Background. The class I phosphatidylinositol 3-kinases (PI3Ks) regulate a variety of cellular functions relevant to oncogenesis. Expression of the PI3K p110δ isoform (PI3K_) is restricted to cells of hematopoietic origin where it plays a key role in B cell proliferation and survival. In chronic lymphocytic leukemia (CLL) and non-Hodgkin lymphoma (NHL) cells, constitutive PI3Kδ-dependent PI3K pathway activation is frequently observed. CAL-101 is an isoform-selective inhibitor of PI3Kδ (EC_{50} of 8 nM in a cell-based assay with >200-fold selectivity relative to other PI3Ks) that inhibits PI3K signaling and induces apoptosis of malignant B cells *in vitro*. *Aims.* A Phase 1 study was undertaken to evaluate the safety and activity of CAL-101 in patients with relapsed or refractory hematologic malignancies. *Methods.* Sequential dose escalation cohorts of 3+3 patients were enrolled to determine dose limiting toxicity (DLT). Subsequently, cohorts of patients with CLL, indolent NHL, aggressive NHL, acute myeloid leukemia (AML) and multiple myeloma (MM) were enrolled. CAL-101 was administered orally twice daily (BID) continuously for 28 day cycles for up to 12 cycles. Clinical response was evaluated according to standard criteria. Written informed consent was obtained from all patients. *Results.* At data cutoff, 90 patients were enrolled: 29 patients with CLL, 19 with indolent NHL, 18 with aggressive NHL, 12 with AML and 12 with MM. Patient characteristics were 36% female, median age 66, 51% had refractory disease and median number of prior therapies was 5. Dose levels were 50 mg (n=3), 100 mg (n=3), 150 mg (n=32), 200 mg (n=35) and 350 mg (n=17) BID. The median duration of treatment was 3 cycles, with 31% completing ≥6 cycles. Three patients completed the study with 48 weeks of therapy and 29 remain on study. Eight patients discontinued for adverse events, most frequently due to the DLT of increased ALT/AST. The DLT appears to be dose dependent with an incidence of 24% at 350 mg, 20% at 200 mg and 9% at 150 mg. ALT/AST abnormalities were reversible and most affected patients were able to resume at a lower dose. Hematological toxicity was minimal. 83 patients were evaluable for clinical response and 25 patients had objective responses, all partial responses. The response rate was 65% (11/17) in indolent NHL patients, 75% (6/8) in mantle cell lymphoma and 30% (8/27) in CLL. None of the 31 patients with diffuse large B-cell lymphoma, AML or MM had a response. Clinical responses were observed at all dose levels. Of 27 CLL patients, 93% had >50% reduction in lymphadenopathy which was commonly associated with a transient increase in peripheral blood lymphocytosis. Plasma exposure increased with dose in a less than dose-proportional manner. PI3K signaling was evaluated in 7 CLL patients and expression of phospho-AKT (T308) in circulating leukemic cells was found to be reduced by >90% following CAL-101 dosing. Updated data will be presented. *Conclusions.* CAL-101, an oral PI3Kδ isoform-selective inhibitor, shows promising clinical activity with acceptable toxicity in patients with indolent B-cell malignancies and mantle cell lymphoma.

1131

A PHASE I/II STUDY OF IPH1101, GAMMA DELTA T CELL AGONIST, IN COMBINATION WITH RITUXIMAB RE-TREATMENT, IN PATIENTS WITH LOW GRADE FOLLICULAR LYMPHOMA

JF Rossi,[1] P Solal-Celigny,[2] P Soubeyran,[3] V Delvail,[4] H Ghesquieres,[5] C Thieblemont,[6] E Jourdan,[7] V Kunzmann,[8] P Feugier,[9] RO Casasnovas,[10] S Le Gouill,[11] E van den Neste,[12] S Lafaye De Micheaux,[13] M Marzetto,[13] L Beautier,[13] P Squiban,[13] H Sicard,[13] G Laurent[14]

[1]Hospital Lapeyronie, Montpellier, France; [2]Hopital Jean-Bernard, Le Mans, France; [3]Institut Bergonié & University Victor Segalen, Bordeaux, France; [4]Hospital Jean Bernard, Poitier, France; [5]Centre Leon Berard, Lyon, France; [6]Hopital Saint Louis, Paris, France; [7]Hopital Caremeau, Nimes, France; [8]Universitatsklinikum, Wurzburg, Germany; [9]Hospital Brabois, Nancy, France; [10]Hopital Le Bocage, Dijon, France; [11]Hopital Hotel Dieu, Nantes, France; [12]Hopital Saint Luc, Bruxelles, Belgium; [13]Innate-Pharma, Marseille, France; [14]Hospital Purpan, Toulouse, France

Background. Non-conventional γδ T lymphocytes have potent antitumoral activity, particularly against malignant B cells. IPH1101 is an agonist of γδ T cells, which in the presence of low doses of IL-2 potentiates their direct cytotoxic activity. ADCC is a major molecular mechanism underlying rituximab's efficacy. Increasing the number and the activation state of killer lymphocytes mediating ADCC is therefore believed to be beneficial for therapeutic potency. Since γδ T cells have been found to be capable of mediating ADCC, modulating γδ T cells in the context of rituximab is worth being tested in a clinical trial. *Aims.* The main purpose of this study was to assess the clinical efficacy of IPH1101 associated with low doses of IL-2, and combined with a standard rituximab treatment, in patients (pts) with follicular lymphoma (FL). *Methods.* This was an open label, multinational study consisting of a dose escalation Phase I like part followed by a phase II part. The phase I part showed a good safety and immuno-biological efficacy profile for the highest dose of IL-2. Consequently, the pts of the phase II part were treated with the combination of rituximab (375 mg/m^2) administered 4 times weekly, IPH1101 (750 mg/m^2) administered i.v. 3 times (every 3 weeks) and IL-2 (8 MIU) administered daily s.c. for 5 days starting on the day of each IPH1101 administration. All pts presented low grade FL which had relapsed after 1 to 4 lines of previous therapy including at least one rituximab-containing line. Inclusion criteria set forth that pts should have no lesion > 7 cm. The primary end point of the trial was the rate of overall response at 6 months. All patients enrolled in the trial had signed informed consent. *Results.* Interim data analysed on the first set of patients (41 for safety and 34 patients assessed for efficacy after independent central review showed a good overall safety, with most of the drug-related adverse events being flu like symptoms of grade 1 or 2. The SAEs reported were 2 hypotensions, 1 bronchospasm, 1 allergic reaction (back pain), 1 glomerular filtration decrease, 1 ALAT elevation, 1 diarrhea, 1 pyrexia, and 1 asthenia. The immuno-biological follow up demonstrated the very good pharmacodynamic profile of IPH1101 in these patients. The overall response rate for this cohort of 34 evaluable patients (20 patients at 6 months, and 14 at 3 months), showed an Objective Response Rate of 47%, and an encouraging 32% Complete Response rate. *Summary/Conclusion.* The response rate in this first set of pts is encouraging in the context of previously treated patients. To date the enrolment has been completed with 45 patients treated, and the 6 month follow up for the last patient has been reached. Independent review is currently on going for the last set of patients, and complete efficacy study results will be presented at the meeting.

PBI-1402: A FIRST-IN-CLASS ERYTHROPOIESIS-STIMULATING AGENT (ESA) WHICH REDUCES THE NEED FOR BLOOD TRANSFUSION IN CHEMOTHERAPY-INDUCED (CIA) ANEMIC PATIENTS

L Gagnon,[1] J Barabé,[1] C Penney,[1] V Kovcin,[2] S Bošnjak,[3] P Laurin[1]

[1]ProMetic BioSciences Inc., Laval, Canada; [2]Centre Bezanijska Kosa, Belgrade, Serbia; [3]Institute for Oncology and Radiology of Serbia, Belgrade, Serbia

Background. PBI-1402 is a first-in-class novel orally active compound that promotes the production of erythrocytes by a mechanism of action distinct from erythropoietin (EPO). This mechanism involves differentiation of earlier progenitor stem cells (CFU-GEMM) than those stimulated by EPO (BFU-E, CFU-E). In a phase I clinical trial, PBI-1402 induced a significant increase (100%, P<0.001, compared to placebo) of relative and absolute reticulocyte count in healthy volunteers after 21

days of oral treatment and was devoid of significant side effects. Furthermore, a phase Ib/II clinical trial confirmed that PBI-1402 increased red blood cell (RBC) counts and hemoglobin (Hb) levels in patients with chemotherapy-induced anemia (CIA). *Aims.* The objectives of this extension clinical phase Ib/II trial were to provide additional data on the safety and tolerability of PBI-1402 and to assess its biological efficacy (including the reduction in the need for transfusion) in patients with CIA. *Methods.* PBI-1402 was administered orally once a day for eight weeks to patients undergoing chemotherapy for various cancers. Patients were assessed every two weeks for safety, tolerability, Hb level, RBC count and clinical biochemistry. The results presented are a combination of the clinical phase Ib/II trial and its extension study. The former consisted of a dose-ranging study of three cohorts of six patients receiving 44, 66 and 88 mg/kg. The latter consisted of 12 patients receiving 44 mg/kg. *Results.* Of the 30 patients enrolled, 29 patients completed their eight-week PBI-1402 treatment. PBI-1402 was well tolerated and no severe side effects were observed. Blood chemistry remained within the normal range of clinical values. 93% of patients (27/29) did not require blood transfusion since their RBCs and Hb increased or remained stable. Moreover, of the 50% of patients who experienced a significant increase ($P<0.001$ relative to their baseline) in their RBCs and Hb, none reached levels currently proscribed by the most recent therapeutic guidelines (no overshoot). No change in white blood cell and platelet counts were observed in this study. *Conclusion.* PBI-1402 is safe and well tolerated. 50% of the patients displayed a significant increase in RBC count and Hb level. Of the 29 patients that completed the study, 93% did not require blood transfusion. Furthermore, preclinical evidence of antitumor activity suggests that PBI-1402 is safe to use in the management of anemia associated with cancer or induced by chemotherapy. Therefore, orally administered PBI-1402 offers significant potential for the treatment of anemia associated with cancer and/or chemotherapy, an unmet medical need.

1133

ANTITUMOR ACTIVITY OF THE INVESTIGATIONAL DRUG MLN9708, A SECOND-GENERATION PROTEASOME INHIBITOR, IN PRECLINICAL MODELS OF DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL)

A Berger, J Donelan, E Lee, B Bannerman, K Bano, T Babcock, Y Cao, M Fitzgerald, P Hales, E Koenig, E Lightcap, A Mazzola, P Smith, B Stringer, Y Yang, J Yu, J Zhang, P Fleming, E Kupperman

Millennium Pharmaceuticals, Inc., Cambridge, USA

Background. The ubiquitin-proteasome system is involved in the degradation of most cellular proteins. The successful development of bortezomib for multiple myeloma and previously treated mantle cell lymphoma has validated the proteasome as a therapeutic target for hematological malignancies. The investigational drug MLN9708, like bortezomib, is a modified dipeptidyl boronic acid that is a potent, reversible and specific inhibitor of the 20S proteasome. MLN9708 is currently in Phase I trials for the treatment of hematologic malignancies as well as solid tumors. *Methods.* We evaluated the ability of MLN9708 to inhibit tumor growth in four preclinical models of diffuse large B-cell lymphoma (DLBCL) which represent several genetic subgroups of this disease including activated B-cell-like (ABC-DLBCL), germinal-center B-cell-like (GCB-DLBCL), and a third group that is distinct from both subgroups (non-ABC and non-GCB-type DLBCL). We aimed to determine whether MLN9708 has broad activity in preclinical models of DLBCL, or whether antitumor activity is subtype-specific. MLN9708 immediately hydrolyzes to MLN2238, the biologically active form, upon exposure to aqueous solutions or plasma. MLN2238 was used for all preclinical studies described below. Immunocompromised mice were implanted with subcutaneous xenografts of OCI-LY10 (ABC-DLBCL), PHTX-22L (ABC-DLBCL), and WSU-DLCL2 (non-ABC and non-GCB-type DLBCL) and dosed once or twice-weekly for three weeks. The treatment over control (T/C) ratio of the mean tumor volume on the last day of the study was used as a measure of antitumor activity. To generate a disseminated model of lymphoma, OCI-LY7 (GCB-DLBCL) cells were luciferase-tagged (OCI-LY7-luc) and inoculated IV into immunocompromised mice, and tumor burden was monitored over time via bioluminescent imaging. *Results.* MLN2238 showed antitumor activity in models classified as ABC-DLBCL. For the OCI-Ly10 xenograft model, once-weekly (QW) IV dosing of MLN2238 at 18 mg/kg (MTD) resulted in T/C of 0.12 and induced tumor regression in 6 of 7 mice, while doses of 8 mg/kg and 4 mg/kg IV QW resulted in T/C of 0.34 and 0.36 in separate studies. PHTX-22L is a primary human tumor xenograft derived from a surgically resected lymph node from a patient diagnosed with DLBCL. MLN2238 showed significant antitumor activity against PHTX-22L at 14 mg/kg twice weekly (BIW), 11 mg/kg BIW, 7 mg/kg BIW, and 11 mg/kg QW ($T/C \leq 0.15$). However, 7 mg/kg QW or 3.5 mg/kg BIW in this model was less efficacious ($T/C=0.76$), consistent with a dose-dependent level of tumor proteasome inhibition. MLN2238 also showed antitumor activity in models that are not classified as ABC-DLBCL. In the WSU-DLCL2 model (non-ABC and non-GCB DLBCL), MLN2238 at 14 mg/kg BIW showed $T/C=0.44$, and this dose provided sustained tumor proteasome inhibition and activated downstream consequences including apoptosis. In the OCI-LY7-luc disseminated model of GCB-DLBCL, MLN2238 reduced tumor burden and improved overall survival compared to vehicle treated controls (median survival of 54 *vs.* 33 days). *Conclusions.* These studies demonstrate that MLN2238 is active in preclinical models of DLBCL across multiple subtypes. Strikingly, all four of the DLBCL models showed minimal or no tumor growth inhibition in response to bortezomib, highlighting the improved antitumor activity of MLN2238 in preclinical models.

LEUKEMIC CD52 NEGATIVE GPI DEFECTIVE CLONES ARE COMMON IN ALL, ESCAPE ALEMTUZUMAB THERAPY, BUT ARE SENSITIVE TO RITUXIMAB MEDIATED COMPLEMENT DEPENDENT CYTOTOXICITY: RATIONALE FOR COMBINATION THERAPY

B Nijmeijer, M van Schie, H Goselink, C Halkes, J Falkenburg

Leiden University Medical Center, Leiden, Netherlands

B-lineage acute lymphoblastic leukemia (B-ALL) in adults is sensitive to polychemotherapy but relapses frequently occur. B-ALL frequently express CD52, and since Alemtuzumab (ALM) is directed against the glycophosphatidyl-innositol (GPI-) anchored membrane protein CD52, ALM may be of therapeutic value. However, loss of CD52 due to acquired defects in GPI biosynthesis has been observed in various hematological disorders. GPI-defective leukemic subclones in ALL will result in resistance to ALM. We analyzed CD52 expression on ALL cells from 24 patients by flow cytometry. To identify GPI-defective cells we also analyzed the GPI-anchored CD55 and CD66c. Of the 24 cases, 19 expressed CD52. In 11 cases clear CD52-CD55-CD66c- GPI-defective subpopulation (median 0.02%, range 0.01-25.8%) were demonstrated. We evaluated the *in vivo* activity of ALM against ALL, and the relevance of the GPI-defective subpopulations, in a preclinical model of human ALL. Two cases were selected: BV (4.0% $CD19^+CD52^-CD55^-$ cells, overall MFI 137) and CM (no detectable $CD19^+CD52^-CD55^-$ cells, overall MFI 616). NOD/scid mice were inoculated with primary BV or CM cells. From day 14 after inoculation, animals received daily injections of 250μg ALM (n=8) or saline (n=4). After 3 weeks bone marrow (BM) was analyzed by flow cytometry. BM of control treated animals engrafted with BV cells contained 80±20% leukemic cells, 95% were CD52+. BM of control treated animals engrafted with CM cells contained 69%±14% leukemic cells, 99% were CD52+. BM of ALM treated animals with BV or CM contained 75% (±5.9%) and 21% (±5.4%) leukemic cells, respectively. These cells were exclusively $CD52^-CD55^-CD66c^-$, demonstrating that ALM eradicated all $CD52^+$cells but selected GPI-defective subpopulations. As known from paroxysmal nocturnal hemoglobinuremia, GPI-defective cells are highly susceptible to complement mediated cytotoxicity (CDC) due to lack of the protective function of CD55. Since ALL cells recovered from ALM treated and control treated mice showed similar expression of CD20, we compared their susceptibility to rituximab (RTX) mediated CDC. In the presence of 10μg/mL RTX, 50% lysis of CD52 positive ALL cells required a 1:40 complement dilution while 50% lysis of CD52 negative GPI-defective cells required a 1:200 dilution. Similarly, in the presence of a 1:100 complement dilution, 2.5 μg/mL RTX mediated 10% lysis of CD52 positive ALL cells but 75% lysis of CD52 negative GPI-defective cells. To investigate the *in vivo* relevance of these findings we engrafted NOD/scid mice with CM or BV cells and administered RTX (250μg daily) or RTX plus ALM (250μg each daily). Administration of RTX alone resulted in only partial reduction of leukemic cells. However, combined administration of ALM and RTX resulted in complete remissions in all CM-engrafted animals, 75% of which were molecular remissions as demonstrated by RT-PCR, and in 4 of 5 BV-engrafted animals. In summary, ALM is highly effective against $CD52^+$ ALL cells but $CD52^-$ GPI-defective subclones may preexist and escape therapy. Since GPI-defective cells are highly susceptible to complement mediated lysis, combination treatment of ALM with antibodies directed against non-GPI anchored proteins, such as RTX is rational and likely to be synergistic.

Chronic myeloid leukemia - Clinical 2

PLERIXAFOR TARGETS PRIMARY CHRONIC MYELOID LEUKAEMIA STEM/PROGENITOR CELLS AND ENHANCES THEIR SENSITIVITY TO TYROSINE KINASE INHIBITORS

J Richmond, M Copland

University of Glasgow, Glasgow, UK

Despite recent advances in the treatment of chronic myeloid leukaemia (CML) with tyrosine kinase inhibitors (TKIs; imatinib, dasatinib, nilotinib) the majority of patients have persistent molecular disease. This is believed to result from the failure of TKIs to target the most primitive quiescent CML stem cells. There is increasing evidence for chemoresistance via the SDF1/CXCR4 axis in CML and other leukaemias. In CML, BCR-ABL interferes with SDF1-induced migration to the bone marrow niche by down-regulating CXCR4 expression. This is restored by TKIs, promoting the survival of quiescent CML cells by increasing their migration to the bone marrow niche (Jin *et al.*, 2008). Plerixafor (Mozobil®; formerly AMD3100; Genzyme Corporation, Cambridge, MA, USA) is a CXCR4 antagonist and is currently used to mobilize $CD34^+$ haematopoietic progenitor cells in humans. *in vitro* studies in CML cell lines have shown that plerixafor inhibits chemotaxis towards SDF1, resulting in increased susceptibility of BCR-ABL-positive cells to TKIs (Dillman *et al.*, 2009). The aim of this study was to determine if plerixafor reverses the quiescence of primary $CD34^+$ CML stem/progenitor cells *in vitro*, rendering these primitive cells sensitive to TKIs. We investigated the *in vitro* response of primary chronic phase (CP) CML $CD34^+$ cells, and the BCR-ABL^+ cell line BV-173, to plerixafor. Total CP CML $CD34^+$ cells were assessed for cell viability (trypan blue exclusion method), proliferation (Brdu incorporation), apoptosis (Annexin V/viaprobe), cell migration (transwell plates), and colony forming potential (colony forming assays). Cells were cultured in both serum free medium supplemented with growth factors (SFM+5GF; IL-3, IL-6, G-CSF, Flt-3L, SCF) and in stromal co-culture assays using M2-10B4 and SL/SL fibroblasts. Plerixafor had no effect on viable cell counts or proliferation of CP CML $CD34^+$ cells up to 3 days following treatment. However from day 6 onwards we observed a dose-dependent reduction in cell numbers in the presence of plerixafor, for cells cultured SFM+5GF or SFM+G-CSF. Annexin V/viaprobe staining demonstrated that plerixafor did not induce apoptosis in these cells. Plerixafor inhibited migration of both primary CML and BV173 cells towards SDF1 and reduced chemotaxis to levels comparable with that of random spontaneous migration. In stromal co-culture experiments, we observed a trend towards reduced viability in cells treated with a combination of plerixafor and imatinib when compared to imatinib alone. After 6 days treatment with imatinib, primary CML $CD34^+$ cells showed decreased colony forming potential ($P<0.001$) and this decrease was enhanced significantly by combination treatment with plerixafor ($P<0.05$). Surface expression of CXCR4 on BV173 and primary $CD34^+$ CML cells was also significantly upregulated after treatment with imatinib ($P<0.05$ and $P<0.01$, respectively). However plerixafor overcomes this response and inhibits CXCR4 expression in a dose-dependent manner, reaching maximum inhibition at 1.0 μg/mL. Plerixafor's ability to inhibit CXCR4 expression and consequently SDF1-induced migration makes this drug an attractive therapeutic agent in the treatment of CML and other leukaemias. We hypothesize that plerixafor could be used to sensitize CML stem cells to TKIs, and be used in combination with TKIs to reduce minimal residual disease and in some cases disease elimination.

1136

SAFETY AND EFFICACY OF SECOND-LINE BOSUTINIB (SKI-606) IN IMATINIB RESISTANT OR INTOLERANT CHRONIC PHASE (CP) CHRONIC MYELOID LEUKEMIA (CML)

T Brümmendorf,[1] J Cortes,[2] A Turkina,[3] T Masszi,[4] S Assouline,[5] S Durrant,[6] A Volkert,[7] J Wang,[7] S Arkin,[7] C Gambacorti-Passerini[8]

[1]Universitäts-Klinikum Hamburg-Eppendorf & Universitätsklinikum Aachen, Aachen, Germany; [2]MD Anderson Cancer Center, Houston, TX, USA; [3]Hematology Research Center, Moscow, Russian Federation; [4]St. László Hospital, Budapest, Hungary; [5]McGill University, Montreal, Quebec, Canada; [6]Royal Brisbane and Women's Hospital, Brisbane, Queensland, Australia; [7]Pfizer, Cambridge, MA, USA; [8]University Milano-Bicocca, Milan, Italy

Background. Bosutinib is an oral Src/Abl kinase inhibitor, with minimal inhibitory activity against PDGFR or c-kit. *Aims.* A phase 1/2 study of CP CML patients (pts) who have failed treatment with imatinib (IM) is ongoing. *Methods.* Pts received 500 mg bosutinib orally, daily, and were followed for safety and efficacy. *Results.* We report preliminary data for 299 pts, 70% CP IM-resistant, 30% CP IM-intolerant, with a median follow-up from start of bosutinib of 16.8 (0.56 - 43.8) months. Median age was 52 (18 - 91) years, and prior treatments other than IM included interferon (92 pts) and stem cell transplant (8 pts). Of 133 pts evaluable for hematologic response, 108 (81%) achieved complete response (CHR). 137/220 (62%) evaluable pts attained a major cytogenetic response (MCyR), of which 109 (50%) were complete. Of 155 pts evaluable for molecular response, 75 (48%) reached a major molecular response, 46 (30%) of which were complete. Responses by outcome after IM are summarized in the table. 20 different mutations were detected at baseline in 45/99 (45%) pts tested. CHR was achieved in 87% of 23 evaluable pts with mutations and in 93% of 28 evaluable pts with no mutation. MCyR was attained in 68% and 56% of 41 and 39 evaluable pts with and without mutations, respectively. The most common adverse events were gastrointestinal (nausea, vomiting, diarrhea), typically grade 1/2, manageable and improving spontaneously after 3 - 4 weeks. Grade 3/4 non-hematologic toxicities (>5% of pts) were diarrhea (8%) and rash (8%). A single pt with a history of left ventricular ejection fraction dysfunction on IM experienced grade 3 pleural effusion. One pt with a history of arrhythmias, myocardial infarction and pacemaker placement experienced grade 3 prolonged QTc interval while on bosutinib. The most frequent grade 3/4 hematologic abnormalities were thrombocytopenia (23%), neutropenia (14%) and anemia (9%). Additional common grade 3/4 laboratory abnormalities included hypermagnesemia (11%) and increased ALT (10%). 91 pts (30%) required at least one dose reduction. Median daily dose was 480 mg for IM-resistant pts and 401 mg for IM-intolerant pts. 59 pts (20%) discontinued bosutinib due to toxicity. *Summary/Conclusions.* Bosutinib is effective in CP CML pts who have failed IM. Clinical responses are achieved in pts with a wide variety of Bcr-Abl mutations except T315I. Bosutinib is well-tolerated with minimal hematologic toxicity.

Table.

	IM-Resistant N (%)	IM-Intolerant N (%)
Hematologic Response

LONG-LASTING P210 PEPTIDE VACCINE TREATMENT IN CHRONIC MYELOID LEUKEMIA PATIENTS: SAFETY PROFILE AND CLINICAL RESULTS

M Defina, M Ippoliti, A Gozzetti, R Crupi, L Aprile, M Tassi, M Rondoni, F Lauria, M Bocchia

Hematology and Transplants, Siena, Italy

Background. In chronic myeloid leukemia (CML) BCR-ABL derived p210 protein is a unique antigen for an immune target therapy and we have designed two p210-derived peptide vaccines CMLVAX100 (5 b3a2 peptides) and CMLVAXb2a2-25 (1 b2a2 peptide) for improving minimal residual disease (MRD) surviving conventional treatment. Pivotal studies have shown that vaccine treatment may induce a reduction of residual CML. Currently, two multicenter clinical trials are ongoing to better define the role of peptide vaccines in a larger cohort of patients with MRD during imatinib. Up to date little is known about safety profile and overall results of long lasting immune therapy with p210-derived peptide vaccines. *Aims.* of the study: Evaluation of safety and efficacy of p210-derived peptide vaccines in CML patients treated for a long period of time. *Methods.* CML patients with MRD during imatinib or interferon alpha (IFN-α) received either CMLVAX100 or CMLVAXb2a2-25 as part of phase I study vaccine trials conducted in our institution. Vaccine schedule included an immunization phase lasting 3 months eventually followed by a maintenance treatment every 3-6 months. Primary endpoint was the evaluation of immune and disease response after immunization phase. Among a total of 31 CML vaccinated patients, 14 continued maintenance treatment for a median of 4 years and are evaluated in this report. *Results.* At beginning of vaccinations 9/14 patients were in late CP (median time from diagnosis 56 months); 12/14 patients were under imatinib treatment for a median time of 24 months (range 6-84); 1/14 was under IFN-α since 84 months and 1/14 was not receiving any CML treatment. All 14 patients were vaccinated in complete cytogenetic response (CCyR) with clear evidence of MRD (median BCR-ABL/ABL ratio 0,8 range 0.03-2.27). They received a median of 17 vaccinations each (range 13-22) during a median time of 49.5 months (range 36-67) from first vaccination. Vaccinations were very well tolerated and no patient showed any clinical toxicity other than mild local redness and itching. *In vitro* vaccine-induced immune response was stably documented in 8/14 patients, while 4/14 patients showed a temporary response and 2/14 patients had no evidence of response. During vaccinations 11/14 patients showed a reduction of MRD. At present time 13/14 patients are still in CCyR after a median time from diagnosis of 124 months (range 60-216); one patient lost CCyR after 70 and 39 months from starting imatinib and vaccinations, respectively. At last follow-up patients' MRD status is as follows: 5/11 patients on imatinib are in complete molecular response (CMolR), while 6/11 maintain MRD (median BCR-ABL/ABL ratio 0,7 range 0,05-1,5); the patient on IFN-α achieved CMolR despite reducing treatment dose; a patient achieved CMolR with vaccine therapy only. *Conclusions.* p210-derived peptide vaccines are safe and may be given for a long period of time without evidence of toxicity. Long lasting treatment resulted in the achievement of a stable CMolR in 7/14 CML patients. As well importantly 6/7 patients with persistent high level of MRD (median BCR-ABL/ABL ratio 0,7) maintain a CCyR after a median time of 43 months from starting vaccinations.

