forming-assays after up to 48-hour co-culture with transduced CIK cells. *Conclusions.*our results indicate that anti-CD33 CARs strongly enhances anti-leukemic CIK functions, suggesting that CAR-expressing CIK cells might represent a promising tool for AML immunotherapy.

0732

CD137 STIMULATION ENHANCES ANTI-LYMPHOMA ACTIVITY OF RITUXIMAB

E Kohrt*,[1] R Houot*,[1] M Goldstein,[1] K Weiskopf,[1] L Chen,[2] T Tedder,[3] R Levy[1]*

[1]Stanford University, Stanford, CA, USA; [2]Johns Hopkins University, Baltimore, USA; [3]Duke University, Durham, USA. Both authors have equal contribution to the abstract

Background and Aims. Rituximab, a monoclonal antibody (mAb) directed against CD20, has significantly improved the outcome of patients with lymphoma. Antibody-dependent cell-mediated cytotoxicity (ADCC), largely mediated by natural killer (NK) cells, is thought to play an important role in rituximab's efficacy. In the current study, we hypothesized that the anti-lymphoma activity of rituximab could be enhanced by stimulation of NK cells with an anti-CD137 agonistic mAb. CD137 (4-1BB) is a costimulatory molecule expressed on a variety of activated immune cells, including T and NK cells.

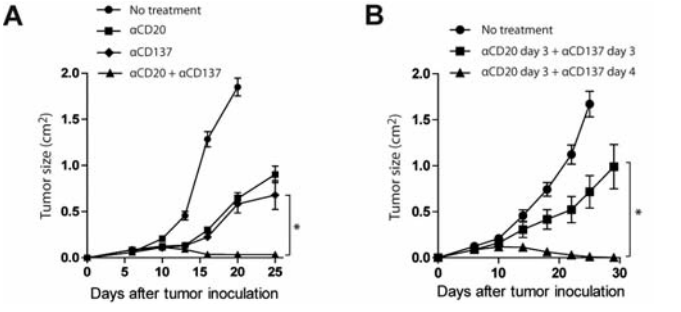

Figure 1.

Methods and Results. Using human primary lymphoma samples, we found that, while resting human NK cells do not express CD137 at baseline, these cells highly upregulate CD137 when encountering rituximab-coated tumor B cells. Furthermore, anti-CD137 agonistic mAb significantly enhances rituximab-induced NK cell degranulation and cytotoxicity as measured by CD107a mobilization (P=.006) and chromium release (P=.01). In a syngenic murine lymphoma model, anti-CD137 mAb significantly enhances anti-tumor activity of anti-CD20 mAb leading to complete tumor resolution (Figure 1A, P<.001) and prolonged survival (P=.048). This synergistic effect is dependent upon sequential administration first of anti-CD20 mAb and then followed by anti-CD137 mAb (Figure 1B, P<.001). We show that in-vivo administration

of anti-CD20 mAb induces upregulation of CD137 on mouse NK cells (P=0.001) after 24 hours, allowing their activity to be enhanced by the anti-CD137 mAb. Consistent with this observation, NK cell depletion completely abrogates the therapeutic effect of anti-CD20 plus anti-CD137 mAb combination (P<.001). Conclusions. Our study presents a novel, sequential antibody approach to enhance rituximab's efficacy in patients with B cell malignancies by selective stimulation of rituximab-activated NK cells with anti-CD137 mAb. These results support the evaluation of anti-CD137 mAb in combination with rituximab in clinical trials for patients with lymphoma.

0733

REDIRECTING T-CELLS AGAINST CANCER CELLS BY TRANSFER OF BROADLY TUMOR REACTIVE GAMMA-DELTA-T-CELL RECEPTORS

V Marcu-Malina, S Heijhuurs, L Hartkamp, J Kuball

UMC Utrecht, Utrecht, Netherlands

Background. Adoptive transfer of alpha-beta-T-lymphocytes is a promising treatment for a variety of malignancies, but often not feasible due to difficulties in generating T-cells reactive with the targeted antigen from patients. To facilitate rapid generation of cells for therapy, T-cells can be programmed with genes encoding for a tumor-specific high-affinity gamma-delta -T-cell receptor (TCR). Selective anti-tumor-reactivity and ignorance of the healthy-environment by gamma9-delta2-T cells arises from its ability to recognize non-classical antigens, including the non-peptidic intermediates of isoprenoid biosynthesis and so called stress signals on the tumor cells. *Aims* and *Methods.* To test the ability of gamma9-delta2-TCRs to redirect alpha-beta-T cells selectively against tumor cells, the gamma9-delta2-TCR was retrovirally transduced into human alpha-beta T cells. *Results.* Thereby, strong surface-expression of introduced gamma9-delta2-TCRs was observed while endogenous alpha-beta TCR chains were down-modulated. Functional analysis revealed that a gamma9-delta2-TCR efficiently reprograms both, $CD4^+$ and $CD8^+$ T-cells against a broad panel of cancer cells while ignoring normal cells. Moreover, tumor-specific T-cell proliferation, cytokine secretion and killing were significantly enhanced by additional application of biphosphonates. Finally, gamma9-delta2-TCR transduced T cells reduced colony-formation of progenitor cells of primary acute myeloid leukemia blasts. Recognition depended primarily on the presence of phospho-antigens. Expression of NKG2D ligands and F1-ATPase contributed to the activity of gamma9-delta2-TCR transduced T-cells but were not mandatory. Summary. Gamma9-delta2-TCRs are an attractive alternative to redirect alpha-beta T cells against cancer cells with both, an improved efficacy and safety profile as compared to currently used TCRs.

0734

PRAME RECOMBINANT PROTEIN VACCINATION CAUSES SIGNIFICANT TUMOR REDUCTION IN THE ANIMAL MODEL

A Misyurin, N Lapshyna, E Aksenova, T Akhlynina, Y Finashutina

Research Center for Hematology, Moscow, Russian Federation

Background. The PRAME (preferentially expressed antigen of melanoma) has been earlier discovered as a naturally occurred target for the cytotoxic $CD8^+$ T-cells in some of the melanoma patients with atypically moderate clinical course of this malignant disease. It is also shown that PRAME gene is overexpressed in the vast variety of the human malignances including not only melanoma and any other solid tumors but also acute and chronic leukemias and lymphomas. There are promising data that PRAME-derived peptides are able to render anti-tumor cytotoxic $CD8^+$ T-cell-based effect being used as a substance for the vaccination. At least one of the molecular functions of the PRAME protein is to inhibit nuclear retinoic acid receptor alpha (RARα). This feature contributes to and aggravates the tumor malignancy. The importance of the PRAME expression is stressed by the fact that it is the main one that is activated in terminal phase of the chronic myeloid leukemia. The PRAME is considered to be a useful target for developing of the anti-tumor approaches based on the immunotherapy techniques as well as on the search for the low-weight inhibitory compounds. *Aim.* The main aim of this study was to estimate the value of the whole-sized human recombinant protein as an anti-tumor vaccine against PRAME-expressing tumor cells. *Methods.* We have cloned a coding sequence of the human PRAME gene in the pET32a expressing vector. The recombinant PRAME protein carrying 6-His tag has been further purified by means of the Ni-agarose column. Prior to purification we have developed conditions to refold recPRAME out of insoluble inclusive bodies. The final recPRAME was of high purity and occurred to be extremely stable in the form of the aqueous sterile 2 mg/mL solution being stored at +4C. The PRAME coding sequence was also cloned in the eukaryotic expressing vector pCEP (Invitorgene) under the strong CMV promoter. All mice were F1 female hybrids Balb/C*DBA2. Mouse SP2/0 multiple myeloma and B16-F1 melanoma cell lines have been transfected by PRAME/pCEP and constantly PRAME expressing cell lines have been selected. In every round of immunization we have used 35 animals. First mice set were vaccinated into abdomen 4 times every 2 weeks by the dose of 100 micrograms of recPRAME supplemented by 300 micrograms of aluminum hydroxide adjuvant (Sigma). The other 35 mice were inoculated with the only Al hydroxide as a negative control. We have also used an equal group of mice without immunizations as the other type of the negative control. 400000 PRAME/pCEP-transfected cells and 400000 cells transfected with the pCEP vector without PRAME insertion were engrafted into upper dorsal part of every mouse. For every cell types we have used the following sets of mice: 15 mice immunized by recPRAME, 15 mice inoculated by only Al hydroxide, and 15 mice without any immunization steps. The extra 5 mice from every group of animals were used for blood counts, ELISA estimation of the anti-PRAME antibodies and in the anit-tumor leukocyte cytotoxicity tests. *Results.* We have demonstrated that recPRAME is not toxic taking into account insignificant difference in blood values among experimental and control groups of animals and integrity of animal tissues analyzed by immunohystochemistry. Immunization by recPRAME created a strong and significant humoral response which has been evaluated by high presence of both IgM and IgG anti-PRAME antibodies in the recPRAME immunized animals. The clear anti-tumor effect of the recPRAME vaccination was demonstrated by the 3 time PRAME-positive tumor growth suppression as compared with the growth of the PRAME-negative tumor cells in the case of myeloma. This effect in the case of the melanoma cells was even more significant due to 5 time PRAME-positive tumor cell growth reduction. We have also used monoclonal antibodies against PRAME obtained in our lab to characterize PRAME protein cellular localization. All transfected cells as well as K562 cells and human melanoma cell lines (a kind gift of Prof. A. Baryshnikov) shows a distinct staining of the cellular membrane surfice. *Conclusion.* Our data confirms previously mentioned anti-tumor effects of the PRAME vaccination. In our study we further extend these observations and have shown that not only PRAME-derived peptides but the full-length recPRAME may be used in the vaccination against PRAME-positive tumors. It is especially important considering necessity to overcome HLA-restriction. The whole-sized recPRAME may potentially cover all HLA isotypes and be an invariant vaccine for every patient who suffers from PRAME- positive malignancy. The localization of the PRAME protein on the tumor cell surfice raised a possibility for the usage of the anti-PRAME antibodies as a therapeutic agent.

THE DNA DEMETHYLATING AGENT 5-AZA-2'-DEOXYCYTIDINE INDUCES EXPRESSION OF NY-ESO-1 AND OTHER CANCER/TESTIS ANTIGENS IN MYELOID LEUKEMIA CELLS

N Blagitko-Dorfs,[1] M Almstedt,[2] J Duque-Afonso,[2] J Karbach,[3] D Pfeifer,[2] E Jäger,[3] M Lübbert[2]

[1]University Medical Center Freiburg, Freiburg, Germany; [2]University Medical Center, Freiburg, Germany; [3]Krankenhaus Nordwest, Frankfurt, Germany

Background. Azanucleoside DNA-hypomethylating agents have remarkable clinical activity in myelodysplastic syndromes (MDS) and acute myeloid leukemia (AML), particularly at low, non-cytotoxic doses. They are able to reactivate epigenetically silenced genes including, among others, a number of immunogenic proteins called cancer/testis antigens (CTAs). Germ cell restricted expression of CTAs in normal tissues and aberrant expression in various human cancers make them attractive targets for cancer immunotherapy. In contrast to solid tumors, CTA expression in myeloid malignancies is usually very low or absent. *Aim.* We aimed to reactivate epigenetically silenced CTAs using 5-aza-2´-deoxycytidine (DAC) and thereby trigger an immune response in various myeloid leukemia cell lines. *Methods.* Myeloid cell lines Kasumi-1, U937, THP-1 and HL-60 were treated with 5-aza-2´-deoxycytidine and mRNA expression of the CTAs NY-ESO-1, MAGEA1, MAGEA3 and MAGEB2 was quantified at days 2, 3, 6, 14 and untreated control using real-time RT-PCR. In addition, microarray expression analysis was carried out in DAC-treated Kasumi-1 cells. Expression of NY-ESO-1 was confirmed at the protein level. Recognition and functional activity of *de novo* expressed NY-ESO-1 in DAC-treated U937 cells was evaluated by IFN-g Elispot and standard 51chromium release

assay using the HLA-B51 restricted NY-ESO-1 p94-102 -specific T cell clone. DNA methylation of the NY-ESO-1 promoter region was analyzed by pyrosequencing. *Results.* Consistent time- and dose-dependent reactivation of all 4 CTA genes was observed, with maximum mRNA levels 72-144 h after treatment start. *De novo* induction of NY-ESO-1 correlated with DNA hypomethylation of the promoter region. As determined by RNA microarray analyses, numerous other CTA genes (located on the X-chromosome) were also derepressed in a time-dependent fashion by DAC. By Elispot and chromium release assays we showed that the *de novo* expressed protein was naturally processed and presented in a time- and dose-dependent fashion up to 8 days after the start of DAC treatment, and converted the cell lines susceptible to antigen-specific recognition by CD8+ T-cell clones. *Conclusions.* NY-ESO-1 and numerous other CTAs localized on the X-chromosome are readily and transiently reactivated in myeloid leukemia cell lines treated with DAC. The susceptibility of DAC-treated AML cell lines to antigen-specific T-cell recognition has clear implications for future clinical trials combining epigenetic therapy and specific immunotherapy in myeloid neoplasia.

NATURAL KILLER T CELL ENGAGEMENT ENHANCES IMMUNOGENICITY OF CHRONIC LYMPHOCYTIC LEUKAEMIA CELLS

R Weinkove,[1] J Carter,[2] I Hermans,[1] F Ronchese[1]

[1]Malaghan Institute of Medical Research, Wellington, New Zealand; [2]Capital & Coast District Health Board, Wellington, New Zealand

Background. CLL is the most common leukaemia in Europe, and may be an attractive target for adoptive immunotherapy: Although CLL can be cured with allogeneic stem cell transplantation, this treatment is not an option for the majority of patients due to advanced age or co-morbidities. Invariant natural killer T (iNKT) cells recognise glycolipid agonists such as alpha galactosylceramide (aGalCer) presented by CD1d, rapidly producing large amounts of cytokines and shaping the subsequent immune response. aGalCer is a highly effective adjuvant to tumour vaccination in some murine models of cancer. *Aims.* We sought to assess the iNKT cell/CD1d axis in patients with chronic lymphocytic leukaemia (CLL) with a view to using aGalCer as an adjuvant in CLL immunotherapy. *Methods.* Following informed consent, peripheral blood mononuclear cells were isolated from 30 patients with untreated CLL and 30 healthy, age-matched controls. iNKT cells were enumerated and phenotyped by flow cytometry. *In vitro* iNKT cell proliferation in the presence of aGalCer and interleukin 2 was assessed, and iNKT cell lines generated from patients and controls. Chronic lymphocytic leukaemia cells were purified by flow cytometric cell sorting, pulsed with aGalCer or vehicle, and used as stimulators in mixed lymphocyte reactions. *Results.* There was a trend towards lower iNKT cell numbers in patients with CLL (median 0.01% of $CD3^+$ lymphocytes *vs.* 0.02% in controls). iNKT cells could be expanded from all controls and from 12 out of 14 patients with CLL, although fold expansion was lower in patients than controls. iNKT cell lines derived from patients and controls had similar cytokine producing capacity and lysed CD1d+ target cells in the presence of aGalCer. CLL cells themselves expressed CD1d, and pulsing CLL cells with aGalCer enhanced the subsequent mixed lymphocyte reaction against the leukaemic cells. *Summary/Conclusions.* The iNKT cell/CD1d axis is largely intact in patients with CLL, and functional iNKT cell lines can be derived from patients. Pulsing CLL cells with aGalCer enhances the subsequent mixed lymphocyte reaction. aGalCer pulsed tumour cells may prove an effective tumour vaccine in CLL.

SERUM IL-7 AND IL-15 KINETICS DRIVE LYMPHOPENIA-INDUCED PROLIFERATION AFTER HIGH-DOSE CHEMOTHERAPY AND AUTOLOGOUS STEM CELL TRANSPLANTATION

D Focosi, M Petrini

University of Pisa, Pisa, Italy

Introduction. Murine models have shown that interleukin (IL)-7 and IL-15 are required for the 2-step recovery of the absolute lymphocyte count (ALC) after high-dose chemotherapy, a phenomenon termed "lymphopenia-induced proliferation (LIP)". No human study to date has ever validated preclinical models. Aim. We studied kinetics of serum IL-7 and IL-15 levels during high-dose chemotherapy supported by autologous hematopoietic stem cell transplantation (HSCT) in patients with multiple myeloma (MM), Hodgkin's lymphoma (HL) or non-Hodgkin lymphoma (NHL). *Methods.* Informed consent was collected from 60 MM (Mel100 or Mel200), 15 NHL (BEAM) and 12 HL (BEAM) patients undergoing autologous HSCT. Blood samples were collected at admission, and on days +3, +6, +10, +40, +70, +100 after HSCT. Plasma IL-7 and IL-15 levels were measured by high sensitivity (> 0.1 pg/mL) Quantikine ELISA kits (R&D Systems, Minneapolis, MN) according to manufacturer's instructions. *Results.* Serum IL-7 and IL-15 levels inversely correlated with the ALC ($P < 0.001$). Serum IL-7 peaked at day 6 in BEAM and on day 10 in Mel100 and Mel200. Serum IL-15 peaked on day 6 in Mel200 and BEAM and on day 10 in Mel100 (Figure 1). The degree of the peak directly correlated with the dose of melphalan administered during conditioning (100 mg/m^2 < 200 mg/m^2 < BEAM). *Conclusions.* The differential day of peak of serum IL-7 and IL-15 is concordant with what is known from murine models about LIP. LIP is a dose-dependent phenomenon which in our model correlated linearly with increasing doses of melphalan. These results have implications for adoptive immunotherapy in the setting of high-dose chemotherapy.

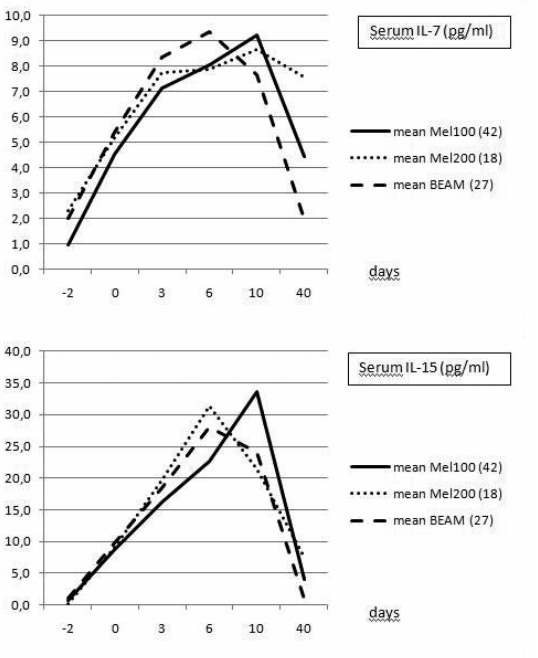

Figure 1. Serum levels of IL-7 and IL-15 according to differ.

IMMUNE- MODULATION OF CD4+ AND CD8+ - CELLS BY 5-AZACYTIDINE

T Stuebig,[1] A Badbaran,[2] S Brandl,[3] C Wolschke,[1] Y Hildebrandt,[4] A Zander,[1] N Kroeger,[1] D Atanackovic,[2] B Fehse[1]

[1]Univesity clinic of Hamburg - Eppendorf, Hamburg, Germany; [2]Univesity Clinic of Hamburg - Eppendorf, Hamburg, Germany; [3]Clinic for Oncology and Haematology, Univerity Medical Center Hamburg, Hamburg, Germany; [4]Clinic for Stem Cell Transplantation, University Medical Center Hamburg, Hamburg, Germany

Background. Demethylating agents like 5-Azacytidine (5-Aza) were introduced for treatment of myeloid dysplastic syndrome (MDS) and acute myeloid leukaemia (AML). Besides induction of differentiation, an additional suggested mechanism for 5-Aza is demethylation of antigens genes such as Cancer-Testis Antigens (CTA) which induce immune response by immunocompetent cells. Despite our extended knowledge on its effect on myeloid cells, 5-Aza impact on immune cells has not been yet clarified. Therefore, we investigated the effects of 5-Aza on T cells. *Materials and methods.* T-cells were isolated from buffy coats by magnetic cell sorting. Cells were stimulated and cultured for 1 week in the presence of IL-2. Thereafter, cells were treated with (5 μM or 20 μM) or without 5-Aza for 48h. mRNA was isolated and used for cDNA synthesis. qPCR was performed under standard conditions for expression of IL-10, FoxP3, and TGF-beta, normalized to GAPDH. T cells were analyzed by flow cytometry using the following antibodies: CD3, CD4, CD8, HLA-DR, FoxP3, CD127, CCR7, CD45RA, CD69, CD62L and CD25. Functional cytotoxicity of an AML cell line (HL60) was measured using a LDH release assay. *Results.* CD3 expression was not altered by 5-Aza treatment, but changes of T cell subpopulation subsets were observed: percentage of $CD8^+$ T cells decreased from 46% to 35%, whereas percentage of $CD4^+$ T cells increased from 57% to 68%. $CD3^+$ cells treated with none, 5 μM and 20 μM 5-Aza were stained for HLA-DR activation marker and exhibited reduced expression of 57%, 48% and 44% respectively, while mRNA level screening of IL10, FoxP3, and TGF-beta indicated upregulation (P=0.02, P=0.003 and P=0.02). Strikingly, $CD4^+FoxP3^+$ Treg cell counts elevated from 5% to 10% and 11% under aforementioned conditions. FoxP3 mRNA levels were also increased in $CD8^+$ cell compartment (P=0.01). In accordance with mRNA data, the different drug concentrations induced upregulation of $CD8^+FoxP3^+$ cells in a climax of 32 to 45%. Furthermore, we observed a persistence of a naive phenotype as indicated by $CCR7^+CD45RA^+$ markers in both T cell subpopulations. Interestingly, this effect was greater in the $CD8^+$ population. In a cytotoxicity assay we observed a significantly reduced capability of Aza- treated $CD3^+$ cells to lyse target cells (P=0.02). *Conclusions.* Our data indicate that 5-Aza induces FoxP3 expression and a regulatory phenotype in $CD4^+$ and $CD8^+$ cells. 5-Aza treatment supports inhibitory phenotypes by induction of inhibitory cytokines like IL10, while killing capacity of Aza treated cells is reduced. Moreover, naive T cells seem to be more stable during 5-Aza treatment. Therefore, we conclude that 5-Aza treatment constrains distribution and function of immune cells.

0739

IMPACT OF KIR-LIGAND AND KIR-GENE EXPRESSION ON NK CELLS MEDIATED KILLING OF MYELOMA CELLS

T Stuebig,[1] Y Hildebrandt,[2] K Jungk,[2] A Konielski,[2] L Lange,[2] T Binder,[3] H Duske,[3] D Atanackovic,[4] B Fehse,[1] T Eiermann,[3] A Zander,[1] N Kroeger[1]

[1]Univesity clinic of Hamburg - Eppendorf, Hamburg, Germany; [2]Clinic for Stem Cell Transplantation, University Medical Center Hamburg, Hamburg, Germany; [3]Department of Transfusion Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [4]Univesity Clinic of Hamburg - Eppendorf, Hamburg, Germany

Background. Natural Killer cells (NK cells) have the ability to recognize and kill malignant cells, like myeloma cells. Their killing ability is regulated by different groups of receptors that either activate the NK cell or inhibit its cytotoxic function. Killer Immunoglobulin like Receptors (KIR, CD158) are a family of molecules found on the surface of NK cells, estimated to inhibit their cytotoxic function. Both KIR2DL1 and KIR2DL3 receptors recognize the HLA-C2 and -C1 molecules respectively, when found on the corresponding cell. Both receptors trigger inhibitory pathways to protect tissues of NK mediated killing. We evaluated the impact of the KIR2DL1/2DL3 on the cytotoxicity of NK cells against different myeloma cell lines which express different HLA-C molecules. *Material and methods.* Three different myeloma cell lines (KMS12BM [C1/C1], MOLP8 [C1/C2] and RPMI8266 [C2/C1]) and a NK cell line (NKL) were cultured under standard conditions. NKL cells were transfected with cDNA for human KIR2DL1 and KIR2DL3, respectively. For RNAi experiments two siRNA and two control siRNA were used. NK cells from healthy donors were isolated by magnetic cell sorting. Thereafter NK cells were transiently transfected with the siRNA or control siRNA for up to 48 h. NK cell cytotoxicity was measured using a LDH release assay. *Results.* This study investigates whether the HLA-C genotype is adequate for protecting myeloma cells of NK mediated cell death. When NK cells, that are genotyped for HLA-C1/C1, were co-cultured with different myeloma cell lines, C1/C1 myeloma cells were rescued in contrast to myeloma cell lines that express C2/C1 (12% cytolyses *vs.* 38% and 45% cytolyses, respectively, P<0.05). KIR receptors, by recognition of HLA-C molecules, are believed to reduce NK cell cytotoxicity. We used NK cells from healthy donors, which express KIR2DL1 (recognizing C2) to evaluate whether receptors´RNAi knock down could increase the ability of NK cells to lyse target cells. Knock down of KIR2DL1 in NK cells results in a highly efficient killing of a C2/C2 target cell line (RNAi treated NK cells showed a cytotoxicity of up to 70%, P<0.05). To evaluate whether KIR receptors are major inhibitory molecules, we used NK cell line (wt NKL), a non expressor of KIR receptors that exhibited high cytotoxic potential against all tested target cell lines (>65% cytotoxicity). This NK cell line was transfected with KIR2DL1 or KIR2DL3 (recognizing C2, or C1). C2 positive myeloma cell lines were significantly rescued when exposed to KIR2DL1 transfected NK cells (wt NKL 72% *vs.* KIR2DL1 NKL 29%, P<0.05). Similar results were obtained when C1 positive target cell line was co- cultured with KIR2DL3 transfected NK cells. RNAi mediated silencing of KIR overexpression restores protection observed. *Conclusion.* We have shown that: 1) genotype recognition is sufficient for inhibition of NK cells dependent cytotoxicity, 2) KIR receptors are important inhibitory molecules for NK mediated cell death, while their down regulation highly affects their killing capacity. Therefore, KIR receptors emerge as an attractive target molecule for modulation of NK cell myeloma surveillance.

Chronic lymphocytic leukemia - Biology 2

IDENTIFICATION OF RHAMM-DERIVED CD8+ RESTRICTED, HETEROCLITICAL, CRYPTIC EPITOPE R9Y AS A PROMISING TARGET FOR IMMUNOTHERAPY OF CHRONIC LYMPHOCYTIC LEUKEMIA

K Giannopoulos,[1] A Dmoszynska,[1] J Rolinski,[1] J Greiner,[2] S Stilgenbauer,[2] M Schmitt[3]

[1]Medical University of Lublin, Lublin, Poland; [2]University of Ulm, Ulm, Germany; [3]University of Rostock, Rostock, Germany

The receptor for hyaluronic acid mediated motility (RHAMM) is leukemia associated antigen (LAA) strongly correlated with proliferation and bearing negative prognosis for chronic lymphocytic leukemia (CLL). Recently, we completed a peptide vaccination clinical trial with dominant RHAMM-derived epitope (R3) for patients with CLL. To our surprise, R3 vaccination induced regulatory T cells (Treg) in 66% vaccinated patients which might limit the clinical efficacy of peptide immunotherapy. Obtained results also pointed to a pre-existing tolerance to LAA-derived peptides. While the tolerance is limited to dominant epitopes we aimed to identify a crypitic epitopes that might circumvent tolerance mechanisms and in order to increase affinity modified them heteroclitically. We screened in silico 50 peptides with different heteroclitical modifications using SYFPEITHI algorithm and calculate affinity to MHC-I complex. Further, we choose 10 peptide pairs (cryptic - modified) which affinity increased to the highest extent and screened them *in vitro* assay for the affinity as well as the peptide-MHC-I complex stability in T2 binding test. In functional studies we screened 5 peptide pairs by ELISPOT analysis using $CD8^+$ T cells isolated from peripheral blood (PB) of CLL patients and healthy donors. We found that $CD8^+$ cells from CLL patients presensitized with peptides: R9Y (YLQLDAFEV); R13YL (YLVQSLEDV); R15Y (YLKQTLDEL); R17YL (YLQEQLNKI) as well as R19YL (YLIKHVVKL) specifically recognized T2 cells pulsed with respective peptides with the highest frequency for R9Y (90%). In chromium-51 release assays, R9Y-primed $CD8^+$ T cells from CLL patients were able to effectively lyse R9Y-peptide pulsed T2 cells as well as CLL leukemic cells presenting RHAMM in a HLA-A2 restricted manner; in contrast, K562 cells and T2 cells lacking either RHAMM or HLA-A2 expression were not lysed above background levels. In addition, mAb-based MHC I blockade demonstrated that the observed peptide-specific lysis was MHC I-restricted. In conclusion, we defined a novel RHAMM-derived CD8+ restricted, heteroclitical, cryptic epitope R9Y which might represent an interesting target for immunotherapy of CLL. In future clinical administration the R9Y peptide might circumvent tolerance to dominant epitopes and thereby increase efficacy of peptide vaccination.

STUDY OF THE QUANTITATIVE, FUNCTIONAL AND IMMUNOREGULATORY PROPERTIES OF BONE MARROW MESENCHYMAL STEM CELLS IN PATIENTS WITH B-CELL CHRONIC LYMPHOCYTIC LEUKAEMIA

MC Kastrinaki, C Pontikoglou, M Klaus, C Kalpadakis, M Psyllaki, P Kanellou, M Fragioudaki, K Pavlaki, H Papadaki

University of Crete School of Medicine, Heraklion, Greece

Background. Leukemic B-lymphocytes in patients with B-cell chronic lymphocytic leukaemia (B-CLL) accumulate in the bone marrow (BM) possibly under the influence of locally produced nourishing/survival/homing signals. The possible involvement of BM mesenchymal stem cells (MSCs), representing the progenitors of the BM microenvironment cells, in the pathophysiology of B-CLL has not been extensively studied. *Aims.* To investigate whether the BM MSCs from B-CLL patients are primarily or secondarily defective by evaluating their quantitative/qualitative characteristics and immunoregulatory properties. *Methods.* BM aspirates from nine B-CLL patients (Binet stage A: 4; Binet stage B: 2; Binet stage C:3) and nine healthy donors were appropriately culture expanded to obtain the MSCs. The immunophenotypic (CD45/CD14/CD34 negative and CD70/CD90/CD105/CD44/CD29/CD73/CD146 positive) and survival characteristics of MSCs were evaluated by flow-cytometry. A colony-forming unit fibroblast (CFU-F) assay was used for the estimation of MSC frequency within the BM mononuclear cell (BMMC) fraction and the population doubling time for the evaluation of their proliferative capacity through passages. MSC differentiation capacity toward the osteogenic and adipogenic lineages was studied using appropriate culture conditions. Patients' MSC immunosuppressive function was evaluated by estimating the proliferation (^{3}H-thymidine method) of mitogen-induced (PHA 2 μg/mL or IL-2 500 Iu/mL) allogeneic normal $CD3^+$ cells in the presence of different concentrations of MSCs from patients or healthy controls. FISH analysis was also performed in MSCs cultures from passage-2 for possible detection of the genetic aberrations identified in patient haemopoietic cells (LSI ATM [11q22.3], CEP12, D13S319 [13q14.3], IGH [14q32.3], TP53 [17p13.1]). *Results.* MSC frequency was decreased in B-CLL patients (5.2±6.17 CFU-F per 10^5 BMMCs) compared to controls (15.32±17.41 CFU-F per 105 BMMCs; $P<0.05$) apparently due to BM leukemic infiltration. The immunophenotypic characteristics and differentiation potential of MSCs towards adipogenic (Oil red O stain and aP2 and PPARG mRNA expression) and osteogenic (ALP/Von Kossa stain and ALP and RUNX2 mRNA expression) lineages did not differ between patients and controls. The proliferative potential of MSCs through passages was reduced in patients compared to controls ($P<0.001$) and MSC cultures from 3 patients could not expand beyond passage-4. A statistically significant increased proportion of apoptotic cells (7-amino-actinomycin-D positive) was also observed in MSC cultures from patients compared to controls through passages ($P=0.0206$). MSC immunosuppressive function in terms of inhibition of mitogen-induced T-cell proliferation did not differ significantly between patient and normal MSCs. FISH analysis of MSC cultures did not identify the genetic aberrations observed in the respective haemopoietic cells in any patient. Summary/*Conclusions.* The BM MSCs from B-CLL patients display normal immunophenotypic characteristics and differentiation potential. The immunosuppressive properties of patient MSCs are normal suggesting that MSCs is unlikely to have a role in the pathogenesis of autoimmune complications associated with B-CLL. Patient MSCs are devoid of the genetic aberrations associated with the disease. MSCs however, display impaired proliferative potential and survival during culture expansion probably due to their previous exposure in the leukemic BM environment. The production of cytokines that may have a role in the survival, growth and homing of the malignant cells by patient MSCs is under investigation.

0742

MDM4/MDMX IS OVEREXPRESSED IN CHRONIC LYMPHOCYTIC LEUKAEMIA (CLL) AND MARKS A SUBSET OF P53WILD-TYPE CLL WITH A POOR CYTOTOXIC RESPONSE TO NUTLIN-3

M Dal Bo,[1] P Secchiero,[2] M Degan,[1] D Marconi,[1] R Bomben,[1] D Benedetti,[1] A Zucchetto,[1] G Pozzato,[3] G Gaidano,[4] G Del Poeta,[5] F Forconi,[6] G Zauli,[2] V Gattei[1]

[1]Centro di Riferimento Oncologico, Aviano, Italy; [2]University of Ferrara, Ferrara, Italy; [3]Maggiore General Hospital, University of Trieste, Trieste, Italy; [4]Amedeo Avogadro University of Eastern Piedmont, Novara, Italy; [5]S. Eugenio Hospital and University of Tor Vergata, Rome, Italy; [6]University of Siena, Siena, Italy

Background. p53 plays a key role in determining the clinical features of chronic lymphocytic leukemia (CLL). Disruption of p53 by point mutations and/or deletion at 17p13 occurs in a fraction of cases at diagnosis and predicts poor survival and chemorefractoriness. In cells with functional p53, p53 activity is inhibited through interaction with MDM2. In this regard, p53 can be activated upon exposure of cells to inhibitors of such interaction, like Nutlins. In fact, exposure of CLL cells to Nutlin-3 is effective in raising the levels of p53 protein with subsequent induction of cell cycle arrest and/or apoptosis independently of the most relevant prognostic markers. However, cells of a minority of p53 wild-type ($p53^{wt}$) CLL cases do not respond to Nutlin-3 treatment and fail to display the canonical signature associated with in-vitro Nutlin-3 exposure. *Aims.* to identify and validate the relevant genes associated with resistance of $p53^{wt}$ CLL cells to the in-vitro Nutlin-3 effects. *Methods.* purified cells from sixteen peripheral blood (PB) CLL samples, all with $p53^{wt}$ gene, were exposed to 10 microM Nutlin-3 for 24 hours. Gene Expression Profile (GEP) was performed using a dual labelling strategy; all validation experiments were performed by quantitative real-time PCR (qRT-PCR). *Results.* i) signature of Nutlin-3 exposure in $p53^{wt}$ CLL: 144 differentially expressed genes (143 up-regulated, 1 down-regulated) were correlated with the response to Nutlin-3. Among up-regulated genes, several genes were related to apoptosis (e.g. BAX, BBC3, IKIP, FAS, TRIAP1, GADD45, TP53INP1, ISG20L1, ZMAT3, TNFRS10C, TNFRSF10B/TRAIL-R2), while other genes were over-expressed upon ex vivo exposure to Nutlin-3 (e.g. MDM2, CDKN1A, PCNA) as a part of a negative feed-back mechanism. Of note, this signature was not shared by 3/16 $p53^{wt}$ cases ("non-responder"$p53^{wt}$ CLL); consistently, cells from these cases were significantly resistant to the in-

vitro cytotoxic effects of Nutlin-3; ii) signature of Nutlin-3 "non-responder"p53^{wt} CLL: comparing the constitutive GEP of 13 "responder"versus 3 "non-responder"p53^{wt} CLL, we obtained 278 differentially expressed genes, 149 up-regulated and 129 down-regulated in "non-responder"p53wt CLL. Among up-regulated genes, we focused on MDM4/MDMX, a gene whose product was known to have an inhibitor activity of p53-dependent transcription and to form Nutlin-3 resistant complexes with p53. iii) MDM4/MDMX expression in CLL: taken together, higher expression levels of MDM4/MDMX were detected in a different series of 43 CLL samples when compared to normal B cells of PB samples from 15 healthy donors (P<0.0001). Moreover, no differences in MDM4/MDMX expression levels were detected between various CLL categories, obtained according to IGHV gene status, FISH groups, and CD38, CD49d or ZAP-70 expression. *Conclusions.* in keeping with an over-expression of MDM4/MDMX detected in primary samples from several solid tumors, including glioblastoma, retinoblastoma, breast, colon, and lung cancers and preclinical studies indicating the anti-neoplastic effects of MDM4/MDMX down-regulation in murine lymphoma models, MDM4/MDMX turned out to be universally over-expressed by CLL cells compared to normal B cells, despite its peculiar over-expression in a subset of Nutlin-3 "non-responder"p53^{wt} CLL. This observation contributes to identify MDM4/MDMX as a potentially useful new therapeutic tar*get* also for CLL.

0743

PROLIFERATIVE CELLULAR COMPARTMENT IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL): CHARACTERIZATION AND PROGNOSTIC SIGNIFICANCE

P Abrisqueta,[1] N Villamor,[2] M Crespo,[1] A Muntañola,[3] A Navarro,[3] C Codony,[3] C López,[2] M Camós,[2] E Calpe,[3] MJ Baptista,[3] G Gutiérrez-García,[3] O Salamero,[1] E Montserrat,[3] F Bosch[1]

[1]Hospital Vall Hebron, Barcelona, Spain; [2]Hematopathology unit, Hospital Clínic, Barcelona, Spain; [3]Hematology unit, Hospital Clínic, Barcelona, Spain

Background. Historically chronic lymphocytic leukemia (CLL) has been considered a non-proliferative disease characterized by the accumulation of resting mature B-lymphocytes. However, recent findings are questioning this concept, suggesting the existence of a significant cell proliferation. Furthermore, CLL cells present in bone marrow (BM) and lymph nodes (LN) seem to be more prone to proliferation than those present in the peripheral blood (PB). The amount of cell proliferation and its prognostic significance has not been properly analyzed. *Aims.* To determine, both in BM and PB, the expression of genes involved in proliferation, to phenotypically characterize the leukemic subpopulation that proliferates and to analyze the relationship between the degree of proliferation and clinical characteristics of the disease. *Methods.* Gene expression profiling of proliferation genes and the amount of cell proliferation in different tissue compartments (BM and PB) were examined in patients with CLL. In isolated CD19/CD5^{+} tumoral cells from 17 paired PB and BM samples, expression of genes (n=93) involved in the initiation and development of the cell cycle was analyzed by low-density TaqMan® arrays. The amount of proliferative (Ki67 positive) CLL cells was measured by flow cytometry in 50 paired samples. In addition, coexpression of molecules associated with cellular activation (CD38, CD71, CD69), adhesion (CD49d), chemokine receptors (CXCR4, CXCR3), interaction between T and B cells (CD86), signaling (ZAP-70), and Toll-like receptors (TLR9) was compared between Ki67^{+} and Ki67^{-} CLL subpopulations. Finally, the degree of proliferation was correlated with the main clinical and biological characteristics.

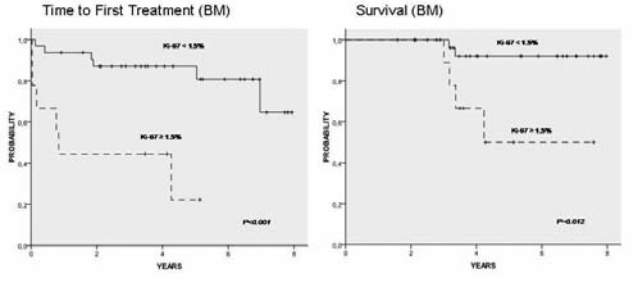

Figure 1. Shorter time to first treatment and inferior survival in patients with increased Ki67(+) CLL cells.

Results. As assessed by gene expression profiling, genes involved in the initiation and progression through the cell cycle had higher expression in CLL cells from BM than in those from PB. Moreover, the percentage of proliferating (Ki-67^{+}) CLL cells analyzed by flow cytometry was significantly higher in BM than in PB. The Ki-67^{+} CLL cells had different immunophenotypic characteristics (increased expression of ZAP-70, CD38, CD49d, CD5, CD86, CD71, and TLR9 and decreased expression of CXCR4 from the non-proliferating (Ki-67^{-}) CLL cells. Adverse clinical and biological prognostic markers (short lymphocyte doubling time, lymph node areas involved, lymphocytosis, and increased expression of ZAP-70, CD38 and CD49d) were associated with the degree of proliferation, and also, the amount of Ki-67^{+} CLL cells correlated with a shorter time to first treatment and a worse survival (Figure). *Conclusions.* Altogether, these results challenge, once more, the concept of CLL as an accumulative disease rather than a proliferating one by showing that a significant fraction of the CLL clone has a proliferating phenotype and, moreover, that a higher degree of proliferation correlates with a more aggressive disease.

0744

IN CHRONIC LYMPHOCYTIC LEUKEMIA THE AMOUNT OF PROLIFERATION CENTERS IN TISSUE-BIOPSIES CORRELATES WITH UNFAVORABLE CYTOGENETIC ABNORMALITIES

M Ciccone,[1] C Agostinelli,[2] G Rigolin,[3] L Rizzotto,[3] F Cavazzini,[3] S Righi,[2] MT Sista,[2] E Sabattini,[2] O Sofritti,[3] P Piccaluga,[2] A Cuneo,[3] S Pileri,[2] PL Zinzani,[4] M Brugiatelli,[5] I Attolico,[6] G Fioritono,[7] C Stilitano[8]

[1]Hematology, Ferrara, Italy; [2]Hemolymphopathology L&A Seragnoli Azienda Ospedaliero Universitaria S Orsola, Bologna, Italy; [3]Hematology Section - Azienda Ospedaliero-Universitaria S.Anna, Ferrara, Italy; [4]Ospedale Seragnoli Hematology Dept, Bologna, Italy; [5]Divisione di Ematologia, Azienda Ospedaliera Papardo, Messina, Italy; [6]Ospedale San Carlo, Potenza, Italy; [7]Department of Hematology, Civic Hospital, Fonteromana, Pescara, Italy; [8]Dipartimento di Emato-Oncologia, Azienda Ospedaliera Bianchi-Melacrino-Morelli, Italy

Background. In chronic lymphocytic leukemia (CLL) molecular cytogenetic abnormalities may identify specific disease entities and may be associated with distinct prognosis. Currently, peripheral blood is the preferred source to assess the biological risk. However, fluorescence in-situ hybridization (FISH) on paraffin-embedded fixed tissues (PEFT) may also be used to study cytogenetic abnormalities in CLL lymph-node where the "proliferation center" (PC) is the histopatologic hallmark. PCs probably represent the sites where T-dependent immune responses to unknown antigens promote clonal B cell selection and expansion. *Aims.* i) to analyze the sensitivity and reproducibility of FISH on PEFT, ii) to correlate specific chromosome lesions to PC extension; iii) to estimate the frequency of chromosome lesions on lymph node samples. Method: 183 CLL cases (including 20 Richter syndrome, RS) arranged in 5 tissue macro-arrays (TMAs) were analyzed by FISH for deletions involving 11q23/ATM, 13q14 and 17p13/p53; trisomy 12; and translocations involving the immunoglobulin gene (IgH) on band 14q32. Cytogenetic features were correlated to 2 histologic patterns: 1) PC-rich group including CLL cases with confluent and large PCs and RS cases and 2) typical group with scattered, well-distinct PCs. *Results.* Assessable data with the complete 5 probe-panel were obtained in 101/183 cases (55,1%); in 58 cases the results were partial and in 24 cases no data were collected for all the probes mainly because of insufficient numbers of cells on TMA samples. Chromosomal aberrations were detected in 79/101 cases (78.2%). The most frequent abnormality was 13q- (36.7% of the cases), followed by 14q32 translocations (30.8%), 11q- (24.7%), +12 (19.5%) and 17p- (15.6%). Ten cases showed 14q32/IgH gene extra-copies (3-5 signals in 10-30% of the nuclei). 17p-, +12 and 14q32/IgH translocations were more frequently encountered in the PCs-rich group (P<.001, .030 and .043 respectively). The PC-rich group was significantly associated to "high-risk"cytogenetic abnormalities (11q- and/or 17p-; P=.001) and to a higher number of abnormalities (≥ 2; P=.001). The difference persists even if RS cases were excluded. *Conclusions.* FISH on TMAs is a reproducible and a feasible tool for the evaluation of cytogenetic abnormalities in CLL allowing for a decreased both time consumption and experimental variability. The incidence of cytogenetic abnormalities in our series resembles that of historical series with exception of 14q translocation and 17p- possibly due to a higher number of patients with resistant or progressive disease. The higher occurrence of unfavourable cytogenetic features in PC-rich lymph nodes suggest that PCs may be sites where, due to an antigenic stim-

uli, B cells are induced to proliferate thus conferring genetic instability. Further studies will clarify if cytogenetic abnormalities occurring in lymph-node and bone marrow PCs precede their appearance in the peripheral blood thus supporting the idea that at tissue level PC is crucial for triggering clonal proliferation nourishing the accumulation compartment.

0745

THE IMPACT OF THE MICROENVIRONMENT ON CLL CELLS

A Schulz,[1] G Tödt,[1] S Stilgenbauer,[2] H Döhner,[2] P Lichter,[1] M Seiffert[1]

[1]German Cancer Research Center, Heidelberg, Germany; [2]Universität Ulm, Ulm, Germany

Background. Chronic lymphocytic leukaemia (CLL) is characterized by high numbers of CD5/CD19 positive cells in the peripheral blood (PB). These cells show prolonged survival and accumulate in the PB and lymphoid organs of the patients. Both, intrinsic defects in the regulation of programmed cell death (apoptosis) as well as an altered, survival-stimulating microenvironment are discussed as major pathogenic factors of CLL. This is emphasised by the fact that CLL cells rapidly undergo apoptosis *in vitro*, but cell survival can be maintained by stromal cell co-cultures for months. *Aims.* Our studies aimed at the molecular characterization of microenvironmental factors that contribute to the abnormal long survival of CLL cells to identify potential targets for novel therapy strategies for CLL patients. *Methods.* To elucidate the impact of microenvironmental factors on the survival of CLL cells, we performed expression profiling of peripheral blood mononuclear cells (PBMC) from CLL patients in three survival inducing culture conditions: a) co-culture with the human bone marrow-derived stromal cell line HS-5, b) culture in conditioned medium of HS-5 cells, and c) high cell density cultures of CLL cells. Additionally, we quantified protein levels of 174 different cytokines in the supernatant of CLL/HS-5 co-cultures by performing antibody arrays. Data validation was performed by qRT-PCR and ELISA. The impact of the candidate gene CCL2 on cell survival, apoptosis and migration was analyzed by flow cytometry after annexin V/7-AAD staining and in transwell assays. *Results.* Expression profiling revealed that there is a large overlap of differentially regulated genes in the three survival inducing culture conditions tested. Among these, we identified many cytokines which were upregulated on transcriptional level. These data could be validated on protein level by cytokine array analysis. Interpretation of the array data revealed CCL2 as one potential candidate gene. By qRT-PCR and ELISA with CD19-sorted B-cells, CD14-sorted monocytes and unsorted PBMC we could observe an upregulation of CCL2 expression and secretion by monocytes in the co-cultures. To evaluate the importance of this chemokine in CLL *in vivo* we have quantified CCL2 serum levels in the PB of patients and healthy donors and detected significantly elevated levels in CLL patients. We could further show by ELISA that CLL cells are able to induce CCL2 production in monocytes. Using transwell assays with recombinant CCL2, conditioned medium of CLL/HS-5 co-cultures, or serum of CLL patients as chemotactic stimuli, we observed induced migration of monocytes, which could be reduced by adding neutralizing antibodies against CCL2. *Conclusions.* Accessory cells within the CLL microenvironment play a critical role for the survival of CLL cells by releasing soluble factors. CLL cells are able to actively contribute to a favourable microenvironment by inducing expression of CCL2 in monocytes. This causes attraction of additional monocytes, which release a variety of different cytokines that contribute to the better survival of the CLL cells. Therefore, neutralization of monocytes-derived factors like CCL2 should be evaluated as a novel approach to improve treatment of CLL patients.

0746

EXPRESSION OF MIR-15A AND MIR-16-1 IN PRIMARY CLL

A Parker,[1] B Gregory,[1] A Gardiner,[1] Z Davis,[1] D Oscier[2]

[1]Royal Bournemouth Hospital, Bournemouth, UK; [2]Bournemouth University, Bournemouth, UK

Background. Heterozygous or homozygous loss of a minimally deleted region (MDR) of 13q14 spanning miR-15a and miR-16-1 is the most common genomic abnormality in CLL, occurring in approximately 70% of cases. Growing evidence supports a role for deregulation of miR-15a and miR-16-1 and hence of their downstream targets as a mechanism of action for a selective advantage conferred by 13q14 deletion. Expression of a DLEU2 transcript variant has been suggested as a mechanism of miR-15a and miR-16-1 production and variable methylation of the DLEU2 promoter has been reported in CLL. *Aims.* To investigate the relationship between expression levels of DLEU2, miR-15a and miR-16-1 and methylation of the CpG islands within the 13q14 MDR in primary CLL samples. *Methods.* To reduce effects of intra-clonal variation, samples from 61 CLL cases were selected based on 13q14 deletion status of either no loss (n=25), >80% homozygous loss (n=27) or >80% heterozygous loss (n=9) by FISH. Relative quantification of DLEU2, miR-15a and miR-16-1 expression levels was performed by taqman RT-PCR, together with quantification of DNA methylation of five CpG islands associated with13q14 MDR genes by bisulphite pyrosequencing. Results. Expression of DLEU2, miR-15a and miR-16-1 was 3-7 fold lower in homozygous loss samples compared to both heterozygous and no loss samples ($P<0.01$). Samples with one or more intact copies of the MDR displayed expression values across a >6-fold range for DLEU2 and >30-fold range for miR-15a and miR-16-1, however no significant difference between heterozygous loss and no loss samples was detected. In the no loss samples miR-15a and miR-16-1 expression levels showed a positive correlation with each other ($P<0.001$) and with DLEU2 expression ($P=0.002$). In the heterozygous loss samples, the same positive correlation was seen between miR-15a and miR-16-1 expression ($P<0.001$) but neither miR-15a nor miR-16-1 correlated with DLEU2 expression ($P>0.9$). Four of five CpG islands analysed showed hypomethylation in all 61 cases. Variable methylation 0-98%, mean 58.8±31.6% was detected within the CpG island associated with the transcription start site for DLEU2. Methylation of this island was not significantly different between deletion groups and did not correlate with expression levels of DLEU2, miR-15a or miR-16-1 transcripts. *Summary/Conclusions.* Considering the samples with high levels of homozygous loss as having almost zero expression of the three transcripts, those with one or more intact copies of the MDR clearly display expression of all three genes. This fact, together with the range of expression levels in the heterozygous loss samples, confirms that loss of one allele does not silence expression of miR-15a and miR-16-1. The close correlation between miR-15a and miR-16-1 transcript levels is suggestive of a linked mechanism for their regulation and it is of note that this may be related to DLEU2 expression in cells with two copies of the MDR but not in those with heterozygous loss. The confirmation of variable methylation of the DLEU2 promoter in the absence of an obvious association with expression suggests that further investigation of the DNA methylation in this region is warranted.

0747

COMPLEMENT-DEPENDENT LYSIS OF MAB-OPSONIZED B CELLS CAN INCREASE RESISTANCE OF NON-OPSONIZED B CELL LINES AND PRIMARY B CELLS TO SUBSEQUENT ATTACK

P Taylor,[1] V Beum,[1] A Lindorfer,[1] W Pawluczkowycz,[1] J Beurskens,[2] G van de Winkel,[3] W Parren[2]

[1]University of Virginia School of Medicine, Charlottesville, USA; [2]Genmab, Utrecht, Netherlands; [3]Genmab and Immunotherapy Laboratory, Dept. Immunology, University Medical Center, Utrecht, Netherlands

Background. Complement (C)-dependent cytotoxicity (CDC) is a major effector mechanism utilized by rituximab (RTX) and ofatumumab (OFA) in cancer immunotherapy. We recently reported that during mAb-mediated CDC, B cell lines, and B cells from chronic lymphocytic leukemia (CLL) patients, release long, thin streamers (aka tunneling nanotubules) from their surfaces. *Aims.* We now report that streamer generation requires calcium entry into cells, suggesting that signaling mediated by streamers may promote intercellular communication. Therefore we investigated whether CDC of mAb-opsonized B cells (sacrificial cells), and the accompanying streaming reaction can induce resistance to CDC in neighboring non-opsonized B cells (indicator cells) that are later subjected to mAb opsonization and C attack. *Methods.* PKH-dyed indicator cells were combined with non-opsonized or mAb-opsonized sacrificial cells and reacted with normal human serum (NHS) for 4 hrs. Additional NHS and mAb were then added, and CDC of the indicator cells was determined. This paradigm allows us to investigate whether the first "wave"of C attack on opsonized sacrificial cells induces resistance to the second wave of C and mAb attack on the indicator cells. *Results.* CDC of indicator Z138 cells was 91% if non-opsonized sacrificial Z138 cells were present in the 4 hr incubation, but CDC was only 63% if OFA-opsonized sacrificial Z138 cells were present, demonstrating development of resistance to CDC in indicator cells. OFA was more effective than RTX at overcoming CDC resistance of indicator cells. Challenge of indicator Daudi cells with RTX gave 85% or 50% CDC using naive or OFA-opsonized sacrificial Daudi cells, respectively, whereas CDC after challenge with OFA was 90% and 85%, respectively. Malignant B cells from CLL patients also acquire

substantial CDC resistance in this system. Challenge of indicator CLL B cells with OFA gave 63% or 21% CDC with non-opsonized or OFA-opsonized sacrificial Daudi cells, respectively. In order to examine the effects of calcium in these reactions, we substituted NHS-Mg-EGTA for NHS in the paradigm. Under these conditions (calcium is chelated by EGTA) the opsonized sacrificial cells are killed by the alternative pathway of C, but the cells do not release streamers. Moreover, indicator cells reacted with OFA-opsonized sacrificial cells in NHS-Mg-EGTA did not acquire resistance to classical or alternative pathway CDC, strongly suggesting that streaming and calcium influx into sacrificial and/or indicator cells play key roles in development of resistance to CDC. *Summary/Conclusion.* Exposure to sacrificial cells undergoing CDC protects indicator cells (B cell lines and primary CLL cells) from subsequent CDC upon challenge with OFA or RTX and C. Loss of protection when sacrificial cells are killed by the alternative pathway of C suggests that calcium fluxes play a key role in the development of resistance to CDC.

THE VEGF-STAT3 AXIS IS ESSENTIALLY INVOLVED IN THE BONE MARROW STROMAL CELL-MEDIATED CLL CELL SURVIVAL SUPPORT AND QUALIFIES AS A TARGET FOR SELECTIVE CLL THERAPY

I Gehrke, K Gandhirajan, J Paesler, R Razavi, J Poll-Wolbeck, M Hallek, K Kreuzer

University at Cologne, Cologne, Germany

Background. The major pathophysiological feature of chronic lymphocytic leukemia (CLL) cells is there resistance towards apoptosis. Thereby, the bone marrow (BM) microenvironment has a substantial role as CLL cells die rapidly when taken out of their natural habitat and are placed in culture. The vascular endothelial growth factor (VEGF) has frequently been associated with the resistance of CLL cells towards apoptosis. Several bystander cells in the BM of the patient such as stromal cells are capable of producing VEGF in high amounts. *Aims.* To describe the effect and functional background of VEGF in the interplay between CLL cells and the BM stromal cell line HS5 to potentially discover targeted for a selective CLL therapy. *Methods.* Primary cells were isolated from peripheral blood of CLL patients and healthy volunteers. Real time PCR was used for mRNA analysis and immunoblotting for protein detection. Secreted VEGF was measured by ELISA. Phosphorylation of the VEGF-receptor 2 (VEGF-R2) was analysed using intracellular phospho flow cytometry. VEGF-specific siRNAs were used to knock down VEGF in HS5 cells. VEGF-R- (GW 786034) and STAT3-inhibitor (S23I-201) were added to HS5/CLL coculture in several concentrations. Cell survival was assessed by annexin V/PI negativity. *Results.* CLL cells express and secrete VEGF in significantly higher levels as healthy B-cells. They also possess constitutively phophorylated VEGF-R2. When kept in monoculture this phosphorylation is lost over time, simultaneously CLL cells die. Vice versa, cocultivation with HS5 cells restores the phosphorylated VEGF-R2 and maintains CLL cell survival. When VEGF is blocked in this coculture setting by either a VEGF-neutralizing antibody (external blockage), by the VEGF-R inhibitor GW786034 or by siRNA-mediated VEGF downregulation in HS5 cells (internal blockage) , the survival advantage is significantly reduced. As a potential mechanism of VEGF-induced CLL cell survival support, STAT3 activation via phosphorylation on tyr705 could be demonstrated. This phosphorylation was induced by exogenous rhVEGF stimulation and also by coculture with HS5. In both cases, VEGF-R blockage by GW 786034 treatment reversed tyr705 phosphorylation and the increased expression of STAT3 targets, such as cyclinD1 and Bcl_{XL}. With this background also the potential of STAT3-inhition to induce CLL cell apoptosis was assessed. Both, the VEGF-R inhibitor GW786034 and the STAT3 inhibitor S3I-201 were capable of significantly reducing the HS5-mediated survival advantage. *Conclusions.* The VEGF-signaling pathway seems to be essentially involved in the survival of CLL cells within their natural microenvironment, as its external (neutralizing antibody) and internal (siRNA-mediated VEGF knock down in HS5 cells) inhibition significantly reduced the HS5-mediated survival advantage. STAT3 activation could be identified as a potential downstream effector. The small molecule VEGF-R inhibitor GW 786034 and the STAT3 inhibitor S3I-201 showed promising effects in inducing cell death of CLL cells within the survival-supporting atmosphere of HS5 coculture, suggesting the VEGF-STAT3 signaling axis to be of high interest for a targeted CLL therapy with them aim of overcoming the apoptotic block.

ANGIOPOIETIN-2 PLASMA DOSAGE PREDICTS TIME TO FIRST TREATMENT (TTFT) AND OVERALL SURVIVAL (OS) IN CHRONIC LYMPHOCYTIC LEUKEMIA

R Marasca,[1] R Maffei,[1] S Martinelli,[1] R Santachiara,[1] D Rossi,[2] C Guarnotta,[3] A Zucchetto,[4] G Rigolin,[5] S Fiorcari,[1] I Castelli,[1] M Fontana,[1] V Coluccio,[1] G Leonardi,[1] P Zucchini,[1] C Tripodo,[3] A Cuneo,[5] V Gattei,[4] G Del Poeta,[6] F Forconi,[7] G Gaidano,[2] G Torelli[1]

[1]University of Modena and Reggio E., Modena, Italy; [2]Hematology, Dept of Clinical and Experimental Medicine, University of Eastern Pi, Novara, Italy; [3]Dept of Human Pathology, University of Palermo, Palermo, Italy; [4]Clinical and Experimental Onco-Hematology Unit, CRO IRCCS Aviano, Aviano, Italy; [5]Dept of medical Sciences, University of Ferrara, Ferrara, Italy; [6]Division of Hematology, S.Eugenio Hospital and University of Tor Vergata, Rome, Rome, Italy; [7]Hematology and Transplants, Dept of Clinical Meicine, University of Siena, Siena, Italy

The clinical relevance of Angiopoietin-2 (Ang2) in CLL was previously suggested by the association between high Ang2, more advanced disease and shorter progression-free survival reported in small series of patients. Here, we further investigate the prognostic role of plasma level of Ang2 in a multicentric study with a large cohort of CLL patients. We measured Ang2 glycoprotein levels in plasma samples from 316 CLL patients using an ELISA method and we investigated its prognostic role in relation to time to first treatment (TTFT) and overall survival (OS). Ang2 dosage ranged from 972 to 17281 pg/mL (median, 2061 pg/mL). The best cut-off point, generated by ROC analysis and Youden's index (state variable, treating), was 2459 pg/mL and divided our cohort in two subsets (high Ang2 and low Ang2) composed by 100 (31.6%) and 216 (68.4%) patients, respectively. The median TTFT resulted significantly shorter (P<.001) in the high Ang2 subgroup (77.5 months) than in the low one (179.2 months). Cox univariate analysis identified Ang2 ≥2459 pg/mL as a predictor of reduced TTFT (HR 2.437; 95%CI 1.621-3.664, P<.001) as well as advanced Binet stage, unmutated IGHV status, high CD38, ZAP-70 and CD49d expression, intermediate/high cytogenetic risk and high β2 microglobulin (P<.001 in all instances). Multivariate analysis confirmed that high Ang2 levels were an independent prognosticator for TTFT (HR 1.739; 95%CI 1.059 - 2.857; P=.029) together with inter/high FISH risk (P<.001) and unmutated IGHV status (P=.002). Comparing OS between high Ang2 and low Ang2 subgroup, we found that 26% of high Ang2 patients were dead at 10-years from diagnosis, in contrast with 7% of low Ang2 ones (P=.002). In univariate analysis, Ang2 ≥ 2459 pg/mL resulted to be a predictor of poor OS (HR 3.566; 95%CI 1.496 - 8.499; P=.004) as well as most of the other known unfavorable prognosticators. Significant association was found between high Ang2 plasma level and Binet stages B-C (P<.001), high β2 microglobulin (P<.001), unmutated IGHV status (P<.001), high CD38 and ZAP-70 expression (P<.001 and P=.003, respectively) and inter/high cytogenetic risk (P=.005). However, a relevant percentage of patients showed high Ang2 levels in the presence of favorable markers and vice versa: in this cases, defined as discordant, Ang2 helps to refine prognosis identifying CLL subgroup with precocious need for treatment and reduced survival despite characterized by favorable prognostic factors. Finally, we studied two serial plasma samples collected from 36 patients (median interval, 19 months; range, 3-30 months) and we did not find significant changes in Ang2 level between the two measurements, both for the 7 patients treated inside this interval (P=.612) and for the 29 cases untreated (P=.347). These data first demonstrate the prognostic role of Ang2 plasma level for TTFT and OS in CLL, and shows how Ang2 contributes to refine the prognostic assessment of CLL and also helped to refine prognosis among CLL subsets with both high and low VEGF plasma levels. Ang2 plasma level may be a useful independent prognosticator for CLL.

0750

XIAP INHIBITION AS A NEW PARADIGM TO INDUCE APOPTOSIS IN CHRONIC LYMPHOCYTIC LEUKEMIA

S Fulda,[1] S Löder,[2] T Zenz,[1] A Schnaiter,[3] D Mertens,[3] D Winkler,[3] H Döhner,[3] K Debatin,[2] S Stilgenbauer[3]

[1]Ulm University, Ulm, Germany; [2]Children's Hospital, Ulm University, ULm, Germany; [3]Internal Medicine III, Ulm University, Ulm, Germany

Evasion of apoptosis is a hallmark of chronic lymphocytic leukemia (CLL), calling for new strategies to overcome apoptosis resistance. We therefore investigated whether targeting the antiapoptotic protein XIAP

by small molecule inhibitors sensitizes CLL cells for apoptosis. Here, we provide first evidence that XIAP inhibitors in combination with the death receptor ligand TRAIL present a new approach to synergistically trigger apoptosis in CLL even in subgroups with resistant disease. Analysis of apoptosis regulatory proteins reveals that XIAP, cIAP1 and cIAP2 are expressed at high levels in primary CLL samples. Proofs of concept studies in CLL cell lines demonstrate that subtoxic concentrations of several distinct XIAP inhibitors significantly enhance TRAIL-induced apoptosis. By comparison, no sensitization for death receptor-induced apoptosis is observed in the presence of a structurally related control compound that only weakly binds to XIAP, demonstrating the specificity of the sensitization effect of XIAP inhibitors. Importantly also in primary CLL samples, subtoxic concentrations of XIAP inhibitors act in concert with TRAIL to trigger apoptosis in 18 of 27 cases (67%), whereas primary CLL cells are resistant to treatment with TRAIL alone. Analysis of combination index reveals that this interaction of XIAP inhibitor and TRAIL is highly synergistic. Mechanistic studies in primary CLL cells show that the addition of XIAP inhibitor profoundly enhances TRAIL-induced cleavage of caspase-3 into active fragments and significantly increases caspase-3 enzymatic activity. The broad range caspase inhibitor zVAD.fmk completely blocks apoptosis in response to combination treatment with XIAP inhibitor and TRAIL, pointing to caspase-dependent apoptosis. Intriguingly, the cooperative interaction of XIAP inhibitor and TRAIL is even evident in several distinct subgroups of CLL patients with poor prognostic features, including patients with 17p deletion, TP53 mutation, chemotherapy-refractory disease or unmutated VH genes. Interestingly, we found that cases with unmutated VH genes are significantly more sensitive to XIAP inhibitor- and TRAIL-induced apoptosis compared to VH gene mutated samples, pointing to a role of B-cell receptor signaling in the regulation of apoptosis in CLL cells. In conclusion, we provide first evidence that XIAP inhibitors in combination with TRAIL present a novel strategy to trigger apoptosis even in resistant forms and poor prognostic subgroups of CLL. These findings have important implications for the development of innovative approaches to overcome the intrinsic resistance to apoptosis in CLL. Since IAP inhibitors as well as TRAIL receptor agonists as single agents are currently under evaluation in early clinical trials, it is feasible that such combination protocols of XIAP inhibitors and TRAIL could be translated into clinical application in CLL.

0751

GLIOTOXIN INDUCES APOPTOSIS IN CLL CELLS BY A MECHANISM INVOLVING INHIBITION OF NOTCH2 ACTIVITY

R Hubmann, M Hilgarth, S Schnabl, D Demirtas, S Badrnya, E Ponath, J Schwarzmeier, P Valent, U Jäger, M Shehata

Medical University of Vienna, Vienna, Austria

Background. NOTCH2 belongs to a highly conserved family of transmembrane receptors that regulate a wide variety of cellular differentiation processes including stem cell renewal, binary cell fate decisions, and adult tissue homeostasis. We have recently shown that constitutively activated NOTCH2 is involved in the high expression and aberrant regulation of CD23 in CLL cells and there is emerging evidence that NOTCH2 has also an antiapoptotic role in the leukemic lymphocytes. In murine B-cell development, constitutively activated Notch2 leads to the selective development of $Cd5^+$ (B-1a) B-lymphocytes whose human equivalents are considered as one of the possible progenitors of CLL cells. Therefore, targeting NOTCH2 might be of therapeutic relevance in CLL. *Aims.* The aim of this study was to identify compounds that interfere with NOTCH2 signaling at the transcription factor level. Several compounds have been tested and we focused the investigations on the secondary fungal metabolite Gliotoxin which has been reported to affect the viability of splenocytes. *Methods.* The nuclear NOTCH2 activity in CLL samples was determined by electrophoretic mobility shift assays (EMSA). FACS analysis was used to quantify the surface expression of the NOTCH2 target gene CD23 and to measure the percentage of apoptotic cells. *Results.* Gliotoxin (0.2μM) completely blocked the activity of nuclear NOTCH2 in CLL cells irrespective of their prognostic marker profile. The inhibition of NOTCH2 signaling by Gliotoxin was associated with downregulation of surface CD23 expression (mean±SD: 42±33 *vs.* 86±14; n=20) and induction of apoptosis (mean±SD: 70±29 *vs.* 13±14). In contrast, normal PBMCs and nuclear NOTCH negative leukemic cell lines (Jurkat, KL562, SH3, RL7) were less sensitive to Gliotoxin. To test whether Gliotoxin directly interferes with the assembly of the NOTCH2 transcription factor complex, we added Gliotoxin to the EMSA reaction and found that Gliotoxin inhibits the formation of DNA-bound NOTCH2 complexes in a dose dependent manner. *Summary/Conclusions.* We identified Gliotoxin as potential NOTCH2 transactivation inhibitor and showed that Gliotoxin possesses a strong antileukemic activity in CLL cells.

0752

THE PARA-ISOMER OF NITRIC OXIDE-DONATING ACETYL SALICYLIC ACID (P-NO-ASA) INDUCES APOPTOSIS IN CLL CELLS IN VITRO AND SIGNIFICANTLY REDUCES TUMOR GROTH IN A CLL-LIKE XENOGRAFT MOUSE MODEL

I Gehrke, R Razavi, K Gandhirajan, J Paesler, J Poll-Wolbeck, M Hallek, K Kreuzer

University at Cologne, Cologne, Germany

Background. Chronic lymphocytic leukemia (CLL) is characterized by an accumulation of mature, non functional B cells. WNT/β-catenin/Lef-1 signalling appears to be constitutively and aberrantly activated in these cells. Furthermore, several compounds related to the non-steroidal anti-inflammatory drugs (NSAIDs) are reported to destabilize β-catenin, therefore inducing apoptosis in β.catenin/LEF-1 active cancers in-vitro. Clinical studies with such substances generated disappointing results as therapeutically effective plasma concentrations could not be reached without producing significant toxicities. Recently, nitric oxide-donating acetyl salicylic acid (NO-ASA) has been developed, which achieves high plasma levels in doses not leading to any relevant side effects in humans. *Aim.* To test two positional isomers of NO-ASA for their ability to selectively induce apoptosis in primary CLL cells *in vitro* and for their *in vivo* efficacy in a CLL-like xenograft mouse model. *Methods.* Primary CLL cells as well as healthy B-cells were treated with varying concentrations of para-(p) and meta-(m) NO-ASA. Cytotoxicity was assessed by microscopic cell viability testing and measurement of the ATP content. Induction of apoptosis was investigated by Annexin V-FITC/Propidiumiodid (PI) staining and immunoblotting of caspases 9, 3 and PARP. Further, protein amount of β-catenin and its specific target gens like cyclin D1, C-MYC and LEF-1 was evaluated by immunoblot analysis. To evaluate the in-vivo efficacy, both substances were tested in a CLL like xenograft mouse model. *Results.* The para-isomer showed a selective cytotoxic effect, whereas the meta-isomer of NO-ASA did not alter survival in CLL cells. At 10 μM for 24 hours p-NO-ASA reduced survival of CLL cells to 46.3±10.1%. Time course experiments revealed that this effect was almost completely achieved as early as 6 hours after treatment (53.4±16.6% survival). Immunoblot analysis showed that p-NO-ASA activates caspase 9, 3 and cleaves PARP, at concentrations of around 10 μM. Furthermore, β-catenin was cleaved and its target genes cyclin D1, C-MYC and LEF-1 were simultaneously downregulated. Pre-treatment with a caspase-inhibitor prevented both, β-catenin cleavage and reduction of protein levels of its target genes. In the xenograft CLL-like mouse model exclusively p-NO-ASA featured a strong antitumor efficacy with an IR_{max} value of 83.1%. As early as 9 days after p-NO-ASA treatment the tumor volume was significantly reduced compared to vehicle control. The meta-isomer showed no significant anti-neoplastic effect. No gross side effects were observed. *Summary/Conclusions.* Our findings show that exclusively the para-isomere of NO-ASA selectively induces Caspase-mediated apoptosis in CLL cells. The mechanism of action might include inhibition of β-catenin/LEF-1 signaling by β-catenin cleavage, since we observed a downregulation of specific target genes at the protein level. In addition, p-NO-ASA resulted in strong inhibition of tumor growth in a xenograft CLL-like mouse model after oral administration, while being well tolerated. Hence, p-NO-ASA might be a valuable compound for the treatment of CLL. Further investigations to determine the exact mechanism of action and the specific difference between the positional isomers are of high interest.

ACADESINE INDUCES DOSE-DEPENDENT CITOTOXICITY IN CHRONIC LYMPHOCYTIC LEUKEMIA REGARDLESS OF IMMUNOGLOBULIN MUTATIONAL STATUS AND ZAP70 EXPRESSION

S Pairet,[1] A Ferrer,[2] E Abella,[2] MC Vela,[2] R Longaron,[2] C Campas,[3] M De Frias,[4] B Espinet,[2] C Besses,[2] S Serrano,[2] B Bellosillo[2]

[1]Fundación IMIM, Barcelona, Spain; [2]Hospital del Mar, Barcelona, Spain; [3]ADVANCELL-Advanced in Vitro Cell Technologies SA, Barcelona, Spain;; [4]ADVANCELL-Advanced in vitro cell technologies SA, Barcelona, Spain

Background. The precursor of nucleotide biosynthesis acadesine or 5-aminoimidazole-4-carboxamide (AICA) riboside induces apoptosis in chronic lymphocytic leukemia (CLL) and other lymphoproliferative dis-

eases such as splenic marginal zone lymphoma and mantle cell lymphoma. This effect is selective for B-CLL cells, at least *ex vivo*, however, there is no evidence of whether this cytotoxic effect is associated with prognostic variables such as ZAP-70 expression or IgVH mutational status. *Aim.* To analyse *ex vivo* the cytotoxic effect of acadesine on peripheral blood CLL cells and non CLL cells and correlate it with variables of prognostic value such as: cytogenetic alterations, ZAP-70 expression and IgVH mutational status. *Methods.* Cryopreserved cells from 22 patients diagnosed with CLL were incubated *ex vivo* with acadesine at 0.2, 0.5, and 1mM for 24 hours. Viability was determined by flow cytometry using Annexin V-FITC and DAPI staining combined with CD19-PE and CD3-PerCP to differentiate cell viability of B- and T-cells. Cells were considered sensitive to the drug when the percentage of acadesine-induced apoptosis was equal to or higher than 15% with respect to the viability of control cells. The mutational status of IgVH genes was determined by RT-PCR amplification using a set of six VH family-specific primers (VH1 through VH6) along with primers complementary to the constant region (IgM and IgG). Products were directly sequenced from both strands using the Big Dye Terminator Cycle Sequencing Ready Reaction (version 3.1, Applied Biosystems). Sequencing analysis and alignments were performed with use of V-QUEST software and the online international immunogenetics information (IMGT) data library. Samples in which fewer than 2 percent of base pairs differed from those of the consensus sequence have been considered unmutated. ZAP-70 expression was quantified by flow cytometry (cut-off: 20%) and cytogenetic alterations associated with CLL (trisomy 12, del13q, del17p and del11q) were determined by FISH. Results. After 24h of *ex vivo* incubation, 0.2 mM acadesine induced a significant cytotoxic effect (>15%) in 19 out of 22 patients (86%). Higher concentrations, 0.5mM and 1mM, induced a significant effect in 95% (21 of 22 patients) and 100% (22 of 22 patients), respectively. The viabilities (mean±SD) of the different culture conditions are shown in the Table 1. The cytotoxic effect induced by acadesine was correlated with the IgVH mutational status and with ZAP-70 expression. No significant differences were observed between unmutated (n=10) and mutated (n=12) cases or between ZAP-70 positive (n=8) and ZAP-70 negative cases (n=14). In addition, no significant differences were observed between cases showing no cytogenetic alterations (n=7) and cases displaying del 13q (n=10). Interestingly, 2 cases showing deletion of 17p were sensitive to treatment with acadesine, in agreement with previously published studies showing that acadesine-induced apoptosis is independent of p53. Conclusions. Acadesine induces apoptosis in B-cells from CLL regardless of ZAP-70 expression, IgVH mutational status and presence or absence of cytogenetic alterations.

Table 1.

	% Viability	%acadesine-induced apoptosis
Control cells	68.58 ± 15.31	-
0.2 mM acadesine	59.12 ± 19.01	14.20 ± 17.50
0.5 mM acadesine	34.79 ± 21.25	50.86 ± 24.30
1 mM acadesine	20.23 ± 19.29	70.21 ± 29.51

0754

INHIBITION OF DNA-PK SENSITIZES A PROPORTION OF CLL CULTURES TO FLUDARABINE, REGARDLESS OF THE TP53/ATM STATUS

M Trbusek, L Rocnova, O Boehmova, J Mayer

University Hospital and Faculty of Medicine, Masaryk University, Brno, Czech Republic

Background. Defects in cooperating tumor-suppressor genes TP53 or ATM significantly deteriorate treatment options for CLL patients. DNA-dependent protein kinase (DNA-PK) is responsible for the process of nonhomologous end-joining DNA repair, through which some cancer cells can escape a chemotherapy-induced apoptosis. Chemical inhibition of DNA-PK was shown to sensitize resistant CLL cells to chemotherapeutics, including some cultures with del(17p) (TP53 locus) or del(11q) (ATM locus). Another (non-CLL) study have shown, however, that inhibition of DNA-PK does make sense only in the ATM-deficient setting in cancer cells, when DNA repair is completely blocked (Jiang *et al.,* Genes Develop 2009; 23: 1895-1909). *Aims.* To assess an effect of DNA-PK inhibition in the high-risk CLL cultures treated *in vitro* with a nucleoside analog fludarabine. *Methods.* PBMNC isolated from CLL patients were exclusively used. The fraction of CLL lymphocytes comprised at least 85% and viability before treatment was >80% in all samples. The cells were treated for 1h with or without the synthetic DNA-PK inhibitor NU7026 (10 μM) and subsequently exposed to four different concentrations of fludarabine (25; 6.25; 1.6 and 0.4 μg/mL) for 48h. A metabolic WST-1 assay was used to assess a cell viability. Two-way analysis of variance (ANOVA) was used to determine a significance of the NU7026 pre-treatment; viability after treatment with NU7026 on its own was set up at 100% (i.e. the same as fully non-treated control). Quantitative real-time PCR (qRT-PCR) was used to monitor an induction of pro-apoptotic (PUMA, BAX), cell-cycle regulatory (p21) and DNA-damage repair (GADD45) genes. *Results.* Forty-four CLL cultures were tested; 15 with p53 inactivation (deletion by FISH and/or mutation by FASAY coupled to sequencing), 15 with heterozygous ATM deletion (by FISH) and 14 without any high-risk abnormality (wt). DNA-PK inhibitor on its own reduced a viability in most of the cultures, with the lowest effect in TP53-affected cells (viability decreased on average to 73%), followed by ATM-deleted (63%) and wt (61%) samples. A sigificant (P<0.01) sensitization effect of DNA-PK inhibitor to fludarabine was observed in 40% (6/15) of p53-defected samples, 20% (3/15) of ATM-deleted samples and 14% (2/14) of wt cultures. The sensitized samples were affected much less with the NU7026 on its own than the rest of cultures (everage viability 88% *vs.* 59%, respectively) and were substantially more resistant to fludarabine at the concentration resembling a clinical situation, i.e. 1.6 μg/mL (everage viability 78% *vs.* 53%, respectively). qRT-PCR was performed in 11 cultures. All tested genes were readily induced by fludarabine and fludarabine with NU7026 (to the very same level in particular sample) in all wt cultures (n=3), all ATM-deleted cultures (n=6) and in sample with sole TP53 mutation (n=1); sample with complete TP53 inactivation was refractory to any induction. Summary/*Conclusions.* Our results support the view that sensitization of CLL cells using DNA-PK inhibition is feasible and may be expected in a case when the cells are resistant to fludarabine. On the contrary, the sensitization may not be dependent in principle on particular genomic abberations.

THE ROLE OF VIMENTIN IN CHRONIC LYMPHOCYTIC LEUKAEMIA

P Corrigan,[1] H Wheadon,[2] R Freeburn,[3] W Jameson,[4] F Mc Nicholl,[5] D McManus,[1] M Quinn,[1] M Catherwood[1]

[1]Belfast City Hospital, Belfast, UK; [2]Wheadon H. Paul O' Gorman Leukaemia Research Centre, Faculty of Medicine, Glasgow, UK; [3]University of the West of Scotland, Paisley, UK; [4]University of Ulster, Coleraine, UK; [5]Altnagelvin Hospital, Londonderry, UK

Background. Chronic Lymphocytic Leukaemia (CLL) is a heterogeneous disease and can be characterized by low proliferation rates and defective apoptotic pathways. Within CLL, two subtypes have been defined by the degree of somatic hypermutation, unmutated (UM) or mutated (M) in the variable region of the immunoglobulin heavy chain (IGHV) gene. Recent data has shown that expression of Wnt genes, associated receptors and downstream signalling molecules are deregulated in CLL compared to normal B cells. The Wnt family of growth factors are secreted glycoproteins, involved in the proliferation and differentiation of normal and malignant cells. Wnts can activate various pathways such as the non-canonical Wnt/$Ca2^+$ pathway, which can lead to the upregulation of Vimentin expression. Vimentin is a type III dominant cytoskeletal protein and intermediate filament, important for determining rigidity of lymphocytes, and is thought to be defective in lymphocytes from CLL patients, potentially contributing to smear cell formation. Recent reports suggest Wnt signalling upregulates Vimentin and that Vimentin expression is higher in leukaemic cells from patients with aggressive disease. *Aims.* This study aims to investigate the role Vimentin plays in CLL. *Methods.* $CD19^+$ cells were purified from peripheral blood (PB) of CLL patients (Miltenyi-autoMAX), IGHV and cytogenetic status was determined. RNA (Trizol), protein lysates and cytospins were prepared. Expression of Vimentin, Wnt genes and associated Wnt signalling pathway genes in CLL cell lines (Mutated-E95, B4, PGA1 HG3, EHEB, Unmutated-HG3, Wac3, CII) and patient samples

was assessed using RQ-PCR and Western Blotting. Co-IP of Vimentin (Millipore) and pERK (Santa-Cruz) from protein lysates was performed. Vimentin distribution and expression in cell lines and patient PB samples and primary lymphoid tissue was visualized by IHC, fluorescent staining (Alexa-Fluor) and Confocal Microscopy. *Results.* Gene expression profiling identified a signature of upregulated Wnts, Wnts 4, 5a, 16b, receptors Fzd3, ROR1, RYK and regulators sFRPs 1,2 and 4, in our cell lines and patient cohort, indicating non-canonical Wnt/$Ca2^+$ signalling is functional with an important role in CLL. RQ-PCR has shown increased Vimentin in patient samples. Immunoblotting identified Vimentin protein in CLL cell lines and UM-CLL patients, an interaction between Vimentin and pERK was demonstrated with Co-IP. IHC and fluorescent staining of cells demonstrated increased Vimentin levels in UM-CLL patients compared to M-CLL patients, also observed in CLL cell lines. Summary. Wnt16b appears to be the most consistently upregulated Wnt gene in CLL patient samples. Aberrant, non-canonical Wnt/$Ca2^+$ signalling potentially upregulates Vimentin expression. Vimentin expression is significantly greater in UM-CLL patients and UM-CLL cell lines at RNA and protein levels and can also be observed at greater levels microscopically throughout the cells. It appears that Vimentin and pERK interaction could potentially be sustaining activation of pERK signalling which may be contributing to the pathogenesis of CLL patients with unmutated IGHV.

VIMENTIN EXPRESSION PREDICTS POOR PROGNOSIS IN CLL

G Siufi,[1] C Rodrigues,[1] M Silva,[1] ML Chauffaille,[1] S Pinto,[2] W Barreto,[1] E Kimura,[1] V Teixeira,[1] MM Rodrigues,[1] M Silva,[1] J Pesquero,[1] M Yamamoto[1]

[1]UNIFESP, Sao paulo, Brazil; [2]INGOH, Goiania, Brazil

Background. Vimentin is an intermediate filament protein essential for lymphocyte rigidity and integrity. In solid tumors its high expression has been associated with metastatic and aggressive disease. In CLL, vimentin expression is heterogeneous and a high expression may indicate more resistant cells but its prognostic value is still undefined yet. *Aims.* 1) to evaluate vimentin expression in CLL patients; 2) to compare vimentin expression with other clinical and biological prognostic factors: Binet staging, IgVH status, expression of CD38 and Zap-70, VEGFR (VEGF receptor) and molecular cytogenetics (by FISH); 3) to evaluate the impact of vimentin expression in the progression free survival (PFS). *Methods.* Sixty-six patients with CLL were studied between September 2005 and October 2009. Flow cytometry analyses for CLL diagnosis (score system of Moreau *et al.*), CD38 and Zap-70 expression (fresh whole peripheral blood) and VEGFR and vimentin (mononuclear cells by Ficoll-Hypaque gradient method) were performed in fresh and/or cryopreserved blood samples at patient admission(figure). Vimentin expression was also evaluated in BM biopsy specimens obtained at diagnosis, by immunohistochemistry. The BM infiltration pattern was also evaluated. The IgVH genes mutational status was determined in mononuclear cells by RT-PCR followed by sequencing analysis. Molecular cytogenetics were characterized by fluorescence *in situ* using the 13q14.3 (D13S319), 13q34 (Proz, CUL4A, LAMP1), 17p13.1 (p53), 11q22 (ATM) and the chromosome 12 centromeric probe CEP 12 (D12Z3) (Vysis inc., USA). At least 200 interphase nuclei with well-delineated signals were counted in each slide. *Results.* Vimentin expression in both circulating and marrow cells was positively associated with unmutated IgVH genes, diffuse bone marrow infiltration, unfavorable cytogenetics abnormalities(del11q; del17p) and VEGFR positive expression. Vimentin expression in PB cells by flow cytometry and in BM cells by immunohistochemistry yielded concordant results, as did vimentin expression in fresh and thawed samples from the same patients. Association between vimentin expression and CD38 expression was observed only when vimentin was determined in BM. Advanced clinical stage, age<68 years, positive expression of CD38 and VEGFR, unmutated IgVH genes, unfavorable cytogenetics abnormalities, vimentin expression in PB and BM cells and diffuse marrow infiltration pattern were factors significantly associated with shorter PFS. The impact of these prognostic markers was also observed when only Binet A patients were analyzed. In multivariate analysis, the Binet's stages B+C (P=0.008), strong unimodal and bimodal MFI (mean fluorescence intensity) histogram pattern of CD38 (P=0.03), diffuse marrow infiltration (P=0.02) and vimentin expression on BM cells by immunohistochemistry (P=0.002) were identified as independent risk factor for reduced PFS. *Conclusions.* Vimentin expression in CLL cells from both PB and BM showed high impact as prognostic marker, predicting poor PFS, even in Binet A patients. Both flow cytometry and immunohistochemistry are relatively easy techniques and are feasible for most flow cytometry and pathology laboratories. Vimentin expression was comparable with IgVH mutational status suggesting its possible usefulness as prognostic marker in CLL patients. In addition, studying vimentin expression might also be useful for better understanding the pathophysiology of CLL and also for possible therapeutic interventions.

GENES ASSOCIATED WITH LIPID METABOLISM SEGREGATE WITH ZAP-70 EXPRESSION AND IGVH MUTATIONAL STATUS IN CLL PATIENTS

A Trojani,[1] B Di Camillo,[2] A Tedeschi,[1] M Lodola,[1] C Colombo,[1] F Ricci,[1] S Veronese,[1] B Scarpati,[1] E Morra,[1] M Montillo[1]

[1]Niguarda Hospital, Milan, Italy, [2]Department of Information Engineering, University of Padova, Padova, Italy

Background. Chronic lymphocytic leukemia (CLL) is a heterogeneous disease. A relevant number of studies have shown IgVH mutation status and ZAP-70 expression as the most relevant prognostic markers in CLL, suggesting the separation of two patients subgroups with good (M IgVH ZAP-70^-), and poor prognosis (UM IgVH ZAP-70^+). *Aims.* Our aim was to determine gene expression profiles of 105 CLL patients divided into three classes: the first (n=61) with M IgVH and ZAP-70^-, the second (n=28) with UM IgVH and ZAP-70^+, and the third (n=16) included CLL patients with UM IgVH and ZAP-70^- or M IgVH and ZAP-70^+, respectively. Finally, the purpose was to identify molecular signatures underpinning the diverse clinical-biological phenotypes. *Methods.* We determined gene expression profiles using Affymetrix HGU133 Plus 2.0 in $CD19^+$ leukemic cells. A first cohort of 62 subjects was analyzed using GeneChip® Expression 3' Amplification One-Cycle Target Labeling kit, while a second cohort of 43 subjects using GeneChip® 3'IVT Express Kit. Differentially expressed genes were detected independently in the two cohorts using ANOVA and t-test adapted for microarray data analysis, and corrected for multiple testing using false discovery rate p-values. Only genes selected as differentially expressed in both datasets were considered for further analysis. To assess the association of the molecular signature based on the identified genes, the samples of five recently acquired CLL patients, not used for the differential analysis, were classified as belonging to class one or two, based only on their expression profile. Results. Statistical analysis revealed 42 differentially expressed genes in the first (M IgVH and ZAP-70^-) *vs.* the second (UM IgVH and ZAP-70^+) group. Interestingly, among them, ZAP-70 (zeta-chain TCR associated protein kinase 70kDa), LPL (lipoprotein lipase), MBOAT1 (membrane bound O-acyltransferase domain containing 1), P2RX1 (purinergic receptor P2X, ligand-gated ion channel, 1), DCLK2 (doublecortin-like kinase 2), and CHPT1 (choline phosphotransferase 1) were overexpressed, while ADAM29 (ADAM metallopeptidase domain 29) and NRIP1 (nuclear receptor interacting protein 1) were underexpressed in the first group with respect to the second. Notably, LPL, MBOAT1, CHPT1 are associated with lipid metabolism process. Cluster analysis (K-means, Euclidean distance) revealed that the 105

subjects are better partitioned in two rather than in three classes, based on their expression profiles. Based on the expression of the 42 genes previously identified, the 16 subjects of the third group were divided in two clusters: 12 more similar to group one, and 4 more similar to group two. Classification of five recently acquired patients, as belonging to class one or two based only on their expression profile, gave precision equal to 100%, thus confirming the molecular signature based on the identified genes. Conclusions. Our studies revealed that the well known LPL, MBOAT1 and CHPT1, associated with lipid metabolism, might be involved in CLL pathogenesis. Correlation of expression of the selected genes with ZAP-70, as well as IgVH and disease progression, will be evaluated to explore the potential value of these genes for future risk stratification. Moreover, functional investigations will be performed to provide new insight in the pathogenesis of CLL.

CHRONIC LYMPHOCYTIC LEUKEMIC (CLL) B CELLS EXPRESS THE HGF RECEPTOR (C-MET) AND ARE SUPPORTED IN THEIR SURVIVAL BY HGF-PRODUCING MESENCHYMAL STROMAL CELLS

D De Totero,[1] P Giannoni,[2] S Scaglione,[3] R Quarto,[4] R Narcisi,[2] M Parodi,[2] E Balleari,[5] S Monteghirfo,[6] F Barbieri,[7] A Pattarozzi,[7] T Florio,[7] S Ferrini,[1] G Corte[6]

[1]National Institute for Cancer Research, Genoa, Italy; [2]Stem Cell Lab,Advanced Biotechnology Center, Genoa, Italy; [3]Dept of Communication, Computer and System Sciences (DIST) University of Genoa, Genoa, Italy; [4]Stem Cell Laboratory, Advanced Biotechnology Center, Genoa, Italy; [5]Hematological Dept, San Martino Hospital, Genoa, Italy; [6]Gene transfer Lab, National Institute for Cancer Research, Genoa, Italy; [7]Pharmacology Lab,Dept of Biology, Oncology, Genetics, Genoa, Italy

Chronic lymphocytic leukemic (CLL) B cells are characterized by an apparent longevity *in vivo* but tend to undergo apoptosis when cultured *in vitro*. This evidence suggests that interactions and factors provided by the microenvironment may promote survival, proliferation and drug resistance of CLL B cells. Understanding CLL-stroma cross talk is actually of great interest to identify signals and molecules supporting leukemia expansion. Bone marrow (BM) is composed by different types of mesodermic cells, mesenchymal stem cells (MSC), differentiating along several lineages. Little is known on the effects exerted by undifferentiated/differentiated MSC on CLL and which cells resident in BM provide a permissive environment that is critical in prolonging survival of leukemic B cells and in mantaining their progenitors. Aim of this study was to determine whether different mesenchymal stromal cell lineages could differently affect CLL survival and to identify growth factors, surface markers and signals involved in mantaining CLL expansion. We utilized bone marrow stromal cells (BMSC) and some different lineages of mesenchymal origin to investigate how mesenchymal stromal cells support CLL cells survival. We determined that different lineages of mesenchymal origin differently affect CLL B cells viability in co-cultures: human BMSC, fibroblasts or cells from trabecular bone significantly prolonged survival of leukemic B cells, while endothelial cells and chondrocytes did not. Moreover supportive effects were also mantained, although to a lesser extent, when leukemic B cells and stromal cells were separately cultured in transwell plates or when only conditioned medium, from different MSC lineages, were added in CLL cultures. Gene expression profiles comparison of different mesenchymal cells suggested two soluble factors, CXCL12 and HGF, as potential candidates involved in enhancement of leukemic B cells viability. In agreement with gene expression analysis we thus demonstrated that CXCL12 and HGF were produced only by mesenchymal lineages sustaining CLL survival and that CLL B cells express the HGFreceptor c-MET, in addition to CXCR4. Furthermore recombinant HGF, when added in *in vitro* cultures, is capable of increasing CLL viability and of inducing STAT3 phosphorylation. In conclusion we demonstrated that BMSC and some differentiated cells of mesenchymal origin prolong CLL survival and that two soluble factors, CXCL12 and HGF, are produced by those MSC capable of sustaining survival of leukemic B cells. Our study further underlines that HGF, together with CXCL12, can be pivotal in mediating resistance to apoptosis of CLL B cells, c-MET$^+$/CXCR4$^+$, at the bone marrow level. Moreover the *in vitro* culture systems that we here designed will be helpful to reveal more insights reflecting *in vivo* mechanisms related to disease progression and to identify novel therapeutic targets.

0759

CD38 AND CD49D ARE PHYSICALLY ASSOCIATED AND FUNCTIONALLY COOPERATING ON B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA CELL MEMBRANE

D Benedetti,[1] T Vaisitti,[2] A Zucchetto,[1] M Dal Bo,[1] R Bomben,[1] M Degan,[1] MI Del Principe,[3] G Del Poeta,[3] F Malavasi,[2] V Gattei,[1] S Deaglio[2]

[1]Centro di Riferimento Oncologico, Aviano, Italy; [2]University of Turin, Turin, Italy; [3]S.Eugenio Hospital and University of Tor Vergata, Rome, Italy

Background. CD38 and CD49d are associated negative prognosticators in chronic lymphocytic leukemia (CLL) with a direct role in the interactions of CLL cells with other microenvironmental cell populations. *Aims.* The propensity of CD38 and integrins to form supramolecular complexes, prompted us to investigate whether specific CD49d and CD38 interactions occur on the CLL membranes, and whether the resulted molecular complexes may have a role explaining the aggressiveness of CD38/CD49d-expressing CLL. *Methods.* Confocal microscopy and biochemical approaches were used to study the membrane organization of CD49d and CD38 in primary CLL cells and other B cell lines. The CLL-derived CD49d+CD38$^-$ cell line Mec-1 (Mec-1-CD38$^-$) was used as a model in adhesion experiments. Viral transduction was used to induce CD38 expression by Mec-1 (Mec-1-CD38$^+$). Apoptosis was investigated by syto-16/7-AAD staining in flow cytometry. *Results.* Co-capping experiments in CLL cells demonstrated a membrane relationship between CD38 and CD49d. Anti-CD49d monoclonal antibodies (mAbs) induced capping in approximately 75% of CLL cells, with a 80% redistribution of CD38 in the context of the capping area. Similar results were obtained with the cell lines Raji and RPMI-8226, both constitutively expressing high CD38 and CD49d levels. The CD38/CD49d lateral association was confirmed at the biochemical level by co-immunoprecipitation experiments with anti-CD49d mAbs and subsequent blotting of immunoprecipitates using anti-CD38 mAbs. CD38-CD49d association was also maintained after engagement of CD49d with its natural ligands, as witnessed by a striking co-localization of CD49d and CD38 in cell uropods formed by CLL and Raji cells adhered and spread onto VCAM-1 and CS-1 fibronectin (FN) fragments. Notably, these experiments also highlighted the involvement of specific CD38 domains in the CD38/CD49d/VCAM-1 molecular complex, as evidenced by staining with anti-CD38 antibodies recognizing different epitopes. To investigate whether the CD38/CD49d association had also a functional meaning, adhesion assays on VCAM-1-coated plates were performed with the Mec-1 cell model. Mec-1-CD38$^+$ showed a marked increase in VCAM-1 adhesion compared to Mec-1-CD38- (mean values of adhered cells relative to control=5.4 *vs.* 2.3 and 5.4 *vs.* 1.9 after 15 and 30 minutes respectively). Moreover, phase-contrast and immunofluorescence microscopy highlighted clear differences in the morphology of adhered cells, with Mec-1-CD38$^+$ cells characterized by a more complex pattern of uropods than Mec-1-CD38$^-$, and a clear colocalization of CD38 and CD49d in adhesion sites. Finally, we tested whether CD38 engagement could have a role in enhancing the protection against spontaneous apoptosis of CLL cells cultured onto CD49d ligands. Purified CLL cells (n=6) were cultured in the presence of anti-CD38 mAb or CS-1 FN fragment, either alone or in combination. Analysis of cell apoptosis after a 72-hour culture, showed 79±1.1% viable cells after CD49d independent engagement, and a substantial improvement of cell viability (94%±0.5) after exposure to both anti-CD38 mAb and CS-1 fragment ($P<0.01$). *Conclusions.* CD49d and CD38 are physically associated on CLL cell membranes. Such a physical association influences the anti-apoptotic cell adhesion process, suggesting a cooperative role for CD38 and CD49d which may explain at least in part the poor clinical outcome of the disease subset co-expressing these molecules.

SYNERGISTIC ACTIVATION AND INCREASED MIGRATION UPON CCL21 ADDITION IN ABNORMAL ZAP-70 EXPRESSING B CELLS

E Calpe,[1] C Codony,[2] M Crespo,[3] MJ Baptista,[2] E Fernandez,[2] P Abriqueta,[3] E Montserrat,[2] F Bosch[3]

[1]Institute Of Hematology And Oncology, Departament Of Hematology, Hospital Clinic, Barcelona, Spain; [2]Institute of Hematology and Oncology, Department of Hematology, Hospital Clinic, Barcelona, Spain; [3]Department of Hematology, Hospital Vall Hebron, Barcelona, Spain

Background. ZAP-70 (ξ-associated protein) is a protein tyrosine kinase (PTK) of the Syk/ZAP family normally expressed in T and NK cells.

When the TCR homodimer transmits the extracellular binding event to the cytoplasma via the immunoreceptor tyrosine-based activation motifs (ITAMs), ZAP-70 protein binds to the double phosphorylated ITAMs. This initiates downstream biochemical events that lead to T-cell proliferation and differentiation. Recent studies have showed that ZAP-70 protein is also expressed in leukemic B cells. Increased ZAP-70 expression in Chronic Lymphocytic Leukemia (CLL) correlates with unmutated IgVH genes, a short time of progression, and a short survival. Mechanisms by which increased ZAP-70 protein expression can influence clinical outcome are not fully understood. Objectives: To study the functional consequences of ZAP-70 exogenous expression and activation in B-cell lymphoma cell lines. *Methods.* Ramos and Raji (Burkitt) cell lines were stably transfected with the ZAP-70 expressing vector pEGFP-N2ZAP-70. Western Blot was used for protein studies. ZAP-70 expression, cell cycle, IgM expression, calcium mobilization, surface molecules and migration were analyzed by flow cytometry. *Results.* Upon BCR engagement simultaneous phosphorylation and activation of ZAP-70 and Syk protein (the equivalent of ZAP-70 in B cells) was observed in Ramos cell line. Interestingly, a constitutive activation of ZAP-70 was observed in Raji cell line. In addition, Erk and Akt proteins were strongly activated this lasting more than 24 hours. This enhanced signalling may be due the observed reduction of BCR internalization after antigen ligation in the ZAP-70 positive B cells. ZAP-70 phosphorylation led to increased percentage of cells in S and G2/M cell cycle phases and an expression of higher numbers of surface molecules, being chemokine receptor CCR7 the more remarkable one. CCR7 increased expression after ZAP-70 activation had a direct positive effect on migration upon CCL21 addition (CCR7 ligand). We observed that CCL21 chemokine also induced activation of Akt protein in ZAP-70 expressing cells. In this regard, after simultaneous BCR and CCR7 stimulation, an additive Erk and Akt phosphorylation was observed. Furthermore, when adding CCL21 after IgM activation an increased and prolonged mobilization of $Ca2^{+}$ was observed in ZAP-70 positive cells, probably due to the increased CCR7 expression induced by BCR stimulation. *Conclusions.* Heterologous ZAP-70 expression into a B-cell system enhances BCR downstream signalling not only through conventional IgM activation but also through CCR7 signaling. Therefore, CCR7 overexpression in ZAP-70 activated B cells, upon CCL21 chemokine addition, induces not only a synergistic activation but also an increased calcium mobilization and migration of the cells. It is important to highlight that CCL21 is expressed in the lymph nodes where ZAP-70 positive cells may have an increased propensity to migrate and the ability to respond to survival signals. Althogether, these data suggest that ZAP-70 expression in CLL and other lymphoproliferative disorders enhances tumoral activity, this explaining in part the poor clinical prognosis of patients with increased expression of ZAP-70.

SMALL CLL-LIKE B-CELL CLONES IN HEALTHY ADULT SUBJECTS: LEUKEMIC PRECURSORS VERSUS COUNTERPART OF CLL CELLS?

J Almeida,[1] W Nieto,[1] C Teodosio,[1] C Pedreira,[2] A Nieto,[1] A Romero,[3] A López,[4] A Rodríguez-Caballero,[1] P Bárcena,[4] A Rasillo,[4] P Fernández-Navarro,[5] T Vega,[6] A Orfao[1]

[1]Cancer Research Center (IBMCC, CSIC/USAL) University of Salamanca, Salamanca, Spain; [2]Faculty of Medicine and COPPEE-PEE Engineering Graduate Program, UFRJ, Rio de Janeiro, Brazil; [3]Gerencia de Atención Primaria de Salud de Salamanca, Sanidad de Castilla y León, Salamanca, Spain; [4]Service of Cytometry, University of Salamanca, Salamanca, Spain; [5]Centro de Atención Primaria de Salud de Ledesma, Salamanca, SACYL, Salamanca, Spain; [6]Junta de Castilla y León, Salamanca, Spain

Background. Chronic lymphocytic leukemia (CLL) is the most common subtype of leukemia in Western countries. In the last decade, it has been reported that circulating CLL-like B cells can be detected at low levels (<5×10^{9}/L) in healthy subjects, this being termed "Monoclonal B-cell lymphocytosis"(MBL), independently of the presence *vs.* absence of lymphocytosis. Although initially the presence of CLL-like B-cell clones was reported to be around 3-6% of healthy adults (>40 years), the use of more sensitive flow cytometry approaches has shown that the actual frequency could be near three times more in healthy adults >40 years. These recent findings prompted us to question about the pathological *vs.* physiological nature of B-cell clones in normal subjects. *Aim.* To estimate whether the frequency of cases in which a CLL-like B-cell clone is detected raises to 100% if higher volumes of peripheral blood (PB) are screened. *Methods.* A total of 639 healthy individuals (46%males / 54%females) >40 years old (62±13 years) with normal lymphocyte counts ($2.1\pm0.7\times10^{9}$/L) were selected across the Primary Health Care area of Salamanca (Spain). Between 0.9-1.2 mL/tube EDTA-anticoagulated PB were immunophenotyped using a high-sensitive flow cytometry approach, based on 8-color staining panels and the systematic screening for >5×10^{6} total PB leucocytes. The minimum number of cellular events required to define a CLL-like B-cell cluster was of 50 cells. In each case, the real volume of blood screened was registered, and in MBL cases, the actual volume of PB containing the first 50 CLL-like B-cell events was calculated. A statistical predictive model (power regression, using the MATLAB software) was built, to estimate for the whole cohort of individuals and for each age-group (40-59, 60-69 and >70 years), the percentage of subjects showing CLL-like cells, in the hypothetical case that higher volumes of PB would be stained. *Results.* Overall 12.5% of cases carrying CLL-like B-cell clones was detected after measuring 0.9 to 1.2 mL of PB. A progressively higher frequency of cases carrying CLL-like B-cell clones was observed in parallel to increasing age. Our predictive model suggested that, if larger volumes of PB (e.g. ≥50 mL) were analyzed, 100% of healthy adults over 70 years may carry detectable CLL-like clones (the lower limit of the 95% confidence interval -CI- reached 100% for PB volumes of ~46 mL). According to this model, in the hypothetical case that 50 mL PB would be stained per case, the estimated frequency of cases carrying CLL-like clones for the 40-59-year group was of 32% (95% CI: 18% to 46%) and of 62% for cases with 60-69 years (95% CI: 36% to 88%); with an estimated rate of 100% for the whole series (lower limit of the 95% CI of 70%). Summary/*Conclusions.* Altogether, these results support the notion that over a certain age, the emergence of one or more CLL-like clones would probably occur, suggesting that these clonal cells may more likely represent the normal counterpart of CLL cells, rather than leukemic precursors. Further studies are necessary to confirm this hypothesis.

CD69 AND CD79B OVEREXPRESSION IDENTIFY POOR RISK CHRONIC LYMPHOCYTIC LEUKEMIA

G Del Poeta,[1] MI Del Principe,[1] A Zucchetto,[2] F Buccisano,[1] R Bomben,[2] F Luciano,[1] M Dal Bo,[2] L Maurillo,[1] F Rossi,[2] L Ottaviani,[1] P De Fabritiis,[1] A Venditti,[1] G Gaidano,[3] V Gattei,[2] S Amadori[1]

[1]University Tor Vergata, Roma, Italy; [2]Hematology Unit, CRO, Aviano (PN), Italy; [3]Hematology, University of Eastern Piedmont, Novara, Italy

Leukemic cells from all chronic lymphocytic leukemia (B-CLL) cases exhibit features of activated and antigen-experienced B-lymphocytes and up-regulation of CD69 is more frequent within unmutated or CD38 positive CLL subsets (Damle, 2002 and 2007). Moreover, high B-cell receptor (BCR) signaling characterized by CD79b overexepression increases cell survival and cell cycle progression. In fact, CD79b has been preliminarly correlated with atypical morphology, unmutated IgVH status and short overall survival (OS) (Zucchetto, 2006). Therefore, a hyperactivated and BCR hyperstimulated B-CLL phenotype could allow us to identify a subset of patients who would have a more aggressive disease. The primary endpoints of our research were: 1) to determine progression free survival (PFS) and OS upon CD69 and CD79b expression; 2) whether CD69 and CD79b expression had additive prognostic value and finally 3) whether CD69 and CD79b were independent prognostic factors in multivariate analysis. We investigated 412 patients, median age 65 years (range 37-87), 219 males and 193 females. With regard to modified Rai stages, 124 had a low stage, 270 an intermediate stage and 18 a high stage. CD69 and CD79b were determined by multicolor flow cytometry, using L78 and SN8 clones, respectively, and fixing the cut-off value at 30%. $CD69^{+}$ and $CD79b^{+}$ B-CLL patients were 108/401 (27%) and 208/402 (52%), respectively. CD69 and CD79b >30% were significantly associated with intermediate/high Rai stage (P<0.0001), lymphocyte doubling time <12 months (P<0.0001), beta-2 microglobulin >2.2 mg/dL (P<0.0001) and soluble CD23 >70 u/mL (P<0.0001). There were significant correlations between CD69 <30% and normal or del13q FISH cytogenetics (296 cases studied, P<0.0001). Noteworthy, there was a strict correlation either between CD79b >30% and trisomy 12 (25/33; P=0.001) or CD79b >30% and del17p (16/20; P=0.001). There were significant correlations between lower CD69 (226 cases studied, P=0.0007) or lower CD79b (253 cases studied, P<0.00001) and IgVH gene mutated status. Equally, significant associations were found between ZAP-70, determined by flow cytometry, and CD69 (P=0.008) or CD79b (P<0.0001). With regard to clinical outcome, both shorter PFS and OS were observed in $CD79b^{+}$ patients (10% *vs.* 56% and 40% *vs.* 93% at 14 years, P<0.00001) as well as in $CD69^{+}$ patients (3% *vs.* 49% at 14 years, P<0.00001 and 44% *vs.* 67% at 14 years, P=0.00004). Noteworthy, CD79b and CD69 showed additive prognos-

tic properties, since CD79b <30% plus CD69 <30% identified a B-CLL subset at better prognosis with regard to PFS (77% *vs.* 2% at 14 years; P<0.00001) and OS (95% *vs.* 31% at 14 years; P<0.00001). The two discordant subsets ($CD69^+CD79b^-$ and $CD69^-CD79b^+$) showed an intermediate outcome (Figure). In multivariate analysis of PFS and OS, in which entered age, Rai modified stages, ZAP-70, lymphocyte doubling time, beta-2 microglobulin, CD38, CD69 and CD79b, both CD69 (P=0.008 and P=0.002) and CD79b (P=0.0003 and P=0.0006) resulted to be independent prognostic factors. Therefore, CD69 and CD79b, determined by flow cytometry, should be considered novel important prognostic parameters in B-CLL. Their easy and rapid laboratory evaluation could allow us to identify early progressive patients taking timely therapeutic decisions.

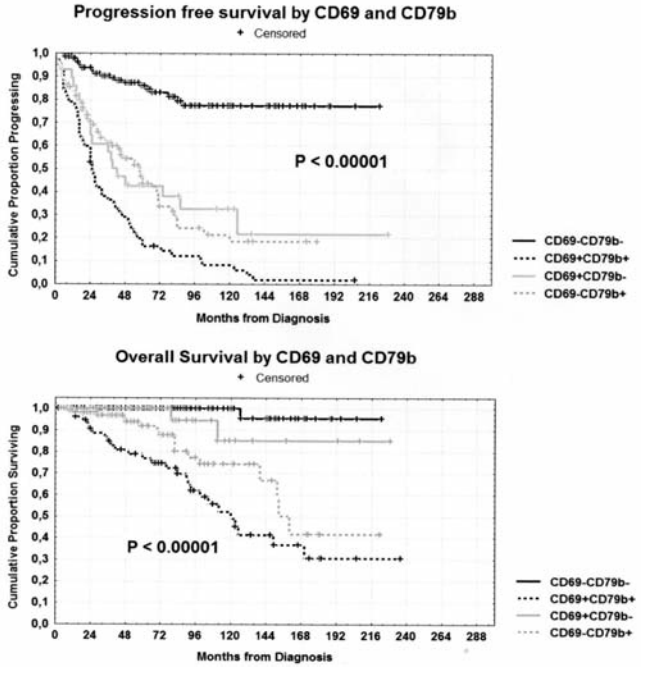

Figure 1. Clinical outcome by CD69 and CD79b.

ASSOCIATION STUDY OF KILLER CELL IMMUNOGLOBULIN-LIKE RECEPTOR GENES AND HUMAN LEUKOCYTE ANTIGEN CLASS I LIGANDS WITH B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA IN THE POLISH POPULATION

I Frydecka,[1] A Jedynak,[2] L Karabon,[2] M Kielbinski,[1] D Woszczyk,[3] D Wolowiec,[1] K Kuliczkowski[1]

[1]Medical University Wroclaw, Wroclaw, Poland; [2]Institute of Immun.& Experimental Therapy, Wroclaw, Poland; [3]Department of Hematology, State Hospital, Opole, Poland

Introduction. B-cell chronic lymphocytic leukemia (B-CLL) patients have several humoral and cellular abnormalities. It has been suggested that innate and immunity, especially natural killer (NK) cells, and subpopulations of T-cells play a key role in antitumor cytotoxicity regulated by the interaction between killer immunoglobulin-like receptors (KIRs) and their HLA-class I ligands on target cells. KIR receptors may be either inhibitory, with long cytoplasmic tails (DL), or activating, with short cytoplasmic tails (DS). 2DL2, 2DL3, and 2DS2 KIRs bind to the HLA-C1 allotype (Asp80), while the 2DL1 and 2DS1 KIRs bind to the HLA-C2 allotype (Lys80). There is strong evidence that polymorphisms in KIR genes and their cognate HLA ligands contribute to the pathogeneses of several diseases, including infections, autoimmunity, and, recently, cancer, but literature data for B-CLL are inconsistent and limited. *Aim.* The aim of this study was to investigate the association between polymorphism of KIR genes and their HLA-ligands and susceptibility to B-CLL. *Materials and methods.* The KIR genes 2DL1, 2DL2, 2DL3, 3DL1, 2DS1, 2DS2, 2DS3, 2DS4full length , 2DS5, 3DS1, and 2DS4with a deletion were genotyped in 197 B-CLL patients and in 200 controls by PCR-SSP methods. The HLA-C1, HLA-C, HLA-Bw4(Thr80), and HLA-Bw4(Iso80) specificities were typed in 185 B-CLL patients and 200 healthy individuals using an Olerup SSP typing Kit. *Results.* The frequencies of the individual KIR genes did not differ in the two studied groups, but a trend toward a lower frequency of KIR2DS3 gene in the B-CLL patients compared with controls (26.9% *vs.* 35.5%, P=0.065, OR: 0.67, 95%CI: 0.44-1.03) was noted. There were no statistically significant differences in haplotype and genotype frequencies; however, the higher frequency of individuals possessing genotypes with prevalanceof inhibitory over activating KIR genes in the B-CLL patients compared with the controls was observed (ratio of activating to inhibitory KIR genes between 0.2-0.83: 83.2% *vs.* 75.5%, P=0.06, OR: 1.6, 95%CI: 0.98-2.64), while healthy individuals were overrepresented in the group of genotypes with a prevalence of activating KIR genes (activating/inhibitory KIR gene ratio: 1- 1.5). Analysis of the distributions of HLA-C1 and HLA-C2 allotypes and genotypes in the B-CLL patients and controls did not reveal any differences, but the frequency of HLA-Bw4 specificity was significantly reduced in the B-CLL patients compared with the controls (48.6% *vs.* 63.0%, P=0.0045, OR: 0.56, 95%CI: 0.37-0.84). Moreover, there were fewer individuals possessing HLA-Bw4 with threonine in the B-CLL group, especially those having HLA-Bw4(Thr80) and lacking HLA-Bw4(Ile80) (21.6% *vs.* 32.0%, P=0.022, OR: 0.59, 95%CI: 0.37-0.93 and 16.2% *vs.* 26.5%, P=0.014, OR: 0.54, 95%CI: 0.32-0.89). 3S1+/HLA-$Bw4^+$ and $3DL1^+$/HLA-$Bw4^+$ combinations were consequently less common in the B-CLL patients than in the controls (14.6% *vs.* 27.0%, P=0.0028, OR: 0.46, 95%CI: 0.28-0.77 and 45.4% *vs.* 57.0%, P=0.023, OR: 0.63, 95%CI: 0.42-0.94), particularly those with the coexistence of 3DL1, 3DS1, and HLA-Bw4 (12.4% *vs.* 21.0%, P=0.025, OR: 0.53, 95%CI: 0.31-0.93). *Conclusions.* These results indicate that genotypes with a prevalence of inhibitory over activating KIR genes confer susceptibility to B-CLL while the presence of activating KIR2DS3 and HLA-Bw4 might be associated with protection from it.

Background. CLL is characterized by the expansion of monoclonal mature B lymphcytes with an extremely heterogeneous clinical course. Proteomic analysis is particularly attractive to provide insights into the biological complexity of CLL and can be used to identify ion signals which are differently expressed in cases exhibiting markers of well-known prognostic impact, including CD38 and ZAP-70 expression, and IgVH gene mutational status. Patients and Methods. A panel of highly purified neoplastic cells (>92%) from 42 untreated, newly diagnosed CLL patients in Binet stage A was investigated. We used proteomic technology, MALDI-TOF MS profiling to examine the protein content of CLL cells. Highly purified neoplastic B lymphocytes were subjected to cell lysis, followed by sub-fractionation of the water-soluble component. An aliquot of this fraction underwent a desalting/concentration step over ZipTip C18 and peptide/protein profiles were analysed using a VoyagerDE PRO MALDI-TOF mass spectrometer (PerSepyiveBiosystem). Separate spectra were obtained for a restricted mass-to charge (m/z) range (1000-25000 Da) in linear mode geometry, by applying an accelerated voltage of 25 kV. The acquired spectra, assayed in duplicate, were then processed for automated advanced baseline correction and noise. The peak area of each signal was normalized as a percentage of the total peak area (individual peak area/total area per cent). Supervised analyses for CD38 and ZAP-70 expression, and IgVH mutational status were performed, and the significance of ion signals differently expressed were evaluated by student's t-test. Results. Supervised analysis allowed the identification of 23, 32 and 28 differentially expressed ion signals with statistical significance (P<0.05), respectively in CD38 (14 positive), ZAP-70 (13 positive), and IgVH (12 unmutated) . Comparing differentially expressed ion signals, 6 m/z values (2162,9; 2782,5; 3110,5; 4572,3; 6973,6; 10463,2 m/z values) were shared by the three ion signal lists. A supervised analysis was also conducted using a recently published prognostic score system (Morabito F *et al.*, BJH, 2009). Comparing cases scored 3 (i.e. CD38-positive, ZAP-

70-positive and unmutated-IgVH) with those scored 0 (i.e. with no negative prognostic marker), we have identified 25 differentially expressed ion signals with statistical significance (P<0.05), among which we recognized the same above mentioned 6 ion signals. Conclusion. These results demonstrate that the B-CLL neoplastic cells may be classified on the basis of their protein/peptide content using the MALDI-TOF profiling analysis. Future studies will focus on the identification of the differentially expressed ion signals.

A PROTEOMIC STRATEGY IDENTIFIED ELEVATED LEVELS OF SERUM AMYLOID A (SAA) PROTEIN IN THE PLASMA OF CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS

C Carniti,[1] I Bongarzone,[1] M Cremona,[1] L Farina,[1] M De Bortoli,[1] A Cortelezzi,[2] B Sarina,[3] G Reda,[2] L Zanetti Domingues,[1] P Corradini[1]

[1]Fondazione Istituto Nazionale Tumori, Milano, Italy; [2]IRCCS Ospedale Policlinico, Mangiagalli e Regina Elena, Milano, Italy; [3]Istituto Clinico Humanitas, Milano, Italy

Background. Chronic Lymphocytic Leukemia (CLL) is the most common leukemia in the western world and is characterized by the accumulation of relatively mature B cells. CLL is notable for variation in aggressiveness of disease. Many patients with low-risk disease at diagnosis can be followed expectantly, while others rapidly require therapy. This clinical heterogeneity appears to be sustained by different biologic parameters, such as the immunoglobulin variable gene (IgVH) mutational status, ZAP-70 expression and specific cytogenetic alterations. Many patients express a combination of all favorable or all unfavorable markers, but there are also patients with different marker combinations. Unique easily accessible prognostic markers helping to predict the individual course of CLL are therefore highly warranted. *Aim of the study.* To use a proteomic strategy to identify differentially expressed proteins in the plasma of CLL patients. *Methods.* Proteomic profiling of plasma or serum is a technique to identify new biomarkers in disease. The objective of this study was to identify new plasma biomarkers in CLL patients using surface-enhanced laser desorption ionization time-of-flight (SELDI-TOF) mass spectrometry. To first establish the feasibility and specificity of the method using a case-control study design, plasma samples from 30 patients with a known CLL diagnosis were compared to samples from 30 age- and sex-matched healthy controls. All samples were run in triplicate and the obtained spectra aligned. Protein spectra were generated and the protein peak intensities normalized to the total ion current m/z values and analysed using Ciphergen ProteinChip software 3.2.0. Comparison of SELDI profiles using the Unsupervised Cluster analysis highlighted that the plasma profiles of patients with CLL could be clearly separated from control groups. Application of the BMV Program to these spectra identified the m/z 11,681 cluster as most significantly different. Preparative monodimensional electrophoresis was used to isolate this cluster from plasma that highly expressed or did not express the m/z 11,681 cluster. MALDI-TOF MS analysis identified the unknown protein as Serum amyloid A (SAA). We have previously demonstrated that plasma SAA SELDI-TOF intensities are correlated with SAA protein concentrations (r=0.41; P=.0001) determined by ELISA. Thus, plasma SAA concentrations were measured by enzyme-linked immunosorbent assay (ELISA) using a commercially available kit (Biosupply Ltd., Bradford, United Kingdom) in a larger group of 86 newly diagnosed B-CLL patients (44 males, 42 females median age of 62 years) and 30 age- and sex-matched healthy controls. *Results.* The analysis revealed statistically significant differences in SAA expression between the plasma of LLC patients and the plasma of healthy subjects (P=0.002). In addition, SAA levels are elevated in the plasma of patients with an unfavourable cytogenetic profile (try12; del17; del11) when compared to patients with normal or other cytogenetic status (P=0.02). In patients, SAA plasma levels are also positively correlated with peripheral lymphocyte doubling times of less than one year (P=0.009). *Conclusions.* Although preliminary, these data suggest that elevated SAA levels are associated with unfavorable known prognostic markers and support the view that inflammation is implicated in CLL development.

GENETIC VARIATION IN TNF AND IL-10 AND CLINICAL OUTCOME OF B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA

E Lech-Maranda,[1] W Mlynarski,[2] O Grzybowska-Izydorczyk,[3] B Cebula-Obrzut,[3] M Borowiec,[2] M Wcislo,[4] A Szmigielska-Kaplon,[3] K Wyka,[2] G Nowak,[5] H Makuch-Lasica,[5] M Majewski,[6] K Warzocha,[5] T Robak[3]

[1]Medical University of Lodz, Lodz, Poland; [2]Department of Pediatrics, Oncology, Hematology, Diabetology, Medical University, Lodz, Poland; [3]Department of Haematology, Medical University, Lodz, Poland; [4]Invicta Fertility and Reproductive Center, Warsaw, Poland; [5]Institute of Hematology and Blood Transfusion, Warsaw, Poland; [6]Department of Haematology, Torun, Poland

Background. Recent studies have demonstrated that common genetic variants in immune and inflammatory response genes can play the important role in lymphomagenesis. TNF and IL-10 are good candidate genes since they code critical cytokines regulating the balance between the T-helper, Th1 and Th2, immune responses. Therefore we tested the hypothesis that single-nucleotide polymorphisms (SNPs) in TNF and IL-10 promoters influence susceptibility and clinical course of B-cell chronic lymphocytic leukemia (CLL). Patients and *Methods.* We genotyped TNF -308G>A (rs1800629), IL-10 -1082A>G (rs1800896) and IL-10 -3575T>A (rs1800890) in 190 newly diagnosed patients with CLL and 192 ethnically-matched healthy individuals using the Taqman™ platform (Applied Biosystems, USA). Some randomly selected DNA samples were analysed by direct sequencing using 3130xl Genetic Analyzer (Applied Biosystems, USA). Haplotype analysis was performed using version 2.0.2 PHASE software. The IgVH mutation status in CLL patients was performed according to the protocol described by van Dongen *et al.* (Leukemia 2003). *Results.* The TNF -308G>A, IL-10 -1082A>G and IL-10 -3575T>A allelic frequencies and distributions were consistent with Hardy-Weinberg equilibrium, and did not differ significantly between CLL patients and the control group. There were no significant differences in estimated frequencies of the IL-10 haplotypes between CLL patients and controls. No association was found between TNF and IL-10 allelic, genotype or haplotype distributions and clinical characteristics of CLL patients at diagnosis, including age, clinical stage according to Rai classification, serum LDH and β2-microglobulin levels, as well as surface CD38 expression, ZAP-70 expression, and IgVH mutation status. The patients with IL-10(-1082G) allele (IL-10-1082GG or IL-10-1082GA genotypes) had significantly shorter time from diagnosis to treatment (11 months *vs.* 24 months, P=0.02, Mann-Whitney test) as compared to individuals carrying IL-10(-1082AA) genotype. Neither of assessed TNF and IL-10 SNPs was associated with response to first-line treatment or progression free survival. With a median follow-up of surviving patients of 58 months (range 1-209 months), the subgroups of patients with TNF(-308A) allele (TNF-308AA or TNF-308AG genotypes) had significantly shorter overall survival (OS) compared to those carrying TNF(-308GG) genotype (P=0.01, log-rank test). No correlations were found between IL-10 alleles, genotypes or haplotypes and OS in CLL patients. To further characterize the prognostic impact of TNF and IL-10 SNPs on CLL patients survival, we divided the patients according to the IgVH mutation status into a IgVH mutated (homology <98%) and IgVH unmutated (homology ≥98%) group. With respect to TNF SNP, the patients carrying TNF(-308A) allele presented significantly shorter OS both in the IgVH mutated and unmutated group compared to those with TNF(-308GG) genotype (P=0.02 and P=0.03, respectively). When IL-10 SNPs were analysed, the IL-10(-1082G) or IL-10(-3575A) alleles retained their prognostic impact on shorter OS only in the IgVH mutated group compared to the IL-10(-1082AA) or IL-10(-3575TT) genotypes (P=0.05 and P=0.02, respectively). *Conclusions.* Our results indicate that TNF and IL-10 gene variations may influence CLL outcome especially in the IgVH mutated subgroup, which points out the importance of innate immunity genes for CLL prognosis.

Chronic lymphocytic leukemia - Clinical

AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION (AUTOHSCT) IN CLL: FIRST RESULTS OF AN EBMT RANDOMIZED TRIAL COMPARING AUTOTRANSPLANT VERSUS WAIT AND WATCH

M Michallet,[1] P Dreger,[2] L Sutton,[3] R Brand,[4] S Richards,[5] A van Biezen,[4] M Sobh,[1] A Gratwohl,[6] K Kolbe,[7] C Dearden,[8] M Hallek,[9] T de Witte,[10] D Niederweiser,[11] M Leporrier,[12] D Milligan[13]

[1]Edouard Herriot Hospital, Lyon, France; [2]University Hospital Heidelberg, Heidelberg, Germany; [3]Victor Dupuis Hospital, Argenteuil, France; [4]Leiden University Medical Centre, Leiden, Netherlands; [5]University of Oxford, Oxford, UK; [6]Swiss Group for Clinical Cancer Research, Basel, Switzerland; [7]Johannes Gutenberg University, Mainz, Germany; [8]Royal Marsden Hospital, Surrey, UK; [9]University of Cologne, Cologne, Germany; [10]Hospital Nijmegen, Nijmegen, Netherlands; [11]University of Leipzig, Leipzig, Germany; [12]CHU Caen, Caen, France; [13]Birmingham Heartlands Hospital, Birmingham, UK

Material and *Methods.* This phase-III randomized EBMT-intergroup trial studied the impact of a consolidating autoHSCT *vs.* wait and watch for patients with CLL in Binet stage A progressive, B or C , in CR, nodular PR or VGPR after first or second line therapy. *Aim.* The primary objective was to show that autoHSCT increase the 5-year progression-free survival (PFS) by 30%. Here we present a first analysis based on 80% of expected follow-up forms. *Results.* Between November 2001 and July 2007, 223 patients were enrolled (SFGM-TC/FCLLG n=99, MRC n=63, GCLLSG n=36, SAKK n=10, other EBMT centers n=15). There were 74% males and 26% females. Binet stages were progressive A 13%, B 67%, C 20%; 59% were in CR, and 41% in very good or nodular PR. Of note, SFGM-TC/FCLLG included only patients in CR. Eighty three percent of the patients were enrolled in 1st, and 17% in 2nd line treatment. Patients were randomized between group 1 (autoHSCT n=112) and group 2 (observation n=111) after an induction treatment which was left at the discretion of the investigators. Median PFS was 26.6 months (18.3-35) in the observation group and 50.1 months (40-60.1) in the autoHSCT group; the 5-year PFS was 29% and 42%, respectively (P<0.001). Accordingly, the 5-year relapse incidence was 54% *vs.*70%.; P<0.001. The Cox modeling for randomization arm, Binet stage, disease status, line of treatment, contributing group (country), and the interaction between randomization arm and contributing group confirmed that autoHSCT significantly improved PFS (HR 0.45 [0.30-0.66] P<0.001). The beneficial effect of autoHSCT was stable over all contributing groups. At 5 years, the probability of OS was 83% and 82% for autoHSCT and observation, respectively; P=0.81. Significant differences in terms of non-relapse death were not observed. *Conclusion.* in patients with CLL in first or second remission, consolidating autoHSCT reduces the risk of progression (PFS) by more than 50%, but has no effect on overall survival. There was no significant difference of non-relapse deaths in the autograft arm compared with the watch and wait arm. Further analyses on variables affecting the outcome are underway and results from a quality of life study on both groups are awaited.

FLUDARABINE (FLU) PLUS ALEMTUZUMAB (FLUCAM) IMPROVES PROGRESSION FREE SURVIVAL VERSUS FLUDARABINE IN PREVIOUSLY TREATED CHRONIC LYMPHOCYTIC LEUKEMIA AND DEMONSTRATES ACTIVITY IN HIGH RISK PATIENTS

A Engert,[1] L Gercheva-Kyuchukova,[2] G Pilipenko,[3] T Robak,[4] J Wu,[5] E Barry,[5] T Elter[1]

[1]University Hospital of Cologne, Cologne, Germany; [2]Varna Clinic of Haematology, Varna, Bulgaria; [3]Cherkasy Oncology Center, Cherkasy, Ukraine; [4]Medical University of Lodz, Lodz, Poland; [5]Genzyme Corporation, Cambridge, USA

Background. After the phase II study of FluCam in previously treated CLL patients demonstrated meaningful efficacy with acceptable safety (Elter JCO 2005), this phase III prospective, multicenter, open-label, randomized, controlled study was conducted. *Aims.* We report updated efficacy and safety results along with subgroup analysis by adverse prognostic factors (PF) including age ≥65 years. *Methods.* Treatment arms were balanced by study center, Rai stage, disease status, age, gender, prior Flu therapy, and maximum lymph node (LN) size. During cycle 1, FluCam patients received escalating doses of Cam IV until the 30 mg dose was tolerated. Then, they received Flu 30 mg/m^2 IV followed by Cam 30 mg IV days 1-3 every 28 days. In the Flu arm, patients received 25 mg/m^2 IV days 1-5 every 28 days. Patients received up to 6 cycles. The primary endpoint was progression-free survival (PFS), secondary endpoints included overall response (OR), complete response (CR), overall survival (OS) and safety. Efficacy analyses were based on assessment by independent review panel. *Results.* Among 335 randomized patients (median age 60 years, range, 33-80), 19% had maximum LN size ≥ 5 cm, 37% were Rai Stage III-IV, 15% had prior Flu exposure, and 35% were ≥ 65years old. The median number of cycles received was 6 for both arms. The median PFS for FluCam was significantly longer compared with Flu (24.1 *vs.* 15.4 months, respectively, P=0.004; HR 0.64 [95% CI: 0.48-0.87]). Superior PFS with FluCam was also observed in patients ≥ 65 years, Rai Stage III-IV, and other adverse PF (Table 1). OR rates and CR rates for FluCam and Flu were 80.4% *vs.*74.3% (P=0.186) and 12.5% *vs.* 2.4% (P<0.001) respectively. No differences in OS have been observed, however, Rai III-IV patients receiving FluCam had significantly improved OS (P=0.005; HR 0.44 [95% CI: 0.24-0.79]). Adverse reactions occurring in >10% in the FluCam arm compared with Flu included pyrexia, leukopenia, chills, lymphopenia, urticaria, infusion related reactions, and rash. Incidence of grade 3/4 thrombocytopenia, neutropenia and anemia for FluCam and Flu were 17.7% *vs.* 22.7%, 63.7% *vs.* 68.9%, and 13.4% *vs.* 22.0%, respectively. Incidence of serious adverse events (SAEs) in FluCam was 32.9% and 25.5% for Flu. The most commonly reported SAE's were neutropenia and febrile neutropenia, with no difference in the frequency of these events (4.9% *vs.* 2.4% and 3.0% *vs.* 4.2% respectively). Symptomatic CMV infection occurred in 2.4% of patients, with 1.2% considered SAEs and none ≥ grade 4. The adverse reaction profile of FluCam in patients ≥ 65 years was comparable to the overall patient population. *Summary/Conclusions.* These data demonstrate that the FluCam combination is superior to Flu in previously treated CLL, including the elderly and advanced stage disease. FluCam demonstrated significantly longer PFS and a comparable safety profile with improved overall survival in Rai III-IV patients. FluCam shows an improved risk/benefit ratio compared to Flu and is an important option for previously treated CLL.

Introduction. Chemoimmunotherapy with CD20 monoclonal antibody (mAb) is the standard frontline treatment for physically fit patients with chronic lymphocytic leukemia (CLL). Ofatumumab is a

human mAb that binds a unique epitope encompassing both the small- and large-loop on CD20. The recent international pivotal study of single-agent ofatumumab demonstrated high overall response rates (ORR) of 47-58% in patients with fludarabine-refractory CLL. *Aims.* We conducted a multicenter, randomized, parallel-group, Phase II trial to evaluate the efficacy and safety of two doses of ofatumumab combined with fludarabine and cyclophosphamide (O-FC) in patients with previously untreated CLL. *Methods.* Patients with active CLL were randomized to ofatumumab 500 mg (Group A) or 1000 mg (Group B) Day 1, with fludarabine (F) 25 mg/m^2 and cyclophosphamide (C) 250 mg/m^2 Days 2-4, Course 1; Days 1-3, Courses 2-6; every 4 weeks for 6 courses. The first ofatumumab dose was 300 mg in both Groups. Dose reduction was allowed for FC only. Premedication for ofatumumab was paracetamol and antihistamine prior to each infusion and glucocorticoid prior to infusions 1 and 2. Growth factors and anti-infective prophylaxis were not mandated. The primary endpoint was complete response (CR; based on 1996 NCI-WG criteria) rate evaluated by an Independent Review Committee during treatment until 3 months after last dose. *Results.* All patients provided informed consent. A total of 61 patients were randomized (Group A, n=31; Group B, n=30). Pretreatment characteristics were as follows: median age 56 years (range, 38-73); Rai stage III-IV in 46%; bulky (>5 cm) lymph nodes in 16%; median serum β2-microglobulin level 4 mg/L (range, 1.8-11.5); median ALC 89 ×10^9/L (range, 3-307); 17p del in 13%; 11q del in 16%; unmutated IGHV in 41%. CR rate was 32% and 50% for Group A and B; ORR was 77% and 73%, respectively. Responses by baseline and treatment parameters are shown (Table). Short median follow-up (8 months) currently does not permit analyses of time-to-event endpoints. Ofatumumab C_{max} (426 *vs.* 201 mg/L) and C_{min} (60 *vs.* 20 mg/L) at 6th infusion were higher in Group B *vs.* Group A. Based on exploratory univariable regression analyses, lower β2-microglobulin (as continuous variable), completion of 6 courses of O-FC, and higher ofatumumab C_{min} prior to last infusion were significantly correlated with increased likelihood for response including CR, and decreased risk for progression. *Conclusions.* O-FC is highly active in previously untreated patients with CLL with CR rates up to 50%. β2-microglobulin level, number of O-FC courses completed, and C_{min} prior to last course correlated with outcomes with O-FC. Follow-up continues for time-to-event endpoints.

INHIBITION OF THE CXCR4/CXCL12 AXIS USING PLERIXAFOR TO IMPROVE THE RESPONSE TO THERAPY IN CHRONIC LYMPHOCYTIC LEUKAEMIA

C Hutchinson,[1] J Adams,[2] K Rees-Unwin,[1] J Burthem[2]

[1]*Manchester University, Manchester, UK;* [2]*Central Manchester University Hospitals, Manchester, UK*

Background. Within tissues, chronic lymphocytic leukaemia (CLL) cells occupy a microenvironmental niche with a complex inter-dependence on secreted factors and stromal ligands. The chemokine receptor CXCR4 is expressed consistently at high levels by CLL cells. The CXCR4 ligand CXCL12 is recognised to promote cell migration, to direct cell interactions, and to enhance CLL cell survival. Inhibition of the CXCR4/CXCL12 axis has been proposed as a potential therapeutic measure in CLL. *Aims.* Plerixafor is a competitive inhibitor of the CXCR4/CXCL12 axis that is entering clinical practice for a number of clinical indications. We examined the *in vitro* effects of plerixafor to test its potential role as an adjunct to chemotherapy in the treatment of CLL. *Methods. Ex vivo* CLL cells were cultured *in vitro* in conditions that promoted sustained survival. Cells were tested in the presence or absence of chemokine, chemotherapeutic agents, or plerixafor. Flow cytometry was used to test surface-expression of CXCR4, relevant receptor proteins, and for apoptotic cell death. Binding of plerixafor to CXCR4 was tested using a flow cytometric blocking assay. Signalling responses were tested by immunoblotting analysis of CXCL12-responsive phospho-proteins. Functional evaluations included morphological and morphometric analyses, immunocytofluorescence of cytoskeletal proteins, and transwell filter-migration assays. Results. CXCL12 caused down-regulation of its receptor on CLL cells and induced rapid phosphorylation of p44/42 Mitogen-activated protein kinase (MAPK). The recognised actin polymerisation, polarisation and chemotactic responses were also observed. Additionally we were able to demonstrate relevant late biosynthetic responses to CXCL12 including up-regulation of the adhesion receptors L-selectin and β1 integrins. Plerixafor was found to bind to CXCR4 at low doses and to act as an inhibitor, blocking the CXCL12-induced phosphorylation of target proteins and preventing functional responses to CXCL12. We were able to show low levels of phosphorylation of MAPK induced by plerixafor in some CLL cases, but no functional agonist effects were observed. Chemotherapeutic agents from a range of classes including steroid, fludarabine, and less conventional agents such as Imatinib, all caused up-regulation of CXCR4 with a mean increase of 2.8-fold at 24 hours. All chemotherapeutic agents tested induced death of CLL cells, although sensitivity to the agents was found to vary between cases. The addition of CXCL12 to cultures consistently reduced the chemotherapy-induced cell death. CXCL12 was active before the formation of recognisable nurse-like cells suggesting direct pro-survival effects. Plerixafor alone did not induce death of CLL cells, but was able to prevent the pro-survival effects of CXCL12 in cells treated with chemotherapy. *Summary/Conclusions.* We have shown that the expression of CXCR4 is up-regulated in response to chemotherapeutic agents, and we suggest that this up-regulation may protect CLL cells from the effects of chemotherapy: by promoting the CXCL12-driven movement of CLL cells into the protective or proliferative environment; by causing phenotypic changes that favour their retention in a tissue environment; and by directly protecting from chemotherapy-induced death. We have demonstrated that plerixafor inhibits these potential chemo-protective effects, and suggest that the drug may have value as an adjunct to established or emerging chemotherapy regimes in CLL.

PRELIMINARY RESULTS FROM A PHASE I DOSE ESCALATION STUDY TO DETERMINE THE MAXIMUM TOLERATED DOSE OF PLERIXAFOR IN COMBINATION WITH RITUXIMAB IN PATIENTS WITH RELAPSED CHRONIC LYMPHOCYTIC LEUKEMIA

L Andritsos,[1] J Byrd,[1] B Hewes,[2] T Kipps,[3] D Johns,[2] J Burger[4]

[1]*The Ohio State University, Columbus, USA;* [2]*Genzyme Corporation, Cambridge, USA;* [3]*University of California San Diego, San Diego, USA;* [4]*M.D. Anderson Cancer Center, Houston, USA*

Background. Dose intensive rituximab in previously-treated patients with CLL has demonstrated modest activity. Preclinical data indicated that the CXCR4/SDF1 axis plays a key role in CLL cell homing and retention in tissue microenvironments, such as the bone marrow. Disruption of these interactions using the small-molecule CXCR4-antagonist, pler-

ixafor, could potentially mobilize CLL cells from the tissues to the blood, and thereby enhance their sensitivity to rituximab *in vivo*. To test this hypothesis, we initiated a phase 1 trial of plerixafor + rituximab in previously-treated patients with CLL. *Aims.* The primary objective was to determine the maximum tolerated dose (MTD) and safety of plerixafor when combined with rituximab. *Methods.* Rituximab-sensitive adult patients≤80 years old with WBC≤ 50×10^9/L, intermediate/high risk CLL and a diagnosis of active disease by NCI criteria were eligible to enroll. Patients were treated with 3x/week of rituximab, administered as a 100 mg flat dose on Day 1, and thereafter at 375mg/m^2 IV for 12 total doses. Plerixafor was administered SC, beginning with the 4th rituximab dose, 4 hours prior to rituximab in escalating doses of 0.08mg/kg, 0.16 mg/kg, 0.24 mg/kg and 0.32 mg/kg. Dose-limiting toxicities (DLT) were defined as any of the following, occurring from the first plerixafor dose (Day 8) through Day 29 and considered study drug-related: non-hematologic toxicity≥ grade 3, neutropenia≥ grade 3 which does not resolve to ≤grade 2 by week 4 of therapy in patients with normal ANC prior to therapy, hyperleukocytosis (WBC count>200×10^9/L) or tumor lysis syndrome requiring dialysis. MTD was defined as the highest dose at which no more than 1 of 6 patients experience a DLT. CD34$^+$ and CLL cells were enumerated in peripheral blood (PB) on Days 8 and 26 by flow cytometry; PB samples were obtained at baseline pre-plerixafor treatment and at 2, 4, 6, 10, and 24 hours post-plerixafor. *Results.* 14 patients (median 62 years; Rai Stage IV: 57%) have been enrolled, 3 patients each in the 0.08 and 0.24 mg/kg cohorts and 4 patients each in the 0.16 and 0.32 mg/kg cohorts (Table 1). No DLTs have been reported. Treatment-emergent, plerixafor-related adverse events (AEs) were seen in 6 patients and included diarrhea, vomiting, nausea, back pain, appetite loss and paraesthesia. All AEs were grade 1 in intensity except nausea that was grade 2 and back pain that was grade 3. Treatment-emergent serious AEs were seen in 2 patients (0.16 mg/kg dose; grade 2 EBV infection, grade 2 gastrointestinal reflux disease and grade 2 dyspnea); all unrelated to plerixafor. On Day 8, there was a median 3.4-fold increase in peripheral CLL cells (range: 1.2-11.7-fold), indicating CLL cell mobilization. On Day 26 fewer CLL cells were detected in the periphery with a median fold increase of 1.6 (range, 0.9-8.0). *Conclusions.* These preliminary data suggest that the combination of plerixafor plus rituximab in CLL patients appears to be well tolerated. Furthermore, plerixafor treatment can mobilize CLL cells to the blood, thereby justifying further investigation into its use as a potential sensitizing agent to enhance the activity of other agents utilized in the treatment of CLL.

PERSISTENT PHENOTYPIC COMPLETE REMISSION OR MAINTENANCE TREATMENT PREDICT FOR LONG-LASTING RESPONSE DURATION AND LONGER OVERALL SURVIVAL IN CHRONIC LYMPHOCYTIC LEUKEMIA

G Del Poeta,[1] MI Del Principe,[1] P Bulian,[2] D Ragusa,[1] D Rossi,[3] A Perrotti,[1] A Zucchetto,[2] F Buccisano,[1] M Degan,[2] L Maurillo,[1] L Giannì,[1] L Ottaviani,[1] F Luciano,[1] A Venditti,[1] P De Fabritiis,[1] V Gattei,[2] G Gaidano,[3] S Amadori[1]

[1]University Tor Vergata, Roma, Italy; [2]Hematology Unit, CRO, Aviano (PN), Italy; [3]Hematology, University of Eastern Piedmont, Novara, Italy

The treatment goal of chronic lymphocytic leukemia (B-CLL) is now the attainment of maximal disease control combining purine analogs with monoclonal antibodies. This approach have produced more complete molecular remissions and longer response duration (RD), often remaining only a minimal residual disease (MRD) detectable by flow cytometry. From 1998 to 2008, we treated in first line 126 B-CLL symptomatic patients (pts), median age 63 years, with six monthly courses of intravenous or oral fludarabine at conventional doses and then, after a median time of 31 days, with four weekly doses (375 mg/sqm) of rituximab (rtx). Fourteen pts had a low Rai stage, 109 an intermediate stage and 3 a high stage. We defined as high risk pts having at least two of these markers: unmutated IgVH, CD38>30%, ZAP-70>20%, intermediate/unfavorable cytogenetics (trisomy 12 or del11q or del17p). Fifty-one pts (40%) belonged to the high risk subset. For MRD flow cytometric study, the threshold was set at >1% CD19+CD5+CD79b- bone marrow (BM) CLL cells. Based on NCI criteria, 96/122 (78%) pts achieved a CR, 24/122 (20%) a partial remission (PR) and 2/122 (2%) no response or progression. Phenotypic CR (CD19+CD5+CD79b- BM cells <1%) was achieved in 71/122 (58%) pts. Ten pts underwent grade 3 (WHO) infective lung toxicity, 1 patient acute fatal B hepatitis and 2 pts progressed towards Richter's syndrome. Hematologic toxicity included mainly neutropenia (grade 3 and/or 4 in 60 pts) and thrombocytopenia (grade 3 and/or 4 in 8 pts). Fifty-four pts either in CR with B-CLL BM cells >1% (MRD$^+$, n=16 pts) or in CR MRD negative, but with B-CLL peripheral cells going up >1000/microl within 2 years after induction (n=22 pts) or in PR (n=16 pts), underwent consolidation and maintenance therapy with four monthly cycles of rtx at 375 mg/sqm followed by twelve monthly low doses of rtx (150 mg/sqm). The median follow-up duration was 53 months. All treated pts experienced a long progression-free survival from the end of induction treatment (40% at 9 years). Overall survival (OS) was 37% at 10 years from the start of treatment. Noteworthy, both persistently MRD negative (>1 year) pts (n=44) and pts undergoing consolidation and maintenance therapy (n=54) showed a longer RD *vs.* MRD$^+$ not consolidated pts (n=21) [97% *vs.* 76% *vs.* 10% at 4 years; P<0.00001, Figure]. Equally, global OS was shorter in MRD+ not consolidated pts in comparison with the other subsets (17% *vs.* 73% *vs.* 97% at 15 years; P=0.02, Figure). Noteworthy, within the high risk subset (n=51), both pts in persistent phenotypic CR (n=13) and consolidated pts (n=18) showed a longer RD (88% *vs.* 60% *vs.* 0% at 2.6 years, P=0.007) *vs.* MRD+ not consolidated pts (n=14). In our experience, both persistent MRD negativity and rituximab maintenance therapy improve RD and OS in B-CLL, also within the high risk subset.

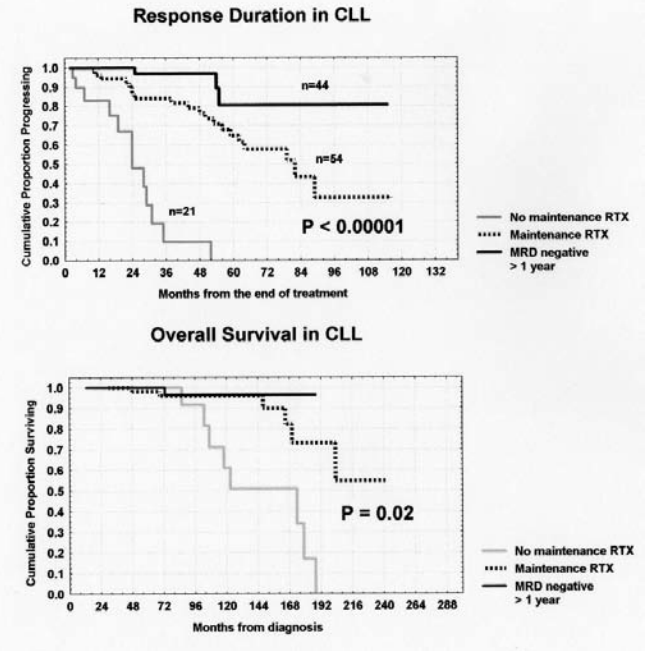

Figure 1. Response duration and overall survival in CLL

Background. Current second-line therapies for CLL produce unsatisfactory clinical *Results.* Bendamustine has shown a considerable degree of efficacy in patients with lymphoid malignancies. There is evidence that the *in vitro* cytotoxic effect of Bendamustine may be enhanced by combination with Rituximab. Encouraging results have been reported with this association (R-B) for the treatment of NHL but data on CLL are scanty. Aim of this study was to retrospectively assess the efficacy and toxicity of the R-B association in a multicentre cohort of relapsed/refractory CLL patients. *ethods.* 109 CLL patients relapsed following, or refractory to, first line therapy including Rituximab and/or fludarabine were treated with R-B in 24 Italian centres. Data on diagnosis and relapse, treatment, toxicity, and outcome were analysed. Results. Patients M/F ratio was 2/1, all had Binet stage C or B and active disease; the median age was 66 years (range 39-85), 39% showed elevated LDH value (median[3DOTS]), 18% had B-symptoms, 43% were relapsed and 57% were resistant after a median of 3 lines of previous therapy (range 1-8). 22 patients received bendamustine alone and 88 patients were given R-B (median B dosage: 100 mg/m^2/d, range 90-130 mg/m^2/d). The ORR was 69.6% (CR=28.6%; PR 41%) and a 26% CR was achieved within the 4th chemotherapy cycle. The ORR was significantly higher in patients treated with R-B (P=0.014) and in those responsive to the latest chemotherapy course (P=0.04). After a median follow-up of 7.9 months (range 1-148), 35% patients had progressed and 31% had died. The median PFS was 16 months and the median Duration-of-Response was 13 months. Patients who achieved a CR had a significantly longer DOR than those in PR (not reached *vs.* 8 months). Median OS was 16.8 months; disease status before Bendamustine administration (relapse *vs.* resistant P<0.0001) and the achievement of a CR (vs PR P=0.006) significantly influenced the OS. In a multivariate Cox model, resistant disease status at start of Bendamustine treatment (HR 3.2, 95% CI 1.4-7.3, P=0.006) and unresponsiveness to R-B (HR 4.5, 95% CI 2.5-10.5, P<0.0001) remained independent prognostic factors for OS. A total of 460 cycles were administered, (median 4 cycles/patient). Grade 3/4/5 CTC toxicity occurred in 56 of the 460 treatment cycles: 5 were infections (4.5%) [herpes-zoster (n=2), herpes encephalitis (n=1), bacterial pneumonia (n=1) and pulmonary aspergillosis (n=1)], and 52 were haematological toxicities. Overall, grade 3/4 anemia was recorded in 16% of patients, neutropenia in 17% and thrombocytopenia in 16%. Three out of 34 (9%) deaths (treatment-related mortality amounted to 2.7%) were due to infections [herpes encephalitis (1), bacterial pneumonia (1) and pulmonary aspergillosis (1)]. Conclusion. Our data demonstrate that patients treated with R-B association can achieve a remarkable ORR and CR rate in relapsed/refractory CLL patients. Responses were obtained promptly and were burdened by limited toxicity, showing that this chemotherapy-regimen should be considered an effective therapeutic option for this group of patients. These findings suggest that further studies aimed to compare the efficacy of R-B with fludarabine, cyclophosfamide and Rituximab should be strongly encouraged.

FLOW CYTOMETRIC MRD NEGATIVITY AT DAY 365 AFTER ALLOGENEIC STEM CELL TRANSPLANTATION (SCT) PREDICTS BETTER THREE-YEAR PROGRESSION-FREE SURVIVAL (PFS) IN PATIENTS WITH ADVANCED B-CLL

U Oelschlaegel, M Bornhäuser, A Kiani, U Platzbecker, C Röllig, M Wermke, C Thiede, G Ehninger, J Schetelig

University Hospital Dresden, Dresden, Germany

Background. In a completed study (NCT00337519), patients with advanced B-CLL received allogeneic SCT after cytoreductive treatment with alemtuzumab followed by a wash-out period for the antibody and conditioning with fludarabine/busulfan. Aim of the present investigation was to correlate flow cytometric MRD levels in the peripheral blood at different time points after transplantation with patient outcome. *Methods.* In 58 CLL patients 900 flow cytometric MRD investigations (at least 4 measurements/patient: at day 30, between d31-100, d101-180, and d181-365 after SCT) were performed measuring the following CLL phenotype: CD19posCD5posCD20dimCD79bneg. Therefore, a 4-color-approach (until 2006) or an 8-color-approach then in combination with T- and NK cell antigens was performed. A patient was defined as MRD negative if less than 0.05% CLL cells were detectable or as relapse if more than 0.05% CLL cells were redetectable in at least two successive investigations. For assessment of PFS, clinical progress was defined according to the NCI criteria. *Results.* The median follow up time after SCT was 536 days (range: 44d-1758d). Considering all 58 transplanted patients the probability of three-year overall survival (OS) including the 95% confidence interval was 64±19% (1-year: 83±10%) and of three-year PFS 45±17% (1-year: 74±12%). In the majority of cases flow cytometric MRD negativity was achieved within the first year post SCT with a cumulative incidence of 36±13% at day 100 and of 73±12% at one year, respectively. Only two additional patients became MRD negative within the second year post SCT. Patients who achieved MRD negativity until day 365 showed a significantly better 3-year OS compared to the MRD positive group (90±15% *vs.* 56±49%; P=0.009). Remarkably, the 3-year PFS of patients achieving flow cytometric MRD negativity until day 365 was also significantly better than in the MRD positive cases (75±20% *vs.* 0%; P=0.002). Of note, early flow cytometric MRD negativity until day 100 was not informative concerning one-year OS or PFS (88±13% *vs.* 79%±15% and 77±18% *vs.* 72±18%). The flow cytometric MRD status was one trigger to give DLI. Interestingly, this kind of immunomodulation resulted in flow cytometric MRD negativity in all eight patients after a median of 130 days. The probability of relapse in the investigated patient cohort was 15±10% after 1 year and 31%±14% after 3 years. Thus, 9/14 patients showed a clinical relapse in parallel with flow cytometric

MRD positivity. Two patients featured an isolated flow relapse with MRD at two successive investigations. Three patients showed a mere nodal relapse, all occurring within the first year post SCT. *Conclusions.* In summary, the present flow cytometric MRD study in B-CLL patients elucidates the dynamics of remission induction and relapse in the first year post SCT. In the majority of patients MRD is eradicated between day +100 and day +365 which is the time interval when chronic GvHD occurs in most cases. Therefore, close monitoring of MRD status in the first year after SCT is necessary. Once patients are flow cytometrically MRD negative at day 365, they seem to have a high probability of long term survival.

MONOCLONAL B-CELL LYMPHOCYTOSIS (MBL) WITH NORMAL WHOLE LYMPHOCYTE COUNTS IS ASSOCIATED WITH REDUCED NUMBERS OF NORMAL CIRCULATING IMMATURE AND MATURE B-LYMPHOCYTES

A Hauswirth,[1] J Almeida,[1] W Nieto,[1] C Teodosio,[1] A Rodriguez Caballero,[1] A Romero,[2] A Lopez,[1] P Fernández-Navarro,[3] T Vega,[4] M Perez-Andres,[1] P Valent,[5] U Jäger,[5] A Orfao[1]

[1]University of Salamanca, Instituto de Biologia Molecular y Celular del Cancer, Salamanca, Spain; [2]Gerencia de Atencion Primaria de Salud de Salamanca, Sanidad de Castilla y Leon, Salamanca, Spain; [3]Centro de Atencion Primaria de Salud de Ledesma Salamanca, Salamanca, Spain; [4]Direccion General de Salud Publica, Castilla y Leon, Spain; [5]Medical University of Vienna, Vienna, Austria

Background. "Monoclonal B-cell lymphocytosis"(MBL) is the international consensus term proposed to indicate the presence of $<5\times10^9$/L circulating monoclonal B cells -with or without increased B-cell counts- in otherwise healthy subjects. Normal B- and T- lymphocytes have been found to be decreased in patients with chronic lymphocytic leukemia (CLL) but until now there is no information about this matter in healthy subjects with MBL. *Aims.* To investigate the distribution -in terms of circulating absolute numbers- of B-, T-, and NK-cell subsets in MBL cases. *Methods.* Using a high-sensitive flow cytometry approach, based on 8-color staining panels and the systematic screening for $>5\times10^6$ total PB leucocytes, we immunophenotyped a total of 95 peripheral blood (PB) samples of healthy subjects with MBL (55 f / 40 m, aged 70±11 years) showing normal lymphocyte counts ($2.2\pm0.6\times10^9$/L). As a control group we analyzed 653 age- and sex-matched healthy subjects with no evidence of a clonal disease. *Results.* Absolute numbers of normal circulating B-cells and all the different maturation B-cell subsets (immature, naïve, memory B-lymphocytes and plasmablasts) were significantly reduced in MBL cases *vs.* controls. In an additional applied aged-matched comparison, immature B cells and $CD4^+/CD8^+$ T cells were also decreased ($P<0.05$) in MBL *vs.* controls. Furthermore, a more progressive decrease in the numbers of circulating B-cell subsets such as immature, naïve, IgM negative memory B-lymphocytes and plasmablasts (but neither in T- nor in NK-cells) was observed, with statistically significant differences at a cut-off point of 1% monoclonal B-lymphocytes in PB. Interestingly, lower absolute numbers of both CD5 neg. immature and naïve B-cells were detected in those MBL cases displaying two B-cell clones in comparison to single clone MBL-subjects, particularly in those biclonal MBL cases carrying one CLL-like clone plus one CD5 negative non-CLL clone ($P<0.05$). Moreover, a significantly higher amount of clonal B-cells *vs.* both monoclonal MBL and CLL-like+CLL-like biclonal MBL were observed in biclonal cases carrying one CLL-like clone plus CD5 negative non-CLL clone (monoclonal CLL-like MBL: $20\pm145\times10^6$ clonal cells/L; CLL-like+CLL-like biclonal MBL: $5\pm10\times10^6$ clonal cells/L and CLL-like plus CD5 negative non-CLL biclonal MBL: $463\pm541\times10^6$ clonal cells/L; $P<0.05$). *Conclusions.* Overall, our results show that MBL cases have reduced absolute numbers of both total normal B-cells and their different B-cell subsets identified in PB, in comparison to controls. This decrease seems to be dependent on the amount of circulating clonal B cells, suggesting a suppressive effect of the MBL-clone on normal B-cell lymphopoiesis. Whether this suppression may be derived from a competitive situation concerning the B-lymphocyte production in the stem cell niche requires further investigations.

0777

BENDAMUSTINE AND ALEMTUZUMAB (BEN CAM) COMBINATION IN RELAPSED AND REFRACTORY CHRONIC LYMPHOCYTIC LEUKAEMIA (CLL): PHASE I SAFETY PROFILE RESULTS OF THE ITALIAN TRIAL

A Tedeschi,[1] M Coscia,[2] D Rossi,[3] E Vismara,[1] F Ricci,[1] C Vitale,[2] E Morra,[1] G Gaidano,[3] M Massaia,[2] M Montillo[1]

[1]Division of Hematology, Niguarda Ca' Granda Hospital, Milano, Italy; [2]Division of Hematology University of Torino, Torino, Italy; [3]Division of Hematology Amedeo Avogadro University of Eastern Piedmont, Novara, Italy

Single-agent alemtuzumab has been shown to be effective when used either as first-line therapy, or in relapsed/refractory CLL. Bendamustine is a bifunctional alkylating agent with considerable activity both in monotherapy or in combination with other cytostatic agents in relapsed /refractory CLL and indolent lymphomas. Both agents exhibit an individual, unique mechanism of action. Therefore, a synergistic or additive effect might be expected when they are used in combination. Ben Cam study is a multicentric Italian, single arm, open label, dose escalation study designed to determine the best tolerable treatment schedule and efficacy of the combination of bendamustine and alemtuzumab in patients with refractory/relapsed CLL. In the first part of the study, the tolerability of a stepwise dose-escalation schedule of bendamustine along with an increasing dose of alemtuzumab has been determined. This schedule explored the Dose-Limiting Toxicities (DLT) and the Maximum Tolerated Dose (MTD) of this treatment. Bendamustine was given at a starting dose of 50 mg/m^2 for 2 consecutive days along with alemtuzumab 20 mg sc on days 1 to 3. If MTD was not reached within the first cohort of 3 patients the second cohort of 3 patients received the same dose of bendamustine with an increased dose of alemtuzumab (30 mg). If the MTD was not reached after completion of Cohort 2 the third cohort of 3 patients received bendamustine 70 mg/m^2 along with alemtuzumab 30 mg sc. A further dose escalation is not foreseen. If one of 3 patients at each dose level experienced DLT three additional patients were added (max 6). If 5 of the 6 subjects were able to complete the first 2 cycles without experiencing DLT, this level was considered tolerable and dose-escalation continued initiating the following cohort. This combination was repeated on day 29 for up to 4 cycles. Twelve patients have been enrolled in the Phase I of this trial: 3 patients in each of the first 2 cohorts, 6 in the third cohort. The median age was 63.7 years (range, 52-77), seven male (58%), 33% had Binet stage C, median number of prior regimens was 2 (range, 1-4). Seven patients received monoclonal antibodies as previous treatment: rituximab in 3 cases and alemtuzumab in 4 cases. Unmutated IGVH genes were detected in 8/12 (66%) patients. Grade III-IV neutropenia episodes were observed in 58%, 19%, 24% of courses in the first, second and third cohort respectively. Grade III-IV thrombocytopenia episodes were detected in 0%, 18%, 0% of cycles in each cohort respectively. Grade III-IV anemia episodes were recorded in 8.3%, 0%, 0% in each cohort respectively. One major infection sustained by Pneumococci (pneumonia) was observed. CMV reactivation occurred in 4 patients: no CMV disease was recorded. Extra-hematological toxicity was mild. Therefore, bendamustine 70 mg/m^2 along with alemtuzumab 30 mg sc resulted as a tolerable treatment. In the second part of the study, patients will receive this dose level to provide data on the anti-tumor activity of the combination.

0778

SUPPORTING RITUXIMAB THERAPY IN CHRONIC LYMPHOCYTIC LEUKEMIA

P Zagoskina,[1] V Malykh,[1] N Zotina[2];

[1]Kirov scientific research institute of hematology and blood transfusion of FMBA, Kirov, Russian Federation; [2]Kirov Scientific Research Institute of Hematology and Blood Transfusion of FMBA, Kirov, Russian Federation

Background. The application of the combination of rituximab with fludarabine-containing chemotherapy regimen in recent years significantly improved the results of overall and disease-free survival of patients with chronic lymphocytic leukemia (CLL). However, to avoid the relapses of a certain group of patients, unfortunately, is not possible, because it is an open question about the possibility of complete eradication of malignant clone in this neoplasia. Therefore, the main task of this modern stage is to develop a strategy lengthening the period till disease progression. *Aim.* The aim of the presented work was to study efficiency of supporting rituximab therapy after induction chemotherapy or immuno-chemotherapy in CLL patients. *Methods.* The study

included 193 patients in remission. The age of patients ranges from 38 to 74 years (a median - 59 years). Complete remission (PR) was observed in 110 (57%) patients, partial remission (CR) in 83 (43%). Remission of the disease was obtained as a result of induction chemotherapy RFC program (rituximab, fludarabine, cyclophosphamide) in 107 patients or FC (fludarabine, cyclophosphamide) in 86 patients. Program RFC included: rituximab 375 mg/m^2 i/v in 1 day, fludarabine 25 mg/m^2 i/v 2-4 days and cyclophosphamide 300 mg/m^2 i/v 2-4 days. Program FC included fludarabine 25 mg/m^2 i/v 1-3 days and cyclophosphamide 300 mg/m^2 i/v 1-3 days. After achieving the overall efficiency, the patients were randomly assigned to either observation (133 patients) or supporting rituximab therapy in the form of 4 weekly injections (375 mg/m^2) every 6 months withing 2 years (60 patients). *Results.* A result of the work showed that patients with CLL who got RFC regimen with subsequent supporting rituximab therapy, had the frequency of relapses and deaths significantly lower compared with patients who were observed without supporting rituximab therapy (P=0.001, P=0,015, respectively). Analyzing these indicators in patients treated with FC, followed by supporting rituximab therapy, we see advantage of maintenance therapy in relation to the observation group (P=0.0001, P=0.002, respectively). Comparative analysis of progression free survival (PFS) CLL patients, who received various regimens, revealed a significant difference. Thus, in patients who completed the program, followed by RFC and supporting rituximab therapy, the median PFS has not been achieved, while in patients without supporting rituximab therapy, it was 42 months (P=0.009). The related indicators of patients receiving the combination of FC with further supporting rituximab therapy (P=0.004) differed significantly, their median PFS was not achieved in contrast to patients of the monitoring group, whose PFS is 24 months (P=0.001). During the period of supporting rituximab therapy, the signs of hematological toxicity did not exceed the I stage. The number of infectious complications tended to be equal in observation group and in the group of patients receiving supporting rituximab therapy and was 7%. Summary. Thus, the results of the study showed the role of supporting rituximab therapy in CLL treatment effectiveness. With the help of supporting rituximab therapy it is possible to maintain a more-expendable remission and overall satisfactory condition of the patients without signs of disease progression, and thereby improve long-term results of tumor therapy process.