1138

NILOTINIB INDUCES RAPID AND DURABLE RESPONSES WITH 24-MONTH MINIMUM FOLLOW-UP IN PATIENTS WITH IMATINIB-RESISTANT OR -INTOLERANT CHRONIC MYELOID LEUKEMIA IN BLAST CRISIS (CML-BC)

Background. Nilotinib is a highly potent and selective inhibitor of BCR-ABL approved for the treatment of chronic phase (CP) and accelerated phase (AP) Philadelphia chromosome positive (Ph^+) CML in adult patients resistant to or intolerant of prior therapy, including imatinib. *Aims.* Here we present results from patients with imatinib-resistant and -intolerant Ph^+ CML-BC treated with nilotinib in the phase 2 registration trial. *Methods.* Patients were treated with nilotinib 400 mg twice daily. Primary endpoint was confirmed hematologic response (HR). *Results.* Patients (N = 136) with imatinib-resistant (82%) or -intolerant (18%) CML-BC (105 myeloid blast crisis [MBC]; 31 lymphoid blast crisis [LBC]), were treated with nilotinib and followed for a minimum of 24 months. In patients who had available baseline data, baseline BCR-ABL mutations were detected in 26/86 (30%) patients with MBC and 17/28 (61%) with LBC; T315I mutations were detected in 1 (1%) patient with MBC and 2 (7%) with LBC. Clonal evolution occurred in 73 (54%) patients. Stable or progressive disease was the best prior response to imatinib in 62 (46%) patients, with only 14 (10%) achieving prior complete HR (CHR) and 15 (11%) achieving major cytogenetic response (MCyR) on imatinib. With nilotinib therapy, 25 (24%) patients with MBC and 6 (19%) with LBC achieved a confirmed HR (Table). CHR was attained by 14 (13%) and 4 (13%) patients with MBC and LBC, respectively. Responses were rapid and durable. Median time to HR was 1 month and median duration of HR was 26 months (range, 1.25 - 29.08) for patients with MBC; 60% of these patients maintained HR at 24 months. For patients with LBC, the median duration of HR was 3.6 months and no patient maintained HR at 24 months. Nilotinib resulted in MCyR and CCyR in 40 (38%) and 31 (30%) patients with MBC and 16 (52%) and 10 (32%) with LBC, respectively. In patients with MBC, median time to MCyR was 2 months and median duration of MCyR was 11 months (range, 0.03 - 29.08). MCyR was maintained in 44% of patients at 24 months. Median duration of MCyR was 3 months for patients with LBC and no patient with LBC maintained MCyR at 24 months. Survival was 42% at 12 months and 27% at 24 months; 12 patients with MBC and 2 patients with LBC underwent transplants following nilotinib therapy. Nonhematologic adverse events were generally mild and manageable and similar to those observed in patients with Ph^+ CML-CP. *Conclusions.* Nilotinib is an effective therapy in patients with imatinib-resistant or -intolerant Ph^+ CML-BC, generating rapid and durable responses for patients with MBC. Nilotinib exhibited a favorable safety profile in patients with Ph^+ CML-BC and no new safety concerns were observed with 24 months minimum follow-up.

Table. Response rates in patioents with CML-BC treated with nilotinib.

Response	Overall (N = 136)	MBC (n = 105)	LBC (n = 31)
HR, n (%)	31 (23)	25 (24)	6 (19)
CHR, n (%)	18 (13)	14 (13)	4 (13)
MCyR, n (%)	56 (41)	40 (38)	16 (52)
CCyR, n (%)	41 (30)	31 (30)	10 (32)
12-month OS, %	42	44	35
24-month OS, %	27	32	10

EARLY CYTOGENETIC AND MOLECULAR RESPONSES AND PHARMACOKINETIC OF DASATINIB AS A FIRST LINE THERAPY IN NEWLY DIAGNOSED CHRONIC PHASE CML PATIENTS: FIRST ANALYSIS OF THE OPTIM DASATINIB TRIAL

P Rousselot,[1] S Bouchet,[2] G Etienne,[3] F Nicolini,[4] E Chauzit,[2] P Cony Makhoul,[5] V Coiteux,[6] A Guerci-Bresler,[7] M Gardembas-Pain,[8] L Legros,[9] L Roy,[10] C Dartigeas,[11] M Janvier,[12] C Berthou,[13] M Molimard,[2] J Guilhot,[10] F Guilhot,[10] FX Mahon[14]

[1]Hôpital Mignot, Université de Versailles, Le Chesnay, France; [2]CHU Pellegrin, Bordeaux, France; [3]Institut Bergonié, Bordeaux, France; [4]Hôpitaux de Lyon, Lyon, France; [5]Hôpital d'Annecy, Annecy, France; [6]Hôpital Claude Huriez, Lille, France; [7]CHU Brabois, Nancy, France; [8]CHU d'Angers, Angers, France; [9]CHU de Nice, Nice, France; [10]INSERM CIC 0,[2] CHU de Poitiers, Poitiers, France; [11]CHU de Tours, Tours, France; [12]Centre René Huguenin, Saint-Cloud, France; [13]CHU de Brest, Brest, France; [14]Université Victor Segalen, INSERM U,[876] Bordeaux, France

Background. Dasatinib 100 mg QD is approved as second line therapy in patients with chronic myelogenous leukaemia in chronic phase (CP-CML) after imatinib failure or intolerance. As suggested in second line therapy, efficacy and tolerance of dasatinib first line may be driven by pharmacokinetic parameters. We initiated an optimization study based on the monitoring of dasatinib plasma levels (Cmin and Cmax) administered as front line therapy in patients with newly diagnosed CP-CML. *Methods.* Patients aged 18 years old or more were eligible if they were newly diagnosed with CP-CML without having being exposed to tyrosine kinase inhibitors. Dasatinib was initiated at 100 mg QD. The pharmacokinetic (PK) evaluation (Cmin and Cmax) was performed after 7 to 10 days of therapy and every 3 months thereafter. Dasatinib dose adaptation was required in patients with a Cmin over 5nM and randomized in the treatment adaptation arm. All other patients were treated with dasatinib 100 mg QD. *Results.* We report the results of the first 57 patients included in the trial. Median age was 51 years (19-78) with a sex ratio M/F of 1.65. 52.9% of the patients presented with a low Sokal score, 29.5% and 17.6% with an intermediate and high score. Median Cmin and Cmax values were 2.3 nM (range 0.2-18.7) and 113.1 nM (range 20.5-261) respectively at first PK analysis. The median Cmin value was significantly lower in patients with age <50y compared to patients >50y (1.6 nM *vs.* 3.3 nM, P=0.007). By contrast, the median Cmax value was comparable in both age groups (119.8 nM *vs.* 92.2 nM, P=0.78). Efficacy was analyzed on the 38 patients with at least 3 months follow-up and on the 20 patients with 6 months follow-up. The complete cytogenetic response (CCR) rates at 3 and 6 months were 68% (26 out of 38) and 85% (17 out of 20) respectively. The major molecular response (MMR) rates at 3 and 6 months were 13.1% and 60%. Of note, the 3 patients not in CCR at 6 months had the highest Sokal score including two patients in cytogenetic failure (Sokal score values 2.5 and 1.8). Median PK values at months 3 and 6 were not statistically different compared to initial PK values, suggesting a stable exposure to the treatment with time. With a median follow-up of 4.3 months, only one pleural effusion was observed (1.6%). Haematological grade 3 and 4 toxicities in patients treated for at least 3 months included 4 episodes of neutropenia and 2 episodes of thrombocytopenia (4 patients out of 38, 10.5%). *Conclusions.* Dasatinib 100 mg QD as first line therapy in CP CML provided high rates of MMR (60%) and CCR (85%) as early as 6 months after treatment initiation. Pharmacokinetic parameters of dasatinib were different in aged patients. A complete pharmacokinetic analysis with correlations to response and tolerance will be presented on more patients with a 6 months follow-up.

Myeloproliferative disorders - Clinical

1140

PATTERNS OF SURVIVAL AMONG 7,249 PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS DIAGNOSED IN SWEDEN 1973-2003

L Hultcrantz,[1] S Kristinsson,[1] T Andersson,[1] S Eloranta,[1] A Derolf,[1] O Landgren,[2] P Dickman,[1] M Björkholm[1]

[1]Karolinska Institutet, Stockholm, Sweden; [2]National Institutes of Health, Bethesda, USA

Background. Available data on survival patterns among patients diagnosed with myeloproliferative neoplasms (MPN) are inconclusive. Based mostly on smaller clinical series, patients diagnosed with primary myelofibrosis (PMF) have a substantially reduced life expectancy and polycythemia vera (PV) is associated with an inferior survival in most, but not all, studies. In essential thrombocythemia (ET), the situation is even more controversial with reports stating that life expectancy is not significantly affected by the disease while other investigators report that ET must be considered a serious disease that significantly decreases life expectancy. *Aims.* To establish patterns of survival in MPN patients in a population-based setting in Sweden. *Methods.* Using the nationwide Swedish Cancer Registry, we assessed patterns of survival among all MPN patients (n=7,249) reported 1973-2002 with follow-up data until 2003. Relative survival ratios (RSR) and excess mortality rate ratios (EMRR) were computed as measures of survival. *Results.* A total of 7,249 MPN patients were identified (PV n=3,784, ET n=1,987, PMF n=852 and MPN not otherwise specified (MPN NOS) n=626); 48% were males and the median age at diagnosis was 70 years. There was a significant overall excess mortality in patients with MPN, reflected in a 1-year RSR of 0.89 (95% CI 0.89-0.90), a 5-year RSR of 0.73 (0.71-0.74) and a 10-year RSR of 0.57 (0.55-0.59). For the different subtypes the 5-year and 10-year RSRs were 0.81 (0.79-0.83) and 0.64 (0.62-0.67) for PV, 0.75 (0.72-0.78) and 0.64 (0.60-0.68) for ET and 0.39 (0.35-0.43) and 0.22 (0.19-0.27) for PMF, respectively (Figure). Survival of patients with MPN has improved significantly over time with an EMRR of 0.55 (0.49-0.62) in 1980-1989 and 0.21 (0.17-0.25) in 1990-1999 using the calendar period 1973-1979 as a reference. Older age at MPN diagnosis was consistently associated with a poorer survival. For example, 10-year RSR for patients <50 years was 0.84 (0.81-0.87) as compared to 0.31 (0.24-0.41; P<0.001) in those >80 years. Females had a better survival than men, EMRR 0.73 (0.67 to 0.80). *Summary/Conclusions.* In this large population-based study including over 7,000 MPN patients, we found all MPN subtypes to have a significantly decreased life expectancy compared to the general population. ET patients were observed to have a poorer survival than patients with PV up to 10 years after diagnosis. A certain misclassification of ET as PMF, especially during earlier years, may have contributed to a reduction in survival rates in the ET group. Survival of MPN patients improved over time in all age groups. This may reflect in part the earlier establishment of a MPN diagnosis in more recent years but also the introduction of more effective treatment strategies and better supportive care. We are now analyzing causes of death in the cohort aiming at a better understanding of the excess mortality which may have implications for the clinical management of these disorders.

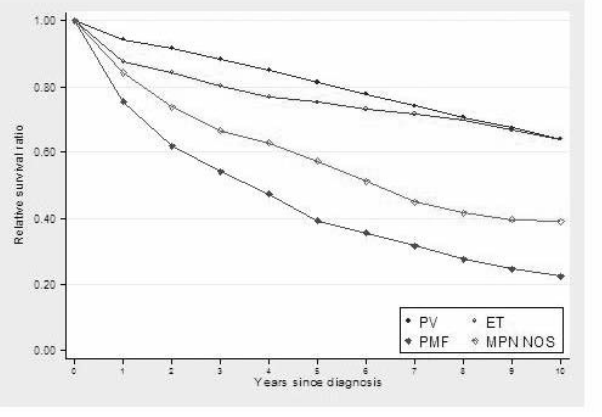

Figure. Cumulative relative survival stratified by subtype.

THE JAK2 46/1 (GGCC) HAPLOTYPE IS ASSOCIATED WITH PRIMARY MYELOFIBROSIS INDEPENDENTLY OF V617F MUTATIONAL STATUS, DISEASE CHARACTERISTICS OR PROGNOSIS

M. Vannucchi,[1] P Guglielmelli,[1] F Biamonte,[1] A Spolverini,[1] A Pancrazzi,[1] L Pieri,[1] A Isgrò,[2] E Antonioli,[1] N Bartalucci,[1] A Bosi,[1] G Barosi[2]

[1]*University of Florence, Florence, Italy;* [2]*Fondaz. IRCCS, Polic S. Matteo, Pavia, Italy*

Background. A germline haplotype block, including most of JAK2, named 46/1, or "GGCC", has been shown in three studies (Jones AV *et al.*; Olcaydu D *et al.*; Kilpivaara O *et al.*; 2009) to be strongly associated with JAK2V617F myeloproliferative neoplasms (MPN). Additional studies showed significant association also with JAK2 exon 12-mutated polycythemia vera, JAK2-wild type essential thrombocythemia or primary myelofibrosis (PMF), suggesting an increased risk of MPN regardless of the V617F mutation. Whether this haplotype also conferred specific clinical characteristics is still under debate. *Aims.* To evaluate the association of JAK2 46/1 haplotype with JAK2V617F mutational status, clinical characteristics and prognosis in series of 202 PMF patients.*Methods.* Screening for 46/1 haplotype was performed in granulocyte DNA using a tag rs12343867SNP (T to C shift), that is in complete linkage disequilibrium with 46/1, in a RT-PCR allelic discrimination assay. The C allele stands for 46/1 haplotype. JAK2V617F allele burden was measured by RTQ-PCR. The study was approved from IRB and patients gave consent to use of their DNA samples. *Results.* Median follow-up was 65.4 months; 42 patients died (20.8%), and leukemia transformation occurred in 25 patients. Patients in the four IPSS risk categories accounted for 36.1%, 22.5%, 23.7% and 17.7% of the 169 who were evaluable. The frequency of C allele was significantly higher in the whole series of PMF patients compared to control population (0.386 *vs.* 0.266; P=0.0002). Such difference was largely due to the category of JAK2V617F mutated patients (C allele frequency, 0.413; P<0.0001 *vs.* controls), while in case of JAK2V617F negative patients a bordeline significance was measured (P<0.05). In JAK2V617F mutated patients with a V617F burden lower than 25% the frequency of C allele was 0.333, similar to JAK2 wild-type population (P=0.434), while a C allele frequency of 0.416 was found in those with greater than 25% V617F allele (P<0.0001 *vs.* controls). Furthermore, the frequency of C allele increased from 0.333 to 0.500 (P<0.0001, chi-square test for trend) in patients divided in JAK2V617F burden quartiles. We found no difference regarding hematological parameters, large splenomegaly, constitutional symptoms, IPSS score, rate of transformation to leukemia or death, depending on the patient rs12343867 genotype. Also, there was no difference in overall survival in the three rs12343867 genotypes even after stratification of the patients according to their JAK2V617F mutational status. *Conclusions.* Present data confirm the significant association of 46/1 haplotype with PMF described in earlier studies, and point to a major contribution of V617F-mutated patients. In line with a recent study from Mayo Clinic (Tefferi A *et al.*, Leukemia 2009) we observed that the C allele was over-represented in patients showing the highest V617F allele burden, thus underlining the contribution of UPD in the progressively increasing rate of 46/1 haplotype according to V617F allele burden. On the other hand, these results are at variance with the Mayo study where the TT allele was significantly associated with shortened survival, particularly in JAK2 wild-type patients. Additional studies are needed to fully clarify the prognostic role of 46/1 in PMF.

MUTATIONS OF IDH1 AND IDH2 IN MYELOPROLIFERATIVE NEOPLASMS: ASSOCIATION WITH LEUKEMIC TRANSFORMATION

F Stegelmann,[1] P Paschka,[1] M Griesshammer,[2] C Blersch,[1] S Kuhn,[1] S Schauer,[1] H Döhner,[1] K Döhner[1]

[1]*University Hospital of Ulm, Ulm, Germany;* [2]*Johannes-Wesling Clinic Minden, Department of Hematology-Oncology, Minden, Germany*

Background. Essential thrombocythemia (ET), polycythemia vera (PV), and myelofibrosis (MF) are myeloproliferative neoplasms (MPN) characterized by clonal expansion of myeloid cells. The understanding of the molecular pathogenesis of MPN is mainly based on the identification of somatic mutations in the genes *JAK2*, *MPL*, and *TET2*. However, a significant number of patients lack any proof of clonality. More recently, mutations in isocitrate dehydrogenase 1 (*IDH1*) and 2 (*IDH2*) genes have been identified in myeloid malignancies resulting in the production of a potential oncometabolite (2-hydroxyglutarate). *Aim.* In our study, we sought to explore the presence of exon 4 mutations of *IDH1* and *IDH2* in a cohort of well-characterized MPN and acute myeloid leukemia cases secondary to MPN (sAML). *Methods.* Exons 4 of *IDH1* and *IDH2* were analyzed for mutations in 115 patients [PV, n=30; ET, n=30, MF, n=20; sAML, n=35] using a combination of denaturing high-performance liquid chromatography and DNA sequencing. Data on the mutation status of *JAK2* (V617F), *MPL* (W515L), and *TET2* (all exons sequenced) were available in all cases. In addition, all cases were analyzed on 250K single-nucleotide polymorphism (SNP) arrays that allow for genome-wide screening of copy-number alterations (CNAs) and uniparental disomies (UPDs). *Results.* In total, seven heterozygous *IDH* missense mutations were identified. Mutations were rare in MPN (n=1), whereas 17% (6/35) of sAML cases harbored *IDH1* (n=2) or *IDH2* (n=4) mutations. In sAML, both *IDH1* mutations affected the same single arginine residue (R132H and R132C, respectively); *IDH2* mutations were restricted to the amino acid residues R140 (n=3; R140Q) and R172 (n=1; R172K). The *IDH1* mutation in one MPN case (ET) was detected in an atypical position (E62K). This patient lacked further genomic aberrations or *JAK2/MPL/TET2* mutations. Although *JAK2* and *TET2* mutations in sAML were relatively frequent in our study (60% and 26%, respectively), additional genetic lesions were rare in the six *IDH* mutated sAML patients: in the one case with *IDH2* R172K mutation an additional *TET2* mutation in exon 10 was found (G1859W), whereas *JAK2* V617F was mutated in two patients with *IDH2* R140Q mutation. Of note, both *JAK2/IDH2* double-mutated cases had leukemic transformation from preceding PV; UPD in 9p including the *JAK2* locus was present in one of the cases. Our previous SNP-array study on sAML patients revealed CNAs in 65% of cases; 35% of samples showed complex genomic aberrations with up to 20 CNAs per patient (Stegelmann *et al.,* ASH 2009, Abstract #2608). Here, only one of the three exclusively *IDH* mutated sAML patients exhibited CNAs (del(7), trisomy 8, and trisomy 15) as assessed by SNP-chip analysis. Consequently, our data indicate that one third (2/6) of *IDH* mutated sAML patients lack additional genetic or genomic aberrations. *Conclusions.* Our study on 115 MPN/sAML patients revealed *IDH1* and *IDH2* mutations as a frequent genetic lesion in sAML secondary to MPN. Validation of the uncommon *IDH1* E62K mutation in ET is currently ongoing. Furthermore, our data suggest that *IDH1* and *IDH2* mutations may be implicated in a subset of sAML patients as an autonomous pathogenetic mechanism.

EVIDENCE OF EFFICACY OF RAD001, AN INHIBITOR OF MTOR, IN A PHASE I/II STUDY IN PRIMARY MYELOFIBROSIS (PMF) AND POST POLYCYTHEMIA VERA/ESSENTIAL THROMBOCYTHEMIA MYELOFIBROSIS (PPV/PET MF)

M. Vannucchi,[1] P Guglielmelli,[1] L Lupo,[2] MC Finazzi,[3] L Tozzi,[1] F Biamonte,[1] E Antonioli,[1] C Bogani,[1] L Pieri,[1] E Gattoni,[2] A Masciulli,[4] S Paratore,[5] MC Susini,[1] G Finazzi,[3] R Marchioli,[4] A Rambaldi,[3] T Barbui,[3] A Bosi,[1] G Barosi[2]

[1]University of Florence, Florence, Italy; [2]Fondaz. IRCCS, Polic S. Matteo, Pavia, Italy; [3]Div. Hematology, Osp. Riuniti, Bergamo, Italy; [4]Mario Negri Sud Inst., Chieti, Italy; [5]Novartis, Milano, Italy

Background. JAK2V617F mutated cells display PI3K/Akt pathway activation. RAD001, a specific inhibitor of mTOR that is downstream of PI3K, inhibited JAK2V617F-pos cells reducing STAT5 phosphorylation, and prevented growth of MPN CD34+ cells (Bogani C *et al.*, ASH2009). *Aim.* We are conducting an investigator-initiated, multicenter phase I/II trial to test safety and efficacy of RAD001, as an off-label drug, in pts with PMF and PPV/PET MF, with intermediate/high risk score (Lille criteria) or requiring treatment because of progressing splenomegaly if in the low score. PMF and PPV/PET-MF were diagnosed according to WHO and IWG-MRT criteria, respectively. Phase I involved a 3+3 patients scheme in 3 sequential cohorts at 5.0, 7.5, and 10 mg once daily, orally, for 3 months. Phase II was a two-stage Simon design at MTD for 4 months. The protocol was approved by IRBs and patients provided informed consent. The trial is supported by Italian government AIFA agency. *Results.* MTD from Phase I was established at 10 mg daily, with no DLT; there were 2 major and 3 moderate responses, while 3 pts had no response (NR). In portion one of Phase II, 16 pts have been included and 10 are evaluable; data will be updated at the meeting. There were 6 PMF, 6 PPV- and 4 PET-MF. Nine pts were low and 7 intermediate Lille score at enrollment; according to IWG-MRT, 3 were low, 5 intermediate-I, 3 intermediate-II and 5 high risk score. In 2 cases therapy was discontinued because of patient's decision at day 60 without evidence of any AE >2 grade. Therapy was generally well tolerated; commonest toxicities were grade 2 mouth ulcers in 5 pts and grade 1/2 hypertrigliceridemia in 7 pts; one grade 3 asymptomatic hypopotassemia. Hematological toxicities were reversible one grade 2 and three grade 3 anemia, and one grade 2 neutropenia. Of the 8 patients who completed therapy a reduction of spleen size consistent with CR, PR or NR was obtained in 2, 5, and 1 pts, respectively. 4 of 5 patients with systemic symptoms had complete resolution, and all 4 pts reported disappearance of pruritus. One of 6 anemic pts had PR becoming transfusion-independent with Hb 108 g/L. A CR in platelet count was obtained in 1 of 6 pts, while none of 5 pts with leukocytosis had measurable response. Overall, there were 3 major, 4 moderate and 1 NR (EUMNET criteria), or 2 CI and 6 stable disease (IWG-MRT criteria); according to intention-to-treat analysis, there were one additional moderate and one NR (EUMNET) or 1 CI and one SD (IWG-MRT). Of the 5 JAK2V617F-pos pts one had reduction of allele burden of 24% (from 82% at baseline to 63%) while in the others minimal changes were measured. Circulating CD34+ were reduced of 18% to 68% the baseline value in 4 pts, in three there was an increase from 90% to 260% the baseline value, and in 1 patients no change. *Conclusion.* Preliminary results from trial Phase II suggest potential activity of RAD001 in pts with myelofibrosis.

1144

FIRST REPORT OF THE PHASE-I STUDY OF THE NOVEL ORAL JAK2 INHIBITOR SB1518 IN PATIENTS WITH MYELOFIBROSIS

F Seymour,[1] B To,[2] A Goh,[3] L Meadows,[1] A Ethirajulu,[4] A Wood,[3] A Zhu,[5] W Roberts[6]

*[1]Peter MacCallum Cancer Centre, East Melbourne, Australia; [2]Institute of Medical and Veterinary Science and Royal Adelaide Hospital, Adelaide, Australia; [3]S*BIO Pty Ltd., Singapore, Singapore; [4]S*Bio Pty Ltd., Singapore, Singapore; [5]S*Bio Pty Ltd, Redwood City, USA; [6]The Royal Melbourne Hospital, Parkville, Australia*

Background. SB1518 is a potent inhibitor of JAK2 (IC_{50}=22 nM) and the JAK2*V617F* mutant (IC_{50}=19 nM) implicated in the pathogenesis of myeloproliferative neoplasms including myelofibrosis. SB1518 is highly selective for JAK2 inhibition compared to JAK1 and JAK3 (58 and 24 fold, respectively) which inhibits proliferation of JAK-2-dependent human leukemia cell lines at nM levels and has antitumor activity in a nude-mouse model of JAK2-dependent (BaF3-JAK2*V617F*) leukemia. Based on these encouraging data, SB1518 was evaluated in subjects with advanced myelofibrosis in a Phase-I dose escalation study. *Aims/Methods.* To determine the safety, tolerability and PK/PD profile of SB1518 when administered orally once daily continuously in 28-day cycles and define the recommended phase-II dose. Plasma samples for full PK analysis were taken at various time points on days 1, 15, and 25-28 of cycle 1. *Results.* From August '08-January '10, 20 patients have been enrolled and treated at 5 dose levels from 100-600mg daily. Demographic data are available for 20 patients and safety data for 18. Median age was 58.5 (range 47-74) years with 60% males, median prior therapies was 1 (0-7), and 85% were JAK2 mutation-positive. The median time from diagnosis was 39 months and 80% had clinical splenomegaly (median 17.5cm below costal margin) at study entry. No dose-limiting toxicities (DLTs) were seen at the 100, 200, or 400mg dose levels (each n=3). At 600 mg, 2 of 4 patients experienced DLTs (Gr 3 nausea/diarrhea/fatigue requiring temporary drug interruption). Cohort expansion at 500 mg has enrolled 4 additional patients without any DLTs in cycle 1, although 3 required later dose interruptions due to diarrhea, elevated ALT and dizziness, respectively. The most common drug-related adverse events have been diarrhea 89% (11% Grade 3, only observed at 500 mg and 600 mg dose levels), nausea and vomiting 39% (6% grade 3 nausea only at 600 and vomiting all Grade 1/2), abdominal pain, fatigue at 22% each (11% Grade 3 only at 600), and dysgeusia and rash 17% (all Grade 1/2). The median treatment duration is 99.5 days (max 414+ days). Six patients have ceased SB1518, while 14 continue on treatment. Using 2006 IWG response criteria, confirmed clinical improvements have been seen in hemoglobin (transfusion independence), platelet, and splenomegaly categories and updated response data will be presented. SB1518 was rapidly absorbed with a Tmax of 3-6 hours and mean elimination half-life of 22-55 hours. Steady-state drug levels showed no accumulation over the studied period. Plasma AUC increased in a dose-related manner between 100 and 400 mg dose levels, with full data from 500 and 600mg dose levels pending. SB1518 achieved potentially pharmacologically active concentrations at the starting dose of 100 mg on day 1. *Conclusion.* SB1518 is well tolerated in cycle 1 at doses below 600 mg daily in patients with advanced myelofibrosis, and shows promising clinical activity. The 500mg dose is not optimally tolerated for chronic dosing beyond cycle 1, and so 400mg is the dose selected for evaluation in the ongoing phase-II studies in patients with myelofibrosis.

Hodgkin's lymphoma

1145

TWO CYCLES OF ABVD FOLLOWED BY INVOLVED FIELD RADIOTHERAPY WITH 20 GRAY (GY) IS THE NEW STANDARD OF CARE IN THE TREATMENT OF PATIENTS WITH EARLY-STAGE HODGKIN LYMPHOMA: FINAL ANALYSIS OF THE RANDOMIZED GERMAN HODGKIN STUDY GROUP (GHSG) HD10 STUDY

A Engert,[1] A Pluetschow,[2] H Eich,[1] R Herrmann,[3] B Doerken,[4] L Kanz,[5] R Greil,[6] J Markova,[7] M Fuchs,[2] P Borchmann,[8] H Mueller-Hermelink,[9] R Mueller,[1] V Diehl[2]

[1]University Hospital Cologne, Cologne, Germany; [2]GHSG, University Hospital of Cologne, Cologne, Germany; [3]Kantonsspital Basel, Basel, Switzerland; [4]University Hospital Berlin Charite, Berlin, Germany; [5]University Hospital Tuebingen, Tuebingen, Germany; [6]University of Salzburg, Salzburg, Austria; [7]University Hospital of Prague, Prague, Czech Republic; [8]University Hospital of Cologne, Cologne, Germany; [9]Dept. of Pathology, University of Wuerzburg, Wuerzburg, Germany

Background. There has been an ongoing debate on the best treatment for patients with early favourable Hodgkin lymphoma (HL). Open questions include the choice between combined modality treatment or chemotherapy only, the number of chemotherapy cycles needed and the optimal radiation dose. The GHSG thus conducted a randomized study for patients with early-stage favourable Hodgkin lymphoma (HD10) in which these questions were addressed. *Methods.* HD10 was an international prospectively randomized multicenter trial comparing 2 and 4 cycles of ABVD as well as 20Gy or 30Gy involved field radiotherapy (IFRT) in a 2 x 2 statistical design. Between 5/1998 and 1/2003, a total of 1370 patients from 329 centers were randomized into four arms: 4 x ABVD + 30Gy; 4 x ABVD + 20Gy; 2 x ABVD + 30Gy; 2 x ABVD + 20Gy. All patients had their initial histology reviewed by a lymphoma expert panel. Documentation was complete in more than 99,1% of cases for this final analysis. *Results.* Patients were equally balanced for age, gender, stage, histology, performance status and risk factors between arms. There were significant differences in major toxicity (WHO grade III/IV) between 4 x ABVD and 2 x ABVD in the overall number of events (52% *vs.* 33%) including leukopenia (24% *vs.* 15%) and hair loss (28% *vs.* 15%). In terms of radiation dose, there also was a difference in toxicity between 30Gy and 20Gy IFRT (all events: 8.7% *vs.* 2.9%), dysphagia (3% *vs.* 2%), mucositis (3.4% *vs.* 0.7%). Complete remission was achieved in 97% of patients treated with 4 x ABVD, 97% with 2 x ABVD, 99% after 30Gy and 97% after 20Gy. With a median follow-up of 79 - 91 months, there was no significant difference between 4 x ABVD and 2 x ABVD in terms of overall survival at 5 years (OS: 4 x ABVD 97.1%; 2 x ABVD: 96.6%), freedom from treatment failure (FFTF: 93.0% *vs.* 91.1%) and progression free survival (PFS: 93.5% *vs.* 91.2%). For the radiotherapy question, there were also no significant differences between patients receiving 30Gy IFRT and those with 20Gy IFRT in terms of OS (97.6% *vs.* 97.5%), FFTF (93.4% *vs.* 92.9%) and PFS (93.7% *vs.* 93.2%), respectively. Importantly, there was also no significant difference in terms of OS, FFTF and PFS when all four arms were compared. *Conclusion.* Two cycles of ABVD followed by 20Gy IFRT is the new GHSG standard of care for Hodgkin patients in early favourable stages.