0779

ACADESINE FOR PATIENTS WITH RELAPSED/REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA: A MULTICENTRE PHASE I/II STUDY

E van den Neste,[1] A Janssens,[2] E González-Barca,[3] B Cazin,[4] MJ Terol,[5] V Lévy,[6] J Pérez de Oteyza,[7] A Saunders,[8] M De Frias,[9] C Campàs[9]

[1]Cliniques universitaires UCL Saint-Luc, Brussels, Belgium; [2]University Hospital Leuven, Leuven, Belgium; [3]Institut Català d'Oncologia, Spain, L'Hospitalet de Llobregat, Spain; [4]Le Centre Hospitalier Régional Universitaire de Lille, Lille, France; [5]Hospital Clínico Universitario de Valencia, Valencia, Spain; [6]Pôle Hématologie-Oncologie Hôpital Avicenne, Bobigny Cedex, France; [7]Hospital Madrid Norte-Sanchinarro, Madrid, Spain; [8]External Consultant, Edinburgh, UK; [9]ADVANCELL-Advanced in vitro cell technologies SA, Barcelona, Spain

Acadesine induces cell death in B-cell chronic lymphocytic leukemia (CLL) cells in a dose-dependent manner. Acadesine enters B-cells where it is phosphorylated to ZMP, which induces apoptosis independently of ATM or p53. It is active *in vitro* against CLL cells from patients who have not responded to prior treatment with fludarabine and/or chlorambucil. A phase I/II open-labeled clinical study was designed to determine the safety and tolerability of acadesine given intravenously as a 4-hour infusion to patients with CLL. Part I is the dose escalation part of the study where patients receive a single dose of acadesine on Day 1 and are followed up to Day 22. In Part II, patients will receive up to 5 doses of acadesine at the maximum tolerated dose (MTD) identified in Part I over a period of up to 20 days. Patient population includes CLL patients with relapsed/refractory disease who have received one or more prior lines of treatment including either a fludarabine or an alkylator-based regimen. A patient is defined as having refractory disease if they fail to achieve less than a partial response (PR) according to the NCI working group guidelines, or relapse within the first 6 months after treatment after achieving at least partial response. Primary endpoints of the study evaluate the safety and tolerability of acadesine. Secondary endpoints evaluate the pharmacokinetics of acadesine and ZMP, and B and T-cell counts in peripheral blood as efficacy biomarkers. Eighteen patients have been included to date in Part I at doses of 50, 83.5, 139.5, 210 or 315 mg/kg. Pharmacokinetic data showed acadesine is rapidly converted into ZMP inside blood cells. The Cmax levels for ZMP in whole blood obtained at 315 mg/kg were similar to the ones obtained at the previous dose (210 mg/kg), suggesting that the saturation plateau was reached, which will be confirmed based on PK modeling. In 5 patients treated with acadesine at 210 mg/kg and 315 mg/kg a decrease in absolute B cell count was observed, ranging from 6% to 54% with respect to the B cell count prior to acadesine administration. Reversible asymptomatic hyperuricaemia was observed in four patients in cohorts 1 to 3, probably due the metabolism of acadesine to ZMP and uric acid. Prophylactic allopurinol was used in cohorts 4 and 5 and it has significantly reduced the incidence of hyperuricaemia. Acadesine 315 mg/kg was the dose limiting toxicity (DLT) dose with 2 of 3 patients having DLTs-Tumour Lysis Syndrome (TLS) and clinically significant acute renal failure (CTCAE V3.0 Grade 3-chronic dialysis not indicated). Additional safety, pharmacokinetics and efficacy data will be presented at the meeting. In conclusion, a MTD was found and multiple dose acadesine administration is currently planned in part II of this ongoing study.

0780

DOSE DENSE HIGH DOSE METHYLPREDNISOLONE (HDMP) AND RITUXIMAB (RTX) ARE EFFECTIVE IN RELAPSED OR REFRACTORY HIGH RISK CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

R Pileckyte,[1] M Jurgutis,[2] V Valceckiene,[1] M Stoskus,[1] E Gineikiene,[1] J Sejoniene,[1] A Degulys,[1] A Jakubauskas,[1] L Griskevicius[1]

[1]Vilnius University Hospital Santariskiu Clinics, Vilnius, Lithuania; [2]Fisherman's Hospital, Klaipeda, Lithuania

Background. Management of high risk CLL remains a considerable challenge. Despite progress using chemoimmunotherapy, many patients would not tolerate the treatment due to toxicity. There is a low response rate in cases with 17p del/p53 mutation. Alemtuzumab has limited activity in patients with bulky lymphadenopathy. Aim of the study. was to evaluate the efficacy and safety of dose dense HDMP and Rtx combination in a prospective study. *Methods.* Patients were included if they had a relapsed or progressive disease after at least one line of chemotherapy with adverse cytogenetics (17p del, p53 mut, 11q del and/or trisomy 12) and / or progressed within 12 months of fludarabine treatment. All patients provided informed consent. Patients were required to have an indication for treatment based on the NCIWG-96 criteria. HDMP was administered at 1 g/m^2 intravenously daily for five consecutive days of each treatment course. Rtx was administered at a dose of 375 mg/m^2 on day 1 and 500 mg/m^2 on day 5 of the first course, on days one and five of the second course, and on day one of courses three to six. Courses were repeated every 21 day for a total of 6. Response was evaluated according NCIWG-96 criteria. All patients underwent a bone marrow biopsy and a CT scan for residual disease. *Results.* 29 patients with CLL were enrolled. Median age was 59 years (range 45-76), 22 (76%) patients had Rai III-IV stage, 17 (59%) had bulky (> 5 cm) lymphadenopathy. 25 (86%) patients had unmutated IgVH, 13 (45%) had 17p del and/or p53 mutation, 11 (38%) had 11q del, and one (3%) patient had trisomy 12, 10 (34%) patients progressed within 6 months of fludarabine treatment. Overall response rate (ORR) in 26 evaluable patients was 69%, one patient (4%) had complete response, 17 (65%) patients achieved partial response (PR), and stable disease was confirmed in 8 (31%) patients. There were no significant differences in ORR in different risk groups: 90% in patients with 17p del/p53 mutation, 64% in patients with 11q del, 70% in fludarabine refractory patients and 62% in patients with bulky lymphadenopathy (P=0.34). 4 patients with PR underwent allogeneic bone marrow transplantation. After the median follow-up of 19 months, the median progression free survival was 12 months (range 10-14) and median overall survival was not reached. The most common toxicity was hyperglycemia not requiring intervention in most cases. 12 cases of III-IV° neutropenia and 2 cases of febrile neutropenia were observed. III° infections were noted in 4 cases. There were 3 early deaths during treatment: one sudden death of unknown reason, one of sepsis, and one death of gastrointestinal bleeding due to preexisting thrombocytopenia. *Conclusions.* The dose dense treatment with HDMP and Rtx is an effective therapy with favorable safety profile in high risk CLL patients, including those with 17p del/p53 mutation. A follow-up study is planned. (ClinicalTrials.gov identifier: NCT005 58181; in part supported by EEA and Norway grant No. 2004-LT0040-IP-1EEE.)

0781

RITUXIMAB IN COMBINATION WITH HIGH-DOSE DEXAMETHASONE: AN EFFECTIVE TREATMENT OPTION FOR PATIENTS WITH RELAPSED/REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA

M Simkovic,[1] A Panovska,[2] D Belada,[1] M Hrudkova,[1] Y Brychtova,[2] J Mayer,[2] L Smolej,[1] M Doubek[2]

[1]University Hospital and Medical School Hradec Kralove, Hradec Kralove, Czech Republic; [2]Department of Internal Medicine - Hematology/Oncology, University Hospital, Brno, Czech Republic

Background. Patients with refractory CLL have poor outcome despite currently used salvage treatment. Regimens based on high-dose corticosteroids seem to offer a promising treatment option in this scenario. High-dose methylprenisolone combined with rituximab (R-HDMP) demonstrated significant activity in relapsed/refractory CLL but serious infectious complications occurred in a substantial proportion of patients. Pilot data have shown that combination of dexamethasone and rituximab (R-Dex) may provide comparable results with less toxicity. *Aims.* and *Methods.* We performed a retrospective analysis of the efficacy and safety of R-Dex in patients (pts) with CLL treated at two tertiary centers between April 2006 and February 2010. Patients received two versions of R-Dex regimen: the dose of rituximab was either 500 mg/m^2 on day 1, 8, 15, 22 (375 mg/m^2 in 1st cycle), repeated every 4 weeks (n=25) or 500 mg/m^2 on day 1 (375 mg/m^2 in 1st cycle) repeated every 3 weeks (n=16). The dose of dexamethasone was identical in both regimens: 320 mg per cycle (40 mg on day 1-4 and 10-13 or 15-18). *Results.* R-Dex was administered to 41 patients (19 males) with median age of 68 years (range, 44-81) indicated for treatment according to NCI-WG criteria. Autoimmune hemolytic anemia or thrombocytopenia was the only indication for the treatment in 7 patients. Rai stage III/IV was present in 37/41 pts. IgVH genes were unmutated in 24/29 pts with available *Results.* Cytogenetic aberrations detected by FISH (n=33) revealed del 17p in 7 patients; del 11q in 11 patients; del 13q in 15 patients and trisomy 12 in 5 patients. Median number of previous therapies was 2 (0-8); 29/41 pts were previously treated with fludarabine-based regimens. The effect of R-Dex in evaluable patients without hemolysis (n=32) was: overall response rate (ORR), n= 21 (62%), complete remission (CR), n=6 (18%), partial remission (PR), n=15 (44%), stable disease (SD), n=4 (12%) and progressive disease (PD), n=5 (15%). All patients treated with R-Dex for autoimmune cytopenia achieved complete resolution of hemolysis. Grade III or IV toxicity included infections in 13 patients (32%), steroid diabetes in 6 patients (15%) and rituximab infusion-related side effects in 3 patients (7%). At the time of analysis (February 2010), median progression free survival (PFS) was 9 months; median overall survival has not been reached. There was no difference in ORR, PFS or OS between the two versions of R-Dex regimen. *Conclusions.* This pilot study shows that R-Dex is a feasible and effective treatment for relapsed/refractory CLL. In particular, R-Dex appears to be highly effective in CLL with autoimmune cytopenias. However, infectious toxicity remains a serious issue. In addition, long-term disease control can be expected in minority of patients only. Interestingly, higher dose of rituximab per cycle did not result in improved efficacy.

Supported by research project MZO 00179906 from Ministry of Health, Czech Republic, by research grant MSM 0021620808 and by the Czech Leukemia Study Group for Life.

HISTONE DEACETYLASE INHIBITION IN CLL WITH TP53 DELETION/ MUTATION

T Zenz, A Sarno, A Schnaiter, M Volden, A Bühler, D Winkler, J Mohr, D Mertens, H Döhner, S Stilgenbauer

University of Ulm, Ulm, Germany

Introduction. Histone deacetylase inhibitors (HDACi) exhibit promising anti-cancer activity (e.g. tumor cell growth and survival inhibition and low toxicity in healthy cells), but their mechanism of action is not fully understood. There exists a discourse as to whether p53 plays a major role in HDACi-mediated cell death and few studies have examined this question in CLL. In this study, we examine HDAC-induced cell death with regards to TP53 status of primary CLL samples. *Materials and Methods.* An initial screen was performed on CLL cells from a genetically diverse cohort to test the efficacy of eight small molecule therapeutic agents with respect to p53 status in CLL primary samples. After initial positive results of the HDACi Trichostatin A (TSA), this compound was tested on three CLL cell lines (Mec1, Mec2, and EHEB) with 24h, 48h, and 72h incubation times and 23 primary CLL cell samples (8 of which with 17p deletion) using a chemiluminescence-based cell viability assay (CellTiterGlo, Promega) with 24 h and 48 h incubation times. These results were confirmed using FACS. HDACi with purportedly similar mechanisms, SAHA (Vorinostat), LBH589 (Panobinostat) and CHAHA, were tested on a subgroup. Results. Significant cell death was observed in all cell lines tested after 24 h incubation with 100 nM TSA. Near absolute cell death was observed after 48 h incubation with 1 μM TSA. Interestingly, Mec1 and Mec2 (both of which have TP53 mutations) exhibited a higher sensitivity to TSA than EHEB (wild-type TP53). Primary CLL cell samples exhibited sensitivity to 100 nM and 10 nM TSA after 24 h and 48 h, respectively. Similar to the cell lines, near absolute cell death was observed after 48 h with 100 nM TSA. Cases with 17p deletion (6/8 of which also had TP53 mutations) showed a distinctly (>two-fold) higher response to TSA than those without (Figure). SAHA and CHAHA were observed to induce less cell death in primary CLL cell samples than TSA at equimolar concentrations: sensitivity was observed after 48 h with 1 μM and 10 μM SAHA and CHAHA, respectively. Unlike TSA, neither SAHA nor CHAHA induced cell death more prominently in cells with 17p deletion. Conclusions. SAHA and CHAHA induced cell death in primary CLL cells irrespective of 17p status suggesting a p53-independent mechanism; however, TSA exhibited a more prominent effect in cell lines with TP53 mutation and primary cells with 17p deletion suggests a potential synthetic lethal interaction with mutant p53. The high sensitivity of primary CLL cells to HDACi at minute concentrations and their activity regardless of 17p-status are promising.

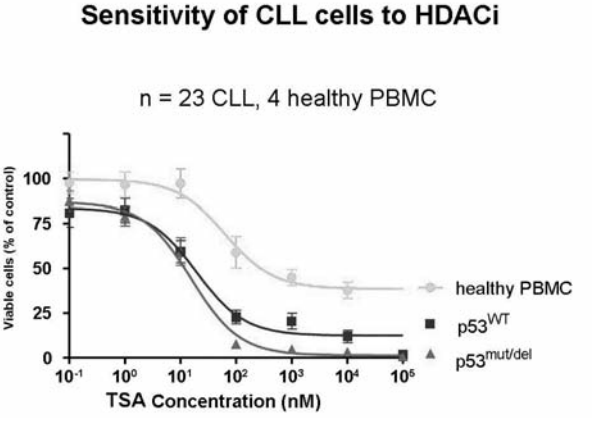

Figure 1. Effect of HDACi in CLL based on p53 status.

A TRIPARAMETRIC QPCR SCORE COMPOSED OF ZAP70, LPL AND MICRORNA-29C AS A NEW PROGNOSTIC TOOL FOR CHRONIC LYMPHOCYTIC LEUKEMIA RISK STRATIFICATION AT THE TIME OF DIAGNOSIS

B Stamatopoulos,[1] N Meuleman,[1] C de Bruyn,[1] K Pieters,[1] G Antoine,[1] P Mineur,[2] D Bron,[1] L Lagneaux[1]

[1]Jules Bordet Institute, Brussels, Belgium; [2]Charleroi Hospital, Charleroi, Belgium

Background. this last decade, several markers have been proposed to predict the outcome of chronic lymphocytic leukemia (CLL) patients. However, several discordances exist between prognostic factors indicating that no factor is totally perfect. The use of only one factor could thus lead to the misclassification of the patient. *Aim.* the present study aimed to investigate the prognostic power of new RNA-based prognostic markers and to assess the prognostic power of a quantitative PCR (qPCR) score composed of the most powerful factors in order to reduce patient misclassification. *Methods.* ZAP70, LPL, CLLU1, microRNA-29c and microRNA-223 were measured by real time PCR in a cohort of 170 patients (Binet stage A=124, B=31 and C=15) with a median follow-up of 64 months (range 3-330). For each patient, cells were obtained at diagnosis and RNA was extracted from highly purified CD19 cells. Each factor was first investigated individually for treatment-free survival (TFS) and overall survival (OS) by Kaplan Meier curves (compared with a log-rank test) and univariate Cox regression. The best markers were

included in a qPCR score which was thereafter compared to each individual factor but also to other classical prognostic markers (IgVH mutational status, Binet stage, CD38, sCD23, beta2-microglubulin, lymphocyte doubling time, cytogenetic abnormalities). *Results.* statistical analysis showed that all 5 RNA-based markers can significantly predict TFS but only ZAP70, LPL and microRNA-29c could significantly predict OS. These 3 markers were thus included in a new and simple qPCR score (where each poor prognosis marker corresponds to an increase of 1 unit) dividing patients in 3 groups (0/3, 1-2/3 and 3/3). This score significantly predicts TFS (P<0.0001) and OS (P=0.0001). Median TFS were >210, 61 and 24 months and median OS were >330, 242 and 137 months, respectively. TFS results were also confirmed in Binet stage A patients (P<0.0001; median TFS were >210, 88 and 34 months, respectively for group 0/3, 1-2/3 and 3/3) but OS analysis only exhibits a trend (P=0.0443) due to the limited number of event in stage A patients (n=8). When compared to other classical factors, this score displays the highest univariate Cox Hazard Ratio (TFS: HR=9.45 and OS: HR=13.88). Finally, this new prognostic tool allows the identification of patient groups with a higher median TFS and OS in poor prognostic subgroup and inversely. *Conclusions.* using a unique and standardized technique, we developed here a simple qPCR score to assess CLL patient prognosis in terms of TFS and OS. This score, able to classify patient in 3 different prognostic groups, seems to be up to now one of the most powerful markers for CLL risk stratification at the time of diagnosis.

T-LARGE GRANULAR LYMPHOCYTOSIS (T-LGL) IN PATIENTS WITH CHRONIC NEUTROPENIA: EPIDEMIOLOGICAL CHARACTERISTICS, CLINICAL COURSE AND RELATION WITH CLONAL DISEASE

X Yiakoumis,[1] G Pangalis,[2] C Kalpadakis,[3] E Kyritsi,[2] E Papageorgiou,[2] F Kontopidou,[2] S Sachanas,[1] T Vassilakopoulos,[2] M Angelopoulou,[2] P Korkolopoulou,[4] H Papadaki[3]

[1]Athens Medical Center, Athens, Greece; [2]Department of Haematology, University of Athens, Athens, Greece; [3]Department of Haematology, University of Crete, Heraklion, Greece; [4]Department of Pathology, University of Athens, Athens, Greece

Background. The disorders of T-LGL constitute a broad group of reactive or clonal conditions requiring further research attention. *Aim.* We studied patients presenting with chronic neutropenia at the Hematology Outpatient Clinic of the University of Athens and analysed the prevalence of T-LGL and clonality, as well as patients' clinical characteristics and course. *Methods.* Between 2005-2008 we prospectively studied patients with chronic neutropenia (<1.8×10^9/L, >6 months). The tests performed included clinical examination, complete blood count (CBC), blood smear examination, full biochemical profile, EBV and CMV antibodies, autoantibodies and blood immunophenotypic study with 9 monoclonal antibodies. Those with immunophenotypic evidence of T- LGL underwent a T-cell gene rearrengement (TCR αβ and γδ). If clonality was proved, patients underwent a thoracic and abdominal CT scan, as well as a bone marrow examination (BME). Patient's follow up was repeated every 3-6 months. *Results.* 224 patients were included in this study. The median duration of neutropenia until presentation was 4 years. Female to male ratio was 4:1with a median age of 55 years. Of the187 patients who underwent an immunophenotypic analysis, 54 were found to have T-LGL lymphocytosis. Female to male ratio in T-LGL group was 2:1, with a median age of 60 years (Table 1). No serious infections were accounted in the T-LGL group; 22/54 (41%) experienced recurrent apthous stomatitis, urinary infections, chronic prostatitis and recurrent lung infections as well as mild asthma and chronic obstructory pulmonary disease exacerbations. In 12/54 allergic conditions were seen. Only 4% presented a concurrent autoimmune disease. 24 patients (44%) had a thyroid disorder; commonly Hashimoto's thyroiditis. Ten patients presented with anemia (haemoglobin 9.2-11.4 g/dL), while 8 had a mild thrombocytopenia (platelets 92-130×10^9/L). Median number of leucocytes was 3.8×10^9/L, with a median neutrophil count 1.5×10^9/L (0.5-2.7×10^9/L). Median lymphocyte count was 1.6 ×10^9/L (0.7-4.3×10^9/L). In 41/54 patients of the T-LGL group a TCR study was performed and 26 were found positive. The severity and rate of infections, the prevalence of underlying conditions, presence of cytopenias, and thyroid disorders in this clonal T-LGL group did not differ from the rest of the patients. A bone marrow trephine examination was performed in 17 patients with clonal T-LGL. In 3 cases T-LGL leukaemia was confirmed histologically and with positive TCR rearrangement in the bone marrow. 11 BME described a scant interstitial and scattered (diffuse) lymphocytic infiltration, as well as reactive bone marrow disorders. It must be noted that in 7 of those patients, TCR of the bone marrow was positive. None of our patients has required specific treatment during their follow up, except from one who receives erythropoietin.

Table 1. Neutropenia and T-LGL patients' characteristics.

Characteristic	# (%)
Median time of duration of neutropenia : 5 years (1-20)	
Male	17/54(31)
Age at diagnosis <50 years	11(20)
Thyroid disease Collagen-tissue disease Malignancies	24 (44) 4 (7) 6 (12)
Infections: Reccurent Apthous ulcers	16(29) 6 (11)
Allergic conditions	12 (24)
Anaemia :Hb<13.5 g/dl, men Hb<12.0 g/dl, women	4 (24) 6 (16)
Thrombocytopenia (<150x10^9/l)	8(14)
Lymphocytosis >4.0x10^9/l	1 (2)
Lymphocytopenia <1.5 x10^9/l	19 (35)
ANA(>1:160)	8/50 (16)
TCR positive	26/41 (63)

Conclusion. Clonal T-LGL disorders in patients with chronic neutropenia are not rare and do not account for serious cytopenias or infectious complications. More longitudinal studies could clarify the clinical course and the need for treatment of T-LGL clonal disorders found in patients with chronic neutropenia.

B-CELL COUNT AND TIME TO FIRST TREAMENT: DIFFERENTIATING CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) FROM MONOCLONAL B-CELL LYMPHOCYTOSIS (MBL) BASED ON CLINICAL OUTCOME: THE GIMEMA EXPERIENCE.

S Molica,[1] F Mauro,[2] V Callea,[3] D Giannarelli,[4] F Lauria,[5] A Cortelezzi,[6] V Liso,[7] R Foà[2]

[1]Azienda Ospedaliera Pugliese-Ciaccio, Catanzaro, Italy; [2]Hematology Department, University La Sapienza, Roma, Rome, Italy; [3]Hematology Department, Azienda Ospedaliera Reggio Calabria, Reggio Calabria, Italy; [4]Biostatistics Unit, Regina Elena Cancer Institute, Rome, Italy; [5]Department of Hematology and transplant, University of Siena, Siena, Italy; [6]Hematology-Bone Marrow Transplant Unit, Fondazione Ospedale Maggiore Policlinico, Milano, Italy; [7]Hematology Section, DAP, University of Bari, Bari, Italy

Rather than using the traditional but arbitrarily derived 5×10^9/L B-lymphocyte threshold, generally utilized to differentiate monoclonal B-cell lymphocytosis (MBL) from chronic lymphocytic leykemia (CLL), our study includes all patients with isolated lymphocytosis to determine which lymphocyte threshold best predicts clinical outcome. To this purpose we analyzed the relationship of either absolute lymphocyte count [ALC] or B-cell count with the clinical outcome in 818 consecutive CLL patients with Rai stage 0 (i.e., no palpable lymphadenopathy or hepatosplenomegaly) who had flow cytometry evaluation at the time of diagnosis and were included in a GIMEMA (Gruppo Italiano Malattie EMatologiche dell'Adulto) database. In this patient cohort, both ALC (P<0.0001) and B-cell count (P<0.0001) when treated as continuous variables (i.e., measuring the risk of a 1.0×10^9/L increase in the cell count) related to time to first treatment (TFT). However, in a Cox multivariate only the B-cell count retained its discriminating power (P<0.0001). Receiver Operating Characteristic (ROC) analysis identified an ALC ≥ 11.5×10^9/L (P<0.0001) and an absolute B-cell lymphocyte count ≥10.0×10^9/L (P<0.0001) as the best thresholds separating patients who subsequently required treatment from those with stable disease. When overall survival was used as endpoint, only a trend towards a longer survival for patients with a B-cell count <10.0×10^9/L could be found (P=0.06). Finally, the B-cell threshold used in the current diagnostic criteria (i.e., 5×10^9/L) was not able to predict both TFT (P=NS) and overall survival (P=0.23). Our results provide a clear justification to retain the B-cell count as the reference gold standard of CLL diagnosis, but imply that a count of 10×10^9/L B-cell is the best lymphocyte threshold predicting TFT. The use of clinical outcome to distinguish CLL from other premalignant conditions, such as MBL, is a pragmatic approach that meets the requirement of reducing patients' psychological discomfort receiving a diagnosis of leukemia when the risk of adverse clinical consequences is low.

IN VITRO ACTIVITY OF THE CD20 ANTIBODY OFATUMUMAB IN GENETIC HIGH-RISK CLL WITH TP53 MUTATION/DELETION

T Zenz,[1] M Volden,[1] T Mast,[1] N Kinzer,[1] D Winkler,[1] A Schnaiter,[1] A Bühler,[1] P Engelberts,[2] J Bakker,[2] F Beurskens,[2] P Parren,[2] H Döhner,[1] S Stilgenbauer[1]

[1]University of Ulm, Ulm, Germany; [2]Genmab, Utrecht, Netherlands

Introduction. CD20 represents a well-established target for immunotherapy of B-cell malignancies. Relatively little is known about activity of different CD20 antibodies in genetic subgroups of chronic lymphocytic leukemia (CLL). Ofatumumab (OFA) is a novel human CD20 monoclonal antibody, which binds a unique membrane-proximal epitope encompassing both the large and small loop on the CD20 molecule. The FDA recently approved OFA (Arzerra), for the treatment of fludarabine-(F) and alemtuzumab (ALM)-refractory CLL. The aim of the current study was to assess the *in vitro* activity of OFA in a group of genetically characterized CLL cases to investigate whether its activity is impacted by TP53 status. *Methods.* To assess the activity of OFA *in vitro*, we studied B cell depletion in a set of CLL patients (n=18), in the presence of serum. CLL samples were characterized with respect to genetics (genomic aberrations, TP53 mutation, IGHV mutation status), clinical course and immunophenotype. The effects of OFA were compared to RTX, ALM and F as references. At different time points (3h, 48h), cell death was measured by use of flow cytometry (staining with 7-AAD + Annexin-PE) and Cell Titer Glo Luminescent Assay. *Results.* OFA induced dose-dependent (0.1-100 μg/mL) cell death and thereby reduced viability to a maximum of 44.5% (n=18; % of viable cells after 3 hrs incubation with 100 μg/mL OFA) as compared to control. At 10 and 100 μg/mL OFA was more effective at killing CLL cells than RTX (10 μg: 63.7% viable cells (OFA) *vs.* 98.8% viable cells (RTX); 100μg 44.5% viable cells (OFA) *vs.* 95.3% viable cells (RTX) (P<0.001). The combination of F (1 μM) with OFA (1 μg/mL) added to the induction of cell death (48h: F: 49.6% viable cells; F+OFA 35.9% viable cells; F+RTX: 41% viable cells). To investigate the effect of OFA on CLL cells carrying a TP53 deletion/mutation, we separated the cohort into two groups, with (n=6) or without (n= 12) TP53 mutation/deletion. In the cohort without TP53 defects, OFA induced CLL cell death in a dose-dependent manner (10 μg: 61% viable cells (OFA) *vs.* 99% viable cells (RTX) (P<0.001); 100 μg: 41.5% viable cells (OFA) *vs.* 92.2% viable cells (RTX) (P<0.001)) (Figure1). In the group with TP53 defects, OFA, interestingly, also showed a dose-dependent effect (Figure 1), and, again, OFA was significantly more potent than RTX (10 μg: 69.1% viable cells (OFA) *vs.* 98.8% viable cells (RTX) (P=0.014); 100 μg 50.6% viable cells (OFA) *vs.* 101.4% viable cells (RTX) (P=0.001)). Furthermore, the response to F at 48 hours was lower in the group with TP53 defects (74.1% viable cells), as compared to the response to F in the group without TP53 defects (36.3%), which is in keeping with the well known association of these aberrations with chemorefractory CLL. *Conclusion.* Compared to RTX which represents the currently most widely used mAb in CLL, OFA appears more potent at equivalent concentration in depleting CLL cells in a CDC assay. Significantly, this activity of OFA appears to be independent of high risk genetic subgroups as cell killing is of similar magnitude in TP53 wild type *vs.* mutated cells.

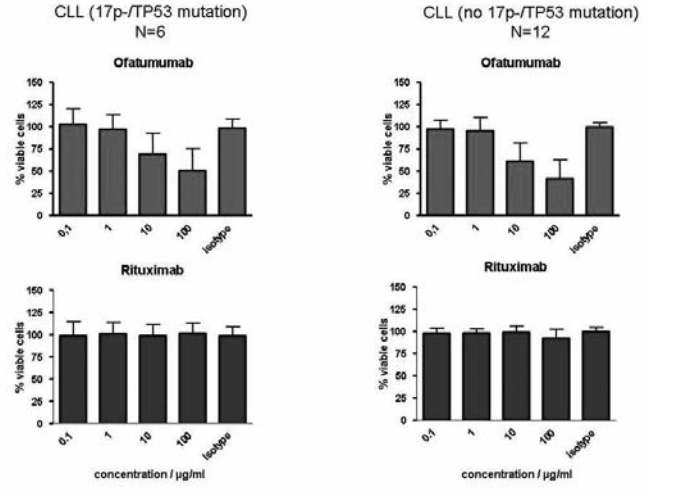

Figure 1. Induction of cell death by Ofatumumab (*in vitro*).

GENETIC FEATURES OF CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS WITH AUTOIMMUNE HEMOLYTIC ANEMIA: VDJ-REARRANGEMENTS AND CHROMOSOMAL ABERRATIONS

A Bühler, T Zenz, D Winkler, S Kless, H Doehner, S Stilgenbauer

University of Ulm, Ulm, Germany

Background. Autoimmune hemolytic anemia (AIHA) is a severe complication during the course of chronic lymphocytic leukemia (CLL). There is little known about triggers and predicting markers for this phenomenon. *Aim.* Evaluate the incidence of AIHA in a unicentric cohort of 548 CLL patients and examine the role of VDJ-rearrangement structure and chromosomal aberrations in the AIHA subgroup. *Methods.* IGHV analysis by PCR plus direct sequencing and evaluation of chromosomal aberrations by FISH in patients with CLL and AIHA. *Results.* 10% (55/548) of the CLL cohort showed an AIHA. 20/55 were diagnosed by standard criteria alone (drop in hemoglobin, increased reticulocyte count and rise in indirect bilirubin with no other cause for anemia identified) whereas 35/55 cases also showed a positive direct antiglobin test. Male gender was significantly overrepresented in the AIHA group. (43/55 *vs.* 295/493; p-value: 0,0082) IGHV analysis was available in 49 patients with a significant overrepresentation of IGHV-unmutated cases 40/49 (18,4%; P: 0,0006). VH1-69, representing the most frequent VH-gene in the AIHA-CLL cases (12/49 = 24,5 %) was significantly overrepresented (P 0.0198) compared to the 446 non-AIHA-CLL cases (57/446 = 14,3%) with available IGHV-data. VH4-34 detected in 8% of all non-AIHA-CLL cases in our analysis was underrepresented with only one single rearrangement in 49 AIHA cases. The analysis of the HCDR3-structure of the AIHA-CLL cases revealed some interesting findings: 2/49 cases showed the identical VDJ-combination VH1-69/D3-16/JH3b with 100% VH-homology and a 21 amino acid (aa) HCDR3 with the highly homologous HCDR3-motif: ARGXXY-DYVWGSYRXNDAFDI (= stereotype 1) In the non-AIHA group the same HCDR3 structure was not detected in a single case (p-value: 0,0096). In our data collection of 4942 multicentric CLL patients with no clinical data available stereotype 1 was detected in only 10/4942 cases (P<0.0001) . Another 2 cases rearranged VH1-69/D2-2/JH6b with 100% VH-homology and a 22 aa HCDR3 with the HCDR3-motif: ARVXPDIVVPAXXXYYYGMDV (= stereotype 2) whereas in the non-AIHA group this stereotype was also not detected in a single case (p-value: 0,0096) and in only 3 of the 4942 collected CLL cases. (P<0.0001). Finally 2 cases showed the highly homologous HCDR3-motif: ARE-QWLXTMXFDY (= stereotype 3) with either VH1-03 or VH1-18 in combination with D6-19 and JH4b, 100% VH-homology and a 13 aa HCDR3. Again non of the non-AIHA-CLL cases and only 2/4942 collected CLL cases showed the same HCDR3-motif. (p-value <0,0001). For 53 AIHA-CLL cases and 371 non-AIHA-CLL cases FISH analysis was performed: The high risk aberrations deletion-11q and deletion-17p are significantly overrepresented compared to the non-AIHA-CLL cases (11q: 15/53 *vs.* 65/371; 17p: 9/53 *vs.* 29/371). *Conlusions.* AIHA is a frequent phenomenon in CLL (~ 10%) with characteristic genetic features. In our analysis AIHA-CLL cases were characterized by a significant overrepresentation of unfavourable prognostic markers like unmutated IGHV-status and high risk chromosomal aberrations. Beyond that the overrepresentation of stereotyped HCDR3-motifs especially using the VH1-69 gene could be a clue to antigentriggered mechanisms in those patients. A more detailed analysis of the whole B-cell receptor including the light chain structure should follow.

0788

PREDICTIVE POWER FOR OVERALL SURVIVAL OF CD38, ZAP-70, DELETIONS OF 17P OR 11Q AND IG MUTATIONS: MULTIVARIATE ANALYSIS ON 747 CASES OF CHRONIC LYMPHOCYTIC LEUKEMIA

Buzzati-Traverso, ICGEB Outstation Monterotondo, Roma, Italy; [12]Department of Medical Sciences, University of Modena, Modena, Italy

Background. We showed previously that a multivariate model based on age, stage, beta2microglobulin levels and sex was able to predict survival in chronic lymphocytic leukemia (CLL). However, expression of ZAP-70 and CD38, deletion of 17p- or 11q- by FISH and immunoglobulin mutational status (IgVH) are also frequently evaluated in untreated CLL patients for better prognostication. Despite this, little is known on the relative importance of each o f these biological predictors or about their actual capability to add independent predictive power to a simple scoring system as that developed by us. Aim. To test the independent predictive power of ZAP-70, CD38, 17p-/11q-, IgVH in a multivariate model adjusted for a 3 level stratification scoring based on sex, age, stage and beta2microglobulin. *Methods.* We developed a prognostic score for predicting overall survival in 1037 CLL patients recruited in 8 Italian and Swiss-Italian centers. The scoring was based on age (0 points ≤ 60, 1 point 61-70, 3 points 71-80, 7 points >80), Binet stage (0 points A, 3 points B or C), sex (2 points male, 0 points female) and standardized bet2microglobulin (0 points ≤1, 1 point >1 and ≤2, 2 points >2). The beta2microglobulin value was divided by its upper reference limit. All the variables were measured at or within 1 year from diagnosis. In a subset of 747 patients with complete data, CD38, ZAP-70, 17p-/11q- and IgVH were each tested by unadjusted Cox models or adjusted for prognostic score. A P≤0.05 was considered statistically significant. Results. Three risk groups were stratified by the prognostic score: low risk (32% of patients) with score ≤2; intermediate risk (50%) with 2<score≤6; high risk (18%) with score >6. Overall survival at 10 years was respectively 92.3, 72.0 and 38.2%. Univariate (unadjusted) hazard ratio of the biological prognosticators increased from 1.44 of ZAP-70 (with borderline p), to 1.77 of CD38, 2.0 of IgVH, 2.38 of 17p-/11q- (Table 1).

Table 1.

	Unadjusted		Adjusted for prognostic score	
predictor	HR	p	HR	p
ZAP-70>20%	1.44	0.077	1.18	0.41
CD38>30%	1.77	0.0063	1.50	0.056
IgVH UM	2.0	0.00076	1.75	0.007
17p-/11q-	2.38	0.000057	2.11	0.00059

In a model adjusted for the 3 level prognostic score, ZAP-70 was not an independent predictor, CD38 was at borderline significance, IgVH

and 17p-/11q- kept to be significant (Table 1). In a further model we simultaneously analyzed CD38, IgVH, 17p-/11q- and the prognostic score. Only 17p- and the prognostic score were significant independent predictors. *Summary/Conclusions.* A simple scoring using clinical data (sex, age, Binet staging) and the easily measurable β 2μg, was able to stratify CLL patients in three groups with different clinical risk. CD38, IgVH and 17p-/11q- could retain prognostic power when adjusted with this prognostic score, but not ZAP-70. This could reflect the lack of standardization in the measurement of this intracytoplasmic antigen, a fact possibly emphasized in a multicenter collection of cases. Moreover, both CD38 and IgVH were not independent in multivariate analysis, the latter with a borderline value (P=0.078, HR 1.47). Larger sample or an higher number of death events are required to overcome these discrepancies.

DIAGNOSTIC AND THERAPEUTIC APPROACH TO SMALL LYMPHOCYTIC LYMPHOMA (SLL): EXPERIENCE OF CZECH LYMPHOMA STUDY GROUP

L Smolej,[1] I Vasova,[2] D Salek,[2] J Salkova,[3] J Karban,[3] D Belada,[1] A Sykorova,[1] M Spacek,[4] M Jankovska,[4] V Campr,[5] H Krejcova,[3] M Trneny[3]

[1]University Hospital and Medical School, Hradec Kralove, Czech Republic; [2]Internal Department of Hematooncology, University Hospital, Brno, Czech Republic; [3]1st Department of Internal Medicine, University General Hospital, Prague, Czech Republic; [4]Department of Clinical Hematology, University Hospital Kralovske Vinohrady, Prague, Czech Republic; [5]Department of Pathology and Molecular Medicine, University Hospital Motol, Prague, Czech Republic

Background. Small lymphocytic lymphoma (SLL) is an indolent lymphoproliferation comprising 3-10% of Non-Hodgkin´s lymphomas (NHL). WHO 2008 classification of lymphoid neoplasms lists SLL together with chronic lymphocytic leukemia (CLL); these entities differ by distribution of tumor load and arbitrary cut-off of lymphocytosis 5×10^9/L. Clinical course of SLL is still relatively ill-defined due to lack of published data because clinical studies in CLL usually exclude patients with SLL. This results in considerable variability in diagnostic and therapeutic approach in daily practice. Aims of the study. to perform a retrospective analysis of patients (pts) with SLL with emphasis on diagnostic procedures and management in real life. *Methods.* We analyzed consecutive patients from 16 centers participating within the Czech Lymphoma Study Group who fulfilled diagnostic criteria for SLL, i.e. coexpression of CD5/C19/23 by flow cytometry or typical histology and immunohistochemistry with peripheral blood lymphocytes $<5\times10^9$/L. *Results.* As of April 2008, data were available on 157 patients (63% males with median age 66 years range, [29-87]). Ann Arbor stage I/II/III/IV was present in 6/3/6/85 %. Splenomegaly was detected in 18%, elevated lactate dehydrogenase (LDH) in 30 % and bone marrow involvement in 79% of pts. Of note, 94% pts underwent computer tomography (CT) of thorax and abdomen and 86% bone marrow biopsy at initial staging. Mediastinal and retroperitoneal lymphadenopathy was discovered in 42% and 68%. Generalized lymphadenopathy (more than 4 involved regions) was found in 49%. Bulky lymphadenopathy (>5 cm) was present in 38%. Thirty per cent of pts had B-symptoms. Data regarding treatment were available on 145 pts; was initiated in 132 (91%) pts. Systemic treatment was used in 123 pts: chemotherapy, n=79; chemoimmunotherapy, n=51 (rituximab, n=50 pts; alemtuzumab, n=1). Furthemore, 11 pts were treated by radiotherapy and 5 by surgery. Surprisingly, only 13 pts were managed using the watch and wait strategy. The most frequently used regimens in first line were CVP (19%), FCR (15%), R-CVP (14%), CHOP (13%), chlorambucil (11%), FC (10%) and R-CHOP (10%). At the median follow-up of 38 months (mo), median overall survival (OS) was 78 mo. OS was significantly influenced by splenomegaly, B-symptoms, IPI, response to therapy, type of treatment (fludarabine-based *vs.* anthracycline-based *vs.* alkylator-based) and use of rituximab. However, in multivariate analysis, only use of rituximab, type of treatment and quality of therapeutic response retained prognostic significance. *Conclusions.* We confirmed previously published epidemiological data on SLL. In contrast to CLL (where routine radiological assessment is not recommended by NCI-WG criteria), nearly all SLL patients underwent CT for staging; however, use of radiological assessment seemed justified as more than two thirds of pts had significant abdominal lymphadenopathy. Therapeutic approach varied considerably; majority of pts were treated by "lymphoma" regimens but fludarabine-based protocols yielded the best *Results.* In our opinion, SLL should be managed identically to CLL but imaging methods appear to be valuable for appropriate staging. Our study underscores the need for standardized diagnostic and therapeutic approach to SLL.

Supported by grant NR/9453-3 and research project MZO 00179906 from Ministry of Health, Czech Republic.

Background. In contrast with other chronic lymphoproliferative disorders, CT scans are not routinely recommended for routine staging CLL patients and there are no studies investigating the clinical significance of integration of total body CT in the initial work-up of CLL patients. *Aims.* We investigated whether total body CT allowed to discriminate among Binet stage A CLL patients on clinical grounds, cases in more advanced stage and whether this subgroup showed a different expression of clinical and biological prognostic markers. Patients & Methods. To date, 380 patients have been enrolled in the trial started in April 2007 and total body CT scan were available for 127 patients. All patients are in Binet stage A, while 91 patients were at low risk (0 stage) and 36 at intermediate risk (I-II stage) by Rai classification. The median age was 60.5 years (range, 33 to 70 years) and 60% were male. Thirty-six% of cases were IgVH unmutated, 42.5% had a high ZAP-70 expression and 22% were CD38 positive (>30%). LDH and B2-microglobulin were elevated in 11% and in 28% of cases, respectively. FISH data are available for 116/127 cases; 53 patients (46%) showed del(13q14), 14 (12%) trisomy 12, 7 (6%) del(11q22.3) and 4 (3%) del(17p13), 38 cases (33%) were normal. Cytogenetic abnormalities were clustered in 3 risk groups [i.e. low (del(13q14) and normal), intermediate (trisomy 12) and high risk del(11q22) and del(17p13)] as suggested by others. Following international standard criteria, lymph nodes

more than 10 mm in diameter were considered abnormal. The abdominal lymphoid areas (diaphragmatic, celiac, mesenteric, iliac, and retroperitoneal) were considered as single lymph-node region, while spleen and/or hepatic enlargement was considered separately. *Results.* Considering total body CT scan, 40/127 (41.5%) patients were re-considered as Binet stage B. Notably, 70% were male, LDH and B2-microglobulin were elevated in 8% and in 34% of cases respectively, 45% were IgVH unmutated, 47.5% had a high ZAP-70 expression, 32.5% were CD38 positive, 16% showed a high-risk FISH. Both main clinical characteristics and biological prognostic markers failed to correlate with a more advanced stage. In fact, no statistically different distribution of gender, age, LDH and β2-microglobulin, such as IgVH mutational status, CD38 or ZAP-70 expression and cytogenetic abnormalities were observed between Binet A and Binet B cases. According to the Rai classification 35/91 (38.5%) low risk patients became at intermediate risk with the integration of total body CT scan. In this subset of patients a statistically significant higher rate of cases with elevated CD38 expression than patients at low risk (P=0.019) was observed. Finally, total body CT scan allowed the early detection of a second neoplasia in 2 cases (lung cancer 1 pt, renal cell carcinoma 1 pt). Conclusion. Our results indicate that the integration of total body CT in clinical staging discriminates within Binet A CLL cases about 40% of patients with a more advanced stage. A longer follow-up will aid in demonstrating whether the inclusion of total body CT scan in the initial work-up of patients in clinical early-stage provides relevant prognostic information.

0791

MODULATION OF CD20 ANTIGEN EXPRESSION IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA AFTER RITUXIMAB THERAPY

F D'Auria, R Guariglia, O Villani, G Pietrantuono, M Martorelli, G Mansueto, V Grieco, A Zonno, E Zifarone, G Bianchino, L Di Giovannantonio, G Vita, P Musto

IRCCS, Centro di Riferimento Oncologico della Basilicata, Rionero in Vulture, Italy

Background. Immunotherapy with CD20-targeting antibody (rituximab) in combination with chemotherapy has significantly improved the survival of patients with lymphoproliferative disorders (LPD), in particular of those with follicular and diffuse large B-cell non-Hodgkin's lymphomas (NHL). In addition, rituximab-containing regimens are now also considered a standard approach for B-cell chronic lymphocytic leukemia (CLL). CD20 antigen down-modulation by anti-CD20 rituximab therapy is a well recognized phenomenon in patients with NHL. However, a few data are currently available on this topic in CLL. *Aims.* Aiming to evaluate the frequency and the clinical significance of the CD20 disappearance on neoplastic cells, we analysed by flow cytometry the CD20 expression in patients affected by CLL treated with rituximab in combinations with other agents. In this setting, that here reported is, to the best of our knowledge, the largest series of CLL so far sequentially analysed. Patients and *Methods.* The surface expression of CD20, CD19, CD5, CD23, CD10, CD22, CD52, FMC7, CD38, kappa and lambda light chains was studied on marrow neoplastic cells by flow cytometer in 11 CLL, and, for comparison, in 4 follicular lymphomas, 3 mantle cell lymphomas, 1 marginal zone lymphoma and 3 otherwise unspecified "indolent"LPD treated with various combinations of rituximab and other cytostatic agents. *Results.* Overall, nine patients (40,9%) achieved a stable complete remission and did not show flow cytometry evidence of CD20-positive neoplastic cells in post-therapy samples. Thirteen patients maintained instead a variable proportion of B clonal cells after rituximab treatment; among them, four CLL (18,2% of the entire population analyzed, 36.3% of all CLL) evidenced CD20 disappearance on residual marrow neoplastic cells after salvage therapies including rituximab (Figure 1). In particular, CD20 antigen was lost in two patients in partial response after R-CHOP-like regimen and chlorambucil/rituximab combination, respectively. Both these patients relapsed 5 to 13 months after their last dose of rituximab, showing reappearance, however, of a CD20-positive phenotype at progression. A third patient did not respond to R-Flu/Cy, showing persistence of about 50% of marrow clonal CD20-negative B cells. CT and PET scans indicated disease progression and lymph-node biopsy documented a transformation toward a high grade, CD20-positive non-Hodgkin lymphoma (Richter's syndrome). The patient died soon after. The last patient received R-CHOP-14 therapy after a biopsy-proven high grade CD20-positive lymphoma transformation (Richter's syndrome). A transient partial response was achieved; however, at this time, residual bone marrow CLL cells infiltration had lost CD20 surface antigen. After further progression, additional treatments, including plerixafor mobilized peripheral blood autologous stem cell transplantation, were ineffective and the patient died. *Conclusion.* In our experience, loss of CD20 was seen in more than one third of CLL patients receiving rituximab therapy. This phenomenon may be transient and clinically heterogeneous. However, a possible relationship with evolution into high grade NHL transformation needs to be further investigated. In fact, Richter's syndrome was observed in 2 out of our 4 CLL patients who lacked CD20 expression, but only in one case out of all other 49 CLL we have followed at our Institution during the last four years.

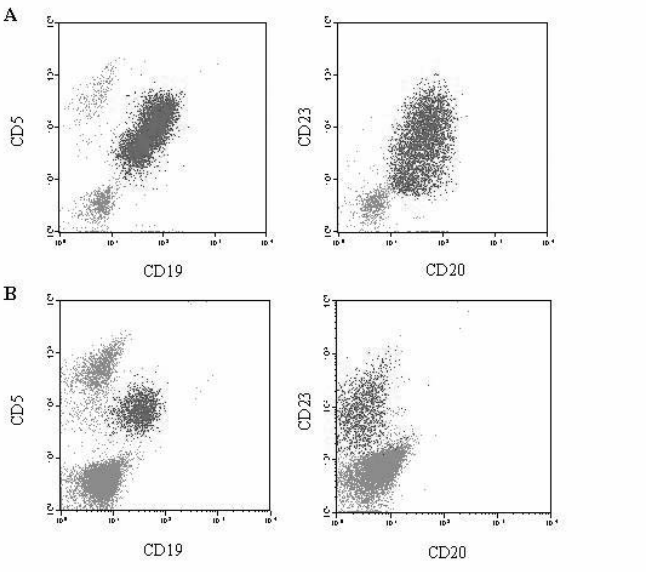

Figure 1. Flow cytometry analysis of bone marrow leukemic cells before (A) and after (B) rituximab therapy showing cpmplete loss of CD20 antigen expression, while CD19, CD5 and CD23 were stillpositive (patient 4).

0792

EFFICACY OF FC AND FCR REGIMENS IN THE FIRST LINE TREATMENT OF PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA: 7,5 YEARS OF FOLLOW-UP

E Stadnik,[1] G Salogub,[1] Y Alexeeva,[2] V Strugov,[2] A Zaritskey[2]

[1]Pavlov State Medical University, Saint-Petersburg, Russian Federation; [2]Federal Almazov Heart, Blood and Endocrinology centre, Saint-Petersburg, Russian Federation

Background. Fludarabine-containing regimens are widely used as the first-line treatment for CLL. Recently phase III trial comparing fludarabine and cyclophosphamide alone (FC) with combination of fludarabine, cyclophosphamide and rituximab (FCR) showed significantly superior results in FCR arm in terms of response rates, PFS and OS. Thus this particular chemoimmunotherapy regimen may become standard for initial CLL treatment. However effectiveness of this treatment approach needs to be confirmed in everyday clinical practice. *Aims.* To estimate survival benefit produced by the addition of rituximab to standard FC regimen for treatment-naïve not selected CLL pts. *Methods.* 77 consecutive pts were included (43 in FC and 34 in FCR arm) between 2002 and 2008 according to intent-to-treatment. Informed consent was obtained in each case. Assignment to FCR was based predominantly on the availability of rituximab in general practice and nearly all newer pts received it as part of treatment. Arms were well balanced with regard to sex (M-to-F ratio ~2:1) and age (median 59 years, range 43-78) though there was tendency towards more advanced disease stage in FC arm (15 *vs.* 7 pts BinetC). Treatment schedules were standard. Treatment was suspended or withdrawn in case of severe toxicity, no dose reduction was done. Only 11 pts received less than 6 cycles (range 4-5). Response was defined according to NCI criteria. CD38 was measured by cytoflow with 30% cut-off (available in 57 pts). VH genes were analyzed by cDNA sequencing with 98% threshold (available in 32 pts). Statistical analysis was performed in SPSS17. *Results.* OR and CR rates in FCR and FC groups were 91% *vs.* 81% (P=0,18) and 67% *vs.* 46% (P=0,05) respectively. PR rates were 24% for FCR and 35% for FC (P=0,2). 3-year OS in FC arm was 54%, compared to 76% in FCR arm based on analy-

sis of 66 pts. Estimated 4-year survival was 45% in FC and 66% in FCR arm (61 pts analysed). After 7,5 years of follow-up there were 39 events in FC (90,7%) and 17 in FCR arm (50%). 27 deaths were registered in FC arm (62,8%) and 8 in FCR (23,5%). Median PFS in FCR arm was 31 mos compared to 19 mos in FC arm (P=0.003), median OS in FCR is n.r. and 45 mos in FC group (P=0.011). CD38 status didn't predict PFS and OS in FCR arm. In FC arm pts with high expression of CD38 had inferior median PFS (19 *vs.* 32 mos, P=0,039) and a tendency towards shorter median OS (40 mos *vs.* n.r., P=0,06). Median PFS was inferior in VH-unmutated cases (52 *vs.* 23 mos, P=0,05). There was also tendency towards inferior OS in this group of pts (n.r. *vs.* 42 mos., P=0,08). Conclusion. FCR regimen has advantage over FC regimen in terms of frequency of induced OR and CR. 3-year survival of pts treated with FCR is nearly 2-fold higher compared to FC alone. Addition of rituximab to FC regimen in first line improves OS and PFS. We recommend FCR regimen as first-line CLL treatment in general clinical practice.

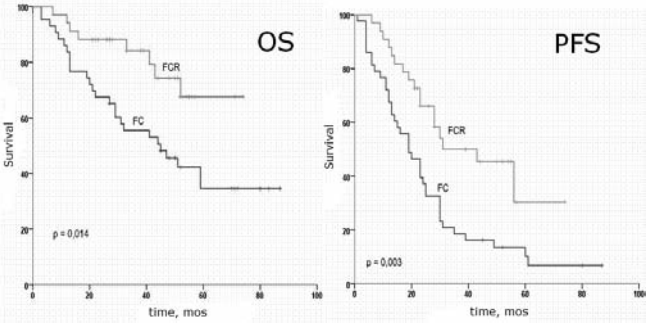

Figure 1. OS and PFS in FC vs. FCR.

BORTEZOMIB DECREASES RB PHOSPHORYLATION IN IMATINIB-SENSITIVE AND -RESISTANT BCR-ABL1 EXPRESSING CELLS

I Perez-Roger,[1] MP Albero,[1] JM Vaquer,[1] E Andreu,[2] JJ Villanueva,[1] E Lledo,[1] F Prosper[2]

[1]Univ. Cardenal Herrera-CEU, Moncada (Valencia), Spain; [2]CIMA, Universidad de Navarra, Pamplona, Spain

Background. Chronic Myeloid Leukaemia (CML), resulting from the expression of the oncoprotein Bcr-Abl1, is usually treated with the specific kinase inhibitor Imatinib. However, point mutations in Bcr-Abl confer resistance to this treatment. We have previously shown that Bcr-Abl1 induces the proteasomal degradation of proteins relevant for cell cycle control, such as p27Kip1. Therefore, we proposed the use of proteasome inhibitors in the treatment of the disease. *Aim.* In this study we wanted to evaluate the effect of the proteasome inhibitor Bortezomib on the proliferation and survival of Bcr-Abl1 expressing cells, including mutant forms that show resistance to Imatinib, and analyse the signal transduction pathways involved. Materials and *Methods.* We have used the BaF/3 cell line and BaF/3 cells expressing wt Bcr-Abl (BaF/3-wt) and different Imatinib resistant mutants of the protein, including the highly resistant mutant T315I (BaF/3-T315I). We have treated these cells with Bortezomib and analysed its effects on cell proliferation and survival by flow cytometry. We have also analysed by western blot the expression and activity of different proteins involved in cell cycle regulation. *Results.* Proteasome inhibition with Bortezomib inhibits growth of BaF/3 cells, but Bcr-Abl1 expressing cells (BaF/3-p210) are more sensitive than the parental BaF/3 control cells. At the dose of 6nM, Bortezomib induces an irreversible cell cycle arrest at G1 only in BaF/3-p210 cells and, later on, cell death by apoptosis. This effect is also seen in BaF/3 cells expressing different Imatinib-resistant mutants of Bcr-Abl1 (Q252H, Y253F, E255K and T315I). At the molecular level, the cell cycle arrest correlates with an accumulation of p27Kip1 and a decrease in the phosphorylation of Rb. By Western-blot, we have analysed the activation of p52 NF-kB, which is processed from p100 to p52 in a proteasome dependent manner. BaF/3-p210 cells show higher levels of active p52 NF-kB than BaF/3 control cells and the treatment with Bortezomib results in a decrease of the active p52 processed form and an increase of the inactive p100 form of the protein. Moreover, two targets of p52 NF-kB that are relevant for the regulation of p27Kip1, such as c-Myc and Skp2, show reduced levels of expression in Bortezomib treated BaF/3-p210 cells, suggesting that in these cells the non-canonical NF-kB pathway may be a target of Bortezomib. Finally, we also show that primary $CD34^+$ cells from a CML patient are more sensitive to Bortezomib than non-CML primary $CD34^+$ cells. *Conclusions.* Our data show that Bortezomib treatment of Bcr-Abl1 expressing cells results in a G1 cell cycle arrest and apoptosis, with a decrease of Rb phosphorylation and caspase activation. Furthermore, BaF/3 cells expressing Bcr-Abl1 mutants resistant to Imatinib are also sensitive to Bortezomib. These results unravel a new molecular target of Bortezomib, i.e. the Rb pathway, and open new possibilities in the treatment of CML especially for patients that become resistant to Imatinib due to the presence of the T315I mutation.

0794

VARIANT PH TRANSLOCATION IN EARLY CHRONIC PHASE OF CHRONIC MYELOID LEUKEMIA: CYTOGENETIC - MOLECULAR CHARACTERIZATION AND CORRELATION TO IMATINIB MESYLATE THERAPY (A GIMEMA WP ON CML ANALYSIS)

G Marzocchi,[1] S Luatti,[1] F Castagnatti,[1] C Baldazzi,[1] M Stacchini,[1] C Gamberini,[1] M Amabile,[1] S Soverini,[1] S Colarossi,[1] G Specchia,[2] M Sessarego,[3] U Giussani,[4] L Zanatta,[4] L Valori,[4] G Discepoli,[5] A Montaldi,[6] A Santoro,[7] L Sebastio,[8] G Giudici,[9] L Bonaldi,[10] A Cianciulli,[11] F Giacobbi,[12] F Palandri,[1] G Rosti,[1] M Baccarani,[1] N Testoni[1]

[1]Insitute of Haematology Seragnoli, Bologna, Italy; [2]Hematology, Foggia, Italy; [3]Department of Internal Medicine, Genova, Italy; [4]Cytogenetics Unit, Bergamo, Italy; [5]Centre of Medical Genetic and Prenatal Diagnosis, Ancona, Italy; [6]Department of Hematology, Vicenza, Italy; [7]Department of Clinical and Biotechnological Research, A.O.U. Cervello, Palermo, Italy; [8]Medical Genetic Service, Napoli, Italy; [9]Research Center Tettamanti, Monza, Italy; [10]Molecolar Oncology and Cytodiagnostic Unit, Padova, Italy; [11]Clinical Pathology Department Regina Elena Institute, Roma, Italy; [12]Hematology University, Modena, Italy

Background. At diagnosis, variant Philadelphia (Ph) translocation occurring in Chronic Myeloid Leukemia (CML), have been reported in 5-10% of patients (patients). Some studies have reported no impact on prognosis after Imatinib Mesylate (IM) treatment. Variant translocation could be three or four-way translocation (involving chromosomes 9, 22 and 1 or 2 additional chromosomes respectively), associated or not with deletions of ABL1, BCR or ABL1-BCR. Two possible mechanisms of generation of these variant translocations have been hypothesized: a one-step mechanism wherein chromosome breakage was on three different chromosomes simultaneously, or a two-step mechanism involving two sequential translocations, in which a standard t(9;22) translocation is followed by subsequent translocation involving additional chromosomes. *Aim.* To investigate the role of occurrence of variant translocations on the response to IM in early chronic phase (CP) CML patients. *Methods.* A sub-analysis of 533 evaluable CML patients in early CP, have been performed within 3 simultaneously running trials of the GIMEMA WP on CML (CML/021; CML/022; CML/023). Median observation time was 42 months. Monitoring: hematologic, continuously; CC, FISH and molecular analysis were performed at baseline, 3, 6, and 12 months and then every 6 months by local or reference labs. *Results.* At enrolment, 30 patients (5.6%) had variant translocation: 2 patients (6.7%) had a four-way translocation; 28 patients (93%) had a three-way translocation. We analyzed 24 patients: 18 patients showed a one-step mechanism, 4 a two-step and 2 a multistep. In 3 patients (10%) translocation was associated with deletion of ABL1, in 2 patients (6.7%) with deletion of BCR and in one patient (3.3%) with deletion of ABL1-BCR; in 2 cases deletion was on third chromosome involved and it has been characterized by FISH and SNPs assays. One case was Ph masked and characterized by multistep mechanism. Another one carried an additional chromosome abnormality: t(7;19)(q21;p13). Patients with or without variant translocation were similar for age, Sokal risk and IM dose. During follow-up, 25 patients achieved complete cytogenetic response (CCgR; 83.3% *vs.* 98.1% in patients without variant) and major molecular response (83.3% *vs.* 83.2%); in 6 treatment was unsuccessful (20% *vs.* 18.1%). The 2 patients with four-way translocation and 4 of 6 patients (66.7%) with deletions reached CCgR. *Conclusions.* In the present large series of early CP patients treated with IM therapy, we found no difference in cytogenetic and molecular response rates between cases with or without variant translocations. Some studies suggested that the formation of variant translocations (in particular those with two-step mechanism) was similar to or was in essence a clonal evolution, and consequently associated with poorer prognosis. Our series of patients did not show similar association.

0795

CML STEM CELLS (CD34+/CD38-) EXPRESS SIGLEC-3/CD33 AND RESPOND TO THE CD33-TARGETED DRUG GEMTUZUMAB/OZOGAMICIN

H Herrmann,[1] S Cerny-Reiterer,[2] K Blatt,[2] S Herndlhofer,[2] H Agis,[2] W Rabitsch,[2] W Sperr,[2] C Sillaber,[2] P Valent[2]

[1]Ludwig Boltzmann Cluster Oncology, Vienna, Austria; [2]Medical University of Vienna, Vienna, Austria

Siglec-3 (CD33) is an established therapeutic target in acute myeloid leukemia (AML). We and others have shown that CD33 is expressed on immature $CD34^+/CD38^-$ stem/progenitor cells in AML. Here, we describe that leukemic progenitor cells obtained from patients with chronic myeloid leukemia (CML) display high levels of CD33, and that CD33 may serve as a potential target in CML. As assessed by multi-color flow cytometry, $CD34^+/CD38^-/CD123^+$ CML stem cells were found to express 5-10 fold higher levels of CD33 compared to normal $CD34^+/CD38^-$ bone marrow stem cells. In chronic phase (CP) CML, CD33 was found to be expressed homogeneously on most or all $CD34^+/CD38^-$ stem cells. In patients with accelerated (AP) or myeloid blast phase (BP), CML stem cells also co-expressed CD33, but the levels of CD33 varied from donor to donor, and in one of these patients, most CML stem cells appeared to be CD33-negative. In two patients with CML, $CD34^+/CD38^-$ cells were highly enriched by cell sorting (purity >98%) and found to contain CD33 mRNA in qPCR analysis. Expression of CD33 was also demonstrable in more mature myeloid CML progenitor cells in all patients. We also examined the effects of the CD33-targeted drug gemtuzumab/ozogamicin (GO) on growth of primary CML cells. As assessed by 3H-thymidine uptake, GO produced growth inhibition in leukemic cells in all patients tested (CP, n=7; AP, n=2). The effects of GO on leukemic cell growth were dose-dependent and occurred at low dose, with IC_{50} values ranging between 1 and 50 ng/mL. In one patient with imatinib-resistant CML in BP, we were also able to determine the effects of GO on survival of leukemic stem cells. As assessed by Annexin-V staining, GO was found to induce apoptosis in $CD34^+/CD38^-$ CML stem cells. In conclusion, CD33 is expressed abundantly on $CD34^+/CD38^-$ stem cells in CML. Whether GO can be employed to eradicate residual leukemic stem cells in CML CP patients remains at present unknown.

0796

CORRELATION BETWEEN GENETIC POLYMORPHISMS OF THE MDR1, HOCT1 AND ORM1 GENES AND THE RESPONSE TO IMATINIB IN PATIENTS WITH NEWLY-DIAGNOSED CHRONIC-PHASE CHRONIC MYELOID LEUKEMIA (CP-CML)

M Camós,[1] M Maffioli,[1] A Gaya,[1] JC Hernández-Boluda,[2] A Alvarez-Larrán,[3] A Domingo,[1] M Granell,[1] V Guillem,[2] R Vallansot,[1] M Suárez-Lledó,[1] D Costa,[1] D Colomer,[1] F Cervantes[1]

[1]Hospital Clinic, IDIBAPS, Barcelona, Spain; [2]Hospital Clínico, Valencia, Spain; [3]Hospital del Mar, Barcelona, Spain

Background. Imatinib (IM), a selective inhibitor of the Bcr/Abl tyrosine kinase, is the current frontline treatment of CP-CML. Although most patients respond to IM, some do not have an adequate response, either primarily or secondarily. In such cases, several mechanisms of resistance have been described, the better characterized being the presence of mutations in the BCR/ABL kinase domain. Recently, the possible impact on the response to IM of polymorphisms in genes encoding for proteins involved in IM transportation has been pointed out. However, the results are controversial. *Aim.* To assess the role in the inadequate response to IM of single nucleotide polymorphisms (SNPs) in the genes OCT1 (codifying for the IM influx protein OCT1), MDR1 (involved in IM efflux), and ORM1 (that codifies a plasma protein binding to different drugs), all of which are involved in IM bioavailability. *Methods.* Sixty-five patients newly diagnosed with CP-CML treated upfront with IM 400 mg daily were studied. Informed consent was obtained. Allelic discrimination by RQ-PCR (ABI Prism 7900; TaqMan probe, Applied Biosystems) of 8 SNPs in OCT1 (rs6935207, rs628031, rs12208357, rs72552763), MDR1 (rs1128503, rs2032582, rs1045642), and ORM1 (Gln38Arg) genes was performed. Genotypes were correlated with the patients' main characteristics at diagnosis and the response to treatment (either optimal, suboptimal or resistance), which was defined according to the recommendations of the European LeukemiaNet (Baccarani *et al.*, J Clin Oncol 2009). For the purpose of the present analysis, suboptimal response plus resistance was considered as inadequate response. In order to rule out other potential causes of inadequate response to IM, bone marrow FISH analysis (to exclude BCR/ABL amplification) and direct sequencing mutational study of the BCR/ABL kinase domain were also performed. *Results.* Patients' median age was 47 (range: 19-75) years; 39 were males. Distribution by Sokal groups was: low risk, n=29; intermediate risk, n=25; and high risk, n=11. Median follow-up was 60 months. Fifteen patients (23%) had primary suboptimal response to IM and 5 (8%) were primarily resistant, for an overall primary inadequate response rate of 31%. Nine patients developed secondary suboptimal response and 3 became resistant. Genotype frequencies observed in the 65 patients were comparable to those reported in a healthy Caucasian population. When the influence of the genetic polymorphisms in the therapeutic response to IM was analyzed, the presence of the CC genotype in the rs1045642 (C3435T, Ile1145Ile)

MDR1 SNP was found to be associated with a higher probability of primary inadequate response (P=0.05). Mutations were detected in 3 patients, but in only one at the time of primary resistance to IM; BCR/ABL amplification was not found in any case. At multivariate analysis, which included the patients' main initial features, Sokal risk group and SNPs genotype, the only factor associated with a primary inadequate response to IM was the Ile1145Ile MDR1 polymorphism (RR=4.118; CI 1.027-16.509; P=0.046). *Conclusion.* In newly-diagnosed CP-CML, the Ile1145Ile MDR1 polymorphism has predictive value for the response to standard dose IM. Patients with CC genotype for this polymorphism have a higher probability of primary inadequate response to IM.

0797

CELLULAR DISTRIBUTION OF HEPATOCYTE GROWTH FACTOR (HGF) AND HGF RECEPTOR (C-MET) IN CHRONIC MYELOID LEUKEMIA

S Cerny-Reiterer,[1] K Aichberger,[1] H Herrmann,[2] L Müllauer,[1] G Hörmann,[1] M Mayerhofer,[1] C Sillaber,[1] P Valent[1]

[1]Medical University of Vienna, Vienna, Austria; [2]Ludwig Boltzmann Cluster Oncology, Vienna, Austria

Chronic myeloid leukemia (CML) is a myeloproliferative disease in which BCR/ABL leads to enhanced survival of leukemic cells. Several different angiogenic molecules, including vascular endothelial growth factor (VEGF), have been implicated in the pathogenesis of CML. Hepatocyte growth factor (HGF) is a key mediator of vascularization in normal and neoplastic tissues and has recently been described to be expressed in CML cells. In the present study, the cellular distribution of HGF and its receptor c-MET, and the mechanism of expression of HGF in CML cells were examined. As assessed by immunostaining of bone marrow sections and isolated blood and bone marrow cells, the HGF protein was found to be expressed in a subset of leukemic cells in all patients tested. In addition, CML cells were found to express HGF mRNA as well as c-MET mRNA. HGF and c-MET transcript levels were found to vary from patient to patient without a clear correlation to the phase of disease. In consecutive experiments, we were able to show that basophils are the primary source of HGF in CML patients. In particular, highly enriched sorted CD203c$^+$ CML basophils were found to express HGF mRNA as well as the HGF protein. Correspondingly, HGF transcripts and the HGF protein were detectable in the basophil-committed CML cell line KU812, but not in K562 cells. c-MET mRNA was found to be expressed in highly enriched CD34$^+$/CD38$^-$ CML stem cells, and more mature CD34$^+$/CD38$^+$ CML progenitor cells, but less abundantly in mononuclear cells. We next asked whether expression of HGF in CML cells (basophils) depends on BCR/ABL kinase activity. For this purpose, Ba/F3 cells with doxycycline-inducible expression of BCR/ABL were employed. However, BCR/ABL failed to induce expression of HGF mRNA or the HGF protein in Ba/F3 cells. Correspondingly, the BCR/ABL-blocker imatinib, despite of its growth-inhibitory effects, failed to inhibit HGF expression in primary CML cells or in KU812 cells. Together, these data suggest that HGF is a BCR/ABL-independent basophil-derived mediator in CML. Basophils and basophil-derived mediators may play a more active role in disease biology and progression in CML than has so far been assumed. Whether basophil-derived HGF can act as an ´intraclone-paracrine´ regulator of CML stem cells is currently under investigation.

AURORA KINASE EXPRESSION IN CHRONIC MYELOID LEUKAEMIA: POTENTIAL MARKERS OF DISEASE PROGRESSION

G Gerrard, S Hill, A Bazeos, J Khorashad, H De Lavallade, J Apperley, L Foroni

Imperial College London, London, UK

Background. In Chronic Myeloid Leukaemia (CML), there is significant heterogeneity of disease behaviour and patient response to Imatinib, the front line therapy. Disease progression from chronic phase to blast crisis (BC) is accompanied by multiple additional genetic abnormalities. *Aims.* In this project, we targeted expression of genes that may be relevant to disease progression. Aurora Kinase A, B and C (AURKA, AURKB and AURKC, respectively) have important roles in regulating cell division. AURKA and AURKB over-expression is frequently observed in solid-tumour malignancies and has been associated with chromosomal instability (CIN) and aneuploidy. *Methods.* Gene expression of AURKA, AURKB, and AURKC was determined using quantitative real-time PCR in a total of 75 patient samples, in varying stages of CML, and 23 normal blood samples. Differences in expression between normal, diagnostic, BC and remission samples were evaluated using nonparametric ANOVA and Dunn's Post Test. *Results.* AURKA and AURKB were found to be significantly (P<0.001) over-expressed at presentation and at AP/BC compared with normal and remission levels. AURKC was significantly (P<0.001) under-expressed at presentation compared with expression of normals and at BC and remission. Further analysis of a subset of patients showed that expression levels of AURKB at diagnosis was higher in those who subsequently progressed to BC compared to those who had a sustained remission, at a level which approached significance (P=0.07). *Conclusions.* The expression levels of AURKA and AURKB are significantly elevated at diagnosis and at BC compared to normal and remission samples, whilst AURKC is significantly under-expressed at diagnosis. Higher expression of AURKB at diagnosis is associated with progression to BC, and may be useful as a prognostic indicator.

Chronic myeloid leukemia (CML) is a malignant disorder of the hematopoietic stem cells characterized by the BCR-ABL oncogene. Previous microarray analysis of CML patients has been performed on CD34$^+$ hematopoietic progenitor cells and mononuclear cells. We expanded studies to combined analysis of CD34$^+$ cells and granulocytes to determine persistent and transient genes, related to various pathways, during cell maturation. Gene expression patterns reflect BCR-ABL-induced functional modifications such as increased cell-cycle and proteasome activity. The microarray analyses have been performed in 10 patients with CML and 8 healthy donors in their CD34$^+$ hematopoietic progenitor cells and granulocytes from peripheral blood. All observed CML Ph$^+$ patients were in chronic phase, with average of 1790 CD34$^+$ cells/μl in peripheral blood. The total gene expression in CML patients was 5248 and 3428 genes in CD34$^+$ cells and granulocytes, respectively what doubled the genes expression in corresponding cells of healthy donors as measured by microarray analysis. The 1620 genes had statistically significant difference (P<0.01) in expression between controls and CML, after 75% filtration, in CD34$^+$ hematopoietic progenitor cells. Restriction of the mean difference, with ±2.5, concentrated the statistical significance to 132 genes. The prominent genes with increased expression were NMI, MIF, HMGN2, HINT1, GCSH, SERBP1 and with decreased expression ADAMTSL3, GNGT1, SERPINB9, BNIP3L, MLLT4 in CD34$^+$ hematopoietic progenitor cells of CML patients. Among genes linked to inhibition of cellular proliferation by Gleevec: MYC and RAF1 had increased expression (2.5 fold), whereas STAT1 and FOS had decreased expression (1.8 fold) in CML. The following genes CDK4 and CDK6 had increased expression and NFKBIA, E2F1 and KRAS genes reduced expression in CML-linked genes of CD34$^+$ cells. The acceleration phase, of CML, sustained genes expression pattern comparable to chronic phase, as well as their ratio to control cells. Expanded microarray analysis of granulocytes revealed 57 statistically significant genes between CML and healthy donors. The following genes THRB, NAMPT, DBX1, TCF7, METRN continued the statistical significance in CML granulocytes *vs.* healthy donors, but with opposite difference in comparison to CD34$^+$ cells. The genes LIN7C, IL3F, REST and ST7L had increased expression in CML granulocytes, whereas TRNT1, SIGLEC1, TCF7, WNK3 and JUNB genes had reduced expression matched wih healthy donors granulocytes. Regarding cell cycle, the new genes emerged: CDC23, CDC26, CHEK1, ANAPC7, as totally absent in corresponding control CD34$^+$ hematopoietic progenitor cells. The cell cycle related genes TFDP1, CDC16, CDK6, SKP1, YWHAQ had elevated expression, in contrast to GADD45B, CDKN2B, CREBBP and E2F1 genes with reduced expression in CD34$^+$ cells of CML patients. This observation highlights the difference in genes expression between primitive and mature cells of CML patients, with the accent on hematopoietic progenitor cells which direct the pathogenetic course of malignancy. Presence of BCRABL fusion gene doubled the quantity of various genes included in regulation of cell cycle, cell

growth, proliferation and leukocyte homeostasis in hematopoietic progenitor cells. This tendency has been largely diminished, or even inverted, in granulocytes of CML patients.

WT1 AND PRAME EXPRESSION IN CML PATIENTS PREDICT IMATINIB RESISTANCE AND BCR/ABL GENE MUTATIONS

A Misyurin, E Aksenova, A Krutov, I Soldatova, L Kesaeva, A Turkina, N Khoroshko

Research Center for Hematology, Moscow, Russian Federation

Background. WT1 and PRAME gene expression detection is broadly used for MRD monitoring of leukemia. Both those genes and their proteins are considered to be a perspective targets for immunotherapy approaches based on anti-tumor vaccination. It was shown that in CML patients there is a strict correlation between dynamic of BCR/ABL and WT1 expression. In our preliminary experiments it was found that CML patients treated by imatinib at the point of 12 mths have a different level of WT1 or PRAME gene expression. It is also know that not all CML patients have the same response on the imatinib therapy. It was shown (J Radich, PNAS 2006) that WT1 and PRAME are overexpressed in blastic crisis of CML. Tacking together these observations we have supposed that WT1 and PRAME gene activation may be connected with some of the basic features of CML progression. We have also assumed that resistance against the therapy of tyrosine kinase inhibitors (TKIs) may be reflected by changes in activity of those genes. Moreover, we have believed that BCR/ABL mutations that are common in cases of TKI resistance may occur in CML patients with some peculiar expression pattern of those genes and it reflects a period of genomic instability that tumor cells have inevitably to run through before obtaining BCR/ABL structure changes. We have decided to see if WT1 and PRAME may be an example of such genes. *Aim.* To study WT1 and PRAME expression levels in CML pts (N=51) at the point of 12 mths and then to see if it may influence future resistance. We have also intended to search for BCR/ABL mutations in resistant CML pts (N=132) and to compare this data with the WT1 and PRAME gene level. *Methods.* This study was based on RQ-PCR testing. We also use a direct PCR fragment sequencing to detect BCR/ABL mutation in imatinib resistant pts. *Results.* WT1 and PRAME expression level was detected in 51 CML pts. Using ELN criteria we register imatinib resistance or suboptimal response in 27 of 51 (54%) in this cohort of pts during the next 6-24 mths of treatment. In 27 resistant pts 21 (78%) had WT1/ABL expression at 12 mths > or = 0,001%. In 24 good responders 16 (67%) had WT1/ABL expression at 12 mths < 0,001%. Coefficient of asymmetry in this case was 7,5 (much more then 1), P=0,000. There was no significant difference between good and bad responders according PRAME expression. Nevertheless, among 132 resistant CML pts in 62 (47%) of them that had BCR/ABL mutations 59 (80%) showed PRAME/ABL meaning > or = 0,1%. In 70 of 132 (53%) BCR/ABL mutation negative pts 58 (83%) have PRAME level <0,1%. Coefficient of asymmetry was 18, P=0,000. *Conclusion.* In the case of CML high WT1 expression is a predictor of imatinib resistance and high PRAME expression in resistant pts is a predictor of BCR/ABL mutations.

0801

HIGH RESOLUTION MELT CURVE ANALYSIS AS A TOOL FOR SCREENING TYROSINE KINASE DOMAIN MUTATIONS IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA ON TYROSINE KINASE INHIBITORS

CH Ang, CL Phan, GG Gan, M Syed Sultan, V Nadarajan

University of Malaya, Kuala Lumpur, Malaysia

Background. Imatinib mesylate (IM), a tyrosine kinase inhibitor (TKI) currently remains the treatment of choice for patients with chronic myeloid leukemia (CML). Continuous administration of IM is however often complicated by the development of clinical resistance and subsequent loss of cytogenetic or molecular remission. One of the most prevalent mechanisms of resistance is through the acquisition of point mutations within the ABL kinase domain of the BCR-ABL fusion gene. Screening and identification of these TKD mutations are thus important in the management of patients with CML on TKIs. Objective. The routine identification of TKD mutations involving direct nucleotide sequencing has a detection sensitivity of about 20% and is generally not suitable for high-throughput screening. We sought to identify if high resolution melt (HRM) curve analysis could instead be used as an initial screening tool for TKD mutations. *Methods.* RNA was extracted from 94 archived serial samples of 45 patients in chronic or accelerated phase and was subjected to semi-nested RT-PCR targeting the TKD of the ABL gene, followed by direct-sequencing of the second step PCR product. The BCR-ABL gene of the same set of samples were in parallel, selectively amplified by conventional RT-PCR, followed by HRM assay using four pairs of primers targeting four overlapping regions that span the entire ABL kinase domain. Amplicons with a shift in HRM differential curves were purified and subjected to direct sequencing to confirm the mutation. Detection sensitivity of the HRM assay was assessed by diluting plasmids containing the specific mutation in wild type DNA from 5% to 100%. *Results.* Twenty of the 94 samples were not evaluable due to poor amplification quality. Twenty-two mutations were detected in 15 samples by direct sequencing. The mutation types detected in these samples included M244V, L248V, G250E, Y253F, T315I, A341T, F359V and E459Q. HRM successfully recognized the presence of 20 of the mutations. The failure of detecting one of the mutations was attributed to poor PCR amplification prior to HRM caused by RNA degradation while one of the samples harbouring G250E did not show a temperature shift due to the presence of 100% mutants as compared to wild type and absence of heteroduplexes. However, HRM detected the additional presence of Y253F mutation in a sample with multiple mutant types that had not been detected by nucleotide sequencing. Five samples that indicated presence of mutants due to temperature shifts were confirmed as wild type by nucleotide sequencing. Plasmid dilutions showed that HRM was capable of detecting 5% of mutant types in wild type DNA. *Conclusion.* The high sensitivity, rapid throughput and cost-effectiveness of HRM make it an attractive screening tool for early identification of CML patients on TKIs who may harbour TKD mutations. Wild type DNA-spiking is however essential in 100% mutant samples in order to form heteroduplexes for better melt curve discrimination. False positive results are also liable to occur with a test specificity of 92%. Samples screened positive by HRM should be subjected to nucleotide sequencing for confirmation.

THE ROLES OF CERAMIDE GENERATING AND CERAMIDE CLEARENCE GENES IN APOPTOSIS IN CHRONIC MYELOID LEUKEMIA CELLS EXPOSED TO DASATINIB

Y Baran,[1] E Gencer,[2] A Ural,[3] F Avcu[3]

[1]Izmir Institute of Technology, Faculty of Science, Dept.of Mol.Biol. & Genetics, Urla Izmir, Turkey; [2]Izmir Institute of Technology, Faculty of Science, Dept. of Mol. Biol. & Genetics, Izmir, Turkey; [3]Gulhane Medical School, Faculty of Medicine, Department of Hematology, Ankara, Turkey

Backround. Chronic myeloid leukemia (CML) is a hematopoietic stem cell disorder that results from the reciprocal translocation of chromosomes 9 and 22. As a result of this translocation, the oncoprotein BCR/ABL is generated. (1) Dasatinib is a rationally designed, multitargeted kinase inhibitor that inhibits the tyrosine kinase activity of this

oncoprotein. (2) Ceramide is a molecule that plays a vital role in lipid metabolism. Ceramide is a novel regulator of differentiation, senescence, proliferation, cell cycle and also acts a strong apoptotic molecule.(3) In this study, we investigated the possible synergistic apoptotic effects of intracellular ceramide concentrations and dasatinib on human K562 and Meg-01 chronic myeloid leukemia (CML) cells, and changes in expression levels of ceramide metabolizing genes in response to dasatinib. *Methods.* The cytotoxicity analyses of dasatinib, C:8 ceramide to induce *de novo* generation of ceramide, PDMP to inhibit glucosyl ceramide synthase (GCS) and SK1 inhibitor to inhibit the conversion of ceramide to antiapoptotic sphingosine-1-phosphate(S1P) were carried out by XTT cell proliferation assay. The changes in caspase-3 enzyme activity and mitochondrial membrane potential (MMP) were measured by caspase-3 colorimetric assay and JC-1 MMP detection kit, respectively. *Results.* We have shown that dasatinib induces apoptosis and arrest the cell-cycle for both cells in a dose dependent manner. When we treat the cells with C:8 ceramide in addition to dasatinib application we have observed significant induction of apoptosis. On the other hand, inhibition of conversion of apoptotic ceramides to anti-apoptotic glucosyleceramide or to sphingosine-1-phophate increased cytotoxic effects of dasatinib as compared to any agent alone. These results are proved not only by decreases in cell proliferation, but also by increases in cytoplasmic/monomeric JC-1 and caspase-3 enzyme activities. RT-PCR results revealed that there were downregulations in expression levels of antiapoptotic GCS and SK-1 genes. On the other hand, while there were increases in expression levels of LASS1, -2, -4, -5, and -6 in K562 cells, in contrast to our expectations, there were downregulation in expression levels of LASS genes in Meg-01 cells in response to increasing concentrations of dasatinib. Conclusion. Taking together all these results have shown for the first time that targeting ceramide metabolism in addition to inhibition of BCR/ABL by dasatinib induces apoptosis synergistically in Philadelphia positive CML cells.

LEPTIN PRODUCTION AND LIPID RELEASE BY BONE MARROW ADIPOCYTES REGULATE IN VITRO THE EVOLUTION OF A MYELOID LEUKEMIC CELL LINE

A Beaulieu,[1] C Humblet,[2] Z Belaid,[2] G Poncin,[2] G Bogdanovic,[3] J Boniver,[2] MP Defresne[2]

[1]Université de Liège, Liège, Belgium; [2]Laboratory of Histology and Pathological Anatomy, ULg, GIGA-Cancer, Liège, Belgium; [3]Institute of Oncology Sremska Kamenica, Institutski put ,[4] Sremska Kamenica, Serbia

Background. We have recently demonstrated that bone marrow (BM) adipocytes inhibit granulocyte differentiation by a mechanism implicating cell-cell contact and leptin production (Belaid Z *et al.*, Stem Cells 2008). They were also described *in vivo* as negative regulators of the hematopoietic microenvironment (Nature, 2009, 460:259). Aim of the work. We postulate that BM adipocytes could also influence malignant myeloid hematopoietic cells. Materials and *Methods.* We realized co-cultures of a leukemic myeloid precursor cell line (LC) exhibiting characteristics of LMC with BM adipocytes or with a BM stromal cell line (HS-5) as control. LC were also cultured in fat medium and/or leptin. Culture medium was analysed by proteome array and ELISA. The phenotype of LC was tested by immunostaining and FACS analysis. BCL-2 expression and NFKB pathway were tested by western blot. *Results.* BM adipocytes, but not HS-5, produce high levels of leptin (100pg/mL) and induce accumulation of lipids in leukemic cells (LC). They increase OB-R (leptin receptor) and TLR-4 expression in LC, activate NFKB pathway, decrease BCL-2 expression and partially inhibit LC proliferation. Lipids added to the culture medium of LC exert the same effects except that they induce an increase in BCL-2 expression. Leptin alone does not have any influence on LC but restores the decrease in the anti-apoptotic BCL-2 expression observed in the presence of BM adipocytes. Adipocytes seems thus to negatively regulate leukemic cells. However, adipocytes, but not HS-5, display morphological evidence of cell death after one week in co-culture with LC: the presence of pro-inflammatory cytokines produced in the culture medium as a consequence of the activation of NFKB pathway induced by the binding of fatty acids to TLR-4 could explain this effect. *Conclusion.* We think that BM adipocytes could negatively regulate myeloid malignant cells in the first stage of the disease; their disappearance in leukemic BM in response to pro-inflammatory cytokines could favour the evolution of the disease.

0804

P-CRKL IS NOT A SURROGATE OF BCR-ABL ACTIVITY *IN VITRO* AT SHORT TIME-POINTS

P Zhou, T Holyoake, J Mountford, H Jørgensen

Universtiy of Glasgow, Glasgow, UK

Background. Phosphorylation of Crk-like (CrkL) protein, a downstream Bcr-Abl binding partner, is commonly used as a surrogate marker for Bcr-Abl kinase activity and response to tyrosine kinase inhibitor (TKI) treatment in Chronic Myeloid Leukemia (CML). However, the accuracy of phospho-CrkL (p-CrkL) as a reflection of Bcr-Abl status at early time-points during *in vitro* TKI treatment (<24h) has not been examined. *Aims.* To investigate if p-CrkL is an accurate surrogate marker of Bcr-Abl kinase activity after TKI treatment in K562 CML cells at early time-points. *Methods.* In this study, K562 CML cells were treated with imatinib or dasatinib. At each time-point, cells were collected and lysed with NP-40 lysis buffer. P-CrkL and tyrosine phosphorylated Bcr-Abl (p-Tyr Bcr-Abl) protein levels were measured by Western blotting, and densitometry was performed. Values are shown as percentage to no drug control. *Results.* After 1μM imatinib treatment, p-Tyr Bcr-Abl level dropped quickly to 24.9%±7.7% of no drug control by 1 h and then plateaued at this level to 48 h, while p-CrkL level dropped to 59.3±13.5% at 0.5 h, but then recovered to 94.4±17.3% at 4 h (P=0.012), before dropping again to 39.0±13.4% at 48 h. The difference between these responses of p-CrkL and p-Tyr Bcr-Abl is statistically significant (P=0.023 at 4 h; P=0.008 at 8 h; P=0.0009 at 24 h) (Figure 1). Furthermore, as p-Tyr Bcr-Abl level dropped sharply within 1 h, we looked at earlier time-points from 1 minute of imatinib treatment. We observed a rapid reduction in p-Tyr Bcr-Abl to less than 50% of no drug control by 10 minutes, however p-CrkL remained at control levels during this period. The difference between p-CrkL and p-Tyr Bcr-Abl is statistically significant (P<0.05 at 5 and 10 minutes; P<0.01 at 15, 30 and 60 minutes). With 10 nM dasatinib, the p-Tyr Bcr-Abl response was similar to that seen with imatinib - dropping rapidly to 14.3±2.0% at 1 h then remaining around this level. However, unlike imatinib, dasatinib caused a strong reduction in p-CrkL to 18.8±4.7% by 1 h, and this reduction was then sustained with no recovery of phosphorylation. We hypothesized the initial sharp drop of p-Tyr Bcr-Abl level after TKI treatment (within 1 h) may be due to protein tyrosine phosphatase (PTPase) driven active dephosphorylation. Therefore, we treated K562 cells with both imatinib and PTPase inhibitor, sodium stibogluconate (SSG). SSG partially inhibited the initial drop of p-Tyr Bcr-Abl level caused by imatinib, suggesting PTPases play a role in Bcr-Abl dephosphorylation. Summary: These results demonstrate that p-CrkL is not a reliable indicator of Bcr-Abl kinase activity within 24 h of imatinib treatment and indicate that the early responses to imatinib and dasatinib differ. Importantly, these data also show that in addition to inhibition of the Bcr-Abl kinase activity there is a rapid and active dephosphorylation of Bcr-Abl within 1 h of TKI treatment, driven at least in part, by PTPase activity.

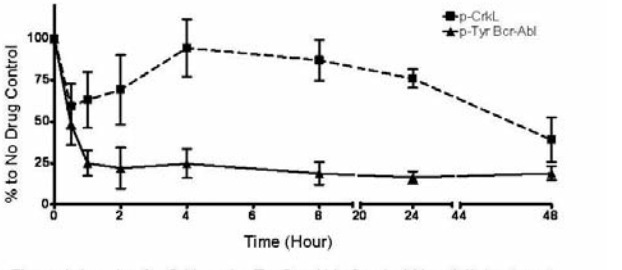

Figure 1: Levels of p-CrkL and p-Tyr Bcr-Abl after 1 μM imatinib treatment measured by Western blotting. Data are shown as percentage to no drug control (mean ± SEM, n=3).

SECOND MALIGNANCIES IN 559 PATIENTS WITH CHRONIC MYELOID LEUKEMIA TREATED WITH IMATINIB FRONTLINE: DATA FROM THE GIMEMA CML WORKING PARTY

G Gugliotta,[1] F Castagnetti,[2] F Palandri,[2] M Breccia,[3] F Radaelli,[4] A Capucci,[5] F Cavazzini,[6] D Ferrero,[7] F Stagno,[8] F Gherlinzoni,[5] R Di Lorenzo,[5] P Leoni,[9] G Rege Cambrin,[7] F Ferrara,[5] G Alimena,[3] G Martinelli,[2] F Pane,[10] G Saglio,[7] M Baccarani,[2] G Rosti[2]

[1]Instiurte L. and A. Seragnoli - S.Orsola Hospital, University of Bologna, Bologna, Italy; [2]Institute L. and A. Seragnoli - S.Orsola Hospital, University of Bologna, Bologna, Italy; [3]Haematology Dept. - University La Sapienza, Roma, Italy; [4]Haematology Dept. - University of Milan, Milan, Italy; [5]Haematology Unit, Brescia, Italy; [6]Haematology Dept. - University of Ferrara, Ferrara, Italy; [7]Haematology Dept. - University of Turin, Torino, Italy; [8]Haematology Dept. - University of Catania, Catania, Italy; [9]Haematology Dept. - University of Ancona, Ancona, Italy; [10]Haematology Dept. - University Federico II, Napoli, Italy

Background. Imatinib, a TKI inhibitor that revolutionized CML therapy, is now approaching ten years since its commercialization. Until now, even in complete durable molecular response, discontinuation of imatinib is not recommended, and imatinib remains a life-saving drug to be taken chronically. For this reason an important issue is represented by long-term side effects and among these the incidence of second malignancies. Roy *et al.* (Leukemia 2005) reported an unexpected incidence of second neoplasms in patients treated with imatinib after interferon (6/189 patients, 3.2%; urinary tract cancer: 4/6); in contrast, an analysis performed by Novartis in 9518 patients treated with imatinib all over the world did not provided evidence for an increased overall incidence of second malignancies (Leukemia 2006). However few data are available from independent studies, and particularly in imatinib-only treated patients. *Aims.* to evaluate the incidence of second malignancies in patients treated with imatinib frontline, enrolled in 3 multicentre independent trials. *Methods.* overall, 559 patients have been enrolled in 3 concurrent clinical studies of the GIMEMA CML Working Party: CML/021, Imatinib 800 mg in intermediate Sokal risk patients (Clin Trials Gov. NCT00514488); CML/022, Imatinib 400 mg *vs.* 800 mg in high Sokal risk patients (Clin Trials Gov. NCT00510926); CML/023, observational, Imatinib 400 mg. The median age was 52 (extr.18 - 84) years; 308 patients (55%) were ≥50 years; the median follow-up is currently 54 months. *Results.* during the follow-up, 14 patients (2.5%) developed a second malignancy at a median distance of 16.5 months (range 2 - 52) from the start of imatinib therapy (Table 1); 4 of these tumors (2 colon cancer and 2 NHL) were diagnosed within 6 months. All patients were older than 50 years (median 64, extr. 53 - 77) at the diagnosis of the second malignancy. Eleven out of the 559 (2%) patients died due to second neoplasm progression. According to epidemiologic data (Registro Tumori) in Italy, the annual incidence of neoplasm varies from 1% in the range of age between 50 and 69 years and 3% for patients over 70 years. *Conclusion.* in this population of CML patients imatinib-treated, the incidence of second neoplasm do not differ from the observed incidence of neoplasm in the national population. In particular, in contrast to what previously reported, no increased incidence of urinary tract cancer was observed.

CHRONIC MYELOID LEUKEMIA (CML) PATIENTS WITH E14A2 BCR-ABL FUSION TRANSCRIPT ACHIEVE A FASTER MAJOR MOLECULAR REMISSION (MMR) ON IMATINIB THAN THOSE EXPRESSING THE E13A2 TRANSCRIPT

B Hanfstein,[1] P Erben,[1] M Agrawal,[1] S Schnittger,[2] T Schenk,[3] T Ernst,[3] WK Hofmann,[1] R Hehlmann,[1] A Hochhaus,[3] M Müller[1]

[1]Medizinische Fakultät Mannheim der Universität Heidelberg, Mannheim, Germany; [2]MLL Münchner Leukämielabor, München, Germany; [3]Universitätsklinikum Jena, Jena, Germany

Background. BCR-ABL positive CML in the vast majority of cases is associated with the expression of one or both of e13a2 and e14a2 BCR-ABL fusion transcripts. Optimal response to imatinib treatment of CML is defined by the achievement of an MMR after 18 months, i.e. the reduction of the BCR-ABL expression below 0.1% according to the international scale (IS). Several markers have been evaluated to predict treatment response, however few data have been presented concerning the impact of the BCR-ABL transcript type in the imatinib era yet. *Aims.* We have evaluated the prognostic impact of the BCR-ABL transcript type on long term molecular and cytogenetic outcome in CML patients on first line imatinib based treatment. *Methods.* 1,036 patients (pts) with newly diagnosed CML (61% male, median age 53 years, range 16-86) were included into the randomized German CML Study IV and treated with an imatinib based therapy consisting of standard dose imatinib (400 mg/d), high dose imatinib (800 mg/d) and combinations of standard dose imatinib with low dose cytarabine or interferon alpha. BCR-ABL expression (IS) was determined by quantitative RT-PCR from 9,072 peripheral blood samples with a median follow up of 33 months (range 0-88). The type of BCR-ABL transcript was defined by multiplex PCR. Cytogenetic response of 949 patients was determined by conventional metaphase analyses of 4,050 bone marrow samples with a median follow up of 21 months (range 0-84). *Results.* Multiplex PCR identified three groups of patients: (i) e13a2 transcript, n=424; (ii) e14a2 transcript, n=464; (iii) e13a2 and e14a2 transcript, n=148. The median time to achieve MMR was 17.5 months (i), 13.4 months (ii) and 13.5 months (iii) revealing a significant difference between group (i) and (ii) (P=0.0072). Group (iii) did not differ significantly from groups (i) and (ii) (P=0.09, P=0.79). Cumulative incidence of achieving MMR was 66.3% for group (i), 73.9% for group (ii) and 72.3% for group (iii). The analysis of time to achieve a complete cytogenetic remission (CCyR) showed a median of 9.4 months (i), 9.0 months (ii) and 9.2 months (iii) indicating no significant differences between groups. 73.2% of pts achieved CCyR in group (i), 75.2% in group (ii) and 73.1% in group (iii). *Conclusions.* The type of BCR-ABL transcript is predictive for the achievement of major molecular response (MMR). Median time to MMR for patients expressing e14a2 is about four months shorter than for patients with e13a2. Regarding the cytogenetic level of response no significant impact of BCR-ABL transcript type could be revealed.

0807

REAL WORLD DATA ON CHRONIC MYELOID LEUKEMIA - A REPORT FROM THE SWEDISH POPULATION BASED CML-REGISTRY

M Hoglund,[1] M Björeman,[2] M Björkholm,[3] M Brune,[4] M Ekblom,[5] K Hellstrom,[6] S Lehmann,[7] P Ljungman,[7] C Malm,[8] B Markevärn,[9] F Sandin,[6] L Stenke,[3] H Wadenvik,[4] A Wahlin,[9] J Richter,[5] B Simonsson[1]

[1]Uppsala University Hospital, Uppsala, Sweden; [2]Örebro University Hospital, Örebro, Sweden; [3]Karolinska Institute-Solna, Stockholm, Sweden; [4]Sahlgrenska University Hospital, Göteborg, Sweden; [5]Lund University Hospital, Lund, Sweden; [6]Regional Onkological Centre-Uppsala/Örebro, Uppsala, Sweden; [7]Karolinska Institute-Huddinge, Stockholm, Sweden; [8]Linköping University Hospital, Linköping, Sweden; [9]Umea University Hospital, Umea, Sweden

Background. The Swedish CML Registry was founded in 2002 by the Swedish CML group and the Swedish Society of Hematology. It is supported by the Swedish Board for Health and Welfare, and run in collaboration with the Oncological Centres in each of the six Swedish health care regions, covering in total a population of 9 million. Each region contains one or two university hospitals and up to twelve county hospitals treating patients (pts) with CML. Clinicians are supposed to report all pts with newly diagnosed CML to this registry. In addition, pathologists and clinicians are obliged by law to report all new cases to the Swedish Cancer Registry. *Aims.* To establish patient characteristics and treatment outcome in a population-based cohort of CML patients after the introduction of imatinib. *Methods.* Pts >16 yrs with CML diagnosed Jan. 1

2002 or later are included. Pts with clinicopathological findings typical for CML but cytogenetics not performed are also accepted. At diagnosis, disease stage, CBC, Sokal score, WHO PS, cytogenetics and aim of treatment are registered. At an annual follow-up, principal treatment and response are reported. Date-of-death data are collected directly from the Swedish Population Registry. *Results.* During 2002-2006, 423 (m/f: 212/211) new cases of CML were reported from 55 hospitals, covering 98 % of all CML cases diagnosed in Sweden according to the compulsory Swedish Cancer Registry. This corresponds to an annual CML incidence of 0.9/100 000. Median age was 58 yrs (17-99), out of which 25% were ≥70 yrs. Diagnosis was confirmed by karyotyping in 82%, FISH (+/-RT-PCR) 7%, RT-PCR only 7%, whereas cytogenetics was not performed or unsuccessful in 4% (n=19; median age 80 yrs). Three hundred-eighty-eight pts (92%) were diagnosed in CP, 14 (3%) in AP, 10 (2%) in BC, data missing in 10 cases (2%). Data on Sokal score was available in 85% of pts with CP: HR 36%, IR 41% and LR 23%. Treatment aim was "CCgR"in 81%, and "palliation only"in 19%. Only 59 pts (14%) were included in an upfront study protocol according to the reporting clinician. Imatinib was "initial treatment"in 75% and 41% of pts <70 and ≥70 yrs, respectively (proportion of imatinib treated pts increasing during the study period). As of Febr.17 2010 (median follow-up: 62 months), 338/423 pts (80%) are alive. In pts with CP at diagnosis, the projected 4-yrs survival for Sokal-LR/IR, Sokal-HR- and Sokal-missing patients, is 88.7% (84.4-93.2), 76.0% (68.6-84.2) and 73.6% (63.0-86.0), respectively (95% CI). Updated results will be presented at the meeting. *Conclusions.* Establishing a population-based national CML registry is feasible. Only a minority of CML patients are included in upfront clinical studies. A relatively large proportion of elderly pts diagnosed during this time period (2002-06) received palliative treatment with mainly non-imatinib regimens.

0808

THE PRE-TREATMENT LEVELS OF PROTEIN PHOSPHATASE 2A (PP2A) AND ITS INHIBITOR SET CAN PREDICT PATIENTS DESTINED TO PROGRESS TO BLAST CRISIS OF CML

C Lucas, RJ Harris, A Giannoudis, R Clark

Royal Liverpool University Hospital, Liverpool, UK

Background. BCR-ABL tyrosine kinase activity induces and maintains chronic myeloid leukaemia, but the molecular factors that contribute to disease progression are not well understood. PP2A is a phosphatase which regulates cell proliferation, differentiation and survival. Blast crisis of CML has been associated with increased levels of SET, a key inhibitor of PP2A function. (Nevaiani *et al.*, Cancer cell 2005, Perrotti *et al.*, Br J Cancer 2006) However, only limited number of cases were reported and so the broader implications of PP2A in CML remain unclear. (Nevaiani *et al.*, Cancer cell 2005). *Aims.* The aim of this study was to investigate if PP2A or its inhibitory protein SET could predict clinical outcome in imatinib treated patients. *Methods.* We investigated the levels of PP2A, phosphorylated PP2A and its inhibitor SET in mononuclear cells from chronic phase CML patients by flow cytometry. Samples were taken at diagnosis and following 12 months of imatinib treatment (n=30). Patients were categorised into three groups - those who subsequently achieved a complete cytogenetic response (CCR group), those who did not achieve CCR though did not progress to advanced disease (no CCR group) and those who subsequently progressed to blast crisis (BC group). Results. At diagnosis, the CCR group had low levels of PP2A (compared to normals P=0.005), low PP2A activity (as indicated by high levels of tyrosine 307 phosphorylation) and high levels of SET protein, indicating impaired PP2A function. In the no CCR group the level of PP2A was significantly lower than in normal blood (P=0.005) and its activity was the lowest of all three patient groups;n SET level was also high. In sharp contrast, patients at diagnosis who were destined to later progress into advance disease were found to have significantly higher levels of PP2A (P=0.0001). The degree of PP2A phosphorylation was higher (low activity) than normals and SET levels were virtually undetectable (P=0.011 and P=0.035 compared to CCR and no CCR groups respectively). Following 12 months of imatinib treatment in the CCR group the levels of PP2A increased, its activity increased (reduced Y307 phosphorylation) and the levels of SET were decreased - all leading to an environment permitting achievement of CCRe. In the no CCR group PP2A levels increased and the amount of phosphorylated PP2A decreased -suggesting that the activity of PP2A had increased - but the function of PP2A remained impaired as the level of SET was not diminished. In the BC group the PP2A protein levels decreased and the activity decreased further. SET levels remained unchanged suggesting an alternative signalling pathway controlling PP2A function in this group. *Summary/Conclusions.* These data suggest that the levels of PP2A, phosphorylated PP2A and SET at diagnosis can give important prognostic information and may identify patients at high risk of disease progression for who strategies other than imatinib may be appropriate.

IMATINIB TROUGH PLASMA LEVELS IN PHILADELPHIA POSITIVE CHRONIC MYELOID LEUKEMIA (CML) PATIENTS: RESULTS OF A MULTICENTER STUDY CSTI571AIL11TGLIVEC

M Koren-Michowitz,[1] Y Volchek,[1] D Ben-Yehuda,[2] E Naparstek,[3] I Gavish,[4] E Levi,[5] P Rannani,[6] J Rowe,[7] A Nagler[1]

[1]Chaim Sheba Medical Center, Tel Hashomer, Israel; [2]Hadassah University Hospital, Jerusalem, Israel; [3]Sourasky Medical Center, Tel Aviv, Israel; [4]Ha'emek Medical Center, Afula, Israel; [5]Soroka Medical Center, Beer Sheva, Israel; [6]Rabin Medical Center, Petach-Tikva, Israel; [7]Rambam Medical Center, Haifa, Israel

Background. Imatinib is the standard of care in the treatment of CML. Almost uniquely in the treatment of leukemia, pts are receiving a fixed dose regimen ranging between 400-800 mg/day. Imatinib trough plasma levels may vary among pts and may correlate with both response and toxicity. *Aims.* Moreover Imatinib plasma levels may predict response and thus serve as a guide in optimizing the anti leukemic effect. *Methods.* We evaluated Imatinib trough plasma levels, using liquid chromatography/mass spectrometry, in 166 CML pts (M-89; F-77), median age 55y (range, 18-85). Seven centers participated in the study, mostly referral university hospitals. None of the evaluated pts were part of an Imatinib clinical study. Pts had to receive Imatinib for at least one month prior to the single plasma level assessment. Pts compliance was assessed by diary logs. *Results.* All pts (96%; na-4%) were in CP. Disease duration was 3.6y (range 0.12-17.9). 76 % of the pts received Imatinib at the conventional dose of 400 mg/day, while 15 % of the pts received higher dose (600-800 mg/day). In 8% of the pts the Imatinib daily dose had to be reduced to 100-300 mg/day due to side effects. Compliance was 97%. Conventional cytogenetics was available in 89% of pts and FISH in 67%. 95% of the pts were positive for bcr/abl by PCR (na-5%). Abnormal liver and renal function tests were observed in 7.0% and 7.5% of the pts, respectively. Initial/previous therapies included: Hydroxyurea - 45.8%, Interferon alpha - 22.9% and Busulfan in 1.2% of the pts. 98.6% of the pts achieved CHR. 72% of the pts achieved stable CCyR and 4.8% had partial CyR, while 3.4% achieved only minimal CyR (mCyR) and 5.5% of pts had no CyR. 76% of the pts had MMolR, while 18.5% had minor MolR (mmolR). Imatinib plasma levels are available for 146 (88%) of the pts (20 pts-pending). Mean plasma levels was 1163+65 ng/mL. Median levels were 1001 ng/mL (range, 175-7460). Imatinib plasma levels were not different between pts achieving complete or partial CyR (1018+62 *vs.* 1077+125 ng/mL, respectively). While in pts that achieved only mCyR imatinib levels were significantly lower (621+ 138 ng/mL, P=0.03). Similarly, in pts that did not achieve CyR plasma levels were significantly lower 688 + 98 ng/mL, P=0.018. No difference was observed in Imatinib plasma levels between pts that achieved major *vs.* minor MolR, 1018+81 *vs.* 973+104 ng/mL, respectively. Abnormal liver or renal function did not affect median Imatinib plasma levels: 990 + 232 and 994 + 172 ng/mL, respectively. *Conclusions.* Imatinib trough plasma levels of 1163+63 ng/mL correlates with CCyR. A significant lower plasma level was observed in CML pts that failed to achieve or achieved only minor CyR. In the current assessment, plasma levels were determined in CP CML pts treated with Imatinib out of Imatinib clinical studies in 7 participating centers. It is thus possible to assess Imatinib plasma levels in common daily practice. Imatinib plasma levels may be a practical tool in optimizing Imatinib therapy for CML pts.

A EUROPEAN OBSERVATIONAL STUDY OF DASATINIB IN THE MANAGEMENT OF IMATINIB-RESISTANT AND -INTOLERANT PATIENTS WITH CHRONIC MYELOID LEUKEMIA: FORTE STUDY (CA180-211)

JL Steegmann,[1] M Michallet,[2] E Morra,[3] D Niederwieser,[4] E Schlögl,[5] M Björeman,[6] K Foryciarz,[7] A Ho,[8] K Kuliczkowski,[9] G Ossenkoppele,[10] A Gozzini,[11] J Gora-Tybor,[12] ML Guerra,[13] G Verhoef,[14] P Roussou,[15] A Mori,[15] D Marin[16]

[1]Hospital de la Princesa, Madrid, Spain; [2]CHU, Lyon, France; [3]Ospedale Niguarda Ca' Granda, Milan, Italy; [4]University of Leipzig, Leipzig, Germany; [5]Hanusch Hospital, Vienna, Austria; [6]University Hospital, Örebro, Sweden; [7]Jagiellonian University, Cracow, Poland; [8]King's College Hospital, London, UK; [9]Klinika Hematologii, Nowotworów Krwi i Transplantacji Szpik, Wroclaw, Poland; [10]VU University Medical Center, Amsterdam, Netherlands; [11]AUO Careggi, Florence, Italy; [12]Medical University of Lodz, Lodz, Poland; [13]CHLN, Hospital Santa Maria, Lisbon, Portugal; [14]University Hospital Leuven, Leuven, Belgium; [15]Bristol-Myers Squibb, Braine-l'Alleud, Belgium; [16]Hammersmith Hospital, London, UK

Background. Even though imatinib has transformed the outcome of patients diagnosed with chronic-phase (CP) chronic myeloid leukemia (CML), at 6-8 years follow-up, 45-56% of patients ultimately discontinue imatinib (Deininger *et al*. Blood 2009; Hochhaus *et al*. Blood 2008), mostly due to unsatisfactory response and/or toxicity. Clinical studies in imatinib-resistant patients with CP-CML suggest that earlier and deeper responses to second-generation TKIs (2G-TKIs) including dasatinib, a potent BCR-ABL kinase inhibitor, correlate with improved outcomes and that time from first detection of imatinib failure to beginning of 2G-TKI therapy is a significant predictor of response (Milojkovic *et al*. Haematologica 2009; Quintas-Cardama *et al*. Cancer 2009). However, little data has been gathered from real-life observation. *Aims.* FORTE (Factors impacting On Response To dasatinib in Europe) aims at identifying explanatory factors of response to dasatinib in a real-life observational, non-interventional study. This study investigates the relationship between time elapsed from detection of imatinib resistance/intolerance to initiation of dasatinib and best response to dasatinib (primary objective). Disease and treatment-pattern characteristics of the observed population monitored and treated with dasatinib in real life are described, and best response to dasatinib is summarized. *Methods.* This large international study, conducted in 141 sites across 12 European countries, enrolled imatinib-resistant/-intolerant CP-CML patients being treated with dasatinib for ≥2 months. Patients gave written informed consent before study entry. Best response to dasatinib was assessed by an ordered categorical variable which combines all types of responses achieved by patients and selects the highest level of response. Disease history, response to imatinib/dasatinib, response-monitoring rates and criteria to define imatinib resistance/intolerance, as determined by physicians' medical judgment, were collected from individual patient charts. The study is compliant with international guidelines. *Results.* This is the first preliminary analysis of 225 CP-CML patients (male/female:102/123). Median age was 56.6 years at start of dasatinib and median time from diagnosis to dasatinib initiation was 46.1 months. Intermediate/high Sokal and Hasford scores at diagnosis were seen in 74.6% and 78.6% of assessable patients, respectively. Imatinib resistance occurred in 133 patients, 62 were imatinib-intolerant and 30 were both imatinib-resistant and -intolerant. Overall, 54.7% of 223 evaluable patients achieved complete cytogenetic response (CCyR) or major molecular response (MMolR) as best levels of response with imatinib. Imatinib had been administered at standard dose (400mg/d) in 38.2% of patients, at 600 mg/d in 35% and at >600 mg/d in 26.7% of patients. Dasatinib was initiated at a median of 7.7 months after imatinib resistance/intolerance, at a starting dose of 100 mg/day in 70.5% of patients. Within the first 12 months of dasatinib therapy, 63.2% of the 215 evaluable patients achieved CCyR or MMolR. At this early assessment, there is yet insufficient evidence to conclude on the primary objective analysis. *Summary/Conclusions.* To date, FORTE data are consistent with results from investigational Phase II and III clinical trials, confirming dasatinib effectiveness in imatinib-resistant/-intolerant patients in a real-life observational study. Updated results, including those related to the study primary objective, will be presented at the congress.

0811

OCCURRENCE OF PLEURAL EFFUSIONS DURING DASATINIB TREATMENT IN ELDERLY CML PATIENTS

R Latagliata,[1] M Breccia,[1] P Vigneri,[2] L Luciano,[3] A Gozzini,[4] F Castagnetti,[5] S Ulisciani,[6] F Cavazzini,[7] M Annunziata,[8] F Sorà,[9] A Russo Rossi,[10] P Pregno,[11] R Porrini,[12] M Trawinska,[13] E Crisà,[14] P Musto,[15] M Tiribelli,[16] G Binotto,[17] U Occhini,[18] C Feo,[15] B Martino,[19] P Avanzini,[20] E Spina,[2] F Pane,[3] V Santini,[4] G Rosti,[5] G Rege Cambrin,[6] G Alimena[1]

Background. Pleural effusions are the most common extra-haematological toxicity observed during Dasatinib (DAS) treatment: their occurrence often requires treatment discontinuation and impairs the otherwise high efficacy of the drug. Aims and Methods We revised 125 patients with Chronic Myelogenous Leukemia (CML) in chronic phase treated in 21 Italian Centers, who received DAS when aged >60 years after being resistant/intolerant to Imatinib (IM), in order to find the most important prognostic factors for pleural effusions. Results There were 63 males and 62 females, Sokal risk score at diagnosis was low in 32 patients, intermediate in 49, high in 19 and not evaluable in 23; median age at DAS start was 69.9 years (IR 65.4-74.4), median interval from diagnosis to DAS therapy was 75.8 months (IR 39.1 - 115.9), 57/125 patients (45.6%) had received an IFN-based therapy before IM. As to IM treatment, all but 9 patients had initially received the 400 mg daily standard dosage and 58/125 patients (46.4%) had increased the dosage to 600 - 800 mg/day; on the whole, median period of IM treatment was 46.6 months (IR 21.8 - 61.8). Starting dosage of DAS was 140 mg in 52 patients, 100 mg in 56 patients and <100 mg in the remaining 17 patients. During treatment, 41/125 patients (32.8%) presented a pleural effusion, which was grade 2 in 31 patients and grade 3 - 4 in 10 patients (24.4% of the 41 patients with pleural effusion and 8% of the entire cohort of patients), according to WHO scale; in 11/41 patients (26.8%), there was a concomitant pericardial effusion. In addition, pleural effusion was recurrent in 19/41 patients (46.4%). Median time from DAS initiation to occurrence of 1st pleural effusion was 10.4 months (IR 2.2-18.1). Among 41 patients with pleural effusion, 8 (19.5%) did not require DAS interruption while 33 (80.5%) discontinued the drug; however, DAS was successfully resumed in 28/33 patients (84.8%) after a median period of 20 days (IR 15 - 38) and, overall, only 5 patients (12.1% of the 41 patients with pleural effusion and 4% of the entire cohort of patients) required permanent DAS discontinuation. The predictive role for pleural effusions of several characteristics (sex, age, Sokal risk, smoke attitude, concomitant cardiological or pulmonary diseases, concomitant diuretic treatment, interval from diagnosis to DAS, state of CHR at DAS start, DAS initial dosage) was evaluated in univariate analysis; only presence of concomitant pulmonary disease (P=0.002), initial dose of DAS (140 mg *vs.* 100 mg, P=0.01) and Sokal risk at diagnosis (high *vs.* low-intermediate, P=0.043) were significant. There were no differences among patients with or without pleural effusions as concerns response rates and overall survival. Conclusions. Pleural effusions were common in our unselected population of elderly patients but were clinically manageable and did not seem to affect treatment results; however, a complete pulmonary evaluation before treatment could be useful to tailor the treatment with DAS in elderly patients.

0812

NILOTINIB 300 MG TWICE DAILY IS EFFECTIVE AND WELL TOLERATED AS FIRST LINE TREATMENT OF PH-POSITIVE CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE: UPDATED RESULTS OF THE ICORG 0802 PHASE 2 STUDY

E O'Dwyer,[1] R Swords,[2] F Giles,[2] P LeCoutre,[3] M McMullin,[4] S Langabeer,[5] S Padmanabhan,[2] E Kent,[6] M Parker,[6] B Moulton,[6] K Egan,[7] E Conneally[5]

[1]National University of Ireland, Galway, Galway, Ireland; [2]University of Texas Health Sciences San Antonio, San Antonio, USA; [3]Charité, Campus Virchow, Universitätsmedizin Berlin, Berlin, Germany; [4]Haematology, Centre for Cancer Research and Cell Biology, The Queen's University, Belfast, UK; [5]Dept. of Hematology, St James's Hospital, Dublin, Ireland; [6]ICORG The All-Ireland Cooperative Oncology Research Group, Dublin, Ireland; [7]Novartis, Dublin, Ireland

Background. Imatinib (IM) 400 mg daily is currently the standard treatment for early chronic phase (ECP) CML. Preliminary results of the recent ENESTnd phase III trial suggests that Nilotinib, a more potent, second generation Abl inhibitor may be superior to imatinib as initial treatment of ECP CML at doses of both 300 mg and 400mg BID. *Aims.* We wished to explore the lower dose schedule, 300 mg BID, believing this could be as effective as 400 mg BID but with the potential for fewer adverse events, as well as fewer interruptions and dose reductions which may be important in achieving deep molecular responses. *Methods.* Since December 2008, ICORG, the All-Ireland Cooperative Oncology Research Group has been conducting an open-label, single stage, multicenter, phase II study (ClinicalTrials.gov NCT00809211) to investigate the safety and efficacy of nilotinib 300 mg BID in untreated, ECP, Ph-pos CML patients. The primary endpoint is the CCyR rate at 6 months; secondary endpoints include the kinetics of molecular response, determined by Q-PCR at baseline and 3 monthly from start of treatment. *Results.* To date a total of 27 patients have been enrolled. This abstract is limited to the 18 patients evaluable for response after at least 3 months follow up. The median age of these 18 patients is 51 (range 20-77); 50% have low risk Sokal score, 11% intermediate and 39% high risk. Median follow up is currently 8 months (range 4-14). By intent to treat analysis at 3 months the CHR rate is 100%, the CCyR rate is 56% and MMR rate is 28%. Following 6 months 14/15 patients have achieved CCyR (100%) while 10/14 patients have achieved MMR (71%). While none of the 18 patients have progressed on study, 2 patients have undergone dose escalation to 400mg BID for suboptimal response. The median daily dose was 600mg (range 218-775mg n=18); 12/18 (67%) interrupted nilotinib at least once with a median duration of interruption of 7 days. The dose of nilotinib at the last visit was 400 mg BID in 2/18 patients (11%), 300mg BID in 14/18 patients (79%), 200 mg BID in 1/18 patients (5.6%) and 200mg OD in one patient (5.6%). Haematologic toxicity was minimal with a single episode of transient grade III thrombocytopenia (5.6%). Grade III non-haematologic toxicity included an elevated lipase in 4/18 (22%). The only other grade III toxicities noted were musculo-sleketal pain and an elevated ALT in 1 patient each. There were no grade IV toxicities. *Conclusions.* Nilotinib 300 mg BID induces high rates of CCyR and MMR within 6 months, equivalent to those reported thus far in phase II and III studies of nilotinib in ECP CML. These responses have been achieved with minimal toxicity and dose intensity has been well maintained with most patients taking at least 300 mg BID at last follow up. The early results of this trial provide independent confirmation that nilotinib 300 mg BID is safe and effective treatment for ECP CML.

0813

IDENTIFICATION OF UNBALANCED GENOMIC ABERRATIONS BY ARRAY CGH IN CHRONIC MYELOID LEUKEMIA PATIENTS WITH SUBOPTIMAL RESPONSE TO IMATINIB TREATMENT

CL Phan,[1] CH Ang,[2] KL Liang,[1] GG Gan,[1] Z Zakaria,[3] V Nadarajan[1]

[1]University Malaya, Kuala Lumpur, Malaysia; [2]University of Malaya, Kuala Lumpur, Malaysia; [3]Institute for Medical Research, Kuala Lumpur, Malaysia

Background. Chronic myeloid leukemia (CML) is associated with the presence of the Philadelphia chromosome (Ph), t(9;22)(q34;q11), leading to the expression of the aberrant tyrosine kinase fusion protein, BCR-ABL. The tyrosine kinase inhibitor, imatinib mesylate (IM), is the current standard frontline therapy for newly diagnosed CML and it has significantly improved the prognosis of these patients. In some patients, IM therapy is however complicated by the emergence of resistance particularly in more advanced phase of CML. Several mechanisms of resistance to IM have been demonstrated, including tyrosine kinase domain (TKD) mutations, amplification and overexpression of BCR-ABL gene and clonal evolution. It has become apparent that multiple factors driven by genomic alterations and mutations would contribute to IM resistance. *Aims.* Our study aimed to identify recurrent genomic aberrations in addition to TKD mutations which could contribute to poor response to IM, primarily utilising array comparative genomic hybridization analysis (aCGH). *Methods.* DNA and RNA samples were extracted from 165 archived cells lysates collected at different time points from 37 CML patients. All patients had prior information on response to IM based on clinical, cytogenetics and BCR-ABL transcript levels. Only 103 samples were however of adequate RNA quality for TKD mutation analysis. Sixteen patients with suboptimal response to IM were subsequently identified (4 with TKD mutations and 12 without), and their 40 serial DNA samples were subjected to aCGH analysis using human genome CGH microarray 44K chips (Agilent Technologies) at a resolution of 1Mbp. Intensity data between the test and reference was processed using Feature Extraction Image Analysis Software. Confirmation by fluorescence *in situ* hybridization (FISH) using corresponding commercial probe was carried out depending on availability of metaphase cells preparations. *Results.* One of 40 samples showed poor quality of the test and was excluded from the study. Lesions were detected by aCGH in all studied patients at least on one time point. The most common genomic losses included the regions at 1p36, 1q31, 2q21, 9q34, 21q, -Y and gains at 8q24, 9q34, 14q, 16p and 22q11. Multiple genomic aberration involving gain of 8q24, losses of 9q24 and 22q11, and loss of ASS gene simultaneously were detected in one of the patient that co-harbored multiple TKD mutations (Y253F; Y253F/F359V/1023G>A). Gain of 8q24 was also noted in serial samples from 2 other patients, one of whom had a G250E TKD mutation. All patients with 8q24 gain showed progressive disease and short survival. *Conclusion.* Our findings show that multiple cryptic unbalanced genomic aberrations occur in patients with suboptimal response to IM. We were however unable to unequivocally show any single recurrent aberration that was associated with IM resistance although certain lesions, in particular, gains of 8q24 is associated with rapid disease progression of CML.

0814

NILOTINIB 400 MG BID DAILY AS FRONTLINE THERAPY OF PH + CHRONIC MYELOID LEUKEMIA: DOSE DELIVERY AND SAFETY PROFILE AT 2 YEARS

Background. Nilotinib is an effective and registered treatment of chronic myeloid leukemia (CML) after imatinib failure. Its efficacy as frontline treatment has been explored in phase II trials from GIMEMA CML WP (Rosti *et al.*, Blood 2009: results at 12 months) and MDACC (Cortes *et al.*, J Clin Oncol 2010: median follow-up 17 months), and in a phase III trial (ENESTnd, ASH Meeting 2009: median observation 14 months). Both 300 mg and 400 mg nilotinib BID induced high and early rates of major molecular response (MMR) and complete cytogenetic response (CCgR), with a favorable tolerability profile. *Aims.* To present a detailed analysis of the dose delivery and the safety profile of nilotinib 400 mg BID in Ph-positive CML in early chronic phase (ECP) after the first year of treatment, with a minimum follow-up of 24 months. *Methods.* A multicentric phase II trial was conducted by the GIMEMA CML Working Party (ClinicalTrials.gov.NCT00481052). By March, 2010 all the patients will complete 24 months on treatment. *Results.* 73 patients received an initial nilotinib dose of 400 mg BID; the median age was 51 yrs; 21/73 patients (29%) were ≥ 65 year old at

enrollment. The median follow-up is currently 724 days. The CCgR rate at 6,12 and 18 months was 96%. Overall, the treatment was interrupted at least once in 38 patients (52%; overall, 100 interruptions), with a median cumulative duration of drug interruption of 19 days per patient (range 3-208 days); 35 pts (48%) received the full prescribed dose. The proportion of patients with ≥1 interruption decreased during the study: 45%, 22% and 7% during the periods 0-6 months, 7-12 months and 12-18 months, respectively. During the first 12 months, the mean daily dose was 600-800 mg, 400-599 mg, and less than 400 mg in 74%, 18% and 8% of patients, respectively. During the period 13-18 months the mean daily dose was 600-800 mg, 400-599 mg, and less than 400 mg in 70%, 23% and 7% of evaluable patients, respectively. At 18 months, the last daily dose was 800 mg, 400 mg and 200 mg in 68%, 25% and 7% of evaluable patients, respectively. Four adverse events accounted for the great majority of dose interruptions: bilirubin increase, skin rash and/or pruritus, amylase and/or lipase increase, transaminases increase. Only 4 events of peripheral edema have been recorded so far (3 events grade 1; 1 event grade 2); no pleural or pericardial effusion. The transient hyperglicemia did not lead to any treatment discontinuation. The hematopoietic toxicity (grade 3-4) was negligible: only 7 events (3 neutropenias and 4 thrombocytopenias) in 5 pts (7%). Two patients went off treatment after 9 and 15 months due to recurrent episodes of amylase and/or lipase increase without pancreatitis (normal ECO scan and MRI). Both patients were in CCgR, and maintained CCgR on imatinib 400 mg daily. *Conclusions.* Nilotinib 400 mg BID daily is feasible and safe in ECP CML. Acknowledgements. IN CHRONIC MYELOID LEUKEMIA PATIENTS WHO ARE IN MAJOR MOLECULAR RESPONSE AFTER 12 MONTHS OF FIRST-LINE NILOTINIB THERAPY, LOW-LEVEL BCR-ABL KINASE DOMAIN MUTATIONS ARE VERY RARE

S Soverini, A Poerio, A Gnani, S Colarossi, G Rosti, F Castagnetti, F Palandri, G Gugliotta, M Amabile, M Baccarani, G Martinelli

University of Bologna, Bologna, Italy

Background. Bcr-Abl kinase domain (KD) mutations have been documented in a variable proportion of residual Ph+ cells in some patients in complete cytogenetic response to imatinib, but their clinical significance is controversial. Nilotinib is an imatinib derivative more selective and more potent in Bcr-Abl inhibition - with reported major molecular response (MMR) rates of 81-85% at 12 months. *Aims.* We aimed to assess whether low-level Bcr-Abl KD mutations are detectable after 12 months of nilotinib treatment. *Methods.* We retrospectively analyzed the samples collected after 12 months of nilotinib treatment from 8 patients (4 males and 4 females, median age 52 years) enrolled on the GIMEMA CML working party study of nilotinib 400 mg BID as frontline treatment of CML. These patients had all achieved MMR (>3-log reduction in Bcr-Abl transcript according to the IS) between 3 and 6 months from nilotinib start and had a Bcr-Abl/Abl ratio ranging from 0.009%I^S and 0.02%^{IS} at the time of analysis. In all 8 patients, MMR was maintained at last follow up (24 months after nilotinib start), with two patients achieving complete molecular response (CMR; >4.5-log reduction) at 18 months and one at 24 months. Patients were equally distributed across Sokal risk categories (low Sokal risk, n=3; intermediate Sokal risk, n=2; high Sokal risk, n=3). Screening for low level mutations was performed by cloning the Bcr-Abl KD (a.a.240-502) in a bacterial vector and sequencing 100 independent clones for each patient. To rule out false positive results, a mutation was considered to be present in a sample if it was detected on both strands of two or more independent clones. The KD of Abl in 3 healthy individuals was analyzed in parallel. *Results.* Our cloning and sequencing approach showed evidence of Bcr-Abl KD mutations in only 1 out of 8 patients analyzed. In this high Sokal risk patient, a Q346L mutation was detected in 3/100 independent clones, and an additional T315I mutation was present in 2 out of these 3 clones. The Q346L has never been reported in imatinib-resistant patients, neither is it among the mutants emerged in the *in vitro* random mutagenesis screenings for nilotinib-resistant mutations - hence it should be devoid of any clinical relevance. The T315I, in contrast, is known to be highly insensitive to nilotinib both *in vitro* and *in vivo*. Nevertheless, Bcr-Abl transcript level continued to decline in this patient down to CMR (24 months from nilotinib start). The remaining 7 patients scored negative for mutations - showing only evidence of some single, mutated clones as also the three healthy individuals did. *Conclusions.* Our results suggest that a) low level Bcr-Abl KD mutations seem to be very rare in patients in MMR after 12 months of nilotinib therapy - a milestone achieved by the vast majority of patients; b) as hypothesized by some authors, tyrosine kinase inhibitor-resistant mutations at low levels do not always predict for subsequent relapse and should not trigger changes in therapy.

CORRELATION OF HOCT1 M420DEL SNP WITH THE CLINICAL OUTCOME OF CHRONIC MYELOID LEUKAEMIA PATIENTS TREATED WITH IMATINIB

A Giannoudis, L Wang, G Xynarianos, T Liloglou, G Austin, J Clark, A Kishore, A Hayes, M Pirmohamed, R Clark

University of Liverpool, Liverpool, UK

Background. Membrane transporters are major determinants of drug pharmacokinetics and pharmacodynamics. The human organic cation transporter 1 (hOCT1), an influx transporter, transports imatinib into chronic myeloid leukaemia (CML) cells. We and others have shown that the level of expression or functional activity of hOCT1 is a powerful predictor of clinical response to imatinib (Wang *et al.*, Clin. Pharm. Therapeut. 2008, White *et al.*, Blood 2007). hOCT1 has also been shown to exhibit several single nucleotide polymorphisms (SNPs). Genetic polymorphisms affecting the expression and transport activity may contribute to inter-individual variations in clinical responses. SNPs in hOCT1, particularly M420del (c.1260del), can affect the action and pharmacokinetics of metformin, an anti-diabetic drug and a well known hOCT1 substrate (Shu *et al.*, Clin. Pharm. Therapeut. 2008). Several alternative SNP have been described at M420, the most common of which is a 3-base deletion that results in deletion of methionine from the resultant hOCT1 protein. Aim. Our aim was to analyse hOCT1-M420del and correlate with clinical response to imatinib in CML patients. *Methods.* Genomic DNA samples were prepared from whole peripheral blood or from fresh leukapheresis samples from 174 CML patients prior to or immediately after commencing imatinib therapy at our centre. The M420del was detected by PCR-pyrosequencing. Direct DNA sequencing was used in a number of cases to reconfirm the *Results.* Twenty samples were also cloned and individual colonies were sequenced. *Results.* A total of 48 patients had a SNP detected at M420 of the 174 screened. All of these were the 3-base deletion resulting in M420del (43 heterozygous; 5 homozygous); no cases of single base deletions or changes were seen. This gives an allele frequency of M420del of 15.2%, which is similar to a previously reported frequency in Caucasians of 18.5%. Clinical information is currently available for 125 CML patients (93 carrying the normal hOCT1 gene, 29 heterozygous and 3 homozygous for M420del). For statistical analysis, cases carrying M420del were grouped together. Survival analysis showed that cases carrying exclusively the normal gene had a 5 year progression free survival of 82.8%, compared to 65.6% for cases carrying M420del (P=0.03, log rank correlation, Mantel-Cox). However, no significant difference was seen in event-free survival between the 2 groups. Summary/*Conclusions.* Our data demonstrate the clinical importance of the M420del SNP on outcome of imatinib treatment in CML. Its adverse effect on progression-free but not event-free survival is intriguing, but may be because the higher number of M420del patients who progress early are not at risk for subsequent imatinib failure within chronic phase. The data are compatible with the view that the rapid early attainment of high intracellular imatinib levels may be critical to minimise disease progression, which is less readily achieved in the presence of M420del. These data are currently being extended to a larger dataset of over 330 cases.

Patients (Pts) adherence to therapy is critically important for optimal outcomes in imatinib (IM) treated CML. The aim. of this report is to evaluate the significance of IM plasma level (IPL) test in the estimation of the adherence to IM treatment in CML Pts. *Methods.* Trough plasma concentrations of imatinib (IMC) were detected in 551 samples of 442 CML Pts (CP - 395, AP - 48) aged 18 or over, male/female ratio - 201/241. Blood samples were collected 24±3h after the last IM dose at 300(n=8), 400(n=337), 600(n=155)mg QD and 12±3h after the last IM dose at 800(n=51)mg BD. All Pts have signed informed consent before blood sampling. IMC were determined by a validated LC/MS/MS method. In large CML Pts population studies in I, II and III phases of clinical trials at 400mg QD, 600mg QD and 800mg BD IM doses the lowest means of IMC were 180, 350 and 1020ng/mL respectively. CML Pts with means of IMC levels less than the lowest revealed means were regarded as nonadherent in our study. *Results.* IPL test (n=406) in CML Pts with IM failure, suboptimal response or loss of response have revealed that the median of IMC in Pts at IM dose 400mg QD(n=242) was 963[0-5140]ng/mL; 8(3,3%) Pts had demonstrated IMC less than 180ng/mL. The median of IMC in Pts at IM dose 600mg QD(n=124) was 1369[2,5-3813]ng/mL; 7(5,6%)Pts have demonstrated IMC less than 350ng/mL. The median of IMC in Pts at IM dose 800mg BD(n=40) was 1845[5-5089]ng/mL; 9(22,5%)Pts have shown IMC less than 1020ng/mL. IPL tests (n= 66) were performed in CML Pts when the physician supposed the nonadherence to therapy. In this cohort the median of IMC in Pts at IM dose 400mg QD(n=46) was 861[0-3394]; 4(8,5%)Pts have demonstrated IMC less than 180ng/mL. The median of IMC in Pts at IM dose 600mg QD(n=14) was 1287[400-3813]; the Pts with IMC less than 350ng/mL were not revealed. The median of IMC in Pts at IM dose 800mg BD(n=6) was 1287[215-3813]ng/mL; 2(33%)Pts have shown IMC less than 1020 ng/mL. IPL tests for Pts with suspicion of drug-drug interaction were performed in 13 cases. The median of IMC in Pts at IM dose 400 mg QD(n=10) was 861[0-3394]; 2(20%)Pts have demonstrated IMC less than 180ng/mL. IMC in 2 Pts at IM dose 600 mg QD(n=14) were 2940 and 3635 ng/mL, in 1 patient at IM dose 800 mg BD was 1580 ng/mL and the Pts with IMC less than 350 and 1020 ng/mL respectively were not revealed. In Pts with adverse events (n=66) the median of IMC at IM dose 300mg QD(n=8) was 699[274-1550] ng/mL, at IM dose 400mg QD(n=39) - 967[269-3827] ng/mL, at IM dose 600mg QD(n=15) - 1223[544-3460] ng/mL and at IM dose 800 mg BD (n=4) - 921[381-2470]ng/mL. Only 2 Pts at IM dose 800 mg BD were nonadherent. *Conclusions.* IMC less than referent means were revealed in 32(5,8%) cases: among Pts at IM dose 400 mg QD in 14(4,2%), 600 mg QD-7(6,5%), 800 mg BD-13(25,5%) cases. IPL test is indicative of the adherence to Imatinib treatment in CML Pts.

0818

RETROSPECTIVE ANALYSIS OF PROGNOSTIC FACTORS AND OUTCOME IN AN IMATINIB TREATED CML POPULATION FROM WEST OF SCOTLAND AND LOTHIAN

P Gallipoli,[1] P Shepherd,[2] L Mitchell,[3] M Drummond,[4] T Holyoake[1]

[1]University of Glasgow, Glasgow, UK; [2]Western General Hospital, Edinburgh, UK; [3]Monklands Hospital, Airdrie, UK; [4]West of Scotland Cancer Centre, Glasgow, UK

Background. Imatinib is an effective therapy for newly diagnosed patients with chronic myeloid leukaemia (CML) in chronic phase (CP) as shown in the IRIS trial. However, about 20% of patients in IRIS were censored for reasons including unsatisfactory response or adverse events, thus potentially excluding patients with a worse prognosis from outcome analysis. Two population based studies (Lucas *et al.,* Leukemia 22 1963-66, 2008; de Lavallade *et al.,* J Clin Oncol 26 3358-63, 2008) have recently shown that when these patients are included in such analyses, event-free survival (EFS) and complete cytogenetic response rate (CCyR) to imatinib are lower than those reported in IRIS. *Aims.* To assess prognostic factors and outcome in a population of CML patients treated with imatinib and compare our results to both IRIS and published population based studies. *Methods.* Data from 120 consecutive patients with CML diagnosed since 2004 in the West of Scotland and Lothian were collected retrospectively from case notes. Only patients who received front line therapy with imatinib at 400 mg/day (adjusted to tolerance and response) were considered for the study. CCyR, overall survival (OS) and EFS rates were calculated according to the Kaplan-Meier method using the log-rank test for group comparisons. A p value <0.05 was considered significant. *Results.* Median follow-up was 32.9 months (range 0.4-69.1). At the time of analysis 46.2% of the patients had discontinued imatinib after a median time of 12 months (range 0.3 - 52.7). Reasons for discontinuation included adverse events (17.6%), failure to respond (7.6%), progression (8.4%), suboptimal response (5%), death (1.7%), elective stem cell transplantation (5.9%). 5 years estimated rates of CCyR and loss of CCyR were 88.2 and 10.8%, respectively. The 5 years OS and EFS (defined as in IRIS) were 90.3 and 82.1%, respectively, consistent with IRIS data. However, when imatinib discontinuation secondary to adverse events/failure to respond are included as imatinib failures, the EFS is 53.6%. Sokal score was significantly associated with improved CCyR (at 5 years 100, 93.5 and 80.8% for low, intermediate and high risk P=0.01). Grade III/IV haematological toxicity on imatinib was associated with poorer 5 years EFS (85.8 *vs.* 60.9% for good *vs.* poor haematological tolerability, P=0.03) and CCyR rate (90.4 *vs.* 67.6% for good *vs.* poor, P= 0.01). Achieving CCyR by 12 months was associated with a non-significant trend towards improved 5 years EFS (90.2 *vs.* 69.6%, P=0.17), but not OS (95.8 *vs.* 93.3%, ns). Conclusions. Our results confirm the clinical value of imatinib, but also show that its efficacy and tolerability are less than those reported in the IRIS study and that caution must be exercised when extrapolating trial results to clinical practice. Sokal score maintained its predictive value. Achieving CCyR by 12 months was not predictive of outcome in our series, probably reflecting early introduction of second generation tyrosine kinase inhibitors in patients with suboptimal/failure to respond in our cohort. Poor haematological tolerance to imatinib appears to be a prognostic factor which might help early identification of a high risk group that warrants a more vigilant clinical approach.

0819

RESPONSE TO NILOTINIB IN PATIENTS WITH IMATINIB-RESISTANT OR -INTOLERANT CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE (CML-CP) WITH DIFFERENT BCR-ABL TRANSCRIPT TYPES

S Saglio,[1] T Hughes,[2] DW Kim,[3] B Hanfstein,[4] E Gottardi,[1] S Branford,[5] H Goh,[3] L Beppu,[6] S Soverini,[7] Y Shou,[8] A Stein,[8] R Woodman,[9] H Kantarjian,[10] J Radich,[6] A Hochhaus,[11] G Martinelli[7]

[1]University of Turin, Orbassano, Italy; [2]SA Pathology, Royal Adelaide Hospital, Adelaide, Australia; [3]The Catholic University of Korea, Seoul, South-Korea; [4]Heidelberg University, Mannheim, Germany; [5]SA Pathology, Adelaide, Australia; [6]Fred Hutchinson Cancer Research Center, Seattle, USA; [7]University of Bologna, Bologna, Italy; [8]Novartis Institutes for BioMedical Research, Cambridge, USA; [9]Novartis Pharmaceuticals Corporation, East Hanover, USA; [10]The University of Texas M. D. Anderson Cancer Center, Houston, USA; [11]Universitätsklinikum Jena, Jena, Germany

Background. Philadelphia chromosome positive (Ph+) chronic myeloid leukemia (CML) is characterized by the BCR-ABL fusion gene which

arises from a reciprocal translocation of most of the cellular ABL gene on chromosome 9 to the BCR gene on chromosome 22. Various breakpoints in the BCR and ABL genes have been described although in most cases BCR exon 13 or 14 is fused to the ABL exon 2 (a2), resulting in the β2α2 and β3α2 transcripts, respectively. *Aims.* Variations in BCR-ABL transcript types may result in differences in disease prognosis and response to therapy. Consequently, an analysis was conducted to investigate the correlation between BCR-ABL transcript type and responses to nilotinib in the second-line setting. *Methods.* Imatinib-resistant or -intolerant patients with Ph^+ CML-CP (N = 321) enrolled on the phase 2 registration trial for nilotinib were included. BCR-ABL transcript types were analyzed in 301 (94%) patients in order to determine if transcript type influenced response dynamics. In addition, the BCR-ABL transcript dynamics were modeled as previously described (Stein *et al*. Blood. 2009;114(22):209). *Results.* Median exposure to nilotinib was 561 days. The majority of patients (95%) had typical β3α2 (63%) and β2α2 (32%) BCR-ABL transcript types; 3% of patients had both β3α2 and β2α2 transcripts and 2% had atypical transcripts (e1a2, e19a2, b3a3). Patients with β3α2 transcripts had a higher incidence of baseline mutations compared with patients with β2α2 transcripts (46% *vs.* 32%, P=.03). Transcript type did not influence response to nilotinib treatment (Table). A two-sample χ^2 test of the four endpoints (CHR, CyR, MMR, and EFS) did not show a significant difference (P>.05) between the β2α2 and β3α2 populations. Modeling results demonstrated no statistically significant difference in the response dynamics between the major BCR-ABL transcript types. *Conclusion.* In this analysis, nilotinib was shown to be effective regardless of transcript type, including in patients with rare atypical transcripts. Patients with typical β3α2 and β2α2 transcripts had similar patterns of response to nilotinib in the second-line setting.

Table.

Best Response to Nilotinib by Transcript Type	Number	Hematologic Response, %	Cytogenetic Response, %		Molecular Response, %	Event Free Survival, %	Baseline Mutation	
Transcript type	n	CHR	CCyR	PCyR	MMR	EFS	n	%
b2a2	95	87.4	44.2	13.7	16.8	58.3	85	31.8
b3a2	190	80.5	34.2	10.0	15.3	51.4	179	45.8
b2a2 + b3a2	10	90.0	50.0	20.0	10.0	71.4	8	37.5
e1a2	2	100.0	0	50.0	--	100.0	2	0

ADHERENCE TO TYROSINE KINASE INHIBITORS (TKI) IN CHRONIC MYELOID LEUKEMIA (CML) SEEMS TO BE RELATED TO DURATION OF TREATMENT AND TYPE OF TKI

MH De Almeida, KB Barbosa Pagnano, HA Sanches Souza, CA Souza

University of Campinas, Campinas, Brazil

Background. Chronic myeloid leukemia (CML) is a mieloproliferative disease, characterized by the Philadelphia chromosome, resulting from reciprocal translocation of chromosomes 9 and 22. Tyrosine kinases Inhibitors (TKI) of first and second generation are presently the choice of treatment for this disease and adherence to the treatment is an important factor to obtain good therapeutically *Results.* The most accepted definition of adherence is: "the extent to which a person's behavior - taking medication, following a diet, and/or executing lifestyle changes, corresponds with agreed recommendations from a health care provider". *Aims.* The objective of this study was to evaluate the adherence to TKI in patients with CML and to identify factors that can affect adherence to TKI treatment. *Methods.* A retrospective and observational analysis was performed with 131 patients taking TKI at Hematology and Hemotherapy Center, University of Campinas, Brazil. The adherence was calculated using the mean medication possession ratio (MPR), calculated as total days' dose of TKI divided by the number of the days in the observation time. This evaluation was done for about six months and correlated with other variables. To the statistical analyses were used Sperman's rank correlation and Wilcoxon rank sun test with continuity correction. *Results.* A total of 131 patients were evaluated: 92 (70.23%) were taking Imatinib, 21 (16.03%) Dasatinib and 18 (13.74%) Nilotinib. The mean age was 50 years. The majority of patients were male (61.83%) and the mean of TKI treatment time was 41 months (range: 7 to 108 months). There were 100 (76.34%) patients in first line treatment, 28 (21.73%) second line and 3 (2.29%) third line. The mean of adherence was 93.88% in all patients. 19.84% of patients were completely adherent with 100% of MPR. In this population, the MPR decreased in patients with longer duration of disease and duration of TKI treatment (P=0.01). The adherence was superior in patients participating in clinical trials (P=0.001) and in patients taking Nilotinib in comparison with patients taking Imatinib (P=0.01) or Dasatinib (P=0.027). However, most of patients that were taking Nilotinib were participating in clinical trials. There was no statistical significant difference in adherence regarding sex, age, socioeconomic status, marital status, level of education and TKI dose. *Conclusions.* The adherence in patients with CML taking TKI seems to be higher compared with other chronic disease. An important factor was how long patients have been diagnosed CML or treated with TKI. In our Cohort adherence behavior was different comparing kinds of TKI.

0821

MEASUREMENT OF TROUGH IMATINIB PLASMA LEVELS IN PATIENTS WITH CML DOES NOT SIGNIFICANTLY CORRELATE WITH TREATMENT RESPONSE BUT MAY BE SUCCESSFULLY USED IN SELECTED PATIENTS FOR DOSAGE ADJUSTMENT

E Faber, D Friedecký, K Micová, I Skoumalová, P Rohon, Š Rožmanová, M Divoká, M Jarošová, K Indrák, T Adam

Faculty of Medicine and Dentistry, Palacký University in Olomouc, Olomouc, Czech Republic

Background. Trough imatinib plasma levels (IPL) were shown to be associated with cytogenetic and molecular response in CML patients treated with imatinib in two major and a few smaller studies. However, other authors have not confirmed this observation. In a recently issued statement of the ELN, any recommendations on IPL have been implemented. *Aims.* In order to analyze the impact of IPL measurement on treatment results we have introduced the determination of IPL into our laboratory follow-up of CML patients in 2007. All patients have signed informed consent before blood sampling. *Methods.* Samples were obtained at routine clinical check-ups. IPL were measured by ultra-performance liquid chromatography-tandem mass spectrometry assay using UHPLC UltiMate 3000 RS (Dionex, USA) coupled with the API 4000 tandem mass spectrometer (Applied Biosystems, USA). The actual sample was eligible for analysis providing patient had been treated with imatinib for at least 18 months allowing evaluation of cytogenetic and molecular response, there was no other evident cause of the suboptimal response or failure and the sample was taken at least one month after initiation of treatment and between 24±6 hours after the ingestion of the drug. Other medication, the actual duration of the therapy, time interval between the dose and the meal ingestion, weight, body-mass index, body surface area or co-morbidity of the patients were not taken into the account. Patients pretreated with interferon were analyzed separately. Statistics were done using Spearmans correlation analysis and Mann-Whitney U-test. *Results.* 553 samples from 112 patients with CML (45 women, 55 of them pretreated with interferon) were available for analysis. Median age of patients was 56 years (range: 22-81) follow-up was 72 months (range: 18-236). 81 % of patients achieved complete cytogenetic and 58 % major molecular response. Despite significant correlation between imatinib dose and IPL CC=0.336; P<0.001 there was no significant correlation between IPL and probability of achievement of optimal cytogenetic or molecular response (at 12 and 18 months, respectively). We found high IPL inter-individual variability (log-norm distribution of data) in the range 394-3133 mg/l (min-max, outliers excluded, n=86, 24±1 hours after 400 mg dose) and intra-individual variability (CV) between 14.2 and 43.3 % (n=82, 24±2 hours after 400 mg dose). In two patients with low IPL (<900 ng/mL) dose escalation led to IPL increase (>2000 and >1400 ng/mL) and substantial improvement of treatment response. *Conclusions.* We were not able to demonstrate a clear correlation between IPL and response to imatinib therapy in our group of patients with CML. We believe that this is caused by differences in patients' compliance, leukemia biology and other variables that are difficult to eliminate in the routine clinical praxis. On the other hand in rare selected patients with low IPL and suboptimal response we were able to demonstrate that escalation of imatinib

dose lead to optimal treatment response. *Acknowledgement.* The work was supported by grants NS9627-3, NS9949-3 (Ministry of Health, the Czech Republic), MSM 6198959223 and MSM 6198959205 (Ministry of Education, Youth and Sports, the Czech Republic).

ADDITIONAL CHROMOSOME ABERRATIONS IN CHRONIC MYELOID LEUKEMIA PATIENTS UNDERGOING TYROSINE KINASE INHIBITORS THERAPY

L Neverova, A Zakharova, A Udovichenko, A Turkina, N Khoroshko, G Alimova, I Kleina, L Dyachenko, M Konnova, N Timofeeva, T Obukhova, E Aseeva, O Vinogradova, O Kremenetskaya, E Domracheva

National Center for Hematology, Moscow, Russian Federation

Background. Variety of additional chromosome aberrations (ACA) is detected in chronic myeloid leukemia (CML) patients, but their influence on achieving cytogenetic response and disease prognosis is not clear. *Aims.* The aim of the present study was to detect frequency of different ACA in CML patients undergoing treatment with tyrosine kinase inhibitors and to estimate their influence on achieving cytogenetic response. *Methods.* We present a retrospective study based on 1060 patients treated for CML with inhibitors of tyrosine kinase (ITK) at National Research Center for Hematology. We performed conventional cytogenetic analysis and interphase fluorescence *in situ* hybridization (FISH) with probes LSI BCR/ABL, CEP 8, LSI 7q31/CEP 7. *Results.* ACA in Philadelphia chromosome-positive (Ph+) cells were detected in 207 patients (see the Table). At diagnosis we detected 4 cases of variant translocations and 37 cases of complex translocations involving three or four chromosomes. BCR/ABL gene in 94-100% of cells was detected in all cases. Ph-chromosome duplication was the most frequent ACA in Ph^+ cells. ACA didn't influenced significantly the disease prognosis but 35% of patients with ACA achieved major cytogenetic response (MCR) and complete cytogenetic response (CCR) later than patients without ACA: at about 12 and 24 months from the beginning of ITK treatment. In some complex karyotypes with multiple chromosome abnormalities Ph-chromosome was masked or detected in small amount of cells, but BCR/ABL gene was detected in the majority of cells. For example in case 1 karyotype 46XX, del(X)(q27), t(14;22)(p11;q11), der(9), del(8)(q27), 16p+ [20] / 46XX, t(9;22)(q34;q11) [5] showed 20% of Ph+ cells but FISH detected BCR/ABL gene in 85% of cells; in case 2 karyotype 53-56 XXY,+8,+8,+12,+15,+18,+19,+20,+21,+21, der(21), t(21;22)[25] showed absence of Ph+ cells but FISH detected BCR/ABL in 100% of cells. All cases of complex karyotypes were associated with blast crisis phase. We report two cases of dicentrics from Ph-chromosome. Patient with karyotype 47XY t[9,dic(22), +dic(22)(22pter-q11;q11-22pter)][25] showed 100% BCR/ABL-positive cells; he achieved CCR 6 months after starting nilotinib as a second line therapy. In case with karyotype 47XY, t[9,dic(22), +dic(22)(22pter-q11;q11-22pter)] [16] / 46XY, t(9;22)(q34;q11) [14] / 46XY [4] FISH detected 85% of BCR/ABL-positive cells, 40% of cells demonstrated BCR/ABL gene amplification. Escalating dose of imatinib to 800 mg reduced the amount of BCR/ABL-positive cells to 30%. ACA in Ph- cells were detected in 110 patients (see the table) in different periods after achieving MCR and CCR: Size of Ph™clones with ACA ranged from 0% to 100% and wasn't associated with treatment response and disease progression.

Table. Types of ACA detected in Ph+ and Ph-cells.

ACA in Ph-positive cells	number of cases	frequency, %
sum total	207	19,53
variant translocations	4	0,37
complex transloc. involving 3-4 chromosomes	37	3,49
+ Ph-chromosome	42	3,96
trisomy 8	32	3,02
inv (9)	21	1,98
-7 / del (7q)	11	1,04
-17 / i(17)(q10)	10	0,94
X or Y abnormalities	10	0,94
inv (3) / dup(3p)	5	0,47
- 21 / +21 / del (21q)	6	0,57
aneuploidy of other chromosomes	11	1,04
complex karyotypes	18	1,70

ACA in Ph-negative cells	number of cases	frequency, %
sum total	110	10,38
trisomy 8	32	3,02
-7 / del (7q)	10	0,94
-17 / i(17)(q10)	9	0,85
X or Y monosomy / deletion	9	0,85
inv(3)/dup(3p)	5	0,47
- 21 / del(21q)	4	0,38
aneuploidy of other chromosomes, rare translocations like t(14:22)(p11:q11), t(15:21)(q21:q21) and other abnormalities	41	3,87

Conclusions. 1. Ph+cells with ACA were detected in 20,28% of patients, Ph-ells with ACA in 10,38%. 2. 35% of patients with ACA in Ph+clones achieved MCR and CCR later then patients without ACA. 3. ACA in Ph-clones didn't influence clinical outcome. 4. Two patients with dicentrics from Ph-chromosome showed MCR and CCR on ITK therapy.

Seràgnoli S.Orsola Malpighi Hospital, Bologna, Italy; [7]Dept. of Hematology/Oncology, Universitätsklinikum Jena, Jena, Germany; [8]Div. of Hematology, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, South-Korea

Background. Resistance to imatinib can occur in chronic myeloid leukemia (CML). Mutations in BCR-ABL kinase domain have been known as the clinically most relevant mechanisms of imatinib resistance. Several studies have shown that 40~80% of the imatinb resistant patients have BCR-ABL kinase domain mutations. However, there has not been much information about mutation status in CML patients with suboptimal response to imatinib. From Tyrosine Kinase Inhibitor Optimization and Selectivity (TOPS) study which investigates efficacy of imatinib 400 mg daily and 800 mg daily with Philadelphia positive CML CP patients, relationship between various responses and emergence of mutation was investigated by both standard and highly sensitive mutation assays. *Aims.* As a clinical correlative study (CCS) program with samples from TOPS study, we analyzed BCR-ABL mutation from patients with suboptimal response or treatment failure to imatinib in order to investigate their mutation status. *Methods.* Suboptimal responders and treatment failures were selected based on European Leukemia Net (ELN) 2009 guideline. CML patients' samples from the TOPS study were collected at particular time points after initiation of imatinib treatment and stored as cryopreserved cells or isolated RNAs in four regional referral laboratories. Mutations in BCR-ABL kinase domain were analyzed using direct sequencing and allele-specific oligonucleotide (ASO)-PCR.

Table. Mutation status of patients.

Response	Base line	6 months		12 months		18 months	
		mutation	Pt	mutation	Pt	mutation	Pt
Optimal		1 (5%)	21	0 (0%)	8	0 (0%)	3
Suboptimal		1 (14%)	7	1 (13%)	8	2 (50%)	4
Failed		1 (20%)	5	6 (38%)	16	4(100%)	4
Total Pt (n=104)	31	33		32		8	

Results. We analyzed total 104 samples collected from 51 patients at different time points including diagnosis, 6 months, 12 months and 18 months after initiation of imatinib treatment. All patients were in CP. We found ten BCR-ABL kinase domain point mutations including G250E, Y253H, T315I, and D444Y in 4 patients. In addition, we also found other mutations including 35 base pair insertion between exon 8 and exon 9 of ABL, and deletion of exon 7 of ABL in other 8 patients. No mutation was found from the patients' samples collected at diagnosis. At 6 months, mutation was found 5% (1 of 21), 14% (1 of 7) and 20% (1 of 5) patients in optimal response, suboptimal response and treatment failure group, respectively. ASO-PCR revealed that one patient in optimal response group had T315I. The same mutation status of the patient maintained at 12 months and the patients showed treatment failure at 12 months. At 12 months, mutation portion was 0% (0 of 8), 13% (1 of 8) and 38% (6 of 16) in optimal response, suboptimal response and treatment failure group, respectively. At 18 months, 50% (2 of 4) of suboptimal molecular responder and 100% (4 of 4) of no CCgR group showed mutations. Conclusions. Patients with suboptimal response or treatment failure showed much higher chance

of BCR-ABL point mutation, 35 base pair insertion or exon 7 deletion in comparison with optimal responders, suggesting that mutation screening is important for patients with suboptimal response as well as treatment failure on the basis of ELN guideline. Highly sensitive ASO-PCR provided early detection of point mutation in BCR-ABL kinase domain. However, clinical relevance of low level mutant clone, 35 base pair insertion and exon 7 deletion require long-term follow up for better understanding.

Background. The Charlson comorbidities index (CCI) is a list of 19 conditions (including cardiologic, pulmonary diseases, diabetes, etc) with a weight assigned from 1 to 6, derived from relative risk estimates of a proportional hazard regression model using clinical data. *Aims.* We retrospectively evaluated the weight of CCI in a cohort of 125 elderly (> 60 years) chronic phase chronic myeloid leukemia (CP-CML) patients receiving dasatinib after imatinib resistance or intolerance. *Methods.* Score point 0 was assigned to 65 patients, whereas a score point >1 was assigned to 60 patients (35 patients =1, 19 patients= 2; 5 patients= 3; 1 patient= 4). Fifty-two patients received 70 mg twice daily and 56 patients received 100 mg once daily, in accordance with the results of the phase III trial, whereas 17 patients started with a dose less than 100 mg. *Results.* We found a significant association between CCI and drug reduction or suspension rate: during dasatinib treatment 49% of score 0 patients experienced a reduction of the dose compared to 63% of patients with score 1, 74% of patients with score 2 and 100% of patients with score 3 and 5 (P=0.03). Of the 65 patients with score 0, 29% had at least one suspension (79% for haematologic and 21% for non-hematologic toxicity, respectively), compared to 46% of patients with score 1 (37% for hematologic and 69% for non-hematologic toxicity), 58% of patients with score 2 (36% for hematologic and 64% for non-haematologic toxicity) and 100% of patients with score 3 and 4 (all patients for both types of toxicity) (P=0.003). Forty-one patients (32.8%) experienced pleural effusion during treatment: of these, 17 patients (26%) had score = 0, 13 patients (40%) score=1, 8 (42%) score=2 and 3 (60%) had score 3-4 (P=0.002). More pleural effusions occurred in patients who had score > 0 and who received higher dasatinib dose (140 mg). Nine patients experienced grade 3 and 31 patients grade 1-2 effusions: although the incidence of this event correlated with CCI stratification and dose received, its severity did not show the same correlation. *Summary.* In conclusion, in elderly CML patients treated with dasatinib, the rate of drug reduction or suspension and the incidence of pleural effusions seem to be associated with the presence of comorbidities: the stratification according to CCI pre-dasatinib therapy may allow to identify patients at risk to have major toxicities.

Chronic myeloid leukemia - Clinical 3

LOW DOSE CONTINUOUS THERAPY WITH DASATINIB SIGNIFICANTLY IMPACT ON SURVIVAL OF PATIENTS WITH CHRONIC MYELOID LEUKAEMIA (CML) RESISTANT OR INTOLERANT TO IMATINIB. RESULTS FROM A REAL LIFE-BASED ITALIAN MULTICENTER RETROSPECTIVE STUDY ON 114 UNSELECTED PATIENTS.

Background. Dasatinib is effective in treating chronic myeloid leukemia (CML) patients resistant/intolerant to imatinib. To date, most of the data come from clinical trials on selected patients. Thus, studies based on real life are opportune. *Aims.* The aim of the study was to evaluate the safety and efficacy of Dasatinib as second line therapy for patients with CML either resistant or refractory to imatinib outside from clinical trials or compassionate use. Patients and *Methods.* 114 unselected CML patients resistant/intolerant to imatinib received dasatinib as second line therapy outside from clinical trials. All patients had chronic phase (CP-CML). Sokal score was low for 29, intermediate for 44 and high for 41 patients, and they were either resistant (n=88) or intolerant (n=16) or resistant and intolerant (n=10) to imatinib therapy. All patients were evaluated for hematologic, cytogenetic and molecular response, discontinuation/dose reduction of Dasatinib, event-free survival (EFS) and overall survival (OS). Moreover, we analyzed toxicities according to NCI-CTC, focusing on grade III-IV toxicities. *Results.* At 12 months, cumulative incidences of complete hematologic response, complete cytogenetic response (CCyR) and major molecular response were 94%, 55%, and 35%. Cumulative event-free survival (EFS) and overall survival (OS) were 91 and 93%. Noteworthy, we did not observe any survival difference between patients with low, intermediate or high Sokal score (P=0.4). We did not found any association between the dose of prior imatinib (400, 600 or 800) and the probability of achieving CCyR at 1 year with dasatinib (P=0.7). Furthermore, we did not found any association neither between the duration of the previous treatment with imatinib and the probability of achieving CCyR at 1 year with dasatinib (P=0.9). Nevertheless, we did not observe any difference between patients who received imatinib for more than 3 years with respect to those receiving it for less than 3 years (P=0.9). Finally, we did not observe any association between best response to imatinib and probability of achieving CCyR after 1 year with dasatinib (P=0.8). As a matter of fact, we observed a statistically significant better outcome in term of both DFS (P=0.04) and OS (P=0.04) for the 54 patients who received dasatinib at lower doses continuously without interruption with respect to the 60 patients receiving higher doses but forced to discontinue the treatment due to grade III-IV toxicity. *Conclusions.* We confirm the safety and efficacy of dasatinib as second line therapy for patients with CML either resistant or refractory to imatinib even outside from clinical trials. This experience challenges the wisdom that dasatinib, a drug characterized by short half life, must achieve nearly continuous target inhibition via high dose therapy for maximal clinical impact. Further studies are warranted, in order to extend the use of low dose continuous dasatinib to real life patients potentially not eligible to receive high dose dasatinib.

IMATINIB MESYLATE INDUCES HIGH COMPLETE CYTOGENETIC AND MAJOR MOLECULAR RESPONSE RATES IN CHILDREN AND ADOLESCENTS WITH PHILADELPHIA CHROMOSOME-POSITIVE CHRONIC MYELOGENOUS LEUKAEMIA IN CHRONIC PHASE

F Giona,[1] MC Putti,[2] N Santoro,[3] E Gottardi,[4] S Ladogana,[5] C Micalizzi,[6] G Iaria,[7] C Consarino,[8] R Burnelli,[9] M Rea,[1] M Nanni,[1] C Messina,[2] D Diverio,[1] A Biondi,[10] A Pession,[11] G Saglio,[4] R Foà[1]

[1]Sapienza University, Rome, Italy; [2]University of Padua, Padua, Italy; [3]University of Bari, Bari, Italy; [4]University of Turin at Orbassano, Turin, Italy; [5]Casa Sollievo della Sofferenza Hospital, San Giovanni Rotondo, Italy; [6]Gaslini Research Institute, Genoa, Italy; [7]Azienda Ospedaliera Bianchi-Melacrino-Morelli, Reggio Calabria, Italy; [8]Azienda Ospedaliera Pugliese-Ciaccio, Catanzaro, Italy; [9]University of Ferrara, Ferrara, Italy; [10]University of Milano-Bicocca, Ospedale S. Gerardo, Monza, Italy; [11]University of Bologna, Bologna, Italy

Background. Imatinib mesylate (IM) has been established as first line treatment for children with Philadelphia-chromosome positive (Ph^+) chronic myeloid leukemia (CML). However, results from controlled trials in children are sporadic. Aim. This study was designed to evaluate the IM efficacy in Ph^+ CML patients in chronic phase (CP) aged <18 years at diagnosis, previously untreated or resistant to Interferon (IFN). *Methods.* According to prospective guidelines, pediatric patients with a diagnosis of Ph^+ CML in CP were treated with IM at a dosage of 340 mg/sqm/day. The informed consent was obtained in all cases. Data were reported to the study center on standardized forms by the treating physician. Specimen from peripheral blood and bone marrow were assessed by cytogenetics and by quantitative PCR for BCR-ABL transcript rates in central laboratories for standardized monitoring at three months intervals. *Results.* From March 2001 to May 2009, 29 Ph^+ CML patients in CP (12 female, 17 male; median age: 1110/12 years [range:36/12-1710/12 yrs]) were recorded from 8 Italian pediatric centers. Twenty-five patients had previously received hydroxyurea and 5 of them alpha-Interferon. IM was started in all patients, including 7 with an HLA identical sibling. The median dose of IM administered was 318 mg/m^2/day. Grade >2 toxicities were observed mostly beyond the first 6 months. Seven patients experienced grade 2-3 neutropenia (n=6) and/or thrombocytopenia (n=2). Eleven patients presented grade 3-4 isolated or combined side effects: vomiting (n=1), muscle pain (n=4), diarrhea (n=1), hepatitis (n=1), pancreatitis (n=1), bone metabolism alterations (n=4), impaired longitudinal growth (n=3). Three patients (10%) stopped IM because of severe toxicities (1 crossed to dasatinib, 1 underwent stem cell transplantation -SCT- and 1 in complete molecular response didn't received any treatment). Twenty-four of 25 (96%) evaluable patients achieved complete cytogenetic response (CCyR) after a median time of 6 months (range 3-12 months), one of them had a cytogenetic relapse after 33 months. One patient was lost to follow-up in CCyR. At month 12 after starting IM, all evaluable patients were in CCyR and 10/11 (91%)presented major molecular response (MMR, defined as <0.1% BCR-ABL). To reduce disturbances of bone metabolism and longitudinal growth impairment, 8 MMR patients are receiving IM at a same daily dosage for 3 weeks a month. Overall, 8 patients underwent SCT (6 from identical siblings, 2 of them in CCyR, and 2 from matched unrelated donors, 1 in partial CyR and 1 after a cytogenetic relapse) after a median time of 6 months (range 3-51 months). All patients are alive in MMR (8 after SCT, 1 in dasatinib, 1 without any treatment and 18 still receiving IM), after a median follow-up of 40 months. *Conclusions.* In our experience, IM induces high CCyR and MMR rates in CML children and adolescents in CP, like in adults. Side effects seem tolerable, as only 10% of the total cohort stopped imatinib. Moreover, IM treatment for 3 week a month seems to improve bone metabolism and longitudinal growth in the not yet outgrown patients, without impairment on the disease outcome.