DACARBAZINE IS AN ESSENTIAL COMPONENT OF ABVD IN THE TREATMENT OF EARLY FAVOURABLE HODGKIN LYMPHOMA: RESULTS OF THE SECOND INTERIM ANALYSIS OF THE GHSG HD13 TRIAL

P Borchmann,[1] V Diehl,[1] H Goergen,[1] A Lohri,[2] J Zijlstra,[3] M Topp,[4] M Fuchs,[1] H Eich,[1] A Engert[1]

[1]Uniklinik Köln, Köln, Germany; [22]Swiss Group for Clinical Cancer Research (SAKK), CH-3001 Bern, Switzerland; [3]VU University Medical Centre Amsterdam, Department of Hematology, Amsterdam, Netherlands; [4]University of Würzburg, Department of Internal Medicine II, Würzburg, Germany

Background. Combined modality treatment consisting of 2-4 cycles of ABVD (adriamycin, bleomycin, vinblastine, dacarbazine) followed by involved field radiotherapy (IFRT) is regarded as standard of care for early favourable Hodgkin Lymphoma (HL). However, the impact of bleomycin and dacarbazine in this combination is unclear and has been questioned for years. *Aims.* To determine the minimum required cytotoxic drugs, the GHSG (German Hodgkin Study Group) HD13 study compared 2 cycles of ABVD (arm A) with a dacarbazine-deleted variant (ABV, arm B), a bleomycin-deleted variant (AVB, arm C), and a variant in which both, dacarbazine and bleomycin were deleted (AV, arm D). *Methods.* Between 01-2003 and 09-2009, 1710 patients were enrolled into the HD13 study. Due to more events (defined as progressive disease, relapse, or death) during a continuous safety analysis, arm D was closed early in 09-2005, and arm B in 02-2006. 323 patients are evaluable for the comparison A (n=167) *vs.* D (n=156), and 389 for A (n=198) *vs.* B (n=191), respectively. Due to these low case numbers, descriptive analyses were performed comparing response and event rates and Kaplan Meier estimates. *Results.* Patient characteristics were well balanced between arm A, B, and D. With regard to toxicity, less leukopenia (CTC grade 3 or 4) was observed with the AV regimen (13% *vs.* 18% for ABVD). With regard to efficacy, the comparison of arm A *vs.* B showed an inferior lymphoma control by the reduced regimen as indicated by the complete remission (CR) rate (97.5% *vs.* 95.8%) and more patients with progressive disease (PD, 1.0% *vs.* 3.1%). The 4 year estimate for freedom from treatment failure (FFTF [95%-CI]) was also inferior (93.5% [88.8% to 96.2%] *vs.* 84.5% [77.9% to 89.2%]). However, overall survival (OS) at 4 years was not substantially different (98.4% [95.0% to 99.5%] *vs.* 95.9% [91.6% to 98.0%]). For significance of differences see Table 1. Very similar results were observed for the comparison of arm A *vs.* D with a CR rate of 97.0% *vs.* 91.0%, and PD in 1.2% and 5.8% of all patients. Accordingly, the 4 year FFTF was inferior (92.3% [86.9% to 95.6%] *vs.* 75.3% [67.0% to 81.8%]), but not the OS (98.1% [94.1% to 99.4%] *vs.* 98.7% [94.8% to 99.7%]). *Conclusion.* Reduction of the ABVD regimen to ABV (arm B) or AV (arm D) results in a decreased CR rate and an increase of patients with progressive disease or relapse. Accordingly, the FFTF difference at 4 years is high with 9% (A *vs.* B) and 17% (A *vs.* D), each in favor of the standard arm. Fortunately, most of these patients were successfully salvaged by second line treatment and this poor PFS did not translate into an inferior OS. To summarize, dacarbazine cannot be omitted in the ABVD regimen without significant loss of efficacy. Final analysis of the HD13 study (arm A *vs.* arm C) will show whether bleomycin can be safely omitted in the ABVD regimen.

Table 1. Estimates and 95%-CIs for 4 year differences (Δ).

	FFTF	PFS	OS
A vs B (ABVD versus ABV)	Δ -9.0% [-15.8% to -2.2%] HR 2.26 [1.19 to 4.28] p=0.01	Δ - 9.8% [-16.3% to -3.3%] HR 2.76 [1.37 to 5.54] p=0.003	Δ -2.4% [-6.4% to 1.5%] HR 1.64 [0.54 to 5.02] p=0.38
A vs D (ABVD versus AV)	Δ -17.0% [-25.6% to -8.4%] HR 2.81 [1.51 to 5.24] p=0.0007	Δ -16.8% [-25.1% to -8.5%] HR 3.25 [1.63 to 6.46] p=0.0004	Δ 0.6% [-3.0% to 4.2%] HR 0.61 [0.15 to 2.54] p=0.491

EVIDENCE OF CLINICAL ACTIVITY IN A PHASE II STUDY OF ORAL PANOBINOSTAT IN PATIENTS WITH RELAPSED/REFRACTORY HODGKIN LYMPHOMA (HL) AFTER AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANT (AHSCT)

A Engert,[1] A Sureda,[2] C Chiattone,[3] V Buccheri,[4] TC Ong,[5] D Ben-Yehuda,[6] N Myke,[7] A Shen,[7] C Le Corre,[7] A Younes[8]

[1]Klinikum der Universität zu Köln, Cologne, Germany; [2]Hospital de la Santa Creu, Barcelona, Spain; [3]Santa Casa de Misericórdia de São Paulo, São Paulo, Brazil; [4]Hospital das Clínicas da Faculdade de Medicina da USP, São Paulo, Brazil; [5]Hospital Ampang, Ampang, Malaysia; [6]Hadassah Medical Organization, Jerusalem, Israel; [7]Novartis Pharmaceuticals Corporation, Florham Park, NJ, USA; [8]University of Texas/MD Anderson Cancer Center, Houston, TX, USA

Background. Panobinostat is a pan-deacetylase inhibitor targeting epigenetic and non-epigenetic oncogenic pathways. *in vitro*, panobinostat decreases proliferation and induces apoptosis in HL cell lines at low nanomolar concentrations. In a Phase I study, promising activity was observed in patients with relapsed/refractory HL (EHA 2009, Abstract

#1064). *Aims.* The aim of this pivotal, open-label Phase II study is to evaluate the efficacy of panobinostat in the post-transplant relapsed/refractory HL population. *Methods.* This study with Simon optimal 2-stage design has completed enrollment. Oral panobinostat is administered at a dose of 40 mg three times per week, every week, in 21-day cycles. Dose delay and modification for management of adverse events (AEs) is allowed. CT/MRI scans are conducted after every 2 cycles for efficacy evaluation. The primary endpoint is objective response rate. Secondary endpoints include time to response (TTR), duration of response (DOR), progression-free survival, overall survival, and safety. *Results.* As of February 8, 2010, 129 patients have been enrolled and treated: median age 32 years [18-75]; 30% had >5 prior lines of therapy; median number of prior regimens was 4 [1-6]; median time to relapse after first AHSCT was 8 months; >83% had 1 or more post-transplant therapies prior to study drug; 29% did not respond to last prior medication regimen. 11 patients also received prior allogeneic transplant. In preliminary efficacy analysis, 112 patients had >1 post baseline CT/MRI result available or discontinued early - 74% had tumor reduction, 4% had early PD, and 3% discontinued prior to first efficacy evaluation (e.g., due to AE). 24 responses (3CR+21PR) have been reported. 17 of 24 responders continue on study and tumor burden continues to decrease even after achieving PR and following dose modification. Although the median DOR cannot yet be determined, 50% of responders have a DOR ranging from 12-64+ weeks, and among the responders 8 patients have maintained response for >6 months. TTR ranged from 4-30 weeks among the 24 responders. Median treatment duration for 129 patients is currently 120+ days [5-511+] and 54% of patients continue on treatment. Common drug-related Grade 1/2 AEs were diarrhea, nausea, fatigue, vomiting, anorexia, and dysgeusia. Common drug-related Grade 3/4 AEs were thrombocytopenia (64%), anemia (14%), and neutropenia (12%). The thrombocytopenia was manageable and reversible with dose hold and modification. *Summary.* Interim results from this pivotal study to evaluate oral panobinostat shows promising activity in post-transplant relapsed/refractory HL patients. Manageable and reversible thrombocytopenia is the major toxicity in these heavily pretreated patients. Analysis of patient samples for predictive biomarkers to panobinostat is currently ongoing. Updated efficacy and safety data will be presented at the meeting.

INCREASED EXPRESSION OF CD4+CD25+FOXP3+ REGULATORY T CELLS PREDICTS POOR RESPONSE AND CORRELATES WITH EPSTEIN-BARR VIRUS PRESENCE IN REED-STERNBERG CELLS IN PATIENTS WITH CLASSICAL HODGKIN LYMPHOMA

M Assis,[1] A Campos,[2] F Soares,[2] J Silva,[1] P Brito,[1] E Souza,[1] J Oliveira,[1] O Baiocchi[1]

[1]Oncology Department, Federal University of Sao Paulo, Sao Paulo, Brazil; [2]Pathology Department, A.C. Camargo Hospital, Sao Paulo, Brazil

Introduction. Unlike most other human malignancies, the Reed-Sternberg (RS) malignant cells of classical Hodgkin lymphoma (cHL) are vastly outnumbered by the surrounding nonmalignant inflammatory cells. The mechanisms of how RS cells perpetuates in this inflammatory milieu remain controversial and the Epstein-Barr virus (EBV) has been shown to play a role in this immune evasion. EBV can be found latently infecting RS cells in approximately 50% of all cases. EBV can increase the migration of $CD4^+$ lymphocytes that also express CD25 and FOXP3, named regulatory T cells (Tregs), which are specialized $CD4^+$ T cells that inhibit effector $CD4^+$ and $CD8^+$ T cells. In cHL, an increased number of Tregs is associated with loss of EBV-specific immunity. *Aims.* In this study, we assessed the distribution and biological significance of $CD4^+/CD25^+/FOXP3^+$ regulatory T-cells (Tregs) in 38 patients with cHL and its correlation with EBV presence in RS cells. *Methods.* Tissue microarrays were constructed using diagnostic biopsies available in 38 cHL patients and stained with CD4, CD25 and FOXP3 antibodies. Quantification of Tregs was performed using automated slide scanning and image analysis and correlated to phenotypic and clinical parameters in uni- and multivariate models. All patients had locally extensive or advanced stage disease and underwent similar chemotherapy protocols. For the present study, only cHL patients whose histology could be confirmed and EBV-association established were studied. *Results.* From the 38 cHL patients selected for this study, 21 were classified as EBV related and 17 EBV non-related cHL. The expression of FOXP(3) alone or together with $CD4^+CD25^+$ was more common in the EBV related cHL group ($P<0.001$) and was associated with either refractory disease or early relapse disease (less than 1 year) ($P<0.001$ and $P=0.03$, respectively). In a Cox regression model, considering gender, age and stage, the amount of $FOXP3^+$ cells was of independent prognostic significance for treatment response. Additionally, advanced stage disease, unrelated to EBV status in the tumor, was associated with strong expression of Tregs ($P=0.01$). Overall survival and event free survival were not calculated due to the short follow-up period. *Conclusions.* This study demonstrates that Tregs expression correlates with EBV presence in RS cells, advanced stage disease and poor outcome. Further studies investigating the mechanisms in which EBV recruits Tregs to the tumor microenvironment and its impact on the clinical evolution of cHL will contribute not only to our understanding on the pathogenesis of cHL but also to the development of therapeutic strategies designed to manipulate Treg activity.

EARLY FDG-PET SCAN CONFIRMS ITS PROGNOSTIC IMPACT ALSO IN LOCALIZED STAGE, ABVD TREATED HODGKIN LYMPHOMA PATIENTS

L Rigacci,[1] PL Zinzani,[2] B Puccini,[1] A Broccoli,[2] A Gallamini,[3] F Merli,[4] G Antognoli,[1] V Stefoni,[2] C Stelitano,[4] M Balzarotti,[5] P Pregno,[4] C Fraulini,[4] F Salvi,[4] R Emili,[4] S Tavera,[3] I Capodanno,[4] U Vitolo,[4] C Pellegrini,[2] AM Liberati,[4] A Bosi[1]

[1]Azienda Ospedaliera Careggi, Florence, Italy; [2]Ospedale Seragnoli Hematology Dept, Bologna, Italy; [3]Hematology Department and BMT Unit. Az. Ospedaliera S. Croce e Carle, Cuneo, Italy; [4]Hematology Department, Reggio Emilia, Italy; [5]Hematology Dept. Humanitas, Milano, Italy

Background. Hodgkin's lymphoma is a malignant diseases with the highest rate of cure particularly if diagnosed in early stage. Nevertheless a small proportion of patients with localized stage do not respond to therapy and progressed. *Aims.* We explored the predictive value on therapy outcome of an early evaluation of treatment response by 18F-fluorodeoxyglucose positron emission tomography (FDG-PET) scan performed after two corses of ABVD in pts with localized Hodgkin's disease. *Methods.* From 2002, 232 new localized stage Hodgkin's lymphoma pts were consecutively admitted to ten Italian hematological centers on behalf of Intergruppo Italiano Linfomi. Pts with stage I-IIA according to Ann Arbor stage, independent of presence of bulky disease, were considered for the study. FDG-PET was mandatory at baseline, after two cycles and at the end of therapy. Mediastinal blood pool activity is recommended as the reference background activity to define PET positivity. We evaluated the progression free survival of pts starting from the time of diagnosis to relapse or progression of disease or last follow-up. No treatment variation based only on PET-2 results was allowed. *Results.* The median age was 33 years (13-78), 123 pts were female, 213 pts were stage II, bulky was reported in 68 pts. Two-hundred and seventeen pts were treated with combined modality and 15 pts were treated with chemotherapy alone. The FDG-PET performed after two cycles (PET2) was positive in 32 pts (14%): 17 (53%) progressed or relapsed and 15 remained in CR. By contrast 190/200 (95%) pts with a negative PET2 remained in CR. Thus the positive predictive value of a PET2 was 53% and the negative predictive value was 95%. The sensitivity and specificity of PET2 were 63% and 93%, respectively. Twenty-one pts showed disease progression within 12 months after having reached CR, 13/21 were PET2 positive. Eight pts died due to the disease, five were PET2 positive and three were PET2 negative. In univariate analysis negative FDG-PET performed after two cycles (p .0000), absence of bulky disease at diagnosis (.005) were statistically correlated with a better progression free survival. In multivariate analysis only PET2 was independently predictive of relapse/progression probability (p .000). With a median follow-up of 35 months (range 4-87) 224 pts are alive and 205 (88%) are free from progression. The 2-yr FFS probability for PET2 negative and for PET2 positive patients were 94% and 44% respectively (P:.000). *Conclusion.* This multicentric study confirms that FDG-PET scan performed after two courses of conventional standard dose chemotherapy was able to predict treatment outcome in early stage Hodgkin disease. Due to the large number of false positive PET2 in localized lymphoma we suggest new PET evaluation methods in this subset of pts.

SCT and immunotherapy

VCAM1 RS1041163 POLYMORPHISM INFLUENCES G-CSF MOBILIZATION OF CD34+ CELLS

B Martin-Antonio, M Carmona, A Baez, P Trujillo, J Falantes, I Espigado, A Urbano-Ispizua

Hospital Universitario Virgen del Rocio, Sevilla, Spain

Background. The amount of CD34+ cells mobilized from bone marrow (BM) to peripheral blood (PB) after G-CSF administration greatly varies among healthy donors. Constitutional differences in genes involved in the disruption induced by G-CSF of the interactions tethering CD34+ cells to the BM might be associated with the number of G-CSF mobilized CD34+ cells. *Aims.* To evaluate a possible association between polymorphisms in genes involved in adhesive and chemotactic interactions to retain CD34+ cells within the BM with the number of G-CSF mobilized CD34+ cells influencing in the CD34+ cells yield obtained/kg of donor in healthy donors. *Methods.* Twenty seven polymorphisms described in sixteen genes (*CXCL12*, *CXCR4*, *VCAM-1*, *VLA-4*, *G-CSF*, *CSF3R*, *CD34*, *ADRB3*, *CXCL2*, *CXCR2*, *CD44*, *Kit ligand*, *c-Kit*, *MMP-9*, *CTSG*, *GNAS*) were analyzed by allelic discrimination PCR in 112 healthy donors receiving G-CSF (filgrastim; 10 μg/kg; 5 days) in a single institution and in 107 blood donor's volunteers from the Regional Center for Blood Transfusion of Seville. Univariate and multivariate regression analysis were performed to assess potential association between SNPs and the end points of the study. mRNA was measured by real-time quantitative PCR for those genes with SNPs found to influence CD34+ cell count at fifth day and CD34+ cells yield/kg of donor. *Results.* A genetic variant in *VCAM1* and another in CD44 were associated with a lower and higher quantity of CD34+ cells in PB after G-CSF (P=0.018 and P=0.039, respectively), with the yield of the first apheresis in terms of CD34+ cells/kg of donor (P<0.001 and P=0.025, respectively), and with the total CD34+ cells yield (P<0.002 and P=0.012, respectively). G-CSF administration was associated with a complete disappearance of *VCAM1* mRNA expression in PB and it did not affect the expression of different genotypes in the genetic variant in *CD44*. Moreover, a genetic variant in G-CSF receptor (*CSF3R*) and in *CXCL12* were associated with a lower and higher number of G-CSF mobilized CD34+ cells (P=0.002 and P=0.018, respectively). G-CSF greatly diminished the expression levels of *CXCL12* genetic variant. Finally, of the two variants in *CXCR4*, expression level of *CXCR4* variant.2 was the most influenced by G-CSF (P=0.001 and P<0.001 for variant.1 and variant.2, respectively) and a genetic variant in *CXCR4* was associated with lower yield of CD34+ cells/kg of donor (P=0.025), being this genotype the only one not affected by G-CSF at expression levels. *Conclusions.* Genetic individual variability in, *VCAM1*, *CD44*, *CSF3R*, *CXCL12* and *CXCR4* seems to influence HPC mobilization. *VCAM1* appears as the most important factor among all the molecules involved in mobilization. These findings might be useful in planning mobilizing strategies.

1151

POLYMORPHISMS OF THE HEPARANASE GENE (HPSE) ARE ASSOCIATED WITH THE INCIDENCE AND SEVERITY OF GRAFT *VS.* HOST DISEASE AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

O Ostrovsky,[1] A Shimoni,[1] I Vlodavsky,[2] A Nagler[1]

[1]*Chaim Sheba Medical Center, Ramat Gan, Israel;* [2]*Cancer and Vascular Biology Research Center, Technion, Haifa, Israel*

Background. Graft-versus-host disease (GVHD) is the most common cause of overall mortality after HSCT. Heparanase, endo-β-glucuronidase that specifically cleaves the saccharide chains of heparan sulfate proteoglycans, is involved in the process of inflammation and release of heparan sulfate-bound chemokines, cytokines and bioactive angiogenic factors that are main players in the development of GVHD. *Aims.* The aim of the study is to investigate the association of HPSE gene SNPs with the risk of post HSCT GVHD and transplantation outcome. *Methods.* Four hundred and fourteen patients with hematological malignancies and their HLA matched donors were included in the study. Genotyping of two SNPs rs4693608 and rs4364254 was performed using allele-specific amplification. *Results.* Assessment of heparanase gene SNPs among healthy persons demonstrated a significant correlation between HPSE gene SNPs (rs4693608 and rs4364254) and the expression level of heparanase. All possible HPSE genotype combinations were distributed into three groups (LR, MR and HR) correlating with low, intermediate and high heparanase expression levels. In the group of HSCT patients we found a highly significant correlation between these SNPs, their combinations and risk of acute GVHD. The cumulative incidence of acute GVHD, grade II-IV, was 54.4% (95% CI 44.7-66.2) in the recipient group HR, while in recipient groups MR and LR, the cumulative incidences were 40.5% (95% CI 33.2-49.4) and 24.9% (95%CI 17.7-34.9), respectively (P=0.0001). Moreover, discrepancy between recipient and donor in these SNPs combinations significantly affected the risk of acute GVHD. Genotype combination LR in patients exerted a protective effect against GVHD regardless of the donor genotype combinations (D3 group: LR-LR, LR-MR, and LR-HR pairs). Acute GVHD rates were highest when recipients possessed genotype combinations HR, while their donors possessed the MR or LR genotype combinations (D1 group: HR-MR and HR-LR pairs). The other combinations were associated with an intermediate risk (D2 group: MR-MR, MR-HR, MR-LR and HR-HR pairs). Cumulative rate of acute GVHD incidence was 71.2% (95% CI 58.2-87.0) in the D1 group, 41.5% (95% CI 34.4-50.1) in the D2 group, and 24.9% (CI 95% 17.7-34.9) in the D3 group (P< 0.00001). The multivariate analysis revealed a strong association of HPSE gene SNPs with the risk of acute GVHD and a statistically significant correlation with extensive chronic GVHD. The significant associations of heparanase gene SNPs with TRM and overall survival, observed by univariate analysis, appear secondary to the effect on acute GVHD incidence. Summary: The study demonstrated that discrepancy in HPSE gene SNPs between recipients and donors is more relevant for the risk of developing acute GVHD than the patients' genotype profile of HPSE gene SNPs. Our findings may imply the involvement of heparanase in the pathogenesis of GVHD. We speculate that secreted levels of cytokines and chemokines affected by heparanase are higher in patients possessing HR genotype in comparison to possessors of the MR and LR genotypes. Higher cytokine and chemokine signals originating from the patient activate donor T-cells and increase the risk of GVHD. This aggressive phenotype of donor T lymphocytes results in infiltration and destruction of patient tissues and GVHD development.

1152

RESISTANCE OF AGGRESSIVE MINOR CML BLAST SUBSET TOWARD BOTH IMATINIB AND NK-CELLS KILLING CAN BE REVERSED BY PGP- MODULATORS

H Galski, S Berlinsky, M Simanovsky, T Oved-Gelber, A Nagler

Chaim Sheba Medical Center, Tel Hashomer, Israel

Background. Although very effective in chronic phase CML, imatinib (IM) is usually less effective in advanced CML since drug-resistant clones inevitably shortly emerge. Moreover, immunotherapy via NK-cells is also less efficient in advanced CML. We have found that at blast crisis CML, blasts of the same CML clone are heterogeneous, containing a small subset (1-3%) of blasts that are significantly more aggressive than the major malignant population (Differentiation. 76: 908-922, 2008). These minor subsets (MS) of blasts (both from patients and human CML-BC cell lines) display higher clonogenicity than the common subsets (CS) and exclusively overexpress the multidrug transporter P-glycoprotein (Pgp). *Aims.* To evaluate whether the MS blasts also exhibit differential resistance mechanisms toward IM and NK-cells mediated killing, we compared the two blast subsets for the level of resistance to IM and for their sensitivity towards NK-cells in relation to expression of a functional Pgp. *Methods.* Various CS and MS blasts of CML-BC were evaluated before and after a range of single-drug selections (IM, doxorubicin, vinblastine, or colchicine) in culture. Protein and drug-efflux activity levels of the Pgp (ABCB1) multidrug transporter were evaluated by Western blotting, flow cytometry measurements and by UIC2-shift assays. The anti-proliferative effects of imatinib were measured by MTT proliferation assay, in the absence or the presence of the Pgp-specific modulator, R-verapamil (R-VRP). The killing capacity of healthy donor NK-cells and the NK-cell line NK-92 toward various target CS and MS blasts was measured by standard cytolysis assay, in the absence or the presence of the Pgp-modulator, R-VRP. *Results.* While Pgp could not be detected on the cell surface of the CS blasts, Pgp is exclusively highly expressed in the MS blasts. Functional Pgp assays in the MS blasts indicated unequivocally that IM is a substrate for Pgp. As IM efficiently inhibited the proliferation of the CS blasts in dose-dependent manner, the proliferation rate of the MS blasts was essentially not affected. Similarly, the MS blasts were significantly less affected by NK cells than the CS blasts (2.2±0.2 -fold, P<0.001). Further analyses indicated that the Pgp-expressing MS blasts become mainly less sus-

ceptible to the TRAIL-mediated apoptotic killing pathway of NK cells. Moreover, after short drug selections Pgp activity levels were further elevated by 1-order magnitude in the MS blasts with subsequent similar increase in the resistance levels to IM and the other abovementioned cytotoxic drugs. Similarly, the drug-selected MS blasts resistance toward NK cells killing was further increased (2.6±0.6 -fold, P<0.001). However, both the anti-proliferative effect of IM on the MS blasts and their sensitivity to killing by NK cells could be restored by addition of the Pgp inhibitor R-VRP, in a dose-dependent manner. *Conclusions.* The existence of a minor 'pool' of CML blasts of both greater clonogenicity and high expression and activity levels of Pgp, apparently signify clonal evolution toward both increased malignancy and lower therapeutic sensitivity to both IM and NK cells. Moreover, this study suggests that combination therapies with Pgp-modulators might also be clinically effective in targeting the MS aggressive blast population.

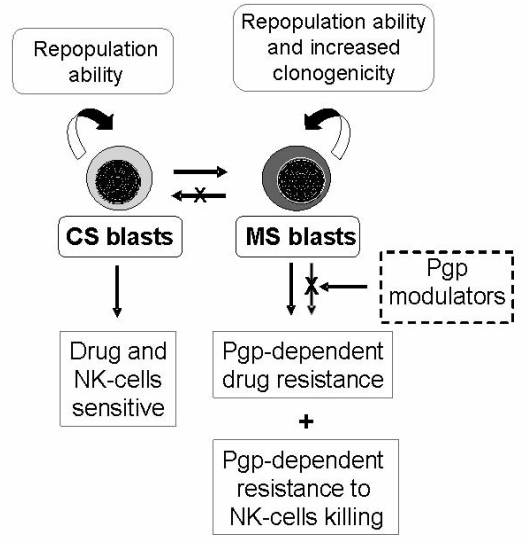

Figure. Differential properties and targeting of an aggressive CML blast subset.

1153

QUIESCENT LEUKEMIC STEM CELLS RESIDING AFTER TYROSINE KINASE INHIBITOR TREATMENT ARE NOT TARGETED BY ALLOREACTIVE T CELLS AND NK CELLS

I Jedema, L van Dreunen, J Falkenburg

Leiden University Medical Center, Leiden, Netherlands

Tyrosine kinase inhibitors (TKI) like imatinib and dasatinib are the current treatment of choice for patients with chronic myeloid leukemia (CML). Most patients enter a complete remission during treatment, but recurrence of the disease is seen in the majority of patients upon discontinuation of treatment, and drug resistance may eventually occur illustrating that a fraction of leukemic stem cells is apparently capable of escaping the treatment. In these patients, allogeneic stem cell transplantation (allo-SCT) and application of immune effector cells may be a curative treatment. The aim of this study was to investigate whether the leukemic stem cells residing during TKI treatment are susceptible targets for immunological interventions using either alloreactive T cells or NK cells. $CD34^+$ positive CML cells were isolated from bone marrow and labeled with the fluorescent dyes CFSE or PKH to allow monitoring of single cell proliferation. CML cells were exposed to imatinib (1-100 μM) or dasatinib (0.01-50nM), and/or to $CD8^+$ alloreactive cytotoxic T lymphocyte (CTL) clones or donor-derived NK cells. The number, phenotype, and proliferative status of the CML cells residing after single and combined interventions were measured by quantitative flowcytometric analysis. In the absence of therapeutic interventions the majority of CML cells entered proliferation. However, a small population of $CD34^+$ CML stem cells residing in the non-dividing peak could be identified in all samples despite the addition of cytokines. TKI treatment resulted in efficient dose-dependent induction of cell death in the majority of cells. However, the population of quiescent $CD34^+$ CML stem cells was not affected and was even increased compared to the non-treated controls, indicating additional growth arrest of proliferating CML cells by TKI treatment. Next we tested the capacity of different HLA-A2 restricted $CD8^+$ CTL clones to kill non-treated or imatinib or dasatinib treated CML cells. Whereas the proliferating CML precursors were efficiently lysed, the population of quiescent stem cells was capable of withstanding CTL exposure. Detailed phenotypic analysis revealed significant downregulation of HLA-A2 and several adhesion molecules on these quiescent cells, probably resulting in the inability of these target cells to form a high avidity interaction with the T cells. Attempts to overcome the impaired HLA expression by treatment with interferon gamma or exogenous peptide loading were not successful. Next, we tested whether the impaired HLA class I expression on the quiescent population increased their susceptibility to NK cells. However, although the proliferating CML cells were efficiently targeted by the NK cells, the population of quiescent cells was not affected. In conclusion, TKI treatment results in selection of a population of quiescent leukemic stem cells showing cross-resistance to alloreactive T cells due to the impaired expression of molecules necessary for the formation of a high avidity interaction like HLA and adhesion molecules. Moreover, despite the impaired HLA class I expression, these cells were also not targeted by NK cells. These data indicate that TKI treatment does not act synergistically with immunological interventions. Furthermore, the anti-proliferative effect of tyrosine kinase inhibitors may potentially even hamper the potentially curative immune response after allo-SCT.