0827

COMPLETE MOLECULAR RESPONSE IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA ON IMATINIB THERAPY

E Aksenova, E Chelysheva, A Krutov, I Soldatova, A Misiurin, O Vinogradova, G Gusarova, E Zakharova, M Sokolova, I Nemchenko, S Kuznetsov, O Lazareva, A Vorontsova, T Kolosheinova, L Kolosova, S Goryacheva, T Ivanova, A Turkina, N Khoroshko

Research Centre for Hematology, Moscow, Russian Federation

Background. Imatinib treatment in chronic myeloid leukemia (CML) patients leads to significant suppression of Ph^+-positive leukemia cells. Identification of patients with continuous and stable complete molecular response (CMR) defined by RQ-PCR opens a discussion of possible complete leukemia eradication. Aim. To analyze frequency and stability of CMR in early chronic phase (ECP) and late chronic phase (LCP) CML patients on imatinib therapy. *Methods.* We analyzed 863 peripheral blood samples in 2 groups of 184 chronic phase (CP) CML patients on imatinib therapy (dose 400-600 mg). 1st group: 78 ECP CML patients, median age 40 years (15-65), median time from diagnosis 50.8 months (5-99), imatinib started in median 2 (1-6) months after diagnosis. 10 of these 78 patients received imatinib combined with interferon alpha. 2nd group: 106 LCP CML patients with previous interferon alpha failure or intolerance, median age 41 years (9-68), median time from diagnosis 106.8 months (43-244). Imatinib started in median 35.5 months (12-143) after diagnosis. A standardized RQ-PCR with sensitivity 0.01% was performed 1-4 times a year (median 1.7). BCR-ABL expression results presented in international scale (IS) with samples quality approved by >1000 copies per reaction of control gene ABL. CMR dynamics was examined from 6th to 60th month therapy within 6 months intervals, patients number for every term was 20-45% from total number. *Results.* Frequency and duration of CMR in ECP and LCP CML patients were different (Table 1). In ECP group 21 (26.9%) of patients achieved CMR for the first time during 18 months of therapy: 10 (12.8%) and 11(14.1%) for 12th and 18th month of treatment consequently. CMR was achieved for 9 (90%) patients in the subgroup of 10 ECP patients receiving combination of imatinib and interferon alpha; 4 (40%) of them achieved CMR on 18th therapy month. Maximum percentage of CMR patients was observed on 30th therapy month - 21(79.2%) of 24 analyzed on that term, on the 60th therapy month later CMR rates lowered: 11 (33.3%) of 27 analyzed on that term. In LCP group most of the patients achieved CMR for the first time on 12th and 42nd month of treatment: 4(23.5%) of 17 and 7(22.6%) of 31 analyzed on that term consequently. Maximum percentage of CMR patients was observed on 18th month of treatment: 6 (54.6 %) of 11 analyzed on that term. *Conclusion*. The early start of imatinib therapy changes CMR achievement dynamics and enables the growth of CMR patients proportion and CMR duration in ECP CML patients. The decreasing number of CMR ECP patients after 30th therapy month possibly reflects the patients with the secondary resistance. Imatinib and interferon alpha combined therapy can increase the CMR patients proportion.

Table 1. Frequency and duration of CMR.

	ECP CML (n=78)		LCP CML (n=106)	
	n	%	n	%
Without CMR	39	50	65	57.50
With CMR	39	50	45	42.45
Continuous (stable) CMR	15	19.23	7	6.60

C-MYC SCORE IN CHRONIC MYELOID LEUKAEMIA: A NEW BIOLOGICAL MARKER OF DISEASE PROGRESSION

N Sadek

Medical Research Institute -Alexandria University, Alexandria, Egypt

Chronic myeloid leukaemia (CML) is a clonal myeloproliferative disorder characterized by the Philadelphia chromosome. The disease runs a chronic phase followed by an accelerated phase and ends by an acute blastic crisis. The mechanisms underlying disease progression include molecular events that involve the action of signaling pathways by BCR-ABL, resistance to apoptosis in both accelerated and blastic phases, differentiation blockade, decreased immune surveillance as well as drug resistance. C-myc is considered a key gene in many cancers, yet the clinical relevance of c-myc score in CML has not yet been investigated. The aim of the present study was to assess c-myc score and its value in predicting disease progression. Forty consecutive patients with CML were enrolled. Diagnosis was established by complete blood picture, bone marrow, leukocyte alkaline phosphatase score, RT-PCR for detection of BCR-ABL fusion gene. Risk stratification of patients was calculated using both scoring systems according to Sokal and Euro score. C-myc detection was carried out immunohistochemically on peripheral blood smears and scored according to Kyriakou. Patients in accelerated and blastic phase had a statistically significant higher mean c-myc score compared to those in chronic phase (t=6.09, P=0.000). Patients with Sokal stage 3 and high risk by Euro score had the highest c-myc score (F=19.57 and F=16.14, P=0.000 respectively). Those who transformed throughout the study period had significantly higher c-myc value (t=2.28,P=0.02). We established a cut-off value of c-myc score, accordingly patients scoring 300-350 had a better overall survival compared to those who scored 350-400. An inverse relationship was found between c-myc score and overall survival (r= -0.812,P=0.000) . Moreover, patients having a lymphatic blast crisis exhibited a significantly higher c-myc score compared to those in myeloid crisis (t=2.11,P=0.03). In conclusion, c-myc scoring could be a reliable marker of disease progression in CML. Its cut-off value is a good prognostic indicator of the blastic lineage and of overall survival. A new clinical scoring system incorporating c-myc score is envisaged.

Background. Mutations of the BCR-ABL kinase domain represent a frequent cause of Imatinib (IM) resistance in chronic myeloid leukemia (CML) patients (pts). Dasatinib (DS) is highly effective against the majority of BCR-ABL mutants detected in pts failing IM. However, little is known about the incidence of mutations in elderly CML pts resistant to IM and on their impact on response to DS in this setting. Aim and Methods. To evaluate the role of pre-DS BCR-ABL mutations, we analysed 81 pts aged >60 years who received DS for chronic phase (CP) CML resistant to IM. Forty-five pts (55.5%) did not display any BCR-ABL mutation, while 36 (44.5%) had one or more mutations. Twenty-four different mutations were detected in the 36 mutated pts, with 4 cases displaying multiple mutated clones. Most frequent mutations were: M244V (n=7), Y253H (n=4), F317L (n=3), F359V (n=5), M531I (n=3) and H396R (n=3). Overall, these 6 mutations represented 69% of all cases. V299L and T315I mutations insensitive to DS were detected in one case each. Results. The mutated and non-mutated groups were comparable for sex distribution, age at DS start, concomitant diseases, medications and cause of IM resistance. DS daily starting dose was higher in mutated pts (140 mg in 24 pts, 100 mg in 11 pts, < 100 mg in 1 pt) than in non-mutated ones (140 mg in 13 pts, 100 mg in 27 pts, < 100 mg in 5 pts). Consequently, the dose reduction rate, owing to toxicity, was higher in the mutated pts (26/36, 72% *vs.* 19/45, 42%; P=0.01). Final DS dose was almost identical in the two groups (mean dose: 90 mg in mutated and 100 mg in non-mutated), as was the percentage of pts that suspended therapy and the rate of adverse events (including pleural effusion). When considering best response to DS therapy, non-mutated patients did significantly better than mutated ones. Complete cytogenetic responses (CCyR) and/or major/complete molecular responses (MMolR and CMolR) were obtained in 24 of the 39 evaluable non-mutated patients (61.5%) and in 11 of the 35 evaluable mutated patients (31.5%) (P=0.02). The rate of primary resistance was higher in the mutated group (16/36 *vs.* 7/45, P=0.009), and even excluding the 5 pts with mutations unresponsive to DS (i.e. 3 with F317V, 1 with V299L and 1 with T315I), mutated pts had a lower CCyR/MolR rate (11/31 *vs.* 24/39, P=0.05) and more frequently displayed primary resistance (13/31 *vs.* 7/45, P=0.02). On the contrary, secondary resistance (4/36 *vs.* 0/45), severe toxicities (4/36 *vs.* 6/45) and suspensions due to other causes (2/36 *vs.* 5/45) did not significantly differ in the two cohorts. Summary. Our data suggest that BCR-ABL mutations account for roughly half of IM resistance in elderly CP-CML pts, a proportion similar to that found in the general population. In the elderly setting, however, presence of pre-DS BCR-ABL mutations seems to reduce optimal response to therapy, in terms of lower CCyR and MolR rates.

DYNAMICS OF CHRONIC MYELOID LEUKEMIA UNDER NILOTINIB THERAPY

D Dingli,[1] T Lenaerts,[2] F Castagnetti,[3] A Traulsen,[4] J Pacheco,[5] G Rosti[3]

[1]Mayo Clinic, Rochester, USA; [2]Université Libre de Bruxelles, Brussels, Belgium; [3]St Orsola University Hospital, Bologna, Italy; [4]Max Planck Institute, Plon, Germany; [5]Universidade do Minho, Braga, Portugal

Background. Understanding the molecular mechanisms behind the appearance and clonal expansion of BCR-ABL expressing cells in chronic myeloid leukemia (CML) has transformed therapy and prognosis for this disease. Rationally designed tyrosine kinase inhibitors such as imatinib and nilotinib lead to deep and durable responses and have reduced the risk of progression to blast crisis. Although the current standard of care is imatinib, nilotinib may give superior results with the advantage of efficacy in the presence of mutations that render imatinib inactive. *Aim.* In this work, we utilized serial quantitative estimation of BCR-ABL transcripts from patients with newly diagnosed CML and treated with nilotinib to understand the dynamics of the response and why responses with this agent are faster compared to imatinib. *Methods.* The GIMEMA group has conducted a Phase II trial of nilotinib in a cohort of 73 patients with early chronic phase CML (Rosti *et al.* Blood 114:4933, 2009). Serial quantitative RT-PCR data of BCR-ABL were recorded and fitted to a mathematical model of hematopoiesis that has been used to understand CML dynamics under imatinib therapy (Dingli *et al.*, Clin Leukemia 2:133, 2008, Lenaerts *et al.*, Haematologica, in press 2010). The model was fitted to the data using a non-linear least squares approach with constraints based on established observations. The fraction of cells responding to nilotinib and the effect of the drug on the behavior of CML progenitors was determined. *Results.* The fraction of CML cells responding to nilotinib is 2.4% which is lower than estimates for imatinib (4.6-5.0%). BCR-ABL expression enhances the self-renewal of progenitor cells. Comparison between Model and data suggests that nilotinib effectively reduces self-renewal propensity of treated compared to normal progenitor cells (epsilon_CML=0.72, epsilon_normal=0.84, epsilon_IMAT=0.9, epsilon_NIL=0.92). This results in a significant fitness disadvantage on the CML progenitor cells (f_CML=2.2, f_normal=1, f_IMAT=0.63, f_NIL=0.49), leading to their washout from hematopoiesis and a return to blood formation dominated by normal cells. *Conclusion.* The reduction in reproductive fitness of CML progenitor cells achieved with nilotinib is higher than what is

achieved by imatinib. This explains the faster and deeper response observed in patients with CML treated with nilotinib. By reducing the fitness advantage of CML cells, nilotinib enables Darwinian selection within hematopoiesis to effectively eliminate the leukemic population.

PROJECTING THE LONG-TERM SURVIVAL OF NEWLY DIAGNOSED PATIENTS WITH CHRONIC MYELOID LEUKEMIA (CML) IN CHRONIC PHASE (CP) RECEIVING NILOTINIB OR IMATINIB

F Botteman,[1] J Stephens,[1] J Coombs[2]

[1]Pharmerit North America LLC, Bethesda, USA; [2]Novartis Pharmaceuticals Corporation, Florham Park, NJ, USA

Background. The international randomized Phase III ENESTnd Trial has recently demonstrated that CML-CP patients who received nilotinib 300mg BID or 400mg BID experienced significantly higher rates of major molecular response (MMR) and complete cytogenetic response (CCyR) after 12 months than patients receiving imatinib 400 mg QD. In this head to head trial, significantly fewer patients on nilotinib progressed to accelerated phase or blast crisis (AP/BC) compared with imatinib (0.7% nilotinib 300 mg BID v. 3.9% imatinib [log-rank test of time-to AP/BC p-value is 0.0095], and 0.4% nilotinib 400 mg BID v. 3.9% imatinib [log-rank test of time-to AP/BC P=0.0037]). Survival prognosis in AP/BC is significantly worse compared with CP, thus preventing or delaying progression is expected to translate into survival gains. *Aims.* The present study modeled the survival of newly diagnosed CML-CP patients receiving first line therapy with nilotinib 300mg BID or imatinib 400 mg to infer long term outcomes. *Methods.* A three-state Markov model linking the rate of conversion from CP to AP/BC to mortality was developed to project the survival for a representative CML-CP patient enrolled in the ENESTnd trial (male, average age 47 years at treatment initiation). To project overall survival and conversion rates to AP/BC over time, a commonly used survival model (Weibull) was fitted to the 12-month Kaplan-Meier curve of transformation from CP to AP/BC from the ENESTnd trial. The model assumed that patients who have not progressed are not at risk for CML-related death but experience the age-specific mortality of the general population. Patients progressing to AP/BC were assumed to switch therapy to dasatinib 140 mg/day. These patients' survival was then simulated using data from published trial literature. *Results.* The Weibull model fit the data well: the sum of squared difference between the observed and predicted rates of progression at 3, 6, 9 and 12 months was 0.000958. The model-projected life expectancy for a representative newly diagnosed CP-CML patient was 22.76 years for imatinib. In comparison, the corresponding estimate was 31.59 years for nilotinib. This resulted in a projected survival improvement of 8.83 additional years for nilotinib compared to imatinib. To put these estimates in perspective, a 47-year old British man without CML would be expected to live approximately 32.56 years (source: 2008 UK Interim Life Tables). *Conclusion.* This long-term survival model projection based on the clinical trial data resulted in an estimated improvement in life expectancies for patients initiated on nilotinib 600 mg/day compared with imatinib 400mg/day as first line therapy for CML-CP. These projections require confirmation and validation through actual longer-term observations that are ongoing. The analysis suggests that the reduction in rates of progression to AP/BC observed in the ENESTnd trial with nilotinib as first line therapy will translate into survival gains over first-line therapy with imatinib. This analysis also suggests that the use of nilotinib may improve life expectancy of CML-CP patients close to the life expectancy of the general, age-matched population.

SECOND-GENERATION TYROSINE KINASE INHIBITORS TREATMENT CHANGES THE PROGNOSIS IN CML PATIENTS WITH ADDITIONAL PH-CHROMOSOME

A Turkina,[1] O Vinogradova,[1] A Voroncova,[1] E Aseeva,[2] A Zakharova,[2] S Kuznetsov,[1] E Domracheva,[1] N Khoroshko[1]

[1]National Research Center for Hematology RAMS, Moscow, Russian Federation, Moscow, Russian Federation; [2]National Research Center for Hematology RAMS, Moscow, Russian Federation

Introduction. Clonal evolution is defined as additional chromosomal abnormalities (ACA) in Ph-positive cells. Such karyotypic abnormalities were described more than 30 years ago and can be found in more than 70% patients in advanced disease stages. The most frequent ACA, the second Ph-chromosome, is associated with disease progression. The ACA in Ph-positive cells during imatinib treatment is associated with more rapid CML progression, while it's appearance in Ph-negative cells has no adverse prognostic impact, since 50”'75% such patients achieve major or complete cytogenetic response. The study goal. Estimate the possibility of clonal evolution supression at imatinib treatment with the help of second-generation tyrosine kinase inhibitors (TKI). Materials and *methods.* The complete blood counts, morphological and cytogenetic studies of bone marrow cells were done in 393 CML patients. The median follow-up is 94 months. *Results and discussion.* The ACA in Ph-positive cells were revealed by conventional cytogenetic study in 50 (13%) of 393 CML patients. The most frequent of them was the additional Ph-chromosome, found in 60% cases (30 of 50 patients). The majority of these patients was in chronic phase (16 patients), 6 “' in accelerated phase and 8 “' in blastic phase. Seventeen patients had additional Ph-chromosome alone, while 13 “' in association with other abnormalities: trisomy 8 (8 cases), del 7 or monosomy 7 (3 cases) and complex abnormalities (2 cases - in accelerated and blastic phase). There was evident male predominance (M:F=23:7). At the moment when additional Ph-chromosome was found the median age of our patients was 50 years (16”'61), the previous treatment duration (hydroxyurea, busulfan, 6-mercaptopurine, combined chemotherapy, interferon) was rather long (median 5 years). At present 43% (13 of 30) patients have died: 11% (2) in chronic, 50% (3) in accelerated and all 8 patients in blastic phase. The CML chronic phase patients are the most interesting from prognostical standpoint. The duration of imatinib treatment in 16 patients with additional Ph-chromosome varied from 6 months to 5,5 years. The follow-up duration of patients with additional Ph-chromosome varies from 26 to 176 months (median 107 months). All 16 patients have achieved complete hematological response after 3 to 6 months of imatinib treatment, but all patients receiving standard imatinib doses had primary cytogenetic resistance. Only 13% patients (2 of 16) have achieved cytogenetic response after escalation of imatinib dose to 600”'800 mg daily (CCyR - 1, PCyR - 1). Due to imatinib resistance 14 patients were switched to second-generation TKI (dasatinib - 10, nilotinib - 3, bosutinib - 1 patient). Three of these patients later progressed to accelerated phase; in 2 of them we have found T315I mutation. All of the 11 patients still in chronic phase have achieved complete hematological response; PCyR was found in 45%, and CCyR in 36% cases. Conclusion. The additional Ph-chromosome is associated with cytogenetic resistance to both standard (400 md daily) and high (600”'800 mg daily) doses of imatinib. The dose escalation was ineffective in the majority of cases. The second-generation of TKI allows to restore Ph-negative hematopoiesis, suppress the subclone with additional Ph-chromosome and achieve PCyR in 45% and CCyR in 36% patients. This approach should be tested in large-scale studies. The male predominance in patients with doubling of Ph-chromosome also needs further investigation.

0834

MEGAKARYOCYTIC BLASTIC PHASE (BP) OF CHRONIC MYELOID LEUKEMIA (CML) - A SINGLE INSTITUTION EXPERIENCE

M Baljevic,[1] H Kantarjian,[2] A Al Ameri,[2] F Ravandi,[2] G Borthakur,[2] A Quintas-Cardama,[2] E Jabbour,[2] S Pierce,[2] J Cortes[2]

[1]Weill Cornell Medical College in Qatar, Doha, Qatar; [2]Department of Leukemia, MD Anderson Cancer Center, Houston, USA

Background. BP transformation of CML with megakaryocytic phenotype is uncommon, accounting for <3% of all CML BP (Faderi S, Ann Intern Med. 1999;131:207-19). Megakaryocytic BP as initial manifestation of CML is even more rare, with few cases reported in the literature (Pullarkat S. Leuk Res. 2008 Nov;32(11):1770-5). CML-BP (including those with megakaryocytic transformation), carries a dismal prognosis, and successful therapeutic approach to this group of patients remains a clinical challenge (Kantarjian H, Blood. 2002;99:3547-3553). *Aim.* To evaluate the natural history, clinical characteristics, response to treatment and outcome of patients with megakaryocytic BP CML. *Methods.* Since 1965, 16 patients with the megakaryocytic BP were treated at MDACC (only 2 since 2000): 5 as initial presentation of CML and 11 as transformations of previous CML. Their medical records were reviewed to define their clinical, laboratory, and pathologic characteristics, as well as treatment and outcome. *Results.* Megakaryocytic BP represented 1.3% of all BP seen during this period. Median age of presentation was 50 years (range, 30 to 67). Splenomegaly ≥5 cm bellow costal margin was seen in 9 patients; 4 had extramedullary presentation in (bone, gastrointestinal tract, central nervous system, and subcutaneous, respectively); 8 had hemoglobin ≤10 g/L. The median WBC was 16.3 $\times 10^9$/L (range,

3.8 to 100), platelets 248×10⁹/L. (6 to 960). Bone marrow fibrosis ≥50% was seen in 7 patients; 9 had clonal evolution with wide range of complex chromosomal translocations. Molecular analysis was done on 3 patients who had 210kDa transcript detected, and only 1 patient had mutational analysis completed (NPM1 mutation detected, no abl kinase domain mutation). At the time of BP diagnosis, 2 patients received tyrosine kinase inhibitor (TKI)-based therapy (TKIs + chemotherapy), 6 received Ara-C + anthracyclins-based chemotherapy, and 8 had other forms of chemotherapy (including fludarabine, mitoxanthrone, decitabine, DHAD, and hydroxyurea). Subsequently, 7 patients received one, 6 patients received two and 3 patients received ≥3 salvage treatments. Fifteen patients were evaluable 4 weeks after the treatment: 6 had complete response, 9 had no response (including 2 early deaths). The median survival for the total population was 7 months, with 29% alive at 1 year, with no difference in outcome between patients with *de novo* presentation and those with transformation. *Conclusion.* Megakaryocytic BP of CML is a rare entity, with poor response to therapy and short median survival. Addition of TKI may improve the response.

0835

EFFICACY AND SAFETY PROFILE OF DASATINIB IN A SUBSET OF VERY ELDERLY PATIENS WITH CHRONIC MYELOID LEUKEMIA (CML) RESISTANT/INTOLERANT TO IMATINIB

Dasatinib is a second generation TK inhibitor active in CML resistant and/or intolerant to imatinib. Data on efficacy and safety profile in "very elderly"patients (age >75 yrs) are scanty. We studied 28 patients with CP-CML treated with dasatinib when aged >75 yrs at 16 Centers. Median age at diagnosis was 72.3 yrs (IR 62.8-83.9). Male/female ratio was 1.33 (M=16, F=12); Sokal risk was calculated in 20/28 cases (low risk n=4, intermediate n=12, high n=4). Twenty-four patients (85.7%) received a treatment before imatinib. Imatinib starting dose was 400 mg/day in 21 cases (75%) and median period of therapy was of 36.6 months (IR 2.8-71.3). Cause of imatinib failure was primary resistance in 15 patients (53.6%), secondary resistance in 11 (39.3%) and intolerance in 2 (7.1%). Median age at dasatinib start was 79.3 years (IR 75.0-76.5), with a median time from diagnosis of 76.4 months (IR 4.7 - 173.9). Eleven patients (39.3%) have received a second-line treatment after imatinib stop. Baseline BCR/ABL mutational status was evaluated in 11 cases: 4 displayed no mutation; 3 cases had M244V; M315T, E494G, V299L were present in 1 case each; 1 case presented M351T and F317L. Twenty-three patients had at least one co-morbidity, and median number of concomitant medicaments was 3.5 (IR 1-11). Dasatinib was started at 140 mg/day in 12/28 cases (42.8%), 100 mg in 8 (28.6%), ≥50 mg in 8 (28.6%). After a median treatment period of 18.1 months (IR 0.9-39.8), grade 3-4 toxicity was evaluated: 5/28 patients (17.8%) showed hematological toxicity (140 mg n=2; 100 mg n=1; 50 mg n=2); 11 (39.3%) extra-hematological toxicity (140 mg n=6, 100 mg n=2, 50 mg n=3). Seven patients (25%) presented serosal effusions (SE): WHO grade 1-2 in 5 cases (17.8%; 4 cases 140 mg, 2 cases 50 mg); grade 3-4 in 2 (7.1%) (1 case 140 mg, 1 case 50 mg). Sixteen patients (57.1%) underwent dose reduction: of the patients treated with 140 mg (n=12), 11 had a dose reduction *vs.* 5 reductions in the 16 cases receiving ≤100 mg (P=0.005). Nine patients discontinued dasatinib for ≤6 weeks, while 7 (25%) permanently discontinued therapy: 3 (10.7%) due to drug-related toxicity (n=1 with 100 mg and gastrointestinal toxicity; n=2 with 50 mg and SE, grade 2 and grade 3 respectively), 4 (14.3%) for emergency of a T315I mutation, after a median of 11 months of treatment. Response to treatment was assessable in 24/28 patients (85.7%): 14 (53.8%) had a cytogenetic response (CCyR in 9 cases, PCyR in 3 and minCyR in 2); of these, 5 attained also a molecular response. Nine patients (57.5%) reached at least a complete hematological remission. One case (4.1%) was resistant. The mean Overall Survival and Event Free Survival of the whole cohort were 24.2 and 14.3 months respectively. The present analysis shows that dasatinib may have a major role in the treatment of very elderly patients resistant/intolerant to imatinib; moreover dasatinib 100 mg showed great efficacy and a favorable safety profile in pretreated patients.

0836

IMPROVING EQUITY FOR CML PATIENTS: DESIGN AND IMPLEMENTATION OF REAL-TIME QUANTITATIVE PCR (RQ-PCR) ASSAYS FOR MONITORING RARE VARIANT BCR-ABL1 FUSIONS, AND CHARACTERISATION OF A NOVEL BCR-ABL1 FUSION

J Mason, C Bowles, S Akiki, M Griffiths

West Midlands Regional Genetics Lab, Birmingham, UK

Molecular residual disease (MRD) monitoring using quantitative techniques is the standard of care for chronic myeloid leukemia (CML) patients and is recommended by the European LeukemiaNet (Baccarani M. *et al*. J Clin Oncol 2009; 27(35):6041-51). Approximately 98% of CML patients have common e13a2 or e14a2 (formerly b2a2 or b3a2) BCR-ABL1 gene fusions, with breakpoints in introns 13 or 14 of BCR, and intron 1 (1a or 1b) of ABL1. Standardised protocols for real-time quantitative RT-PCR (RQ-PCR) designed within the Europe Against Cancer (EAC) program are widely used to monitor these common BCR-ABL1 fusion types (Gabert J. *et al*. Leukemia. 2003; 17(12):2318-57). Around 2% of CML patients have rare BCR-ABL1 fusions with breakpoints outside the typical regions. Such patients are usually monitored using 'end-point' nested RT-PCR which, being non-quantitative, does not permit comparison of disease levels between sequential samples. This can preclude early detection of molecular relapse via increasing MRD levels, and impending treatment failure, resulting in an essentially second rate service for these patients. It was our aim to develop RQ-PCR assays for every rare variant BCR-ABL1 fusion type encountered by our laboratory. We characterised rare BCR-ABL1 fusions detected by RT-PCR in thirteen of our CML patients by sequencing the variant transcripts. This enabled us to design RQ-PCR assays based on modified EAC protocols. Now validated, these assays are being used to provide a clinical service, meaning that every CML patient (n=>500) within our region has access to quantitative molecular monitoring. Twelve patients have rare variant BCR-ABL1 fusions that have been reported previously (e13a3 n=6, e14a3 n=5, e19a2 n=1). The final patient has a variant of a typical e13a2 fusion, with a rare exonic break in exon 13 which has the effect of removing the standard EAC RQ-PCR forward primer binding site. Full characterisation of this apparently novel BCR-ABL1 variant is presented. None of these rare variant fusions can be detected by the standard EAC RQ-PCR protocol, and would thus be missed if genetic diagnosis of CML is based on standard RQ-PCR alone.

0837

PROGNOSTIC SIGNIFICANCE OF HOCT1 GENE EXPRESSION IN CML PATIENTS IN CHRONIC PHASE TREATED WITH IMATINIB

T Sacha,[1] S Czekalska,[1] K Foryciarz,[1] M Zawada,[1] I Florek,[1] D Cwynar,[1] G Wator,[2] W Balwierz,[2] A Skotnicki,[1] A Skotnicki[1]

[1]Jagiellonian University Hospital, Kraków, Poland; [2]Children's Jagiellonian Uniwersity Hospital, Oncology and Hematology Department, Kraków, Poland

Background. The human organic cationic transporter 1 (hOCT1) is a membrane protein which actively transports imatinib (IM) into the CML cells. It was shown that its high expression and activity in mononuclear cells is associated with higher probability of major and complete cytogenetic response (CCyR) and major molecular response (MMR), while low expression could be the cause of resistance to standard dose of IM. *Aim.* To evaluate the prognostic significance of hOCT1 expression in patients with CML-CP treated with imatinib. *Methods.* The expression of hOCT1 gene was measured by RQ-PCR in WBC obtained from 55 patients with CML-CP after informed consent was signed (45 pts resistant to standard dose of IM and 10 who achieved complete molecular response (CMR). hOCT1 expression was defined according to Wang LH *et al.* with the baseline of 181 arbitrary units

(a.u.) with the level of hOCT1 expression in CEM VBL 100 cell line kindly provided by Dr Wiliam T. Beck arbitrally defined as 1,0 a,u. In IM resistant patients direct sequencing was used to detect ABL kinase domain point mutation. The treatment failure, CHR, CCyR, MMR and CMR were defined according to the ELN guidelines criteria (Baccarani, J.Clin.Oncol., 2010). *Results.* In IM resistant pts the hOCT-1 expression (0,09-179, median: 63 a.u.) was low in 38% (17/45). 17 out of 28 resistant patients with high hOCT1 expression (191-23010, median: 596 a.u.) were available for mutation analysis. ABL mutations were detected in 4 patients (23,5%; 4/17) (2 mutations resistant to IM; 1 - sensitive to IM; 1 - sensitivity unknown). The expression of hOCT1 was high (516-1045, median: 617 a.u.) in all 10 patients who achieved CMR. Within the group of patients with high (>181 a.u) hOCT1 gene expression the difference between number of patients who achieved CMR and no responders was not statistically significant (P=0,8). Within the group of patients with low (<181 a.u) hOCT1 gene expression the difference between number of patients who did not respond to IM and achieved CMR was statistically significant (P=0,025). Patients with resistant mutations to IM were excluded from the analysis. Low hOCT1 expression seemed to be the cause of resistance to standard dose of imatinib in 28,9% of patients (13/45) as no other resistance predictor was identified. The probable cause of treatment failure in 2 patients with high hOCT1 expression was the presence of ABL gene point mutation resistant to imatinib. In remaining patients with high hOCT1 expression the mechanism of resistance was unknown. Expression of hOCT1 was high in all patients with CMR. *Conclusions.* hOCT1 gene expression analysis using RQ-PCR is convenient and clinically available. Our data suggest that the analysis of hOCT-1 gene expression more likely identifies poor responders to IM (with low hOCT expression); however if it is high the method seems to be insufficient to identify good responders.

IMATINIB IN THE FIRST LINE CHRONIC MYELOID LEUKEMIA (CML) TREATMENT. CAN WE COMPARE THE REAL-LIFE DATA TO CLINICAL TRIAL RESULTS?

D Zackova,[1] H Klamova,[2] L Dusek,[3] J Muzik,[3] B Dobesova,[1] J Rysava,[2] Z Racil,[1] M Doubek,[1] D Dvorakova,[1] T Jurcek,[1] F Razga,[1] J Moravcova,[2] K Machova Polakova,[2] J Rulcova,[2] P Cetkovsky,[2] J Mayer[1]

[1]Dept. of Internal Medicine and Hemato-Oncology, Univ. Hospital and Masaryk Univ., Brno, Czech Republic; [2]Institute of Hematology and Blood Transfusion, Prague, Czech Republic; [3]Institute of Biostatistics and Analyses, Masaryk Univ. Brno, Brno, Czech Republic

Background. Imatinib (IM) substantially changed management of the CML and dramatically improved its prognosis, particularly in patients diagnosed in chronic phase (CP). The most robust source of data about the efficacy of IM in the first line CP-CML treatment is the IRIS trial. The data from real-life are still scarce. *Aims.* To evaluate the efficacy of IM in the first line treatment of a consecutive unselected population of CP-CML patients and to compare the real-life data to those obtained in clinical trials. *Methods.* We analyzed data about the 1st CP-CML patients from the defined region collected into the database called INFINITY (tyrosine kinase Inhibitors iN the FIrst aNd followIng CML Treatment). The evaluation of treatment responses was based on the valid definitions and recommendations according to European LeukemiaNet. We assessed rates and the cumulative incidences of complete hematologic responses (CHR), complete cytogenetic responses (CCyR), major (MMR) and complete molecular responses (CMR), and a comprehensive set of time-to-end points: overall (OS), transformation-free (TFS), progression-free (PFS), where progression was defined as in the IRIS, event-free (EFS), where also loss of CCyR, failure to achieve of particular response at the defined time-point and IM discontinuation due to toxicity were included, and our original point: an alternative treatment-free survival (ATFS), reflecting the real proportion of patients staying on IM despite of event. Among others we evaluated also tolerability of IM. *Results.* A total of 152 patients (median age 55 years, 20-77; 69 males and 83 females) treated with IM between 2003 and 2009 underwent the analysis. The median follow-up on IM treatment was 31.2 months (5.7-68.1). At 4 years, the cumulative incidences of CHR, CCyR, MMR and CMR were 95.3%, 80.6%, 65.4% and 39.2%, respectively. Overall response rates were as follows: 95.4% of CHR, 74.3% of CCyR, 57.2% of MMR and 24.3% of CMR. Estimated OS, TFS, PFS, EFS and ATFS at 4 years were 91.5%, 88.4%, 78.1%, 60.7% and 67.6%, respectively. In total, non-hematological and hematological toxicities of all grades occurred in 78.3% and 62.5%, respectively. However, in a majority of cases it was mild to moderate, with only 8.5% and 12.5% of gr. 3/4 of non-hematological and hematological toxicities, respectively. In total, 36 patients (23.7%) permanently discontinued imatinib after a median of 16.1 months (1-51) from various reasons: allogeneic stem cells transplantation (alloSCT) (n=4), IM intolerance (n=9), failure (n=7), failure + intolerance (n=1), progression (n=7), progression + failure (n=8). In total, 35 (23%) patients were given on alternative treatment, mainly on dasatinib (n=21). There were 7 deaths in total (4.6%); 3 patients died due to CML progression. Summary. We confirmed very good efficacy and tolerability of IM also in the cohort of patients treated outside of clinical trials in experienced specialized centers. However, with more appropriate definition of events in calculation of EFS, the overestimation of time-to-event analysis in IRIS trial is obvious.

EFFICACY OF IMATINIB MESYLATE ON CHRONIC PHASE CML PATIENTS ACCRUED IN THE SCREEN MULTICENTER STUDY: INTERIM REPORT ON THE FIRST 193 CASES

F Stagno,[1] P Vigneri,[2] S Stella,[2] A Cupri,[1] M Massimino,[2] V Del Fabro,[1] C Consoli,[1] A Branca,[1] A Antolino,[3] V Abbadessa,[4] M Brugiatelli,[5] C Musolino,[4] P Guglielmo,[6] M Russo,[7] G Pagnucco,[8] F Morabito,[9] L Levato,[9] M Rizzo,[9] M Musso,[10] B Martino,[9] D Turri,[11] A Messina,[2] F Di Raimondo[1]

[1]Hematology Section, Ferrarotto Hospital, Catania, Italy; [2]General Pathology Section, Dept.of Biomedical Sciences, Catania, Italy; [3]Department of Transfusional Medicine, Ragusa, Italy; [4]Division of Hematology, Policlinico, Palermo, Italy; [5]Division of Hematology, Papardo, Messina, Italy; [6]Division of Onco-Hematology, Garibaldi, Catania, Italy; [7]Division of Hematology, San Vincenzo, Taormina, Italy; [8]Division of Hematology, Civico, Palermo, Italy; [9]Division of Hematology, Cosenza, Italy; [10]Division of Hematology, La Maddalena, Palermo, Italy; [11]Division of Hematology, Cervello, Palermo, Italy

Background and Aims. Imatinib mesylate (IM) has shown unprecedented effectiveness for the treatment of Chronic Myeloid Leukemia (CML) patients (pts) in the chronic phase of the disease. However, while most individuals achieve an optimal response to IM therapy, approximately 20% either fail IM or obtain an unsatisfactory suboptimal response. We analyzed the outcomes of all CML pts accrued to the observational SCREEN (Sicily and Calabria CML REgional ENterprise) multicenter study to evaluate the hematological, cytogenetic and molecular responses of this unselected population to IM according to the 2006 European Leukemia Net criteria. Patients and *Methods.* Although the study is still ongoing, 193 consecutive CML pts, after informed consent, have been enrolled in approximately five years by all the institutions involved. Each center was responsible for the diagnosis, treatment (IM 400 mg qd) and follow-up of the recruited pts, while all molecular analyses were centralized in Catania. Median follow-up time was 22 months. Pts characteristics were as follows: Age (median yrs): 54 (range 24-90); Sex (M/F): 108/85; WBC×10^9/L (median): 64.8 (range 3.4-718.0); Hb (g/dL): 12.1 (range 7.5-17.0); PLT×10^9/L (median): 330.0 (range 67.0-1690.0); Organomegaly %: 58; Sokal risk stratification %: 49 Low / 36 Intermediate / 15 High; Ph+ (mean % diagnosis): 96; ACA (% diagnosis): 7; BCR-ABL transcript variants %: 38, e13a2 / 53, e14a2 / 18, other; BCR-ABL IS % (median at Dx): 58.454. *Results.* Interim analysis was performed on an Intention to Treat basis. Currently 15 pts (7.7%) are off study. Cumulative incidences of complete hematologic response (CHR) and complete cytogenetic response (CCyR) were 98.3% and 84%, respectively. 58% of pts who obtained a CCyR also achieved a major molecular response (MMR). According to the ELN criteria, 121 pts (62.6%) presented an optimal response to IM; 36 pts (18.6%) had a suboptimal response (9 because of failure to achieve a CCyR by 12 months of therapy and the remaining 27 because of lack of a MMR after 18 months); 32 pts (16.5%) presented resistance to IM, because of either primary (20 pts) or secondary (12 pts) resistance. Only 4 pts were intolerant to IM. Interestingly, the median amount of BCR-ABL transcript at diagnosis (measured according to the International standardized Scale) displayed by pts that failed IM or achieved a suboptimal response (105.2 IS) was significantly higher than that of pts obtaining an optimal response (53.4 IS; P<0.001). *Conclusions.* In conclusion, IM was a highly effective and well-tolerated treatment for most chronic phase CML pts, producing high rates of CHR, CCyR and MMR. However, 35% of patients treated with IM either failed the drug or attained only partially satisfying results (suboptimal response). High levels of BCR-ABL transcript at diagnosis might allow a rapid identification of this less responsive CML patient population.

CONCOMITANT BCRP OVER-EXPRESSION AND FLT3-ITD MUTATION IDENTIFY A SUBSET OF ACUTE MYELOID LEUKEMIA PATIENTS AT HIGH RISK OF RELAPSE

M Tiribelli,[1] D Damiani,[1] A Geromin,[1] A Michelutti,[1] M Cavallin,[1] A Pianta,[2] D Fabbro,[2] A Candoni,[1] E Toffoletti,[1] M Cerno,[1] L Marin,[1] G Damante,[2] R Fanin[1]

[1]Division of Hematology and BMT, Udine, Italy; [2]Institute of Genetics, Udine, Italy

Background. Over-expression of different multidrug resistance (MDR) - related proteins in acute myeloid leukemia (AML) cells is associated with clinical resistance to chemotherapy and, consequently, treatment failure. Among MDR proteins, breast cancer resistance protein (BCRP, or ABCG2) is associated with a worse prognosis in AML patients. Another well-known prognostic factors is mutation of FLT3 gene, as patients with internal tandem duplication (ITD) mutation display a worse outcome. *Aims.* Test the role of BCRP and FLT3 on disease outcome and the correlations between these two factors. *Methods.* We analysed 118 cases of adult AML patients, homogeneously treated with a fludarabine-based induction therapy and two consolidation courses with cytarabine and idarubicine. Results. BCRP was over-expressed in 56/118 (47%) patients, and FLT3-ITD mutation was found in 33/118 (28%) cases. A significant correlation was found between BCRP positivity and FLT3 mutation, with 23 ITD in 56 BCRP-positive cases (41%) compared to 10 ITD in 62 BRCP-negative patients (16%) (P=0.004). After induction therapy, 78 patients (66%) attained a complete remission (CR). CR rate was negatively affected by FLT3-ITD mutation (P=0.02) but not by BCRP expression (P=0.13). Conversely, BCRP status had a strong impact on disease-free survival (DFS), with 18 relapses in 41 $BCRP^+$ cases (44%) and 8 relapses in 37 BCRP- patients (22%) (P=0.03). FLT3 mutation did not have an impact on relapse rate (P=0.14) when considered alone, but its negative effect on DFS was additive to BCRP over-expression, as $BCRP^+/FLT3^+$ patients had a highest relapse rate (10/19, 53%), compared to $BCRP^+/FLT3^-$ (8/22, 36%) and BCRP- cases, independently of FLT3 status (8/37, 22%) (P=0.04). Overall survival (OS) was affected by BCRP status (P=0.04), but not by FLT3 mutation (P=0.6). FLT3-ITD positivity did not significantly impact on OS in $BCRP^+$ patients, but this can be due to the high transplant rate in our population (70/118 patients were transplanted, 60%). BCRP and FLT3-ITD have a different impact on AML prognosis, as the first negatively affects DFS while the latter reduces CR rates, but the two factors are often co-expressed and $BCRP^+/FLT3^+$ patients display a significantly higher relapse rate and shorter DFS, with FLT3 mutation having an additive effect in $BCRP^+$ cases. Summary. In conclusion, in our study the co-expression of high BCRP levels and FLT-ITD mutation identifies a subgroup of AML patients with worse prognosis, that can beneficiate of an aggressive, post-consolidation therapy (i.e. allogeneic transplantation).

A MECHANISM FOR INDUCTION OF APOPTOSIS FOLLOWING SHORT-TERM TYROSINE KINASE INHIBITOR (TKI) TREATMENT: INTRACELLULAR RETENTION OF TKI RESULTS IN PROLONGED CELLULAR TKI EXPOSURE AND INHIBITION OF KEY SIGNALING PATHWAYS

D Lipka,[1] MC Blum,[1] M Dsiadosz,[1] F Heidel,[2] T Fischer[1]

[1]Otto-von-Guericke-University Magdeburg, Magdeburg, Germany; [2]Children´s Hospital, Harvard Medical School, Boston, USA

Background. Small molecule tyrosine kinase inhibitors (TKI) have become a valuable tool in treatment of malignant disease. It has been widely accepted that continuous target inhibition *in vivo* is a prerequisite for successful TKI treatment. Surprisingly, administration of dasatinib once daily is clinically efficacious in CML despite transient target inhibition only and reappearance of BCR-ABL kinase activity after 24h. Recent data demonstrated that apoptosis is induced in BCR-ABL positive cells upon 2-4h incubation using dasatinib, whereas standard concentrations of imatinib were not effective in this setting. However, if high doses of imatinib are applied, one can also observe apoptosis upon short-term exposure. So far, the underlying molecular mechanism is unclear. *Aims.* Our study aims to elucidate the underlying molecular mechanism of induction of apoptosis upon short-term high-dose (HD) TKI treatment in hematopoietic cells dependent on oncogenic kinases. *Methods.* We employed cellular reconstitution models of hematopoietic Ba/F3 cells stably transfected with p190-BCR-ABL, and FLT3-ITD, respectively. Cells were incubated either with dasatinib or imatinib (BCR-ABL inhibition) or with PKC412 (FLT3-ITD inhibition) at three different dose levels (IC_{50}, IC80, HD) for 2-24h, followed by thorough washing steps. Cells were then incubated in medium without TKI. Upon a total incubation period of 24h, apoptosis was measured using flow cytometry and by Western blotting (caspase 3 cleavage). In parallel, inhibition of intracellular signaling pathways (pSTAT5, pERK) was determined by flow cytometry and Western blotting. To test for cellular retention of TKI, untreated cells were incubated with cell culture supernatant obtained after re-incubation of TKI treated cells for 2h in TKI-free medium. Again, apoptosis was measured at 24h and inhibition of signaling pathways was analyzed at various time points. Drug levels of imatinib in the cell culture supernatants before and after the washing procedures were determined by HPLC. *Results.* At the IC_{50} and IC80 TKI dose levels, a minimum incubation period of 16h was necessary to effectively induce apoptosis at 24h. However, using HD TKI (100 x IC_{50}) exposure for a period of 2h only was sufficient for induction of apoptosis. To test for possible cellular retention upon HD TKI treatment, we introduced additional washing steps and applied the supernatants to previously untreated cells. This analysis revealed: 1) Cells were completely rescued from apoptosis when additional washing steps were applied. 2) Supernatants induced high levels of apoptosis in previously untreated cells. To confirm that the nature of this effect is indeed cellular TKI retention, imatinib concentrations in cellular supernatants were monitored at various time points (0, 30, 60, and 120 min). This revealed a time-dependent dramatic increase in imatinib concentrations: 0 min: <0.2 μM; 30min: 0.71 μM, 60 min: 0.77 μM, 120 min: 0.82μM, while the IC_{50} has been determined as 0.25 μM in our assays. Additional studies employing imatinib plus PKC412 demonstrated that inhibition of MDR proteins is not responsible for this phenomenon. Summary/Conclusions. Together, our data derived from two tyrosine-kinase-mutant driven cell-models suggest that cellular TKI retention and consecutively prolonged inhibition of signaltransduction is the underlying molecular mechanism in short term HD TKI treatment.

0842

APOPTOTIC EFFECTS OF RESVERATROL ON IMATINIB SENSITIVE AND RESISTANT K562 CHRONIC MYELOID LEUKEMIA CELLS

Y Baran,[1] G Can[2]

[1]Izmir Institute of Technology, Faculty of Science, Dept.of Mol.Biol. & Genetics, Urla Izmir, Turkey; [2]Izmir Institute of Technology, Fac.of Science, Dept.of Mol.Biol.& Genetics, IZMIR, Turkey

Background. Chronic myelogenous leukemia (CML) is a white blood cell disorder characterized by high levels of immature white blood cells. CML results from translocation between chromosome 9 and 22 that generates BCR/ABL fusion protein. BCR/ABL protein has constitutive tyrosine kinase activity which has important roles in cell growth, differentiation and evasion of apoptosis. Imatinib is the first target specific chemotherapeutic agent that specifically binds to the ATP binding pocket of the BCR/ABL. However, as seen in several cases, resistance to imatinib is the major problem of CML patients. Resveratrol is a naturally produced phytoalexin that is mostly synthesized in red gapes. It has anti-oxidant, cardioprotective, anti-inflammatory, and more importantly anti-tumor activities. *Aims.* In this study, we aimed to examine antiproliferative and apoptotic effects of resveratrol on imatinib sensitive and imatinib resistant K562 chronic myeloid leukemia cells and determine the mechanisms of resveratrol-regulated cell death. *Methods.* $Philadelphia^+$ human K562 cells were exposed to step-wise increased concentrations of imatinib and 3 μM imatinib resistant cells were developed, and referred as K562/IMA-3. Antiproliferative effects of resveratrol were determined by XTT cell proliferation assay and IC_{50} values (drug concentration that inhibit cell proliferation 50% comparing to untreated controls) were calculated from cell proliferation graphics. Apoptotic effects of resveratrol on K562 and K562/IMA-3 cells were determined through changes in caspase-3 enzyme activity, loss of mitochondrial membrane potential, and apoptosis by caspase-3 colorimetric assay kit, JC-1 mitochondrial membrane potential detection kit, and Annexin V-FITC, respectively. On the other hand, expression profiles of BCR/ABL in response to resveratrol were analysed by RT-PCR. *Results.* IC_{50} value of resveratrol were calculated as 85 and 122 μM in K562 and K562/IMA-3 cells, respectively. Three different concentrations (10, 50 and 100 μM) were selected from cell proliferation plots for assessment of apoptotic activity of resveratrol. The results revealed that there were 1.91, 7.42 and 14.73-fold increases in loss of mitochondrial

membrane potential in 10, 50, and 100 μM resveratrol applied K562 cells comparing to untreated controls. The same concentrations of resveratrol resulted in 2.21, 3.30, and 7.65-fold increases in loss of mitochondrial membrane potential in K562/IMA-3 cells as compared to untreated K562/IMA-3 cells. Caspase-3 enzyme activity results showed that there were 1.04, 2.77, 4.8-fold increases in K562 and 1.02, 1.41, 3.46-fold in K562/IMA-3 cells increases in response to the same concentrations of resveratrol, respectively. Annexin-V apoptosis assay results validate both caspase-3 enzyme activity and mitocondrial membrane potential *Results.* There were 4 and 3.7-fold increases in apoptotic K562 and K562/IMA-3 cell populations in response to 100 μM resveratrol as compared to their untreated controls. RT-PCR results showed for the first time that resveratrol downregulated expression levels of oncogenic BCR/ABL gene in a dose-dependent manner in both imatinib sensitive and resistant K562 cells. *Summary/Conclusion*. Taking together all these results may suggest potential use of resveratrol in both from responding chronic phase CML and from patients with primary and/or acquired resistance to imatinib.

0843

A NOVEL AUTOMATED ASSAY FOR THE DETECTION OF BCR-ABL KINASE DOMAIN MUTATIONS

R Tanaka,[1] S Kimura,[2] T Hosomi,[3] M Hirai,[3] R Nagao,[1] M Takeuchi,[1] H Yao,[1] K Sakai,[1] H Hirai,[1] E Ashihara,[1] T Maekawa[1]

[1]Kyoto University Hospital, Kyoto, Japan; [2]Saga University, Saga, Japan; [3]Arkray, Inc., Kyoto, Japan

Background. Chronic myelogenous leukemia (CML) is caused by a consistent genetic abnormality, termed the Philadelphia chromosome (Ph). Imatinib mesylate (IM), now used as a standard first-line treatment of CML patients. However, resistance develops in a significant proportion of cases, and is predominantly mediated by single point mutations within the BCR-ABL kinase domain. Second generation TKIs such as dasatinib and nilotinib represent viable alternatives for IM-resistant or intolerant CML patients. Each mutated BCR-ABL has different sensitivity to those TKIs. Thus, it is significantly important to detect early the existence of BCR-ABL mutations and their specificities in treating Ph+ leukemia. *Methods.* We have developed a novel automated method that has high sensitivity to detection for a few copies of mutation sequences. This method is composed of PCR amplification step and Tm (melting temperature) analysis step that uses a quenching probe. When a whole blood sample or a purified DNA sample reacts with reagents, PCR and Tm analysis automatically processed in the same tube, and whole procedure finishes in approximately one hour. As Tm value of mutation sequence is higher than that of normal one, it is easy to detect the existence of mutation from the Tm analysis data. We have constructed the probes for 14 mutations concerned for IM-resistance (M244V, G250E, Q252H, Y253F, Y253H, E255V, E255K, T315I, T315A, F317L, M351T, E355G, F359V, and H396R). Considering the clinical significance of T315I mutation, which renders resistance to all currently available TKIs, we refined this method to higher sensitivity for detecting T315I mutation. *Results.* First, we analyzed the sensitivity of this system on BCR-ABL. In dilution assays, the system consistently quantified the mutation in a population containing as few as 3.0% mutant. Moreover, for T315I, we successfully detected as few as 0.3% (30 copies from 10,000 copies) mutations by a higher-sensitive assay. Next, we examined the clinical samples. Each sample was also examined by direct sequencing in comparison to our method. Kinase domain mutations were identified in 24 of the 50 (48%) patients. Our automated analysis was enabled to detect mutations in 19 patients, including p-loop mutations (G250E: n=3; E255K: n= 5), IM-binding domain mutations (T315I: n=10), and an activation-loop mutation (H396R: n=1). And all the positive cases showed a concordance with the result of direct sequencing. On the other hand, 5 cases were detected just by direct sequencing, but all that cases were out of setting mutations (Q252E, V379I, S417F, E459K). Impressively, in one case, only higher-sensitivity assay could reveal T315I mutation, although it was detected as a wild type both by direct sequence and our usual method. It suggests that the higher-sensitive system could detect low amount of T315I mutation in the earlier stage of disease. *Conclusions.* This rapid and accurate detection of clinically significant mutations enables us to contribute to better clinical practice in treating Ph+ leukemia patients, such as in selecting alternative strategies of IM dose escalation, second generation TKIs, or allergenic stem cell transplantation.

ANTI-ANGIOGENIC EFFECT OF RESVERATROL AND CURCUMIN THROUGH THE INHIBITION OF MICROVESSEL DENSITY, VEGF AND ITS RECEPTOR VEGFR-2 (FLK-1) IN EHRLICH ASCITES CARCINOMA-BEARING MICE

F El-Azab, H Hishe, Y Moustafa, E El-Awady

Suez Canal University, Ismailia, Egypt

Background. Large numbers of chemo-preventive phytochemicals (naturally occurring substances found in plants) have been shown to possess anticancer activities by targeting different aspects of cancer progression and development. Since angiogenesis is pre-requisite for the growth of solid tumors, vascular targeting has been explored as a potential strategy to suppress tumor growth and metastasis. *Aims.* The present study was carried out to investigate the anti-angiogenic effect of two phytochemicals, resveratrol or curcumin, when used alone or in combination with carboplatin in Ehrlich ascites carcinoma (EAC)-bearing Swiss mice. Microvessel density (MVD) was used to evaluate anti-angiogenic effect. The levels of vascular endothelial growth factor (VEGF) in plasma and its receptor VEGFR-2 (Flk-1) in tumor tissue were measured as a possible mechanism through which these agents have achieved their anti-angiogenic effect. *Methods.* Solid tumors were induced by intradermal injection of EAC cells (2.5×10^6 cells/mouse), at 2 sites bilaterally, on the lower ventral side of Swiss mice. These tumors were used to evaluate effects of resveratrol (10 mg/kg, i.p), or curcumin (10 mM, 100 μL/mouse, i.p.) as individual treatments or in combination with carboplatin (5 mg/kg, i.p.), on MVD, VEGF and VEGFR-2 (Flk-1). All treatments were started 24 hours after tumor cells inoculation. Immunohistochemistry was performed for assessment of MVD and evaluation of tissue VEGFR-2 (Flk-1). Blood samples were collected on EDTA through the orbital sinus using heparinized microcapillaries and plasma levels of VEGF were determined using ELISA. MVD, VEGF, and VEGFR-2 (Flk-1) were determined as a time course on days 7, 14, and 21 post-inoculation. *Results.* Individual treatments with resveratrol or curcumin, alone or combined with carboplatin, produced a significant reduction in MVD compared to control and carboplatin-treated groups. Monotherapy of resveratrol or curcumin as well as their combination with carboplatin produced a significant difference in % reduction of MVD from control as compared to carboplatin monotherapy (Figure 1). Resveratrol or curcumin and their combination with carboplatin significantly reduced plasma levels of VEGF compared to control and carboplatin-treated groups on day 7 post-inoculation. EACs in the control group showed a strong expression of VEGFR-2 (Flk-1). Individual treatment with resveratrol or curcumin could reduce the percentage of VEGFR-2 (Flk-1)-rich tumors to reach 42.9% and 28.6%, respectively. The co-administration of resveratrol or curcumin with carboplatin has produced a further reduction in the percentage of VEGFR-2 (Flk-1)-rich tumors to reach 28.6% and 14.3%, respectively. *Conclusions.* We conclude from the current study that the phytochemicals, resveratrol and curcumin, inhibited angiogenesis as demonstrated by the reduction of MVD by these agents. Resveratrol and curcumin proved to exert their anti-angiogenic effect by inhibition of VEGF and its receptor, VEGFR-2 (Flk-1). The results suggest the beneficial role of these phytochemicals as adjuvant to chemotherapy in the treatment of cancer.

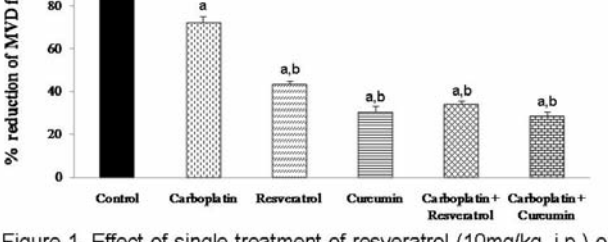

Figure 1. Effect of single treatment of resveratrol (10mg/kg, i.p.) or curcumin (10mM, 100μl/mouse, i.p.) and their combinations with carboplatin (5mg/kg, i.p.) on % reduction of MVD from control on day 21 post-inoculation in EAC-bearing male Swiss albino mice.

a: Significantly different from EAC-control at $p\leq0.05$
b: Significantly different from carboplatin at $p\leq0.05$

STAT5 IS A KEY MEDIATOR OF IMATINIB RESISTANCE IN ABELSON-INDUCED LEUKEMIA

W Warsch,[1] K Kollmann,[1] E Eckelhart,[1] S Fajmann,[1] S Cerny-Reiterer,[2] P Valent,[2] R Moriggl,[3] V Sexl[1]

[1]Institute of Pharmacology, Vienna, Austria; [2]Department of Internal Medicine I, Vienna, Austria; [3]Ludwig Boltzmann Institut for cancer research, Vienna, Austria

Background. In Bcr-Abl$^+$ leukemia, drug resistance is often associated with upregulation of Bcr-Abl or multidrug transporters as well as Bcr-Abl mutations. Nevertheless, many reportet cases of imatinib resistance still can not be explained with one of the known mechanisms. *Aims.* We want to find a new molecular factor responsible for reduced imatinb response of patients in late CML phases (accelerated and blast phases) and of patients with imatinib resistant chronic phase. The signal transducer and activator of transcription (Stat) family of transcription factors were promising screening candidates due to their reported implications in leukemias. *Methods.* We used primary Abelson (v-Abl, $p^{210Bcr\text{-}Abl}$ and $p185^{Bcr\text{-}Abl}$) transformed mouse cell lines harbouring different Stat5 protein levels due to gene dosage effects of Stat5 heterozygote cells or by overexpressing Stat5 using retroviral expression-vectors. To confirm our *in vitro* data, we could establish an *in vivo* model to evaluate imatinib sensitivity of leukemic cells in immuno-compromised NOD/SCID mice. To link our research data to the clinic, we analyzed Stat5 mRNA and protein level of several CML patients. *Results.* We show that the expression level of the transcription factor Stat5 is another parameter that determines the sensitivity of Bcr-Abl$^+$ cells against Bcr-Abl tyrosine kinase inhibitors (TKI) such as imatinib, nilotinib or dasatinib. Abelson-transformed cells expressing high levels of Stat5 were found to be significantly less sensitive to TKI-induced apoptosis *in vitro* and *in vivo*. This protection requires tyrosine-phosphorylation of Stat5 and transcriptional activity. In support of this concept, under imatinib treatment and with disease progression, Stat5 mRNA and protein levels increased in patients with Ph$^+$ chronic myeloid leukemia. *Conclusion.* Based on our data, we propose a model in which disease progression in Bcr-Abl$^+$ leukemia leads to an upregulated expression of Stat5, which subsequently confers protection against TKI-induced apoptosis. This process provokes the selection of cells with high Stat5-expression during treatment with TKIs and suggests that Stat5 may serve as a novel, attractive target to overcome imatinib resistance in Bcr-Abl$^+$ leukemia.

A SINGLE DOSE, CROSSOVER, PLACEBO- AND MOXIFLOXACIN-CONTROLLED STUDY TO ASSESS THE EFFECTS OF BOSUTINIB (SKI-606) ON CARDIAC REPOLARIZATION IN HEALTHY ADULT SUBJECTS

R Abbas, B Hug, C Leister, J Burns, D Sonnichsen

Pfizer, Inc., Collegeville, USA

Background. Bosutinib, an orally bioavailable, small molecule, dual inhibitor of Src and Abl tyrosine kinases, is in phase 3 development for the treatment of patients with chronic myeloid leukemia (CML). An oral-dose of bosutinib 500 mg daily showed clinical efficacy in patients with Ph+ CML (Cortes *et al.*. Blood 112:1098, 2008). Tolerability and pharmacokinetic studies (Abbas *et al.*. Mol Cancer Ther 8:B215, 2009; Abbas *et al.*. Nature 85:S44, 2009; El Gaaloul *et al.* Eur J Cancer Suppl 7:132, 2009) demonstrated that single oral-doses of bosutinib 500 mg were well tolerated in healthy subjects, independently of increases in bosutinib exposures resulting from coadministration with food or ketoconazole (potent inhibitor of bosutinib metabolism that results in supratherapeutic exposures). Therefore, assessment of the effect of therapeutic and supratherapeutic bosutinib exposures on prolongation of cardiac repolarization, defined as prolongation of the corrected QT (QTc) interval, is feasible in healthy subjects. *Aims.* This study was conducted to assess the effects of therapeutic and supratherapeutic bosutinib concentrations on cardiac repolarization in healthy adults, in accordance with ICH E14 guidelines. *Methods.* This was a 2-part, randomized, single-dose, double-blind, crossover, placebo- and open-label moxifloxacin-controlled study in healthy subjects. In part 1, subjects received placebo, moxifloxacin 400 mg and bosutinib 500 mg with food (therapeutic dose). In part 2, subjects from part 1, following a washout, received placebo and bosutinib 500 mg coadministered with ketoconazole (supratherapeutic dose). Triplicate ECG readings were obtained. Repeated measures ANOVA was used to compare the baseline adjusted QTc interval for bosutinib with placebo (reference), and for bosutinib plus ketoconazole with placebo plus ketoconazole (reference) at each postdose time-point. The primary endpoint was QTcN (corrected QT based on a population-specific correction). Secondary endpoints based on Bazett's correction (QTcB), Fridericia's correction (QTcF), and individual-specific correction (QTcI) were also examined. PK/PD analyses and categorical summaries of interval data were performed. Linear regression models on change from baseline QTcN *vs.* log-transformed concentrations were fitted with postdose data for bosutinib and ketoconazole separately. Assay sensitivity was evaluated by the effect of moxifloxacin on the QTc interval compared with placebo. *Results.* Data for 56 healthy subjects (median age: 29 y; range: 18-50 y) were included in this study. Upper bounds of the 90% CI were <10 ms for the maximum mean change in QTcN from reference (4.57 and 6.82 ms) and at all postdose time-points for both the therapeutic and supratherapeutic bosutinib plasma concentrations, respectively, suggesting that therapeutic exposures (mean C_{max}, 114 ng/mL; mean AUC, 2330 ng$^-$h/mL) and supratherapeutic exposures (mean C_{max}, 326 ng/mL; mean AUC, 15,200 ng$^-$h/mL) of bosutinib were not associated with changes in QT interval. Results similar to QTcN were obtained for QTcB, QTcF and QTcI. No clinically relevant PK/PD relationship was observed between bosutinib concentrations and QTc interval. No subjects had a QTcB, QTcF, QTcI, or QTcN interval >450 ms or a change from baseline >30 ms. Moxifloxacin produced a significant increase in QTcN compared with placebo. Summary/*Conclusions.* This study demonstrated that therapeutic and supratherapeutic bosutinib exposures are not associated with QTc prolongation in healthy subjects.

0847

LIFE-THREATENING COMPLICATIONS DUE TO CLINICAL PHARMACOKINETIC INTERACTIONS BETWEEN CYCLOSPORINE A (CSA) AND TRIAZOLE ANTIFUNGAL AGENTS IN THE TRANSPLANTATION SETTINGS

T Yang,[1] F Dan-Hui,[2] H Jian-Da,[2] L Jian,[3] Z Xiao-Yun,[2] L Xiao-Feng,[2] Q Hong-Qiang,[4] W Xue-Mei,[4] C Ru-Ling,[2] C Zhi-Zhe[2]

[1]Fujian institute of Hematology, Fuzhou, China; [2]Department of Hematology, Union Hospital of Fujian Medical University, Fuzhou, China; [3]Department of Pediatrics, Union Hospital of Fujian Medical University, Fuzhou, China; [4]Department of Pharmacy, Union Hospital of Fujian Medical University, Fuzhou, China

Background. It is well documented that the co-medication with the triazole antifungal agents is associated with a flattening of the CSA blood concentration profile via the cytochrome P450 3A4 dependent metabolic pathway in allogeneic hematopoietic stem cell transplantation (allo-HSCT). Then it raises the question if the therapeutic monitoring of CsA trough levels is sufficient enough to reflect the drug exposure and to assess the transplant-related complications such as transplant rejection and drug toxicity. *Aims.* To evaluate the tolerability, toxicity and clinical outcome of the co-administration of CSA and triazole antifungal agents in allo-HSCT recipients. *Methods.* A retrospective review of the medical records of 104 consecutive patients undergoing allo-HSCT for hematologic malignancies at our transplant center over past 5 years was conducted. The causality of administration of CSA in combination with triazole in 12 cases (11.54%) with graft rejection or life-threatening complications experiencing supratherapeutic trough levels of CSA were identified and analyzed. *Results.* Out of 12 patients, 5 patients received itraconazole prophylaxis, 3 voriconazole treatment, 4 itraconazole prophylaxis sequenced with voriconazole treatment. 2 cases developed acute graft rejection but still alive, in which CSA dosage and trough levels were not influenced by the presence of itraconazole prophylaxis. That indicates the trough plasma concentration might be inadequately reflect CSA absorption profile. In other 10 patients, the CSA trough levels remained highly than therapeutic range even after gradual tapering of CSA dosage. Shortly after the engraftment, 6 patients (50%) developed acute graft-versus-host disease (aGVHD) and, either idiopathic pneumonia syndrome (IPS) or diffuse alveolar hemorrhage (DAH); Whereas, 3 (25%) patients were evaluated with Progressive multi-focal leukoencephalopathy (PML), 1 (8.33%) PML accompanied by acute renal failure and liver dysfunction, that might be ascribed to CSA-related adverse effects. These 10 patients eventually died. The median survival time was 46.5 days and the major causes of death were non-infectious pulmonary complication or PML. *Conclusions.* Although preemptive CSA dosage reduction and the close monitoring of its whole blood trough levels may minimize the drug-toxicity when co-administration with triazole antifungal agents, the different clinical spectrum and different disease evolution post transplant in this group warn that in the settings of hematopoietic cell transplantation with CSA as immunosuppression agent the individual variables influence the drug-exposure and drug-toxicity. Thereof, as clinicians we should not be mis-

lead by trough plasma concentrations as a routine therapeutic drug monitoring in terms of CSA exposure related efficacy or toxicity, especially when CSA in combination with triazole.

VORICONAZOLE PHARMACOKINETICS DURING TREATMENT OR PROPHYLAXIS OF FUNGAL INFECTIONS IN IMMUNOCOMPROMIZED PEDIATRIC PATIENTS

M Cusato,[1] G Giorgiani,[1] L Strocchio,[1] A Bertaina,[1] P Villani,[1] F Locatelli,[2] M Regazzi[1]

[1]Foundation IRCCS Policlinico San Matteo, Pavia, Italy; [2]Ospedale Bambin Gesù, Rome, Italy

Background. Voriconazole is increasingly used for prophylaxis or treatment of fungal infections in patients treated for hematologic malignancies and/or recipients of allogeneic hematopoietic stem cell transplantation. In adults, voriconazole shows a non-linear pharmacokinetic profile, a narrow therapeutic window, drug-drug interactions and marked variability in plasma levels. Suggested voriconazole Ctrough concentrations for prophylaxis and treatment are reported to be >0.5 and >1.0 μg/mL, respectively. *Aims.* The study investigated voriconazole pharmacokinetics in a special population. *Methods.* 68 patients (44M, 24F) with hematological disorders, aged 1-23 years [16<7y;52≥7y], were enrolled. 36 patients received voriconazole for prophylaxis and 32 for treatment of aspergillosis. 21 patients were switched from OS to IV at different times during therapy. Voriconazole plasma samples were collected before and 2h after drug administration and levels measured on HPLC-UV. *Results.* We analyzed 304 Ctrough and 134 C2h plasma samples. An inverse correlation between D(mg/kg/12h)/Ctrough (mg/L) and age or BW was found. Patients under 7 years required higher doses/kg to obtain therapeutic levels (Table 1). Patients undergoing treatment received a median (range) dose/kg of 4.3mg (3.1-7.8) and 4.1mg (3.1-8.2) every 12h after OS and IV administration, respectively. Median Ctrough was 1.4 μg/mL (<0.1-4.6) and 2.2 μg/mL (<0.1-6.5) after OS and IV administration, respectively. Patients on prophylaxis received a median (range) dose/kg of 3.9 mg (1.47-6.13) and 4.51mg (1.82-6.73) every 12h, with OS and IV administration, respectively. Median Ctrough was 1.2 μg/mL (<0.1-5.1) and 1.3 μg/mL (<0.1-6.2) after OS and IV administration, respectively. Interpatient variability (CV%) in Ctrough levels was high, about 80%. Intrapatient variability was lower, that is 55%. Voriconazole oral bioavailability (F%) estimated in patients older than 7 years was 71%. *Conclusions.* Our data suggest the necessity to perform TDM in pediatric patients, to ensure a minimal level of exposure, with special consideration for children under 7.

Table 1. Pharmacokinetic parameters of voriconazole in the pediatric population.

Patients N.	Age (years)	Dosage (mg/kg/h)	C_{trough} (mg/L)	C_{2h} (mg/L)
Intravenous administration				
30	13 (7-18)	4.2 (2.2-6.6)	1.4 (<0.1-6.5)	
12	3.5 (1-5)	4.8 (3.1-6.0)	0.35 (<0.1-1.9)	
Oral administration				
25	15 (7-18)	3.9 (2.1-7.5)	0.9 (<0.1-2.9)	2.6 (0.1-5.2)
5	4 (3-6)	5.9 (3.6-8.0)	0.12 (<0.1-0.6)	1.26 (0.3-1.9)

CYTOTOXIC EFFECT OF TETRACYCLINE ANALOGUES ON ACUTE MYELOID LEUKEMIA K562 CELLS

M Fares, Z Hassan

Karolinska Institute, Stockholm, Sweden

Background. Despite extensive research to find appropriate treatment, still acute myeloid leukemia is one of the major causes of death among adults and children. Treatment related toxicity and poor outcome are the major limiting factors in cancer therapy. New effective mechanism-based treatment strategies with fewer side effects are warranted for further improvement. Tetracycline analogues (TCNAs) are used mainly as antimicrobial drugs. Recently, these drugs have been shown to possess cytostatic properties in several cell lines. Three major families of TCNAs have been identified, natural products, semisynthetic compounds and chemically modified tetracyclines. Doxycycline (DOXY) and minocycline (MINO) belong to semi-synthetic tetracyclines, while COL-3 belongs to the chemically modified tetracyclines that have no antibiotic properties. K562 is a myeloid cell line with M6 phenotypes and BCR/ABL fusion gene that is associated with resistance to cytostatic drugs. Effective therapy against this cell line might be potential treatment for cytostatic resistance leukemia. *Aim.* In this study, we investigated the cytotoxic effect of DOXY, MINO and COL-3 in human myeloid leukemia cell line K562. *Methods.* K562 cells were cultured in RPMI 1640 medium (supplemented with 10% FBS). Stock solutions of DOXY and MINO were prepared in sterile water, while COL-3 was dissolved in DMSO. Cells were treated (24-72h) with DOXY, MINO at concentrations of 10 to 200 μg/mL and with COL-3 at concentrations of 2.5 to 50 μg/mL. Control cells were incubated with either drug-free medium or DMSO (0.1%). Cell viability was evaluated using resazurin assay. Type of cell death was assessed by morphological criteria using May-Grünwald-Giemsa staining. Further confirmation of cell death type was carried out using Anexin V and propidium iodide staining and flow cytometry. Loss of mitochondrial membrane potential was investigated using tetramethylrhodamine methylester and flow cytometry. *Results.* All three drugs induced concentration-dependent decrease in viability of K562 cells at 24 h of incubation. The IC_{50} was 26, 20 and 21 μg/mL for DOXY, MINO and COL-3, respectively.Apoptotic and necrotic features were detected 6h after incubation with COL-3 (20 and 50 μg/mL) and after 48h at lesser concentrations. These features were observed after 24h of incubation with DOXY and MINO (50 μg/mL). No cytotoxic effect could be detected with DOXY and MINO at lower concentrations even after prolonged incubation-time. These results were in agreement with those found using Annexin V and propidium iodide staining. Loss of mitochondrial membrane potential started after 2h of incubation with COL-3 (20 and 50 μg/mL) and at 48h (2.5-10 μg/mL). However, the loss of mitochondrial membrane potential was first observed at 24h incubation with DOXY and MINO (50 μg/mL). No evidence of loss of mitochondrial membrane potential with DOXY and MINO at lower concentrations even with prolonged incubation, was observed. *Summary/Conclusion.* Cytotoxic effect of TCNAs on leukemic K562 cells was exposure dependent especially with COL-3. All three TCNAs induced apoptosis in the K562 myeloid cell line through mitochondrial-dependent pathway. COL-3 showed high anti-proliferative and pro-apoptotic effect compared to that observed for DOXY and MINO. Our results show that TCNAs may have treatment potential in acute myeloid leukemia.

THE APOPTOTIC EFFECT OF BENDAMUSTINE COMBINED WITH CYTOSINE ARABINOSIDE (ARA-C) ON A MANTLE CELL LYMPHOMA CELL LINE

S Castegnaro, C Visco, M Bernardi, K Chieregato, D Madeo, F Rodeghiero

San Bortolo Hospital, Vicenza, Italy

Background. Bendamustine is a bifunctional agent that acts as an alkylating agent as well as a purine analogue with relevant clinical activity in mantle cell non-Hodgkin's lymphomas (MCL). Cytosine arabinoside (Ara-C) is widely used for treating young patients with MCL due to its recognized efficacy in this disease. Since these two agents exhibit individual and unique mechanisms of action in this tumor, a synergistic or additive effect might be expected when they are used in combination. *Aim.* Our aim was to investigate the effect of Bendamustine and Ara-C, alone and in combination, in modifying apoptotic pathways and cell proliferation of a MCL cell line model (JEKO-1). *Methods.* JEKO-1

cells were incubated with Bendamustine or Ara-C at concentrations ranging between 0 and 1000 µg/mL in RPMI medium supplemented with 10% fetal bovine serum, 2% L-glutamine and 1% penicillin/streptomycin. Drug dosages were chosen to reach the IC25, IC_{50}, IC75 and IC90 defined as the dosage of drug necessary to cause apoptosis of 25%, 50%, 75% and 90% of JEKO-1 cells, respectively. The two drugs were incubated simultaneously (24h and 48h, respectively) or consecutively (drug A or B for 2h, then washed and incubated for further 21h without any drug, then supplemented with drug B or A for 24h). Apoptosis was measured with the fluorescent DNA-binding agent 7-AAD (7 amino-actinomycin D), while cell proliferation/metabolic activity was measured using the tetrazolium-based assays, WST-1. Flow cytometric analysis was used for the first test, and the formazan dye (formed by the cleavage of tetrazolium salt in metabolic active cells) was quantified by a spectrophotometer. Results were expressed in terms of combination index (CI) which is a quantitative measure of the degree of drug interaction in terms of additive effect, synergism or antagonism. Calcusyn software was used to analyze results. *Results.* The cytotoxicity of Bendamustine alone was directly proportional to increasing drug concentrations, while Ara-C alone demonstrated a cytotoxic effect that was independent of the drug concentration. Noteworthy, the combination of Bendamustine and Ara-C was strongly synergistic on induction of apoptosis in all drug incubation schedules. In Figure 1 we show the CI values determined by apoptosis of all simultaneous and consecutive applied drug combinations. The highest CI (0.0076) was obtained with the incubation of Bendamustine followed by Ara-C (B+A in the higher two concentrations, as shown in Figure 1). Similarly, with the WST-1 test, we observed a stronger decrease in metabolic activity, which correlated to the cytotoxic effect of the drug, when Bendamustine and Ara-C were combined consecutively, even at low concentrations (data not shown). Discussion. Our data confirm the individual strong apoptotic effect of Bendamustine and Ara-C on JEKO-1 cells and reveal a considerable synergistic effect of the two drugs when used in combination, especially when Bendamustine was incubated before Ara-C. These findings give a rationale for the use of these two drugs in combination in the treatment of patients with MCL. We are now running a Phase II study with a regimen combining Rituximab, Bendamustine and Ara-C (R -BAC) in the treatment of MCL patients who are not candidate to high dose therapy.

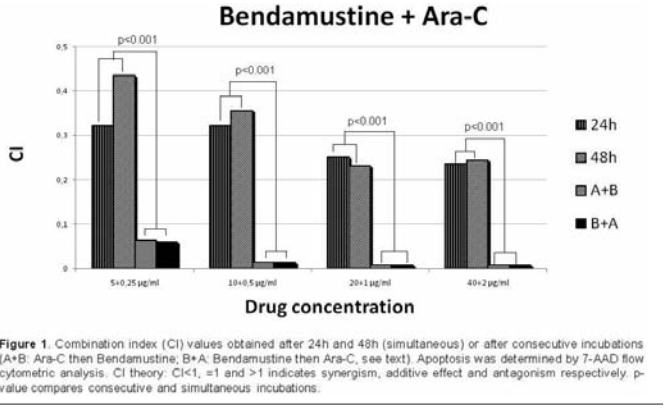

Figure 1. Combination index (CI) values obtained after 24h and 48h (simultaneous) or after consecutive incubations (A+B: Ara-C then Bendamustine; B+A: Bendamustine then Ara-C, see text). Apoptosis was determined by 7-AAD flow cytometric analysis. CI theory: CI<1, =1 and >1 indicates synergism, additive effect and antagonism respectively. p-value compares consecutive and simultaneous incubations.

Figure 1.

SENSITIVE DETECTION OF E255K AND E255V P-LOOP MUTATION AND THEIR FREQUENCY AND CLINICAL SIGNIFICANCE IN IMATINIB RESISTANT CHRONIC MYELOID LEUKAEMIA PATIENTS

R Mir,[1] S Sazawal,[1] J Jamsheed,[2] M Masroor,[3] A Saxena,[3] S Saxena[1]

[1]All Indian Institute of Medical Sciences, New Delhi, India; [2]Biochemistry Mamc, New Delhi, India; [3]Biochemistry MAMC, New Delhi, India

Background. Despite durable responses to imatinib in chronic myeloid leukaemia (CML), mutations in Bcr-Abl kinase domain (KD) are known to induce imatinib resistance and cause poor clinical outcome.But the prevalence and prognostic significance of two P-loop E255K and E255V mutations in Indian patients. To shed light on the frequency, distribution, and prognostic significance of P-loop mutations this study was carried to identify a fast and sensitive method for screening E255K and E255V. *Aims.* To identify a fast and sensitive method for screening for E255K and E255V mutation in patients with imatinib-resistant chronic myeloid leukemia (CML). To study the frequency and clinical significance of E255K and E255V mutations in Imatinib resistant chronic myeloid leukemia patients. Patients and methods. The study included 80 imatinib resistant chronic myeloid leukemia patients registered during 2003-2009. DNA was isolated from the peripheral blood and Allele specific oligonucleotide polymerase chain reaction (ASO-PCR) assay was developed for the detection E255K and E255V mutations. Mutated and wild-type allele was specifically amplified in a 25ul reaction mixture . The incidence of mutation was correlated with different clinical and molecular parameters of the patient. The dosage of imatinib was 400mg to 800 /day. All patients were monitored for hematologic and molecular responses, time to progression, survival and toxicity. Results. All patients were monitored for hematologic and molecular responses and only resistant cases were selected and screened for E255K and E255V mutations. After a median follow-up of 3 years (range 3 to 5 years 60 (31.6%) patients had developed molecular relapse and hematological progression. The prevalence of E255K p-loop mutation was 50% (40/80) and of E255V p-loop mutation was 43.75% (34/80). Out of 34 E255V positive cases, 10 progressed to BC-CML and 10 responded to high dose Imatinib 800mg/day and three died. Out of 40 E255V positive cases, 08 progressed to BC-CML and 20 responded to high dose Imatinib 800mg/day. All were treated with imatinib at 600 to 800 mg/day. Survival and time-to-progression curves were obtained from Kaplan-Meier method. There was a significant difference in the survival rate of patients with or without E255V p-loop mutations. Patients with E255V p-loop mutations had short survival. Side-effects of imatinib included anemia (n=20), thrombocytopenia (n=19) and hypopigmentation of skin (n=10). The overall clinical outcome or prognostic significance of Imatinib resistant CML patients carrying E255V mutations was poor. Conclusions. Our findings suggest that the early detection of E255K and E255V mutations proved helpful in clinical management of therapeutic decisions. ASO-PCR is a very economical, sensitive and rapid technique for detection of E255K and E255V mutation and is more sensitive than mutation detection by sequencing. The fastness, simplicity, and sensitivity of ASO-PCR assays will be useful for routine monitoring of mutations, especially for frequently identified mutations in the developing countries where direct sequencing facilities are not available. The detection of E255V and E255K mutation was associated with imatinib resistance, and poor prognosis.

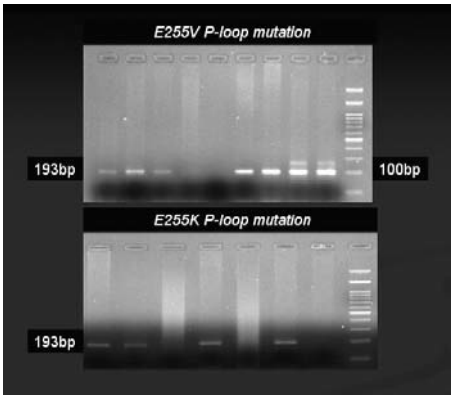

Figure. Gel picture of E255V mutation.

A STUDY OF THE INFLUENCE OF TNF-ALPHA ON THE EFFICACY OF TREATMENT WITH RECOMBINANT HUMAN ERYTHROPOIETIN IN PATIENTS WITH MALIGNANCIES OF THE LYMPHOID SYSTEMS

N.A. Romanenko,[1] O Rosanova,[1] T Glazanova,[2] K Abdulkadyrov[1]

[1]Russian Research Institute of hematology and transfusiology, Saint-Petersburg, Russian Federation; [2]Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background. Anemia in patients with malignancies of the lymphoid systems (MLS) frequently occurs and decreases the efficacy of antitumor therapy and survival of patients, also altering their quality of life. In such patients anemia is being corrected using transfusions of red blood cells and preparations of recombinant human erythropoietin (rHuEPO); rHuEPO significantly decrease volume of red blood cell transfusions and risk of complications. Nevertheless, it is not always possible to predict the rHuEPO treatment efficacy, while the cost of such treatment is high.

Aims. The goal of this study was to evaluate the efficacy of anemia correction using rHuEPO in patients with malignancies of the lymphoid systems and to study the influence of serum TNF-alpha level on the results of rHuEPO therapy. *Methods.* The studied group of patients with MLS (n=21) consisted of patients with chronic lymphocytic leukemia (n=5), indolent forms of Non-Hodgkin lymphoma (n=7) and multiple myeloma (n=9). Age varied from 49 to 80 years (63.6±8.2 years). Anemia with hemoglobin level below 10.0 g/dL was an indication for rHuEPO prescription. All patients have previously received not less than 3 courses of chemotherapy. Before rHuEPO treatment 3 patients received red blood cell transfusions, according to vital indications (Hb<6.5 g/dL), after which hemoglobin increased to 8.0 g/dL. Those patients, in whom there was observed hemorrhage, hemolysis, iron or B_{12} deficiency, were not included in this study. Treatment with recombinant human erythropoietin was performed subcutaneously using 150 ME per kilogram body weight three times a week (weekly dose was 450 ME/kg). Before prescription of rHuEPO there were measured initial indices of hemogram (hemoglobin level, hematocrit, red blood cell count, reticulocyte rHuEPO treatment, Hb level increased to 12.0 g/dL and its monthly increase was ≥1.0 g/dL. *Results.* Duration of rHuEPO treatment was in average 10.1±3.6 weeks (4-16 weeks). Positive response to rHuEPO was observed in 13 of 21 patients (61.9%). There was observed significant (P<0.01) increase of hemoglobin level, in average from 8.68±1.85 g/dL (4.6-10.0 g/dL) to 11.14±2.65 g/dL (6.7-14.7 g/dL), red blood cell count - from 2.78±0.74×10^{12}/L (1.30-3.50×10^{12}/L) to 3.50±0.93×10^{12}/L (2.08-4.78×10^{12}/L), hematocrit - from 26.8±6.3% (13.4-32.7%) to 34.9±6,8% (20.6-46.2%). Also there was observed increase of reticulocyte count from 28.1±10.9×10^{9}/L to 79.9±50.3×10^{9}/L. In the whole group of patients TNF-alpha level before prescription of rHuEPO varied from 3.2 to 484.3 pg/mL (50.2±110.5 pg/mL). Depending on TNF-alpha level patients were divided into two groups. First group consisted of 14 patients with level of TNF-alpha less than 15 pg/mL (from 3.2 to 13.2 pg/mL, average 8.6±3.3 pg/mL). In this group positive response to therapy with rHuEPO was reached in 13 patients. Second group consisted of 7 patients with level of TNF-alpha more than 15 pg/mL (from 19.2 to 484.3 pg/mL, average 133±167 pg/mL). In this group positive response to therapy with rHuEPO preparations was not observed in any of the patients. There was established a reverse correlation between TNF-alpha level and efficacy of rHuEPO treatment (r=-0.487; P<0.03; n=21). Thus, in those cases when TNF-alpha was higher than 15 pg/mL, there could not be reached a positive response. *Conclusions.* Thereby, we have revealed that initial serum level of TNF-alpha in patients with MLS affects the efficacy of correction of anemia by rHuEPO, and its evaluation can be used as a predictor of response to rHuEPO treatment. Low level of serum TNF-alpha (<15 pg/mL) presumes a positive response to treatment, while high level (>15 pg/mL), as a rule, indicates resistance to rHuEPO treatment in such patients and non-expedience of prescription of stimulators of erythropoesis.

0853

ACTIVATION OF CYCLIC AMP SIGNALING INHIBITS CHEMOTHERAPEUTIC-INDUCED P53-MEDIATED APOPTOSIS IN WILD-TYPE P53 ALL CELLS

M Safa,[1] A Kazemi,[1] H Zand,[2] F Zaker,[1] A Azarkeivan[3]

[1]Iran University of Medical Sciences, Department of Hematology, Tehran, Iran, Tehran, Iran; [2]Faculty of Nutrition Science and Food Technology, Shahid Beheshti University, Tehran, Iran; [3]Iranian Blood Transfusion Organization Research Center, Tehran, Iran

Background. The p53 tumor suppressor protein is a potent roadblock to tumor development. Cells that are insulted by chemotherapeutic DNA-damaging agents or other forms of stress stabilize the p53 protein by phosphorylation or other modifications. Stabilized p53 accumulates in the nucleus to regulate the expression of numerous pro-apoptotic genes. We evaluated the effect of cAMP signaling pathway, an important regulator of hematopoietic cell proliferation, differentiation and apoptosis, on p53-mediated apoptosis in response to DNA-damaging agents. *Aims.* The aim of this study was to evaluate the effect of activation of cAMP signaling system on wild-type p53 leukemia cells upon exposure to chemotherapeutic drugs. In addition, we dissect the molecular mechanisms of cAMP action on p53 in order to find the main mediator of p53 destabilization. *Methods.* Cultured pre-B ALL NALM-6 cells and T-ALL MOLT-4 cells were exposed to doxorubicin in the presence or absence of cAMP-increasing agents for 24h and then cells were subjected to apoptosis analysis by flow cytometry. Western blot method was used to analyze phosphorylation state of p53 protein, total p53, and the levels of other proteins which were involved in doxorubicin-induced apoptosis. Real-time PCR was performed to analyze the expression levels of p53 target genes. cAMP specific analogs were used to find the mediator of cAMP action on p53 destabilization. In addition, RITA was used to show the role of HDM2, a physiological negative regulator of p53, in cAMP-induced p53 degradation. Results. Our results indicate that elevation of cAMP in B cell precursor acute lymphoblastic leukemia (BCP-ALL) cells and T-ALL MOLT-4 cells profoundly inhibit the apoptotic response to doxorubicin. We further demonstrate that this effect depends on the ability of elevated cAMP levels to quench DNA damage-induced p53 accumulation and phosphorylation. Increased cAMP levels also repressed the expression of proapoptotic p53 target genes. Using cAMP specific analogs we found that this inhibitory effect of cAMP is not mediated through PKA or EPAC which are the main mediators of cAMP-signaling system. The results of specific inhibitor of p53-HDM2 interaction showed this action of cAMP in not mediated through HDM2. *Summary/Conclusions.* In conclusion, recognition that elevated cAMP levels may abrogate p53-dependent apoptosis carries clinical implications for patients with wild-type p53 leukemia cells undergoing curative antineoplastic therapy, because a large number of common agents modulate cAMP metabolism.

LABORATORY VALIDATION OF THE MULTIDRUGQUANT™ ASSAY KIT

K Tauber Jakab,[1] J Márki-Zay,[1] S Baráth,[2] E Gyimesi,[2] Z Hevessy,[2] V Sziráki Kiss,[2] É Nagy,[3] P Szabó,[4] M Tokés-Füzesi,[4] Z Holló,[1] J Kappelmayer[2]

[1]Solvo Biotechnology, Budaörs, Hungary; [2]University of Debrecen-Medical and Health Science Center, Debrecen, Hungary; [3]University of Szeged-Albert Szent-Györgyi Clinical Center, Szeged, Hungary; [4]University of Pécs-Medical School, Pécs, Hungary

Background. The multidrug resistance usually results from the expression of ATP-binding cassette (ABC) transporters, such as the ABCB1 (MDR1 or P-gp), ABCC1 (MRP1), and ABCG2 (MXR or BCRP) which are known to function as drug efflux pumps. Although it is believed to be a major barrier to successful chemotherapy in cancer patients, neither the genetic polymorphisms nor the mRNA or protein expression levels correlate closely with the functional activity and studies using the methods above have given conflicting and inconsistent results. On the other hand, although the functional methods separately gave promising results, standardization and reproducibility of these tests failed to conform to the values required from routine diagnostic methods. MultiDrugQuant kit was developed an improved functional assay system, which can measure the multidrug resistance activity of the three, clinically most relevant efflux transporters, such as MDR1, MRP1 and BCRP in living tumor cells. *Aim.* Our purpose was the laboratory validation of the MultiDrugQuant-kit prior to the performance evaluation in haematological diseases. *Methods.* Validation of the kit was carried out according to the standards of the Clinical Laboratory Standards Institute in three university centres in Hungary. Mononuclear cells were separated using Ficoll gradient and tested at 2×'5×-10^{6}/mL within 6 hours after specimen collection. The kit applies fluorescent dyes (substrates) and inhibitors of the all three transporters implicated. The activity of the multidrug transporter was calculated from the difference between the mean fluorescent intensity of cells w/o the specific inhibitors, respectively. Inaccuracy and comparative measurements were carried out using cell lines with low and high activity of transporters. Results on different flow cytometers were compared using CD45 or CD19 or CD3 monoclonal antibodies for gating to detect the population of interest. *Results.* The assay proved to be specific and quite robust at 10-100% of the fluorescent dyes or 50-150% of the inhibitors. Both intraassay and interassay reproducibility were <5%. We found comparable and eligible multidrug resistance activity values, which were determined on different flow cytometers. *Conclusion.* The MDQ-kit provides quantitative results on the multidrug resistance activity of the MDR1, MRP1 and BCRP. Measurement of the activity of these membrane transporters in the target cells might be used to predict the resistance of these cells to particular cytotoxic agents. Recently, clinical trial was started in haematological diseases and we will follow up the therapeutic response and the correlation with the transporter activity in order to evaluate the predictive value of the biomarker.

PRECLINICAL EVALUATION OF ANTITUMOR ACTIVITY OF BORTEZOMIB IN COMBINATION WITH EPIGALLOCATECHIN GALLATE (EGCG), A COMPONENT OF GREEN TEA

B Bannerman,[1] L Xu,[2] M Jones,[2] C Tsu,[2] J Monbaliu,[3] P Fleming,[2] L Dick,[2] M Manfredi,[2] C Claiborne,[2] E Kupperman,[2] A Berger[2]

[1]Millennium: The Takeda Oncology Company, Cambridge, USA; [2]Millennium Pharmaceuticals, Inc., Cambridge, USA; [3]Johnson & Johnson, GPCD, Beerse, Belgium

Background. Bortezomib is a first in class proteasome inhibitor, currently approved in the United States and Europe for the treatment of patients with multiple myeloma (MM) and approved in the US for relapsed or refractory mantle cell lymphoma. The boronate group of bortezomib can chemically interact with 1,2 diol groups on polyphenols including epigallocatechin gallate (EGCG), a major component of green tea. Previously published studies in cultured cells indicate that high concentrations of EGCG (2.5 μM-10 μM) can antagonize the ability of 10 nM bortezomib to inhibit the proteasome and kill cells. However, it is unknown whether this antagonism would occur in patients receiving bortezomib treatment while consuming green tea or EGCG supplements. *Aims.* To evaluate whether EGCG can antagonize the antitumor effects of bortezomib *in vivo*, using the bortezomib-sensitive CWR22 prostate-derived xenograft tumor model grown in immunocompromised mice. *Methods.* We first characterized the pharmacokinetics (PK) of EGCG dosed orally, intravenously (IV), and subcutaneously (SC) in immunocompromised mice. Our goal was to find a dose and route of administration resulting in EGCG plasma concentrations in the range of those measured in human PK studies of EGCG dietary supplements, so that our preclinical studies would test clinically relevant plasma concentrations of EGCG. Published studies of EGCG in human plasma show maximal concentrations of approximately 0.4 μM and 3 μM when 800 mg supplements are taken with food or on an empty stomach, respectively. 800 mg of these supplements is equivalent to approximately 8 cups of brewed green tea. In mice, oral dosing of EGCG at 50 mg/kg resulted in very low plasma concentrations, with C_{max} of only 0.076 μM. SC and IV dosing of 50 mg/kg EGCG achieved much higher plasma concentrations (30 μM and above), and these routes were used in combination studies with bortezomib. *Results.* Bortezomib dosed IV at its twice-weekly maximum tolerated dose (0.8 mg/kg) in CWR22-xenograft bearing CB17-SCID mice results in a consistent antitumor response, with a ratio of average tumor volume in the treated *vs.* control group (T/C)=0.37-0.46. Twice-weekly dosing of 50 mg/kg EGCG by IV or SC administration had no antitumor activity on its own (T/C=0.8-1.15). In combination studies using SC dosing of EGCG and IV dosing of bortezomib, when EGCG plasma concentrations as high as 11-15 μM were present at the time of bortezomib dosing, no antagonism was detected (T/C=0.36-0.54). However, antagonism was detected in a combination study using IV dosing of EGCG and bortezomib, when the EGCG plasma concentration was 233 μM at the time of bortezomib dosing (T/C=1.18). This concentration of EGCG is more than 75 times higher than the maximal concentration of EGCG measured in humans taking 800 mg supplements while fasting. *Conclusions.* These results suggest that the level of EGCG required to antagonize bortezomib is not physiologically relevant in patients taking oral EGCG supplements or drinking green tea.

0856

SUPPRESSION OF STAT5A INCREASES CHEMOTHERAPEUTIC SENSITIVITY IN IMATINIB-RESISTANT AND IMATINIB-SENSITIVE K562 CELLS

Y Baran,[1] B Kosova,[2] B Tezcanli,[2] H Ekiz,[3] Z Cakir[3§], S Selvi[2]

[1]Izmir Institute of Technology, Faculty of Science, Dept.of Mol.Biol. & Genetics, Urla Izmir, Turkey; [2]Ege University, Faculty of Medicine, Department of Medical Biology, Izmir, Turkey; [3]Izmir Institute of Technology, Faculty of Science, Dept of Mol Biol & Genetics, Izmir, Turkey

Background. STATs (Signal Transducers and Activator of Transcription Proteins) are latent cytoplasmic transcription factors that upon activation carry information coming from outside the cell into the nucleus. Extensive studies in mammalian systems revealed that STATs consist of seven structural and functional homolog family members. STAT activation is normally achieved by phosphorylation of specific tyrosine residues accomplished either by ligand-activated receptor-tyrosine kinases or receptors lacking intrinsic tyrosine kinase ability. Chronic myeloid leukemia (CML) is a hematological cancer that is characterized by the accumulation of immature leukemic cells of myeloid origin in the bone marrow and bloodstream. Main driving force of this malignancy is the reciprocal translocation between the q arms of the 9. and 22. chromosomes, bringing the BCR and ABL genes together. The resultant chromosomal structure is referred as the Philadelphia chromosome (Ph) and the whole translocation process results in the expression of the BCR/ABL fusion protein. Imatinib, a tyrosine kinase inhibitor, binds to the ATP binding domain of the fusion protein and prevents the subsequent phosphorylation of the target proteins. Survival periods of CML patients can substantially prolonged by means of this drug, but in most cases gained resistancy can affect the clinical outcome of this therapy. Resistancy, on the other hand, is conferred by various mechanisms. *Aims.* In this study we aimed to identify the differentially expression pattern of STAT genes in imatinib-sensitive and -resistant K562 CML cell lines; and further, to reveal the effects of STAT5A siRNA knockdown on cellular growth and apoptotic induction. *Methods.* mRNA expressions of STAT genes were assessed by quantitative real-time PCR (Q-PCR). For silencing the STAT5A gene in imatinib-sensitive and 3 μM imatinib-resistant K562 cell lines (K562/IMA-3), HiPerFect Transfection Reagent was used combination with cholesterol-conjugated anti-STAT5A siRNAs. Cell proliferation was detected by the XTT cell proliferation assay and apoptosis was evaluated by changes in Caspase-3 enzyme activity. *Results.* Q-PCR analysis revealed that the expression level of STAT5A most significantly changed among the other STATs examined in K562-IMA3 cells compared to imatinib-sensitive K562 cells. Its expression increased by 67%, whereas the expressions of STAT5B and STAT3 were increasing 56% and 4%, respectively. Our results demonstrated that silencing of STAT5A sensitized both sensitive and resistant K562 cells to imatinib. Transfected resistant cells became almost 4.5-times more sensitive than the non-transfected counterparts, while transfected sensitive cells showed approximately 1.12-fold increased sensitivity. These results indicate that imatinib-resistant K562 cells are more effectively sensitized by silencing of STAT5A compared to imatinib-sensitive K562 cells. For both sensitive and resistant cells, enhanced apoptotic induction was concurrent with suppression of STAT5A expression. Non-transfected K562/IMA-3 cells showed 1.85- and 3.46-fold increases in Caspase-3 enzyme activation in the presence of 5- and 10 μM of imatinib, while siRNA-transfected counterparts showed 11.21- and 20.17-fold increases. Conclusion. Observing these significant responses to imatinib after transfection with single gene-specific siRNAs might provide new opportunities for dealing with the frequent occurrence of resistance to chemotherapeutic agents in leukemia.

MUTATIONS IN KIT PREDICT RESISTANCE TO SEVERAL TKI (SORAFENIB, SUNITINIB, AND MASATINIB) IN NEOPLASTIC HUMAN AND CANINE MAST CELL LINES

E Hadzijusufovic,[1] B Peter,[1] H Herrmann,[1] K Schuch,[1] T Thaiwong,[2] V Yuzbasiyan-Gurkan,[2] W Pickl,[1] M Willmann,[3] P Valent[1]

[1]Medical University of Vienna, Vienna, Austria; [2]Comparative Medicine and Integrative Biology Program, Michigan State University, East Lansing, USA; [3]University of Veterinary Medicine, Vienna, Austria

Advanced mast cell (MC) disorders are characterized by uncontrolled growth of neoplastic MC in various organs, resistance against cytoreductive drugs, and a poor prognosis. In most patients, transforming mutations in the KIT proto-oncogene are detectable and are considered to contribute to resistance. MC lines are an important model for analyzing drug resistance. We have established a novel canine mastocytoma cell line, NI-1 from a canine patient suffering from mast cell leukemia. NI-1 cells were found to harbour several homozygous KIT mutations including two single nucleotide mutations, one at nucleotide 107 (C to T, leading to a missense mutation, P36L) and another at 1187 (A to G, leading to a missense mutation, Q396R), a 12 bp duplication at nucleotide 1263, and a 12 bp deletion at nucleotide 1550, the latter reflecting a transcriptional variant. Drug response profiling revealed that NI-1 cells differ markedly from canine mastocytoma C2 cells harbouring an exon 11 KIT mutation, and the human mast cell lines HMC-1.1 (exon 11 mutation in KIT) and HMC-1.2 (exon 11 and exon 17 mutation). In contrast to C2 cells, NI-1 cells were found to be largely resistant against the apoptosis-inducing effects of masatinib, sorafenib, and sunitinib. Similarly, in contrast to HMC-1.1 cells, HMC-1.2 cells were found to be largely resistant against masatinib, sorafenib, and sunitinib. Drug resistance was specific for KIT tyrosine kinase blockers in that vorinostat, an HDAC inhibitor, produced growth-inhibitory and apoptosis-inducing effects with comparable IC_{50} and ED50 values in all MC

lines tested. Together, these data provide further evidence that KIT mutations are associated with resistance to KIT-targeting drugs. The novel MC line NI-1 may serve as a valuable tool to investigate the mechanisms of drug resistance in canine mast cell tumors and the role of novel KIT mutations.

0858

THE EFFECT OF FOOD ON THE PHARMACOKINETICS OF ANAGRELIDE AND ITS ACTIVE METABOLITE 3-HYDROXYANAGRELIDE

C Jones,[1] R Franklin,[1] R Francis[2]

[1]Shire Pharmaceuticals, Basingstoke, UK; [2]Harpenden, Herts, UK

Background. Anagrelide, a novel imidazoquinalone, reduces platelet counts in humans and is licensed for the treatment of essential thrombocythemia. Since the active metabolite, 3-hydroxyanagrelide, appears to be exclusively produced by CYP1A2, anagrelide metabolism may be influenced by normal dietary constituents such as caffeine. *Aims.* To compare the pharmacokinetics of anagrelide and 3-hydroxyanagrelide when anagrelide is administered in fed and fasted states. To assess the safety and tolerability of anagrelide. To measure individual levels of expression of CYP1A2 by measuring the plasma caffeine:caffeine metabolite (paraxanthine) ratio and relate this to observed exposure to 3-hydroxyanagrelide. *Methods.* This was an open-label, single-dose crossover study of healthy, adult volunteers. Subjects were randomized to receive a single oral dose of anagrelide 1 mg alone (fasted), or following a standardized high-fat meal, including 2 cups of coffee (fed/caffeine), and crossed over to the other treatment after an interval of ≥3 days. Plasma concentrations of anagrelide and 3-hydroxyanagrelide were monitored for 24 hours after dosing. Adverse events (AEs) were recorded throughout the study. Caffeine:paraxanthine plasma ratios were measured 4-hours post-dose. *Results.* In total, 35 subjects (20 males, 15 females) entered the study, and 34 completed both the fasted-fed/caffeine and fed/caffeine-fasted treatment sequences. One female subject discontinued for personal reasons. Pharmacokinetic data are summarized in Table 1. There were significant differences between fed/caffeine and fasted states for both anagrelide and 3-hydroxyanagrelide for t_{max} and t_{lag}. In addition the C_{max}, $AUC_{0-\infty}$ and $t_{1/2abs}$ were non-equivalent between fed/caffeine and fasted states for anagrelide and 3-hydroxyanagrelide. There were no marked differences in pharmacokinetic parameters between genders. AEs were reported by a similar number of subjects in the fasting (23 [66%] subjects) and fed states (19 [56%] subjects). The most common AE observed during the study was headache, recorded in 19 fasted subjects (54%) *vs.* 8 subjects (23%) following food/caffeine. The next most common AE reported were palpitations, all of mild intensity, involving 6 fasted subjects (17%) and 12 (35%) following food/caffeine. ECGs were captured at the time of the events in a majority of subjects and were deemed to be normal. Transient rises in heart rate were observed at the time of the event. Measurement of the caffeine:paraxanthine plasma ratio following ingestion of two cups of coffee did not provide any evidence for a possible relationship between exposure to 3-hydroxyanagrelide and CYP1A2 status.

Table 1.

Arithmetic mean pharmacokinetic parameters for anagrelide and 3-hydroxyanagrelide (fasted and fed)

	Median t_{max} (h)	C_{max} (ng/mL)	AUC_{last} (ng.h/mL)	$AUC_{0-\infty}$ (ng.h/mL)	$t_{1/2z}$ (h)	t_{lag} (h)	$t_{1/2abs}$ (h)
Anagrelide							
Fasted	**1.50**	**5.1**	**12.9**	**13.1**	**1.7**	**0.34**	**0.43**
Fed	**4.00**	**4.4**	**15.2**	**15.9**	**1.8**	**1.34**	**0.74**
3-hydroxyanagrelide							
Fasted	**1.25**	**8.3**	**28.2**	**29.2**	**3.1**	**0.33**	**0.78**
Fed	**4.00**	**5.9**	**27.9**	**29.7**	**3.3**	**1.01**	**1.02**

t_{max} – time of maximum observed plasma concentration, C_{max} – maximum observed plasma concentration, AUC_{last} – area under the plasma concentration-time curve up to the last quantifiable concentration, $AUC_{0-\infty}$ – total area under the concentration-time curve, $t_{1/2z}$ – apparent half-life of the terminal elimination phase, t_{lag} – lag time before the first quantifiable plasma concentration, $t_{1/2abs}$ – apparent half-life of the absorption phase

Conclusions. In both fed/caffeine and fasted states anagrelide was rapidly absorbed following a single oral dose. Anagrelide and 3-hydroxyanagrelide are eliminated rapidly, with no appreciable pharmacokinetic differences between genders. The main effects of food/caffeine were to delay t_{max} of anagrelide and 3-hydroxyanagrelide by approximately 3 hours and to lower the maximum concentration of 3-hydroxyanagrelide by 30%. However, total exposure to either compound was not affected by food/caffeine. AEs observed during the study were in line with those previously reported and were similar in the fed and fasted states. Caffeine inclusion in the standardized meal may have contributed to the slightly higher rate of palpitations experienced in the fed state.

GENERATION OF A DATABASE ON INTERACTION OF DRUGS WITH MDR ABC TRANSPORTERS

P Krajcsi, E Kis, K Heredi-Szabo, K Tauber Jakab, J Marki-Zay

Solvo Biotechnology, Budaors, Hungary

Background. Since the beginning of the 90's several studies have confirmed the role of multidrug transporter proteins in chemoresistance in a variety of haematological malignancies. The studies focused on rapidly progressing acute leukaemia's, with the emphasis being on acute myeloid leukaemia (AML). To characterize drug - transporter interactions we developed two major forms of ABC transporter assays: whole cell-based assays and membrane assays. MultiDrugQuant™ Assay Kit was used to assess function of the clinically most important multidrug resistance transporters (ABCB1/MDR1, ABCC1/MRP1) in living tumor cells. BCRP (ABCG2/MXR) a protein also implicated in multidrug resistance was also tested. *Aims.* Aims of this study were to test the interactions several drugs and ABC efflux transporters, characterize the interaction and correlate membrane as well as cellular data using in silico passive permeability values. *Methods.* In our study we used *in vitro* membrane based methods (ATPase and vesicular transport assay) and cellular assays (Hoechst assay and calcein assay) to show interactions between the MDR1/MRP1/BCRP transporters and different chemotherapeutic (e.g. chlorambucil, cisplatin, taxane) and immunosuppressive drugs (e.g.NSAID, DMARD). ATPase and VT assays were performed on membrane preparations from recombinant baculovirus infected Sf9 cells. Cellular dye efflux assays (Calcein, Hoechst) were performed on transfected or selected cell lines overexpressing the implicated transporter as well as inhibitors (verapamil, KO134). *Results.* We had characterised substrate or inhibitory profile of 35 drugs. IC_{50} values (dye efflux, inhibition of vesicular transport and ATPase as well as EC50 values (ATPase activation) will be presented. Passive permeability greatly affects correlation between membrane and cellular data. In general, the lower the passive permeabilty is the greater the $IC_{50\ cell}/IC_{50\ membrane}$ ratio is. *Conclusion.* This database will be useful in personalized medicine. The toolkit presented here can be used in drug discovery and development of chemotherapeutics.

Infectious diseases and supportive care

GALACTOMANNAN-GUIDED PRESUMPTIVE VS EMPIRICAL ANTIFUNGALS IN THE PERSISTENTLY FEBRILE NEUTROPENIC - A PROSPECTIVE RANDOMISED STUDY

GC Wong, J Low, N Chlebicka, A Kurup, FK Cheah, R Lin, YT Goh, BH Tan

Singapore General Hospital, Singapore, Singapore

Background. Invasive mold infections (IMI) cause significant morbidity and mortality in neutropenic patients. The risk of IMI increases with the severity and duration of neutropenia. As a result of the difficulty in making a diagnosis of IMI, empiric antifungals for persistent febrile neutropenia has become the standard of care. However, the empirical use of antifungals may lead to over-treatment. A new strategy, "presumptive"antifungal therapy, has emerged as an alternative to empirical antifungals in the management of febrile neutropenia. *Aims.* To determine if serial galactomannan (GM) monitoring, with effective anti-candidal prophylaxis, can obviate the need for empirical broad-spectrum antifungal treatment in patients receiving intensive chemotherapy for hematological malignancies and allogeneic hematopoietic stem cell transplant (HSCT) recipients. *Methods.* This prospective, randomized, non-blinded, ethics committee-approved study was conducted from June 2006 to October 2007 in the Department of Hematology, Singapore General Hospital. Patients receiving intensive chemotherapy for hematologic malignancies where neutropenia is expected to last longer than 7 days and patients undergoing alloHSCT were randomized to either the monitoring (presumptive) arm or observational arm. Patients in the presumptive arm had regular GM assays and received caspofungin, amphotericin or voriconazole (CAV) for persistent febrile neutropenia(FN) if there were 2 positive GM results or a positive GM result and a CT thorax suggestive of invasive pulmonary aspergillosis (IPA). Patients in the observational arm received antifungals according to international and departmental guidelines. All patients received ciprofloxacin and itraconazole prophylaxis. Treatment episodes were classified as proven IA, probable or possible IA based on the definitions of the Invasive Fungal Infections Cooperative Group of the European Organization for Research and Treatment of Cancer/Mycoses Study Group (EORTC-IFIG/MSG). The primary end-point was the use of a broad-spectrum antifungal agent. Results. One hundred and twenty-five patients, representing 145 potentially eligible episodes, were screened. Forty-seven patients with 52 episodes were randomized. Of the 27 episodes in the monitoring arm, the primary end-point was reached in 9 (33.3%). Two cases of IPA were diagnosed as a result of positive GM. One patient was classified as a failure of the presumptive strategy as IMI was diagnosed clinically while undergoing GM monitoring. Of the remaining 24 episodes, CAV was started empirically in 6, despite persistently negative GM results. False-positive GM readings occurred in 9 in the monitoring arm. Of the 25 episodes in the observational arm, CAV was started empirically in 10 for persistent FN. One patient had CT features of IPA. In the intent-to-treat analysis, the presumptive approach saved 11% of patients from empirical antifungals, while in the evaluable-episode analysis, the presumptive approach saved 14%. Twelve-week survival was 85.2% in the monitoring arm and 84% in the observational arm. Conclusions. A presumptive approach to antifungals has the potential to be an alternative to empirical antifungals in the persistently febrile neutropenics. However, one must recognize that the GM assay may not be the ideal diagnostic trigger as clinically significant mold infections (fusariosis, scedosporiosis, zygomycosis) are not diagnosable by this.

0861

IMPACT OF MULTIRESISTANT P. AERUGINOSA BLOODSTREAM INFECTIONS ON OUTCOME OF HAEMATOLOGICAL PATIENTS: RESULTS OF A PROSPECTIVE SURVEILLANCE PROGRAM

C Cattaneo,[1] F Bracchi,[1] L Baushi,[1] E Cerqui,[1] E Casalone,[2] G Ravizzola,[3] M Gelmi,[3] E Borlenghi,[1] A Re,[1] N Manca,[3] G Rossi[1]

[1]Hematology, Spedali Civili, Brescia, Italy; [2]Dept. of Biologia Evoluzionistica, University of Florence, Florence, Italy; [3]Institute of Microbiology, Univeristy of Brescia, Brescia, Italy

Background. Mortality rate of bloodstream infections (BSI) among neutropenic cancer patients ranges between 5-10%. However, little is known about the real impact on outcome of single pathogens, particularly if multiresistant. *Aims.* Since June 2004, a prospective epidemiological surveillance program is ongoing at our Haematology Unit. At the beginning of 2009, as a consequence of environmental contamination (EHA 2009, abstr. n. 1025), an outbreak of multiresistant P. aeruginosa (MR Pseud), was detected. Herein we determined the impact of MR Pseud BSI on the outcome of haematological patients at our Institution. *Methods.* BSI consecutively occurred at our Institution during a 70 month period (June 2004-January 2010) were evaluated and correlated with type of pathogen, state of underlying disease, neutropenia (<0.5 x $\times 10^9$/L), exposure to previous antibiotic therapy, including prophylaxis with fluoroquinolones, resistance to antibiotics and outcome. Beta-lactam +/- aminoglycoside +/- vancomycin was the regimen adopted for empiric antibiotic therapy in neutropenic patients with fever. P. aeruginosa showing resistance to >1 class of antibiotic with antipseudomonal activity was defined "multiresistant". *Results.* During the observation period, 445 BSI were recorded. Fungi were responsible for BSI in 6 (1.3%) cases (all Candida spp); Gram-positive (G+) bacteria in 150 (33.7%), Gram-negative (G-) bacteria in 256 (57.5%). In 34 (7.6%) cases a polymicrobial BSI was observed. Overall, 67 P. aeruginosa BSI were recorded; 28 out of 67 were MR Pseud. Crude mortality for all BSI was 46/445, 10.3%. Lethality was 3/6 (50%) for fungi, 6/150 (4%) for G+, 29/256 (11.3%) for G-, 8/34 (23.5%) for polymicrobial BSI. Death due to P. aeruginosa BSI was observed in 17/67 cases (25.4%) (MR Pseud: 11/28, 39.3%). Univariate statistical analysis showed that fungal BSI (P=0.016) as well as polymicrobial BSI (P=0.016) and uncontrolled haematological disease (P<0.0001) were predisposing factors for death. Considering single pathogens, only P. aeruginosa was responsible for an increased risk of death (17/67, 25.4% *vs.* 29/378, 7.7%) (P<0.0001) and, in this subset, MR Pseud fully accounted for the increased risk (11/28, 39.3% *vs.* 35/417, 8.4%) (P<0.0001). Neither polymicrobial BSI, nor P. aeruginosa BSI (including MR Pseud) were associated to a diagnosis of acute leukaemia, status of disease, neutropenia or previous exposure to levofloxacin/other antibiotics. In 24 cases of MR Pseud data about empiric first-line antibiotic therapy were available and its relative appropriateness according to antibiogram was evaluated. All but two MR Pseud showed susceptibility to amikacin; in 5 cases aminoglycosides were the only class of active antibiotics. In 6 cases first-line empiric therapy was inadequate; 5 out of 6 patients receiving inadequate treatment died, in comparison with 4/18 receiving at least 1 class of active antibiotics (P=0.017). Summary/*Conclusions.* Together with uncontrolled disease, fungal and polymicrobial etiology, MR P. aeruginosa BSI, wase responsible for an increased risk of death among haematological patients admitted at our Institution. In this setting, beta-lactam+aminoglycosides combination as early empiric antibiotic strategy reduced the mortality when compared to the use of single agent empiric therapy.

THE DETECTION OF GALACTOMANNAN IN BRONCHOALVEOLAR LAVAGE FLUID FOR THE DIAGNOSTICS OF INVASIVE PULMONARY ASPERGILOSIS IN HEMATOONCOLOGICAL PATIENTS

M Toskova,[1] Z Racil,[1] I Kocmanova,[2] M Lengerova,[1] M Rolencova,[1] J Mayer[1]

[1]Masaryk University and University Hospital Brno, Brno, Czech Republic; [2]University Hospital Brno, Brno, Czech Republic

Background. Invasive pulmonary aspergilosis (IPA) is a severe infectious complication of hematological patients and its early diagnosis can contribute to improve survival of affected patients. *Aims.* To compare the value of galactomannan (GM) detection in bronchoalveolar lavage (BAL) fluid in patients with proven/ probable IPA and patients without IPA. *Methods.* A retrospective analysis of GM detection (Platelia Aspergillus, Bio-Rad, France) in BAL fluid performed in 286 hematology patients between 7/2003 and 12/2009. IPA (EORTC/MSG 2008 criteria) was documented in 17% (50 pts.: proven IPA 7 pts., probable IPA 43 pts.). 28% (79 pts.) with possible IPA were excluded and 55% (157 pts.) without evidence of IPA were considered as negative control. *Results.* 207 samples from 201 pts. were included into analysis. The mean BAL GM index for patients with proven and probable IPA was 1.53 (range 0.07-9.01) and for negative control 0.15 (range 0.07-0.65). For patients with proven IPA mean BAL GM was 2.83 (range 0.12-9.01) *vs.* 1.31 (range 0.07-8.58) for pts. with probable IPA. The subgroup analysis (pts. with proven and probable IPA) shows that the mean value of GM for neutropenic pts. was higher as for non-neutropenic patients (0.86 *vs.* 0.29). 50% pts. with IPA (25/50) had also positive GM in blood sample (cutoff 2x ≥0.5). 70% pts. (35/50) from the group with IPA received mold-active antifungal drug (as prophylaxis or empirical therapy) before

BAL was performed, with median 2 days (range 1 - 60 days). 50% (3/6) of pts. with proven IPA and 45% (13/29) of pts with probable IPA on antifungals at the time of BAL performance had GM index < 0.5 in BAL fluid. The performance of galactomannan in BAL fluid tested at various cutoffs is presented in Table. *Summary/Conclusions.* Our study shows limited sensitivity and high specificity and high positive predictive value of GM detection in BAL fluid in pts. with hematological malignity. Limited sensitivity can be due to high rate of mold-active therapy and prophylaxis at the time of BAL performance.

Supported by grant of Ministry of health Czech Republic NS 10442-3/2009 and NS 10441-3/2009.

Table. Performance of BAL GM tested at various cutoffs.

cutoff BAL GM	sensitivity	specificity	PPV	NPV
≥0.5	54%	99%	90%	87%
≥0.7	46%	100%	100%	85%
≥1.0	38%	100%	100%	83%

VORICONAZOLE PLASMA CONCENTRATIONS IN HEMATOONCOLOGICAL PATIENTS

J Winterova, Z Racil, L Malaskova, M Lengerova, I Kocmanova, K Hrncirova, M Toskova, M Rolencova

University Hospital Brno, Brno, Czech Republic

Background. Voriconazole (VORI) is a broad spectrum antifungal agent, which exhibits a wide inter- and intrapatient variability of its plasma concentrations.VORI plasma levels monitoring could help us to optimize the individual dosing and improve the efficiency of antifungal treatment. *Aims.* To evaluat VORI plasma concentrations achieved during the VORI treatment in hematooncological patients in our institution. *Methods.* Trough VORI plasma concentrations were measured using a high-performance liquid chromatography assay. Retrospective analysis of laboratory results and documentation from patients treated with VORI from August 2005 to January 2010 was performed.

Table.

PC=plasma concentration

Daily dose	200 mg	400 mg	600 mg	800 mg
samples	81	564	109	31
patients	24	145	29	11
VORI PC <1 μg/ml	75% (n=60)	46% (n=257)	56% (n=61)	41% (n=13)
VORI PC <0.2 μg/ml	13% (n=10)	10% (n=58)	10% (n=11)	9% (n=3)
VORI PC >5 μg/ml	n=4	n=12	n=2	n=4
Mean VORI PC μg/ml	0,94	1,4	1,24	2,3
Median of VORI PC μg/ml	0,66	1,09	0,81	1,08

Results. 836 plasma samples from 148 patients were analyzed. The voriconazole plasma concentration was obtained once in 17% (n=25) patients and twice or more times (2-29) in 83 % (n=123). The monitoring time was 4-420 days after the start of voriconazole treatment. VORI was administered in 38% as prophylaxis, in 10% as an empirical antifungal treatment, in 48% as a preemptive treatment of invasive fungal infection. Only in 4% of cases was voriconazole administered as a treatment of proven invasive fungal infection. The total daily dose of voriconazole was from 200 to 800 mg. Achieved voriconazole plasma concentration varied between 0 and 13.41 μg/mL. 9.8% (n=82) of all obtained samples were below the detection limit of the metod (< 0.2μg/mL). Median plasma concentration achieved after standard daily dose of VORI (400 mg/day) was 1.35 μg/ ml (range: 0.2-7.64) after oral administration and 1.47 μg/ ml (range: 0.2-13.41) after intravenous administration. In 257 samples (45.6 %) after standard daily VORI dose 400 mg the plasma concentration was under 1 μg/mL - below the level associated with a better response to therapy of invasive aspergillosis. The increase of daily dose from 400 to 600 mg lead to elevation of VORI plasma level ≥ 1 μg/mL in 12 cases and in 10 patients the concentration did not changed or decreased. In 12 samples (2%) in 12 patients after the standard dose of VORI (400 mg/ day) plasma level was ≥ 5 μg/mL. However, only in 3 patients toxicity was observed (1 neurotoxicity and 2 hepatotoxicities). *Conclusion.* Measurement of VORI plasma levels during its treatment enables to achieve optimal dosing and an effective concentration, which improves the response to antifungal treatment in hematological patients with high risk of invasive fungal infection. In some cases also could help to identify the side effects and toxicity associated with VORI treatment.

POSACONAZOLE PLASMA LEVELS MONITORING IN HEMATOLOGICAL PATIENTS

J Winterova, Z Racil, L Malaskova, M Lengerova, I Kocmanova, M Toskova, M Rolencova, K Hrncirova

University Hospital Brno, Brno, Czech Republic

*Background.*Posaconazole (POSA) is a broad spectrum antifungal used in prophylaxis and treatment of invasive fungal infections in hematological patients.Due to its different oral bioavailability and potential drug interactions POSA exhibits variability in plasma concentrations. *Aims.* To analyse POSA plasma concentrations obtained during the POSA treatment in hematological patients in our institution.*Methods.* The high-performance liquid chromatography assay was used for the identification of POSA plasma concentrations. Retrospective analysis of laboratory results and clinical data from patients treated with POSA from November 2006 to January 2010 was performed. *Results.* 110 plasma samples from 25 patients were analyzed, 1-17 samples per patient. POSA plasma concetrations have been monitored in single patient once (n=10), twice (n=5) or more then three times (n=10) and it was 3-205 (median 31) days after start of POSA therapy. POSA was administered in 55% as prophylaxis, in 32% as a preemptive antifungal theraphy, in 7% as an empirical antifungal treatment and in 6% as a treatment of invasive fungal infection. POSA was administered as an oral suspension with some fat food and the total daily dose varied from 200 to 980 mg, divided in 2-4 portions. In 30% (n=32) of all samples did not achieve the concentration 0.5 μg/mL and thus the treatment could be insufficient.The POSA plasma concentration after daily dose 600 mg (3×200) was 0.2-3.1 μg/mL (median 1.12). After 800 mg daily the plasma concentrations varied between 0 and 3.1 μg/ mL, median was 0.7 and 1.01 after 4×200 mg and 2×400 mg, respectively. There were observed a considerable increase of POSA plasma concentrations in two patients after the change of POSA administration schedule from 2×400 mg to 4×200 mg/ daily.*Conclusion.* POSA plasma concentrations monitoring could be useful guide during the antifungal treatment. It help us to achieve the effective plasma and tissue concentrations and thus could improve the outcome of invasive fungal infection in hematological patients.

POSACONAZOLE IN PROPHYLAXIS OF FUNGAL INFECTIONS IN NEUTROPENIC PATIENTS A SINGLE CENTRE EXPERIENCE

E Zappone, S Nardelli, U Coppetelll, E Ortu La Barbera, A Centra, C Ciabatta, F Ciccone, G Potente, A De Blasio

Ospedale S.M. Goretti, Latina, Italy

Invasive fungal infections (IFI) in patients affected by hematologic malignancies remain an important cause of morbidity and mortality. In attempt to prevent the onset of IFI antimycotic prophylaxis or pre-emptive treatment have been proposed but their role and efficacy are still uncertain. Introduction of Posaconazole as prophylactic agent seems reduce the onset of IFI in patients undergoing stem-cell transplant; it is also recommended in patients with Acute Leukemia undergoing induction chemotherapy. Timing of prophylactic approach is also controver-

sial: there's no evidence, in term of number and evolution of IFI, showing better results in early prophylaxis (in patients with high risk of IFI not yet neutropenic) rather than prophylaxis in febrile persistent neutropenia. We investigated the efficacy, safety and feasibility of Posaconazole as prophylactic agent against IFI in patients with anticipated neutropenia (N<500/mmc), all hospitalized in our Department. During a 18 months period (July 2008 - January 2010) we enrolled 76 adult patients all submitted to intensive chemotherapy or autologous stem cell transplant; the expected severe neutropenia was at least 7 days. Patients with evidence of previous fungal infection were excluded. Patients received posaconazole oral suspension 600 mg from day 1 of chemotherapy until neutrophyls recovery (>500/mmc). Study failure was defined by the following events: start of empiric antifungal therapy for persistent FUO; antifungal therapy for proven or probable IFI; early death; toxicity resulted in too short prophylaxis period (<7-10 d) and/or assumption of <75% fixed dose. We enrolled 39 males and 37 females, median age 53 years (range 19-72), the median prophylaxis period was 20.5 days (range 6-42); 46 patients underwent intensive chemotherapy and 28 pts underwent conditioning regimens for autologous transplant. Diagnosis were: Acute Myeloid Leukemia 31 patients; Acute Lymphoblastic Leukemia 13 patients; Lymphoma 17 patients; Multiple Myeloma 9 patients. The median duration of neutropenia was 20,5 days (range 4-42). 66 of the 76 patients (86%) had at least one episode of fever, in 44 patients the fever duration was less than 3 days. The median duration of fever was 2 days (range 1-16). We observed 18/76 failure (24%), 6 patients (8%) assumed <75% of the fixed dose. IFI proven or probable was diagnosed in 5 patients (6.5%) and possible IFI in 7 patients (9.2%), all but one were acute leukemia patients. 4 patients (5%) died, 3 of them while treated for IFI. Tolerability was very good in 56/76 patients (>90% dose taken) and good in 7/76 patients (>80%). Hepatic or gastrointestinal toxicity grade 2/3 was observed in 13/76 pts (17%). These encouraging results suggest that Posaconazole used in an early phase of intensive chemotherapy can reduce the number and duration of febrile episodes as well as of IFI proven or suspect in a high risk population of hematologic patients.

0866

MALARIA: NEW DIAGNOSTIC APPROACHES

MA Molina-Arrebola, JA García-Bautista, R Pérez-Moyano, MJ Giménez-López, MT Cabezas-Fernández, J Salas-Coronas, C Avivar-Oyonarte

E.P. Hospital de Poniente, El Ejido - Almeria, Spain

Background. Migrations have turned malaria into a re-emerging worldwide health problem. *Aims.* To present the demographic, clinical and laboratory features of all cases of malaria diagnosed in our hospital. *Material and Methods.* Study period: January 1998 to December 2009. Diagnostic *Methods.* peripheral blood smear, rapid immunodiagnostic test (Leti Laboratories ®) (for cases diagnosed between 2002 and 2009) and Polimerase Chain Reaction (PCR), since 2008. PCR for malaria has been included in the battery of analytical tests ordered for first-time consultation immigrant patients seen in our Tropical Medicine Unit who have been less than one year in our country. *Results.* the study comprises 55 patients (49 male, 6 female): average age 30 years (range 3-71). Most frequent countries of origin: Senegal (9 cases), Ghana (9), Mali (8), Nigeria (7), Guinea-Bissau (7), Equatorial Guinea (4) and Mauritania (3). Of 25 cases up to 2007, 2 were infested with Plasmodium vivax (385 and 180 days of residence in Spain), and the rest P. falciparum in patients who, coming from their native countries, had arrived to Spain in the 30 days prior to diagnosis. After 2007: 30 cases, including one double parasitization (falciparum+ovale), 2 cases of P. malariae (3 and 4 years of residence), 1 case of P. ovale, and 26 P. falciparum. Among these, 5 were children, 6 women (1 pregnant) and 10 patients who had stayed in Spain between 3 and 8 months. Since the implementation of routine screening, 10 cases have been diagnosticated only by PCR (9 P. falciparum and 1 P. ovale). All others presented clinical features: fever, headache, malaise, abdominal discomfort, while only one presented with serious cerebral malaria. Among hematological abnormalities, the mos frequent were a low platelet count (34/55, 61,8% of total), 34/45 (76% in those diagnosed by blood film observation, none of those diagnosed by PCR) and anemia (25/55, 45,4%; 22/45, 49% diagnosed by blood smear, only 3 diagnosed by PCR). *Conclusions.* Malaria cases diagnosed in our hospital are immigrants. Thrombocytopenia is the most common finding in the complete blood count, not so in asymptomatic patients. We are witnessing a demographic change from 2007 with the appearance of cases in children and women. Interestingly, we have found cases of P. falciparum in patients who have been in our country continously for longer than 10 months. The analytical systematic screening has proved useful in unveiling cases of unsuspected parasitizations.

H1N1V INFECTION IN CHILDREN WITH DREPANOCYTOSIS

S Nóbrega,[1] T Ferreira,[2] P Correia,[3] A Dias[4]

[1]Hospital Fernando Fonseca, Lisbon, Portugal; Amadora-Lisbon, Portugal; [3]Paula, Amadora-Lisbon, Portugal; [4]Alexandra, Amadora-Lisbon, Portugal

Background. with the new Influenza A H1N1virus it was expected more severe infection in patients with drepanocytosis (sickle cell homozygote hemoglobinopathy). *Methods.* retrospective, descriptive study, of drepanocytic children with H1N1v infection confirmed by Polymerase Chain Reaction observed at a tertiary hospital from October to December 2009. *Aims.* analysis of demographic, vaccinal, hospitalization, clinical, laboratory, radiological features, treatment, complications and outcome of sickle cell patients with H1N1 infection. *Results.* 74 patients are followed at this tertiary hospital, 15 (20%) of whom had H1N1v infection. The majority (11) occurred in November and December. Mean age 7 years (min-1,8; max-15), 10 were admitted. Thirteen patients were not vaccinated with the pandemic vaccine, but 2 had had a first dose less than 3 weeks before infection. Frequent symptoms were: fever, cough and pain. The laboratorial features (73%): haemoglobin (mean-7.9 g/dL, min-4.8), reticulocytes (mean-260000/µl, min-28000), leukocytes (mean-12700/µL, min-11500, max-20300), CRP (mean-0.75 mg/dL, max-14.4). Chest radiography (12): interstitial infiltrate (6), pneumonia (1). Treatment included: oseltamivir (15), antibiotics (4), transfusion (3). Complications were noted: hypoxemia (5), severe anaemia with reticulocytopenia (2), pneumonia (1), moderate to severe pain (3). Mean time of admission was 5 days (min-3, max-21). No deaths occurred. Summary. drepanocytic patients are a risk group for complications of influenza infection and therefore should have the pandemic vaccine. Most cases occurred in November-December, reflecting the importance of early and complete immunization schedule. Nevertheless, although some complications did occur, the general outcome was good.

0868

ASSESSMENT OF HEMATOLOGY PATIENTS WITH CONFIRMED H1N1 POSITIVITY

F Ozdemirkiran, C Cicek, H Pullukcu, S Cagirgan, M Tombuloglu, F Vural, G Saydam

Ege University Hospital, Izmir, Turkey

Background and *Aims.* Pandemic influenze virus known as H1N1 causes serious complications in immunosuppressive patients. Morbidity and mortality risks are increasing in patients with hematological disorder and have been treated with chemotherapy and stem cell transplantation. In this study, clinical and laboratory findings of hematology patients whose H1N1 positivity has been confirmed while under treatment in our clinic. *Methods.* H1N1 Swine Influenza Suspicious Case Notification Form and Inpatient Follow-up Form have been prepared for 15 patients with a suspicion of H1N1 infection (4 women, 11 men) among inpatients that are being treated at our clinic as of October 2009. Nasopharyngeal swab taken form patients have been forwarded to our virology laboratory. Pandemic influenza A 2009 H1N1 virus was detected by real time RT PCR assay by under the guidance of producer's instructions. *Results.* Nasopharyngeal swab specimens taken from 15 (11 men, 4 women) patients with a suspicion of H1N1 infection. Among 15 patients, H1N1 positivity has been confirmed in 9 patients (7 men, 2 women; age average 49) using real-time PCR. One of 9 patients had been followed due to aplastic anemia, one due to Evans Syndrome, and the remaining 7 due to hematological malignity. Most prominent symptoms are as follows; high fever, cough, vomiting, nausea, diarrhea respectively. 3 patients had concurrent bacterial infection and in one patient fungal infection was present. All patients have been treated with oseltavimir treatment (10 days for patients with pneumonic infiltration, 5 days for the other patients) 8 patients have responded to the treatment and recovered clinically. One patient died due to severe sepsis and pneumonia. *Summary/Conclusion.* Subjective findings like headache and fatigue often seen in influenza infections are seen not to be dominant for these patients. It is remarkable that nausea and diarrhea that are prominent findings for the pandemic H1N1 influenza infections have rarely been detected in these patients. Most of our patients have recovered with intensive support treatment and anti-viral treatment. However one

patient with severe pneumonia died in the clinical course. Associating unaccountable high fever with the currently seen infections and early sampling can be life saving and clinicians should be aware of potential pandemic influenza H1N1 in patients with hematological disorder.

0869

CHARACTERISTICS OF SEPTIC COMPLICATIONS IN PATIENTS, RECEIVING CHEMOTHERAPY, STEM CELL TRANSPLANTATION AND IMMUNOSUPPRESSIVE TREATMENT OF GRAFT-VERSUS-HOST DISEASE

V Vavilov, O Goloshchapov, O Ponomarenko, M Toropova, M Averjanova, N Kostin, L Zoubarovskaya, B Afanasyev

I.Pavlov State Medical University, Saint-Petersburg, Russian Federation

Background. Patients, receiving intensive chemotherapy of hematologic diseases, hematopoietic stem cell transplantation (HSCT) and immunosuppressive treatment of its main complication, "graft-versus-host"disease (GVHD), are known to bee under extremely high risk of bacterial and fungal infections, which severity varies from neutropenic fever to septic shock. Trends in etiology, risk factors and treatment strategy of severe sepsis and septic shock are well described in literature. Nevertheless in the majority of studies concerning sepsis didn't include hematological and transplanted patients. *Aim.* This study was provided to characterize the etiology of septic complications, factors which determinates mortality from sepsis in patients receiving chemotherapy or HSCT. *Methods.* Forty patients with confirmed diagnosis of sepsis, severe sepsis and septic shock were included in the study. Patients received conventional chemotherapy (72%), HSCT (10%) and immunosuppressive therapy of GVHD after transplantation (18%) for acute leukemia (67,5%), malignant lymphoma (10%), Ewing sarcoma (7,5%), chronic myeloid leukemia (5%), MDS (5%), severe aplastic anemia (2,5%) and SCID (2,5%). 45% of patients were in remission or stable disease at time of sepsis development. The diagnoses of septic complications were provided according to the classical ACCP/SCCM criteria and confirmed with quantitative CRP and semiquantitative procalcitonin evaluation. *Results.* The etiology of sepsis was identified in 77,5% of cases. In 10% of patients sepsis was confirmed by high procalcitonin levels without microbiological verification. In 62,9% of patients sepsis was caused by Gram-negative bacteria and in 25,7% by Gram-positive cocci. Most common bacterial agents were Klebsiella pneumoniae (20%), Pseudomonas aeruginosa (14,3%) and Staphylococcus epidermidis (14,3%). Fungal sepsis was observed in 11,4% of patients. Analysis of antibiotic resistance reveals high rates of multiresistant bacteria (especially Pseudomonas aeruginosa, Klebsiella pneumoniae and Acinetobacter baumanii). Infections caused by these microorganisms were more common for patients admitted to ICU. No cases of septic complications caused by MRSA or VRE were observed. Severe sepsis was observed in 77,5% of patients with the rate of septic shock - 55%. In 70% of cases patients have respiratory failure, in 35% - renal failure, in 35% - liver impairment. Coagulopathy was observed in 42,5% of patients. Overall mortality was 65% in the group, 77,5% in patients with severe sepsis and 68,2% with septic shock. The involvement of liver and kidney in multiorgan failure (MOF) was associated with 100% mortality rate. Another factor, influencing mortality rate was disease status at the time of infection. Patients with stable disease or remission have lover mortality risk, than patients in progression or relapse (39% and 86%, respectively). *Conclusion.* Septic complications in patients with hematological disorders, solid tumors and after HSCT stay an actual problem because of high mortality rates especially in cases of MOF. Risk of mortality is also influenced by the disease status. Most common microorganisms causing sepsis in this high-risk group are multi-drug resistant Gram-negative rods. In the absence of microbiological verification of sepsis the determination of procalcitonin level became valuable diagnostic tool. These factors should be taken into account while planning the treatment of the patient.

0870

HIGH DOSE LIPOSOMAL AMPHOTERICIN B (HD-L-AMB) IN THE PROPHYLAXIS OF INVASIVE FUNGAL DISEASES (IFD) IN ADULT AND ELDERLY ACUTE LEUKEMIA (AL) PATIENTS (PTS)

B Anaclerico, A Chierichini, S Fenu, M Cedrone, V Bongarzoni, B Ronci, P Anticoli Borza, S Cortese, P Iacovino, L Annino

Az Osp S. Giovanni-Addolorata, Rome, Italy

Background. IFDs cause morbidity and mortality in AL pts , with an high attributable mortality rate when filamentous fungi are involved. Prophylaxis is an used strategy because the diagnosis of IFD is often difficult to obtain in due time to establish an early treatment .Oral posaconazole is the drug of choice,although mucositis, impaired dietary intake, proton pump inhibitors, influence absorption with pharmacokinetic variability. In these cases the use of a broad spectrum intravenous drug may be preferred. Animal models demonstrate that L-AMB accumulates in the reticulo-endothelial system for several weeks providing effective prophylaxis even at single high dose. *Aim.* We have conducted an exploratory prospective single centre study to test the safety, efficacy and PK profile of HD-L-AMB (15 mg/kg) as IFD prophylaxis in AL pts during intensive induction chemotherapy. Patients and *methods.* From 2004 to 2009, 44 AL pts (AML 40 , ALL 3 , MPAL 1) entered this study. They were 27 adult pts (Group A) - median age 49 years (range 32 -59)- and 17 elderly pts (Group B)- median age 68 years (range 61-78)-; in 3/17 a pulmonary infection was documented at diagnosis and cured before start of chemotherapy. Pts received first HD-L-AMB the day after last dose of chemotherapy . A 2nd dose was given two weeks later in the event of persistent neutropenia in pts without sign of IFD . L-AmB plasma levels were measured by chromatography at d 1st (0,1,4 ,24 h), d 7th and d 14th. To date, PK data are available in 9/26 pts in group A and 8/17 pts in group B. *Results.* The median dosage of administered L-AMB was 900 mg (range 500-1200) in both groups. In Group A, median duration of neutropenia was 22 d (range16 -30) and 3 pts received a 2nd dose. Median L-AMB serum levels at 0h,1h, 4h, 24h, 7th d and14th d were 0, 7.76 , 23.09, 11.8, 0.23 and 0 mg/L, respectively. No IFD was documented at 28 days of follow up. In Group B, median duration of neutropenia was 21 d (range 11-42) and 3 pts received a 2nd dose. Median L-AMB plasma level at 0h, 1h, 4h, 24h, 7th and14th d were 0, 5.4, 13.9, 7.79, 0 and 0 mg/L, respectively. In this group a fatal invasive aspergillosis was documented in the 3 above patients with pulmonary co-morbidity at onset. A serious adverse event CDC grade 3-4 (allergy) requiring drug discontinuation was reported in only one patient of Group A. *Conclusions.* Our preliminary experience seems to show that a single HD-L-AMB is tolerated and safe in adult and elderly AL pts. This antifungal regimen was able to prevent IFDs in pts without co-morbidities involving the respiratory tract. A single HD-L-AMB may be an alternative antifungal prophylactic regimen in AL pts with gastrointestinal problems impairing the absorption of posaconazole. Although no correlation between PK and efficacy can be made with the few available data, the possibility of a less favourable PK profile in elderly pts should be carefully assessed.

0871

PREVALENCE OF SUBTYPES OF HUMAN IMMUNODEFICIENCY VIRUS CIRCULATING AMONG BLOOD DONORS IN PERNAMBUCO, BRAZIL

E Borges Vitor Anjos,[1] A Bezerra,[2] M Valença,[2] D Albuquerque,[3] P Andrade,[4] S Costa[4]

[1]UNICAMP, Campinas, Brazil; [2]Hematology and Hemotherapy Foundation of Pernambuco, Recife, Brazil; [3]Hematology and Hemotherapy Center, UNICAMP, Campinas, Brazil; [4]Department of Internal Medicine, Faculty of Medical Sciences, UNICAMP, Campinas, Brazil

Background. AIDS is a disease manifested after infection with Human Immunodeficiency Virus (HIV). It is estimated that about 600 thousand people are living today with HIV in Brazil, which included a total of 40 million worldwide. In Pernambuco were reported about 11 cases between 1980 and 2007 by SINAN (Sistema de Informação de Agravos de Notificação - Information System for Notifiable Diseases). The virus is characterized by a high genetic variability and is classified into two types: HIV-1 and HIV-2. Nine subtypes (A, B, C, D, F, G, H, I, J) are described, in addition to recombinant forms of Circulating Recombinant Forms called. The identification of circulating subtypes is of paramount importance for understanding the epidemic and for future vaccine programs are successful. The natural dynamics of the HIV epidemic in Brazil has led us to evaluate the present subtypes of HIV-1 in blood donations infected with HIV. Blood donors represent a broad cross section of the population of selected groups of high risk and therefore may provide a broader view of circulating strains of HIV-1 in Brazil. *Aims.* The objective of this study is to determine the prevalence of circulating subtypes of HIV-1 in blood donors of the HEMOPE Foundation. *Methods.* We analyzed 40 blood samples from blood donors positive for HIV-1 of the HEMOPE Foundation, being performed DNA extraction of lymphocytes and amplification of the region ENV (gp120 - C2V3 region) of the integrated viral DNA. From this procedure, the glycoprotein 120 gene was amplified by nested-PCR and subjected to automated sequencing. The subtype assignment was confirmed by bootstrapped phylogenetic analysis using SEQBOOT with 1000 replicates,

followed by DNAdist (with Kimura 2-parameter method and transition/transversion ratio of 2.0), Neighbour and Condense programs contained in PHYLIP (PHYlogeny Inference Package). *Results.* Of the 40 samples sequenced, we identified 35 samples (87.50%) of subtype B, 4 samples (10.0%) were subtype C and 1 sample (2.50% [-]) was the recombinant form CRF02_AG. In the rest of Brazil, subtype B is also the most frequent, except in the southern region where the predominant subtype is subtype C. *Conclusions.* The results indicate a greater prevalence of subtype B in the Northeast, especially in Pernambuco, which is consistent with work already published. The preliminary findings of this study demonstrate the need for studies to monitor the epidemiological profile of HIV, especially in regard to screening of circulating viruses and the development of a vaccine program. Also, a clinical follow-up of these donors with defined subtypes can generate information about the specificity of the response of each viral subtype, working with specific treatments.

0872

PNEUMOCYSTIS JIROVECI PNEUMONIA IN AN ONCOLOGY POPULATION, NEW LESSONS FOR AN OLD INFECTION

M FitzGerald, D O'Keeffe

Mid Western Regional Hospital, Limerick, Ireland

Background. Pneumocystis jiroveci is an opportunistic organism and a common cause of pneumonia in patients with impaired cellular immunity. Pneumocystis jiroveci pneumonia (PCP) is the commonest opportunistic infection in AIDS patients and carries a mortality rate of 10-30%. In non-HIV patients with impaired cellular immunity, due to high corticosteroid use, chemotherapy or malignancy, PCP has a mortality rate of 30-60%. With oncology patients living longer, the exact risk and optimum management incorporating investigation, treatment and prophylaxis for PCP is now unclear. *Aim.* To assess the risk factors involved in the development of PCP, to review its diagnosis and the use of PCP prophylaxis in a non-HIV cancer population. *Methods.* A retrospective case note analysis of all patients who were treated for PCP with IV cotrimoxazole between 2006 and 2009 (inclusive) was conducted. Data collected: Malignancy, Risk Factors (corticosteroid in previous 2 months, chemotherapy, immunosuppressants in previous 12 months, previous organ transplantation, previous PCP infection), PCP Prophylaxis, Clinical Presentation (symptoms, onset, SaO2, temperature, lymphocytes count, time to treatment), Diagnosis (definite *vs.* probable) and Outcome. *Results.* 14 patients were included in the study, 9 had haematological malignancies (4 Lymphoma, 3 Multiple Myeloma, and 3 CLL) and 6 had solid malignancies (1 each of NSCLC, SCLC, Cholangiocarcinoma Rectal, and Breast). 2 had early stage cancer, 6 had relapsed, 3 metastatic and 2 were palliative. Risk factors: 12 received corticosteroids in the 2 months prior to infection (daily average 26 mg). 13 received chemotherapy, 7 received other immunosuppressives, and 3 received radiotherapy in the 12 months prior to infection. On presentation, all had signs of symptoms of pneumonia (dry cough, dyspnoea, or lung crepitations), 10 were lymphopenic, 9 were hypoxic (4 severely) and 8 were pyrexic. Diagnosis: 6 patients had definitive PCP diagnosis (5 Bronchoalveolar lavage and 1 expectorated sputum positive for P. jiroveci DNA), 7 had probable (clinical) diagnosis and 1 patient was negative for P. jiroveci DNA in Bronchoalveolar lavage. There were no incidences of failed prophylaxis. Antibiotic treatment for PCP commenced on average 3.3 days after admission. 12 patients recovered from the infection and 2 died. *Conclusion.* Development of PCP was associated with a diverse range of risk factors and a heterogeneous array of malignancies. However, the study highlighted several important points: - Despite the varied chemotherapy received, 85% of patients received corticosteroids in the 2 months prior to infection. - 5 of the 6 Bronchoalveolar lavages tested for PCP DNA were positive, proving it to be a very advantageous investigation. - The mortality rate of PCP amongst patients was better that expected (14% *vs.* 30-60% in the literature). This is a reflection of the prompt initiation of PCP treatment (3.3 days) and emphasises the importance of having a high level of clinical suspicion and a low threshold for treatment. - 4 lymphoma patients (>5% of lymphoma population) were included in the study, highlighting the need to further investigate whether this group is suitable for PCP prophylaxis.

0873

HEMATOPOIETIC STEM CELL TRANSPLANTATION FROM A RELATED DONOR INFECTED WITH SWINE-ORIGIN H1N1 INFLUENZA VIRUS

SH Lee, H Chueh, KW Sung, HH Koo, DH Kim, SJ Kim, JH Jang, K Kim, CW Jung

Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South-Korea

Background. Swine-origin H1N1 influenza virus (S-OIV) has caused significant illness worldwide. Complications of influenza infection generally arise in those populations that are most susceptible to infection, such as hematopoietic stem cell transplantation (HSCT) recipients. Among HSCT patients with influenza pneumonia, the 30-day mortality rate can be as high as 28%. Therefore, a guideline for prevention, diagnosis, and treatment of S-OIV is required in HSCT in the pandemic setting, with a concern for transmission of the virus from donor to recipient. *Aims.* We report our experiences of 3 patients whose related donors caught S-OIV during pandemic successfully undergoing hematopoietic stem cell transplantation. Patients and *methods.* From October to December 2009, 26 patients underwent allogeneic hematopoietic stem cell transplantation (13 in the department of medicine and 13 in the department of pediatrics) at Samsung Medical Center. Among them, 10 patients received stem cells from their matched related donors. To detect S-OIV, RT-PCR was performed in various samples including upper respiratory sample obtained by nasal wash, whole blood, and PBSC product. *Results.* Three related donors were infected with S-OIV while recipients (2 patients with severe aplastic anemia and 1 patient with relapsed lymphoma) were treated with conditioning regimens. In two donors, they admitted for PBSC collection a day before transplantation. After admission, they showed fever and cough and tested positive for S-OIV RT-PCR in nasal wash specimen. PBSC collection and transplantation was performed without delay. Donors' blood and PBSC products were also tested for S-OIV by RT-PCR. Although the results were negative in donors' blood, PBSC product showed positive result in one sample. The recipients and donors were given oseltamivir and the recipients did not show any symptoms or signs related to influenza after transplantation. In remaining one donor, he caught S-OIV flu four days before transplantation. He was treated with oseltamivir and he showed progressive leucopenia. G-CSF was given after recovery of leukocyte counts, therefore, transplantation was deferred for five days. In this case, PBSC collection and transplantation were performed after confirmation of negative result on donor's blood and PBSC product by RT-PCR. The recipient was not given oseltamivir because the donor already was treated with oseltamivir for 7 days. The median number of infused $CD34^+$ cells was 5.3×10^6/kg (range 2.0-8.8). Neutrophil and platelet engraftment were occurred at a median of 11 days (range 10-11) and 18 days (range 17-36), respectively. *Conclusion.* The recipients were successfully transplanted from donors infected with S-OIV. Further studies are required to establish a guideline for recipients and donors in hematopoietic stem cell transplantation during influenza pandemic.

ANTIFUNGAL PROPHYLAXIS WITH VORICONAZOLE IN PAEDIATRIC PATIENTS TREATED FOR HEMATOLOGICAL MALIGNANCIES

P Panagopoulou,[1] F Fragandrea - Sidi,[2] P Panagopoulou,[3] E Roilides,[4] S Sofianou,[5] K Koliouskas[2]

[1]Ippokratio Hospital, Thessaloniki, Greece; [2]Pediatric Oncology Dept, Ippokratio Hospital, Thessaloniki, Greece; [3]Pediatric Oncololgy Dept, Ippokratio Hospital, Thessaloniki, Greece; [4]3rd Dept Pediatrics, Ippokratio Hospital, Thessaloniki, Greece; [5]Microbiology Dept, Ippokratio Hospital, Thessaloniki, Greece

Background. Invasive fungal infections (IFI) remain a major cause of death in immunocompromised hosts, such as patients with haematological malignancies receiving chemotherapy, despite the availability of highly effective antifungal agents. The risk of IFI is associated with the degree and duration of neutropenia, the disruption of mucosal barriers and the prolonged use of antibiotics and corticosteroids. Voriconazole is a triazol antifungal agent that exhibits broad antifungal activity against both Aspergillus and Candida (including non-albicans) species, which has been used for the treatment of invasive candidiasis and aspergillosis. Its use as a prophylactic agent is under study, especially in children. *Aims.* the aim of the study was to evaluate the efficacy and safety of voriconazole as antifungal prophylaxis in children suffering from hematological malignancies with chemotherapy induced neu-

tropenia. *Methods.* The files of 69 children (42 Acute Lymphoblastic Leukemia (ALL), 1 mature B ALL, 8 Acute Myelogenous Leukemia (AML), 16 Non-Hodgkin Lymphoma, 2 Hodgkin Disease), were retrospectively reviewed. All patients were treated at a single institution, between January 2006 and December 2009, and received antifungal prophylaxis with voriconazole during chemotherapy induced neutropenia. Age, gender, diagnosis, treatment regimen and laboratory investigations (namely: WBC counts and liver function tests) were recorded. Voriconazole was administered at a dose of 4mg/Kg bid, intravenously or orally. *Results.* In total, 236 patient - cycles were studied. Median duration of neutropenia after chemotherapy during which time voriconazole prophylaxis was administered was 15 days. Treatment success rate defined as absence of proven, probable, possible or suspected IFI was 95.64% (229/236). Proven IFI was documented in two patients with ALL (1 pulmonary aspergillosis, 1 Candida albicans fungemia), one had probable IFI (splenic candidiasis) and in four cases were considered suspected IFIs. No severe adverse reactions or interactions with concurrent medications were observed that could be attributed to voriconazole administration. *Conclusions.* These results suggest that voriconazole, at the described dosage, is an effective and well-tolerated alternative for antifungal prophylaxis in children with hematological malignancies during chemotherapy induced neutropenia. Randomized, double-blind, case-control studies are needed to confirm the efficacy of this approach in comparison to standard treatments.

THE USE OF CELL POPULATION DATA FOR THE DIAGNOSIS OF NEONATAL SEPSIS

F Raimondi,[1] M Sellitto,[2] L Capasso,[2] D Del Buono,[2] R Pisanti,[2] M De Rosa,[2] E Grimaldi,[3] F Scopacasa[3]

[1]Università Federico II di Napoli, Naples, Italy; [2]Department of Pediatrics, Università Federico II, Naples, Italy; [3]Department of Biochemistry and Medical Biotechnology, Università Federico II, Naples, Italy

Background. Larger, immature neutrophils pour in the bloodstream during neonatal sepsis. Current technology allows to assess the neutrophil volume distribution, an index that has previously been used to detect acute bacterial infections in the adult. We have studied automated neutrophil volume and its distribution as a screening tool for late onset sepsis in very low birth weight neonates. Patients and *Methods.* Consecutive very low birth weight symptomatic neonates were screened for sepsis using complete blood count (CBC), absolute neutrophil count (ANC), immature /total (I/T) ratio, C- reactive protein (CRP). Neutrophil volume (NeV) and neutrophil volume distribution width (NDW) were determined both in infants with suspected sepsis and in a group of controls matched for gender, birth weight and gestational age who were not symptomatic for sepsis. Blood culture was used as the gold standard for infection. Receiver operator curves, area under the curve, sensitivity, specificity, positive and negative predictive values were calculated for each test. *Results.* We enrolled 120 neonates with suspected sepsis and 60 asymptomatic infants. NeV proved to be a useful diagnostic test for sepsis on a single determination (sensitivity= 95%; specificity=88%; cut off =148 arbitrary units) performing better than CRP (sensitivity= 65%; specificity=96%; cut off =0.9 mg/dL), white blood cells count, ANC and I/T ratio. NDW was of poor value (sensitivity=80% specificity=52% cut-off=27.5) . When CRP and NeV were considered together, sensitivity was unchanged while specificity rose to 97%. NeV was positive in 1 out 60 asymptomatic infants. *Conclusion.* NeV is a reliable and inexpensive adjunct to the current screening tests for neonatal late-onset sepsis.

ASPERGILLUS GALACTOMANNAN (GM) ANTIGEN IN THE BRONCHOALVEOLAR LAVAGE (BAL) FLUID FOR THE DIAGNOSIS OF INVASIVE PULMONARY ASPERGILLOSIS (IPA) IN HEMATOLOGICAL PATIENTS

I Vengalyte,[1] R Pileckyte,[1] L Griskevicius[2];

[1]Vilnius University Hospital Santariskiu Clinics, Vilnius, Lithuania; [2]Vilnius University Hospital and Vilnius University, Vilnius, Lithuania

Background. IPA is a diagnostic challenge in immunosupressed patients. Recently developed BAL GM assay shows promising *Results.* A positive BAL GM has also been proposed as a criterion of IPA, although it has not been fully validated. *Aims.* Our purpose was to investigate the role of GM in BAL fluid as a tool for diagnosis of IPA in hematological patients. *Methods.* We prospectively collected clinical and laboratory data in patients who had BAL GM performed in Hematology, Oncology and Transfusion Medicine Center of Vilnius University Hospital between 2006 and 2009. A BAL GM cut-off value of ≥ 0.5 was considered positive. Patients were categorized as having proven, probable, or possible IPA according to the revised EORTC/MSG definitions. The sensitivity, specificity, negative and positive predictive values of positive BAL GM were calculated with respect to proven or probable IPA. *Results.* 84 patients had BAL GM performed. 48 (57%) were male and 36 (43%) were female. Median age was 48 years (range 18-84). 9 (10.7%) patients had chronic myelogenous leukemia, 39 (46.4%) had acute leukemia, 9 (10.7%) had chronic lymphocytic leukemia, 13 (15.5%) had lymphoma, and 14 (16.7%) had other hematological diseases. In 44 (52%) cases neutrophil count was $<0.5x10^9$ L. Autologous or allogeneic stem cell transplantation had been performed in 8 and 24 patients, respectively. 2 (2.4%) patients had proven, 41 (48.8%) had probable, and 41 (48.8%) had possible IPA. BAL GM and serum GM were simultaneously obtained in 47 (56%) cases, and both tests were positive in only 4. Chest CT scan was performed in 63 (75%) patients at the time of suspected IPA and was positive in 53 cases. The sensitivity, specificity, negative and positive predictive values of positive BAL GM were 100%, 70.7%, 100% and 77.8%, respectively. *Conclusions*. BAL GM has a high negative but a moderate positive predictive value. Serum GM is only rarely positive in IPA.

Lymphoma - Clinical 3 (including Hodgkin lymphoma)

IMPACT OF FEBRILE NEUTROPENIA ON RCHOP CHEMOTHERAPY DELIVERY AND HOSPITALIZATIONS: RESULTS FROM AN INTERNATIONAL OBSERVATIONAL STUDY IN PATIENTS WITH NON-HODGKIN LYMPHOMA (IMPACT NHL)

R Pettengell,[1] HE Johnsen,[2] P Lugtenburg,[3] A Salar,[4] U Duehrsen,[5] C Haioun,[6] G Verhoef,[7] F Rossi,[8] M Schwenkglenks,[9] K Bendall,[10] Z Szabo,[11] U Jaeger[12]

[1]St George's University of London, London, UK; [2]Aalborg Hospital, Aalborg, Denmark; [3]Erasmus MC, Rotterdam, Netherlands; [4]Hospital del Mar, Barcelona, Spain; [5]University Hospital Essen, Essen, Germany; [6]Hematology, Henri Mondor Hospital, Creteil, France; [7]University Hospital Leuven, Leuven, Belgium; [8]Fondazione Policlinico MaRe IRCCS, Milan, Italy; [9]European Center of Pharmaceutical Medicine, University of Basel, Basel, Switzerland; [10]Biostatistics, Amgen Ltd., Uxbridge, UK; [11]Amgen (Europe) GmbH, Zug, Switzerland;[12] Medical University of Vienna, Vienna, Austria

Background. Data indicate that reductions in CHOP (cyclophosphamide, doxorubicin, vincristine, prednisolone) chemotherapy dose intensity below 90% may decrease survival in patients with aggressive non-Hodgkin lymphoma (NHL).[1] Due to its myelotoxicity, the delivery of CHOP chemotherapy is frequently impeded by severe neutropenia and/or febrile neutropenia (FN), particularly if a period of hospitalization is required. *Aims.* In this post-hoc analysis from the IMPACT NHL study, we aimed to describe the impact of FN on chemotherapy delivery. *Methods.* IMPACT NHL included patients (≥18 years) with NHL receiving either CHOP-14 or CHOP-21 chemotherapy±rituximab (R). Centres in Europe (123 sites) and Australia (5 sites) each included the five consecutive, eligible patients that had most recently completed their (R)CHOP chemotherapy, and recruited 10-15 further patients prospectively. This analysis focuses on chemotherapy delivery parameters and unplanned hospitalizations for patients with diffuse large B cell lymphoma (DLBCL) receiving R-CHOP chemotherapy depending on whether or not they experienced FN. *Results.* A total of 1111 patients treated between 2005 and 2008 were included in this analysis (R-CHOP-21, N=702; R-CHOP-14, N=409). Respectively, 36% and 84% of the R-CHOP-21 and R-CHOP-14 groups received G-CSF primary prophylaxis; 133 (19%) and 81 (20%) patients respectively experienced FN. In the R-CHOP-21 group, 47% of patients who experienced FN did so in cycle 1, as did 30% of those who experienced FN with R-CHOP-14 chemotherapy. Patients who experienced FN tended to be older than those who did not, and to have higher risk disease according to the International Prognostic Index (IPI) (Table). More patients with FN had bone marrow involvement and a history of comorbidities than those without FN (*data not shown*). Unplanned hospitalizations were substantially more frequent in patients who experienced FN than in patients with no FN. Chemotherapy dose delays were more frequent in patients who experienced FN than in those who did not (Table), as were dose reductions in the R-CHOP-21 group. Overall, fewer patients with FN received optimal (≥90%) relative dose intensity (RDI).

Table.

	R-CHOP-21		R-CHOP-14	
	FN (N=133)	No FN (N=569)	FN (N=81)	No FN (N=328)
Patient characteristics, n (%)				
Age ≥65 years	85 (64%)	275 (48%)	39 (48%)	129 (39%)
IPI intermediate-high	86 (65%)	285 (50%)	62 (77%)	184 (56%)
Outcomes in any cycle, n (%) [95% CI]				
Unplanned hospitalization	105 (79%) [71%, 85%]	100 (18%) [15%, 21%]	63 (78%) [68%, 85%]	68 (21%) [17%, 25%]
Dose reduction ≥10%†	40 (30%) [23%, 38%]	102 (18%) [15%, 21%]	14 (17%) [11%, 27%]	41 (13%) [9%, 17%]
Dose delay > 3 days*	73/128 (57%) [46%, 63%]	226/563 (40%) [36%, 44%]	61/80 (76%) [65%, 83%]	148/325 (46%) [40%, 51%]
RDI ≥90%†	83 (62%) [54%, 70%]	434 (76%) [73%, 80%]	30 (37%) [27%, 48%]	234 (71%) [66%, 76%]

*denominator is patients who received ≥2 cycles
†Excluding vincristine.

Conclusions. In this study of everyday clinical practice, fewer DLBCL patients received R-CHOP chemotherapy at the planned time and dose if they experienced FN. Unplanned hospitalization was also more frequent for patients with FN - with possible implications for chemotherapy delivery as well as costs. FN frequently occurred in the first cycle. Physicians should consider G-CSF primary prophylaxis for patients scheduled to receive R-CHOP-21 who are at overall FN risk of 20% or higher, and for patients prescribed R-CHOP-14.[2]

This study was sponsored by Amgen (Europe) GmbH. (ClinicalTrials.gov NCT00903812).

THE NEWLY DEVELOPED PVAG-REGIMEN IS ACTIVE AND FEASIBLE IN ELDERLY PATIENTS WITH INTERMEDIATE OR ADVANCED STAGE HODGKIN LYMPHOMA: RESULTS OF A PHASE II STUDY OF THE GERMAN HODGKIN STUDY GROUP (GHSG)

B Böll, H Görgen, H Bredenfeld, H Eich, T Halbsguth, M Fuchs, P Borchmann, A Engert

University Hospital Cologne, Cologne, Germany

Background and *Aims.* About 20% of all patients diagnosed with Hodgkin lymphoma (HL) are older than 60 years. These patients have a rather poor prognosis, particularly when presenting in intermediate or advanced stages. Besides a biologically more aggressive disease, the main reason is a drastically increased toxicity of chemo- and radiotherapy resulting in a higher treatment-related mortality and insufficient dosing of the applied treatment. In the GHSG-HD9 trial, elderly patients did not benefit from the BEACOPP regimen in terms of overall survival due to a high toxicity related death rate. In order to improve tolerability, the PVAG regimen (prednisone, vinblastine, doxorubicin, and gemcitabine) was developed. This is a modification of the ABVD regimen in which bleomycin and dacarbazine were replaced by prednisone and gemcitabine. Here we report for the first time on the final analysis of this multi-center phase II study for elderly HL patients. *Methods.* 61 patients were recruited between 2004 and 2007. 3 patients were excluded due to histology review not confirming HL, resulting in 58 patients with HL in intermediate or advanced stages aged between 60 and 75 years. Treatment consisted of 6 cycles PVAG in patients achieving a complete remission (CR) after 4 cycles or 8 cycles PVAG in case of partial remission (PR) after 4 cycles. Patients who did not achieve CR after the end of chemotherapy received additional radiotherapy. Primary endpoints were administration of adequate dose without excessive delays, and response rate 3 months after end of treatment. Secondary endpoints included WHO grade III/IV toxicities, and occurrence of early progression. *Results.* 58 patients with a median age of 68 years were evaluated, of which 59% were male and 93% had advanced stage disease. The relative dose intensity (relative dose divided by relative chemotherapy duration) was at least 80% in 44 patients (76%). Regarding the single cycles, of which 85% started without major delay (max. 1 day), the mean relative dose of all agents was slightly decreasing over time but always exceeded 90%. WHO grade III/IV toxicities were documented in 43 patients (75%). Only 3 patients terminated CT because of excessive toxicity. 10 Patients (17%) received consolidating radiotherapy. In total, 44 patients responded with CR/CRu (76%), 2 with PR (3%), 2 with no change (3%) and 4 with progressive disease (7%). In the remaining 6 patients, treatment outcome is currently being re-evaluated and final results will be presented. With a median observation time of 31 months, 15 progressions or relapses and 16 deaths have been observed, of which only 1 was due to PVAG related toxicity but 8 were due to HL. The 2-year-estimates for overall survival and for progression-free survival were 82% (95%-CI 67% to 90%) and 64% (95%-CI 49% to 76%), respectively. *Conclusion.* PVAG is safe and feasible in Hodgkin patients older than 60. The PFS indicates activity of this regimen in this poor prognosis patient cohort. However, a controlled randomized trial to determine the best treatment in this patient population is warranted.

0879

TANDEM AUTOLOGOUS/REDUCED-INTENSITY ALLOGRAFT FOR RELAPSED/REFRACTORY HODGKIN'S LYMPHOMA: EARLY ALLOTRANSPLANT AFTER INTENSIVE CYTOREDUCTION MAY MAXIMIZE GRAFT VS LYMPHOMA EFFECT?

E Todisco,[1] A Congiu,[2] L Castagna,[1] S Nati,[2] L Giordano,[1] A Santoro,[1] AM Carella[2]

[1]*Istituto Clinico Humanitas, Milano, Italy;* [2]*Ospedale San Martino, Genova, Italy*

Background. Hodgkin's Lymphoma (HL) patients primary chemorefractory and with disease at the time of autolgous transplantation (ASCT), have high probability of progression after ASCT. Reduced-intensity conditioning allotransplant (RICT) aims to exploit graft *vs.* lymphoma (GvLy) effects while reducing conditioning-related toxicity. RICT is considered as the last therapeutic option and is usually offered to HL patients failing ASCT and in this contest GvLy responses might be insufficient. *Aims.* we pionered that offering RICT as an earlier option after intensive cytoreduction (ASCT) may allow GvLy reaction to be better exploited (Carella *et al*. JCO 2000; 18:3918). Patients and *Methods.* 35 HL patients (21M/14F), 75% primary chemorefractory and 26% relapsed after first line chemotherapy, underwent RICT preceeded by autografting (ASCT), after one (71%) or multiple salvage chemotherapy lines (29%). Patients progressing after ASCT were excluded from the analysis. Median age at diagnosis was 27 (range 15-47). Twentyeight patients (80%) had disease before tandem (CR=7; PR=14; SD=4; PRO=10). High-dose therapy consisted of Melphalan 200mg/mq (n=9) and BEAM (n=26). The time interval between ASCT and RIC was 2.5 months (range 1.5-5.5). RIC consisted of fludarabine-cyclophosphamide (n=20) or fludarabine-melphalan (n=15). Thirty patients were allotrasplanted from an HLA identical donor, four from a MUD and one patient from a family-mismatched donor. *Results.* the median time to neutrophils and platelets recovery was 14 days and 15 days, respectively. Chimerism studies indicated 100% donor-derived engraftment. Eleven patients (31%) developed aGVHD (grade I-IV) and 13 cGVHD (2 limited and 11 extensive). No serious complication occurred after both transplantation procedures. ASCT induced a disease response (CR+PR) in 18/35 patients (51%). After tandem ASCT-RICT, 69% of the patients (CR=22;PR=2) were responsive, 31% (N=11) had persistent disease (PRO=10;SD=1). With a median follow-up of 48 months (range 6-127), 62% of patients (n=22) were alive and of these 82% in CR (n=18) and 18% (n=4) had persistent disesase. Overall, 37% of the patients (n=13) died: 23% (n=8) of progressive disease and 14% in CR (n=5) of toxic events. No patients died before one hundred days. Three patients died before one year and two after three years. Non relapse mortality (NRM) was 8.6% (n=5). Median OS and PFS were 60.5 months and 11.5 months respectively and 3-years OS and PFS was 76.5% and 41.6% respectively. In univariate analysis, disease status before tandem influenced PFS a statistically significant manner (3-years PFS 66.7% (chemosensitive) *vs.* 21.4% (chemoreferactory) (P<0.0002). GVHD did not influence the outcome. Median survival of patients progressing and relapsing after tandem was 36 months. *Conclusions.* with the limits of a retrospective study, these encouraging results suggest that GvLy may have a role on residual disease after ASCT. We can speculate that RICT determines a disease chronicization. A prospective study based on genetic randomization (ASCT *vs.* ASCT followed by RICT) would help to answer these important issues.