VACCINATION WITH DENDRITIC CELLS LOADED WITH APOPTOTIC BODIES (APO-DC) OF AUTOLOGOUS LEUKEMIC CELLS INDUCES IMMUNOLOGIC RESPONSES IN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS

L Hansson,[1] M Palma,[1] L Adamson,[1] I Eriksson,[1] B Näsman-Glaser,[1] P Kokhaei,[1] K Widen,[1] A Choudhury,[1] A Österborg,[2] H Mellstedt[2]

[1]Karolinska Institutet, Stockholm, Sweden; [2]Hematology Center, Karolinska University Hospital, Solna, Stockholm, Sweden

Background. We previously demonstrated that dendritic cells (DC) that have endocytosed apoptotic bodies of autologous leukemic cells (Apo-DC) can boost antileukemic T cell responses *in vitro*. *Aims.* To study the safety and induction of immunity of Apo-DC vaccination in CLL patients. *Methods.* In this pilot study, sixteen patients with slowly progressing CLL, from whom informed consent had been obtained, were injected intradermally five times in 14 weeks with a mean of 16x106 ex-vivo generated Apo-DC. DC were generated from immunomagnetically enriched monocyte precursors, cultured *ex vivo* with GM-CSF and IL-4 and loaded with autologous apoptotic leukemic cells as antigen source. The patients were accrued stepwise to three different cohorts, receiving Apo-DC alone (n=5), Apo-DC + GM-CSF (n=5), or Apo-DC + GM-CSF + low-dose cyclophosphamide (n=6). Clinical and immune effects of the vaccination were evaluated at regular time intervals for 1 year. After 1-year follow-up, vaccination was re-initiated on a monthly schedule in five clinically stable patients belonging to cohorts II and III. A vaccine-induced immune response is defined as a ≥ 2-fold increase compared to pre-immunization values in either proliferation or ELISpot assay. Levels of regulatory T cells (Tregs) were also evaluated as well as secreted cytokines in the proliferation assay supernatants. CD107 cytotoxic assay was also performed. *Results.* To date, all 16 patients have completed the immunization protocol. No signs of autoimmunity were detected and only mild injection site reactions were noted, mainly associated to GM-CSF administration. Vaccine-induced immune responses were noted in 10/16 evaluable pts (2/5 in cohort I, 3/5 in cohort II and 5/6 in cohort III) and accompanied by high levels of IL-2, IL-5, IL-10 and IFN-γ in the proliferation assay supernatants. No clinical objective remissions were observed. Median time to progression was 14 months in immune responders *vs.* 8 months in non-immune responders (n.s.). The normalized frequency of regulatory T cells (Tregs) in 1-year follow-up was significantly lower in immune-responders *vs.* non-immune responders (P<0.0001). The presence of $CD8^+$, $CD4^+$ and CD16+CD56dim cells degranulating (CD107 cytotoxicity assay) in the presence of leukemic cells could be detected in almost all patients upon vaccination, with CD107-positive cells particularly found in cell aggregates (CLL cells fusing with T cells) as verified by confocal microscopy. *Summary/Conclusions.* The results show that immunization of patients with tumor-loaded DC induces specific immune responses in CLL patients especially when combined with GM-CSF and low-dose cyclophosphamide. Our data also confirmed that low levels of Treg are associated with the probability of inducing an immune response. This therapeutic approach shall be explored further in CLL patients without emerging need of chemotherapy.

ETO2 CONTROLS HEMATOPOIETIC STEM CELL EXPANSION VIA THE NERVY HOMOLOGY DOMAIN 1

S Barakat, J Lambert, G Sauvageau, T Hoang

IRIC, Montreal, Canada

Background. Hematopoietic stem cells (HSCs) self-renew *in vivo* to sustain the life-long production of blood cells. However, HSCs rapidly decline in culture. Although some of the genes controlling self-renewal have been identified, overall, mechanisms governing HSC maintenance and self-renewal remain to be elucidated. We recently show that SCL (stem cell leukemia), a bHLH transcription factor, controls HSC quiescence and long term competence. Using a proteomics approach to identify components of the SCL complex in erythroid cells, we and others identified the ETO2 co-repressor that limits the activity of the SCL complex via direct interaction with the E2A transcription factor. ETO2/CBFA2T3 is highly homologous to ETO/CBFA2T1 and both are translocation partners for AML1. *Aims.* The objective is to define ETO2 function in HSCs. *Methods.* Eto2 expression was defined by qRT-PCR of purified long term -HSC (LT-HSCs, CD34-Kit+Sca+Lin- or CD150+CD48-Kit+Sca+Lin-), short-term HSC (CD34+Flt3-Kit+Sca+Lin-) and lympho-myeloid progenitors (LMPP, CD34+Flt3+Kit+Sca+Lin-) and protein levels were assessed by flow cytometry analysis of these populations. Eto2 functional studies include overexpression using the MSCV vectors, and RNA interference using lentiviral delivery. Transduced HSCs were analyzed by transplantation. *Results.* We initially found that ETO2 is highly expressed in populations of cells enriched in ST-HSCs and LMPP, and at lower levels in LT-HSCs, correlating with ETO2 protein levels detected by flow cytometry. Next, we showed that shRNAs directed against ETO2 knocked down ET02 protein levels in the KSL population, causing a ten-fold decrease in this population after transplantation; this was associated with reduced short-term and long-term reconstitution in mice. Conversely, ectopic ETO2 expression induced a 100 fold expansion of LT-HSCs *in vivo* in transplanted mice associated with differentiation blockade in all lineages, suggesting that ETO2 overexpression overcomes the mechanisms that limit HSC expansion *in vivo*. Furthermore, this expansion was abrogated when NHR1 domain of ETO2 was deleted. Surprisingly, overexpression of ETO2 but not of the NHR1 mutant resulted in a 1500 fold expansion of the KSL and KSL150+48- *in vitro* over 4 weeks. At the cellular level, we found that ETO2 facilitates the G0/G1 as well as G1/S transitions in LT-HSCs, whereas the NHR1 mutant causes G1/S blockade associated with apoptosis in the KSL population. *Sumary/Conclusions.* In conclusion, we show that ETO2 is highly expressed in ST-HSCs and lymphoid progenitors, and controls their expansion by regulating cell cycle entry both at the G0/G1 and the G1-S transitions. In addition, ETO2 overexpression converts the self-renewal of maintenance into self-renewal of expansion in LT-HSCs.

1156

DNA DAMAGE FROM STALLED REPLICATION IN HEMATOPOIETIC STEM CELLS LEADS TO P53-DEPENDENT BONE MARROW FAILURE THAT PREVENTS LEUKEMIC OUTGROWTH

J Haanstra,[1] J Verhagen-Oldenampsen,[1] P van Strien,[1] M Valkhof,[1] B Schumacher,[2] I Touw,[1] M Von Lindern[1]

[1]ErasmusMC, Rotterdam, Netherlands; [2]University of Cologne, Cologne, Germany

Background. DNA damage can result in tumorigenic mutations, but concurrently activates tumor suppressor pathways that abrogate expansion of progenitors to prevent cancer. Although generally accepted, this general theory fails to explain why different DNA repair syndromes have distinct phenotypes. We previously showed that mice deficient for the DNA repair protein Ercc1 age prematurely including loss of the transiently amplifying progenitors in the bone marrow (BM). Ercc1 functions in concert with the Fanconi Anemia (FA) pathway in removal of interstrand cross links (ICL) at the replication fork, but Ercc1 is also required for nucleotide excision repair (NER) in actively transcribed genes. *Aim.* The aim of our study was to investigate how DNA damage causes bone marrow failure and which tumour suppressor system is involved in hematopoietic dysfunction and leukemia. *Methods.* Mice deficient for the interstrand crosslink (ICL) and nucleotide excision repair (NER) protein Ercc1 and mice deficient for NER only were compared and crossed with p53 or Ink4A/Arf deficient mice. Hematopoietic parameters were analyzed by flow cytometry and colony assays. In addition, transplantation experiments were performed to study leukemogenesis *in vivo*. *Results.* Comparison of hematopoietic parameters between NER-deficient mice subject to severe premature aging and Ercc1-deficient mice indicated that defective NER causes the aging-related small stature, but hardly affects hematopoietic progenitors. This indicates that hematopoietic stem- and progenitor cells (HSPC) are exquisitely sensitive to replication fork stalling. The sensitivity to a stalled replication fork predicts progressive degeneration dependent on cell replication. Analysis of the fraction HSC and proliferating multipotent progenitors within the lineage-negative, $Sca1^+$, $cKit^+$ (LSK) BM fraction showed that quiescent stem cells were indeed protected from decay in Ercc1-deficient mice. Next, Ercc1-deficient mice were crossed with p53 and Ink4A/Arf deficient mice. This showed that the aging-related small stature is independent of the p53 or Ink4A/Arf tumour suppressor loci. Instead, loss of p53, but not loss of the Ink4a/Arf locus, restored the LSK fraction and colony forming ability of Ercc1-deficient BM. Outgrowth of Ercc1-deficient mouse embryonic fibroblasts was restored by loss of either p53 or the Ink4A/Arf locus. Thus the FA phenotype of Ercc1-deficient mice can be explained by a specific sensitivity of HSPC to ICL, and to p53 activation at the stalled replication fork. To investigate whether p53 controls leukemogenesis of Ercc1-deficient BM, we transplanted BM of Ercc1-deficient, p53 heterozygote mice in wt recipients. Whereas mice transplanted with BM of mice heterozygous for p53 but proficient in Ercc1 remained healthy for at least 12 months, 80% of mice transplanted with Ercc1-deficient BM heterozygous for p53 died within 5-10 months after transplantation. In 4 out of 8 leukemia's analyzed, the second p53 allele was deleted as well. *Conclusion.* Together these results show that stalled replication caused by deficiency in the repair of ICLs results in a strong p53-dependent bone marrow senescence which protects from leukemic outgrowth.

1157

MEGAKARYOCYTES SUPPORT THE INTEGRITY OF BONE MARROW (BM) VASCULAR NICHES AND ATTRACT METASTATIC TUMOUR CELLS TO THE BM IN MURINE MODELS OF METASTASIS AND IN PATIENTS WITH CARCINOMA

B Psaila,[1] S Lavotshkin,[2] J Podolanczuk,[2] S Granitto,[2] M Papaspyridonos,[2] N Kaplan,[2] B Bussel,[2] N Kikkeri,[3] I Roberts,[3] D Lyden[2]

[1]Imperial College, London, London, UK; [2]Weill-Cornell Medical School, New York, USA; [3]Imperial College, London, UK

Background. Bone marrow (BM) vascular niches maintain and regulate physiological haematopoietic cells and are implicated as areas of preferential engraftment for metastasizing tumour cells. *Aims.* To investigate the role of megakaryocytes in regulating the vascular niche in BM metastasis we used B16-F10 melanoma in normal (C57Bl/6 wild-type) mice and in mice with severely reduced megakaryopoiesis (C57Bl/6 $thrombopoietin\ (TPO)^{-/-}$ mice). *Results.* In wild-type mice with intradermal B16 melanoma, mean platelet volume progressively increased from 18 days following tumour injection ($P<0.0001$), suggesting increased thrombopoiesis; the number and size of megakaryocytes and mean BM vessel diameter were also increased compared to controls (P's<0.01). The majority of BM sinusoids were surrounded by one or more large megakaryocytes, forming the megakaryocyte-vascular niche, with megakaryocytes tightly abutting the vascular endothelium. From day 15, metastatic mCherry-transduced B16 cells were visible closely associated with megakaryocytes in the BM vascular niche. B16 cells expressed several thrombopoietic factors, particularly VEGF, SCF, and IL11, as well as smaller amounts of IL6 and TPO. In $TPO^{-/-}$ BM, megakaryocytes were largely absent and blood vessels appeared more tortuous with increased diameter ($P<0.002$). Expression of TGFβ, platelet factor 4 (PF4) and thrombospondin (TSP)1 was reduced by 70-90% ($P<0.0001$) indicating that these factors are primarily megakaryocyte-derived; VEGF was reduced by 40% ($P<0.01$, Figure 1). Consistent with a modulatory effect of the megakaryocyte-vascular niche on tumour phenotype, in $TPO^{-/-}$ mice, B16 tumour growth was markedly retarded with reduced metastasis to BM and lung. Furthermore, in wild-type mice, BM expression of megakaryocyte-derived VEGF and TGFβ increased during tumour growth while expression of PF4, an autocrine inhibitor of megakaryopoiesis and angiopoiesis decreased, consistent with a role of PF4 in increasing megakaryocyte-vascular niches. Megakaryocyte-conditioned medium (MCM) significantly enhanced proliferation and chemotaxis (P's <0.01) of B16 cells, an effect reduced using MCM from $TSP1^{-/-}$ mice ($P<0.05$). Coculture of megakaryocytes with B16 cells increased megakaryocyte VEGF and TGFβ expression but decreased PF4, consistent with *in vivo* observations, while cocultured

B16 cells displayed increased VEGF and TGFβ and upregulation of adhesion integrins, α4, α5 and α6 (P's <0.05). Moreover, pretreating B16 cells with MCM prior to tail vein injection enhanced tumour engraftment of the lung. Pilot studies to investigate megakaryocyte-tumour interactions in human malignancy showed increased megakaryocytes in trephine biopsies from patients with metastatic disease with and without overt BM metastasis and megakaryocyte clusters with abnormal morphology and localization. Immunohistochemisty of human BM confirmed megakaryocyte localization of VEGF, TGFβ, TSP1, and PF4 and demonstrated megakaryocyte SDF1 staining, suggesting that although megakaryocytes do not produce SDF1 they may 'organize' SDF1 gradients by localizing it to megakaryocyte-vascular niches, thereby influencing homing dynamics of $CXCR4^+$ haematopoietic cells and tumour cells to BM niches. *Conclusions.* Together these findings suggest that megakaryocytes support the integrity of the vascular niche and that homeostasis of the niche may be disrupted in the absence of megakaryocytes. Cellular/molecular cross talk between megakaryocytes and tumour cells at the vascular niche may promote metastasis. Targeting these interactions may be a useful as adjunctive therapy to prevent dissemination of cancer to the BM.

THE CDK-INHIBITOR P26INCA1 IS REQUIRED FOR THE MAINTENANCE OF MYELOID LEUKEMIA STEM CELL SELF- RENEWAL

P Tschanter,[1] N Bäumer,[2] L Lohmeyer,[2] F Berkenfeld,[2] L Tickenbrock,[2] S Diederichs,[2] M Stehling,[3] G Köhler,[4] W Berdel,[2] S Koschmieder,[2] C Müller- Tidow[2]

[1]University of Münster, Germany, Münster, Germany; [2]Department of Medicine, Hematology/Oncology, University of Münster, Münster, Germany; [3]Max-Planck Institute for Molecular Biomedicine, Muenster, Germany; [4]Gerhard Domagk Institute for Pathology, University of Münster, Münster, Germany

Acute myeloid leukemia (AML) frequently relapses despite initially effective therapy. Relapse might depend on leukemia stem cells that are not susceptible to standard therapy. A better understanding of biological stem cell regulatory mechanisms might help to design new therapeutic interventions in AML therapy. Stem cell functions in normal hematopoiesis and leukemia relay on the tight regulation of the cell cycle. Recently, we identified p26INCA1 as a novel cell cycle regulator and inhibitor of Cyclin - CDK2 complexes. Loss of Inca1 increased the number of hematopoietic stem cells (HSC) and increased replating efficiency in colony formation assays. Exposing Inca1-deficient mice to cytotoxic stress such as 5- FU exposition induced faster exhaustion of stem cells and early death. These data suggested that Inca could play an important role in HSC expansion and leukemogenesis. To examine the role of Inca1 in leukemogenesis we performed transplantation experiments. We retrovirally transduced wildtype (WT) or Inca1-/- bone marrow cells with AML1-ETO9a and transplanted the retrovirally transduced bone marrow cells into wildtype recipient mice. Five months after transplantation wildtpye recipients developed acute myeloid leukemia. All analysed wildtype recipients showed a leukemic phenotype with an increased white blood cell count and bone marrow infiltration by leukemic blasts. But only one Inca1-deficient mice developed a tumor with myeloid cell infiltration. Further transplantation into secondary recipients demonstrated that AML1-ETO9a induced leukemia in wildtpye mice was transplantable and lethal, while secondary recipients of leukemic Inca1-/- bone marrow did not develop any disease. C-myc induced leukemia developed in both wildtype and Inca1-/- bone marrow. Leukemic bone marrow cells were transplanted into secondary recipients. The frequency of leukemic stem cells was significantly higher in the wildtype bone marrow compared to Inca1 deficient bone marrow. As a consequence only secondary recipients transplanted with leukemic wildtype bone marrow cells died due to leukemia. These findings suggest that the loss of the cell cyle inhibitor p26INCA1 leads to a premature exhaustion of stem cells in the presence of an oncogene. Our results identify an important role of Inca1 in the maintenance of leukemia and potentially the self-renewal of leukemic stem cells.

THE EMT INDUCER SIP1/ZEB2 IS ESSENTIAL FOR DEFINITIVE EMBRYONIC HEMATOPOIESIS

S Goossens,[1] T Yokomizo,[2] B Drogat,[1] S Bartunkova,[1] K Haigh,[1] E Seuntjens,[3] M Crisan,[2] T Riedt,[4] G Berx,[1] E Dzierzak,[2] V Janzen,[4] D Huylebroeck,[3] J Haigh[1]

[1]University Ghent, VIB, Gent (Zwijnaarde), Belgium; [2]Erasmus University, Rotterdam, Netherlands; [3]K.U. Leuven, VIB, Leuven, Belgium; [4]University of Bonn, Bonn, Germany

Mature blood cells are generated from a small number of hematopoietic stem cells (HSCs) that have enormous regenerative capacity throughout life. The HSC pool size is regulated by a finely controlled self-renewal and differentiation program orchestrated by a number of growth factors and transcription factors. SIP1/ZEB2 is a member of the ZEB family of transcriptional repressors that have been demonstrated to be involved in epithelial to mesenchymal transitions (EMT), processes that direct morphogenesis during development in multicellular organisms. Recently, it was postulated that EMT modulators play key roles in stem cell formation and function, although solid *in vivo* proof of this hypothesis is lacking. Initially we have demonstrated that the EMT inducer SIP1 is expressed in embryonic HSCs, budding out from the hemogenic endothelium in aorta-gonad-mesonephron (AGM) region at embryonic day (E)10,5 and is highly enriched in FACS sorted adult HSCs from wild type mouse bone marrow. Through the use of novel gain and loss of function mouse models, we further investigated the role of SIP1 in HSC formation and function. Conditional loss of SIP1 resulted in embryonic lethality by E12.5 mainly due to cephalic bleedings. This phenotype is very reminiscent of the ubiquitous loss of the hematopoietic transcriptional regulators AML/RUNX1, FLI-1 and GATA-3 that all show identical abnormalities and which are published to be essential for HSC formation. By whole-mount immunostaining and FACS analysis, we have demonstrated that SIP1 is not essential for the formation of HSCs from the AGM region or their migration to the fetal liver. However, SIP1 null hematopoietic progenitors isolated from different hematopoietic organs are unable to differentiate *in vitro* and do not form any hematopoietic colonies. In addition, we observed increased apoptosis and mis-localization of the SIP1 deficient hematopoietic progenitors in the fetal livers. These initial findings suggest key roles for SIP1 in hematopoietic lineage differentiation and stem cell survival. Through the use of these novel mouse models in combination with cell based assays and detailed molecular analysis we will further determine the specific functions and identify hematopoietic targets of the EMT inducer SIP1 in embryonic and adult hematopoiesis and its relevance in leukemia development and progression.

VASCULAR PROGENITOR CELLS CAN INSTRUCT DEVELOPMENTAL FATE DECISION OF CD146+ MESENCHYMAL STROMAL/STEM CELLS IN VIVO

A Reinisch,[1] N Hofmann,[1] A Ortner,[1] N Etchart,[1] C Beham-Schmid,[1] C Dullin,[2] C Diwoky,[3] A Hofmeister,[1] R Stollberger,[3] F Alves,[2] D Strunk[1]

[1]Medical University of Graz, Graz, Austria; [2]Universitätsmedizin Göttingen, Göttingen, Germany; [3]Graz University of Technology, Graz, Austria

Background. Multilineage differentiation potential of mesenchymal stromal/stem cells (MSCs) made them attractive candidates for tissue regeneration purposes. Guiding the differentiation of MSCs towards single lineages would facilitate their application for targeted therapies *in vivo*. MSCs in multiple human organs show a CD146+ perivascular phenotype.[Cell Stem Cell 3:301; 2008] Subendothelial localized self-renewing bone marrow (BM)-derived skeletal stem cells (SSCs) display similar characteristics. These osteoprogenitors are capable of establishing the entire bone and marrow organ including the hematopoietic microenvironment. [Cell 131:324; 2007] We observed that CD146+ MSCs can adapt pericyte phenotype and function to support. vascular regeneration *in vivo* [Blood 113:6716; 2009] in addition to their mesodermal lineage differentiation potential. We hypothesized that environmental conditioning by ECFCs plays a role during the developmental fate decision of MSCs *in vivo*. *Methods.* CD146+ SSCs/MSCs as well as CD146+ endothelial colony forming progenitor cells (ECFCs) were isolated from adult BM, umbilical cord blood (UCB) and perivascular cord tissue. Proliferation potential and clonogenicity were monitored. Phenotype was analyzed by flow cytometry and immune cytochemistry. Cell function was studied in differentiation assays and during vascular network assembly *in vitro*. Models for *in vivo* human vessel as compared to bone formation were established in immune-deficient mice. Non-invasive imaging was performed using computed tomography (CT), magnetic resonance (MRI) and fluorescence imaging. Immune histochemistry was applied for morphologic studies in the time course of organogenesis. *Results.* Baseline analysis confirmed MSC and ECFC purity, immune phenotype and sustained proliferation potential. Progenitor cell hierarchy within ECFC cultures was preserved after oligoclonal large-scale expansion. We could show that human BM-derived CD146+ MSCs are capable of forming bone and the marrow organ *in vivo*. Co-transplanted human ECFCs could instruct the MSCs to differentiate either into pericytes or chondrocytes and osteoblasts, depending on the applied MSC/ECFC cell ratio. Non-invasive imaging and histological staining revealed that ectopic organogenesis had already started after 2-4 weeks and was stable during the observation period of 20 weeks. Non-BM-derived CD146+ populations, although phenotypically resembling SSCs, invariably lacked the capacity to build bone and marrow environment *in vivo*. *Conclusion.* This demonstrates that human ECFCs can instruct MSCs and induce developmental fate decisions early in the time course of organ regeneration after transplantation. This model is a promising tool to study the therapeutic applicability, modulation and risk profile of ECFC/MSC-based transplantation strategies.

1161

DIFFERENCES IN ALLOREACTIVE T CELL MIGRATION IN MHC MATCHED VERSUS MHC MISMATCHED HCT ARE CAUSED BY WAVES OF T CELL EXPANSION

C Bäuerlein,[1] S Riedel,[1] C Brede,[1] AL Jordán Garrote,[1] C Kiesel,[1] M Ritz,[1] S Schulz,[2] M Grether,[2] G Beilhack,[3] R Negrin,[4] H Einsele,[1] A Beilhack[1]

[1]University Hospital Würzburg, Würzburg, Germany; [2]Institute of Pathology, Munich, Germany; [3]Dapartment of Medicine III, Vienna, Austria; [4]Division of Blood and Marrow Transplantation, Stanford, USA

Background. Acute graft-versus-host disease (aGvHD) can be characterized by an initiation phase (activation and proliferation of alloreactive T cells) and an effector phase (infiltration of target tissues). Yet, it remains important to better understand aGHVD pathogenesis to pinpoint critical time points for improved diagnostic and therapeutic interventions. *Aim.* To analyze the course of T cell activation, proliferation and homing in a clinical relevant fully MHC-matched transplantation mouse model with mismatches in minor histocompatibility antigens. *Methods.* Luciferase-labeled C57Bl/6 T cells were transplanted into MHC mismatched Balb/c or MHC matched Balb/b recipients. Donor T cell migration was visualized by *in vivo* bioluminescence imaging (BLI). Activation and proliferation were analyzed using multiparameter flow cytometry. GVHD scoring was performed by histopathology. *Results.* By closely monitoring light emitting donor T cells for 30 days after allogeneic hematopoietic cell transplantation (allo-HCT) we observed that they highly proliferated exclusively in secondary lymphoid organs (initiation phase) in both models until day+3. Between day+3 and day+5 T cells migrated via the peripheral blood into target organs (effector phase). Both models showed similar cell distribution patterns but markedly differed in absolute T cell expansion and gastrointestinal tract, liver and skin infiltration. When comparing the BLI results in the MHC mismatched model a continuous strong signal increase could be measured from day+3 to day+6 (55-fold increase by day+6 as compared to day+3). T cell expansion peaked between day+6 and day+8 according to highest photon emission rates. In contrast, in the MHC matched model whole body BLI signals increased constantly but slower (10-fold increase by day+6 as compared to day+3) as well as for single target organs until day+30. BLI signal increase resembled an undulating curve with plateaus at certain time points (day+11, day+15, day+21) rather than a continuous signal accumulation. Clinical GVHD symptoms appeared after day+23. Syngeneic transplanted mice demonstrated a steady signal increase due to T cell expansion and not an undulating course of amplifying proliferation loops. Daily flow cytometric measurements of alloreactive T cell numbers in the peripheral blood confirmed these *Results.* CD4+ donor T cells left the secondary lymphoid organs shortly before CD8+ donor T cells in both models but in the MHC mismatched model absolute cell numbers increased faster (peak on day+6) compared to the MHC matched situation (peak on day+11). Additionally, alloreactive peripheral blood CD8+ T cells upregulated certain tissue specific homing receptors (e.g. $\alpha 4\beta 7$, CXCR3, P-selectin ligand) and activation markers (e.g. CD44, CD25). These results correlated with subsequent histopathological GVHD-scorings of transplanted mice. *Conclusion.* Our results in this clinical relevant mouse model provide evidence for progressive waves of T cell expansion and migration rather than a continuous increase in alloreactive T cell numbers. As alloractive T cells expand at early time points, before aGVHD becomes apparent, our results offer an improved basis for optimized diagnostics and therapeutic interventions.

1162

FUNCTIONAL IMMUNE RECOVERY AFTER ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION: NASCENT DONOR T CELLS ARE SUPERIOR TO MATURE GRAFT T CELLS IN THEIR REACTIVITY AGAINST CYTOMEGALOVIRUS

A Mueller, S Shashidhar, J Brown, J Shizuru

Stanford School of Medicine, Stanford, USA

Infections due to impaired immune recovery are a major cause of morbity and mortality after allogeneic hematopoietic cell transplantation (HCT). Donor (do) T cells (TC) in the graft are thought to provide protective immunity, as TC-depleted grafts are associated with increased rates of viral infections post HCT (pTX). However, TC-containing grafts require stronger pharmacologic immunosuppression, and doTC target lymphoid organs with subsequent immune dysfunction. Using an MHC-matched, minor antigen (miAg) mismatched GVHD model, we compared immune response against murine cytomegalovirus (MCMV) in recipients of purified hematopoietic stem cells (HSC; cKit+Sca1+Thy1.1loLin-) *vs.* HSC supplemented with TC. Anti-viral reactivity was assessed for (1) transferred doTC from uninfected and pre-immunized donors; (2) HSC-derived doTC, and (3) residual host TC. Lethally irradiated BALB.B mice were infused with C57BL/6 (B6) HSC or HSC+TC (TC from CD45 congenic B6). 2 or 8 weeks (w) pTX hosts were infected with sublethal doses of MCMV. 2w later lymphoid organs were harvested to assess anti-MCMV reactivity of CD8+ TC using M45 tetramers. Splenocytes were separated into doTC-, doHSC, and host-derived populations, to compare their IFNγ production in an MCMV ELISPOT assay. Mice infected at 2w pTX (modeling early CMV reactivation) and given TC-replete grafts mounted significantly lower tetramer responses (attributable to doTC-derived cells), than control congenic recipients, or recipients of HSC alone. In the latter group tetramer-reactive cells originated from the residual host. ELISPOT analysis confirmed that best responses were mounted by doTC transplanted into control congenic mice, followed by host-type TC. Pre-sensitization of TC donors did not improve the low response of doTC transplanted into miAG-mismatched hosts. However, when HSC were supplemented with naïve (CD62L+CD44-) or memory (CD62L±CD44+)

CD8+ TC from immunized donors, there were no signs of GVHD and recipients of memory, but not naïve CD8 TC mounted strong responses in both assays. At 8w pTX recipients of pure HSC were mixed donor/host TC chimeras. Mice given TC-replete grafts were full donor chimeras with the majority of TC originating from the transferred doTC. When mice were infected 8w pTX anti-MCMV reactivity of $CD8^+$ TC in tetramer and ELISPOT assays were strikingly superior in recipients of pure HSC, as compared to weak responses seen with TC-replete grafts. In recipients of pure HSC donor and host populations demonstrated strong reactivity, while mice given TC-replete grafts not only had low responses of the doTC-, but also of the doHSC-derived TC (Figure 1). Thus, our key findings are 1.) Mature doTC do not maintain their full anti-viral potential when transplanted into miAg-disparate mice, even when obtained from pre-immunized donors. 2.) Residual host cells contribute substantially to protective immunity, but are eradicated by conventional TC-replete grafts. 3.) HSC-derived TC arising in a healthy host are superior to those that develop and undergo selection in a GVHD-affected lymphoid system. Our results are of critical importance as they question the conventional assumption that doTC are required for optimal protection. Rather, our studies suggest that long-term immune function will greatly benefit from rigorously TC-depleted grafts and a GVHD-free lymphatic environment.

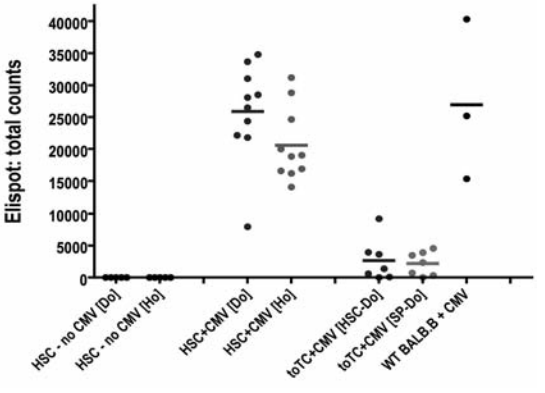

Figure 1. Total counts (Elispot) of CMV reactive CD8 TC.

CD11B+CD11C+ DENDRITIC CELLS INTERACT WITH ALLOREACTIVE T CELLS IN THE INTESTINAL MUCOSA IN ACUTE GRAFT-VERSUS-HOST DISEASE

AL Jordán Garrote,[1] C Brede,[1] C Baeuerlein,[1] S Riedel,[1] C Kiesel,[1] M Grether,[2] K Mattenheimer,[1] M Ritz,[1] J Baker,[3] R Negrin,[4] H Einsele,[5] A Beilhack,[1] S Schulz[2]

[1]Wuerzburg University, Wuerzburg, Germany; [2]Institute of Pathology, Technical University München, Munich, Germany; [3]Divison of Blood and Marrow Trabsplantation, Standford University, Standford, USA; [4]Division and Blood Marrow Transplantation, Stanford University, Standford, Germany; [5]Interdisciplinary Center for Clinical Research, Wuerzburg University, Wuerzburg, Germany

Background. Recipient dendritic cell - donor T cell interactions in secondary lymphoid organs are essential to initiate acute graft-versus-host disease (aGVHD). Yet, to which extend mucosal dendritic cells (DCs) contribute to augment, maintain or even down-modulate aGVHD in peripheral tissues remains elusive. *Aim.* To investigate whether DCs in the intestinal mucosa are required to perpetuate aGVHD. *Methods.* To address this question we used a murine allogeneic hematopoietic cell transplantation (allo-HCT) model [luciferase+ FVB/N (H-2q) or C57Bl/6 (H-2b) splenocytes (CD90.1)] plus wild type bone marrow into myeloablative conditioned allogeneic Balb/c recipients (H-2d, CD90.2, 8Gy).To visualize cell migration we employed non-invasive bioluminescence imaging. Phenotyping studies were performed by using multiparameter flow cytometry, and cell interaction was analyzed by fluorescence/confocal microscopy. *Results.* Analysis of the intestinal mucosa revealed high numbers of DC - donor T cell contacts during the aGVHD effector phase. Persisting host APCs (I-Ad) co-localized with both, $CD4^+$ $CD90.1^+$ and $CD8^+$ $CD90.1^+$ donor T cell subtypes. Although myeloablative conditioning augmented the numbers of infiltrating alloreactive T cell in the intestinal tract, we observed no reduction in DC - donor T cell contacts in non-conditioned recipients when compared to conditioned Balb/c Rag-/-common-γ-chain-/- allo-HCT recipients. Next we investigated which peripheral mucosal DC subtypes engaged with donor T cells. DC subsets shifted from migratory $CD103^+$ CD11blo $CD11c^+$ DCs, observed during steady state conditions, to a dominating $CD103^-$ CD11bhi $CD11c^+$ DC population during the aGVHD effector phase. Confocal microscopy confirmed interactions between this DC subset and donor T cells and at sites of contact revealed engagement of costimulatory molecules such as CD80. *Conclusion.* Our data provide evidence for a likely underappreciated role of mucosal DCs during later stages of aGVHD. This suggests that disruption of mucosal DC - donor T cell interactions may provide an attractive therapeutic target in patients suffering from persisting therapy refractory GVHD.

UMBILICAL CORD BLOOD REGULATORY T CELLS: FUNCTIONAL ANALYSIS AND GENE PROFILING

G Torelli, R Maggio, N Peragine, S Chiaretti, M De Propris, M Screnci, B Lucarelli, M Mascolo, A Iori, G Girelli, A Guarini, R Foà

Sapienza University, Rome, Italy

Background. Cord blood (CB) transplant is characterized by a reduced incidence of graft-versus-host disease (GVHD). The possible role played by CB regulatory T cells (Tregs) for the suppression of the allogeneic T-cell response is now under investigation. *Aims.* Aim of this study was to analyze and compare the functional properties and gene expression profile of Tregs expanded from CB units with those expanded from the peripheral blood (PB) of normal donors. *Methods.* Tregs were purified from mononuclear cells obtained from 23 CB units and from the PB of 13 adult normal donors using the Treg isolation kit (Miltenyi Biotec) and expanded for 6 days with anti-CD3, anti-CD28 and IL-2. Immunophenotypic analyses were performed before and after expansion. In order to measure the suppressor activity of expanded Tregs, mixed lymphocyte reaction (MLR) cultures were performed with autologous effector T cells stimulated with allogeneic dendritic cells (DC) in the presence or absence of Tregs. The IL-10 production capacity was tested using an ELISA assay. Gene expression profile experiments were performed using the HGU133 Plus 2.0 arrays (Affymetrix); statistical and functional annotation analysis were carried out using the dChip and the DAVID software. *Results.* CB and PB Tregs presented similar immunophenotypic appearances; after expansion, a comparable expression of surface CD4, CD25, CD62L, CCR5 and CD45RO, and of cytoplasmic CTLA-4 and Foxp3 was observed; in addition, they both were negative for the CD45RA antigen, indicating the loss of their naïve features. On the contrary, Tregs obtained from CB (n=23) presented a significantly higher expansion capacity compared to those obtained from PB (n=13): mean fold increase (range), CB 10.3 (1.6-24), PB 3.9 (1.5-10), p 0.003. CB expanded Tregs (n=6) exerted a potent suppressive function on MLR that resulted slightly but not significantly inferior to that exerted by PB expanded Tregs (n=5): mean fold suppression (range), CB 7.8 (2.5-15.1), PB 14.3 (1.5-23.7), p 0.14. Tregs expanded from CB (n=5) and PB (n=3) presented a high and comparable *in vitro* IL-10 production capacity: mean pg/mL (range), CB 325.6 (320-334), PB 341.3 (319-382). Gene expression profile analysis revealed 481 probesets differentially expressed between CB (n=4) and PB (n=6) expanded Tregs; functional analysis showed in CB Tregs a significant enrichment of genes involved in cell proliferation, chromatin modification and regulation of gene expression, thus possibly providing an advantage in cell expansion. In contrast, PB expanded Tregs showed an overexpression of genes involved in the adaptive immune response, including several cytokines and/or their receptors. Finally, when looking at the Foxp3 gene expression levels, no differences were observed between the two populations. *Summary/Conclusions.* These results demonstrate that Tregs contained in CB units retain an expansion potential superior to Tregs isolated from the PB of normal donors. The maintenance of the modulatory properties after expansion is confirmed by the expression of the Foxp3 gene and protein, and by the production of IL-10. These data offer further insights into the understanding of the biology of CB transplantation, indicating a possible role played by CB Tregs in the suppression of the allogeneic T-cell response.

Prognostic markers in acute myeloid leukemia

FURTHER STUDIES IN CEBPA DOUBLE MUTATIONS AS REGARDS TO FAVOURABLE PROGNOSTIC IMPACT, RELATION WITH OTHER GENE MUTATIONS AND IMPROVED GENE EXPRESSION SIGNATURE IN A LARGE COHORT OF AML

E Taskesen,[1] L Bullinger,[2] M Sanders,[1] C Erpelinck,[1] B Wouters,[1] F Damm,[3] J Krauter,[3] R Schlenk,[2] D Hartmut,[2] B Löwenberg,[1] R Delwel,[1] P Valk,[1] K Döhner[2]

[1]Erasmus Medical Centre (EMC), Rotterdam, Netherlands; [2]Department of Internal Medicine III, University of Ulm, Ulm, Germany; [3]Department of Hematology, Hannover Medical School, Hannover, Germany

Introduction. CEBPA, a gene encoding a transcription factor that is essential for myeloid development, is mutated in 8-10 percent of human cytogenetically normal acute myeloid leukemia (CN-AML). CEBPA mutant AML can be subdivided into two categories, i.e. cases with mutations of both alleles (CEBPAdouble-mut) or with single mutations (CEBPAsingle-mut). We previously reported that patients with a CEBPAdouble-mut represent a distinct AML subtype with a unique gene expression profile (GEP) and a more favourable outcome, this in contrast to CEBPAsingle-mut AML. *Aims.* In this study we examined the distribution of CEBPAsingle-mut and CEBPAdouble-mut in a large *de novo* adult CN-AML cohort (n=1175) and studied the impact on survival. Furthermore, we investigated whether a previously defined CEBPAdouble-mut GEP-signature could be improved using continuous selection procedures, i.e., Lasso regulation. *Methods.* AML patients (age ≤60) were included from the Dutch-Belgian-Swiss HOVON-SAKK and German-Austrian AMLSG and SHG studies. For CEBPA mutational screening, denaturing high performance liquid chromatography and nucleotide sequencing was performed. Gene expression profiles were derived using Affymetrix (Santa Clara, CA, USA) HGU133Plus 2.0 GeneChips. Unsupervised analyses were performed using hierarchical clustering based on Pearsons correlation coefficients. Prediction analyses were done using Lasso regulation, as it takes into account the correlation structure between the genes and selects genes in a continuous way such that their combinatorial effect is stronger than discrete selection of genes, e.g. Prediction Analyses of Microarrays (PAM). *Results.* Among the 1175 CN-AML cases we identified 88 $CEBPA^{double\text{-}mut}$ and 57 $CEBPA^{single\text{-}mut}$ patients. A significant favourable outcome was observed for $CEBPA^{double\text{-}mut}$ AML as compared to $CEBPA^{wt}$ ($P<0.001$, HR=0.3). In this analysis $CEBPA^{single\text{-}mut}$ group showed a favourable outcome as well ($P=0.03$, HR=0.6). Importantly, the latter group showed a significantly higher incidence of concurrent mutations in NPM1 and FLT3 ($FLT3^{ITD}$) than the $CEBPA^{double\text{-}mut}$ group ($P=7\times10^{-8}$ and $P=1\times10^{-4}$ respectively). These concurrent mutations are indicative for the clinical outcome within the $CEBPA^{single\text{-}mut}$ group. A favourable response was observed for $CEBPA^{single\text{-}mut}$/$NPM1^{mut}$/$FLT3^{wt}$ AML as compared to $CEBPA^{wt}$ ($P=0.03$), whereas $CEBPA^{single\text{-}mut}$/$NPM1^{wt}$/$FLT3^{ITD}$ AMLs showed an unfavourable trend with regard to therapy. These data reflect the predictive value of NPM1 mutations and $FLT3^{ITD}$ in CN-AML. Unsupervised analysis of GEP data (n=674) showed that $CEBPA^{double\text{-}mut}$ (n=42) and not $CEBPA^{single\text{-}mut}$ (n=18) AML clustered tightly together. Moreover, by using Lasso we derived a 25 GEP-signature that outperformed the previous $CEBPA^{double\text{-}mut}$ GEP-signature derived with PAM. This has the additional advantage that it can correctly classify AML cases with hypermethylation of the proximal promoter region of CEBPA. This increased the classification of $CEBPA^{double\text{-}mut}$ to 100% sensitivity and specificity in both training as well as validation set. *Conclusions.* We showed that $CEBPA^{double\text{-}mut}$ AML is a distinct AML subtype in contrast to $CEBPA^{single\text{-}mut}$ AML, in terms of molecular characteristics, clinical outcome and GEP. The $CEBPA^{single\text{-}mut}$ group has a higher incidence of concurrent mutations, in which $FLT3^{ITD}$ and NPM1 mutations are indicative for the prognostic relevance. The $CEBPA^{double\text{-}mut}$ group is a homogeneous group which has a favourable outcome and can be classified with excellent accuracy by GEP.

PROGNOSTIC IMPORTANCE OF HUMAN MIXED LINEAGE LEUKEMIA 5 (MLL5) EXPRESSION LEVELS IN ACUTE MYELOID LEUKEMIA

F Damm,[1] T Oberacker,[1] J Krauter,[1] M Morgan,[1] K Wagner,[1] F Thol,[1] K Döhner,[2] H Döhner,[2] A Ganser,[1] M Heuser[1]

[1]Hannover Medical School, Hannover, Germany; [2]University Hospital of Ulm, Ulm, Germany

Background. The human Mixed-Lineage-Leukemia-5 (MLL5) gene is located on chromosome 7q22 in a genomic region frequently deleted in patients with myeloid malignancies. Monosomy 7 or deletions of the long arm of chromosome 7 are asscociated with poor outcome in AML and MDS. Recently, functional analysis revealed that MLL5 is involved in terminal myeloid differentiation and in regulating proliferation and functional integrity of hematopoietic stem/progenitor cells. In homozygous loss-of-function Mll5 mice, a combined maturation defect of the myeloid and erythroid lineage has been described. *Aims.* In the present study we investigated the prognostic impact of MLL5 expression levels in 509 AML patients. *Methods.* All patients were uniformly treated according to AML SHG 0295 or AML SHG 0199 treatment protocols. RNA was extracted from diagnostic bone marrow or peripheral blood cells, reversely transcribed, and amplified by quantitative RT-PCR. RT-PCR was carried out on a StepOne Plus real-time PCR system using ABL as an endogenous control. Statistical analyses were performed using SPSS. Patients were divided into quartiles by MLL5 expression values. *Results.* While patients with low MLL5 transcript levels in quartiles 2, 3 or 4 did not show a significant difference in outcome when compared with each other in univariate analysis, the 127 patients with high MLL5 expression (quartile 1) had a higher CR rate (83% v 74%; P=.02), a longer RFS (P=.009) and a longer OS (P=.001) compared with the 382 patients with lower MLL5 expression. No correlation between MLL5 expression and cytogenetic aberrations was found. When analyzing the prognostic impact of MLL5 expression in cytogenetically normal AML (CN-AML, n=268), high MLL5 expressers had a longer RFS (P=.03) and longer OS (P=.007). In multivariate analysis for RFS and OS, MLL5 expression status was an independent favorable prognostic factor (RFS: HR 0.71, 95% CI 0.5 to 0.98, P = .041; OS: HR 0.65, 95% CI 0.48 to 0.88, P=.005) in the total cohort of 509 patients when considered together with age, karyotype, WBC count, platelet count, and type of AML (*de novo vs.* secondary). To test the prognostic value of MLL5 expression in the context of other prognostic molecular markers in CN-AML, multivariate analysis for OS was performed also considering the NPM1/FLT3 and the CEBPA mutation status, the WT1 SNP rs 16754 status, the WT1, MN1, BAALC, and the ERG expression status, age, WBC count, and platelet count. Strikingly, MLL5 remained an independent favorable prognostic marker in the context of this well characterized cohort (HR 0.58, 95% CI 0.36 to 0.94, P=.028). *Conclusion.* We identified MLL5 transcript levels as an independent favorable risk marker in AML, enabling the identification of a significant proportion of patients with favorable prognosis that are neither identified by mutational nor cytogenetic analysis.

SINGLE CELL NETWORK PROFILING (SCNP) OFFERS A NOVEL APPROACH TO IDENTIFY AT DIAGNOSIS AML CHEMOTHERAPY RESISTANT CELL PHENOTYPES

A Cesano,[1] A Cohen,[1] T Covey,[1] S Putta,[1] U Gayko,[1] X Xiaohua,[1] W Fantl,[1] S Kornblau[2]

[1]Nodality, South San Francisco, USA; [2]MD Anderson Cancer Center, Houston, USA

Background. Despite improvements in AML response to initial chemotherapy the risk of relapse, especially in older patients, remains high. While chemotherapy regimens can eliminate the majority of the AML blasts, the remaining cells, ultimately responsible for disease relapse, have unique characteristics that render them resistant to the chemotherapy. Current tools to predict disease relapse at diagnosis are inexact. In fact, while many genomic (e.g. gene expression arrays) or proteomic (e.g. reverse phase protein arrays) technologies are capable of revealing the biology of "bulk" AML, biologic tools that detect small chemo-resistant cell populations in AML samples are needed. Single cell network profiling (SCNP) is a biologic tool using multiparameter flow cytometry that allows a comprehensive functional assessment of intracellular signaling pathways in heterogeneous tissues at the single cell level. *Aims.* Our aims were to use SCNP to determine whether: a) in longitudinally collected AML samples, cell surface phenotypes and/or intracellular signaling profiles dominant at relapse could be identified in subpopulations of cells present at diagnosis and b) whether the presence of (rare) blasts with these intracellular signaling profiles could predict for disease relapse in an independent set of AML diagnostic samples. *Methods.* Three paired diagnostic and relapse AML bone marrow samples were examined using SCNP after sample incubation with cytokines, growth factors, chemotherapeutic agents, and other modulators. The use of fluorochrome-conjugated antibodies that recognized leukemic blasts and intracellular phospho-epitopes allowed signaling to be measured in specific cell types at the single cell level. In addition, drug transporters and surface receptor levels were also measured. *Results.* Analysis of the myeloblast subpopulations as defined by surface markers revealed heterogeneity between samples (both at diagnosis and relapse) which was not informative in term of relapse risk. By contrast, the intrapatient characterization of intracellular signaling profiles between relapsed and diagnostic samples revealed in all the three relapsed samples the presence of a subpopulation of leukemic cells characterized by simultaneous phosphorylation of Akt and S6 in response to SCF (SCF:p-Akt/p-S6). This functionally defined leukemic subset, although dominant in the relapse samples, was detectable at a much lower frequency in the diagnostic samples. We hypothesized that the presence of this SCF:p-Akt/p-S6 subpopulation at diagnosis could be predictive for early disease relapse and applied the SCF:p-Akt/p-S6 gate to an independent SCNP data set containing 52 diagnostic AML samples from patients who achieved complete remission (CR) after standard induction therapy. Seven of those patients showed a detectable SCF:p-Akt/p-S6 subpopulation in their diagnostic samples and six of the latter patients experienced disease relapse within 2 years. Of note, the presence of a SCF:p-Akt/p-S6 subpopulation was shown to be independent from the blasts c-Kit (SCF receptor) expression levels. In addition, the SCF:p-Akt/p-S6 profile was independent from patient age, AML cytogenetics and Flt-3 mutational status. *Conclusions.* Our study showed that longitudinal SCNP analysis of AML samples could provide unique insights into the nature of AML chemo-resistance allowing for identification of subpopulations of cells present at diagnosis with unique signaling characteristics predictive of higher rates of relapse.

A STUDY ON THE CLINICAL SIGNIFICANCE OF THE WHO AML SUBTYPE INV(3)(Q21Q26.2)/T(3;3)(Q21;Q26.2) AND VARIOUS OTHER 3Q CHROMOSOMAL ABNORMALITIES IN 6,819 AML CASES

S Lugthart,[1] S Gröschel,[2] H Beverloo,[1] P Valk,[1] U Schanz,[3] S Bhola,[4] E Vellenga,[5] S Kayser,[2] G Ossenkoppele,[6] G Verhoef,[7] A Ferrant,[8] E van den Berg-de Ruiter,[9] A Ganser,[10] M Jotterand,[11] J Krauter,[10] T Pabst,[12] B Schlegelberger,[10] R Schlenk,[2] R Delwel,[1] K Döhner,[2] B Löwenberg,[1] H Döhner[2]

[1]Erasmus MC, Rotterdam, Netherlands; [2]University Hospital Ulm, Ulm, Germany; [3]University Hospital Zürich, Zürich, Switzerland; [4]VU University Amsterdam, Amsterdam, Netherlands; [5]University Medical Center, Groningen, Netherlands; [6]VU University Medical Center, Amsterdam, Netherlands; [7]University Hospital Gasthuisberg, Leuven, Belgium; [8]Hôpital St Luc, Bruxelles, Belgium; [9]University Medical Centre Groningen, Groningen, Netherlands; [10]Hannover Medical School, Hannover, Germany; [11]University Hospital and University of Lausanne, Lausanne, Switzerland; [12]Bern University Hospital, Bern, Switzerland

Background. Among patients with newly diagnosed acute myeloid leukemia (AML), inv(3)(q21q26.2) or t(3;3)(q21;q26.2) [inv(3)/t(3;3)] occurs in 1-2% of the cases. Although it has been reported that the prognosis of inv(3)/t(3;3) AML is poor and the disease associates with aberrant EVI1 expression, a comprehensive study on this AML subtype is lacking due its low frequency. Furthermore, the clinical significance and molecular basis of the diversity of other 3q rearrangements involving either chromosome 3q26 or 3q21 remain to be elucidated. *Aim and Methods.* We evaluated the frequency and the clinical significance of AML with inv(3)/t(3;3) and various other 3q abnormalities in comparison to non-3q cytogenetically abnormal (CA) AML in 6,819 newly diagnosed adult AML patients treated on Dutch-Belgian-Swiss HOVON/SAKK (n=3,318) and German-Austrian AMLSG protocols (n=3,501). In a subset of cases, we assessed for aberrant EVI1 and MDS1/EVI1 expression using real-time quantitative PCR (qPCR), and we studied the association with common gene mutations. *Results.* Chromosome 3q abnormalities were detected in 4.2% of AML cases (n=288/6,819). Patients ≤ 60 years of age more frequently carried a 3q abnormality (4.5%; 231/5,061) than patients > 60 years (3.2%; 67/1,758). Four different AML subgroups with distinct 3q aberrations were considered: (A) inv(3)/t(3;3) (WHO defined subtype of AML, n=94); (B) other balanced 3q26 translocations, e.g. t(3;12)(q26.2;p13), t(3;21)(q26.2;q22) (n=52); (C) other balanced 3q21 translocations, e.g. t(1;3)(p36;q21), t(3;5)(q21;q31) (n=19); (D) other 3q abnormalities (n=123). Patients with inv(3)/t(3;3) or balanced 3q21 translocations presented with significantly higher white blood cell (WBC) and platelet counts. Monosomy 7 was a common additional aberration, in particular in Group A (66%), but also in Groups B (31%) and D (37%). N-RAS mutations were significantly associated with inv(3)/t(3;3) and balanced 3q26 translocations. All four 3q groups showed poor survival outcomes; within inv(3)/t(3;3) cases, the adverse prognostic impact was strengthened by the presence of monosomy 7. In addition, the prognostic impact of the 3q groups was determined by multivariable analysis considering the variables age, WBC and platelets counts, monosomy 7, monosomal karyotype, complex karyotype, and type of AML. Inv(3)/t(3;3) (Group A) independently predicted low CR rate (OR; 0.29, P<.0001), adverse relapse-free survival (HR, 2.0, P<.0001), event-free survival (HR, 2.0, P<.0001), and overall survival (HR, 1.4, P=.006). EVI1 was highly expressed in Groups A and B, but the disproportionate EVI1 *vs.* MDS1/EVI1 overexpression was characteristic of inv(3)/t(3;3) AML. Interestingly, disproportionate EVI1 *vs.* MDS1/EVI1 overexpression was also found in a small subset of Group D 3q aberrant AML. Most of these AML carried del(3)(q26), add(3)(q26), del(3)(q21) or add(3)(q21) pointing to the presence of cryptic inv(3)/t(3;3) lesions leading to altered EVI1/MDS1/EVI1 expression. *Summary/Conclusion.* AML with inv(3)/t(3;3) represents a distinctive subgroup with poor prognosis, which discriminates from most other AML with 3q aberrations. Adverse prognostic impact was further enhanced by additional monosomy 7. EVI1/MDS1/EVI1 qPCR may allow for the identification of cryptic inv(3)/t(3;3) AML.

RUNX1 MUTATIONS FORM A DISTINCT MOLECULAR SUBGROUP IN ACUTE MYELOID LEUKEMIA: RESULTS OF THE AML STUDY GROUP (AMLSG)

V Gaidzik,[1] L Bullinger,[2] R Schlenk,[2] A Zimmermann,[2] J Röck,[2] B Schlegelberger,[3] J Krauter,[4] A Ganser,[4] D Späth,[2] H Döhner,[2] K Döhner[2]

[1]Universtiy Hospital of Ulm, Internal Medicine III, Ulm , Germany, Ulm, Germany; [2]University Hospital of Ulm, Internal Medicine III, Ulm, Germany; [3]Institute of Cell and Molecular Pathology, Hannover Medical School, Hannover, Germany; [4]Department of Hematology, Hemostasis, Oncology and Stem Cell Transplantation, Hannover, Germany

Background. The highly conserved runt-related transcription factor 1 gene (*RUNX1*) is required for definitive hematopoiesis; functional dysregulation of *RUNX1* has been shown to be involved in leukemogenesis. In acute myeloid leukemia (AML) *RUNX1* is implicated by chromosomal translocations [e.g. *RUNX1-RUNX1T1* in t(8;21)], point mutations or amplifications. In addition, *RUNX1* germline mutations that can be found in patients with familial platelet disorder predispose to the development of myeloid leukemia. Recent data suggest that *RUNX1* mutations are related to distinct cytogenetic subgroups such as trisomy 13, trisomy 21, loss of chromosome 7q, and trisomy 8. *Aims.* To characterize the biological and clinical features of *RUNX1* mutations in a large cohort of younger (16 to 60 years of age) adult AML patients (pts) who were entered on two consecutive AMLSG treatment protocols (AML HD98A, AMLSG 07-04). *Methods. RUNX1* mutation screening was performed in 977 AML-pts (*de novo* AML, n=904; s-AML, n=27; t-AML, n=38) using a DNA-based PCR assay for amplification of exons 1 to 8 followed by direct sequencing. For a subset of cases (n=269) gene expression profiling (GEP) was performed using 40k cDNA microarrays. *Results.* The incidence of *RUNX1* mutations was 5.5% in the entire cohort (54 of 977 pts); mutations clustered in exon 3 (10) and exon 8 (21), but were also located in other regions of the gene. With regard to cytogenetic subgroups, *RUNX1* mutations mainly occurred in the intermediate risk group [7,1%; 47/657] predominantly in normal karyotype AML (CN-AML; 32/546); in the high risk group the frequency was lower [4,5%; 5/106] whereas in the low risk group no *RUNX1* mutations were identified [0/146]. With respect to pts characteristics such as age, WBC, LDH and platelet count there were no differences between the *RUNX1* mutated (*RUNX1*^{mut}) and *RUNX1* wildtype (*RUNX1*^{wt}) group. *RUNX1*^{mut} were more frequent in s-AML (4/27) compared to t-AML (3/38) and *de novo* AML (46/904) (P=0.05). Correlations with molecular markers (*NPM1*, *FLT3*-ITD, *FLT3*-TKD, *MLL*-PTD and in addition for CN-AML *WT1*, *CEBPA*, *NRAS*) revealed a significant association of *RUNX1*^{mut} with *MLL*-PTD (P=0.0005) and an inverse correlation with *NPM1* mutations (P<0.0001). Furthermore, *RUNX1*^{mut} showed a characteristic gene expression pattern characterized by the enrichment of genes belonging to pathways associated with TNF signalling and apoptosis. These findings suggest a distinct biology for *RUNX1*^{mut} AML that also seems to translate clinically as *RUNX1*^{mut} pts had a higher rate of resistant disease (RD) with 30% refractory cases compared to 16% for *RUNX1*^{wt} pts (P=0.02). In accordance, *RUNX1*^{mut} cases showed a significantly lower complete remission (CR) rate (61% *vs.* 75%, P=0.04). In univariable analysis, event-free survival (EFS; P=0.00003), relapse-free survival (RFS; P=0.007), and overall survival (OS; P=0.02) were significantly inferior in *RUNX1*^{mut} pts; in multivariable analysis, *RUNX1*^{mut} was an independent prognostic marker for lower EFS. *Conclusions.* In younger adult AML-pts, *RUNX1* mutations mainly occur in the intermediate risk group, in particular in CN-AML. Correlations of *RUNX1*^{mut} with clinical, genetic and gene expression data suggest that this gene mutation confers a distinct biological impact that is associated with inferior outcome in younger AML-pts.