RECURRENT HODGKIN LYMPHOMA - IS IT ALWAYS A RELAPSE OF THE ORIGINAL CLONE?

A Tzankov, N Mueller, A Rufle, T Menter, S Dirnhofer, E Obermann

University Hospital Basel, Basel, Switzerland

Background. Though the fast majority of Hodgkin lymphomas (HL) can be cured by multimodal therapy, a small number of patients will experience a relapse. Early relapses seem to be associated with a worse prognosis than late recurrences. Relapses are usually treated with intensive chemotherapy regimens. *Aims.* We investigated if the first and all further manifestations of HL in a patient are morphologically, virologically and clonally related to each other, i.e. if the recurrence is really a relapse of the first tumor or rather an independently arising second neoplasia. *Methods.* We identified a collective of 13 patients with, sometimes multiple (6 patients), recurrences of HL from our archives (Figure 1). Specimens were cut onto adhesive coated slides. Hodgkin and Reed-Sternberg cells were microdissected after immunohistochemical staining for CD30 using the laser-capture technique (PALM microbeam system from Zeiss). Immunoglobulin heavy chain (IgH) fragment lengths were analyzed after DNA pre-amplification and polymerase chain reaction, applying consensus FR3 and J primers by an ABI 310 Genetic Analyzer. A total number of 31 formalin-fixed, paraffin-embedded tissue samples [primary tumors and (multiple) recurrences] were analyzable for clonality. *Results.* Relapses were classified as early, if the recurrence occurred within 12 months after primary diagnosis (two events in two patients) or after a first (three events in three patients) or second relapse (one event), or as late recurrences, if occurring later than one year after a previous diagnosis (15 events in eleven patients) (Figure 1). All two early relapses after first HL diagnosis (cases 2 and 5) were clonally related to the initial tumor, while three of four early relapses after a first or second relapse (cases 10, 11 and 13) were not. Two late relapses (cases 4 and 12) were clonally unrelated to the initial HL, which was accompanied by a switch of phenotype and EBV-association in one case. One patient (case 10) had two simultaneous clonally unrelated early second relapses, at different anatomical sites and with divergent EBV-association, after first recurrence. Another two cases (cases 3 and 9), initially presenting as HL and relapsing as diffuse large B-cell lymphoma or vice versa, showed clonal relationships between both entities. *Summary*. Not all cases of relapsing HL are clonally related to the initial and/or previous neoplasm. Recurrent HL, especially after a relapse has taken place, or those accompanied by phenotypic and/or EBV-association switch, may represent clonally unrelated second neoplasms. Assessment of the clonal relationship on formalin-fixed paraffin-embedded HL specimens is technically feasible and might play a role in clinical decision making.

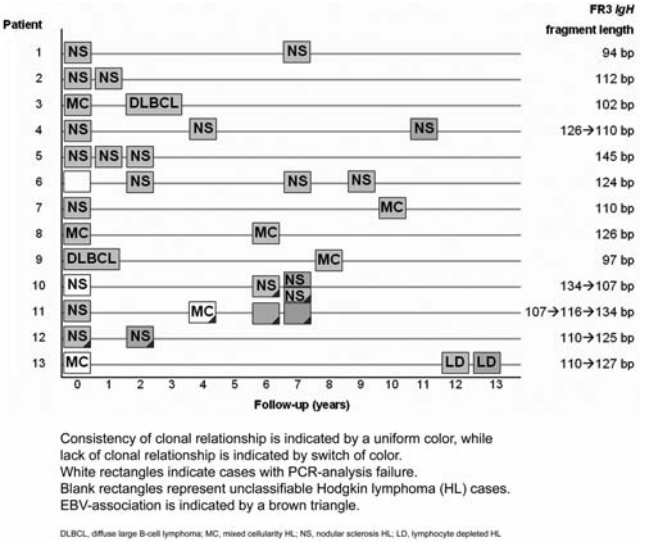

Figure 1. Summary of the analyzed cases.

0881

ABERRATIONS OF THE 9P24 REGION HARBORING JAK2, PDL1 AND PDL2 GENES ARE RECURRENT IN CLASSICAL HODGKIN LYMPHOMA

K Van Roosbroeck,[1] T Tousseyn,[2] B Cauwelier,[3] P De Paepe,[3] P Vandenberghe,[1] P Marynen,[1] C de Wolf-Peeters,[2] I Wlodarska[1]

[1]*K.U.Leuven, Leuven, Belgium;* [2]*University Hospitals Leuven, Leuven, Belgium;* [3]*AZ St Jan AV, Brugge, Belgium*

Background. Classical Hodgkin lymphoma (cHL) is a clinically well characterized tumor. The biology of this lymphoma, however, is poorly investigated due to the rarity of the neoplastic Hodgkin and Reed-Sternberg (H/RS) cells in the tumor mass, their genetic instability and low proliferation abilities. Interphase FISH studies showed that H/RS cells are characterized by frequent gain/amplification of the 2p16/REL and 9p24/JAK2 loci. The important role of 9p24 aberrations in the pathogenesis of cHL was recently highlighted by our finding of the novel SEC31A-JAK2 fusion as the first recurrent rearrangement in cHL (Van Roosbroeck *et al.,* Blood, 2009, 114: 140). This fusion, associated with the t(4;9)(q21;p24), was identified in two cHL cases and we showed that SEC31A-JAK2 is a constitutively activated tyrosine kinase that has oncogenic potential *in vitro* and *in vivo*. Aim. The objective of this study was to determine the prevalence of 9p24/JAK2 aberrations

in cHL. *Methods.* Interphase FISH analysis with a dual color JAK2 break apart (BA) assay combined with an aqua-labeled centromeric probe for chromosome 8 (for ploidy control) was performed on 137 unselected cHL cases. Several additional 9p24 BACs/fosmids were applied in cases with an aberrant JAK2 BA signaling pattern. Only huge cells (2-10/case), likely representing H/RS cells, were evaluated. Results. Interphase FISH analysis detected aberrant hybridization patterns of the JAK2 BA assay in 72% of analyzed cHL cases. These patterns suggested (i) structural rearrangements (5 cases) and (ii) copy number changes of the JAK2/9p24 region (93 cases). Further FISH analyses of the former five tumors identified one case with a 9p24 breakpoint in the 5' region of JAK2. This aberration possibly represents a novel JAK2 fusion because interphase FISH with 3' JAK2 probes combined with 5' probes of all 6 known JAK2 fusion partners did not show colocalized signals. The remaining four cases analyzed with additional 9p24 probes displayed breakpoints in the region harboring the PDL1 and PDL2 genes mapped 34 kb centromeric to JAK2. In addition, copy number changes of the 9p24/JAK2 region were very frequent in cHL (68%). Besides gain of 1-5 copies (38%) and (clustered) amplification (28%) of JAK2/9p24, we found three cHL cases with a predominant amplification of PDL1/2. Whether these genes, coding for regulators of T cell activation, are targets of the 9p24 rearrangements in cHL is currently investigated. Of interest, previous studies showed that expression of both PDLs is frequently upregulated in cHL cell lines as well as in primary H/RS cells. It has been postulated that tumors use the programmed death 1 (PD1)/PDL pathway to reduce tumor immunity and increase tumor survival. Conclusions. We confirmed that 9p24 aberrations are recurrent in cHL. In rare cHL cases, JAK2 is targeted by rearrangements leading to the generation of oncogenic fusion proteins. In the vast majority of cHL cases, however, the 9p24 region is affected by copy number changes. Given a selective gain of the neighboring PDL genes in a few cases, further studies are needed to define the true target(s) of the 9p24 amplifications in cHL.

0882

AN ANALYSIS ON THE ROLE OF FDG PET IN HODGKIN LYMPHOMA STAGING

G Cimino,[1] N Cenfra,[2] F De Angelis,[3] S Panfilio,[3] G Annechini,[3] E Cavalieri,[3] G D'Elia,[3] S Mecarocci,[2] A Rago,[2] R Foà,[3] A Pulsoni[3]

[1]University Sapienza Rome, Latina, Italy; [2]Hematology Sapienza University, Rome - Polo Pontino, Latina, Italy; [3]Hematology, University Sapienza, Rome, Italy

Background. FDG-PET is necessary for the early evaluation (EE) of treatment response in Hodgkin lymphoma (HL) patients, while its use is recommended but not mandatory for disease staging. *Aim.* To evaluate the role of FDG-PET in comparison with TC scan in HL staging. *Methods.* One hundred six new consecutive HL patients seen between 2007 and 2009 at the Hematology Units of the "Sapienza"University of Rome and of "Polo Pontino. We studied 61 males and 45 females; median age was 40 year (range 19-70). The patients were staged with both conventional techniques (CT [TC scan, echography and bone marrow biopsy]) and whole body FDG-PET. The results of CT and FDG-PET staging were compared. *Results.* CT and FDG-PET results were concordant in 96/106 patients (90.7%) while in 10/106 (9.3%) were discordant; of these, 8 (7.4%) were up-staged by FDG-PET: 2 cases became stage III because of a sub-diaphragmatic nodal and spleen involvement not identified by CT, whereas 6 cases advanced to stage IV because of bone (5 cases) and hepatic lesions (1 cases) detected at the FDG-PET (TC scan and Bone Marrow Biopsy = negative). In these 8 cases changes were as follows: from stage II to IV: 3 cases; from stage III to IV: 3 cases; and from stage II to III: 2 cases. In two cases (1.9%) FDG-PET downstaged from III to II. Because of FDG-PET staging results treatment plan was changed in 5 patients. As concern the EE after 2 cycles of ABVD, all the 8 cases upstaged by FDG-PET analysis converted to a FDG-PET negativity. In particular, comparing the groups of patients with FDG-PET and CT stage IV HL, we observed that all the 6 (100%) and 4 of the 12 (33%) patients with a FDG-PET and CT defined stage IV, respectively, converted to a FDG-PET negative rate after 2 ABVD cycles (P=0.01; Fisher's Exact Test). Thus, the 8 persistently PET-positive patients received an intensification treatment with high dose chemotherapy and Autologous Stem Cell Trasplantation. After a median follow-up of 16 months (3-38) all patient up-staged on the basis of PET results are in persistent Complete Remission. *Summary/Conclusions.* Our data confirm a good concordance between conventional methods and FDG-PET. This latter analysis, seems to possess a higher accuracy in detecting bone lesions, as further suggested by present findings showing the early conversion to negativity in all the 8 FDG-PET up-staged patients. In addition, the worst rate of conversion to FDG-PET negativity observed in the "conventional"stage IV group suggests that, among patients with disseminated HL disease, those with a FDG-PET-defined stage IV may have a more favourable clinical outcome. Thus ad hoc future studies are mandatory to define the more appropriate treatment for FDG-PET up-staged patients, to avoid a putative risk of over-treatment of this patient category.

POORER OUTCOME OF LYMPHOCYTE-DEPLETED HODGKIN LYMPHOMA: A COMPREHENSIVE ANALYSIS FROM THE GERMAN HODGKIN STUDY GROUP

B Klimm,[1] J Franklin,[2] M Fuchs,[3] H Stein,[4] H Müller-Hermelink,[5] V Diehl,[6] P Borchmann,[3] A Engert[3]

[1]University Hospital Cologne, Köln, Germany; [2]IMSIE, University of Cologne, Cologne, Germany; [3]Dept. I of Internal Medicine, University Hospital Cologne, Cologne, Germany; [4]Institute of Pathology, Charité Campus Benjamin Franklin, Berlin, Germany; [5]Institute of Pathology, University Hospital Würzburg, Würzburg, Germany; [6]GHSG, University Hospital Cologne, Cologne, Germany

Background. Lymphocyte-depleted classical Hodgkin lymphoma (LDcHL) is a rare entity accounting for approximately 1% of classical Hodgkin lymphoma (cHL) patients, which made analyses difficult in the past. *Aims.* To investigate the clinical characteristics and treatment outcome of patients with LDcHL compared with other histological subtypes of cHL. Patients and *Methods.* From a total of 10,020 patients with biopsy-proven HL treated within the trials HD4 to HD15 of the German Hodgkin Study Group, 84 patients with LDHL (<1%) were identified. Only patients who underwent a central expert pathology review were included. *Results.* Compared with all other histological subtypes, e.g. nodular sclerosis (NS) or mixed cellularity (MC), patients with LDcHL presented more often with advanced stage of disease (74% *vs.* 42%) and B-Symptoms (76% *vs.* 40%). Risk factors including large mediastinal bulk, elevated erythrocyte sedimentation rate, extranodal disease, involvement of 3 or more lymph node areas, and organ involvement of bone marrow or liver were more frequently in LDcHL patients. The median follow-up was 67 months. Complete remission (CR) or CRu (unconfirmed) was achieved in 82% of LDcHL patients compared to 93% of other cHL patients. More LDcHL patients had progressive disease. Progression-free survival (PFS) and overall survival rates were significantly lower in LDcHL patients [PFS at 5 years: 71% (LD) v. 85% (NS) or 84% (MC); P<0.0001)]. However, when analysing the subgroup of patients that underwent modern treatments with intensified or dose dense regimen such as BEACOPP-escalated or BEACOPP-14, LDcHL patients (n=39) had no longer an inferior outcome compared to non-LDcHL patients (n=3564) (P=0.61). *Conclusions.* LDcHL has a different pattern of clinical presentation with more clinical risk factors at presentation than other types of HL. Thus, this entity is associated with a significantly poorer prognosis. LDcHL patients should be treated with modern dose-intense treatment strategies.

0884

A SYSTEMATIC REVIEW COMPARING BEACOPPESCALATED AND ABVD-LIKE CHEMOTHERAPY FOR HODGKIN LYMPHOMA PATIENTS

C Brillant, K Bauer, C Herbst, I Monsef, N Skoetz, A Engert

Cochrane Hamatological Malginancies Group, Köln, Germany

Introduction. The main challenge in treating Hodgkin lymphoma (HL) is to find the optimal treatment with the best efficacy and least toxicity. So far there are two different international standards for the treatment of intermediate and advanced stage HL: chemotherapy with ABVD (doxorubicin, bleomycin, vinblastine, dacarbazine) regime and chemotherapy with $BEACOPP_{escalated}$ (bleomycin, etoposide, doxorubicin, cyclophosphamide, vincristine, procarbazine, and prednisone) regime. This review aims to clarify advantages and disadvantages of both treatments. *Methods.* MEDLINE, CENTRAL and EMBASE were systematically searched for randomised controlled trials from 1985 to 2008. Trials comparing treatment with at least 2 cycles $BEACOPP_{escalated}$ *vs.* chemotherapy with at least 4 cycles of ABVD for patients in early-unfavorable or advanced stages HL were included. Trials without any published results (e.g. trial 20012 from the EORTC) were excluded from the meta-analysis. Trial selection, quality assessment and data extraction were done independently by two review authors. Time-to-event outcomes were analyzed

with hazard ratios (HR) and 95% confidence interval (CI) in a fixed effects model. *Results.* A total of 683 references were screened. Four eligible trials with 1970 patients were identified and included in the main analysis: the HD9 and HD14 trials from Germany, the HD2000 and GSM-HD trials from Italy. Two trials report toxicity during treatment: the $BEACOPP_{escalated}$ regime causes statistically significant more haematological toxicities WHO grad 3-4 than ABVD-like regimen and statistically significant more infections, alopecia, mucositis and pain. No differences between $BEACOPP_{escalated}$ and ABVD-like regimen were found for constipation, nausea and neurologic toxicity. Progression free survival (PFS) was statistically significantly longer for $BEACOPP_{escalated}$: HR was 0.52 (95% CI [0.43, 0.64], I2=0%). In the main analysis of overall survival (OS), $BEACOPP_{escalated}$ was statistically significantly better than ABVD: HR was 0.71 (95% CI [0.50, 0.99], I2=0%). However, this result is not robust. In the OS-analysis restricted to the 3 advanced stage trials (HD9, HD2000 and GSM-HD), the HR was 0.74 (95% CI [0.52, 1.06], I2=0%). Due to the high weight of the HD9 trial (57%), the overall OS-results are strongly influenced by this trial. In a sensitivity OS analysis without the HD9 trial the HR was 0.83 (95% CI [0.50, 1.38]). Only one trial (HD9) had a follow-up of more than 5 years; the median observation time of the other trials was approx. 3 years. *Conclusions.* This meta-analysis confirmed the higher haematological toxicity of the $BEACOPP_{escalated}$ regime in comparison to ABVD-like regimen. It showed a better PFS and suggests a benefit in OS for $BEACOPP_{escalated}$ in comparison to ABVD-like regimen. However, 3 trials had a short follow-up. Longer follow-up and the inclusion of the ongoing EORTC 20012 trial should allow a more definitive answer concerning OS.

0885

ESHAP VS IGEV AS SALVAGE AND MOBILIZING REGIMENS IN RELAPSED OR REFRACTORY HODGKIN LYMPHOMA (HL)

P Tsirkinidis,[1] T Vassilakopoulos,[1] O Tsopra,[1] V Pappis,[1] M Moschoyianni,[2] Z Galani,[1] K Anargyrou,[3] I Vardounioti,[1] A Dimitrakopoulou,[4] M Masouridis,[1] MC Kyrtsonis,[1] P Panayiotidis,[1] G Pangalis,[1] P Beris,[1] M Angelopoulou[1]

[1]University of Athens, Athens, Greece; [2]Athens Medical Center, Athens, Greece; [3,2,5,1] General Air Force Hospital, Athens, Greece; [4]Laikon General Hospital, Athens, Greece

Background. The standard treatment approach for patients with relapsed or refractory HL is salvage chemotherapy and subsequent high dose therapy and autologous stem cell transplantation (HDT/ASCT). Salvage chemotherapy aims to disease debulking, testing of chemosensitivity, and mobilization of peripheral blood stem cells. Platinum-based regimens (DHAP, ESHAP, ICE) are frequently used for this purpose. However, the optimal salvage chemotherapy regimen is still not known. Recently the combination of gemcitabine, ifosphamide, vinorelbine and solumedrol (IGEV) has been shown to be an effective salvage and mobilizing regimen in HL. *Aims.* To compare the efficacy of ESHAP (etoposide, methylprednisolone, high dose cytarabine and cis-platinum) *vs.* IGEV chemotherapy as 2nd line treatment for relapsed or refractory HL patients eligible for HDT/ASCT. *Methods.* Between 2001 and 2006 most patients scheduled for ASCT received ESHAP as first salvage (n=37), while IGEV was introduced as first salvage during the last 3 years (n=33). We retrospectively compared these two regimens regarding successful mobilization, disease control (overall response rate) and a combined endpoint, including both successful mobilization and disease control prior to ASCT. *Results.* Patients' characteristics did not differ between ESHAP and IGEV groups, except of bulky disease at relapse/progression, which was more frequent in the latter (P=0.008). IGEV was more effective as a mobilizing regimen: peak circulating $CD34^+$ cell counts were higher (median 198.6 *vs.* 75.2, P<0.001), the number of total CD34+ collected cells was higher (median 11.6×10^6/kg *vs.* 4.32×10^6/kg, P<0.001), while all patients were successfully mobilized with IGEV *vs.* 90% in the ESHAP group. In addition, time to neutrophil engraftment following ASCT was faster with IGEV (median 9 *vs.* 10 days, P=0.002). The median time to apheresis was also shorter with IGEV (12 *vs.* 16 days, P<0.001). Moreover, IGEV was administered as an outpatient regimen. Response (complete and partial remission) rate was similar with both regimens (50% *vs.* 51% with ESHAP *vs.* IGEV). The combined endpoint of successful mobilization and disease control was achieved in a similar percentage of patients with both regimens (60% *vs.* 56%). *Conclusions.* ESHAP and IGEV have comparable efficacy regarding disease control in relapsed/refractory HL patients as salvage chemotherapies. However, IGEV is a more effective and convenient mobilizing regimen compared to ESHAP.

POSITIVE PRETRANSPLANTATION POSITRON EMISSION TOMOGRAPHY INDICATES POOR PROGNOSIS IN RELAPSED HODGKIN LYMPHOMA PATIENTS

H Mocikova,[1] R Pytlik,[2] L Raida,[3] J Markova,[4] Z Kral,[5] K Steinerova,[6] B Vackova,[2] M Trnkova,[7] M Trneny,[2] D Belada,[8] E Faber,[3] V Válková,[9] J Mayer,[5] V Koza,[6] T Kozak[10]

[1]Charles University Hospital Kralovske Vinohrady, Prague, Czech Republic; [2]First Faculty of Medicine and General Teaching Hospital,Charles University, Prague, Czech Republic; [3]Department of Hematooncology, Palacky University Hospital, Olomouc, Czech Republic; [4]Dept.of Clinical Hematology, Charles University Hospital Kralovske Vinohrady, Prague, Czech Republic; [5]Dept.of Internal Medicine and Hematology, University Hospital, Brno, Czech Republic; [6]Dept.of Hematooncology, Charles University Hospital, Pilsen, Czech Republic; [7]Data Center Czech Stem Cell National Registry, Prague, Czech Republic; [8]Dept.f Clinical Hematology, University Hospital, Hradec Kralove, Czech Republic; [9]Institute of Hematology and Blood Transfusion, Prague, Czech Republic; [10]Dept. of Clinical Hematology, Charles University Hospital Kralovske Vinohrady, Prague, Czech Republic

Background. Autologous stem cell transplantation (ASCT) is the standard of treament in relapsed Hodgkin lymphoma (HL) patients however, it cures only half of them. Several risk factors have been studied to determine the risk of relapse after ASCT. *Aims.* This retrospective study evaluated the secondary clinical risk score at relapse, the prognostic significance of pretransplantation positron emission tomography (PET) and achievement of complete remission (CR) assessed by CT after salvage chemotherapy before ASCT in 76 relapsed/refractory HL patients. *Methods.* Progression-free survival (PFS) and overall survival (OS) of patients was calculated using Kaplan-Meier method. Differences of survival between subgroups were analyzed with log-rank test. *Results.* Median follow-up of patients after ASCT was 23 months. Overall 11 (55%) of 20 PET positive patients and 14 (25%) of 56 PET negative patients relapsed after ASCT. The 2-year PFS in PET negative *vs.* PET positive patients was 72.7±6.3% *vs.* 36.1±11.6%, respectively (P=0.01). The 2-year OS in PET negative *vs.* PET positive patients was 90.3±4.1% *vs.* 61.4±11.6%, respectively (P=0.009). In univariate analyses, the secondary clinical risk score at HL relapse, primary refractory disease or achievement of CR evaluated according to CT scan was not statistically significantly associated with PFS and OS. In multivariate analysis PET was statistically significant for PFS only in combination with other variables (clinical risk score and CR assessed by CT) (P=0.017). Multivariate analysis of these variables, however, was not significant for OS (P=0.08). Conclusion. Positive pretransplantation PET identified a high-risk subgroup with worse overall survival when comapared to PET negative patients. This high-risk patients may benefit from further treatment after ASCT.

BASELINE SERUM C-REACTIVE PROTEIN LEVELS (CRP) IN HODGKIN LYMPHOMA (HL) AND ALTERATIONS DURING ABVD CHEMOTHERAPY: CORRELATION WITH CLINICAL, LABORATORY FEATURES AND PROGNOSTIC SIGNIFICANCE

V Pappi,[1] M Angelopoulou,[1] O Tsopra,[1] M Dimou,[1] M Kyrtsonis,[1] M Siakantaris,[1] X Yiakoumis,[1] A Gassiamis,[1] P Panayiotidis,[1] G Pangalis,[2] P Beris,[1] T Vassilakopoulos[1]

[1]University of Athens, Athens, Greece; [2]Athens Medical Center, Athens, Greece

Background. Serum CRP levels are elevated in the majority of patients with Hodgkin's lymphoma at diagnosis, reflecting tumor burden and aggressive biologic behaviour. A rapid metabolic response (negative PET-2) is a very strong favourable prognostic factor in advanced disease. CRP alterations might parallel disease activity. However there are very few data regarding the short- and mid-term CRP alterations during chemotherapy and their potential prognostic significance. *Aim.* (1) To analyze the correlation between baseline CRP and clinical-laboratory findings and outcome of HL (2) To evaluate the alterations in CRP levels during ABVD chemotherapy and correlate them with the post-chemotherapy PET findings and failure free survival (FFS). Patients and *methods.* Baseline CRP levels were recorded in 273 patients. Serial CRP measurements prior to ABVD and prior to cycles 1b,2a,3a and 4a were performed in 71 patients. CRP levels at that time-points were correlated with post-chemotherapy PET findings (chi-square test) and FFS (Kaplan-Meier curves, log-rank comparison). CRP levels >5 mg/L were

considered elevated. *Results.* (1) For the 273 patients with baseline CRP available, the median value was 19.7 mg/L; 28% and 72% had normal and elevated CRP levels respectively. Baseline CRP levels correlated with virtually all other parameters reflecting tumor burden or disease aggressiveness. 3-year FFS for patients with CRP levels <5, 5-19.69, 19.7-68.96 and >68.96 mg/L (roughly the CRP quartiles) was 80%, 68%, 58% and 67% (P=0.10). Although the difference was significant for patients with normal *vs.* elevated CRP levels (P=0.01), it was not retained in multivariate analysis. (2) For the 71 patients with serial CRP determinations, the median baseline CRP was 28.1 mg/L; 27% and 73% had normal and elevated CRP levels respectively. The median CRP levels prior to cycles 1b,2a,3a and 4a ranged between 3.16 and 3.30 mg/L. The proportion of patients with normal CRP levels increased from 27% at baseline to 69%, 68%, 79% and 73% prior to cycles 1b,2a,3a and 4a. At the time of the analysis, post-ABVD PET was available in 62 patients: It was negative in 48 patients and positive in 14. There was no correlation between interim CRP normalization at any time and post-ABVD PET findings. Only 6 patients have progressed for a 18-month FFS of 90%. Normal CRP levels prior to cycles 3a and 4a were associated with better 18-month FFS rates (92% *vs.* 83%, P=0.32 and 95% *vs.* 86%, P=0.33 respectively), but differences were small and did not reach statistical significance. Similar results were obtained when the analysis was restricted to patients with elevated baseline CRP levels. *Conclusions.* CRP levels are elevated in ~70% of HL patients at diagnosis but did not correlate with FFS independently from other established prognostic factors in the present series of patients. CRP levels are subjected to very rapid alterations during ABVD chemotherapy, which are already demonstrable by the end of the second week. Our preliminary results did not reveal differences in short-term FFS, large enough to be statistically significant. However, analysis of larger number of patients and extension of follow-up are needed.

0888

SEROPOSITIVITY FOR HUMAN CYTOMEGALOVIRUS IS ASSOCIATED WITH BOTH EBV-NEGATIVE AND EBV-POSITIVE CLASSICAL HODGKIN LYMPHOMA

K Farrell,[1] L Shield,[1] D Montgomery,[1] W Carman,[2] S Cameron,[2] R Jarrett[1]

[1]*University of Glasgow, Glasgow, UK;* [2]*West of Scotland Specialist Virology Centre, Glasgow, UK*

Background. Classical Hodgkin Lymphoma (cHL) is associated with Epstein-Barr Virus (EBV) in a proportion of cases. Risk of EBV-associated cHL increases with age. EBV persistently infects the majority of healthy adults and the virus is normally controlled by the cytotoxic T-lymphocyte (CTL) response. Cytomegalovirus (CMV) is also associated with persistent infection in ~60%-90% of adults. Control similarly relies on CTL responses. In infected healthy adults, much of the T-cell response is CMV restricted, 10-50% over 60 years of age. Evidence is emerging for an association between CMV infection and immune senescence. The presence of CMV has been shown to impair the CTL response to EBV. The increased proportion of the CTL response directed toward CMV with increasing age may hinder the ability of the remaining T-cell population to respond to other challenges, leading to subtle immune suppression. *Aims.* We investigated the a priori hypothesis that the increased proportion of the immune response diverted to CMV would reduce immunity to EBV, thus increasing the risk of EBV-positive cHL in CMV+ve individuals. *Methods.* Serum was available from 549 cases and 396 controls. EBV status of cHL was available for 491 cases. Ethical approval had been granted. CMV serotyping was performed using the Abbot CMV IgG chemiluminescent microparticle immunoassay. CMV seropositivity was compared in: cHL cases *vs.* controls; EBV-positive cHL cases *vs.* controls; EBV-negative cHL cases *vs.* controls; and EBV-positive cHL cases *vs.* EBV-negative cHL cases using logistic regression. *Results.* 51.1% of all subjects were CMV+ve. As expected, incidence of CMV seropositivity increased with age (15-34 years 33.7%, 35-49 years 49.8%, >50years 73.6%.) After correcting for age and sex, cHL was independently associated with CMV seropositivity (odds ratio (OR) cases *vs.* controls=1.4, 95% confidence interval (CI) 1.05-1.86, P=0.022.). EBV-positive cHL was associated with CMV seropositivity (OR EBV-positive cases *vs.* controls=1.59 95% CI 1.06-2.46, P=0.026.) This association was also seen in EBV negative cases (OR 1.407, 95% CI 1.015-1.949, P=0.040.) There was no difference in CMV seropositivity between EBV-positive and negative cHL cases after adjusting for the effect of age. In order to exclude the possibility that increased nosocomial exposure accounted for the increased seroprevalence in cases, we repeated the analysis using specimens obtained at the time of diagnosis (n=105). The association of cHL with CMV seropositivity was maintained (OR 1.61, 95% CI 1.01- 2.57 P=0.045.) The seroprevalence was not significantly different between pre-treatment (52.4%) and follow-up specimens obtained >200 days post diagnosis (51.2%.) Following stratification by age, the increased odds of cHL associated with CMV seropositivity was observed only in adults >50 years (OR 1.76, 95% CI 1.08- 2.85, P=0.022.) Case:control ORs were greatest for EBV-positive cHL cases (OR 2.37, 95% CI 1.16-4.82, P=0.017.) *Summary/Conclusions.* Classical HL is associated with CMV seropositivity. This effect was observed in EBV-positive and EBV-negative cHL cases and was greatest in older adults. Among older adults, CMV-seropositive individuals had a 2.4-fold increased odds of EBV-positive cHL. This observation supports the hypothesis that reduced immune surveillance due to CMV infection leads to an increased risk of cHL.

0889

A NEW APPROACH TO LONG TERM FOLLOW UP OF LYMPHOMA PATIENTS: TRANSFER TO THE PRIMARY CARE SETTING

R Flatley, K Ardeshna, S D'Sa, L Percy, S Basu

Mount Vernon Cancer Centre, Middlesex, UK

Background. The follow up of patients more than 5 years from completion of treatment for curable lymphomas is largely aimed at the detection of late effects of treatment as the risk of relapse decreases. Since follow up appointments usually do not coincide with significant events, we began to question the appropriateness, effectiveness and safety of maintaining annual long term follow-up for this particular patient population within our tertiary centre. *Aim.* We decided to initiate a policy of patient education regarding possible late effects with a view to transferring care of certain patients on long term follow up to their primary care physicians. *Methods.* Patients ≥5 years since completion of treatment for curable lymphomas (Hodgkins and high grade) were considered potentially suitable for this policy. Patients who had undergone high dose therapy with stem cell support were excluded. A proforma was devised, with primary care physician input, to facilitate discussion of prior treatment(s) and potential late effects with patients in clinic. Information recorded included histological diagnosis and a detailed history of all previous treatments. Risks discussed with all patients were: relapse, secondary malignancies, (including breast cancer in patients who had received mantle radiotherapy), sub fertility and early menopause. Cardiovascular and pulmonary toxicities, hypothyroidism and infection post splenectomy/splenic irradiation were discussed, depending on previous treatments, allowing consultation tailored to the individual patient. Emphasis was placed on developing an awareness and early recognition of symptoms and signs of late effects or recurrence. Lifestyle and diet, particularly geared towards cardiovascular risks, were also discussed. Verbal information was supplemented by a written patient information leaflet. A detailed summary was sent to their general practitioner and copies offered to patients. The medical or clinical nurse specialists were able to initiate the discharge plan. *Results.* 100 patients have been discharged from the lymphoma clinic to date. 3 patients (3%) preferred to continue follow up in the specialist centre. The remaining 97% were comfortable with follow up being transferred to primary care. 6 patients (6%) were re-referred and seen promptly. Two are undergoing investigations for suspected relapse. Two were confirmed relapse. One is being monitored. One presented with pericardial effusion as the first indication of a radiation induced sarcoma. *Summary/Conclusions.* The implementation of a new policy of long-term follow up patients with curable lymphomas has been well received by patients (97%) and has led to streamlining our busy clinical service. Those patients within this new system who have needed urgent review following discharge have received timely re-introduction into the service (6%). This change in approach to routine follow-up care has identified an emerging need for the introduction of 'health and well being' clinics at the end of patients' treatments. The implementation of such a clinic is underway.

Background. Hodgkin's lymphoma (HL) is a potentially curable disease in at least 80% of patients. However, up to a 10% of patients do not achieve a complete response (CR) with first line therapy and 10~40% of CR patients suffer a relapse. HL is an uncommon disease, especially rare in Korea, around 5% of all lymphoma. *Aims.* In this current study clinical features and outcomes of relapsed HL in Korea were evaluated. *Methods.* Between January 1984 and October 2009 clinical data were collected retrospectively from 15 centers in Korea. *Results.* Four hundred and ninety two patients with newly diagnosed HL were included in this study and 425 of entire patients were adequate for response analysis. After first line therapy, 375 patients (88%) exhibited CR. The CR rate was 93.3% in the radiotherapy group, 82.1% in chemotherapy group, and 76.3% in combined chemo-radiotherapy group. Twenty patients (4.7%, 20/425) were refractory to initial therapy. A total of 105 (28%) of 375 patients who had achieved CR relapsed. Clinical characteristics including no palpable mass, presence of B symptoms, ECOG performance status (2 or 3), and stages (3 or 4) were significantly associated with relapse after achieving CR with initial therapy. Seventy five patients received salvage chemotherapy with various regimens including DHAP (18%), ESHAP (11%), ABVD (11%), C-MOPP (7%) or others. Of the 75 patients who received salvage therapy, 60 patients achieved 80% response, including 59% CR (n = 44), 21% partial response (PR) (n = 16), and 20% progressive disease (PD) (n = 15). The salvage regimens were classified in two groups according to whether the regimens contained cisplatin. The outcome of salvage therapy was evaluated. There was no significant difference in response rate between two groups (cisplatin containing regimens 58.8%, non-cisplatin containing regimens 82.4%, unknown 71.7%, P=0.3). Twenty one patients received high-dose chemotherapy (HDT) followed by autologous stem cell transplantation (ASCT). Of the 21 patients who completed HDT followed by ASCT, 12 patients (57.1%) exhibited CR, 2 patients (9.5%) exhibited PR, 1 patient (4.8%) experienced stable disease (SD), and 6 patients (28.6%) experienced refractory disease. *Conclusions.* Relapse rate in patients with HL in Korea was similar to that in western people. A majority of relapsed patients could be salvaged with chemotherapy and/or HDT followed by ASCT. Both cisplatin containing or non-cisplatin containing regimens were reasonable option as a salvage treatment. An optimal regimen needs to be defined with prospective trials.

FIRST-LINE CHEMOTHERAPY LEADS TO HIGH BONE TURNOVER AND REDUCED BONE MASS IN PATIENTS WITH NON-HODGKIN'S LYMPHOMA: RESULTS FROM A PROSPECTIVE STUDY

K Anargyrou,[1] T Vassilakopoulos,[2] K Tsionos,[1] P Kokkoris,[1] G Boutsikas,[1] M Angelopoulou,[2] D Christoulas,[2] S Masouridou,[2] M Dimou,[2] A Papatheodorou,[1] D Chatzifotiadis,[1] P Panayiotidis,[2] G Pangalis,[2] P Beris,[2] E Terpos[2]

[1]251 General Air-Force Hospital, Athens, Greece; [2]University of Athens School of Medicine, Athens, Greece

Background. Chemotherapy-associated osteoporosis increases the risk for fractures and deteriorates quality of life in several malignancies. There are very limited data for the effect of chemotherapy on bone metabolism of adult patients with non-Hodgkin's lymphoma (NHL). *Aim.* The aim of this prospective study was to evaluate bone remodeling in NHL patients, pre- and post- first-line chemotherapy. *Patients/Methods.* As of February 2010, 60 patients were enrolled in this study and 43 (26M/17F, median age 60 years, range: 18-90 years) had completed first-line chemotherapy. Twenty-eight patients (65%) had diffuse large B-cell lymphoma, 5 (12%) follicular lymphoma (grade III), 4 (9%) mantle-cell lymphoma, 4 marginal-zone lymphoma and 2 T-cell NHL. Sixteen (37%) had stage IV disease and 19 (44%) had B-symptoms before therapy. Thirty-nine patients (91%) received R-CHOP, 2 R-COP and 2 CHOP as first-line therapy. Bone mineral density (BMD) of the lumbar spine (L1-L4, antero-posterior view), and femoral neck (FN) was measured by DXA on day 1 of cycle 1 (baseline) and on day 30 post the last cycle of chemotherapy. The following serum indices of bone metabolism were measured on the days of DXA: i) osteoclast stimulators (sRANKL and osteoprotegerin), ii) osteoblast regulators [PTH, vitamin-D and dickkopf-1 (Dkk-1)], iii) bone resorption markers (CTX and TRACP-5b) and iv) bone formation markers [bone alkaline phosphatase (bALP) and osteocalcin]. The above markers were also evaluated in 24 gender- and age-matched controls. Patients were followed for skeletal-related events (SREs) throughout the period of the study. *Results.* At baseline, NHL patients had a median T-score of L1-L4 BMD of -0.59 (range -4.27 to +3.68) and of FN BMD of -1.02 (-4.01 to +1.67). The median T-score of the lumbar vertebra with the major bone loss (LVMBL) was -1.41 (-4.6 to +3.03). There was a strong correlation between L1-L4 and FN BMD (r=0.687, P<0.0001), between L1-L4 BMD and Dkk-1 (r=-0.62, P<0.0001) and between CTX with TRACP-5b (r=0.463, P<0.0001) and sRANKL (r=0.386, P=0.004). The administration of chemotherapy resulted in a dramatic reduction of BMD both in L1-L4 and FN (L1-L4 median T-score: -1.12; range -4.49 to +3.04; P<0.0001, LVMBL median T-score: -1.41; range: -4.6 to +3.03; P=0.002, FN median T-score: -1.16; range: -3.68 to +1.12; P<0.0001) compared to baseline values. The reduction of L1-L4 and FN BMD post-chemotherapy was more profound in males (P=0.009 and P=0.009 respectively) than in females (P=0.023, P=0.013) and in patients of >55 years (P=0.001 and P=0.003, respectively) compared to all others (P=0.094, P=0.03). Patients who received 8 cycles of chemotherapy had a greater reduction of L1-L4 (P=0.001) and FN (P=0.006) BMD compared to all others. CTX (P=0.031) as well as both markers of bone formation, bALP (P<0.0001) and osteocalcin (P<0.0001) were significantly increased post chemotherapy. During study period, one patient had a pathological fracture in his right FN. *Summary/Conclusions.* Our on-going study suggests that first-line chemotherapy results in high bone turnover, which leads to increased bone loss and reduced BMD of L1-L4 and FN in NHL patients. The prophylactic use of anti-resorptive agents, such as bisphosphonates, may be useful in these patients.

0892

SAFETY AND EFFICACY OF BENDAMUSTINE WITH OR WITHOUT RITUXIMAB IN THE TREATMENT OF HEAVILY PRETREATED LYMPHOMA PATIENTS. A MULTICENTER RETROSPECTIVE STUDY.

L Rigacci,[1] E Iannitto,[2] B Puccini,[1] G Antognoli,[1] A D'Arco,[2] E Orciuolo,[2] S Cortelazzo,[2] G Gaidano,[2] R Freilone,[2] C Patti,[3] F Zaja,[2] M Gobbi,[2] P Musto,[2] PL Zinzani,[4] S Storti,[2] A Isidori,[2] V Bongarzoni,[5] A Carpaneto,[2] N Di Renzo,[2] M Musso,[2] D Rota Scalabrini,[2] A Santagostino,[2] C Stelitano,[2] N Cascavilla,[2] AM Liberati,[2] R Sancetta,[2] A Bosi[1]

[1]Azienda Ospedaliera Careggi, Florence, Italy; [2]Hematology Department, Palermo, Italy; [3]Hematology Department Ospedale Cervello, Palermo, Italy; [4]Ospedale Seragnoli Hematology Dept, Bologna, Italy; [5]Hemtology S. Giovanni, Roma, Italy

Background. Bendamustine is an alkylating agent with a nitrogen mustard group and a purine like benzimidazol group. Recently this drug was introduced in Italy and it was used in patients pretreated to test its efficacy and safety. *Aims.* The aim of this study was to collect all the Italian experiences to evaluate the results in term of response to therapy and hematological and extra-hematological toxicities. *Methods.* We analized lymphoma patients treated in twenty-four hematological Italian centers with Bendamustine alone or in combination with anti-CD20 antibody. Patients who have received at least one complete cycle were evaluated for response and toxicity. The treatments consisted of: Bendamustine 60-90 mg/m^2 days 2,3 alone or in combination with Rituximab 375 mg/m^2 day 1, every 21 or 28 days. *Results.* One-hundred sixty-eight patients were analized, median age was 69 (range 26-87), 103 were male and 65 female, the diagnosis were: 61 indolent non-follicu-

lar lymphoma (small lymphocitic, marginal, lymphoplasmocitic), 34 diffuse large B cell lymphoma, 44 follicular lymphoma, 29 mantle cell lymphoma, 3 Peripheral T cell lymphoma. Patients were heavily pretreated the median number of previous treatments was 3 (range 1-9), 60 patients have experienced more than three chemotherapy schemes. One-hundred twenty-nine patients were previously treated with Rituximab and 21 have performed an autologous transplantation. The Bendamustine pre-treatment condition was: 72 relapsed patients, 35 with refractory disease and 60 with a progressive disease after partial response. The median number of Bendamustine cycles was 4 (range 1-11). All patients were evaluable for response: 49 (29%) complete remission, 72 (43%) partial response or stable disease with an overall response rate of 72% and 47 non responders. No differences were observed according to Bendamustine dosage or scheduling. According to histotype we observed that 20/29 mantle cell lymphoma (11 CR and 9 PR) obtained a response to therapy, 48/58 (13 CR and 35 PR) indolent non follicular lymphoma, 42/44 (21 Cr and 21 PR) follicular lymphoma obtained a response and 11/34 (4 CR and 7 PR) DLBCL obtained a response. With a median period of observation of 8 months (1-36) 70% of patients are alive. In this group of heavily pretreated patients 685 cycles were performed: the extrahematological toxicity was really mild and the hematological toxicity was trombocytopenia grade 3-4 in 16 patients (9%) and neutropenia grade 3-4 in 29 patients (17%). *Conclusion.* In summary this retrospective study shows that treatment with Bendamustine alone or in combination with Rituximab is a safe and efficacy regimen in a subset of pluriresistent patients. This data shows also that the best results could be obtained in indolent lymphoma and incouraging data in mantle cell lymphoma.

A PHASE I TRIAL OF BTK INHIBITOR PCI-32765 IN PATIENTS WITH RELAPSED NON-HODGKIN'S LYMPHOMA: EVIDENCE OF ANTITUMOR ACTIVITY

N Fowler,[1] J Sharman,[2] S Smith,[3] D Pollyea,[4] T Boyd,[5] B Grant,[6] K Kathryn,[7] J Buggy,[8] D Loury,[8] A Hamdy,[8] R Advani[9]

[1]UT MD Anderson Cancer Center, Houston, USA; [2]Willamette Valley Cancer, Springfield, USA; [3]University of Chicago, Chicago, USA; [4]Stanford University, Stanford, USA; [5]Yakima Valley Memorial Hospital, Yakima, USA; [6]University of Vermont and Fletcher, Burlington, USA; [7]Northwest Cancer Specialists, P.C., Vancouver, Canada; [8]Pharmacyclics, Inc., Sunnyvale, USA; [9]Stanford University School of Medicine, Stanford, USA

Background. A functional B cell receptor is maintained in the majority of B-cell malignancies. PCI-32765 is a novel oral agent that has been shown to selectively inhibit Bruton's tyrosine kinase (Btk), a downstream mediator of B-cell receptor signaling. *Aims.* This single-arm, multicenter, phase I study was conducted to determine the safety and tolerability of PCI-32765 in patients with relapsed/refractory non-Hodgkin's lymphoma. *Methods.* Adult patients with relapsed or refractory B-cell lymphoma were eligible for trial entry. Cohort I was dosed at 1.25 mg/kg/day, with subsequent dose escalation (2.5, 5.0, 8.3, 12.5, 17.5 mg/kg) based on safety evaluation. Adverse events (AEs) were graded using the CTCAE v3.0 and by laboratory assessment of hematologic toxicity. In the absence of DLTs, dose escalation was planned to proceed to three dose levels above the cohort that achieved >90% occupancy of Btk by PCI-32765 assessed using a PD probe assay. Blood was collected before and after treatment on Days 1 and 8 for determination of pharmacokinetic and pharmacodynamic (PD) profiles and clinical responses were assessed every two cycles. *Results.* 30 pts (11 follicular lymphoma (FL), 7 CLL/SLL, 5 DLBCL, 4 mantle cell lymphoma (MCL), 3 marginal zone lymphoma) with a median of 3 prior therapies have been enrolled on four cohorts (1.25, 2.5, 5.0 and 8.3 mg/kg/day). Therapy was well tolerated with most adverse events < grade 2. Two protocol defined DLTs have been observed. 1 patient required dose delay > 7d due to neutropenia, and 1 patient developed hypersensitivity reaction to study drug. 19 patients are currently evaluable for response. The ORR is 42%; 1 CR (SLL), 7 PR (4 CLL/SLL, 2 MCL and 1 FL). In cohort 2, PD assays demonstrate complete occupancy of Btk by PCI-32765, with >95% enzyme occupancy 4 hours post dose in all pts. Basophil degranulation, a Btk-dependent cellular process, was completely inhibited up to 24 hrs. T-cell responses were not affected, and no significant depletion of peripheral blood B, T or NK cell counts observed. Plasma concentrations of PCI-32765 generally increased with increasing dose. Trough levels of PCI-32765 did not increase meaningfully with repeated dosing. Analysis of pharmacokinetic and pharmacodynamic profiles on Day 1 showed that Btk active-site occupancy was saturated 4 and 24 hours postdose at AUC values of ≥ 200 ng-h/mL. At steady state all patients that received doses of greater than 1.25 mg/kg/day had AUC values ≥245 ng-h/mL. *Conclusion.* PCI-32765 is an oral agent that selectively inhibits Btk at low dose levels. Monotherapy appears to be well tolerated in patients with relapsed B-cell NHL with encouraging clinical activity and a mild toxicity profile. Toxicity and response assessment is ongoing. Phase II trials in indolent lymphoma and MCL are planned.

0894

PHASE 1 STUDY OF NAVITOCLAX (ABT-263) PLUS RITUXIMAB IN CD20-POSITIVE LYMPHOID MALIGNANCIES

W Roberts,[1] R Advani,[2] B Kahl,[3] D Persky,[4] H Xiong,[5] Y Cui,[5] T Busman,[5] A Krivoshik,[5] S Enschede,[5] R Humerickhouse[5]

[1]Royal Melbourne Hospital, Parkville, Australia; [2]Stanford University Medical Center, Standford, USA; [3]University of Wisconsin, Madison, USA; [4]Arizona Cancer Center, Tucson, USA; [5]Abbott Laboratories, Abbott Park, USA

Background. Navitoclax (ABT-263) is a novel, orally bioavailable, small molecule that binds with high affinity (Ki ≤1nM) to Bcl-2, Bcl-xL, and Bcl-w, promoting apoptosis. *in vitro*, navitoclax shows potent targeted cytotoxicity (EC_{50} ≤1μM) against T and B lymphoid malignancies that over-express Bcl-2. Phase 1 monotherapy results show that oral navitoclax is well-tolerated and with daily dosing has activity in some patients (pts) with lymphoid malignancies and many pts with chronic lymphocytic leukemia (CLL). Thrombocytopenia is a dose-limiting toxicity (DLT). Rituximab is an established treatment for pts with low-grade, CD20-positive B-cell malignancies, as monotherapy or in combination with chemotherapy. Navitoclax showed enhancement of rituximab efficacy in multiple preclinical models of B-cell lymphoma, both with rituximab monotherapy and in combination with chemotherapy. *Aims.* The primary objective of this, international, phase 1b/2 dose-escalation study is to assess safety and compatibility of oral navitoclax added to standard rituximab monotherapy in pts with relapsed/refractory B-cell malignancies. Secondary objectives include navitoclax pharmacokinetics (PK) and maximum tolerated dose (MTD) determination for the combination. *Methods.* Key eligibility includes presence of ≥1 lesion ≥1.5 cm, ECOG score ≤1, and platelet count of >75,000/uL. Following a 7-14 day 150 mg/day dose lead-in, navitoclax was dosed at 200mg or 250mg per day continuously. Patients received 375mg/m^2 rituximab once weekly for 4 doses, commencing after 7 days of navitoclax. A cycle was defined as 28 days of therapy. Tumor responses were evaluated using IWG criteria and NCI-WG criteria (for CLL pts) every 2 months. Patients may continue on navitoclax therapy for 2 years in the absence of progressive disease or significant toxicity. *Results.* As of February 1, 2010, 11 pts (5 with follicular lymphoma [FL], 1 with B-lymphoblastic lymphoma, 1 with CLL, 1 with DLBCL, 1 with transformed disease (DLBCL), 1 with SLL, 1 with lymphoplasmacytic lymphoma), median age 60 years (range 46-79), have been dosed with navitoclax and rituximab (4 in the 200 mg; 7 in the 250mg cohort). Informed consent was obtained. One pt in the 250mg cohort had a DLT of Grade 3 diarrhea. Two pts (1 with B-lymphoblastic lymphoma, 1 with DLBCL) discontinued due to disease progression, and 1 pt withdrew consent. Eight pts remain on study: 2 in the 200mg cohort, 6 in the 250mg cohort. Preliminary efficacy data indicate 1 PR (FL 189+ days) and 1 SD (CLL 176+ days) in the 200 mg cohort, and 2 PRs in the 250mg cohort (1 FL 126+ days, and 1 SLL 111+ days). Based on the limited data, PK of navitoclax in this combination study appears to be comparable to PK in the navitoclax monotherapy study. *Summary/Conclusions.* The combination of navitoclax and rituximab is well tolerated and shows preliminary evidence of activity. The MTD has not been reached. Accrual is ongoing and following completion of the dose-escalation component of this study, an expanded cohort of pts will be assessed using the recommended phase 2 dose of navitoclax to estimate the objective response rate of this combination.

0895

THE CLINICAL UTILITY OF FDG PET-CT IN EVALUATION OF BONE MARROW INVOLVEMENT BY LYMPHOMA

HJ Kim,[1] JS Kim,[1] HY Kim,[1] JY Jung,[2] HS Kim,[2] HH Song,[2] JH Kwon,[2] GD Jang,[2] YK Lee,[1] SK Min,[1] HS Hwang,[1] DY Zang[1]

[1]Hallym University Sacred Heart Hospital, Anyang, South-Korea; [2]Hallym University Medical Center, Seoul, South-Korea

Background. In lymphoma, bone marrow (BM) involvement is a sign of extensive disease and BM biopsy is a standard method in the evaluation of BM infiltration. Because of focal BM involvement pattern by

lymphoma, the reported rates of unilateral involvement in bilateral biopsies range from 10% to 50%. However BM biopsy is an invasive and painful procedure. The value of unilateral *vs.* bilateral BM biopsy remains controversial. Fluorodeoxyglucose positron emission tomography-computed tomography (FDG PET-CT) is a noninvasive imaging technique and currently it shows potential to detect BM involvement by lymphoma. *Aims.* We assess the abilities of FDG PET-CT to ascertain the presence of BM involvement and to define the patients whose bilateral BM biopsies could be replaced by unilateral biopsy in lymphoma. *Methods.* We retrospectively reviewed medical records of histologically proven lymphoma patients from 2004 through 2009 at the Hallym University Medical Center. All patients were examined by FDG PET-CT and iliac crest BM biopsy for initial staging work-up. We used both qualitative and quantitative methods to evaluate FDG PET-CT. All lesions in iliac crest were analyzed by maximum standardized uptake value (SUVmax) and cut-off value for positivity was 2.0 g/mL. We calculated sensitivity, specificity, positive predictive value and negative predictive value for FDG PET-CT in evaluation of BM infiltration, using BM biopsy as the reference standard. *Results.* Study population comprised 101 consecutive patients (median age 58.4, range 20-86 years ; 62 male) with Hodgkin's disease (n=8) or non-Hodgkin's lymphoma (NHL, total, n=93; diffuse large B cell, n=56; angioimmunoblastic T cell, n=10; marginal zone B cell, n=8; NK/T-cell, n=7; peripheral T cell, n=3; Mantle cell, n=3; Anaplastic large cell, n=3; Small lymphocytic, n=2; Follicular, n=1). Overall, BM involvement that confirmed by BM biopsy occurs in 25 patients. SUVmax values on iliac crest of patients with lymphoma infiltrated BM were significantly higher than those of patients with intact BM (2.97±1.83 *vs.* 1.30±0.35 g/mL; $P < 0.0001$). Table1 shows the calculated values for FDG PET-CT in evaluation of BM infiltration which had been measured by quantitative method. The values measured by qualitative method were similar (sensitivity 42%, specificity 99%, positive predictive value 92%, negative predictive value 83%). There was no significant difference in the ability of the FDG PET-CT detecting BM involvement among Hodgkin's lymphoma, Indolent NHL and aggressive NHL. *Conclusions.* This study demonstrates good concordance of FDG PET-CT with the results of BM biopsy for the detection of BM infiltration in lymphoma patients. Because of the excellent positive predictive value, FDG PET-CT will be a useful tool for image-guided biopsy for lymphoma staging. And in lymphoma patients with increased iliac crest FDG uptake, unilateral BM biopsy could be substituted for bilateral BM biopsy.

Table. FDG PET-CT and Bone marrow involvement result.

	Bone marrow involvement (%)			
	HD	Indolent NHL	Aggressive NHL	Total
Sensitivity	50 (1/2)	46 (6/13)	50 (5/10)	48 (12/25)
Specificity	100 (6/6)	100 (11/11)	98 (58/59)	99 (75/76)
PPV	100 (1/1)	100 (6/6)	83 (5/6)	92 (12/13)
NPV	86 (6/7)	61 (11/18)	92 (58/63)	85 (75/88)

PPV: positive predictive value; NPV: negative predictive value; HD: Hodgkin's disease; NHL: non-Hodgkin's lymphoma; FDG PET-CT: Fluorodeoxyglucose positron emission tomography-computed tomography

ANEMIA AND ESA ADMINISTRATION IN PATIENTS TREATED WITH RCHOP CHEMOTHERAPY: RESULTS FROM AN OBSERVATIONAL STUDY OF PATIENTS WITH NON-HODGKIN LYMPHOMA

P Lugtenburg,[1] A Salar,[2] R Pettengell,[3] H Johnsen,[4] U Duehrsen,[5] F Rossi,[6] G Verhoef,[7] M Schwenkglenks,[8] U Jaeger,[9] L Hamilton,[10] B Pujol,[11] C Haioun[12]

[1]Erasmus MC, Rotterdam, Netherlands; [2]Hospital del Mar, Barcelona, Spain; [3]St. Georges University of London, London, UK; [4]Aalborg Hospital, Aalborg, Denmark; [5]University Hospital Essen, Essen, Germany; [6]Fondazione Policlinico MaRe IRCCS, Milan, Italy; [7]University Hospital Leuven, Leuven, Belgium; [8]European Center of Pharmaceutical Medicine, University of Basel, Basel, Switzerland; [9]Medical University of Vienna, Vienna, Austria; [10]Biostatistics, Amgen Ltd., Uxbridge, UK; [11]Amgen (Europe) GmbH, Zug, Switzerland; [12]Hematology, Henri Mondor Hospital, Creteil, France

Background. The CHOP (cyclophosphamide, doxorubicin, vincristine, prednisolone) regimen and its variants are regarded as the standard of care for treating aggressive advanced-stage non-Hodgkin lymphoma (NHL). Anemia is a common side effect of myelosuppressive chemotherapy (CT), and anemia greater than grade 2 (WHO definition; hemoglobin (Hb) <8 g/dL) has been found in 25% of patients receiving RCHOP chemotherapy. Erythropoiesis-stimulating agents (ESAs) are approved for the treatment of CT-induced anemia to raise Hb concentrations and reduce the need for blood transfusions. *Aims.* In this primary analysis from the IMPACT NHL study, we aimed to describe predictors of anemia, current treatment practices of ESA administration, and efficacy outcomes relating to hemoglobin (Hb) levels in NHL patients treated with ESAs. *Methods.* IMPACT NHL was a retrospective and prospective multi-center observational study in Europe and Australia. NHL patients (≥18 years) were enrolled between 2005 and 2008 and received either CHOP-14 or CHOP-21 chemotherapy±rituximab (R). Data were collected on patients who were treated with ESAs (darbepoetin-α, epoetin-α, or epoetin-β) according to routine clinical practice, at any time during the study. The analysis reported here presents the results of pre-specified anemia-related outcomes. Anemia was defined as Hb <10 gdL. Multivariate logistic regression was used to explore predictors of anemia during chemotherapy treatment (CT). *Results.* A total of 1829 patients treated with at least one cycle of CHOP (± R) chemotherapy were enrolled in the study. Of the patients with available Hb values (n=1687 at start of CT treatment; n=1810 during CT treatment), 11% were anemic at the start of CT treatment, while 33% were anemic during CT treatment. Significant predictors of anemia were older age, higher number of chemotherapy cycles, lower Hb at start of CT treatment, female gender, Ann Arbor Stage IV, CHOP-14 (± R) chemotherapy, and diffuse large B-cell lymphoma. During the study 404 patients (22%) received ESA treatment (see Table for baseline characteristics). Two thirds of these patients initiated their ESA treatment within the first three cycles of CT, and most frequently in response to low Hb concentrations (81%). Mean Hb value at initiation of ESA treatment was 10.07 g/dL (SD 1.28): 45% of patients had Hb <10 g/dL, 15% Hb <9 g/dL and 63% had Hb 9-11 g/dL (per EORTC guidelines). After initiation of ESA treatment, Hb concentrations increased regardless of the CT cycle. Of 181 patients with Hb <10 g/dL at ESA initiation, 57% achieved Hb 10-12 g/dL during the ESA treatment phase (Kaplan-Meier (KM) estimate 88%; 95% CI 79, 97). *Conclusions.* In this observational study, 33% of patients were anemic during CT treatment. Twenty-two percent (22%) were treated with ESAs, most frequently in response to low Hb concentrations. In ESA treated patients, 2/3 of patients were started on ESA treatment according to EORTC guidelines (Hb 9-11 g/dL), and 88% (KM %) of ESA-treated patients with Hb <10 g/dL at ESA initiation achieved Hb concentrations within the target range of 10-12 g/dL.

This study was sponsored by Amgen (Europe) GmbH (ClinicalTrial.gov NCT00903812).

STANDARDIZED UPTAKE VALUE OF 18F-FDG ON PET/CT IN NEWLY DIAGNOSED PATIENTS WITH NON-HODGKIN'S LYMPHOMA CORRELATES WITH PROLIFERATIVE INDEX OF LYMPHOMA CELLS

T Papajik,[1] M Myslivecek,[1] E Buriankova,[1] Z Sedova,[1] V Prochazka,[1] P Koranda,[1] Z Kubova,[1] M Palova,[1] L Kucerova,[1] P Flodr,[1] J Jarkovsky,[2] L Dusek,[2] K Indrak[1]

[1]University Hospital, Olomouc, Czech Republic; [2]Masaryk University, Brno, Czech Republic

Background. Positron emission tomography integrated with computed tomography (PET/CT) using 2-[fluorine-18]-fluoro-2-deoxy-D-glucose (18F-FDG) is currently considered to be the most beneficial imaging method for staging patients with non-Hodgkin's lymphoma (NHL). The intensity of 18F-FDG accumulation may be semiquantitatively determined by calculating the so-called standardized uptake value (SUV). *Aims.* The prospective study aimed at assessing the benefit of SUVmax determination in staging 18F-FDG PET/CT in 149 untreated patients with NHL, and comparing the SUVmax values with the Ki-67 proliferative index of tumor cells and serum lactate dehydrogenase (LDH) levels. The prospective study was approved by the Multicenter Ethical Committee of the Faculty of Medicine and Dentistry and University Hospital Olomouc. The patients gave written informed consent to examination and anonymous data analysis. *Methods.* For each patient, SUVmax of the suspicious lesion was calculated. This was based on values measured in the area of interest around the pathological lesion seen in the PET scan as a pixel with the highest accumulation of 18F-FDG. For this purpose, the longer axis of each evaluated lymph node or organ lesion had to be longer than 20 mm. *Results.* In the entire group of patients, the geometric mean of SUVmax values was 10.2 (95% CI; 9.1 - 11.5). The highest mean and median values of SUVmax were observed in patients with diffuse large B-cell lymphoma (DLBCL), follicular lymphoma (FL) and peripheral T-cell lymphoma (PTCL); the lowest mean and median values were found in mantle cell lymphoma (MCL), marginal zone lymphoma (MZL), and small lymphocytic lymphoma / chronic lymphocytic leukemia (SLL/CLL). Statistically significant differences in SUVmax values ($P<0.001$) were found between patients with DLBCL and those with MCL, DLBCL and MZL. The overlap of SUVmax between DLBCL, FL and PTCL was very significant. A similar overlap in SUVmax < 10 was found between DLBCL and the other subgroups of NHL. Statistically, no correlation was found between the LDH and SUVmax values. On the other hand, a correlation of the Ki-67 proliferative index of tumor cells and SUVmax was revealed ($r=0.409$, $P<0.001$). In patients with Ki-67 ≤ 60, the geometric mean of SUVmax was 8.8 (95% CI; 7.3 - 10.5) and the median was 9.4 (range; 2.0-43.2). In patients with Ki-67 > 60, the geometric mean of SUVmax was 14.3 (95% CI; 12.2-16.8) and the median was 15.7 (range; 2.2-40.6). *Conclusions.* The study results confirm that SUVmax determined during initial staging 18F-FDG PET/CT is not beneficial for making a more precise diagnosis in most patients with NHL. Correlation of SUVmax with the Ki-67 values suggests that SUVmax might have a prognostic values in certain NHL subtypes.

Supported by the Czech Ministry of Health grant project No. NR/9502-3.

PREVALENCE OF CHRONIC INFLAMMATORY DISORDERS IN PATIENTS WITH MALIGNANT LYMPHOMA AT DIAGNOSIS

K Vanura, F Späth, A Gleiss, T Le, E Porpaczy, C Skrabs, A Hauswirth, K Flei_, A Gaiger, L Müllauer, U Jäger

Medical University of Vienna, Vienna, Austria

Background. There is evidence for the role of chronic antigenic stimulation (CS) in the development of cancer. However, clinical data are rare as is information on how the presence of a chronic inflammatory disease influences outcome. *Aims.* To assess the presence of chronic infections and autoimmune diseases at diagnosis in patients with malignant lymphoma and to investigate the association of these data with basic clinical information and survival. *Methods.* Patient charts were reviewed to assess the presence of chronic infections and autoimmune diseases in lymphoma patients. Data collected included sex, age, age at diagnosis, mortality, lymphoma subtype, and treatment. Data analysis sought to detect correlations between patient characteristics and absence, presence, and type of chronic inflammatory disorder, respectively. *Results.* In this retrospective, monocentric study, 367 patients diagnosed with malignant lymphoma at our institution between 2001 and 2005 were included. Of these patients, 297 suffered from non-Hodgkin´s lymphoma (NHL) and 70 from Hodgkin´s lymphoma (HL). In total, 9.8% (N=36) had a history of chronic antigenic stimulation (4.4% autoimmune diseases, 5.4% chronic infections). After a median observation time of 74.7 months (quartiles: 62.6 to 89.1 months), 118 patients have died (32.2%). Interestingly, CS patients had a slightly better performance than non-CS patients, although no significant difference in overall survival could be observed (Kaplan-Meier estimates for survival after 48 months in HL: CS 100%, non-CS 88.7%; aggressive NHL: CS 66.7%, non-CS 58.6%; indolent NHL: CS 84.6%, non-CS 77.0%). Slightly more men than women had malignant lymphoma (52.2% *vs.* 47.8%), both in the entire patient cohort and in NHL and HL subgroups. However, in all groups sex prevalence among patients showing chronic antigenic stimulation was skewed in favor of women where they constituted over 60% of patients ($P=0.018$). Women were in particular overrepresented among lymphoma patients with autoimmune diseases ($P=0.001$). Patients with chronic inflammatory conditions were more likely to suffer from an aggressive lymphoma ($P=0.256$). In particular, NHL patients with autoimmune diseases showed a tendency for diffuse large B cell lymphoma (NHL+AI 8/12 (66.7%), NHL-AI 107/285 (37.5%); $P=0.066$). Among patients with T-cell lymphoma and lymphoplasmocytic lymphoma, no history of chronic antigenic stimulation could be observed. *Conclusions.* The pre-existence of chronic antigenic stimulation appears to be associated with a higher risk of aggressive lymphoma and a higher prevalence of women. However, in our study we did not observe a difference in overall survival between CS and non-CS patients in the respective lymphoma subgroups. This suggests that in the presence of a chronic inflammatory condition no special treatment strategies are required.

0899

CLINICAL EXPERIENCE OF BENDAMUSTINE TREATMENT FOR NON-HODGKIN LYMPHOMA AND CHRONIC LYMPHOCYTIC LEUKEMIA: SPANISH REGISTRY

B Sánchez-González

Hospital del Mar, Barcelona, Spain

Introduction. Bendamustine (B) is a purine analog/alkylator hybrid that has demonstrated clinical activity in relapsed indolent non-Hodgkin lymphoma (NHL), including those refractory to other alkylating or purine analog agents, chronic lymphocytic leukemia (CLL) and multiple myeloma patients. Bendamustine is currently licensed in Germany and Switzerland for use in NHL and CLL, and is in evaluation process by European Medication Agency (EMEA) in other european countries. *Aim.* To analyze retrospectively the efficacy and toxicity of bendamustine as a single-agent or in combination for NHL and CLL in Spain. *Patients and Methods.* A questionnaire form was sent to Spanish centers in which bendamustine had been used. Patients with relapsed or refractory NHL or CLL after at least 1 prior treatment regimen were eligible. Any bendamustine regimen was included. *Results.* 22 institutions responded favourably for participating in the study and 116 patients (pts) were included in the registry. Median age was 68 years (range: 36-88); male: 61%; ECOG/PS 0-1: 74%; Ann Arbor III-IV: 80% and IPI score >3: 48% in NHL, and Binnet B-C stage in CLL: 66%. Histology was as follows: 47 pts CLL; 20 pts aggressive NHL (16 mantle cell lymphoma, 3 diffuse large B-cell lymphoma and 1 T cell lymphoma); 49 pts indolent NHL (41 follicular lymphoma, 5 extranodal marginal zone B-cell lymphoma of MALT type and 3 lymphoplasmocytic lymphoma); Median time from diagnosis to Bendamustine treatment was 4.9 years (range 1-19) and median number of previous treatment regimens was 3 (range 1-11). 46 pts (41%) were refractory to prior treatment. The most frequent used regimen was rituximab plus B (RB) independently of the histology (see Table 1). No case of Stevens-Johnson syndrome has been recorded. Median number of bendamustine cycles was 4 (range 1-7). 441 cycles of B were administered. 63% of de pts had adverse events grade III/IV, being hematologic toxicity the most frequent adverse event grade III/IV (33% leucopenia, 53% neutropenia, 28% thrombocytopenia, and 20% anemia). 14% cycles of B required pts admission in hospital. 101 pts were assessable for response at the time of analysis. Response rate is showed in Table 1. 39 pts died (22 progression, 9 infection, 6 infection plus progression, 1 acute renal failure and 1 isquemia). *Conclusions.* 1. Bendamustine, at dose of 90 mg/m^2/day for two consecutive days, associated with rituximab was the most common regimen. 2. Bendamustine containing therapy achieved a high response rate in this heavily pretreated population of CLL and NHL patients. Responses were seen in indolent and aggressive histologies, and also in patients with chemoresistant disease to the immediately previous regimen. 3. Treatment with bendamustine was associated with an acceptable toxicity profile in this population of patients.

ELEVATED CD44 SERUM LEVELS REPRESENT AN INDEPENDENT PROGNOSTIC FACTOR IN MYELODYSPLASTIC SYNDROMES

R Stauder,[1] R Stauder,[2] U Germing,[3] W Sperr,[4] H Zwierzina,[5] H Ulmer,[6] P Valent,[4] J Löffler-Ragg[4]

[1]Dept. of Internal Medicine V (Haematology and Oncology), Innsbruck Medical Univ., Innsbruck, Austria; [2]Innsbruck Medical University, Innsbruck, Austria; [3]Dep. Internal Medicine I, Div. Hematology & Hemostaseology, Düsseldorf, Germany; [4]Dep. Internal Medicine I, Vienna Medical University, Vienna, Austria; [5]Department of Internal Medicine I, Innsbruck Medical University, Innsbruck, Austria; [6]Department of Biostatistics and Documentation, Innsbruck Medical University, Innsbruck, Austria

Background. Overexpression of the adhesion molecule CD44 correlates with poor prognosis in various neoplasms. The cleavage of the ectodomain of CD44 results in elevated levels of soluble CD44 (solCD44). SolCD44 retains important biological functions including the regulation of tumor cell proliferation and apoptosis. Aim of this study was to analyse serum levels of solCD44 in a well-defined cohort of MDS patients and to evaluate the relevance of solCD44 in clinical prognostication. *Methods.* Serum levels of soluble CD44 standard (solCD44s) were measured in 130 myelodysplastic syndromes (MDS) patients (median age 68 yrs) using an enzyme-linked immunosorbent assay (ELISA). *Results.* solCD44s levels were significantly elevated in MDS patients as compared to those of healthy donors (P< 0.001) and were found to correlate with distinct MDS subtypes. The highest levels of solCD44s were found in patients with CMML, in RAEB-t and in patients with MDS transformed into secondary acute myeloid leukaemia (AML). In univariate analysis elevated levels of solCD44s (cut-off level > 688.5 ng/mL) correlated significantly with shorter overall survival in MDS patients (12 *vs.* 39 months; P<0.001). In multivariate analysis solCD44s displayed prognostic significance independent of the International Prognosis Scoring System (IPSS). To test for refined prognostication, IPSS risk groups were split into two separate categories based on solCD44s levels. Using this approach, MDS patients with a shorter survival were identified both in the IPSS low-risk (P=0.037) and in the IPSS intermediate-1-risk group (P= 0.015). *Summary/Conclusions.* Elevated sCD44s levels define a cohort of MDS patients with unfavourable prognosis, which might be helpful in risk stratification and in therapeutic algorithms. Understanding of solCD44-mediated processes will offer an important clue toward defining mechanisms responsible for tumour propagation in MDS and AML. Thus, the rationale for therapeutic strategies directed at CD44-mediated interactions will be provided.

0901

ROLE OF RIBOSOMAL GENES IN MYELODYSPLASTIC SYNDROMES EVOLUTION TO ACUTE MYELOID LEUKEMIA

S Santiago,[1] I Isabel,[1] K Karen,[1] G Miguel,[1] R Rosa,[1] F Francisco,[2] M Mar,[2] J Joaquin[1]

[1]Hospital [12] de Octubre, Madrid, Spain; [2]IMIM-Hospital del Mar, Barcelona, Spain

Background. The haploinsufficiency of the ribosomal protein RPS14 has been involved in the defective erythroid differentiation in the 5q-syndrome. Moreover, a low RPS14 expression has been recently described as a common alteration in other myelodysplastic syndromes (MDS) different to 5q- syndrome, that defines a subgroup of patients with prolonged survival. *Aims.* We aimed to correlate RPS14, RPL28, EE1D ribosomal genes expression, as well as SPARC tumor suppressor gene expression with the different subtypes of MDS, their kariotype, International Prognostic Score System (IPSS), and to determine their role and prognostic value in the evolution to AML. *Methods.* 48 patients diagnosed of MDS (10 with isolated 5q deletion, 7 with chromosomal 7 alterations, and 4 with trisomy in chromosome 8), 10 AML secondary to MDS, 3 myeloproliferative neoplasms (MPN) and 3 controls were included in the present study. Patients were diagnosed and classified according to the WHO criteria. The cDNA was collected from bone marrow aspirate samples. RPS14, RPL28, EE1D and SPARC gene expression was analyzed in duplicate with TaqMan individual assays in an ABI PRISM 7900HT Sequence Detection system (Applied Biosys-

tems). The ratio for each sample was achieved using the comparative Ct method as -2Δct. C18S, ABL and Gus were used as control genes. Statistical significance (P<0.05) was obtained by non-parametric wilcoxon analysis in SPSS15 software. *Results.* The statistical analysis showed a significant decrease in RPS14 (P=0.001) expression in patients with isolated 5q- alteration, compared to the other MDS. On the other hand, RPS14 was significantly decreased in not 5q- MDS compared to AML secondary to MDS (P<0.001), NMP (P<0.001) and controls (P=0.017) (see attached figure). The analysis performed with other clinical variables (gender, SMD type, IPSS, bone marrow blasts percentage and associated cytopenias) showed no significant gene expression differences. *Conclusions.* RPS14 down expression, observed in isolated 5q- syndrome, as previously referred, is a coherent finding, due to the haploinsufficiency of RPS14 in this entity. On the other hand, RPS14 overexpression in AML secondary to MDS could play a role in progression to AML. These results will be confirmed by studies of RPS14 gene expression in a group of patients with AML secondary to MDS, before and after progression to AML.

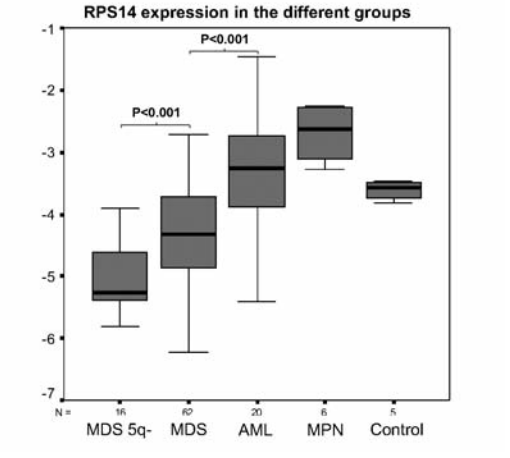

Figure. RPS14 gene expression in the differents groups.

HUMAN TELOMERASE REVERSE TRANSCRIPTASE EXPRESSION (HTERT) DETECTED BY FLOW CYTOMETORY IN CD34 POSITIVE PROGENITOR FRACTION IN MYELODYSPLASTIC SYNDROME AND ACUTE MYELOID LEUKEMIA.

H Handa, H Murakami, T Matsushima, N Nishimoto, M Inoue, T Saitoh, A Yokohama, H Koiso, T Mitsui, N Tsukamoto, H Ogawara, M Karasawa, Y Nojima

Gunma Univiersity, Maebashi, Gunma, Japan

Telomerase activity (TA) has been found in most common cancers indicating that telomerase detection may be a useful marker in cancer diagnosis. TRAP assay and RT-PCR for hTERT mRNA expression are customarily used for detection of TA, however such methods cannot measure the TA in cell subpopulation. Immunohistochemical detection of hTERT is useful to detect telomerase-positive cells in a background of non- cancerous cells. We developed a method for the detection of intra-nuclear hTERT protein, in a sub-population of hematopoietic cells, using concurrent staining cell surface antigen and multi color flow cytometry hTERT expression detected by flow cytometory were correlated with TA (r=0.0735, P=0.002) (Published in Leukemia Res 2010). We applied this method to analyze hTERT expression in myelodysplastic syndrome (MDS). Nineteen acute myelogenous leukemia and 40 MDS patients samples were obtained, 36 patients were diagnosed as low risk MDS (RCUD, RCMD, MDS-U), 14 patients were diagnosed as high risk MDS (RAEB) according to WHO classification. All samples were acquired after informed consent was obtained from the patients. Expression of hTERT protein in CD45 dull blast population was analyzed and it was higher in $CD34^+$ than $CD34^-$ cells. The percentage of the $CD34^+$ cells expressing hTERT ranged from 9.66% to 90.91% in low risk MDS patients, whereas from 50.46% to 97.68% in high risk MDS. The expression level was higher in the high risk group compared to that in the low risk group in MDS (P=0.0084). This observation implied that telomerase up-regulation and hTERT expression were important for disease progression and could be a marker of more advanced disease. Then we examined the hTERT expression in $CD34^+$/CD38 high cells and $CD34^+$/CD38 low cells containing stem cell fraction in 26 MDS and 11 AML bone marrow specimens. Of interest, hTERT expression in CD34+/CD38 low cells were higher than in $CD34^+$/CD38 high cells (P=0.021) in MDS but no significant difference was found in AML (P=0.217). $CD34^+$CD38 low cells in high risk MDS demonstrated higher hTERT expression compared to those cells in low risk MDS (P=0.02). This observation is inconsistent with previous reports describing normal bone marrow hematopoietic cell findings. We speculated that this phenomenon could be a marker of MDS abnormality and that telomerase up-regulation may be initiated in the more primitive precursor fraction containing hematopoietic stem cells during the disease progression. Telomerase studies may be useful for definition of the risks associated with disease severity. Multi-parameter nature of flow cytometry and its ability to identify cellular sub-populations will facilitate a fuller understanding of the mechanisms of activation of telomerase.

HETEROGENEOUS EXPRESSION PATTERN OF HEDGEHOG SIGNALLING PATHWAY IN HEMATOPOIESIS OF MYELODYSPLASTIC SYNDROME

D Neureiter,[1] R Kemmerling,[2] B Alinger,[2] T Kiesslich,[3] V Faber,[4] M Stöcher,[4] L Pleyer,[4] R Greil,[4] O Dietze[2]

[1]Salzburger Landeskliniken/PMU, Salzburg, Austria; [2]Institute of Pathology, Salzburger Landeskiniken/PMU, Salzburg, Austria; [3]I. Medical Department, Salzburger Landeskiniken/PMU, Salzburg, Austria; [4]III. Medical Department, Salzburger Landeskiniken/PMU, Salzburg, Austria

Background. Recent investigations provide evidence that the Hedgehog (HH) pathway is essentially involved in apoptosis, proliferation and differentiation of hematopoietic cells via autocrine or paracrine signalling. *Aims.* Therefore, we investigated the expression pattern of the HH signalling components in hematopoiesis of different stages of myelodysplastic syndromes (MDS) compared to control samples from healthy donors. *Methods.* 18 normal controls and 80 cases with MDS (subgroups according WHO: n=40 refractory cytopenia (RA) with multilineage dysplasia, n=13/22 refractory anaemia with excess of blasts I/II and n=5 secondary acute myeloid leukaemia) were included in the investigations. All MDS cases were fully characterized for dysplastic change of bone marrow as well as for risk factors (IPSS), laboratory parameters and follow-up. Bone marrow sections were analyzed by immunohistochemistry for HH ligands (Desert, Sonic, and Indian HH), receptors (Smoothened (Smo), Patched and HIP) and transcription factors Gli (1-3). Additionally, the findings were related to mRNA expression levels of MDS and control samples. *Results.* Overall, the mRNA and protein levels of HH signalling components were low and increased from ligands to transcription factors in the hematopoiesis. Most significant differences could be evaluated inside granulopoiesis (especially for Smo and Gli, ANOVA P<0.05) comparing controls and cases as well as different IPSS scoring levels. Interestingly, up- or down-regulation of HH signalling members could be detected inside different MDS subgroups. Finally, significant independent predictors of the HH signalling family for survival probability could be evaluated. *Summary.* Our investigation revealed that (i) HH signalling pathway is significantly heterogeneous expressed in normal and dysplastic hematopoiesis, and that (ii) expression of some particular HH signalling components is partly associated with the survival rate of patients with MDS.

CLINICAL AND BIOLOGICAL FEATURES OF MYELODYSPLASTIC SYNDROMES WITH BONE MARROW FIBROSIS

A Ricco,[1] P Carluccio,[2] A Napoli,[3] A Mazzone,[2] P Casieri,[2] R Angarano,[2] V Fesce,[2] N Sgherza,[2] G Nardelli,[2] R Ricco,[3] V Liso,[2] G Specchia[2]

[1]A.O.U. Policlinico, Bari, Italy; [2]Hematology, Bari, Italy; [3]Pathological Anatomy, Bari, Italy

Background. Owing to the notable clinical heterogeneity of Myelodysplastic Syndromes (MDS), ranging from indolent conditions developing over years to forms rapidly progressing to leukemia, clinical decision-making and the timing of interventions are still a matter of debate. *Aims.* To search for unifying biological and clinical features stratifying MDS patients in distinct subgroups, so as to improve the evaluation of prognosis and the prediction of clinical outcome in MDS patients. In several studies bone marrow histological pictures have emerged as an important prognostic parameter influencing marrow insufficiency and MDS

outcome. *Methods.* We retrospectively collected clinical and hematological data, including bone marrow fibrosis (MF), on 180 consecutive patients with a diagnosis of MDS. All patients were reclassified according to the WHO criteria; 43 patients were excluded because their disease was classified as CMML (23 patients) and AML with more than 20% marrow blasts (20 patients). The grading of MF was established according to the European Consensus guidelines. Cytogenetic analysis was successful in 97 (69%) out of 137 patients; the IPSS and WPSS scores at diagnosis were also assessed in these 97 patients. *Results.* Of the 137 evaluated patients, 43 (32%) showed grade 0 fibrosis, while 94 (67%) showed pictures of marrow fibrosis ranging from mild (grade 1) to severe (grade 3), in 36 (26%), 52 (38%) and 6 (4%)patients, respectively. There were no significant differences between patients without MF and those with grade 1 MF, regarding clinical characteristics, karyotype and outcome, so we unified patients with grade 0 and grade 1 fibrosis in a single subgroup (58% of patients) and matched their clinical findings and outcome with those of the grade 2 and 3 fibrosis subgroups (42%). Among these two populations we found that MF is significantly related to more severe thrombocytopenia, splenomegaly, a poor-risk cytogenetic status, bi and trilineage dysplasia, a higher risk of leukemic evolution and poor O.S. *Conclusion.* Besides the main changes in hematopoiesis and the cytogenetic pattern , that are the well-known, distinctive hallmarks of MDS providing significant prognostic information, it is becoming apparent that other cellular and mesenchymal marrow components not involved in the neoplastic clone have a role in marrow insufficiency and leukemic transformation. Evaluation of marrow histology will thus be an essential tool in predicting prognosis in MDS patients, with the presence of MF as an independent unfavorable prognostic factor. Moreover, the evaluation of MF in the setting of the new therapeutic strategies (antiangiogenetic, epigenetic) will probably provide new insights into their biological activity and impact on the clinical outcome.

0905

COMORBIDITIES DO NOT MODIFY OUTCOME AND FREQUENCY OF ADVERSE EVENTS DURING AZA, BUT INFLUENCE SURVIVAL

A Sanna, T Lunghi, A Gozzini, F Sassolini, A Bosi, V Santini

UF Ematologia, AOU Careggi, Università degli Studi di Firenze, Florence, Italy

Background. Myelodysplastic syndromes (MDS) are affecting mainly elderly patients, and age is considered per se a negative prognostic factor. Most of the elderly patients have comorbidity that presumably negatively impact the overall survival and quality of life and may influence response to therapy. A subanalysis demonstrated that MDS patients aged >75 yrs treated with azacitidine have a significantly longer overall survival respect to best supportive care treated patients (Fenaux, Lancet Oncol. 2009). *Aims.* We wanted to verify whether elderly and very elderly patients receiving azacitdine in our Center, outside clinical trials, were less prone to respond to azacitidine or presented more side effects related to therapy. We also analyzed number of comorbidities their impact on the response and management of azacitidine treatment. *Methods.* We analyzed 39 elderly MDS patients (IPSS INT-1 14/39 and INT-2/high 27/39) treated with subcutaneous Azacitidine 75 mg/kg/day for 7 days every 28. Mean number of cycles was 11 (range:42-2). Mean age was 70 yrs (60-82); 33% of patients (13/39) were >= 75 yrs and 38% of the latter (5/13) >= 80 yrs. *Results.* Overall response rate according IWG criteria 2006 was 44%, stable disease was obtained in 34.1 % of MDS patients. Response to azacitidine treatment was evaluated according to IWG 2006 criteria as CR, PR, HI, SD, DP. We demonstrated by Fisher test that these IWG responses did not correlate with age. We also evaluated Charlson comorbidity index (26 patients scored 0, 9 patients 1 and 4 patients >= 2) the Cumulative Illness Rating Scale (CIRS) (24 patients scored 0, 12 patients 1 and 4 patients >= 2) and the Adult Comorbidity Evaluation-27 in relation to age and to hematological response and no correlation was showed. Respectively 75% and 64% of patients did not suffer from any hematological or non hematological adverse events. Adverse events were uniformly distributed independently from age. Median overall survival (OS) of our patient cohort was comparable to that obtained in AZA-001 trial (29,5 months *vs.* 24,6). Median OS in patients < 75yrs and >= 75 yrs was not significantly different (p value > 0.7). In conclusion very elderly patients with comorbidities may be treated with success with azacitidine, without any substantial increase in AE. Nevertheless comorbidities negatively influence overall survival.

0906

DETECTION OF MOLECULAR TARGETS ON THE SURFACE OF CD34$^+$CD38$^-$ STEM CELLS IN MDS

W Xie,[1] XH Wang,[2] W Du,[1] W Liu,[1] XM Qin,[2] LL Guo,[1] P Wang,[1] SA Huang[1]

[1]*Union Hospital of Tongji Medical College, Wuhan, China;* [2]*High Trust Diagnostics, Peking, China*

Background. Myelodysplastic syndrome (MDS) is a kind of clonal stem-cell disorder in which aberration within a haematopoietic stem cell (HSC) gives rise to the entire disease as in acute myeloid leukemia (AML). A lot of studies on the phenotype of leukemic stem cell have showed that contrasting normal stem cells, AML stem cells express substantial amounts of CD96, CD123 and the C-type lectin-like molecule-1 (CLL-1), but lack the expressions of CD90, although both normal HSC and leukemic stem cells are resided within CD34$^+$CD38$^-$ population. So far, however, little is known about expression of the markers and targets on MDS HSC. *Aims.* To investigate whether there are some specific cell surface antigens expressed on MDS HSC that could distinguish MDS stem cells from normal/reactive stem cells, and the correlation of abnormal antigen expression profile to development, progression and risk stratification in MDS. *Methods.* We analyzed the immunophenotypic characteristics of CD34$^+$CD38$^-$ bone marrow (BM) cells from MDS patients compared to normal/reactive BM. Expression of a series of target antigens on CD34$^+$CD38$^-$ cells were analyzed by multi-color flow cytometry in 38 patients with MDS and 10 patients with nonneoplastic hematologic diseases as control using a FACS CaliburTM. Positivity was defined as no less than 10% of cell expression on CD34$^+$CD38$^-$ cells, unless CD90 (≥5%). *Results.* In both groups, CD34$^+$CD38$^-$ progenitors co-expressed CD13, CD33, CD117, CD133 and HLA-DR almost in all patients, but in MDS they expressed obviously higher amounts of CD13 (79±16% *vs.* 36±13%, P<0.05) and CD133 (66±20% *vs.* 25±13%, P<0.05). CD90 was found to be expressed in all control patients but just in 63% of MDS patients, and there was significant difference in expression amounts between the two groups (32±19% *vs.* 12±3%, P<0.05). By contrast, no patients in control group had an expression of CD2, CD5, CD7, CD44, CD96 and CD123 on CD34$^+$CD38$^-$ cells, which expressed variable amounts in 17~53% of MDS patients: CD2 (47±22%), CD5 (44±28%), CD7 (20±9%), CD44 (35±15%), CD96 (43±19%) and CD123 (54±23%). The level of CD13 on CD34$^+$CD38$^-$ cells in RCMD (89±7%), RAEB-1 (88±11%) and RAEB-2 (81±13%) groups were obviously higher than that of RA group (63±16%, P<0.05). Lymphoid markers such as CD2, CD5 and CD7 were more frequently observed in RAEB subtype or INT and HIGH-R cases, although the level of these markers was rather low. *Conclusions.* MDS stem cells display complex phenotypic abnormalities different from both normal stem cells and AML stem cells and risk-associated alterations, which may contribute to the evaluation of development, progression and risk-stratification in MDS and be a potential prognostic indicator in the future.

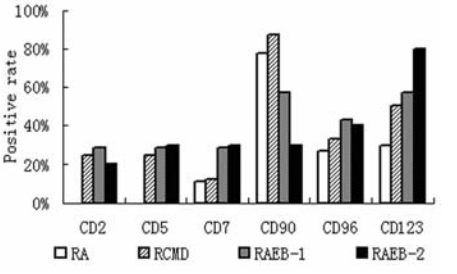

Figure. Antigen expression in MDS subgroups.

0907

IN VITRO STUDY OF BIOLOGICAL CHARACTERISTICS AND FUNCTIONS OF MESENCHYMAL STEM CELLS IN LOW-RISK MYELODYSPLASTIC SYNDROMES

YZ Zhang,[1] DD Zhao,[2] XP Han,[2] WM Da[2]

[1]*Tianjin Medical University Cancer Institute and Hospital, Tianjin, China;* [2]*Chinese PLA General Hospital, Beijing, China*

Background. The myelodysplastic syndromes (MDS) include a diverse

group of clonal and potentially malignant bone marrow disorders. Evidences exist that microenvironment cells from MDS marrow show functional abnormalities, which may be relevant to the incidence of such a disease. Mesenchymal stem cell (MSC) is a very important component of hematopoietic microenvironment. *Aims.* This study focused on the biological characteristics and functions of MSC derived from patients with MDS in low-risk. *Methods.* MSC from Bone marrow samples of 11 low-risk MDS patients were isolated, cultured and expanded. Morphology, immunophenotype and osteoblasts differentiation were analyzed. Their capacity of proliferation and hematopoietic supporting *in vitro* were measured. A real-time quantitative reverse transcriptase polymerase chain reaction method (RQ-RT-PCR) was estiblished for detecting the expression levels of relative cytokines and chemokines in MSC. MSCs from healthy donors were obtained as controls. *Results.* Culture-expanded cells from MDS patients present a typical fibroblast-like morphology. Cells were positive for SH2 (CD105), SH3(CD73), Thy-1(CD90), while negative for CD34 and CD45. After induction, these cells could differentiate into osteoblasts. The proliferative ablity of MSCs in MDS patients are not different from those of MSC isolated from normal bone marrow (P>0.05), however, their capacity of hematopoietic supporting *in vitro* were significantly weaker (P<0.05). SDF-1 gene expression levels in MSCs of low-risk MDS patients were significantly higher than that in MSC derived from healthy donors by RQ-RT-PCR (P<0.01), which were further confirmed by ELISA assays in protein level. *Conclusions.* It is inferred that the abnormal function of MSC may influence the regulation of hemotopoiesis in the bone marrow microenvironment of MDS patients. It is worthy of further investigation of new clue of etiological mechanism and therapeutic stratigies of MDS.

VALPROIC ACID AND AZACITIDINE COMBINATORIAL EFFECT ON PHOSPHOINOSITIDE-PHOSPHOLIPASE C (PI-PLC) BETA1 AND CYCLIN D3 IN HIGH RISK MYELODYSPLASTIC SYNDROMES

M Follo,[1] C Finelli,[1] S Mongiorgi,[1] C Clissa,[1] C Bosi,[2] F Chiarini,[1] S Paolini,[1] A Curti,[1] M Baccarani,[1] A Martelli,[1] R Fiume,[1] I Faenza,[1] G Martinelli,[1] L Cocco[1]

[1]University of Bologna, Bologna, Italy; [2]Ospedale Civile di Piacenza, Piacenza, Italy

Background. Myelodysplastic syndromes (MDS) are clonal haematopoietic stem cell disorders characterized by ineffective haematopoiesis in one or more of the lineages of the bone marrow. The disease can result in a slow decrease in blood cell counts, but it may also have a more aggressive evolution, that is a worsening severe cytopenia or, in about 30% of all the patients, transformation into acute myeloid leukemia (AML). Azacitidine, a DNA methyltransferases inhibitor, has been proven effectiveness in prolonging survival and delaying evolution into AML, alone or in combination with the histone deacetylase inhibitor valproic acid (VPA), which improves the clinical response induced by azacitidine alone. Nuclear inositides are essential co-factors for several nuclear processes, including DNA repair, transcription regulation and RNA dynamics in normal and pathological conditions. Namely, nuclear phosphoinositide-phospholipase C (PI-PLC) beta1 appears to play a fundamental role as a checkpoint in the G1 phase of the cell cycle, mainly targeting cyclin D3. Moreover, PI-PLCbeta1 has been demonstrated to be a marker for monitoring the effect of azacitidine on high risk MDS patients. *Aims.* The clinical observation that VPA enhances the clinical response given by azacitidine in high risk MDS, as well as the fact that at a biological level azacitidine has been demonstrated to induce the expression of lipid signaling molecules, prompted us to further investigate the effect of these combinatorial strategies on nuclear inositide signalling. *Methods.* The effect of azacitidine and VPA on inositide signaling pathways was studied on MDS (IPSS risk: intermediate-2 or high) receiving the combination of azacitidine (75 mg/sqm/die SC for 7 days/28 days) with VPA (600-1.500 mg/die orally). Their results were compared with patients receiving only best supportive care and a pool of healthy subjects. We also analyzed the effect of azacitidine and VPA, alone or in combination, on HL60 cell line, which shows a hyper-methylation of PI-PLCbeta1 and is affected by azacitidine treatment. We performed MTT experiments, cell cycle analyses and quantified the gene and protein expression of PI-PLCbeta1, cyclin D3 and p-Akt before and after the treatment. *Results.* We report that p-Akt, PI-PLCbeta1 and cyclin D3 are affected by azacitidine and VPA, alone or in combination. In particular, the combination of the two treatments not only increases the demethylation effect of azacitidine on PI-PLCbeta1, but also induces the cell cycle progression in the G1 phase. This is demonstrated by an increase in both PI-PLCbeta1 and cyclin D3 expression, as well as MTT and cell cycle analyses. As for p-Akt, it is slightly down-regulated by azacitidine and by the combination of azacitidine with VPA. *Summary/Conclusions.* Our findings indicate that VPA enhances the effect of azacitidine on inositide signalling pathways. *in vitro* experiments on HL60 cells showed that these treatments increase PI-PLCbeta1 and cyclin D3, thus inducing cells towards the G1 phase of the cell cycle. Taken together, our results demonstrate for the first time that, at a molecular level, azacitidine and VPA can modulate key molecules involved in cell cycle progression, thus hinting at a role for these molecules in the MDS pathogenesis.

0909

DECREASE OF TELOMERE LENGTH IN BONE MARROW HEMATOPOIETIC CELLS IS AN ADVERSE PROGNOSTIC FACTOR IN PATIENTS WITH MYELODYSPLASTIC SYNDROME: MEASUREMENT OF TELOMERE LENGTH OF INTERPHASE NUCLEI BY QUANTITATIVE FLUORESCENCE *IN SITU* HYBRIDIZATION METHOD

SM Hwang,[1] JE Choi,[2] SY Kim,[3] CJ See,[3] MY Kim,[3] TY Kim,[4] B Oh,[4] SS Yoon,[5] HK Kim,[3] DS Lee[3]

[1]Seoul National University Hospital, Seoul, South-Korea; [2]Korea University Hospital, Department of Laboratory Medicine, Seoul, South-Korea; [3]Seoul National University Hospital, Department of Laboratory Medicine, Seoul, South-Korea; [4]Cancer Research Institute, Seoul National University College of Medicine, Seoul, South-Korea; [5]Seoul National University Hospital, Department of Internal Medicine, Seoul, South-Korea

Background. Telomere is a region of repetitive DNA at the end of a chromosome, which is essential for cell division and protects a cell's chromosome from abnormalities. We assessed the length of telomeres in myelodysplastic syndromes (MDS), characterized by paradoxical coexistence of hyperplasia of dysplastic hematopoietic cells and enhanced apoptosis of hematopoietic cells, resulting in peripheral cytopenias. *Aims.* The aim of this study was to examine telomere length and to assess the prognostic significance of telomere length of bone marrow interphase nuclei in patients with myelodysplastic syndromes by quantitative fluorescence *in situ* hybridization (FISH). The relative telomere length was presented by telomere to centromere ratio. *Methods.* Quantitative FISH with peptide nucleic acid probe of centromere and telomere was performed on bone marrow nucleated cells of 54 patients with MDS and 4 healthy donors. The relative telomere length presented by telomere to centromere (T/C) ratio was measured with an automated image analyzer. *Results.* Patients with MDS had shorter telomere length than the normal healthy donors (P=0.007). The T/C ratio had a tendency of decrement with age but with no statistical significance. Higher than average relative telomere length group showed poorer survival (P=0.045). Multivariate analysis showed old age, lower relative telomere length, no history of hematopoietic stem cell transplantation, low International Prognostic Scoring System grade and acute myeloid leukemia transformation as independent poor prognostic factors for survival (P=0.012, 0.034, 0.048, 0.013, 0.027, respectively). *Summary.* The relative telomere length presented as T/C intensity ratio of interphase nuclei can be useful as a prognostic factor in myelodysplastic patients. Advantages of interphase measurements include the automated measurement and the possibility of studying nonproliferating cells without the need of cell culture, thus avoiding selection.

Table 1. Multivariate Cox proportional hazard analysis of 54 patients with myelodysplastic syndrome (overall survival)

Variables	P value	Hazard ratio	95% confidence interval
Age	0.012	1.058	1.013-1.106
International Prognostic Scoring System	0.013		
Hematopoietic stem cell transplantation	0.048	0.09	0.008-0.979
Acute myeloid leukemia transformation	0.027	5.073	1.200-21.439
Telomere/centromere ratio *100	0.034	7.655	1.172-49.984

ANALYSIS OF MICRO RNA EXPRESSION DURING ERYTHROID DIFFERENTIATION OF RARS MYELOID STEM CELLS IN COMPARISON WITH NORMAL BONE MARROW STEM CELLS

M Karimi Arzenani,[1] M Corcoran,[2] M Nikpour,[3] A Liu,[3] M Jansson,[3] L Forsblom,[3] D Grander,[2] E Hellström-Lindberg[3]

[1]Karolinska Institutet, Stockholm, Sweden; [2]Dept. Oncology and Pathology, Karolinska Institute, Stockholm, Sweden; [3]Dept. Medicine, Karolinska Institutet, Stockholm, Sweden

Background. The MDS subtype refractory anemia with ring sideroblasts (RARS) is characterized by profound erythroid apoptosis, at least 15% ring sideroblasts of bone marrow erythroblasts, hyperplastic ineffective erythropoesis, mitochondrial ferritin accumulation, and constitutive cytochrome c release from the mitochondrial intermembrane space. BM progenitors are clonal, as shown by HUMARA analysis. The molecular basis for the abnormal iron accumulation, defect mitochondrial function and ineffective heme biosynthesis in RARS remains unknown. Recently there have been several publications regarding regulation of erythroid differentitation by miRNA expression. In this study we investigated the expression pattern of specific miRNAs in erythroid differentiation cultures from RARS and normal CD34$^+$ cells. *Aims.* The aim was to identify specific miRNAs, which expression patterns are significantly different during RARS and normal erythroid differentiation in order to shed light over the vast differences in gene expression in these two cell populations. *Methods.* Bone Marrow aspiration samples collected from RARS-MDS patients and healthy controls according to national ethical requirements were subject to CD34$^+$ cell isolation by Immuno-separation. Cells were cultured over 14 days to differentiate to mature GPA$^+$ erythroblasts. Samples were collected at 0, 4, 7, 11 and 14 days. Total RNA was extracted and expression of miRNAs was analysed using commercial miRNA assays. *Results.* Based on previously published papers on erythroid differentiation, 9 miRNA was selected (miR-15a, miR-15b, miR24, miR-144, miR-150, miR-155, miR-221, miR-222 and miR-451). Significant differences in miRNA expression between RARS and normal bone marrow was observed for miR24, miR-155 and miR-221. In spite of morphological maturation, several miRNAs were overexpressed in RARS at day 14 indicating a defect in differentiation (miR-24 3 fold, miR-155 4 fold and miR-221 4 fold).*Summary/Conclusion.* We report pronounced differences in miR-24, miR-155 and miR-221 expression during erythroid differentiation of RARS compared to normal progenitors. Functional studies will be performed to validate the role of each of these miRNAs in the acquisition of the RARS phenotype.

SURVIVAL OF PATIENTS WITH MYELODYSPLASTIC SYNDROMES DIAGNOSED IN THE AREA OF SOUTH WESTERN GREECE DURING THE PERIOD 1990-2009

C Avgerinou,[1] Y Alamanos,[1] I Tavernarakis,[1] P Zikos,[2] A Aktypi,[3] A Kouraklis,[1] M Karakantza,[1] N Zoumbos,[1] A Symeonidis[1]

[1]University of Patras, Medical School, Patras, Greece; [2]St Andrew General Hospital of Patras, Patras, Greece; [3]Olympion Hospital of Patras, Patras, Greece

Background. Myelodysplastic syndromes (MDS) are acquired hematopoietic stem cell disorders, characterized by ineffective hematopoiesis, peripheral blood cytopenias, and an increased risk of leukemic transformation. Overall survival of patients with MDS has been associated with the percentage of marrow blasts, number of cytopenias, cytogenetics, and transfusion rate. The precise impact of comorbidities on survival has not yet been fully elucidated. *Aim.* To examine the impact of disease characteristics and comorbid conditions on the overall survival of patients with MDS in the region of South Western Greece. *Methods.* Data from medical files and electronic databases of all hospitals, diagnosing and treating patients with MDS were retrieved. All patients diagnosed with an MDS in the area of South Western Greece between January 1st, 1990 and December 31st, 2009 were retrospectively analyzed. Mean and median overall survival of patients were estimated according to clinical data such as gender, age at diagnosis, residence in a rural or urban area, MDS subtype according to FAB and WHO classification, karyotype and IPSS score. In addition, the effect of comorbid conditions on survival was also estimated. The analysis was performed by SPSS version 17.0 using Kaplan Meier estimates, and Cox regression model. *Results.* Totally, 771 patients with an MDS have been diagnosed during the above-mentioned period. According to FAB classification 279 patients had RA, 78 RARS, 241 RAEB, 32 RAEB-t, 119 CMML and 22 were unclassified. The mean overall survival for the whole patient population was 38.3 months [CI 95% 34.1-42.5] and the overall median survival time was 21.1 months [CI 95% 18.5-23.7]. Median survival was 37.9 months for RA [CI 95% 29.6-46.2], 34.2 [CI 95% 23.0-45.4] for RARS, 13.3 [CI 95% 11.7-14.9] for RAEB, 11.0 [CI 95% 6.4-15.6] for RAEB-t, and 21.1 [CI 95% 14.8-27.4] for CMML. Analyses with unadjusted Cox proportional hazard models showed that older age at diagnosis had a significant negative impact on survival (P<0.0001, HR=1.83, 95% CI=1.56-2.15), whereas gender and residence in a rural or urban area did not have any impact (P=0.985 and P=0.113 respectively). FAB and WHO subtypes with increased marrow blasts (P<0.0001), Int-2 or High IPSS score (P<0.0001) and poor karyotype according to IPSS (P=0.023) were also associated with shorter survival. Comorbid conditions were consequently taken into consideration in a multivariate Cox regression model, where diseases, such as congestive heart failure (P=0.033, HR=1.43, 95% CI=1.03-1.99) and peptic ulcer (P=0.035, HR=0.77, 95% CI=0.60-0.98) appeared to have an impact on survival, whereas other conditions, such as coronary heart disease, diabetes mellitus and COPD were not shown to have a significant impact on survival. *Conclusive remarks.* The impact of various comorbid conditions on the survival of patients with MDS needs to be further investigated. Specific comorbidity scores taking into consideration the real impact of various diseases on the course of MDS should be created and verified.

0912

TELOMERE SHORTENING AND AML PROGRESSION IN PATIENTS WITH MYELODYSPLASTIC SYNDROME AND DELETION 5Q TREATED WITH LENALIDOMIDE

G Göhring,[1] K Lange,[1] W Hofmann,[1] G Buesche,[1] H Kreipe,[1] E Hellström-Lindberg,[2] A Giagounidis,[3] B Schlegelberger[1]

[1]Hannover Medical School, Hannover, Germany; [2]Karolinska Institutet, Stockholm, Sweden; [3]St. Johannes Hospital, Duisburg, Germany

Background. Lenalidomide has been shown to induce transfusion independence and cytogenetic response in a high proportion of patients with MDS and isolated 5q deletion (del5q). However, some of these patients progress into acute myeloid leukemia, particularly those without a cytogenetic response, and those who develop complex karyotypes. Yet the mechanisms inducing the leukemic transformation still have to be elucidated. Since dysfunctional telomeres play an important role in the development of genetic instability and since shorter telomeres are associated with advanced MDS and AML, we reasoned whether telomere shortening may contribute to leukemic progression in patients with MDS and del5q. *Aims.* To determine whether telomere length is associated with the risk of leukemic transformation in patients with MDS and del5q treated with lenalidomide. *Methods.* This study included 14 patients with transfusion-dependent anemia and low- or intermediate-1-risk MDS enrolled in the studies MDS-003 (n=42) or MDS-004 (n=260) who were treated with lenalidomide according to the study protocols. Written informed consent was provided according to the Declaration of Helsinki. 7 patients progressed into RAEB-1 or AML while on study and 7 patients did not. Time span between diagnosis and study entry was similar in both groups. Combined fluorescence R-banding and T/C-FISH analysis to determine the telomere length of each individual chromosome was performed as described earlier (Lange *et al.* 2009). *Results.* Telomere length at study entry was 5.9 kb (range 4.8 to 7.9 kb) in patients with MDS and del5q who later underwent leukemic transformation. Patients without later disease progression had a median telomere length of 9.3 kb (range 8.4 to 10.2kb). Thus, patients, who progressed after a median of 25 months (range 5 to 51 months) had significantly (P<0.05) shorter telomeres than patients who had a cytogenetic response or stable disease. Notably, during treatment with lenalidomide, telomeres had a median increase in length of 2.9kb (range: 0.5 to 3.4kb) in the group of patients who underwent leukemic transformation. Three of the patients acquired additional chromosome aberrations and developed complex karyotypes. They had a median telomere length of 6.4kb (range: 4.8 to 7.9kb), which was not significantly different from the median telomere length of 5.8 kb (range: 4.8 to 7.5kb) in the group of patients who showed an isolated del5q during the leukemic transformation. *Summary.* Telomere shortening seems to predispose to leukemic transformation in patients with MDS and del5q. These data need confirmation in larger patient cohorts, before telomere length measurement can be used for risk assessment prior to starting lenalidomide treatment.

Lange K, Holm L, Vang Nielsen K, Hahn A, Hofmann W, Kreipe H, Schlegelberger B, Göhring G. Telomere shortening and chromosomal instability in myelodysplastic syndromes. Genes Chromosomes Cancer. 2010;49:260-269.

LOW FREQUENCY OF ASXL1 MUTATIONS IN A SERIES OF 42 PATIENTS WITH REFRACTORY ANEMIA WITH RING SIDEROBLASTS

M Ibañez, J Cervera, E Such, A Valencia, S Oltra, I Gomez, I Luna, B Costan, M Sanz, G Sanz

Hospital Universitario La Fe, Valencia, Spain

Background. The identification of genes which are frequently mutated in myelodysplastic syndromes (MDS) is critical to a full understanding of the molecular pathogenesis of these disorders. Recently, mutations of the *ASXL1* (additional sex combs 1) gene have been reported in 11% of MDS patients, 43% of chronic myelomonocytic leukemia patients and 25% of acute myeloblastic leukemias. However, preliminary available data suggest that *ASXL1* mutations seem to be a rare event in early (i.e. low-blast) subtypes of MDS. *ASXL1* belongs to a family of three identified members that encode poorly characterized proteins regulating chromatin remodelling. The *ASXL1* gene is located in the chromosomal region 20q11, a region commonly affected in malignancies of the myeloid lineage. Several studies suggest that *ASXL1* may function as a tumor suppressor gene in myeloid malignancies by affecting stem or progenitor cell self-renewal or differentiation. Reported mutations, located in exon 12 of the gene, are mostly frameshift mutations caused by deletion or duplication of a nucleotide and are predicted to lead to the truncation of the C-terminus of the protein, which contains a PHD finger. This could prevent it from binding methylated histone lysines and interacting with chromatin modifiers, thus enhancing self-renewal in hematopoietic progenitors. *Aim.* To screen *ASXL1* mutations in a series of patients with refractory anemia with ring sideroblasts (RARS) in order to determine their frequency and any potential association with disease outcome. *Patients and Methods.* Bone marrow samples obtained at diagnosis from 42 *de novo* RARS (FAB criteria) were studied [27M/15F; median age: 71 yr. (range: 44-87); median Hb level, 9.9 g/dL (5.9-16.9); median platelet count, 271×10^9/L (67-852) and median absolute PMN count, 3.5×10^9/L (5.9-16.9); median marrow blasts, 1% (0 - 4); and ring sideroblasts, 37% (15-78)]. According to IPSS, 40 patients belonged to the low-risk category whereas the rest two patients were intermediate-1. According to WHO 2008 criteria, patients were classified as RARS (n=23), RCMD (n=18) and '5q syndrome' (n=1). Genomic DNA was amplified using specific primers for ASXL1. Direct sequencing was performed on an ABIPRISM 310 DNA Analyzer (Applied Biosystems, Foster City, CA). Sequence analysis was checked by GeneBank Accession NT_011362. *Results.* Among the 42 patients, only a single heterozygous missense mutation c.3147C>T p.Val908Ala of ASXL1 was found (2.3%). In addition, we found three previously reported polymorphisms and five different non-reported synonymous single base changes that could be theoretically polymorphisms. *Conclusions.* Our results confirm that *ASXL1* mutations are an uncommon event in RARS.

This study was supported in part by research funding from "Ministerio de Ciencia e Innovación" grant BES2008-008053 and from the "Instituto de Salud Carlos III" grants R06/0020/0031, RD07/0020/2004 and CA08/00141.

TELOMERE MAINTENANCE IN MYELOID MALIGNANCIES

A Poloni, F Serrani, E Berardinelli, G Maurizi, B Costantini, S Trappolini, S Mancini, P Leoni

Clinica di Ematologia, Ancona, Italy

Background. Telomeres are regions of highly repetitive GC-rich DNA sequence at the end of eukaryotic chromosomes that act to protect loss of genetic information due to incomplete DNA replication at the ends of chromosomes in late S phase. Telomeres are progressively shortened with cell divisions and trigger cellular senescence in somatic cells. Most stem cells and cancer cells are able to proliferate indefinitely, because of a telomere maintenance mechanism as activation of telomerase, a ribonucleoprotein that synthesizes telomeric DNA sequences and almost universally provides the molecular basis for unlimited proliferative potential. Loss of telomerase function produces short telomeres, potentially resulting in chromosome recombination, end-to-end fusion and recognition as damaged DNA. Regulation of hTERT expression depends on different transcription factors that bind hTERT promoter and positively or negatively control hTERT expression. In particular the c-Myc and Mad1 network can regulate hTERT expression through the binding to E-box binding sites. *Aims.* In this study we evaluated telomerase enzymatic activity (AT), telomeres length and hTERT expression, in mononuclear cells (MNC) from bone marrow at diagnosis of 60 patients with AML *de novo* and secondary to Myelodysplastic Syndrome (AML) and High Risk Myelodysplastic Syndrome (HR-MDS), (n=23) and Low Risk Myelodysplastic Syndrome (LR-MDS, n=37). We also evaluate the expression of c-myc, mad-1 and Wilms' tumor 1 gene (WT1), transcription factors acting over hTERT promoter. These results are compared with the control (normal bone marrow, n=10) to increase our knowledge upon telomere maintenance mechanism and correlation to the clinical features in MDS and AML patients. *Methods.* The telomerase activity (AT) was quantified using a real-time PCR-based telomeric repeats amplification protocol. All gene expressions were determined by real-time PCR. Telomere length was analyzed by Telomere Restriction Fragments (TRFs) length method. *Results.* Compared with the controls, telomerase activity (AT) was increased 2- to 6- fold in 8% of low risk MDS patients and 2- to 6-fold in 13% of HR-MDS and AML patients. HTERT expression is higher than in controls in 40% of LR-MDS and in 50% of HR-MDS and AML patients. Levels are not homogeneous among groups. WT1 levels were not increased in LR-MDS patients, in 70% of HR-MDS and AML patients were significantly higher than in control bone marrow. Mad expression was significantly higher in AML and in all MDS samples than in controls. Preliminary results suggest no significantly differences in controls and patients for c-myc expression. Despite of the increased AT and hTERT expression, both in MDS and AML patients TRFs length was lower than in controls. *Summary.* Our data suggests that in MDS and AML patients AT and hTERT expression is higher than those found in normal donors. In particular AML and HR-MDS patients showed hTERT and AT generally higher than LR-MDS patients. On the other hand, telomere length was similar in patients with MDS and AML. WT1 levels of AML and HR-MDS patients were higher than LR-MDS and control values and mad expression was higher in AML and in MDS.

0915

FLOW CYTOMETRY PREDICTS TREATMENT OUTCOME IN INTERMEDIATE-2 AND HIGH RISK MYELODYSPLASTIC SYNDROME PATIENTS TREATED WITH 5-AZACITIDINE

C Alhan, T Westers, C Cali, C Eeltink, G Ossenkoppele, A van de Loosdrecht

VU University Medical Center, Amsterdam, Netherlands

New treatment strategies that potentially change the natural course of intermediate (int)-2 and high risk myelodysplastic syndromes (MDS), such as 5-azacitidine, are emerging. Recently, we reported that flow cytometric analysis of bone marrow in low and int-1 risk MDS is instrumental to identify clinically relevant subgroups. (Westers *et al.*, Blood 2010) Moreover, it was reported that a flow cytometric scoring system, based on aberrancies in the (im)mature myelo-monocytic lineage is predictive for worse outcome in MDS. (Wells *et al.*, Blood 2003, van de Loosdrecht *et al.*, Blood 2008). The current study aimed to investigate the role of this flow cytometry-based scoring system to assess and monitor response to treatment in int-2 and high risk MDS patients treated with 5-azacitidine. Bone marrow aspirates were analysed by flow cytometry in 13 MDS patients who were treated with 5-azacitidine. Aspirates were drawn before treatment and after every three cycles of 5-azacitidine. Response to treatment was evaluated using IWG-2006 criteria. (Cheson *et al.*, Blood 2006). The median age was 67 (range 62-78). Distribution over WHO 2001 categories was RCMD-RS n=1, RAEB-2 n=5, AML with 20-30% blasts n=5 and MDS/MPD n=2. International prognostic scoring system (IPSS) categories comprised int-2 n=5 and high n=4. In 4 patients the IPSS score could not be assessed. Follow up was present in 7 patients, including 4 responders, 1 progressive disease (PD) patient and 2 stable disease (SD) patients; 2 patients stopped due to toxicity, 1 patient died of PD. Median follow up was 6 months (range 3-9). Median pretreatment Hb was 6.4 mmol/L, platelets 36×10^9/L and absolute neutrophil count (ANC) 1.0×10^9/L. Responders had a significant increase in Hb (median 7.8 mmol/L, P=0.01), platelets (291.5×10^9/L, P=0.04) and ANC (1.4×10^9/L, P=n.s.). Non responders (PD and SD) had a median Hb of 6.4 mmol/L, platelets 69×10^9/L and ANC 0.6×10^9/L. The median pretreatment flow score was 6 (range 3-8). Interestingly, responders had a significant decrease in flow score from median 5 to median 2 (range 1-3, P=0.006) after 3 months of treatment. No change in flow scores was seen in PD and SD patients after 3 months of treatment (median=6, range 4-7). A sustained decrease in flow score was seen in 3 responders after 6 months of treatment (median 2, range 1-3) parallel to a further

increase in median Hb (8.8 mmol/L), platelets (176×10⁹/L) and ANC (1.7×10⁹/L). Moreover, loss of aberrant marker expression on myeloid progenitors was only detected in patients who responded to 5-azacitidine treatment. In conclusion, our data indicate that flow cytometry identifies high risk MDS patients who may benefit from 5-azacitidine treatment. Whether or not flow cytometry may be instrumental in selection of SD patients who may benefit from prolonged treatment with 5-azacitidine is under investigation.

0916

EFFECT OF ALTERNATIVE DOSING SCHEDULES OF AZACITIDINE ON PHOSPHOINOSITIDE-PHOSPHOLIPASE C (PI-PLC) BETA1 IN HIGH RISK MDS PATIENTS

M Follo,[1] C Finelli,[1] S Mongiorgi,[1] C Clissa,[1] C Bosi,[2] S Paolini,[1] A Curti,[1] G Ramazzotti,[1] M Baccarani,[1] G Martinelli,[1] L Cocco[1]

[1]University of Bologna, Bologna, Italy; [2]Ospedale Civile di Piacenza, Piacenza, Italy

Background. Nuclear inositides are key cellular second messengers with well established roles in signal transduction pathways, being involved in cell proliferation and differentiation. In particular, the nuclear metabolism elicited by phosphoinositide-phospholipase C (PI-PLC) beta1 plays an important role in the control of the balance between cell cycle progression and apoptosis. Recent findings indicate that the lipid signalling pathways can become therapeutic targets in myelodysplastic syndromes (MDS), which are a heterogeneous group of hematological malignancies characterized by an increased although variable risk of evolution in acute myeloid leukemia (AML). Our group previously demonstrated that PI-PLCbeta1 is a target for azacitidine, an inhibitor of DNA methyltransferases which has been proven to be effective in prolonging survival and delaying evolution into AML, and that the reduction of PI-PLCbeta1 methylation could predict the clinical response to azacitidine. *Aims.* The currently approved azacitidine regimen is 75 mg/sqm/die, administered subcutaneously (SC) or intravenously (IV) for 7 days every 28 days. Recently, alternative azacitidine dosing regimens, which avoid week-end dosing, have shown to induce therapeutic responses consistent with the currently approved schedule. This clinical observation prompted us to further investigate the effect of alternative dosing schedules of azacitidine on nuclear lipid signalling, in order to clarify the molecular mechanisms leading to the response to demethylating therapies. *Methods.* From September 2004, 20 MDS patients, with a IPSS risk intermediate-2 or high and a median age of 70 (50-84) years, were treated with azacitidine (AZA), following 3 different treatment regimens. Group 1 (8 patients) received the currently approved regimen (AZA 75 mg/sqm/die SC for 7 days/28 days). Group 2 (6 pts.) received the combination of AZA (75 mg/sqm/die SC for 7 days/28 days) with VPA (600-1.500 mg/die orally) and ATRA (30 mg/sqm/die, orally, from cycle n. 5, in case of non-response). Group 3 (6 pts.) received the alternative 5-2-5 AZA regimen: AZA 50 mg/sqm/die SC for 5 days, followed by 2 days without treatment, then 50 mg/sqm/die for 5 days. We quantified the degree of PI-PLCbeta1 methylation and gene expression before and during azacitidine administration. *Results.* Here we show that the amount of PI-PLCbeta1 is linked to azacitidine responsiveness in MDS patients. Following azacitidine treatment, and in correlation with the therapeutic response, but not with the dose schedule, PI-PLCbeta1 expression increased, whereas PI-PLCbeta1 promoter methylation was reduced in responder patients. Moreover, independently from the dose schedule, we observed that the decrease of PI-PLCbeta1 promoter gene methylation may anticipate the hematologic response, given that the variations in PI-PLCbeta1 gene expression may occur some cycles prior to the hematologic improvement. *Summary/Conclusions.* PI-PLCbeta1, which has been demonstrated to be hyper-methylated in MDS patients and is therefore useful for monitoring the effect of demethylating therapies, can be used for assessing azacitidine responsiveness in high risk MDS independently from the dose schedule.

0917

FLUORESCENT *IN SITU* HYBRIDIZATION (FISH) TECHNIQUE IS A GOOD TOOL FOR IMPROVING DIAGNOSIS OF PRIMARY MYELODYPLASTIC SYNDROMES (MDS)

L Luciano, V Cacciapuoti, R Della Pepa, G Cerciello, F Alfinito, F Pane

University Federico II, Naples, Italy

Myelodysplastic syndromes are a heterogeneous group of clonal haematological diseases characterized by bone marrow failure with abnormal differentiation of myeloid cells, peripheral cytopenias, dysplastic features in one or more myeloid lineages and enhanced risk of transforming in acute myeloblastic leukaemia (AML). Several efforts have been performed to classify these syndromes evaluating the risk of leukemic transformation (WHO classification, IPSS score). For such evaluation, cytogenetic abnormalities are the most relevant parameter to consider in combination with cytopenias , dysplasia and numbers of bone marrow blast cells. Furthermore, the recent introduction of targeted-based drugs for treating subgroups of MDS, led to an updated of response criteria, including the complete cytogenetic response as for patients treated with Lenalidomide in the 5 q- syndrome. The aim of this work was to evaluate the contribute of fluorescent *in situ* hybridization (FISH) to improve the cytogenetic analysis of MDS to better characterization of the patients. We studied 121 patients suspected to be affected by primary MDS. The conventional cytogenetic analysis was performed on bone marrow samples. 90 patients (74%) showed an informative karyotype (at least 20 metaphases); 25 out of 90 (28%) had a normal karyotype, while 65 (72%) showed chromosomal abnormalities. The 31 cases with none or insufficient number of metaphases, were studied with FISH analysis, using the following probes: 1) LSI CSF1R/D5S23, D5S721 Dual Color Probe for 5q31-35 region, 2) LSI D7S486/CEP 7 Dual Color Probe for chromosome 7 and 3) probe specific for the alpha satellite (centromeric) region, 8p11.1-q11.1. of chromosome 8 (VYSIS). 9/31 cases had an abnormal karyotype (del 5q: 4 cases; +8: 2 cases; - 7: 1 case; del 5q and + 8: 2 cases). FISH technique was consistent with the results of conventional cytogenetic analysis in both positive and negative control. Using conventional cytogenetics and/or FISH analysis, 100% of patients had cytogenetic informations with 61% (74 pts) exhibiting an abnormal karyotype. According to WHO classification (2001), our patients were stratified as: 42 AR, 5 ARS, 42 RCMD, 18 5q- syndromes, 11 AREB and 3 LAM. Using IPSS score the patients resulted in: 37% LOW, 50% Int 1, 6% Int 2 and 7% HIGH risk class. All the eighteen patients affected by 5q- syndrome were treated with Lenalidomide with fairly good results. FISH analysis combined to conventional cytogenetic is able to better classified MDS especially for differential diagnosis between low risk group *vs.* idiopathic cytopenias of uncertain significance (ICUS). Moreover, the identification of defined cytogenetic sub groups (e.g. 5q-) is extremely relevant for using target-based drugs. Finally the identification of cytogenetic marker is the best tool for monitoring response to therapy and/or clone evolution/transformation.

0918

BONE MARROW CELLS FROM MYELODYSPLASTIC SYNDROMES SHOW ALTERED IMMUNOPHENOTYPIC PROFILES WHICH MAY CONTRIBUTE TO THE DIAGNOSIS AND PROGNOSTIC STRATIFICATION OF THE DISEASE: A PILOT STUDY

S Matarraz,[1] A Lopez,[1] S Barrena,[1] C Fernandez,[1] E Jensen,[1] J Flores,[1] A Rasillo,[1] JM Sayagues,[1] ML Sanchez,[1] P Bárcena,[1] JM Hernandez-Rivas,[2] C Salvador,[3] N Fernandez-Mosteirín,[3] M Giralt,[3] L Perdiguer,[4] P Laranjeira,[5] A Paiva,[5] A Orfao[1]

Hospital de Alcañiz, Teruel, Spain; [5]Servicio de Citometría. Centro de Histicompatibilidade do Centro-Coimbra, Coimbra, Portugal

Background. A heterogeneous spectrum of immunophenotypic abnormalities have been reported in myelodysplastic syndromes (MDS). However, most studies are restricted to the analysis of $CD34^+$ cells and/or other major subsets of $CD34^-$ cells frequently not exploring the diagnostic and prognostic impact of immunophenotyping. *Methods.* We propose for the first time an immunophenotypic score (IS) based on the altered distribution and immunophenotypic features of maturing/mature compartments of bone marrow (BM) hematopoietic cells in 56 MDS patients that could contribute to a refined diagnosis and prognostic evaluation of the disease. *Results.* Although MDS-associated phenotypes were detected in reactive BM, the overall immunophenotypic profile of BM cells allowed an efficient discrimination between MDS and both normal and reactive BM, once the number and degree of severity of the abnormalities detected per patient were simultaneously considered in the proposed IS. Interestingly, increasingly higher IS were found among MDS patients showing adverse prognostic factors as well as in low- *vs.* high-grade cases. The most informative prognostic factors included: the number of $CD34^+$ cells, presence of aberrant $CD34^-/CD117^+$ precur-

sors, decreased mature neutrophils and CD34$^-$ erythroid precursors, and increased numbers of CD36$^-$/lo erythroid precursors; additionally, the IS was an independent prognostic factor for overall survival. *Summary/Conclusions.* Assessment of immunophenotypic abnormalities of maturing/mature BM cells allows an efficient discrimination between MDS and both normal and reactive BM, once the number and degree of severity of the abnormalities detected are simultaneously scored. Interestingly, progressively higher IS were found among MDS patients with adverse prognostic features and shorter overall survival.

Background. Immunological responses are important in the initiation and progression of myelodysplastic syndromes (MDS). It has been suggested that T cells be involved in the pathogenesis of MDS. Cytokine levels, such as IL-7 and IFN-gamma, are associated with low-risk disease. Patients with MDS with del(5q) are generally at low risk with severe anemia requiring transfusions. Treatment with lenalidomide has proven efficacy in MDS patients with del(5q) inducing erythroid responses and suppression of the del(5q) clone; its anti-angiogenic, antiproliferative, and pro-erythropoietic mechanisms remain unclear. It has been shown that lenalidomide inhibits the proliferation and function of T regulatory cells (Tregs). *Aims.* In a multicenter Italian phase II trial to evaluate safety and efficacy of lenalidomide in primary MDS patients with del(5q) and low or Int-1 risk IPSS, we investigated changes in the transcription of cytokines and their receptors during treatment. *Methods.* The starting dose of lenalidomide was 10 mg p.o once daily on a continuous daily schedule for a maximum of 12 months. Bone marrow aspirates were obtained on study entry and every 12 weeks. Assays were performed using TaqMan® Low Density Array Fluidic card (TaqMan® Human Array, Applied Biosystems, Foster City, CA, USA) based on Applied Biosystems PRISM® 7900HT comparative ddCT method, according to the manufacturer's instructions. Target gene expression levels were measured in triplicate and normalized against the expression of the 18S housekeeping gene from a bone marrow pool of normal, healthy subjects at all timepoints. Median relative gene expression values in MDS patients were compared to healthy subjects, set as a value of 1. *Results.* Informed consent was obtained in all patients. Twenty-one patients were evaluated at baseline and after 12 weeks. Mean age was 73±8 years. Mean Hb was 8.7±0.9 g/dL and 17 patients were transfusion-dependent. Five patients had additional cytogenetic abnormalities. Eighteen patients experienced erythroid responses. Significant variations in gene expression of cytokines and receptors were observed during treatment. Genes significantly regulated during lenalidomide treatment ($P<0.05$) are shown in the Table. FAS and IL-7 gene expression were prevalently under-expressed and significantly increased after 12 weeks. Accordingly, IL7R was over-expressed in all patients at baseline and its expression was significantly reduced during treatment. Furthermore, IFN-gamma expression increased during therapy. Summary. The protein encoded by FAS gene is a member of the TNF-receptor superfamily and its interaction with its ligand leads to apoptosis. Interleukin (IL)-7 is an essential cytokine that promotes the proliferation and survival of B- and T-lymphocyte progenitors. The IL7R gene on chromosome 5 (5p13) codifies for the IL7 receptor, which blocks apoptosis during differentiation and activation of T lymphocytes. It functions, in part, through the induction of the expression of the antiapoptotic protein Bcl-2 . The results of the present study indicate that lenalidomide may act through immunological changes. Further detailed analyses in these patients may provide new insights into the pathogenesis of MDS with del(5q), and the long-term effects of lenalidomide treatment on immunological changes in bone marrow cells.

Table 1. Changes in cytokine expression during treatment.

Gene	Baseline median	IQ range	After 3 mos, median	IQ range	*P*-value
FAS	0.03	0.01 – 0.38	4.94	0.66–1382.50	<0.0001
IL-7R	2719.00	1907–4987	0.22	0.03–6.20	0.003
IL-7	0.16	0.05–0.49	12.37	0.16–25.07	0.012
IFN-γ	0.69	0.23 -10.38	45,23	21.41 – 35134.14	0.001

INCREASED GLOBAL DNA METHYLATION AND REDUCED HISTONE H3 (LYSINE 9) ACETYLATION IN PATIENTS WITH MYELODYSPLASTIC SYNDROME

A Poloni,[1] G Goteri,[2] A Zizzi,[2] B Costantini,[1] S Trappolini,[1] M Mariani,[1] A Tassetti,[3] F Alesiani,[4] R Ranaldi,[2] P Leoni[1]

[1]Clinica di Ematologia, Ancona, Italy; [2]Anatomia Patologica, Ancona, Italy; [3]Divisione di Medicina, Civitanova Marche, Italy; [4]Divisione di Oncologia, Camerino, Italy

Background. Epigenetic aberrations are now well recognized as very frequent and also as early events in the process of malignant transformation. These molecular mechanisms regulate gene expression without changing the DNA sequence and include alterations in the methylation status of DNA, covalent modification of histone tails, chromatin remodeling, and microRNAs. Somewhat contradictory, in patients with myelodysplastic syndrome (MDS), the induction of hypomethylation using DNA methyltransferase inhibitors leads to very promising clinical response rates and haematological improvement. *Aims.* We investigated global DNA methylation and histone H3 lysine 9 acetylation by immunohistochemistry in bone marrow trephine biopsy specimens in a cohort of 110 MDS patients comprising all subgroups. Results were compared to an age-matched control group of healthy subjects and to a group of AML patients. *Methods.* Immunohistochemistry was performed on paraffin-embedded sections, using anti-5-methylcytosine/5mc and anti-Acetyl-Histone H3 (Lys9)/AcH3K9 antibodies. Scoring of immunohistochemistry was evaluated with a four-point scale for both the number of positive tumor cells and their intensity of immunoreactivity. *Results.* Our results showed that in MDS the 5mc immunostaining score was intermediate between normal controls and AML cases, whereas the AcH3K9 immunostaining score was lower than normal control. The 5mc score correlated significantly with the risk score according to the International Prognostic Scoring System, the blast count and the karyotype. Our results suggest that global hypermethylation and histone hypoacetylation correlate with MDS aggressiveness. *Summary.* These results may provide a molecular explanation for the success in treating MDS patients with hypomethylation-inducing agents and why patients with a poor karyotype respond best. Future studies have to analyse whether the determination of global methylation and histone acetylation levels may serve as a new predictive marker for therapy response.

HIGH SERUM SCLEROSTIN CORRELATES WITH ADVANCED MULTIPLE MYELOMA AND EXTENDED LYTIC BONE DISEASE; REDUCTION POST BORTEZOMIB MONOTHERAPY

E Terpos,[1] D Christoulas,[1] E Katodritou,[2] C Bratengeier,[3] A Parharidou,[2] E Michalis,[2] M Migkou,[1] M Gavriatopoulou,[1] M Gkotzamanidou,[1] M Iakovaki,[1] K Anargyrou,[2] E Kastritis,[1] G Hawa,[2] K Zervas,[2] M Dimopoulos[1]

[1]University of Athens School of Medicine, Athens, Greece; [2]Greek Myeloma Study Group, Athens, Greece; [3]Biomarker Design Forschungs GmbH, Vienna, Austria

Background. Osteoblast dysfunction characterizes bone metabolism in multiple myeloma (MM). To-date dickkopf-1 (Dkk-1) is considered as the main osteoblast inhibitor which is overproduced by myeloma cells and inhibits Wnt signaling. Sclerostin is another canonical Wnt antagonist through its binding to LRP 5/6. *Aim.* To evaluate the serum levels of sclerostin in MM patients and explore possible correlations with clinical and laboratory data. *Patients/Methods.* We studied 157 patients (87M/70F, median age 68 years) with MM at diagnosis before the administration of any type of therapy, including bisphosphonates and 25 patients (14M/11F, median age 68 years) with relapsed disease who were treated with bortezomib monotherapy (with the addition of dexamethasone if <PR was achieved after 4 cycles). Serum sclerostin and osteonectin (SPARC) were measured using an ELISA methodology developed by BDF for Biomedica Medizinprodukte (Vienna, Austria). Bone remodeling was studied by the measurement of a series of serum indices within one week from diagnosis in newly-diagnosed patients and on day 1 of cycle 1 and on day 21 of cycles 4 and 8 of bortezomib therapy in relapsed patients: i) osteoclast regulators [sRANKL and osteoprotegerin (OPG)], ii) Dkk-1, iii) bone resorption markers (CTX and TRACP-5b), and iv) bone formation markers [bone-specific alkaline phosphatase (bALP) and osteocalcin]. The above molecules were also determined in 21 MGUS patients and 21 healthy controls, of similar gender and age. *Results.* MM patients at diagnosis had increased levels of serum sclerostin compared with MGUS patients (mean value±SD: 0.48±0.46 *vs.* 0.26±0.29 ng/mL; P=0.004) and healthy controls (0.31±0.20 ng/mL, P=0.01). In contrast, both MM and MGUS patients had reduced levels of serum SPARC (2632±1621 and 2724±1802 ng/mL, respectively) compared to controls (5281±5020 ng/mL; P<0.001). Sclerostin values strongly correlated with beta2-microglobulin (r=0.354, P<0.0001), cystatin-C (r=0.389, P<0.0001), creatinine (r=0.380, P<0.0001), bALP (r=-0.541, P<0.0001) and Dkk-1 (r=0.328, P<0.001). Patients (both newly-diagnosed and relapsed) with advanced bone disease (>3 lytic lesions and/or a pathological fracture) had increased sclerostin values compared to all others (median: 0.58 *vs.* 0.41 ng/mL, P=0.03). Patients with ISS-3 disease had increased levels of sclerostin compared to ISS-1 and ISS-2 patients (ANOVA P=0.001). Median survival of MM patients at diagnosis was 48 months and median follow-up period was 20 months. Patients who had a serum sclerostin of ≥0.62 ng/mL (upper quartile, n=40 patients) had a median survival of 27 months, while median survival of all other patients was 98 months (P=0.031). In relapsed patients, sclerostin levels were increased even compared to newly-diagnosed patients (0.62±0.34 ng/mL; P=0.01). Bortezomib produced a dramatic reduction of sclerostin after 4 cycles of therapy (0.32±0.24 ng/mL; P<0.01) in both responders (n=16) and non-responders (n=9). *Summary/Conclusions.* Our study provides evidence that sclerostin is increased in the serum of MM patients and correlates with advanced disease features. Sclerostin seems to participate in the MM biology and thus it may be a possible target for the development of novel therapies that can both increase osteoblast function and target myeloma cells. Reduction of sclerostin post-bortezomib monotherapy may reflect another mechanism for the restoration of osteoblast function by bortezomib in MM.

SERUM FREE LIGHT CHAINS RATIO: AN INDEPENDENT PROGNOSTIC FACTOR FOR OVERALL SURVIVAL AND PROGRESSION FREE SURVIVAL IN MULTIPLE MYELOMA

M Sobh, S Morisset, T Guilli, S Ducastelle-Lepretre, F Barraco, Y Chelghoum, X Thomas, G Cannas, A Praire, H Labussiere, F Nicolini, C Chapuis-Cellier, M Michallet

Edouard Herriot Hospital, Lyon, France

Background. The serum free light chain (sFLC) analysis has been used for the diagnosis and monitoring of plasma cell dyscrasias, also in monoclonal gammopathy of undetermined significance (MGUS) evolving to multiple myeloma (MM). Some studies have evaluated the prognostic value of the sFLC levels expressed as K/L ratio (sFLCR), but this factor has not been introduced yet into the international staging system (ISS) for MM and its associated prognostic factors. *Aim.* We have evaluated in this study, the impact of sFLCR, measured at diagnosis in MM patients, on the progression free survival (PFS) and overall survival (OS). *Methods.* A total of 118 consecutive MM patients diagnosed in our hospital between years 2002 and 2008, and for which we have assessed the sFLCR at diagnosis, were included in this study. There were 73 (62%) males and 45 (38%) females with a median age of 57 years [34-72], 63 IgG (49K & 14L), 35 IgA (18K & 17L), 2IgD (1K & 1L) and 18 light chains (9K &9L). According to the ISS, there were 11 (9%) in stage I, 13 (11%) in stage II and 94 (80%) in stage III. Among 55 (47%) FISH analysis done, 28 (24%) detected a chromosome 13 deletion. Measurements of sFLC were made using the Freelite® test from the Binding site on a BNII®, Dade Behring©. According to the distribution of the different ratios, we have defined three groups: group1 (n=25): patients with 0.13<sFLCR<3.3 which represents the double of the normal range (0.26-1.65); group2 (n=63): patients with sFLCR>3.3 and group3 (n=30): patients with sFLCR<0.13. Kaplan Meier and cox regression analysis were performed to study the PFS and OS in different groups using R statistical software (version 2.9.2) *Results.* After a median follow-up of 38 months [3.3-93.7], the probability of OS at 5 years for groups 1, 2 and 3 was 75% [56-100], 60% [47-76] and 40% [23-69] respectively; and the probability of PFS at 5 years was 69% [49-96], 43% [31-60] and 29% [15-54] respectively (Figure).The multivariate analysis studying age, ISS, sex, cytogenetics and sFLCR, showed that both OS and PFS are worslty affected with a more abnormal sFLCR, Group2 *vs.* Group1: for OS [HR=2.06 (0.7 - 6.06) P=0.19], for PFS [HR=2.63 (1.01 - 6.83) P=0.048]; Group3 *vs.* Group1: for OS [HR=3.14 (0.97 - 10.21) P=0.056], for PFS [HR=3.4 (1.21 - 9.51) P=0.02]. *Conclusion.* Our study has showed that abnormal sFLCR at diagnosis affects OS and more strongly the PFS independently of any other concomitant variable. We suggest that this factor deserves more focus for its validation as a prognostic factor in MM.

STUDY OF CIRCULATING ENDOTHELIAL CELLS IN MULTIPLE MYELOMA: BIOLOGICAL ASPECTS AND EFFECT OF NOVEL AGENTS

I Vande Broek,[1] X Leleu,[2] D Duda,[3] B van Camp,[1] K Vanderkerken,[4] I Van Riet[1]

[1]UZ Brussel, Brussel, Belgium; [2]Service des Maladies du Sang, Hopital Huriez, Lille, France; [3]Department of Radiation Oncology, Steele Laboratory for Tumor Biology, Harvard, Boston, USA; [4]Laboratory of Hematology and Immunology, Free University Brussels, Brussels, Belgium

Background. There is accumulating evidence from preclinical studies that circulating endothelial cells (CEC) and their precursors (CEP) (ie. mobilized EC from the BM in response to angiogenic cytokines) are involved in tumor angiogenesis. Rare in healthy individuals, CEC and CEP are increased in cancer patients (pts). CEC or CEP enumeration has been proposed as surrogate biomarker for (anti-angiogenic) treatment response and is currently being applied in multiple clinical studies. Preclinical studies also suggest a role of CEP in tumor regrowth after therapy. Cytotoxic agents administered at MTD induce a rapid CEP mobilization during therapy-free intervals, with possible paradoxal rebound angiogenesis. This CEP mobilization can be inhibited by anti-angiogenic agents, resulting into sustained EC suppression. In MM, angiogenesis is increased in the BM and the effect of novel agents such as Bortezomib (VEL) and Thalidomide (THAL) is partially mediated by inhibition of BM angiogenesis. *Aims.* In the present study, we evaluated CEC and CEP numbers in MM pts and monitored their kinetics during therapy with Melphalan (MEL)-, THAL- and VEL- based regimens. *Methods.* CEC ($CD31^+CD45^-CD34^+CD133^-$) and CEP ($CD34^+CD133^+CD45$dim cells) were enumerated among blood mononuclear cells by multicolor FACS at baseline and at multiple time points during treatment. Baseline levels and changes during treatment were correlated with response and survival. *Results.* At baseline, MM pts (n=71) show significant higher CEC and CEP levels *vs.* healthy controls (n=10) (7 and 2,5-fold increase, P<0,02). CEC numbers where are higher in pts with active *vs.* inactive disease (1,9 fold increase, P<0,05) and in pts with relapsed/refractory disease (2,1 fold increase, P<0,05), reflecting increased angiogenesis associated with disease progression. Therapy with VEL and THAL resulted in a rapid and sustained decline in CEC/CEP numbers. Therapy with MEL initially decreased CEP levels, followed by a transient, significant increase at the end of each cycle. Interestingly, CEP increase was less pronounced by MEL in combination with VEL or THAL, suggesting that VEL/THAL inhibited MEL-induced CEP mobilization. This finding may reflect an additional mechanism for the anti-angiogenic and chemosensitizing effect of VEL and THAL, resulting into increased anti-tumoral efficacy and clinical benefit as shown in recent randomized trials. *Conclusion.* This study shows that CEC and CEP levels are increased in MM pts and correlate with disease progression. In addition, CEC and CEP enumeration may represent a surrogate biomarker to assess prognosis or therapy response in MM. Future large-scale studies are necessary to determine their prognostic and predictive value.

0924

CC-4047 (POMALIDOMIDE) INHIBITS MULTIPLE MYELOMA-INDUCED OSTEOCLAST FORMATION

N Giuliani,[1] M Bolzoni,[1] M Abeltino,[1] P Storti,[1] V Sgobba,[1] S Bonomini,[1] R Pariyarath,[2] V Rizzoli[1]

[1]Hematology, Parma, Italy; [2]Celgene srl, Milano, Italy

Multiple myeloma (MM) is a plasma cell malignancy characterized by high incidence of osteolytic bone lesions due to an increase of osteoclast formation and activation that occur into the bone marrow (BM). The alteration of the RANKL/OPG ratio in BM stromal cells (BMSC) and osteoprogenitor cells in favor of the critical osteoclastogenic factor RANKL is induced by MM cells through the cell contact and it is mainly involved in MM-induced osteoclast formation. MM cells also up-regulate RANKL expression and secretion by activated T cells that contribute to the high RANKL level observed in the MM BM microenvironment. Soluble factors such as CCL3/MIP-1α, IL-3 and IL-7 produced by MM cells contribute to the increase of osteoclast formation both directly and indirectly trough RANKL stimulation. Recent data suggest that thalidomide and its derivative immunomodulatory drug (IMiD) lenalidomide may inhibit osteoclast formation directly through the block of osteoclast maturation. In this study we have investigate the potential *in vitro* effect of the new more potent IMID CC-4047 (pomalidomide) on MM-induced osteoclast formation. First we confirmed that pomalidomide as lenalidomide reduced osteoclast formation from $CD14^+$ progenitor cells in presence of RANKL and M-CSF. Secondly we found that pomalidomide significantly inhibits RANKL expression and secretion by primary BMSC and osteoprogenitor cells obtained from MM patients but not from activated T lymphocytes at concentration ranging from 2 to 100 μM. In addition pomalidomide blunted RANKL up-regulation in BMSC/osteoprogenitor cells induced by MM cells in a cell-to-cell contact co-culture system decreasing the RANKL/OPG ratio level. Consistently the pro-osteoclastogenic property of the conditioned medium of MM cells co-cultured with BMSC/osteporgenitor cells was reduced in the presence of pomalidomide. To go further inside to the capacity of pomalidomide to blunt MM-induced RANKL/OPG imbalance in co-culture, we investigated the effect of this IMID on cell adhesion molecules. We show that pomalidomide significantly reduced the expression of CD49d (VLA-4), a molecule critically involved in RANKL up-regulation, by MM cells co-cultured with or without BMSC/osteoprogenitor cells. On the other hand, we did not find a significant inhibitory effect of pomalidomide on the production of soluble pro-osteoclastogenic factors as CCL3/MIP-1α, IL-3 and IL-7 by MM cells. In conclusion our data suggest that pomalidamide inhibits MM-osteoclast formation targeting the microenvironment through the block of RANKL overexpression induced by MM cells.

CYP2C8 GENE POLYMORPHISM AND BISPHOSPHONATE-RELATED OSTEONECROSIS OF THE JAW IN PATIENTS WITH MULTIPLE MYELOMA

E Such,[1] J Cervera,[1] J Bagán,[2] A Avaria,[1] A Valencia,[1] B Costán,[1] M Ibañez,[1] I Gómez,[1] M Margaix,[2] M Sanz,[1] J De la Rubia[1]

[1]University Hospital La Fe, Valencia, Spain; [2]University General Hospital, Valencia, Spain

Background. Bisphosphonates (BP) are considered the standard of care for the prevention of skeletal complications in patients with multiple myeloma (MM). Osteonecrosis of the jaw (ONJ) is an uncommon but potentially serious complication of BP, which is characterized by the presence of exposed bone in the mouth. Dental problems or interventions are risks factors for the development of ONJ. Besides, the risk for ONJ increases with BP treatment duration and has been shown to be 5% - 15% at 4 years. More recently, it has been suggested that the presence of one or two minor alleles of the cytochrome P450, subfamily 2C polypeptide 8 gene (CYP2C8) SNP rs1934951 constitutes an independent prognostic marker associated with the development of ONJ in patients with MM receiving BP therapy. *Aim.* To validate the impact of rs1934951 polymorphism in the development of ONJ in 65 patients with MM treated with zoledronic acid. *Patients and methods.* Sixty-five consecutive patients diagnosed with MM between 1993 and 2008 and receiving treatment with zoledronic acid form the basis of this study. Twenty out of the 65 patients had ONJ and the remaining 45 did not develop ONJ. Using dbSNP (http://www.ncbi.nlm.nih.gov/projects/SNP) we compiled all functional information and frequencies data in the polymorphic range in caucasian population from rs1934951. Finally, we analyzed 45 samples from heath volunteers to know the polymorphic distribution in the general Spanish population. DNA samples were extracted from peripheral blood or serum. The rs1934951 polymorphism was analysed by a TaqMan® assay method (TaqMan® SNP genotyping Assay, Applied Biosystems) and was read on a LightCycler 480 Endpoint Genotyping Software.

Table. Allelic distribution of the SNP rs1934951.

		CYP2C8 rs1934951 polymorphism, N (%)				
Study group	N	CC	CT	TT	C	T
Patients with MM	65	54 (83)	11 (17)	0 (0)	119 (92)	11 (8)
With ONJ	20	14 (68)	6 (32)	0 (0)	34 (85)	6 (15)
Without ONJ	45	40 (91)	5 (9)	0 (0)	85 (94)	5 (6)
Healthy volunteers	45	39 (86)	6 (13)	0 (0)	84 (93)	6 (7)
Applied Biosystems' SNP Browser	120	56 (67)	23 (28)	4 (5)	135 (80)	31 (19)

Results. There were 30 (46 %) males and 35 (54 %) females and the median age was 62 years (range 40 to 87). The median follow-up was 18 and 30 months for patients who developed and who did not develop ONJ, respectively. Clinical and biologic characteristics of the patients at diagnosis and their response to therapy were homogeneous between controls and cases. Six (32%) out of the 20 patients who developed ONJ were heterozygous (CYP2C8CT) for SNP rs1934951 in intron 8 of

CYP2Y8 *vs.* 5 (9%) out of 45 patients without ONJ and 6 (13%) of the 45 healthy volunteers (P=0.056). None of the individuals analyzed was found to be homozygous for SNP rs1934951 (CYP2C8TT, T will be denoted as a minor allele). No differences in the homozygous genotype for mayor allele (CYP2C8CC) were observed within the three groups (see Table), the most frequent allele in the three populations studied: 14 (70%) patients in MM with ONJ, 40 (89%) patients in MM without ONJ, and 39 (86%) individuals healthy volunteers. These proportions results were similar to those reported into SNP databases (67%). *Conclusion.* In this independent series, we found a trend towards a higher risk of development of ONJ in those patients with MM with the rs1934951 polymorphism on CYP2C8 gene.

This study was supported in part by grants BES2008-008053 R06/0020/0031, RD07/0020/2004 and CA08/00141.

DICKKOPF-1 IS ELEVATED IN NEWLY-DIAGNOSED, SYMPTOMATIC PATIENTS AND IN RELAPSED PATIENTS WITH MULTIPLE MYELOMA. CORRELATIONS WITH ADVANCED DISEASE FEATURES: A SINGLE-CENTER EXPERIENCE IN 284 PATIENTS

E Terpos,[1] D Christoulas,[1] A Papatheodorou,[2] M Gkotzamanidou,[1] M Iakovaki,[1] M Gavriatopoulou,[1] M Migkou,[1] M Roussou,[1] E Kastritis,[1] M Dimopoulos[1]

[1]University of Athens School of Medicine, Athens, Greece; [2251] General Air-Force Hospital, Athens, Greece

Background. Dickkopf-1 (Dkk-1) protein is an inhibitor of Wnt signaling and is implicated in the pathogenesis of myeloma bone disease. It disrupts osteoblast differentiation and function and is considered as the main factor responsible for osteoblast exhaustion in multiple myeloma (MM). Although serum Dkk-1 correlates with the presence of lytic lesions at diagnosis, there is very limited data for the Dkk-1 concentrations in different phases of MM. *Aims.* The aim of the study was to evaluate circulating serum Dkk-1 levels in MM patients at different phases of the disease and examine possible correlations with clinical and laboratory data. *Patients/Methods.* We studied 284 MM patients (153M/131F, median age 66 years) at different phases of their disease. Twenty patients had asymptomatic myeloma at diagnosis, 147 symptomatic MM at diagnosis, 29 patients were at the plateau phase of MM and 88 patients had relapsed MM after previous response to therapy. For newly-diagnosed and relapsed patients, serum was stored at the time of diagnosis or relapse, respectively, while for patients at the plateau phase of the disease serum was collected at the time of confirmation of the plateau (at least 6 months with stable M-protein without criteria confirming progression). Serum Dkk-1 was measured using ELISA methodology (R&D Systems, Minneapolis, MN, USA). Evidence of bone involvement was documented using plain radiography in patients at diagnosis or relapse. Dkk-1 was also measured in 20 gender- and age- matched controls. *Results.* The serum Dkk-1 concentrations of symptomatic MM patients at diagnosis (median: 1383 pg/mL, range: 274-32,862 pg/mL) were increased compared to controls (1069 pg/mL, 540-2,709 pg/mL; P<0.001), to asymptomatic patients at diagnosis (1044 pg/mL, 480-2,335 pg/mL; P<0.001) and to patients at plateau phase (1013 pg/mL, 414-1729 pg/mL; P<0.001) (Figure).

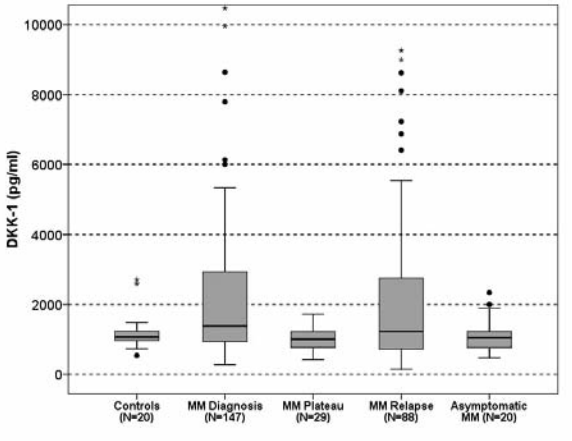

Figure.

There was no significant difference between asymptomatic patients, patients at plateau phase and controls, while relapsed patients had increased Dkk-1 levels (1218 pg/mL, 161-19,325 pg/mL) compared to controls (P=0.001), to asymptomatic patients at diagnosis (P<0.001), and to patients at plateau phase (P<0.001). Patients with ISS-3 myeloma at diagnosis had higher values of DKK-1 than ISS-1 and ISS-2 patients [median Dkk-1 values for ISS-1, ISS-2 and ISS-3 were: 1059, 1290 and 2649 pg/mL, respectively; p(ANOVA)=0.031]. Patients with lytic disease at diagnosis (n=116) had increased levels of Dkk-1 compared with patients with no lytic disease (n=51): 1475 pg/mL, 327-32,862 pg/mL *vs.* 840 pg/mL, 274-1112 pg/mL; P=0.002. Similar results were obtained for relapsed patients (1293 pg/mL, 282-19,325 pg/mL *vs.* 772 pg/mL, 161-2562 pg/mL; for patients with osteolysis (n=77) and for those without osteolysis (n=11), respectively; P=0.01). Dkk-1 serum levels at diagnosis correlated with beta2-microglobulin (r=0.238, P<0.01), LDH (r=0.2, P<0.01) and sRANKL levels (r=0.19, P=0.02), while serum Dkk-1 correlated with serum Ca in all patients (r=0.246, P<0.01). *Conclusions.* Serum DKK-1 is increased in symptomatic MM at diagnosis and in relapsed MM, while serum Dkk-1 of asymptomatic patients at diagnosis and at plateau did not differ from control values. Serum Dkk-1 correlated with advanced disease features, including the presence of lytic lesions. Thus, targeting Dkk-1 may be a treatment option for MM.

0927

SOLUBLE DECOY RECEPTOR 3 (DCR3) MODULATES THE SURVIVAL OF OSTEOCLASTS DERIVED FROM PATIENTS WITH MULTIPLE MYELOMA LYTIC BONE DISEASE

S Colucci,[1] G Brunetti,[1] R Rizzi,[1] A Oranger,[1] G Mori,[2] R Miccolis,[1] E Rinaldi,[1] P Curci,[1] G Specchia,[1] V Liso,[1] M Grano[1]

[1]University of Bari Aldo Moro, Bari, Italy; [2]University of Foggia, Foggia, Italy

Background. Decoy receptor 3 (DcR3), belonging to the tumor necrosis factor (TNF) receptor superfamily, is overexpressed in several types of cancer cells and involved in the protection of these cells against the cytotoxic and regulatory effects of apoptotic molecule FasL. The role of DcR3 in the regulation of Multiple Myeloma (MM) osteoclastogenesis has not been investigated so far, although it is unknown why elevated levels of FasL fail to induce osteoclast (OC) apoptosis in MM lytic bone disease. *Aims.* In this study, we purposed to assess the expression of DcR3 in MM lytic bone disease, focusing on DcR3 and FasL interaction, possibly affecting MM OC survival. *Methods.* OCs were obtained from unfractionated PBMCs, freshly isolated from 32 untreated patients diagnosed as having MM lytic bone disease and from 32 control-subjects with monoclonal gammopathy of uncertain significance (MGUS), as previously described. Approval from a local board and patient's informed consent according to the Declaration of Helsinki were obtained. By means of real-time PCR and western blot analysis, we evaluated the expression of DcR3 by T-cells, $CD138^+$ plasma-cells, and human myeloma cell line Karpas 909. DcR3 and FasL were co-immunoprecipitated by anti-FasL MAb in T-cell lysates and OC culture media. OCs from MM lytic bone disease, treated for 48 hr with anti-DcR3 MAbs (R&D System Inc.), were subjected to MTT assay for cell viability, DAPI staining, DNA fragmentation, and lysed and analyzed by western blot to detect the protein levels of caspase-8 and -3. *Results.* We found that T-cells and $CD138^+$ plasma-cells from patients with MM lytic bone disease and Karpas 909 expressed higher levels of DcR3 than T-cells and $CD138^+$ plasma-cells from control-subjects with MGUS. The formation of a DcR3-FasL immunocomplex was detected in both T-cell lysates and culture media of the OCs derived from MM lytic bone disease. In the latter cells, DcR3 neutralization induced the reduction of cell viability, increase of apoptotic cell number, DNA fragmentation, and caspase-8 and -3 activation. *Summary/Conclusions.* In our osteoclastogenesis culture system derived from PBMCs obtained from patients with MM lytic bone disease, OCs displayed a prolonged lifespan in spite of the high levels of apoptotic molecules such as TRAIL and FasL. In the present study, we focused on a possible binding and inactivation of FasL by any molecule present in our culture system. Our findings showed the overexpression of DcR3 by freshly prepared *ex vivo* T-cells and plasma-cells from the patients with MM lytic bone disease, and they suggest a possible involvement of DcR3 in the resistance to FasL-induced apoptosis displayed by the OCs from MM lytic bone disease.

0928

PATHOPHYSIOLOGICAL IMPLICATIONS OF POMALIDOMIDE IN TARGETING THE CLONOGENIC MULTIPLE MYELOMA SIDE POPULATION IN THE CONTEXT OF THE BONE MARROW MILIEU

J Jakubikova,[1] D Cervi,[1] J Daley,[1] D Cholujova,[2] M Ooi,[1] S Klippel,[1] S Blotta,[1] M Leiba,[1] J Delmore,[1] D McMillin,[1] E Kastritis,[1] J Laubach,[1] P Richardson,[1] K Anderson,[1] J Sedlak,[2] C Mitsiades[1]

[1]Dana-Farber Cancer Institute, Boston, USA; [2]Cancer Research Institute, Bratislava, Slovakia

Background. Multiple myeloma (MM), a malignancy hallmarked by the accumulation of malignant plasma cells in the bone marrow, remains incurable despite the use of conventional and novel therapies. It has been proposed that currently established anti-MM regimens based on tumor regression may target and kill differentiated tumor cells, comprising the bulk of malignant plasma cells, while sparing the rare tumor-initiating and/or drug-resistant sub-populations, including presumptive MM stem cells. *Aims.* Therefore, the development of new strategies targeting these subpopulations of MM cells is important. *Methods.* and *Results.* In our study, we evaluated the existence of a MM population with "stem-like"features, known as side population (SP) cells, by flow cytometry-based Hoechst 33342 staining. SP cells exhibit substantial heterogeneity in MM cell lines and display higher mRNA expression and functional activity of ABCG2 transporter compared to non-SP cells. We observed evidence for high clonogenic potential of SP cells, as well as repopulation ability of SP cells. Moreover, SP cells had a high proliferation index compared to non-SP cells. Thalidomide and chemically-related IMiDs® drugs, such as lenalidomide, have in recent years become important agents for the treatment of MM. Another IMiD®, pomalidomide, is currently in clinical trials for the treatment of relapsed and refractory MM. In our study, pomalidomide significantly decreased the percentage and clonogenicity of SP cells at clinically relevant concentrations. Pomalidomide decreased ABCG2 transcript; induced activation of signaling pathways in SP cells (including phosphorylation changes in Akt, GSK-3 alfa/beta, MEK1, c-Jun, p53 and p70S6K). The bone marrow stromal cells (BMSCs) represent an important part of the bone marrow milieu, promote tumor cell growth and survival, and confer drug resistance against conventional agents. In our study, adherence to BMSCs increased the percentage, viability, and proliferation potential of SP cells. Interestingly, pomalidomide abrogated this stimulatory effect of stromal cells by significantly decreasing SP cell percentages. *Summary/Conclusions.* Our data show that pomalidomide targets and eliminates clonogenic SP cells, which raises the intriguing possibility that pomalidomide might represent a new class of cancer therapeutics targeting cancer stem cells. In addition, our data suggest that further studies of this tumor cell population in the context to bone marrow milieu are warranted towards the goal of developing new strategies and designing new cancer therapeutics to treat MM.

BONE MARROW DERIVED MESENCHYMAL STEM CELLS ARE ATTRACTED BY A MULTIPLE MYELOMA CELL-PRODUCED CHEMOKINE (CCL25) AND STIMULATE MYELOMA CELL EXPANSION THROUGH AKT AND ERK PATHWAYS

S XU,[1] E Menu,[2] B van Camp,[2] A De Becker,[1] K Vanderkerken,[2] I Van Riet[1]

[1]Stem Cell Laboratory, Universitair Ziekenhuis Brussel, Brussels, Belgium; [2]Research Group Hematology-Immunology, Vrije Universiteit Brussel, Brussels, Belgium

Background. Mesenchymal stem cells (MSCs) are multipotent stem cells that have immunomodulary properties and that produce a variety of hematopoiesis-stimulating cytokines. They can be expanded *in vitro* at clinical scale and are currently used in several pre-clinical and clinical studies for supporting hematopoiesis and/or controlling graft *vs.* host disease after hematopoietic stem cell transplantation, for tissue engineering or as gene therapy vehicles. MSCs have also been shown to have the capacity to home *in vivo* to tumor sites and to support tumor development by integrating into the tumor stroma. *Aims.* In this study we examined whether *in vitro* expanded bone-marrow-derived MSCs can be recruited by multiple myeloma (MM) cells and at which level MSCs directly affect growth and survival of MM cells. *Methods.* Human MSCs and murine MSCs were isolated from bone marrow aspirates of human voluntary donors and C57BL/KaLwRij mice, respectively. *in vitro* and *in vivo* migration assays were used to evaluate the migration ability of MSCs towards MM cells. Human stroma-dependent myeloma cells (MM5.1) , stroma-independent myeloma cells (RPMI8226) or murine stroma-dependent myeloma cells (5T33MMvv) and stroma-independent myeloma cells (5T33MMvt) were co-cultured with human or murine MSCs. The effect on proliferation/apoptosis was evaluated. Expression of proteins involved in cell cycle progression and apoptosis was tested by Western blot analysis. *in vivo* co-engraftment experiments (MSCs + MM cells) in the 5T33MM model were performed to confirm *in vitro* findings. *Results. in vitro* migration assays revealed that both human and murine MSCs can be attracted by MM cells. Accordingly we found by fluorescence microscopic analysis of paraffin sections from various tissues that DiI-labeled murine MSCs home in the 5T33MM model after intraveneous injection to MM-invaded organs (tibia and spleen) at a higher level as compared to the naive mice. We further identified CCL25 was the most important MM cell-produced chemokine that triggers MSC migration through the CCR9 receptor. By co-culturing MM cells and MSCs, we found that MSCs favor the proliferation of stroma-dependent MM cells by secreting soluble factors and by cell-cell contact, which was confirmed by co-engraftment experiments in the *in vivo* 5T33MM mouse model. We also demonstrated that MSCs protect *in vitro* MM cells against spontaneous and Bortezomib-induced apoptosis. Moreover we found that after co-culturing with mMSCs, murine MM cells show an up-regulation of phosphorylated AKT and ERK, accompanied with increased CyclinD2, CDK4 and Bcl-XL, and decreased cleaved caspase-3 and PARP. *Conclusions.* In conclusion our results provide evidence that reciprocal interaction between MSC and MM cells induce chemoattraction of MSCs by MM cells resulting in MSC-mediated stimulation of MM cell survival and proliferation. As precursors of the bone marrow stroma, MSCs seem to play an active role in the pathophysiology of this disease. Our data also suggest that therapeutical infusion of normal donor-derived MSCs should be considered with caution as these adult stem cells might enhance tumor progression *in vivo* resulting/contributing in disease relapse after MSC-based cytotherapy.

0930

MYELOID-DERIVED SUPPRESSOR CELLS IN PATIENTS WITH MULTIPLE MYELOMA AND MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE

N Parrinello, P La Cava, D Tibullo, C Giallongo, O DI Bartolo, E Spina, P Spina, A Branca, AM Triolo, A Romano, A Chiarenza, M Cavalli, G Palumbo, F Di Raimondo

Divisione di Ematologia, Universita' di Catania, Ospedale Ferrarotto, Catania, Catania, Italy

Background. Myeloid-derived suppressor cells (MDSC) are a heterogeneous population of cells of myeloid origin, and they include immature macrophages, granulocytes, dendritic cells (DC) and other myeloid cells. In mice, they are phenotypically characterized as $CD11b^{+}Gr\text{-}1^{+}$. Humans MDSC have an immature phenotype, including lineage negative (Lin-), $CD14^{-}$, $HLA\text{-}DR^{-}$, $CD15^{+}$, $CD34^{+}$, $CD11b^{+}$, $CD33^{+}$, and $CD13^{+}$ cells. MDSC are considered an important tumor escape mechanism because they 1) impair T-cell functions through secretion immunosuppressive cytokines, perturbation of the arginine metabolism by inducible nitric oxide synthase (iNOS), up-regulation of reactive oxygen species (ROS), 2) promote tumor-dependent angiogenesis as well as tumor metastasis, and 3) provide tumor resistance to antiangiogenic drugs. Their accumulation has been described in the peripheral blood of patients affected by breast, lung, renal and neck carcinoma, melanoma, chronic infections, inflammatory diseases, and traumatic stress. We investigate MSDC in patients with multiple myeloma (MM) and monoclonal gammopathy undetermined significance (MGUS) by flow cytometry. *Methods.* We studied 36 patients with MM at diagnosis, 36 patients with MGUS, and 15 healthy controls (HC). *Results.* we observed that patients with MGUS showed approximately the same number of MDSC (CD11b+,CD13+,CD34+,CD14-,CD45+) in the peripheral blood compared to HC (2.26±1,66/mmc, *vs.*1,69± 0,87/mmc P=0,28). On the contrary, patients affected by MM showed a significant increase of MDSC *vs.* HC (4.09±3.07/mmc *vs.* 1,69± 0,87/mmc, P=0,008). *Conclusion.* Our results underlie the biologic difference between MM and MGUS and suggest that myeloid-derived suppressor cells could be involved in the progression of MGUS towards overt MM, through their immunosuppressive and proangiogenetic mechanisms.

SERUM FREE LIGHT CHAINS ANALYSIS CAN EARLY DETECT RELAPSE/PROGRESSION IN INTACT IMMUNOGLOBULIN MULTIPLE MYELOMA

M Sobh, S Morisset, J Bocquet, T Guilli, S Ducastelle-Lepretre, F Barraco, Y Chelghoum, X Thomas, G Cannas, A Praire, H Labussiere, F Nicolini, C Chapuis-Cellier, M Michallet

Edouard Herriot Hospital, Lyon, France

Background. Serum free light chains (sFLC) analysis has proved its usefulness in disease diagnosis and early treatment response in multiple myeloma (MM). The sFLC ratio (sFLCR) has been included as one of the necessary criteria for achieving a "stringent complete response"in the proposed international response criteria. In contrast, performing this analysis during patient's follow up and after different treatments, in a daily practice setting, is still not very well defined yet. *Aim.* The main objective of this study was to assess the importance of sFLC analysis during MM patient's follow-up especially for relapse/progression detection comparing to concomitant traditional serum protein electrophoresis (sPE). *Methods.* We have analysed 174 MM patients diagnosed at the Edouard Herriot university hospital between years 2002 and 2008, for which a concomitant measurement of sFLC and sPE was done during follow-up. The sFLC analysis was performed using the Freelite® test from the Binding site on a BNII©, Dade Behring®, and for sPE, analysis was done using a Paragon CZE 2000® Beckman Coulter®. There were 92 (53%) males and 82 (47%) females, median age at diagnosis 57 years (34-72). One hundred and twenty patients (69%) had IgG (87K&33L), 52 (30%) IgA (41K&11L) and 2 (1%) IgD (1K&1L). Twenty six (15%) patients had renal insufficiency. We were interested to monitor the behaviour of sFLC and sPE in a way to early detect relapse or progression independently of treatment type. Slopes of the increase period corresponding to each measurement were compared using the student t-bilateral test with R statistical software (version 2.9.2). *Results.* After monitoring all patients, we observed 117 (67%) patients with relapse or disease progression and 57 (33%) patients were still in response to treatment. As our main objective was to detect relapse or progression, the 57 patients in response were excluded from the analysis. Among the 117 patients, in 77 (66%) cases, relapse or progression was detected by concomitant increase of both sFLC and the intact immunoglobulin level (iIg) with a significant earlier increase for sFLC (Figure1A). In 17 (15%) patients, the relapse or progression was characterised by the only increase of sFLC without any increase of the iIg (Figure1B). Contrarily, in 5 (4%) patients there was only an increase of the iIg without increasing the sFLC (Figure1D). Finally, in 18 (15%) patients, the relapse or progression was revealed by the increase of iIg faster than the concerned sFLC (Figure1C). When comparing slopes of increasing sFLC comparing to increasing iIg, we found a very high significant difference (P<0.001), thus showing that sFLC have a faster detection of relapse or progression. *Conclusion.* We have observed that in 81% (66%+15%) of patients, sFLC analysis enabled an earlier detection of relapse or progression compared to sPE, this could be very important for early treatment intervention especially for high risk patients. Since there are no uniform recommendations for the use of this analysis during follow-up, we recommend its concomitant use with sPE, waiting for guidelines.

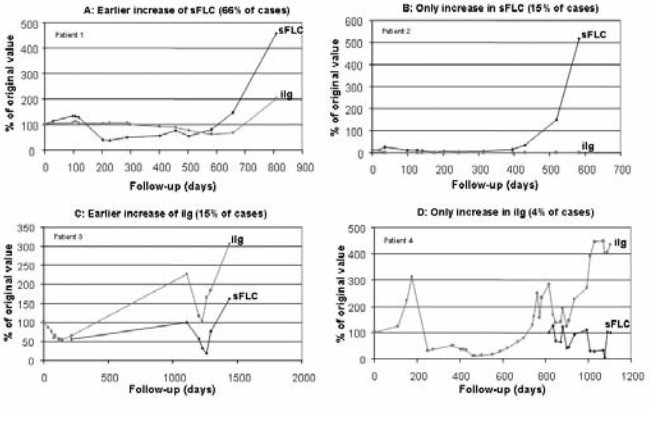

Figure 1. Different relapse/progression profiles.

0932

IMPACT OF THE MAGNITUDE OF FALL OF SERUM SOLUBLE SYNDECAN-1 (S-SYND-1) LEVELS AT PLATEAU PHASE, AFTER TREATMENT WITH BORTEZOMIB OR LENALIDOMIDE IN RELAPSED/REFRACTORY MULTIPLE MYELOMA (MM)

MC Kyrtsonis, T Tzenou, E Koulieris, X Papanikolaou, D Maltezas, N Stavropoulos, V Bartzis, M Dimou, G Georgiou, T Vassilakopoulos, M Angelopoulou, P Beris, P Panayiotidis

Laikon Univ Hospital, Athens' Med School, Athens, Greece

Backgroud. Serum s-synd-1 levels at diagnosis constitute an independent prognostic factor in MM. In addition, the magnitude of its diminution from diagnosis to plateau phase after conventional induction treatment was shown to predict for patients' overall survival. Each time MM relapse after induction and is retreated, remission duration is shorter than the first time. However, new treatment modalities, bortezomib or lenalidomide - containing, have emerged for the management of relapsed/refractory MM patients, and they may improve patients' outcome after relapse, thus prolonging life expectancy. If s-synd-1 levels' decrease results in plateau phase or survival prolongation after treatment with new drugs (bortezomib, lenalidomide), is unknown. *Aims.* to evaluate the magnitude of serum s-synd-1 levels' reduction from relapse to plateau phase in a series of relapsed/refractory MM patients treated with bortezomib or lenalidomide. *Patients and methods.* Serum s-synd-1 was determined in 32 relapsed/refractory MM patients treated with Velcade and dexamethasone (VD) and 16 treated with Revlimid and dexamethasone (RD) before treatment induction and in plateau phase. In addition, s-synd-1 levels were also determined in 30's healthy individuals' sera (HI). s-synd-1 measurements were performed in duplicate by ELISA with a commercially available kit (Diaclone research, France). *Results.* MM type was IgG in 59% *vs.* 69% and IgA in 22% *vs.* 19% in the VD and RD group respectively. Light chain myeloma was present in 13% in both groups, 1 VD patient had IgD MM. More than 50% were in advanced ISS stage. The median time of relapses before treatment was 3 in both VD and RD groups. 90% of patients (including 44% nCR or better) responded in the VD group *vs.* 81% an the RD one (including 38% nCR or better). The median follow-up time from VD or RD treatment to relapse was 8.8 and 13.8 months respectively. At the time of relapse, before treatment, median s-synd levels in all VD and RD patients, were 90.5 ng/mL (10-1100) [median 105 for VD *vs.* 62ng/mL for RD] and became 22.5 ng/mL (7-650) [median 20 for VD *vs.* 26ng/mL for RD], while they were 27 ng/mL in HI (12-40). In the whole group, the achievement of >50% reduction of serum s-synd-1 from relapse to plateau was accompanied with increased plateau duration (median 4.9 months without *vs.* 16,6 months with s-synd-1 fall >50% at plateau, P=0.01). Increased plateau duration was also observed in all patients when a nCR or better was achieved (P=0.006). However, when the VD and RD group were analyzed separately, the quality of response obtained was more important for plateau duration in the VD group (P=0.001 *vs.* 0.65 in RD), while the decrease of s-synd-1 by >50% was more important in the RD group (P=0.01 *vs.* 0.12 for VD). With regard to overall survival after VD or RD treatment, only s-synd-1 decrease was important in the RD group (P=0.04, Figure 1). *Conclusions.* if confirmed in a larger series, our results suggest that the biologic modulation of lenalidomide implicates s-synd-1 and that there is a subgroup of patients that mostly benefit from this modality.

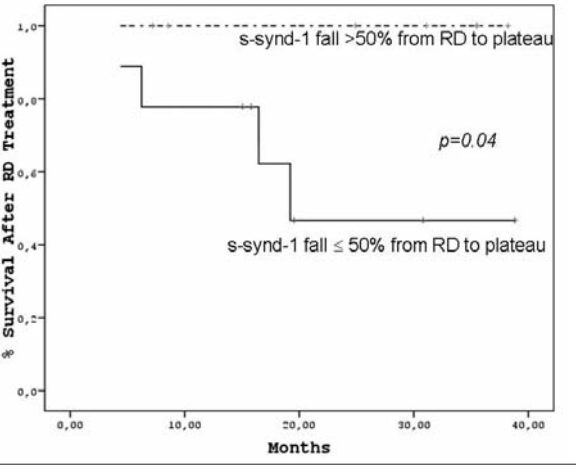

Figure 1.

CLINICAL AND PROGNOSTIC SIGNIFICANCE OF ELEVATED SERUM BAFF LEVELS IN MULTIPLE MYELOMA

G Tsirakis,[1] M Fragioudaki,[2] M Kaparou,[2] A Hatzivassili,[3] K Sfyridaki,[3] C Pappa,[3] D Kyriakou,[4] M Alexandrakis[2]

[1]General Hospital Chania, Chania, Greece; [2]University Hospital of Crete, Heraklion, Greece; [3]Venizeleion Hospital, Heraklion, Greece; [4]University Hospital of Thessalia, Larissa, Greece

Background. Multiple myeloma is characterized by accumulation of malignant plasma cells within the bone marrow in close contact with stromal cells, which secrete factors/cytokines promoting tumour cell growth and survival. Among these factors B-cell-activating factor (BAFF) is a member of the tumour necrosis factor superfamily and is expressed by a number of cell types. BAFF is a critical survival/maturation factor for peripheral B cells and this activity is mediated through a BAFF-specific receptor, BAFF-R. Over expression of BAFF has been linked to autoimmune disease and B cell neoplasia. *Aims.* The purpose of this study was to measure the serum levels of BAFF in multiple myeloma and to assess whether it could be a strong indicator of the magnitude of angiogenesis, disease severity and the patients' survival. *Methods.* 48 patients with multiple myeloma and 12 healthy controls were studied. Patients were staged with Durie-Salmon system. Serum samples were collected from all patients at the diagnosis and at the plateau phase after effective treatment (n=18). We have also performed bone marrow biopsies prior to treatment. Microvascular density was measured by staining bone marrow vessels with anti-CD31. At the diagnosis serum levels of BAFF, PCNA and TNFα were determined by ELISA, as well as LDH levels. BAFF was also measured at plateau phase. *Results.* BAFF's serum levels were significantly higher in myeloma patients compared to control (P<0.001) (988.6±720.3pg/mL *vs.* 279.8±164.3pg/mL). Significantly serum BAFF levels were proportionally increased in accordance with the disease progression (P<0.001). (Stage I:481.1±188.2pg/mL, stage II:754.9± 245.9pg/mL and stage III:1394.1±772.8pg/mL). BAFF's serum levels showed significant correlation with LDH concentration (r= 0.273, P<0.06), the PCNA levels (r=0.578, P<0.001), TNFα (r=0.495, P<0.001) and bone marrow microvascular density (r=0.303, P<0.04). BAFF levels decreased significantly after effective chemotherapy reaching values comparable to healthy controls (values pre and post treatment were 849.3±786.0 pg/mL *vs.* 281.8±174.1pg/mL, respectively) (P<0.001). Analysis of the patients' survival (Kaplan Mayer method) showed that levels >948.92 pg/mL had lower survival rates (P<0.001). *Conclusions.* BAFF serum levels were significantly elevated in patients with multiple myeloma suggesting that BAFF may be involved in the pathogenesis of the disease. Increased levels are correlated with disease activity increased angiogenesis and poor prognosis in MM.

0934

OLIGOCLONAL BANDS IN PATIENTS WITH MULTIPLE MYELOMA IN COMPLETE RESPONSE AFTER INDUCTION CHEMOTHERAPY: ASSOCIATION WITH THE USE OF NOVEL AGENTS

C Fernández de Larrea, N Tovar, MT Cibeira, JI Aróstegui, L Rosiñol, M Elena, X Filella, J Yagüe, J Bladé

Hospital Clínic, Barcelona, Spain

Background. The emergence of oligoclonal bands is a well recognized event after autologous stem cell transplantation in multiple myeloma (MM). These atypical serum immunofixation (IFE) patterns are associated with good prognosis, likely due to a durable immune reconstitution. They can appear with novel immunomodulatory drugs such as lenalidomide, but its prevalence with other induction treatments has not been reported. *Aims.* To determine the prevalence of serum and/or urine oligoclonal bands in patients with MM in CR after primary therapy with cytotoxic agents or new induction chemotherapy regimens incorporating novel drugs up-front. *Methods.* Thirty-three patients (15M/18F; median age at diagnosis 59 years, range 25 to 89) with MM in CR after different induction regimens were studied. Initial baseline demographics, clinical and laboratory data, treatment and follow-up were collected. An oligoclonal band was defined by the presence of a serum and/or urine IFE monoclonal spike different either in heavy and/or light chain component from the original myeloma protein. *Results.* The initial clinical and laboratory findings as well as the induction treatments are shown in the table. Eighteen patients (54.5%) received induction with conventional chemotherapy and 15 with novel agents (45.5%). In the latter group, the induction regimen was based on combinations of glucocorticoids with lenalidomide (26.7%), thalidomide (26.7%), bortezomib (33.3%) or bortezomib plus lenalidomide (13.3%). In the overall series, 11 out of the 33 patients (33.3%) developed an oligoclonal band. In the group treated with cytotoxic agents, the prevalence of oligoclonal bands was observed in 2 patients (11.1%), both of them had been treated with cyclophosphamide and dexamethasone. In contrast, induction with novel drugs resulted in 9 out of 15 patients (60%) developing oligoclonal bands in serum and/or urine (chi-square test 2-sided, P=0.003). *Conclusions.* This is the first report showing a significant different frequency of oligoclonal bands in patients with MM in CR after conventional cytotoxic therapy *vs.* induction incorporating novel agents. This difference is likely due to a strongest immune reconstitution resulting from the effect of novel drugs. However, the prognostic impact of the presence of oligoclonal bands emerging after induction therapy is still unknown.

Table.

Variable	Total group (n=33)	Cytotoxic drugs group (n=18)	Novel drugs group (n=15)
Median age, y (range)	59 (25-89)	57.9 (25-89)	61.4 (47-79)
Male/female	15/18	8/10	7/8
Heavy-chain component (%)			
IgG	27.3	16.7	40
IgA	27.3	27.8	26.7
Only light chains	30.3	38.9	20
IgD	12.1	16.7	6.7
IgM	3	0	6.7
Light-chain component (%)			
κ	48.5	50	66.7
λ	51.5	50	33.3

0935

MULTIDRUG RESISTANCE GENE EXPRESSION IN PLASMA CELL MYELOMA

S Drain,[1] M Catherwood,[1] L Flannely,[2] M Drake,[1] P Kettle,[1] A Bjourson,[2] H Alexander[2]

[1]Belfast City Hospital, Belfast, UK; [2]University of Ulster, Coleraine, UK

Background. Multi-drug resistance (MDR) is a phenomenon that can lead to impaired treatment efficacy in all forms of malignancy. The most prominent forms of MDR are mediated by the drug effluxing actions of certain adenosine tri-phosphate binding cassette (ABC) transport proteins. Recent debates in plasma cell myeloma (PCM) have questioned which of the many ABC transporters are to be implicated in the course of this disease and also in the treatment of PCM post relapse. rs1045642 is a SNP within *ABCB1* which is thought to affect the activity of the protein product (P-glycoprotein) and has demonstrated significant associations with overall survival in PCM1. *Aims.* This study was designed to investigate the expression of the MDR associated genes; *ABCB1*, *ABCB4*, *LRP*, *ABCC1* and *ABCG2* in PCM. We also wished to determine the impact of rs1045642 on *ABCB1* mRNA levels in PCM. *Methods.* 89 patients with a confirmed diagnosis of PCM were studied with ethical consent approved via ORECNI. Of these patients, 81 were biopsied at diagnosis of either MGUS or MM and 8 at relapse. Tumour cells were separated from bone marrow biopsies using $CD138^+$ magnetic microbeads and RNA was extracted using Trizol. mRNA expression was determined for each gene using relative quantification and taqman validated assays. Results are expressed as a fold change from expression in normal plasma cells. *Results.* Of the 5 genes investigated, *ABCB4* (MDR-3) has demonstrated the greatest increase in PCM patients at diagnosis with a mean fold change of 26. In relapsed samples, all genes apart from *ABCB1* have demonstrated a substantial decrease in mean fold change with *ABCB4* mean fold change reduced to 9. *ABCB1* mean fold change was increased from 0.6 at diagnosis to 2.8 in relapsed samples. MDR gene expression was not significantly associated with currently available prognostic factors in PCM (B2M, Albumin, Ig class and light chain restriction). rs1045642 does not affect *ABCB1* mRNA levels in PCM patient samples. *Conclusion.* This study suggests that *ABCB4* may be the most prominent contributor to MDR and initial treatment failure in newly diagnosed PCM. *ABCB1*, however, appears to have

increased mRNA levels in relapsed samples suggesting that P-gp may be a more prominent contributor to treatment strategies, post relapse, in PCM. MDR gene expression may be an independent factor affecting treatment within this patient cohort. rs1045642 does not alter *ABCB1* mRNA levels in PCM suggesting that effects of this SNP manifest at the protein level. Further work will investigate the expression and activity of P-glycoprotein in PCM and will determine the clinical effect of rs1045642 on P-gp.

FLOW CYTOMETRIC IMMUNOPHENOTYPIC CHARACTERISTIC OF 36 CASES OF PLASMA CELL LEUKEMIA

M Kraj, J Kopec- Szlezak, R Poglod, B Kruk

Institute of Hematology and Transfusion Medicine, Warsaw, Poland

Aim of the study was to determine expression of adhesion molecules CD11a/CD18 (LFA1), CD11b, CD29/CD49d (VLA-4), CD44 (H-CAM), CD54 (ICAM-1), CD56(N-CAM) and CD71(Tr1R), CD117 (c-kit), CD126 (IL-6R), on peripheral blood (PB) and bone marrow (BM) plasma cells in 36 plasma cell leukemia (PCL) patients (23 primary, 13 secondary) at diagnosis and in 47 multiple myeloma (MM) patients. Immunophenotyping was performed simultaneously on freshly collected PB and BM samples using flow cytometry. Plasma cells were identified as cells showing high-density expression of CD38, expression of CD138 (syndecan-1) and CD45 low /-. Results of analysis were presented as relative values of numbers of cells with antigen expression and as relative fluorescence indices (RFIs) of studied antigens. BM plasma cells showed expression of particular antigens in a following proportion of cases: CD49d 100%, CD29 94%, CD54 93%, CD44 83%, CD56 60%, CD18 26%, CD11b 29%, CD11a 19%, CD117 27%, CD71 30%, CD126 100% while expression of those antigens on PB plasma cells was present in following percentage of patients: CD49d 100%, CD29 96%, CD54 93%, CD44 95%, CD56 56%, CD18 50%, CD11b 53%, CD11a 29%, CD117 26%, CD71 28%, CD126 100%. Expression of CD54 (BM 71±31%, RFI 16±4; PB 72±3%, RFI 16± 3) was significantly higher than that of adhesion molecules belonging to integrin β2 family: CD11a, CD18 and CD11b, on both BM and PB cells (P<0.01). Expression of CD18, CD11a and CD11b was differential between two cell compartments: lower on BM and higher on PB cells. CD11a - BM 13±17%, RFI 14±3; PB 26±25%, RFI 18.7±3.7, CD18- BM 16±16%, RFI 12.8±3.4; PB 36±20%, RFI 16.2±1.5, CD11b - BM 16±24%, RFI 17±4; PB 33±26%, RFI 20±3. Plasma cells in BM of PCL patients showed significantly greater granularity (786±253) and size (1439±266) than those in PB (554±191) and (1308±186) (P=0.0001 and P=0.04, respectively). However, no differences in cell size and granularity were revealed between BM plasma cells from PCL patients and MM patients (granularity 833±260; size 1414±240) (P=0.249 and P=0.659, respectively). The difference in the rate of BM CD44+ cells between PCL patients (79±33%) and MM patients (46±36%) was significant (P=0.0062). In 55% of primary PCL cases malignant plasma cells did not express CD56 while incidence of CD56 positivity in secondary PCL did not differ from that observed in MM cases (67±37%). *Conclusions.* Immunophenotype of leukemic plasma cells characterizes mainly increased expression of CD38, CD54 and CD138, expression of CD29, CD49d, CD44, CD126 and disturbed expression of CD18, CD11a and CD11b. In one third of cases, tumor cells show expression of CD56, CD71 and CD117. Impaired expression of adhesion molecules such as CD11a/CD18 or CD56 may explain hematogenic dissemination characterizing PCL. Adhesion molecule expression according to proportion of plasma cells expressing a given antigen in PB and BM presents a following pattern (in diminishing order): CD49d>CD44>CD54>CD29>CD56>CD18 >CD11b>CD11a. Immunophenotyping of plasma cells in PCL, alike in MM, might be useful for detecting minimal residual disease in cases with aberrant antigen expression and for selection of therapeutic agents towards specific membrane targets.

CHANGES IN THE EXPRESSION OF TELOMERE-ASSOCIATED GENES IN MULTIPLE MYELOMA AND MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE. CORRELATION WITH CLINICO-PATHOLOGICAL PARAMETERS

J Panero,[1] D Fantl,[2] J Arbelbide,[2] H Garcia Rivello,[2] D Kohan,[2] I Slavutsky[1]

[1]*Academia Nacional de Medicina, Buenos Aires, Argentina;* [2]*Hospital Italiano, Buenos Aires, Argentina*

Background. Telomere-binding proteins protect chromosome ends through telomere end-capping and length control. Several studies have investigated the expression of telomerase and telomeric proteins in different lymphoid neoplasms, but little is known about its expression profile in plasma cell disorders. *Aims.* In this study, we have evaluated the mRNA levels of TRF1, TRF2, TANK1 and hTERT genes and telomere length (TL) in patients with multiple myeloma (MM) and monoclonal gammopathy of undetermined significance (MGUS). Results were correlated with clinico-pathological characteristics. *Methods.* mRNA samples from 132 patients: 68 with MM (33 males; mean age: 68.5 years; range: 30-87 years; 35% ISS stage III) and 64 with MGUS (28 males; mean age: 69.3 years; range: 39-88 years) and 15 normal controls (NC) were studied. All patients gave informed consent and the study was approved by the Ethics Committee of our Institution. Gene expression was quantified on mRNA samples from patients and controls by real time PCR, using TaqMan assay. GAPDH was used as housekeeping gene to normalize the expression of each target gene. TL measurements were performed by Terminal Restriction Fragments. The proliferative index was evaluated by immunohistochemistry with Ki67 antibody. For statistical analysis, Mann-Whitney test, Kendall´s coefficient and receiver operating characteristic (ROC) curves were used. *Results.* Differences in the expression of telomeric genes was observed in patients compared to NC (Figure 1). Significant differences in mRNA levels of TRF1, TRF2 and TANK1 between MGUS and MM were found. TRF1 showed lower levels (P<0.006) meanwhile higher levels for TRF2 and TANK1 (P<0.005) in MM respect to MGUS were detected. In both entities, an up-regulation of hTERT and a positive association between TRF2-TANK1, TRF2-hTERT and TANK1-hTERT (P<0.01) was observed. Patients showed a wide spreading of hTERT values. For a better analysis, hTERT levels were divided into three groups taking into account the cut-off points generated by ROC analysis: low (GI:≤1.08), intermediate (GII: <1.08 y ≥5.0) and high (GIII: >5.0). In both pathologies, a similar distribution of patients per group was observed, with most of cases in GI (70%) and the less proportion in GIII (9%). In MM, higher expression of TRF2 (0.22±0.03) and TANK1 (0.77±0.16) in GIII respect to GI (TRF2: 0.06±0.01; TANK1: 0.28±0.07) and GII (TRF2: 0.07±0.01; TANK1: 0.37±0.05) (P<0.01) was observed, while increased TRF2 levels in GIII (0.10±0.02) compared to GI (0.04±0.004) in MGUS (P<0.01) was found. TL had a significant reduction in patients respect to NC (P≤0.04). In both pathologies, GIII showed the shortest TL (MM: 5.28±2.56kb; MGUS: 4.90±1.75kb). In MM, the percentage of bone marrow infiltration was positively associated with TRF2, TANK1 and hTERT expression (P≤0.005) and negatively with TL (P=0.02), whereas LDH was significantly correlated with TRF2 mRNA (P=0.008). Ki-67 index was positively associated with TRF2, TANK1 and hTERT expression (P≤0.03) and negatively with TL (P=0.002). *Conclusions.* The differential expression pattern observed suggest that changes in telomeric proteins composition may be associated to the establishment and maintenance of short telomeres in MGUS and MM patients, contributing to tumour progression.

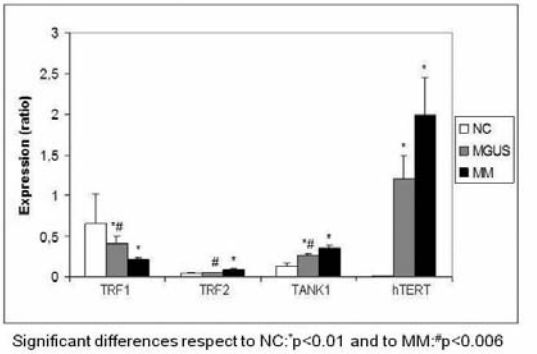

Figure 1. Expression of telomeric genes.

FLOW CYTOMETRY EVALUATION OF BONE MARROW PLASMACELLS IN MONOCLONAL GAMMOPATHY OF UNCERTAIN SIGNIFICANCE (MGUS): CORRELATION WITH MONOCLONAL COMPONENT, FREE LIGHT CHAIN AND MAGNETIC RESONANCE IMAGING

F Morabito,[1] C Mazzone,[1] V Gigliotti,[1] N Caruso,[1] A Madeo,[1] AG Recchia,[1] P Servillo,[1] S Bossio,[1] M Gentile,[1] S Franzese,[1] E Lucia,[1] MG Bisconte,[1] C Gentile,[1] S Cavalcanti,[1] B Amoroso[2]

[1]Hematology Unit, Cosenza, Italy; [2]Clinical Research Direction, The Binding Site,, Birmingham, UK

Background. While neoplastic plasmacells (PCs) retain some of the phenotypic characteristics of normal PCs, including strong CD38 expression, immunophenotyping studies demonstrated that abnormal PCs lack CD19 and express CD56 antigens. Assessment of serum free light chain (sFLC) concentrations is a powerful tool to qualify response stringency and duration in multiple myeloma. The presence of an abnormal sFLC ratio also represents a risk factor for progression in different types of plasmacell dyscrasias. *Aim.* The rationale of this study was to detect the incidence of the abnormal PC phenotype in MGUS compared to polyclonal plasmacytosis as a control cohort. We also addressed whether a BMPC phenotype could differentiate subsets of MGUS cases with different amounts of sMC or abnormal FLC k/L ratio, or cases with pathological MR imaging of the axial skeleton. *Methods.* One hundred MGUS and 68 plasmacytosis were analyzed. BMPCs were identified by their characteristic light scatter distribution and a sequential gating strategy, CD19, CD45, CD38 and CD56 reactivity were assessed using an EPICS Profile II flow cytometer (Coulter Electronics, Inc., Hiealeah, FL). sFLCs were determined using a particle enhanced, high-specificity, homogeneous FLC immunoassay [Freelite; The Binding Site, Birmingham, UK; performed on a Delta Nephelometer (Radim, Milano, Italy)]. *Results.* Considering the lowest CD19 (median 63.4%; range 22.9-93.5) and the highest CD56 (median 63.4%; range 22.9-93.5) values expressed in the 68 benign plasmacytosis, we established 20% as the best cut-off value for CD19 and CD56 to differentiate normal from abnormal BMPC. Thus, MGUS cases were divided into 3 groups: normal BMPC (CD19high/CD56low, 26 cases), abnormal BMPC ($CD19^{low}/CD56^{high}$, 24 cases) and BMPC with an intermediate phenotype (34 cases; CD19low/CD56low, 24 cases; $CD19^{high}/CD56^{high}$, 10 cases). The mean sMC level was 1.01+0.06 gr/dL. A significant direct correlation was demonstrated between BMPC detected by flow (CD45neg/CD38pos) (Rho=0.3, P=0.003) and sMC. Notably, the expression of BMPC CD19 (RHO=-0.44, P<0.0001), but not CD56, inversely correlated with sMC. The mean value of sMC was lower (P=0.002) for cases expressing CD19>20% on BMPC (0.9+0.1) *vs.* those cases with an expression of CD19<20% (1.2+0.1). Moreover, a trend towards a higher amount of sMC was detected in the abnormal phenotype group. sFLC k/L ratio was investigated in 39 MGUS cases (21 abnormal). An abnormal sFLC ratio was associated with significantly lower percentage (P=0.019) of CD19+ BMPCs [16.7(range 2.7-76) *vs.* 6.9 (range 0.1-76)], while no significant association was documented with CD56 expression. Of the 21 cases with abnormal sFLC ratio, only 2 (9.5%) had a $CD19^{high}/CD56^{low}$, 10 (47.6%) a $CD19^{low}/CD56^{high}$, and 9 an intermediate BMPC phenotype. MR imaging of the axial skeleton was carried out in 55 cases. All 4 patients showing a pathologic MR pattern had an abnormal ($CD19^{low}/CD56^{high}$) BMPC pattern. However, the remaining normal MR cases were equally distributed within the different phenotypes. *Conclusion.* Our results indicate that Flow-Cytometry analysis may detect MGUS cases with different BMPC phenotypes associated with amounts of sMC and sFLC k/L ratio. Whether the presence of such a phenotype in MGUS cases may have an impact in predicting a different clinical outcome should be evaluated.

DETECTING MYELOMA - WAYS TO SHORTENING AN OFTEN PAINFUL AND TEDIOUS PATIENT ODYSSEY: RESULTS FROM AN INTERNATIONAL SURVEY CONDUCTED BY MYELOMA EURONET, THE EUROPEAN NETWORK OF MYELOMA PATIENT GROUPS

A Waldmann,[1] B Barragán,[2] V Cursaru,[3] C Heberlein,[4] M Hrianka,[5] F Richter,[6] R Sadzuga[7]

[1]Leukaemiehilfe Rhein-Main, Ruesselsheim, Germany; [2]Asociación Española de Afectados por Linfomas, Mielomas y Leucemias, Madrid, Spain; [3]Myeloma Euronet Romania, Bucharest, Romania; [4]Stiftung zur Foerderung der Knochenmarktransplantation, Ebmatingen, Switzerland; [5]Slovenská Myelómová Spolocnost, Bratislava/_ilina, Slovakia; [6]Myelom- und Lymphomhilfe Oesterreich, Muellendorf, Austria; [7]Polskie Stowarzyszenie Pomocy Chorym na Szpiczaka, Olsztyn, Poland

Background. It is well understood that a prolonged delay in myeloma diagnosis has a significant impact on disease-free survival. Myeloma can have various non-specific symptoms such as back pain, bone pain, bone fractures, recurrent infections, tiredness/weakness, and kidney problems. Patients therefore present to a range of medical professionals before their myeloma is detected, also including general practitioners/family doctors (GP/FD) and orthopaedic surgeons/traumatologists (OS/T). *Aims.* The aims of the study were to obtain information about the path patients take to myeloma diagnosis, what non-haematological/non-oncological medical professionals do to detect myeloma, the time necessary to detect myeloma, and steps required to avoid delays in myeloma diagnosis. *Methods.* A survey of 303 physicians from 56 countries (91.4% European), including 90 GP/FD (29.7%) and 206 OS/T (68.0%), was conducted via self-administered questionnaire including ten multiple-choice questions. In addition, 349 myeloma patients (MP) and myeloma patient relatives (MPR) from 37 countries of treatment (90.3% European), including 239 MP (68.5%) and 110 MPR (31.5%), completed a corresponding questionnaire with nine multiple-choice questions. *Results.* MP/MPR (n=236/109) stated the most frequent symptoms experienced before initial doctor consultation were back pain (45.8%/59.6%), tiredness/weakness (35.2%/37.6%), bone pain (26.7%/36.7%), recurrent infections (16.5%/17.4%), shortness of breath (14.4%/13.8%) and bone fractures (11.4%/11.9%). As a result, the most frequently consulted doctors according to MP/MPR (n=236/108) were GP/FD (64.4%/60.2%), haematologists (8.1%/5.6%) and OS (6.4%/5.6%). From there, MP/MPR (n=238/106) stated, the most frequent referrals were to haematologists (41.6%/24.5%), oncologists (10.5%/11.3%), OS (9.7%/11.3%), GP/FD (6.7%/7.5%) and rheumatologists (5.5%/6.6%). GP/FD (n=90) usually treat back pain (88.9%), tiredness/weakness, bone pain, shortness of breath (60.0% each), and recurrent infections (58.9%); OS/T (n=206) usually treat bone fractures (82.4%), bone pain (68.9%) and back pain (67.5%). Confronted with these symptoms, routine tests by GP/FD (n=89) include blood test (93.3%), x-ray of bones (75.3%) or urine test (68.5%); OS/T (n=204) would do x-ray of bones (90.7%), blood test (73.0%), MRI (51.0%) or CT scan (45.6%). However, 65.9% of GP/FD (n=88) and 47.5% of OS/T (n=202) were not very familiar/not familiar at all with myeloma, 80.7% of GP/FD (n=88) and 63.3% of OS/T (n=199) rarely/never detected myeloma, and 60.7% of GP/FD (n=89) and 46.8% of OS/T (n=201) rarely/never referred patients to myeloma specialists. MP/MPR (n=230/108) stated that myeloma is mainly detected by haematologists (47.0%/47.2%), GP/FD (13.5%/10.2%), oncologists (8.3%/11.1%) and OS (6.1%/3.7%). According to MP/MPR (n=200/104), 44.5%/63.5% of patients received treatment for one/more symptoms before myeloma detection, including (n=89/66) pain treatment (33.7%/42.4%), physiotherapy/chiropractor/osteopath treatment (14.6%/21.2%) and orthopaedic interventions (11.2%/13.6%). According to MP/MPR (n=229/109), 76.0%/63.3% of patients saw 1-3 doctors before myeloma detection, and 23.1%/34.9% of MP/MPR stated it took 4 doctors or more to detect myeloma. According to MP/MPR (n=231/108), the average time for detecting myeloma is 186.8 days. According to GP/FD (n=89), OS/T (n=196) and MP/MPR (n=217/109), the most important steps to avoid delays in myeloma diagnosis are better information for (75.3%/71.9%/57.1%/67.9%), and better education of, medical professionals (53.9%/45.9%/40.1%/49.5%). *Summary/Conclusions.* Little awareness of myeloma among GP/FD and OS/T most likely contributes to delays in myeloma diagnosis. Related information and education should concentrate on GP/FD.

0939a

LYMPHOCYTE ABNORMALITIES WITHIN GAUCHER DISEASE MAY PREDISPOSE TO AN ELEVATED RISK OF HAEMATOLOGICAL MALIGNANCY

R Ayto, R Baker, J North, M Reed, A Mehta, D Hughes

Free Hospital, London, United Kingdom

Background. Gaucher disease (GD), the most common lysosomal storage disorder, secondary to an inherited deficiency of glucocerebrosidase. GD is associated with an increased incidence of polyclonal gammopathy, monoclonal gammopathy of undetermined significance and multiple myeloma. Monocyte-derived lipid laden macrophages or Gaucher cells are the cellular hallmark of Gaucher disease but relatively little is known about lymphocyte abnormalities in this condition. *Aims.* To demonstrate numerical and functional abnormalities of lymphocytes from GD patients. *Methods.* Patients with GD were recruited from the Royal Free Hospital Lysosomal Storage Disorders Unit together with age-matched healthy controls. Lysosomal glucocerebrosidase activity of peripheral blood mononuclear cells was determined by flow cytometry, utilizing the substrate fluorescein di-β-glucopyranoside (FDGlu). Membrane dysfunction was assessed by determining co-localization of lysotracker-red and BODIPY – lactosylceramide by fluorescent microscopy. Lymphocyte subsets were identified by immunostaining of CD19, CD4, CD8, CD56, 6B11 and CD3. Killing assays were performed using various effector:target ratios of IL-2 stimulated peripheral blood mononuclear cells (effector cells) and PKH26 labeled-K562 cells (target cells). The nuclear stain TO-PRO-3 iodide was used as a marker of cell death. *Results.* There was no difference in the proportion of lymphocytes in controls, treated GD patients or untreated GD patients. Membrane dysfunction was demonstrated in GD lymphocytes by accumulation of BODIPY within lysosomes. Glucocerebrosidase activity was significantly less in GD lymphocytes ($P<0.01$), CD4 T-cells ($P<0.01$), CD8 T-cells ($P<0.01$), NK-T cells ($P<0.05$), NK-T like cells ($P<0.05$) and B-cells ($P<0.01$) compared to controls. Immunophenotyping revealed a reduced percentage of CD4 lymphocytes ($P<0.05$), CD3-veCD56+ve NK-T cells ($P<0.05$) and CD3+ve6B11+ve invariant NK-T cells ($P<0.01$) compared to controls. There was an elevated number of CD3+veCD56+ve NK-T like cells ($P<0.01$) and a significantly lowered CD4:CD8 ratio ($P<0.0001$) in GD patients. Further functional anomalies demonstrated enhanced killing of the K562 myeloid cell line by control peripheral blood mononuclear cells compared to GD patients in killing assays at effector:target ratios of 40:1 ($P<0.01$), 20:1 ($P<0.05$) and 10:1 ($P<0.05$). *Conclusion.* GD lymphocyte subsets have statistically less glucocerebrosidase activity than controls and have demonstrable membrane dysfunction. Differences in the lymphocyte profile including a low CD4:CD8 ratio plus reduced NK-T and invariant NK-T cell numbers may contribute to an elevated risk of malignancy. Killing assays additionally support the impaired functionality of GD lymphocytes and raise the question of decreased tumor surveillance.

Myeloma and other monoclonal gammopathies - Clinical 3

LENALIDOMIDE IN COMBINATION WITH MELPHALAN AND DEXAMETHASONE IN PATIENTS WITH NEWLY-DIAGNOSED LIGHT-CHAIN (AL)-AMYLOIDOSIS: A MULTICENTER PHASE I/II DOSE ESCALATION STUDY

G Moreau,[1] A Jaccard,[2] L Benboubker,[1] B Royer,[1] X Leleu,[1] F Bridoux,[1] G Salles,[1] V Leblond,[1] M Roussel,[1] M Alakl,[3] O Hermine,[1] JL Harousseau,[1] JP Fermand[1]

[1]University Hospital, Nantes, France; [2]Department of Hematology, Limoges, France; [3]Celgene, Paris, France

Introduction. The combination of melphalan and dexamethasone (M-dex) is widely used in patients with newly diagnosed AL-amyloidosis, with hematologic and organ response rates of 50 and 40%, respectively (Jaccard, New Engl J Med 2007). Lenalidomide has also been evaluated, mainly in the relapse setting, and the initial dose of 25 mg/day was poorly tolerated. However, a 15 mg/day dose regimen was well tolerated and effective, with both hematologic and organ responses (Dispenzieri, Blood 2007 & Sanchorawala, Blood 2007). Combining M-dex with lenalidomide could increase the response rate but the toxicity of this regimen is still unknown. Thus we have initiated a multicenter single-arm open-label phase I/II dose escalation study of lenalidomide administered in combination with M-dex. *Patients and methods.* The primary endpoint was the incidence of dose limiting toxicities (DLT) during the first cycle of lenalidomide at a given dose level in order to determine the maximum tolerated dose (MTD). In addition to melphalan 0.18 mg/kg/day from day 1-4 of each 28 day cycle and dexamethasone 40 mg/day from day 1- 4 of each 28 day cycle, patients were successively exposed to escalating doses of lenalidomide (5, 10, 15 and 20 mg once daily on days 1-21 of a 28 day cycle). Nine cycles were planned at each dose level, according to safety and efficacy. DLT was defined using National Cancer Institute common toxicity criteria during the first 4 weeks of treatment (one cycle) as the following: at least grade 2 cardiac arrhythmia, at least grade 3 non hematologic toxicity, grade 4 neutropenia lasting >7 days or any other Grade 4 hematologic toxicity, or treatment delay due to toxicity that occurred during the first cycle. Organ involvement and the response to therapy were evaluated according to the international consensus guidelines (Gertz Am J Hem 2005). *Results.* From 03/2008 to 01/2009, 27 patients were enrolled. 1 patient withdrew consent after the first month of therapy and was thereafter lost to follow-up. No DLT was observed among the patients treated at 5 (3 patients), 10 (4 patients) and 15 mg lenalidomide/day (12 patients). 4 / 7 patients treated in cohort 4 at the dose of 20 mg lenalidomide/day experienced DLT, grade 4 hematologic toxicity and treatment delay due to toxicity; thus 15 mg lenalidomide/day, in combination with M-dex, was considered as the MTD. With a median follow-up of 16 months, 21/26 patients (80.8%) are alive. Five deaths were observed, due to progressive disease in 4 cases (median time from diagnosis 1 month, 1 to 3), or cholangiocarcinoma in 1 case (7 months after the diagnosis of AL-amyloidosis). Hematologic and organ responses were observed in 58 and 50% of the cases, respectively. At the reference date of Feb1st, 2010 none of the responding patients experienced progression, and all were able to receive 9 cycles according to the protocol. *Conclusion.* The recommended dose of lenalidomide in combination with M-dex in subjects with AL-amyloidosis previously untreated is 15 mg/day (days 1-21 of a 28 day cycle). Response and survival rates compare favourably with those achieved with M-dex alone. A prospective phase III trial comparing M-dex with M-dex lenalidomide should be valuable.

0941

PHASE III STUDY OF ENOXAPARIN VERSUS ASPIRIN VERSUS LOW-DOSE WARFARIN AS THROMBOPROPHYLAXIS FOR PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA TREATED UPFRONT WITH THALIDOMIDE-CONTAINING REGIMENS

M Cavo,[1] A Palumbo,[2] S Bringhen,[2] F Di Raimondo,[3] F Patriarca,[3] D Rossi,[3] A Levi,[3] M Offidani,[3] V Montefusco,[3] F Narni,[3] R Zambello,[3] G Benevolo,[3] M Grasso,[3] A Falcone,[3] P Musto,[3] T Guglielmelli,[3] F Gherlinzoni,[3] D Gottardi,[3] C Musolino,[3] N Di Renzo,[3] L Masini,[3] C Cangialosi,[3] F Dore,[3] S Ballanti,[3] S Storti,[3] E Angelucci,[3] R Vallone,[3] V Magarotto,[3] F Morabito,[3] P Tosi,[4] M Boccadoro[2]

[1]Istituto di Ematologia Seragnoli, Bologna, Italy; [2]Division of Hematology, University of Turin, Italy; [3]GIMEMA Italian Myeloma Network, Bologna, Italy; [4]Seràgnoli Institute of Hematology, University of Bologna, Italy

Thalidomide as part of upfront therapy for multiple myeloma (MM) is associated with an increased risk of venous thromboembolism (VTE) which necessitates routine prophylaxis. Controversies exist concerning the best thromboprophylactic regimen to be used in these patients. To address this issue, we designed a phase III study aimed at prospectively comparing low molecular weight heparin (LMWH) (Enoxaparin 40 mg/d) with low-dose aspirin (ASA) (100 mg/d) with fixed low-dose warfarin (WAR) (1.25 mg/d) in MM patients treated with regimens incorporating thalidomide. Nine hundred and ninety one patients with newly diagnosed MM were primarily randomized to receive the following induction treatments: 1) Velcade-Thalidomide-Dexamethasone (VTD) (Velcade, 1.3 mg/m^2 twice weekly for 2 weeks; Thalidomide, 200 mg/d; Dexamethasone, 320 mg per cycle); 2) Thalidomide-Dexamethasone (TD) (Thalidomide 200 mg/d; Dexamethasone 320 mg per cycle); 3) Velcade-Melphalan-Prednisone (VMP) (Velcade, 1.3 mg/m^2 twice weekly for 2 weeks; Melphalan, 9 mg/m^2 d 1-4; Prednisone, 60 mg/m^2 d 1-4); 4) Velcade-Melphalan-Prednisone-Thalidomide (VMPT) (Velcade, Melphalan and Prednisone as in VMP, with added Talidomide, 50 mg/d). Patients randomly assigned to VTD or TD or VMPT were subsequently randomized to receive anticoagulation prophylaxis with either LMWH or ASA or WAR. By the opposite, patients randomized to Velcade-Melphalan-Prednisone (VMP) did not receive any prophylaxis and were used as controls. Study end points included incidence of VTE, acute cardiovascular events, sudden death, bleeding and any other serious adverse events. The frequency of major risk factors for VTE was similar in the three groups of patients receiving different antithrombotic prophylaxis. The incidence of VTE was 5% in the LMWH group, 6% in the ASA group and 8% in the WAR group (p not significant). The corresponding value in the VMP group was 2%. Median times to onset of VTE for patients who received LMWH or ASA or WAR were 4.7, 2.4 and 2.4 months, respectively. Patients treated with VTD and VMPT had a lower, albeit not statistically significant (P=0.08), incidence of VTE (5%) in comparison with those on TD (8%). Cardiovascular events with LMWH, ASA and WAR were 2%, 1% and 0.5%, respectively. The risk of bleeding events was higher with ASA (3%) in comparison with WAR (1%) (p not significant). The incidence of combined thrombosis, bleeding and cardiovascular events was 9% in the LMWH group, 10% in the ASA group and 9.5% in the WAR group (p not significant). In conclusion, the overall incidence of VTE in the three thromboprophylactic groups was less than 10%, a value not superior to that expected during the natural course of MM. LMWH, ASA and WAR are likely to be effective thromboprophylactic treatments in standard-risk MM patients receiving thalidomide-based induction regimens.

0942

IMPROVED PROGRESSION-FREE SURVIVAL AND OVERALL SURVIVAL WITH THALIDOMIDE MAINTENANCE THERAPY IN MULTIPLE MYELOMA: A META-ANALYIS OF RANDOMIZED TRIALS IN 2274 PATIENTS

C Hahn-Ast, M von Lilienfeld-Toal, P van Heteren, S Mückter, O Renz, C Leyendecker, P Brossart, A Glasmacher

Universitätsklinikum Bonn, Bonn, Germany

Background. A meta-analysis (Hicks *et al*. Cancer Treat Rev 2008) from four randomized trials testing maintenance thalidomide in patients with multiple myeloma (MM) showed no significant improvement in overall survival (OS). After publication of the article, one of the included trials was retracted and new studies or updates of previous data were published. *Aims.* A new meta-analysis was performed to re-evaluate the influence of thalidomide maintenance on OS in patients with MM. In addition, we also analysed progression-free survival (PFS) and toxicity. *Methods.* PubMed, the Cochrane Library and conference proceedings from ASH, ASCO, IMW, and EHA were searched using the headings "myeloma"and "thalidomide", lastly in January 2010. Studies were included if they were randomized controlled trials (RCTs) of patients with MM receiving thalidomide maintenance treatment as monotherapy or combination therapy. Data were pooled using the random effects model. Measures of treatment effect were hazard ratios (HR) for survival data and relative risk (RR) for toxicity. When not available from the articles, HRs were estimated using the methods of Parmar *et al.*. (Statist Med 1998). *Results.* Nine RCTs of thalidomide maintenance therapy (5 published as full papers, 4 in abstract form) were identified. Three trials were excluded because no survival data were reported. The six remaining trials included 2274 patients and compared thalidomide as monotherapy (one trial) or combination therapy (corticosteroids two trials, corticosteroids + interferon one trial, interferon one trial and pamidronate one trial) with interferon (2 trials), interferon + dexamethasone (2 trials), prednisolone (one trial) or no maintenance (one trial). Five trials included patients with newly diagnosed MM, one trial included newly diagnosed and relapsed/refractory patients. Prior therapy was autologous stem cell transplantation (four trials) or conventional chemotherapy (two trials). In three trials thalidomide was also part of the induction regimen. PFS was significantly improved with maintenance thalidomide (HR 0.64, 95%CI 0.56-0.73, P<0.001). The effect was similar in trials with or without prior thalidomide induction treatment. Interestingly, OS was also improved with maintenance thalidomide (HR 0.70, 95%CI 0.55-0.89, P=0.004). In the subgroup of trials with prior thalidomide induction, the effect did not reach significance (HR 0.78, 95%CI 0.60-1.01, P=0.06). No significant heterogeneity among all RCTs existed between PFS or OS HRs (I^2=23%, P=0.26 and I^2=48%, P=0.09 respectively). Toxicity was not significantly different between thalidomide and comparators except for grade 3/4 neuropathy, which was worse in the thalidomide arm (RR 5.57, 95%CI 2.37-13.1, P<0.001). The rate of thromboembolic events (TE) grade 3/4 was reported in four trials. No significant difference was detected although there was a trend to more thromboembolic events in the thalidomide arm (RR 1.68, 95%CI 0.96-2.95, P=0.07). *Conclusion.* In our meta-analysis we found an improved PFS and for the first time also an improved OS for thalidomide maintenance therapy in patients with MM. This effect was accompanied by a higher rate of grade 3/4 neuropathy whereas the rate of TE was not increased.

Supported by Celgene Pharma GmbH and Leukämie-Initiative Bonn e.V.

THE ROLE OF THALIDOMIDE MAINTENANCE FOLLOWING HIGH DOSE THERAPY IN PATIENTS WITH MULTIPLE MYELOMA

J Bila,[1] D Lekovic,[1] M Smiljanic,[1] A Sretenovic,[1] D Vujic,[2] D Veljkovic,[2] D Antic,[1] D Sefer,[1] N Kraguljac,[1] B Andjelic,[1] M Todorovic,[1] I Elezovic,[1] D Tomin,[1] M Gotic,[1] B Mihaljevic[1]

[1]Institute of Hematology, Belgrade, Serbia; [2]Institute Dr.Vukan Cupic, Belgrade, Serbia

Background. Thalidomide has well established role in the therapy of multiple myeloma (MM) referring mainly to induction or consolidation therapy. Limitations of conventional chemotherapy initiated application of the high-dose treatment and autologous stem cell transplantation (ASCT) in MM patients (pts). The aim of study was to analyse results of the thalidomide maintenance following high dose therapy in MM pts. Patients and *Methods.* The study included 50 newly diagnosed MM pts (29 male/ 21 female, mean age 53 yrs, range 41-65). IgG myeloma was diagnosed in 28pts, IgA in 10pts, light chains in 10pts and non-secretory in 2pts. According to the clinical stage (CS, Durie-Salmon), patients were distributed as follows: II 19pts; III 31pts. Regarding ISS score, the group included: ISS1 8pts; ISS2 18pts; ISS3 24pts. Renal impairment was present in 3pts. Conventional induction treatment according to the VAD regimen (mean no. 4 cycles, range 3-6cycles) was applied in 35/50pts (70%). In 15/50 pts (30%) was applied induction treatment according to the CTD regimen (mean no. 4 cycles, range 3-6cycles). Stem cell mobilization was performed in all pts by combination of the CAD chemotherapy and G-CSF. High-dose therapy (HDT) with Melphalan 200 mg/m^2 and ASCT were performed 4-8 weeks after mobilisation. In the pts group treated with VAD induction, in 9pts who failed to achieve CR/VGPR (EBMT criteria), tandem ASCT was performed during average period 6m (range 3-12m) after first ASCT. In 10/35pts (27%) treated with VAD induction, Alfa-Interferon maintenance was applied after ASCT. Thalidomide maintenance (100 mg/day) was applied in 35/50 pts (70%) treated with VAD/CTD induction with median duration 19m (range 6-36 m). Routine thromboprophylaxis was applied in all pts receiving

thalidomide. *Results.* In the group of pts treated with VAD, VGPR was achieved in 4/35 pts (11%), and PR in 25/35pts (72%) after induction treatment. After HDT, CR was achieved in 7/35pts (20%); VGPR in 9/35pts (26%); and PR in 14/35pts (40%). Further improvement in response was obtained after tandem ASCT by achievement of VGPR in 8/9pts. In the group of pts treated with CTD, CR was achieved in 3/15pts; VGPR/PR in 8/15pts. Median follow-up was 26m (18-60m). The 3-yrs probability of event-free and relapse-free survival was significantly improved in the group treated with CTD induction and thalidomide maintenance (VAD+HDT+aIFN: EFS 20%, RFS 25% *vs.* VAD+HDT+Thal: EFS 30%, RFS 37% *vs.* CTD+HDT+Thal: EFS 45%, RFS 51%, P<0,0025). Furthermore, according to the analysis of 3-yrs probability, pts treated with thalidomide maintenance had a significantly longer overall survival (VAD+HDT+aIFN: 70% *vs.* VAD+HDT+Thal: 77% *vs.* CTD+HDT+Thal: 85%, P<0,0039). The main reason for thalidomide discontinuation was peripheral neuropathy recorded in 21/35pts (60%) with occurrence of grade 3-4 toxicity in 4/35pts. Thrombosis was not a risk in this setting. *Conclusion.* Thalidomide maintenance improves quality and duration of the response, as well as overall survival after HDT, mainly due to the better quality of response in the thalidomide group and further reduction of tumor mass after HDT. However, recommended duration of such treatment is to be defined predominantly due to the limitations caused by the toxic effects.

Klinik fuer Innere, Salzburg, Austria; [7]Royal Adelaide Hospital, Adelaide, Australia; [8]Wilhelminenspital der Stadt Wien. Medizinische Abteilung mit Onkologie, Wien, Austria; [9]University College Hospital, Galway, Ireland; [10]Hospital Germans Trias i Pujol, Barcelona, Spain; [11]Peter MacCallum Cancer Centre, East Melbourne, Australia; [12]Mater Private Medical Centre, Brisbane, Australia; [13]Celgene Corporation, Summit, NJ, USA; [14]Celgene International, Boudry, Switzerland

Background. Lenalidomide is an oral IMiD® immunomodulatory compound with established clinical efficacy and safety in patients with multiple myeloma (MM). Lenalidomide plus dexamethasone (Len+Dex) was well tolerated and demonstrated significant improvements in response and favorable overall survival compared with Placebo+Dex in two pivotal phase III registration trials in patients with relapsed/refractory MM (RRMM; Weber *et al.*, NEJM 2007; Dimopoulos *et al.*, NEJM 2007). *Aims.* In this phase III study, Len was administered to 587 patients with RRMM to assess the safety of Len+Dex and its impact on quality of life (QoL). *Methods.* Eligible patients with progressive disease (PD) after >2 cycles of anti-myeloma treatments, including thalidomide and bortezomib, or with PD having relapsed after treatment were enrolled into 3 geographic cohorts (Spain, UK/Ireland, and Austria/Australia). Patients received Len (25mg/day, day 1-21 every 28-day cycle) plus pulsed high-dose Dex (40mg/day, day 1-4, 9-12, and 17-20 every 28-day cycle for Cycles 1-4). Starting at Cycle 5, Dex was reduced to 40mg/day for days 1-4 every 28-day cycle. Deep vein thrombosis (DVT) prophylaxis with aspirin, warfarin, or low-molecular-weight heparin was strongly recommended. Bisphosphonates, erythropoietin, and antibiotics were administered at Investigator's discretion. The primary endpoint was safety of Len+Dex as measured by physician-reported adverse events (AEs; MedDRA 9.0 and NCI CTCAE 3.0). EORTC QLQ C-30 and QLQ MY-20 questionnaires at baseline and week 24 provided QoL outcome assessments. *Results.* 587 patients receiving ≥1 dose of Len+Dex were evaluated for safety and QoL. Median age was 65 years (273 [46.5%] were >65 years). During the study, 116 (19.8%) patients had ≥1 dose reduction due to treatment-emergent AEs. Prior to enrollment, 437 (74.4%) patients had received thalidomide, 209 (35.6%) had received bortezomib, 77 (13.1%) patients had a history of DVT, and 350 (59.6%) had a history of peripheral neuropathy. AEs observed in this study were consistent to those previously reported with Len+Dex. Grade 3/4 hematologic events were experienced by 267 (45.5%) patients, including neutropenia in 207 (35.2%) patients (Grade 3:167 [28.4%], Grade 4: 40 [6.8%]), thrombocytopenia in 89 (15.2%), anemia in 80 (13.6%), and febrile neutropenia in only 21 (3.6%). DVT (all grades) was experienced in 37 (6.3%), and new-onset peripheral neuropathy in 29 (4.9%) (Grade 3: only 1 [0.2%], no Grade 4). EORTC QLQ-30 revealed no significant median change (>5 points) from baseline in 14 of 15 scales for patients completing questionnaires at baseline and 24 weeks. Median fatigue increased in the UK/Ireland population (score 11.1). EORTC QLQ MY-20 revealed no significant median change from baseline of all scores except a statistically significant improvement in future perspective in Spanish patients (median 11.1), for patients completing questionnaires at baseline and 24 weeks. *Conclusions.* Len+Dex has previously been reported to significantly improve response and demonstrated favorable overall survival in patients with RRMM compared to Placebo+Dex. Despite co-treatment with high-dose Dex, preexisting neuropathy in >50% patients, prior MM treatment, and late disease course, patients were able to maintain median QoL scores over 24 weeks. High tolerability of Len+Dex in RRMM was also confirmed. (Data update at meeting).

THE COMBINATION OF LENALIDOMIDE WITH LOW DOSE DEXAMETHASONE AND CYCLOPHOSPHAMIDE IS AN EFFECTIVE REGIMEN FOR PATIENTS WITH PRIMARY SYSTEMIC (AL) AMYLOIDOSIS: RESULTS OF A PHASE 1/2 STUDY

M Roussou,[1] E Kastritis,[1] M Gavriatopoulou,[1] M Migkou,[1] K Pamboukas,[1] D Gogos,[2] K Liapis,[3] E Michalis,[2] S Delimpasi,[3] E Psimenou,[1] S Toumanidis,[1] S Kontoyannis,[1] E Terpos,[1] M Dimopoulos[1]

[1]University of Athens School of Medicine, Athens, Greece; [2]Georgios Gennimatas General Hospital, Athens, Greece; [3]Evangelismos General Hospital, Athens, Greece

Background. Lenalidomide (R) and cyclophosphamide (C) have shown activity in primary systemic (AL) amyloidosis. We designed a phase I/II trial of the combination RdC, with low-dose dexamethasone (d), in AL. *Aims.* Primary objective was to determine the MTD for RdC and to assess hematologic response. *Patients/Methods.* Patients received dexamethasone 20 mg on days 1-4, cyclophosphamide on days 1-10, lenalidomide on days 1-21 every 28 days, according to dose level (level 0: R 10 mg, C 50 mg; level 1: R 10 mg, C 100 mg; level 2: R 15 mg, C 100 mg). In the phase I part of the study, patients were observed for 2 cycles for determination of DLT, according to a standard 3+3 design. Patients with a creatinine ≤2.5 mg/dL and adequate hepatic function were enrolled. All patients received anticoagulation. *Results.* So far, 31 patients have been enrolled in the study (16 in phase I, 15 in phase II). In the phase I study, 3 patients were enrolled in dose level 0, 7 in dose level 1 and 6 in dose level 2. Dose level 2 is being further explored; 15 patients have been enrolled in phase II and accrual is ongoing. So far, 12 patients have received ≥6 cycles and 8 have completed 12 cycles. Heart was involved in 62% of patients, kidneys in 62%, liver in 12% and 19% had AL-related peripheral neuropathy; 95% of patients were Mayo stage II or III and 65% were previously untreated. Hematologic response rate, for patients who received ≥2 cycles (n=26), was 58% for all cohorts and 63% for patients treated at dose level 2. Median time to hematologic response was 2.9 months for all patients and 1.4 months for those treated at dose level 2. Organ responses have been recorded in 5 patients so far. After a median follow-up of 10 months, 14 patients have died (9 due to progressive heart amyloid). The most common hematologic toxicities were anemia (grade 3/4 in 17%) and neutropenia (grade 3/4 in 19%). Most common non-hematologic toxicities included infection (grade ≥3 in 22%), fatigue (grade ≥3 in 9%), and rash (in 22%, grade 3 in 4%). In parallel, and on a compassionate basis, AL patients with creatinine >2.5 mg/dL or on dialysis, were offered RdC with lenalidomide dose adjusted according to CrCl. Initially lenalidomide was given 15 mg every other day for CrCl <30 ml/min or 15 mg thrice per week on the day after dialysis, but due to toxicity, lenalidomide dose was reduced to 10 mg. So far, 13 patients have been treated with attenuated-dose RdC: 3 patients achieved a CR, one achieved a cardiac and one a liver response. The non-hematologic toxicity was significant including fatigue (53%), infections (38%), rash (31%), diarrhea (15%) and hyponatriemia (15%). Three patients discontinued treatment due to toxicity after the first cycle. *Summary/Conclusions.* RdC is an effective oral regimen for patients with AL amyloidosis. Toxicity is manageable for patients with serum creatinine <2.5 mg/dL but can be significant for patients with more severe renal impairment.

OUTCOME OF AUTOLOGOUS STEM CELL TRANSPLANTATION FOR AL-AMYLOIDOSIS IN SWEDEN

S Rosengren,[1] L Ahlberg,[2] K Forsberg,[3] S Lenhoff,[4] U Mellqvist,[5] H Nahi,[6] K Carlson[7]

[1]Department of Haemathology, Uppsala University Hospital, Uppsala, SwedenL; [2]Linköping University Hospital, Linköping, Sweden; [3]Umeå University Hospital, Umeå, Sweden; [4]Lund University Hospital, Lund, Sweden; [5]Sahlgrenska University Hospital, Göteborg, Sweden; [6]Karolinska University Hospital, Stockholm, Sweden; [7]Uppsala University Hospital, Uppsala, Sweden

Background. High-dose melphalan with autologous stem cell transplantation (HDM/ASCT) is considered to be an effective therapy in AL-amyloidosis, but with high treatment related mortality. In Sweden, patients with AL-amyloidosis have been treated with HDM/ASCT since 1994, and no report has been made on the outcome. *Aims.* To evaluate all patients with AL-amyloidosis treated with HDM/ASCT in Sweden regarding response, survival and treatment related mortality. *Methods.* Information was collected on all patients treated at the six centra in Sweden where HDM/ASCT was performed. Only patients with amyloid classified as AL were included. Patients with myeloma or lymfoma, and those with only soft tissue involvement were excluded. Criteria from the 10th International Symposium on Amyloid and Amyloidosis (2005) were used to establish organ involvement, response and progression. *Results.* 67 patients treated with HDM/ASCT between 1994 and 2009 were evaluated. Median age at time of treatment was 58 years (range 41-69). 29 patients (43%) had cardiac involvement, 52 (78%) had kidney involvement and 17 (25%) had liver involvement. In 5 patients (7.5%) all three of these organs were involved, in 24 patients (36%) two of the organs were involved and in 35 patients (52%) one of the organs was involved. 3 patients (4.5%) had only gastrointestinal involvement. Response, either organ or haematologic, was seen in 36 patients (54%). Median time to response was 4.5 months (range 1-24). Of all 67 patients, 41 patients (61%) were alive at time of evaluation. Median follow up was 49 months (range 1-176). For the whole patient group overall median survival was not reached. Whereas for patients with cardiac involvement median survival was 28 months. Mortality within 100 days from ASCT was 13.4%. Causes of death were sudden cardiac death (n=3), heart failure (n=3), sepsis (n=2) and liver failure (n=1). *Conclusions.* HDM/ASCT leads to response and prolonged survival to a substantial degree. For patients with cardiac involvement survival is worse. Treatment related mortality is high (13.4%), but on a level with what is seen in other studies.

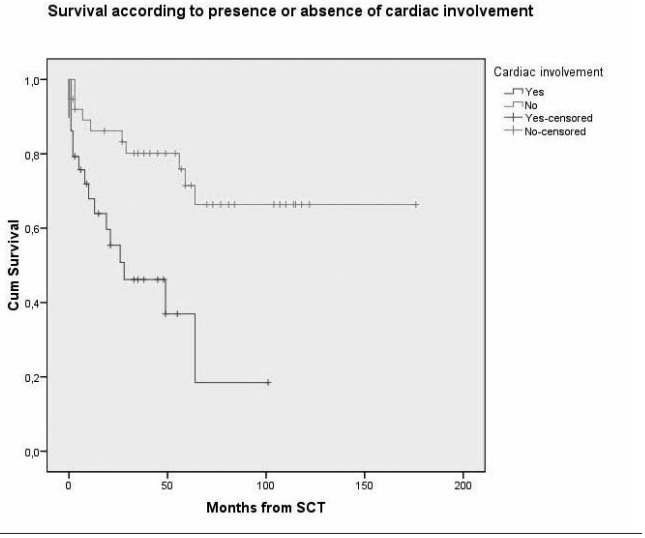

Figure.

IN VIVO VISUALIZATION OF AL- AMYLOID DEPOSITS IN THE HEART USING [11C]PIB AND [11C]ACETATE AND POSITRON EMISSION TOMOGRAPHY (PET)

S Rosengren,[1] G Antoni,[2] J Sörensen,[3] G Wikström,[4] J Axelsson,[2] K Carlson,[1] O Vedin,[4] B Långström,[5] P Westermark[6]

[1]Department of Haemathology, Uppsala University Hospital, Uppsala, Sweden; [2]Uppsala Imanet AB, Uppsala, Sweden; [3]Department of Nuclear Medicine, Uppsala University Hospital, Uppsala, Sweden; [4]Department of Cardiology, Uppsala University Hospital, Uppsala, Sweden; [5]Department of Biochemistry and Organic Chemistry, Uppsala University, Uppsala, Sweden; [6]Department of Genetics and Pathology, Uppsala University, Uppsala, Sweden

Background. SAP scintigraphy is used for visualizing systemic AL amyloidosis, however the method is not reliable regarding amyloid deposits in the heart. *Aims.* To develop a method for visualizing amyolid deposition in the myocardium. *Methods.* After informed consent was obtained, 7 patients with AL amyloidosis affecting the heart and 2 healthy volunteers were examined with PET using tracers [11C]PIB and [11C]acetate. PIB (Pittsburgh Compound B) binds to amyloid. When combined with 11C, [11C]PIB is a PET amyloid imaging agent, whereas [11C]acetate measure blood flow in the heart. The amyloid type AL was confirmed with immunochemistry. Heart involvement was diagnosed either directly by myocardial biopsy (n=2), or indirectly by identification of AL amyloid in biopsy from another location in combination with UCG findings consistent with amyloid deposition. *Results.* All patients showed [11C]PIB retention in the heart whereas the uptake in healthy volunteers followed blood kinetics without any sign of retention. Our data thus indicates that we can visualize amyloid deposits in the myocardium of patients diagnosed with systemic AL amyloidosis measured as uptake and retention of the radiotracer [11C]PIB. [11C]PIB and [11C]acetate had different uptake patterns in patients which shows that [11C]PIB uptake is not representing blood flow and probably is a measure of binding to amyloid. Preliminary evaluation of the data show different patterns and degree of [11C]PIB uptake, which tentatively could be interpreted as heterogeneous amyloid deposits in the heart. We attempt to develop a tracer kinetic model, based on the assumption that the [11C]PIB uptake represents binding to amyloid, to quantify the amounts of amyloid deposits in the myocardium which could be correlated with the severity of the disease. *Conclusions.* The use of [11C]PIB and PET could be a method to study the distribution of deposits in systemic amyloidosis affecting the heart and most importantly, a non-invasive method for treatment follow-up.

0948

AN ANALYSIS OF THE ENDOCRINE DISEASE ASSOCIATED WITH SYSTEMIC AL AMYLOIDOSIS

S Gibbs, M Vanderpump,[1] D Hutt, P Sattianayagam, J Pinney, N Wassef,[2] J Gillmore, H Lachmann, P Hawkins, A Wechalekar

National Amyloidosis Centre, London, UK; [1]Department of Endocrinology, Royal Free Hampstead NHS Trust, London, UK; [2]Department of Clinical Biochemistry, Royal Free Hampstead NHS Trust, London, UK

Background. Amyloid infiltration of the thyroid and testes has been previously reported but hormone function has not been studied in detail. *Aims.* We analysed the hormone profile of patients with systemic AL amyloidosis and correlated this with symptoms, extent of amyloidosis, and overall survival. *Methods.* All patients attending the National Amyloidosis Centre, UK with newly-diagnosed systemic AL amyloidosis between December 2008 and April 2009 were studied. Patients were tested for free T4 (FT4), thyroid stimulating hormone (TSH), luteinizing hormone (LH), follicule stimulating hormone (FSH), testosterone and sex hormone binding globulin (SHBG). They completed questionnaires for symptoms of hypothyroidism, date of menopause and erectile dysfunction. Analysis of amyloidotic organ involvement and function and medications potentially influencing hormone measurements was undertaken. *Results.* 79 patients (44 men, 35 women) were included, aged between 38 - 84 years (median 65 years). Cardiac involvement and autonomic neuropathy was observed in 50 (63%) and 21 patients (27%) respectively. Proteinuria >1g daily was seen in 66%, serum albumin <30 g/L in 30% and eGFR <30 mL/min in 19%. Symptoms of hypothyroidism were common: 62 patients complained of fatigue; 33 of excessive cold; 23 of constipation; 23 of deepening voice; 20 of low mood; and 8 of weight gain. 32 men (73%) had decreased or absent erectile function, 21 with autonomic neuropathy, low testos-

terone or both. All women were post-menopausal with no evidence of disease-related early menopause (all >51 years). Median TSH was 2.98 mU/L (range 0.19 - 15.95). A high TSH was observed in 19 patients (12 men, 7 women); only 2 had a low FT4 also (biochemically hypothyroid) with the other 17 patients having subclinical hypothyroidism. Eight were on medications that can confound measurements. Seven patients (2 men, 5 women) were on thyroxine. The median number of amyloidotic organs for those with high TSH and/or on thyroxine was 3 (range 1-4) *vs.* 2 (range 1-6) for other patients. There was no difference in median symptom scores between those with abnormal thyroid measurements and/or on thyroxine and other patients. Median testosterone in men was 10.5nmol/L (range 2 - 24.8). 21 men (49%) had low testosterone, 13 with erectile dysfunction, 9 with elevated FSH and/or LH. FSH was below normal in 1 man and 6 women. LH was below normal in 5 women. Raised SHBG was seen in 9 women and 30 men - this did not correlate with proteinuria, albumin or testosterone levels. 24 patients have died: 9/21 with thyroid profile abnormalities and/or who were on thyroxine (43%) compared to 15/58 (26%) without either characteristic (P=0.24). There was no difference in survival between low and normal testosterone men. *Conclusions.* Symptoms of hormone dysfunction are common in AL amyloidosis and are not reliable for predicting biochemical abnormalities. Interpretation of endocrine tests is complex due to medications and organ impairment. A third of patients had abnormal thyroid measurements and/or were on thyroxine, possibly associated with larger amyloidotic disease bulk. Low testosterone and impotence is common. With improving outcomes in AL amyloidosis, further analysis, including the role of hormone replacement should be undertaken.

0949

PREVALENCE OF MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE IN A DENSELY POPULATED, HIGHLY INDUSTRIALIZED AREA IN GERMANY

L Eisele,[1] J Dürig,[1] A Hüttmann,[1] U Dührsen,[1] A Führer,[1] S Kieruzel,[1] R Assert,[2] B Bokhof,[3] R Erbel,[3] K Mann,[3] KH Jöckel,[3] S Moebus[3]

[1]University Hospital Essen, Essen, Germany; [2]Department of Endocrinology and Division of Laboratory Research, Essen, Germany; [3]Heinz Nixdorf Recall Study Investigative Group, Essen, Germany

Background. We utilized the biobank of the ongoing population-based, prospective Heinz Nixdorf Recall study to determine the prevalence of monoclonal gammopathy of undetermined significance (MGUS) in the densely populated and highly industrialized Ruhr area in Germany. *Methods.* The Heinz Nixdorf Recall study cohort comprises 4814 men and women from 3 large adjacent cities. Subjects were randomly selected from statutory lists of residence and gave informed consent. We screened serum samples from the baseline examination which took place from 2000 until 2003. Standard serum electrophoresis was combined with parallel screening immunofixation electrophoresis (IFE) using pentavalent antisera (Hydragel 12 IF, Penta-Kit, Sebia, Fulda, Germany). Where a monoclonal band was visible or suspected, confirmatory IFE followed. All gels were evaluated independently by LE and AH. Definition of MGUS cases was based on common criteria including monoclonal protein concentration, laboratory results, and disease history. Direct standardization with U.S. population 2000 as reference was performed to compare results to those of Olmsted County, U.S., published by Kyle *et al*. To quantify the impact of the screening IFE in detecting monoclonal proteins, we re-evaluated standard electrophoresis strips using a mask covering the pentavalent tracks on the gels. *Results.* 165 MGUS cases were identified in a total of 4708 screened samples, translating into a prevalence of 3.5% (95% confidence interval, 3.0-4.1). The median age of MGUS cases was 63 years (range 47-75), 103 (62%) were of male gender, and we observed an increase in prevalence with increasing age. The age-standardized prevalence was 3.9% (95% CI 3.2-4.5) which was higher than that reported for Olmsted County (P<0.05). We found the following distribution of monoclonal protein isotypes: IgG 59%, IgA 17%, IgM 28%, biclonal 2.4%, kappa 55%, and lambda 44%. Concentrations of the monoclonal proteins ranged from unmeasurable - 22.4 g/L with a median of 5.3 g/l. After a median observational time of 5 years, 3 MGUS cases progressed to multiple myeloma and 1 case developed a diffuse large B-cell lymphoma, representing a progression rate of 0.5%/year (95% CI 0.13 - 1.3). After re-evaluation of >1000 gel strips with masked pentavalent tracks, 9 MGUS samples previously identified were not detected. All but one had unmeasureable M-protein concentrations. Notably, the sample with a measurable M-protein was identified as IgA and the protein was hidden within the physiologic beta fraction. *Conclusion.* The higher age-standardized prevalence of 3.9% in the Heinz Nixdorf Recall cohort compared with that reported by Kyle *et al*. and the differences in isotype distribution (IgG 59% *vs.* 69%, IgA 17% *vs.* 11%) may at least in part be explained by the different screening strategies. Our preliminary results suggest that screening IFE increases sensitivity to detect monoclonal proteins and may be especially helpful in detecting IgA monoclonal proteins. A complete analysis of the gel re-evaluation using the cover for the pentavalent tracks will be presented at the conference. Whether environmental factors might also contribute to the increase in prevalence is the focus of ongoing research.

0950

LENALIDOMIDE PLUS LOW DOSE DEXAMETHASONE AS FIRST LINE THERAPY IN PATIENTS WITH PRIMARY PLASMA CELL LEUKEMIA: PLANNED INTERIM ANALYSIS OF A PILOT STUDY FROM THE GIMEMA-ITALIAN MYELOMA NETWORK

P Musto,[1] F D'Auria,[1] MT Petrucci,[2] F Morabito,[2] F Nobile,[2] M Offidani,[2] F Di Raimondo,[2] A Falcone,[2] R Lerose,[1] E Zifarone,[1] A Zonno,[1] V Callea,[2] A Levi,[2] C Mazzone,[2] G Pietrantuono,[1] M Martorelli,[1] O Villani,[1] R Guariglia,[1] G Mansueto,[1] V Grieco,[1] G Bianchino,[1] A Neri,[2] K Todoerti,[3] P Omedè,[2] S Bringhen,[4] M Cavo,[4] M Boccadoro,[2] A Palumbo[4]

[1]IRCCS, Centro di Riferimento Oncologico della Basilicata, Rionero in Vulture, Italy; [2]Multiple Myeloma Network, Gimema, Italy; [3]Centro di Ricerca per lo Studio delle Leucemie, Fondazione IRCCS Policlinico, Milano, Italy; [4]Multiple Myeloma and Acute Leukemias Working Parties, Gimema, Italy

Background. Primary Plasma Cell Leukemia (PPCL) is an aggressive, rare variant of myeloma characterized by poor prognosis . Lenalidomide is an IMiD immunomodulatory agent with proven efficacy in myeloma. No data are currently available on the use of lenalidomide as first line therapy in PPCL. *Aims.* On March, 2009, we started an open-label, multicenter, exploratory, single-arm, two-stage study aiming to evaluate safety and antitumor activity of the lenalidomide/low dose dexamethasone combination (Rd) in previously untreated PPCL. The primary endpoint was response rate according to International Uniform Criteria. The secondary endpoints were TTP, PFS, OS, percentage of eligible patients able to undergo stem cell transplantation (SCT) after Rd, and safety. *Methods.* Newly diagnosed patients with PPCL receive lenalidomide at a dose of 25 mg daily for 21 days of each 28-day cycle. Oral dexamethasone is administered at a dose of 40 mg daily on days 1, 8, 15, and 22 for each 28-day cycle. After 4 cycles, patients achieving at least PR and not eligible for SCT continue until 8 cycles of full-dose Rd, if tolerated, followed by a maintenance dose of single agent lenalidomide equal to 10 mg/day on days 1-21 of each 28-day cycle. Patients responding after 4 Rd cycles and eligible for SCT proceed according to single Centre transplant policy. Patients not responding after 4 cycles or progressing during Rd treatment are considered off-study. Appropriate dose reductions, contraception methods and anti-thrombotic prophylaxis are required. *Results.* According to the Simon Optimal Two-Stage Adaptive Design, a planned interim analysis was done (Stage 1) to evaluate the first 12 enrolled patients (5 male, 7 female, median age 64, range 45-81), out of 22 total patients required to complete Stage 2 of the trial. At baseline, circulating plasma cells ranged from 655 to 34,000 × 10e9/L. Six patients had a moderate degree of renal failure (serum creatinine levels up to 2.6 mg/dL), five had increased LDH, three had extramedullary disease, nine had anemia and/or thrombocytopenia. Among 11 patients with cytogenetic analysis, nine had del13: two in combination with del17 and t(14;16), two with t(14;16), one with del17 and t(11;14), one with del17, one with t(4;14). One patient had del17 alone. After a median of 3 Rd cycles (range 1-5), 1 CR, 1 nCR, 3 VGPR, and 4 PR were achieved (ORR 75%). Two of responders underwent adequate peripheral blood stem cell collection followed by autologous SCT. One patient died during the first cycle because of progressive disease. Two patients developed extramedullary disease under Rd therapy, despite the complete clearance of circulating plasma cells. One of responders died in PR, due to causes unrelated to PPCL or treatment. Grade 3-4 hematological toxicities occurred in 8 patients. Two patients experienced pneumonia, one patient an intestinal perforation due to fecalith. After a median follow-up of 7 months, ten patients are alive (83.3%), eight of whom still responders. *Conclusions.* Rd is a promising initial therapy for PPCL patients. An update of this study, including SNP and GEP analyses, will be presented at the Meeting.

LONG, EVEN EXCEEDING 20 YEARS, SURVIVAL IN MULTIPLE MYELOMA

M Kraj, R Poglod, U Sokolowska, B Kruk, E Czajkowska

Institute of Hematology and Transfusion Medicine, Warsaw, Poland

The study reports the long-term survival of 600 multiple myeloma patients on conventional chemotherapy, with a follow-up of at least 10 years. The study was especially focused on estimation of real frequency of long-term survivals in patients with multiple myeloma and finding common clinical and laboratory features present in long-term surviving patients as possible good prognostic factors. Of 600 studied patients with multiple myeloma diagnosed before 2000 and treated in our Institute 88 (14.7%) survived over 7 years, including 45 (7.5%) over 10 years, 11 (1.8 %) over 15 years and 7 patients (1.1%) over 20 years (Table 1) from the disease diagnosis and beginning of antitumor treatment. The patients with long survival were younger (median age 55 years) at diagnosis than those in a whole studied group and had normal creatinine, calcium and beta2-microglobulin levels in the serum. Sixty eight percent of these patients presented I or II stage of clinical progression, 60% had IgG monoclonal protein and 58% showed osteolysis. Treatment with melphalan only, was given to 18 patients, 30 were treated with melphalan followed by vincristine, cyclophosphamide, BCNU, doxorubicin and prednisone or dexamethasone. Beginning from the time of diagnosis, polychemotherapy was given to 16 patients, 15 patients, besides chemotherapy, received radiotherapy or 60Co irradiation and 9 received new agents: thalidomide, bortezomib, lenalidomide. In 66% of evaluated cases the response to treatment was good and in remaining 34% of cases stabilization of the proliferative process was achieved. The mean duration of the treatment till achieving of partial response was 10 months, ranging from 2 to 89 months. The mean duration of the good therapeutic response was 70 months. Twelve patients are alive and further treated and 7 patients remain without treatment. The longest follow- up of a still living patient with multiple myeloma is 31 years after detection of monoclonal protein and 25 years after beginning of antitumor treatment. The longest follow-up of a still living patient with initially isolated bone involvement is 23 years after detection of the first bone lesion and 19 years, after generalization of the process. In 6 cases, the cause of death was acute myeloid leukemia in 5 cases solid tumors. In 2 patients with myeloid leukemia no plasma cell infiltrates were found at autopsy; it confirms curing multiple myeloma.

Table 1. Parients with myeloma surviving ≥ 20 years.

Case	Sex	Age	M-protein	Osteolysis	Main therapy	Survival years	Cause of death
1.	F	40	IgAκ	-→+	MP	33	myeloma progression
2.	F	53	IgGκ	-→+	M, Rtx	>25	
3.	M	40	IgGκ	+	Rtx, MP, VMCP	>23	
4.	F	52	IgGκ	-→+	VMBCP	22	myeloma progression
5.	F	41	0→BJκ	-→+	Surgical Rtx, M, VBCP	22	myeloma progression
6.	M	43	IgGκ	-	M, VBCP	20	myeloma progression
7.	F	57	BJλ	+	MP, VMCP	20	myeloid leukemia

Abbreviations: B- BCNU; C- cyclophosphamide; M-melphalan; P- prednisone, V-vincristine; Rtx-radiotherapy.

BORTEZOMIB-CONTAINING COMBINATIONS AS FRONT-LINE THERAPY IN PRIMARY PLASMA CELL LEUKEMIA: A RETROSPECTIVE STUDY FROM GIMEMA MULTIPLE MYELOMA AND ACUTE LEUKEMIA WORKING PARTIES

P Musto,[1] C Valentini,[2] F D'Auria,[1] C Musolino,[2] N Giuliani,[2] G Visco,[2] A Candoni,[2] A Gamberi,[2] S Bringhen,[2] E Zamagni,[2] D Onofrillo,[2] MT Villa,[2] A Falcone,[2] F Rossini,[2] V Pitini,[2] N Filardi,[2] G Quintini,[2] G Musuraca,[2] G Specchia,[2] G Semenzato,[2] N Di Renzo,[2] A Venditti,[2] L Mastrullo,[2] G Fioritoni,[2] F Ferrara,[2] M Cavo,[2] A Palumbo,[2] L Pagano[2]

[1]IRCCS, Centro di Riferimento Oncologico della Basilicata, Rionero in Vulture, Italy; [2]Multiple Myeloma and Acute Leukemias Working Parties, Gimema, Italy

Background and Aim. The aim of this study was to evaluate the role of chemotherapy combinations including bortezomib as first line therapy in primary plasma cell leukemia (PPCL), a rare variant of multiple myeloma, characterized by very poor prognosis. To this purpose, a retrospective survey was performed in 21 hematologic Italian Institutions of previously untreated patients with PPCL who had received bortezomib associated with other agents for the initial treatment of their disease. *Methods.* Twenty-nine unselected and previously untreated PPCL patients were collected (M/F ratio 1.3; mean age 62 years, range 47-82). Circulating plasma cells ranged from 10 to 95% (mean 39%). Median WBC count was 14.6 x 10e9/L (range 2.2-81). Variable degrees of renal impairment were observed in 14 patients. Seven patients had concomitant extramedullary disease. Cytogenetic/FISH abnormalities were observed in 14 out of 17 evaluated patients, the most frequent being complex caryotype (including various combinations of t(4;14), t(14;16), del17 and del13q. Bortezomib was given using the standard schedule of 1.3 mg/sqm days 1, 4, 8, 11, with an interval of 10 days between cycles. Nine patients received bortezomib in combination with dexamethasone and thalidomide (VTD), seven with dexamethasone alone (BD), seven with doxorubicin and dexamethasone (PAD), two with oral melphalan and prednisone (VMP), two with doxorubicin, dexamethasone and vincristine (PAD-V), one with melphalan, prednisone and thalidomide (VMPT) and one with cyclophosphamide and dexamethasone (BCD). A total number of 104 cycles was administered (mean 3.7, range 1-9). After bortezomib containing induction therapy, seven patients underwent double (n.4) or single (n.3) autologous stem cell transplantation (AuSCT), 4 patients underwent AuSCT followed by reduced intensity (RIC) allogeneic stem cell transplantation (Allo-SCT, one with an unrelated donor), while one patient underwent myeloablative Allo-SCT. *Results.* According to the International Uniform Response Criteria, twelve partial remissions, three very good partial remissions, and eight complete remissions were achieved (overall response rate: 79.3%). After a median follow-up of 24 months, sixteen patients are alive (55%): twelve out of them remain in remission phase, four relapsed after 4, 11, 16 and 31 months, respectively. Eleven out of the 13 deceased patients did not receive stem cell transplantation. Grade 3-4 hematological, neurological, infectious and renal toxicities occurred in 5, 6, 4 and 1 patients, respectively. *Conclusions.* These findings confirm and extend previous data suggesting that chemotherapy combinations including bortezomib are safe and effective first line treatments for PPCL, in particular in patients eligible for stem cell transplantation.

SERUM IMMUNOGLOBULIN HEAVY/LIGHT CHAIN RATIOS ARE INDEPENDENT RISK FACTORS FOR PREDICTING PROGRESSION FREE SURVIVAL IN MULTIPLE MYELOMA

H Avet Loiseau,[1] L Mirbahai,[2] JL Haroussea,[3] P Moreau,[1] C Mathiot,[4] T Facon,[5] M Attal,[6] A Bradwell,[7] S Harding[2]

[1]Laboratory of Hematology, Clinical Hematology Department, University Hospital, Nantes, France; [2]The Binding Site Group Ltd, Birmingham, UK; , Nederland; [4]Department of Hematology, Institut Curie, Paris, France; [5]Maladies du Sang, CHU, Lille, France; [6]CHU Dept Hematologie, University Hospital, Toulouse, France; [7]Department of Immunology, Medical School,University of Birmingham, Birmingham, UK

Background. Genetic aberrations have emerged as important prognostic factors in multiple myeloma (MM), although detection methods are not readily available and require skilled personnel. The current international staging system (ISS) for MM relies upon measurement of Beta 2 Macroglobulin (β2M) and albumin. Measurement of immunoglobulin production is not prognostic, but is required for monitoring. Newly developed nephelometric assays allow the accurate measurement of serum heavy/light chain (IgAκ / IgAλ and IgGκ / IgGλ) proteins; the measurement of which can quantify the immunoglobulin produced by the tumour and indicate the level of polyclonal immunoglobulin suppression. *Aims.* To determine the prognostic value of serum immunoglobulin heavy/light chain (HLC) ratios. Furthermore, to comment on the role of isotype specific *vs.* systemic immunoparesis in MM. *Methods.* Archived, presentation sera from 339 patients enrolled on the IFM 2005-01 trial were assayed. Free light chain (FLC), β2M and albumin were measured in all sera. In addition, IgGκ & IgGλ concentrations were measured in sera from the 245 IgG MM patients (166 IgGκ, 79 IgGλ). IgAκ and IgAλ concentrations were measured in the sera from the 94 IgA MM patients (60 IgAκ, 34 IgAλ). Association with progression free survival (PFS) was determined using univariate and multivariate analysis (SPSS Version 18). *Results.* Cox regression analysis identified abnormal the HLC ratio as being associated with reduced PFS (P<0.001). The association was independent of other serum markers including B2M, albumin and markers of genetic aberrations including Del_13, t4_14 and Del_17p. There was good correlation between an increasing-

ly abnormal HLC ratio and the relative risk of progression (Figure 1). Separation of the HLC values into monoclonal protein production and polyclonal suppression clearly showed that monoclonal production was not associated with shorter PFS (P=0.142), similarly to SPE densitometry results (P=0.1). Levels of polyclonal isotype-matched immunoglobulin suppression were associated with shorter PFS (P=0.002), although not as significant as the overall HLC ratio (P=0.00005). Systemic immunoparesis (i.e. IgG and IgM in IgA MM and IgA and IgM in IgG MM) was defined as a reduction in immunoglobulin measurement ~33% below the normal range (IgG=5g/L, IgA=0.5g/L and IgM=0.3g/L). Levels of IgG and IgM were not prognostic in IgA MM (P=0.169, P=0.477), similarly level of IgA and IgM were not prognostic in IgG MM (P=0.952, P=0.977). *Summary.* Increasingly abnormal HLC ratios were associated with shortened PFS in MM patients. The association is independent of serum markers such as β2M, albumin, SPE densitometry and genetic markers (Del_13, t4_14 and Del_17p). Isotype matched polyclonal immunoglobulin measurements are significantly associated with shorter PFS, although the use of ratio is more powerful prognostically. Systemic immunoparesis is not associated with shortened PFS, supporting the presence of immunoglobulin specific myeloma niches in the bone marrow.

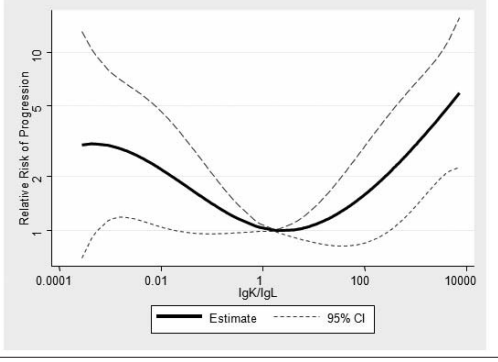

Figure 1. Relative risk of progression for heavy/l.

CIRCULATING PLASMA CELLS (CPC) PREDICT THE OUTCOME OF RELAPSED OR REFRACTORY MULTIPLE MYELOMA (RR MM)

V Peceliunas, A Janiulioniene, R Matuzeviciene, L Griskevicius

Vilnius University Hospital Santariskiu Clinics, Vilnius, Lithuania

Background. Pretreatment detection of peripheral blood malignant CPCs by immuophenotyping has been shown to be of negative prognostic value in MM and related disorders. The number of CPCs tends to decrease in response to treatment. We hypothesized that assessment of CPC kinetics in response to one therapy cycle may be of prognostic significance and could be helpful in the early detection of MM refractoriness to treatment. *Aims.* The aims of our study were to assess the prognostic significance of pretreatment values of normal and aberrant CPC subsets as well as the prognostic significance of CPC kinetics in response to the first treatment cycle in RR MM. *Methods.* Patients were prospectively included if they had RR MM according to EBMT criteria after at least one prior line of therapy and were scheduled to receive either a Bortezomib containing regimen or VAD (vincristin, doxorubicin and dexamethasone). All patients provided informed consent. We used six-color flow cytometry to identify immunophenotypically normal (nCPC) and aberrant plasma cell (aCPC) subsets in peripheral blood (PB). Assays were performed with two tubes stained with antibody combinations: CD56/CD138/CD45/CD19/CD38/CD20 and cLambda/cKappa/CD138/CD19/CD38/CD45. Plasma cells were identified as normal (nCPCs) if they were $CD138^+/CD38^+/CD19^+/CD56^-$/normal kappa/lambda ratio/CD45 variable or aberrant(aCPCs) if they displayed $CD138^+/CD38^+/CD19^-/CD56^{+/-}$/abnormal kappa/lambda ratio/CD45 variable. We measured aCPC and nCPC subsets immediately before and then after one therapy cycle in RR MM patients. *Results.* 31 adult patient was enrolled into the study. Median age was 59 years. After the median observation time of 16.7 months, patients with detectable pretreatment aCPCs had shorter time to progression (TTP) compared to patients with undetectable aCPCs (median 258 *vs.* 456 days, respectively (P=0.022)). TTP of 57 days and overall survival (OS) of 139 days was shortest in patients whose aCPCs increased after one therapy cycle compared to patients with decreasing (TTP 259 days and OS not reached) or undetectable (TTP and OS not reached) aCPCs (P<0.001 and P=0.043 for TTP and OS, respectively) (Figure 1). Detection of nCPC before treatment did not showed prognostic significance, however kinetics of nCPC were prognostically important: patients with either absent or decreasing nCPCs after one therapy cycle had significantly shorter TTP as compared to patients with increasing nCPCs (217 and 388 days, respectively (P=0.029)). *Summary.* Detection of aCPCs in PB before treatment may identify patients with more aggressive disease. Nonreduction of aCPCs in RR MM patients after the first cycle of therapy may be useful in identifying patients early who are resistant to the administered therapy. If our findings are confirmed in larger studies, these patients may be candidates for immediate switch to alternative therapy. Figure 1 Time to tumor progression in three aCPC kinetic groups: group I - patients with no detectable aCPCs in both pre and postchemotherapy samples, group II - patients with a decrease in aCPCs postchemotherapy as compared to aCPCs before chemotherapy, group III - patients with no change or increase in aCPCs postchemotherapy as compared to aCPCs before chemotherapy.

PREVALENCE OF MONOCLONAL GAMMOPATHY OF UNKNOWN SIGNIFICANCE IN KOREAN URBAN ELDERLY POPULATION

HK Park,[1] KR Lee,[2] HJ Kim,[3] JE Kim,[4] KW Kim,[5] YJ Kim,[6] KW Lee,[6] JH Kim,[6] SM Bang,[6] LS Lee[6]

[1]Seoul Clinical Laboratories, Seoul, South-Korea; [2]Seoul Medical Science Institute, Seoul, South-Korea; [3]Department of Obstetrics & Gynecology,School of medicine, Konkuk University, Chungju, South-Korea; [4]Department of Radiology, Seoul National University Bundang Hospital, Seoul, South-Korea; [5]Department of Neuropsychiatry, Seoul National University Bundang Hospital, Seoul, South-Korea; [6]Department of Internal Medicine, Seoul National University Bundang Hospital, Seoul, South-Korea

Background. Studies on the epidemiology of monoclonal gammopathy of undetermined significance (MGUS), a premalignant precursor of myeloma, are limited in Korean. *Aims.* The aim of this study is to investigate the prevalence and characteristics of MGUS in an elderly urban Korean population. *Methods.* Among 1,000 randomly sampled participants aged more than 65 years (sourced from the Korean Longitudinal Study on Health and Ageing in 2006), 945 subjects were evaluated for MGUS. MGUS was assessed using agarose-gel electrophoresis (SPIFE 3000, Helena), immunofixation (SPIFE 3000, Helena) and free light chain quantitation (BNII nephelometry, FREELITE The Binding Site Ltd.). Laboratory and radiologic tests were also performed. *Results.* MGUS was identified in 35 (3.7%) of the 945 study participants. The prevalence of MGUS was 1.7% among persons 65-69 years, 3.4% among 70-79 years and 5.8% among those 80 years or older. The prevalence increased with age and was higher in men (5.3%) than women (2.5%). The isotype of the M protein was IgA in 37%, IgG 29%, light chain 20% and IgM 14%. *Conclusions.* The prevalence of MGUS is slightly lower in this Korean population than that reported in Minnesota study among people older than 70 years (3.4% *vs.* 4.6%), but simi-

lar with Japanese data (3.4% *vs.* 3.0%). We suggest that MGUS is less prevalent among Korean elders than American. This is the first study to estimate the prevalence rate of MGUS in Korean elderly population and these findings are needed to confirm with further study using 2010's follow-up samples. We will also seek the transformed cases to multiple myeloma.

COMPARISON OF FIXED DOSE PEGFILGRASTIM AND DAILY FILGRASTIM AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION IN PATIENTS WITH MULTIPLE MYELOMA AUTOGRAFTED ON A OUTPATIENT BASIS

F Ferrara,[1] C Criscuolo,[1] T Izzo,[1] C Riccardi,[1] M Annunziata,[2] M Celentano,[1] S Palmieri,[1] A Viola[2]

[1]Hematology and stem cell tranpslantation unit, Naples, Italy; [2]Hematology and Stem Cell Tranpslantation Unit, Naples, Italy

Background. There is a growing demand for autologous stem cell transplantation (ASCT) in patients with multiple myeloma (MM), with increasing pressure on available hospital beds. Accordingly, different authors have explored the feasibility of autografting patients on an outpatient basis. G-CSF is used to accelerate hematopoietic recovery following ASCT, although there is no consensus about its optimal use in this setting. Pegfilgrastim (PEG), a long-acting recombinant G-CSF, has been shown to have similar efficacy when compared to conventional G-CSF for chemotherapy-induced neutropenia, but little is known about its use in the ASCT setting, namely in patients programmed to be autografted on outpatient basis. *Aims.* To compare therapeutic results in terms of hematopoietic recovery, non hematologic toxicity, duration of hospitalization and percentage of hospital readmission between patients receiving either conventional G-CSF or PEG. *Methods.* Forty-eight patients with MM were autografted by using PEG, given at a single dose of 6 mg at day +5 from stem cell infusion, while 113 received G-CSF from day + 2 up to stable neutrophil recovery (median 8 days, range 6-11). The conditioning regimen was high dose melphalan (HDM) in all patients (200 mg/sqm up to 65 years and 140 mg/sqm over 65 years). All patients were discharged the day after stem cell infusion as programmed. The median age was comparable between the two groups (57 for G-CSF and 59 for PEG, p:0.11). The median number of CD34+cell infused was 5.9×10^6/kg and was comparable in the two groups (5.8 for PEG and 5.9 for G-CSF, p:0.67). *Results.* Out of 161 patients, 125 (68%) did spend the aplastic phase entirely at home following HDM and stem cell infusion. A second hospital admission was required in 36 patients (32%). Febrile neutropenia and severe mucositis needing total parenteral nutrition were the most frequent causes of hospitalization. However, there was only one documented infection and either fever or mucositis were easily resolved at the time of hematopoietic recovery in all patients. Median time to neutrophil recovery for the whole patient population was 12 days and there was no difference between the PEG subgroup (12 days) and controls (12 days), P:0.87. In addition, the incidence of FUO (34% *vs.* 29 %, P:0.22) and grade 3 mucositis (18% *vs.* 20 %, p:0.34) was comparable. Finally there was no statistically significant difference as percentage of hospital readmission is concerned: in the PEG group 6 out of 48 patients (12%) were hospitalized as opposed to 30 out of 113 (26%), p:0.06. The median time of hospital stay for readmitted patients was 5 days (4-26) and was identical for the two subgroups (5 days *vs.* 5 days, p.0.94). Finally no case of transplant related mortality occurred in the whole patient series. *Conclusions.* ASCT on an outpatient basis is feasible and safe in patients with MM, the majority of whom are manageable at home. The administration of single dose PEG results in no different outcome in terms of safety and efficacy as compared to 8 days of G-CSF and is better accepted by patients.

0958

THE COMBINATION OF LENALIDOMIDE AND DEXAMETHASONE REDUCES BONE RESORPTION IN RESPONDING PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA BUT HAS NO EFFECT ON BONE FORMATION

D Christoulas, M Dimopoulos, E Katodritou, M Kyrtsonis, A Parharidou, S Delimpasi, X Papanikolaou, E Koulieris, Z Kartasis, P Repousis, K Zervas, E Terpos

Greek Myeloma Study Group, Athens, Greece

Background. Lenalidomide plus dexamethasone (RD) is very effective for the management of refractory and relapsed multiple myeloma (MM). However, there is very little information for its effect on myeloma bone disease. *Aim.* The aim of this prospective study of the Greek Myeloma Study Group was to evaluate the effect of RD regimen on bone remodeling in relapsed/refractory MM. *Patients/Methods.* We evaluated 106 consecutive patients (54M/52F; median age 68 years) who received lenalidomide at the standard dose of 25mg PO daily (or adjusted to creatinine clearance) on days 1-21 of a 28-day cycle in combination with dexamethasone at a dose of 40mg PO on days 1- 4 and 15-18 for the first four cycles and only on days 1-4 thereafter. All patients were under zoledronic acid both pre- and during treatment period. The following serum indices of bone metabolism were measured on cycle 1/day 1, and then on day 28 of cycles 3 and 6: (i) osteoblast inhibitor dickkopf-1 (Dkk-1); (ii) osteoclast regulators: sRANKL and osteoprotegerin (OPG); (iii) bone resorption markers: CTX and TRACP-5b; and (iv) bone formation markers: bone-specific alkaline phosphatase (bALP) and osteocalcin (OC). These markers were also evaluated in 44 healthy controls of similar gender and age. *Results.* At baseline, 16 patients had no lytic lesions (14.8%, group A), while 35 (33%) had 1-3 lytic lesions (group B) and 55 (50.9%) had >3 lytic lesions and/or a pathological fracture (group C) in skeletal survey using conventional radiography. Patients at baseline had increased levels of Dkk-1, sRANKL, and bone resorption markers (P<0.01) and reduced levels of OC and bALP (P<0.01) compared to controls. Group C patients had increased Dkk-1 compared with all others (P=0.012). Patients with ostelolysis (groups B+C) had elevated levels of sRANKL/OPG ratio compared with group A (P=0.04). The pre-treatment values of sRANKL correlated with CTX and Dkk-1 (r=0.266, P=0.007 and r=0.200, P=0.047, respectively), while serum Dkk-1 correlated with TRACP-5b (r=0.403, P<0.001). To-date, 80 patients have completed 3 cycles of therapy while 55 have completed 6 cycles. The objective response was 55% (CR 12%, VGPR 11%, PR 32%). The administration of RD produced a reduction of Dkk-1 after 3 cycles of treatment in patients who showed an objective response to therapy (at least PR) but not in patients who did not respond to treatment (P=0.035). There was also a reduction in CTX serum levels (-4% median change) in responders (ranging from -100% to +209%) in contrast to patients who did not respond to RD and showed a median increase of 17% (ranging from -97% to +3913%; P=0.04). Non-responders had increased TRACP-5b serum levels after 3 cycles of treatment compared to baseline (P=0.04). There were no changes in markers of bone formation even in responders. *Summary/Conclusions.* RD regimen reduces bone resorption only in responding patients with relapsed/refractory myeloma but has no effect on bone formation. Combination with agents with known anabolic effect on bone, such as proteasome inhibitors or anti-Dkk1 drugs, may be of benefit for the management of bone disease in patients treated with RD.

0959

EXTRAMEDULLARY RELAPSED MULTIPLE MYELOMA HAS EXTREMELY POOR PROGNOSIS EVEN IN THE ERA OF THE NEW DRUGS

L Pour,[1] V Sandecka,[1] P Kaisarova,[2] Z Adam,[1] M Krejci,[1] L Zahradova,[1] M Klincova,[2] P Szturz,[1] S Sevcikova,[2] R Hajek[3]

[1]Faculty Hospital Brno,Masaryk University Brno, Brno, Czech Republic; [2]Babak Research Institute, Brno, Czech Republic; [3]Faculty hospital Brno,Masaryk university Brno, Brno, Czech Republic

Introduction. Multiple myeloma (MM) is 2nd most common hematological malignancy. Extramedullary lesions (EM) mean aggressive disease. Patients (pts) with EM have poor prognosis if conventional chemotherapy is used for treatment. About 10 % of MM patients eventually relapse with EM disease after autologous stem cell transplant. *Aims, methods.* The aim of this study was to define incidence and prognosis of patients with EM in era of new drugs. We studied all consecutive 226 relapsed MM pts (115M/111F,median age:61 years,median follow-up 3.7 years) who received treatment in our centre between 2005 and 2008. EM relapse was proven by CT or MRI if it was not possible to verify EM histologically. Pts with EM at the time of diagnosis were excluded from analysis. All pts were treated with thalidomide and/or bortezomib. Patients with EM were divided into two groups: first group with EM related to bone (B-EM) and second group pts with EM in soft tissues not related to bone or with plasmocyte infiltration of parenchymatous organs (ST -EM). Thalidomide (33%), bortezomib (38%) and lenalidomide (5%)-based regimens were used as treatment of EM relapse, in 42 % pts together with autologous transplantation. Mann-Whitney test and Log-rank test were used for evaluation of differences between groups of pts. *Results.* Totally 24% pts (55/226) had proven relapse with EM (42% (22/55) - B-EM; 58% (32/55) - ST-EM). The most common site of EM was skin infiltration

occuring in 42% (22/55) of pts. Surprisingly, EM was present in 53% (29/55) of pts in the first relapse, in 33% (18/55) of pts in second relapse but later only in 14% (8/55). Overall response rate was 24% (13/55) with 5% (3/55) of complete remission and 21% (10/55) partial remission. Time to progression in these pts was only 5.4months. Median of OS (89.5 months for all of 226 pts) was significantly shorter in the group with EM when compared to group without EM (109m *vs.* 38m; P=0.0001). Median OS in pts with ST-EM was also decreased compared to pts with B-EM (30mvs45m,P=0,002). Median OS from date of relapse was only 8m in all EM pts. However, OS in pts with ST-EM was shorter than in B-EM pts.(12mvs4m,P=0.006). *Conclusion.* Our data showed higher incidence of EM relapse in comparison with 90´s .Interval of survival after EM relapse and is extremely short if EM occurs, although all new drugs including IMIDs and bortezomib are used for the treatment. Our findings indicate that EM still means very poor prognosis of MM patients even in the era of the new effective drugs, especially if ST-EM occurs. We have not yet fully understood why the incidence of EM is so high in the last 4 years. In our opinion, the treatment of EM became a crucial problem in MM, and effective treatment is unfortunately not available.

MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE AND RISK OF VENOUS THROMBOEMBOLISM

H Gregersen,[1] M Nørgaard,[1] M Tang Severinsen,[2] M Cramer Engebjerg,[3] P Jensen,[4] H Toft Sørensen[3]

[1]Aalborg Hospital, Aalborg, Denmark; [2]Department of Clinical Chemistry, Aalborg Hospital, Aalborg, Denmark; [3]Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark; [4]Department of Haematology, Aalborg Hospital, Aarhus University Hospital, Aalborg, Denmark

Background. The risk of venous thromboembolism (VTE) in multiple myeloma is increased but little information is available on the risk of VTE in patients with the precursor condition monoclonal gammopathy of undetermined significance (MGUS) and the results of previous studies are contradicting. *Aims.* To evaluate the risk of VTE in MGUS in a large population-based study. *Methods.* We identified 1,610 MGUS patients without prior VTE in the 1978-2006 period in North Jutland County, Denmark and 16,100 members of the general population were randomly selected from the Danish Central Population Registry, matched by age, gender, comorbidity and year of diagnosis. Data on VTE in the two groups were obtained from the National Patient Registry covering all Danish hospitals. The follow-up period began one year after detection of the M-component. Cox regression analysis was used to estimate the relative risk of VTE adjusting for age, gender and comorbidity. In addition, we used Cox-regression analysis to estimate the mortality rate ratio (MRR) of MGUS patientens with VTE compared to MGUS patients without VTE.

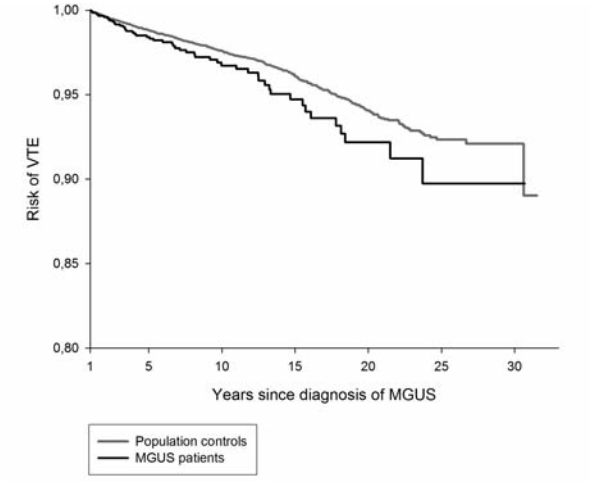

Figure 1.

Results. The MGUS cohort comprised 823 males and 787 females, all together with a median follow-up time of 6.0 years (range, 0-29.7 years), totaling 12,558 person-years at risk. The median age at MGUS was 70.1 years (range, 10.1-96.5 years). During follow-up 50 cases of VTE (28 cases of deep venous thrombosis of the legs and 22 cases of pulmonary embolism) were identified in the MGUS cohort, corresponding to an incidence rate of 4.0 VTEs/1000 person-years. The cumulative risks of VTE in MGUS patients and population controls are shown in Figure 1. The relative risk for VTE among MGUS patients compared to population controls was 1.37 (95% confidence interval (CI), 1.00-1.88). Only one MGUS patient with VTE was later diagnosed with malignant transformation. The crude MRR for MGUS patients with VTE compared to MGUS patients without VTE was 2.4 (95% confidence interval (CI), 1.7 - 3.4). After adjustment for age, sex, and comorbidity the MRR was 2.0 (1.4 - 2.8). *Summary/Conclusions.* The overall risk of VTE in the MGUS patients was increased compared to the population controls. The study does not support an association between VTE and later malignant transformation. Our results indicate that VTE in the MGUS patients is associated with reduced survival.

COMPARE - RESULTS OF A RANDOMISED STUDY TO ASSESS THE RENAL SAFETY AND EFFICACY OF IBANDRONATE AND ZOLEDRONATE IN MULTIPLE MYELOMA PATIENTS

U Knauf,[1] R Bergner,[2] M Kropff,[2] W Poenisch,[3] C Kiewitz,[4] H Goldschmidt[5]

[1]Onkologische Gemeinschaftspraxis, Frankfurt, Germany; [2]Med. Klinik A, Ludwigshafen, Germany; [3]Med. Klinik II, Leipzig, Germany; [4]Roche Pharma AG, Grenzach-Wyhlen, Germany; [5]Med. Klinik V, Heidelberg, Germany

Background. Bisphosphonates (BPs) are widely used to prevent skeletal complications in patients (pts) with Multiple Myeloma (MM), which is characterised by osteolytic bone lesions or diffuse bone disease. As MM pts are at high risk for renal damage, renal safety may be a discriminator for selecting a particular BP. *Methods.* COMPARE is a randomised, multi-centre, open-label, parallel-group study to assess the renal safety of ibandronate (IBA) and zoledronate (ZOL) in pts with MM stage II-III (Salmon, Durie). Exclusion criteria included prior treatment with IBA or ZOL, serum creatinine >4.0 mg/dL, and estimated creatinine clearance (eCrCl; Cockcroft-Gault equation) ≤30mL/min. Pts were randomised to receive IBA (6 mg) or ZOL (4mg), administered as IV infusion over 15 min Q4W for up to 92 weeks. ZOL dosage could be reduced at the physician's discretion. Primary endpoint was a relevant deterioration of renal function, defined as a decrease in eCrCl of ≥30% or to ≤30mL/min, respectively. Secondary endpoints included reductions of ZOL dose, number of, and time to first occurrence of, skeletal related events (SREs), and cases of osteonecrosis of the jaw (ONJ). Statistics were descriptive. *Results.* 81 pts were randomised to receive IBA (n=41) or ZOL (n=40). The number of pts experiencing a relevant decrease in renal function was similar for treatment with IBA (6 pts, 14.6%) and ZOL (5 pts, 12.5%), respectively; however, 12 pts (30%) in the ZOL group underwent at least one dose reduction. The mean treatment period was 52.6 and 44.3 weeks for IBA and ZOL treated pts, respectively (based on safety population). With IBA treatment, 9 pts (22.0%) experienced an SRE compared to 12 SREs (30.0%) reported in ZOL treated pts. Median time to first occurrence of an SRE was 393 days for IBA treatment and 244.5 days for ZOL treatment. ONJ was not observed in either treatment group. *Conclusions.* In this randomised, multi-centre, open-label, parallel-group study comparing the renal safety and efficacy of IBA and ZOL in pts with stage II-III MM, the incidence of relevant decreases in estimated creatinine clearance was similar between treatment groups. With 30% of ZOL treated pts having had at least one dose reduction, physicians may have titrated ZOL dosing to achieve acceptable renal safety. SREs seemed to occur earlier and more frequently with ZOL compared to IBA treatment.

This trial was sponsored by Roche Pharma AG, Grenzach, Germany. Protocol number: ML18508.

ARTERIAL AND VENOUS THROMBOSIS IN PATIENTS WITH MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE: INCIDENCE AND RISK FACTORS IN A COHORT OF 1,491 PATIENTS

T Za,[1] V De Stefano,[1] E Rossi,[1] MT Petrucci,[2] A Andriani,[2] L Annino,[2] G Cimino,[2] T Caravita,[2] F Pisani,[2] A Ciminello,[1] F Torelli,[2] N Villivà,[2] V Bongarzoni,[2] A Rago,[2] S Betti,[1] A Levi,[2] S Felici,[2] F Gentilini,[2] E Calabrese,[2] G Leone[1]

[1]Institute of Hematology, Catholic University, Rome, Italy; [2]Multiple Myeloma GIMEMA-Latium Region Working Group, Rome, Italy

Background. Monoclonal gammopathy of undetermined significance (MGUS) has been reported to be associated with an increased risk of venous thrombosis. *Aims.* To investigate the incidence of arterial and venous thrombosis in patients with MGUS and the associated risk factors. Patients and *Methods.* We carried out a retrospective multicenter cohort study on 1,491 patients with MGUS (M/F 789/702, median age at diagnosis 63 years, range 24-94). The type of M-protein was IgG in 1,115 patients (75.1%), IgA in 185 (10.4%), IgM in 173 (11.7%), and biclonal in 48 (3.2%); 520 (34.8%) had M-protein level >1.6 gr/L. Forty-nine (3.2%) of the patients were diagnosed as MGUS carriers at the time of a thrombotic event, with no significant difference in sex, age, type or level of M-protein in respect to the remaining patients. The patients without recent thrombosis (<2 years) when MGUS was diagnosed and with a recorded follow-up were 1,238; the risk of thrombosis during the follow-up was estimated as hazard ratio (HR) using a Cox model having as covariates gender, age >60 years at the time of diagnosis, history of remote thromboses (>2 years before diagnosis of MGUS), presence of cardiovascular risk factors, M-protein level >1.6 gr/L at diagnosis, and presence of biclonal gammopathy. *Results.* Thirty-three patients of 1,238 (2.6%) had thrombosis during the follow-up: nine acute coronary syndrome, nine cerebrovascular disease, one splenic infarction, seven deep venous thrombosis, five superficial vein thrombosis, and two retinal vein thrombosis. The total observation time was 7,334 years (median 3.3, range 1-27.7); thus, the overall incidence of thrombosis was 4.4 per 1,000 patient-years, 2.5 for arterial events and 1.9 for venous events. Multivariable analysis showed a significant increase in risk for arterial thrombosis in the patients having cardiovascular risk factors (HR 4.92, 95%CI 1.42-17.0), as expected; an increased risk for venous thrombosis was present in patients with M-protein level >1.6 gr/L (HR 3.34, 95%CI 1.06-10.48), and in patients with biclonal gammopathy (HR 9.02, 95%CI 1.07-75.61). No thrombotic event was observed in the patients who evolved to multiple myeloma (n=56) or another neoplastic disease (n=24). *Conclusions.* The incidence of arterial and venous thrombosis in the patients with MGUS does not seem higher than that expected in the general population. However, the risk of venous thrombosis is increased in the presence of M-protein >1.6 gr/L or biclonal gammopathy.

THE C618R MUTATION OF JAK2 POTENTIATES THE JAK2V617F-INDUCED PHOSPHORYLATION AND ACTIVATION OF DOWNSTREAM TARGETS

A Vaz

Departamento de Genética, Instituto Nacional de Saúde Dr. Ricardo Jorge, Lisboa, Lisboa, Portugal

Background. A single *JAK2* exon 14 mutation (*JAK2*V617F) occurs in over 90% of patients with polycythemia vera (PV). Other *JAK2* exon 14 mutations have been recently described in association with *JAK2*V617F in PV patients. We previously reported the finding of a *JAK2*C618R alteration in a *JAK2*V617F-positive patient. Molecular studies revealed that *JAK2*C618R is also an acquired mutation and that *JAK2*V617F and *JAK2*C618R are located in the same *JAK2* allele. However, the functional consequences of *JAK2*C618R on *JAK2*V617F-induced phosphorylation and downstream JAK-STAT, ERK and AKT pathway activation have not been analyzed. *Aims.* To study the effect of *JAK2*C618R on JAK2 protein phosphorylation and activation *in vitro*, and compare the results with those obtained for *JAK2*V617F or the double mutant *JAK2*V617F+C618R. *Methods.* A full-length wild-type *JAK2* cDNA was amplified by PCR and cloned into a GFP-tagged expression vector. *JAK2*V617F, *JAK2*C618R and *JAK2*V617F+C618R alterations were introduced by direct mutagenesis. Western blotting analysis of JAK2, STAT5, ERK 1 & 2 and AKT protein phosphorylation was performed after transfection of wild-type or mutant constructs into HEK293 cells. The levels of cyclin B1 and cyclin E protein expression were also determined to assess cell cycle progression. *Results.* The phosphorylation of JAK2 and its downstream targets STAT5, ERK 1 & 2 and AKT in the presence of JAK2C618R mutant alone was lower than that of *JAK2*V617F mutant and similar to those of wild-type JAK2. In striking contrast, the double mutant *JAK2*V617F+C618R potentiated the JAK2V617F-induced phosphorylation level of JAK2 (4-fold), STAT5a (3-fold) and AKT (3-fold). A minor increase (1,2-fold) was also observed in the phosphorylation levels of ERK 1 & 2. Furthermore, the *JAK2*V617F+C618R mutant showed a 2-fold and 11-fold increase in cyclin B1 and cyclin E expression, respectively, compared with *JAK2*V617F. *Conclusions.* The presence of *JAK2*C618R alone has no relevant effect in the activation of JAK-STAT, ERK and AKT signalling pathways. However, *JAK2*C618R plays a role as an adjuvant mutation of *JAK2*V617F by promoting a higher activation level of the JAK-STAT and AKT proliferative pathways. Moreover, *JAK2*C618R sinergizes with *JAK2*V617F to increase the levels of cyclin E, suggesting that double mutant cells may proliferate further as a result of cell cycle progression. This work supports the hypothesis that mutations in neighboring residues of 617 are unable to sustain constitutive activation of kinase function of JAK2 unless the *JAK2*V617F mutation is also present. It ultimately provides the rationale for the fact that only *JAK2*V617F is selected in the overwhelmingly majority of PV patients

DIFFERENTIAL EFFECTS OF TUMOR NECROSIS FACTOR-ALPHA (TNF) IN MYELOPROLIFERATIVE NEOPLASMS (MPN) AND MODULATION BY INHIBITION OF TNF BY JAK2 V617F

K Aichberger,[1] A Fleischman,[2] S Doratotaj,[2] T Bumm,[2] R Silver,[3] T DeLoughery,[2] H Pahl,[4] B Druker,[2] C Burns,[5] M Deininger[2]

[1]Medical University of Vienna, Vienna, Austria; [2]OHSU Knight Cancer Institute, Portland, OR, USA; [3]Weill Medical College of Cornell University, New York, NY, USA; [4]Universitaetsklinikum Freiburg, Freiburg, Germany; [5]YM Biosciences, Melbourne, Australia

Background. Myeloproliferative neoplasms (MPN) are hematpoietic stem cell diseases encompassing chronic myeloid leukemia (CML), essential thrombocythemia (ET), idiopathic myelofibrosis (IMF), and polycythemia vera (PV). More than 95% of all patients with PV and some 50% of patients with ET and IMF have an activating mutation of JAK2 (JAK2 V617F). Tumor necrosis factor-alpha (TNF) is a pleiotropic cytokine produced by multiple cell types, including macrophages, NK cells, T and B cells. TNF plays a key regulatory role in immune and inflammatory responses. There is also evidence that TNF is involved in the regulation of erythropoiesis. We have previously reported that TNF levels are elevated in mice with retrovirally-induced JAK2 V617F-positve

PV-like MPN and that lack of TNF attenuates MPN in this model. *Methods and results.* We studied the expression of TNF in white blood cells from PV patients (n=43) and normal controls (n=21) using qPCR. PV patients expressed on average 2.5-fold higher levels of TNF than controls (P<0.0004). Upon examination of a panel of human leukemia cell lines (n=8) we found the highest TNF expression in HEL cells, which are homozygous for JAK2 V617F, suggesting that JAK2 V617F may upregulate TNF expression. Consistent with this, we found 6.9-fold higher TNF expression in Ba/F3 cells constitutively expressing EPOR and JAK2 V617F compared to parental cells. In a murine model of retrovirally-induced MPN, TNF expression was found to be two-fold higher in cells expressing JAK2 V617F as compared to JAK2 V617F-negative cells. Exposure of HEL cells or Ba/F3 EPOR JAK2 V617F cells to the JAK2 inhibitor CYT387 resulted in a time dependent 3.3 to 7.5-fold decrease of TNF mRNA as assessed by qPCR. By contrast, TNF mRNA expression was not found to be down-regulated by CYT387 in HL60 cells lacking mutated JAK2. CYT387 was also found to down-regulate TNF mRNA expression in MNC derived from MPN patients. To assess differential effects of TNF on normal *vs.* MPN progenitor cells, we performed clonogenic assays of peripheral blood MNC from normal donors (n=4) and MPN patients (n=9) in the presence of graded concentrations of EPO (0, 0.05, 0.5, 5 Iu/mL) and TNF (1, 10, 100 ng/mL). Intermediate and high TNF (10, 100 ng/mL) caused a dose-dependent reduction of BFU-E and CFU-GM compared to controls. However, in all conditions colony survival in MPN samples was higher compared to normal controls. Low TNF (1 ng/mL) in cultures supported by EPO (0.5 or 5.0 Iu/mL) increased BFU-E formation by MPN cells to 142% of controls, but reduced BFU-E formation by normal MNC to 65%. Analyzing BFU-E and CFU-GM from the clonogenic assays for the presence or absence of the JAK2 V617F mutation, we found, that the proportion of mutated colonies increased in the presence of TNF (10 ng/mL) compared to controls in all MPN patients tested (n=6), suggesting that TNF postively selects for mutated colonies. *Conclusions.* Our data indicate that JAK2 V617F upregulates TNF expression in cell lines and primary MPN cells. Compared to normal progenitor cells, MPN progenitor cells are less sensitive or even stimulated by TNF. These data suggest that JAK2 V617F-induced TNF may contribute to MPN pathogenesis by conferring a growth advantage to MPN over normal cells.

THROMBIN GENERATION IN PLATELET RICH PLASMA IS INCREASED AND CORRELATE TO IMMATURE PLATELETS IN PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA AND POLYCYTHEMIA VERA

M Panova Noeva,[1] M Marchetti,[1] S Buoro,[1] L Russo,[1] G Finazzi,[1] A Rambaldi,[1] T Barbui,[1] C Ottomano,[1] H Ten Cate,[2] A Falanga[1]

[1]Ospedali Riuniti di Bergamo, Bergamo, Italy; [2]Maastricht University, Laboratory for Clinical Thrombosis and Hemostasis, Maastricht, Netherlands

Background. Numerous platelet and leukocyte abnormalities have been identified in Essential Thrombocythemia (ET) and Polycythemia Vera (PV) patients that can contribute to the increased hypercoagulable state typical of these diseases. *Aims.* Our aim is to pursue characterizing the platelet procoagulant properties in both ET and PV patients. *Methods.* In this study we performed the thrombin generation (TG) assay in platelet rich plasma and the PFA-100 assay in whole blood in a group of 45 ET and 44 PV patients to characterize the platelet procoagulant and adhesive properties, respectively. In addition, in the same samples we measured for the first time the peripheral blood immature platelets fraction (IPF) using the Sysmex XE-2100 system. *Results.* Our results show significantly increased levels of IPF, as both absolute count and percentage, in whole blood as well as in PRP samples from PV patients compared to controls, and an increase in IPF, as absolute count, in samples from ET patients. The patients carrying the JAK2V617F mutation had significantly increased IPF compared to controls. PRP from both ET and PV patients generated significantly higher TG compared to control subjects. PV patients on cytoreductive therapy had significantly lower (P<0.05) levels of IPF (9.4×10^9/L) and TG activity (28.5 nM/min) compared to ASA-treated patients (20.2×10^9/L; 33 nM/min respectively). Linear regression analysis showed that a higher IPF count determined higher TG activity (B=0.52; P<0.05) in PV patients. Accordingly, in ET carriers of the JAK2V617F mutation, there was a direct correlation between TG activity and high-IPF% (B=0.2, P=0.07) and/or mean platelet volume (B=0.5, P<0.05). *Conclusion.* This study provides new insight into the characteristics of platelets from PV and ET patients. IPF might be an important contributor to the thrombotic diathesis of these patients, also worth to be tested prospectively for the capacity to identify those patients at high thrombotic risk.

REGULATORY NETWORKS OF JAK2/STAT5 PATHWAY ACTIVITY IN MYELOPROLIFERATIVE NEOPLASIA CELL LINES

EM Salas Cintora, MJ García-Barchino, JL Vizmanos, FJ Novo

University of Navarra, Pamplona, Spain

Background. The JAK/STAT signal transduction pathway is frequently altered in hematological cancers and, in chronic myeloproliferative neoplasms (CMN) in particular, the JAK2/STAT5 pathway is most frequently involved. Many studies have focused on the main components of this pathway (JAKs and STATs) and on its negative regulators (PTP, SOCS and PIAS). Although previous studies have identified some genes transcriptionally regulated by the activation of this pathway, other target genes, yet undiscovered, might be playing a role in STAT5-mediated oncogenesis and could represent new therapeutic targets in these neoplasms. *Aims.* Our goal is to identify and characterize new STAT5 target genes, using cell lines where the activation status of the pathway can be modified. This will allow us to improve our understanding of the transcriptional program resulting from JAK2/STAT5 activity, and to uncover new mechanisms that could be modulating this pathway in myeloid cells. Specifically, we will study the existence of hypothetical regulatory networks centered on microRNAs. *Methods.* We used M-07e cell line, where the activity of the JAK2/STAT5 pathway can be induced by IL-3, and the HEL cell line, where the pathway is constitutively activated owing to the presence of the V617F mutation in *JAK2*. We measured by RT-qPCR the expression levels of 64 genes that were predicted as transcriptional targets of STAT5 using bioinformatics tools and expression microarrays. To validate the interaction between STAT5 transcription factor and gene promoters, a chromatin immunoprecipitation assay (ChIP) was performed with a specific anti-STAT5 antibody, and gene promoters were detected in the immunoprecipitated fraction by PCR. Taqman Low Density Arrays (TLDAs) were used to measure the expression of 667 microRNAs after JAK2/STAT5 induction, after treatment with JAK2 and STAT5 inhibitors, and after treatment with a demethylating agent (5-azacytidine). *Results.* We identified ten genes with at least two-fold change in expression levels when the pathway is either induced or inhibited, six of which have confirmed interaction between their promoters and STAT5. We also identified 48 microRNAs that could regulate post-transcriptionally these ten genes and which show significant expression changes in these cell lines. With these data, we have built interaction networks between novel STAT5 target genes and their regulatory microRNAs. *Conclusions.* Our results provide new insights on the transcriptional program triggered by JAK2/STAT5 activation, which is constitutively activated in patients with myeloproliferative neoplasms. The identification of novel transcriptional targets of STAT5 and microRNA-target gene interactions has allowed us to generate new regulatory networks which could lead to a deeper understanding of STAT5-mediated oncogenesis.

This work has been funded with the help of the Spanish Ministry of Science and Innovation (SAF 2007-62473), the PIUNA Program of the University of Navarra and the Caja Navarra Foundation through the Program "You choose, you decide"(Project 10.830).

GENE EXPRESSION PROFILE IN JAK2 V617F POSITIVE POLYCYTHEMIA VERA AND ESSENTIAL THROMBOCYTHEMIA RELATED TO RESPONSE TO HYDROXYUREA TREATMENT

G Miguel,[1] S Santiago,[1] A Enriqueta,[1] I. Inmaculada,[1] R. Rosa,[1] A Jimenez,[1] D. Daniel,[1] E. Eulalia,[2] B. Blanca,[2] L. Lourdes,[2] C. Carles,[2] J. Joaquin[1]

[1]Hospital 12 de Octubre, Madrid, Spain; [2]IMIM-Hospital del Mar, Barcelona, Spain

Background. JAK2 V617F has improved the diagnosis and knowledge on the pathogenesis of the classic chronic Philadelphia-negative myeloproliferative neoplasms. Several hypotheses try to explain how a unique mutation can cause three different phenotypes. The current first line of treatment for PV and ET is hydroxyurea, but up to 15 to 25% of patients show resistance or intolerance. *Aims.* We aimed to analyze the differential gene expression profile of JAK2 V617F positive PV and ET, with and without HU treatment. We hoped to identify additional molecular alterations responsible for their divergent phenotypes. In addition, we aimed to correlate these results with clinical and laboratory features, particularly for those patients who had been referred on the basis of their response to treatment, to determine possible mechanisms for a poor response. As a consequence, we hoped to identify alternative

routes for targeted therapy. *Methods.* Twenty-one PV (10 with treatment, 11 at diagnosis), 28 ET (16 with treatment, 12 at diagnosis), eight secondary erythrocytosis patients, and 30 controls were included in the study. cDNA of granulocytes from venous peripheral blood was extracted. A first microarray analysis was performed (Whole Human Genome Microarray Kit, 4 × 44K de Agilent Technologies) and significant genes were validated by low-density quantitative real time PCR array (LDA). Statistical analyses of data were performed using the non-parametric Wilcoxon analysis. Statistical significance was considered when P value was under 0.05. In addition, the bioinformatics tool "Tnasas"was used to construct a prediction modelling. *Results.* Eighty-four genes showed differential expression between ET and PV by microarray analysis. PCR confirmed MMP14 over-expression in PV compared to ET, both at diagnosis and under HU treatment. Thirty-four genes were over-expressed in patients who did not respond to HU. Of these, some participate in proliferative pathways: the MAPK, AKT, Src family kinase (SFK), and JAK2 pathway (see attached Figure). In addition, a minimum error rate 10-gene prediction model was constructed, which included FRMD4B, LRMP, RAF1, FCER1G, ITGAM, CD44, MAPK14, JAK2, EDN1, and SKAP2 genes, over-expressed in the non responder group. JAK2 V617F allele burden was measured at diagnosis and after HU treatment in PV and ET patients. When measured after HU treatment, it diminished in PV, but only significantly in ET (P=0.003). However, the allele burden differences between patients who responded, or those who did not respond to HU, were not statistically significant. *Summary/Conclusions.* To summarize, our results suggest that MMP14 could be involved in the phenotypic divergence between PV and ET. A differential molecular fingerprint of genes distinguishes PV and ET patients who either do or do not respond to HU treatment. JAK2, MAPK14, PIK3CA and SFK genes are over-expressed in patients who do not respond to HU. In our group of patients JAK2 V617F allele burden decreased with HU treatment, however a significant diminution was not observed in response to treatment. On the other hand, patients with no response to treatment over-expressed JAK2. These results should be confirmed with further functional studies.

BIOLOGICAL AND FUNCTIONAL CHARACTERIZATION OF *EX VIVO* EXPANDED MESENCHYMAL STROMAL CELLS FROM BONE MARROW OF PATIENTS WITH PRIMARY MYELOFIBROSIS

V Achille,[1] M Mantelli,[2] MA Avanzini,[3] V Rosti,[4] F Novara,[5] ME Bernardo,[2] R Maccario,[2] G Bergamaschi,[6] V Poletto,[4] E Bonetti,[1] F Locatelli,[7] G Barosi[4]

[1]Fondazione IRCCS Policlinico S. Matteo, Pavia, Italy; [2]Oncoematologia Pediatrica, Fondazione IRCCS Policlinico S. Matteo, Pavia, Italy; [3]Oncoematologia Pediatrica, Fondazione IRCCS policlinico S. Matteo, Pavia, Italy; [4]Unità di Epidemiologia Clinica, Fondazione IRCCS Policlinico S. Matteo, Pavia, Italy; [5]Biologia Generale e Genetica Medica, Fondazione IRCCS Policlinico S. Matteo, Pavia, Italy; [6]Dipartimento di Medicina Interna, Fondazione IRCCS Policlinico S. Matteo, Pavia, Italy; [7]Ospedale Bambin Gesù, Roma, Italy

Background. Myelofibrosis (MF) is classified among myeloproliferative disorders, being characterized by variable degrees of cytopenia(s), bone marrow fibrosis and extramedullary hematopoiesis. An acquired somatic Janus Kinase 2 (JAK2) mutation (V617F) has been identified in hematopoietic cells of 60% of patients. Mesenchymal stromal cells (MSCs) have been considered for many years a component of marrow stroma with structural support properties only; it is now clear that MSCs substantially contribute to the hematopoietic stem cell niche. *Aims.* The aim of the present study was to characterize the biological and functional properties of MSCs derived from myelofibrotic (MF) patients. *Methods.* MSCs were isolated and expanded *ex vivo* from bone marrow (BM) and from trabecular bone fragments (TBF) of 5 patients , from BM of 2 and from TBF of other 3 patients. MSCs were investigated for clonogenic efficiency (CFU-F), proliferative capacity (population doubling-PD), morphology, immunophenotype (flow cytometry), differentiation potential (histological staining and spectrophotometry), genetic characterization (comparative Genomic Hybriditation, array CGH) and molecular analyses (Polimerase Chain Reaction, PCR). The ability of patients' MSCs to suppress *in vitro* proliferation to mitogens (PHA, OKT3) of both autologous and allogeneic lymphocytes was also assessed at different MSC:PBMC ratios. Results were compared to those obtained in BM-MSCs from 9 healthy donors (HD). *Results.* CFU-F frequency was comparable in MF- (median±SD: 5.37±1.1 for BM and 6.84±1.9 for TBF, respectively) and HD-MSCs (median±SD: 5.29±0.64). Proliferative capacity of BM-MSCs (mean cumulative PD from P1 to P4: 8.42) and TBF-MSCs (mean cumulative PD from P1 to P4: 8.48) of patients was comparable to that of HD-MSCs (mean cumulative PD from P1 to P4: 8.24). MF-MSCs displayed the typical spindle-shaped morphology and were able to differentiate into both adipocytes and osteoblasts. In particular, the osteogenic differentiation capacity of TBF-MSCs resulted higher than that observed in BM-MSC from the same 5 patients as demonstrated by spectrophotometry (mean±SD: 882±873; 264±354 µg/mL, respectively). Surface immunological markers did not differ between MF- and HD-MSCs. MF-MSCs ceased their growth at variable passages (BM-MSCs from P8 to P14 and TBF-MSCs from P10 to P14) and entered senescence, without any change in morphology/proliferation rate. Results of the array-CGH analysis showed that MF-MSC expanded *in vitro* did not exhibit chromosomal abnormalities. MSCs were tested negative for JAK2V617F mutation even in those patients with hematopoietic cells positive. Both in the autologous (MF-MSCs/MF-PBMCs) and allogeneic (HD-MSCs/MF-PBMCs) setting, proliferation of PBMCs was reduced up to 81% and 93.4%, respectively, and resulted to be comparable to that obtained in the setting HD-MSCs/HD-PBMCs (maximum inhibition 95%). *Conclusions.* Further studies are needed to investigate if the biological and functional properties of MF-MSCs are involved in the etiopathological mechanisms responsible for this myeloproliferative disorder.

0969

ASSOCIATION OF POLYMORPHISMS IN THE JAK2 LOCUS WITH A PREDISPOSITION TO POLYCYTHEMIA VERA DEVELOPMENT, AND THE ACQUISITION OF THE JAK2V617F MUTATION IN CHRONIC MYELOPROLIFERATIVE NEOPLASMS

A Bernal Vicente

Morales Meseguer University Hospital, Murcia, Spain

Background. Myeloproliferative neoplasms (MPN) are heterogeneous blood diseases characterized by clonal hematopoiesis, chronic excessive production of differentiated blood cells and increased risk for thrombosis and secondary leukemic transformation. A recurrent unique somat-

ic clonal mutation in the JAK2 kinase gene, JAK2V617F, has been identified in the majority of individuals with MPN (65-97% Polycythemia Vera (PV), 23-95% primary myelofibrosis (PMF), 41-57% essential thrombocythemia (ET)). This mutation is, however, not found in some patients indicating that is a secondary event. Three recent studies identified several polymorphisms associated with the acquisition of the JAK2V617F mutation. *Aims.* Analyze the association of three polymorphisms, rs10974944, rs12340895 (JAK2) and rs12500918 (4q31), with the risk to develop MPN, to acquire the JAK2V617F mutation and the MPN phenotype. *Methods.* Our study was performed on 525 Caucasian subjects: 356 controls and 169 patients with MPN: 46 with PV, 107 with ET and 16 with PMF. 56 patients were JAK2 V617F negatives and 113 positives. Genotyping of these polymorphisms were determined by validated TaqMan SNP Genotyping Assay and analyzed with the SNPstats software. *Results.* There was a significant association between the two JAK2 SNPs rs10974944 and rs12340895 (OR=2.87, 95% CI=2.16-3.82, P-value=<0.0001; OR: 2.78, 95% CI=2.09-3.69, P-value=<0.0001) with the acquisition of the JAK2 V216F mutation. Also, we found a significant association between the haplotype formed by the G allele of rs10974944, the G allele of rs12340895 and the A allele of rs12500918, with the susceptibility to acquire JAK2V216F mutation (OR=3.63, 95% CI=2.23-5.92, P-value=<0.0001). Moreover, we observed a significant association between development of MPN and rs10974944 (OR=2.10, 95% CI=1.59-2.78, P-value=<0.0001) and rs12340895 (OR: 2.06, 95% CI=1.56-2.72, P-value=<0.0001). In addition, the presence of genotype G/G of rs10974944 and G/G of rs12340895 was associated with the development of PV (OR=8.54, 95% CI=4.35-16.76, P-value=<0.0001 and OR=8.42, 95% CI=4.24-16.74, P-value=<0.0001, respectively). However, we don't find the reported association of the rs12500918 SNP on chromosome 4 and the MPN phenotype. *Conclusions.* Ours results confirmed that presence of the G allele of rs10974944 and rs12340895 are predisposing factors to acquire the JAK2V216F mutation. In addition, we demonstrated a significant association of genotype G/G of rs10974944 and G/G of rs12340895 and the development of PV. Our results support previous data suggesting that germline variations are important contributor to MPN phenotype and predisposition.

BONE MARROW STROMA-MEDIATED PARACRINE INHIBITION OF JAK2 INHIBITOR-INDUCED APOPTOSIS OF JAK2V617F-MUTATED CELLS

T Manshouri,[1] A Quintás-Cardama,[1] Z Estrov,[1] J Burger,[1] Y Zhang,[1] L Knez,[1] D Harris,[1] C Creighton,[2] H Kantarjian,[1] S Verstovsek[1]

[1]MD. Anderson Cancer Center, Houston, USA; [2]Dan L. Duncan Cancer Center, Division of Biostatistics, Baylor Collage of Medic, Houston, USA

Signals emanating from the bone marrow niche are suspected to support the growth of malignant clones in patients with myeloproliferative neoplasms (MPN), but also to protect them from targeted therapies. Little is known about the crosstalk between MPN clones and the marrow stroma. We have streamlined a co-culture platform designed to interrogate the interplay between JAK2V617F-positive cells and the stroma microenvironment in the context of JAK2 inhibitor therapy. Treatment with atiprimod, a potent JAK2 inhibitor, causes marked apoptosis of both human (SET2) and mouse (FDCP-EpoR) JAK2V617F-positive cells but this effect was abrogated when the latter were directly co-cultured (cell-on-cell) for 48h with human marrow stromal cell lines (HS5, NK.tert, or TM-R1). Co-culture with stromal cells hampered the ability of atiprimod to inhibit the phosphorylation of JAK2, STAT3, and STAT5. Notably, the protective effect of stromal cells was also observed in non-contact co-culture assays (cell lines separated by 0.4 μm micropore membranes), suggesting a paracrine effect. Cytokine profiling of supernatants generated in non-contact co-cultures in the presence or absence of atiprimod identified IL-6, FGF, and CXCL10/IP10 as elevated during atiprimod treatment. Exposing stromal monolayers to neutralizing antibodies against IL-6, FGF, or CXCL10/IP10 prior to coculture with JAK2V617F-positive cells ablated the protective effect of stromal cells and markedly increased atiprimod-induced apoptosis. Our results suggest that specific humoral factors secreted by stromal cells protect MPN clones from JAK2 inhibitor therapy, thus underscoring the importance of targeting the marrow niche in MPN for therapeutic purposes.

C-CBL, CBL-B AND CBL-C ANALYSIS IN BCR-ABL1 NEGATIVE CHRONIC MYELOPROLIFERATIVE NEOPLASMS

P Aranaz, C Hurtado, I Erquiaga, C Ormazábal, MJ Calasanz, M García-Delgado, FJ Novo, JL Vizmanos

University of Navarra, Pamplona, Spain

Background. BCR-ABL1 negative chronic myeloproliferative neoplasms (CMPNs) are a heterogeneous group of clonal hematological malignancies. Some genetic aberrations have been described to cause these diseases, most of them activating tyrosine kinase (TK) genes. However, in last years, different groups have described mutations in other molecules involved in the same signaling pathways that could have important roles in the disease. One of them is the CBL (Casitas B-lineage Lymphoma) family of E3-Ubiquitin-ligase proteins encoded by three genes: *C-CBL*, *CBL-B* and *CBL-C*. CBLs are involved in the negative regulation of several tyrosine-kinases, as *EGFR*, *FGFR* or *SYK*. Several groups have demonstrated that mutations in the RING Finger domain of *C-CBL* result in deregulation of downstream targets of this protein. *Methods.* We have used dHPLC to detect sequence mutations on samples from 382 *BCR-ABL1* negative CMPN patients, 145 *V617FJAK2* negatives and 237 positives. We included 20 samples from healthy individuals as controls. *Results.* We have found four non-described mutations in *C-CBL*, three of them located in the *RING Finger domain* (T402H, C416W, P417R), and two in the *Proline-Rich domain* (S675C and A678V). T402H, P417R and S675C were found in *V617FJAK2* positive patients. We have found and additional change (R462W) in the RING Finger domain of *CBL-B*, detected in a patient with *V617FJAK2* positive polycythemia vera. *Conclusion.* Our results suggest that mutations in *CBL* and *JAK2* genes are not exclusive events.

This work has been funded with the help of the Institute of Health Carlos III (FIS PI040037), Spanish Ministry of Science and Innovation (SAF 2007-62473), the PIUNA Program of the University of Navarra and the Caja Navarra Foundation through the Program "You choose, you decide"(Project 10830).

SUPPRESSOR OF CYTOKINE SIGNALING 3 IS DOWN-REGULATED BY BCR-ABL AND RESULTS IN LOSS OF JAK2 V617F IN A PATIENT WITH CONCURRENT BCR-ABL TRANSLOCATION AND JAK2 V617F MUTATION

CH Ang, GG Gan, V Nadarajan

University of Malaya, Kuala Lumpur, Malaysia

Background. The JAK2 V617F mutation, found in approximately 95% of polycythemia vera (PV) cases results in constitutive phosphorylation of JAK2 kinase while the BCR-ABL fusion gene is observed in chronic myeloid leukemia (CML) and results in dysregulated ABL kinase activity. Both these mutations rarely occur together and only a few cases of Ph^+, JAK2 $V617F^+$ myeloproliferative neoplasm (MPN) have been reported. We have recently reported such a case and observed a reciprocal relationship between JAK2 V617F and BCR-ABL, whereby an increase in BCR-ABL mRNA levels resulted in disappearance of JAK2 positive cells and reappearance of the JAK2 $V617F^+$ clone once BCR-ABL had been suppressed by imatinib mesylate (IM). The co-existence and interaction between JAK2 V617F, genes involved in the JAK/STAT signaling pathway, and BCR-ABL is yet to be studied. We sought to examine this relationship from serial archived samples collected over a 4-year period from this unusual patient. *Methods.* RNA was extracted from archived cell lysates obtained at different time-points from the patient. The patient had an initial clinical presentation consistent with PV, during which he was JAK2 $V617F^+$ with low level BCR-ABL transcripts (period-1). He subsequently progressed to a picture consistent with CML, and at peak levels of BCR-ABL transcripts, JAK2 V617F mutations was not detectable (period-2). With commencement of IM, JAK2 V617F was detectable again with gradual decline of BCR-ABL transcripts (period-3). The patient achieved major molecular remission in 24 months from commencement of IM. We investigated the expression of 84 selected genes involved in the JAK/STAT pathway in 4 representative samples, one collected during period-1, two at period-2 and one at period-3. Gene expression analysis was performed using SYBR-Green quantitative RT-PCR on 384-well microplates, measured in triplicates on a real-time PCR analyser. Significant differentially expressed genes between periods-1 and 3 combined and period-2 were identified using Significant Analysis of Microarray (SAM). Identified genes were subsequently validated by quantitative RT-PCR using specific primers on a total of 7 samples obtained at varying periods. *Results.* Twelve genes showed significant down-regulation during the period when BCR-ABL

transcripts was high with absence of JAK2 V617F (period-2). Of specific interest was the suppressor of cytokine signaling 3 (SOCS3), which showed 110-fold down-regulation during loss of JAK2 V617F and high expression of BCR-ABL. Further gene expression analysis using SOCS3 specific primers on seven samples from the same patient, confirmed the marked decline of SOCS3 gene expression in samples with increased BCR-ABL mRNA burden and absence of JAK2V617F. SOCS3 expression was also shown to be significantly higher in JAK2 V617F$^+$ samples with low BCR-ABL mRNA level as compared to normal subjects and Ph$^+$ CML. *Conclusion.* Our study reiterates that JAK2 V617F escapes negative regulation by SOCS3. Indeed, SOCS3 may play a permissive role in maintaining the JAK2 V617F clone, as abolishing SOCS3 expression in the presence of BCR-ABL is associated with loss of JAK2 V617F allelic burden. Furthermore, BCR-ABL transcripts are capable of down-regulating SOCS3 expression which may partly contribute to its anti-apoptotic potential.

THERAPY RELATED GENE EXPRESSION OF HEMATOPOIETIC PROGENITOR CELLS IN CHRONIC MYELOPROLIFERATIVE NEOPLASMS

V Cokic,[1] J Han,[2] B Beleslin-Cokic,[3] K Mirkovic,[3] S Damjanovic,[3] M Gotic,[4] P Raj,[2] C Noguchi,[5] A Schechter[5]

[1]Institute for Medical Research, Belgrade, Serbia; [2]Center for Biologics Evaluation and Research, FDA, Bethesda, USA; [3]Institute of Endocrinology, Diabetes and Diseases of Metabolism, Belgrade, Serbia; [4]Institute of Hematology, University Clinical Center, Belgrade, Serbia; [5]Molecular Medicine Branch, NIDDK, National Institutes of Health, Bethesda, USA

The gene expression profiles in chronic myeloproliferative neoplasms (CMN) may reveal gene markers of potential clinical utility for the diagnosis and prediction of response to therapy. Investigating the extent to which these genes participate in the complex molecular and cellular mechanisms of CMN, by microarray analysis, will likely lead to new insights. The JAK2V617F mutant allele burden can determine the laboratory and clinical characteristics of CMN associated to various genes and signaling pathways, described by microarray analysis. The quantity of CD34$^+$ hematopoietic progenitor cells, determined by flow cytometry, and leukocytes have been elevated in JAK2V617F mutation homozygous *vs.* heterozygous patients with polycythemia vera (PV), as well as in JAK2V617F homozygous and heterozygous *vs.* no mutation patients with primary myelofibrosis (PMF). In addition, the thrombocytes levels were reduced in JAK2V617F heterozygous (1003×10^9/L) *vs.* no mutation (1369×10^9/L) patients with essential thrombocythemia (ET). Splenomegaly was more prominent in homozygous patients with PV and PMF, whereas the presence of JAK2V617F mutation delayed the age beginning of PMF. The 118 genes had statistically significant difference in expression ($P<0.05$) between controls and ET, as measured by microarray analysis in CD34$^+$ hematopoietic progenitor cells. The presence of heterozygous JAK2V617F mutation increased 4 fold the quantitative difference in genes expression. The prominent genes with increased expression were OAZ1, MTPN, SOD2, HLA-G, WDR1, whereas with reduced expression were ADAMTSL3, HIF3A, GNGT1, SUCLG2, NFS1 in ET heterozygosity. The 175 genes had statistically significant difference in expression between controls and heterozygous PV, while the homozygous form of JAK2V617F mutation doubled the difference in genes expression. The outstanding genes with increased expression were NMI, SOD2, TALDO1, GNAI2, KIF2A whereas with reduced expression were MLLT4, HIF3A, NFS1, ADAMTSL3 and DGKB in patients with PV. The genes with increased expression in PMF *vs.* controls were NMI, TNFRSF1A, NCOA4, PDCD10, KIF2A whereas with reduced expression were CDRT1, RUNDC2B, MCC, S100PBP and SDHAP3 in CD34$^+$ hematopoietic progenitor cells. Hydroxyurea and Interferon-alpha are drugs used in therapy of CMN patients. Hydroxyurea treatment stimulated expression of G-protein coupled receptors related genes activated by cAMP/PKA pathway (ADIPOQ, 3.1 fold), PI-3 kinase pathway (AKT1, 1.6 fold), NO/cGMP pathway (PRPF18, 2.6 fold), PKC pathway: JUNB and IL-8 (1.5 and 3.7 fold, respectively), MAP kinase pathway: SERPINE1, JUN and MAX (1.2, 1.6 and 4.3 fold, respectively) and JAK-STAT pathway: SOCS1, HSD3B1 (2.7 and 1.8 fold, respectively). The gene expression of PRPF18 was increased in PV, MAX in PV and PMF, while IL-8 gene expression was increased in ET patients. Regarding IFN alpha signaling pathway related genes, JAK1 has been elevated in PV patients with JAK2V617F mutation; TYK2, STAT1, STAT2, IFNA2 have been elevated in all CMN. The increased expression of OAZ1, SOD2, NMI, TALDO1 genes and decreased expression of ADAMTSL3, MLLT4, HIF3A genes, observed in all CMN, have a potential for a cellular transformation and may contribute to myeloid leukemia development. The presented drug related genes, especially IL-8 and SOCS family members, contribute principally in cancer cells response and adaptability to chemotherapy.

0974

MUTATIONS OF TET2, ASXL1, CBL AND IDH1 IN MYELOFIBROTIC TRANSFORMATION OF ESSENTIAL THROMBOCYTHEMIA AND POLYCYTHEMIA VERA

L Martinez Aviles, C Besses, A Alvarez-Larrán, A Pons, S Serrano, B Bellosillo

Hospital del Mar, Barcelona, Spain

Background. Acquired mutations in the TET2 and ASXL1 gene have been described in approximately 14% and 8% of myeloproliferative neoplasms (MPN), respectively. In addition, mutations in the CBL and IDH1 gene, as well as TET2 and ASXL1, have been reported as genetic events associated to secondary acute or chronic myeloid transformation in MPN. A variable percentage of ET and PV patients develop myelofibrotic transformation during the evolution of the disease, although the genetic events that underlie myeloid transformation are still unclear. *Aim.* To analyze the presence of TET2, ASXL1, CBL and IDH1 mutations in a cohort of ET and PV patients who underwent transformation to myelofibrosis (MF). *Patients and methods.* Seventeen ET and PV patients with myelofibrotic transformation were assessed for mutations in: TET2 (whole exome), ASXL1 (exon 12), CBL (exons 8&9) and IDH1(R132). The mutational analysis of the aforementioned molecular markers was performed by direct sequencing using cDNA from purified granulocytes. All the samples analyzed were obtained at the myelofibrotic phase of the disease. *Results.* From the 17 patients analyzed, 3 of them (2 post-PV MF, 1 post-ET MF) presented mutations in the TET2 gene. The three TET2 mutations were: P463Lfsx23, T229NfsX25 and Q706X. Moreover, 2 additional patients (1 post-PV MF, 1 post-ET MF) presented mutations in the ASXL1 exon 12. The ASXL1 mutations were: Y591X and L765AfsX11. The 2 post-ET MF patients were JAK2V617F-negative whereas the 3 post-PV MF patients harbored the JAK2V617F mutation in homozygosis. CBL and IDH1 mutations were not detected in any of the patients analyzed suggesting that these genes might not be involved in the myelofibrotic evolution of a MPN. Overall, pathogenic mutations were observed in 29.4% of MF patients. In the patient with a TET2 mutation, the Q706X mutation was detected in an advanced phase of the myelofibrosis but not in a sample corresponding to the initial phase of the transformation. *Conclusions.* 1-TET2 and ASXL1 pathogenic mutations are present in nearly 30% of ET and PV patients who develop myelofibrotic transformation. 2-CBL and IDH1 mutations might not be genetic events involved in the myelofibrotic transformation of ET and PV patients. 3-TET2 mutations can be acquired during the evolution of a MPN.

SCREENING FOR PDGFRA FUSIONS IN EOSINOPHILIA IS HINDERED BY THE EXISTENCE OF MULTIPLE PDGFRA TRANSCRIPTS

I Erquiaga Martínez, C Ormazábal, C Hurtado, P Aranaz, MJ Calasanz, M García-Delgado, FJ Novo, JL Vizmanos

Universidad de Navarra, Pamplona, Spain

Background. Hypereosinophilic syndromes comprise a heterogeneous group of hematologic malignancies with persistent eosinophilia and eosinophil infiltration as main features. The lack of genetic markers in a large number of cases makes it difficult to distinguish these primary or clonal diseases from reactive or secondary eosinophilias. However the discovery of genetic alterations in *PDGFRA*, *PDGFRB* and *FGFR1* associated with the development of some eosinophilia cases has allowed to improve the classification and treatment of these diseases. *FIP1L1-PDGFRA* fusion is the most common recurrent genomic aberration found in myeloproliferative neoplasms with eosinophilia, although five more *PDGFRA* fusion genes have been described to date. Additionally, *PDGFRA* abnormalities have also been found on gastrointestinal tumours, glioma/glioblastoma, prostate cancer metastasis, testicular germ cell tumors, hepatocellular carcinoma and systemic mastocytosis. Previous reports looking for *PDGFRA* fusions have found *PDGFRA* TK domain overexpression at mRNA level not explained by the existence of putative *PDGFRA* transcripts. However we hypothesized that this differential expression of *PDGFRA* regions could be due to the expression of alternative and shorter *PDGFRA* transcripts from an alternative promoter, described years ago in teratocarcinoma. *Aims.*

Confirm the existence of *PDGFRA* alternative transcripts in hematological tissue. Find a relation between *PDGFRA* reported TK coding region overexpression and alternative transcripts expression. In case this proves real, develop a methodology to properly discriminate putative *PDGFRA* fusions and expression from different promoters. *Methods.* We studied overexpression of *PDGFRA*'s TK domain coding region in HES samples by competitive multiplex RT-PCR as described previously. The existence of several transcription start sites (TSSs) was assessed using 5' RACE on commercial bone marrow total RNA. Identification of different *PDGFRA* transcripts in peripheral blood samples was carried out using specific RT-PCR designs for each transcript. Real time quantitative PCR (RQ-PCR) assays were designed to evaluate expression of three different regions of *PDGFRA* present only in certain transcripts or fusion genes. *Results.* We confirmed the existence of an internal TSS in *PDGFRA*'s intron 12. We also found that expression from this TSS is common in peripheral blood of healthy individuals. Expression from *PDGFRA*'s internal TSS was found in the samples were TK coding region overexpression had been found. We found that our three-assay RQ-PCR methodology was able to distinguish expression from exon 1 and intron 12 TSSs and the presence of putative *PDGFRA* fusion genes. *Conclusions.* Our work has revealed that alternative *PDGFRA* transcripts should be taken into account when studying *PDGFRA* expression aberrations, such as fusions. The existence of these transcripts has allowed us to explain the TK coding region overexpression observed in HES cases where PDGFRA fusions were not found. Our RQ-PCR approach proved adequate for detecting and discriminating expression from both TSSs and *PDGFRA* fusions.

This work has been funded with the help of the Spanish Ministry of Science and Innovation (SAF 2007-62473), the PIUNA Program of the University of Navarra and the Caja Navarra Foundation through the Program "You choose, you decide"(Project 10830).

0976

DNA METHYLATION IN POLYCYTHEMIA VERA AND ESSENTIAL THROMBOCYTHEMIA

S Santiago, G Miguel, A Enriqueta, A Ana, R Rosa, J Joaquin

Hospital 12 de Octubre, Madrid, Spain

Background. DNA methylation plays a critical role in regulation of gene expression in development, differentiation and diseases. Aberrant DNA methylation has been demonstrated to participate in pathogenesis of haemathologic malignancies, as MDS and NHL. An aberrant methylation pattern has been described in SOCS as a potential contribution to pathogenesis and differential phenotype in MPN. *Aims.* The purpose of this study was to study DNA methylation in classic chronic Ph negative Myeloproliferative Neoplasms (MPN), Polycythemia Vera (PV) and Essential Thrombocythemia (ET) in order to identify possible specific methylation signatures related to pathogenesis and susceptible of potential therapeutic targets. *Methods.* 48 samples, 36 from patients diagnosed of classic chronic Ph negative MPN (12 ET JAK2 V617F positive, 12 ET JAK2 V617F negative, 12 PV JAK2 V617F positive) and 12 from healthy donors were included in the study. Diagnosis was established according to WHO criteria. Peripheral venous blood samples were collected in EDTA and immediately processed extracting DNA. Bisulphite conversion of the DNA was performed using the "Zymo EZ DNA Methylation Kit"according to the manufacturer's procedure (Zymo Research, Orange, CA). The processed DNA samples were hybridized to a beta-test version of the "HumanMethylation27 DNA Analysis BeadChip"(Illumina Inc.). This array was developed to assay 27,578 CpG sites selected from more than 14,000 genes. A bioinformatics tool GenomeStudio (Illumina Inc.) was used to statistical analysis applying the following criteria: Delta Beta > 0.3 and Mann-Whitney statistic corrected by false discovery rate (FDR), Differential Score > 20.0. A dichotomic analysis among the four groups was performed. *Results.* After a dichotomic pair matched analyses among the four referred groups was performed, only comparison between JAK2 V617F positive PV and ET, and between JAK2 V617F positive PV and controls generated a different methylation pattern. On the other hand all groups showed a very homogeneous methylation pattern (see attached Figure). VCY gene showed a differential methylation pattern, with clear statistical significance, between JAK2 V617F positive PV and ET. ZNF577 gene showed a differential methylation pattern between JAK2 V617F positive PV and controls. *Conclusions.* VCY gene, located in Y chromosome, is involved in sexual differentiation. For this reason it seems difficult to establish a link with pathogenesis in MPN. ZNF577 gene, methylated in JAK2 V617F positive PV in comparison to controls, encodes for a zinc finger family member protein, with to date undetermined physiologic function. According to our results aberrant methylation pattern does not seem to play a crucial role in MPN pathogenesis.

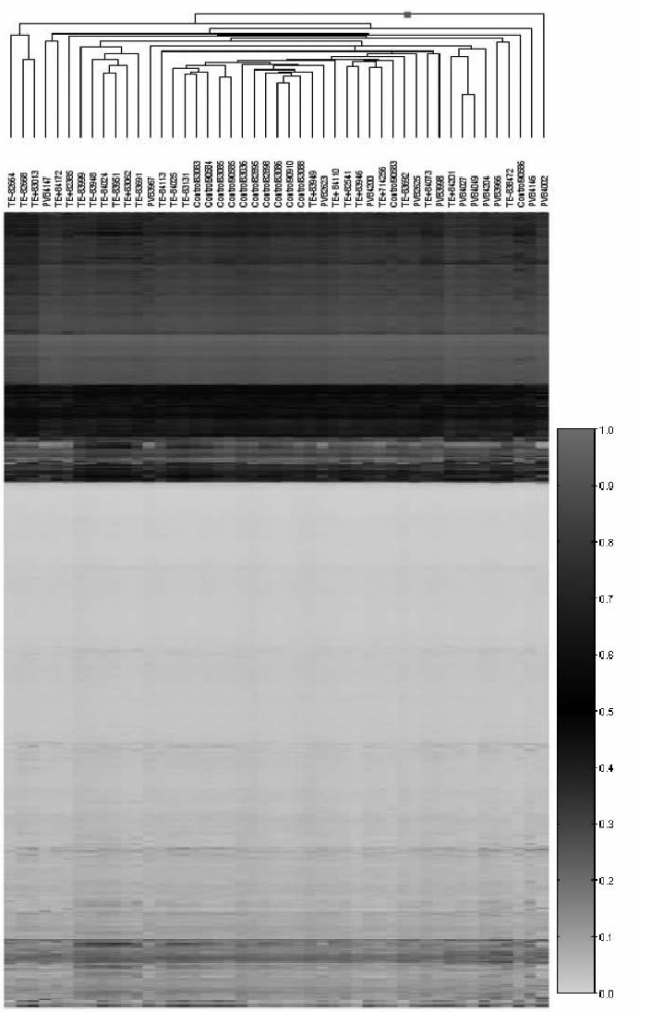

Figure. Heat Map of methylation profile in MPN.

JAK2V617F MUTATIONAL STATUS BUT NOT ALLELE BURDEN PREDICTS SURVIVAL AFTER ALLOGENEIC STEM CELL TRANSPLANTATION FOR MYELOFIBROSIS

H Alchalby,[1] A Badbaran,[1] T Zabelina,[1] G Kobbe,[2] J Hahn,[3] M Bornhäuser,[4] H Baurmann,[5] Y Hildebrandt,[1] U Bacher,[1] B Fehse,[1] A Zander,[1] N Kröger[1]

[1]University Hospital Hamburg Eppendorf, Hamburg, Germany; [2]University Hospital Düsseldorf, Düsseldorf, Germany; [3]University Hospital Regensburg, Regensburg, Germany; [4]University Hospital Dresden, Dresden, Germany; [5]DKD Clinic, Wiesbaden, Germany

Background. Allogeneic stem cell transplantation (ASCT) after reduced-intensity conditioning (RIC) has become a reasonable treatment option for patients with advanced myelofibrosis. The role of characteristic molecular genetic abnormalities such as JAK2V617F on outcome of ASCT is not yet elucidated. *Aims and methods.* In 139 out of 162 myelofibrosis patients with known JAK2V617F mutation status who received ASCT after RIC the impact of JAK2 genotype, JAK2V617F allele burden and clearance of mutation after ASCT was evaluated. *Results.* Overall survival was significantly reduced in multivariate analysis in patients harbouring JAK2 wild-type (HR 2.23, P=0.007) in comparison to JAK2 mutated patients, due to a non-significant higher treatment-related mortality (31% *vs.* 19%, P=0.1) and relapse incidence (30% *vs.* 21%, P=0.2). No significant influence on survival was noted for the mutated allele burden analyzed either as continous variable or after division in quartiles. Achievement of JAK2V617F negativity after ASCT was significantly associated with a decreased incidence of relapse (HR 0.22, P=0.04). In a Landmark analysis, patients who reached an undetectable JAK2 mutation level in peripheral blood 6 months after ASCT had a significant lower risk of relapse (5% *vs.* 35%, P=0.03) than patients who remained positive. *Summary and Conclusion.* We conclude that JAK2V617F mutated status but not allele frequency was associated in an improved survival, and that its rapid clearance after allografting reduced the risk of relapse.

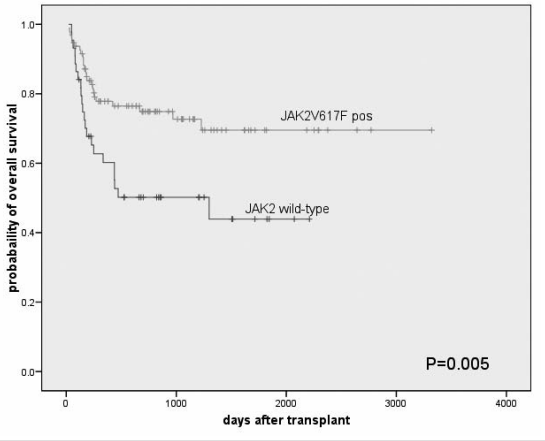

Figure. Propability of overall survival acoording to JAK2.