ROLE OF CYTOCHROME P1A1 AND GLUTATHIONE S TRANSFERASE GENE POLYMORPHISMS IN THE PATHOGENESIS OF EGYPTIAN PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA

G Ebid,[1] A Kamel,[1] B Rong,[2] H Moussa[1]

[1]*NationalCancer Institute,Cairo University, Cairo, Egypt;* [2]*KFSHRC, Reydh, Saudi Arabia*

Background. Xenobiotic-metabolizing enzymes constitute an important line of defense against a variety of carcinogens. Many are polymorphic, constituting the basis for the wide inter-individual variation in metabolic capacity and possibly a source of variation in the susceptibility to chemical-induced carcinogenesis. *Aims.* The aim of this study was to determine the existence of any association between the genetic polymorphisms of P450 1A1 (CYP1A1) & glutathione S-transferase M1, T1&P1 (GSTM1, T1&P1), and altered risk for pediatric ALL. *Methods.* A total of 92 patients and 314 controls were genotyped by means of PCR and PCR-RFLP-based assays. Mutated alleles comprising CYP1A1*2A,*2B,*4, GSTM1*Null, GSTT1*Null, GSTP1Ile105Val and Ala114Val, were analyzed along with the wild-type alleles. *Results.* The frequency of the GSTP1 114Ala/Val (2293CT) heterozygous genotype was 16(17.9 %) among patients compared to 27 (8.3 %) among controls; the difference was found to be statistically significant (P=<0.001, O.R=2.494 & 95% C.I 0=1.272-4.890). The frequency of the GSTP1 114Val/Val (2293TT) homozygous genotype was 6 (6.7 %) among patients compared to 1 (0.3 %) among controls; the difference was found to be statistically insignificant (P=<0.001, O.R=25.254 & 95% C.I 0=2.99-213.294). this results pointed to 2.5 folds and 25 fold increased risk of ALL for both heterozygous and homozygous respectively. although a near significant increase in GSTP1 Ile105Val was also found in ALL group (P = 0.054). Our results showed no significant association between the CYP1A1 *2A, *2B and*4 genotypes and the risk of childhood ALL. Also the combined genotype of the three polymorphisms did not affect the ALL risk. Also no statistically significant difference for GSTM1 null or deletion genotype was encountered between patients and controls (P=0.553). *Summary and Conclusion.* The results suggest an association of impaired Xenobiotic-metabolizing enzymes specially GSTP1 activity with an increased risk for pediatric ALL, possibly by a decrease in the metabolic detoxification of chemical carcinogens. Further wide scale studies will be needed to confirm such effect on ALL pathogenesis.

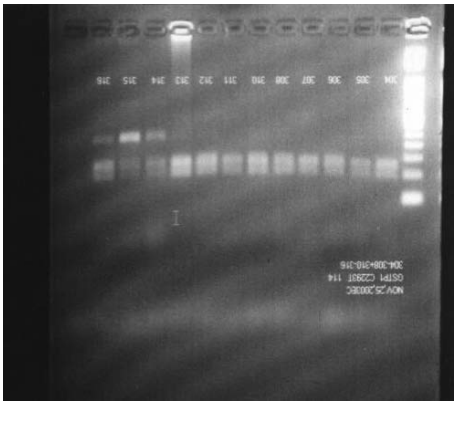

Figure 1. GSTP1 Ala114Val polymorphism.

A NEW ENTITY OF T LINEAGE ACUTE LYMPHOBLASTIC LEUKEMIA (T-ALL) RESPONDING TO TYROSINE KINASE INHIBITOR (IMATINIB MESYLATE): COMPLETE CHARACTERIZATION OF A PEDIATRIC CASE WITH RESISTANT DISEASE

L Lo Nigro,[1] V Barresi,[2] E Mirabile,[1] N Musso,[2] C Capizzi,[2] S Corbacioglu,[3] A Poli,[1] M Tumino,[4] D Condorelli[2]

[1]*Azienda Policlinico University of Catania, Catania, Italy;* [2]*Scuola Superiore University of Catania, Catania, Italy;* [3]*University of Ulm, Ulm, Germany;* [4]*University of Catania, Catania, Italy*

Background. T cell acute lymphoblastic leukemia (T-ALL) accounts for 15% of pediatric ALL cases. Prognosis has improved in recent years but some cases suffer from relapse/resistant diseases, which are mostly fatal. Application of new methodologies have shown that several genes with tyrosine kinase activity are involved in the leukemogenic process, co-operating with pro-survival molecules. *Aim.* To characterize a case of pediatric T-ALL who showed a clinical response to Imatinib Mesylate (IM). *Methods.* We performed immunophenotypic, conventional karyotype, FISH, RT-PCR, sequencing and western-blot analyses, detection of minimal residual disease (MRD) using TcR rearrangements, SNPs arrays using GeneChip Operating Software (GCOS) and Genotyping Console GTC 3.0.1. *Results.* A 4-year-old black boy from Mauritius with T-ALL was firstly treated with a FRALLE-2000 and further with AIEOP-BFM-2000 protocols. During maintenance, he showed a bone marrow isolated relapse with FAB L2 and myeloid features and aberrant expression of CD10, CD13 and CD117/cKit antigens. Karyotypic analyses showed a 47,XY,+8,del(11)(q13q23). FISH, molecular screening and SNPs analyses excluded the MLL gene involvement. SIL/TAL1 del(1), and NUP214/Abl episomes were not detected. The child was treated with two courses of Idarubicin-CytosineArabinoside, but always recovered with circulating blasts. Based on cKit expression and trisomy of chromosome 8, we designed a therapy with IM (300 mg/mq/daily) followed by a course with Etoposide and Cyclophosphamide. After few days of IM administration, we observed a rapid reduction of peripheral blasts count and splenomegaly. He achieved a partial remission, which persisted for 6 months. Afterwards he suffered from a relapse and died for progression disease. Sequencing analyses of cKit gene did not show any alteration. We retrospectively performed the detection of MRD, confirming that the clone of relapse was the same as diagnosis, because of ots persistence during first line therapy. By SNPs, we found two 1.7 Mb deletions: one in band 9p21.3 (CDKN2 genes) and the other in band 16q22.1 (NFATC3 gene). FGFR2 , cKit, FGFR3, FGFR4, PDGFRB and ABL1 genes, encoding putative IM targets, did not show copy number abnormalities or loss of heterozigosity. Conversely we observed a somatic loss of 0.6 Mb at 4q12 includes part of the 5'region of the PDGFRA gene encoding a tyrosine kinase receptor. A del(4)(q12q12) of about 800 kb generating the fusion between the 5'part of the FIP1L1 gene and the 3'part of the PDGFRA has been described as the molecular abnormality responsible for the development of idiopathic hypereosinophilia which usually responds to IM. We here detected a fusion transcript, strongly suggesting a biological basis of response to IM. We also found by western blot analyses an up-regulation of AKT pathway associated with a downregulation of PTEN, a potential marker of disease and a novel target of treatment. *Conclusions.* We pointed out on a potential new entity of T-ALL subtype which could benefit from treatment with tyrosine kinase inhibitors. We suggest to take into account the role of cKit expression, trisomy of chromosome 8, and mainly PDGRA-FIP1L1 fusion transcript as molecular alterations for a targeted therapy as well as AB1 fusion genes. Further studies are needed.

E2A-HLF ACTS THROUGH LMO2 AND BCL-2 TO IMMORTALIZE LYMPHOID PROGENITORS

J de Boer,[1] J Yeung,[1] J Ellu,[1] R Ramanujachar,[1] O Solarska,[1] M Hubank,[1] O Williams,[1] H Brady[2]

[1]*UCL Institute of Child Health, London, UK;* [2]*Imperial College, London, UK*

The t (17;19) (q22;p13) translocation occurs as a non-random translocation in approximately 1% of childhood B-lineage acute lymphoblastic leukemias. This translocation results in the formation and expression of the chimeric transcription factor E2A-HLF. The concept of "oncogene addiction"has been proposed to explain the observation that some cancers are dependent on a small number of genes, or even a single gene,

for both maintenance of the malignant phenotype and cell survival. For instance, switching off expression of the BCR-ABL oncogene in mice reverses the leukemic phenotype. Therefore, inhibiting the activity of one or two key target genes required for the leukemic phenotype could inhibit cancer cell growth which could translate to improved outcome. These targets can either be activated oncogenes or their downstream targets. The "oncogene addiction"model also implies that overexpression of a few key downstream targets, of an initiating oncogenic lesion, could recapitulate the cancer phenotype. Therefore, the identification of genes that have altered expression in leukemogenesis by E2A-HLF and which are directly involved in tumor initiation and maintenance will be instrumental for identifying crucial therapeutic targets. We identified several novel targets of E2A-HLF, in particular Lmo2 and Bcl-2, the co-expression of which was sufficient to immortalize HPCs with a pre-B cell phenotype similar from that caused by E2A-HLF expression alone. Retroviral-mediated shRNA knockdown of Lmo2 expression or inhibition of BCL-2 family function both have severe consequences for the survival of E2A-HLF immortalized cells. Overall these data suggest that targeting of specific downstream targets of E2A-HLF is feasible and may provide a novel approach to treating patients with t (17;19) leukemia, which has hitherto proved fatal.

Background. T cell acute lymphoblastic leukemia accounts for about 15% of pediatric acute lymphoblastic leukemia cases. In Poland, about 40 children are diagnosed with T-ALL every year, and among those children as many as 30% relapse. This, relatively high failure rate is partly caused by the molecular and genetic heterogeneity of this disease. Many molecular genetic factors are suspected to contribute to clinical aggressiveness and response to treatment and among them mutations in genes controlling T cell maturation and proliferation seem to be the most promising targets for risk group classification and application of targeted therapies. *Aim.* The study was focused on the analysis of mutations in NOTCH1, FBXW7 and FLT3 genes in a group of Polish T-ALL patients. *Patients and Methods.* The study group consisted of 60 consecutive children with T-ALL treated at the centers of Polish Pediatric Leukemia and Lymphoma Study Group (PPLLSG). The mutation analysis was focused on exon 9 and 10 of FBXW7, exon 26, 27, 28 and 34 of NOTCH1 and was performed by specific amplification of regions of interest by PCR and followed by direct sequencing. The internal tandem duplication (ITD) of FLT3 was screened by PCR amplification of the regions of interest and fragment size assessment by agarose gel electrophoresis. *Results.* In total, we have detected 36 mutations in the whole group of T-ALL patients. Among those 36 events, 34 led to change of amino acid sequence (2 were synonymous). The mutations of FBXW7 were detected in 8% of patients, mutations of NOTCH1 were detected in 41.6% of patients, FLT3-ITD in 1.6% of patients. *Conclusion.* The frequency of detected mutations is slightly lower (12% for FBXW7 and 56% for NOTCH1) than reported by other authors from different countries. FLT3-ITD is rare phenomenon in pediatric T-ALL. We aim to continue our study in a larger group of patients to verify these observations and to evaluate clinical and prognostic significance of these molecular data after longer follow-up.

1174

VASCULAR ENDOTHELIAL GROWTH FACTOR-C AND ITS RECEPTOR TYPE-3 WERE EXPRESSED IN TWO CASES OF ACUTE LYMPHOCYTIC LEUKEMIA WITH T(1;19)

R Shirasaki,[1] H Tashiro,[2] Y Oka,[2] N Akiyama,[2] K Kawasugi,[2] N Shirafuji[2]

[1]Teikyo University School of Medicine, Tokyo, Japan; [2]Japan/teikyo university school of medicine, Tokyo, Japan

Background and Aims. Vascular endothelial growth factor (VEGF)-C and VEGF receptor type-3 (VEGFR-3) play an important role in creation of systematic lymphatic vessels. VEGF-C and VEGFR-3 also play an important role in progression of malignant solid tumors; however, on our knowledge, there have been no reports on the relationship of acute lymphocytic leukemia (ALL) and VEGF-C system. We analyzed *de novo* ALL blasts to clarify whether VEGF-C and VEGFR-3 influenced ALL-pathogenesis. *Materials and Methods.* Bone marrow cells were obtained from informed ALL patients, whose mononuclear cells were prepared with density-gradient sedimentation method. Cells were cultured short term for the elimination of an adherent cell-fraction. RNA was extracted from the prepared non-adherent mononuclear cells, and the expression of VEGF-C and VEGFR-3 was analyzed with reverse transcription-polymerase chain reaction (RT-PCR). On the protein level, cells were analyzed with fluorescent activated cell sorter, and VEGF-C levels in patients' sera and in the conditioned media from the cultured ALL blasts were assayed with ELISA kit (R & D Systems, USA). When ALL blasts expressed VEGFR-3 and VEGF-C, a growth-inhibition effect by the administration of anti- VEGF-C-neutralizing antibody (Sigma, USA) was assayed with Cell-Counting Kit (Dojindo, Japan). *Results.* In 21 cases examined, VEGF-C production was observed in 4 cases. Of these four, VEGFR-3 was expressed in 2 cases, whose karyotypic analysis of the bone marrow cells showed t(1;19), and demonstrated E2A-Pbx1 fusion molecule with cDNA sequence (Applied Biosystems, USA). When anti-VEGF-C-neutralizing antibody was added to the blast cell-cultures, the cell-growth was significantly inhibited. *Conclusion.* These observations indicate that VEGF-C autocrine system works on proliferation in ALL with t(1;19).

1175

IN VITRO PROLIFERATION DYNAMICS OF GLUCOCORTICOID-TREATED CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) CELLS

G Lambrou, E Koultouki, M Adamaki, S Vlahopoulos, F Tzortzatou-Stathopoulou, M Moschovi

University of Athens, Athens, Greece

Background. Glucocorticoids are the most potent anti-inflammatory agents, widely used in lymphoid malignancies. Resistance or sensitivity to glucocorticoids is considered to be of major importance for the prognosis of leukemia, especially in lymphoid leukemia. While little is known on resistance to glucocorticoid-induced apoptosis, the proliferation dynamics governing leukemic cell systems under glucocorticoid influence could possibly elucidate the mechanisms leading to resistance. *in vitro* models present a powerful tool for the study of drug influence and have been utilized extensively in the study of glucocorticoids. *Aims.* Our previous work[1] elucidated that glucocorticoids can evoke mitogenic along with cytotoxic effects in leukemic blast cells. Cell viability, apoptosis, necrosis as well as DNA content have been studied. Attention has been drawn to the proliferation dynamics describing those cell populations. *Materials and Methods.* The childhood T-cell ALL CCRF-CEM cell line was utilized for the *in vitro* system. Cell count was measured with a NIHON KOHDEN hematocytometer. Cytotoxicity and DNA content were studied with flow cytometry on the FC500 Flow Cytometer (Beckman Coulter Inc.). Curve approximation was performed either linearly or quadratically ( ). Statistical analysis was performed using Microsoft Excel and Matlab® (Mathworks Inc.). Early apoptosis was calculated by using gating with Boolean functions. *Results.* Lower prednisolone concentrations increased cell growth speed, (Figure 1A), where N is the cell population measured at time t. Cells treated with lower prednisolone concentrations, started at a higher initial cell population (average: 1.8×10^3/uL). To test the possibility that growth speed was higher due to the initial cell population we per-

formed an independent experiment with no glucocorticoid addition, starting from ~2.8_103 cells/ul (Figure 1A). It appeared that increased proliferation was due to prednisolone treatment. Viable cells followed an expected pattern of proliferation with a<0 for all concentrations, where a is the quadratic coefficient (Figure 1B). Total cell death manifested a positive correlation as a function of time and concentration (Figure 1C, a>0) (Pearson's correlation 0.97). Different patterns of proliferation were revealed, when total cell death was discerned into its subcategories. Necrotic cells appeared to be significantly higher at low prednisolone concentrations as compared to untreated cells (Figure 1D, a>0). For 10nM and 1uM treatments (a<0) opposing proliferation patterns were observed as compared to higher doses and untreated cells (a>0) (Figure 1E). The same applied to early apoptotic cells (Figure 1F). *Conclusions.* Prednisolone manifested differential proliferation effects with mitogenicity at low concentrations and cytotoxicity at higher concentrations. This, could be partly explained by the differential proliferation of cell sub-populations i.e. the progression of viable, apoptotic, necrotic and early apoptotic cells. Proliferation dynamics could provide a useful tool for designing more efficient therapeutic protocols and our results could play a major role in determining prednisolone dosage in childhood ALL patients, as the response to glucocorticoids during the first week of treatment is considered to be crucial in the BFM-ALL protocol.

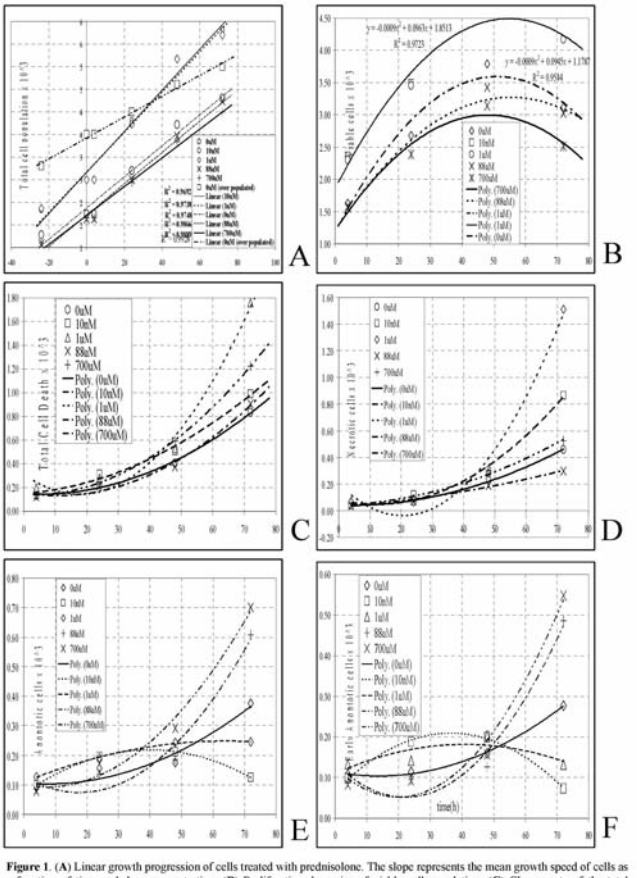

Figure 1. (**A**) Linear growth progression of cells treated with prednisolone. The slope represents the mean growth speed of cells as a function of time and drug concentration. (**B**) Proliferation dynamics of viable cell population. (**C**) Change rate of the total cytotoxic effect. Growth curve has been approached quadratically with $R^2>0.9$ for all concentrations. (**D**) Progression of necrotic cells during prednisolone treatment. (**E**) Population of cells undergoing apoptosis and similarly early apoptosis (**F**).

PREVALENCE OF THIOPURINE METHYLTRANSFERASE GENE POLYMORPHISM IN EGYPTIAN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA

A Tantawy,[1] A Adly,[1] E AlGhoroury,[2] M Abdel Maksoud[1]

[1]Faculty of Medicine,Ain Shams University,Cairo,Egypt, Cairo, Egypt; [2]National Research Center, Cairo, Egypt

Background. There is wide inter-individual variability in the pharmacokinetics, pharmacodynamics and tolerance of anticancer drugs. Polymorphisms that reduce the activity of thiopurine S-methyltransferase (TPMT) cause adverse reactions to conventional doses of thiopurines including 6-mercaptopurine (6MP), routinely used as anti-leukemia treatment. There are more than 20 variant alleles of TPMT that cause decreased enzymatic activity. *Aim.* To determine the frequency distribution of the most common variant alleles of Thiopurine methyltransferase (TPMT) gene polymorphism in a cohort of Egyptian children with acute lymphoblastic leukemia (ALL) and its correlation with response to chemotherapy and toxicity of 6MP. *Methods.*The study included 70 ALL patients diagnosed and treated in the Haematology /Oncology Clinic, Children's Hospital, Ain Shams University, Egypt during the period from January 1st 2004 till December 31st 2009, and followed up for a mean of 2.9±1.2 years. They ages ranged between 2-15 years (mean 6.16±4.3 years), with a M:F ratio of 2:1.6.The ALL treatment protocol was modified CCG 1991 (standard risk ALL), and modified CCG 1961 (high risk ALL). Patient's files were revised for patient's data at diagnosis including age, gender, ethnicity, initial total leucocytic count, immunophenotyping , hepatitis B or C infections; data about infectious complications including hospital admission, hepatic toxicity , neutropenia were recorded. Detection of TPMT gene mutation polymorphism was done using PCR technique followed by RFLP analysis. Three common alleles were examined:G238C, G460A and A719G. Seventy healthy age and sex matched children served as controls.*Results.* Neither the studied leukemic patients nor the controls had the TPMT variant alleles in either homozygous or heterozygous form. None of our patients had experienced relapse. 26.9% had T lineage immunophenotype and 73.1% had a pre-B phenotype. 50% of patients experienced at least one attack of febrile neutropenia which required hospital admissions. Infection necessitating hospitalization during the course of chemotherapy occurred in 62%(once), 6.3 %(twice) and 3.1% (more than 3 times). Liver enzymes were mildly elevated in 40.6% of patients and were elevated more than 200 IU/L in 13.3% and all of them had evidence of viral hepatitis. As a result of neutropenia and serious infections, patients needed 6-MP dose modification once in 53.1% , twice in 15.6%, 3 times or more in 6.3% , while 18.8% had no dose modification. Dose interruption occured in 62.5% of patients: 28.1% had 2 weeks interruption and 6.3% had more than 2 weeks interrupted therapy.*Conclusion.* TPMT variant alleles type G238C, G460A and A719G were not present in the studied patients, so genetic polymorphism in TPMT is not one of the determinant causes of 6-MP toxicity. The important causes of dose modification and interruption were infections and febrile neutropenia (environmental factors). So causes for chemotherapy interruption or modification other than TPMT gene polymorphism should be considered in Egyptian ALL patients.

1177

THE CASE REPORT: MINIMAL RESIDUAL DISEASE MONITORING USING PATIENT-ASSOCIATED ANTIBODY PANEL IN A PATIENT WITH MLL+ ACUTE B-LYMPHOBLASTIC LEUKEMIA

M Gorchakova,[1] K Slobodnyuk,[1] E Rusanova,[1] E Boychenko,[2] Y Zueva[1]

[1]Pavlov State Medical University, Saint-Petersburg, Russian Federation; [2]First Children State Hospital, Saint-Petersburg, Russian Federation

Background. MRD monitoring by flow cytometry aims to identify cells with aberrant or rare phenotype. One of the approaches is to use patient-associated panels for MRD monitoring, which include (i) phenotypic markers of transformed cells identified at the date of a primary diagnostics and (ii) markers, often occurring in a particular variant of ALL. Immunological MRD monitoring is an individualized laboratory diagnostics, since individual patients can have a complete preservation of an aberrant phenotype, as well as the changes in the expression of several markers. *Aims.* We present a case of MRD monitoring using the patient-associated antibody panel in a patient with MLL+ acute B-lymphoblastic leukemia. *Materials and Methods.* The patient (female, 3 months old), came to the First Children State Hospital to the hemato-

logic department in July 2008. Analysis of the bone marrow samples by five-color flow cytometry was performed in Pavlov State Medical University. There were 6 points for MRD detection during monitoring of the disease. *Results.* According to the results of immunophenotyping by flow cytometry at the day of primary diagnostics, the bulk of bone marrow cells was represented by a homogeneous population of $CD19^+CD34^+CD22^+CD38^+CD33^+CD16^+CD13^+$ B cells. Molecular biological studies identified MLL-AF4. The aberrant expression of antigens CD33, CD13 and CD16 was assumed as a basis for the patient-associated algorithm of MRD monitoring. Because of the five color limitation, the antibody panel was formed in such a way, that the expression of myeloid markers could be evaluated on the $CD19^+CD34^+CD22^+CD38^+$ B-cells. At the day +15 from the beginning of the therapy transformed cells were revealed in amount 1,68%. Expression of CD33 remained stable, expression of CD16 decreased and expression of CD13 increased. At the day +36 expression was the same with 0,13% of the transformed B cells. At the day +43 expression of CD117 was newly revealed on the transformed B cells (0,2%) with decreased expression of CD33, CD13 and CD16. At the day +83 MRD was 0,11% confirmed by detection MLL-AF4. Expression of CD33 and CD117 remained stable and expression of CD13 and CD16 decreased again. MRD was more than 0,1% at the most of points, that means a high risk group. At the last point before the bone marrow transplantation (day +139) the tumor B-cells were revealed as 0,03%. Expression of CD33 and CD117 remained stable and expression of CD13 increased. *Summary*. During the MRD monitoring in the patient with MLL^+ acute B-lymphoblastic leukemia the aberrant expression of CD33 was stable. Other markers such as CD13, CD16, CD117 were not stable on the transformed cells. CD117 was newly revealed during the MRD monitoring. Expression of CD16 decreased with the beginning of the therapy and then disappeared at all. CD13 was firstly revealed only on a small part of transformed B cells. When the clone reduced, the expression of CD13 increased. Thus B cells with coexpression of CD13 could be more resistant for the chemical therapy. Results of flow cytometry using patient-associated antibody panel agreed accurate with the results of molecular biological studies and clinical data.

1178

ADULT T-CELL LEUKEMIA/LYMPHOMA ASSOCIATED WITH HUMAN T LYMPHOTROPIC VIRUS TYPE 1, REVEALED BY A SEVER HYPEREOSINOPHILIC SYNDROME: A CASE-REPORT

C Mohr,[1] P Zunic,[1] A Clabe,[1] C Lemonnier,[1] S Ihamouine,[1] E Antok,[1] JE Kahn,[2] O Hermine[3]

[1]Groupe Hospitalier Sud Réunion, Saint Pierre Reunion Island, France; [2]Hôpital Foch, Suresnes, France; [3]Groupe Hospitalier Necker Enfants Malades, Paris, France

Background. Hypereosinophilia may be secondary to a malignant lymphoid hemopathy. The multiple manifestations can be sudden, dramatic and potentially fatal. *Aims.* We present here a case of secondary eosinophilia with cardiac, neurologic and pulmonary complications, revealing an Adult T-cell Leukemia/lymphoma. *Methods*. A case-report *Results*. Ms S., 55 years old, living in Reunion Island (Indian Ocean), had a major hypereosinophilia (2 giga/liter) for 18 months, with only a diffuse skin rash. Parasitic, allergic and toxic etiologies are initially excluded. The patient is hospitalized in the intensive care unit with a multivisceral failure secondary to eosinophilic infiltrates in the myocardium, the lungs and the central nervous system. On the hemogram, we found a major hyperleukocytosis with a count of 74 giga/liter, 53 giga/liter of eosinophils and 9 giga/liter of lymphocytes. The diagnosis of Adult T-cell Leukemia/lymphoma was made by the presence of clonal lymphoid T cells (positive T-Cell Receptor Gene rearrangement) with an aberrant phenotype, the presence of Sezary-like cells CD25 positive and the positive serology of Human T Lymphotropic Virus type 1. The FIP1L1/PDGFRA and BCR-ABL mutations are negatives; the medullar karyotype is normal; an eosinophilic infiltrate was found in both bone marrow biopsy and aspiration, and a dermal superficial lymphoid T infiltrate in the skin biopsy. All the symptoms of hypereosinophilia disappeared after few days of corticoid pulse therapy associated to Hydroxyurea, with normalisation of the hemogram. So, the specific treatment of Adult T-cell Leukemia/lymphoma by the association of Interferon alpha and Zidovudine was introduced. The mother of the patient, 96 years old, has been found to be positive for the Human T Lymphotropic Virus type 1 serology without any symptom. The mode of transmission of the virus was probably the maternal breast-feeding, with the first clinical symptoms appearing for the period known from 10 to 50 years later. Thus, the philogenetic study of this virus is ongoing. *Conclusion*. T malignant hemopathy and viral infections are known to be responsible of hypereosinophilia, mostly moderated and asymptomatic, governed by several cytokines such as IL-3 and IL-5, stimulating the production of eosinophil cells. So, due to a meticulous etiological investigation and to advances in the diagnostic techniques, secondary causes of eosinophilia can be identified in a proportion of cases which would have otherwise been classified as idiopathic hypereosinophilic syndromes and then can be specifically treated. The originality of this observation is the extremely severe impact of the hypereosinophilia, including in particular cardiac failure, more classically observed in the myeloproliferative forms of hypereosinophilic syndromes.

1179

THE AMMONIA CONCENTRATION EVALUATION AS THE ADDITIONAL METHOD FOR THE ASPARAGINASE ACTIVITY MEASUREMENT

M Zalewska-Szewczyk, L Wyka, M Zubowska, M Mlynarski

Medical University of Lodz, Lodz, Poland

In the last years some authors have suggested, that the evaluation of ammonia concentration in serum could be an effective and simply way to the estimation of L-asparaginase activity during the treatment. The aim of the study was to evaluate the possible usability of the estimation of serum ammonia concentration as the method of the evaluation of L-asparaginase activity. *Material and Methods.* Fifteen patients with *de novo* ALL, treated with several doses of L-asparaginase (5000 IU/m^2, 10000 IU/m^2 and 25000 IU/m^2) were enrolled to the study. The blood samples were collected from each patient in two time points: before the administration of the drug and three days after the administration. The estimation of ammonia concentration was performed using the standard spectrophotometric method, L-asparaginase activity was established with ELISA method. *Results.* Ammonia concentration was strongly associated with the dose of L-asparaginase, the highest values were observed after the dose of 25000 IU/m^2. There was the significant association between the concentration of serum ammonia, estimated three days after drug administration and the serum L-asparaginase activity (R=0.495, P=0.019 The AUC value ammonted 0.794 with 95% confidence range of 0.57-0.934. The threshold ammonia value corresponding with L-asparaginase activity of 100 U/L, estimated using the ROC curve, amounted 66 µg/mL. The sensitivity of the method was assessed as 52.94%, the specificity as 100% , P=0.004. *Conclusion.* The method based on the measurement of ammonia concentration might be useful in case in which the measurement of L-asparaginase activity is not accessible.