THE MYELOPROLIFERATIVE NEOPLASM SYMPTOM ASSESSMENT FORM (MPN-SAF): PROSPECTIVE VALIDATION OF AN EVIDENCE BASED MPN SPECIFIC INSTRUMENT

R Mesa,[1] R Scherber,[2] A Dueck,[1] J Camoriano,[1] A Gentry,[1] C Reeder,[1] K Baumgartner,[1] S Jones,[1] D Radia,[3] A Tefferi,[1] C Harrison[3]

[1]Mayo Clinic, Scottsdale, USA; [2]Chicago Medical School, North Chicago, USA; [3]Guys and St. Thomas, London, UK

Background. Symptomatic burden in myeloproliferative neoplasms (MPNs) is present in over 70% of MPN patients (Mesa *et al.* Cancer 2007), and may be improved by JAK2 inhibitors. Given no current instrument assesses the range of MPN symptoms we previously created and validated the Myelofibrosis Symptom Assessment Form (MF-SAF) (Mesa *et al.* Leukemia Research 2009). We sought to validate an expanded instrument (MPN-SAF) to assess symptoms in myelofibrosis (MF), essential thrombocythemia (ET) and polycythemia vera (PV). *Methods.* MPN-SAF: Using the previously validated MF-SAF as a base instrument, we added several key additional symptoms previously identified as present in all subtypes of MPNs including headaches, concentration, dizziness, extremity tingling, insomnia, sexual problems and mood changes on a 0 (absent) to 10 (worst-imaginable) scale. Validation. The MPN-SAF was administered jointly with the EORTC-QLQ-C30 as the co-validation instrument as well as a physician assessment of patient symptoms, and the patient's perception on the clarity, ease of completion, and comprehensiveness of the MPN-SAF. *Results.* Patients: 76 patients were prospectively enrolled (ET (N=14;18%), PV (N=17; 23%) and MF (N=45; 59%)) a median of 4 years (range:0-43) from their diagnosis. Patients were of a median age (65; range 26-88 years) and gender (50% females) typical of the disease. 79% (N=60) had received some form of cytoreductive therapy for their disease. MPN-SAF *Results.* Consistent with our prior symptomatic inventory trials we found the majority of MPN patients to be symptomatic with the majority of patients (>50%) in all prior areas of questioning except the advanced MF symptoms of fever (13%), weight loss (36%), and bone pain (42%). New items for the MPN-SAF were common including headache (45%), decreased concentration (59%), dizziness (54%), numbness (50%), insomnia (71%), sad mood (60%), and challenges with sexuality (57%). Symptoms were present across the subtypes of MPNs with MF being more noteworthy for abdominal symptoms, inactivity, fever, and weight loss (P<0.05 for all). Comparison to EORTC-QLQ-C30: Pearson correlations between MPN-SAF individual symptom scores and the EORTC-QLQ C30 showed excellent correlations with co-validation questions including fatigue, pain, headache, insomnia, early satiety, and sad mood (all P<0.001). Correlations with EORTC-QLQ-C30 subscales demonstrated excellent correlations between MPN-SAF measurements of fatigue (and EORTC physical function subscale), early satiety, abdominal symptoms, inactivity, decreased concentration, insomnia, mood (and EORTC emotional functioning subscale), and challenges with sexuality (Multiple correlations) (all P<0.001). Additionally the MPN-SAF single item assessment of overall quality of life was highly correlated (P<0.001) with all EORTC-QLQ-C30 subscales.Correlation of MPN-SAF to Physician Perceptions: The MPN-SAF results correlated well with physicians perception of fatigue, pruritus, night sweats, fever, weight loss, and bone pain (all P<0.001). Patient Assessment of MPN-SAF: The majority found the MPN-SAF easy to understand (98%) and "addressed most of my MPN symptoms"(96%). *Conclusions.* The MPN-SAF is comprehensive, clear, simple to administer, and valid instrument using of 19 separate MPN associated symptoms. Serial validation on current clinical trials, as well as validated translations into multiple languages is ongoing to establish the MPN-SAF as a uniform symptom assessment tool for MPN patients on clinical trials globally.

A standardized definition of response by cytoreductive therapy in Polycythemia Vera (PV) and Essential Thrombocythemia (ET) was recently provided by the European LeukemiaNet (ELN) investigators. These experts reached a consensus in defining three categories of response. In ET, clinico-hematological (CH) response included: 1) Complete response (CR), defined as platelet count less than or equal to 400×10^9/L, no disease-related symptoms, normal spleen size, and white blood cell count less than or equal to 10×10^9/L; 2) Partial response (PR), recognized in patients who did not fulfil the criteria for CR, and with a platelet count less than or equal to 600×10^9/L or a decrease greater than 50% from baseline; 3) non response (NR), classified as any response that did not satisfy PR criteria. However, it should be mentioned that these definitions resulted from a consensus process and their clinical significance is unknown. To provide estimates and clinical correlation of responses according to these criteria we retrospectively examined 416 ET patients (median age 66 years, 154 male/262 female) treated with Hydroxyurea (HU) for at least 12 months with the goal to keep platelet number less than 600×10^9/L. The first purpose was to estimate the frequency of CH responses, as defined by the ELN. CR rate progressively

increased over time and reached the maximum after 12 months (25%). In contrast, the majority of our treated patients (58%) achieved PR. In this subgroup, reasons for PR classification were due to persistence of leukocytosis (n=28/242, 11%) or incomplete recovery of microvascular symptoms or splenomegaly (n=37/242, 15%). No responders were 72/416 (17%). The probability of being a responder was higher in patients with age more or equal to 60 years and JAKV617F status, confirming a major drug sensitivity in this latter group. The second purpose of our analysis was to correlate the ELN responses with clinical outcomes. After a median follow-up of 3.9 years, we registered 23 deaths, 16 haematological transformations in post-ET myelofibrosis (MF)/acute myeloid leukaemia (AML) and 27 major thrombotic events (rate 1.66% patient/year). The rate of post-ET MF and AML was comparable to the HU arm of PT1 trial (0.68 *vs.* 0.84% patient/year, respectively). These events were not associated with the achievement of haematological responses. In univariate and multivariate analysis, age and previous thrombosis were independently associated with major vascular events, while the achievement of ELN responses, at 12 months of therapy, did not predict future vascular complications. Different levels of platelet count (<400 or <600×10^9/L) at 12 months of therapy did not influence the occurrence of future thrombosis. In contrast, patients with more than 10×10^9/L leucocytes had a significant higher rate of vascular complications independently from the other meaningful variables (P=0.015). In conclusion, our findings would indicate that the response of platelet count does not seem of prime relevance in the definition of ELN response, since the correlation with vascular events is more affected by leukocyte than platelet count. This notion should be considered in future clinical trials with novel JAK2 inhibitors.

SINGLE AGENT BEVACIZUMAB FOR MYELOFIBROSIS: RESULTS OF AN INTERNATIONAL MYELOPROLIFERATIVE DISORDERS-RESEARCH CONSORTIUM (MPD-RC) TRIAL

R Silver,[1] S Verstovsek,[2] R Mesa,[3] J Mascarenhas,[4] C Kessler,[5] D Rondelli,[6] J Goldberg,[7] R Marchioli,[8] E Demakos,[9] L Silverman,[9] T Barbui,[10] R Hoffman[9]

[1]Cornell, New York, USA; [2]MD Anderson, Houston, USA; [3]Mayo Clinic, Scottsdale, USA; [4]Mt. Sinai, New York, USA; [5]Georgetown, Washington, DC, USA; [6]University of Illinois, Chicago, USA; [7]New York University, New York, USA; [8]Mario Negri Sud, CH, Italy; [9]Mt. Sinai School of Medicine, New York, USA; [10]Ospedale Riuniti, Bergamo, Italy

Background. Myelofibrosis (MF) has no approved or effective medical therapy, and has been associated with the development of very significant intra-medullary angiogenesis potentially from an increased release of growth factors such as vascular endothelial growth factor (VEGF) and other cytokines. We conducted a 2-stage multicenter phase II trial of the VEGF inhibitor bevacizumab through the clinical trial branch of the MPD-RC in patients with MF. *Methods.* Patients: Symptomatic, relapsed/ refractory and intermediate/ high risk MF patients (both primary and post ET/PV MF) were eligible. Although no minimal requirements for hematologic parameters at study entry, patients with either recent vascular events or surgery were not eligible. Therapy: Patients received bevacizumab at a dose of 15 mg/kg intravenously on day 1 of a 21-day cycle for 4 cycles. Patients were evaluated for response after cycle 4 and 8. Non-responders would go off study after cycle 8, responders could receive up to 17 cycles. *Results.* Enrollment: 13 patients (10 males: 77%) were enrolled beginning May 2008 (8 PMF, 3 Post ET MF, 2 Post PV MF) of an age typical for the disease (median 71 years: range 48-84). Anemia was universally present median hemoglobin of 9.2 g/dL (range 3.0-10.7, 5 erythrocyte transfusion dependent) and six patients (46%) had an MF associated molecular mutation (5 JAK2-V617F, 1 MPL-515). Safety: Eight patients (61%) experienced a moderate to severe adverse event that was attributable to the bevacizumab therapy. Serious events (CTC 3.0 Grade 3 or 4) at least possibly related to therapy included change in LFTs (n=2), myelosuppression (n=2), pain (n=2), infection (n=2), diarrhea (n=1), heart failure (n=1), and other (n=3). One event possibly related to treatment led to a fatality in a patient with multiple co-morbidities and history of cardiac disease. No hemorrhagic or thrombotic events were observed. Response: 11 patients were eligible for response assessment as 2 patients withdrew consent prior to initiating therapy. A total of 40 cycles of bevacizumab have been given of which 5/11 (46%) patients received 4 or more cycles and were evaluable for response. Three patients continued on the second phase of therapy (cycles 5-8) for "stable disease"; one of these 3 patients completed the 8th cycle and stopped secondary to lack of response. No patient has had an objective response. Reasons for termination of therapy included toxicity (n=5), disease progression (n=1), removal from study (n=4), other (n=1). Analysis of the first stage, of this 2 stage trial design, demonstrated inadequate responses occurred for trial continuation to the second stage. Additionally, review by the external MPD Data Safety Monitoring Committee supported premature termination of the trial based on observed toxicities. Correlative biomarker studies are being conducted. *Conclusions.* Bevacizumab at the standard dose and schedule was poorly tolerated in patients with MF. Effects of treatment on biomarker profiles may be informative to guide further studies. Bevacizumab at lower doses, or other angiogenesis inhibitors, alone or in combination, may still be worthy of future study.

LONG TERM PATIENT-ADJUSTED MAINTENANCE SCHEDULE OF MEPOLIZUMAB IS SAFE AND EFFECTIVE IN HYPEREOSINOPHILIC SYNDROME (HES)

S Paolini,[1] M Rondoni,[2] E Ottaviani,[1] S Parisi,[1] C Papayannidis,[1] N Testoni,[1] I Iacobucci,[1] M Baccarani,[1] G Martinelli[1]

[1]Institute of Hematology Seràgnoli, Bologna, Italy; [2]Department of Hematology and Transplants, University of Siena, Siena, Italy

Background. Steroids are currently considered as the gold standard treatment of FIP1L1/PDGFRalpha negative HES. However, such approach has limited efficacy and possible side effects if chronically used. Mepolizumab is an anti-IL-5 monoclonal antibody recently shown to be effective in reducing peripheral blood eosinophilia and controlling symptoms. However, long term results have not been assessed yet. *Aim.* In this study we aimed to assess the long term effects of Mepolizumab in treatment-requiring HES patients. *Methods.* We treated 7 patients with HES refractory or intolerant to steroid. Mepolizumab was administered at the dose of 750 mg ev monthly until response. Maintenance therapy was subsequently given according to clinical indications at the same dose. Four patients had a prevalent respiratory involvement while 3 patients had a prevalent peripheral hypereosinophilia. Two patients had also cardiomyopathy and 1 had a eosinophilic gastritis; 6/7 patients had previously failed therapy with imatinib. *Results.* Five out seven patients achieved a response: 4/4 with respiratory involvement obtained a remission of the symptoms. Notably, one patient with chronic rhinitis also recovered from the associated anosmia after six infusions. 1/3 patients with peripheral hypereosinophilia showed a drastic eosinophil reduction after the first Mepolizumab administration. The other two patients did not show significant improvement. Duration of response was variable among patients, ranging from 4 to 16 weeks (mean 10.2). Notably, all patients re-achieved signs/symptoms remission when re-treated at relapse and, interestingly, clinical remission duration after maintenance courses was comparable, for each patients, to that recorded after induction. The mean number of maintenance cycles was 7.6 (range 3-17). With a median follow-up of 26 months (range 7-52) no patient has lost response. Neither Mepolizumab-related adverse events nor allergic reactions during infusion were reported. *Conclusions.* Though in a limited series, our study confirmed that Mepolizumab is safe and effective in controlling symptoms in HES patients. Notably, sensitivity to Mepolizumab was maintained after repeated cycles and no acquired resistance as well as late toxicity were recorded. Finally, response duration was variable among patient but, being consistent in each case, a patient-adjusted maintenance schedule might be used for symptoms recurrence prevention. *Aknowledgements.* BolognAIL, European LeukemiaNet, AIRC, Fondazione Del Monte di Bologna e Ravenna, FIRB 2006, PRIN 2008, Ateneo RFO, Project of Integrated Program (PIO), Programma di Ricerca Regione - Università 2007-2009.

Seragnoli, University of Bologna, Bologna, Italy; [6]Dpt. Pathology, Pathological Anatomy Section, University of Verona, Verona, Italy; [7]Dpt. Biomed Surg Sciences, Rheumatology Section, Az. Ospedaliera Universitaria, Verona, Italy

Background. The diagnosis of mastocytosis in absence of the typical skin lesions is often difficult. It should be considered in the differential diagnosis of a number of unexplained clinical conditions, such as severe anaphylaxis, osteoporosis, neurological or constitutional symptoms, and chronic diarrhoea. Isolated bone marrow mastocytosis (BMM) is considered a rare subcategory of indolent systemic mastocytosis (ISM), characterized by low burden of mast cells (MC), absence of skin, lymph node or multiorgan involvement, slightly elevated serum tryptase (sT) levels, and a good prognosis. The term Monoclonal Mast cell Activation Syndrome (MMAS) is used to define those patients with mediator-related symptoms and absence of skin lesions in which bone marrow (BM) biopsy fails to demonstrate multifocal MC aggregates (i.e. the major criterion for diagnosing mastocytosis), but there is a proof of MC clonality (abnormal MC immunophenotype or detection of a KIT mutation). Data about these conditions are scanty. *Aims.* To define the frequency and characteristics of clonal MC disorders limited to BM in a cooperative multidisciplinary setting. *Methods.* From January 2006 to December 2009 144 adult patients with a clinical suspect of mastocytosis were referred to our multidisciplinary ambulatory for Mastocytosis, based on close collaboration between Hematologists, Allergists, Dermatologists and Rheumatologists. All patients underwent BM evaluation that included histology/citology, flow cytometry, and detection of KIT mutations, performed as described (Bonadonna *et al.*, JACI 2009).

Table. Characteristics of pts with clonal MC disorders.

	BMM	MMAS	ISM*	p#
N° of patients	40	13	48	
M/F	25/15	13/0	19/29	.001
Age at diagnosis (years)	49.5 (19-74)	51 (25-69)	42 (25-77)	ns
Time from first symptoms (months)	41.2 (2.9-365)	60.2 (9.3-164)	126.2 (0-480)	.001
Serum tryptase (ng/mL)	23.6 (10.6-108)	17.4 (12.7-27)	40.0 (7.7-761)	.001
% abnormal BM mast cells at flow cytometry (CD2+ and/or CD25+)	0.12 (0-0.78)	0.02 (0-0.11)	0.11 (0-2.3)	.007
Mediator-related symptoms (other than anaphylaxis)	10 (25%)	1 (7.7%)	20 (41.7%)	.03
Anaphylaxis	38 (95%)	13 (100%)	12 (25%)	<.0001
Allergy	11 (27.5%)	0	10 (20.8%)	ns
Loss of bone mineral density (osteopenia/osteoporosis)	8/33 (24.2%)	4/13 (30.7%)	10/30 (33.3%)	ns

* without skin involvement; # p value refers to BMM+MMAS vs ISM

Results. According to the current WHO guidelines, we made 111 diagnoses of clonal MC disorders: ISM with skin involvement were 48 (43.2%), BMM 40 (36%), MMAS 13 (11.7%). The remaining patients had Cutaneous Mastocytosis (9) and Mast Cell Leukemia (1). Among the 53 patients with clonal MC disorders limited to BM, the large majority of them (96%) had experienced one or more episodes of severe anaphylaxis after hymenoptera sting, drug or food or showed unexplained anaphylaxis. Two patients were referred to our Ambulatory because of unexplained osteoporosis. Compared to cases of ISM with skin involvement, patients with BMM or MMAS were predominantly males and, as expected, they had an inferior burden of MC, as suggested by the lower sT levels and the inferior percentage of BM abnormal MC at flow cytometry (see Table). Moreover, mediator-related symptoms other than anaphylaxis, such as pruritus, flushing, diarrhoea, hypotension, were less frequent in patients with MC disease limited to BM. Densitometric examination revealed 22/76 cases (29%) of osteoporosis or osteopenia, according to WHO definitions, without differences between subgroups. After a median follow-up of 22 months (range 1-48) all patients are alive and have stable disease. *Conclusions.* Clonal MC disorders limited to BM are a challenge for the physician. A close collaboration between different specialists may allow that more patients with clinical suspicion of mastocytosis could be referred to the opportune diagnostic procedures. In our experience this led to individuate 53 cases of isolated BMM or MMAS, the largest series reported to date. Besides making a correct diagnosis, this approach revealed a significant proportion of patients with loss of bone mineral density, so improving the management of this disease.

PROGNOSTIC IMPLICATIONS OF THE EUROPEAN CONSENSUS FOR GRADING OF BONE MARROW FIBROSIS IN PRIMARY MYELOFIBROSIS: COMPARISON WITH THE PROGNOSTIC SCORING SYSTEM OF THE IWGMRT

C Vener,[1] U Gianelli,[1] A Iurlo,[1] N Fracchiolla,[1] A Bossi,[2] I Cortinovis,[2] G Lambertenghi Deliliers[1]

[1]Fondazione IRCCS Ca' Granda - Ospedale Maggiore Policlinico, Milano, Italy; [2]Dipartimento di Medicina del Lavoro, Sez. Biometria, Università degli Studi, Milano, Italy

Background. The WHO classification proposes strict diagnostic criteria for primary myelofibrosis (PMF), and a European consensus has recommended the four-class grading of bone marrow fibrosis (BMF) as assessed by means of trephine bone marrow biopsies. We have previously generated a prognostic model for overall survival (OS) based on the WHO classification and the European consensus for BMF grading: in 98 consecutive PMF patients, our histological model significantly associated with differences in OS and, unlike other validated prognostic scoring systems (PSSs) (Mayo, Dingli, Cervantes, and Dupriez), clearly discriminated the OS of intermediate- and high-risk patients. The International Working Group for Myelofibrosis Research and Treatment (IWGMRT) has recently proposed a PSS for PMF that is structurally based on five clinical parameters predicting shortened survival: an age of >65 years, the presence of constitutional symptoms, hemoglobin levels of <10 g/dL, leukocyte counts of >25x10^9/L, and circulating blast cells ≥1%. These variables delineated four risk groups with distinct survival curves: low risk (0), intermediate risk-1 (1), intermediate risk-2 (2), and high risk (≥3). *Aims.* To establish the relationship between the BMF grading model and the IWGMRT PSS in PMF, and verify whether the fibrosis grading system helps to discriminate prognosis in patients with equal IWGMRT PSS scores. *Patients and methods.* The study involved 196 consecutive PMF patients (104 M, 96 F; median age 65.6 years, range 27-85 years), who were diagnosed between 1996 and 2008 (median follow-up 51.4 months, range 7.4-159 months), and classified using the WHO criteria. On the basis of the BMF grading model, 83 cases were classified as MF-0, 58 as MF-1, 41 as MF-2, and 14 as MF-3; on the basis of the IWGMRT PSS, 42 cases were classified as low risk, 73 as intermediate risk-1, 69 as intermediate risk-2, and 12 as high risk. OS curves were calculated according to Kaplan-Meier and compared by means of the log-rank test, and clinicopathological relationships were examined using the x2 test. A p value of <0.05 was considered significant. *Results.* OS was significantly shorter in the patients with MF-3 *vs.* MF-2 *vs.* MF-1 *vs.* MF-0 (Kaplan-Meier analysis, log-rank test: P<0.0001), and in the patients at high risk *vs.* intermediate risk-2 *vs.* intermediate risk-1 *vs.* low risk (Kaplan-Meier analysis, log-rank test: P<0.0001). The BMF grading model was capable of identifying at diagnosis patients at equal IWGMRT PSS risk with a different prognosis insofar as some of the patients with an equal risk score who died as a result of the disease had a higher degree of fibrosis. There was no good direct correlation between fibrosis grading and IWGMRT PSS scores, but the patients with lower MF values (0+1) more frequently had low or intermediate risk-1 IWGMRT PSS scores, and those with higher MF scores (2+3) more frequently had intermediate risk-2 or high risk IWGMRT PSS scores (x2 test: P<0.0001). *Conclusion.* The histological model significantly associated with differences in OS and could identify at diagnosis patients with the same IWGMRT PSS score but a shorter OS.

0984

GERMLINE HOMOZYGOSITY FOR JAK2 46/1 HAPLOTYPE IS A RISK FACTOR OF DEVELOPING PRIMARY OR POST-POLYCYTHEMIA VERA/ESSENTIAL THROMBOCYTHEMIA MYELOFIBROSIS

H Andrikovics,[1] S Nahajevszky,[2] M Koszarska,[1] N Meggyesi,[1] A Bors,[1] G Halm,[2] S Lueff,[2] N Lovas,[2] Z Matrai,[2] J Csomor,[2] R Rasonyi,[2] M Egyed,[3] J Varkonyi,[4] G Mikala,[2] A Sipos,[2] A Kozma,[2] E Adam,[2] A Tordai,[1] T Masszi[2]

[1]Hungarian National Blood Transfusion Service, Budapest, Hungary; [2]St. Istvan and St. Laszlo Hospital, Budapest, Hungary; [3]Kaposi Mor Hospital, Kaposvar, Hungary; [4]Semmelweis University, Budapest, Hungary

Background. Recently a germline JAK2 haplotype (designated '46/1' or 'GGCC' haplotype) was described as a risk factor for acquiring JAK2 V617F-positive myeloproliferative neoplasms (MPN). The role of 46/1 haplotype as a predisposition factor for V617F-negative MPN is controversial. Previous studies have extensively investigated the relationship between the presence of acquired V617F mutation and the presentation of MPN. As carriership of 46/1 haplotype increases the risk of acquisition JAK2 V617F mutations, it may also have an impact on disease phenotype. *Aims of our study were the following.* (a) to examine and confirm associations of MPN and the presence of the JAK2 46/1 haplotype in Hungarian MPN patients; (b) to examine associations of the 46/1 haplotype with distinct clinical characteristics of MPN (especially the occurrence of complications affecting life expectancy such as thrombosis and myelofibrotic or leukaemic transformation). *Methods.* We genotyped 46/1 haplotype in 334 MPN-patients and 331 controls by a novel approach allowing the specific amplification of 617V and 617F alleles separately and genotype-detection of the rs12343867 tagging 46/1 haplotype. *Results.* The frequency of JAK2 V617F was 75.1% (251/334) in the MPN group: 87.4% (153/175) in polycytaemia vera (PV) patients, 59.5% (78/131) in essential thrombocythaemia (ET) patients, and 71.4% (20/28) in primary myelofibrosis (PMF) patients. In agreement with previous studies, increased frequency of allele 'C' linked to 46/1 was found among V617F-positive MPN-patients (n=251) compared to controls (44.3%±3.8% *vs.* 29.3%±3.5%, P<0.0001) and compared to V617F-negative MPN (31.3±7.2%; P=0.001). Excluding V617F-negative PV, the 'C' allele frequency was also increased among V617F-negative ET and PMF (n=61, 34.4%±8.6%, P=0.05) compared to controls. At presentation, significantly elevated hemoglobin (Hb) levels were found in V617F-positive patients compared to V617F-negative counterparts (P<0.000). Vascular complications were more common in V617F-positive patients (P=0.039, 26.6% *vs.* 15.2%). Although 46/1 haplotype is associated with the development of V617F mutation, neither hemoglobin level nor the occurrence of vascular complications were influenced by 46/1 genotype. Transformation to myelofibrosis was more frequent in CC-homozygotes (17/53, 32%) compared to patients with CT and TT genotypes (32/275, 12%; P<0.001) in the entire MPN-cohort. *Conclusions.* Our study confirms earlier observations that JAK2 46/1 haplotype is a susceptibility factor for JAK2 V617F-positive MPN and raises the possibility of a similar effect in JAK2 V617F-negative ET and PMF. The enrichment of 46/1 haplotype carriers among V617F negative MPN supports the 'fertile ground hypothesis'. 46/1 haplotype is not associated with MPN manifestations like disease type, splenomegaly, signs of increased erythropoiesis or myelopoiesis, vascular complication or leukaemic transformation except for the increased risk of the development of myelofibrosis in homozygous cases. In our hypothesis, clonal cells carrying 46/1 haplotype in homozygous form may be more susceptible to somatic recombination resulting in uniparental disomy (UPD) compared to 46/1 heterozygous cells, because of the perfect match between large portions (approx. 280 kb corresponding to the haplotype block) of the two parental 9p chromosome regions. Once UPD occurs, the affected clones may have proliferational advantage, therefore an increase of allele burden can be observed, which may be a natural evolution of MPN.

DOWNREGULATION OF P53 BY HYDROXYUREA ASSOCIATED WITH A LACK OF APOPTOSIS INDUCTION IN CULTURED HUMAN KERATINOCYTES

J Eberle, C Schwarz, R Deva, F Braun, E Stockfleth

Charité-Universitätsmedizin Berlin, Berlin, Germany

Hydroxyurea (HU) is commonly used for cytoreduction in patients with myeloproliferative neoplasms such as essential thrombocythaemia (ET). Nevertheless, this agent may have genotoxic and mutagenic properties and the possibility of long-term leukaemogenicity in patients with ET remains a serious safety concern. In addition, HU is associated with a variety of cutaneous side effects including skin atrophy, hyperpigmentation, alopecia, leg ulcers, actinic keratosis and, most seriously, squamous cell carcinoma. Importantly, HU-induced skin cancers may metastasize and are a potentially life-threatening complication. The tumour suppressor protein p53 is a transcriptional master regulator that protects against malignant transformation. By inducing cell cycle arrest and activating apoptotic pathways in response to DNA damage or other cellular stressors, p53 provides an important safeguard mechanism against malignant transformation. Inactivation of such pathways is thought to be a key mechanism of tumourigenesis. In order to investigate potential mechanisms linking HU to skin cancers, we investigated the effect of this agent on the apoptotic responses of cultured normal human keratinocytes and normal human melanocytes. Although HU treatment was associated with morphological changes and reduction in cell numbers in both cell types, there was a striking difference in the apoptotic response between melanocytes and keratinocytes. In melanocytes, HU led to the accumulation of p53, as demonstrated by Western blot analyses of total and nuclear protein extracts, and induced significant apoptosis starting around 48 hours post-treatment. Functional p53 was assayed by its DNA binding capacity. In contrast, there was only limited induction of apoptosis by HU in keratinocytes, which was correlated with p53 downregulation at 24 hours and 48 hours post-treatment. HU exerted significant damage on melanocytes and keratinocytes, but it is the downregulation of the tumour suppressor protein p53 in surviving keratinocytes which could provide a mechanistic rationale for the occurrence of skin cancers in ET patients treated with HU.

This study has been supported by Shire Pharmaceutical Development LTD.

SEVEN YEAR FOLLOW-UP SHOWS THAT WHO BONE MARROW CRITERIA EFFECTIVELY IDENTIFIES TRUE ET WITH NO FIBROSIS

E Ejerblad,[1] H Kvasnicka,[2] J Thiele,[2] B Andreasson,[3] M Björkholm,[4] E Löfvenberg,[5] B Markevärn,[6] M Merup,[5] L Nilsson,[7] J Palmblad,[5] J Samuelsson,[8] G Birgegård[1]

[1]Uppsala University Hospital, Uppsala, Sweden; [2]Institute of Pathology, University of Cologne, Cologne, Germany; [3]Department of Medicine, Uddevalla Hospital, Uddevalla, Sweden; [4]Department of Medicine, Division of Hematology, Karolinska Hospital, Stockholm, Sweden; [5]Hematology Center, Karolinska University Hospital, Huddinge, Stockholm, Sweden; [6]Department of Medicine, University Hospital, Umeå, Umeå, Sweden; [7]Department of Hematology, Lund University Hospital, Lund, Sweden; [8]Department of Medicine, Stockholm South Hospital, Stockholm, Sweden

Background. At present, the usefulness of the new World Health Organisation (WHO) classification bone marrow criteria for MPN (myeloproliferative neoplasms) is under debate. A high incidence of clinical manifestations of myelofibrosis in a cohort of patients with essential thrombocythemia (ET) and polycythemia vera (PV) initiated a blinded re-evaluation of diagnosis with the use of the new WHO bone marrow criteria. *Aims.* To examine the development of bone marrow fibrosis in patients with ET and PV followed for a minimum of 7 years. In addition, to re-evaluate the diagnosis of ET based on old criteria, using the WHO classification. *Methods.* This prospective study of 60 patients with newly diagnosed or previously treated MPN, (42 ET, 17 PV and 1 PMF), was set up in 1998 to evaluate platelet reduction treatment. Informed consent was obtained. Two-year follow-up results

are previously reported. Bone marrow trephine biopsy specimens were requested from patients at study start, after 2 and 7 years of follow-up. The biopsies were assessed jointly by two experienced hematopathologists (HK, JT). The examination was blinded, without knowledge of time of sampling or any clinical data, except age and sex. WHO criteria were used for diagnosis and fibrosis grading. *Results.* At 7 years 2 patients had transformed to MDS, 2 to AML, 7 to myelofibrosis (WHO 2008 criteria). Ten patients were dead, 2 with PV, 2 with true ET (one trauma, one respiratory insufficiency), 6 with PMF. One was lost-to-follow-up. Of the 42 patients with initial diagnosis ET, there were bone marrow specimens of good quality from 40 patients at study start. The blinded bone marrow analysis identified 21 of the 42 initial ET patients as true ET (WHO criteria). 19 were alive, and in the 12 with available follow-up biopsies none had fibrosis. 15/21 had an available JAK2V617F test, 8 were positive (53%). Out of the 42 patients with initial diagnosis ET, 17 were reclassified as PMF (12 PMF-0, 3 PMF-1, 2 PMF-2), 2 as MPN-U. JAK2V617F results were available in 10/17 with PMF, only 1 was positive (P= 0.034 *vs.* ET). In the PMF cases, fibrosis progressed: 9 had a fibrosis grade of 2 or higher at study end, 7 of these patients had a WHO-compatible PMF. In PV patients, representative bone marrow specimens from study start were available from 15/17. Three of the PV-patients had fibrosis grade 1. At 7-year follow up, from the 14 patients still alive, we received 10 representative bone marrow samples showing that 2 patients had grade 1 fibrosis and 3 grade 2. JAK2 results were available in 11 PV patients, 10/11 were positive. *Conclusions.* A high incidence of bone marrow fibrosis in a cohort of ET and PV patients diagnosed before 1998 was explained by re-evaluation of the initial ET diagnosis with the use of the new WHO criteria. These criteria were able to differ blindly between true ET and PMF with a marked difference in follow-up outcome. Relations between fibrosis development and treatments are under analysis and will be reported separately.

TIME-DEPENDENT ANALYSIS IN PATIENTS WITH PRIMARY MYELOFIBROSIS SHOWS THAT RED BLOOD CELL TRANSFUSION DEPENDENCY AFFECTS SURVIVAL AND IMPROVES DYNAMIC RISK STRATIFICATION

C Elena,[1] F Passamonti,[1] E RUMI,[1] E Boveri,[1] L Arcaini,[2] C Pascutto,[1] M Cazzola,[1] M Lazzarino[1]

[1]*Fondazione IRCCS Policlinico San Matteo, University of Pavia, Pavia, Italy;* [2]*Division of Hematology, Fond. IRCCS Policlinico San Matteo, University of Pavia, Pavia, Italy*

Background. Primary Myelofibrosis (PMF) is a Philadelphia-negative myeloproliferative neoplasm (MPN) with a heterogeneous clinical presentation, encompassing anemia, splenomegaly, leukocytosis or leukopenia, thrombocytosis or thrombocytopenia, and constitutional symptoms. Current risk stratification is based on the International Prognostic Scoring System (Cervantes *et al.*, Blood 2009), developed to predict survival at diagnosis, (IPSS) and on dynamic IPSS (DIPSS), to be applied anytime during follow-up (Passamonti *et al.*, Blood 2010). Both models do not take into account the potential impact on survival of red blood cell (RBC) transfusion-dependency, which may be present at diagnosis or acquired during follow-up. *Aim.* To investigate whether RBC transfusion-dependency (at diagnosis or dynamically acquired) affects survival of PMF patients. *Methods.* This study includes 296 consecutive patients with PMF diagnosed between 1980 and 2009 and followed at the Division of Hematology, IRCCS Fondazione Policlinico San Matteo, University of Pavia. This study was in accordance with the Helsinki Declaration of 1975. Diagnosis of PMF was based on the presence of megakaryocyte proliferation and atypia accompanied by increased reticulin and/or collagen in bone marrow as major criterion, as well as of the JAK2 (V617F) or the MPL mutations if available and two criteria among anemia, splenomegaly, increased lactate dehydrogenase level, and leukoerythroblastosis. Transfusion-dependency was defined as the persistence of RBC transfusion need to correct anemia (Hb <8.5 g/dL). The effect of RBC transfusion-dependency on survival was evaluated by Cox proportional hazards regression with time-dependent covariates on 226 patients with a regular follow-up. *Results.* Median follow-up was 3.3 years (range, 0-18) with 1401 persons/year of follow-up. Median age at diagnosis was 61 years (range, 24-86) and male/female ratio was 193/103. IPSS risk stratification at diagnosis (n=263) grouped patients as low (77, 29%), intermediate-1 (70, 27%), intermediate-2 (73, 28%) and high risk (43, 16%). RBC transfusion-dependency was present at diagnosis in 44 (15%) of 296 patients. Kaplan Meyer analysis showed that RBC transfusion-dependency significantly affects survival (P<0.001). Median survival was 2.6 years in patients who received RBC transfusion at diagnosis and 8.1 years in those who did not. After adjusting for IPSS categories in multivariable Cox proportional hazard regression, transfusion-dependency retained a significant impact on survival (HR 1.71, 95%CI: 1.07-2.75; P=0.03). During follow-up, 39 (17%) of 226 regularly followed patients became RBC transfusion-dependent. To investigate the dynamic impact of RBC transfusion-dependency on survival, a univariable analysis by Cox regression using transfusion status as time-dependent covariate was carried out. We found that patients who acquire RBC transfusion-dependency anytime during follow-up have a significantly worse survival compared to those who remain transfusion-independent (HR: 5.06, 95%CI: 3.36-7.63; P<0.001). In a multivariable analysis with DIPSS categories and transfusion status as time-dependent covariates, RBC transfusion-dependency retained its prognostic impact on survival (HR 3.69, 95%CI: 2.43-5.6; P<0.001).*Conclusions.* This study indicates that RBC transfusion-dependency, either present at diagnosis or acquired anytime during follow-up, is a significant prognostic factor for survival in patients with primary myelofibrosis. Transfusion status results as a useful complement to IPSS and to DIPSS.

EXTRA-HAEMATOLOGICAL ADVERSE EVENTS IN ESSENTIAL THROMBOCYTHAEMIA PATIENTS TREATED WITH HYDROXYUREA: A PRELIMINARY REPORT OF THE REGISTRO ITALIANO TROMBOCITEMIA (RIT)

L Gugliotta,[1] A Tieghi[2]

[1]*Institute L.and A. Seragnoli S.Orsola Hospital, University of Bologna, Bologna, Italy;* [2]*Arcispedale S.Maria Nuova, Hematology Unit, Reggio Emilia, Italy*

Background. Hydroxyurea (HU) is the cytoreductive drug more frequently used for the first-line treatment of Essential Thrombocythemia (ET) patients. The HU efficacy in reducing the rate of thrombotic complications is well documented, and its use is limited only by the potential leukaemogenicity and by the haematological and extra-haematological toxicity and side effects. *Objective.* To evaluate the extra-haematological toxicity/side effects of HU in a large series of ET patients. *Material and methods.* One thousand and seventy-five ET patients of the RIT treated with HU are the object of this report. The patients, 641 females (59.6%) and 434 males (40.4%), 2-93 years old (median age 71), diagnosed according to the PVSG or WHO criteria, received HU as first or second line treatment in seventy haematological centres. The administered dose of HU was 0.25-3.0 g/day, with a median value of 1g/day; the HU dose was 1.5-2.0 g/day in 75 cases (7.0 %) and >/= 2 g/day in 33 cases (3.1%). The following adverse events (AE) reported as related to the HU treatment were considered for the analysis: dermatological (hyperpigmentation, rash, lichen, carcinoma, leg ulcers); gastro-intestinal (nausea/vomiting, diarrhoea); general (fever, myalgia); other. Moreover, the causes of HU withdrawal were analysed. *Results.* During the follow-up, in the ET patients treated with HU, the reported dermatological AE were: hyperpigmentation 41 cases (3.8%), rash 27 cases (2.5%), lichen 13 cases (1.2%), carcinoma 8 cases (0.7%), leg ulcers 30 cases (2.8%); the gastro-intestinal AE were: nausea/vomiting 42 cases (3.9%), diarrhea 36 cases (3.3%); the general AE were: fever 34 cases (3.2%), myalgia 57 cases (5.3%); the other AE were 88 cases (8.2%). The HU withdrawal referred to extra-haematological AE were 56 cases (5.2%). By distinguishing the ET patients diagnosed before the year 2004 (432, 40.2%) and diagnosed since 2004 (642, 59.7%), the rate of all subgroups of extra-haematological AE was appreciably reduced in the patients diagnosed more recently. *Conclusion.* This preliminary analysis shows that the extra-haematological AE referred to the HU treatment in the ET patients of the RIT were not negligible and allowed to the drug withdrawal in more than 5% of cases.

The RIT is a Gimema project sponsored by Shire. This study was partially supported by the Regione Emilia Romagna, Progetto Regione-Università 2007-2009.

IN PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA, LEUKOCYTOSIS AT DIAGNOSIS IS A NEGATIVE PROGNOSTIC FACTOR FOR PROGRESSION TO MYELOFIBROSIS

I Bertozzi,[1] F Tezza,[2] M Scapin,[2] E Bonamigo,[2] F Fabris,[2] M Randi[2]

[1]*University of Padua, Padua, Italy;* [2]*Dept of Medical and Surgical Sciences, University of Padua, Padua, Italy*

Background. About half patients with Essential Thrombocythemia (ET) carry the JAK2V617F mutation; they rarely progress to myelofibro-

sis (MF)(rr 4% at 15 years). At present, no simple test is available to expect the progress to MF (PET-MF). As an example, no meaningful difference between JAK2V617F mutated and non mutated patients has been found in the respect of PET-MF, even if the accumulation of mutant V617F alleles has been reported to be a mechanism of evolution toward MF in JAK2V617F mutated ET patients. *Patients and methods.* We evaluated retrospectively a cohort of 146 patients affected by ET (M 35, F 111, median follow up 10.46 y, mean age at diagnosis 51.2±17.2 y) diagnosed in agreement with WHO criteria. We compared the white blood cells (WBC) number at diagnosis of 13 patients progressed to MF (PET-MF) with133 cases who did not evolve (ET). Considering that the patients with ET had very wide durations of their follow-up, we selected within this cohort, 20 patients (ET-2) who were comparable for sex, age and follow-up duration to PET-MF patients. The comparison between means was performed with One-way ANOVA and the threshold of WBC number has been defined with ROC curve. *Results.* The main hemochrome data and mutational status of patients are summarized in Table 1. WBC counts at diagnosis were statistically higher in PET-MF than in ET and ET-2 (P=0.0001). The threshold WBC count significant for MF progression was identified at 10.2×10^9/L (sensibility 83%, specificity 81%) comparing group PET-MF with ET and at 9×10^9/L (sensibility 80%, specificity 92%) comparing with ET-2. No statistical differences were found in mean platelet counts and in mean hemoglobin levels. *Discussion.* As expected, most PET-ET patients were JAK2V617F. This study shows that an increased number of WBC at diagnosis is a relevant marker of MF progression in patients with ET. In contrast, the contribution of Hb level and platelets number at diagnosis to MF progression remains not significant. We suggest to monitor JAK2 allele burden mainly in patients with ET and a high WBC number at diagnosis.

Table 1.

	WBC x 10^9/L	Hemoglobin (Hb) g/L	Platelets (Plts) x 10^9/L	JAK2 V617F MT/WT
ET	8.52 ± 2.65	13,76 ± 1,40	781,8 ± 273,8	67/42
PET-MF	13.7 ± 6.3	14,6 ± 1,3	780,7± 366,1	8/4
ET-2	8.2 ± 2.8	14,2 ± 1,17	694.6 ± 158.7	14/6

INCREASED RISK OF SPLANCHNIC OR CEREBRAL VENOUS THROMBOSIS IN PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA CARRYING THE JAK2 V617F MUTATION

V De Stefano, E Rossi, T Za, A Ciminello, S Betti, C Luzzi, D De Ritis, P Chiusolo, G Leone

Institute of Hematology, Catholic University, Rome, Italy

Background. We previously reported in a cohort of patients with splanchnic venous thrombosis (SVT) or cerebral venous thrombosis (CVT) the presence of the JAK2 V617F mutation in 95% of patients with an overt Philadelphia-negative myeloproliferative neoplasm (MPN), in 21% of patients with SVT and without overt MPN, and in 5% of patients with CVT and without overt MPN (De Stefano *et al.*, J Thromb Haemost 2007; 5: 708). Moreover, the mutation is actually known to be associated with an increased risk of thrombosis in patients with essential thrombocythemia (ET). *Aims.* To investigate the impact of the JAK2 V617F mutation on the risk of thrombosis in unusual sites in patients with ET. *Patients and ethods.* We carried out a retrospective cohort study on 224 patients with ET (M/F 75/149, median age at diagnosis 55 years, range 20-92): 156 were asymptomatic and the remaining ones had suffered from arterial thrombosis (n=39,17.4%), venous thrombosis in common sites (n=13, 5.8%), SVT (n=13, 5.8%), and CVT (n=3, 1.3%). All the patients were tested for the presence of the JAK2 V617F mutation and inherited thrombophilia. *Results.* The mutation was present in 144 patients (64.2%), namely in 87 asymptomatic ones, in 41 with arterial thrombosis or venous thrombosis in common sites, in 11 with SVT, and in all the three patients with CVT. Therefore, in ET patients the relative risk (RR) of thrombosis in unusual sites (SVT or CVT) associated with the mutation was 1.56 (95%CI 1.24-1.97) in comparison with the patients without history of thrombosis, namely 1.51 (95%CI 1.15-1.98) for SVT, and 1.79 (95%CI 1.55-2.06) for CVT. All the patients with SVT or CVT were aged <60 years: among the patients within this age range, the RR associated with the mutation in respect to the asymptomatic individuals was 1.81 (95%CI 1.36-2.41) for overall thromboses in unusual sites, 1.75 (95%CI 1.27-2.40) for SVT, and 2.07 (95%CI 1.66-2.57) for CVT. Those results did not substantially change after exclusion of the patients with inherited thrombophilia: one with SVT, one with CVT, and five without thrombosis (data not shown). Notably, in the patient cohort the mutation did not increase the risk of venous thrombosis in common sites (RR 1.24, 95%CI 0.84-1.83). *Conclusions.* In ET the risk for venous thrombosis associated with the JAK2 V617F mutation preferentially targets splanchnic or cerebral veins in young patients, and is independent of inherited thrombophilia.

0991

ANAGRELIDE AND FIBROBLAST GROWTH FACTOR-2 LEVELS IN PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA

R Cacciola, E Di Francesco, C Ferlito, F Pezzella, E Cacciola

Hematology, Catania, Italy

Background. Essential thrombocythemia (ET) is characterized by platelet-coagulant-endothelial and angiogenic activation. Fibroblast growth factor-2 (FGF-2) is released by platelet-endothelial activation and upregulated by fibrinogen (Fg). It has been reported that FGF-2 induces myeloproliferation. The standard treatment includes cytoreduction with hydroxyurea (HU) or anagrelide (ANA) and antiplatelets. *Aims.* We evaluated platelets, platelet factor 4 (PF4) and fibrinogen (Fg), as markers of platelet and coagulant activation, tissue factor pathway inhibitor (TFPI) and von Willebrand factor (vWF), as markers of endothelial activation, FGF-2 and vascular endothelial growth factor (VEGF), as indicators of angiogenesis, and white blood cell (WBC) count, as myeloproliferative index. *Methods.* We recruited 42 patients with ET (21 males and 21 females, mean 60 years) who fulfilled WHO criteria. Their mean duration of disease was 8 years (range, 4-21 years). None of patients had splenomegaly. Of 42 patients, 21 were on HU and 21 were on ANA. The average dose of HU was 1.25 g/day. ANA was administered in dose of 0.5 mg/day, with increases of 0.5 mg/day every 7 days until the platelets decreased below 400×10^9/L and with a average maintenance dosage of 2.1 mg/day. All patients were on aspirin. Platelets, PF4, Fg, TFPI, vWF, FGF-2, VEGF and WBC were measured before cytoreduction and to complete response defined as platelets $<400\times10^9$/L. Platelets and WBC were measured by automated analyser. PF4, TFPI, FGF-2 and VEGF and Fg and vWF were assayed by ELISA and Clauss and immunoturbidimetric assay, respectively. Considering that FGF and VEGF may be produced by platelets, we adjiusted FGF and VEGF per platelet (FGFPLT /106 and VEGFPLT/106). *Results.* Before treatment all patients had thrombocytosis ($966\pm286\times10^9$/L), high PF4 (167±100 Iu/mL *vs.* 4.1±2.4 Iu/mL) (P<.0001) and Fg (388±96 mg% *vs.* 237±42 mg%) (P<.0001), elevated TFPI (130±71 ng/mL *vs.* 94±10 ng/mL) (P<.0001) and low vWF (26±9 % *vs.* 77±18%) (P<.0001), elevated FGF-2PLT (0,06±0.06 pg/106 *vs.* 0.01±0.001 pg/106) (P<.0001) and VEGFPLT (1.6±1.0 pg/106 *vs.* 0.5±0,5 pg/106) (P<.0001), leukocytosis ($9.3\pm2.1\times10^9$/L *vs.* $5.2\pm1.1\times10^9$/L) (P<.0001). After treatment, all patients had platelets $<400\times10^9$/L ($385\pm55\times10^9$/L) and normal WBC ($7.3\pm2\times10^9$/L). PF4, Fg, TFPI, FGF-2PLT and VEGFPLT remained elevated (190±90 Iu/mL *vs.* 4.1±2.4 Iu/mL and 465±140 mg% *vs.* 237±42 mg% and 138±39 ng/mL *vs.* 94±10 ng/mL and 0.13±0.13 pg/106 *vs.* 0.01±0.001 pg/106 and 1.5±1 pg/106 *vs.* 0.5±0,5 pg/106) (P<.0001 and P<.0001 and P<.0001 and P<.0001 and P<.0001 and P<.0001, respectively) and vWF was low (33±7 % *vs.* 77±18%) (P<.0001) in the HU group whereas the ANA group normalized PF4 (8.5±3 Iu/mL), Fg (295±46 mg%), TFPI (100±49 ng/mL), vWF (91±35 %), FGF-2PLT (0.01±0.0 pg/106) and VEGFPLT (1.1±0.6 pg/106). A positive correlation there was between PF4 and platelets and Fg and TFPI and vWF (P=0.042 and P<.0001 and P=0.067 and P<.0001, respectively) and FGF-2PLT (P<.0001) and between FGF-2PLT and Fg (P<.0001). A significant correlation there was between FGF-2PLT and TFPI and vWF (P=0.011 and P<.0001, respectively). A correlation was found between FGF-2PLT and VEGFPLT (P<.0001) and WBC (P=0.008). *Conclusions.* These data suggest that FGF-2PLT may be a platelet-coagulant-endothelial-activation thrombotic marker that normalizes after ANA ameliorating the prognosis of ET.

Platelet biology

A NOVEL SPLICE-DONOR SITE MUTATION IN THE GPIIIA GENE IDENTIFIED IN FOUR WOMEN WITH REDUCED FIBRINOGEN RECEPTOR EXPRESSION

I Randen, R Hauge, K Sorensen, J Kjeldsen-Kragh, L Osnes

Department of Immunology and Transfusion Medicine, Oslo University Hospital, Oslo, Norway

Background. The fibrinogen receptor GPIIb-GPIIIa is the most abundant platelet receptor and crucial for the clotting process. Mutations in the genes coding for the GPIIb-GPIIIa complex result in qualitative and/or quantitative changes of the receptor and is the molecular background for the bleeding disorder Glanzmann thrombasthenia (GT). Two different genes encode the two subunits _II_ (GPIIb) and _3 (GPIIIa) which are associated by non-covalent and calcium dependent bonds. Complex formation is imperative for surface expression. The human platelet antigen-1 (HPA-1) is defined by the SNP T176C in the GPIIIa gene, resulting in a Leu33Pro polymorphism giving rise to the antigens HPA-1a and HPA1b, respectively, in the mature GPIIIa protein. We have identified four women who were phenotypically HPA-1a negative whereas genotyping showed that they were HPA1-ab. Flow cytometry studies revealed that the expression of the fibrinogen receptor was reduced by approximately fifty percent, indicating that they might be carriers of the recessive hereditary bleeding disorder GT. *Aims.* We sought to delineate the molecular background for the genotype/phenotype discrepancy and reduced fibrinogen receptor expression. *Methods.* DNA and cDNA sequencing were used to identify possible mutations, whereas expression vector cloning in CHO cells was used for fibrinogen receptor expression analysis. *Results.* DNA sequencing revealed a previously not described intron mutation in GPIIIa, IVS6(+4)A>G, heterozygously present in all four women. Sequencing of GPIIb showed no mutations. cDNA sequencing of the women's platelet mRNA indicated that exon 6 was missing. Subsequent cloning of the PCR fragments showed that exon 6 was lacking in several transcripts. Co-tranfection of the GPIIb subunit with GPIIIa as wild type or lacking exon 6 revealed that the GPIIb-GPIIIa complex with GPIIIa lacking exon 6 hardly had any surface expression compared to wild type. *Conclusion.* The novel splice-donor site mutation identified in the GPIIIa gene show skipping of exon 6 and a fifty percent reduction of the fibrinogen receptor expression in four women who had the mutation in heterozygous form.

0993

RAPID EXCLUSION OR CONFIRMATION OF HEPARIN-INDUCED THROMBOCYTOPENIA: A SINGLE-CENTRE EXPERIENCE WITH 1291 PATIENTS

L Alberio, V Nellen, I Sulzer, G Barizzi, B Lämmle

Inselspital University Hospital, Bern, Switzerland

Background. Untreated heparin-induced thrombocytopenia (HIT) may lead to lethal thrombotic events and administration of alternative anticoagulants may be complicated by severe bleeding. It is therefore most desirable to confirm or exclude HIT as soon as its diagnosis is suspected. *Aim.* To evaluate the negative (NPV) and positive (PPV) predictive values of the 4T clinical score and three immunoassays for the presence of platelet-activating HIT-antibodies (abs). *Methods.* Assessment of 4T score, semi-quantitative result (titer) of rapid ID-HPF4-PaGIA, optical densities (OD) of two commercial immunoassays (HPIA, GTI-PF4) and heparin-induced platelet aggregation test (HiPAT) in 1291 patients investigated for suspected HIT. A positive HiPAT was the gold-standard for *in vitro* platelet-activating HIT-abs. *Results.* Among 859 patients with a low clinical probability for HIT (4T score = 0-3), 7 had a positive HiPAT, resulting in a NPV of 99.2%. Fifty out of 358 patients with an intermediate 4T score (4-5), and 39/74 patients with an high 4T score (6-8) had a positive HiPAT, resulting in PPV of 14.0% and 52.7%, respectively. Among laboratory assays, the rapid ID-HPF4-PaGIA and both ELISAs performed similarly, with AUC of ROC-curves of 0.992 (Titer), 0.990 (OD HPIA) and 0.985 (OD GTI-PF4). All three assays were able to exclude the presence of platelet-activating HIT-abs (ID-HPF4-PaGIA titer ≤1, HPIA OD <0.300, GTI-PF4 OD <0.870). The cut-offs with the best compromise between sensitivity and specificity for functionally relevant HIT-abs were a titer of ≥4 (ID-HPF4-PaGIA), OD >0.943 (HPIA) and OD >1.367 (GTI-PF4). Most interestingly, only the ID-HPF4-PaGIA showed a PPV of 100% for a positive HiPAT, at titers of ≥32. *Conclusions.* HIT can neither be diagnosed nor refuted on clinical grounds alone. A negative immunoassay among patients with low and intermediate 4T scores makes HIT very unlikely. Of note, a titer of ≥32 by ID-HPF4-PaGIA has a PPV of 100% for *in vitro* platelet-activating HIT-abs. This is the first report showing that the quantitative result of an immunoassay is equivalent to a positive functional assay for HIT-abs. A high-titer positive ID-HPF4-PaGIA allows for rapid laboratory confirmation within a few hours after HIT has been suspected.

0994

FCGRIIB RECEPTOR IS NOT REQUIRED FOR THE THERAPEUTIC ACTION OF IVIG IN AN ITP MOUSE MODEL

D Leontyev, Y Katsman, X Ma, D Branch

Canadian Blood Service, Toronto, Canada

Background. One of most recognized theories of therapeutic action of IVIg on immune thrombocytopenia (ITP) suggests that up-regulation and activation of Fc_RIIB in the spleen following IVIg treatment is critical to provide negative regulation of platelet clearance via decreased phagocytosis of opsonized platelets by mononuclear phagocytic cells in the spleen. We have not been able to support these previous findings but instead find the presence of Fc_RIIB receptor not necessary for successful treatment of experimental ITP through IVIg administration. *Methods.* Mice were purchased from Taconic (Germantown, NY, USA) and Jackson Labs (Bar Harbor, USA). To induce ITP in mice, daily administration of an escalating dose of antiplatelet antibody (anti-CD41; MWReg30) was used. IVIg (1-2 g/kg; Gammagard 5%) was obtained from Baxter Corporation (Toronto, ON, Canada). Blood samples were taken daily and platelet counts monitored by FACS. *Results.* Administration of IVIg to wild-type Balb/c mice previously made thrombocytopenic with antiplatelet antibody leads to amelioration of experimental ITP while in untreated mice platelet counts stay close to nadir. Similar dynamics were found using FcγRIIB knockout Balb/c mice despite the absence of FcγRIIB. However, as previously published, IVIg does not work with FcγRIIB knockout mice on a B6 background obtained from the Jackson Labs. Indeed, B6 (129S4-Fcgr2btm1Rav/J) FcγRIIB-/- knockout mice made thrombocytopenic are essentially unresponsive to IVIg treatment. However, surprisingly, we found that when using the proper control wild-type mice for this knockout, the B6.129SF2 mouse strain, we found that this wild-type FcγRIIB+/+ mouse also does not respond to IVIg treatment. Confirmation of genotype was done; thus, we suggest that something about the 129S4 background prevents a response to IVIg therapy and this phenomenon is independent of the FcγRIIB. Previous publications that indicated a lack of response to IVIG using the Jackson Labs FcγRIIB knockout mice failed to use the proper control animals, using instead, C57BL/6 wild-type mice which respond well to IVIg treatment. It was also reported that the protective effect of IVIg was associated with its ability to induce surface expression of FcγRIIB on splenic macrophages. However, our data showed that splenectomy does not affect the ability of IVIg to ameliorate ITP and there is no upregulation of FcγRIIB mRNA in the spleen following IVIg treaatment. *Conclusions.* Our results using Balb/c FcγRIIB knockout and splenectomized mice indicate that FcγRIIB is not a factor in whether or not IVIg treatment will be effective in ITP. Our results are consistent with a single previous report showing that Balb/c mice lacking FcγRIIB respond to IVIg treatment. Furthermore, our results provide an explanation for the discrepant published results using the Jackson mice by showing that the wild-type conrol animals for the B6 FcγRIIB knockout mice also do not respond to IVIg treatment; thus, the lack of response of the knockout animal is unrelated to FcγRIIB but to other factors related to its derivation. These data taken together lead us to the conclusion that the presence of the FcγRIIB receptor is not important for the therapeutic action of IVIg.

0995

BERNARD SOULIER SYNDROME IN A PATIENT AFFECTED BY KLINEFELTER DISEASE: NOVEL A386G HOMOZYGOUS MUTATION OF GPIBα GENE WITH ANOMALOUS BEHAVIOUR

S Vettore,[1] F Tezza,[2] N Candeo,[2] A Balduini,[3] A Malara,[3] A Pecci,[4] R Scandellari,[2] M Floris,[5] S Moro,[6] F Fabris[2]

[1]University of Padua, Padova, Italy; [2]Dept of Medical and Surgical Sciences - University of Padua, Padova, Italy; [3]Dept of Biochemistry University of Pavia - IRCCS S. Matteo Foundation, Pavia, Italy; [4]Deptof Internal Medicine- University of Pavia IRCCS S. Matteo Foundation, Pavia, Italy; [5]Laboratorio Bioinformatica CRS[4] - Parco Polaris, Loc Pixinamanna - Pula (CA), Italy; [6]Molecular Modeling Section, Dept of Pharmaceutical Sciences University of Padua, Padova, Italy

Background. Bernard Soulier Syndrome (BSS) is a rare inherited form of macrothrombocytopenia characterized by defective platelet membrane von Willebrand Factor (vWF) receptor. This complex is made of 4 subunits (glycoproteins (GPs) Ibα, Ibβ, IX, and V) belonging to the Leucine Rich Repeats (LRR) proteins family. Mutations of these GPs have been recognized as responsible of different forms of classical (recessive) or autosomal dominant BSS. In particular, many different gene mutations affect GPIbα, the major component, leading to amino acid substitutions or stop codons, often occurring after a frameshift producing aberrant protein sequences. *Aims.* In the present work we present the characterization of a new homozygous mutation of GPIbα gene in a patient affected by Klinefelter Syndrome. Moreover we had the opportunity to observe how the absence of vWF receptor on the platelet surface influences the megakaryopoiesis process. *Methods.* A 32-year-old man affected by Klinefelter syndrome and initially diagnosed as affected by idiopatic trombocytopenic purpura, was investigated for inherited BSS with functional studies (RIPA: Ristocetin agglutination), flow cytometry, Megakaryocytes cultures (MK), molecular biology tests (Sequencing, Western Blot, RTPCR) and computer modelling techniques. The patient gave his informed consensus to the study. *Results.* RIPA was absent, as is typical in BSS subjects. Flow cytometry and Western blot (WB) analysis showed the absence of GPIbα in patient's platelets. Sequencing results revealed a homozygous substitution A386G affecting the first base of the DNA codon codifying for N110 of GPIbα. This result do not explain the absence of the protein. In order to clarify flow cytometry and WB data, megakaryocytes (MK) cultures from patient and healthy control blood were set for further analysis. Although patient's MK morphology and maturation profiles were normal, immunofluorescence on cultured cells confirmed the absence of the protein Moreover, in the patient cultures proplatelets formation resulted defective, and GPIbα mRNA was absent Computational analysis of the mutant mRNA showed that the A386G mutation disrupt an ESE motif (Exon Splicing Enhancer) which can be involved in the correct maturation of the GPIba transcript, explaining the lack of the protein. *Conclusions.* This is, to our knowledge, the first report of BSS affecting a Klinefelter subject. The homozygous A386G substitution found in GPIbα gene of this patient, has an anomalous behaviour: theoretically it would be supposed to change the residue N110 of the protein in D. On the contrary, it cause the disappearing of the GPIbα protein without creating a stop codon in mRNA sequence, but disrupting an ESE motif and hypothetically interfering with the transcript correct maturation. Further analysis will be needed to confirm this hypothesis. Moreover, we could confirm with MK culture studies that the presence of the vWF receptor on MK surface is mandatory for proplatelets formation.

0996

PRIMARY BONE MARROW FIBROSIS IN INMUNE THROMBOCYTOPENIC PURPURA

N Claros, C Bellas, E Ojeda, I Krsnik, P Beltran, R Gonzalez-Daganzo, M Cabero, J Bravo, A Sebrango, I Vicuña, M Piris, A De Laiglesia, G Bautista, B Navarro, R Fores, S Gil, J Garcia Marco, C Regidor, I Sanjuan, J Cabrera

Hospital Puerta Hierro Majadahonda, Majadahonda, Spain

Bone marrow fibrosis in ITP has become a matter of discussion since the introduction of thrombopoietin receptor-stimulating agents. It is usually recommended to perform a bone marrow (BM) biopsy before the administration of these drugs in patients with ITP. Prospective studies have been conducted in this sense to investigate the presence of fibrosis after the administration of Romiplostin.[1] The incidence of marrow fibrosis in patients with ITP is unknown, mainly because clinical guidelines do not recommend a routine bone marrow biopsy in most of the patients with this disease. In order to determine the incidence of BM fibrosis in ITP, we have reviewed 175 bone marrow samples from patients diagnosed with ITP in our Unit in the past ten years. A bone marrow biopsy was obtained at diagnosis in 28 of them. Eight were women and seven men, age range: 16 - 89 years (mean 56.2). Bone marrow samples had been included in paraffin. For this review, new specimens were sliced and stained with hematoxylin-eosin and reticulin techniques. Samples were analysed by the Hemathopathologist of our Center. Assessment of fibrosis has been made according to the WHO criteria as follows: Grade 0 (scattered linear reticulin with no intersections (cross-overs), corresponding to normal bone marrow, Grade 1 (loose network of reticulin with intersections, especially in perivascular areas), Grade 2 (diffuse and dense increase in reticulin with extensive intersections, ocasionally with focal bundles of collagen and/or focal osteosclerosis) Grade 3 (Diffuse and dense increase in reticulin with extensive intersections and coarse bundles of collagen, often associated with osteosclerosis). Fibrosis was found in the bone marrow samples of 53% of the patients. Most of them showed Grades 1 to 2 (14 patients). Only one patient showed grade 3. A review of the medical records of that patients confirmed the diagnosis of ITP, excluding primary myelofibrosis. We conclude that fibrosis can be found in patients with ITP who have not been treated previously with thrombopoietin receptor-stimulating agents. The role of megakaryocytes, which are usually increased in the bone marrow of ITP patients, in the pathogenesis of the fibrosis may be a matter of future investigations.

CONGENITAL AMEGAKARYOCYTIC THROMBOCYTOPENIA (CAMT): A DIFFICULT EARLY DIAGNOSIS

N Conde, AE Quintero, S Rives, T Toll, A Català, R Berrueco, M Camós, J Estella

Sant Joan de Déu Hospital, Esplugues de Llobregat,Barcelona, Spain

Background. CAMT is an extremely rare autossomal recessive disorder characterized by absent or reduced number of megakaryocites in the bone marrow (BM) since birth. Mutations in the c-MPL gen, coding for the Thrombopoietin (TPO) receptor, are responsible for CAMT. Children develop a tri-linear marrow aplasia that is fatal without BM transplantation. Therefore, an early diagnosis is recommended in order to minimize morbility and mortality of the aplasia. Historically, the evaluation of children with persistent thrombocytopenia has relied on serial bone marrow aspirates and biopsies. However, recently, the diagnosis can be confirmed by the demonstration of mutations in cMPL gen. *Aims.* to describe the clinical and molecular findings of a new case of CAMT. *Case report.* a Caucasian 2-year-old girl who presented with petechiae and ecchymosis, with a platelet count of 29.000/mcL. White blood cells count and hemoglobin were normal. She did not presented any bone alteration. However, she had a special phenotype geneticall ly not filiated (short stature and low weight, microcephaly, unilateral ptosis and low hair implant) and mild psychomotor retardation. Parents were not consanguineous. Alloimmune and autoimmune thrombocytopenia, immunodeficiency and serologies evaluation were negative. The first BM aspirate was normal. Cytogenetic was also normal and DNA breakage studies were negative. Fetal hemoglobin was 8%. In the next three months platelet count was around 30×10^9/L without any mucosal bleeding. A second aspirate and biopsy were performed. It revealed a reduced number of megakaryocytes. The study of growth hematopoietic progenitors showed an impaired growth of megakaryocytic progenitors. The TPO level was 2100 pg/mL (normal <168 pg/mL). We had already the clinical diagnosis of CAMT. 4 years later, cMPL gene´s mutations were investigated with these *Results.* a heterozygous nonsense mutation in exon 7 (maternal allele) and a heterozygous silent mutation in exon 4 (paternal allele). Currently, she is 12 years old. The platelet count is around 10×10^9/L, hemoglobin level 9 g/dL, neutrophil count 1×10^9 /L. She has been treated with corticotherapy and platelet transfusion due to parvovirus B19 infectious. She is waiting for an unrelated matched BM donor. *Conclusions.* regardless of the presence of megakaryocytes on early BM aspirates, if there is on-going thrombocytopenia that can not be attributed to another etiology, CAMT should be considered. Supportive evidence may

include an elevated hemoglobin F and levels of TPO nearly 30 times higher than healthy children. As aspirates can not definitively assess BM architecture or cellularity, a biopsy is required. Our case shows two different mutations, one a silent mutation. Since CAMT is recessively inherited, these findings are not sufficient to confirm the molecular diagnosis of CAMT. Nevertheless, mutations in the MPL gene are so rare in healthy donors, that a coincident occurrence of a MPL mutation in a patient with symptoms of CAMT is very unlikely. Probably, this fact could explain the late onset and the slow development to pancytopenia. Once the diagnosis is established, a search for a HLA-related/unrelated matched BM donor should be started.

REDUCED EXPRESSION OF TRANFORMING GROWTH FACTOR–β1 AND CORRELATIVE ELEVATION OF INTERLEUKIN-17 AND INTERFERON-G IN PEDIATRIC PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIC PUPURA

J Wang,[1] T Chang,[1] MC Wu[2]

[1]*Taichung Veterans General Hospital, Taichung, Taiwan;* [2]*Chang Bing Show Chwan Memorial Hospital., Changhua, Taiwan*

Background. Dysregulated T helper (Th) cells are considered important in the pathophysiology of chronic immune thrombocytopenic purpura (ITP). Although there was evidence supporting Th1 polarization in chronic ITP, recent reports show that Th17 cells have more potent than Th1 cells in inducing autoimmune disease. *Aim.* The present study aims to investigate the roles of Th cells cytokines involved in pediatric patients with chronic ITP. *Methods.* After approval of institutional ethic committee and written inform consent obtained from patients and/or patients' parents, 57 pediatric patients with chronic ITP and 28 healthy controls were enrolled. Patients was divided into three groups based on their platelet counts at the time of the study: (i) 'active disease' $<50\times10^9$/L (n=23), (ii) 'stable disease' $50\text{-}150\times10^9$/L (n=23), (iii) 'in remission' $>150\times10^9$/L (n=11). Plasma concentration of Th1 (IFN-γ, IL-2), Th2 (IL-4, IL-10), Th3 (TGF-β1), and Th17 (IL-17) cytokines were investigated by enzyme-linked immunosorbent assay. *Results.* IFN-γ were significantly increased in patients with active ($P < 0.001$) and stable disease ($P < 0.026$) when compared to controls. Otherwise, there were no significant differences of IL-2, IL-4 and IL-10 between patients and controls. IL-17 was significantly increased in patient groups ($P = 0.011$). In addition, there was a positive correlation of IL-17 and IFN-γ levels in ITP patients ($r= 0.640$, $P<0.001$). Reduced TGF-β1 expression was observed in patients with active ($P < 0.001$) and stable disease ($P = 0.001$), and its level was positively correlative to the platelet count ($r= 0.355$, $P=0.007$). *Summary/Conclusions.* In addition to Th1 polarization, the study shows correlative elevation of IL-17 and IFN-γ could be an important dysregulation of cellular immunity in pediatric patients with chronic ITP. Moreover, Th3 cytokine (TGF-β1) is considered as a bystander immune suppression associated with remission of the disorder.

SUCCESSFUL MANAGEMENT OF GESTATION AND LABOR IN A 33-YEAR-OLD WOMAN WITH BERNARD SOULLIER SYNDROME

F Carretero,[1] J Sánchez,[1] M Infante,[1] A Rodriguez,[1] G Pérez,[1] I Conde,[1] C González-Manchón,[1] V Ortega,[2] JL Díez,[1] C Pascual[1]

[1]*Gregorio Marañón General Hospital, Madrid, Spain;* [2]*Pathophysiology and Human Molecular Genetics, Centro de Investigaciones Biologíc, Madrid, Spain*

Background. Bernard Soullier Syndrome (BSS) is a rare qualitative and quantitative autosomal recessive platelet disorder. It is usually associated with prolonged platelet functional tests and low platelet count with giant sized platelets. In BSS GPIb-IX-V membrane glycoprotein is absent or decreased and the result is deficient binding of vWF to the platelet membrane at sites of vascular injury. Our patient presented hemorrhagic symptoms since she was 18 months old with an average platelet count of 40×10^3/μL and an increased platelet volume that required multiple platelet transfusions throughout her childhood. On December 2007 she consulted for pregnancy. Platelet count was 40×10^3/μL, antiplatelet antibody studies were negative for membrane glycoprotein but positive for antiHLA-1 antibodies against 98% of tested donors. Following these tests HLA compatible donors were sought. Cesarean section was performed on the 38th week in order to avoid fetal hemorrhagic complications. On the day of surgery two platelet aphaeresis were transfused one hour before the procedure and one every 12 hours after. The next 4 days one apheresis was transfused every 48 hours. The fetus was born asymptomatic with a normal platelet count and volume. *Aim.* We present a case of successful management of gestation and labor in a 33-year-old woman with BSS. *Methods.* Ristocetin induced platelet agglutination test and membrane glycoprotein study were performed. *Results.* Lysed platelets were incubated with anti-GPIbα SZ2 monoclonal antibody. Platelets were subsequently incubated with anti-αIIb and anti-β3 to verify that the patient and control had the same amount of protein. Flow cytometry analysis revealed that patient αIIb and β3 were correctly expressed and GPIb_ remained undetectable. Control and patient DNA segments were amplified by PCR to obtain GPIbα sequence. Sense segment revealed simultaneous presence of G-C nucleotides at position 688 and T-A nucleotides at position 715. These mutations translate into a heterozygotic Ala200Pro and Cys209Ser replacement in the mature peptide. Anti-sense segment analysis confirmed the presence of these two mutations. Ala200Pro mutation has not been previously reported in BSS. Heterozygotic Cys209Ser mutation has not been described alone either. *Conclusions.* We present a case of successful management of gestation and labor in a young woman with BSS. Flow cytometry analysis reveals absence of GPIα and under expression of GP IX. Molecular analysis shows 2 mutations, one of them; Ala200Pro had not been previously reported. Up to date there are only 12 published cases of labor related BSS. Most of them presented severe hemorrhagic complications. None was molecularly diagnosed. Platelet transfusion is the main treatment in BSS. Antiplatelet antibody study should be performed as they are frequently increased in these patients. Management of this condition requires a multidisciplinary approach involving coordination between gynecology and hematology departments. BSS is a rare condition (less than 1 case per million) and there are currently no well-established protocols for the management of BSS in pregnancy.

ASSOCIATION OF PLATELET PARAMETERS WITH GLYCOSYLATED HEMOGLOBIN IN DIABETIC PATIENTS WITH MYELODYSPLASIA AND NORMAL PLATELET COUNT

M Dalamaga,[1] K Karmaniolas,[2] G Antonakos,[3] A Thrasyvoulides,[3] N Spanos,[3] M Triantafilli,[2] E Papadavid,[3] C Dimas,[3] A Lekka[2]

[1]*Attikon University General Hospital, Agia Paraskevi-Athens, Greece;* [2]*NIMTS General Hospital, Athens, Greece;* [3]*Attikon General University Hospital, Athens, Greece*

Background/Aim. Altered thrombocyte morphology and function have been reported in patients with diabetes mellitus type 2. High mean platelet volume (MPV) values are related with an increased risk of devel-

oping micro- and macrovascular diabetic complications such as cardiovascular disease. The aim of the present study was to determine the associations between platelet markers and glycemic indices such as glycohemoglobin (HbA1c) and fasting glucose, hypertension and coronary heart disease (CHD) in diabetic patients with primary myelodysplastic syndrome (MDS), in patients with diabetes mellitus type 2 and in controls. *Methods.* This cross-sectional study included thirty incident, histologically confirmed cases with primary MDS with normal platelet count (>150×10^9/L) and non-insulin dependent diabetes (Group A), thirty non-insulin dependent diabetic patients (Group B) and thirty non-diabetic healthy controls (Group C) without any neoplastic and infectious conditions matched on age (±5 years), gender and time of diagnosis to Group A and B. Platelet count, MPV and platelet distribution width (PDW) were measured in blood samples anticoagulated with sodium citrate within 90 min after collection by venipuncture. Each measurement was performed in two different automated blood cell counters (Sysmex XE 2100 and Cell Dyn 1700). HbA1c was measured using high-performance liquid chromatography (G7 TOSOH Glycohemoglobin analyzer, TOSOH Corporation, Japan). Fasting blood glucose was determined by glucose oxidase methodology. Statistical analysis of the data was performed using SPSS for Windows version 10 statistical software package. *Results.* MPV and PDW in diabetic patients were significantly higher than those in MDS diabetic patients (P<0.001) and controls (P<0.001). In the group of MDS patients with diabetes (Group A), there were no correlations between MPV and fasting glucose (r=-0.157, P=0.408), and MPV and HbA1c (r=0.014, P=0.941). MPV and PDW were statistically significantly higher in MDS patients with hypertension (P=0.03 and 0.02 respectively) and in MDS patients with CHD (P=0.02 and 0.05 respectively). Adjusting for age, gender, body mass index (BMI), platelet number, CHD and hypertension, HbA1c as well as fasting blood glucose did not present any statistically significant association with MPV (P=0.55 and P=0.26 respectively) and PDW (P=0.66 and P=0.28 respectively) in MDS diabetic patients. Adjusting for the aforementioned confounding factors, HbA1c and fasting glucose were significant predictors of MPV and PDW in diabetic patients (P<0.001 and P=0.014, respectively). In controls, glucose, platelet count and hypertension predicted significantly platelet morphology. *Conclusions.* MPV and PDW are associated with glycemic control indices in diabetic patients reflecting association with macrovascular disease. HbA1c and glucose were not correlated with MPV or PDW in diabetic MDS patients suggesting that other factors inherent to bone marrow dysplasia are involved in platelet morphology.

EVALUATION OF ACTIVATION AND APOPTOSIS PHOTOCHEMICAL TREATED AND GAMMA-IRRADIATED PLATELET CONCENTRATES

M Ogorodnikova,[1] T Zabotina,[2] A Borunova,[2] N Ocheeva,[2] Z Kadagidze,[2] O Rukavitzin[3]

[1]N.N.Burdenko Main Military Clinical Hospital, Moscow, Russian Federation; [2]N.N. Blochin Cancer Research Center, Moscow, Russian Federation; [3]N.N. Burdenko Main Military Clinical Hospital, Moscow, Russian Federation

Background. The safety of blood components is the main task of transfusion medicine. Photochemical treatment (PCT) of apheresis platelet concentrates (A-PLT) for inactivation of pathogens and residual leukocytes with amotosalen and long-wavelength ultraviolet A (UVA) light has been developed to prevent transfusion complication, associated with pathogens and donors leukocytes. Gamma irradiation (GI) of blood components, including A-PLT, is used for inactivation of allogenic T-lymphocytes. The accepted dose of GI in Russia is 25 Gy. *Aim.* The aim of this study is to evaluate and compare the functionality and viability of PCTed platelets (PLTs) and GIed PLTs on the base of apoptosis and activation markers. *Material and methods.* 12 samples of A-PLT were investigated before and after PCT, 10 samples of A-PLT were investigated before and after GI . PLTs for PCT were prepared in 35% plasma and 65% platelet additive solution, pre-PCT yield was 2.5-6.0×10^{11} in volume 320±5 Ll. Each unit was treated with 150 μM amotosalen and 3,6 J/CM^2 UVA light followed by 4-5 hours of incubation with a compound adsorption device. A-PLT concentrates for GI were prepared in the same condition and were irradiated with 25 Gy during the first 24 hours after collection. All samples were investigated by flow cytometry. PLT apoptosis was measured by phosphatidylserine (PS) exposure with FITC-labeled Annexin V. PLT activation was measured by surface P-selectin (CD62P) expression. *Results.* The pre-treatment level of CD62P+ PLT wa.0±1.8%. P-selectin expression was decreased to19.3±2.8% after PCT. The initial level CD62P$^+$ PLT was maintained unchanged after 25 Gray of gamma irradiation. Pre-treatment and post-treatment levels of P-selectin (CD62P) expression were compatible with viable PLT function. PS exposure at the membrane surface was detected on 8.8±2.0% PLTs and was not changed significantly after PCT (10.7±2.6%). Increasing of Annexin V binding was detected only in some GIed samples and was <2.5-fold, but it was not exceed the initial maximum level. *Conclusions.* PCT and GI (25 Gy) of A-PLT was not lead to increasing of PLT apoptosis and activation, like markers of viability and functionality. PCTed and GIed A-PLT concenrates were comparable with untreated controls.

PERIPHERAL BLOOD PHENOTYPIC ANALYSIS IN AUTOIMMUNE THROMBOCYTOPENIC PURPURA

S Raptis,[1] M Mantzourani,[1] L Dimitrakopoulou,[2] G Konomos,[3] A Katsandris,[2] G Vaiopoulos,[1] J Meletis[1]

[1]National and Kapodistrian University of Athens, Athens, Greece; [2]Laikon Hospital, Athens, Greece; [3]Statistician, Athens, Greece

Background. Autoimmune Thrombocytopenic Purpura (AITP) is a common acquired hematologic disorder. Accumulating evidence suggests that different T-cell dominant and B-cell dominant pathophysiologic mechanisms may be present and responsible for the chronic, refractory form of the disease. *Aim.* In this study we examined peripheral blood phenotypic analysis abnormalities as well as possible correlations among circulating lymphocyte subtypes, age, sex, serological findings and course elements of AITP. *Methods.* Twenty adult AITP patients (15 women and 5 men, median age 32.5 years) and three children (2 boys and 1 girl, median age 14 years) were studied retrospectively. Peripheral blood phenotypic analysis data were compared to those of 20 age- and sex-matched healthy volunteers. All tests had been conducted either at diagnosis or during relapse after a minimum 3 months drug therapy free period in our department's laboratories. Data were statistically processed using appropriate methods and software. *Results.* Although no differences were observed between well-responding and relapsing patients, a significant negative correlation between CD20$^+$/CD23$^+$ B-cell levels and the number of the patients' relapses per year, as well as a significant positive correlation between high CD19$^+$ and CD22$^+$ levels and the frequency of splenectomy were noted. CD5$^+$ and CD7$^+$ T-cell levels were significantly reversely correlated with the frequency of positive ANA and IgG anti-Cardiolipin autoantibodies. Patients beyond 60 years of age had significantly lower levels of CD2$^+$ and CD3$^+$ T-cells as well as significantly higher levels of the CD5$^+$/CD19$^+$ co-expression. Finally, CD19$^+$, CD20$^+$, CD22$^+$ B-cell levels, CD19$^+$/CD79b$^+$, CD19$^+$/CD25$^+$ and CD20$^+$/CD23$^+$ markers and the Fmc7$^+$/CD11c$^+$ co-expression were significantly elevated among patients in comparison to healthy subjects. No differences between the two groups were observed as far as NK cells and T suppressor cells are concerned. *Conclusion.* Our findings suggest that B-lymphocyte abnormalities as well as T-cell defects related with age may be responsible for the pathogenesis and outcome of the disease, although additional studies will be useful in order to elucidate the biology of AITP.

1003

DETERMINATION OF REGULATORY CELLS IN PATIENTS WITH IDIOPATHIC THROMBOCYTOPENIC PURPURA USING FLOW CYTOMETRY

P Sakellaraki,[1] L Galanopoulou- Sfetcu,[2] A Mouzaki[1]

[1]Patras University, Patras, Greece; [2]Pyrgos General Hospital, Microbiology Laboratory, Pyrgos, Greece

Background. ITP (Idiopathic Thrombocytopenic Purpura) is an autoimmune disease with multi-dysfunctional pathophysiology. Although, production of autoantibodies by autoreactive B cells is considered as the primary immunologic defect, there are several other mechanisms which also seem to play critical role. Such a mechanism are regulatory T cells which participate in peripheral tolerance and seem to interfere in autoimmune diseases. *Aims.* Our primary aim was to detect and measure the percentage and absolute numbers of naturally arising CD4$^+$CD25^{high}FoxP3$^+$ T regulatory cells in peripheral blood of patients with ITP and healthy donors using flow cytometry. We also investigated the subpopulations of CD4$^+$CD25^{high}FoxP3$^-$ and CD4$^+$CD25$^-$FoxP3$^+$ cells. *Methods.* In order to identify the subpopulations of T regulatory cells, we used two different protocols. The first one concerned the determination of transcriptional factor FoxP3 in the subpopulations of CD4$^+$CD25^{high} and CD4$^+$CD25$^-$ cells. Additionally, as a confirmation we developed a second protocol to determine the interleukin-7 receptor (CD127). *Results.* Comparing the results of 21 patients with ITP with

those of 20 healthy donors, the absolute number of naturally arising T regulatory cells $CD4^+CD25^{high}FoxP3^+$ as well as that of $CD4^+CD25^{high}FoxP3^-$ and $CD4^+CD25^-FoxP3^+$ appeared significantly decreased in patients with ITP who were either in remission or in active disease. *Summary/Conclusions.* Our findings showed that patients who suffer from ITP have an impairement concerning not only thymus derived $CD4^+CD25^{high}FoxP3^+$ T regulatory cells, but also $CD4^+CD25^{high}FoxP3^-$ and $CD4^+CD25^-FoxP3^+$ subpopulations.

1004

HEPARIN-INDUCED PLATELET THROMBOCYTOPENIA: THE ROLE OF PLATELETS GENETIC POLYMORPHISMS

P Scarparo,[1] AM Lombardi,[1] F Tezza,[1] E Allemand,[1] S Vettore,[1] A Greinacher,[2] F Fabris[1]

[1]Padua University, Padua, Italy; [2]Ernst-Moritz-Arndt-Universität, Greifswald, Germany

Background. Heparin induced thrombocytopenia (HIT) is a severe complication of heparin therapy, characterized by great reduction of platelet's count, that may be complicated in 30-50% of cases by thrombosis (HITT), either arterial or venous. Heparin treatment can induce antibodies (Ab, IgG class), that recognize a complex of heparin (H) and PF4. H/PF4/Abs bind platelets receptor FcgRIIA, inducing platelet activation and aggregation, by modulating the affinity of GpIIb-IIIa for fibrinogen. PECAM-1 has been shown to negatively regulate activation downstream FcγRIIA, but the mechanism is still unclear. Moreover the receptor FcγRIIIA, expressed on macrophages, seems to play an important role on the clearance of IgG-coated platelets. However HIT and HITT does not develop in all patients, the onset of clinical syndrome depends on different factors: heparin type, antibodies functionality, other autoimmune pathologies and individual genetic variations. We studied four different polymorphisms, located in the receptors previously described: FcgRIIA-H131R, GpIIb/IIIa-HPA1, PECAM1-L125V (in linkage-disequilibrium with S563N and R670G) and FcγRIIIA-F158V. *Aims.* The aim of the present study is to understand if polymorphisms of platelets receptors may influence the clinical features of patients who develop H/PF4/Abs, HIT or HITT, combining immunological, functional and genetic studies. *Methods and patients.* First we used ELISA to determine the presence of H/PF4/Ab in plasma samples, than we used heparin induced platelet activation (HIPA) as functional test to understand whether the antibodies found were able to activate donor's platelets. Using the 4T score for HIT and the result of immunological and functional tests, we define three groups: 51 H/PF4/Ab patients: antibodies not able to activate platelets-no thrombocytopenia. 50 HIT patients: Abs able to activate platelets + thrombocytopenia. 53 HITT patients: Abs able to activate platelets + thrombocytopenia + thrombosis. We used molecular biology techniques to determine the genotype of polymorphisms: allele-specific-PCR for FcγRIIA-H131R, PECAM1-L125V and FcγRIIIA-F158V; an allelic discrimination real-time-PCR using taqman probes for HPA1. Hardy-Weinberg equilibrium was tested for each polymorphism. Allele or genotype frequencies between patients were compared by the χ^2 test; we use Multiple Regression Analysis for confront between polymorphisms. *Results.* Comparing the polymorphisms frequencies between the patients groups (H/PF4/Ab; HIT; HITT) we found statistical differences between HIT and HITT. R/R131 genotype frequency (FcγRIIA) is increased in HITT ($P<0,05$), the same for A/B genotype frequency (GpIIIa-HPA1) in the same group ($P<0,05$). The frequency of the polymorphic setting VNG (V/V125-N/N563-G/G670) for PECAM1 is also increased in HITT group compared with the other groups, but p-value is not statistically significative. There were no genotype differences comparing HIT with H/PF4/Ab group. *Conclusions.* We suppose that platelets R/R (receptor FcγRIIA), cleared less efficiently than H/H ones, can circulate longer enhancing the risk for HIT thrombosis; and that the setting VNG for PECAM1 can have less inhibitory activity on FcγRIIA. Furthermore theallele for HPA1 is a known risk factor for thrombosis. We found that R/R131 associated with HPA1 have a relation with HITT but with a p-value (0,07) near significance. We think that increasing our cases we could obtain a significant association between our polymorphisms and HITT.

1005

EVALUATION OF PLATELET FUNCTION UNDER HIGH SHEAR CONDITIONS IN IMMUNE THROMBOCYTOPENIA DURING ELTROMBOPAG TREATMENT

J Haselboeck, I Pabinger, C Ay, S Koder, S Panzer

Medical University Vienna, Vienna, Austria

Introduction. Eltrombopag, a small, non-peptide thrombopoietin receptor agonist, has been proven to raise platelet counts and diminish bleedings in immune thrombocytopenia (ITP). Data on its effect on platelet function are scarce. *Objectives.* We examined functional characteristics of Eltrombopag-induced platelets in 3 patients enrolled in the RAISE Study. *Methods.* Platelet function was assessed before treatment and in weekly intervals during 12 weeks of treatment. Platelet adhesion under high shear conditions was evaluated by IMPACT-R *ex vivo* as well as after *in vitro* ADP and TRAP-6 induced activation. P-selectin expression was measured without and after activation with suboptimal concentrations of TRAP-6 and ADP. *Results.* Expression of P-selectin [%] *ex vivo* was elevated (20.95, 27.01, 29.90) before treatment and declined to normal (11.41, 11.45, 5.85) after 5 weeks of treatment at platelet counts [G/l] of 161, 65 and 230, respectively. TRAP-6 induced platelet activation normalised (reaching >80%) within the first week of treatment in two cases and stayed in subnormal range in one. P-selectin expression upon activation with ADP as well as the agonists´ induced *in vitro* activation under high shear conditions showed no interrelation with rising platelet counts. *ex vivo* platelet adhesion under high shear conditions [%] was very low before Eltrombopag treatment (0.9, 0.7 and 1.6) and increased to normal (>4%) in all patients as platelet counts rose to > 100 G/l. *Conclusion.* Compared to baseline our results show decreasing values in P-selectin expression corresponding to reduced platelet activation *in vivo* and an increase of platelet adhesion under high shear conditions after Eltrombopag-induced platelet increase.

1006

SINGLE NUCLEOTIDE POLYMORPHISMS OF THE INFLAMATORY CYTOKINE GENES INTERLEUKIN-1?, TUMOR NECROSIS FACTORS ? AND ? IN ADULT PATIENTS WITH IMMUNE THROMBOCYTOPENIC PURPURA

M Pavkovic,[1] A Dimovski,[2] M Spiroski,[3] T Sotirova,[1] S Trajkova,[1] O Karanfilski,[1] L Cevreska,[1] A Stojanovic[1]

[1]Department of Hematology, Medical Faculty, Skopje, Macedonia; [2]Faculty of Pharmacy, Skopje, Macedonia; [3]Institute for Immunobiology and Human genetics, Medical Faculty, Skopje, Macedonia

Background. Immune thrombocytopenic purpura (ITP) is an autoimmune disease characterized by thrombocytopenia due to platelet autoantibodies specific for platelet membrane glycoproteins, such as GPIIb/IIIa, GPIb/IX and GPIa/IIa. These autoantibodies cause an accelerated clearance of opsonized platelets by phagocytes in the reticuloendothelial system. The etiology of ITP remains unclear, but both genetic and environmental factors are thought to play role in the development of the disease. Several genes involved in immune system regulation like cytokine genes, Fc gamma receptor genes and HLA genes, as well as some infective agents like hepatitis C virus, HIV virus, and helicobacter pylori have been associated with susceptibility to ITP in several studies. *Aims.* The aim of our study was to investigate a possible association of some single nucleotide polymorphisms (SNP) in genes for interleukin beta (IL-1β -511 C/T), tumor necrosis factor beta (TNF β +252 G/A) and tumor necrosis factor alpha (TNF ασ -308 G/A) with ITP. *Methods.* We have analyzed 35 adult patients with ITP (7 men and 28 women) with average age of 48,8±17,8 and 100 healthy matched controls. Informed consent was obtained from all participants. The median follow up of the patients was 8.6 years. DNA was isolated from peripheral blood mononuclear cells with standard phenol-chloroform extraction. Genotyping was performed by using PCR and RFLP methods. *Results.* Our results demonstrated significantly different distribution of the TNF β genotypes in patients with ITP (n=35; G/G=0, A/G=9, A/A=26) comparing with controls (n=100; G/G=14, A/G=29, A/A=57), P=0.043. Allele frequencies for TNF β (+252 G/A) were also significantly different in patients with ITP (A allele 87,2%, G allele 12.8%) comparing with controls (A allele 71,5%, G allele 28,5 %), P=0.014 with Yates correction. We didn't found significant differences in the genotype distribution or allele frequencies for two other genes. Allele frequencies for TNF α (-308 G/A) were 5.7% for A allele and 94.3% for G allele in patients and 12% for A allele and 88% for G allele in controls, P=0.208 with Yates correction. For IL-β (-511 C/T) allele frequencies were 65.7% for C allele and 34.3% for T allele in patients and 69.5% for C allele and

30,5% for T allele in controls, P=0.662 with Yates correction. *Conclusion.* The obtained data indicate that the A allele of TNF β+252 is more frequent in patients than in controls and that this polymorphism may play role in disease susceptibility. Our results are similar with previously reported results in Caucasian patients with childhood chronic ITP by Foster *et al*. (2001), but different from the results reported by Satoh *et al*. (2004) in Japanese patients with ITP. The reason for this difference is unclear. Possible explanation may be the differences in patient's ethnic background. These results also implicate that multiple other factors play role in the etiopathogenesis of immune thrombocytopenia.

1007

SERUM PF4 AND HOMOCYSTEINE LEVELS IN CONTEXT OF PATHOGENETIC AND PROTHROMBOTIC MUTATIONS IN ET PATIENTS.

B Sokolowska,[1] A Nowaczynska,[1] K Bykowska,[2] S Chocholska,[1] K Wejksza,[3] A Walter-Croneck,[1] T Gromek,[1] M Kowalska,[4] A Dmoszynska,[1] M Kandefer-Szerszen[3]

[1]Medical University of Lublin, Lublin, Poland; [2]Virology and Immunology ,University of Marie Curie-Sklodowska, Lublin, Poland; [3]University of Marie Curie-Sklodowska, Lublin, Poland; [4]The Children's Hospital of Philadelphia, Philadelphia, USA

Background. Platelets of ET(Essential thrombocythemia) patients are characterized by specific morphological, biochemical and metabolic defects. The most frequent dysfunction is a complete loss of platelet responsiveness to epinephrine. On the other hand there are some evidence of *in vivo* platelet activation. Active platelets secrete platelet factor 4 which is the most important marker of their activation. *Aims.* In this study we assessed serum PF4 and homocysteine levels in context of presence of pathogenetic and prothrombotic mutations , bleeding and thrombotic complications and correlation between these parameters and main coagulation factors activity. *Methods*. We have examined 32 patients with ET(24 females and 8 males , mean age 56.0±14.2). The control group(CG) consisted of 20 healthy person: 6 males and 14 females (mean age 41.4±8.3). In 11 patients from ET group 19 thrombotic complications occurred and in 7 ET patients bleeding episodes were noticed. We evaluated PF4, homocysteine, folic acid, witamin B12, cholesterol and triglicerydes serum levels. We searched for JAK2 V617F, Factor V Leiden, prothrombin gene and MTHFR gene mutations. We assessed plasma activity of fibrinogen, factors: VIII, XII, vW; AT , protein C and S. Platelet aggregation was measured using ADP and epinephrine as agonists. *Results.* Concentration of PF4 was higher in patient serum as compared to the CG (median 24500, P25-75%: 22750-25500 *vs.* 17500,12250-22650 Iu/mL, P<0.001). To eliminate the influence of elevated PLT amount on PF4 concentration a ratio of PF4 per million PLT was calculated. The ratio PF4/PLT was significantly lower in ET group as compared to CG(median 30.4; P25-75%: 27.8-38.9 IU/106PLT *vs.* 62.9; 45.1-94.6; P=0.000002). The PF4/PLT ratio was in positive correlation with vWF Ag (P<0.05) and in negative correlation with triglycerides concentration (P<0.05). Median homocysteine serum level was similar in both group (ET 9.77 umol/l,P25-75% 8.11-12.4 *vs.* CG 9.21umol/L, P25-75%7.94-10.60 umol/L). In 31% of patients of ET group hiperhomocysteinemia was detected, only in 2 person simultaneously with MTHFR gene mutation. One of ET patient, a 76 year- old woman underwent three times heart infarct. Other risk factors were: hypertension , JAK 2 mutation, extremely high homocysteine level (24.6 umol/L) without MTHFR gene mutation. The coronarography revealed normal coronary artieries. The second patient, a 79 year-old man, with very high homocysteine level (21.7umol/l) had obliterative atheromatosis diagnosed at the some time as ET. No JAK2 and MTHFR gene mutations was detected. Erytromelalgia was complained by 65% of ET patients and correlated with higher level of witamin B12 and cholesterol. 57% of ET patients and 7% person from CG displayed a complete loss of platelet responsiveness to epinephrine. *Conclusion.* Platelets of ET patients release significantly less PF4 during thrombus formation than platelets of control group, which may indicate impaired platelet function. A very high homocysteine level in some ET patients may contribute to thrombotic complications especially in connection with other risk factors.

1008

IDENTIFICATION OF PATIENTS WITH THROMBOCYTOPENIA IN PADUA UNIVERSITY AND CITY HOSPITAL THROUGH THE ADMINISTRATIVE DATABASE

F Tezza, M Galdarossa, R Scandellari, S Vettore, G Berti de Marinis, F Fabris

University of Padua, Padua, Italy

Background. The use of administrative database can be a powerful method to estimate the disease prevalence in a population. We identify patients with thrombocytopenia having an International Classification of Disease, 9th Revision, Clinical Modification (ICD9CM) code of 287.3 (immune thrombocytopenic purpura), 287.4 (secondary thrombocytopenia) and 287.5 (unspecified thrombocytopenia). *Methods.* The administrative database, we used, contains information on all patient admission and discharge including patient demographics, diagnostic and procedure codes, functional areas of discharge and the diagnoses related group code. We evaluate patients discharged from the Padua University-City Hospital in Padua from 2004 to 2007 to identify all cases of thrombocytopenia as a primary or secondary diagnosis, the diseases associated to primary or secondary diagnosis, therapeutics procedures and bleeding complications. Results. In 301 patients (160 female, 53%, 141 male, 47%) have been used one of the ICD9CM related to thrombocytopenia: 199 as primary diagnosis and 102 as secondary one; 154 patients were billed with 287.3 (131 as primary diagnosis, 23 as secondary), 79 patients with 287.4 (40 as primary and 39 as secondary one) and 68 were billed with 287.5 (28 as primary diagnosis, 40 as a secondary diagnosis). 84 patients with immune thrombocytopenia (ICD-9-CM code 287.3) were discharged from internal medicine units, 40 from pediatric area, 15 from haematology and oncology area, 5 from medical specialties, 7 from general surgery, 2 patients from cardiovascular area and 1 from clinical surgery. 51 patients with secondary thrombocytopenia (ICD-9-CM code 287.4) were discharged from internal medicine units, 18 from haematology and oncology area, 4 from pediatric area, 3 from medical specialties, 1 from cardiovascular area, 1 from clinical surgery and 1 from general surgery. 27 patients with unspecified thrombocytopenia (ICD-9-CM code 287.5) were discharged from internal medicine units, 18 from haematology and oncology area, 11 patients from pediatric area, 6 from medical specialties, 5 from general sugery, 1 from clinical surgery. The analysis of associated diagnoses at discharge showed a wide heterogeneity; 32% were missing; 10% regarded cancer; 9% regarded blood and hematopoietic diseases, 12% concerned cardiovascular and respiratory system diseases, 8% regarded digestive diseases, 7% regarded infective diseases, 4% regarded endocrine diseases and 18% regarded miscellany. 27(9%) patients had bleeding complications and most were over 60 years. 54 patients (18%) were subjected to therapeutic procedures related to the thrombocytopenia: 10 of the patients underwent to splenectomy; 26 to transfusion of packed red cells or platelets; 14 were subjected to infusion of high doses immunoglobulins; 4 were subjected to therapeutics plasma-exchange. *Conclusions.* The incidence of thrombocytopenia calculated by the rate of hospitalization of the area was 3,2/100.000/year. Therefore trough the administrative database it's possible identify patients with thrombocytopenia. Most discharged patients are from medicine (internal medicine and medical specialties). Bleeding complications are not so high if related to the large number of therapeutic interventions and it may be assumed that there is no registration of bleeding events. It would be interesting to compare data with medical records to assess the accuracy and the truthfulness of the discharge schedule.

Red cell and iron 2

INCREASED EFFLUX OF OXIDIZED GLUTATHIONE (GSSG) CAUSES GLUTATHIONE DEPLETION AND INCREASED SUSCEPTIBILITY TO OXIDATIVE STRESS IN SICKLE ERYTHROCYTES

E Nur,[1] R de Waart,[2] M Verwijs,[2] JJ Schnog,[3] HM Otten,[1] D Brandjes,[1] B Biemond,[2] R Oude Elferink[2]

[1]Slotervaart Hospital, Amsterdam, Netherlands; [2]Academic Medical Center, Amsterdam, Netherlands; [3]Sint Elisabeth Hospital, Curacao, Netherlands Antilles

Introduction. Sickle cell disease (SCD) is characterized by increased oxidative stress, playing an important role in the pathophysiology of acute and chronic organ complications in sickle cell patients. Sickle erythrocytes are both an important source and target of reactive oxygen species (ROS). Levels of both total and reduced form of glutathione (GSH), a major antioxidant, are decreased in sickle erythrocytes. The mechanism leading to glutathione depletion in sickle erythrocytes is not known yet. After reacting with ROS, GSH is oxidized into glutathione-disulfide (GSSG) and can be transported actively out of the erythrocyte. *Aims.* We questioned whether under oxidative conditions, GSSG efflux is increased in sickle erythrocytes. *Methods.* Erythrocytes of 18 homozygous sickle cell patients and 9 race-matched healthy controls were stimulated with 2,3-dimethoxy-l,4-naphthoquinone (DMNQ), which induces intracellular ROS generation, to stimulate GSH consumption. Intra- and extracellular levels of GSH and GSSG were measured at baseline and after 90, 150 and 210 minutes DMNQ stimulation. *Results.* While comparable at baseline, GSSG production and efflux (μM) were higher in sickle erythrocytes after 90 (P=0.013 and NS respectively), 150 (P<0.0001 and =0.004 respectively) and 210 minutes (P=0.002 and P<0.0001 respectively) DMNQ stimulation. In contrast to control erythrocytes, where GSH levels remained unchanged, GSH in sickle erythrocytes decreased significantly during DMNQ stimulation. Adding multidrug resistance-associated protein-1 (MRP-1) inhibitor (MK571) to erythrocytes blocked GSSG efflux in both sickle and normal erythrocytes. *Conclusions.* GSSG efflux, mediated by MRP-1, is increased in sickle erythrocytes, resulting in net loss of intracellular glutathione and thus higher susceptibility to oxidative stress. The increased GSH consumption upon oxidative exacerbation in sickle erythrocytes suggests a reduced antioxidative reserve capacity in SCD.

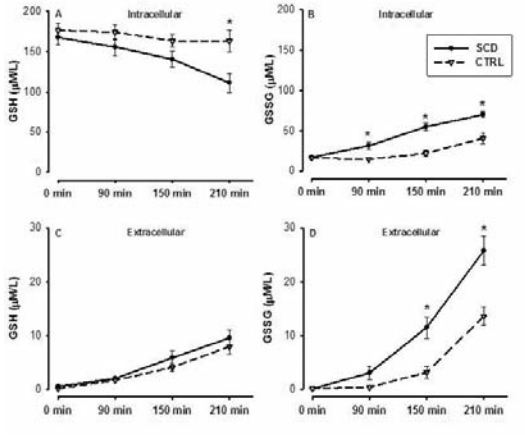

Figure. GSSG efflux upon oxidative stimulation.

PENTRAXIN 3 AS MARKER OF DISEASE SEVERITY DURING SICKLE CELL PAINFUL CRISIS

E Nur,[1] E van Beers,[2] S Martina,[2] I Cuccovillo,[3] HM Otten,[1] JJ Schnog,[4] J Meijers,[2] A Mantovani,[3] D Brandjes,[1] B Bottazzi,[3] B Biemond[2]

[1]Slotervaart Hospital, Amsterdam, Netherlands; [2]Academic Medical Center, Amsterdam, Netherlands; [3]Istituto Clinico Humanitas Rozzano, Milan, Italy; [4]Sint Elisabeth Hospital, Curacao, Netherlands Antilles

Background. The painful crisis accounts for the majority of sickle cell disease (SCD) related hospital admissions. The prototypic long pentraxin 3 (PTX3), an acute phase protein, is elevated in patients with inflammatory and ischemic states. *Aims.* As the sickle cell painful crisis is associated with both inflammation and tissue ischemia, we questioned whether plasma PTX3 levels are increased and associated with disease severity during painful crisis. Furthermore, since PTX3 up-regulates endothelial expression of tissue factor we studied PTX levels in relation to markers of coagulation activation. *Methods.* Plasma levels of PTX3, ultra-sensitive C-reactive protein (US-CRP), prothrombin fragment 1+2, thrombin-antithrombin (TAT) complexes and von Willebrand Factor antigen and serum levels of soluble vascular adhesion molecule-1 were determined in 105 asymptomatic sickle cell patients, 33 patients during painful crisis and 30 race matched healthy controls. *Results.* Plasma PTX3 levels (ng/mL) were comparable between patients in asymptomatic state and healthy controls, but significantly higher during painful crisis (P<0.01). Also in paired sample analysis of 24 patients, PTX3 levels increased during painful crisis (P<0.001). US-CRP levels were higher in asymptomatic patients compared to controls (P<0.0001) and increased further during painful crisis (P<0.0001). PTX3 levels at presentation with painful crisis correlated significantly to the duration of related hospital stay (rs=0.43; P=0.013), whereas US-CRP levels did not. The hemolytic rate, but not PTX3 levels, was related to markers of hypercoagulable state in sickle cell patients. *Conclusion.* The significant increase of plasma PTX3 levels during sickle cell painful crisis and their correlation to the duration of subsequent hospital stay suggest that PTX3 is a potential marker of painful crisis severity. PTX3 seems to have no significant role in coagulation activation in SCD.

INTRONIC LINE-1 INSERTION IN THE BETA-GLOBIN GENE CAUSES BETA-THALASSEMIA DUE TO ABERRANT SPLICING, NONSENSE-MEDIATED DECAY AND DECREASED RATE OF BETA-GLOBIN L1 ALLELE TRANSCRIPTION

L Piterkova,[1] J Kucerova,[1] K Indrak,[2] V Divoky[1]

[1]Palacky University, Faculty of Medicine, Olomouc, Czech Republic; [2]University Hospital, Department of Hemato-oncology, Olomouc, Czech Republic

Background. β-thalassemia is a common hereditary hemoglobin disorder characterized by quantitative reduction of functional β globin chains. The patients, mother and daughter of Ukrainian descent exhibited typical laboratory features of β-thalassemia trait. Molecular analyses revealed that the full-length (6 kb) retrotransposon L1 was inserted in the antisense orientation into the intron-2 of the *β globin* gene (collaboration with Dr. J. Prchal, Salt Lake City, UT). The total level of expression of the affected *β globin* gene transcript was reduced to 10-15% of the total *β globin* mRNA and thus leading to β$^+$-thalassemia. Based on recently published data we hypothesize that RNA production of mutated gene was affected by the combination of several events. Aim. The exact mechanism by which the intronic insertion of transposable element attenuates human gene expression is not known. We have tested several hypotheses which could contribute to the final elucidation of the molecular mechanism leading to the thalassemia phenotype caused by mutated *β globin* gene. *Methods.* Interspecific hybrids of the propositus´ lymphocytes and mouse erythroleukemia (MEL) cells were generated in order to evaluate expression of the mutant and unaffected *β globin* gene allelles (laboratory of Dr. T. Papayannopoulou, Seatlle, WA). The total RNA from differently treated (emetine, 5-aza-2'-deoxycytidine (Sigma)) *in vitro* cultured cell hybrids were isolated and *β globin* transcripts were analyzed by Real-Time qPCR with gene-specific primers. Nuclei from hybrid MEL cells were isolated to performed nuclear run-on assay. Bisulfite modification was done on genomic DNA from MEL hybrids and the enhancer region of *β globin* gene was amplified, PCR products were subcloned and sequenced. *Results.* We demonstrated that the observed reduction in steady-state level of *β globin* mRNA is partially caused by aberrant splicing followed by activation of nonsense-mediated decay (NMD) pathway, leading to increased degradation of aberrant *β globin* mRNA variants. Reduction in expression of *β globin* mRNA from *β globinL1* allele comes also from altered rate of transcription. We performed PCR-based nuclear run-on assay and forty minutes of *in vitro* transcription revealed 30% decrease in *β globinL1* allele transcription rate compared to wild-type *β globin* allele. We also observed the *β globinL1* 3' enhancer sequence was fully methylated. However, treatment with a demethylating agent did not increase the expression of the *β globin* transcript of the *β globinL1* gene. Therefore the methylation of the *β globinL1* 3' enhancer sequence is only a secondary event probably associated with enhancer displacement by L1 insertion. The other known mechanisms of intronic L1-mediated gene disruption

as premature polyadenylation and gene breaking were not detected in our case. *Conclusions.* The molecular mechanisms of β+-thalassemia phenotype caused by intronic insertion of LINE-1 in the *β globin* gene seem to be a combination of aberrant splicing, NMD and decreased rate of *β globinLA* allele transcription. We submit that retrotransposition of active mobile elements may alter gene expression and should be considered an independent molecular mechanism leading to human diseaseGrant support: NS10281-3/2009 Ministry of Health, Czech Republic.

HEREDITARY SPHEROCYTOSIS (HS): RELATIONSHIP BETWEEN CLINICAL OUTCOME, DIAGNOSTIC TESTS RESULTS AND MEMBRANE PROTEIN DEFICIENCY. A PROSPECTIVE STUDY FROM ARGENTINA

R Crisp,[1] L Solari,[1] M Chamorro,[2] D Gammella,[1] D Vota,[2] E Garcia,[1] B Venegas,[1] G Miguez,[1] G Schvartzman,[3] S Caldarola,[1] C Ricchieri,[1] G Alfonso,[1] A Nesse,[2] H Donato[4]

[1]Hospital Nacional A Posadas, Universidad de Buenos Aires, Buenos Aires, Argentina; [2]Facultad de Ciencias Exactas y Naturales, Universidad de Buenos Aires, Buenos Aires, Argentina; [3]Consultorios De Hematologia Infantil, Buenos Aires, Argentina; [4]Consultorios De Hematologia Infantil, Buenos Aires, Argentina

Background. HS may be difficult to diagnose because no positive family history is evident in around 25% of patients and accuracy of diagnostic tests is variable No predictive factor for HS outcome based on laboratory tests results is clearly established. Previous large trials simultaneously performing osmotic fragility (OF), autohemolysis (AH), hypertonic cryohemolysis (CH), eosin-5'-maleimide flow cytometry (EMA-FC), and SDS-PAGE analysis of membrane proteins have not been reported. Prevalence of each protein deficiency in Argentine patients is unknown. *Aims.* a) Assessing relationship between membrane protein defects, laboratory features and clinical outcome; b) Evaluating usefulness of CH and EMA-FC; c) Determining prevalence of protein deficiencies. No previous report concerning these subjects has been published in Argentina. *Methods.* 106 individuals (60 patients and 46 asymptomatic relatives), aged 1m-77y, belonging to 46 families were prospectively studied; 9 patients had been previously splenectomized; 42 cases were <18y; 255 healthy blood donors served as controls. Following tests were performed: OF, AH, CH, EMA-FC, and SDS-PAGE. Blood samples were collected simultaneously with samples from 6 normal controls and processed within 48 hours. EMA-FC results were expressed as percentage of decrease of mean channel fluorescence (MCF) and as increase of the coefficient of variation (CV). Diagnostic criteria for HS were evidence of hemolytic anemia plus two positive tests. In non-splenectomized patients, anemia was defined as severe, moderate or mild (hemoglobin <8, 8-10 or >10 g/dL, respectively). Relatives showing any membrane protein deficiency but otherwise asymptomatic with negative diagnostic tests were considered as HS silent carriers. *Results.* HS was diagnosed in 47 patients and 7 relatives; 16 carriers were detected. Inheritance pattern was dominant in 31, non-dominant in 14 and undetermined in 9 cases. Anemia was severe in 9, moderate in 13, and mild in 23 non-splenectomized patients. Percentages of positive tests were: EMA-FC 81.5%, CH 81.1%, OF 76.1%, SDS-PAGE 72.7%, and AH 65.9%. Only 19 patients (35.2%) were positive for all the tests. Regarding only CH and EMA-FC, at least one of them was positive in 92.6% of patients. SDS-PAGE showed single or combined protein deficiencies in 48 cases belonging to 27 families. Most frequently found deficiencies were spectrin in analysis by individuals (28.3%) and ankyrin in analysis by families (31.7%). All spectrin-deficient cases showed dominant inheritance. No significant relationship between tests results, inheritance pattern, neonatal jaundice or deficient protein was observed. Analysis of tests in relation to anemia only showed significantly higher increases of CV in moderate and severe anemia than in mild anemia or splenectomized patients (p: 0.004); a trend to significantly lower values of MCF in severe anemia than in other groups was also observed. No relationship between protein deficiencies and severity of anemia was found. *Conclusions.* A) EMA-FC seems to be a reliable predictor of severity; no other relationship between tests results and outcome was observed. B) Accuracy of EMA-FC and CH for diagnosis was higher than for other tests; simultaneous reading of MCF and CV improves EMA-FC diagnostic usefulness. C) Predominant spectrin and ankyrin deficiencies agree with reports from other Latin American countries.

1013

GENETIC VARIABILITY OF TMPRSS6 GENE AND ITS ASSOCIATION WITH IRON DEFICIENCY ANEMIA

P Delbini, V Vaja, G Graziadei, C Cesaretti, I Motta, MD Cappellini

Fondazione IRCCS Ca' Granda-Ospedale Maggiore Policlinico, University of Milan, Milan, Italy

Background. TMPRSS6 (Transmembrane Protease, Serine 6) has a key role in iron homeostasis, as proved by previous studies, and TMPRSS6 mutations have been shown to greatly affect iron status. Loss of function of this gene, causing elevated hepcidin levels, is associated with iron-refractory iron deficiency anemia (IRIDA). Although the pathogenic TMPRSS6 mutations that underlie IRIDA appear to be relatively rare, many common variants have been reported in several studies. The possibility that these variants in TMPRSS6 may contribute to susceptibility to iron deficiency anemia has not yet fully understood. *Aim.* 16 patients with iron deficiency anemia refractory to oral iron therapy were genotyped for TMPRSS6 gene, in order to evaluate the association of iron deficiency anemia with single mutations/polymorphisms and haplotype combinations. Fifty healthy control individuals were selected from the general population. *Methods.* Polymerase chain reaction (PCR) and direct sequencing were used to screen for genetic variations in the TMPRSS6 gene cluster. Allele and genotype frequencies were compared between cases and unrelated controls using the χ^2 test or Fisher's exact test. The strength of the association was estimated by odds ratio of risk (OR) and 95% confidence intervals (95%CI). Linkage disequilibrium (LD) calculations and haplotype association analysis were done using the Haploview package version 4.0. *Results.* Two novel single nucleotide substitutions, H448R and F5F, and two rare known non-synonymous polymorphisms, rs2235324 and rs2235979 were found in the coding region of TMPRSS6. Moreover, twenty-seven different DNA polymorphisms, eight of which are novel, were identified in patients TMPRSS6 gene. Among them, rs11704654, rs2235324 and rs4820268 were most significantly associated with iron-refractory anemia (P<0.0001). The frequency of the C allele of rs855791 and T allele of rs2235321 were significantly increased in patients compared to healthy controls (P<0.0001, OR=5.18, 95%CI 2.21<12.11 and P=0.011, OR=3.33, 95%CI 1.27<8.71, respectively) and in LD with each other (D'=1.0, r2=0.444, CI=0.8-1.0). Among the SNPs, rs2543519, rs2543607 and rs2543633 were associated with iron-refractory anemia (P<0.001, OR=6.90, 95%CI 2.49<19.07) and in LD with each other (D'=1.0, r^2=0., CI=0.73-1.0). For rs2235454, the minor *G allele frequency was higher in the patients (0.281) than in control subjects (0.000; P<0.001, OR=6.13, 95%CI 1.98<18.96). For rs2112025 the allele frequency of minor *G was 0.906 in patients and 0.600 in control subjects (P=0.0012, OR=6.44, 95%CI 1.83<22.58). Haplotypes and haplotype blocks were derived for the patient group, the control group and the combined patient-control cohort. We divided the TMPRSS6 gene region into 3 haplotype blocks, containing 6, 8 and 2 SNPs each. Four haplotypes (three in Block 1 and one in Block 2) were observed to be linked to the iron deficiency anemia (P<0.0001, P<0.001 and P=0.0020, respectively, for haplotypes in Block 1 and P=0.0033 for haplotype in Block 2). *Conclusions.* Our preliminary results suggest a possible association of genetic variants and specific haplotypes of TMPRSS6 gene with IRIDA, and deserve further investigations in large cohorts of subjects with iron deficiency disorders.

1014

LOW PREVALENCE OF CARDIAC SIDEROSIS IN HEAVILY IRON LOADED EGYPTIAN THALASSEMIA MAJOR PATIENTS

A El Beshlawy,[1] M El Tagui,[1] M Hamdy,[1] K El Ghamrawy,[1] E Abdel Azim,[1] D Pennell[2]

[1]Cairo University, Giza Cairo, Egypt; [2]Royal Brompton Hospital, London, UK

Background. Myocardial siderosis in thalassemia major remains the leading cause of death in developing countries. Once heart failure develops, the outlook is usually poor with precipitous deterioration and death. Cardiovascular magnetic resonance (CMR) technology can measure cardiac iron deposition directly using the magnetic relaxation time T2*. This allows earlier diagnosis and treatment and helps to reduce mortality from this cardiac affection. *Aims.* To find out the prevalence of cardiac siderosis among our patients who are heavily iron loaded by CMR technology and its relation to liver iron concentration, serum ferritin and left ventricular ejection fraction. *Methods.* 89 β thalassemia patients (10 to 43 years, mean age of 20.78±6.36) were recruited in this study. All patients were receiving chelation therapy of subcutaneous desferrox-

amine. Evaluation of hemosiderosis was based on CMR, liver magnetic resonance R2 and serum ferritin. *Results.* T2* values ranged between 4.3 to 53.8 ms with a mean of 28.5±11.7 ms among our study group. The left ventricular ejection fraction (LVEF) as measured by CMR ranged between 55 and 78%; mean=67.7±4.7%.and liver iron concentration (LIC) ranged between 1.5 to 56 mg/g dry weight with a mean of 26.1±13.4 mg/g. Serum ferritin varied among our study group from 533 to 22360ng/mL; mean=4510±2847ng/mL with 83.2% above 2500 ng/mL. The prevalence of myocardial siderosis (T2*<20 ms) among our patients was 22/89 patients (24.7%) whose mean age was 20.9±7.5 years with a mean T2* value of 12.7±4.4ms and LVEF of 68.6 ±5.8%. LIC and serum ferritin results were 30.9±13.5mg/g and 6120±4190ng/mL respectively. There was no correlation between T2* results and the age, LVEF, LIC and serum ferritin of this group (P=0.65, P=0.085, P=0.99 and P=0.63 respectively). Those patients with severe cardiac siderosis (T2*<10ms) constituted 7/89 (7.9%) with a mean age of 18.4±4.4 years. Although these patients had a mean T2* of 7.8±1.7 ms, the LVEF value was 65.1±6.2 % and only one patient had clinical cardiac disease (T2*=4.3 ms and LVEF =55%). LIC and serum ferritin results were 29.8±17.0 mg/g and 7200±6950ng/mL respectively. In this group of severe cardiac siderosis, T2* was not correlated to age (P=0.5), LVEF (P=0.14), LIC (P=0.97) and serum ferritin (P=0.82). *Conclusion.* There was a low prevalence of myocardial siderosis in the Egyptian thalassemia patients in spite of very high serum ferritin. T2* is the best test that can identify at risk patients who can be treated with optimization of their chelation protocols. The possibility of a genetic component for the resistance to cardiac iron loading in our population should be considered.

1015

AUTOMATION OF HEPASCORE AS A BIOCHEMICAL INDEX OF LIVER FIBROSIS IN PATIENTS WITH THALASSEMIA: THE IMPORTANCE OF HYALURONIC ACID

I Papassotiriou,[1] M Papastamataki,[2] P Delaporta,[3] E Premetis,[4] A Kattamis,[3] V Ladis[3]

[1]Aghia Sophia Children's Hospital, Athens, Greece; [2]Department of Clinical Biochemistry, Aghia Sophia Children's Hospital, Athens, Greece; [3]First Department of Pediatrics, Athens University Medical School, Athens, Greece; [4]Hematology Laboratory, Aghia Sophia Children's Hospital, Athens, Greece

Background. Patients with transfusion depended thalassemia major often develop liver fibrosis due to liver iron overload and/or hepatitis virus C (HCV) infection. Hyaluronic acid (HA) plays a prominent role in the pathogenesis of liver fibrosis, and the elevation of serum HA concentration is due to either increased synthesis by inflammatory cells and hepatic stellate cells or impaired degradation by sinusoidal endothelial cells (SECs) and thus is proposed as a non-invasive biomarker of liver fibrosis either by itself and/or included in the HEPASCORE formula.[1] *Patients and methods.* In this study we evaluated prospectively a screening of liver fibrosis in 201 adult patients aged 19-54 years with transfusion depended thalassemia major, based on HA measurements. 46/201 patients were HCV-mRNA(+). HA was measured with a turbidimetric assay (Wako Chemicals GmbH) applied on Siemens ADVIA 1800 Clinical Chemistry Analyser. This assay contains hyaluronic acid binding protein (HABP), which binds the HA in serum forming a complex that combines with latex particles coated by anti-HABP antibody. The above insoluble aggregate increases turbidity in the solution. The HEPASCORE was computed from the results by using the model previously published: HEPASCORE =y/(1+y) with y=exp [-4.185818-(0.0249 age (years))+(0.7464 sex (M=1, F=0)+(1.0039 _2-macroglobulin (g/l))+(0.0302 HA (μg/l))+(0.0691 bilirubin (μmol/L))-(0.0012 GGT (U/L))]. *Results.* The main results of the study showed that: a) HA levels were increased in 110/201 (55%) thalassemia patients 85.0±10.3 ng/mL, ranged from 15.0-1495.0 ng/mL, compared to 20.8 ±7.4 ng/mL reference laboratory values, P<0.001, b) HA levels were significantly higher in HCV-mRNA(+) compared to HCV-mRNA(-) patients, 192.9±40.5 *vs.* 53.0±2.7 ng/mL, P<0.0001 c) no significant correlations were found between HA levels and/or HEPASCORE with ferritin and liver iron content (LIC) assessed with MRI (p>0.324 and p>0.270, respectively). *Conclusions.* In recent years, there has been considerable interest in the use of non-invasive markers of hepatic fibrosis and cirrhosis in patients with thalassemia, because liver biopsy is an invasive and expensive procedure with potential complications. Our findings indicate that hyaluronic acid measurements contribute to the assessment of liver fibrosis in patients with thalassemia and might be helpful for further evaluation of patients with liver biopsy if this is truly needed. Furthermore, these results are in accordance with the results published recently with the other non-invasive method Fibroscan (transient elastography), indicating that liver fibrosis in thalassemia is independent from liver siderosis.[2]

T2* EVALUATION OF IRON OVERLOAD AT 3T AND COMPARISON WITH 1.5 T

A Pepe,[1] A Meloni,[1] D De Marchi,[1] V Positano,[1] L Menichetti,[1] P Keilberg,[1] MC Dell'Amico,[1] MC Rizzello,[2] G Valeri,[3] M Lombardi[1]

[1]Fondazione G.Monasterio CNR-Regione Toscana and Institute of Clinical Physiology, Pisa, Italy; [2]Ospedale Sant'Eugenio Papa - Centro Talassemie, Roma, Italy; [3]Department of Radiology, University of Ancona, Ancona, Italy

Background. To date the gradient echo multiecho T2* MRI technique is the most robust method for the sensitive, fast, and reproducible quantification of iron overload in transfusion dependent patients. The 1.5T MRI scanner is generally used in the clinical arena. However, given that 3T scanners are becoming largely widespread, there is a growing need to assess the practicality of evaluating MIO at 3T. *Aims.* The aim of this study was to establish the relationship between T2* values at 3T and 1.5T over the range of clinical interest of tissue iron concentrations. *Methods.* Twenty borosilicate test-tube phantoms containing increasing concentrations of Fe(III)Cl3 in 0.1N standard solution of HCl were scanned at 1.5T and 3T using a T2* GRE multiecho sequence. The phantoms T2* values were calculated within a circular region of interest (ROI). Then, 24 transfusion-dependent patients enrolled in the MIOT (Myocardial Iron Overload in Thalassemia) network were scanned at 1.5T and 3T. A single transverse slice through the liver was acquired. The T2* value was determined over a large ROI of standard dimension, chosen in a homogeneous area. Three parallel short-axis views of the left ventricle were obtained using T2* GRE multislice multiecho sequence. The global heart T2* value was obtained. *Results.* Figure 1 shows the relationships between the phantom T2* values (left), the patient liver (centre) and global heart T2* values (right) at 3T and 1.5T. In each graph, the line of the best fit is indicated. A similar conversion factor (about 0.6) was identified in phantom and patient data. *Conclusions.* A strongly significant linear relationship between T2* values at 1.5T and at 3T was found for both liver and phantoms data. The significant lower goodness of the fit between global heart T2* values at 1.5T and at 3T could be explained tacking into account that the 96% of the patients had a normal global heart T2* value at 1.5T (> 20 ms), so that the range of clinically relevant T2* values was not fully covered in patient data. Moreover, measurement errors were relevant at high T2* values due to technical constraints in sequence design and presence of susceptibility artefacts.

CARDIAC IRON OVERLOAD AND HEART FUNCTION BY CMR IN DIFFERENT PHENOTYPIC GROUPS OF THALASSEMIA MAJOR PATIENTS

A Pepe,[1] MC Dell'Amico,[1] A Meloni,[1] A Filosa,[2] G Rossi,[3] V Positano,[1] B Favilli,[1] D De Marchi,[1] C Salvatori,[1] A Pietrapertosa,[4] S Renne,[5] M Lombardi[1]

[1]Fondazione G.Monasterio CNR-Regione Toscana and Institute of Clinical Physiology, Pisa, Italy; [2]UOC Pediatria - DH Talassemia - AORN A. Cardarelli, Napoli, Italy; [3]Institute of Clinical Physiology of CNR, Epidemiology and Biostatistics Unit, Pisa, Italy; [4]Servizio Regionale Talassemie, Policlinico di Bari, Bari, Italy; [5]Struttura Complessa di Cardioradiologia-UTIC P.O. "Giovanni Paolo II", Lamezia Terme (CZ), Italy

Background. β-thalassemia major is a genetic disorder characterized by the absence (β°) or reduced output (β⁺) of the β chains of haemoglobin. This disorder displays a great deal of phenotypic heterogeneity, not ful-

ly investigated in terms of cause-effect. *Aims.* The aim of our study was to detect if different phenotypes could be related to different levels of cardiac impairments, evaluated by cardiovascular magnetic resonance (CMR). *Methods.* We performed a retrospective review of the CMR results and of clinical data about 328 TM patients (age 29±9 years, 52% females) enrolled in the Myocardial Iron Overload in Thalassemia (MIOT) project. In the MIOT network all CMR and thalassemia centers are linked by a web-based network, configured to collect patients' anamnestic, clinical, and diagnostic data. Myocardial iron overload was assessed by using a multislice multiecho T2* approach. Cine sequences were obtained to quantify biventricular morphological and functional parameters. *Results.* Three groups of patients were identified: heterozygote (N=172), homozygote β+ (N=58), homozygote β° (N=98). No significant differences for sex and age were found among the groups. The homozygote β+ group showed higher global heart T2* values than the heterozygote and homozygote β° group (32±11 ms *vs.* 26±13 ms *vs.* 23±13 ms, P=0.001) (Figure). The homozygote β+ group showed lower LV mass indexes than the heterozygote group (54±10 g/m^2 *vs.* 60±14 g/m^2, P=0.045). The homozygote β+ group showed higher LV EF values than the heterozygote group (64±5% *vs.* 60±7 %, P<0.0001) and higher RV EF values than the heterozygote and homozygote β° group (64±5% *vs.* 59±8 % *vs.* 60±7 %, P<0.0001). *Conclusions.* The homozygote β+ TM patients showed less myocardial iron overload and a concordant better global systolic heart function and cardiac remodelling. These data support the knowledge of the different phenotypes in the clinical and instrumental management of the TM patients.

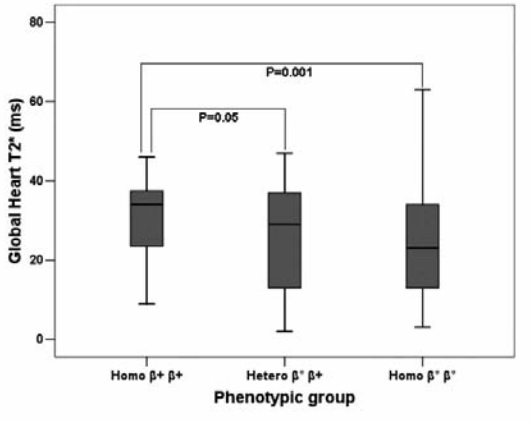

Figure.

1018

THE EFFICACY OF 4 DIFFERENT IRON CHELATION REGIMES IN PATIENTS WITH _-THALASSEMIA MAJOR: A 3 YEARS INSTITUTIONAL ANALYSIS

V Perifanis,[1] E Vlachaki,[1] S Kotsiopoulou,[1] M Economou,[1] A Teli,[1] K Matiou,[1] G Spanos,[2] I Tsatra,[1] M Athanassiou-Metaxa[1]

[1]Hippokration General Hospital, Thessaloniki, Greece; [2]Diagnostic laboratory Eurodiagnosis, Thessaloniki, Greece

The aim of this study was to compare the effect of different long-term chelation regimens on iron overload markers with the use of magnetic resonance imaging (MRI) and feritin in patients with transfusion-dependent beta-thalassemia major. Sixty one patients (25 men, 36 women; mean age, 28.12 +/- 8.08 years) were enrolled in the study. Four groups were formed, based on the chelation therapy received. The first group (10 patients) received deferoxamine (DFO) (30-50 mg/kg per day subcutaneously at least 5 times/week), the second group (10 patients) received deferiprone (DFP) (75 mg/kg per day orally), the third group (26 patients) received a combination of DFO (30-50 mg/kg per day, 2-3 days/week) and DFP (75 mg/kg per day, 7 days/week) and the fourth group (15 patients) received Deferasirox (30 mg/kg per day). MRI scans were acquired with an imager equipped with a 1.5 T magnet, and the data included myocardial and hepatic iron measurements obtained by means of T2*. Additionally, calculation of MRI-HIC values was based on an algorithm using liver to muscle (L/M) ratios in five axial gradient-echo sequences. All MRI scans were acguired at the beginning of the study and 3 years later. The results revealed that the Deferasirox group had significantly better Ferritin, T2* Heart, T2* Liver and MRI.HIC at the end of the study, compared with baseline (Table 1, a=P<0,05 , b=P<0,001 and c=P<0.0001). Although patients receiving combined chelation therapy did not show any statistical significant change at the end of the study as a group, a subgroup of them, consisting from 11 patients (except two treated with DFO monotherapy) with abnormal T2* heart (<20 ms) showed remarkable improvement (9.36 *vs.* 17.53 ms, P=0.04) 3 years later. *Conclusions.* There are now 3 different classes of iron chelators used mainly as monotherapy and one combination regimen with Desferrioxamine (DFO) and Deferiprone (DFP). The mode of action of each chelator is different and the choice is individualized. Combination therapy has encouraging results for patients with heart iron overload, while Deferasirox, with appropriate dosing, provides effective control of iron burden in thalassemic patients.

Table 1.

	FERRITIN (ng/ml)		T2* HEART (ms)		T2* LIVER (ms)		MRI.HIC (µmol/g dw)

SERUM HEPCIDIN LEVELS, INFLAMMATORY PARAMETERS AND IRON STATUS DURING LONG-TERM ENDURANCE TRAINING IN FEMALE RUNNERS

I Auersperger,[1] B Škof,[2] R Blagus,[3] B Knap,[4] M Skitek,[5] M Lainščak,[6] A Jerin[5]

[1]University of Ljubljana, Faculty of sport, Ljubjana, Slovenia; [2]University of Ljubljana, Faculty of Sport, Ljubljana, Slovenia; [3]University of Ljubljana, Faculty of Medicine, Ljubljana, Slovenia; [4]University Medical Centre Ljubljana, Department of nephrology, Ljubljana, Slovenia; [5]University Medical Centre Ljubljana, Institute of Clinical Chemistry and Biochem, Ljubljana, Slovenia; [6]Hospital Golnik, Department of internal medicine, Golnik, Slovenia

Background. Exercise- induced iron deficiency is a common disorder in endurance athletes. Recently, an acute phase protein hepcidin has been suggested to have a key role in regulation of iron homeostasis. It is synthesized in liver in response to number of triggers including iron availability, inflammation, anemia and hypoxia. It was suggested that exercise induced inflammation and/or hemolysis induce hepcidin activity, which inhibits iron absorption from the gut and release from macrophages and hepatocytes. *Aims.* This study aimed to assess the influence of long term endurance training on hepcidin, inflammatory parameters and iron status in moderately trained long-distance female runners. *Methods.* Eighteen healthy women had four training session per week in training load phases. Training protocol was composed of two interval trainings (at 88-95% maximum heart rate - MHR) and two continuous runs (at 80-87% MHR). We recorded training load and measured the following parameters: Hb and RBC, serum hepcidin, interleukin (IL)-6, high sensitivity C-reactive protein (hsCRP) and iron. Samples were taken after an overnight fast at five different time-points during the eight-weeks training programme: first at Baseline Pre (BPre), than after First and Second 3 weeks Training Load (1TL, 2TL), each followed by recovery week (1R and 2R) and sixth sample was taken 10 days after the competition, Baseline Post (BPost). *Results.* During eight weeks women completed 26.3 training (3.3/week) and ran 232 kilometers (29 km/week). The time spent in heart zones was as planed (44% at 70-87% MHR, 44% at 88-100% MHR). Results are shown in mean values±SD. The levels of hepcidin decreased with time in 1TL compared to BPre (100.64±27.95 µg/L *vs.* 177.54±72.67 µg/L; P<0.001) and increased in 2TL compared to 1TL (161.09±45.67 µg/L *vs.*

100.64±27.95 μg/L; P<0.001). After the study BPost levels of hepcidin did not return to BPre (110.67±60.32 μg/L *vs.* 177.54±72.67 μg/L; P<0.001). Levels of serum iron (Fe) decreased non-significantly during 2TL (17.93±9.97 μmol /L) and 2R (16.66±8.41 μmol/L) compared to BPre (21.49±9.59 μmol/L). At the highest training points, 1TL (128.61±6.34 g/L) and 2TL (127.67±6.22 g/L), subjects had lower levels of Hb compared to BPre (133.65±7.49 g/L; P<0.001 for both). RBC levels decreased significantly at 2TL comared to BPre (4.15± 0.26 *vs.* 4.35± 0.19×10^{12}/L; P=0.01). No significant effect was found for IL-6, hsCRP at any time points. BPre IL-6 levels was below 2 ng/L and hsCRP was 1.16±1.24 mg/L. *Conclusions.* The main finding of this study is that our exercise protocol did not have significant long-term effect on inflammatory parameters as IL-6 and hsCRP. The decrease of hepcidin in 1TL is probably associated with increased iron needs induced by strenuous training stimulus. Hepcidin increase at the highest training intensity point (2TL), probably reflects cumulative effect of prolong training result from-exercise induced inflammation. In recovery process (BPost), hepcidin decrease could be explained by increased iron needs, caused by increased turnover of red blood cells.

1020

PULMONARY HYPERTENSION IN YOUNG CHILDREN WITH SICKLE CELL DISEASE: WHEN DOES IT START? SURVEY AMONG IMMIGRANT PATIENTS IN NORTH-EAST ITALY

R Colombatti,[1] N Maschietto,[1] E Varotto,[1] A Grison,[1] N Grazzina,[2] L Meneghello,[3] S Teso,[1] M Carli,[1] O Milanesi,[1] L Sainati[1]

[1]University of Padova, Padova, Italy; [2]Ospedale di Cittadella, Cittadella, Italy; [3]Ospedale S.Chiara, Trento, Italy

Background. Acute Chest Syndrome (ACS) and Pulmonary Hypertension (PH) are among the leading causes of death in adults with Sickle Cell Disease (SCD). Several studies have been conducted in children utilizing a Tricuspid Regurgitant Velocity (TRV) TRV≥2.5 m/sec as a marker of PH. Despite the finding of elevated TRV in children below 5 years of age, the prevalence, age at onset and evolution of PH in children with SCD are still not clear. Evaluation of TRV has been performed mainly in African-Americans and mean age of analyzed populations is above 10 years. It is well known that SCD displays phenotypic variability among populations and individuals and that vascular complications may vary in different ethnic groups. In Italy, like in the rest of Europe, SCD patients are mainly African immigrants and they are very young. *Aims.* To determine prevalence and natural evolution of elevated TRV in a population of young African patients with SCD, mainly treatment free. To identify social, clinical, laboratory or echocardiographic predictive factors for precocious development of PH in children. *Methods.* Since 2007 we performed annual echocardiography with evaluation of TRV and Tissue Doppler Imaging (TDI) to SCD children ≥3 years of age at steady state and to racially/age-matched controls. Clinical, laboratory and echocardiographic variables were analysed to identify predictive factors for early development of PH. Patients receiving chronic transfusion were excluded.

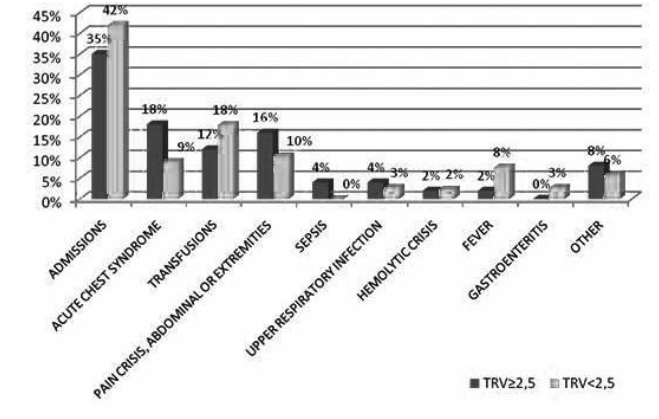

Figure.

Results. 41/75 patients were ≥ 3 years and 37 had measurable TRV. Mean age was 6.2 years (range 3,07-15,68), 86% were Africans, 85% were HbS/HbS. 8/37 (21.6%) had TRV≥2.5 m/sec, three of them being only 3 yrs old. Three patients were on hydroxyurea, all in the TRV<2.5 m/sec group. Patients with higher TRV displayed higher platelet (P=0.017) and reticulocyte counts (P=0.033) and a higher mitral E/A ratio (P=0.024). They had higher Blood Pressure (50% with BP>90th percentile *vs.* 35%) and more ACS (18 *vs.* 9%), even if steady state Oxygen Saturation remained normal (97% *vs.* 98%). In the multivariate analysis only ACS remained as a predictive factor for development of high TRV (P=0.035). After 3 years of follow-up all patients in the TRV ≥2.5 m/sec group had further elevation of the TRV, with the overall prevalence of PH in the population increasing to 40,5%. TDI revealed initial signs of diastolic dysfunction of the left ventricle (LV) as demonstrated by higher late diastolic velocities. At follow-up, TRV patients showed a progressive dilatation of the LV, probably related to their chronic volume overload. *Conclusions.* Our study suggests that elevation of TRV and diastolic dysfunction of the LV in SCD children begin earlier than previously expected. Factors leading to early onset of PH in children might not exactly be the same as the ones causing its development in older children or adults. Studies with longer a follow-up and larger population are warranted in order to better define significance of elevated TRV in childhood and to evaluate the steps leading to cardiac dysfunction. Nevertheless, it seems that African children with SCD might benefit from early screening and yearly re-assessment.

1021

CHARACTERIZATION OF ALPHA-THALASSEMIC GENOTYPES BY MLPA (MULTIPLEX LIGATION-DEPENDENT PROBE AMPLIFICATION)

MF Sonati,[1] C Suemasu,[2] E Kimura,[2] D Oliveira,[2] M Bezerra,[3] F Costa[2]

[1]State University of Campinas-UNICAMP, School of Medical Sciences, Campinas, Brazil; [2]School of Medical Sciences - State University of Campinas, Campinas, Brazil; [3]Hemope, Recife-PE, Brazil

Background. Alpha (α) thalassemia is an inherited hemoglobin disorder characterized by a quantitative reduction of the α-globin chains. Genomic deletions involving the α-globin gene cluster on chromosome 16p13.3 result in one or more α-globin genes being missing and are the most common molecular cause of α-thalassemia. The molecular test commonly used to identify these deletions is gap-PCR, which can only be used to detect known deletions in which both breakpoint sequences have been previously characterized. Recently, a simple technique suitable for rapid quantitative analysis called Multiplex Ligation-dependent Probe Amplification (MLPA) has been described. *Aims.* We describe here eight deletions (α0) and one segmental duplication involving the α-globin gene cluster in unrelated individuals using the MLPA method. *Patients and Methods.* Approximately 38 to 57 probes were used; these had lengths between 90 and 409bp and were distributed along a 700kb genomic region from the tip of the short arm of chromosome 16. Five of the patients had HbH disease and were found to have both the α0 and common α+3.7 deletions, the latter of which had already been identified by gap-PCR; three cases were α0 heterozygotes and in one the MLPA analysis revealed a full duplication of the α-cluster, extensive to the chromosome 16p telomer. *Results.* Four of the deletions found are large and remove the complete α-cluster and its upstream regulatory element (HS-40). These deletions span at least a genomic region of 270kb, 450kb, 540kb and 760kb (positions 43625-288064, 43625-583598, 43625-583598 and 43625-756403 of the UCSC Genome Browser, respectively). Another four deletions were limited to a region that contains the HS-40 element, leaving the α-globin genes intact but without expression. These deletions span a region of at least 60kb in the first case and 140kb in the others (positions 75563 - 132952, 43625-142344, 43625-152736 and 43625-152736 of the UCSC Genome Browser, respectively). Finally, in the case with α-cluster duplication, the duplicated allele spans at least 170kb (position 43625-175806 of the UCSC Genome Browser). *Conclusion.* These results show that MLPA is a suitable method for detecting unknown and uncommon deletions and duplications. Although breakpoints have not been determined yet, most of the deletions seem to be novel. Financial Support: FAPESP, CNPQ and CAPES / Brazil.

EVALUATION OF PAROXYSMAL NOCTURNAL HEMOGLOBINURIA DISEASE BURDEN IN PATIENTS ENROLLED IN THE INTERNATIONAL PNH REGISTRY

A Urbano-Ispizua,[1] H Schrezenmeier,[2] R Brodsky,[3] P Muus,[4] M Bessler,[5] J Szer,[6] J Maciejewski,[7] G Socie,[8] W Rosse,[9] Y Kanakura,[10] A Karnell,[11] C Bedrosian,[12] P Hillmen[13]

[1]Hospital Clinic of Barcelona, Barcelona, Spain; [2]University of Ulm, Ulm, Germany; [3]Johns Hopkins University Medical Center, Baltimore, USA; [4]University Medical Center St. Radboud, Nijmegen, Netherlands; [5]Washington University School of Medicine, St. Louis, USA; [6]The Royal Melbourne Hospital, Parkville, Australia; [7]Cleveland Clinic Foundation, Cleveland, USA; [8]Hospital Saint-Louis, Paris, France; [9]Duke University Medical Center, Durham, USA; [10]Osaka University Graduate School of Medicine, Osaka, Japan; [11]Alexion Pharmaceuticals, SAS, Paris, France; [12]Alexion Pharmaceuticals, Inc, Cheshire, USA; [13]Leeds Teaching Hospitals NHS Trust, Leeds, UK

Background. Paroxysmal nocturnal hemoglobinuria (PNH) is a rare clonal hematopoietic stem cell disease which can lead to life-threatening complications including thrombotic events (TE), kidney disease, and pulmonary hypertension. Greater use of high sensitivity diagnostic tests and the availability of targeted terminal complement blockade treatment have lead to an increase in PNH disease awareness and improved prognosis, respectively. We have established an international PNH Registry in order to assess disease burden and examine the natural history of PNH. *Aims.* To describe the spectrum of disease burden assessed by patient-reported symptoms, history of thrombosis (TE), and PNH granulocyte clones size (PNH clone), together with evaluation of co-existent bone marrow disorders (BMD). *Methods.* Data from 78 clinical sites in 14 countries on 4 continents (as of February 2010) was analyzed to determine symptom presentation of patients with PNH. Sites collected disease-specific data including demographics, laboratory values, PNH clone size, medical history, symptoms, TE, and treatments. *Results.* As of February 2010 there were 524 enrolled patients in the Registry. Mean age at enrollment was 44±17 (range 5-89) and 54% were female. Median PNH clone size was 80% (15% of patients with PNH clone <10% and 70% with clone ≥50%). History of BMD was noted in 42% of patients (37% aplastic anemia [AA], 5% other). 74% of patients with AA had PNH clones >10% compared to 93% without any BMD (P<.01). The mean LDH was 1.2 times the normal upper limit in patients with PNH clones <10%, 2.5 times with clones 10-49%, and 4.3 times with clones ≥ 50% (P<.01). LDH was similar in patients with and without a history of BMD (3.1 and 3.7 times the normal upper limit, P=0.33). Mean age at first symptoms was 36±17 (range 5-79). At study enrollment, 46% of patients reported abdominal pain, 58% reported shortness of breath, 28% reported chest pain, 76% reported fatigue and 65% reported discolored urine. PNH symptoms were present regardless of PNH clone size (Table). Additionally, patients with underlying AA demonstrated symptoms at equal frequency to patients with no history of BMD. Patients with PNH clone >50% were more likely to have a history of thrombotic events (22%) compared to patients with smaller PNH clones, however the risk of TE is still high in patients with PNH clones <10% (5%) over the general population. Less than half the patients entering the registry required transfusions in the year prior to enrollment (38%). Other treatments that patients received in the prior year were anticoagulants (32%), eculizumab (28%), and immunosuppressive therapies (21%).

Table. Symptoms and complications of PNH.

	PNH Clone				Bone Marrow Disorder		
Symptom or complication	<10%	10-49%	>50%	P-value*	Aplastic or Hypoplastic Anemia	No Bone Marrow Disorder	P-value**
TE	5%	5%	22%	<.01	18%	19%	0.89
Abdominal Pain	41%	53%	46%	0.58	48%	47%	0.92
Shortness of breath	49%	44%	53%	0.63	53%	61%	0.23
Chest pain	14%	31%	24%	0.21	31%	27%	0.43
Fatigue	59%	72%	76%	0.15	75%	76%	0.99
Discolored urine	30%	56%	75%	<.01	60%	72%	0.05

*Chi-square test for differences across three PNH clone size categories.
** Chi-square test for differences across two BMD categories.

Conclusions. Clinical presentation at study enrollment showed that abdominal and chest pain, shortness of breath, fatigue, and discolored urine is prevalent in PNH patients. PNH symptoms were reported in patients irrespective of large or small clones, including evidence of a clinical TE, or history of BMD. This global PNH Registry will continue to evaluate disease burden and determine the long-term natural history of PNH and treatments outcomes. New clinical sites and geographic regions are encouraged to participate in the Registry.

1023

FOK-I GENE POLYMORPHISM OF VITAMIN D RECEPTOR IN PATIENTS WITH β-THALASSAEMIA MAJOR. ASSOCIATION WITH LEVELS OF VITAMIN D METABOLITES

M Dimitriadou,[1] A Christoforidis,[1] L Fidani,[2] M Economou,[1] V Perifanis,[3] I Tsatra,[3] G Katzos,[1] M Athanassiou-Metaxa[1]

[1]Aristotle University, Thessaloniki, Greece; [2]General Biology, Medical School, Aristotle University, Thessaloniki, Greece; [3]Thalassaemia Unit, Ippokratio Hospital, Thessaloniki, Greece

Background. Vitamin D deficiency is increasingly identified among patients with β-thalassaemia, whereas recent evidence associates it with increased myocardial iron accumulation. Most of the biological actions of vitamin D are mediated by an intracellular receptor (VDR) in whom several single nucleotide gene polymorphisms, that could potentially modify its action, have been identified. *Aims.* The aim of the study was to assess the distribution of Fok-I genotype of VDR among Greek children and young adults with β-thalassaemia major and consecutively to investigate its association with levels of $25(OH)D_3$ and $1,25(OH)_2D_3$. *Methods.* Blood samples from 69 patients with β-thalassaemia major on conventional treatment (35 females and 34 males), with a mean decimal age of 23.05±6.07 years, were collected for the determination of $25(OH)D_3$ and $1,25(OH)_2D_3$ serum concentrations and the genotyping of Fok-I polymorphism in exon 2 of the VDR gene on chromosome 12. *Results.* With regard to Fok-I polymorphism, results showed no deviation from Hardy-Weinberg equilibrium as 44.9% of the patients were homozygotes for F allele, whereas homozygosis for f allele and heterozygosis (Ff) were presented in 11.6% and 43.5% of the patients respectively. Markedly decreased levels of serum $25(OH)D_3$ were observed as 41 patients (59.4%) were below the cut-off limit of 50 nmol/l that determines deficiency, whereas, levels of $1,25(OH)_2D_3$ showed a wide variability ranging from deficiency (≤ 50 pmol/L) in 34 patients (49.3%) to excess (≥ 125 pmol/L) in 13 patients (18.8%). When patients were stratified according to their $1,25(OH)_2D_3$ status, a higher prevalence of f allele was recorded in the insufficiency group (P=0.03, Figure). Finally, levels of the two metabolites of vitamin D showed a negative correlation, approaching statistical significance (r=-0.204, P=0.09). *Summary/Conclusions.* Our study showed significantly decreased levels of 25(OH)D3 in patients with β-thalassaemia major and an association between levels of 1,25(OH)2D3 and the presence of f allele of the Fok-I polymorphism. More studies are required to further investigate the genetic contribution to the regulation of vitamin D metabolites as their deficiency has been lately associated with unfavorable sequelae in patients with β-thalassaemia major.

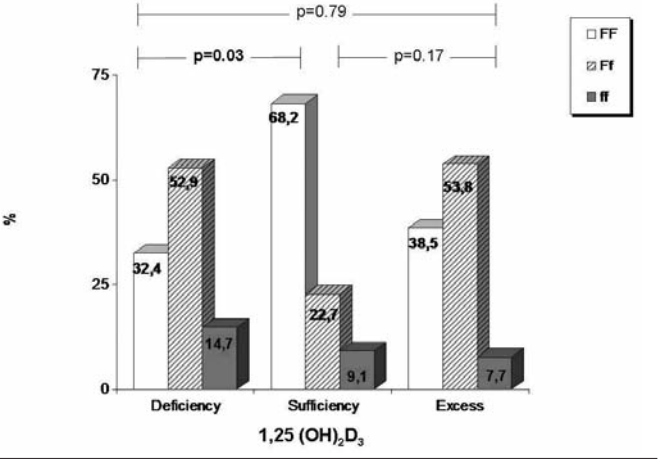

Figure. Higher prevalence of f allele in vitD deficiency.

SICKLE CELL DISEASE: FROM NEONATAL SCREENING TO CLINICAL MANAGEMENT

PQ Le,[1] A Ferster,[1] F Vertongen,[2] C Vermylen,[3] A Vanderfaeillie,[2] L Dedeken,[1] C Heijmans,[1] O Ketelslegers,[4] MF Dresse,[4] A Efira,[5] C Epalza,[2] B Gulbis[6]

[1]Children' University Hospital Reine Fabiola, ULB, Brussels, Brussels, Belgium; [2]Hopital Universitaire Saint Pierre, Brussels, Belgium; [3]Cliniques Universitaires Saint Luc, Brussels, Belgium; [4]Centre Hospitalier Regional de la Citadelle, Liege, Belgium; [5]Centre Hospitalier Universitaire de Brugmann, Brussels, Belgium; [6]Hopital Erasme- Cliniques Universitaires de Bruxelles - ULB, Brussels, Belgium

A neonatal haemoglobinopathy screening programme was implemented in Brussels more than a decade ago and in Liège five years ago, the programme being adapted to the local situation. It is universal, performed using liquid cord blood and an isoelectric focusing technique. All samples with abnormalities undergo confirmatory testing. Major and minor haemoglobinopathies are reported. Affected children are referred to a specialist centre. A central data base in which all screening results are stored are available and accessible to local care workers. A central clinical database to monitor follow-up is under construction. The objectives of the clinical data base are learning the characteristics of this population, creating a network between practionners (general, emergency and specialist practionners), State-of-the art, Guidelines, a tool for disseminating information, a tool for education projects, a basis for research, and could represent a pilot project for other chronic diseases. Since 1994, around 250,000 newborns were screened. The annual incidence of sickle cell disease is±1/1500, of β thalassaemia major and haemoglobin H disease is <1/25,000. All major haemoglobinopathies were confirmed and follow-up of the infants was undertaken except for three of them who did not attend the first medical consultation despite our best efforts. The clinical data base, approved by local ethical committee and with the informed consent of each patient, contains actually 280 patient records. The first information provided are the predominance of patients from DR Congo (67.5%), the high amount of severe clinical events (85%, the predominance of Hb SS phenotype in number and severity (90%), the report of severe infections which remain still very worrying (8.2%), but also that clinical and radiological neurological events are sizeable, and that there is a good response to treatment intensification, particularly to BMT and hydroxyurea. Of course it raises also many questions. In conclusion, the universal neonatal screening programme was effective because no case of major haemoglobinopathy was reported to be unidentified. The affected children received dedicated medical care from birth. The screening programme and specifically the reporting of minor haemoglobinopathies has been an excellent health education tool in Belgium for more than 12 years. On the other hand, the clinical database is important to improve clinical management of patients with SCD. It is a possibility to identify risk factors and tailor treatments; it constitutes a basis for prospective studies to valid criteria of disease severity and to adopt guidelines for adequate treatment.

PHOSPHOGLYCERATE KINASE DEFICIENCY: FUNCTIONAL PROPERTIES OF THE L89P, K191DEL, C316R AND A354P PATHOLOGICAL VARIANTS

S Morera,[1] L Chiarelli,[2] P Bianchi,[3] E Fermo,[3] A Zanella,[3] G Valentini[2]

[1]Università di Pavia, Pavia, Italy; [2]Dipartimento di Biochimica Università di Pavia, Pavia, Italy; [3]U.O. Ematologia ,[2] Fondazione IRCCS Cà Granda-Ospedale Maggiore Policlinico, Milan, Italy

Background. Phosphoglycerate kinase 1, (PGK1) the isoenzyme that catalyzes the first ATP-generating step in the glycolytic pathway, is encoded by a gene located on the X-chromosome, and is ubiquitously expressed. It is a relatively small monomeric molecule characterized by two hinge-bent domains, with a highly conserved structure. The N-terminal domain binds 1,3-bisphosphoglycerate (1,3BPG) or 3-phosphoglycerate (3PG), whereas the C-terminal domain binds Mg-ADP or Mg-ATP. During the catalytic cycle, the enzyme undergoes large conformational rearrangements, proceeding from an open form to a closed form. Mutations of the PGK1 gene result in an enzyme deficiency that is characterized by mild to severe haemolytic anaemia, neurological dysfunctions and myopathy. Patients rarely exhibit all the three clinical features. To date, 20 different mutations with worldwide distribution have been described. *Aims.* To gain knowledge on molecular bases of the haemolytic anaemia and/or neurological and muscolar dysfunctions associated to PGK deficiency, an in depth characterization of the PGK variants has been undertaken. The present study describes the biochemical characterization of L89P (c.266T>C), K191del (delAAG c.571>573), C316R (c.946T>C) and A354P (c.1060G>C) variant enzymes. K191del mutation was found in a patient affected by haemolytic anaemia; L89P, C316R and A354P mutations were identified in patients with haemolytic anaemia and neurological dysfunctions. *Methods.* Site-directed mutagenesis was used to introduce mutations into the PGK cDNA. All variants were expressed as recombinant forms in a microbial system and purified to homogeneity after a single anion exchange chromatographic step. *Results.* All mutations turned out to have detrimental effects on the molecular properties of PGK enzyme. All variants displayed high heat instability, being L89P, C316R and A354P the most affected (T50 values approximately 10°C lower than that of the wild type enzyme; t1/2 at 37°C, 9, 12 and 30 min, respectively, *vs.* >2h of the wild type). Differently from the wild type enzyme, all variants were not protected from heat inactivation by ATP or 3PG. In addition, A354P variant showed a Km value *vs.* 3PG 15-fold higher than that of the wild type enzyme, accounting for a 18-fold lowered catalytic efficiency. K191del and C316R enzymes exhibited 6- and 4-fold reduced kcat values. *Conclusions.* On the whole, these data primarily indicate that all mutations affect residues crucial for protein stability. Most probably, the inability to maintain proper folding *in vivo* makes the enzymes good targets for degradation by the ubiquitin-proteasome pathway, thus reducing their intracellular concentration, mainly in red blood cells. Moreover, the altered kinetic properties displayed by K191del, C316R and A354P variants render these enzymes unable to fulfil properly the catalytic cycle, contributing to lower the ATP generation.

1026

REGIONAL AND GLOBAL PANCREATIC T2* MRI FOR IRON OVERLOAD ASSESSMENT IN A LARGE COHORT OF HEALTHY SUBJECTS: NORMAL VALUES AND CORRELATION WITH AGE AND GENDER

A Pepe,[1] A Meloni,[1] MC Dell'Amico,[1] V Positano,[1] M Missere,[2] A Maggio,[3] C Borgna-Pignatti,[4] M Capra,[5] A Pietrapertosa,[6] M Lombardi,[1] G Sallustio,[2] G Restaino[2]

[1]Fondazione G.Monasterio CNR-Regione Toscana and Institute of Clinical Physiology, Pisa, Italy; [2]Catholic University of the Sacred Heart, Department of Radiology, Campobasso, Italy; [3]Ematologia II con Talassemia, V. Cervello Hospital, Palermo, Italy; [4]University of Ferrara, Department of Clinical and Experimental Medicine, Ferrara, Italy; [5]P.O. G. Di Cristina, ARNAS Civico, Palermo, Italy; [6]Servizio Regionale Talassemie, Policlinico di Bari, Bari, Italy

Background. Impairment of the endocrine and exocrine function of the pancreas is a common complication in patients with systemic iron overload, especially in thalassemia patients. Multiecho T2* MRI is a well-established technique for iron overload assessment but there are few reports concerning the pancreas. *Aims.* Our aims were to assess the feasibility and reproducibility of the MRI technique for measuring pancreatic regional and global T2* values, to establish the lower limit of normal in a large cohort of healthy subjects and to correlate the gained values with age and gender. *Methods.* One hundred and twenty healthy subjects (61 males, mean age 51±17 years) underwent MRI exam (1.5T) using a breath-hold multiecho T2* gradient-echo sequence. T2* measurements were performed in pancreatic head, body and tail. The global value was calculated as the mean.

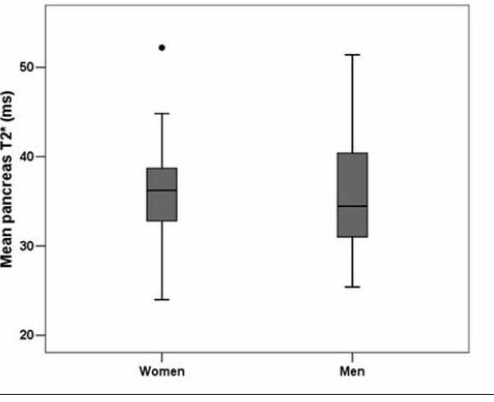

Figure.

Results. Measurement of pancreatic T2* values was feasible in all subjects and in 86% it was possible to perform measurements in each region. For the T2* global value the CoV for intra-operator and inter-operator reproducibility were 7.7% and 13%, respectively. The global T2* value ranged from 24 to 52 ms with the lower limit of normal of 26 ms. There were no significant differences among the regional pancreatic T2* values. No significant correlation was found between T2* and patient age or gender. *Conclusions.* In conclusion, pancreatic T2* measurements appear to be feasible, reproducible, non-time-consuming and reliable. In a large cohort of healthy subjects gender- and age-related differences concerning pancreatic T2* were not found.

SIRES: A WEB-SERVER TOOL FOR SEARCHING OF IRON-RESPONSIVE ELEMENTS

M Sanchez,[1] M Campillos,[2] I Cases,[1] G Frigola-Quintana,[1] M Hentze[2]

[1]Institute of Predictive and Personalized Medicine of Cancer (IMPPC), Badalona, Spain; [2]European Molecular Biology Laboratory (EMBL), Heidelberg, Germany

The IRP/IRE regulatory system plays a crucial role in the post-transcriptional regulation of gene expression and its disruption results in human disease. Iron-responsive elements (IREs) are cis-acting regulatory motifs present in mRNAs that encode for proteins involved in iron metabolism. They function as binding sites for two related trans-acting factors, namely the iron regulatory proteins (IRP1 and IRP2). Among the cis-acting oligonucleotide patterns, the IRE is one of the best characterized. It is defined by a combination of RNA sequence and structure. However, currently available programs to predict IREs do not show a satisfactory level of sensitivity and fail to detect functional IREs. Here, we report an improved software for the prediction of IREs implemented as a user-friendly web-server tool. The SIREs web-server uses a simple data input interface and provides structure analysis, predicted RNA folds, folding energy data and an overall quality flag based on properties of well characterized IREs. Results are reported in a tabular format and in a schematic visual representation that highlights important features of the IRE. The SIREs (Search for iron-responsive elements) web-server is freely available on the web at http://ccbg.imppc.org/sires/index.html.

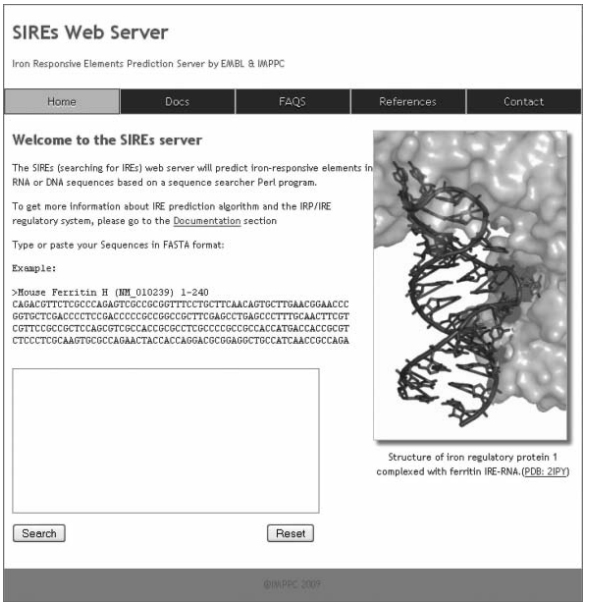

Figure. SIREs web-server input page.

CENTRAL NERVOUS SYSTEM FINDINGS IN YOUNG PATIENTS WITH THALASSEMIA INTERMEDIA

A Teli,[1] M Economou,[2] D Zafeiriou,[2] J Rudolf,[3] E Kontopoulos,[2] N Gombakis,[2] I Tsatra,[1] M Athanasiou[2]

[1]Thalassemia Unit, [1]st Department of Pediatrics, Aristotle University, Thessaloniki, Greece; [2]1st Department of Pediatrics, Aristotle University, Thessaloniki, Greece; [3]Department of Neurology and Stroke, Papageorgiou General Hospital, Thessaloniki, Greece

Background. Several reports have demonstrated involvement of the nervous system in thalassemia patients, with a high incidence of thromboembolic events especially in thalassemia intermedia (TI) patients. Brain involvement has not been widely studied in TI, although limited reports confirm a low incidence of stroke and high incidence of silent brain infracts. In most cases, neurological involvement does not initially present with relevant signs or symptoms and can only be detected during neurophysiological or neuroimaging evaluation. *Aim.* To evaluate possible CNS involvement in young patients with thalassemia intermedia. *Methods.* 19 patients with thalassemia intermedia , 12 females and 7 males, with a mean age of 13 years (range: 8-20 years) participated in a systemic neurophysiologic and neuroimaging study. None of them were on a regular transfusion program or on chelation therapy. Neurological examination was carried out and hemoglobin and serum ferritin were measured in every patient. Neurophysiological evaluation consisted of electroencephalogram (EEG), brainstem auditory (BAEP), visual (VEP) and somatosensory (SEP) evoked potentials examination, as well as, transcranial Doppler (TCD) ultrasonography, magnetic resonance imaging (MRI) and angiography (MRA) of the brain. *Results.* None of the patients reported symptoms of overt stroke and none demonstrated abnormal neurological findings on clinical examination. From the neuroimaging evaluation none of the patients had abnormal findings on MRI or MRA of the brain. The blood flow velocity in the basal intracranial arteries was normal for all patients. There was 1/19 (5.2%) patient with prolonged latencies in BAEP examination. VEP and SEP examinations were normal in all patients. 8/19 (42%) patients had abnormal findings in EEG, consisting of diffused slow waves (21%), slow waves mixed with sharp waves (15.7%) and paroxysmal atypical spikes (10.5%). No correlations were found between EEG findings and age, gender, hemoglobin or serum ferritin levels. *Conclusions.* The results of our study show the presence of neurophysiological abnormalities even in young patients with thalassemia intermedia. The EEG findings are probably attributed to the anemia dependent chronic hypoxia, as suggested previously by other authors in thalassemia major groups of patients. There were no abnormal MRI-MRA findings, probably because of the young age of our group, as other studies have demonstrated brain lesions in adult TI patients and increasing age has been associated with higher incidence and multiplicity of events.

1029

THE IMPACT OF RECENTLY-PUBLISHED NEGATIVE ERYTHROPOIETIN STIMULATING AGENTS (ESA) STUDIES ON CLINICAL MANAGEMENT OF CANCER RELATED ANEMIA. A COMPREHENSIVE CANCER CENTER EXPERIENCE

H Abdel-Razeq, S Hijjawi, H Abdulelah, R Amarin, M Asawaeer, H Shaheen

King Hussein Cancer Center, Amman, Jordan

Anemia is the most common hematological abnormality in cancer patients. Unfortunately, it is often under-recognized and under-treated. Erythropoietin stimulating agents (ESA) were widely used to prevent and treat cancer and chemotherapy-related anemia. However, many recent studies suggested a negative impact on disease progression and survival associated with their use. This study describes the prevalence of anemia in cancer patients and the recent trends in its management given the recent negative studies. A total of 959 patients were included, the mean age (SD) was 53 (16) years, 492 (51%) of the patients were males. Main reasons for admission at time of enrollment were chemotherapy in 217 (22.6%), infections including neutropenic fever in 190 (19.8%), palliative and supportive care in 145 (15.1%). Primary cancer diagnoses were: gastrointestinal in 203 (21.2%), breast in 154 (16.1%), lymphoma/multiple myeloma in 151 (15.7%), and lung in 106 (11.1%). At time of enrollment, anemia (Hb <12 g/dL) was detected in 755 (78.7%) patients. Mean Hb value for anemic patients was 9.5 g/dL (range 3.5-11.9, median 9.6). Severe anemia (Hb <8.0 g/dL) was detect-

ed in 126 (16.7%), moderate (Hb: 8.0-9.9 g/dL) in 319 (42.3%) and mild (Hb: 10-11.9 g/dL) in 310 (41.1%) patients. Prevalence and severity of anemia varied according to tumor type and reason for admission. More than two thirds [518 (68.6%)] of the anemic patients were not offered any kind of anemia treatment, however, most (60%) of them had mild anemia. Mean Hb value at which treatment was started was 8.0 g/dL, while mean Hb for the patients who were not treated was 10.2 g/dL. Anemia treatment was related to its severity; 119 (94.4%) of the patients with severe anemia were treated compared to a treatment rate of 32.9% in the group with moderate anemia, and 5.0% in patients with mild anemia (P<0.0001). Treatment offered for patients with anemia varied; blood transfusion was given to 188 (79.3%), while ESA were offered for only 8 (3.4%) of the treated patients. Treatment rate also varied according to reason for admission; only 29 (21.6%) of anemic patients admitted for chemotherapy were offered any treatment compared to a rate of 33.4% for the rest of the cancer patients, (P=0.0075). Length of hospital stay was affected by the presence of anemia; the mean hospital stay was 7.27 [95% CI: (6.95, 7.59)] days in anemic patients compared to 4.85 [95% CI: (4.59, 5.11)] days among the non-anemics (P<0.001). In addition to anemia status; age, reason for admission, primary tumor site and stage were studied for impact on length of hospital stay; primary disease (P<0.0001) and reason for admission (P=0.053) were associated with significant impact. *Conclusions.* Given the recent negative ESA studies and FDA warnings, anemia is under-recognized and under-treated. Only severe anemia was adequately treated; mostly with blood transfusion while ESA were rarely used. Majority of patients with moderate anemia were not treated including patients on active chemotherapy. Better guidelines addressing anemia management in this subgroup of patients are highly needed.

THE EFFECT OF HELICOBACTER PYLORI INFECTION ON SERUM VITAMIN B12 AND HOLOTRANSCOBALAMIN LEVELS IN CHILDREN

O Afyoncu, A Atay, AE Kurekci, O Gursel, N Balamtekin, A Hasimi, MA Ozguven, O Ozcan

Gulhane Military Medical Academy, Ankara, Turkey

Background. Helicobacter pylori (H pylori) is a gram negative bacterium that has been found to be associated with vitamin B12 deficiency. Vitamin B12 is required by all cells for its role in one-carbon metabolism and in DNA-synthesis and maintenance. The clinical consequences of vitamin B12 deficiency include megaloblastic anemia and progressive neurologic disease of the central and peripheral nervous systems. Early diagnosis of vitamin B12 deficiency is crucial because of the possible risk of irreversible neurological damage. Holotranscobalamin assay is considered as a convenient approach that measures the active portion of B12 and the only part available for the cell-use. *Aims.* The purpose of this study was to evaluate the association between serum vitamin B12 levels and H pylori infection and examine the clinical usefulness of holotranscobalamin measurement in children. *Methods.* A total of 30 children, who suffered from abdominal pain, nausea, vomiting or lack of appetite and diagnosed to have H. pylori infection by C-14 urea breath test, constituted the study group. The control group consisted of 26 children without H. pylori infection. In both the study (before and after treatment) and the control groups, complete blood count (CBC), creatinine, vitamin B12, folate, plasma total homocystein, and holotranscobalamin measurements were performed. The children in the study group were given a 2- week course of oral proton pump inhibitor plus Amoxicilline plus Clarithromycine therapy. The study was approved by the local ethics committee. *Results.* There were no statistically significant differences between the study and control groups with respect to age and gender. The study group pre-treatment and post-treatment parameters and control group parameters did not differ significantly in values for CBC, creatinine, vitamin B12, folate and plasma total homocystein. In the study group, the pretreatment plasma holotranscobalamin concentrations were significantly lower than post-treatment (P<0.02) and those in the control group (P<0.05). No statistically significant differences were found between the study group post-treatment values and the control group with respect to holotranscobalamin. *Conclusions.* Direct measurement of holotranscobalamin has been postulated to provide a better indicator of an individual's vitamin B12 status. The measurement of total serum vitamin B12 suffers from a number of limitations, most particularly that the majority of vitamin B12 measured is that bound to haptocorrin. Given that holotranscobalamin has a shorter circulating half-life than holohaptocorrin, the earliest change that occurs when an individual enters a negative vitamin B12 balance is very likely to be a decrease in the plasma holotranscobalamin concentration. In this study, we demonstrated that H pylori infection in children may significantly decrease plasma holotranscobalamin concentrations, which can be reversed by eradication therapy. The findings of our study suggest that H pylori infection has a negative effect on vitamin B12 levels.

1031

RELATIONSHIP BETWEEN GDF-15 (GROWTH DIFFERENTIATION FACTOR 15) AND IRON OVERLOAD IN THALASSEMIA INTERMEDIA PATIENTS

L Duca, I Nava, G Graziadei, C Cesaretti, MD Cappellini

Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico,University of Milan, Milan, Italy

Introduction. Thalassemia intermedia (TI) encloses a wide spectrum of transfusion independent thalassemias, nevertheless patients have iron loading due to increased intestinal iron absorption and ineffective erythropoiesis. Accumulation of iron in absence of blood transfusions may result from inappropriate suppression of hepcidin by high erythropoietic activity that overwhelms iron load. Hepcidin is a small liver peptide that reduces iron absorption via degradation of ferroportin. GDF-15 is a divergent member of the transforming growth factor-_ superfamily identified as a hypoxia-inducible gene product involved in hepcidin regulation. Recent reports have described GDF-15-dependent suppression of hepcidin in β-thalassemia patients. *Aim.* To evaluate if GDF-15 relates with iron status in thalassemia, serum ferritin (SF), transferrin saturation (TS%) and NTBI were determined in 40 TI patients (aged 43±11; 28 splenectomized and 12 occasionally transfused), in 12 TI very mild due to triplicated α genes plus β mutation (β°/ααα) aged 43±13 years and in 20 healthy subjects as controls. *Methods.* Serum GDF-15 was evaluated by enzyme-linked immunosorbent assay using DuoSet Sandwich ELISA Kit (R&D Systems, Minneapolis, MN); serum hepcidin was measured by ELISA Kit (DRG Instruments GmbH, Germany). NTBI was assayed by HPLC after nitrilotriacetic acid chelation. *Results.* GDF-15, hepcidin and NTBI values were significantly higher in TI (23567± 17911 pg/mL; 9.71±8.58 ng/mL; 1.47±2.26 μM respectively) compared to controls (581±242 pg/mL, P<0.0001; 3.5±2.5 ng/mL, P=0.05; -0.72±0.70 μM, P=0.05 respectively). In splenectomized patients GDF-15 levels were higher although non significant than in non splenectomized (26730±15852 pg/mL *vs.* 22785±18331 pg/mL), hepcidin was lower (7.6 ± 5.8 ng/mL *vs.* 11.4±10.9 ng/mL) and NTBI was increased (2.02±2.29 μM; 0.51±2.0 μM respectively). In transfused patients GDF-15 and NTBI were significantly higher than in non transfused (P=0.05; P=0.015 respectively), whereas hepcidin levels, although higher, were not significant. GDF-15 showed a significant positive correlation with SF in transfused and splenectomized patients (r=0.766 P=0.0061; r=0.521 P=0.05). In subjects with β°/ααα GDF-15, hepcidin and NTBI were significantly lower (4085±2011 pg/mL, P=0.018; 4.8±2.0 ng/mL, P=0.015; 0.13 ±1.61 μM, P=0.023 respectively) compared to other forms of TI. *Conclusions.* Our results confirmed that in TI iron regulation is also mediated by high concentrations of GDF-15 related to ineffective erythropoiesis, tissue hypoxia, and erythroblasts apoptosis. In fact by our study GDF-15 production affecting consequently hepcidin synthesis seems related to iron overload in splenectomized and transfused patients. In mild forms of TI, such as β°/ααα, GDF-15, hepcidin and NTBI are slightly affected.

1032

PULSED DEXAMETHASONE FOR THE TREATMENT OF PATIENTS WITH AUTOIMMUNE HEMOLYTIC ANEMIA (SINGLE CENTER EXPERIENCE)

I Ionita,[1] L Cheveresan,[1] M Cheveresan,[1] M Ionita,[1] D Calamar,[1] CO Ionita,[1] G Borzac,[2] H Ionita[1]

[1]*UMF Victor Babes, Timisoara, Romania;* [2]*County Clinical Hospital, Timisoara, Romania*

Background. Steroid administration is still first-line therapy for autoimmune hemolytic anemia (AIHA). The activity of high dose dexamethasone has been largely investigated in immune thrombocytopenic purpura, and in AIHA. *Aims.* The aim of this study is to evaluate the therapeutic results and side effects of dexamethasone pulse therapy in AIHA patients in the Hematology Clinic of Timisoara. *Methods.* Between I 2007 and XII 2009, 35 patients with a newly diagnosed AIHA (23 cases) or a first relapse of AIHA (12 cases) were treated. The median age of patients was 54 years (range: 26-74), 22 patients were females and 13 males. The immunohematologic study revealed an anti-erythrocyte antibody (AeAb) in all cases (IgG: 26; IgM:6; IgG + IgM:1; IgA:1;

IgG+IgA:1). An idiopathic AIHA was diagnosed in 25 cases (71,4%), while in 10 (28,5%) a concurrent disease was identified. (tumor: 3; autoimmune disease: 3; lymphoproliferative disease: 4 cases). Treatment consisted of 4-6 courses of dexamethasone 20 mg, total dose, administered i.v. for 5 consecutive days, every 4 weeks. Between each dexamethasone course, patients received prednisone orally at the initial dose of 0.5 mg/kg/day. During the subsequent course, prednisone was slowly tapered by 5 mg every 1-2 weeks to a minimum dose of 10 mg 3 times a week in patients who reached a Hb value ≥12 g/dL. After maximum 6 courses of dexamethasone, response was assessed according to the Hb value combined with the evaluation of the direct antiglobulin test (DAT). Patients with no detectable AeAb and persistent Hb values ≥ 12 g/dL were considered as complete responders (CR) and steroid treatment withdrawn. Patients with persistent AeAb, but with a Hb increase of at least 3 g/dL, were considered as partial responders (PR). 2-3 further dexamethasone courses were given to PR patients, while patients with a persistent Hb value ≥ 12g/dL underwent a maintenance dose of 10 mg three times a week. All patients received folic acid supplementation, trimethoprimcotrimoxazole as Pneumocystis carinii prophylaxis and proton pump inhibitors as prophylaxis of related gastritis. Red cells were infused in the presence of severe and symptomatic anemia. *Results.* Response was assessed in 30 cases. The OR was 83% (CR:15%; PR: 68%) was similar in previously treated and untreated patients. A hemolytic relapse was observed in 3 cases. The median duration of response of patients with PR and maintained with low doses of prednisone was 23 months (range: 3-44), and 36 months, respectively, in patients with idiopathic AIHA who achieved a CR. No significant side effects were recorded. *Conclusions.* Pulsed dexamethasone therapy is effective and well tolerated in AHA patients. CR is rare. Additional studies need to be designed to explore new dexamethasone schedules and another treatment approaches such as rituximab.

A T2* MRI PROSPECTIVE SURVEY ON HEART AND LIVER IRON IN THALASSEMIA MAJOR PATIENTS TREATED WITH DEFERASIROX, DEFERIPRONE AND DESFERRIOXAMINE

A Pepe,[1] G Rossi,[2] A Meloni,[1] MC Dell'Amico,[1] A Spasiano,[3] M Capra,[4] P Cianciulli,[5] V Caruso,[6] B Favilli,[1] E Cracolici,[7] M Lombardi,[1] A Maggio[8]

[1]Fondazione G.Monasterio CNR-Regione Toscana and Institute of Clinical Physiology, Pisa, Italy; [2]Institute of Clinical Physiology of CNR, Epidemiology and Biostatistics Unit, Pisa, Italy; [3]Unità Microcitemia, A.O.R.N. Cardarelli, Napoli, Italy; [4]P.O. G. Di Cristina, ARNAS Civico, Palermo, Italy; [5]Ospedale Sant'Eugenio Papa - Centro Talassemie, Roma, Italy; [6]Centro Microcitemia, Ospedale Garibaldi, Catania, Italy; [7]Department of Radiology, University of Palermo, Palermo, Italy; [8]Ematologia II con Talassemia, V. Cervello Hospital, Palermo, Italy

Background. Most deaths in thalassemia major (TM) result from cardiac complications due to iron overload. Available three iron chelation regimes in thalassaemia may achieve different changes in cardiac iron and function and liver iron, but to date no data are known in literature. Magnetic Resonance (MR) is the unique non invasive suitable technique to evaluated quantitatively this issue. *Aims.* The aim of this multi-centre study was to assess prospectively in the clinical practice the efficacy of the three available iron chelator regimes in monoterapy in a large cohort of TM patients by quantitative MR. *Methods.* Among the first 739 TM patients enrolled in the MIOT (Myocardial Iron Overload in Thalassemia) network, 253 patients performed a MR follow up study at 18±3 months according to the protocol. We evaluated prospectively the 140 TM patients who had been received one chelator alone between the 2 MR scans. We identified 3 groups of patients: 66 treated with desferrioxamine (DFO), 44 treated with deferasirox (DFX) and 30 treated with deferiprone (DFP). Myocardial and liver iron concentrations were measured by T2* multislice multiecho technique. Biventricular function parameters were quantitatively evaluated by cine images. *Results.* The dose of DFO was 41±7 mg/kg for 5.5 d/wk, DFX was 26±6 mg/kg/d and DFP was 73±16 mg/kg/d Excellent/good levels of compliance were similar in the 3 groups (DFO 92%, DFX 100%, DFP 97%; P =0.1). Among the patients with no significant myocardial iron overload at baseline (global heart T2*±20 ms), there were no significant differences in all 3 groups to maintain the patients without myocardial iron overload (DFO 100%; DFX 96%; DFP 100%; P=0.5). Among the patients with myocardial iron overload at baseline (global heart T2* <20 ms), in all 3 groups there was a significant improvement in the global heart T2* value (DFO P=0.003, DFX P=0.0001 and DFP P=0.001) and in the number of segment with a normal T2* value (DFO P=0.0001, DFX P=0.003 and DFP P=0.031); only in the DFO and DFP group there was a significant improvement in the right global systolic function (P = 0.045 and P = 0.031, respectively). The improvement in the global heart T2* was significantly greater for the DFP than the DFO and DFX group (mean difference global heart T2* 10.7±7.1 ms *vs.* 3.6±5.4 ms *vs.* 4.6±4.8 ms; P = 0.009) (Figure). The changes in the mean serum ferritin level and in the global systolic bi-ventricular function were not significantly different among groups. In patients with liver iron overload at baseline (liver T2* <5.1 ms), the change in the liver T2* was not significant among groups (mean difference liver T2* DFO 2.9±4.9 ms *vs.* DFX 2.4±5.2 ms *vs.* DFP 2.3±5.8 ms; P=0.95). *Conclusions.* Prospectively in a large clinical setting DFP monotherapy was significantly more effective than DFO and DFX over 15 months in improving myocardial siderosis in TM patients.

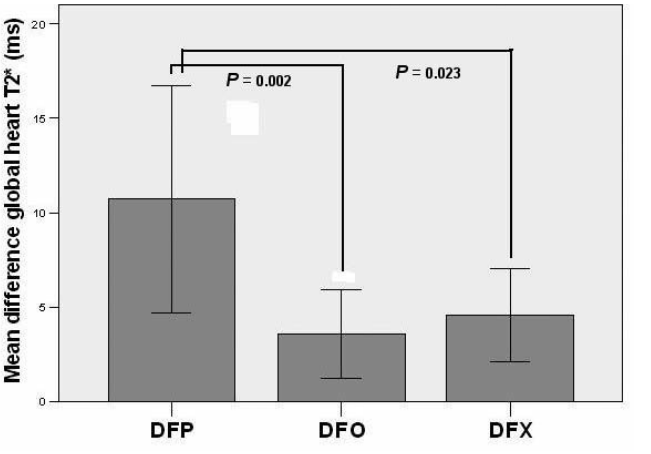

Figure.

LIVER STIFFNESS MEASUREMENTS BY TRANSIENT ELASTOGRAPHY IN THALASSEMIA MAJOR

V Perifanis,[1] E Sinakos,[2] E Vlachaki,[1] M Economou,[1] A Teli,[1] K Patsaoura,[3] B Bellou,[2] I Tsatra,[1] M Athanassiou-Metaxa[1]

[1]Hippokration General Hospital, Thessaloniki, Greece; [2]Liver unit, [2]nd Department of Internal Medicine, Aristotle University, Thessaloniki, Greece; [3]Department of Pathology, Hippokration General Hospital, Thessaloniki, Grenada

The aim of this study was to investigate the correlation between liver stiffness, measured by transient elastography (TE) and liver iron overload markers with the use of magnetic resonance imaging (MRI) in patients with transfusion-dependent beta-thalassemia major. *Methods.* 91 patients with TM were included in the study. All patients were under chelation treatment with a pre-transfusion haemoglobin level of 9.7 g/dL. Liver stiffness measurements (LSM) were performed by the same operator, blinded to the results of the patients, using Fibroscan®, Echosens, Paris. The measurements were considered applicable if a success ratio of >60% and an interquantile range of <0.2 were achieved. Liver iron concentration (LIC) was evaluated by two magnetic resonance imaging methods (T2* and MRI.HIC) in 69/91 (76%) patients and by three methods (including R2) in 51/91 (56%) patients. MRI scans were acquired with an imager equipped with a 1.5 T magnet, and the data included hepatic iron measurements obtained by means of T2*. Additionally, calculation of MR-HIC values was based on an algorithm using liver to muscle (L/M) ratios in five axial gradient-echo sequences. Liver biopsy specimens were available in 16 patients. Hepatic inflammation and fibrosis were scored using the METAVIR score system. *Results.* The mean age of our patients was 28.2±8.6 years and 48 (53%) were females. The median values of liver tests were: AST= 25 IU/L (range 11-76), ALT= 24 IU/L (7-97), γgt= 20 IU/L (7-180), alkaline phosphatase= 80 IU/L (21-346). 69 (76%) patients were anti-HCV negative. The median ferritin level was 1010 ng/mL (100-7975). The applicability of LSM was 100%. The overall median LSM value was 6.8 kPa (4-40.3). LSM was higher in HCV positive patients (7.7 kPa *vs.* 6.6 kPa) when compared with HCV negative patients (P=0.04). Total LSM correlated adequately with liver tests (AST r=0,39 , P=0,0002 , ALT r=0,33 , P=0,0018, γGT r=0.44 , P<0,0001 and ALP r=0,26 , P=0,01) but showed no correlation wth serum ferritin (r=0.14 , P=0,18). LSM correlated weakly with LIC as assessed by MRI-T2* (ρ=-0.19, P=0.12), MRI-HIC (ρ=0.24, P=0.05) and MRI-R2 (ρ=0.22, P=0.13). However, these associations became statistically significant in the HCV negative group: MRI-T2* (ρ=-0.42, P=0.002), MRI-HIC (ρ=0.42, P=0.002) and MRI-R2 (ρ=0.46, P=0.003). Although the number of patients with liver biopsy was small, LSM seemed to correlate with the stage of fibrosis (5.9±1.5 for stage <2 *vs.* 8.1±2 for stage ≥2) as assessed in the biopsy (P=0.06). *Conclusions.* TE is a feasible alternative for the determination of liver fibrosis in TM patients. LSM seem to correlate with the histological findings and the HCV status of the patients. Additional data are warranted to clarify the relationship of LSM with LIC.

HFE, HEMOJUVELIN, AND HEPCIDIN GENES SEQUENCING IN BRAZILIAN PATIENTS WITH PRIMARY IRON OVERLOAD

C Santos,[1] A Pereira,[2] R Cançado,[3] I Schettert,[2] R Hirata,[4] M Hirata,[4] M Figueiredo,[5] C Chiattone,[3] J Krieger,[2] E Guerra Shinohara[4]

[1]University of Sao Paulo, Sao Paulo, Brazil; [2]Laboratory of Genetics and Molecular Cardiology, Heart Institute, University of, Sao Paulo, Brazil; [3]Department of Hematology and Oncology of Santa Casa School of Medicine/Santa Cas, Sao Paulo, Brazil; [4]Department of Clinical Chemistry and Toxicology, School of Pharmaceutical Scienc, Sao Paulo, Brazil; [5]Hematology and Hemotherapy , EPM/UNIFESP, Sao Paulo, Brazil

Background. Low frequency of the *HFE* p.C282Y mutation was found in HH-affected Brazilian patients suggesting other HFE-related or HJV and HAMP gene mutations could be implicated in the pathogenesis or phenotypic expression of HH in our population. *Aims.* to evaluate mutations in HFE, HJV and HAMP genes and to identify the impact of HJV and HAMP mutations on HH phenotype in a possible digenic inheritance with HFE gene. *Methods.* Twenty-five Brazilian patients with primary iron overload (transferrin saturation >50% in females and 60% in males and absence of secondary causes) were included. Subsequent bidirectional sequencing for each HFE, HJV, HAMP exons and intron-exon regions was performed. The effect of HFE mutations on protein structure were analyzed by molecular dynamic and free energy calculations. Potential for change on the site of splicing were carried out. *Results.* Eighteen (72.0%) out of the 25 individuals presented at least one HFE mutation. Only 24.0% of patients carried 282YY genotype (n= 6) and 12.0% carried p.C282Y/p.H63D compound heterozygosity (n= 3). One novel mutation (*HFE* p.V256I) was indentified and the protein structural analysis showed that p.V256I mutation reduces the affinity binding between HFE and β2-microglobulin (β2M) in the same way that p.C282Y mutation when compared with the wild-type protein. HJV sequencing revealed a substitution in heterozygosis, c.929C > G, that corresponds to *HJV* p.A310G polymorphism; and in another individual, *HJV* IVS1 -36C > G intronic variant was detected in heterozygosis. In HAMP gene, one *HAMP* IVS3 +42G > A intronic variant was identified. *Conclusions.* The novel *HFE* p.V256I mutation reduces the interaction between HFE and β2M that may influence iron homeostasis, but further studies are necessary to investigate the effect of this mutation on HFE function and activity *in vivo*. *HJV* p.A310G polymorphism and two intronic variants were found, but none of these alterations were associated with digenic inheritance with HFE gene. Our data indicate that HJV and HAMP functional mutations are rare in these patients.

THE RELEVANCE OF ANEMIA IN THE ELDERLY: A HOSPITAL-BASED ANALYSIS

R Stauder,[1] R Stauder,[2] G Schruckmeyer,[3] I Sam,[3] G Kemmler,[4] G Gastl[5]

[1]Dept. of Internal Medicine V (Haematology and Oncology), Innsbruck Medical Univ., Innsbruck, Austria; [2]Innsbruck Medical University, Innsbruck, Austria; [3]Dep. Internal Medicine V, Innsbruck Med. University, Innsbruck, Austria; [4]Department of Biological Psychiatry, Innsbruck Medical University, Innsbruck, Austria

Background. Anemia represents a relevant challenge among the elderly as anemia is associated with decreased functional capacities and an increased mortality rate. *Aims.* To provide demographic data in a representative Middle-European population. To define the subtype and cause of anemia to form the basis for treatment algorithms. *Methods.* Laboratory values from 19758 patients older than 64 years treated at the Medical University Innsbruck, Austria from 1.10.2004 -29.9.2005 were analyzed. The cohort consisted of 10917 women and 8841 men, the median age was 75 yrs in women and 72 yrs in men (P<0.001). 10737 (54.3%) patients were treated on an outpatient basis, whereas 9.021 (45.7%) were inpatients. *Results.* Women revealed in general lower hemoglobin (Hb) values than men (median 13.4 *vs.* 14.3 g/dL; P<0.001). This phenomenon was not age-dependent as assessed by age-matched regression-analyses. Based on the WHO-criteria for the definition of anemia (Hb < 12 in female and < 13 g/dL in male), 19.3% of women and 23.4% of men suffered from anemia. The incidence of anemia was significantly correlated with advanced age as shown by correlation analysis (r=0.21; P<0.001). In the age groups 75-79, 80-84, 85-89, ≥ 90yrs, women were anemic in 20, 25, 29 and 33%, whereas men were anemic in 25, 34, 40 and 47% of cases, respectively. Based on the mean corpuscular volume of red blood cells, anemia was defined as microcytic in 3.7%, normocytic in 78% and macrocytic in 18.4% of cases. Microcytic and normocytic anemia were more frequent in women (58.2% and 52.5% of cases), whereas macrocytic anemie revealed a male preponderance of 58%. In microcytic anemia an iron deficiency as defined by lowered serum ferritin levels was observed in 73% and in 63.4% of cases (male/female). In macrocytic anemia lowered serum B12 levels were detected in 3% and decreased levels of folic acid in 7.4% of cases. In normocytic anemia C-reactive protein (CRP) was elevated in 64.7% and serum creatinine in 36.6%. Pronounced gender differences were observed, as elevations of creatinine were more often oberved in men (45%) than in women (28.4%). *Summary/Conclusions.* These data clearly demonstrate that late-life anemia is frequent in patients admitted to the hospital as well as in outpatients. Anemia increases dramatically with advanced age reaching a prevalence of nearly 50% in elderly men. A recognizable cause of anemia for which a specific treatment is available is found in a small but relevant proportion of patients. In the majority of elderly the pathogenesis of anemia is complex and includes a mixture of different subtypes including the anemia of chronic inflammation, of renal insufficiency and of decreased erythropoietin and androgen function.

PRECISION OF MULTI-ECHO CMR FOR MYOCARDIAL IRON OVERLOAD EVALUATION IS DEPENDENT FROM MR SEQUENCE DESIGN

A Pepe,[1] V Positano,[1] A Meloni,[1] MC Dell'Amico,[1] L Menichetti,[1] D De Marchi,[1] B Favilli,[1] MC Rizzello,[2] A Spasiano,[3] F Gagliardotto,[4] L Landini,[1] M Lombardi[1]

[1]Fondazione G.Monasterio CNR-Regione Toscana and Institute of Clinical Physiology, Pisa, Italy; [2]Ospedale Sant'Eugenio Papa - Centro Talassemie, Roma, Italy; [3]Unità Microcitemia, A.O.R.N. Cardarelli, Napoli, Italy; [4]P.O. G. Di Cristina, ARNAS Civico, Palermo, Italy

Background. T2* multiecho CMR is largely used to assess iron overload in heart because of the established inverse relationship between the T2* value and the iron concentration in tissues. The decay of CMR signal is sampled at several echo times (TEs) and the T2* is inferred by fitting the decay curve to an appropriate model. *Aims.* Our aim was to quantify the reliance on TEs of the expected error in T2* value determination. *Methods.* The Cramer-Rao lower bounds theory (CRLB) was used. CRLB were evaluated for a commonly used multiecho sequence with the first TEs equal to the minimum achievable with the used scanner, echo spacing of 2.26 ms to minimize the fat-water interface artefacts, 10 echoes to assure acquisition in a single breath-hold. *Results.* Percent error in T2* values assessment was lower than 10% in the range of clinical interest, with the exception of very low T2* values. Precision in measurement of low T2* values is strongly dependent on the value of the first TE, that is limited by the used scanner. T2* values greater than 1.8 ms and 1.5 ms can be assessed with an error below 20% using a first TE of 2 ms and 1.5 ms, respectively (Figure). *Conclusions.* T2* multiecho sequences used in clinical practice assure an acceptable precision for T2* values greater than 2 ms or less, depending from the used hardware. For patients with very high myocardial iron overload sequences with lower minimum echo time and/or lower echoes interval may be useful.

EPIDEMIOLOGICAL DATA OF HAEMOGLOBINOPATHIES AMONG IMMIGRANT POPULATION IN NORTHERN GREECE. A 15 YEARS REPORT

S Theodoridou, M Alemayehu, E Katsimpourlia, P Perperidou, S Ganta, O Karakasidou, V Aletra, A Manitsa, L Papayiannis, G Papaioannou

Hippokration Hospital, Thessaloniki, Greece

Greece is a Mediterranean country with a high frequency of thalassaemia and haemoglobinopathies. Since 1993, an unprecedented wave of immigration of people of different backgrounds towards Greece and other states of the European Union has taken place. Consequently, the number of affected individuals and the spectrum of mutations have both increased and somehow changed. The immigrant population consisted mainly of people from Albania, the former Soviet Union, Africa, the Middle East and south East Asia. We report the results of haemoglobinopathy screening among this immigrant population during the period 1993-2007. *Methods.* The carrier identification was carried out by a standard scheme, which included, CBC and red cell indices using the Coulter ONYX, a Cation Exchange HPLC variant system (Bio-Rad, Variant β-Thalassaemia Short Program), to determine HbA, HbA2 and HbF levels and the different abnormal structural Hbs, electrophoretic techniques both at alkaline pH on cellulose acetate and at acid pH on citrate agar, sickling test and tests for HbH inclusion bodies. Haemoglobin A2 was also quantified by column micro chromatography and serum ferritin levels were measured by micro Elisa technique. Biosynthesis of the α- and β- globin chains and DNA techniques are also performed on selected cases. *Results.* From the total 50.194 subjects who underwent screening during this period, 5.399 (10.75%) were immigrants. 299 (5.5%) were carriers of thalassaemic genes or other haemoglobinopathies. The frequency of β-, α-, δβ-thalassaemia carriers was found to be 3.5 %, 0.8 %, and 0.16%, respectively. The prevalence of sickle cell carriers was 0.68 % and carriers for haemoglobinopathy Lepore (was) 0.16%. Two cases of haemoglobinopathy H and 3 cases of heterozygotes for HPFH were detected. Heterozygosities for HbO-Arab, HbC, HbE, Hb D were rare, and there was only one case from each group. Few cases of homozygotes and compound heterozygotes were encountered. These were β-thal/HbD- Punjab (1 case), homozygous β-thal. (1 case), α-thal/HbS (1 case), and HbS/HbC (1 case). Pertaining to their ethnic background, 32.5% were Albanians, 16.15 % from Pontos in Asia Minor, 13.7% from Georgia, and 6.1% were Albanian citizens of Greek origin who lived in South Albania, also known as North Epirus. Other minority groups were Armenians, Cypriots, Bulgarians, Serbians, citizens of the EU, Asia, Africa and Latin America, that consisted 15.1% of the total. During the last 7 years, 278 immigrant couples have been given genetic counselling in our Thalassaemia Prevention Unit. Knowledge of the epidemiology of haemoglobinopathies in this population group provides important information for public health planning and appropriate counselling of couples at risk of having an affected offspring. In addition, we conclude that, the spectrum of mutations has indeed been affected by the immigration of people of different ethnic backgrounds.

MLPA CHARACTERIZATION OF THE (δβ)° SPANISH DELETION IN THALASSEMIC PATIENTS: A PROCEDURE FOR THE OPTIMIZATION OF DIAGNOSIS AND GENETIC COUNSELING

A Villegas,[1] J Martínez-Nieto,[2] L Vinuesa,[2] F De la Fuente-Gonzalo,[2] S Redondo,[2] P Ropero,[2] FA González[2]

[1]Hospital Clinico San Carlos, Madrid, Spain; [2]Hematología. Hospital Clínico San Carlos, Madrid, Spain

Background. Nowadays, due mainly to the demographics changes have occurred in recent decades, the thalassemias are a group of emerging diseases in different European countries. Within this framework, both the genetic counseling and the prenatal diagnosis become crucial issues in order to minimize the effects in public health caused by these chronic diseases. The MLPA analysis allows, unlike other screening techniques, quick and easy identification of any copy number variation in the globin cluster. *Aim.* To characterize, by MLPA method, the typical genetic profile of individuals presenting a (δβ)° Spanish deletion. *Methods.* MLPA (Multiplex Ligation-dependent Probe Amplification) analysis of β globin cluster in 15 patients with the (δβ)° Spanish deletion in heterozygous state (detected previously by gap-PCR). This technique is based on the quantitative amplification and a subsequently fragment analysis of multiple probes hybridized across a region of interest. This method allows for a genetic profile showing the copy number of fragments of DNA that have been analyzed. A deletion is detected when a reduction of the amount of amplified product of several consecutive probes is observed in the genome. Here we used a commercial kit (SALSA MLPA kit P102-B1 HBB, MRC-Holland) that contains 28 probes designed to detect copy number changes in the beta cluster, from LCR to 10Kb downstream of β globin gene, spanning more than 80Kb. *Results.* All the patients showed an identical profile after MLPA analysis. The reduction of the amplified product was found in the same 12 probes, from the exon1 δ gene probe to the last probe located downstream of the β globin gene. These results are consistent with the previous works in which this deletion has been mapped. *Summary/conclussions.* Large deletions are usually difficult to be characterized by sequencing owing to the loss of entire genes. Uptime, the molecular characterization of this kind of deletions has required specific PCR based methods or laborious techniques like Southern Blot. In Spain the most frequently deletion associated to δβ-thalassemia is the (δβ)° Spanish. To know the cut-offs in the beta globin cluster allows the identification by PCR-Gap of this deletion, however, can not characterize other deletions. This study shows that MLPA is a rapid and reproducible technique for identification of this deletion. Because immigration changes probably will see a greater heterogeneity at the molecular level in the cases of (δβ)° thalassemia in our environment, so the study by MLPA will allow a correct characterization of the molecular basis of (δβ)° thalassemia.

GROWTH AND DEVELOPMENT OF PAEDIATRIC PATIENTS WITH BETA-THALASSAEMIA TREATED WITH DEFERASIROX FOR UP TO 5 YEARS

Y Aydinok,[1] L Agaoglu,[2] M Bejaoui,[3] D Canatan,[4] G Drelichman,[5] M Economou,[6] S Fattoum,[7] A Kattamis,[8] Y Kilinc,[9] S Perrotta,[10] L Griffel,[11] D Lagrone,[11] J Clark,[12] MD Cappellini[13]

[1]Ege University Medical Faculty, Izmir, Turkey; [2]Istanbul University, Istanbul Medical Faculty, Istanbul, Turkey; [3]Centre National de Greffe de Moelle Osseuse, Bab Saadoun, Tunis, Tunisia; [4]Suleyman Demirel University Medical Faculty, Isparta, Turkey; [5]Hospital de Ninos Ricardo Gutierrez, Buenos Aires, Argentina; [6]Hippokration General Hospital of Thessaloniki, Thessaloniki, Greece; [7]Hospital d'Enfants, Tunis, Tunisia; [8]First Department of Pediatrics, University of Athens, Athens, Greece; [9]Cukurova University Medical Faculty, Adana, Turkey; [10]OI° Policlinico II° Università di Napoli, Naples, Italy; [11]Novartis Pharmaceuticals, East Hanover, NJ, USA; [12]Novartis Pharma AG, Basel, Switzerland; [13]Universitá di Milano, Policlinico Foundation IRCCS, Milan, Italy

Background. Growth and development in β-thalassaemia patients may be adversely affected by iron-induced endocrine abnormalities or by iron chelator-induced toxicity, a well-recognised effect of intensive chelation with deferoxamine (DFO).[1] In study 107, a 1-year, Phase III trial, β-thalassaemia patients were randomized to receive the oral iron chelator deferasirox or DFO. Patients completing this core phase continued with deferasirox (deferasirox cohort) or switched to deferasirox (crossover cohort) during a 4-year extension. Approximately half the patients were paediatric, therefore it is of interest to assess the effects of long-term deferasirox on paediatric growth and development. *Aim.* To evaluate the effects of up to 5 years' deferasirox treatment on serum ferritin, growth and development of paediatric β-thalassaemia patients. *Methods.* β-thalassaemia patients with transfusional iron overload aged 2-<16 years who received deferasirox during the core and/or extension were included. Deferasirox dose was initially based on liver iron concentration at start of treatment; dose adjustments based on monthly serum ferritin and safety trends. Height, weight and sexual development were analyzed annually.

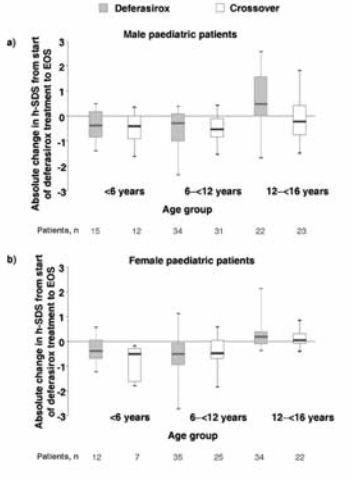

Figure. Absolute change in h-SDS start of deferasirox treatment to EOS for a) male and b) female paedriatric β-thalasseaemia patients receiving deferasirox or up to 5 years.

Results. 273 paediatric patients were included. In the deferasirox (n=153) and crossover (n=120) cohorts respectively, 28 and 19 patients were aged 2-<6 years, 69 and 56 were aged 6-<12 and 56 and 45 were aged 12-<16. Mean actual deferasirox dose in the deferasirox and crossover cohorts, respectively, was 25.2±6.1 and 23.2±4.2 mg/kg/day (2-<6 years), 22.7±6.4 and 23.7±5.5 mg/kg/day (6-<12 years) and 20.0±6.4 and 22.7±5.5 mg/kg/day (12-<16 years). Median serum ferritin decreased from 2409 to 1208 ng/mL after 5 years' deferasirox treatment (n=107, P<0.001) in the deferasirox cohort, and from 1922 to 1047 ng/mL after 4 years' deferasirox (n=83, P<0.001) in the crossover cohort. Overall, mean height standard deviation score (h-SDS) at start of deferasirox was -0.96±0.99; at end-of-study (EOS) was -1.17±1.03 (similar in males and females). Absolute change in h-SDS from start of deferasirox to EOS was not notably impaired in patients aged 2-<6 and 6-<12 years, whereas a positive change in patients aged 12-<16 years may indicate that deferasirox does not retard growth for both genders (Figure). Individual growth curves showed most patients were within normal percentile ranges and did not show growth impairment. In females aged 12-<16, the proportion of patients at Tanner Stage 5 for breast development increased from 8.8% to 51.5% and 18.1% to 72.7% from start of deferasirox to EOS in the deferasirox and crossover cohorts, respectively. In males none of the patients aged 12-<16 were at Tanner Stage 5 for testicular volume at start of deferasirox, whereas at EOS, 27.2% and 28.5% were at Stage 5 in the deferasirox and crossover cohorts, respectively. There were no clinically relevant differences in sexual development between deferasirox and crossover cohorts. *Conclusions.* Deferasirox treatment for up to 5 years was effective in decreasing serum ferritin down to maintenance levels of around 1000 ng/mL without an adverse effect on growth and sexual development in paediatric β-thalassaemia patients.

COMPLICATIONS AND TREATMENT OF PATIENTS WITH β-THALASSEMIA IN FRANCE: RESULTS OF THE NATIONAL REGISTRY

C Badens,[1] C Pondarré,[2] D Bachir,[3] D Steschenko,[4] R Girot,[5] C Rose,[6] I Thuret[7]

[1]Hôpital d'enfants de la Timone, Marseille, France; [2]IHOP, Lyon, France; [3]Hôpital Henri Mondor, Créteil, France; [4]Hôpital Brabois, Nancy, France; [5]Hôpital Tenon, Paris, France; [6]Hôpital Sr Vincent de Paul, Lille, France; [7]Hôpital d'Enfants de la Timone, Marseille, France

Background. β-thalassemia is rarely encountered in France (prevalence less than 1/100 000) where the disease is mainly diagnosed in subjects originated from Italy and Algeria. *Aim.* In order to improve clinical care, a national registry for Thalassemia has been developed since 2005. Epidemiological and clinical data are collected on living beta-thalassemia major (TM) or intermedia patients (TI), including those who received a HSC transplantation. *Results.* In January 2010, the French register included 437 patients, 303 TM, 125 TI and 9 not yet classified, 71% of them were born in France (74% for TM). The patients are spread all over the country in 65 centres, 46% of the patients being treated in 6 centres. Median age was 20 years (0-78). Iron overload related complication rates and serum ferritin levels are presented in Table 1 (univariate analysis). Rate of parenthood were not statistically different between TM and TI patients after age adjustment. Cardiac MRI was increasingly used over the last 4 years and was performed for 45% of TM patients aged more than 10. Deferoxamine was prescribed to 2/3 of the patients receiving chelation treatment during the years 2005-2006 while 70% received deferasirox over the years 2008-2009 and less than 10% a combination of DFP/DFO. A hematopoietic stem cell transplantation has been performed for 60 patients. *Conclusion.* French beta-thalassemia patients are treated all over the country in numerous centres. The global state of health appeared very similar to the reported data in Europe and North America, in particular concerning the median serum ferritin levels, the rates of iron overload related complications and the use of HSC transplantation This register is also a valuable tool for identifying clinical care aspects which should be improved in the future, especially the use of cardiac MRI and of chelation treatment with combined therapy.

Table 1. Iron related complications rates, parenthood and serum ferritin levels according to the type of thalassemia.

	Thalassemia Major	TM with successful HSC transplant	TM with Graft failure	Thalassemia Intermedia

FATIGUE AND IMPAIRED QUALITY OF LIFE IN PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA (PNH) IS ASSOCIATED WITH HEMOLYSIS, BUT NOT WITH ANEMIA

Y Kanakura,[1] K Ohyashiki,[2] T Shichishima,[3] S Okamoto,[4] K Ando,[5] H Ninomiya,[6] T Kawaguchi,[7] S Nakao,[8] H Nakakuma,[9] J Nishimura,[1] T Kinoshita,[10] C Bedrosian,[11] M Valentine,[11] K Ozawa,[12] M Omine[13]

[1]Osaka University Hospital, Suita, Japan; [2]Tokyo Medical University Hospital, Tokyo, Japan; [3]Fukushima Medical Univ, Fukushima, Japan; [4]Keio University School of Medicine, Tokyo, Japan; [5]Tokai University, Isehara, Japan; [6]University of Tsukuba, Tsukuba, Japan; [7]Kumamoto University, Kumamoto, Japan; [8]Kanazawa Univ, Kanazawa, Japan; [9]Wakayama Medical University, Wakayama, Japan; [10]Research Institute for Microbial Diseases, Osaka University Hospital, Osaka, Japan; [11]Alexion Pharmaceuticals, Cheshire, USA;[12] Jichi Medical University Hospital, Tochigi, Japan; [13]Showa University Fujigaoka Hospital, Yokohama, Japan

Background. PNH is a progressively debilitating and life-threatening blood disease characterized by chronic complement-mediated intravascular hemolysis. Historically, physicians have tended to view and treat PNH as a disease of anemia. In particular, patients with PNH often suffer from severe fatigue and dyspnea (shown to be a measure of pulmonary hypertension), which contribute to impaired quality of life (QoL). Clinically, these measures of disease burden have historically been assessed by both the level of anemia and transfusion history. However, recent studies have demonstrated that primary patient symptoms, life-threatening complications and significantly shortened lifespan are also significantly associated with the degree of chronic hemolysis. *Aims/Methods.* The current investigation examines the impact of hemolysis and anemia on fatigue and dyspnea in patients with PNH.Twenty-nine Japanese PNH patients (14 men and 15 women; median patient age, 47 years; range 26-70 years) were treated with eculizumab for 12 weeks at 9 institutions in Japan participating in the AEGIS study. *Results.* Serum LDH decreased 87% from a median of 1,814 U/L at baseline to 244 U/L at 12 weeks of eculizumab treatment (P<0.001; normal range 103-223 U/L). The reduction in hemolysis led to significant improvement in dyspnea within 1 week of eculizumab treatment (P=0.02 from baseline) and the improvement was sustained throughout the study (P<0.001). Furthermore, 41% of patients reported a major improvement (10% or greater) in dyspnea (mean among general population = 11.8)1 with eculizumab treatment that was sustained through Week 12. Importantly, dyspnea is a primary characteristic of pulmonary hypertension, which has been found in other studies to occur in approximately 50% of PNH patients. Similar to dyspnea, improvements in fatigue (measured by the FACIT-Fatigue scale) were also observed at 1 and 2 weeks of eculizumab treatment (P=0.03; P<0.0001 respectively) (Table 1).

Table 1. Effects of eculizumab on fatigue, dyspnea and hemoglobin during first 4 week of treatment.

	Baseline	Change from Baseline Mean ± SE Median (P-value)			Overall Effect from Baseline *P*-value
		Week 1	Week 2	Week 4	
Fatigue-FACIT Score	38.5 ± 1.9 41.0	2.1 ± 1.1 2.0 (0.03)	4.2 ± 1.0 4.0 (<0.001)	4.9 ± 1.4 4.0 (<0.001)	<0.001 ‡
Fatigue – EORTC Score*	33.7 ± 1.1 33.3	-7.7 ± 2.3 -11.1 (<0.001)	-13.4 ± 2.5 -11.1 (<0.001)	-11.1 ± 2.9 -11.1 (<0.001)	<0.001 ‡
Dyspnea – EORTC Score*	37.9 ± 5.2 33.3	-11.5 ± 4.1 0.0 (0.02)	-13.8 ± 3.9 0.0 (<0.001)	-13.8 ± 4.5 0.0 (<0.001)	<0.001 ‡
Hemoglobin (g/dL)	7.9 ± 0.3 7.6	N/A	0.2 ± 0.2 0.0 (NS)	0.4 ± 0.2 0.0 (NS)	= 0.002 ‡

NS = not significant; *P*-value based on signed ranked test.
‡Overall was based on the average of least square means from Week 1 to Week 12.
* A negative change in EORTC score of fatigue and dyspnea indicates improvement.

Among the general population, the mean FACIT-Fatigue score is 43.6.2 By the end of the first week of treatment, 27.6% of treated patients experienced a clinically meaningful improvement in fatigue (at least a 4-point increase on the FACIT-Fatigue scale), while 51.7% improved at Week 2, and a sustained benefit was observed with 58.6% of patients reporting a clinically important improvement in fatigue at Week 12. The early improvement in fatigue measured by FACIT-Fatigue score was confirmed by a large median improvement in EORTC QLQ-C30 Fatigue score (among the general population mean = 24.1)1 of 11.1 points by Week 1 (P<0.0001). In contrast, hemoglobin did not significantly improve until week 8, and increased from 7.6 to 9.0 g/dL (P<0.001) by week 12 despite a concomitant reduction in transfusions. *Conclusions.* These data demonstrate that hemolysis, independent of anemia, drives the risks and burden of disease in PNH. Further, inhibition of terminal complement activation with eculizumab improves hemolysis, fatigue, dyspnea and other significant morbidities of disease, independent of anemia, in Japanese patients with PNH.

FOUR NOVEL PKLR GENE MUTATIONS IN ASSOCIATION WITH PYRUVATE KINASE (PK) DEFICIENCY

L Manco,[1] L Relvas,[2] U Rebelo,[2] MJ Murga,[3] A Santos,[3] L. Yanez,[4] C Bento,[2] ML Ribeiro[2]

[1]University of Coimbra, Coimbra, Portugal; [2]Centro Hospitalar Coimbra, Coimbra, Portugal; [3]Hospital Virgen de la Salud de Toledo, Toledo, Spain; [4]Hospital Universitario Marqués de Valdecilla, Santander, Spain

Background. Pyruvate Kinase (PK) deficiency is the most common enzyme abnormality in the erythrocyte glycolytic pathway causing chronic nonspherocytic haemolytic anaemia. The PK-R isozyme, exclusively expressed in erythrocytes, is transcribed from the PKLR gene (1q21). Clinical symptoms occur in patients homozygous or compound heterozygous for an abnormal allele and vary from severe haemolysis to a well compensated form of chronic anaemia. More than 190 mutations had been found associated with PK deficiency. *Aims.* To report the molecular characterization on 3 PK-deficient patients with chronic haemolytic anaemia and in 1 heterozygous individual, and to understand the genotype/phenotype correlation. *Methods.* Three patients with haemolytic anaemia, a 2-yr-old and a 3-yr-old Spanish girls and a 28-yr-old Portuguese woman, and another individual from Portugal, were referred to our Haematological unit for diagnostic purposes and molecular characterization. Haematological parameters and red blood cell PK enzyme activity were measured by standard *Methods.* After informed consent, genomic DNA was extracted from EDTA peripheral blood samples and PKLR gene was studied by PCR, SSCP and sequencing analysis. *Results.* The molecular analysis identified seven different PKLR mutations. All PK-deficient patients are compound heterozygotes for two different mutant alleles. Patient 1: Hb 92 g/L, reticulocytes 8.3% and PK activity 38% of normal, is a compound heterozygous for mutations IVS6(+2)T>G and c.1492C>T (p.Arg498Cys); Patient 2: Hb 74 g/L, reticulocytes 5.6%, is a compound heterozygous for mutations c.1463G>A (p.Arg488Gln) and c.721G>T (p.Glu241stop); Patient 3: Hb 127 g/L, reticulocytes 7% and PK activity 19% of normal, is a compound heterozygous for mutations c.815T>C (p.Leu272Pro) and c.1456C>T (p.Arg486Trp). Mutation c.491C>A (p.Thr164Asn) in heterozygous state was identified in an individual with normal haematological parameters and PK enzymatic activity 72% of normal. *Conclusions.* Four mutations are reported here for the first time: the splice site mutation IVS6(+2)T>G, and three missense mutations, predicting the substitution of well-conserved amino acids, p.Thr164Asn, p.Leu272Pro and p.Arg488Gln. Mutation IVS6(+2)T>G affects the invariant sequence GT located at the intron 6 donor splice site and most probably abolishes the normal splicing of the mRNA transcript. In patient 1 this mutation is associated in trans with the previously described missense mutation p.Arg498Cys (L-Cβ2-Cα4), resulting in a moderate clinical phenotype. The new mutation p.Arg488Gln affects a C domain (L-Cα3-Cβ2) residue. The side chain of Arg488 points to the PK subunit cleft between C and A domains and the Arg>Gln substitution affects the A/C interdomain interaction disturbing the enzyme structure and alosteric properties. The association in trans with the nonsense mutation p.Glu241stop, explains the severe chronic haemolytic anaemia in patient 2. Mutation p.Leu272Pro (Aα3) targets the hydrophobic core of A domain and was found in trans with the known substitution p.Arg486Trp in patient 3, causing a mild phenotype. The new substitution p.Thr164Asn, identified in a heterozygous individual, involves an amino acid change in PK B domain (Bβ1) near the cleft between A and B domains, where the active site is located. Until now, only 7 mutations had been described in the PK B domain.

1044

CHRONIC ORGAN DAMAGE IS NOT RELATED TO PREGNANCY COMPLICATIONS IN SICKLE CELL DISEASE

C van Tuijn, R van der Stap, J van der Post, M Peters, B Biemond

Academic Medical Center, Amsterdam, Netherlands

Background. Patients with sickle cell disease (SCD) develop accumulating organ damage throughout their lives as result of chronic hemolytic anemia and ongoing vaso-occlusion. Chronic organ damage has been related to significant morbidity and increased mortality. Previous studies have shown significant increased fetal and maternal complications in patients with SCD. It is unclear whether the presence of chronic organ damage is related to pregnancy complications in these patients. *Aims.* To determine the relation between chronic organ damage and pregnancy complications in women with SCD. *Methods.* We performed a retrospective analysis of pregnancy complications in all women known with SCD (defined as HbSS, HbS-β^0, HbSC and HbSβ^+) in a teaching hospital in the Netherlands. Pregnancy complications consisted of: (pre)eclampsia, preterm birth, urinary tract infection, hypertension, still birth, perinatal mortality, maternal mortality, painful crisis and acute chest syndrome (ACS). In all patients organ damage (retinopathy, avascular osteonecrosis, microalbuminuria, pulmonary hypertension, chronic leg ulcers and cholelithiasis) and the history of sickle cell complications in the previous 5 years (pain rate >1 crises/year, ACS and stroke) was assessed. The patients were divided in a severe (HbSS/HbSβ^0) and a mild genotype group (HbSC/HbSβ^+). Chronic organ damage and the history of previous sickle cell-related complications were related to pregnancy complications, birth weight and laboratory tests. *Results.* All 96 female patients known with SCD in our hospital were systematically evaluated for organ damage and sickle cell related complications. Thirty-six patients had not been pregnant at time of evaluation, of 7 women medical information about their pregnancy was missing and 6 women were only known with an elective abortion. Forty-seven women with SCD (18 HbSS, 3 HbSβ0, 21 HbSC and 5 HbSβ^+) were evaluated for pregnancy complications. In the severe genotype group significantly more pregnancy complications were observed as compared to the milder group (18/21(86%) *vs.* 13/26(50%), P=0.011). Chronic organ damage or a history of severe sickle complications in the previous 5 years was present in 17/21(81%) of the patients with a severe genotype and 15/26 (58%) patients with a mild genotype. (P=0.13) No relation between pregnancy complications and the presence of organ damage or a history of sickle cell-related complications was found. Children of patients with the severe genotype had a significant lower birth weight as compared to the children of patients with a milder genotype (2606±675 *vs.* 3032±560 gram; P=0.027) which correlated with hemoglobin concentration (Hb) (r=0,432; P=0.05). When analyzed according to genotype, a weaker but no significant correlation between Hb and birth weight was observed (r=0.355, P=0.62 for HbSS/HbSβ0 and r=0.356, P=0.10 for HbSC/HbSβ^+). No correlation between Hb or LDH concentrations and pregnancy complications was found. *Conclusions.* The majority of patients with SCD had at least one pregnancy complication which was significantly more frequent observed in patients with a severe genotype. Birth weight was significantly lower in the severe genotype group which could partly be explained by a more severe anemia. However, no correlation between pregnancy complications and manifestations of chronic organ damage or a history of previous sickle cell-related complications was demonstrated.

MYOCARDIAL IRON OVERLOAD ASSESSED BY MAGNETIC RESONANCE IMAGING (MRI)T2* IN MULTI-TRANSFUSED PATIENTS WITH THALASSEMIA AND ACQUIRED ANEMIAS

A Fragasso,[1] A Ciancio,[1] C Mannarella,[1] C Gaudiano,[1] O Scarciolla,[1] MN Nardella,[2] CT Turchetti,[3] A Peluso,[4] G Quarta,[5] A Melpignano,[5] MR Veglio[6]

[1]U.S. Ematologia, Ospedale Madonna delle Grazie, Matera, Italy; [2]Struttura Complessa di Radiologia, Ospedale Madonna delle Grazie, Matera, Italy; [3]Alliance Medical Srl. Roma. Unità di Risonanza Magnetica. Ospedale Madonna delle, Matera, Italy; [4]Struttura Semplice di Microcitemia, ASL TA,[1] Ospedale SS. Annunziata, Taranto, Italy; [5]U.O.C. Ematologia, Ospedale Perrino, Brindisi, Italy; [6]U.O. Pediatria, Ospedale Sacro Cuore di Gesù, Gallipoli, Italy

Iron-induced cardiomyopathy is the commonest cause of death for patients suffering from thalassemic disease, as well a recurrent request in the case of multi-transfused patients with acquired anemias. MRI T2* is, at the moment, the gold standard for assessing myocardial iron. The aim of our study was to evaluate a population of patients of the southern Italy using MRI T2* and to find clinic and serologic parameters that might be correlated with this technique. Three subsets of patients were studied: 1) 95 with thalassemia major (TM), 30 years mean age (range 15-48); 2) 18 multi-transfused patients with thalassemia intermedia (TI), mean age 38 years (range 25-63); 3) 11 multi-transfused patients with acquired anemias (AA) (9 with myelodysplastic syndromes, 1 with aplastic anemia and 1 with primary myelofibrosis), mean age 75 years (range 66-85). In the latter group median number of packed red blood (PRBC) units was 77 (range 12-234); all were negative for HFE mutations and 7 out of 11 patients were on iron chelation. In the group 1), cardiac MRI T2* mean (±SD) values were 26±14msec; pathologic values (≤20 msec) were found in 36 (38%) patients. Three out of 95 patients had significantly impaired left ventricular ejection fraction (LVEF≤30%) assessed with echocardiography. Only 1 of these 3 patients had T2*≤20msec. Nine patients had LEVF within the range 30 to 50 %. Mean serum ferritin values were 1615±1834 ng/mL. We found a significant negative correlation only between serum ferritin and age (R=-0,33, P=0.001). We divided the patients according to their T2* values into subgroup 1a (T2*≤20msec, N=36), and 1b (T2*>20 msec, N=59). Comparing data between these subgroups, we found no difference either for age or chelation regimen; a difference, but not significantly, was found between serum ferritin values (557± 385, P=0.15). Besides, 17 (47%) patients in the subgroup 1a had serum ferritin values<1000 ng/mL *vs.* 38 (64%) patients in the subgroup 1b. In the group 2), cardiac MRI T2* mean values were 30±10 msec; pathologic value (16msec) was found in 1 patient. None had impaired ejection fraction. Mean serum ferritin values were 910±713 ng/mL. No correlation was found between cardiac T2* and ferritin. The mean difference in T2* values between group 1) and 2) was -4 msec (P=0.25). In the group 3) cardiac MRI T2* mean values were 34±10 msec; pathologic value (17.7msec) was found in 1 patient, who had received 234 PRBC units. Echocardiography results were in the normal range for the age. Mean serum ferritin values were 1936±1226 ng/mL. No correlation was found between cardiac T2* and ferritin. T2* values were negatively associated, but not significantly, with the number of PRBC transfused (R=-0,43, P=0,18). *Conclusion.* 1) in our experience 38% of TM patients had a myocardial iron overload assessed by MRI T2*, higher if compared to TI patients; 2) 47% of TM patients with pathologic T2* values had serum ferritin values<1000ng/mL, therefore serum ferritin measurement was a poor predictor of myocardial iron overload; 3) in patients with AA more than 200 PRBC units transfused are likely required to induce cardiac hemosiderosis.

1046

CARDIAC IRON OVERLOAD AND FUNCTION BY CMR IN DIFFERENT PHENOTYPIC GROUPS OF THALASSEMIA INTERMEDIA PATIENTS

A Pepe,[1] MC Dell'Amico,[1] A Meloni,[1] A Filosa,[2] V Positano,[1] B Favilli,[1] P Keilberg,[1] C Salvatori,[1] P Pepe,[3] A Ciancio,[4] E Cracolici,[5] M Lombardi[1]

Cardarelli, Napoli, Italy; [3]Institute of Clinical Physiology of CNR, Epidemiology and Biostatistics Unit, Pisa, Italy; [4]DH Talassemia, Ospedale Madonna delle Grazie, Matera, Italy; [5]Department of Radiology, University of Palermo, Palermo, Italy

Background. Thalassemia intermedia (TI) indicates a clinical condition of intermediate gravity between the asymptomatic carrier and the transfusion-dependent form. The genetic bases of the TI are likewise variable. Cardiac involvement in TI patients seems to be more related to an high cardiac output state than to myocardial iron overload (MIO). The relationship between the presence of a precise phenotype and the cardiac impairment in TI has not been investigated. *Aims.* Our study aimed to detect if different phenotypes could be related to different levels end kind of cardiac involvement, evaluated by cardiovascular magnetic resonance (CMR). *Methods.* We performed a retrospective review of the CMR results and of clinical data about 52 TI patients (age 38±10 years, 54% females) enrolled in the Myocardial Iron Overload in Thalassemia (MIOT) project. In the MIOT network all CMR and thalassemia centers are linked by a web-based network, configured to collect patient anamnestic, clinical and diagnostic data. MIO was assessed using a multislice multiecho T2* approach. Cine sequences were obtained to quantify biventricular morphological and functional parameters. *Results.* Three groups of patients were identified: heterozygote (N=18), homozygote β^+ (N=19), homozygote β^0 (N=15). No significant

differences for sex and age were found among the groups. The global heart T2* value was significantly higher in the homozygote β° group compared to the homozygote β+ group (42±5.6 ms *vs.* 34±8 ms, P=0.006). The homozygote β° group showed significantly higher Left Atrial Area values than the heterozygote group (28±4 cm^2 *vs.* 22±5 cm^2, P=0.014). The homozygote β° group showed significantly higher left ventricular (LV) end-diastolic volume index (EDVI) than the heterozygote and homozygote β+ group (116±19 mL/m^2 *vs.* 94.7±21.7 mL/m^2 *vs.* 96±23 mL/m^2, P=0.019) and significantly higher LV mass index than the heterozygote group (70±15 g/m^2 *vs.* 57±14 g/m^2, P=0.032). The homozygote β° group showed significantly higher right ventricular (RV) EDVI and end-systolic volume index (ESVI) than the heterozygote group (113±24 mL/m^2 *vs.* 90±24 mL/m^2, P=0.031; 43±17 mL/m^2 *vs.* 29±10 mL/m^2, P=0.01). *Conclusions.* Heart remodelling related to a high cardiac output state cardiomyopathy was more pronounced in the homozygote β° TI patients. These data support the knowledge of the different phenotypes in the clinical and instrumental management of the TI patients.

1047

HELICOBACTER PYLORI RELATIONSHIP WITH IRON DEPLETION AND VITAMIN B12 DEFICIENCY

A Remacha,[1] P Sarda,[2] T Royo,[2] C Carrascosa,[3] J Queralto[3]

[1]Complejo Hospitalario Toledo, Toledo, Spain; [2]Hematology Department, Hospital de Sant Pau, Barcelona, Spain; [3]Biochemistry Department, Hospital de Sant Pau, Barcelona, Spain

Helicobacter Pylori (HP) infection has been associated with iron deficiency (ID) and poor response to oral iron. Moreover, some patients showed anti-parietal cell antibodies (PCA) and low vitamin B12, suggesting a relationship between ID, vitamin B12 deficiency and HP. *Objective.* To study in low vitamin B12 (LB12) patients the presence of ID and HP. *Methodsology.* Etiology of 198 patients with LB12 (serum vitamin B12 < 201 pmol/l) was evaluated using clinical findings, laboratory parameters and digestive studies. Clinical characteristics of patients with ID and LB12 were studied, including the presence of HP. Iron deficiency was diagnosed using iron variables (serum iron, total iron binding capacity, transferrin saturation, serum ferritin and soluble transferrin receptor). HP was confirmed by Breath test and/or gastric biopsy. *Results.* In 57 out of the 198 (28.8%) patients with LB12, ID was showed, including 42 (73.7%) with pernicious anemia (PA). Interestingly, macrocytosis or macrocytic anemia was demonstrated in 6 cases (10.5%) and microcytosis or microcytic anemia in 16 (29%). With regard to the 42 cases with PA, macrocytic and microcytic anemia was observed in 3 (7%) and 11 cases (26%), respectively. Anti-intrinsic factor antibodies (IFA) and PCA were demonstrated in 57% and 90% of patients, respectively. Serum gastrin > 60 U/l was increased in all cases. An increase of serum homocystetine (Hcy) (> 16.9 micromol/L) was showed in 20 out 23 cases in whom Hcy was determined. With regard to the 15 cases with LB12, ID and without PA, in 8 patients (53%) HP was positive, (4 were in treatment with omeprazole, 1 after gastroplastia and in 2 no etiology was found, but Hcy levels were normal, 8.6 and 9.8). In the 8 cases with HP, ID and LB12, serum B12 ranged from 121 to 158, Hcy was increased in 5 (62.5%) and Hcy decreased after treatment. IFA were negative in the 8 cases and PCA positive in 4 cases. Increased serum gastrin was also showed in 4 cases. Furthermore in 14 out of the 141 with LB12 without ID (10%) HP was positive. Interestingly, PCA were negative, but Hcy was increased in 12 out of 14 cases (from 17.5 to 35micromol/l) and Hcy normalized after treatment. An increase in serum methylmalonic acid (> 0,4 mmol/L) was showed in the 5 cases in which it was determined. Conclusion. In our experience, in 74% of cases with ID and LB12, this deficiency is caused by PA and few of them showed macrocytosis. In 26% of the remaining cases, HP is positive, most of them with a real vitamin B12 demonstrated by an elevated Hcy. Therefore, HP is probably the second cause of ID and LB12. Moreover, in some cases (approximately 10%) with vitamin B12 deficiency without ID, HP was also demonstrated. HP investigation should be carried out in patients with ID and LB12 and patients with LB12 without a clear cause of the LB12.

1048

HEREDITARY HYPERFERRITINEMIA-CATARACT SYNDROME (HHCS) PRESENTING WITH IRON DEFICIENCY ANEMIA AND THE IDENTIFICATION OF A NEW AND PATHOGENETIC RELEVANT HETEROZYGOUS MUTATION +24T>C (=HGVS C.-176T>C) IN THE IRON RESPONSIVE ELEMENT OF THE L FERRITIN GENE IN A SWISS FAMILY

A Rüfer,[1] J Howell,[1] A Lange,[1] R Yamamoto,[2] J Heuscher,[1] M Gregor,[1] W Wuillemin[1]

[1]Kantonsspital Luzern, Luzern, Switzerland; [2]Medizinisches Versorgungszentrum Dr. Eberhard & Partner, Dortmund, Germany

Hereditary hyperferritinemia-cataract syndrome (HHCS) is one of the differential diagnoses of hyperferritinemia (HF) with low or normal transferrin saturation (TS) but is usually not associated with anemia. We report a case of a 39-year old woman who was referred for an evaluation of a microcytic, hypochromic anemia with a hemoglobin of 102g/L (normal range 115-148 g/L), MCV 68fl (80-97fl), MCH 22 pg (27-34 pg) and an elevated ferritin of 383 μg/L (15-150 μg/L). Reticulocyte hemoglobin was 22.7pg (28-35pg), TS 9% (16-45%), soluble transferrin receptor 9.8 mg/L (1.9-4.4 mg/L) and ferritin index 3.79 (<3.2), which all was in favour of iron deficiency despite HF. HFE gene mutation studies showed a heterozygous mutation for H63D. Vitamin B12, vitamin B6, erythrocyte folate, copper, zinc and coeruloplasmin were all in the normal range, a hemoglobinopathy could be excluded. Bone marrow examination could exclude a myelodysplastic syndrome and revealed empty iron stores on Prussian blue staining, therefore the diagnosis of an iron deficiency anemia was made. To evaluate the cause of the HF with low TS further an ophthalmological examination was performed. In spite of absent visual impairment or glare there was evidence of bilateral cataract with scattered small snowflake-shaped opacities throughout the lens compatible with the diagnosis of HHCS. HHCS is an autosomal dominant disorder characterized by distinctive cataracts and HF in the absence of iron overload. Therefore sequencing studies were done to look for mutations in the iron responsive element (IRE) of the L ferritin gene. A heterozygous single point mutation for a +24T to C substitution in the IRE of the L ferritin gene (=HGVS c.-176T>C) was detected which has not been described before. To evaluate the pathogenetic relevance of this new mutation we performed family studies of parents and siblings. We could identify the father and one brother with HF, cataract and the heterozygous +24T>C mutation. Neither the mother nor the five other siblings had HF, cataract or that mutation. We therefore conclude that this here first described heterozygous +24T>C mutation in the IRE of the L ferritin gene causes HHCS. As our patient had a symptomatic iron deficiency anemia caused by hypermenorrhagia we substituted iron sucrose intravenously and applied 1200mg in total. Anemia and all laboratory parameters suggestive of iron deficiency normalized and ferritin was 506μg/l at the end of substitution. *Acknowledging.* HHCS is important as phlebotomies are contraindicated and cataract formation needs ophthalmological attention.

1049

AGE-RELATED COMPLICATIONS IN TREATMENT-NAÏVE PATIENTS WITH THALASSEMIA INTERMEDIA

A Taher,[1] K Musallam,[1] A El-Beshlawy,[2] M Karimi,[3] S Daar,[4] K Belhoul,[5] M Saned,[5] G Al-Helou,[1] G Graziadei,[6] M Cappllleini[6]

[1]American University of Beirut Medical Center, Beirut, Lebanon; [2]Cairo University, Cairo, Egypt; [3]Shiraz University of Medical Sciences, Shiraz, Iran; [4]Sultan Qaboos University, Muscat, Oman; [5]Al Wasl Hospital, Dubai, United Arab Emirates; [6]University of Milan, Milano, Italy

Background. Age-related complications have never been evaluated in patients with thalassemia intermedia (TI) partly because of the confounding effects of various treatment modalities used in any studied cohort. *Aims.* To evaluate the occurrence of several disease-related complications with advancing age in a large cohort of TI patients who never received any form of disease treatment. *Methods.* We re-evaluated data collected for the Thalassemia Intermedia Registry, a database of 584 TI patients currently registered at six comprehensive care centers in Lebanon, Italy, Iran, Egypt, United Arab Emirates, and Oman. Institutional review boards (IRBs) at each center approved the study protocol. Patients who never received any treatment intervention (splenectomy, transfusion therapy, iron chelation therapy, fetal hemoglobin inducing agents) were identified and included in this study (n=120). Retrieved data included demographics (age and gender); identified mutation; mean hemoglobin (Hb) and steady-state serum ferritin (SF) levels of three con-

secutive measurements within the year corresponding to patient age; and presence of complications (extramedullary hematopoiesis [EMH], leg ulcers, thrombosis, pulmonary hypertension [PHT], heart failure [HF], cholelithiasis, abnormal liver function [ALF], diabetes mellitus [DM], hypothyroidism, osteoporosis, and hypogonadism). Patients were divided into four quartiles (n=30 each) according to their age: < 10, 11-20, 20-32, and > 32 years. *Results.* The mean age of the patients was 21.4±13.4 years (range: 2-56 years). The male to female ration was 61:59. Homozygosity for IVS-I-6 (T -> C) was the most common mutation (87.5%), followed by IVS-I-5 (G -> C) (8.3%), IVS-II-1 (G -> A) (2.5%) and Codon 39 (C -> T) (1.7%). There was no statistically significant difference between age quartiles in the proportion of patients with co-inheritance of alpha thalassemia or determinants associated with increased gamma-chain production. The mean Hb and SF levels of the whole study group were 7.7±1.6 g/dL (range: 4.1-11 g/dL) and 610.7±515.1 ng/mL (range: 16.7-2520 ng/mL), respectively. There was a statistically significant negative correlation between age and Hb level (r = -0.679, P<0.001) and a statistically significant positive correlation between age and SF (r = 0.653, P<0.001). Between age quartiles, there was a statistically significant difference in the rate of EMH (P=0.007), leg ulcers (P=0.034), and DM (P=0.030), but not thrombosis (P=0.082), PHT (P=0.159), HF (P=0.664), cholelithiasis (P=0.103), ALF (P=0.536), hypothyroidism (P=0.069), osteoporosis (P=0.124), or hypogonadisim (P=0.055). However, with advancing age, there was a statistically significant trend towards a higher rate of EMH (P=0.001), leg ulcers (P=0.004), PHT (P=0.010), thrombosis (P=0.030), hypothyroidism (P=0.039), and osteoporosis (P=0.018). *Summary/Conclusions.* Despite having a milder form of the disease at initial presentation and diagnosis, TI patients are still at risk of acquiring several serious complications as they become adults.

1050

COMPILATION OF ALPHA-CHAIN HEMOGLOBINOPATHIES THAT OCCUR WITH MICROCYTOSIS

A Villegas,[1] F De la Fuente-Gonzalo,[2] L Vinuesa,[2] J Martínez-Nieto,[2] P Ropero,[2] FA González,[2] S Redondo[2]

[1]Hospital Clinico San Carlos, Madrid, Spain; [2]Hematología. Hospital Clínico San Carlos, Madrid, Spain

Background. The molecular basis of most _-thalassemias are deletions in some of _ globin genes. However, about 5-10% of the cases are due to point mutations in these genes. The majority of these mutations are unique to the individual family, nevertheless some alterations such as mutation in the initiation codon and 5 bp deletion in the donor site of first intron know as Nco and Hph mutations respectively, are more frequent in some populations. *Aims.* In this work we show point mutation cases in α-globin genes diagnosed in our hospital during 2009, except to Nco and Hph mutations which have been ruled out. *Methods.* In 2009, 186 samples collected by the Hematology department of the Hospital Clinico San Carlos in Madrid were studied to show microcytosis with normal HbA2 and HbF, and without iron deficiency. Which 170 was due to deletions (91.4%) and 8 to the mutation Hph (4.3%). The geographical origin of patients covers all the spanish territory. For the molecular study was necessary the genomic DNA extraction from peripheral blood leukocytes, employing a Bio-Robot EZ1. α gene deletions, Nco and Hph mutations were ruled out by α-thalassemia StripAssay. The remaining 8 samples were studied by automated DNA sequencing with BigDye v1.1, specific for α2 and α1 genes. *Results.* This study found the following variants of hemoglobin, all in heterozygote condition: Hb Agrinio [CD29 CTG->CCG (Leu->Pro)α2] found in 2 different families; CD 23 [CD23 GAG->TAG (Glu->AMB)α2]; Hb Groene Hart or Bernalda [CD119 CCT->TCT (Pro->Ser)α1] in 2 families; Hb Plasencia [CD125 CTG->CGG (Leu->Arg)α2] found in 2 different families and Hb Utrecht [CD129 CTG->CCG (Leu->Pro)α2]. *Conclusions.* In recent years the migratory movements have had a great relevance in the genetic structure of populations, significantly changing the frequency of molecular alterations in the globina genes. The identification in 8 different families of 5 point variants different from Nco and Hph mutations, reveals the molecular heterogeneity of cases of non-deletional α thalassemia in our average. This heterogeneity can have important implications in their phenotypic expression interacting with other more common deletion and non-deletional forms of α thalassemia, which are increasing in our average by the migratory changes. The integration of different molecular techniques, especially the automatic DNA sequencing, has a great importance for the clinical diagnosis of thalassemic syndromes mainly in non-deletional α thalassemia rare cases. The diagnosis of less frequent variants of this disease is essential to be applied to genetic counselling and prenatal diagnosis, and thus decrease sanitary and social costs that the treatment of these pathologies leads.

THE EFFECTIVENESS OF LIPOSOMAL AMPHOTERICIN IN THE TREATMENT OF INVASIVE FUNGAL INFECTIONS IS NOT AFFECTED BY PRIOR AZOLE ADMINISTRATION: THE AMBI-PROF STUDY

J De la Serna,[1] I Jarque,[2] J López,[3] R Mar,[2] V Gómez-García,[4] J Serrano,[5] A Bárez,[6] A Sampol,[7] P Amat,[8] C Berrenetxea,[9] R Del Campo[10]

[1,12] de Octubre Hospital, Madrid, Spain; [2]La Fe Hospital, Valencia, Spain; [3]Ramón y Cajal Hospital, Madrid, Spain; [4]De la Princesa Hospital, Madrid, Spain; [5]Reina Sofía Hospital, Córdoba, Spain; [6]Nuestra Señora de Sonsoles Hospital, Ávila, Spain; [7]Son Dureta Hospital, Palma de Mallorca, Spain; [8]Clínico Universitario de Valencia Hospital, Valencia, Spain; [9]Vall d'Hebrón Hospital, Barcelona, Spain; [10]Son Llatzer Hospital, Palma de Mallorca, Spain

Background. It is a matter of debate whether mold-active azole prophylaxis may reduce the effectiveness of Liposomal Amphotericin (L-AmB) due to the potential antagonism in antifungal mechanisms. Recent data suggested that sequential azole and L-AmB did not reduce the efficacy of L-AmB (Cornely O, JAC 2010). *Aim.* To determine the non-inferiority of prior azole administration in the efficacy of treatment of Invasive Fungal Infections (IFI) with L-AmB in hematologic and allogeneic HSCT patients. *Methods.* We retrospectively studied patients who met the EORTC/MSG criteria for IFI and received treatment with L-AmB. Eligible patients were distributed in two arms according to: (A) mold-active azole exposure prior to L-AmB, and (B) fluconazole or no prior azole. Patients were stratified according to the type of IFI and evaluated for disease related risk factors and comorbidities at the time of L-AmB therapy. The primary endpoints were favorable response, defined as complete or partial response, and survival at the end of antifungal therapy, at 4 and after 12 weeks. *Results.* From Feb/2008 to Sep/2009, 182 consecutive patients were recruited from 26 institutions. The median age was 45 years (range 1-78). Most patients undergoing chemotherapy had acute leukemia (AL) or myelodysplasia (MDS) (129; 70.0%). Baseline disease was treated for induction, post-remission, or refractory/relapse status in 23.6%, 45.0% and 31.4%, respectively. A 40.1% of patients had received an allogeneic HSCT. A severe comorbidity and prior IFI were present in 20.3% and 14.8%, respectively. Arm A included 100 patients with prior itraconazole 39%, voriconazole 35% and posaconazole 26%. Arm B included 82 patients with fluconazole 49% or no azole 51%. Patients characteristics were not different in both arms, except for more cases of AL or MDS (P=0.002) and prolonged neutropenia in arm A (P=0.021), and more use of high dose steroids in arm B (P=0.01). The rates of possible, probable and proved IFI were 52.7%, 28.6% and 18.7%, respectively. Aspergillosis was the proven IFI in 28 of 35 cases. L-AmB was given at 3 mg/kg/d a median of 18±17 days in arm A and 15±13 in arm B. Up to 58% of patients in arm A, and 75% in arm B continued therapy after L-AmB with a different antifungal. Time to achieve a favorable response was 21 days in arm A and 27 days in arm B (P=0.252). The favorable response rate to L-AmB was 75.0% and 74.4% in both groups, with no differences in the responses at the end of treatment, at 4 weeks or at 12 weeks. The response rates for possible and probable or proven IFI were similar in both groups but survival was reduced in arm A (Table 1).

Table 1.

Table 1 **L-AmB treatment outcome**	**Group A** prior azole N=100	**Group B** no azole N=82	**Total** N=182	p value*
	n (%)	n (%)	n (%)	
Favorable response[1]	75 (75.0)	61 (74.4)	136 (75.0)	*ns*
Possible IFI	44 (83.0)	32 (74.4)	76 (79.2)	*ns*
Proven or Probable IFI	31 (66.0)	29 (74.4)	60 (69.8)	*ns*
End of treatment				
Favorable Response	73 (73.0)	55 (67.1)	128 (70.3)	*ns*
Survival	83 (83.0)	70 (85.4)	153 (84.1)	*ns*
At 4 weeks				
Favorable Response	57 (57.0)	50 (61.0)	107 (58.8)	*ns*
Survival	62 (62.2)	64 (78.0)	126 (69.2)	*0.020*
At 12 weeks				
Favorable Response	41 (41.0)	41 (50.0)	82 (45.0)	*ns*
Survival	42 (42.0)	49 (59.8)	91 (50.0)	*0.017*

*Group A vs B
[1] Number of complete or partial responses obtained at any time throughout the 12 weeks of the study

The Cox-odds ratio for death was 0.013 with a favorable response, 3.129 for arm A, 3.479 for high risk disease and 5.389 for refractory disease the time of L-AmB treatment (P<0.05). *Conclusions.* Prior exposure to

mold-active azoles does not seem to affect the effectiveness of L-AmB for the treatment of IFI in this high risk patient population, further indicating that a reduction in the response rate is not expected when given sequentially.

1052

SIGNIFICANT AND SAFE REDUCTION OF TRANSFUSION REQUIREMENTS BY CHANGING FROM DOUBLE- TO SINGLE-UNIT RED BLOOD CELL TRANSFUSION STRATEGY

B Gerber, M Berger, K Arn, O Senn, U Schanz, G Stussi

University Hospital, Zürich, Switzerland

Background. Traditionally, single-unit red blood cell (RBC) transfusions are believed to be insufficient for correction of hyporegenerative anemias during intensive chemotherapies and stem cell transplantation. Although suggested by some guidelines, single-unit transfusion has neither been incorporated into modern transfusion medicine nor studied appropriately. *Aims.* Based on theoretical calculations of reducing the transfusion requirements, we have changed our transfusion policy in hospitalized patients from double- to single-unit transfusions by dispending only one RBC unit at the time from the in-hospital blood bank. Operation areas and intensive care units were excluded from this change. *Methods.* Here, we retrospectively evaluated the impact of the single-unit transfusion policy by comparing two patient cohorts before and after the change of the transfusion policy. *Results.* During the study period 139 patients received 274 therapy cycles and 1553 RBC transfusions. 135 (49%) cycles were administered during the double-unit and 139 (51%) during the single-unit period. During the double-unit period, in 78% of the transfusions two units were administered simultaneously, while only one RBC unit was given in 87% of the transfusions during the single-unit period. The mean units per transfusion during the two periods were 1.76 (range 0-4) and 1.12 (0-4), respectively (P<0.001). RBC transfusions were given at hemoglobin levels of 64g/L and 61g/L in the double- and single-unit period with a median increase of 14g/L and 6g/L with two and one RBC unit. The hemoglobin value at the start of the therapy did not differ between the two groups (89 *vs.* 90 g/L) while patients during single-unit period had slightly lower hemoglobin levels at the end of the therapy (74 *vs.* 78.5 g/L, P=0.001). The median time of aplasia was similar among the two groups (17 *vs.* 18 days, P=0.304). Single-unit transfusion strategy resulted in a 27% reduction of RBC requirements per therapy cycle (mean 9.6 *vs.* 7.0, P=0.002). Likewise, the mean number of RBC units per day of aplasia was significantly reduced (0.66 *vs.* 0.40 units per aplasia day, P=0.028). In a linear regression model, the change from a double-unit to a single-unit transfusion policy remained independently associated with a significant reduction of 2.5 units per cycle (P=0.002) when controlled for the duration of aplasia and the therapy regimen. Importantly, the overall survival of the single unit-cohort with a median follow-up of 118 (9-872) days was not different compared to cohort with the double-unit transfusion strategy (P=0.934 by log-rank test). *Conclusions.* The adherence to a single unit transfusion policy is excellent and the change from double- to single-unit transfusion strategy has the potential of saving approximately 25% of RBC units. The single-unit transfusion strategy proves to be safe and cost-effective and reduces the risks associated with allogeneic blood transfusions.

1053

ROUTINE ANTENATAL ANTI-D PROPHYLAXIS - IS THE PROTECTION ADEQUATE?

M Davies,[1] R Chant,[2] S Simpson[2]

[1]Royal Devon and Exeter NHS Foundation Trust, Exeter, UK; [2]Basingstoke and North Hampshire NHS Trust, Basingstoke, UK

Background. The use of Routine Antenatal Anti-D Prophylaxis (RAADP) was recommended by the National Institute for Clinical Excellence (NICE) in the U.K. in 2002 in order to prevent sensitisation of RhD negative women during the last trimester of the pregnancy. *Aims.* Prophylactic anti-D (IgD) given during a pregnancy can be detected in current indirect antiglobulin tests (IAT), using this as a measure of the persistence of prophylactic anti-D, this study set out to determine whether there was a correlation between IgD detectable at delivery and the RhD status of the foetus and /or the duration of the pregnancy post the standard 28 week dose of the RAADP. The study also investigated whether there was a difference in the detection of IgD at delivery if given in a two dose regime (2 doses of 500i.u at 28 and 34 weeks) or a one dose regime (one dose of 1500i.u. given at 28 weeks). *Methods.* All antibody screening IAT tests were undertaken using fully automated Diamed gel technology using LISS/Coombs IAT screening cards and Diamed 3 cell antibody screening cells. The results from 407 women were included in the two dose regime study, and 157 in the one dose regime study. All of these women had traceability data confirming the administration of RAADP. *Results.* Of the 407 women on the two dose regime 160 (39%) had no detectable IgD at delivery. The number of women delivering RhD positive and negative infants and the relationship with detectable IgD at delivery was analysed using the Fishers two-tailed test (with the level of statistical significance set at a P<0.05). This gave a P value of 0.59, showing that there is no correlation between the RhD status of the foetus and detectable IgD at delivery. The duration of the pregnancy and whether IgD was detectable at delivery was also analysed, giving a P<0.0001. This demonstrates that there is a strong correlation present between the time lapse from the 28 week dose to delivery and detectable IgD at delivery.Of the 157 women on the one dose regime 123 (78%) had no detectable IgD at delivery. Analysis of the relationship between IgD detectable at delivery and the RhD status of the infant gave a P value of 0.32 which again suggests that there is no correlation between these two variables. The relationship between the duration of the pregnancy and IgD detectable at delivery gave a P value of <0.0001 which confirms a strong correlation between whether IgD is detectable at delivery and the duration of the pregnancy post the 28 week dose. *Summary.* Our data show that neither the two dose regime nor the one dose regime appear to provide adequate cover at delivery for a large percentage of pregnant women, especially if those pregnancies go beyond 12 weeks from the administration of the primary dose.

1054

RED BLOOD CELL ALLOIMMUNIZATION AND FEMALE SEX PREDICT THE PRESENCE OF HLA ANTIBODIES IN PATIENTS UNDERGOING LIVER TRANSPLANT

C Sanz, G Ghita, I Martinez, C Franquet, A Pereira

Hospital Clinic, Barcelona, Spain

Background. Refractoriness to platelet transfusion due to HLA antibodies poses a serious risk to patients who require platelet support during surgery. Since routine screening for HLA antibodies would pose a tremendous burden on presurgical work-ups, a stratification of patients according to the risk of having HLA antibodies is warranted. *Aims.* To determine the prevalence of red blood cell (RBC) and HLA immunization in a large number of patients submitted to liver transplant and, to estimate the accuracy of RBC alloimmunization and other patient features to predict the coexistence of HLA antibodies. *Material and Methods.* Every patient considered for liver transplant in our hospital is routinely tested for the presence of RBC and HLA antibodies in the pretransplant workup. RBC antibodies are determined by a LISS-based antiglobulin test against commercial panels of reagent RBCs. The screening for HLA antibodies is done by lymphocytotoxicity against a panel of 20 selected cells. For the purpose of this study, the clinical and laboratory records of patients submitted to liver transplant from 1988 to 2008 (n=1491) were reviewed. Patients younger than 16 years and those not tested for HLA antibodies were excluded from the analysis. Predictive variables were selected through binary logistic regression and their accuracy to prognosticate HLA alloimmunization was calculated by contingent table Methods. *Results.* 1351 patients were included in this study. Median (range) age at the time of liver transplant was 53 (16-70) years and 876 (65%) were males. HCV and alcohol related cirrhosis constituted the 65% of the diagnosis. Seventy (5.2%) patients had RBC alloantibodies. The most common individual specificities were D (23 cases), E (21), C (19), Kell (19), c (6), e (6), Fya (5), and Jka (5). Twenty-two patients presented with two or more RBC alloantibodies simultaneously. HLA antibodies were detected in 71 (5.3%) patients. They include five cases of anti-HLA-A2 and one case each of anti-HLA-A10 and anti-HLA-A12. The remaining 64 cases had no definite specificity. The panel reactivity activity was 100% in 29 cases and ranged from 50-99% in 42 cases. Female sex and RBC alloimmunization were the only features independently associated with HLA aloimmunization. The risk for having HLA antibodies increased from male patients without RBC alloimmunization (n= 842; 1.5% with HLA antibodies) to female patients with RBC alloimmunization (n= 36, 36.2% with HLA antibodies), being of 9.7% in the remaining 473 patients. In females, the positive and negative predictive values of RBC alloimmunization to prognosticate HLA alloimmunization were 36% and 90%, respectively. In male patients, such values were 12% and 99%, respectively. *Conclusions.* RBC alloimmunized female patients submitted to elective surgical procedures that may require platelet support should be preoper-

atively evaluated for HLA antibodies. Such evaluation is unnecessary in male patients without detectable RBC antibodies. Decision-making in the remaining patients must be individualized.

1055

INCIDENCE AND CARACTERISTS OF SERIOUS ADVERSE EFECTS RELATED TO TRANSFUSION

N Carpio, F Moscardó, I Vaquero, F Arriaga, M López, M Sanz

Hospital Universitario La Fe, Valencia, Spain

Background. Blood component transfusion can lead to undesirable side effects which range from mild complications to life-threatening reactions. Data from the incidence and characteristics of serious adverse events related to transfusion are required in order to install preventive strategies to increase the transfusion safety. The aim of this study is to analyze the incidence and characteristics of serious adverse events after blood component transfusion. *Study design and methods.* Between January 1st 2000 and December 31th 2009 all side effects related to transfusion were recorded as a part of our hemovigilance program. For all cases, adverse events were analyzed for its direct relation with transfusion and its severity, including the treatment response whenever applicable. For the purpose of this study only side effects with long term-morbidity (severity 2) or direct life-threatening (severity 3) or death (severity 4) that could be explained for the transfusion procedure (grade 2 association) or in which the transfusion was the certain cause (grade 3 association), were included in the analysis. All hemolytic, immune and infectious complications were registered for each of the blood component transfused. *Results.* During the study period a total of 359.671 units of red blood cells (234.805), platelets (70.431) and fresh frozen plasma (54.435) were transfused. The incidence of serious adverse events according to the previously defined criteria was 0.01%, which means 40 SAEs. Three additional SAEs were reported with the use of other blood or cell components. The incidence of SAEs was clearly higher for platelet transfusion than red blood cell transfusion (P<0.0001) and also higher for fresh frozen plasma (P=.04). The majority of SAEs were allergic/anaphylactic or febrile reactions (26 of 40) followed by hemolytic reactions (5 cases) and TRALI (4 cases). The majority of SAEs (83.7%) were of grade 2 severity and the patients survived without problems after treatment. These SAEs include all the hemolytic reactions, errors in blood component administration, febrile and hypotensive reactions, allergic or anaphylactic reactions, 2 cases of TRALI and 1 case of bacterial contamination. Three cases were grade 3 severity with serious consequences for the patients (one chronic respiratory failure after TRALY and two cases of human immunodeficiency virus infection). Four patients died: two of them due to TRALY after platelets transfusions, one due to septic shock and one allogeneic stem cell transplant recipient due to a CMV infection. *Conclusions.* The safety of blood components transfusion has been increased during last years. The incidence of SAEs is low (0.01%) with a mortality rate of 0.001%. However, SAEs can result in severe consequences for the patients and efforts should be made to reach a six sigma quality confidence level. Control of platelet transfusion indications seems to be an urgent measure to reduce transfusion related mortality.

1056

ROUTINE AUTOLOGOUS BLOOD COLLECTION AND SUBSEQUENT TRANSFUSION FOR DONORS OF BONE MARROW (BM) IS UNNECESSARY

S Kaplan, C Hogan, J Szer, A Grigg

Royal Melbourne Hospital, Melbourne, Australia

Background. Australian Bone Marrow Donor Registry and World Marrow Donor Association guidelines stipulate harvest centres should collect ≥1 autologous red cell units from allogeneic donors for transfusion during or after a marrow harvest. However, the necessity for routine autologous collection has not been established. This practice increases cost and inconvenience and does not eliminate the most significant transfusion associated risks, including bacterial contamination and administrative error. *Aim.* To perform a single centre retrospective analysis of the utility of autologous blood collection pre-allogeneic BM donation and review transfusion practices of stored autologous units. *Methods.* Fifty-nine consecutive BM donors presenting between January 2004 and December 2008 were identified. Sibling and volunteer unrelated donors were included. Haemoglobin (Hb) measurements pre-autologous blood collection, pre-harvest and post-harvest (prior to transfusion), where available, were retrospectively analysed. Transfusion of autologous units was audited. *Results.* The donors comprised 34 males (mean age 40yrs-range:16-52) and 25 females (mean age 39yrs-range:24-66). Forty-seven donors had autologous blood collected (33:1unit and 14:2units). The mean Hb pre-autologous donation for males (n=27) was 156 g/L (range:139-179 g/L) and for females (n=20) was 137g/L (range:116-157g/L). The mean reduction in Hb post-autologous collection was 12 g/L (-31 g/L to -1 g/L) and 7g/L(-30 g/L to +4g/L) for males (n=23) and females (n=17) respectively, despite routine iron supplementation. The mean BM harvest volume was 1068 mL (range:200-1725ml). The mean post-harvest Hb pre-transfusion in males (n=19) was 122g/L (range:92-151 g/L) with a mean drop of 23g/L (range:5-43 g/L), for females (n=12) the respective results were 108g/L (range:84-145 g/L) and 26 g/L (range:10-49 g/L). No donor who had a post-harvest Hb measured met National Health and Medical Research Council minimum criteria for transfusion (Hb<70 g/L). Twenty-seven of the 47 donors who had autologous blood collected, were transfused, although in 56% their Hb pre-transfusion was not checked. There was no significant difference in post-harvest Hbs of transfused (pre-transfusion 115g/L range:84-151g/L) *vs.* non-transfused donors (118 g/L range:88-145 g/L). *Conclusion.* Routine autologous blood collection prior to BM harvest leads to a drop in Hb pre-harvest, wasting of blood and unnecessary transfusions. Post-harvest Hb did not decrease to levels considered detrimental to healthy persons in any donor. We conclude routine autologous blood collection from healthy BM donors is unnecessary.

1057

DAILY REVIEW FOR UNDERTRANSFUSION

L López-Anglada Fernández, L Lopez Corral, J Alonso Rodríguez, T Caballero Velázquez, MT Villaescusa de la Rosa, M Corral Alonso

Hospital Clínico Salamanca, Salamanca, Spain

Background. Most published reviews and audits of blood and blood-component transfusion have focused on the issue of overtransfusion and the inappropriate use of red cell components.[1] Efforts to curb unnecessary transfusion may result in a trend towards undertransfusion of patients.[2,3] There is little published information addressing this matter or the magnitude of its practice.[4] We herein report a study of the daily review of transfusion in the University Hospital of Salamanca, a 912-bed tertiary-care facility. *Aims.* The main objective is to detect the inappropriate use of red cell components due to undertransfusion, and, where this is found, secondarily, to determine whether the undertransfusion confers an increased risk of a negative outcome on the patients.[5] *Study design and methods.* Undertransfusion was evaluated by examining daily transfusion records of 3,201 patients for a 12-month period. Patients transfused in the previous 24 h, whose pretransfusional haemoglobin level was <7.5 g/dL were reviewed and evaluated for clinical undertransfusion criteria. *Results.* Over the 12-month period (February 2009 - January 2010) a total of 15,294 red blood concentrates were transfused by the University Hospital of Salamanca in 3,201 patients, 396 of whom were reviewed. The median age was 72 years; 75% of the population were over 64 years old, and 50% of the patients were older than 78 years of age. 36.4% (144) patients met the clinical criteria for undertransfusion. 41% (91) of these patients attended the Accident & Emergency Unit; their median age was 84 years. One of the undertransfused patients presented with an acute myocardial ischemia due to a sustained low haemoglobin level following orthopaedic surgery, and required admission to the Coronary Unit. After the review it was found that low haemoglobin levels (<7.5 g/dL) and symptomatic anaemia had been sustained during the previous week. *Summary/Conclusions.* Undertransfusion may occur in older patients (80+ years old), most of whom arrive in the Accident & Emergency Unit from an institution. Death or morbidity related to low or delayed transfusion are poorly documented, probably because there is no detection network and no methods dedicated to the detection of low or delayed transfusion. The population at greatest risk of undertransfusion are old people who live in institutions, where signs and symptoms may not be detected in time and where provision of care and a good diet is lacking.

HIGH ACTIVATION STATE OF APHERESIS PLATELETS AFTER LOW VOLUME CENTRIFUGATION DURING MULTICOMPONENT COLLECTION

S Macher, S Sipurzynski, K Rosskopf, E Rohde, A Groselj-Strele, A Griesbacher, G Lanzer, K Schallmoser

Medical University of Graz, Graz, Austria

Oncologic and hematologic patients treated by chemotherapy and possibly stem cell transplantation are usually poly-transfused and therefore exposed to multiple donor-derived blood products. Multicomponent collection (MCC) in apheresis enables the production of various standardized blood components during one donation session and may help to reduce the donor exposure to poly-transfused patients. In this paired prospective study we prepared platelet concentrates (PCs) by MCC using two different cell separators to compare metabolic, functional and activation parameters of platelets (PLTs) immediately after apheresis and during storage. Twenty-four donors underwent MCC donation on two different cell separators (Fenwal Amicus® and Caridian BCT Trima Accel®) within an interval of at least two months where one double dose of PLTs and one unit of packed red blood cells were collected. These two devices differ in the mode of PLT collection as in the Amicus® separator centrifuged PLTs remain highly concentrated as so-called "dry PLTs"within the collection chamber and are manually re-suspended in plasma at the end of apheresis. In contrast, in the Trima Accel® separator, PLT rich plasma is continuously collected outside the cell separator during centrifugation. On days 0, 2 and 7, PCs were tested for metabolic parameters and PLT function by aggregometry, rotation thrombelastometry and hypotonic shock response. PLT activation was analyzed by flow cytometry. Until day 7, metabolic parameters were well maintained in both groups. PLTs collected by the Amicus® device were significantly more activated as evidenced by higher CD62P and CD63 expression as compared to Trima PCs. This was observed in parallel to impaired *in vitro* PLT function revealed by aggregometry, hypotonic shock response and also partly rotation thrombelastometry. In multicomponent apheresis, standardized PC collection is effective and well tolerated. The higher activation of PLTs derived from the Amicus® separator may be due to the distinct modality of PLT collection. However, the causes for impaired PLT function and possible consequences for the clinical outcome have to be evaluated in further studies.

BLOOD AND MARROW-DERIVED PROGENITORS ARE SUSCEPTIBLE TO MAPK P38-DEPENDENT FOAM CELL INDUCTION

E Rohde,[1] K Schallmoser,[1] A Reinisch,[1] N Hofmann,[1] T Pfeifer,[1] G Rechberger,[2] G Lanzer,[1] D Kratky,[1] D Strunk[1]

[1]Medical University of Graz, Graz, Austria; [2]University of Graz, Graz, Austria

Clinical trials for therapeutic angiogenesis use blood- or marrow-derived transplants containing endothelial progenitor cells (EPCs), myelomonocytic cells and mesenchymal stromal cells (MSCs) to support vascular regeneration. Safety concerns have emerged since all three cell types can also contribute to atherosclerosis. We therefore asked whether human monocytes, EPCs or MSCs do in fact accumulate lipid droplets (LDs) and form foam cells *in vitro* as a surrogate marker for potential pro-atherogenic side effects of therapeutic angiogenesis. LD accumulation was quantified by flow cytometry, confocal laser scanning microscopy and cholesterol measurement in each of the cell types following exposure to low density lipoprotein *in vitro*. The impact of an initial three-day pro-angiogenic culture on subsequent foam cell formation was studied to mimic a relevant setting already used in clinical trials. The phosphorylation state of intracellular signalling molecules in response to pro-angiogenic stimulation was determined to delineate the operative mechanisms and to establish a basis for interventional strategies. Foam cells developed from monocytes but not from EPCs or MSCs after pro-angiogenic induction. The mitogen-activated protein kinase (MAPK) p38 phosphorylation related to foam cell development and stress-induced stimuli was enhanced in monocytes after pro-angiogenic stimulation. MAPK p38 inhibition almost abrogated intracellular LD accumulation *in vitro*. These data raise serious concerns that cellular therapy with hematopoietic cell preparations containing monocytes may be counterproductive or even aggravate atherogenesis in patients with cardiovascular diseases. We therefore support the argumentation that the role of transplanted cells in the various aspects of vascular homeostasis, regeneration and therapeutic angiogenesis must be re-examined prior to further clinical trials.

1060

INFORMED CONSENT AND PATIENT UNDERSTANDING OF BLOOD TRANSFUSION

E Court, J Robinson, D Hocken

The Great Western Hospital, Swindon, UK

Background. Patient autonomy and informed consent underpin medical ethics and clinical governance. For consent to be valid, the person giving consent must be competent, acting voluntarily and be provided with sufficient information to make an informed decision. The minimum elements of informed consent to treatment are: 1) a description of the risks and benefits, the expected outcome without the treatment and available alternatives; 2) the opportunity to ask questions; and 3) the right to accept or refuse treatment. Obtaining separate informed consent for blood component transfusion is mandatory in some countries. Although there is widespread agreement that patients ought to be informed about risks and benefits of transfusion, studies in the United Kingdom suggest this does not happen as routinely as it should and the patient perspective is lacking in current literature. *Aims.* This study aimed to assess patient recall of the consent process, the information conveyed (verbally or by Blood Transfusion Patient Information Leaflet) and ease in understanding discussions concerning blood transfusion. *Methods.* A previously validated questionnaire was used as a framework in assessment of patient recall. All 342 adult patients for whom blood was cross-matched between 1st March and 30th April 2009 were sent postal questionnaires, whether transfused or not. *Results.* One hundred and sixty-four of the 342 questionnaires were returned. Overall, 59.1% of patients said someone had explained they might need a blood transfusion; of those 86.7% felt the reason why they might need a blood transfusion had been explained. Only 58.8% of patients felt they had been informed of what blood transfusion involves, whereas 67.0% said they had been informed of benefits of blood transfusion. When asked if they felt the information they received was explained in a way they could understand, 51.5% of patients agreed, but only 26.8% were aware of the Blood Transfusion Patient Information Leaflet. Of those who received the leaflet, all said they read it and had no questions. A particularly low compliance with standards was related to risks of blood transfusion, with just 27.8% of all patients feeling they had been informed of risks. Despite this, 61.9% of patients said they were satisfied overall with the information they received about blood transfusion. *Conclusions.* Although the level of recall and patient satisfaction exceeds that of many studies, there is room for improvement. Given time constraints in busy District General Hospitals such as The Great Western, a Blood Transfusion Patient Information Leaflet could prove invaluable in increasing the level of information available to patients, with minimal impact on health care professionals' time. These leaflets are available, free of charge, from the United Kingdom National Blood Service website and could be distributed relatively easily. These are currently being introduced at each bedside, in pre-operative information packs and in Outpatient Clinics, with re-audit of compliance with standards planned in six months.

Stem cell transplantation 2

ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION WITH REDUCED-INTENSITY CONDITIONING IN PATIENTS WITH REFRACTORY AND RELAPSING MULTIPLE MYELOMA: LONG-TERM FOLLOW-UP

A Shimoni,[1] I Hardan,[1] F Ayuk,[2] G Schilling,[2] D Atanackovic,[2] R Yerushalmi,[1] N Shem-Tov,[1] A Zander,[2] N Kröger,[2] A Nagler[1]

[1]*Chaim Sheba Medical Center, Tel-Hashomer, Israel;* [2]*University Hospital Hamburg, Hamburg, Germany*

Background. Allogeneic stem cell transplantation (SCT) with myeloablative conditioning is potentially curative therapy for multiple myeloma (MM) but is associated with excessively high rates of non-relapse mortality (NRM). Reduced-intensity conditioning (RIC) allows reduction of NRM compared with myeloablative conditioning but relapse rate is increased. The role and timing of allogeneic SCT during the disease course are controversial. There is only limited data on the long-term outcome of RIC in the relapsing/ refractory setting. *Methods.* We retrospective analyzed SCT outcomes in 50 patients given RIC for relapsing/ refractory MM between the years 2000-2004. Patients given an auto/allo tandem transplant were not included in this analysis. RIC consisted of fludarabine and melphalan (100-140 mg/m^2). Disease response was assessed at day +100. *Results.* The median age was 53 years (32-64). Donors were HLA-matched related (n=27) or unrelated (n=23) donors. This was a relatively heavily pretreated patient group, a median of 3 years from diagnosis (0.5-14 years). Forty-seven patients failed one (n=31) or two (n=16) prior autologous SCT while 3 patients did not have an autologous transplant due to a failed stem-cell collection, but failed other therapies. Thirty patients were in PR (n=26) or CR (n=4) at the time of SCT and 20 patients had stable or progressive disease. By day +100, 23 pts achieved CR (4 in CR pre-transplant, 15 of 26 in PR pretransplant; 4 of 20 in stable/PD); 17 PR, 7 died and 3 have already progressed. With median follow-up of 6.4 years (5-7.9 years), 16 patients are alive and 34 have died; 13 had NRM (cumulative incidence 26%) and 21 died of relapse. Three additional patients relapsed, but are currently alive with further therapies. The median survival is 2.3 years and the estimated 7-year overall and progression-free survival (PFS) rates were 34% (95 C.I. 21-47%) and 26% (95 C.I. 14-38%), respectively. The PFS curve showed an apparent plateau after 3 years, with no later relapses, suggesting potential cure. In multivariate analysis, adverse prognostic factors for survival included SCT not in remission, long duration of disease (> 5 years from diagnosis) and SCT from a female donor to a male recipient. Related and unrelated donor SCT had similar outcome. The 7 year PFS in 19 patients with none of these adverse factors was 47%. Chronic GVHD and achievement of CR after SCT were associated with improved outcome. *Conclusions.* Allogeneic SCT can result in long-term PFS in a subset of MM patients failing prior therapy and should be considered early after failure and preferably after achieving a response with salvage therapy. The treatment goal is to achieve CR as this is associated with better outcome. Relapsing disease is still the major cause of treatment failure. Additional strategies, such as maintenance therapy with novel agents or judicious use of donor lymphocyte infusions merit further investigation for converting PR to CR and reducing relapse risk.

1062

PEGFILGRASTIM REDUCES FEBRILE NEUTROPENIA, MUCOSITIS, DURATION OF HOSPITALIZATION AFTER AUTOLOGOUS PERIPHERAL BLOOD STEM CELL TRANSPLANTATION (PBSCT) FOR MALIGNANT LYMPHOPATHIES: REPORT OF 733 PBSCTS

S Auger, P Quittet, MC Bozonnat, S Bouya, N Fegueux, T Kanouni, P Ceballos, G Cartron, JF Rossi

CHU Montpellier, Montpellier, France

Granulocyte colony-stimulating factor (G-CSF) has been shown to decrease time to neutrophil recovery following PBSCT. Three products are available : 2 standard G-CSFs (filgrastim and lenograstim), and pegfilgrastim (PegG-CSF). In order to determine whether a single subcutaneous injection of Peg-G-CSF is as effective as a daily injection of standard G-CSF, in terms of haematological recovery, febrile neutropenic episodes (FN), antibiotic usage, hospitalization duration, mucositis, progressive free survival (PFS) and overall survival (OS), we retrospectively analyzed series of 604 patients having myeloma and lymphoma who underwent 733 PBSCT between 2000 and 2009 in our institution. Statistical analysis included univariate, Wilcoxon and χ^2 fisher tests, logrank test for PFS and OS, and Cox model for multivariate analysis. From January 2000 toDecember 2009, 377 patients received standard G-CSF (filgrastim or lenograstim), from May 2005 to December 2009, 330 patients received PegG-CSF. Since 2000, 26 patients did not receive G-CSF for any reasons. 455 PBSCTs have been performed for multiple myeloma (MM) after high dose melphalan, 211 for Non Hodgkin Lymphoma (NHL) and 67 for Hodgkin lymphoma (HL) with BEAM conditioning regimen. 121 patients underwent 2 or 3 PBSCT. The median of CD34 dose infused was 5.2×10^6/kg (1.2-30) with 96.2% of the grafts containing more than 2.5×10^{6}CD34/Kg. The median number of days of standard G-CSF given to reach an absolute neutrophil count (ANC) ≥500/mL was 9 days (4-29). Median time to neutrophil engraftment (ANC of 500/mL) was 11 days (5-30). The platelet recovery (platelet>20 000/mL) was 10 days (0-54) The platelet and RBC transfusion requirement are stastitically lower in the PegG-CSF group. As listed on the table I, we have analyzed the following parameters for all patients: number of FN and their beginning and duration, number of antibiotic lines, duration of hospitalization, duration of mucositis, and the percentage of grade III and IV mucositis.The same significantly differences are observed in MM, NHL and HL patients. The use of standard G-CSF or PegG-CSF does not modify OS at 1 and 5 years for both NHL and HL patients. In MM population PFS is unmodified. There is a trend of better OS in the PegG-CSF group compared to standard G-CSF : respectively OS at 1 year, 97% *vs.* 92%, OS at 5 years: 67% *vs.* 53% (pLog-rank=0.07) (pWilcoxon=0.05). Such a difference could be explained by the early use of bortezomib for induction therapy more frequently in PegG-CSF group. This feature has been analyzed. Among patients undergoing PBSCT, the use of Peg G-CSF seems to show an advantage in terms of duration of hospitalization and reduce the percentage of grade III, IV mucositis and the number of febrile neutropenic episodes.

Table.

Median, (range)	Peg G-CSF	Standard G-CSF	p	None G-CSF
N	330	377		26
FN rate (%)	74.5	80.9	<0.05	84.6
Duration of FN (days)	2 (0-27)	2 (0-18)	0.65	2 (0-13)
First day of FN (day)	5 (-3-16)	4 (-5-17)	<0.01	4 (0-11)
Number of antibiotic lines	2 (0-8)	2 (0-5)	<0.01	3 (0-4)
Duration of hospitalization (days)	18 (8-62)	19 (8-65)	<0.01	24 (18-35)
Duration of mucositis (days)	0 (0-75)	6 (0-60)	<0.01	7.5 (0-30)
Mucositis grade III, IV (%)	19.62	39.26	<0.01	ND

1063

QUANTIFICATION OF WT1 GENE EXPRESSION FOR MRD DETECTION AS PREDICTOR OF RELAPSE IN PATIENTS WITH AML AFTER ALLOGENEIC STEM CELL TRANSPLANTATION COMPARED TO FLOW CYTOMETRY AND CHIMERISM

M Kwon, M Infante, F Carretero, J Anguita, A Perez-Corral, D Serrano, J Gayoso, J Diez Martin, I Buño

Hospital Gral. Univ. Gregorio Marañon, Madrid, Spain

The detection of minimal residual disease (MRD) in AML patients after allogeneic stem cell transplantation (SCT) is important for the early detection of relapse and the selection of patients who can benefit from immunomodulation. Up to 65% of patients with AML lack a molecular marker useful for follow-up. The Wilms tumor gene (WT1) is overexpressed in more than 80% of AML patients at diagnosis, hence its utility as MRD marker. The objective of this study is to analyze the usefulness of WT1 quantification for MRD study and relapse prediction in patients with AML after allogeneic SCT and to compare the results with those from flow cytometry and chimerism. *Methods.* 174 samples were studied (69 BM and 105 PB) from 14 patients with AML (table 1), who underwent allogeneic SCT in a single center from 2003 and 2009. Quantification of WT1 expression was performed by quantitative RT-PCR (LightCycler 1.2) using cDNA obtained from 1 ug of RNA (Trizol®, Invitrogen). K562 cell line was used as calibrator and ABL as reference

gene (relative quantification). Cut-off values were defined as 0.5% in BM samples and 0.01% in PB. Results were correlated with those from flow cytometry and chimerism from the same samples. *Results.* WT1 overexpression correlated with the presence of disease before transplantation (Table 1). Post-transplantation, 6 of the 14 patients showed low and stable WT1 levels in BM and PB in the follow-up, remaining in CR (median follow-up 32 months, range 6-61). These 6 patients showed complete chimerism (CC) and negative MRD by flow cytometry. On the other hand, 8 from the 14 patients showed WT1 overexpression after SCT (Figure A): 6 of them showed, after initial low values, a significant increase in WT1 expression up to reaching positive levels in a median of 169 days (43-172), while 2 patients showed positive values continuously. Three patients showed positive levels only in PB samples, one only in BM and 4 both in BM and PB. From these 8 patients, 7 relapsed (1 with extramedullar disease who showed WT1 overexpression only in PB) in a median of 9 months after SCT (2.4-20). In one case, WT1 overexpression occured at the same time as relapse, while in the other 6 cases, relapse occured in a median of 137 days (47-438) after a significant increase in WT1 levels was seen in two consecutive samples. In these 7 relapsed patients, neither flow cytometry nor chimerism were earlier predictors of relapse. *Conclusions.* WT1 overexpression correlated with disease burden in AML patients after allogeneic SCT. In relapsed patients, relapse both medullar and extramedullar was anticipated sinificantly by WT1 overexpression compared to flow cytometry and chimerism. Quantification of WT1 overexpression by RT-PCR should be used for MRD detection in the follow-up after SCT in AML patients (not only in BM but also in PB for extramedullar disease detection) in order to facilitate immunossupresive therapy management and to select early DLI candidates.

Table 1. Caracteristics of 14 AML patients.

Case	Age	Sex	FAB	Karyotype	FLT3/NPM1	Pre-SCT status	TPH	Conditioning	Pre-SCT WT1

DONOR-SPECIFIC DIFFERENCES IN LONG-TERM OUTCOMES OF TOTAL BODY IRRADIATION-BASED MYELOABLATIVE TRANSPLANTATION IN ADULTS WITH PHILADELPHIA-NEGATIVE ACUTE LYMPHOBLASTIC LEUKEMIA

S Lee,[1] JY Kwak,[2] JA Kim,[1] SK Park,[3] NG Chung,[1] BS Cho,[1] YJ Kim,[1] HJ Kim,[1] CK Min,[1] SG Cho,[1] DW Kim,[1] JW Lee,[1] WS Min,[1] CW Park[1]

[1]Catholic BMT Center, The Catholic University of Korea, Seoul, South-Korea; [2]Chonbuk National University Medical School, Chonju, South-Korea; [3]Soonchunhyang University Medical School, Bucheon, South-Korea

Background. The graft-versus-leukemia effect in adult acute lymphoblastic leukemia (ALL) has now been definitely confirmed from the "sibling donor (SD) *vs.* no donor"comparisons. However, the role of stem cell transplantation (SCT) for Philadelphia chromosome (Ph)-negative acute lymphoblastic leukemia (ALL) remains unclear. In addition, "SD *vs.* no donor"approach is becoming outmoded, as in many studies those previously in a "no donor"category are now undergoing matched unrelated donor (URD)-SCT. *Aims.* We report long-term outcomes of total body irradiation-based myeloablative SCT in 292 consecutive adults with Ph-negative ALL who received transplants at our center between 1995 and 2008 (median follow-up of survivors, 84 months). This study focused on following questions: (1) How different are the outcomes of SCT according to the donor sources? (2) Which patients should be offered SCT using SD or URD? (3) Is there a role of autologous (AUTO)-SCT plus maintenance chemotherapy? *Methods.* Median age was 25 years (range, 15-63 years). Overall, 227 (77.7%) of 292 patients had one or more high-risk features, including adverse cytogenetics [t(4;11), t(8;14), complex (≥5 abnormalities), Ho-Tr], older age (≥35 years), high leukocyte counts (≥30×10^9/L for B-ALL, ≥100×10^9/L for T-ALL), or delayed first complete remission (CR1; >28 days). Two hundreds forty-one patients (82.5%) were transplanted in CR1; 22 (7.6%) in CR2; and 29 (9.9%) in advanced status. URD sources were classified as well-matched (WM), partially matched (PM), and mismatched (MM) based on recently published NMDP-CIBMTR guidelines. Of the whole group, donor grafts were SD (n=132), URD (n=68), and AUTO (n=92). All patients and donors provided written informed consent, and the treatment protocol was approved by the institutional review board of The Catholic University of Korea. *Results.* The cumulative incidence of relapse at 7 years was 50.4% for AUTO *vs.* 32.6% for SD, 19.4% for WM-URD, 32.3% for PM-URD, and 51.0% for MM-URD (HR=3.05 [1.82-5.10]; P<0.001). In multivariate analyses, other factors associated with relapse included transplant in beyond CR1 (P<0.001), T-lineage ALL (P=0.021), and adverse cytogenetics (P=0.033). The cumulative incidence of non-relapse mortality (NRM) at 7 years was 40.5% for MM-URD *vs.* 19.6% for SD, 20.3% for WM-URD, 15.8% for PM-URD, and 9.8% for AUTO (HR=3.10 [1.25-7.69]; P=0.015). Patients aged more than 35 years had a higher NRM (P=0.027). As a result, disease-free survival (DFS) at 7 years was inferior using AUTO (44.5%; HR=1.69 [1.14-2.51]; P=0.010) or MM-URD (26.3%; HR=2.03 [1.05-3.95]; P=0.036), while DFS from all other donor sources was approximately equivalent (53.5% for SD, 63.3% for WM-URD, and 57.0% for PM-URD). Transplant in beyond CR1 (P<0.001), older age (P=0.020), and adverse cytogenetics (P=0.041) were associated with poorer DFS. In a separate analysis including only patients in CR1, improved outcome was more pronounced in high-risk patients with a SD, WM-URD, or PM-URD. Interestingly, AUTO-SCT can induce durable DFS in standard-risk patients. *Summary/Conclusions.* Our long-term data suggest that outcomes are similar for transplantation using SD, WM-URD, or PM-URD sources, and these may be considered the best donor sources for patients with Ph-negative ALL, especially for those with high-risk features.

1065

THE SYNERGISTIC EFFECT OF HUMAN PARATHYROID HORMONE WITH MESENCHYMAL STEM CELLS ON ENHANCING HEMATOPOIESIS IN CORD BLOOD TRANSPLANTATION MODEL

YH Lee,[1] YJ Lim,[2] MY Kim,[1] SY Kim,[1] SK Lee,[1] JJ Seo[3]

[1]Hanyang University Medical Center, Seoul, South-Korea; [2]Chung-Nam National University Hospital, Daejeon, South-Korea; [3]Ulsan University Asan Medical Center, Seoul, South-Korea

Background. Bone marrow niche and osteoblasts have important roles in maintenance and differentiation of hematopoietic stem cells(HSCs). Osteoblasts which are in contiguity with HSCs produce hematopoietic growth factors and insulin-like growth factors (IGF) and enhance hematopoiesis. Some investigators have reported parathyroid hormone (PTH) could activate osteoblast and hematopoiesis. *Aims.* We evaluated the effect of human PTH (hPTH) on engraftment or *in vivo* expansion of HSCs in a umbilical cord blood (UCB)-xenotransplantation model. In addition, the hPTH effect on hematopoietic activity of osteoblasts in co-transplantation of UCB derived mesenchymal stem cells (MSCs) and the role of hPTH in enhancing the expression of cell adhesion molecules was evaluated. *Methods.* Female NOD/SCID mice received sublethal total body irradiation with a single dose of 250 cGy. After 18 to 24 hours of irradiation, 1×10^7 human UCB-derived mononuclear cells (MNCs) and 5×10^6 human UCB-derived MSCs were infused via the tail vein. The mice were randomly divided into the three groups: Group 1 (n=3) received MNCs only, Group 2 (n=3) received MNCs only and then treated with hPTH, Group 3 received MNCs and MSCs, and then treated with hPTH. The mice of Group 2 and Group 3 were injected intraperitoneally with 40 μ/kg/day of recombinant hPTH 5 times/week during the first 4 weeks after transplantation. At the fourth, sixth and

seventh week after transplantation, blood samples were drawn for complete blood count (CBC) and then both femora and tibiae were excised and marrows were aspirated. Assessment of the bone marrow cellularity, flow cytometric analysis for human hematopoietic progenitor cell markers and cell adhesion molecules as CXCR4, VLA-4, VLA-5 were performed at the seventh week. *Results.* Engraftment was performed in all mice of three groups. At the fourth, sixth and seventh week after transplantation, there were no statistical differences of white blood cell (WBC), red blood cell (RBC) and platelet counts among 3 groups. Bone marrow cellularity was approximately 20% in Group 1, but 70-80% in Group 2 and Group 3. Although hPTH-treated groups showed higher cellularity, MSC co-transplantation had no effect on bone marrow cellularity. The flow cytometric analysis showed that the proportion of myeloid(human CD13, CD33) and lymphoid(human CD19) lineages were predominantly higher in Group 3. In particular, the percentage of total human hematopoietic progenitor cells in Group 2 and 3 was larger than in Group 1. The proportion of CXCR4 in Group 3 was larger than in Group 1 and 2. However, the differences did not reach statistical significance among the 3 groups. *Summary/Conclusion.* This study showed a possible synergistic effect of MSCs and hPTH for enhancing the proportion of human hematopoietic progenitor cells in UCB xenotransplantation model. These findings might suggest that the differentiated osteoblasts from co-transplanted MSCs, resulted in hematopoietic progenitor cell expansion in UCB-xenotransplantation model.

1066

CLINICAL FEATURES AND OUTCOME OF 2009-H1N1 INFLUENZA AMONG ADULT ALLOGENEIC HEMATOPOETIC STEM CELL TRANSPLANT RECIPIENTS

B Mohty, M Nagy, M Vukicevic, T Thomas, C van Delden, K Kaiser, Y Chalandon, J Passweg

Geneva University Hospital, Geneva, Switzerland

Background. Recently, a new type of influenza virus, the 2009 H1N1-Influenza A virus (H1N1-influenza) has been involved in a worldwide pandemic outbreak. *Aims.* The impact of H1N1-influenza in allo-HSCT recipients is unknown. The aim of this prospective study was to define the features and outcome of this novel infection among adult allo-HSCT recipients. *Methods.* From May 2009 through February 2010, all adult allo-HSCT patients who presented with respiratory viral symptoms (RVS) were screened for the presence of H1N1-influenza virus. Specimens were taken from nasopharyngeal swabs or bronchoalveolar lavage. Laboratory confirmation was based on a H1N1-influenza specific real-time RT-PCR. Oseltamivir resistance was assessed in patients who had a clinical severe course. Complete clinical and biological chart reviews were performed for all cases. *Results.* In all, 9 patients out of 248 had a confirmed H1N1-influenza diagnosis, giving an overall incidence of nearly 4% over the study period. At time of infection, all patients but one were in CR and had full donor chimerism. Infected patients were heavily pretreated before allo-HSCT. Close contact with children and young adults was the most frequently suspected transmission mode (4 out of 9). With regards to their immunological status, all patients but one were vaccinated against seasonal influenza and 5 against H1N1-influenza. All infected patients presented upper respiratory tract symptoms (URT) with fever and cough. Lower respiratory tract symptoms (LRT) were present in 4 cases. The duration of symptoms before diagnosis confirmation ranged between 0 to 15 days. Other reported manifestations were runny nose, sore throat, muscular pain and dyspnea. Chest radiographies were available in 4 patients at presentation and abnormalities were detected in 2 cases. All patients received oseltamivir (initiated 0 to 8 days after symptoms) for a duration of 5 days. 4 patients were hospitalized. 5 patients had other associated viral or bacterial pathogens in respiratory secretions, and 7 received systemic antibiotics in addition to antiviral treatment. 3 patients with significant comorbidities and active chronic extensive GVHD had prolonged hospitalization and required mechanical ventilation. In addition to oseltamivir, IV zanamivir was given for a period ranging from 8 to 15 days. Interestingly, these patients had a prolonged viral shedding as assessed by serial virologic testing. Sequencing of the neuraminidase gene showed an oseltamivir resistant strain in 2 patients. Among them, one patient died within 60 days after diagnosis due to sepsis and respiratory failure for an overall H1N1-influenza attributable death around 11%. *Conclusions.* This large comprehensive single centre analysis suggest that although most allo-HSCT recipients had mild symptoms from H1N1-influenza, high immunosuppression and emergence of oseltamivir resistant strains are still a matter of concern. Although H1N1-influenza vaccination might have prevented infections or decreased the severity of disease in many patients, our study suggests that the efficacy of this vaccine in eliciting a protective antibody response is still poor in allo-HSCT patients. Close contact with children and young adults was the most frequently reported risk factor for contamination supporting the need for considering vaccination and monitoring of family members and close contacts.

1067

DEVELOPING A PREDICTING SCORE FOR SUBOPTIMAL MOBILIZATION IN LYMPHOMA PATIENTS

E Morello,[1] C Skert,[2] C Almici,[1] L Arcaini,[3] L Baushi,[1] B Botto,[4] A Castelli,[5] AM Nosari,[6] G Pica,[7] F Ripamonti,[3] F Salvi,[8] AM Carella,[7] G Gaidano,[5] A Levis,[8] E Morra,[6] D Russo,[9] U Vitolo,[4] G Rossi[1]

[1]Azienda Spedali Civili di Brescia, Brescia, Italy; [2]Chair of Hematology, Brescia, Italy; [3]Division of Hematology - University of Pavia, Pavia, Italy; [4]AOU San Giovanni Battista - Hematology, Torino, Italy; [5]Amedeo Avogadro University - Hematology, Novara, Italy; [6]Niguarda Hospital - Hematology, Milano, Italy; [7]AOU San Martino - Hematology/BMT Unit, Genova, Italy; [8]Oncology and Hematology, Alessandria, Italy, Brescia, Italy

Background. Autologous stem cell transplantation (ASCT) is a potentially curative treatment for lymphoma. A suboptimal mobilization, defined as a collection of 2 to 5×10^6 $CD34^+$ cells/kg, could impair the outcome of high dose treatment, even more if a tandem transplant is planned. New agents were recently developed which may improve the rate of SC mobilization. *Aims.* To identify a predictive score for suboptimal mobilization defined on a large series of lymphoma pts candidates to ASCT according to factors influencing SC mobilization outcome as previously reported (Morello, ASH 2009). *Patients and methods.* A total of 415 attempts of PBSC collection, consecutively performed at 7 Italian centres in 388 pts affected by lymphoma, were previously analysed. A collection of 2 to 5×10^6 $CD34^+$ cells/kg was defined as "suboptimal mobilization". The following parameters were analysed for correlation with poor mobilization: lymphoma diagnosis, disease status at mobilization, type of mobilizing chemotherapy, bone marrow infiltration at collection, n° of previous lines of therapy, prior use of fludarabine, alkylating agents or radiotherapy. The ratio between circulating $CD34^+$cells/μL and total WBC/μL on the first day of $CD34^+$ count (SCratio) was also analysed, trying to predict mobilization failure. Multivariate statistical analyses by logistic regression was performed with NCSS 2007. *Results.* The identified variables at the multivariate analysis affecting suboptimal mobilization were: age >60 (P=0.03, OR 2.26), previous treatment with alkylating agents (P=0.009, OR 3.41), 1.5≤CD34/μl<125 (P=0.0001, OR 5.24), 0.0006≤SCratio<0.004 (P=0.005 OR 2.75), mobilization with cytarabine (P=0.015 OR 0.32). Based on the regression coefficients of the multivariate analysis for each variable, a scoring system for suboptimal mobilization was established as following: Age >60=1, Alkylating agents=1, 1.5≤CD34/μL<125=2, 0.0006≤SCratio<0.004=1, Cytarabine=-2. A score for each specific risk profile was calculated by summing integer points. The score had a theoretical range between -2 and 5. A score of 3, 4 and 5 has a probability of suboptimal mobilization of 50, 69 and 83% respectively. *Conclusions.* This prognostic score should be confirmed by a validation set, currently under investigation, and thereafter a prospective trial will be implemented in order to rationally explore the use of new mobilizing agents in patients with lymphoma undergoing SC mobilization with chemotherapy and G-CSF.

1068

FACTORS DETERMINING T CELL DONOR CHIMERISM AFTER AN ALEMTUZUMAB BASED REDUCED INTENSITY ALLOGRAFT

E Nikolousis,[1] S Nagra,[1] C Brookes,[2] S Jeffries,[3] M Griffiths,[3] F Clark,[1] M Cook,[1] P Mahendra,[1] C Craddock[1]

[1]University Hospital Birmingham, Birmingham, UK; [2]Clinical trials Unit, Birmingham, UK; [3]Cytogenetics lab,Womens hospital, Birmingham, UK

Background. Reduced intensity conditioned (RIC) allogeneic transplants are widely used to deliver a graft-versus-leukaemia (GvL) effect in older patients with haematological malignancies. It is postulated that the presence of mixed chimerism in the T lymphocyte compartment post-transplant is indicative of bidirectional tolerance and therefore a predisposing factor for disease relapse. However the factors determining donor T cell chimerism after an alemtuzumab based RIC allograft have not been systematically studied to date. *Aims.* We therefore analysed pre-transplant characteristics in 140 patients undergoing a RIC allograft for a haematological malignancy in order to identify factors determining post transplant chimerism. *Methods.* 71 patients were transplanted for a

myeloid malignancy (acute myeloid leukaemia (n=44), chronic myeloid leukaemia (n=10) or myelodysplasia (n=17)) and 69 for a lymphoid malignancy (Non Hodgkin's (n=57) or Hodgkin's lymphoma (n=12)) The conditioning regimen used was Fludarabine and melphalan or busulphan for patients with a myeloid malignancy and BEAM (Carmustine, Etoposide, Cytarabine, Melphalan) for patients with a lymphoid malignancy. 91 patients received a transplant from a sibling donor and 49 from an unrelated donor. The median follow up was 23 months (3-50 months). Pretransplant parameters considered were age, sex, stem cell dose, transplant type(sibling *vs.* MUD), stem cell source (BM *vs.* PBSC), CD34 dose, CD3 count , disease type(myeloid *vs.* lymphoid), and disease status at transplant (CR *vs.* not CR). RESULTS In univariate analysis transplantation from an unrelated donor, a higher CD3 count in the stem cell inoculum and advanced patient age were associated with a higher rate of full donor T cell chimerism (FDTC) on day+90. Multivariate logistic regression of the above baseline covariates found that stem cell source (sibling v unrelated) and patient age predicted FDTC at day 90. FDTC at 90 days did not impact on overall survival, disease free survival, or chronic GvHD. In contrast FDTC at day 90 was associated with an increased risk of acute GvHD. *Conclusions.* This study has identified factors influencing chimerism status after an alemtuzumab based RIC allograft. Whilst acquisition of FDTC was associated with an increased risk of acute GVHD no effect on overall survival or disease free survival was noted. Confirmatory studies in a larger cohort of patients will be important but our data are consistent with the hypothesis that the GvL effect may be mediated through a T cell independent mechanism in the setting of an alemtuzumab based RIC allograft.

LOW DOSE METHOTREXATE COMBINED WITH LOW DOSE METHYLPREDNISOLONE AS FIRST-LINE THERAPY FOR THE TREATMENT OF ACUTE GRAFT-VERSUS-HOST DISEASE - SAFETY AND FEASIBILITY STUDY

Y Wang,[1] XJ Huang,[2] LP Xu,[2] DH Liu,[2] KY Liu,[2] J Wang,[2] H Chen,[2] YH Chen,[2] W Han[2]

[1]*Peking University People's Hospital,Institute of Hematology, Beijing, China, Beijing, China*

Background. The current standard therapy for aGVHD is glucocorticoid methylprednisolone 2mg/kg/d, but it still has drawbacks. Recent studies have suggested that low dose of MTX, in addition to having anti-mitotic effects, can induce a sustained suppression of T-cell activation, supporting its use in GVHD therapy. Our recently published data found that low dose of methotrexate can be used to treat different types of GVHD including aGVHD, cGVHD and post-DLI GVHD as salvage therapy. *Aims.* The current study was initiated to evaluate the safety and both the efficacy of low dose of methotrexate combined with low dose of methylprednisolone as first line therapy in the treatment of acute graft-versus-host disease (aGVHD) after allogeneic hematopoietic stem cell transplantation (allo-HSCT). *Methods.* The study was approved by the Institutional Review Board of the Peking University Institute of Hematology. All included patients were informed and signed an informed consent form. Patients who had not received drug treatments for aGVHD and whose peripheral blood white blood cell counts were higher than 1.5×10^9/L were selected. From May 2007 to June 2008, 32 patients received intravenous MTX at a dose of 10 mg or oral MTX at a dose of 15 mg every 3-7 days (repeated at day three after the first dose and then at a weekly interval) combined with low dose of methylprednisolone (started with 0.5mg/kg/d, and dose was reduced by half after 5-7 days) until a complete or partial response was achieved, or until treatment failure or intolerable side effects were found. Patients were observed for 3-5 days and would be switched to second line treatment (Daclizumab) if no response to first line therapy. *Results.* The median time from HSCT to the start of MTX was 32 days. The median number of MTX administrations was four (range, 2-6). Median time to achieve maximal response (CR or PR) was 5 days. By day 30 after drug administration, accumulated MP dose was 5.78 mg/kg. The overall response rate was 81% (26/32 patients). The response rate for GVHD involving various organs was 88% (23/26) in skin, 75% (3/4) in liver, 81% (9/11) in gut. Six of 32 (18%) patients required Daclizumab as second-line treatment. Grade 3 toxicities occurred in only 3 patients presenting cytopenias. Eighteen of 32 (56%) patients developed cGVHD. Two-year cumulative incidence of leukemia relapse was 7%. Two-year cumulative incidence of TRM was 11%. Twenty-seven patients (84%) remain alive without leukemia relapse with a median survival of 682 days from onset of aGVHD and 699 days from HSCT. The estimated survival at 2 years was 77%. *Summary/Conclusions.* Our study showed that low-dose MTX combined with low dose of methylprednisolone is effective and safe. There are maybe synergistic effect between methotrexate and methylprednisolone. The combination regimen might be eligible for alternative forms of first-line treatment of aGVHD and it is especially preferential for those high risk patients of relapse. However, a randomized, controlled study is needed to compare the results of this new regimen and the standard therapy with methylprednisolone (2 mg/kg/d).

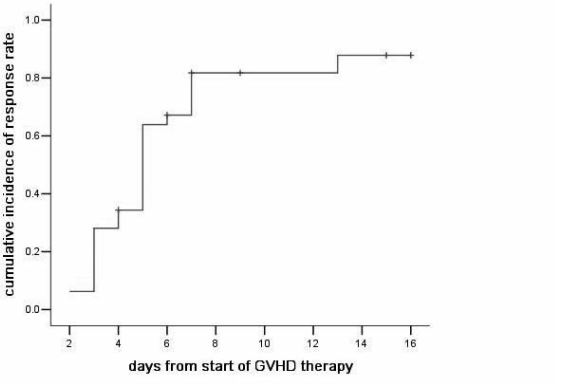

Figure. Cumulative incidence of acute GVHD response.

KINETICS OF IMMUNE CELL RECONSTITUTION FOLLOWING SUCCESSFUL MIXED CHIMERISM BY NONMYELOABLATIVE BONE MARROW TRANSPLANTATION IN MICE

SG Cho,[1] HS Park,[2] HJ Lee,[3] BH Chung,[1] MJ Park,[1] ML Cho,[2] YN Kang,[1] SH Park,[3] JW Park[1]

[1]*Seoul St. Mary's Hospital, The Catholic University of Korea College of Medicine, Seoul, South-Korea;* [2]*A Rheumatism Research Center, Catholic Research Institutes of Medical Science, Seoul, South-Korea;* [3]*School of Life Sciences and Biotechnology, Korea University, Seoul, Korea, Seoul, South-Korea*

Nonmyeloablative bone marrow transplantation (BMT) utilizes low-doses of radiation and relatively nontoxic conditioning. Allogeneic mixed chimeras following nonmyeloablative conditioning showed donor-specific tolerance and superior immunocompetence. In this study, we induced stable allogeneic mixed chimerism by host natural killer (NK) cell depletion and T cell-depleted BM grafts in a major histocompatibility complex (MHC)-mismatched murine model and analyzed the kinetics of donor and recipient engraftment in the weeks following transplantation. Donor BM cells were well engrafted and stabilized without graft-versus-host disease (GVHD) as early as one week post-BMT. Donor-derived thymic T cells were reconstituted four weeks after BMT; however, the emergence of newly developed T cells was obvious at the periphery as early as two weeks after BMT. Also, NKT cells developed four weeks after BMT, and the ratio of recipient- to donor-derived NKT cells was the same twelve weeks after BMT. Interestingly, the emergence of donor-derived antigen presenting cells (APCs) such as dendritic cells (DCs) and B cells was noted as early as one week after BMT, but changed only modestly between weeks 2 and 12 after BMT. Here, we report a kinetic model of the development of donor- and recipient-originated hematopoietic cells in a mouse model of allogeneic mixed chimerism during the early post-transplant period. These data expand our understanding of immune cell reconstitution at early time points after nonmyeloablative BMT and may be used to develop guidelines for the treatment of patients post-BMT.

18F-FLUORODEOXYGLUCOSE POSITRON EMISSION TOMOGRAPHY IN THE DIAGNOSIS OF INTESTINAL GRAFT VERSUS HOST DISEASE: A NEW TOOL?

N Jacque,[1] P Maksud,[1] F Archambaud,[1] R Chollet,[1] JF Finet,[1] S Nguyen,[1] M Uzunov,[1] JP Vernant,[1] N Dhédin[2]

[1]*Hopital Pitie Salpetriere, PARIS, France;* [2]*Hôpital Pitié-Salpêtrière, PARIS, France*

Background. The diagnosis of gastrointestinal graft-versus-host disease (GVHD) after allogeneic stem cell transplantation is usually assessed by

clinical symptoms and histological analyses after digestive endoscopy. This approach is frequently not satisfactory because of its lack of specificity. A murin transplantation model has suggested that inflammatory activity associated with intestinal GVHD can be assessed by 18F-fluorodeoxyglucose positron emission tomography (FDG-PET) *Aim.* We evaluated the relevance of FDG-PET in the diagnosis of intestinal GVHD in transplanted patients. *Methods.* Between February 2008 and March 2009, patients with a suspected diagnosis of gastrointestinal GVHD after haematopoietic stem cell transplantation (HSCT) were enrolled in our study. They were examined by FDG-PET and digestive endoscopy (gastroduodenal fibroscopy, rectosigmoidoscopy and colonoscopy when feasible) with biopsy. Stool samples were screened for bacterial, viral, mycological and parasitic gastrointestinal infections. Patients were systematically screened for adenovirus and cytomegalovirus (CMV) infections by specific PCR in the blood and immunofluorescence in digestive biopsies. *Results.* Eleven patients with clinical symptoms of GVHD in a median time of 35 days (4-392) after HSCT were tested. Two patients had a stage 2 digestive GVHD and 9 patients a stage 3-4. None of them was positive for viral, mycological or parasitic infections in the stool, 6 were colonized with an intestinal bacteria but all were negative for clostridium difficile toxin. One patient presented a CMV colitis based on the biopsy and blood samples. FDG-PET was performed in a median time of 6 days after the beginning of the symptoms (1-159). Seven patients presented a FDG uptake of the gut. All of the 11 patients had sigmoid biopsies, 6 had staged biopsies of all colon and 4 gastroduodenal biopsies. For 6 patients, histological and FDG-PET results were concordant (5 were both positive and 1 both negative). In 3 patients, the FDG-PET showed no uptake whereas the histological analysis was positive. For the 2 remaining patients, FDG uptake was localized in the ileum and therefore not accessible to biopsy. *Conclusion.* FDG-PET is a non invasive tool that can be useful in some patients with suspected intestinal GVHD. This approach may be interesting to guide biopsy when the diagnosis is difficult with the usual assessment, in particularly in the small intestinal localization.

STRATEGIC DESIGN OF THE HELLENIC UMBILICAL CORD BLOOD BANK NETWORK

C Keramydas,[1] A Anagnostopoulos,[2] D Vlachos,[1] E Iakovou,[1]
M Spyropoulou-Vlachou,[3] M Varla-Lefterioti,[4] C Stavropoulos-Giokas[3]

[1]Aristotle University of Thessaloniki, Thessaloniki, Greece; [2]Haematology Dept-BMT Unit-Cell & Gene Therapy Centre, G. Papanicolaou Hospital, Thessaloniki, Greece; [3]Immunology Dept - National Tissue Typing Center, G. Gennimatas Hospital, Athens, Greece; [4]Immunobiology Dept - RSA Clinic, Helena Venizelou Maternity Hospital, Athens, Greece

Background. Umbilical Cord Blood (UCB) has emerged as a widely accepted source of Hematopoietic Stem Cells (HSCs) for allogeneic transplantations thus leading to a number increase of public UCB banks worldwide. In Greece the development of such a UCB bank network is in its infancy, while there are still several issues to be regulated. *Aims.* This research work presents a methodological framework for the systemic design of the Greek National UCB bank network that may be applicable to other countries with no national UCB bank and relatively isolated population. We aimed at the determination of the UCB banks capacity, the key design parameter, including the supplementary cost estimations, banks' location, and personnel planning. *Methods.* The main dataset (histocombatibility data) encompasses: (i) the haplotypes (HLA-A, -B, -DR, all in low resolution) and their frequencies of 7,710 Greek bone marrow and UCB donors (BMDW registry), and (ii) the genotypes (HLA-A, -B in low resolution, and HLA-DR in high resolution) of 410 Greek donors (Greek National Histocombatibility Center). Following the statistical analysis of the available data, extensive Monte Carlo simulation experiments were conducted to determine the quantitative relationship between the inventory level of a national UCB network (capacity planning) and the probability that a transplant candidate finds a matching unit (service level). *Results.* The pivotal result is a methodology for determining the relationship between the inventory level and the service level of a national UCB bank. Specifically, the simulation process outcomes reveal that an inventory of 10,000 cryopreserved UCB units provides a 96% likelihood that a Greek transplant candidate finds a matching unit (4 out of 6 HLA-match/ HLA-A, -B, -DRB1). Taking into account a 60% discard proportion for the donations - according to literature and applied practices - and a realistic annual collection rate of 3,125 units, the desired inventory level could be reached in approximately 8 years. The bank network design documented the need for operating two public UCB banks (dipolar system) located in Athens and Thessaloniki, respectively. The necessary personnel (administrative officers/medical doctors, technicians, employees, and a trainer) are 11 persons per bank during the inventory build-up period and 7 persons per bank during the regular operating period. The initial investment cost is approximately €1.1M, while the inventory build-up cost is estimated at € 12.4M. Additionally, the annual average operational cost (steady-state) is about €1.2M. This cost could be easily balanced by a fee of approximately €7,000 received for every unit used for transplantation, paid by the relative social health insurance companies. *Summary/Conclusions.* The findings document the importance of developing a national UCB bank network, the subsequent improvement in provided health, and economic ramifications, while providing the necessary input for the NHS to decide on developing or not a UCB bank. Furthermore, the entire network's design is feasible and economic sustainable, according to the NHS economic capabilities, the national and European legislation, and the applied practices worldwide. Finally, the support from the Greek government and sponsors are of critical importance for its success.

ELEVATED SERUM FERRITIN AND MAJOR TRANSPLANT-RELATED COMPLICATIONS AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION

D Pastore, P Carluccio, M Delia, A Ricco, F Gaudio, T Perrone,
P Curci, F Laddaga, R Angarano, N Sgherza, V Fesce, G Specchia

Hematology-University of Bari, Bari, Italy

Background. Iron overload (IO), mainly from red cell transfusions, is a frequent condition in hematopoietic stem cell transplantation (HSCT). IO is associated with free radical generation and tissue damage which can increase toxic and infectious events after HSCT. We retrospectively evaluated the clinical impact of pretransplantation iron status on early transplant related toxicity. Patients and *Methods.* The charts of 224 (110 M, 114 F, median age 43 years, range 17-70 years) patients who underwent HSCT [142 autologous (auto) and 82 allogeneic (allo)] were reviewed. Serum ferritin, a surrogate marker of iron overload, was measured before the beginning of the conditioning regimen. The range of diagnoses included 83 patients with acute myeloid leukemia, 35 with acute lymphoblastic leukemia, 2 with myelodysplasia, 45 with myeloma, 59 with lymphoma. In the allo group, myeloablative conditioning was employed for 63 pts and reduced intensity conditioning for 20 pts. The median pretransplant serum ferritin of the 224 patients was 720 ng/mL with values ranging from 20 to 9255 ng/mL. We set 800 ng/mL as the cut-off value for pre-transplant serum ferritin, obtaining a group of 143 patients with ferritin levels <800 ng/mL (low ferritin group) and a group of 81 above the cut-off level (high ferritin group). The effect of elevated pretransplant ferritin on the incidence of mucositis, blood stream infections, day 100 mortality, acute GvHD and invasive fungal disease was assessed. Student's t-test or the Mann-Whitney test was performed for comparisons of means. *Results.* The high ferritin group showed a higher incidence of grade 3 and 4 mucositis than the low ferritin group after both auto (30 % *vs.* 15%, P=0.05) and allo transplantation (34% *vs.* 15%, P=0.03). At univariate analysis, the incidence of bloodstream infections was significantly lower in the low ferritin group after auto (15% *vs.* 30%, P=0.05) and allo HSCT (25% *vs.* 40%, P=0.05). In the autologous group, the high ferritin group had increased day 100 mortality (5% *vs.* 1%, P=0.06). In allogeneic group, the high ferritin group had increased day 100 mortality (due to hepatic veno-occlusive disease, pneumonitis and severe endothelial leakage syndrome) (20 *vs.* 8%, P=0.03), increased acute GvHD grade II-IV (57 % *vs.* 25%, P=0.02), increased invasive fungal disease (18% *vs.* 5 %, P=0.05). The time to engraftment was shorter in the low ferritin (median: 13 days, range: 11-16 days) than the high ferritin group (15 days, 13-23 days) after allogeneic HSCT (P=0.05). *Conclusions.* Pre-transplant serum ferritin was a predictor for major transplant-related complications, especially after allogeneic HSCT. Our results need to be validated by further prospective studies. Methods for modifying IO in candidate patients for HSCT should be developed.

1074

EBMT RISK SCORE IN ADDITION TO HLA-DRB11 AND HLA-A3 PREDICTS NON-RELAPSE MORTALITY IN A SINGLE CENTER ANALYSIS

C Pfrepper,[1] M Scholz,[2] T Lange,[1] W Pönisch,[1] HK Al-Ali,[1] D Niederwieser,[1] N Basara[1]

[1]Department of Hematology/ Oncology/ Hemostaseology, University Hospital Leipzig, Leipzig, Germany; [2]Institute for Medical Informatics, Statistics and Epidemiology, University of Le, Leipzig, Germany

Background. Matched related donor peripheral blood stem cell transplantation (MRD-PBSCT) is associated with a low incidence of non relapse mortality (NRM) and graft-versus-host-disease (GvHD). EBMT risk score for outcome after PBSCT has been shown to be predictive across all disease categories for overall survival (OS) and NRM (Gratwohl *et al.*, Cancer 2009). *Aims.* We have analysed the influence of the EBMT risk score and other patient specific factors in patients undergoing MRD-PBSCT in a single center. The endpoints of this study were OS, relapse incidence (RI), NRM and incidence of acute and chronic GvHD. *Methods.* The outcome of 97 patients undergoing MRD- PBSCT after myeloablative conditioning without T-cell depletion and a post-grafting immunosuppression with cyclosporine and short course MTX was analyzed. The EBMT risk score (disease stage, time from diagnosis to transplant, patient`s age and donor/recipient sex combination) was evaluated and type of disease, conditioning regimen, donor's age, CMV status, and HLA-type added into a multivariate analysis. *Results.* After a median follow up of 42 months OS was 66%, NRM 18% and RI 22% The incidence of acute GvHD grade III-IV was 18%, chronic GvHD was 55% (37% limited and 18% extensive). Main causes of death were: relapse, GvHD and infectious complications in 15, 12, and 6 patients, respectively. In multivariate analysis, patients with a risk score ≥ 4 had a higher NRM (P=0.004), while patients with HLA-DRB1-11 and HLA-A3 had a higher NRM and a poorer OS (P<0.002). Patients with a higher risk score had more skin GvHD grade II-IV (P=0.002), while patients with HLA-C7 had more overall GvHD (P=0.0014). No significant risk factors for the development of chronic GvHD and RI were detected in this analysis. *Conclusion.* In conclusion, EBMT risk score was a predictive factor for NRM and GvHD in a group of patients undergoing MRD-PBSCT in a single center evaluation. In addition, the presence of HLA-C7 was associated with more overall GvHD, while HLA-DRB1-11 and HLA-A3 had a poorer outcome.

1075

ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION (HSCT) IN CHRONIC MYELOID LEUKAEMIA (CML): LONG TERM RESULTS

M Benakli, R Ahmed Nacer, A Talbi, F Mehdid, R Belhadj, M Baazizi, N Rahmoune, F Harieche, F Zerhouni, RM Hamladji

Pierre and Marie Curie Center, Algiers, Algeria

Background. Allogeneic HSCT is recognized as being the only effective treatment in the CML with cure. We report our experiment of this procedure with a comparative study between myéloablative and reduced intensity conditioning regimen. *Material and methods.* From July 98 to June 2009, 274 patients (pts) with CML underwent allogeneic HSCT with HLA identical sibling donors. The myeloablative stem cell transplantation (MST) based on Tushka protocol was employed in 101 pts including 56 in first chronic phase(CP), 39 in accelerated phase (AP) and 6 in blast crisis(BC). The prevention of the graft *vs.* host (GVHD) associated ciclosporine and méthotréxate according to Seattle protocol. The non myeloablative SCT (NST) based on the use of Fludarabine and Busulfan was employed in 173 pts including 149 pts in first CP and 24 in AP. The GVHD prophylaxis consisted of cyclosporine with mycophenolate mofetil. The median age of the pts at transplant for MST and NST is 24 years (4-44) and 36 years (18-55) respectively with a significant difference (P<0.01). The sex-ratio is 1,2 and 0,96 respectively; interval diagnosis was longer in MST pts: 15 months (3-82) than in NST pts: 11 months (4-58) (P<0.01). The grafts used are peripheral blood stem cells (MST=90, NST=173), bone marrow (9 MST) and umbilical cord blood (2 MST). *Results.* Aplasia is occurred in 76 pts (44%) NST group and all pts of MST group (100%), (P<10-8). The incidence of acute GVHD was the same in the MST and NST group (P=0,35) with respectively 48 pts (47,5%) and 72 pts (42,8%). The incidence of chronic GVHD was also the same (P=0.14), 58 MST pts (63.7%) and 114 NST pts (71.2%). The cytomegalovirus (CMV) infection was seen in 23 MST pts (22.7%) and 28 NST pts (16%) without significant difference (P=0.16). Relapse of disease occurred in 15 MST pts (14.8%) and complete remission was obtained in 5 pts (immunosuppression discontinuation :1, DLI: 2 and Imatinib: 2); In the group NST 31 pts relapsed (17,9%) and in 15 pts remission obtained after salvage treatment (immunosupression discontinuation: 8, DLI: 3 and 2d myeloablative allograft: 4) (P=0.7). At December 2009, 56 MST pts (55.4%) and 109 NST pts (63%) are alive with a median follow-up in 69 months and 64 months respectively. The Overall Survival (OS) is 41.9% for the MST group and 56,8% for NST group (P<0.001); Event Free Survival (EFS) is 36.7% and 49.5% respectively with significant difference (P<0.001). *Conclusion.* No differences were observed between MST and NST group concerning acute and chronic GHVD, CMV infection and incidence of relapse. However in long term results, OS and EFS are better in NST group than MST group.

1076

SIGNIFICANCE OF INCREASED BONE MARROW BLASTS AFTER MYELOID ENGRAFTMENT IN ADULT PATIENTS UNDERGOING UNRELATED CORD BLOOD TRANSPLANTATION

A Gascón, P Montesinos, ML Senent, A Sempere, L Cordón, ML Pérez-Sivent, F Gomis, M López, D Martínez, M Roig, I Gómez, M Romero, G Martín, I Lorenzo, S Saavedra, J Sanz, G Sanz, M Sanz

Hospital Universitario La Fe, Valencia, Spain

Background. Abnormal expansion of naïve B-lymphocytes has been reported after unrelated cord blood transplantation (UCBT). In some cases, blastic-appearing lymphocytes may be difficult to distinguish from malignant blasts. *Aims.* Analyze the incidence and significance of an increase in the bone marrow (BM) blast count by cytomorphology after UCBT. *Methods.* Between May 2001 and February 2010, BM samples of patients undergoing UCBT in a single institution were evaluated by cytomorphology and multi-parametric flow cytometry (MPFC). All patients included in the study had myeloid engraftment. BM samples were stained using May-Grünwald-Giemsa stain and viewed under light microscope. Immature B-lymphocytes and leukemic blast cells were discriminated by MPFC on the basis of the normal B-cell maturation using the combination of CD10, CD20, CD19, CD34 and CD45 antigen surface markers. Malignant blastic cells were characterized according to the blast phenotype at diagnosis. BM samples were taken from day +40 to day +365 after UCBT. Chimerism analyses of BM samples using multiplex PCR amplification of short tandem repeat-markers (STR) were also performed. The diagnostic sensitivity and specificity of cytomorphology for the detection of BM leukemia was determined using the MPFC as validation test. *Results.* One-hundred and nineteen samples from 75 patients were analyzed by cytomorphology and MPFC. Median age at UCBT was 32 years (range, 15 to 64), 42 (56%) patients were male and underlying diseases were acute lymphoblastic leukemia (ALL) in 32 (43%), acute myeloid leukemia (AML) in 25 (33%), and other malignancies in the remaining 18 (24%). Non-myeloablative conditioning regimens were used in 9 (12%) patients. The median percentage of blasts in BM samples by cytomorphology was 4% (range, 0% to 95%), and 53 (45%) showed an increase of blasts (≥5%). Thirty-one (58%) of the 53 samples with ≥ 5% blasts by cytomorphology were characterized as non-malignant cells by MPFC. In those samples, the median percentage of blasts by cytomorphology and MPFC were 7% (range, 5% to 14%) and 4% (range, 0.5% to 10%), respectively. Among those 31 samples, the median percentage of lymphocytes by MPFC was 26% (range, 8% to 56%), predominantly corresponding to B-lymphocytes in 28 (90%) cases. In all these cases, STR analyses showed full-donor chimerism. Twenty-two (42%) of the 53 samples with ≥5% blasts by cytomorphology were characterized as leukemic cells by MPFC, with a median percentage of blasts by cytomorphology and MPFC of 50% (range, 9-95%) and 35% (range, 3-93%), respectively. Relapses corresponded to ALL in 13 cases and to AML in 9 cases. No cases of leukemic relapse were detected by MPFC when BM blast count by cytomorphology was <5%. Diagnostic sensitivity, specificity, and positive predictive value of cytomorphology for the detection of BM leukemia were 100%, 75%, and 58%, respectively. ì*Conclusions.* The observation of ≥ 5% blasts by cytomorphology in BM samples after myeloid engraftment in adult patients undergoing UCBT is relatively frequent. However, this finding will indicate in most cases an increase of immature B-lymphocytes that should be distinguished from malignant blasts using MPFC.

1077

CYTOKINE PRODUCTION BY GRAFT CELLS IN RESPONSE TO PATIENT'S ANTIGENS MAY PREDICT THE OCCURRENCE OF ACUTE GRAFT VERSUS HOST DISEASE IN ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FROM A SIBLING

A Kamel, N El-Sharkawy, E Kamal, R Abd El-Fattah, M Abd El-Moeti, H Mahmoud

NCI, Cairo University, Cairo, Egypt

Background. Allogeneic hematopoietic stem cell (HSC) transplantation whether bone marrow (BM) or peripheral blood (PBSCT) is a widely used therapeutic modality. Graft *vs.* host disease (GVHD) continues to be the main concern of transplanters. There is substantial evidence to implicate that cytokines play a major role in GVHD induction and grade. GVHD was reported to be associated with increased production of IFNgamma and IL10. IL 10 cytokine level and gene polymorphism have been used as predictors of acute GVHD (aGVHD). IFNgamma was also reported to have a protective role if administered at the time of transplantation possibly via induction of T regulatory cells and immunological tolerance. *Aims.* The aim of this work was to develop an experimental setup to mimic the response of the immune cells of the graft to the host antigens expressed by cytokine production. The final aim was to correlate the cytokine pattern to the development of aGVHD and verify if this pattern could possibly predict the occurrence of aGVHD. *Methods.* The study included 46 patients who received allogeneic PBSCT from an identical sibling. Under informed consent, a sample was obtained from the patient before conditioning, mononuclear cells separated and cryopreserved. On the day of transplant, the cryopreserved cells were thawed, mitomycin treated to serve as stimulators while the mononuclear cells of the graft served as the responders in a mixed lymphocyte culture setup. After 3 days culture, supernatant was collected and stored at -80 degree C till tested. IFNgamma and IL10 were measured by microbead array technology using luminex 200. Patients were followed up and development of aGVHD was recorded. *Results.* Of the 46 patients, 14 developed aGVHD. In the culture supernatant, cytokines were below the detection limit in 26/32 of cases that did not and in 3/14 of those who developed aGVHD. The level of cytokines in the other cases varied widely. Of the 11 cases that showed cytokine production, 4 produced IFNgamma only and one produced IL10 only. The other 6 cases produced both; IL10 was higher in one case; in the other 5 cases, IFNgamma was much higher. In the 6/32 cases without GVHD, IL10 only was detected in 3 cases; the other 3 cases showed much higher level of IL10 than IFNgamma. At a cutoff level of 15.9 pg/mL, IFNgamma was predictive of aGVHD with a sensitivity of 64.3%, specificity of 96.8% and a total accuracy of 80.4%. At a cutoff of 2.27pg/mL, IL10 showed a sensitivity of 50%, specificity of 80.6% and a total accuracy of 71.1%. At a cutoff of 1.13, IFNγ/IL10 ratio showed a sensitivity of 85.7%, specificity of 83.3% and a total accuracy of 84.6%. *Conclusions. In vitro* cytokine production by graft immune cells in response to host antigens is extremely variable; it may serve as a surrogate system of the immune reaction following allogeneic stem cell transplantation. IFNgamma production apparently reflects potential development of aGVHD while IL10 production is apparently protective. When both are produced the IFNgamma/IL10 ratio is more informative than either alone.

1078

ISOLATED EXTRAMEDULLARY RELAPSES AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR ACUTE AND CHRONIC LEUKEMIAS: A SINGLE INSTITUTE EXPERIENCE WITH 545 PATIENTS

D Kata, T Czerw, G Helbig, M Seweryn, S Kyrcz-Krzemien

Medical University of Silesia, Katowice, Poland

Background. Isolated extramedullary relapses (IER) of leukemias are rare after allogeneic hematopoietic stem cell transplantation (alloHSCT) and the data regarding their incidence in larger series of patients (pts) and long-term outcome are scarce. *Aims and methods.* We retrospectively analysed incidence, clinical presentations, treatment options and long-term outcome of this mode of leukemia recurrence in a cohort of 545 consecutive pts (123 with ALL, 201 with AML, 208 with CML, 13 with CLL) who underwent alloHSCT in our institution between June 1993 and December 2007. 81 pts (34 with ALL, 28 with AML, 17 with CML, 2 with CLL) relapsed (any site). *Results.* 9 (11%) out of all pts who relapsed (4 with B-line ALL, 4 with AML, 1 with CML, F/M 4/5, median age 29 years, range 28 - 44 years) developed IER after a median time of 17 months (mts) (range, 8 - 80 mts) following alloHSCT. We revealed complete donor chimerism in 7/9 studied pts. 4 pts (3 with ALL, 1 with AML) developed skin and/or subcutaneous tissue infiltrates; in one of them (patient with ALL) leukemic tumor of the peritibial soft tissues was additionally observed. Other sites of IER included (No. of cases/diagnosis): leptomeninges of the brain (1/ Ph^+ ALL), paraspinal soft tissues (1/AML), small intestine and the root of mesentery (1/AML), inguinal lymph nodes (1/AML), paranasal sinuses (1/AML). Treatment plans for those IER included (No. of cases/diagnosis): 1/involved-field radiotherapy (IF-RT) followed by chemotherapy (CHT) and interferon-alpha (2/ ALL), 2/ imatinib + CHT + steroids and methotrexate intrathecally (1/ ALL), 3/ imatinib + CHT (1/ ALL), 4/ CHT (2/ AML), 5/ dasatinib (1/ $CD117^+$ AML,), 6/ surgery (1/AML), 7/ surgery + IF-RT (1/CML). 7/9 patients died after a median time of 10 mts (range, 1 - 30) due to resistant systemic relapse and/or infectious complications, 2/9 are currently under CHT. *Conclusions.* Our data indicate that IER following alloHSCT occur predominantly in acute leukemia pts, being rarely observed in pts with CML. No cases of IER have been reported among CLL patients. Sites of IER vary widely among the pts with skin and/or subcutaneous tissue being frequently involved. Local radiation therapy seems to be effective treatment option, but it does not prevent from systemic relapse and should be followed by other therapeutic modalities. Our observations suggest also that insufficient graft *vs.* leukemia mechanism may result in unusual clinical appearance of disease progression, temporarily restricted to focal infiltrates that precede leukemic generalization. Occurrence of isolated extramedullary disease offers only a narrow window for quick intervention, however, optimal treatment remains a challenge.

Stem cell transplantation 3

1079

REVERSE SEROCONVERSION OF HEPATITIS B VIRUS (HBV) AFTER ALLOGENIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN HBV ENDEMIC AREA

S Park, KH Kim, HK Ahn, SJ Lee, JH Yi, CW Jung, DH Kim, JH Jang, WS Kim, SJ Kim

Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South-Korea

Background. Reverse seroconversion (RS) of Hepatitis B virus (HBV), appearance of HBsAg in patients previously negative for HBsAg, has been reported as complication after allogeneic transplantation. But the frequency of RS in literature is very wide range, varies from 14 % to 86%. *Aim.* Korea is endemic area for HBV infection. In this study, we evaluated the changes in HBV serology and examined the prevalence of HBV RS in single center in Korea. In addition, we attempt to evaluate how the HBV serologic status of recipients and donors before transplantation influence on changes in post-transplant HBV serologic status in recipients. *Material and methods.* A total of 288 patients underwent allogeneic hematopoietic stem cell transplantation (HSCT) between February 1996 and June 2008. We reviewed the medical records of 288 patients and examined changes in HBV serology. HBV serologic markers of donors were also evaluated. *Results.* HBsAg and anti-HBs were examined in all 288 patients prior to transplantation; 20 recipients were positive for HBsAg and 268 recipients were negative for HBsAg, and among 268 patients negative for HBsAg before transplantation, the proportion of anti-HBs positivity was 89.6 % (240 of 268 patients). Of the 268 patients, all but 12 patients were assessed for anti-HBc IgG before allo-HSCT; 150 patients (58.6%) had anti-HBc. Among 288 donors, 204 cases had information of HBsAg. Of these 204 donors, 199 were negative for HBsAg and 5 were positive for HBsAg. Among 199 donors without HBsAg, 163 cases were assessed for anti-HBc and 170 cases were assessed for anti-HBs; 57 donors (35.0%) were positive for anti-HBc and 108 donors (63.5%) had anti-HBs before transplantation. With a median follow-up period of 66.9 months (range, 11.6-160.2), 3 of 268 recipients negative for HBsAg before transplantation experienced RS (1.1 %). All of these 3 patients had anti-HBc and anti-HBs before transplantation. Among donors of these 3 recipients, 2 had information about HBV serolologic markers, and both of them were negative for HBsAg and anti-HBs. Of the 168 cases in which HBV serologic markers of both recipients and their donors were evaluated, 14 cases who were negative for anti-HBs prior to transplantation received stem cell from donors who had anti-HBs. Among 12 patients who had follow-up HBV serology, 1 of 4 patients who were in chronic HBV infection experienced HBsAg clearance after transplantation and 5 of 8 patients who had negative HBsAg and negative anti-HBs experienced acquisition of anti-HBs without vaccination. *Conclusion.* In this examination, the prevalence of RS among patients who were negative for HBsAg before transplantation was 1.1 %. This is very low in comparison to the results of other studies in non-endemic area for HBV infection. This might be related to high rate of positivity of anti-HBs in donors. In addition, transfer of anti-HBs from donors to recipients seemed to make adoptive immunity in some patients, which resulted in HBsAg clearance or acquisition of anti-HBs.

LONG-TERM IMPACT OF IMATINIB ON THE OUTCOME OF ALLOGENEIC TRANSPLANTATION IN ADULT PHILADELPHIA-POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA: SIMILAR OUTCOMES BETWEEN REDUCED-INTENSITY AND MYELOABLATIVE CONDITIONING TRANSPLANTS

S Lee,[1] NG Chung,[1] JY Kwak,[2] JA Kim,[1] SK Park,[3] BS Cho,[1] YJ Kim,[1] HJ Kim,[1] CK Min,[1] SG Cho,[1] DW Kim,[1] JW Lee,[1] WS Min,[1] CW Park[1]

[1]*Catholic BMT Center, The Catholic University of Korea, Seoul, South-Korea,* [2]*Chonbuk National University Medical School, Chonju, South-Korea;* [3]*Soonchunhyang University Medical School, Bucheon, South-Korea*

Background. Imatinib in combination with conventional chemotherapy as a front-line treatment have demonstrated an improved complete remission rate and a better outcome in adults with Philadelphia-positive acute lymphoblastic leukemia (Ph-positive ALL). However, despite a short follow-up, most patients who do not undergo allogeneic stem cell transplantation (SCT) eventually relapse and die as a result of disease progression. On the other hand, high transplant-related mortality remains a major obstacle in a subset of transplants, particularly those with advanced age or concurrent co-morbid conditions. From this point of view, it is reasonable to look to reduced-intensity conditioning (RIC)-SCT as a way to provide a graft-versus-leukemia effect and a survival advantage for Ph-positive ALL patients who are poor candidates for myeloablative conditioning (MAC). *Aims.* Previously, we observed the positive impact of imatinib on the outcome of allogeneic SCT in adults with Ph-positive ALL (Blood 2005;105:3449). We report here the updated results of this study with a longer median follow-up of 48 months, and we focused particularly on the role of RIC-SCT. *Methods.* From 2000 to 2008, 92 consecutive adults with newly diagnosed Ph-positive ALL who received allogeneic SCT following imatinib therapy were enrolled in this study. Donor grafts were matched sibling donor (n=55), well-matched unrelated donor (n=15), partially matched unrelated donor (n=12), and mismatched unrelated donor (n=10). Of the whole group, 83 (90.2%) patients were transplanted in CR1. Sixty-nine (75.0%) patients received MAC (total body irradiation-based), and the remaining 23 (25.0%) patients received RIC [fludarabine (150 mg/m^2) plus melphalan (140 mg/m^2)]. The indications for RIC-SCT were: (1) aged more than 50 years (n=7) and (2) decreased organ function or active infections (n=16). All patients received the same graft-versus-host disease prophylaxis consisting of calcineurin inhibitor (cyclosporine for sibling transplants; tacrolimus for unrelated transplants) plus methotrexate. All patients and donors provided written informed consent, and the treatment protocol was approved by the institutional review board of The Catholic University of Korea. *Results.* For all transplants, median age was 35 years (range, 16-59 years). The incidence of acute (grade II-IV) and chronic graft-versus-host disease were 57.3% and 55.3%, respectively. The 4-year cumulative incidence of relapse and non-relapse mortality were 21.1% and 19.3%, respectively, and the 4-year disease-free survival and overall survival rates were 63.1% and 64.4%, respectively. Although RIC transplants were older (45 years *vs.* 30 years, P<0.001) and received peripheral blood stem cells more frequently (91% *vs.* 22%; P<0.001) as compared to MAC transplants, overall transplantation outcomes were not significantly different in terms of relapse (15.2% *vs.* 22.9%, P=0.526), non-relapse mortality (30.8% *vs.* 15.5%, P=0.301), disease-free survival (58.7% *vs.* 64.5%, P=0.834), and overall survival (57.8% *vs.* 66.6%, P=0.687). *Summary/Conclusions.* Our long-term follow-up data suggest that the positive impact of imatinib therapy on the outcome of allogeneic SCT is well preserved. In addition, RIC-SCT is a potential therapeutic approach for adults with Ph-positive ALL who are not eligible for MAC-SCT. Large prospective studies are needed to elucidate the role of RIC-SCT for adult Ph-positive ALL in the era of tyrosine kinase inhibitors.