1180

MINIMAL RESIDUAL DISEASE DETECTION IN CHILDHOOD B-LINEAGE ACUTE LYMPHOBLASTIC LEUKEMIA BY MULTICOLOR FLOW CYTOMETRY USING THE ST JUDE APPROACH

SP Chen,[1] A Yeoh,[2] PL Tan,[2] D Campana,[3] E Coustan-Smith[3]

[1]National University Healthcare System, Singapore, Singapore; [2]National University Healthcare System, Singapore, Singapore; [3]St. Jude Children's Research Hospital, Memphis, USA

Background. Minimal residual disease (MRD) is a powerful and independent prognostic factor in childhood acute lymphoblastic leukemia (ALL). This submicroscopic detection of residual blasts during therapy is typically performed by flow cytometry or polymerase chain reaction (PCR) amplification of antigen-receptor gene rearrangement. Currently, our center utilises PCR methodology as part of the routine assessment of therapeutic response. This study aims to evaluate the applicability of the St Jude flow cytometry approach to detect MRD in our patient cohort recruited in the Malaysia-Singapore ALL Study. *Methods.* Ficoll-purified mononuclear cells were obtained from 112 follow-up bone marrow/peripheral blood samples collected from 29 patients diagnosed with B lineage ALL (B-ALL). Institutional ethical committee approval and informed consent from parents were obtained. Leukemia associated antigens (LAA) were identified from diagnostic or relapse samples with 4 colour flow cytometry using fluorochrome-conjugated monoclonal antibodies to fluorescein isothiocyanate (FITC), phycoerythrin (PE), peridinin chlorophyll protein (PerCP), and allophycocyanin (APC). Discrimination of leukemic blasts was achieved by using one or more of the selected LAA stained with a backbone panel of antibodies consisting of CD10, CD19 and CD34. Those combinations that would allow identification of one leukemic cell in 104 or more normal nucleated bone marrow cells were selected and applied to the MRD samples.

Analysis was performed by comparing the staining pattern of each combination to that of 'normal' bone marrows. *Results.* Good concordance was obtained in 96% of the follow-up samples (P<0.001) when we compared dichotomous MRD status (positive/negative) by flow cytometry and PCR *Methods.* Overall, 58 samples were MRD negative (<0.01%) and 49 samples were MRD positive (≥0.01%) by both techniques. Of the samples that were MRD positive by both methods, 67.4% were within half log difference, 22.4% and 10.2% were within one log and 1-1.5 logs respectively. In the remaining 5 samples that were MRD<0.01% by flow cytometry but ≥0.01% by PCR, 5 were around the threshold level. *Conclusion.* A good correlation was obtained between MRD results by flow cytometric and molecular *Methods.* The use of both assays in tandem would enable us to monitor MRD in a larger proportion of patients with B-ALL as neither technique alone can be used to follow MRD in all patients. The methods in tandem will also reduce the chance of false negativity due to phenotypic shifts or clonal evolution.

*The authors declare that there is no conflict of interest. This study is funded by Biomedical Research Council/A*STAR, Singapore Cancer Syndicate/ A*STAR and Viva Foundation.*

PEDIATRIC THERAPY IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA: EXPERIENCE OF A SINGLE CENTRE

S Paolini, S Parisi, I Iacobucci, C Papayannidis, MC Abbenante, A Curti, E Ottaviani, N Testoni, M Baccarani, G Martinelli

Institute of Hematology Seràgnoli, Bologna, Italy

Background. Acute lymphoblastic leukemia (ALL) shows different outcome in children and adults, with event-free-survival (EFS) rates of 70-80% and 30-40% at 5 years, respectively. This reflects both a different disease biology and different therapeutic approaches. Recently, results apparently improved in young adults/adolescents aged 15-21 years, with *de novo* ALL, when treated with pediatric intensive regimens rather than with typical adult regimens. Similarly, clinical studies are ongoing in older patients, toxicity related-therapy seeming the limiting issue. *Aims.* We report a single centre experience on adult ALL patients treated with an intensive pediatric-inspired schedule, aiming to assess its tolerability and efficacy. *Methods.* From November 2007 to June 2009 eleven ALL patients (M/F=9/2) were treated at our Center according to modified AIEOP-LAL2000 regimen. Treatment consisted of 7 days steroid pre-treatment, and four drugs 78-days induction (phase IA and phase IIB) after which high risk (HR) patients were treated with three polychemotherapy blocks, while intermediate (IR) and standard risk (SR) patients went on 8-weeks consolidation and subsequent delayed intensification. Allo-SCT was planned for all patients with HLA-matched donor; 2-years maintenance therapy was given to the others. Median age was 31 years (range, 17-47). According to cytogenetic, response to steroid and minimal residual disease patients were classified into HR (n=5), IR (n=4) and SR (n=2). *Results.* 9/11 patients completed the induction phase IA, two being out for toxicity (grade IV infection and intestinal occlusion). Seven (64%) obtained a complete remission (CR); two were refractory. However, one of them subsequently achieved CR after polychemotherapy blocks, for an overall response rate of 73% (8/11). Seven patients then completed the 28-days induction IB. Median induction duration was 92 days (range 82-136). Delays were mostly due to extra-hematological toxicity, the commonest being gastrointestinal (n=12), infective (n=7) and thrombotic (n=3). Delays were accumulated in both induction phases without significant difference between phase IA (median 18.5 days, range 4-37) and phase IB (median 17 days, range 9-66), despite an absolute number of moderate-severe AE superior in phase-IA *vs.* phase-IB (12 *vs.* 5). After induction, 3/8 patients received consolidation therapy; 2/3 then received allo-SCT. The median duration of consolidation was 51 days (range 22-94). Conversely, 5/8 patients received polychemotherapy-blocks: 1/5 dropped out after one block due to reversible grade III renal failure. All the other four received allo-SCT. The median CR duration was 17 months (range 7+-35+); two patients relapsed, both after allo-SCT. With a median follow-up of 23 months (range 8-36) 8/11 (73%) patients are alive, 7 in CR (4 undergone allo-SCT). Three patients dead, one in CR for infection after allo-SCT, 2 for relapsed/refractory disease. *Conclusions.* Though in a small series, pediatric-like intensive chemotherapy seemed to be feasible in adult ALL. Extra-hematological toxicity, however, caused significant treatment delays during induction. Finally, the overall outcome appeared promising, though longer follow-up and larger populations are needed to draw definitive conclusions.

MRD-BASED TREATMENT STRATEGY FOR CHILDHOOD ALL (PROSPECTIVE STUDY OF 62 PATIENTS: TUNISIAN EXPERIENCE)

Y Ben Abdennebi, L Aissaoui, W Bouteraa, E Gouider, R Jeddi, O Ben Amor, K Kacem, N Ben Salah, Z Belhadj Ali, H Ben Abid, B Meddeb

Aziza Othmana Hospital, Tunis city, Tunisia

Background. In a previous retrospective analysis of 58 children with ALL treated according to the EORTC 58951 protocol between 2001 and 2003, patients were stratified by , WBC at diagnosis, immunophenotype, karyotype and steroids response in peripheral smears after 7 days of corticosteroid and one IT dose of MTX. 3-year EFS and OS were unsatisfactory: 46% and 55.4%. In order to improve our *Results.* blast cell count in the BM on D7 and D19, and determination of MRD measured by flow cytometry (CMF) in the BM at D35 were included in our stratification strategy. Patients whose blast cells were ≥25% in BM (M3 marrow) at D7 and or at D19, or whose MRD was positive at the end of induction, had their treatment one step upgraded. The aim was to determine the prognostic impact of morphological assessment of BM blasts on D7 and D19 during remission induction and the prognostic impact of the presence of MRD after remission induction. *Methods.* from January 2006 to December 2007; 62 children (1.5 years - 21 years) with newly diagnosed ALL were treated according the protocol of EORTC 58951 modified. We performed a prospective study of an early treatment response as assessed by morphological examination of BM blasts on D7,D19, and MRD determination by CMF, based strategy. All patients received phase IA with HD-MTX (D8) and cyclophosphamide (D9). 19 patients were treated according to the EORTC 58951 AR2 arm and 35 enrolled to the VHR protocol. *Results.* 62 pediatric patients (37 males and 25 females) were enrolled, 37,1% aged ≥10 years at diagnosis, 32% with a WBC ≥50 Giga/L. Immunophenotyping was done for all patients: 40 (64,5%) B-ALL, 17 (27, 4%) T-ALL, 1 undifferenciated and no contributive in 4 cases. 3/40 (7,5%) B-ALL were steroid poor responders *vs.* 12/17 (70,5%) with T-ALL; P<0.001. 42 (67.7%) patients had M3 marrow (>25%) responses on D7. On D19, 4 patients had M3 marrow. CR was 84% (52/62), induction failure and death rates were 3% (2/62) and 13% (8/62) respectively. MRD results available in 45 cases, sensitivity of 0,01%, between 0,01% and 0,1% , between 0,1% and 1% and ≥1% was achieved respectively in 33%, 27%, 20% and 20%. 3-year EFS and OS were 62.6±6.7% and 73.4%±6%. MRD < 10^{-4} at the end of induction had significantly better outcome than those with a level ≥10^{-4} (3-year EFS: 81.5%±11% if MRD <10^{-4} *vs.* 68,2%±15% if 10^{-4}<MRD≤10-3 *vs.* 77.8±13% if 10^{-3}<MRD≤10^{-2} *vs.* 37%±18% if MRD>10^{-2} , P:0.004). *Conclusion.* the treatment results of this cohort were significantly better than those of previous cohorts in terms of 3-year EFS (62.6% *vs.* 46%) and 3-year OS (73.4% *vs.* 55.4%). Early treatment as assessed by morphological examination or MRD based treatment strategy seems to be highly successful and may improve the outcomes of children with ALL in terms of relapse. However the induction death rates increased.

1183

OXIDATIVE STRESS, ANTIOXIDANT STATUS AND THEIR RELATION TO APOPTOSIS IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

A Al-Tonbary, S Abo Al-Hassan, M Zaky, A Hammad, A Fouda, S Kandil

Mansoura University Children's Hospital, Mansoura, Egypt

Introduction. Oxidative stress may play a role in the development of carcinogenesis. It is well established that some chemotherapeutic agents and radiation therapy generate reactive oxygen species (ROS) in patients during cancer therapy. Acquisition of mechanisms to evade apoptosis is a hallmark of cancer. Defective apoptotic mechanisms allow genetically unstable cancer cells to avoid elimination and confer resistance to chemotherapy. Apoptosis and cancer are opposed phenomena, but ROS may play a key role in both. *Aim of the work*. Evaluate oxidative stress (malondialdehyde (MDA) and total antioxidant capacity (TAC)) and apoptosis level in childhood ALL at diagnosis and their impact on outcome at the end of induction of remission phase. *Patients and Methods.* This study included 50 newly diagnosed children

with ALL. They were 29 males and 21 females with age mean±SD (6.84±3.73 year). Evaluation of oxidative stresses (MDA and TAC) at diagnosis and after the end of induction phase. Apoptosis was evaluated by Fluorometric TUNEL System for patients at diagnosis and after one week of treatment. *Results.* There was a significant increase of oxidative stress in children with ALL at diagnosis compared to controls (MDA: 16.61±6.55 nmol/mL *vs.* 6.42±1.52 nmol/mL, and TAC: 0.88±0.33 mM/L *vs.* 1.57±0.36 mM/L) (P<0.001). Also there was further significant increase in oxidative stress in the same patients after 5 weeks treatment with chemotherapy compared to the level at diagnosis (P<0.001). Apoptosis index was found to be significantly higher after one week treatment with chemotherapy when compared to its level at diagnosis (26.58±14.06 % *vs.* 88.45±12.11 %). Oxidative stress was found higher at diagnosis in patient who died before completion of induction. A lower apoptotic index at diagnosis was found among patients who were resistant to treatment in comparison to responsive patients. There was a significant negative correlation between TAC and MDA at diagnosis (r=-0.461, P=0.001) and after treatment (r=-0.518, P=0.001). Also, there was a positive correlation between level of oxidative stress at end of treatment and apoptosis index after 1 week. *Conclusion.* There is increased oxidative stress in children with ALL, increased ROS or decreased antioxidant capacity, which may participate in leukemia pathogenesis. Chemotherapeutic agents may further increase oxidative stress and apoptosis in ALL. Apoptotic index may serve as a predictor for response to chemotherapy. Level of apoptosis after therapy may be correlated with level of oxidative stress.

1184

CHROMOSOMAL ABNORMALITIES IN ACUTE LYMPHOBLASTIC LEUKEMIA (ALL): KARYOTYPE AND FISH STRATIFIED WORK UP

ML Chauffaille,[1] L Catelani,[2] N Kusagari,[2] G Rizzatti[2]

[1]Fleury / Unifesp, São Paulo- SP, Brazil; [2]Fleury, São Paulo- SP, Brazil

ALL constitutes a heterogeneous group of diseases resultant from the clonal expansion of lymphoid progenitors. The diagnosis is established by morphology, flow cytometric immunophenotyping and identification of chromosomal and molecular abnormalities. Different ALL subtypes have distinct response to therapy as well as diverse prognosis. Adults and children with the same genetically defined subtype can have markedly different responses to therapy and prognosis. Thus, patient age and cytogenetics are extremely important variables to stratify risk and to select therapy. The present study was conducted to evaluate the rate of chromosomal abnormalities in ALL patients diagnosed in Brazil, and to compare the rate of cytogenetically defined subtypes of ALL between adults and children in a central laboratory in São Paulo, which receives samples from the whole country. From January 1997 until December 2005 we identified 173 consecutive cases with available results from morphologic, immunophenotyping and cytogenetic tests. There was a 1.5:1 male-to-female rate; age varied from less than 1yr-old till 87yr, with the following distribution: 4% with <1 year-old; 56% from 1 to 10yr; 22% from 11 to 25yr; and 18% from 26 to 87yr. Thus, 60% of the patients were children (<10 yr), with median age of 8 years, and 40% were teenagers or adults, with median age of 47 years. Chromosomal abnormalities were detected in 80% of the cases, as follows: pseudodiploid: 15%; 47-50 chromosomes: 9%; 51-60 chromosomes: 23%; >60 chromosomes: 3%; hypodiploid: 4%; Philadelphia: 6%; t(4;11): 5%; del(11q23): 2%; t(1;19): 8%; t(8;14) or variants: 2%; Down syndrome-ALL: 2%; no *Results.* 3%. Comparing aberrations between children/teenagers (<20 years) and adult patients, the following statistically significant differences (P<0.05; student t-test) were observed: high hyperdiploid: 31% *vs.* 9%; Philadelphia: <2% *vs.* 27%, and t(1;19), 8.8% *vs.* 0%, respectively. Karyotype is considered an independent variable for ALL prognosis and allows the stratification of patients for different therapeutic options. The rate of success observed in karyotype results (80%) was satisfactory, with less than 3% of failures. Pullarkat *et al.*, (2008) have found 70% of cytogenetic evaluable results among 200 ALL cases from 15 to 60 year-old patients in the SWOG study. The Philadelphia chromosome was more frequently detected among adult patients in the present study, as previously shown by others (Pullarkat *et al.*, 2008), while the t(1;19) was not detected in adults. High hyperdiploid karyotypes (51-60 chromosomes) was frequent among children, as expected. The percentage of normal cases was 21.6% and 20% for children and teens/adults, respectively, similar to others (Pullarkat *et al.*, 2008). As fluorescent *in situ* hybridization (FISH) is still an expensive method for routine use in developing countries, the strategy designed was to add FISH for the investigation of chromosomal abnormalities only in patients with normal karyotype. A subsequent analysis with FISH using probes for ALL (Chromoprobe Multiprobe ALL-System,Cytocell, England) in 19 ALL cases with normal karyotype identified abnormalities in 9 of them, involving the following genes: CHIC2, P16, IgH, E2A and AML1. Therefore, this stratified work up is a cost-effective approach to detect clinically relevant genetic abnormalities in ALL.

1185

TREATMENT OF PHILADELPHIA-POSITIVE ADULT ACUTE LYMPHOBLASTIC LEUKEMIA IN REAL LIFE: EXPERIENCE OF ONE CENTRE

F Folber, T Jurcek, M Krejci, Y Brychtova, J Mayer, M Doubek

University Hospital Brno, Brno, Czech Republic

Background. Philadelphia chromosome positive acute lymphoblastic leukemia (Ph+ ALL) in adult patients is associated with a particularly unfavorable prognosis, although some progress has been made recently with the use of tyrosine kinase inhibitors (TKIs). *Aims.* Assessment of outcomes of Ph+ ALL patients treated with or without a TKI in one hematological center. *Methods.* Twenty-four consecutive patients with newly diagnosed Ph+ ALL were included in the analysis, 14 (58%) patients were treated with chemotherapy and a TKI (imatinib in all cases), 10 (42%) with chemotherapy alone, mostly in the pre-TKI era. Eleven (46%) patients underwent stem cell transplantation (SCT); 8 matched unrelated donor SCT, one HLA identical sibling donor SCT and 2 autologous SCT. Data were evaluated for complete hematologic remission (CR), complete molecular remission (CMR) and relapse rates and for risk factors affecting overall survival (OS). We were mostly interested in the effect of adding a TKI to chemotherapy. *Results.* Out of the total number of 24 patients, 19 (79%) achieved a CR (median time to CR 37 days, range 6-68 days), 12 (75%) of 16 evaluable patients achieved a CMR (median time to CMR 67 days, range 32-358 days). Nine (47%) patients experienced a relapse (median time to relapse 7.6 months, range 1.1-37.5 months) with a very short post-relapse survival regardless of the type of salvage therapy. Molecular relapse was in all but one cases followed by a hematological relapse (median time to molecular relapse 2.9 months, range 1.4-13.1). At the end of the follow-up period with a median of 8.7 months, 8 (33%) patients were still alive in CR (only one treated in the pre-TKI era) and 16 (67%) died, mainly of infection (9 patients, 56%) and disease progression (5 patients, 31%). Median OS was 9.2 months; the highest survival benefit was seen in patients achieving a CR (P<0.001) or a CMR (P=0.026) and treated with allogeneic SCT (P=0.003). The addition of a TKI to chemotherapy was associated with a higher CR (P=0.075) and CMR rate (P=0.05), but neither with a lower relapse rate (P=0.26) nor a prolonged OS (P=0.13). *Summary/Conclusions.* According to our analysis, in patients with Ph+ ALL the best outcome is achieved with the combination of chemotherapy, TKI and allogeneic stem cell transplantation.

SECOND GENERATION TYROSINE KINASE INHIBITORS CAN INDUCE COMPLETE MOLECULAR RESPONSE IN PH-POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA RELAPSING AFTER ALLOGENEIC STEM CELL TRANSPLANT

S Ulisciani,[1] C Fava,[2] M Falda,[3] F Locatelli,[3] A Busca,[3] S D'Ardia,[3] E Gottardi,[2] F Daraio,[2] E Giugliano,[2] L Giaretto,[2] G Saglio,[2] G Rege Cambrin[2]

[1]Internal Medicine, Orbassano, Italy; [2]Internal Medicine, S. Luigi Hospital, Orbassano (TO), Italy; [3]Bone Marrow Unit, Molinette Hospital, Torino, Italy

Background. Allogeneic stem cell transplant (SCT) is thought to be the only curative therapy for Ph+ acute lymphoblastic leukemia (ALL). New therapeutic strategies, including combination of tyrosine-kinase inhibitors (TKI), chemotherapy and SCT may improve results in terms of complete remission and disease free survival. Dasatinib was highly active both in imatinib-resistant patients and as front-line treatment. Nilotinib has also shown activity in Ph+ALL in phase I studies. Few cases of successful dasatinib and nilotinib therapy in Ph+ALL relapsing after BMT have been reported, either in adults or pediatric patients *Aims.* We report two cases of Ph+ALL relapsing after allo-SCT who obtained a complete response with II generation TKI. *Results. Case 1.* A 21-year-old man was diagnosed of Ph+ALL in March 2006. He was administered chemotherapeutical treatment with Hyper-CVAD plus imatinib, obtaining a complete haematological response (CHR) and complete cytogenetic response (CCyR) maintained over treatment while major molecular response (MMR) was never achieved. Eight months after diagnosis the patient was submitted to a SCT from match unrelated donor (MUD)

with myeloablative conditioning (TBI and cyclophosphamide). Three months after transplant the disease relapsed. Treatment with dasatinib was started at 70 mg bid. Blast clearance in PB was obtained in 5 days, and was accompanied by a tumor lysis syndrome. CHR was achieved after 1 month, and complete molecular response (CMR) was obtained after 4 months of therapy. Donor Lymphocyte Infusions (DLI) were administered every 6 weeks for a total of 5 infusions. No signs of GVHD were observed. Due to a grade 2 diarrhea, dasatinib dosage was reduced to 120 mg/day. The patient is in good clinical conditions and bone marrow is persistently PCR negative 34 months after relapse. *Case 2.* A 18-years-old boy was diagnosed as Ph+ALL in December 2008. He was treated with high dose chemotherapy and imatinib, obtaining a CHR with persistence of molecular disease. In May 2009 he underwent a allogeneic MUD transplant after TBI and cyclophosphamide. In spite of complete engraftment and BCR/ABL transcript reduction (not reaching MMR), he relapsed in October 2009. He started treatment with dasatinib 70 mg bid, resulting in blast clearance and recovery of 93% chimerism at day 15. A single dose of DLI was administered at day 60. After 3 months a full donor chimerism with <0.1% blasts was observed in the bone marrow. The patient however complained of diarrhea G3 and dasatinib was stopped at month 4, when nilotinib 400 mg bid was started. Diarrhea resolved and the patient is well and in CMR five months after relapse. *Conclusions.* Our patients showed a prompt response to dasatinib treatment. In one case, it was associated with DLI infusion, and CMR is stable 34 months after relapse, with full donor chimerism. In the second case, dasatinib therapy was accompanied by gastrointestinal toxicity which resulted in change to nilotinib, with persistent disease response. Second generation TKI can rescue Ph+ ALL patients after SCT failure. Role of DLI in this setting is unclear, but warrants further investigation.

1187

ACQUISITION OF THE NOVEL COMPOUND ABL KINASE DOMAIN MUTATION T315L IN A RELAPSED PHILADELPHIA-POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA PATIENT

GF How,[1] M Mueller,[2] LC Lim[1]

[1]Singapore General Hospital, Singapore, Singapore; [2]III. Med. Klinik, University of Heidelberg, Mannheim, Germany

Background. The incorporation of the tyrosine kinase inhibitor imatinib mesylate for frontline treatment of Philadelphia-positive acute lymphoblastic leukemia (Ph^+ ALL) has significantly improved the antileukemic efficacy of induction therapy. Several ALL study groups have demonstrated complete remission rates above 90% in patients undergoing imatinib-containing therapeutic regimens and improved long-term outcome in these patients. Despite such improvement, however, relapse does occur largely due to acquisition of imatinib resistance. Although numerous point mutations in the ABL kinase domain that impair imatinib binding have been identified as a major mechanism of acquired resistance in CML patients, similar data on Ph^+ ALL patients are more limited. Here, we describe a case in which a novel ABL kinase domain mutation was detected at relapse in a patient with Ph^+ ALL. *Case report.* A 50-year old male was diagnosed with acute lymphoblastic leukemia at our institution in January 2009. His bone marrow karyotype was 46,XY,t(9;22)[15]/ 47, idem,+der(22)t(9;22)[4],46,XY[1]. Reverse transcriptase polymerase chain reaction (RT-PCR) demonstrated presence of the p190 BCR-ABL fusion transcript. He underwent chemotherapy with hyperCVAD-imatinib mesylate. Complete morphological and cytogenetic remissions were achieved as documented by bone marrow studies performed after 2 rounds of chemotherapy, following complete recovery of white cell and platelet counts. Molecular studies did not detect the p190 fusion transcript in 2 consecutive peripheral blood specimens collected in March and April 2009. However, following the sixth cycle of chemotherapy in September, he was noted to have 3% blasts in his peripheral blood and reappearance of p190 BCR-ABL fusion transcript. Bone marrow aspirate revealed relapsed ALL. Cytogenetic studies revealed recurrence of the Philadelphia clone. Mutation analysis to detect ABL kinase domain mutations was performed on both peripheral blood and bone marrow specimens collected on relapse. Both demonstrated the presence of a novel ABL kinase mutation, T315L, which has not been previously described in the literature. This mutation was absent in the bone marrow specimen collected at diagnosis. Mutational analysis of the ABL kinase domain was performed using direct sequencing approach. Amplified products were sequenced in both forward and reverse directions. Nucleotide changes were observed at positions 943A>C and 944C>T (Genbank NM_005157.3 CDS), resulting in a T315L mutation. Cloning experiments confirmed the presence of the T315L mutation in a single clone. Therapy with dasatinib was initiated. The patient failed to achieve remission after 2 months and the disease was refractory to chemotherapy. He subsequently died of fulminant sepsis. *Conclusions.* This is a unique case report detailing the finding of a novel compound mutation T315L detected at relapse in a p190 Ph^+ ALL patient which was associated with TKI resistance. Although the impact of a T315L mutation on the clinical efficacy of imatinib or dasatinib is not certain, it is likely that this mutant disrupts binding of TKIs in a way similar to the T315I mutant. Perhaps in-vitro studies to evaluate its grade of resistance towards all common TKIs could help to assess this further.

1188

ERWINIA ASPARAGINASE AS THE ALTERNATIVE USAGE FOR E. COLI ASPARAGINASE-ALLERGIC CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA IN KOREA

KD Park,[1] HY Shin,[1] HJ Kang,[1] HS Ahn,[1] SH Lee,[2] KH Yoo,[2] HH Koo,[2] HJ Lim,[3] JJ Seo,[3] SK Kim,[4] JO Hah,[5] HJ Park,[6] JE Park,[7] SS Park,[8] YT Lim,[8] JA Lee[9]

[1]Seoul National University College of Medicine, Seoul, South-Korea; [2]Samsung Medical center, Seoul, South-Korea; [3]Asan Medical Center, Seoul, South-Korea; [4]Inha University College of Medicine, Incheon, South-Korea; [5]Yeungnam University College of medicine, Daegu, South-Korea; [6]National Cancer Center, Goyang, South-Korea; [7]Aju University College of Medicine, Suwon, South-Korea; [8]Pusan National University College of Medicine, Busan, South-Korea; [9]Korea Cancer Center Hospital, Seoul, South-Korea

Background. Escherichia coli (*E. coli*) asparaginase is an active drug of treatment for childhood acute lymphoblastic leukemia (ALL). However, the side effects of E. coli asparaginase develops very often. We inquired out the incidence of the side effects of E. coli asparaginase in Korea, and evaluated the safety of subsequent use of Erwinia asparaginase, an alternative preparation, in E. coli asparaginase-allergic patients. *Patients and Methods.* Between 2006 and 2009, medical records of 379 children with newly diagnosed ALL in 8 hospitals of South Korea were reviewed to inquire out the major side effects, which made the administration of L-asparaginase discontinued, including allergic reaction, pancreatitis, hemorrhagic event, and thrombotic event. *Results.* 1) Seventy-three patients(19.2%) developed the side effects of E. coli asparaginase. Sixty of 73 patients had allergic reaction. 37 patients had mild local reaction, but the 23 patients had systemic allergic reaction. Other E. coli asparaginase related side effects included pancreatitis(4 patients), coagulopathy (3 patients), and a hemorrhagic event(a patient). Side effects were more frequent in high risk group (55patients) than in standard risk group (19 patients). 2) Sixty-one patients switched to Erwinia. Among them, 4 patients had allergic reaction. 3 patients had local reaction, and a patient had systemic reaction. Only 4 patients(1%) from 379 patients had a allergic reaction to both type of E. coli and Erwinia asparaginase. *Conclusions.* Erwinia asparaginase was well tolerated and acceptable for E. coli asparaginase-allergic patients. E. coli asparaginase with subsequent Ewinia asparaginase in E. coli asparaginase allergic patients could be the way to overcome the sensitization by asparaginase antibody. Especially in high risk ALL, Erwinia asparaginase should be considered for E. coli asparaginase-allergic patients.