IN VITRO DIFFRENTIATION POTENTIAL OF MESENCHYMAL STEM CELLS DERIVED FROM NATAL, WISDOM, DECIDUOUS TEETH DENTAL PULP AND HUMAN BONE MARROW: A COMPERATIVE STUDY

A Aksoy, S Ayhan, A Okcu, E Karaöz

Institute of Health Sciences, Kocaeli, Turkey

Background. Their characteristics of high proliferation, self renewal capacity even in later passages, multi-lineage differentiation and their simplicity in the isolation make mesenchymal stem cells (MSCs) considerably important sources for regenerative medicine. Considerably, MSCs obtained from patients and donors can be used in many applications of tissue engineering, in which the obtaining of tissue in most suitable cell/tissue culture conditions by growing the isolated cells on biocompatible/biodegradable scaffold. In particular MSCs derived from different sources were usually used experimentally in the improvement of bone defects and in the development of tissue grafts. *Aim.* It is important to know osteogenic differentiation capacity of MSCs derived from different sources in detail for finding appropriate source in future studies and applications. Because of this reason in our study we used human bone marrow (hBM)(n=3), human exfoliated deciduous tooth dental pulp (hDP)(n=2), human natal tooth dental pulp (hNDP) (n=2) and human wisdom tooth dental pulp (hWDP) (n=2) derived mesenchymal stem cells to determine osteogenic differentiation capacity. *Methods.* All cells were treated with osteogenic stimulatory medium for 30 days and the alkaline phosphatase activity (ALP) assay were performed on the cells at 3., 7., 11., 14. and 21. days after the begining of stimulus. Absorbance was read at 405 nm and ALP activity was normalized by total protein concentration. In addition, at the end of 4 weeks osteogenic differentiation was assessed by staining with Alizarin Red,

Osteocalcin, Osteonectin, BMP2 and BMP4. *Results.* In all groups, cells were displayed positive reaction for osteogenic markers (Osteocalcin, Osteonectin, BMP2 and BMP4), and bone nodules stained with Alizarin Red S were observed. The results demonstrate that in the 3. day from the begining, the ALP activity started to increase and at day 14, activity was highest, and in later days, it decreased in all groups. We determined that hBM MSCs displayes highest capacity for osteogenic differentiation. However, at 7.,11. and 21. days, second highest ALP activity was observed in hNDP-MSCs. *Conclusions.* We demonstrated here that hBM MSCs and hNDP MSCs were most efficient sources for bone tissue engineering researches and their applications. In addition, hDP and hWDP derived mesenchymal stem cells can be use for bone regeneration studies as an alternative source for the reason that these tissues are obtained easy from patients or donors. Although hNDP can be obtained rarely as a potential source of mesenchymal stem cell for tissue engineering applications, they can be used in experimental approaches.

1082

A COMPARISON OF FUNCTIONAL AND PHENOTYPIC FEATURES OF MOBILIZED CD34⁺ CELLS IN PATIENTS AND HEALTHY DONORS BASED ON THE INTENSITY OF THEIR RESPONSE TO G-CSF.

F Bijou,[1] M Hammoud,[1] M Vlaski,[1] P Duchez,[1] JN Milpied,[2] X Lafarge,[1] M Sauvezie,[2] R Tabrizi,[2] J Chevaleyre,[1] R Bouzgarrou,[1] B Dazey,[1] JM Boiron,[1] Z Ivanovic[1]

[1]Etablissement Français du Sang, Bordeaux, France; [2]Hematology, CHU de Bordeaux, Bordeaux, France

Background. Since the mid 1985 the combination of hematopoietic growth factors and/or chemotherapy is applied to allow mobilization of CD34⁺ cells from marrow to the blood. Once harvested, this cell population, containing both progenitors and stem cells (HPC/HSC), has become the common source for autologous or/and allogeneic transplantations procedures. *Aims.* Indeed, the new development of cell-based therapies in hematologic settings requires the understanding of mechanism involved in HPC/HSC migration and cell cycle kinetics during mobilisation. With respect to the percentage and absolute number of CD34+ cells after Granulocyte-Colony Stimulating Factor mobilisation (G-CSF) the patients (Pts) and healthy donors were divided in two groups: Good mobilizers (GM) and poor mobilizers (PM). *Methods.* We studied in their CD34⁺ cells: cell cycle (Ki67/IP staining), clonogenic and *ex vivo* expansion potential, aldehyde deshydrogenase activity (Aldefluor), expression of some adhesion molecules relevant for CD34⁺ cells mobilisation as: VLA-4, LFA-1 and CXCR4. *Results.* Twenty Two Pts (Myeloma=13 and Lymphoma=9) and 9 healthy donors underwent G-CSF mobilisation with or without chemotherapy. CD34⁺ cells were purified using the MACS cell isolation kit and Mini-Macs columns obtaining a purity of more than 88%. Based on the percentage of circulating CD34⁺, 2 populations of subjects were identified (<0.1%: PM and >0.1%: GM). Total white blood cells number was higher in PM arm (48.8 G/l) than in GM arm (36.75) (P=0.03). The median pCD34+ cell was higher in GM (60:31-153) than in PM (35:11-64) (P=0.001). Interestingly, PM showed more G0 cells than GM with mean percentages 46±10 and 31±10 respectively (P=0.004). Indeed, the percentage of the S/G2/M fraction of CD34⁺ cells was higher in GM (2±0.9) than in PM (0.69±0.7) (P=0.002). Moreover, there was a trend to observe a higher total nucleated cells fold expansion potential in PM arm 27±11 *vs.* 17±13 in GM (P=0.06). It should be stressed that those results were observed also when Pts and healthy donors were studied separately. Analysis of ALDH activity revealed an unexpected population of CD34⁺ cells that were ALDH⁺ despite their CD133 negativity. These CD34⁺ALDH⁺CD133⁻ cells were present in both Ps and healthy donors but were more pronounced in Pts (38% in PM *vs.* 9% in GM; P=0.01). Moreover, GM among healthy donors showed more cells expressing VLA-4 (87% *vs.* 61% in PM arm, P= 0.05). The analysis of the data related to neutrophils and platelets recovery after autologous HSC transplantation and available for 16 patients among 22 showed a reduced median duration of neutropenia $<0.5\times10^9$/L in PM (Pts= 6) in comparison to GM (Pts=10) respectively 9 days (7-24) for GM and 7 days (5-8) for PM (P=0.02); while the median duration of thrombopenia $<20\times10^9$/L was: 7 days (4-14) in GM and 4 days (3-5) in PM group. These observations are important since no statistically significant difference was observed in the median number of CD34⁺ cells infused between GM (median 2.42; range 1.5-6.9) and PM (median 3.04; range 1.9-3.9) in these patients not heavily pretreated (1 line=11 Pts, 2 lines=5 Pts). *Conclusion.* These results suggest important phenotypic and functional variations in CD34⁺ cells between PM and GM (cell cycle, expression of CD133 by ALDH⁺ cells) as well as some differences between the healthy donors and Pts (VLA-4 expression). These differences are confirmed as for the early neutrophils and platelet engraftment after myeloablative chemotherapy. Further studies will be required on a larger cohort of Pts and healthy donors in the context of rapid and durable recovery of hematopoietic function.

THE IMPACT OF MINOR HISTOCOMPATIBILITY ANTIGENS MISMATCH ON SIBLING CORD BLOOD TRANSPLANTATION FOR THALASSEMIA

M Guarene,[1] C Badulli,[1] C Capittini,[1] AL Cremaschi,[1] G Giorgiani,[2] P Bergamaschi,[3] C Tinelli,[4] V Genovese,[3] A Marchesi,[3] B Romano,[3] F Locatelli,[2] M Martinetti,[1] L Salvaneschi[3]

[1]Immunogenetics Lab, Transfusion Med. Dept., IRCCS Policlinico S. Matteo Found., Pavia, Italy; [2]Onco-Haematology, Dept. of Paediatrics, IRCCS Policlinico S. Matteo Found., Pavia, Italy; [3]Pavia CBB, Transfusion Med. Dept., IRCCS Policlinico S. Matteo Found., Pavia, Italy; [4]Dept. of Statistics, IRCCS Policlinico S. Matteo Found., Pavia, Italy

Cord blood (CB) transplantation from HLA-identical siblings is becoming an effective treatment for thalassemic patients, for whom HLA compatibility represents a stringent requirement. Besides major histocompatibility complex (MHC) antigens, minor histocompatibility antigens (mHAgs) may be considered to play a role in this setting. In HLA identical sibling transplantation, mHAgs mismatches can lead to T-cell activation with specific alloreactivity against recipient's or donor's antigens, thus supporting the Graft-Versus-Host Disease (GVHD) or rejection response respectively. To investigate the role of mHAgs, 9 thalassemic patients and their CB sibling donors were typed for 12 mHAg : HA-1, HA-2, HA-3, HA-8, HB-1, ACC-1, ACC-2, CD31 (codons 125, 563 and 670), CD62L (codons 206 and 213), PANE-1, UGT2B17, SP110 (mHA Minitray kit, University Clinic Heidelberg, Germany). The characteristics of CB units are shown in the table. The patients were omogeneous for age, weight, diagnosis, conditioning regimen and GVHD prophylaxis. Moreover each donor/recipient pair was HLA identical (two digits for the class I and four digits for the class II). The examined group represented an ideal model thanks to the characteristics of the patients, that are well standardized allowing to exclude other variable factors related to donor (HLA and cell dose) and transplant (conditioning and GVHD prophylaxis regimen). We studied the mHAgs-mismatching grade in both GVHD and rejection directions. As shown in the graph, the greater was the number of donor *vs.* recipient mismatches the shorter was the neutrophil and platelet recovery time; on the contrary, the recovery time increased considering the recipient *vs.* donor disparities. All patients are alive and well, no-one developed acute or chronic GVHD. Moreover no-one experienced graft failure, all recipients reaching full-donor chimerism, except of two (10% recipient residue) and one (20% recipient residue).

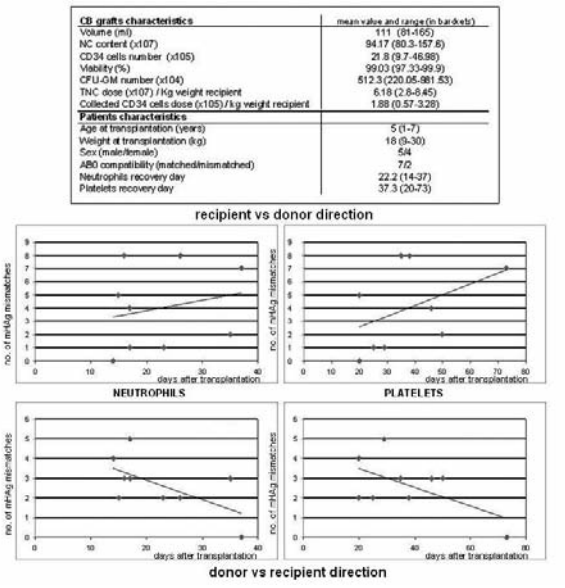

Figure.

The lower impact of donor *vs.* recipient mHAgs mismatches on the recovery times confirmed the natural tolerogenicity of the CB graft. All the more so because for thalassemia patients no Graft-Versus-Leukemia

(GVL) effect is required and even a light GVHD risk is not accettable. On the contrary, recipient *vs.* donor mHAg mismatches correlated with delayed engraftment of neutrophils and platelets. The analysis of these nine patients showed that the the recipient presenting the lower recovery time (+14 days for neutrophils and +20 days for platelets) had no recipient *vs.* dionor mismatches. Consequently recipient's T-cells recognizing mismatched mHAgs of the cord could be responsible for the delayed recovery. Anyway the disparities analyzed seemed not to translate into a concrete increased risk of graft failure, as the observed recovery times remained under a minimum limit and all patients engrafted. Further investigations are needed to confirm the role of mHAgs by enrolling in the study an increased number of patients and performing a qualitative analysis of mHAgs, in particular the most immunogenic phenotypes.

1084

LONG-TERM IMMUNE RECONSTITUTION FOLLOWING STEM CELL TRANSPLANTATION IN CHRONIC LYMPHOCYTIC LEUKEMIA

E Hodgson, G Ferrer, C Martinez, M Juan, M Rovira, M Aymerich, L Carretero, F Fernández-Avilés, E Carreras, E Montserrat, C Moreno

Hospital Clinic, Barcelona, Spain

Background. Chronic lymphocytic leukemia (CLL) is associated with profound immune disturbances, which are exacerbated by therapy. Although CLL is still considered incurable, long term remissions are observed in patients after allogeneic stem cell transplantation (SCT). The extent of recovery of immune function in such patients remains unknown *Aim.* To investigate the immune function of 21 patients with CLL who were in long complete remission following autologous (n=6) and allogeneic (n=15) SCT. *Methods.* Lymphocyte subsets were studied using multiparameter flow cytometry and compared to healthy controls. Immunoglobulin subtypes, complement proteins, and β2-microglobulin (B2M) were quantified by standard techniques and IL-10 and VEGF by flow-based cytometric bead array technology. CD8+ T cell response to CMV was assessed using a pentameric HLA-A2 binding CMV pp65-derived peptide and functionality was confirmed using an interferon gamma (IFNγ) ELISPOT. *Results.* Median age was 51 (range, 33-64) and median follow-up since SCT was 6 years (range, 2-17). Three patients had chronic graft-versus host disease (cGVHD) at sample collection, with two receiving immunosuppression. Three patients (all post allogeneic SCT) had detectable residual CLL cells ($>10^{-4}$) in peripheral blood despite being in CR. In the remaining 18 patients with no detectable minimal residual disease (MRD), normal $CD19^+CD5^-$ and $CD19^+CD5^+$ B cell populations were higher than in healthy individuals (160/mm^3 *vs.* 88/mm^3; P=0.008 and 24/mm^3 *vs.* 1/mm^3; P=0.003 respectively). Although CD4 and CD8 counts were similar in patients and controls, an abnormal CD4:CD8 ratio was seen in 8 out of 21 patients and 4 patients had a $CD4^+$ T cell count <400/mm^3. In contrast, $CD8^+$ T cells with a chronically activated phenotype, $CD3^+CD8^+DR^+$, were significantly elevated compared to controls (200/mm^3 *vs.* 78/mm^3; P=0.05). The nine CMV^+/HLA-A2 patients all showed specific cytotoxic $CD8^+$ T cells which exhibit predominantly a $CD45RA^+CD27^-$ phenotype. An expansion of $CD45RA^+CD27^-$ cells was only observed in CMV positive patients. The ability of these cytotoxic T cells to secrete IFNγ in response to pp65 was confirmed by ELISPOT. All patients showed a functional response to a peptide pool containing a mixture of CMV, EBV and influenza peptides. $CD4^+CD25^+FOXP3^+$ regulatory T cells were significantly elevated in CLL patients compared to controls (3.6% *vs.* 1.95% of $CD4^+$ cells; P=0.03). There were no quantitative abnormalities in $CD3^-CD56^+$ cells. Prior to transplant, hypogammaglobulinemia was present in most of the patients. Fourteen patients restored their serum levels of immunoglobulin after SCT whereas 7 patients persisted with hypogammaglobulinemia. Three of these were in CR but MRD positive, and two patients were receiving immunosuppression for cGVHD. Only two patients had otherwise unexplained persistent hypogammaglobulinemia. Complement proteins C3 and C4 were all within the normal range. The direct Coombs test (DCT) was also negative in all patients. B2M levels were increased (>2.5 mg/dL) in 5 out of 21 patients. No significant differences were found in IL-10 and VEGF levels between patients and normal controls. *Conclusion.* These data suggest that immune function is not completely restored in CLL patients with a long CR post-SCT, even in those who are MRD negative.

1085

ASSESSMENT OF IRON OVERLOAD WITH T2*MRI IN EX-THALASSAEMIC PATIENTS AFTER STEM CELL TRANSPLANTATION: AN INTRIM REPORT

F Moeininia, A Ghavamzadeh, A Hamidieh, F Moeininia, K Alimoghadam, M Jalili, A Shamishiri

Hematology-Oncology and Stem cell Transplantation Research Center, Tehran Univer, Tehran, Iran

Background. The excess iron acquired during years of thalassaemia eliminate slowly after hematopoetic stem cell transplantation (HSCT). T2* relaxation time approach could be used as an appropriate and non invasive method in the assessment of myocardial and liver iron overloaded after HSCT. *Aims.* To assess the changes of myocardial and liver iron concentration after successful HSCT by T2*MRI. *Methods.* Fourteen beta-thalassaemic patients were assessed for tissue iron overload by serum ferritin level, liver biopsy and T2* MRI of heart and liver before HSCT and at the end of sixth month of ex-thalassaemia feature. Chelation was not started in this time. *Results.* Myocardial T2* (mean 23.47ms ±10.91 befor, *vs.* 20.03 ms±9.77 SD, after) and liver iron concentration estimated by MRI (mean 5.23mg/g±3.33 befor, *vs.* 5.34 mg/g±3.13 SD, after) and liver iron score were not changed significantly after 6 months ex-thalassaemia feature. There was no significant correlation between myocardial T2* values and liver iron concentrations either before or after HSCT. Although serum ferritin levels and liver T2* 6 months after HSCT were correlate significantly (P<0.001), it was not true for myocardial values. *Conclusions.* T2*MRI allows monitoring of iron deposition in a non invasive way after HSCT and could be even used instead of liver biopsy before HSCT in beta-thalassaemia patients. Serum ferritin is an inaccurate parameter to guide iron chelation after transplantation but T2* values before HSCT are usually enough for early treatment.

1086

A SHORT BORTEZOMIB-COURSE RESTORES THE BLUNTED IMMUNOMODULATORY PROPERTIES OF MESENCHYMAL STEM CELLS IN AN INFLAMMATORY MILIEU OF EXPERIMENTAL ARTHRITIS, PROVIDING SIGNIFICANT CLINICAL BENEFIT

A Papadopoulou,[1] M Yiangou,[2] E Athanasiou,[1] P Kaloyannidis,[1] D Bougiouklis,[1] A Anagnostopoulos,[1] A Fassas,[1] E Yannaki[1]

[1]George Papanicolaou Hospital, Thessaloniki, Greece; [2]Aristotle University, Thessaloniki, Greece

Background. Mesenchymal stem cells (MSCs) exert unique immunomodulatory properties and currently a lot of research has been dedicated to the investigation of MSCs in autoimmune diseases. However, their potential in treating rheumatoid arthritis in animal models has been thus far contradictory. The inflammatory milieu in collagen-induced arthritis (CIA) has been proposed to inhibit their immunosuppressive effects preventing thereby their speculated therapeutic benefit (Djouad *et al.*, Arthr Rheum 2005). In other reports, infused MSCs were shown to ameliorate CIA (Augello *et al.*, Arthr Rheum 2007/Gonzalez *et al.*, Arthr Rheum 2009). We have shown (under revision) that Bortezomib (Bzb), a potent NF-kb inhibitor, significantly ameliorates advanced adjuvant-induced arthritis (AA) by reducing inflammation and bone loss. *Aims.* We sought to investigate whether MSCs could play a therapeutic role in a rat model of AA. Given the strong anti-inflammatory capacity of Bzb, we also explored the effect of a short Bzb-course, aiming to alter the inflammatory AA environment before MSCs infusion. *Methods.* Bone marrow-derived MSCs were identified by FCM analysis and differentiation assays for trilineage potential. Four groups of animals were tested: AA control, MSCs-alone, Bzb-alone and Bzb+MSCs. Bzb (0.25 mg/kg, ip) was initiated at the onset of arthritis (day 13,16,19 after AA-induction) and 8-14×10^6/recipient allogeneic (allo) MSCs were infused ip during advanced disease (day 21, 25 after AA-induction). Rats were sacrificed and target tissues excised for analysis on d32. The proliferation of AA-Fibroblast-Like Cells (FLS) and Con-A activated AA-splenocytes (SPLCs), cultured in the presence or absence of MSCs or MSC supernatant (sup), was measured by thymidine incorporation. $CD4^+/CD25^+/Foxp3^+$ (T-reg) cells in blood were determined by FCM. A pattern of pro- and anti-inflammatory cytokines in serum and in the sup of cultured SPLCs was measured by a cytometric bead array. *Results.* AA-FLS or Con-A activated AA-SPLCs cultured in the presence or not of MSCs sup, were inhibited in a dose-dependent manner (P=0.02 P=0.018, respectively). Cell to cell contact of MSCs with AA-SPLCs -even at a minimal ratio of MSCs/SPLCs 0.05/1- resulted in profound inhibition of SPLCs proliferation(P=0.000004). Despite

the strong inhibition *in vitro* of AA-target cells by MSCs, AA-rats treated with MSCs-alone didn't show signs of improvement compared with control rats. In contrast, Bzb+MSCs-treated animals demonstrated significantly decreased arthritis score over AA-, MSCs-alone- Bzb-alone-treated animals (4.3±0.8 *vs.* 9.3±2.2 *vs.* 10.3±2.0 *vs.* 7.5±2.5/P=0.005, P=0.009, P=0.03, respectively). The clinical remission was in line with markedly improved joint histology. After Bzb and before MSCs infusion (day21) a significant increase of blood T-regs and restoration of SPLCs proliferation was observed in treated animals and both were further improved after MSCs infusion. An altered cytokine secretion pattern (decreased levels of IL-6, TNF-a) was detected in serum of Bzb-treated rats before the infusion of MSCs. After infusion of MSCs, increased IL-10 and decreased IFN-γ were counted in the sup of SPLCs from Bzb+MSCs-treated rats. *Conclusions.* MSCs exert clinical benefit in AA only in combination with Bzb. Early administration of a short Bzb-course allows MSCs to retain their immunomodulatory function by probably altering the inflammatory AA milieu.

THE COMBINATION OF AMD3100 + G-CSF SUCCESSFULLY MOBILIZES HSCS INTO THE PERIPHERAL BLOOD COMPARED TO G-CSF ALONE, IN A THALASSEMIC MOUSE MODEL

N Psatha,[1] E Yannaki,[1] E Athanasiou,[1] E Sgouramalli,[2] O Mantenoudi,[2] M Arsenakis,[2] A Anagnostopoulos,[1] A Fassas[1]

[1]George Papanicolaou Hospital, Thessaloniki, Greece; [2]School of Biology, Aristotle University, Thessaloniki, Greece

Gene therapy (GT) for thalassemia has been recently brought to the clinic and G-CSF-mobilized hematopoietic stem cells (HSCs) may represent the optimal source of autologous cells for genetic modification due to the higher yield of $CD34^+$cells compared to bone marrow (bm) harvest. We have previously shown that G-CSF-mobilization in thalassemic (HBBth-3) mice is less efficient than normal (C57Bl6) mice due to increased trapping of hematopoietic stem (Lin-sca-1+ckit+/LSK) and progenitor (CFU-GM) cells in the enlarged thalassemic spleen. AMD3100, a reversible inhibitor of the CXCR4/SDF-1 interaction, has been shown to induce rapid mobilization of $CD34^+$ cells in healthy donors and cancer patients. In the current study we explored whether AMD alone or in combination with G-CSF could improve the mobilization efficiency of thalassemic mice. C57Bl6 and HBBth-3 mice received G-CSF-alone (250 μg/kg×7days), AMD-alone (5 mg/kg×3days) or the combination of two. Hematopoietic tissues (blood, bm, spleen) were collected and the LSK and CFU-GM were assayed (by FCM and clonogenic assays) and calculated in absolute numbers. Spleen weight was determined as a ratio (×1000) to body weight. For migration assays, bm cells were cultivated in transwell system in the presence or not of the chemoattractant SDF-1. AMD-alone didn't significantly improve the HSC yield in thalassemic mice as compared to G-CSF mobilization (LSK/μL blood:103±85 *vs.* 67±19, P=ns). In contrast, the combination of AMD3100+G-CSF restored the less efficient mobilization (LSK cells/μL blood: 224±104 *vs.* 67±19 P=0.04, CFU-GM/mL blood: 1671±984 *vs.* 330±123 P=0,05, respectively) and resulted in successful mobilization at levels comparable with normal G-CSF-mobilized mice (LSK cells/μL blood:224±104 *vs.* 197±162 P=ns, CFU-GM/mL blood:1671±984 *vs.* 1429±1020 P=ns, respectively). AMD released stem cells to the circulation by detaching them from bm because reduced numbers of bm LSK cells were counted in the AMD-alone as compared to the untreated group (LSK/2 femurs×10^3: 692±429 *vs.* 1472±1049, P=0,05). In contrast, G-CSF mobilized HSCs by inducing bm hyperplasia before peripheralization of HSCs (LSK/2femurs×10^3: 2684±1743 *vs.* 1687±1016 P=0.02 / CFU-GM/2femurs:111841±15391 *vs.* 76774±31728 P=0.01). In contrast also to G-CSF, AMD-alone did not cause increased trapping of stem and progenitor cells in the spleen and importantly, it rather forced the egress of HSCs from the spleen (LSK cells/spleen×10^3, *vs.* the untreated condition: 5719±2999 *vs.* 8303±4515 P=0.1). Consequently, the addition of G-CSF to AMD did't not induce marrow hyperplasia (LSK/2femursX103 *vs.* untreated: 1681±862 *vs.* 1472±1049, P=ns/ CFU-GM/2femursX102: 863±262 *vs.* 887±317, P=ns) or increased splenic accumulation of HSCs (LSK cells/spleen×10^3: 8415±3718 *vs.* 8303±4505 P=ns) compared with the steady-state condition. Although AMD-alone didn't significantly increase the spleen size in thalassemic mice [spleen ratio (vs untreated): 26±4,1 *vs.* 23±3.3, P=ns], the combination of AMD3100+G-CSF still resulted in significant spleen size increase over the untreated condition (31.6±8,6 *vs.* 23±3.3, P=0,02). Bm cells of the AMD+G-CSF group demonstrated increased migration to SDF-1 compared with AMD-alone, G-CSF-alone and steady-state condition (57% *vs.* 17% *vs.* 28% *vs.* 18.4%) implying a better engraftment profile after transplantation. AMD3100+G-CSF may be proved beneficial for obtaining high numbers of HSCs with enhanced engraftment potential in a thalassemia GT setting.

OLDER AGE, THE NUMBER OF PRECEDED EVENTS OF ACUTE KIDNEY INJURY AND THE IN VIVO T CELL DEPLETION ARE RISK FACTORS FOR KIDNEY INJURY AFTER HEMATOPOIETIC CELL TRANSPLANTATION

I Sakellari,[1] G Bamichas,[2] A Barbouti,[1] D Mallouri,[1] S Fragidis,[2] C Apostolou,[1] V Konstantinou,[1] E Yannaki,[1] M Partsiali,[2] K Sombolos,[2] A Fassas,[1] A Anagnostopoulos[1]

[1]Haematology Department-BMT Unit, G.Papanicolaou Hospital, Thessaloniki, Greece, Thessaloniki, Greece; [2]Nephrology Department, G. Papanicolaou Hospital, Thessaloniki, Greece, Thessaloniki, Greece

Background. Chronic kidney disease (CKD) is one of the late effects following allogeneic stem cell transplantation (HCT) and has been associated with a variety of factors. *Aim.* Evaluation of Kidney injury after hematopoietic cell transplantation in terms of incidence, risk factors and outcome. *Methods.* We retrospectively evaluated the development of CKD in 164 patients (pts), aged 9-65 years, after a median follow up of 7 (3-120) months. The patients underwent HCT for hematological disease from sibling (137) or unrelated donors (27) after myeloablative (144) or reduced intensity conditioning regimens (20) and survived for at least 3 months post transplantation (median follow up 23.5 months). CDK was defined as a GFR<60 mL/min/1.73 m^2, estimated by the modification of diet in renal disease (MDRD) formula and the Schwartz formula for children. *Results.* The median time for CKD development was 6 months with a probability of 23.8% at 18 months. The mean value of preHCT- GFR was within normal limits (111.5±26) for pts who did not develop CKD and 97.21±19 for those who developed CKD, while the GFR at 12 months post transplant was 108±28 and 54.7±5.4 (ml/min/1.73 m^2), respectively. The course of CKD was asymptomatic until the end-stage disease when 3 pts were on dialysis and 1 patient received a renal transplant from his mother. On univariate analyses, the probability of developing CKD was 25% at 18 months for pts with 0 or 1 event of kidney injury *vs.* 60% for those with 2-5 preceded events (P:0.006). The type of conditioning, hyper fractionated TBI, administration of Thiotepa or Fludarabine, acute or chronic GVHD, the toxicity of antiviral or antifungal treatment did not correlate with the CKD. Calcineurin inhibitors were not included as risk factors because of the universal administration as prophylaxis and because of their toxicity appearing in the long term treatment. On multivariate analysis, the only predictive factors were older age (P=0.01), the number of preceded events of acute kidney injury, and the *in vivo* T cell depletion with antithymocyte globulin or alemtuzumab (0.013). The CKD did not influence the non relapse mortality of the HCT. Summary/*Conclusions.* Kidney injury seems to be an early complication after hematopoietic cell transplantation because the number of preceded events of acute kidney injury, *in vivo* T cell depletion and older age were found to be the main risk factors in multivariate analysis. The profound lymphocytopenia of T-cell depletion might possibly be related to an excess of secretion of the transforming growth factor beta (TGF beta) which may promote early and rapid renal fibrogenesis. Close monitoring of the patients for early events of acute kidney injury due to drug toxicity is necessary for CKD prevention.

Plerixafor is a CXCR4 receptor inhibitor which was recently introduced for stem cell mobilization in myeloma and lymphoma patients

identified as proven or predicted poor mobilizers. In order to assess the efficiency and factors affecting the outcome of plerixafor-based stem cell mobilization, we retrospectively collected data from 11 Polish centers that used this drug. In total, data regarding 57 patients was collected. 21 of them (37%) suffered from multiple myeloma, 17 of non-Hodgkin's lymphoma (30%) and 19 of Hodgkin's lymphoma (33%). The ratio of males to females was 32/25 and the median age was 51 (range 19-71). All of them have been treated with chemotherapy with the median of 12 courses (range 4-37). 14 patients (25%) have been treated with radiotherapy and 10 (18%) underwent autologous hematopoietic stem cell transplantation in the past. 48 patients (84%) failed at least one previous mobilization attempt, while in 9 (16%) plerixafor was used in first-line mobilization. At the time of mobilization with plerixafor, 24 (42%) were in complete remission, 25 (44%) in partial remission, 5 with stable disease (9%) and 3 (5%) with progressive disease. In 9 patients (16%) plerixafor was added to chemotherapy-based mobilization regimen. Based on available data, median number of 22 circulating $CD34^+$ cells/μL (range, 0-121) was observed following first plerixafor administration and in 28 patients (60%) it exceeded the No. of 20 $CD34^+$ cells/μL. In 48 patients (84%) median of 2 leukapheresis were performed (range 0-4) and the median No. of $2,8\times10^6$ $CD34^+$ cells/kg b.w. was collected (range 0,17-8,0). The total dose of $> 2,0\times10^6$ $CD34^+$ cells/kg b.w. required for autologous stem cell transplantation was collected in 38 patients (67%). The median No. of nucleated cells in stem cell product was 10.2×10^8/kg b.w. (range 1.3-40.4) and the median volume was 650 mL (range 169-2050). The univariate analysis (Chi-Square Test) revealed that diagnosis of non-Hodgkin's lymphoma, previous radiotherapy and mobilization line >2 were associated with significantly lower probability of collection of sufficient No. of $CD34^+$ cells. Only 41% of patients with non-Hodgkin's lymphoma *vs.* 76% of myeloma and 79% of Hodgkin's lymphoma patients have been efficiently mobilized ($P<0.05$). Similarly, only 43% of patients after radiotherapy collected required No. of $CD34^+$ cells compared with 74% of patients not treated with radiotherapy ($P<0.05$). All patients who received plerixafor in first mobilization attempt collected required No. of stem cells, contrary to 60% of those who failed at least one previous mobilization ($P<0.05$). This has been confirmed in multivariate logistic regression analysis and age adjusted relative risk for collection of sufficient number of $CD34^+$ cells was higher for patients without previous radiotherapy and lower for NHL patients (Odds Ratio 5.,74 and 0.09, correspondingly). In summary, plerixafor-based mobilization regimen was proven successful in majority of patients and it seems to be affected by similar risk factors as traditional mobilization regimens. However, in order to make final conclusions, collection of data from larger number of patients is warranted.

GRAFT-VERSUS-TUMOR EFFECT OF CHRONIC GRAFT-VERSUS-HOST DISEASE IN THE SETTING OF UNRELATED TRANSPLANTATION

BS Cho, SA Yahng, SE Lee, KS Eom, YJ Kim, HJ Kim, S Lee, CK Min, SG Cho, DW Kim, WJ Lee, WS Min, CW Park

Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, South-Korea

Background. Recently, there has been a marked increase in the number of unrelated hematopoietic stem cell transplantation (URD-SCT). The use of peripheral blood stem cells (PBSCs) has been rapidly increased in the setting of URD-SCT, which is caused by easy acquisition and donor choice, and previous reports demonstrating more rapid engraftment, similar survival outcomes and graft-versus-host disease (GVHD) rates compared to bone marrow (BM) stem cells. Recent some reports also raised concerns of late chronic GVHD-related morbidity and mortality. However, there has been few data about the presence of graft-versus-tumor (GVT) effect in the setting of URD-SCT. *Aims and methods.* To investigate the effect of pre-transplantation factors such as stem cell source, infused cell numbers, conditioning intensity, and the kind of donor registries on key outcomes and the presence of GVT effect, we retrospectively analyzed 303 patients who underwent URD-SCT from January 2003 to December 2008 for hematologic diseases in Catholic Blood and Marrow Transplantation Center. *Results.* HLA matching was based on molecular typing for HLA-A, -B, -C and DRB1, and well-matched cases, partially mismatched cases, and mismatched cases were 46%, 40%, and 14%, respectively. Donors were found in two Korean registries (78%) and four foreign registries (22%). Stem cell source consisted of BM (60%) and PBSCs (40%), and disease status at transplantation were standard (81%) and advanced (19%). The intensities of conditioning regimens were myeloablative (MAC, 76%) and reduced-intensity conditioning (RIC, 24%). With a median follow-up of 33 months (range, 3-76), 3-year overall survival (OS), disease-free survival (DFS), and cumulative incidences of relapse (RI) and non-relapse mortality (NRM) were 58%, 51%, 26% and 24%, respectively. The cumulative incidences of acute GVHD grade II-IV and chronic GVHD were 53% and 59%. On multivariate analyses, both mismatched HLA and advanced disease status at transplantation were major independent factors predicting lower OS and DFS, and higher NRM. Additionally, NRM was significantly higher in patients transplanted from four foreign registries compared to two Korean registries, but they included significantly higher number of donors with mismatched HLA and recipients with malignant diseases or advanced disease status at transplantation. The use of PBSCs was an independent factor associated with the development of both acute and chronic GVHD. On the other hand, there were no differences of key outcomes according to stem cell sources (BM *vs.* PBSCs), conditioning intensity (MAC *vs.* RIC), and infused cell numbers of $CD34^+$ or $CD3^+$ cells in both all patients and patients who received PBSCs. Notably, in patients with malignant diseases, we found that patients who developed chronic GVHD had significantly higher OS and DFS, and lower RI on multivariate analyses adjusted with significant pre-transplantation factors affecting each outcome, which reflects the presence of GVT effect in the setting of URD-SCT. *Conclusion.* These single center data demonstrated the GVT effect of chronic GVHD in the setting of URD-SCT, in contrast to CIBMTR data (Biology of Blood and Marrow Transplantation 2007:13;1461-8). It should be further investigated with large prospective studies of homogeneous cohort.

1091

IRON OVERLOAD IN HEMATOPOIETIC STEM CELL TRANSPLANT (HSCT) RECIPIENTS

AJ Gonzalez Huerta, C Buesa, F Taboada, S Gonzalez, E Colado, E Baniela, J Carbajal, C Rayón, C Vallejo

Hospital Universitario Central de Asturias, Oviedo, Spain

Background. transfusional iron overload (IO) can cause severe long term morbidity among HSCT recipients. Objective: to analyze the iron status of multitransfused HSCT pts and the effectiveness of iron depletion therapy of those with IO. Patients and method: during the period Sept'04 - Sept'09, 213 HSCT were performed in our institution. Since the majority of the pts had been referred for HSCT from different centers and were discharged from our institution by day +100, we do not have a proper follow-up of a good proportion of them. Long-term surviving pts who continued their follow-up at our Center were screened with serum iron studies after day +180. To be considered evaluable, high ferritin levels had to be confirmed at least twice at a minimum interval of one month, and any concomitant acute process had to be ruled out.

Table .

Type of depletion	Pts	PRBC Transfused	Ferritin (ng/ml) pre-depletion	Ferritin (ng/ml) post-depletion	Phlebotomies to ferritin <1000 ng/ml	Months to ferritin <1000 ng/ml
Phlebotomies	9	14-55*	1039-6647*	217-925*	3-27*	3-28*
Deferasirox	5	26-70*	1289-2673*	362-494*	-	1-2*
Both	1	26	3047	395	8	9
*Range						

Results. fifty-nine pts were fully evaluable (54% male, 46% female). Median age was 53 years (range: 9-68). The pts were diagnosed with: 16 MM (27%), 11 NHL (19%), 8 AML (13%), 6 ALL (10%), 6 HL (10%), 4 MDS (7%), 3 CLL (5%), 3 AA (5%), 1 CML (2%), and 1 WM (2%). Twenty-nine pts (49%) had undergone allo-HSCT (21 from matched sibling donors, 8 from unrelated donors) and 30 (51%) auto-HSCT. Median follow up was 12 months (6-45). The patients received 1 to 70 PRBC units. Eighteen pts were transfused with more than 20 PRBC and 41 pts got less than 20 PRBC. Among the first group of pts, 89% (16/18) reached ferritin levels > 1000 ng/mL (median: 1742; range: 1025-6647). Among the second group of pts, just 7% (3/41) reached ferritin levels

> 1000 ng/mL; the median ferritin of the resting 38 pts was 316 ng/mL (range: 67-872). No pts transfused with less than 13 PRBC had ferritin levels > 1000 ng/mL. Fifteen (79%) out of the 19 pts with ferritin levels > 1000 ng/mL underwent some kind iron depletion therapy: 9 with repeated phlebotomies (all allo-HSCT), 5 with deferasirox (4 allo-HSCT, 1 auto-HSCT) and 1 pts with both (allo-HSCT) (see table); the remaining 4 pts with ferritin >1000 ng/mL (6 to 9 months after auto-HSCT) are currently been evaluated for depletion. Allo-HSCT pts who received deferasirox were included in a multicenter clinical trial. (Introduced Table). *Conclusions.* 1. A good correlation was found between the number of PRBC units transfused and the serum ferritin six months post-HSCT, measured under appropriate conditions. 2. Phlebotomies and deferasirox were effective for iron depletion. 3. Deferasirox was well tolerated and faster than the therapeutic program of phlebotomies for reducing IO in the post-HSCT setting.

1092

ROLE OF IMMUNOSUPPRESSIVE TOTAL NODAL IRRADIATION-BASED RECONDITIONING REGIMENS AFTER GRAFT REJECTION OR GRAFT FAILURE IN PEDIATRIC PATIENTS TREATED WITH MYELOABLATIVE ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

F Heinzelmann, P Lang, R Handgretinger, F Paulsen, M Bamberg, M Bleif

University of Tuebingen, Tuebingen, Germany

Background. Primary non-engraftment or early graft rejection after myeloablative allogeneic hematopoietic stem cell transplantation (=HSCT) represent a life-threatening complication because patients are often in poor clinical condition and at high risk for fatal infections increasing with time of pancytopenia. Since graft failure is a rare event, standardized treatment protocols addressing the type of non-myeloablative reconditioning regimens prior to a second transplantation are lacking. *Aims.* The retrospective analysis aims to address the efficacy of total nodal irradiation (TNI)- based reconditioning regimens on pediatric patients with graft failure or graft rejection after allogeneic HSCT. *Methods.* The results of 14 pediatric patients with different hematologic diseases (ALL (n=5), MDS (n=4), CML (n=2), AML (n=1), paroxysmal nocturnal hemoglobinuria (n=1), Kostmann disease (n=1)) treated with a TNI-based reconditioning regimen were retrospectively analysed. TNI consists of a supradiaphragmatic "mantle" field encompassing the cervical, supraclavicular, infraclavicular, axillary, hilar and mediastinal lymph nodes including the thymus whereas the infradiaphragmatic modified "inverted y" field encompasses the spleen and para-aortic, inguinal and iliacal lymph nodes while shielding non-lymphoid tissues in the head, chest (lung, breast), abdomen (liver, kidneys) and pelvis (bladder, rectum). Seven Gray (Gy) single dose TNI was combined with anti-T lymphocyte antibody OKT3 (n=11), antithymocyte globulin (ATG) (n=12), fludarabine (n=13), thiotepa (n=11), cyclophosphamide (n=2), and etoposide (n=1) followed by an infusion of peripheral blood stem cells. Twelve patients had haploidentical family donors, one child had a HLA-C mismatched unrelated donor and one child had a sibling donor. All children received T-cell depleted grafts. Various GvHD prophylaxis were employed and comprised ciclosporine A, mycophenolatmofetil, tacrolismus, basiliximab, prednisolone and methylprednisolone. *Results.* The median interval between initial transplantation and retransplantation was 41 days (range, 31-93 days). All patients were transplanted in aplasia. Engraftment was seen in all children after a median of 10 (range 9-32) days with sustained complete donor chimaerism in 13/14 children. One child receives donor lymphocyte infusions due to mixed chimaerism. TNI-based reconditioning was well-tolerated with no severe toxicity. All patients had mild to moderate mucositis and fever. In contrast, no permanent constraint of lung function and clinical signs of veno-occlusive disease were detected. In addition, no cardiac or neurotoxicity occurred. After a median follow-up of 928 (range 27-2550 days), disease-free and overall survival rates are 64%/71%, respectively. Despite sustained engraftment, 4 patients died due to disease relapse (n=3) and Moschkowitz syndrome (n=1) and one child is alive with MDS relapse. *Summary/Conclusions.* In patients with graft failure or graft rejection after allogeneic HSCT, TNI-based reconditioning regimens allow sustained engraftment paralleled by favourable toxicity profile potentially leading to long-term overall/ disease-free survival. Our results are encouraging since graft failure or early graft rejection have been fatal for the majority of patients.

1093

UNRELATED DONOR IS COMPARABLE WITH SIBLING DONOR AS A DONOR TYPE FOR PERIPHERAL BLOOD STEM CELL TRANSPLANTATION IN ACUTE MYELOID LEUKEMIA PATIENTS

SY Kim,[1] HJ Kim,[2] MH Lee,[1] JW Lee,[2] WS Min[2]

[1]KonKuk University Medical Center, Seoul, South-Korea; [2]Catholic Blood and Marrow Transplantation Center, Seoul, South-Korea

Background. The immune cell profiles of G-CSF mobilized peripheral blood cells are different from those of bone marrow cells. Therefore, the post-transplant immune mediated complications and transplant outcomes can differ between bone marrow transplantation and peripheral blood stem cell transplantation. Although the outcomes of sibling donor bone marrow transplantation are generally better than those of unrelated donor bone marrow transplantation, there has been no comparison study in a single disease between sibling and unrelated donor peripheral blood stem cell transplantation (PBSCT) setting. *Aims and methods.* We performed a retrospective study for adult acute myeloid leukemia patients who had received an allogeneic PBSCT from an HLA-matched sibling or unrelated donor to compare the transplant outcomes and post-transplant complications between sibling and unrelated donor PBSCT. The median follow up duration was 23.7 months. *Results.* The neutrophil and platelet recovery were not different between the two groups. The cumulative incidence of acute GVHD at day 100 posttransplant was higher in unrelated donor PBSCT (59.8% *vs.* 32.3% in sibling donor PBSCT; P=0.003), while the cumulative incidence of chronic GVHD at two years was not different between sibling and unrelated donor PBSCT (83.7% *vs.* 61.3%; P=0.113). There were no statistically significant differences in disease-free survival (sibling donor: 51.9% *vs.* unrelated donor: 55.4%; P=0.961), overall survival (sibling donor: 55.9% *vs.* unrelated donor: 58.8%; P=0.524), transplant-related mortality (sibling donor: 30.9% *vs.* unrelated donor: 26.7%; P=0.554), and relapse incidence (sibling donor: 55.9% *vs.* unrelated donor: 58.8%; P=0.524) at two years. Multivariate analysis indicated that chronic GVHD was favorable prognostic factor (HR = 0.206; 95% CI = 0.117-0.576; P=0.001) and pre-transplant disease state (>CR1) was unfavorable prognostic factor (HR=2.279; 95% CI=1.070-4.851; P=0.033) for DFS. *Conclusions.* Although unrelated donor PBSCT was associated with a higher risk of acute GVHD, the risk of chronic GVHD was not different between the two groups. The transplant outcomes were not different between sibling and unrelated donor PBSCT in AML patients. The unrelated donor was comparable with sibling donor as a donor type for PBSCT.

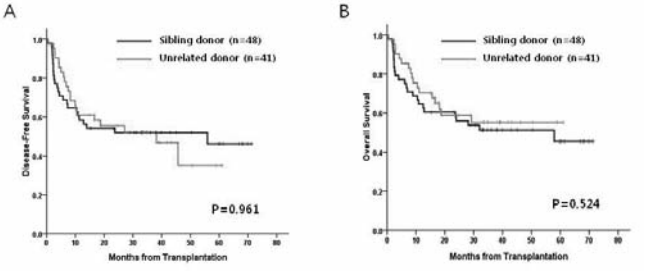

Figure. Disease-free survival (A) and overall survival (B) in allogeneic peripheral blood stem cell transplantation from sibling and unrelated donor.

1094

INTRAVENOUS BUSULPHAN IN COMBINATION WITH ETOPOSIDE AND MELPHALAN USED AS CONDITIONING REGIMEN FOR AUTOLOGOUS HEMATOPOIETIC CELL TRANSPLANTATION IN LYMPHOMAS: EVALUATION OF TOXICITY

D Mallouri,[1] V Constantinou,[1] P Baliakas,[1] A Papalexandri,[1] V Penopoulos,[2] I Sakellari,[1] A Anagnostopoulos,[1] A Fassas[1]

[1]Hematology Department-BMT Unit, G. Papanicolaou Hospital, Thessaloniki, Greece, Thessaloniki, Greece; [2]B Surgical Department, G. Papanicolaou Hospital, Thessaloniki, Greece, Thessaloniki, Greece

Background. The standard conditioning regimen used in autologous hematopoietic cell transplantation (autoHCT) for lymphomas is BEAM. During the last twelve months, due to carmustine (BCNU) unavailability, the combination of busilvex (3.2 mg/kg/day for 3 days), etoposide (400 mg/m^2/day for 2 days) and melphalan (140 mg/m^2) was used as conditioning regimen. *Aim.* Evaluation of the safety of the above regimen.

Methods. We retrospectively evaluated 20 patients, aged 27 (16- 65) years, transplanted for Hodgkin (12) and non Hodgkin Lymphomas (DLBCL 5; large B cell mediastinal 1; T-anablastic 1; MCL 1) between May 2009 and February 2010. The patients received a median of 3 (2-5) treatment lines before autoHCT. Disease status was refractory in 12, relapsed in 5, and complete remission (CR) in 3 (1 CR1, MCL; 2 CR2). According to the Hematopoietic cell transplantation specific comorbidity index, 15 were low (score 0) and 5 intermediate (score 1) risk. In 19 mobilization was successful after chemotherapy and GCSF (dexamethasone, ifosfamide, cisplatin, etoposide - DICE 16, DHAP 1, mini BEAM 1, R-DICE 1) and in 1 with GCSF plus AMD3100 (plerixafor) due to poor mobilization with DICE/GCSF. Fifteen/20 received palifermin and all received cotrimoxazole, antifungal, antiviral and antibiotics as prophylaxis for at least 3 months. The median $CD34^+$ cell dose was 5.65 (1.7-19.59) $\times 10^6$/Kg and patients received GCSF for a median of 9.5 (7- 53) days. *Results.* The median time for neutrophil engraftment (ANC> 500) was day +11 (9- 31), +13 (9 days- 5 months) for platelet (>20000) and +11 (8- 43) for erythroid engraftment (transfusion independency) in 19/20 patients. A second transplantation with double cord blood was offered in one patient because of engraftment failure. In one patient stable engraftment was achieved after a second infusion of autologous cells due to delayed engraftment. The median number of red blood cell transfusions were 3 (0-15); median single donor platelet units were 3.5 (0- 36). Infection during conditioning developed in 3 (urinary 2, respiratory 1) and during neutropenia developed in 15 patients (bacteremias mostly; no fungal or respiratory infections). Patients were febrile for a median of 4 (1-42) days. Nineteen developed mucositis (grade I 5, II 7, III 7) and 16 received parenteral nutrition for 5.5 (5-12) days. Eighteen developed liver and gastrointestinal toxicity (elevation of transaminases, nausea/vomiting) grade I- III. The median day of discharge was +14 (10- 32) in 19/20 patients. The patient allografted post autoHCT died at day +63 due to refractory disease and infections. The median follow-up was 4 (1-11) months. Eighteen/20 patients are alive. Eight/18 (44%) were evaluated at +3 months with PET scan and are in CR. Two/18 are in refractory/progressive disease, 1/18 in CR, 6/18 in stable disease without further treatment and 1/18 is not evaluated yet. Two/20 patients died; one due to refractory disease and another due to refractory disease and infection post allogeneic transplantation. *Summary/Conclusions.* The toxicity of the conditioning regimen seems acceptable, but no definite conclusions can be made on efficacy, because of the short follow up and limited number of patients.

Myeloma and other monoclonal gammopathies - Clinical 2

1095

THALIDOMIDE MAINTENANCE SIGNIFICANTLY IMPROVES PROGRESSION FREE (PFS) BUT NOT OVERALL SURVIVAL (OS) OF MYELOMA PATIENTS, WITH PFS BENEFITS IN FAVOURABLE FISH SUBGROUPS ONLY: MRC MYELOMA IX RESULTS

A Child,[1] F Davies,[2] W Gregory,[1] K Cocks,[1] S Bell,[1] A Szubert,[1] N Navarro Coy,[1] M Drayson,[3] R Owen,[4] F Ross,[5] G Jackson,[6] G Morgan[2]

[1]Clinical Trials Research Unit, Leeds, UK; [2]Institute of Cancer Research, London, UK; [3]University of Birmingham, Birmingham, UK; [4]St James's University Hospital, Leeds, UK; [5]Wessex Regional Genetics Laboratory, Salisbury, UK; [6]University of Newcastle, Newcastle-upon-Tyne, UK

Background. The role of maintenance thalidomide in myeloma remains unclear, with other major studies reporting some effect on PFS, but with variable results on survival. Also, the impact of maintenance dependent on patient risk group has not been fully evaluated, with the Arkansas group having shown a survival benefit in poor prognosis patients with cytogenetic abnormalities, while in contrast the IFM group showed a benefit in a study restricted to good prognosis patients defined by B2M and chromosome 13 deletion. *Aims.* The study aimed to randomise 762 patients with myeloma to maintenance thalidomide or not, with 80% power to detect a 10% difference in five-year OS, and with PFS as a joint primary endpoint. *Methods.* Following induction treatment in an intensive pathway for younger/fitter patients, and a non-intensive pathway for the remaining patients, the MRC Myeloma IX Study randomised 820 patients to either maintenance thalidomide, aiming for an initial dose of 50 mg increasing to 100mg daily, or to no maintenance, with 818 patients evaluable. Patients of all ages were randomised (median age 65, range 31-89). FISH was performed using standard approaches for t(4;14), t(6:14), t(11;14), t(14;16), t(14;20), del (13), gain 1q, del1p32 and del 17p. Written informed consent was obtained at the outset for all patients. ISRCTN6845411.

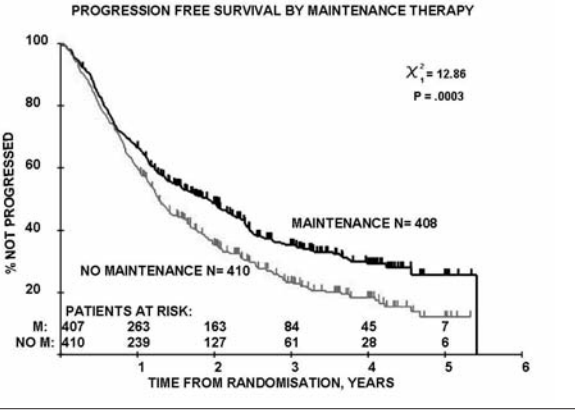

Figure.

Results. Median follow-up from maintenance randomisation was 3.2 years, range 1 year to $5^1/_2$ years. The results show that maintenance thalidomide significantly improves PFS (Figure), with a difference between the curves of 13% (95% CI 6%-20%) established by two years and maintained to the current maximum follow up at $5^1/_2$ years, logrank P=.0003, HR 1.36 (95% CI 1.15-1.61). However, there was no impact on OS (logrank P=.40). For the 61% of patients who had FISH evaluated, there were differing effects dependent on the FISH group. Defining adverse FISH groups as any of t(4;14), t(14;16), t(14;20), 1p32-, 1q+ or 17p-, and the rest as favourable, the PFS benefit was seen in the favourable FISH group (P=.05) with no effect on OS (P=.94). In the adverse FISH group there was no effect on PFS (logrank P=.98) and OS appeared to be impaired, though the result was not significant (n=127, logrank P=.07). To understand the impact of these potentially important beneficial effects on PFS we looked at survival after relapse. In this analysis there was a significant negative impact of maintenance thalidomide on survival after relapse, logrank P=.005, more pronounced in the

adverse FISH group (logrank P=.004), although there was still some initial separation of the curves in the favourable FISH group (logrank P=.35 but a 15% difference at 18 months). This could, at least partly, be attributable to the lack of an effect of thalidomide at relapse for those patients previously treated with maintenance thalidomide and the lack of availability of bortezomib or lenalidomide as alternative treatments. *Conclusions.* Maintenance thalidomide significantly improves PFS, particularly in favourable prognosis myeloma defined by FISH analysis, although there is no impact on OS due to poorer survival after relapse, particularly in adverse prognosis myeloma defined by FISH analysis.

IMPACT OF UPFRONT BORTEZOMIB-BASED REGIMENS ON CLINICAL OUTCOMES OF NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS ACCORDING TO CYTOGENETIC ABNORMALITIES BY FISH ANALYSIS

M Cavo,[1] A Palumbo,[2] S Bringhen,[2] F Di Raimondo,[3] F Patriarca,[3] D Rossi,[3] A Levi,[3] M Offidani,[3] V Montefusco,[3] F Narni,[3] R Zambello,[3] G Benevolo,[3] M Grasso,[3] A Falcone,[3] P Musto,[3] T Guglielmelli,[3] F Gherlinzoni,[3] D Gottardi,[3] C Musolino,[3] N Di Renzo,[3] L Masini,[3] C Cangialosi,[3] F Dore,[3] S Ballanti,[3] S Storti,[3] E Angelucci,[3] R Vallone,[3] V Magarotto,[3] F Morabito,[3] P Tosi,[4] M Boccadoro[2]

[1]Istituto di Ematologia Seragnoli, Bologna, Italy; [2]Division of Hematology, University of Turin, Italy; [3]GIMEMA Italian Myeloma Network, Bologna, Italy; [4]Seràgnoli Institute of Hematology, University of Bologna, Italy

The role of novel agents for the treatment of newly diagnosed multiple myeloma (MM) patients with high-risk cytogenetic abnormalities [t(4;14) and/or del(17p)] is still controversial. To more carefully address this issue, we analyzed the clinical outcomes of a large series of MM patients who received bortezomib as part of upfront induction therapies. Regimens evaluated were bortezomib-thalidomide-dexamethasone (VTD), bortezomib-melphalan-prednisone (VMP) and bortezomib-melphalan-prednisone-thalidomide (VMPT). A total of 587 patients who could be evaluated for del(13q), t(4;14) and del(17p) by interphase FISH were included in the present analysis. Study end points included achievement of immunofixation negative complete response (CR) and progression-free survival (PFS). Three cytogenetic subgroups of patients were identified, including those without any of the three genomic abnormalities (n=261), with del(13q) alone (n=174) and those with t(4;14) and/or del(17p) (n=152). Overall, the frequency of patients with no abnormalities, with del(13q) alone and with t(4;14)±del(17p) was 45.8%, 29.8% and 24.3%, respectively. No statistically significant difference in terms of CR rate was detected by comparing high-risk patients with those who lacked cytogenetic abnormalities (38.1% *vs.* 32.5%; P=0.2) or who carried del(13q) alone (46.5%; P=0.1). By the opposite, the CR rate in patients with del(13q) alone was significantly higher than among those without cytogenetic abnormalities (P=0.003). The 30-month projected PFS was 62% (27.6% events) for patients with high-risk cytogenetics *vs.* 66% (19.5% events) for those without abnormalities (P=0.06) *vs.* 64% (21.2% events) for those with del(13q) alone (P=0.5). To more carefully investigate the impact on prognosis of different high-risk cytogenetic abnormalities, we compared the clinical outcome of patients with t(4;14) but lacking del(17p) with that of patients who were del(17p) positive but t(4;14) negative. These latter patients had a significantly lower probability to achieve CR (28.3%) than those who were t(4;14) positive but del(17p) negative (47.6%) (P=0.02). By the opposite, the 30-month PFS for these two subgroups of patients was almost superimposable, with values at 66% (26.4% events) and 69% (21.4% events), respectively (P=0.3). These results, based on a post-hoc analysis, should be cautiously interpreted, although consistencies exist between data herein shown and previous reports on the activity of bortezomib in patients with high-risk cytogenetic abnormalities. Further analyses of homogeneously treated series of patients are warranted to draw firm conclusions about the ability of bortezomib-based regimens to overcome the adverse prognosis related to the presence of t(4;14) and/or del(17p).

1097

BORTEZOMIB PLUS DEXAMETHASONE VERSUS REDUCED-DOSE BORTEZOMIB PLUS THALIDOMIDE-DEXAMETHASONE AS INDUCTION PRIOR TO AUTOLOGOUS TRANSPLANTATION IN NEWLY DIAGNOSED MYELOMA

JL Harousseau,[1] H Avet-Loiseau,[2] J Mary,[3] T Facon,[4] M Attal,[2] C Doyen,[5] C Hulin,[2] L Garderet,[6] M Tiab,[7] G Lepeu,[8] C Araujo,[7] D Caillot,[2] M Petillon,[4] C Mathiot,[9] P Moreau[2]

[1]Rene Gauducheau Cancer Center, Nantes/St Herblain, France; [2]CHU, Nantes, France; [3]Université Jussieu, Paris, France; [4]CHRU, Lille, France; [5]Université Catholique Louvain, Yvoir, Belgium; [6]CHU St. Antoine, Paris, France; [7]CHD, La Roche sur Yon, France; [8]CH Avignon, Avignon, France; [9]Insitut Curie, Paris, France

Background The Intergroupe Francophone du Myelome (IFM) has shown that induction treatment prior to ASCT with VD is superior to VAD in terms of complete response (CR) or CR plus very good partial response(VGPR) both before and after ASCT (Harousseau 2008 Joint ASH/ASCO session). The Italian and the Spanish groups have presented impressive results with the three-drug combination velcade,thalidomide,dexamethasone (VTD)(Cavo Blood 2009;114:148 and Rosinol 2009,114:59) However in these studies, bortezomib-associated peripheral neuropathy (PN)was frequent and sometimes severe (9-14% Grade 3). *Aims.* To show that with reduced doses of bortezomib, vTD is superior to TD and better tolerated. *Patients and Methods.* The IFM has conducted a randomized trial comparing four 21-day cycles of induction with VD(V1.3 mg/m^2/d on days 1,4,8,11 plus D 40mg:d on days 1-4 and 8-11 for the first 2 cycles, on days 1-4 for the last 2 cycles) or vTD (v 1mg/m^2 /d on days 1,4,8,11 plus thalidomide 100mg:d d1-21 plus dexamethasone same dosing as for VD). Results were assessed after cycle 2 and 4 and after ASCT. Responses were evaluated according to IMW uniform criteria . Samples for serum and urine electrophoreses were centralized (HAL,CHU Nantes). In the vTD arm, if after cycle 2, the response was<PR, the doses of v and T were to be increased to 1.3 mg/m^2 and 200mg/d respectively (in the absence of PN). *Results.* From 03/2008 to 01/2009, 205 patients with newly diagnosed symptomatic MM and up to 65 years of age were recruited and randomized at diagnosis (stratification according to β-2 microglobulin and presence of del(13) by FISH). As of December 2009, 191 patients are evaluable for response after cycle 4 (95 VD,96 vTD). According to investigators'assessment,the efficacy results are the following (VD *vs.* vTD): CR 12%vs 14% (P=0.68),≥VGPR 36%vs 50 % (P=0.047), ≥PR 81%vs 90%(P=0.09),stable disease 12%vs 5%, progression/failure 7%vs 4%.In the vTD arm the doses of v and T were increased due to <PR after cycle 2 in only 7 patients. The post-ASCT results are the following CR 26% *vs.* 20% (P=0.33),[3] VGPR 54%*vs.* 66% (P=0.044)[3] PR 84% *vs.* 92% (P=0.33). Bortezomib treatment was reduced or interrupted due to toxicity in 17 % of cases in the VD arm and 7% of cases in the vTD arm. There was no difference in the incidence of adverse events and of severe adverse events. There were 4 severe adverse events related to PN in the VD arm *vs.* 0 in the vTD arm . The proportion of patients with at least one report of PN was: all grades 63% *vs.* 56%(P=0.39);Grade ≥ 2 28 % *vs.* 16 % (P=0.04), Grade ≥36% *vs.* 3 % (P=0.3). *Conclusion.* The combination of reduced-dose bortezomid and thalidomide induces significantly more CR+VGPR than VD with usual doses of V. Despite the addition of thalidomide, the incidence of PN was markedly reduced In the vTD arm with only 3% Grade ≥3 PN. vTD should be considered a new standard for induction treatment prior to ASCT.

FINAL DONOR VERSUS NO DONOR COMPARISON OF NEWLY DIAGNOSED MYELOMA PATIENTES INCLUDED IN THE HOVON 50/54 STUDY

H Lokhorst,[1] P Sonneveld,[2] B van der Holt,[3] M Kersten,[4] M van Oers,[4] R Raymakers,[1] M Minnema,[1] S Zweegman,[5] J Janssen,[5] G Bos,[6] G Huls,[7] E Vellinga,[7] M Schaap,[8] J Zijlmans[2]

[1]University Medical Center Utrecht, Utrecht, Netherlands; [2]Erasmus MC, Rotterdam, Netherlands; [3]Hovon data center, Rotterdam, Netherlands; [4]Amsterdam Medical Center, Amsterdam, Netherlands; [5]VU Medical Center, Amsterdam, Netherlands; [6]Academisch Medical Center Maastricht, Maastricht, Netherlands; [7]Academisch Medical Center Groningen, Groningen, Netherlands; [8]Radboud Medical Center, Nijmegen, Netherlands

Background. The role of Allogeneic Stem Cell Transplantation (Allo-SCT) in myeloma is disputed. Its value should be determined by prospective randomized trials. It is widely accepted that for the evalu-

ation of treatment results of Allo-SCT genetic randomization based on the availability of an HLA identical sibling donor is a reliable surrogate for such a truly randomization. *Aims.* To evaluate the value of nonmyeloablative Allo-SCT as part of first line therapy. *Methods.* Patients with an HLA-identical sibling donor, included in the phase-III HOVON50 study, that was designed to assess the effect of thalidomide in induction treatment and as maintenance after high-dose therapy (HDM 200 mg/m^2) and auto-SCT could proceed to the Hovon 54 study in which an Allo-SCT after conditioning with low dose TBI only was performed between 2-6 months after HDM. 122 patients could be classified as having a sibling donor of which 100 patients underwent the Allo transplant and139 patients had no sibling donor of which 122 patients started with maintenance therapy. Both groups were comparable with regard to age, myeloma stage, and prognostic factors including cytogenetics and ISS stage. *Results.* 95% of the patients in the no donor group achieved at least a PR, including 75% of patients with a VGPR and 20% with a CR, *vs.* 96% of the patients in the donor group including 35% CR and 70 % VGPR. After a median follow-up of 60 months after HDM, PFS and OS were comparable between the two groups. Median PFS was 30 *vs.* 28 months for the donor group and no donor group respectively (HR 0.8, CI:0.6-1.1). Median OS was not reached with at 60 months 58% of patients alive in the donor group *vs.* 60% of patients in the no donor group (HR 1,27, CI 0.85-1.89). For patients that did receive their allocated transplant or maintenance treatment median PFS was 29 months (HR 0.76,CI: 0.54-1.06) and OS at 60 months from HDM was 60% for the donor group *vs.* 55 % for the no donor group (HR 0.92, CI 0.58-1.45). *Conclusion.* This analysis showed no improvement of tandem Auto Allo-RIC as part of first line therapy in myeloma as compared Auto-SCT followed by maintenance therapy.

Background. Carfilzomib (CFZ) is a proteasome inhibitor with unique target selectivity and an irreversible binding mechanism that results in sustained proteasome suppression. In preclinical studies CFZ overcomes bortezomib (BTZ)-resistance *in vitro* (Kuhn *et al.*, Blood 2007) and, lacks non-proteasome off-target activities associated with BTZ (Kapur *et al.*, Blood 2008). This may account for observed differences in tolerability of CFZ (e.g. low neuropathy rates), permitting consecutive day dosing and treatment over extended periods of time. In a previous Phase II study (PX-171-003), single-agent CFZ achieved durable responses and maintained stable disease in patients with relapsed/refractory multiple myeloma (MM) despite prior resistance to all available agents, including BTZ. *Aims.* We present here updated data from PX-171-004, an ongoing Phase II study of single-agent CFZ in MM patients with relapsed or refractory disease (R/R MM) following 1-3 prior therapies with emphasis on the BTZ-naïve and BTZ-treated cohorts. *Methods.* Patients with relapsed or refractory (defined as <25% response or disease progression during therapy) MM were enrolled and stratified based on prior BTZ exposure (i.e., BTZ-naïve and BTZ-treated) and CFZ dose level (see Table). For the BTZ-treated cohort, tolerability and prior response to BTZ were not an eligibility requirement. CFZ 20 or 27 mg/m^2 was administered on days 1, 2, 8, 9, 15 and 16 every 28 days, for up to 12 cycles. The primary endpoint was overall response rate (ORR; ≥ partial response [PR]) by IMWG criteria. Secondary endpoints included clinical benefit response (CBR; ≥minimal response [MR]), duration of response (DOR), and safety. *Results.* For BTZ-naïve patients, cohort 1 (20 mg/m^2) included 59 patients and cohort 2 (27 mg/m^2) included 20 patients. Patients received a mean of 5 cycles of CFZ (range 1-12). The BTZ-treated cohort included 35 patients (14 refractory to most recent treatment). For BTZ-naïve patients, 54 patients in cohort 1 and 19 patients in cohort 2 were evaluable with ORRs of 46% and 53%, respectively. Median DOR (≥MR) was ≥8.8 months (mo). Thirty-three patients previously treated with BTZ were also evaluable with an ORR of 18% (Table). In the combined patient population, the most common adverse events (AEs) included fatigue (66%), nausea (49%), dyspnea (40%), anemia (34%), diarrhea (32%) and were primarily ≤ Grade 2. The most common ≥ Grade 3 AEs were anemia, thrombocytopenia, and neutropenia (10% each). Febrile neutropenia (all Grades, 2%; ≥ Grade 3.2%) and treatment-emergent peripheral neuropathy (PN) (all Grades, 6%; ≥ Grade 3, 1%) were uncommon. Of 23 patients (21%) who completed all 12 cycles of the protocol, 7 chose to continue CFZ therapy on an extended treatment protocol. *Conclusions.* Single-agent CFZ is active in patients with R/R MM with 53% of BTZ naïve patients responding to 20 mg/m^2 in cycle 1 followed by 27 mg/m^2 thereafter. AEs were generally mild and durable disease control was achieved with continued dosing. Severe PN is rare (≥ Grade 3, 1%) and does not limit therapy, despite pre-existing PN. These data support the continued evaluation of CFZ as a safe and effective treatment option in MM.

Table. Treatment groups and patient responses.

	BTZ-treated	BTZ-naïve	
	N=35	Cohort 1 N=54	Cohort 2 N=19

TRANSGENIC MICE EXPRESSING A JAK2 EXON 12 MUTATION DISPLAY ISOLATED ERYTHROCYTOSIS CLOSELY RESEMBLING THE HUMAN JAK2 EXON 12 POLYCYTHEMIA

S Li,[1] H Hao-Shen,[1] R Tiedt,[2] R Skoda[1]

[1]University Hospital Basel, Basel, Switzerland; [2]Novartis, Basel, Switzerland

Background. JAK2-V617F mutation and JAK2 exon 12 mutations together account for more than 98% of patients with polycythemia vera (PV). Mutations in exon 12 of JAK2 are detected in approximately 50% of PV patients that are negative for JAK2-V617F. *Aims.* To study the *in vivo* role of JAK2 exon 12 mutations in the pathogenesis of PV, we generated inducible transgenic mouse strains carrying the most frequent exon 12 mutation (JAK2-N542-E543del). *Methods.* A human JAK2 gene with the sequences of exon 12 were placed in the inverse orientation and flanked by antiparallel loxP sites. Recombination of loxP sites by Cre recombinase results in flipping of exon 12 sequence, restoring a functionally active transgene. *Results.* Three transgenic mouse lines (E12-N1, E12-N2 and E12-N3) were established. Real-time PCR analysis revealed that E12-N1 had 2 copies, E12-N2 had 5 copies and E12-N3 had 7 copies of the transgene. These strains were crossed with MxCre transgenic mice that allow induction of Cre expression and thus activation of the JAK2 transgene by injection of polyinosine-polycytosine (pIpC). All three mouse lines developed PV-like phenotype within 12 to 16 weeks after pIpC injection, with significant increase in red blood cells, hemoglobin, and hematocrit. Interestingly, unlike the PV-like phenotype induced by JAK2-V617F, which in addition to increase in red blood cell parameters also showed thrombocytosis and neutrophilia, the PV-like phenotype induced by JAK2-N542-E543del had neutrophils within normal range and platelet counts that were normal or even slightly decreased. This phenotype closely resembles clinical features of human PV patients with JAK2 exon 12 mutations, who usually have normal counts of white blood cells and platelets. The PV phenotype in JAK2-V617F transgenic mice was only present with higher expression levels of JAK2-V617F. However, the expression levels of the N542-E543del transgene were markedly lower than those of the JAK2-V617F, suggesting that qualitative differences in the signals generated by the two mutated Jak2 proteins may exist. *Summary.* Since JAK2-V617F and JAK2-N542-E543del both signal through the same tyrosine kinase domain, these results raise the interesting question why the phenotypes are different. Since the genetic background of these mice is identical, the JAK2-V617F and N542-E543del transgenic mice now allow examining the molecular basis for the phenotypic differences between these two PV subtypes.

PEGYLATED INTERFERON-ALFA (IFNA) 2A TREATMENT TARGETS JAK2V617F CLONES WITHOUT AFFECTING TET2 MUTANT CELLS IN POLYCYTHEMIA VERA (PV)

JJ Kiladjian,[1] A Massé,[2] B Cassinat,[1] H Mokrani,[2] I Teyssandier,[3] JP Le Couédic,[2] N Cambier,[4] C Almire,[2] E Pronier,[2] N Casadevall,[3] W Vainchenker,[2] C Chomienne,[1] F Delhommeau[5];

[1]Hopital Saint-Louis, Paris, France; [2]INSERM U1009 - Institut Gustave Roussy, Villejuif, France; [3]Hopital Saint-Antoine, Paris, France; [4]CHRU Huriez, Lille, France; [5]Hopital Saint-Antoine & INSERM U100,9 Paris, France

Background. In a phase 2 trial of peg-IFNa-2a, we observed a substantial decrease of *JAK2V617F* allele burden in granulocytes from 29 patients treated with IFNa, including complete molecular remissions (CMR) in 7/29. These 7 CMR constitute the first homogeneous cohort of patients with measurable reduction of the PV clone, which may allow answering whether such CMR are associated with elimination of the PV clone. *Methods.* We performed bone marrow (BM) erythroid progenitor cultures (using BMMC in plasma clot, and purified CD34$^+$ cells in methylcellulose assay) and *JAK2* and *TET2* genotyping of individual colonies from 5 patients in CMR after 18 to 40 months of pegIFNa-2a treatment. *Results.* At *JAK2V617F* CMR, few residual endogenous erythroid colonies (EEC) were still found in the 5 patients, representing only 0.2 to 6% of the total of colonies grown with Epo. In 1 patient with 3 sequential BM samples, numbers of EEC continuously decreased during IFNa, and no residual *JAK2V617F* positive colonies were detected after 34 months. In 1 patient, we found a single nucleotide deletion in exon 11 of *TET2* leading to a frameshift (FS) and a premature stop codon. At baseline, both mutant *TET2* and *JAK2* represented 20% of their wild-type (WT) counterparts. The *TET2* mutated and *JAK2V617F* clones didn't decrease in parallel, the burden of mutant *TET2* remaining unchanged in 2 samples taken after *JAK2V617F* CMR (after 24 and 36 months of IFNa). We next sequenced *TET2* in *JAK2V617F* positive and negative colonies grown from CD34$^+$ cells at time of peripheral *JAK2V617F* CMR. *TET2* mutation was found in 1/5 (20%), and 10/12 (83%) of *JAK2V617F* positive, and negative colonies, respectively. Presence of JAK2V617F homozygous/ *TET2WT* and *TET2FS* homozygous/ *JAK2WT* colonies, suggested occurrence of mitotic recombinations or deletions on *JAK2* and *TET2* loci in separate clones. Genotyping of informative SNPs in each gene suggested that two separate primary clones coexisted. The first clone initially acquired *JAK2V617F* giving rise to *JAK2V617F / TET2WT* colonies, which next generated a subclone with homozygous *JAK2V617F* mutation. The second clone acquired the *TET2FS* mutation and generated two subclones: one that lost *TET2WT* allele, and one that secondarily acquired *JAK2V617F*. We found a striking discrepancy in the frequency of *TET2 vs. JAK2* mutant cells after therapy whereas both mutations had the same allelic burden before IFNa: 11/17 (65%) colonies carried the *TET2* mutation in contrast to 7/89 (5%) with *JAK2V617F* suggesting that IFNa targets *JAK2V617F* cells without affecting *TET2* mutant cells. *Conclusion.* We showed that IFNa therapy led in all studied patients to a dramatic decrease in the size of the clone harboring the JAK2 mutation, including complete elimination of *JAK2* mutant colonies in 1/5 patient. In contrast in another patient with a biclonal *TET2/JAK2* disease, IFNa therapy had a drastic effect on *JAK2* mutated clones but did not affect the TET2 mutant clone. As this patient achieved hematologic and *JAK2* molecular complete remissions on IFNa without reduction of the *TET2* clone we hypothesize that this treatment brought the patient back to a 'pre-proliferative' phase of his disease.

V617F MUTATION INDUCES NUCLEAR LOCALIZATION OF JAK2 IN CD34+ CELLS BUT NOT GRANULOCYTIC, MEGAKARYOCYTIC OR ERYTHROID CELLS OF PATIENTS WITH PHILADELPHIA-NEGATIVE MYELOPROLIFERATIVE DISORDERS

CR Rinaldi,[1] P Rinaldi,[1] V Senyuk,[2] N Esposito,[1] G Nucifora,[2] F Pane[1]

[1]Federico II University, Naples, Italy; [2]University of Illinois in Chicago, Chicago, USA

Background. Recently, Dawson *et al.*. identified a previously unrecognized nuclear role for JAK2 in the phosphorylation of the tyrosine 41 of the histone H3 with the exclusion of HP1a from chromatin and resulting in a disregulation of several JAK2-regulated genes such as IMO2 in haematopoietic cell lines and in one case on peripheral CD34+ cells from a JAK2V617F mutated primary myelofibrosis (PMF) patient. Activation of JAK2 by chromosomal translocations or point mutations is a frequent event in haematological malignancies particularly in Philadelphia negative myeloproliferative disorders (MPDs). *Aims and Methods.* To investigate and confirm a possible nuclear localization of JAK2 in presence of V617F mutation, we stably transfected K562 with pMSCV-Puro-JAK2V617F construct and compare with K562 expressing pMSCV-Puro-wild type-(WT)-JAK2 and performed immunofluorescence and western blot analysis. To confirm the *in vitro* results we searched the possible nuclear localization of JAK2 in total BM of 10 patients affected by all types of JAK2V617F positive MPDs [PMF n= 3, polycitemia vera (PV) n= 3, essential thrombocythemia (ET) n= 4] and 5 patients with WT MPDs (PMF n= 2 , ET n=3). To define which cells show nuclear JAK2, we selected by fluorescence activated cell sorting (FACS) 4 cell populations: CD34$^+$, CD15$^+$, CD41$^+$ and CD71$^+$ cells from total BM of 3 JAK2-mutated-MPDs (1 ET, 1 PV, 1 early PMF). *Results.* Confocal immunofluorescent images on nuclear and cytoplasmic fractions confirmed nuclear JAK2 in K562 although with the strongest nuclear signal in JAK2V617F expressing cells. This latter was also seen by western blot analysis which showed nuclear and cytoplasmic JAK2 only in JAK2V617F expressing K562 comparing with untransfected and WT cells. No differences in JAK2 nuclear signal was observed by the addiction of the nuclear export inhibitor leptomycin B suggesting that export is not involved in nuclear JAK2 shuttling. We found a strong nuclear signal within the nuclei of 3-5% of mononucleated cells in 10 of 10 JAK2 mutated patients but not in un-mutated cases. We found nuclear JAK2 in CD34$^+$ cells but not in other cell populations of the 3 studied patients. Western blot performed on nuclear and cytoplasmic fractions of the JAK2V617F-CD34$^+$ cells confirmed the result. No nuclear JAK2 was detected in differentiated erythroid, granulocytic or megakaryocytic

colonies obtained from all the studied patients (n=15). *Conclusions.* Our data corroborate the recent findings, obtained in hematopoietic cell lines, of a role of JAK2 in direct nuclear signaling. Furthermore we report, for the first time, a nuclear JAK2 in total BM and in sorted CD34+ cells of patients affected by all subtypes of JAK2 mutated MPDs and not in patients with WT diseases. We described also the absence of nuclear JAK2 in sorted mature cells and in differentiated colonies derived from the same patients. Possible chromatin modification due to JAK2 nuclear localization has to be better assessed in patients, where further studies are needed to understand the effects of mutated JAK2 in the nuclei, its target proteins and consequences on gene expression. This intriguing insight reveals a new scenario in the pathogenesis of malignant haematopoiesis and in myeloproliferative phenotype.

SIGNALING PATTERNS IN MYELOPROLIFERATIVE NEOPLASMS SEGREGATE WITH DISEASE PHENOTYPE RATHER THAN JAK2 GENOTYPE

S Anand,[1] F Stedham,[1] P Beer,[2] E Gudgin,[2] A Bench,[2] W Erber,[2] A Green,[1] B Huntly[1]

[1]Cambridge Institute of Medical Research, University of Cambridge, Cambridge, UK; [2]Cambridge University Foundation Hospital Trust, Cambridge, UK

The recent discovery of acquired mutations in signaling pathways, such as the JAK2 V617F mutation, has provided a molecular basis for the pathogenesis of the myeloproliferative neoplasms (MPN). However, the nature of aberrant signaling in primary cells from MPN patients remains poorly understood. Most work has been described in cell lines or in animal model systems which may not adequately reflect the cellular context or the molecular complexity of human MPN. In addition where patient material has been used, technical aspects limit the interpretation of these experiments. We undertook a detailed and physiological characterization of the signaling abnormalities in human MPN to understand how these abnormalities contribute to the cellular characteristics and disease phenotype. We first developed a reproducible and quantitative "Phosphoflow" assay to measure levels of the activated signaling intermediates phospho-STAT5, phospho-STAT3, phospho-AKT and phospho-ERK 1/2, using intracellular staining with phospho-specific-antibodies and detection with flow-cytometry. This allowed us to consistently interrogate signaling in both the CD34+ hematopoietic stem and progenitor compartment (HSPC) and the CD34- maturing cell compartments in up to 27 MPN patients (10 PV, 9 ET and 8 MF) comparing them to similar compartments from the bone marrow of 6 normal controls. In addition, we also studied dynamic signaling in MPN patient samples following stimulation with EPO or inhibition with a JAK2 inhibitor and correlated signaling with disease characteristics such as clonal burden and stem cell, progenitor and later compartment size. Our results demonstrated significant activation of the STAT5, ERK and STAT3 pathways in MPN patients over normal controls. Aberrant signaling was detected in both the CD34+ and CD34- compartments, but often varied between these compartments in individual diseases. In contrast, compartment size only increased in later compartments. The pattern of aberrant signaling correlated with the disease phenotype (PV, ET or MF) but not the JAK2 mutations status of MPN patients. In addition, although EPO stimulation increased STAT5 signaling in normal controls MPN samples were maximally stimulated. MPN samples also showed modest inhibition of signaling with TG101209, a JAK2 specific inhibitor in both the CD34+ and CD34- compartments and the degree of inhibition was similar to that seen in CML patient cells treated with Imatinib. However, this inhibition was not JAK2 V617F specific, as MPN patients with wild-type JAK2 and normal control patients were inhibited to a similar degree. Finally, JAK2 V617F mutant burden demonstrated a poor correlation with signaling and compartment size. Our results provide the first systematic demonstration of specific intracellular signaling events in human MPN samples. Our data also demonstrate that JAK2 status and mutation burden correlate poorly with disease and cellular phenotype. We further demonstrate only modest inhibition of cellular signaling with a JAK2 inhibitor which occurs in both MPN and normal samples. This suggests that other factors, such as germline modifiers or other co-existing mutations, significantly contribute to the MPN phenotype. Taken together our study has major implications for both the pathogenesis and therapy of MPN.

OVEREXPRESSION OF TRANSCIPTION FACTOR NF-E2 IN VIVO CAUSES A MYELOPROLIFERATIVE DISORDER WITH EXPANSION OF THE STEM CELL COMPARTMENT

B Kaufmann, A Gruender, R Bogeska, M Gothwal, H Pahl

University Hospital Freiburg, Freiburg, Germany

Background. The transcription factor nuclear factor erythroid-2 (NF-E2) is expressed in hematopoietic stem cells as well as in myeloid, erythroid and megakaryocytic precursors. It is known to play an important role in both erythropoiesis and platelet formation as NF-E2 deficient mice display marked anemia at birth and die perinatally due to thrombopenia, However, its role in hematopoietic stem cells has not been studied in detail. We have previously shown that NF-E2 is overexpressed in the vast majority of patients with Myeloproliferative Neoplasms (MPNs), a group of acquired disorders of the hematopoietic stem cell (HSC). Recently we have engineered a transgenic mouse model, in which NF-E2 is overexpressed specifically in the hematopoietic compartment including the HSCs. *Aims.* We therefore investigated the effect of NF-E2 overexpression on the HSC pool. *Methods.* Two independent founder strains were generated, which express NF-E2 under control of the vav promoter. Hematological parameters were determined by CBC every two months. Colony formation in the bone marrow was assessed by growth in methylcellulose media (Stem Cell Technologies). Subfractions of HSC were displayed by FACS analysis using the following 7-color stain: Lin-cocktail-FITC, c-kit-APC-eFlour780, Sca-1-PacificBlue, CD34-AlexaFlour647, Fc-gamma-II/III-R-PE-Cy7, Thy1.1-PerCP, Flt3-PE. *Results.* NF-E2 transgenic (tg) mice develop thrombocytosis with a latency of 12-14 months. Concomitantly, megakaryocyte colony formation in the bone marrow is drastically increased. In addition, Epo-independent colony formation, a pathognomonic feature of polycythemia vera, is significantly increased in NF-E2 transgenic animals. Bone marrow histopathology shows findings characteristic of MPNs, including increased numbers of megakaryocytes with cytologically abnormal forms, often in clusters. Paralleling the histological observation, total bone marrow cellularity was significantly increased in NF-E2 transgenic mice (wt: $5.1 \pm 1.6 \times 10^6$ cells/femur *vs.* tg: $7.2 \pm 1.8 \times 10^6$ cells/femur; $P<0.05$). The stem cell compartment was further characterized using FACS analysis of phenotypically defined subfractions. Both the KSL ($kit^+/sca\text{-}1^+/lin^-$) and the KL ($kit^+/sca\text{-}1^-/lin^-$) compartments were significantly increased in NF-E2 tg mice (KSL as % of lin--cells: wt: 5.3 ± 2.7%, tg: 9.0 ± 5.4%, P=0.005; KL as % of lin--cells: wt: 19.2±3.9%, tg: 23.6 ± 6.2%; P=0.02). In addition, both the percentage and the absolute numbers of LT-HSCs (long-term HSCs) was significantly elevated in NF-E2 tg mice (LT-HSC as % of lin--cells: wt: 0.33 ± 0.08%, tg: 0.54 ± 0.11%, P=0.02). Moreover, NF-E2 tg mice contain significantly elevated numbers of both CMP and MEP (common myeloid progenitors; CMP per femur: wt: 46,600±5,300, tg: 63,200±5,100, p =0.02; megakaryocyte-erythroid progenitors; MEP per femur: wt: 58,600 ± 13,700, tg: 115,600 ± 28,800, P=0.02). In order to determine whether enhanced proliferation of HSCs contributes to their increase, cell cycle analysis of the various stem and progenitor compartments is being conducted and the data will be presented. *Summary.* In a murine model, NF-E2 overexpression causes expansion of the hematopoietic stem and progenitor compartments, specifically the most primitive stem cells, LT-HSC, as well as the megakaryocytic and erythroid precursors, the MEPs. These data strongly suggests that the NF-E2 overexpression observed in CD34+ cells of MPN patients contributes to the increase in HSCs present in these disorders.

IDH mutations in acute myeloid leukemia

ACQUIRED MUTATIONS IN THE GENES ENCODING IDH1 AND IDH2 BOTH ARE RECURRENT ABERRATIONS IN ACUTE MYELOID LEUKEMIA (AML): PREVALENCE AND PROGNOSTIC VALUE

S Abbas, S Lugthart, F Kavelaars, A Schelen, J Koenders, A Zeilemakers, W van Putten, A Rijneveld, B Löwenberg, P Valk

ErasmusMC, Rotterdam, Netherlands

Introduction. Somatic mutations in the genes encoding the isocitrate dehydrogenases IDH1 and IDH2 were revealed in more than 70% of astrocytomas, oligodendrogliomas and glioblastomas. Mutations in *IDH1* and *IDH2* affects the arginines on position 132 of IDH1 and position 172 of IDH2, resulting in disturbed function of both isocitrate dehydrogenases, as demonstrated by impaired production of NADPH. Recently, acquired mutations in the gene encoding IDH1 were identified in 8% and 5.5% of newly diagnosed AML cases. Overall, the *IDH1* mutation status did not suggest a relationship with overall survival. In this study, we determined the frequencies of both *IDH1* and *IDH2* mutations in cohorts of AML, ALL, CML and JAK2 V617F MPN. In a cohort of 893 cases of AML, we investigated their distribution in relationship with cytogenetic and molecular risk categories as well as recurrent gene mutations commonly apparent in AML and we evaluated the impact of *IDH* mutations on treatment outcome. *Methods. IDH1* and *IDH2* mutations in AML, RAEB, ALL, CML and JAK2 V617F MPN were determined by cDNA amplifications. All IDH1 and IDH2 RT-PCR products were subjected to denaturing high performance liquid chromatography (dHPLC) analyses using a WAVE system. PCR products showing aberrant dHPLC profiles were purified using the Multiscreen-PCR 96-well system followed by direct sequencing. We validated this strategy using 350 cases of *de novo* AML that were previously analyzed using PCR on genomic DNA followed by direct sequencing. The relation between *IDH* mutations and various patient characteristics were determined by the Student's t-test equal variances not assumed (continuous variables) and the Fisher's exact test (categorical variables). Distribution estimations and survival distributions of overall survival (OS) and event-free survival (EFS) were calculated by the Kaplan-Meier method and the log-rank test. *Results.* A RT-PCR/dHPLC screen of 893 newly diagnosed AMLs followed by direct sequencing, identified *IDH1* mutations in 54 AML cases (6.0%) and IDH2 mutations in 23 cases (2.6%). A total of 77 (8.6%) mutations in either *IDH1* or *IDH2* were apparent in 76 cases. No *IDH* mutations were found in the ALL and CML cohorts. *IDH1* and *IDH2* mutations were significantly more frequently present among cytogenetically defined intermediate risk AML, as well as cytogenetically normal AML. In addition, *IDH* mutations appear to be significantly associated with $NPM1^{mutant}$. To investigate the prognostic value of *IDH* mutations, 893 AML patients were considered for survival analysis in various AML subtypes. There was a trend for worse EFS for IDH^{mutant} patients within the AML subtype $NPM1^{wild\text{-}type}$ (P=0.04). However, among the $FLT3^{wild\text{-}type}/NPM1^{wild\text{-}type}$ AML subtype (n=15 cases) the presence of *IDH1* mutations predicted for both significantly reduced OS (P<0.032) and EFS (P=0.005). *Conclusions.* Acquired *IDH* gene mutations, i.e., not only in *IDH1* but also *IDH2*, are common abnormalities in AML. Together, *IDH1* and *IDH2* mutations account for a considerable frequency of approximately 9% in adult AML. *IDH* gene mutations are associated with normal karyotypes and *NPM1* mutations. *IDH1* mutations appear to correlate with significantly inferior outcome in patients $FLT3^{wild\text{-}type}/NPM1^{wild\text{-}type}$ AML, but requires confirmation in future studies.

Background. Recently, whole-genome sequencing in acute myeloid leukemia (AML) identified recurrent *IDH1* mutations (*IDH1m*), previously reported to be involved in gliomas as well as *IDH2* mutations (*IDH2m*). IDH1 is a cytosolic protein that catalyzes the oxidative carboxylation of isocitrate to α-ketoglucarate (α-KG), leading to NADPH production in Krebs cycle. Isocitrate dehydrogenase 2 (IDH2) gene encodes a mitochondrial protein homologous to IDH1 that also catalyses isocitrate carboxylation. Mutations affecting analogous amino acids R132 IDH1 and R172 IDH2 that are located in the active site of the enzymes, lead to inhibition of wild-type IDH1 and IDH2 activity and catalyse α-KG to R-2-hydroxyglutarate (R2H), a metabolite that is suspected to trigger brain tumors. In AML patients, IDH1m have been shown to be associated with FAB M1 subtype and CN-AML The prognosis of both IDH1m and IDH2m in AML remains unclear. *Methods.* The prevalence and the prognostic impact of R132 IDH1 and R172 IDH2 mutations were evaluated in a cohort of 520 adults with AML homogeneously treated in the French ALFA-9801 and -9802 trials. The screening of *IDH1m* and *IDH2m* was performed by direct sequencing. *Results.* The prevalence of *IDH1m* and *IDH2m* was respectively 9.6% and 3.0%, mostly associated with normal cytogenetics (CN). Among the 50 patients harbouring *IDH1m*, we found 22 R132H (44%), 21 R132C (42%), 6 R132S (12%) and 1 R132L mutation (2%), contrarily to what was reported in gliomas where R132 IDH1 is found mutated to histidine in more than 88% of the cases. All cases with *IDH1m* or *IDH2m* were heterozygous for the mutation. Patients with CN-AML and *IDH1m* or *IDH2m* were slightly older (respective median age: 54y and 57y *vs.* 48y, P=.07 and P=.09). In those patients, *IDH1m* was associated with *NPM1m* (P=.008) but exclusive of *CEBPAm* (P=.03). The rate of *FLT3*-ITD was similar in *IDH1m* and *IDH1wt* patients (18% *vs.* 20%, P=.99). In contrary, no other mutations were detected in IDH2m patients. In CN-AML patients, *IDH1m* were found in 19% of favorable genotype ((*NPM1m* or *CEBPAm*) without *FLT3*-ITD) and were associated with a higher risk of relapse (5y-RR: 71% for *IDH1m vs.* 38%, P=.01) and a trend to shorter overall survival (5y-OS: 45% for *IDH1m vs.* 64%, P=.10). Favorable genotype in CN-AML could thus be defined by the association of *NPM1m* or *CEBPAm* with neither *FLT3*-ITD nor *IDH1m*. Patients with this favourable profile (N=62) had a lower RR (5y-RR: 39% *vs.* 76%, P<.0001) and a better OS (5y-OS: 68% *vs.* 29%, P<.0001). In *IDH2m* CN-AML patients (N=7), we observed a higher risk of induction failure, a higher RR (5y-RR: 100% for *IDH2m vs.* 60%, P=.01) and a shorter OS (5y-OS: 0% for *IDH2m vs.* 46%, P=.005). In multivariate analysis, age, WBC count, the 4-gene favorable genotype and *IDH2m* were independently associated with a higher RR and a shorter OS. *Conclusion.* Contrarily to what is reported in gliomas, *IDH1m* and *IDH2m* are associated with a poor prognosis in AML. Screening of *IDH1m* could help to identify high risk patients within the subset of CN-AML with a favorable genotype.

1107

IDH1 AND IDH2 GENE MUTATIONS IDENTIFY NOVEL MOLECULAR SUBSETS WITHIN DE NOVO CYTOGENETICALLY NORMAL ACUTE MYELOID LEUKEMIA (CN-AML): A CANCER AND LEUKEMIA GROUP B (CALGB) STUDY

G Marcucci,[1] K Maharry,[1] YZ Wu,[1] M Radmacher,[1] K Mrózek,[1] D Margeson,[1] K Holland,[1] S Whitman,[1] H Becker,[1] S Schwind,[1] K Metzeler,[1] B Powell,[2] T Carter,[3] J Kolitz,[4] M Wetzler,[5] M Baer,[6] A Carroll,[7] M Caligiuri,[1] R Larson,[8] C Bloomfield[1]

[1]The Ohio State University, Columbus, OH, USA; [2]Wake Forest University, Comprehensive Cancer Center, Winston-Salem, NC, USA; [3]University of Iowa, Iowa City, IA, USA; [4]North Shore University Hospital, Manhasset, NY, USA; [5]Roswell Park Cancer Institute, Buffalo, NY, USA; [6]University of Maryland, Baltimore, MD, USA; [7]University of Alabama at Birmingham, Birmingham, AL, USA; [8]University of Chicago, Chicago, IL, USA

Background. Recent studies revealed that mutations in the *IDH1* and *IDH2* genes, which encode isoforms of the NADP(+)-dependent isocitrate dehydrogenases, are recurrent in brain tumors and are associated with favorable outcome. Importantly, *IDH1*, but not *IDH2*, mutations were also discovered in AML. The presence of *IDH1* mutations was associated with CN-AML, and found to confer adverse prognosis in a subset of CN-AML patients without mutations in the *NPM1* gene (Mardis *et al*. N Engl J Med 361:1058-1066, 2009). However, larger studies of similarly treated patients are necessary to assess the frequencies and prognostic significance of mutations in both the *IDH1* and *IDH2* genes in CN-AML. *Aims.* To evaluate the frequency and analyze associations with prognostic markers and outcome of mutations in the *IDH1* and *IDH2* genes in adults with *de novo* CN-AML. *Methods.* Diagnostic marrow or blood samples from 358 patients treated with age-adapted intensive chemotherapy regimens on CALGB first-line protocols were analyzed for *IDH1* and *IDH2* mutations by DNA PCR amplification/sequencing. *FLT3*, *NPM1*, *CEBPA*, *WT1* and *MLL* mutational analyses and gene- and microRNA-expression profiling were performed centrally. *Results. IDH* mutations were found in 33% of the patients. *IDH1* mutations were detected in 49 patients (14%; 47 with R132). *IDH2* mutations, previously unreported in AML, were detected in 69 patients (19%; 13 with R172 and 56 with R140). R172 *IDH2* mutations were mutually exclusive with all prognostic mutations analyzed. Younger (<60 years) molecular low-risk (*NPM1*-mutated/*FLT3*-ITD-negative) *IDH1*-mutated patients had shorter disease-free survival than molecular low-risk, *IDH1/IDH2*-wild-type (wt) patients (P=.046). R172 IDH2-mutated patients had lower complete remission rates than *IDH1/IDH2*wt patients (P=.007). Distinctive microarray gene- and microRNA-expression signatures accurately predicted R172 *IDH2* mutation status (95.5% and 93.4% cross-validated prediction accuracy for gene- and microRNA-expression signatures, respectively). The highest expressed gene and microRNAs in R172 *IDH2*-mutated patients compared with the *IDH1/IDH2*wt patients were, respectively, APP, previously associated with complex karyotype AML, and *miR-1* and *miR-133*, involved in embryonal stem-cell differentiation. *Summary. IDH1* and *IDH2* mutations are recurrent in CN-AML and impact unfavorably on outcome. *IDH1* mutations are associated with shorter disease-free survival in younger patients with molecular low-risk CN-AML. R172 *IDH2* mutations are mutually exclusive with other known prognostic mutations and denote a novel subset of older CN-AML characterized by resistance to induction chemotherapy, whereas R140 *IDH2* mutations do not appear to confer prognostic significance. By deriving gene- and microRNA-expression signatures, we uncovered intriguing features in R172 *IDH2*-mutated patients that may lead to better understanding of the biologic role of this mutation, and to designing of novel therapies targeting aberrant IDH-driven activation of metabolic pathways.

1108

IDH1 AND IDH2 GENE MUTATIONS ARE FREQUENT MOLECULAR LESIONS IN ACUTE MYELOID LEUKEMIA (AML) AND CONFER ADVERSE PROGNOSIS IN CYTOGENETICALLY NORMAL AML WITH NPM1 MUTATION WITHOUT FLT3-ITD

P Paschka,[1] R Schlenk,[1] V Gaidzik,[2] M Habdank,[1] J Krönke,[3] L Bullinger,[1] D Späth,[1] S Kayser,[1] M Zucknick,[4] K Götze,[5] H Horst,[6] U Germing,[7] H Döhner,[1] K Döhner[1]

Background. Isocitrate dehydrogenase 1 (*IDH1*) and 2 (*IDH2*) genes encode metabolic enzymes that convert isocitrate into α-ketoglutarate (α-KG). *IDH1* and *IDH2* (hereafter commonly referred to as *IDH*) mutations have been described as recurrent molecular lesions in gliomas and in acute myeloid leukemia (AML). *IDH* mutations cluster in exon 4 and result in a neomorphic enzymatic activity to convert α-KG into 2-hydroxyglutarate. While in gliomas IDH mutations have been associated with favorable outcome, their prognostic relevance in AML still remains to be elucidated. *Aims.* The objectives of this study were to assess the frequencies of *IDH* mutations and to explore their associations with clinical, cytogenetic and molecular characteristics as well as their prognostic relevance in a large cohort of AML patients. *Methods.* Pretreatment bone marrow or blood specimens from 805 patients with AML aged <60 years and entered on one of two AMSLG treatment trials [AML HD98A (n=734) and APL HD95 (n=71)] were studied for the presence of *IDH* mutations; exon 4 of *IDH1* and *IDH2*, respectively, was amplified by PCR and the amplicons were analyzed using a combination of denaturing high-performance liquid chromatography and DNA sequencing. The patients were also assessed for *FLT3* (ITD and TKD), *NPM1*, *CEBPA* and *MLL*-PTD mutations by standard PCR techniques. *Results. IDH* mutations were found in 129 (16.0%) patients [*IDH1* in 61 (7.6%), *IDH2* in 70 (8.7%)]; two cases had both *IDH1* and *IDH2* mutations. All but one *IDH1* mutation caused substitutions of residue R132. *IDH2* mutations resulted in changes of residues R140 (n=48) or R172 (n=22). *IDH* mutations were associated with cytogenetics; 67% of the patients with IDH mutations had a normal karyotype, 22 (19%) cases had other intermediate-risk cytogenetics, and 15 (13%) cases had adverse-risk cytogenetics. Only 1 one of 71 APL patients, and no patients with core-binding factor AML harbored *IDH* mutations. In AML with adverse-risk cytogenetics, *IDH* mutations were mainly represented by *IDH2* mutations (13 of 15; $IDH2^{R140Q}$, n=6; $IDH2^{R172K}$, n=7). With regard to clinical and molecular features, *IDH* mutations were associated with older age (P<.001; effect conferred by *IDH2* mutations only), higher platelets (P<.001), cytogenetically normal (CN)-AML (P<.001), and *NPM1* mutations, in particular with the genotype "mutated *NPM1* without *FLT3*-ITD"(P<.001). In univariable and multivariable analyses, IDH mutations did not impact response to induction; the same was true when patients with APL were excluded or the analysis was restricted to CN-AML patients. In univariate analyses, *IDH* mutations adversely impacted overall survival (OS; P=.03) only in CN-AML with mutated *NPM1* without *FLT3*-ITD (5-year OS rates: 41% v 65% for patients with and without *IDH* mutations, respectively); however, in multivariate analyses, *IDH* mutations were a poor prognostic factor for relapse-free survival (P=.03) and OS (P=.007) in this patient subset. *Summary/Conclusions. IDH* mutations are recurring genetic changes in AML, in particular in *NPM1*-mutated cases and constitute a poor prognostic factor among CN-AML with mutated *NPM1* without *FLT3*-ITD allowing to further refine the risk stratification of this favorable AML subset.

1109

IDH1 MUTATIONS ARE DETECTED IN 6.6% OF ALL AML AND ARE STRONGLY ASSOCIATED WITH INTERMEDIATE RISK KARYOTYPE AND UNFAVOURABLE PROGNOSIS: A STUDY OF 1414 PATIENTS

S Schnittger, C Haferlach, U Ulke, T Tamara, W Kern, T Torsten

MLL Munich Leukemia Laboratory, Munich, Germany

Introduction. IDH1 is the gene coding for the soluble isocitrate dehydrogenease 1 ($NADP^+$), which catalyzes the oxidative decarboxylation of isocitrate to 2-oxoglutarate. The gene has been shown to be frequently mutated in high-grade gliomas at residue p.R132, which is located in the substrate binding site of IDH1. Recently a next generation sequencing project found IDH1 mutated in AML with normal karyotype (Mardis *et al.,* NEJM, 2009). *Aim.* To further evaluate the importance of IDH1R132 (IDH1mut) in AML we have analyzed a cohort of 1414 comprehensively characterized AML cases. *Methods.* The respective base exchange was analysed by a LightCycler based melting curve assay with subsequent sequencing of the positive samples. *Results.* The cohort was comprised of 1170 *de novo* AML (82.7%), 157 AML following MDS (s-AML,11.1%) and 87 AML after previous treatment of different malignancies (t-AML, 6.2%). Median age was 63 years (range (17.1-93.3 years). Karyotype was available in all cases: 673 had a normal karyotype (NK) AML, and 741 had chromosomal aberrations (t(15;17): n=88; inv(16): n=57, t(8;21): n=83, t(11q23): n=31, t(6;9): n=5, inv(3): n=15; -7: n=32, +8: n=30, +13: n=12, complex aberrant: n=288, others: n=1806). Overall, in 93 pts IDH1 p.R132 mutations were detected (6.6%). Five different amino acid exchanges were observed: R132C (n=51), R132L (n=22), R132 H (n=6), R132G (n=9), and R132S (n=5). With respect to history of the patient IDH1mut were found in 80/1170 of *de novo* AML (6.8%), 11/157 (7.0%) of s-AML, and 2/87 (2.3%) of t-AML, respectively (n.s.). Significantly more females (58/668, 8.7%) than males (35/741; 4.7%) revealed the IDH1mut (P=0.003). Age was slightly higher in the mutated cases (66.0 *vs.* 62.6 years, P=0.075). There was a clear association to the intermediate risk karyotype group (10.4%, P<0.001). Although IDH1R132 mutations were detected incidentally together with all other molecular markers there were strong associations with NPM1 mutations (14.2 *vs.* 5.4% in NPM1wt, P<0.001) and MLL-PTD (18.2% *vs.* 7.0% in MLLwt, P=0.020). There were further strong associations to AML without maturation/FAB M1 (P<0.001) and an immature immunophenotype. Prognosis was adversely affected by IDH1 mutations with trend for shorter OS (533 days *vs.* median not reached; P=0.110) and a shorter EFS (365 *vs.* 523 days; P<0.003). Although IDH1 mutations were detected preferentially in NPM1 mutated AML, an adverse impact of IDH1 mutations was detected only in the NPM1wt group (median 283 days for IDH1mut *vs.* 668 days for IDH1wt, P=0.044). In the age group <60 years IDH1 mutations were of independent prognostic relevance (P=0.028). Conclusions, these data show that IDH1R132 is a further important marker in AML that is useful for further characterization and prognostication. In addition, IDH1 mutations seem to be a new class of mutation probably complementing with the classical type 1 and type 2 mutations.

Background. Imatinib mesylate (IM) 400 mg once daily (OD) is the current standard first-line therapy for CML. Several biological and clinical observations suggest that combining IM with interferon (IFN) alpha may improve the outcome of treatment. *Aim.* To compare the effects of standard-dose IM to combination of IM and IFN alpha in newly diagnosed chronic phase CML patients with an intermediate or low Sokal risk score in IM induced complete hematological remission (CHR). The primary objective was to compare the major molecular response (MMR) rate after 12 months between the treatment arms (intention-to-treat analysis). *Patients and therapies.* In a Nordic CML Study Group (NCMLSG: Denmark, Finland, Norway and Sweden) and Israel multicenter study we randomized (after informed consent was obtained) 112 newly diagnosed CML patients in CHR following 3 months of IM 400 mg OD induction therapy. The study arms were IM (Glivec, Novartis) and the combination of IM and IFN alpha-2b (PegIntron, Schering-Plough) (Peg-IFN). IM dose was fixed at 400 mg OD. The starting dose of Peg-IFN was initially 50 μg once weekly, but rather soon due to side effects reduced to 30 μg once weekly. Depending on tolerability it could then be escalated to 50 or reduced down to 15 _g once weekly. Molecular response was evaluated by blood RQ-PCR for BCR-ABL1 and expressed on the international scale (IS). *Results.* MMR rate at 52 weeks was significantly higher (P=0.002) for the IM+Peg-IFN arm (82%) compared to the IM only arm (54%) (intention to treat analysis). No unpredictable complications or adverse events were reported. Four patients (8%) discontinued IM in the IM arm (progression to ABP, protocol violation, loss of CCgR, biochemical AE). In the combination arm 4 patients (8%) discontinued IM (progression to ABP, no CgR, nonhematological AEs) and 30 (58%) discontinued Peg-IFN (refusal, hematological and non-hematological AEs,). The MMR rate increased with the duration of Peg-IFN treatment (<12 weeks MMR rate 67%, >38 weeks MMR rate 91%). *Conclusions.* In newly diagnosed CML patients with an intermediate or low Sokal risk score and in IM induced CHR, the MMR rate at 52 weeks was significantly higher (P=0.002) for the IM+Peg-IFN arm (82%) compared to the IM only arm (54%) (intention to treat analysis). There were no unpredictable complications or adverse events reported.

Initial imatinib therapy has never been optimized. Faster induction of molecular and cytogenetic remissions by imatinib 800 mg has been reported. The German CML Study Group therefore compared imatinib 800 mg (IM 800) with standard dose imatinib ± IFN (IM 400, IM+IFN) in newly diagnosed, not pretreated CP-CML with regard to major molecular response (MMR) at 12 months in a randomized clinical trial. By April 30, 2009, 1022 patients were randomized. Comparison was for molecular and cytogenetic remissions, overall (OS) and progression free (PFS) survival and toxicity. 1016 patients were evaluable at baseline, 954 for survival analysis (305 for IM 400, 310 for IM 800, 339 for IM+IFN), 845 for cytogenetic and 871 for molecular remissions. Median follow-up was 28 months in the IM 800 arm and 47 (44) months in the imatinib 400±IFN arms, respectively. The difference is due to a later start of the IM 800 arm. The median daily doses of imatinib were 646 mg (209- 800 mg) in the IM 800 arm and 400 mg (184- 720 mg) in the IM 400±IFN arms. Of 218 patients receiving IM 800 and evaluable for dosage at 12 months, 100 (45.9%) received more than 700 mg, 27 (12.4%) 601-700 mg, 37 (17.0%) 501-600 mg, 48 (22.0%) 401-500 mg and only 6 (2.8%) 400 mg/day or less. The cumulative incidences of achieving complete cytogenetic remission (CCR) and MMR with IM 400, IM 800 and IM+IFN at 6, 12, 18 and 24 months after start of treatment and the differences of CCR and MMR rates between treatment arms are summarized in the table. MMR at 12 months was reached in more patients with IM 800 than with IM 400 (P=0.0001) or IM+IFN (P=0.0009). Optimal molecular response (<0.01% BCR-ABL according to the international scale) was reached with IM 800 after a median of 31.3 *vs.* 47.5 and 42.5 months with IM 400±IFN, respectively. Also CCR was reached faster with IM 800 (P<0.01). The more rapid achievement of MMR with IM 800 was observed in low and intermediate risk, but not in high risk patients. At the time of this evaluation, OS (92%) and PFS (88%) at 5 years showed no difference between treatment arms. After dose adjustments IM 800 was well tolerated. Hematologic (thrombocytopenia 7% *vs.* 4%) and non-hematologic adverse events (AE) (gastrointestinal 35% *vs.* 15-24% and edema 29% *vs.* 16-19%) were more frequent with IM 800, fatigue (14% *vs.* 7-13%) and neurological problems (15% *vs.* 6-7%) more frequent with IM+IFN. Grade III/IV AEs as analyzed over the total time of therapy were rare and did not differ between treatment arms. In conclusion, these data show a significantly faster achievement of MMR and CCR with IM 800 as compared to IM 400±IFN. The data indicate that the optimal imatinib dose in CP may be higher than 400 mg per day. Longer observation will determine whether or not this more rapid achievement of MMR and CCR will translate into better survival.

Table.

Time after start of treatment	Cumulative incidences of achieving a									
	CCR(%)					MMR(%)				
	IM400 n=273	Δ	IM800 n=268	Δ	IM+IFN n=304	IM400 n=279	Δ	IM800 n=283	Δ	IM+IFN n=309

Background. IM 400 mg daily is the front-line treatment of CP CML, but provides only 50% major molecular responses (MMR) at 18 months (Mo). *Aims.* we designed a phase III randomized multicenter open-label prospective trial comparing IM 400 mg/d (n=159) with 3 experimental arms: IM 600 mg/d (n=160), IM 400 mg/d combined to s/c cytarabine (Ara-C), (20 mg/m^2/d, d15-28 of 28-day cycles)(n=158) and IM 400 mg/d combined to s/c Peg-IFN2a (90 µg/wk) (n=159). *Methods.* Pts were allocated at a 1.1.1.1 ratio, stratified by Sokal risk groups, molecular assessments being calculated according to the international standardized scale (IS). The purpose of this trial ,conducted according to 2 part, was to first determine whether higher doses of IM or combining IM with interferon or Ara-C would result in higher rates of molecular responses and if so, in better survival. During the part 1, the increased dose of IM or a combination regimen would be considered as promising at 1 year, if it increased the 4 log reduction response rate by at least 20 percentage points, e.g. from 15% to 35%. A planned interim analysis of 636 pts based on an optimal molecular response (OMR = BCR-ABL/ABL ratio ≤0.01) (α=0.85%, β=10%) at 1 year has suggested the superiority of the combination of Peg-IFN2a and imatinib (ASH 2008). We now report the 24 months update of this planned interim analysis. *Results.* Pts of the part 1 were recruited between 9/2003 and 10/2007, median age 51 yrs (18-82), 62% males; Sokal score was low 37%, intermediate 39% and high risk 24%. Median follow-up was 48 Mo. (range 24-73) for alive patients. Rates of MMR at 24 months (ITT) were for IM+Peg-IFN2a , IM 400 mg, IM 600 mg, and IM + Ara-C 71%, 48%, 62% and 63% (P value PegIFN *vs.* IM 400 mg:P<.0001); the corresponding number for OMR were 46%, 26%, 34%, and 34% (P=.0006); for undectable molecular residual disease 22%, 11%, 11%, 10% (P=.0028). During the first year of treatment the median dose of IM was 400 mg for the 3 arms including IM 400 and 590 mg for IM 600; the median dose for Peg IFN2a was 54 µg per week (range11-166) and was 24mg per day (range 10-40) for Ara-C. Overall, 45% of the pts discontinued Peg-IFN2a during the first 12 months. Of interest, duration of treatment with Peg-IFN2a had an impact on responses. In pts who have been treated less than 4 months as compare to more than 12 months, rate of MMR, OMR and UMRD increased from 48-82%, 23-49% and 8-20% respectively. Grade 3/4 neutropenia and/or thrombocytopenia occurred more frequently with the combination arms; the proportion of patients with grade 3 or 4 adverse events was relatively low in all arms. *Conclusions.* Based on these results accrual was stopped into the IM 600 mg and IM 400 mg

+ Ara-C arms and the trial is currently recruiting with IM 400 mg as control arm and the combination IM400 mg + Peg-IFN2a as best experimental arm.

Background. Results of ENESTnd demonstrated superior efficacy of nilotinib 300 and 400 mg bid over imatinib, including significantly higher rates of major molecular response (MMR) and complete cytogenetic response (CCyR). *Aims.* Here, we present new data including molecular and cytogenetic responses in evaluable patients and event-free survival (EFS). *Methods.* 846 patients with CML-CP were randomized to nilotinib 300 mg bid (n=282), nilotinib 400 mg bid (n=281), and imatinib 400 mg qd (n=283). Primary endpoint was MMR (≤ 0.1% BCR-ABLIS) rate at 12 months. EFS events defined as death due to any cause, progression to advanced phase or blast crisis, loss of CCyR, loss of partial CyR, or loss of complete hematologic response. *Results.* Rates of MMR at 12 months were superior for nilotinib 300 and 400 mg bid compared with imatinib (Table). Superior rates of MMR at 12 months were observed in both nilotinib arms compared with the imatinib arm across all Sokal risk groups (Table). Higher rates of MMR were also observed in both nilotinib arms at 15 months in evaluable patients, with 57% achieving MMR in both nilotinib arms compared with 33% in the imatinib arm. Molecular responses were deeper on nilotinib, with more patients achieving BCR-ABL (IS) transcript level reductions of ≤ 0.01% and ≤ 0.0032% compared with imatinib. CCyR rates by 12 months were higher in evaluable patients treated with nilotinib 300 mg bid (93%) and nilotinib 400 mg bid (93%) compared with imatinib (76%). More patients experienced cytogenetic treatment failure (ELN 2006) on imatinib (8%) compared with nilotinib 300 mg bid (1%) or 400 mg bid (2%). Progression to advanced disease was significantly lower for nilotinib at both doses compared with imatinib (Table).

Table.

	Nilotinib 300 mg bid (n = 282)	Nilotinib 400 mg bid (n = 281)	Imatinib 400 mg qd (n = 283)
MMR, %			
At 12 months (ITT)	44 $P < .0001$*	43 $P < .0001$*	22
At 12 months (evaluable patients) (n=242, 240, 235)	51	50	27
At 15 months (evaluable patients) (n=154, 155, 145)	57	57	33
MMR at 12 months by Sokal risk group (ITT), %			
Low	41 $P = .0238$†	53 $P < .0001$†	26
Intermediate	51 $P < .0001$†	40 $P = .0085$†	23

* CMH test stratified by Sokal vs imatinib

† Chi-square test

‡ Log-rank test stratified by Sokal vs imatinib for EFS and time to AP/BC

Estimated 12-month rate of EFS was higher in nilotinib 300 mg bid (97.6%) and nilotinib 400 mg bid (99.6%) compared with imatinib (95.7%). No patient who achieved MMR progressed. Of 11 patients who progressed on imatinib, 10 had secondary resistance, and 6 had mutations. Both drugs were well-tolerated. Discontinuations due to adverse events or laboratory abnormalities were lowest for nilotinib 300 mg bid (7%). Minimum 16-month follow-up data will be presented (maximum, 29 months). *Conclusions.* Nilotinib induced higher response rates compared with imatinib with longer follow-up. This superior efficacy resulted in significantly improved progression rates. These data support the potential of nilotinib to become the new standard of care in patients with newly diagnosed CML.

1114

NILOTINIB 400 MG BID IN EARLY CHRONIC PHASE PH+ CHRONIC MYELOID LEUKEMIA: RESULTS AT 2 YEARS OF A PHASE II TRIAL

Background. Imatinib (IM) 400 mg daily is the standard treatment for Ph^+ chronic myeloid leukemia (CML) in early chronic phase (ECP). According to the IRIS trial, the rate of progression to advanced phase and the rate of any event (loss of complete hematologic response, loss of major cytogenetic response, progression or death) are higher during the first period of treatment: particularly, during the first 2 years they were 10.8% and 4.3%, respectively. Moreover, only 3% of patients who achieved a complete cytogenetic response (CCgR) progressed to advanced phase, all but 1 within 2 years of achieving CCgR. In a phase III trial (ENESTnd, ASH Meeting 2009), nilotinib at both 300 mg and 400 mg bid induced significantly higher and faster rates of major molecular response (MMR) and CCgR compared with imatinib 400 mg daily; the median observation time was 14 months. *Aims.* To investigate the dynamics and deepness of molecular response, the stability of responses, the progression-free and event-free survival, in ECP Ph-pos CML patients treated with nilotinib 400 mg BID, with a minimum follow-up of 24 months (results at 12 months have been previously published , Rosti *et al.*, Blood 2009). *Methods.* A multicentric phase II trial was conducted by the GIMEMA CML Working Party (ClinicalTrials.gov.NCT00481052). The molecular response was studied serially by Q-PCR (MMR, ≤ 0.1% according to the International Scale). By March, 2010 all the patients will complete 24 months on treatment. *Results.* 73 patients have been enrolled; median age 51 years (range 18-83), 45% low, 41% intermediate and 14% high Sokal risk. Median follow-up is currently 724 days. The cumulative CCgR rate within 12 months was 100%. The CCgR rate was 78% at 3 months and 96% at 6,12 and 18 months. The median duration of CCgR was 18 months. The rates of MMR at 1, 2, 3, 6, 12, 15, 18 and 21 months were 3%, 21%, 52%, 66%, 85%, 87%, 87% and 87%, respectively. At 12 and 18 months, 7% and 16% of patients tested negative with nested PCR, respectively. One patient only progressed at 6 months to advanced phase (ABP) with T315I mutation. Adverse events (AEs) were mostly grade 1 and 2 and manageable with appropriate dose adaptations; 2 pts went off treatment after 9 and 15 months due to recurrent episodes of amylase and/or lipase increase (no pancreatitis). *Conclusions.* At 2 years, an increasing number of patients achieved transcript-undetectable status; responses to nilotinib, either CCgR and MMR, remain stable. No progressions to advanced phase have been observed during the second year. *Acknowledgements.* European LeukemiaNet, COFIN, Bologna University, BolognAIL.

PRELIMINARY RESULTS OF A PHASE II TRIAL OF LOW-DOSE CLOFARABINE IN COMBINATION WITH THE MTOR INHIBITOR TEMSIROLIMUS AS FIRST SALVAGE THERAPY FOR ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA (GIMEMA AML-1107)

S Amadori,[1] A Venditti,[1] A Martelli,[2] E Ammatuna,[1] G Meloni,[3] L Pagano,[4] G Saglio,[5] M Lunghi,[5] V Rizzoli,[5] C Fozza,[5] G Martinelli,[5] E La Sala,[6] P Fazi,[6] M Vignetti[6]

[1]Tor Vergata University Hospital, Rome, Italy; [2]Cell Signaling Laboratory, University of Bologna, Bologna, Italy; [3]La Sapienza University, Rome, Italy; [4]Catholic University, Rome, Italy; [5]University Hospital, Orbassano, Italy; [6]Gimema Data Center, Rome, Italy

Background. Elderly patients with refractory/relapsed AML have a dismal prognosis and new treatments are needed for these patients. Constitutive activation of the PI3K/AKT/mTOR pathway regulates the growth and survival of AML cells and may contribute to chemoresistance. mTOR inhibition with rapamycin analogs has been associated with responses in AML and may enhance the sensitivity of leukemic cells to cytotoxics. Clofarabine is a nucleoside analog with activity in elderly AML. Based on this, we designed a multicenter phase II study of low-dose Clofarabine in combination with Temsirolimus in elderly patients with advanced AML. *Aims.* To assess efficacy and toxicity of this regimen when given as first salvage therapy; primary endpoint is the rate of CR+CRi. Enrollment is proceeding according to a 2-stage design with a minimum of 19 pts in stage 1 and expansion to a total of 54 evaluable pts if at least 5 CR/CRi were observed in the initial cohort. In addition, correlative biomarker studies will examine if leukemia mTOR pathway status predicts clinical response. *Methods.* Eligible were pts age ≥ 60 yrs with first relapse or primary refractory AML. Induction consisted of one course of Clofarabine 20 mg/m^2 iv d 1-5 and Temsirolimus 25 mg (flat dose) iv d 1, 8 and 15; a second course was allowed in pts achieving PR. Pts achieving CR/CRi receive up to 12 monthly courses of maintenance with Temsirolimus (25 mg iv d 1 and 8 per course). *Results.* Between 04/09 and 10/09, 21 pts were enrolled and all are evaluable for response. Demographics: 52% males; median age 69 yrs (range 60-77); primary refractory AML 24%, first relapse AML 76% (duration of CR1 < 12 mos 75%, ≥ 12 mos 25%); cytogenetics: intermediate 67%, adverse 14%, and unknown 19%. Eight pts achieved a CR (3) or CRi (5) for an ORR of 38%. The 30-day all-cause mortality rate was 14% (2 pts died from infection, 1 pt died of progressive AML+pneumonia). CR/CRi was achieved in 1/5 pts with primary refractory AML (20%), and 7/16 in first relapse (44%). In particular, responses were noted in 6/12 (50%) pts with short CR1 (< 12 mos), and in 1/4 (25%) pts with longer CR1. CR/CRi rates by cytogenetics and age are: intermediate 4/14 (29%), adverse 0/3, unknown 4/4 (100%); < 70 yrs 4/12 (33%), ≥ 70 yrs 4/9 (44%). Median duration of remission is 3 mos; 5 pts have relapsed to date and 3 (1 CR, 2 CRi) remain on Temsirolimus maintenance at 5+, 6+ and 7+ mos from remission. Median follow-up is 5 mos and 11 pts remain alive at 6-9+ mos. Besides cytopenias, the most common CTCAE grade 3/4 were infection (67%), febrile neutropenia (43%), diarrhea (10%), nausea/vomiting (10%), and transaminase elevation (10%). Median times to recovery of neutrophils to 500/cmm and platelets to 50,000/cmm in responders were 28 and 32 days, respectively. *Conclusion.* These preliminary results suggest that the combination of low-dose Clofarabine and Temsirolimus has encouraging clinical activity in this difficult-to-treat patient population, with a manageable safety profile. Accrual and correlative biomarker analyses continue.

1116

PP2A IMPAIRED ACTIVITY IS A COMMON EVENT IN ACUTE MYELOID LEUKEMIA, AND ACTIVATION BY FORSKOLIN TREATMENT INDUCES A POTENT ANTILEUKEMIC EFFECT

I Cristóbal, L García-Ortí, L Urquiza, M Alonso, E Bandrés, MJ Calasanz, MD Odero

CIMA, University of Navarra, Pamplona, Spain

Protein phosphatase 2A (PP2A) is a major phosphatase and tumor suppressor that has been described as a potential therapeutic target for chronic myeloid leukemia, Philadelphia-chromosome positive acute lymphoblastic leukemia, and B-cell chronic lymphocytic leukemia. Moreover, it has been described a reduced PP2A activity in a small series of 13 AML patients with complex karyotype (n=7), in comparison with intermediate-risk karyotype (n=6). We have previously reported that SETBP1 overexpression is a recurrent event in AML (27%) that impairs PP2A activity, promoting proliferation of the AML cells. This would suggest that PP2A inhibition could be a recurrent event in AML. To test this hypothesis we first investigated the PP2A status in AML cell lines, observing an increased inhibition of PP2A in 11 out of 13 cell lines. Restoration of the PP2A phosphatase activity by treatment with forskolin in AML cells had antileukemic effects, blocking proliferation, and inducing caspase-dependent apoptosis. We also analyzed the status of previously described PP2A targets, and determined that enhanced PP2A activity induced by forskolin treatment decreased the levels of Akt and ERK1/2 phosphorylation, without affecting their expression. Moreover, there was an additive effect between forskolin and chemotherapic reagents idarrubicin and Ara-c, both used in standard induction therapy in AML patients. We next assessed whether PP2A was also altered in patient samples. Analysis at protein level of the PP2A activation status in 35 samples of patients with AML at diagnosis showed that all samples presented a reduced PP2A activity in comparison with normal donors. Altogether, these results suggest that functional inactivation of the PP2A tumor suppressor represents an important mechanism in AML transformation. To investigate other possible mechanisms that could be contributing to PP2A inhibition, we performed SNP and mRNA arrays in 12 AML cell lines. This approach allowed us to identify novel genomic aberrations affecting PPP2R5B and PPP2R5C expression. Our data suggest that loss of PPP2R5B and PPP2R5C, both PP2A subunits previously implicated in cancer, could be playing a role in AML development, contributing to deregulate the accurate PP2A function. Further studies are necessary to clarify the importance of these PP2A subunits in AML. In summary, we show that PP2A inhibition is a recurrent event in AML, and that restoration of the PP2A phosphatase activity in AML cells has antileukemic effects, showing an additive action in combination with idarrubicin and Ara-c. Therefore, PP2A activators, such as forskolin, could represent a future therapeutic alternative for treating patients with AML.

AC220, A POTENT, SELECTIVE, SECOND GENERATION FLT3 RECEPTOR TYROSINE KINASE (RTK) INHIBITOR, IN A FIRST-IN-HUMAN PHASE 1 AML STUDY

M Trikha,[1] J Cortes,[2] J Foran,[3] D Ghirdaladze,[4] M DeVetten,[5] M Zodelava,[6] P Holman,[7] M Levis,[8] H Kantarjian,[2] G Borthakur,[2] J James,[1] R Armstrong,[1] P Zarrinkar,[1] N Padre,[1] W Wierenga,[1] R Corringham[1]

[1]Ambit Biosciences, San Diego, USA; [2]University of Texas, MD Anderson Cancer Center, Houston, USA; [3]University of Alabama at Birmingham, Birmingham, USA; [4]Medulla Clinic, T'bilisi, Georgia; [5]University of Nebraska Medical Center, Omaha, USA; [6]Hema Clinic, T'bilisi, Georgia; [7]University of San Diego, La Jolla, USA; [8]John's Hopkins University, Baltimore, USA

Background. Activating mutations in FLT3 RTK are present in ~30% of AML patients (pts), who have worse prognosis than wild-type (WT) pts. AC220 is a highly-selective 2nd generation RTK inhibitor of WT and mutant FLT3 with significant KIT activity. *Aims.* This was a Phase 1 open-label, dose escalation, first-in-man study to determine safety, tolerability, and PD of AC220 in AML pts. *Methods.* This study of predominantly relapsed/refractory AML pts was recently completed using a standard 3+3 dose escalation with 50% increments. Once-daily oral AC220 was administered initially with an intermittent dosing (ID) regimen: 14 on, 14 off (1 cycle). Starting dose was escalated from 12 to 450 mg/day. Additional continuous dosing (CD) cohorts were investigated: 200 and 300 mg/day for 28 days (1 cycle). *Results.* Seventy-six pts (46 male, 30 female) received AC220. Median age was 60 yrs (23-86 yrs), median prior therapies was 4 (0-8), with 16 pts having prior MDS or MDS/MPD, 11 pts having prior allogeneic transplant and 3 pts (≥72 yrs; unfit for induction chemotherapy) being previously untreated. Eighteen pts (24%) had FLT3-ITD mutations, 45 (59%) were ITD negative, and 13 (17%) undetermined. Pts were evaluated for PK and biomarkers such as phosphorylated (p) FLT3, pKIT, pSTAT5, and ex-vivo plasma inhibitory activity. AC220 plasma exposure was sustained between dose intervals and dose-proportionally increased from 12-450 mg with a half-life of ~1.5 days. Patient plasma at ≥12 mg potently inhibited pFLT3 in *ex-vivo* FLT3-ITD cell lines, with complete inhibition in WT cell lines observed at higher doses. Target inhibition was

observed, with suppression of pFLT3, pSTAT5 and pKIT in peripheral blasts. Most commonly reported possibly drug-related AEs were GI events, peripheral edema, and dysguesia, (predominantly Grade ≤2). DLT was observed at 300mg CD; 200mg CD was declared MTD. Two 300mg CD pts had possibly drug-related DLTs with Grade 3 QTc prolongation, but had confounding factors including concomitant QTc-prolonging medications. Responses (IWG criteria) were observed in 23 (30%) pts. PR and CR were observed as low as the 18 and 40mg cohorts, respectively. Most responses occurred within cycle 1. Overall, 10 (13%) pts had CR (2 CR, 6 CRi, and 2 CRp). One patient had complete resolution of leukemia cutis. Thirteen pts (18%) achieved PR. Median duration of response (MDOR) was 14 weeks (4-67+); median survival was 14 weeks (1-67+). In FLT3-ITD positive and negative pts, MDOR was 12 and 32 weeks. Ten (56%) of 18 FLT3-ITD pts were responders (1 CR, 4 CRi, 5 PR), 9/45 (20%) FLT3-ITD negative pts (1 CRi, 2 CRp, 6 PR), and 4/13 (31%) undetermined pts (1 CR, 1 CRi, 2 PR). At 200mg CD (MTD expansion), 4/6 FLT3-ITD positive pts responded (1 CR, 2 CRi, 1 PR). Of these responders, 2 failed prior sorafenib treatment and 2 refractory pts went onto transplant. The 2 non-responders had 6 and 8 prior lines of therapy, respectively. SUMMARY: These encouraging efficacy results and acceptable safety profile warrant continued evaluation of AC220 monotherapy and combination therapy in AML. Phase 2 studies in FLT3-ITD positive and negative pts are in progress.

1118

INDUCTION OF COMPLETE AND MOLECULAR REMISSIONS IN ACUTE MYELOID LEUKEMIA BY WILMS' TUMOR 1 ANTIGEN-TARGETED DENDRITIC CELL VACCINATION

N. Berneman,[1] A van de Velde,[1] S Anguille,[1] A van Driessche,[1] N Cools,[1] K Vermeulen,[1] K Pieters,[1] G Nijs,[1] B Stein,[1] W Schroyens,[1] A Gadisseur,[1] I Vrelust,[1] J de Vries,[2] Y Oji,[3] Y Oka,[3] H Sugiyama,[3] V van Tendeloo[1]

[1]Antwerp University Hospital (UZA), Edegem, Belgium; [2]Radboud University, Nijmegen, Netherlands; [3]Osaka University Graduate School of Medicine, Osaka, Japan

Background. Active immunization using tumor antigen-loaded dendritic cells (DC) holds promise for the adjuvant treatment of cancer to eradicate or control residual disease, but so far most DC trials have been performed in end-stage cancer patients with high tumor load. *Aims.* The majority of patients with acute myeloid leukemia (AML) will relapse and - except for allogeneic stem cell transplantation in subsets of patients - there is no consensus as to which post-remission treatment has to be applied in order to prevent relapse. Here, in a phase I/II trial, we investigated the effect of autologous DC vaccination in 20 patients with AML in remission but at high risk of full relapse. *Methods.* The Wilms' tumor 1 antigen (WT1), a nearly universal tumor antigen, was chosen as an immunotherapeutic target because of its established role in leukemogenesis and superior immunogenic characteristics. Myeloid DC were derived from immunoselected $CD14^+$ monocytes by culture with GM-CSF + IL-4, matured with TNF-α, prostaglandin E2 and in a majority of cases with keyhole limpet hemocyanin (KLH), electroporated with *WT1* mRNA and administered intradermally, at least 4 times on a biweekly basis. Quantitative levels of *WT1* mRNA in blood and marrow were followed as a marker of (minimal) residual disease. *Results.* Out of twenty patients, 17 are evaluable. Two out of 3 patients who were in partial remission with morphologically demonstrable disease after chemotherapy were brought into complete remission following intradermal administration of *WT1* mRNA-electroporated DC. In those 2 patients as well as in 7 other patients who were in complete remission but who had molecularly demonstrable residual disease, there was a return to normal of the *WT1* mRNA tumor marker following DC vaccination, compatible with the induction of molecular remission in 9/17 patients vaccinated thus far. Out of those 9 patients, 2 have relapsed with morphologically demonstrable disease and 4 have shown over the time signs of molecular relapse, as demonstrated by increase above normal background levels of *WT1* mRNA expression levels. In those 4 patients, *WT1* expression then usually normalised under further bi-monthly DC vaccination. Immunomonitoring, performed in 10 patients vaccinated with KLH-exposed DC vaccines, showed a significant increase in WT1-specific $CD8^+$ but not $CD4^+$ T cells and signs of general immune stimulation, such as a significant increase post-vaccination of plasma levels of interleukin 2 and of HLA-DR^+ $CD4^+$ T-cells. There was an inverse correlation between clinical response and degree of skin induration in delayed type hypersensitivity reactions to KLH alone. There was no significant change post-vaccination in WT1 antibody levels. *Conclusions.* Vaccination with *WT1* mRNA-loaded DC elicits immunological and clinical responses in AML patients. DC-based immunotherapy emerges as a feasible and effective strategy to control residual disease and prevent full relapse in AML.

1119

LONG-TERM OUTCOMES OF RESPONDERS IN A RANDOMIZED, CONTROLLED PHASE II TRIAL OF APTAMER AS1411 IN AML

R Stuart,[1] K Stockerl-Goldstein,[2] A Wei,[3] R Herzig,[4] F Erlandsson,[5] D Rizzieri[6]

[1]Medical University of South Carolina, Charleston, USA; [2]Washington University, St. Louis, MO, USA; [3]The Alfred Hospital, Melbourne, USA; [4]University of Louisville, Louisville, USA; [5]Antisoma Research Limited, London, UK; [6]Duke University Medical Center, Durham, NC, USA

Background. AS1411 is the most advanced aptamer in oncology clinical development. It targets nucleolin, a protein upregulated on the surface of cancer cells. Data from a phase II study of AS1411 in relapsed and refractory AML were reported at ASCO 2009. In this update, we report follow-up data for the responders in the study. *Methods.* This randomized, multi-center phase II trial compared AS1411 plus high-dose cytarabine (HiDAC) to HiDAC alone as treatment for relapsed (≤3 previous lines of therapy) or refractory AML. Patients in cohort I were randomized 2:1 to receive AS1411 10 mg/kg/day IV CI days 1-7 + HiDAC 1.5 g/m^2 bid days 4-7 (AS1411-10), or HiDAC alone for 4 days (control). Following safety assessment, a second cohort was randomized to receive AS1411 40 mg/kg/day + HiDAC (AS1411-40) or HiDAC alone. Objectives were comparison of response rates (CR+CRp), safety and tolerability between groups. For this analysis, we collected data on post-remission therapy (PRT) and overall survival (OS) among responders. *Results.* 71 patients were randomized: 22 to AS1411-10, 26 to AS1411-40 and 23 to control. 67 patients were evaluable for safety (AS1411-10, 21; AS1411 40, 25; control, 21). Grade 3 and 4 toxicities were similar across all groups: febrile neutropenia, neutropenia, thrombocytopenia, and infections. Deaths within 28 days of treatment were: AS1411-10, 1/21; AS1411-40, 2/25; and control, 3/21. 59 patients were evaluable for response; AS1411-10, 21% (4CR/19); AS1411-40, 19% (2CR+2CRp/21); and control, 5% (1CRp/19). PRT and OS data for responding patients are tabulated. *Conclusions.* This phase II trial suggested that addition of AS1411 to cytarabine may enhance anti-leukemic activity and that the combination has an acceptable safety profile in patients with relapsed and refractory AML. Follow up suggests substantial survival durations in some patients responding to AS1411 + cytarabine. A phase IIb study is now evaluating responses, duration of responses and survival in AML patients randomized to AS1411 + cytarabine or cytarabine alone.

INHIBITION OF HISTONE DEACETYLASE ACTIVITY SUPPRESSES THE 60S SUBUNIT MATURATION DEFECT IN A YEAST MODEL OF SHWACHMAN DIAMOND SYNDROME

S Ellis, J Moore

University of Louisville, Louisville, USA

Background. Shwachman Diamond Syndrome (SDS) is an autosomal recessive bone marrow failure syndrome that predisposes patients to developing leukemia. *SDO1* is the yeast ortholog of SBDS, the gene affected in SDS. Sdo1 is required for late stages of 60S subunit maturation. Strains depleted of Sdo1 contain half-mer polysomes as a consequence of the retention of pre-60S subunits in the nucleus. *Aims.* Recent studies have shown that certain classes of histone deacetylase inhibitors ameliorate the growth defect of *SDO1* mutants. Our goal was to identify mechanisms whereby histone deacetylase inhibitors rescued the growth defect of cells depleted of Sdo1. *Methods/Results.* We have found that trichostatin A showed a dose dependent increase in growth rate of cells depleted of Sdo1, with a corresponding resolution of half-mer polysomes. We have examined yeast cells extracts for proteins differentially acetylated between *SDO1* mutants and wild-type cells. Through the course of these studies we showed that a number of ribosomal proteins are subject to histone deacetylation and that a reciprocal relationship exists between the degree of acetylation of ribosomal proteins and the binding of Tif6 to 60S ribosomal subunits. Since the role of Sdo1 in 60S subunit maturation is thought to be mediated in part through its effect on the association of Tif6 with 60S subunits, these data suggest a mechanism whereby Sdo1 could influence subunit maturation by influencing protein acetylation. We also provide evidence that Sdo1 may influence translational accuracy through an effect on protein acetylation. *Summary/Conclusions.* These observations establish a previously unappreciated link between SBDS/Sdo1p, HDAC regulation, and 60S subunit maturation, and also uncover potential HDAC-directed therapeutic strategies for treating SDS and related diseases.

1121

ABNORMAL TELOMERE SHORTING IN PERIPHERAL BLOOD MONONUCLEAR CELLS AND GRANULOCYTES OF PATIENTS WITH CHRONIC IDIOPATHIC NEUTROPENIA

K Pavlaki, MC Kastrinaki, K Pyrovolaki, I Mavroudi, G Gvazava, E Stavroulaki, S Mastrodemou, H Papadaki

University of Crete School of Medicine, Heraklion, Greece

Background. Abnormal telomere shortening in peripheral blood mononuclear cells (PBMCs) and/or granulocytes has been reported in patients with acquired bone marrow failure syndromes, including aplastic anaemia, myeolodysplasia syndromes, and paroxysmal nocturnal haemoglobinuria. The abnormality has been mainly attributed to the rapid turnover of haemopoietic progenitor cells in an attempt to compensate for the marrow failure. *Aims.* To evaluate the telomere length of PBMCs and granulocytes in patients with chronic idiopathic neutropenia (CIN). CIN is an acquired disorder of granulopoiesis characterised by increased apoptosis of the granulocytic progenitor cells and presence of activated T-lymphocytes in the peripheral blood and bone marrow. *Methods.* We studied 22 CIN patients (18 females, 4 males) aged 31 to 72 years (median 52.5 years) and 28 healthy individuals (23 females, 5 males) aged 31 to 74 years (median 51.5 years). DNA was extracted from peripheral blood granulocytes and PBMCs and telomere length was evaluated by means of real time PCR using β-globin as control single copy gene. Individual telomere length was reflected by the relative telomere/single-copy-gene (T/S) ratio based on the formula $T/S=2^{-\Delta Ct}$ ($\Delta Ct = Ct^{telomere} - Ct^{\beta\text{-globin}}$), in both cell populations tested. *Results.* Individual T/S ratio in the group of patients was characterized as appropriate or inappropriate for a given age by defining the observed/predicted (O/P) relative telomere length ratio for each cell population (granulocytes or PBMCs) on the basis of the equation derived from the linear regression analysis of the correlation between T/S ratio and age (years) of the controls. We found that the mean O/P telomere length ratio of patient PBMCs (0.43±0.21) was out of the lower 95% confidence limit of the healthy controls (mean O/P telomere length ratio 1.00±0.48; P<0.0001) suggesting inappropriate telomere loss by age in CIN patients. Regarding peripheral blood granulocytes, the mean O/P telomere length ratio in patients was within the 95% confidence limit of the controls. By analyzing, however, the mean T/S ratio per decade of years, we found that in the group of 31-40 years, CIN patients displayed significantly lower telomere length (3705±460, n=5) compared to controls (9481±5528, n=7) (P=0.01). Furthermore, the anticipated inverse correlation between granulocytes' T/S ratio and age was abrogated in the group of CIN patients but not in the healthy controls (r= -0.486, P=0.0087) suggesting that additional factors regulate granulocytes' telomere length in CIN patients. Finally, no association was found between absolute neutrophil counts and granulocyte T/S values in the group of CIN patients. *Summary/Conclusions.* Patients with CIN display inappropriate telomere loss in PBMCs compared to age- and sex-matched healthy individuals. This abnormality might be attributed to the increased activation of peripheral blood T-lymphocytes previously described in CIN. The granulocytes of CIN patients display an age-independent telomere length whereas inappropriate telomere loss may be seen in the younger age group. Overall, these data indicating inappropriate telomere loss in PBMCs and granulocytes of patients with CIN, support further the hypothesis that CIN shares common pathophysiologic features with other acquired bone marrow failure syndromes.

1122

MECHANISTIC INSIGHT INTO THE NAMPT / SIRT1 MEDIATED DOWN REGULATION OF P53 AND FOXO3A LEADING TO IMPAIRMENT OF GENES INVOLVED IN CELL CYCLE REGULATION AND DNA DAMAGE REPAIR

B Thakur, Y Lippka, T Dittrich, J Skokowa, K Welte

Hannover Medical School, Hannover, Germany

Severe congenital neutropenia (CN) is a heterogeneous disorder of hematopoiesis characterized by a maturation arrest of granulopoiesis. CN is also considered as a pre-leukemic syndrome, since app. 20% of CN patients develop AML/MDS. Surprisingly no mutations in genes, which are typical for AML/MDS were detected in patients with CN who developed leukemia. But studies in CN patients reveal high association of G-CSF receptor mutation with the incidence of leukemia. In search of a factor dysregulated downstream of G-CSF receptor signaling we found that Nicotinamide Phosphoribosyltransferase (NAMPT), a protein involved in biosynthesis of NAD+ was significantly increased in CN patients treated with G-CSF as compared to healthy individuals (Skokowa *et al.*, Nature Medicine, 2009). Increased NAD^+ levels correlated with the elevated levels of SIRT1, a NAD^+-dependent deacetylase involved in the deacetylation of histone and non-histone proteins. The tumor suppressor p53 and FOXO3a are among the non-histone proteins targeted by SIRT1 therefore we asked if deacetylation dependent inactivation of p53 and FOXO3a plays a role in the leukemic transformation in CN. In this study we demonstrate that presence of NAMPT or NAD^+ enhances the activity of SIRT1 to deacetylate p53 and FOXO3a. The compound FK866 specifically inhibits NAMPT and has recently entered clinical trials as a potential chemotherapeutic agent. We show that the treatment of promyelocytic leukemia cell line NB4 with FK866 increases the endogenous acetylation of p53 and FOXO3a proteins and this increased acetylation is in part due to decreased interaction of p53 or FOXO3a protein with SIRT1. The cell cycle regulator p21 and DNA damage repair protein GADD45A were among the target genes down regulated in $CD34^+$ and NB4 cells on treatment with NAMPT and the levels of these both genes were rescued on use of FK866. In reporter gene assay we show that the presence of NAMPT or NAD^+ increases the ability of SIRT1 to inhibit the p53 and FOXO3a mediated activation of p21 and GADD45A promoter respectively. Additionally use of FK866 rescues the ability of p53 and FOXO3a to activate p21 and GADD45A promoter activity by inhibiting NAMPT/SIRT1 pathway. Knockdown of p53 or FOXO3a using specific shRNA against these proteins inhibits the expression of p21 or GADD45A respectively. Further inhibition of NAMPT/SIRT1 pathway using shRNA against SIRT1 leads to increased expression of p21 and GADD45A mRNA. Taken together our working hypothesis is that NAMPT/NAD^+ activated SIRT1 mediates deacetylation of p53 and FOXO3a leading to downregulation of downstream target genes p21 and GADD45A respectively. This inhibition of tumor suppressor functions of p53 and FOXO3a might possibly be involved in the leukemic transformation in CN.

1123

THE RISK OF LEUKEMIA IN GENETIC SUBGROUPS OF CONGENITAL NEUTROPENIA

C Zeidler,[1] A Bolyard,[1] P Vandenberghe,[2] G Pracht,[1] L Hoy,[1] M Zimmermann,[1] D Link,[1] C Klein,[3] M Germeshausen,[1] D Dale,[1] K Welte[1]

[1]SCNIR, Hannover, Germany; [2]UZ Leuven, Leuven, Belgium; [3]Paed.Haem/Onc, Hannover, Germany

An increased risk for malignant transformation (MDS or leukemia) is well documented in patients with congenital neutropenia (CN). In this study we assessed the incidence of leukemic transformation and potential risk factors for leukemic transformation in CN patients with known gene mutations, e.g. ELA2, HAX1, G6PC3, p14, WAS or no identified mutation, respectively, by combining all available data from the European and US Branches of the Severe Chronic Neutropenia Registry (SCNIR). Data from mutational analysis were available for 369 patients. Mutations were identified in 206 CN patients, of whom 149 patients revealed ELANE mutations, 23 HAX1 mutations, 20 WASP, 10 G6PC3 and 4 p14 mutations. In addition, in 35 patients neither ELANE nor HAX 1 mutation were detectable and in another 41 patients ELANE mutations could be excluded, but further genetic evaluation is not yet completed. Mutational analysis were also available in 87 patients with cyclic neutropenia, of whom 63 revealed ELANE mutations and 24 were negative for ELANE mutations. Secondary malignancies occurred in 45 of the 281 CN patients. The distribution by genetic subtype is shown in the Table below:

Table. Congenital Neutropenia subtype by gene mutation Total patient number (n) MDS/Leukemia (n/%).

ELANE-CN	149	27 (18.1%)
HAX1-CN	23	4 (17.4%)
ELANE neg + HAX1 neg	35	6 (17.1%)
ELANE neg/ HAX1 nt	41	4 (9.8%)
WAS	20	4 (20%)
G6PC	3	10 0
p	14	4 0
ELANE+Cyclic Neutropenia	63	1 (0.01%)
ELANE- Cyclic Neutropenia	24	0

All subgroups benefit from G-CSF treatment. Median G-CSF maintenance doses required during the years prior to leukemic transformation differ significantly between patients with or without leukemia. *Conclusion.* Patients with severe congenital neutropenia who have mutations in ELANE, HAX1, or WAS as well as those with no recognized mutation are at risk of secondary leukemia. So far, progression to MDS leukemia has not yet been described in the small number G6PC3 or p14 CN cases in our database. Patients requiring higher doses of G-CSF are at greater risk. Despite mutations in the ELANE gene patients with cyclic neutropenia exhibit no increased risk for malignant transformation. Mutational analysis is helpful to identify the genetic cause of severe congenital or cyclic neutropenia but does not serve to identify patients at risk of leukemic transformation.

1124

INHIBITION OF THE NAMPT/SIRT2 PATHWAY LEADS TO THE REDUCED PROLIFERATION AND INCREASE APOPTOSIS OF THE ACUTE LEUKEMIA CELLS VIA MODULATION OF THE AKT/GSK3β PATHWAY

D Lan, A Gigina, K Welte, J Skokowa

Hannover Medical School, Hannover, Germany

Recently we demonstrated that nicotinamide phosphoribosyltransferase (NAMPT) is an essential enzyme mediating granulocyte colony-stimulating factor (G-CSF)-triggered granulopoiesis and that sirtuin-1 activation is a key molecular event during this process. Sirtuins are the members of the NAD^+-dependent class III histone deacetylases, and they have been associated with many physiological and patholo gical processes. We herein investigated whether NAMPT is involved in leukemogenesis by mediating SIRT dependent deacetylation. Screening of the mRNA and protein levels of the different sirtuins in primary acute myeloid leukemia blasts revealed significant upregulation of SIRT2 mRNA and protein. Therefore, we evaluated the role of SIRT2 in leukemogenesis and potential mechanisms of SIRT2 activation via NAMPT. We found that both specific inhibition of NAMPT (using 10 nMol of FK866) or SIRT2 (using 100nMol of AC93253) significantly reduced proliferation and induced apoptosis in a wide range of human myeloid leukemia cell lines (NB4, HL60 and U937). NAMPT inhibition resulted in the reduced activity of SIRT2, as assessed by the colorimetric SIRT2 activity assay. Interestingly, we additionally observed that treatment with AC93253 (25nM) did not affected the proliferation of $CD34^+$ bone marrow progenitor cells of healthy individuals, but inhibited their G-CSF-triggered myeloid differentiation. This suggested that different mechanisms are operating downstream of NAMPT in the "normal"and leukemogenic myeloid cells. The anti-tumour activity of FK866 and AC93253 was accompanied by hyperacetylation of α-tubulin, inhibition of the activation of Akt via phosphorylation on Thr308 and Ser473 and elevated activation of GSK-3β via inhibition of phosphorylation on Ser9. GSK-3β is a known inhibitor of Wnt signaling pathway and we demonstrated that treatment with FK866 was accompanied by diminished expression of Wnt target genes LEF-1 and cyclin D1. Taken together, our results provide strong evidence that NAMPT and SIRT2 participate in leukemogenesis and that Akt/GSK-3β pathway acts as a target in FK866- or AC93253-induced inhibition of the proliferation of leukemia cells. This is the first report on the role of Sirt2 in leukemias.

Clinical stem cell transplantation

Haematology and Stem Cell Transplant, Budapest, Hungary; [9]EBMT Data Office, Paris, France; [10]Addenbrookes Hospital, Cambridge, UK; [11]Yorkshire Blood & Marrow Transplant Programme, Leeds, UK; [12]Hopital de Purpan, Toulouse, France; [13]University of Saarland, Homburg, Germany; [14]CHU Nantes, Nantes, France; [15]Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background. Autologous stem cell transplantation (ASCT) remains the treatment of choice for patients (pts) with diffuse large B cell lymphoma (DLBCL) that relapse after first line chemotherapy (CT). Nevertheless, the impact of the use of the anti-CD20 monoclonal antibody (Rituximab) (RTX) with combination CT on the ulterior results of the transplantation procedure has to be determined. *Aims.* This study was designed to evaluate the benefit of this strategy, in pts with DLBCL achieving after salvage CT a 2nd complete remission (CR2), by retrospectively comparing for each pt the progression free survival (PFS) after ASCT with the duration of the previous CR. *Methods.* Adult DLBCL pts with MEDB information available autografted in CR2 between 1990 and 2005 in EBMT centres were included in the analysis. A total of 470 pts (262 males, median age 52 (18-74) years] were evaluated. 351 pts (74%) did not receive RTX prior to ASCT, 119 pts (25%) did receive it. Duration of CR1 was 11 (1-112) months [median (range)]; it lasted less than 12 months in 49% of the cases. Median time from diagnosis to ASCT was 24 (6-395) months. Peripheral blood was used as the source of hematopoietic stem cells in 399 pts (85%). The BEAM protocol was the conditioning regimen most frequently used (n=258, 63%) and only 5.5% pts were conditioned with TBI-containing regimens. *Results.* After a median follow up after ASCT for surviving pts of 52 months, 5 years overall survival (OS) was 63% and PFS 48%. 196 (41%) pts did relapse after ASCT [median (range), 10 (1-172) months] and 35 (7%) pts died from non-relapse mortality. Factors negatively affecting PFS were treatment before 2002 (P=0.01) and age over 50 years (P=0.004). Patients treated after 2002 with RTX at first line treatment or at relapse had a better PFS (80%) than patients treated with RTX at first line and at relapse (56%). In 289 patients the PFS period after ASCT was longer than the previous CR1 duration and in 121 cases the PFS period was shorter. This difference in favour of post ASCT period was significant for patients with or without prior exposure to RTX (P<0.01) and age >50 years or <50 years (P<0.001). Finally, when each patient was taken as his/her own control, PFS after ASCT was longer than PFS for CR1 (P<0.001). *Conclusions.* The use of RTX prior to ASCT did not impair the beneficial effects of the autologous procedure in the whole population of pts (RTX yes: 58% *vs.* no 41%, (P<0.05)). 2-years PFS after ASCT was significantly lower in pts with a CR1 < 12 months (P<0.005). ASCT can significantly increase PFS in comparison with the duration of CR1 in DLBCL and can modify disease course. The use of RTX prior to ASCT does not decrease the beneficial effect of pts autografted in CR2 when compared to their prior CR1 duration. The duration of CR1 remains one of the most important prognostic factors for ASCT outcome.

CONSTITUTIONAL VARIABILITY IN GENES INVOLVED IN INNATE IMMUNITY AND IN CELL PROLIFERATION INFLUENCES DISEASE FREE SURVIVAL AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

B Martin-Antonio, R Cardesa, I Alvarez, F Marquez-Malaver, P Trujillo, M Carmona, J Falantes, I Espigado, A Urbano-Ispizua

Hospital Universitario Virgen del Rocio, Sevilla, Spain

Background. Innate immunity plays an important role in infections and in activation of adaptive immunity modulating the intensity of the inflammatory response after allogeneic stem cell transplantation (allo-SCT). Thus, genetic variability in donor and recipient in these genes and in genes involved in cell proliferation might be an important factor influencing the outcome of allo-SCT. *Aims.* To study the potential influence of 15 single nucleotide polymorphisms (SNPs) in donor and recipient in genes of innate immunity (IRF-3, HAMP, PTX3, HBD2) and regulation of cell proliferation (ATBF1, NFAT5, AKT2, NM1, CD151, TCIRG1, SH3KBP1) on clinical outcomes after allo-SCT, specifically on the incidence of acute GvHD (aGvHD), chronic GvHD (cGvHD), presence of infections, transplant related mortality (TRM), relapse, and disease free survival (DFS). *Methods.* Study population consisted of 106 donor-patient pairs undergoing HLA identical sibling allo-SCT in a single institution. Patient median age was 38 years (range, 5-66). 42% of the patients were in advanced phase of disease. Cumulative incidence for GvHD, TRM, relapse and DFS was computed with the cmprsk package and with Kaplan-Meier. Analysis of GvHD and infections were restricted to 87 donor-patient pairs. *Results.* Patient IRF3 rs2304205 AA, donor ATBF1 rs719327 AA and patient AKT2 rs12460555 CC dominant genotypes, were associated with a higher incidence of relapse (P=0.02, P=0.04 and P=0.002, respectively) and lower DFS (P=0.02, P=0.04 and P=0.009, respectively). All of them retained significance at multivariate analysis. Variant rs719327 AA in ATBF1 showed the same prognostic values when present in donor or in patient (relapse: 55% *vs.* 34% and DFS: 26% *vs.* 46%). When it was present both in donor and patient, the differences were more prominent (relapse: 69% *vs.* 33%, P=0.003 and DFS: 15% *vs.* 45%, P=0.01). Donor HAMP rs7251342 GG recessive genotype and donor NFAT5 rs6499244 AA dominant genotype were associated with a higher incidence of TRM (P=0.016 and P=0.02, respectively) influencing in lower OS and DFS (P=0.0016 and P=0.02, respectively). They retained its significance at multivariate analysis. Genetic variant in donor for HAMP and in patient for NFAT5 were associated with a higher and lower frequency of infections (P=0.04 and P=0.05, respectively). NFAT5 is necessary for optimal T cell development and rs6499244 AA variant showed the highest mRNA expression. Donor IRF3 rs7251 CC and patient EP300 rs20551 AA genotypes were associated with a higher incidence of cGvHD (P=0.023 and P=0.049, respectively) influencing in a lower DFS (P=0.012 and P=0.009, respectively) and OS (P=0.02 and P=0.02, respectively). None of the 25 patients with a donor carrying PTX3 rs18040680 AA recessive genotype had TRM but patients carrying this genotype showed higher frequency of infections (P=0.04). *Conclusions.* Genetic variability in innate immunity and in cell proliferation has a strong influence on the clinical outcome of allo-SCT, which might be important when choosing allo-SCT protocols.

A NOVEL HIGH DOSE CHEMOTHERAPY STRATEGY WITH BENDAMUSTINE IN ADJUNCT TO ETOPOSIDE, ARACYTIN AND MELPHALAN (BEEAM) FOLLOWED BY AUTOLOGOUS STEM CELL RESCUE IS SAFE AND HIGHLY EFFECTIVE FOR THE TREATMENT OF RESISTANT/RELAPSED LYMPHOMA PATIENTS: A PHASE I-II STUDY ON 33 PATIENTS

[1]Hematology and Stem Cell Transplant Center, Pesaro, Italy; [2]Hematology, Ca'Foncello Hospital, Treviso, Italy; [3]Department of Biotechnologies and Hematology, University La Sapienza, Roma, Italy; [4]Hematology, Ascoli Piceno, Italy; [5]Division of Hematology, Bari, Italy; [6]Hematology, San Martino Hospital, Genova, Italy; [7]Department of Oncology and Hematology, Istituto Clinico Humanitas, Rozzano, Milano, Italy; [8]Insitute of Biomathematics, Urbino University, Urbino, Italy

Background. Carmustine, etoposide, cytarabine, and melphalan (BEAM) regimen is the most used conditioning regimen to proceed to autologous stem cell transplant (ASCT) in lymphoma patients. However, those patients receiving BEAM show a significant number of side effects, and relapse rate after transplant is still a matter of concern. Therefore, new regimens with a higher efficacy and a better toxicity profile in comparison to BEAM are highly needed. *Aims.* We designed a phase I-II study to evaluate the safety and the efficacy of increasing doses of Bendamustine for the conditioning regimen to ASCT for resistant/relapsed lymphoma patients. *Methods.* Thirty-three patients (median age 51 years, range 18-70) with resistant/relapsed non-Hodgkin (23) or Hodgkin (10) lymphoma were consecutively enrolled in the study.

The new conditioning regimen consisted of increasing doses of Bendamustine coupled with fixed doses of Etoposide (200mg/m^2/day on days -5 to -2), Cytarabine (400mg/m^2 on days -5 to -2) and Melphalan (140 mg/m^2 on day -1) (BeEAM regimen). Three cohorts of 3 patients each were treated starting with Bendamustine 160 mg/m^2/daily given on days -7 and -6. The dose of Bendamustine was then escalated according to the Fibonacci's increment rule until the onset of severe adverse events and/or the attainment of the expected MTD, but not higher than 200 mg/m^2. Patients were carefully monitored for adverse events. The study was registered at EMEA with the EUDRACT no 2008-002736-15. *Results.* The administration of Bendamustine was safe in all the 3 cohorts of patients. The major side effect was a grade III-IV oral mucositis developed by 4 patients during neutropenia. We then fixed the dose of Bendamustine 200 mg/m^2 as safe and effective for the Phase II study. A median number of 6.1×10^{6}CD34$^+$/kg cells (range 2.4-15.5) collected from peripheral blood was reinfused to patients. All patients engrafted, with a median time to ANC>0.5×10^9/L of 10 days. Median times to achieve a platelet count >20×10^9/L and >50×10^9/L were 12 and 15 days respectively. Sixteen out of 33 patients presented a fever of unknown origin (48%). The median number of days with fever was 2 (range: 0-7), with a median number of 9 days of intravenous antibiotics (range: 3-22). All patients received G-CSF after transplant for a median time of 8 days (range: 8-13). Twenty-two out of 33 patients are evaluable up to now for the response to treatment. All evaluable patients are alive. 20/22 are in complete remission whereas 2/22 are in partial response, after a median follow-up of 7 months from transplant. It is of note that 3/22 patients achieved the first complete remission after receiving the high-dose therapy with autologous stem cell rescue. *Conclusions.* The new BeEAM regimen is safe and seems to have a high efficacy in heavily pretreated lymphoma patients. All the future studies who want to incorporate Bendamustine on such conditioning regimens for ASCT in lymphoma patients have to use 200 mg/m^2/day of Bendamustine given overt 2 days.

ACUTE LYMPHOBLASTIC LEUKAEMIA IN CHILDHOOD: OUTCOMES OF UNRELATED CORD BLOOD TRANSPLANT

A Ruggeri,[1] JH Dalle,[2] G Michel,[3] N Kabbara,[1] D Purtill,[1] C Díaz de Heredia,[4] AP Iori,[5] M Diaz,[6] M Mauad,[7] A Verdeguer,[8] T O'Brien,[9] F Locatelli,[10] C Peters,[11] E Gluckman,[1] V Rocha[1]

[1]Eurocord-Hopital Saint Louis, Paris, France; [2]Hôpital Robert Debre, Paris, France; [3]Hôpital d'Enfants de la Timone, Marseille, Franc; [4]Vall d`Hebron Hospital, Barcelona, Spain; [5]Univ La Sapienza, Roma, Italy; [6]Niño Jesus Children`s Hospital, Madrid, Spain; [7]Amaral Carvalho Hospital, Sao Paolo, Brazil; [8]Hospital Infantil La Fe, Valencia, Spain, [9]Centre for Children's Cancer & Blood Disorders, Sydney Children`s Hospital, Sydney, Australia; [10]Oncoematologia Pediatrica, Ospedale Bambino Gesù, Roma, Italy; [11]BMT Unit, St. Anna Kinderspital, Vienna, Austria

Allogeneic stem cell transplantation (SCT) is indicated in approximately 20-30% of childhood acute lymphoblastic leukaemia (ALL). Unrelated umbilical cord blood (UCB) is an established stem cell source for SCT. We retrospectively analyzed 532 children with ALL in complete remission (CR)1 (n=186), CR2 (n=238) and CR3 or advanced disease (n=108) who received UCBT as first transplant. Patients were transplanted in EBMT centres from 2000-2008. Median age at transplant was 6.8 years (y) (29 patients less than 1y). The most common immunophenotype was B-cell precursor ALL and 17 patients had biphenotypic ALL. Of 186 patients transplanted in CR1, 45% had poor risk cytogenetics (t4;11 or t9;22).Grafts were composed of one (n=504) or two (n=28) units; 62% had 0-1 HLA mismatch with recipients while 38% had 2-3 mismatches (antigen level for HLA-A and B, allelic level for DRB1). Median TNC cell dose at freezing and infusion were 5.9×10^7/kg and 4×10^7/kg, respectively. Myeloablative conditioning regimen and TBI>6 Gy were used in 96% and 52% of cases, respectively. Other regimens included busulphan with cyclophosphamide ±thiotepa or melphalan. ATG was used in 88% of cases. GVHD prophylaxis was CSA ±steroids in 75%. Median follow-up was 18.5 months (3-109). Cumulative incidence (CI) of neutrophil recovery (NR), acute GVHD and TRM were 82±2%, 27±3% and 21±3%, respectively. In multivariate analysis, TNC infused >4×10^7/kg (P=0.001) and remission status at UCBT (P=0.01) were associated with improved NR. CI of 2y relapse was 37±3% (31% for CR1, 34% for CR2, 50% for advanced). Disease status at UCBT (HR=0.36, P= 0.001) and use of TBI>6Gy (HR=0.58, P=0.01) were independently associated with lower CI of relapse. The 2y probability of leukemia-free-survival (LFS) was 38±2% (49% for CR1, 42% for CR2, 10% for advanced; P=0.001). In multivariate analysis, disease status at UCBT was the only factor associated with improved LFS (HR=0.32, P=0.001). Causes of death were infections or other transplant-related events (n=172) or disease progression (n=95). In conclusion, in the absence of an HLA identical donor, UCBT remains a valuable alternative option for children with high risk ALL. Disease status at transplantation and cell dose are the most important factors influencing transplant outcome. Use of TBI in the conditioning regimen decreases the incidence of relapse but is not associated with improved LFS. The role of minimal residual disease as a predictor of outcomes of UCBT is currently under investigation.

LATE PROPHYLACTIC DONOR LYMPHOCYTE INFUSIONS IN HIGH RISK ACUTE LEUKEMIAS

M Stadler, E Dammann, S Buchholz, H Diedrich, H Kamal, A Breithaupt, E Mischak-Weissinger, B Hertenstein, M Eder, J Krauter, A Ganser

Hannover Medical School, Hannover, Germany

Background. Prophylactic donor lymphocyte infusions (pDLI) given early (i.e. before day +100) after allogeneic hematopoietic stem cell transplantation (HSCT) have been shown to convert mixed to full donor chimerism in T cell-depleted stem cell transplants and to enhance the graft-versus-leukemia effect, however, at the expense of excessive graft-versus-host disease (GvHD). We prospectively studied pDLI administered late (i.e. after day +120) in high risk acute leukemias (AL). PATIENTS AND *Methods.* From 2004 to 2009, 279 patients received a T-cell replete allogeneic HSCT at our institution for AL at high risk of relapse. High risk criteria included adverse cytogenetics, relapsed or refractory disease, extramedullary leukemia, MDS with excess blasts, and therapy-related AML. 114 patients had *de novo* acute myelogenous leukemia (AML), 118 advanced myelodysplasia or secondary AML (MDS/sAML), and 47 acute lymphoblastic leukemia (ALL). 126 were females and 153 males, with a median age of 52 years (range: 17 to 71). Among these, 43 patients (14 AML, 25 MDS/sAML, 4 ALL) who did not have experienced GvHD even after withdrawal of immunosuppression, were treated with pDLI between days +125 and +469. Unmodified pDLI were started at 5×10^{5}CD3$^+$/kg and increased monthly in a maximum of two steps up to 1×10^7 CD3$^+$/kg, unless symptoms of GvHD occurred. pDLI were not given to the other 236 high risk AL patients due to prior GvHD, early relapse, recurrent infectious complications, or patient refusal. *Results.* 23 patients received all three doses of pDLI, 15 patients two, and 5 patients only the first dose. 9 of the 43 patients developped acute GvHD grade II to IV or extensive chronic GvHD after pDLI (five-year GvHD incidence 23%), compared to 51% in survivors beyond day +120 of the high risk AL patients not given pDLI (P=0.001), and compared to 58% in survivors beyond day +120 of high risk AL patients transplanted during the previous six years, 1998 to 2003, at our institution (P<0.001). Leukemic relapse occurred in 9 of the 43 patients despite pDLI (five-year relapse incidence 28%), compared to 45% in day-120-survivors of high risk AL patients without pDLI (P=0.020), and compared to 52% in day-120-survivors of historical controls (P=0.008). With 29 months of median follow-up (range: 5 to 61), five-year overall (OS) and disease-free survival (DFS) probabilities of pDLI patients are 76% and 71%, respectively, compared to 47% (P=0.001) and 42% (P=0.001) of day-120-survivors of the contemporary high risk AL patients, and 30% (P<0.001) and 25% (P<0.001) of the historical controls. When pDLI patients are compared with all contemporary and historical controls, respectively, differences in relapse rate, GvHD incidence, OS and DFS remain highly significant (P<0.001). *Conclusions.* In patients without GvHD after T-cell replete HSCT for high risk acute leukemias, unmodified prophylactic DLI after day +120 are safe and effective, reducing the relapse rate as well as the incidence of severe GvHD, and improving both overall and disease-free survival.