1189

FLT3 MUTATIONS IN MLL-REARRANGED INFANT ACUTE LYMPHOBLASTIC LEUKEMIA (ALL): EXPERIENCE OF A SINGLE PEDIATRIC INSTITUTION

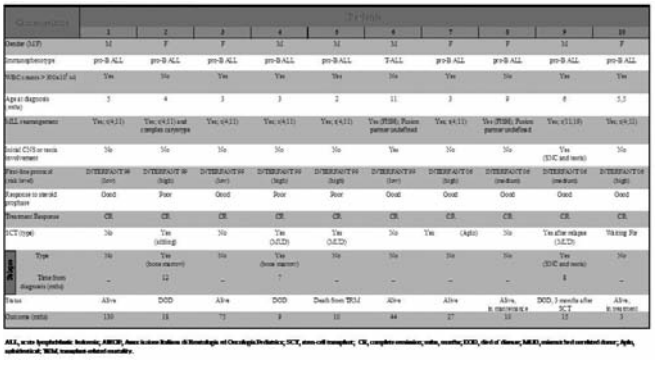
R Parasole,[1] F Petruzziello,[1] B Izzo,[2] R Parasole,[1] G Muccioli Casadei,[2] V Farina,[2] G Menna,[1] G Maisto,[1] A Mangione,[1] F Pane,[2] V Poggi[1]

[1]Pausilipon Hospital, Naples, Italy; [2]BBM Department, Ceinge Institute, University of Naples, Naples, Italy

Background. Acute lymphoblastic leukemia (ALL) of infant (up to 1 years of age) is characterized by poorer prognosis compared with older children, high frequency of MLL-rearrangement and major resistance to chemotherapeutic agents. New therapeutic targets have to be identified for improving the outcome of MLL-rearranged ALL. Recent study have demonstrated mutations of FLT3 in approximately 15% of infants with MLL-rearranged ALL and various clinical trials with FLT3 inhibitors are under investigations. Besides highest levels of FLT3 mRNA expression have been reported in leukemic infant cells with MLL-rearrangement. Aim of the study was to assess the presence of FLT3/internal tandem duplications (ITDs) as well as D835 mutation of

FLT3 in infant ALL with MLL-rearranged treated in a single pediatric Institution. *Patients and Methods.* From January 2000 to January 2009, 10 infants (range, 2-11 months), with MLL-rearranged ALL, were enrolled in INTERFANT-99 and INTERFANT-06 protocols in our Institution. All patients, except one with a T-cell ALL, had a CD10- proB immunophenotype; 6 infants presented at diagnosis a WBC counts more than 300×10^3/mmc and two-thirds of patients were younger than 6 months. Table 1 resume the characteristics of patients. Primary bone marrow samples of patients were retrospectively studied for ITDs and D835 mutation and possible correlation between FLT3 mutations and prognosis was investigated. Genomic DNA of all patients was extracted from bone marrow aspirate using standard procedures. PCR fragments of FLT3 gene were amplified using the following oligonucleotide primers: ITD-Forward (ITD-F) (5'-TGTCGAGCAGTACTCTAAACA-3'), ITD-Reverse (ITD-R) (5'-ATCCTAGTACCTTCCCAAACTC-3'), D835-F (5'-AGAAGAGGAGGACTTGAATGTGCTTA-3'), D835-R (5'-TCCATATGACCAGACATCACTCTTAAT-3'). Internal tandem duplication as well as D835 mutation in the FLT3 gene were screened by DHPLC (denaturing high performance liquid chromatography; Wave System; MD Transgenomic Inc., Omaha, NE). Electropherograms from patients were compared with normal sequenced controls. The levels of FLT3 mRNA expression using quantitative real-time PCR were not performed. *Results.* None of the infant ALL harboured ITDs and D835 mutation of FLT3, so no correlations with prognosis could be found. Six infants are alive in CR (of whom 4 off-therapy and 2 in treatment) and 4 died (3 from disease and 1 from transplant toxicity). Five patients underwent an allogeneic transplant, of whom only one is alive in CR ; 3 infants relapsed after BMT and one died from TRM. Four patients were treated with chemotherapy alone and are alive in CR (1 is still in maintenance) and the last one is waiting for a mismatched unrelated donor (MUD) transplant. No patient was treated with FLT3 inhibitors. *Conclusions.* Our results are in accordance to previous studies indicating a lower incidence of FLT3 mutations in MLL-rearranged infant ALL. In our simple size sample, we analyzed only ITDs and D835 mutation of FLT3 in infant ALL. Probably other FLT3 mutations are involved in the ethiology of FLT3 expression. Since FLT3 inhibitors seem effective in MLL-rearranged infant ALL, further study are necessary to assess the potential impact of FLT3 in the pathogenesis of infant ALL.

Table 1. Clinical characteristics o infant ALL.



1190

TREATMENT OUTCOME OF ADOLESCENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA IN A TUNISIAN CENTER

L Aissaoui, Y Ben Abdennebi, W Bouteraa, R Jeddi, K Kacem, R Ben Amor, R Ben Lakhal, Z Bel Hadj, H Ben Abid, B Meddeb

Aziza Othmana Hospital, Tunis, Tunisia

Introduction. Retrospective studies have shown that adolescents with acute lymphoblastic leukemia (ALL) treated with paediatric protocols have better outcomes than those treated with adult ones but with an increase in hematologic toxicity. *Purpose.* Comparison of the clinical characteristics, laboratory features, results of the treatment outcome and specially the toxicity of adolescent and younger children with newly diagnosed ALL treated at the department of hematology of Aziza Othmana Hospital. *Patients and Methods.* Between January 2005 and December 2006, 62 ALL up to 21 years of age were assessed and treated according to the EORTC 58951 paediatric protocol. The patients were subdivided in two groups according to their ages: -First group children who were <15 years old and the second group consisted of adolescents aged between 15 and 21 years old. *Results.* 11 patients were assessed in the second group (18%).There were no differences between the two groups with respect to gender, WBC count and CNS involvement at diagnosis. However the distribution of T ALL and the poor corticosteroid response were more frequent in the second group with respectively 46% *vs.* 23.5% (P<0.0001) and 54.5% *vs.* 19.6% (P=0.02). When adolescent and younger were compared to each other, there were no statistically significant differences in hematologic toxicity in induction, consolidation and reinforcement cycles, in CR (100%vs 89%), in relapse rates (27% *vs.* 18%), in OS (81% *vs.* 70%) and in EFS (61.4%vs 62.4%). *Discussion.* Data seem to indicate that adolescents with ALL have a similar prognostic to this of young children, despite predominance of T ALL and poor corticosteroid response, when treated with paediatric protocols without more toxicity. *Conclusion.* Adolescents and young adults with ALL might benefit from paediatric protocols

1191

AZACYTIDINE AS A NOVEL AGENT IN THE TREATMENT OF ACUTE LYMPHOBLASTIC LEUKEMIA

C Paulson, R Kumar, M Seftel

University of Manitoba, Winnipeg, Canada

Background. 5-Azacytidine (AZA) is a hypomethylating agent with activity in myelodysplastic syndrome (MDS) and acute myeloid leukemia (AML), but not in acute lymphoblastic leukemia (ALL). The transformation of MDS into ALL, while far less common than transformation into AML, is a rare but known complication. *Aims.* We present the first case report of AZA with activity in ALL evolving from MDS. *Methods.* A 74-year-old woman initially presented in 2005 with moderate thrombocytopenia (83×10^9/L). An initial bone marrow aspirate (BM) was consistent with MDS (refractory cytopenia with multilineage dysplasia). She did not require chemotherapy or transfusions at that time. In January 2009, she developed worsening pancytopenia, and a BM showed an abnormal population of immature lymphocytes, with a pre-B cell phenotype (CD34, CD19, CD10, CD79a, and CD22 positive, and CD20 and surface immunoglobulin negative). This population represented 43% of all nucleated cells in the marrow by flow cytometry. She received therapy targeting the ALL, consisting of intravenous cyclophosphamide (750 mg/m^2), vincristine (1.4 mg/m^2), and oral prednisone. She tolerated therapy poorly, with a prolonged hospital admission for a febrile neutropenic episode. A second regimen consisting of 6-mercaptopurine (50 mg/m^2 given intravenously 14 days out of a 21 day cycle), vincristine (1.4 mg/m^2), and dexamethasone was administered. Again, she did not tolerate this chemotherapy, and no additional systemic chemotherapy was offered. A repeat bone marrow aspirate showed that the pre-B cell immature lymphocytes persisted. Hypothesizing that a portion of her pancytopenia was due to the underlying MDS, she received AZA as per protocol for MDS (75 mg/m^2, subcutaneously for seven consecutive days out of a 28 day cycle) with the objective of improving cell counts and decreasing transfusion requirements. *Results.* She received a total of 6 cycles of AZA, with a significant hematological response. There was improvement in all of her cell lines, with a platelet count rising from 26 at presentation to 65 after four cycles of azacytidine. A repeat bone marrow aspirate performed after four cycles of AZA showed the immature B-cell population, which had represented 43% of all nucleated cells initially, had been reduced to 2% while the del20q abnormality remained. *Conclusion.* AZA has demonstrated activity in patients with MDS and in AML, but not in ALL or other lymphoproliferative disorders. In this ALL patient with underlying MDS, AZA resulted in significant anti-leukemic activity. Azacytidine deserves further laboratory and clinical investigation as a possible novel agent in the treatment of ALL.

Table. Bone marrow aspirate findings.

	WBC (10^9/L)	ANC (10^9/L)	Hb (g/L)	Platelet Count (10^9/L)	Blast Count (% of nucleated cells by flow cytometry)	Karyotype
April 7, 2005 (Initial Presentation)						
	3.7	1.5	128	70	None	N/A
January 23rd, 2009 (Clinical Deterioration)						
	2.7	1.35	106	26	43%	del20q
April 24, 2009 (Post Systemic Chemotherapy)						
	2.8	1.29	86	24	28%	del20q
November 9th, 2009 (Post 4 Cycles 5-AZA)						
	3.52	1.58	102	64	2%	del20q

FEASIBILITY OF HYPER-CVAD IN ADOLESCENTS AND ADULTS PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA

R Portugal, W Pulcheri, M Loureiro, M Nucci

Federal University of Rio de Janeiro, Rio de Janeiro, Brazil

Background. Despite improvement in cancer treatment during the last decade, the majority of adult patients with acute lymphoblastic leukemia eventually relapses and has a long term survival of less than 40%. *Aims.* The objectives of the current study were to evaluate the rate of complete remission and long term survival of patients treated in a single institution with the Hyper-CVAD regimen (four cycles of fractionated cyclophosphamide, vincristine, doxorubicin, and dexamethasone alternating with four cycles of methotrexate and cytarabine). *Methods.* Between December 2000 and April 2009, 38 adolescents and adults patients admitted to our institution received at least one cycle of frontline Hyper-CVAD. No exclusions were made because of older age, poor PS, organ dysfunction, or infection (including HIV infection). *Results.* The median age of the patients was 27 years (range 13-71 years) and 14 (37.8%) patients were classified as standard risk according to MRC UKALL/ECOG criteria. We identified 10 patients with T immunophenotype (27%), 4 patients with Ph^+ (23.5% of patients where the research was performed) and one patient with HIV. A complete response (CR) was achieved in 36 patients (94.7%) and 2 patients (5.3%) died during remission induction. Only two patients received allogeneic marrow transplantation in first CR. After a median follow-up time for alive patients of 45.4 months (range 10 to 102 months), 16 patients (42.1%) are still alive, 13 in first complete remission. The median overall survival (OS) was 24.4 months and the estimated 5-year OS was 34%. Among patients that achieved CR, the median event (relapse or death) free survival (EFS) was 19 months and the 5-year EFS was 30.5%. The median OS (36.2 months) and EFS (25.5 months) were favorable for standard risk patients but the difference did not reach statistical signifficance. *Conclusion.* The Hyper-CVAD regimen yielded satisfactory results in our institution. The rates of CR and survival were similar to obtained by other published series.

1193

IMPROVEMENT IN SURVIVAL OF ADULTS WITH ACUTE MYELOID LEUKEMIA IN A BRAZILIAN UNIVERSITY CENTER FROM 1980S TO THE EARLY 21ST CENTURY

R Portugal, J Souto Filho, M Loureiro, M Nucci, W Pulcheri

Federal University of Rio de Janeiro, Rio de Janeiro, Brazil

Background. Treatment of acute myeloid leukemia (AML) has improved during the last decades with enhancement of induction and postremission chemotherapies, development of autologous and allogeneic transplantation and supportive care progress. Nevertheless, population-based studies describe lower rates of long-term remissions. Previous report from our group showed that 37.6% of patients were too ill to receive chemotherapy and that was a main cause of failure. *Aims.* To evaluate recent treatment outcomes of AML diagnosed patients admitted to the University Hospital - Federal University of Rio de Janeiro over the past 30 years. *Methods.* By chart review, we retrospectively evaluated all patients diagnosed with AML at our institution, from January 1979 to December 2008. The diagnostic of AML was performed based on available procedures at the time, including bone marrow aspiration, bone marrow biopsy, cytogenetic and immunophenotyping analysis. Cases were classified according to de French-American-British (FAB) criteria and cases of acute promyelocytic leukemia (M3) were excluded. Patients were arranged into curative-intent, paliative-intent or no chemotherapy groups. *Results.* Of 295 patients with AML identified in hospital records, 68 were excluded (65 APL and 3 previously treated in other institutions). Among 227 patients analyzed, 125 were male and 102 female and the median age was 45 years (12-91), with 24.7% older than 60 years. Remission induction chemotherapy was used in 169 patients and 52.1% reached complete remission and 36.1% died before remission evaluation. Overall survival (OS) at 3 and 5 years for all patients was 14% and 13%, and in the treated group 18% and 17%, respectively. The distribution of cases for each time period was: 39% in 1980s, 32% in 1990s and 29% in 2000s. Stratifying by decades, the median survival were 40, 77 and 112 days (P=0.01), and 5 year OS were 7%, 13% and 22%, respectively. The proportion of treated patients was respectively 66.3%, 75.3%and 84.6%. Among treated patients (n=169) the median survival were 68, 205 and 208 days (P=0.05), and 5 year OS were 10%, 17% and 26% in each decade, respectively. The decade distribution was associated with better survival in a multivariate analysis. *Conclusion.* Previously, our group reported that no less than 37% of patients with AML were too ill to receive any treatment. This is in agreement with the current data of 66.3% of treated patients during the 80´s. In the last decade almost 85% of patients were treated. The survival expectations of patients with AML have substantially improved during a 30 years period and seems to be closer to those reported for patients living in developed countries and treated in randomized clinical trials

1194

THE OUTCOME OF THE ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS TREATED WITH INTENSIVE CHEMO-RADIOTHERAPY FOR THE FIRST 45 DAYS OF DISEASE - ROMANIAN WORKING GROUP FOR ADULT ACUTE LEUKEMIA STUDY EXPERIENCE

A Moicean,[1] A Catana,[2] A Dumitrescu,[1] E Benedek,[3] I Benedek,[3] I Kopeczi,[4] A Dascalescu,[5] B Ionescu,[1] M Brinza,[1] H Bumbea,[6] C Marinescu,[6] C Truica,[2] A Gaman,[7] G Gaman,[7] V Teleanu[1]

[1]Fundeni Clinical Institute, Bucharest, Romania; [2]Districtual Hospital, Sibiu, Romania; [3]Clinic of Hematology and Bone Marrow Transplantation, Targu-Mures, Romania; [4]Clinic of Hematology and bone Marrow Transplantation, Targu-Mures, Romania; [5]Sf. Spiridon Hospital, Iasi, Romania; [6]University Hospital of Emergency, Bucharest, Romania; [7]University of Medicine and Pharmacy, Craiova, Romania

Background. The treatment is the main prognostic factor in adult acute lymphoblastic leukemia. The outcome of these patients is considerably determined by the first months of treatment. Minimal residual disease (MRD) negative patients after inductions have a better outcome *vs.* the MRD positive patients. *Material and Methods.* We have studied 42 adult patients with acute leukemia enrolled after written consent signature in Romanian National Protocol for acute lymphoblastic leukemia treatment (RWGALS-NP1) between 2007 and 2009. The range of age was 37.2 years (17-74). There were 5 bifenotypic acute leukemia, 1 T-ALL, and 5 Ph+ ALL. For first 45 days of treatment the patients received 2 inductions chemotherapy: Induction I: Dexametazone 10 mg/sm p.o. days 6-7, 13 - 16, Vincristin 2 mg i.v, days 6, 13, 20, Daunorubicine 45 mg/sm i.v. days 6-7 and 13 - 14, E.Coli Asparaginaze 5000 U/sm days 18, 20, 22, 24, 26. Induction II: Ciclofosfamida 1000 mg/sm days 26 and 46, AraC 75 mg/sm i.v. days 28 - 31, 35 - 38, and 42-45, Purinethol 60 mg/sm p.o days 26-46. For CNS prophylaxis the patients received: Metotrexat 15 mg i.t days 1, 28, 35, and 42 and radiotherapy 24 Gy, from day 24 until day 44. *Results.* After first induction (day 26), 25 patients (60%) were in complete remission and 7 patients (17%) in partial remission. Two patients died during first induction and other 2 patients refused to continue the treatment due to severe treatment-related toxicity (mucositis grade III-IV, liver toxicity and infections). More 8 patients had complete remission after the second induction (day 45). Overall complete remission day 45 was 78.5%. During the second induction (combined chemotherapy and radiotherapy), 82% of patients had severe treatment related toxicity (mucositis grade III-IV, liver toxicity, infections, thrombocytopenia with cerebral or gastric bleeding). For 35% of patients there were protocol violation concerning the doses and the timing of chemotherapy, with a range delay of 14 days. Three patients died during second induction and other 4 patients refused to continue intensive chemotherapy after second induction due to severe treatment related toxicity. Overall survival was 19 months and disease-free survival was 17 months. *Conclusion.* The intensive induction therapy for adult acute leukemia patients combining chemotherapy and radiotherapy is not feasible in low income countries due to the difficulties to provide the supportive therapy. The new protocols for treatment of acute lymphoblastic leukemia patients that avoid radiotherapy using liposomal cytarabine based CNS prophylaxis seem be more appropriate in low income countries.

1195

TREATMENT OUTCOMES OF ADULT ACUTE LYMPHOBLASTIC LEUKEMIA TREATED WITH CALGB 1188 WITHOUT L-ASPARAGINASE

M Ghadiany, M Tabarrai, M Mehdizadeh, P Sadri, A Hagifathali

Shahid Beheshti University of Medical Science, Tehran, Iran

Background. Acute lymphoblastic leukemia (ALL) is a treatable hematologic malignancy .Importance of L-asparaginase in treatment of adult ALL is controversial. CALGB 1188 is an effective protocol for treatment of adult ALL. This protocol contains L-asparaginase with signifi-

cant side effects in adults. To find the importance of L-asparaginase , we evaluated patients treated with CALGB 1188 without L-asparaginase . *Materials and Methods.* we searched the hospital documents from 2007 to 2009 for ALL patients treated with CALGB 1188 but did not receive L-asparaginase . Response rate , disease free survival and overall survival of these patients were analyzed. *Results.* Seventeen patients were treated with above protocol . Patients' age ranged from 16 to 64 years with mean age of 24.8 years. 57% were male and 23% were female. Complete response was achieved in 65% (11 of 17 patients). Disease free survival was 11.8 months in patients with complete response. Median of overall survival was 14.3 months. 5 of 17 patients were alive at the time of writing this paper. *Conclusion.* In our study 65% of patients achieved CR that is acceptable in comparison with most other studies (64% to 74%), but it is lower than CALGB 1188(85%). DFS and OS were also less than CALGB 1188. The cause of this lower result can be omitting L-asparaginase. Other factors such as our ward's conditions, facilities, prognostic and cytogenetic factors have effects on CR and survival. Since this study was retrospective, we could not evaluate the exact roles of these factors. It seems that L-asparaginase is important in CALGB1188 and if possible it should not be omitted.

1196

PHILADELPHIA POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA. IMPROVED OUTCOME IN THE TYROSINE KINASE INHIBITOR ERA

M Dima,[1] A Cucuianu,[1] M Patiu,[1] L Petrov,[1] H Dohner[2]

[1]Ion Chiricuta Cancer Institute, Cluj-Napoca, Romania; [2]Department of Internal Medicine III, Ulm, Germany

Background. The prognosis of Philadelphia chromosome (Ph) positive acute lymphoblastic leukemia (ALL) is poor. But the incorporation into frontline treatment of tyrosine kinase inhibitor (TKI) imatinib has significantly improved the antileukemic efficacy of induction therapy and the prognosis in these patients. *Aim.* To assess the prevalence of Ph^+ ALL in a cohort of Romanian ALL patients and their outcome after treatment with tyrosine kinase inhibitors and chemotherapy. *Methods.* There were 35 ALL patients diagnosed and treated in our institution between 2007 and 2009. There were 20 males (57%) and 15 females (43%), with median age of 38 years (19-66). Fifteen patients were diagnosed with preB/common ALL, 7 patients with mature B cell ALL, 11 patients with T cell ALL and the phenotype could not be determined in 2 patients. Eight patients (22%) presented Ph positive ALL. Four patients presented complex karyotype (in one case associated with Ph chromosome), there was a duplication of Ph chromosome in 1 patient and a loss of chromosome 9 in 1 patient. Among the Ph positive ALL patients the major and minor breakpoint cluster region (BCR) rearrangements were equally distributed. 24 patients presented with leucocytes<30000/μL and 11 patients with >30000 leucocytes/μl. There were 3 patients with clinical CNS disease and 2 other patients with blastic meningitis with no clinical expression. All patients were treated with ALL-type combination chemotherapy. Imatinib at 600mg/day was added to chemotherapy in 6 out of 8 Ph positive ALL patients. Allogeneic stem cell transplantation was only available in one patient, Ph-negative. *Results.* We observed 25 complete hematological remissions (71%). Of the 8 Ph positive ALL patients, complete response was obtained in 6 patients (75%); in 1 patient complete cytogenetic response was obtained and in another patient major molecular response was obtained. There were 11 relapses (44%) among the whole group, only one in the Ph positive group (16.6%). There were 3 deaths among the Ph+ALL patients, 2 of these patients dying soon after the diagnosis (before TKI treatment was started) and the third died after relapse and failure of salvage treatment with chemotherapy and second generation TKI nilotinib and dasatinib. The median overall survival (OS) (determined by Kaplan Meyer) for our cohort was 36 months and the median disease free survival (DFS) was 24 months. The median OS for Ph positive ALL patients was not reached, 53% being still alive as of February 2010. The median OS for non-Ph positive ALL patients was 36 months. The median DFS for Ph^+ALL patients was not reached, 53% being in remission while the median DFS for non-Ph positive ALL patients was 26 months. Despite this apparently better results in Ph-positive patients, the differences were not statistically significant. *Conclusions.* Even though Ph-positive ALL is considered to have a particularly poor prognosis, this did not reflect in our series, although the number of patients was small and the follow-up was relatively short. Is is possible that the routine introduction of TKI treatment in Ph-positive ALL may also improve the long-term prognosis of Ph positive ALL patients, even in the absence of allogeneic hematopoietic stem cell transplantation.

1197

ACUTE LYMPHOBLASTIC LEUKEMIA AND PREGNANCY: A CASE REPORT

MR Specchia, P Mazza

Hospital S.G. Moscati, Taranto, Italy

In August 2008 a 19 years old girl was referred to our institution because of superficial lymph nodes without systemic symptoms. The peripheral blood showed leucocytosis, anemia and thrombocytopenia (WBC 21800/mmc, Hb 9.9 g/dL, PLT 99000/mmc). The patient was at the 16th week of pregnancy. A lymph node biopsy was compatible with pheripheral T cell Lymphoma, while the bone marrow analysis by morphology and multiparametric flow cytometry were compatible with diagnosis of T Acute Lymphoblastic Leukemia ($cyCD3^+$, $cyTdT^+$, $cy79a^+$, $CD7^+$, $CD5^+$, $CD4^+$, $CD2^+$, $CD10^+$) with blast counts superior to 75%; the cytogenetic analysis showed a complex cariotype: 46,XX, add(2)(q?33), del(6)(q?31), del(10)(q?24). Our aim was to cure leukaemia possibly avoiding any hindrance against pregnancy. After informed consent the patient received induction chemotherapy with Adriamycin (30 mg/sqm iv) plus Oncovin (1.4 mg/sqm iv) days 8,15,22,29 and Prednisone 60 mg/sqm/d for 30 consecutive days. Prophylaxis on CNS was performed with intrathecal administration of liposomal Cytarabine days 1,15,30,45. A bone marrow biopsy performed at the fourth week of therapy showed a CR either morphological either at flow cytometry, the cariotype was normal too. The pregnancy was uneventful and the child was growing correctly. The second course of induction therapy consisted of Cytarabine (75 mg/sqm/d iv for 4 days/weekly for 4 cycles). At the 34th week of pregnancy an healty newborn baby was delivered by caesarum partum with a weight of 2100 g. After one month the patient received consolidation therapy with HAM regimen and collection of pheripheral blood stem cells. In Febrary 2009 she underwent autologous stem cell transplantation. Conditioning regimen consisted of Thiotepa (10 mg/Kg iv day -5) plus Cyclophosphamide (60 mg/Kg/d iv from day -3 to -2) followed by reinfusion PBSC for 9.75×10^6/Kg $CD34^+$ cells. She achieved haematological recovery at day +10. The extrahaematological toxicity during phase of cytopenia was mild and transient. In April 2009 she started maintance therapy according scheduled ALL GIMEMA protocol. The patient is still in CR and her little baby grows normally without apparent deformities. In conclusion the cure of ALL during pregnancy is possible safeguarding the foetus and its maturation. A reasonable therapeutic strategy should be warranted in order to avoid main problems due to single chemotherapy agents.

1198

CA 125 IS A USEFUL MARKER FOR SEROSAL INVOLVEMENT IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA

M Badr, L Sherif, A Fathy, M Almalky

Zagazig University, Zagazig, Egypt

*Background.*Cancer antigen 125 is a glycoprotein expressed in normal tissues originally derived from celomic epithelia and has long been known as an ovarian tumor marker, but more recently, it has been known that its serum level is elevated in various benign and malignant conditions.It has also been reported to be elevated in adults with acute leukemia with extramedullary localization and serosal effusion. *Aims.* We aimed to study CA125 as a marker for detection of serosal involvement in children with acute lymphoblastic leukemia(ALL). *Methods.* Thirty patients with ALL,21 males and 9 females, their age ranged from 1.5 to 13 years and 20 healthy controls were included.Serum level of CA 125 was measured at initial diagnosis and after remission in the patient group while it was measured once in the control group. *Results.* Serum level of CA 125 was significantly higher in our patients than the control group and it was significantly lowered after achievement of remission. The highest levels were observed in patients with serosal involvement. *Summary/Conclusions.* CA 125 is a useful marker for serosal involvement in children with ALL.

1199

SUCCESSFUL TREATMENT OF L-ASPARAGINASE INDUCED PANCREATITIS WITH OCTREOTIDE IN A CHILD WITH ACUTE LYMPHOBLASTIC LEUKEMIA

M Kourti,[1] E Hatzipantelis,[1] A Tragiannidis,[2] T Papageorgiou,[2] F Athanassiadou[2]

[1]Aristotle University of Thessaloniki, Thessaloniki, Greece; [2]Second Pediatric Department, Aristotle University of Thessaloniki, Thessaloniki, Greece

Acute pancreatitis (AP) is one of the complications that occur during chemotherapy in acute lymphoblastic leukemia (ALL) patients. The main etiology of AP in ALL patients has been reported to be associated with L-asparaginase (L-asp) therapy. Somatostatin, a naturally occurring tetradecapeptide, and its synthetic analogue octreotide, have been used to treat various pancreatic disorders in adults. The pediatric experience with this medication is limited. We report a case of a 7 year-old female diagnosed with common ALL stratified to the high risk (HR) BFM95 protocol due to leukemic infiltration of the CNS and blasts >1000/_L on day 8. After the induction therapy and towards the end of the HR 1 sheet of the protocol after the administration of L-asp (25,000 IU/m^2) she developed abdominal pain with bilious emesis, and watery guaiac positive stools. Laboratory studies included normal serum electrolytes and renal function studies, hypertriglyceridemia and transaminasemia. Serum amylase was 787 IU/L (normal range: 28-100 IU/L), serum lipase was 2560 IU/L (normal range: 7-60 IU/L) and urine amylase 6550 IU/L(normal range: 0-460 IU/L). Ultrasonography showed changes indicative of acute pancreatitis. Initial management included nasogastric tube placement, bowel rest, analgesics, and broad spectrum antibiotics. Octreotide therapy was initiated within the first 12 hours for a total of 7 days. In the following 5 days her clinical status showed steady improvement as evidenced by decreasing levels of serum and urine amylase to 85 IU/L and 61 IU/L, respectively. After recovery from acute pancreatitis the patient was not rechallenged with L-asp However additional medications that have been associated with pancreatitis, including corticosteroids, 6-mercaptopurine and trimethoprim-sulfamethoxazole were re-instituted following resolution of the acute episode, without recurrence of pancreatitis and were thus not thought to be the major contributor to pancreatic toxicity. Clinicians should be aware of AP in patients presenting with acute gastrointestinal symptoms, especially in those being treated with a high-risk protocol. A high index of clinical suspicion will allow early diagnosis and appropriate therapy that may improve the outcome. Octreotide as part of the management of L-asp induced pancreatitis in children is safe and effective in limiting the severity of the disease process.

PROLIFERATION OF ACUTE MYELOID LEUKEMIC CELLS MEASSURED BY KI-67 AND PCNA EXPRESSION

A. Bogdanovic,[1] V. Cemerikic Martinovic,[1] M Colovic,[1] V. Bumbasirevic[2]

[1]Inst of Hematology CCS Belgrade, Belgrade, Serbia; [2]Inst of Histology, School of Medicine, Belgrade, Serbia

Autoradiographic studies in 80's revealed that myeloid leukemia cells have different proliferation rate, and in general it is low, with most cells in G0 phase of cell cycle. Introduction of flow cytometry with DNA/RNA measurement confirmed those data. As these measurements have certain technical obstacles, proliferative markers were introduced in several human neoplasm to evaluate cell proliferation and therefore behaviour of tumour. *Objective.* We analyzed proliferative fraction of leukemic cells by the application of monoclonal antibodies to Ki-67 and PCNA proliferative markers, and compared these findings with clinical features and initial treatment outcome (CR/NR). *Patients and Methods.* In order to avoid permeabilization of cells for nuclear antigens, we analyzed proliferation on bone marrow samples (trephines) in a cohort of 42 patients suffering from *de novo* AML. Mean age was 46 yrs. (19-66 yrs), and all were treated with similar treatment (ADE/MAE 30 pts, and DA/MC schedule 12 pts). After obtaining informed consent, bone marrow biopsy samples were taken at diagnosis and fixed in B5, embedded in paraffin. After deparaffinization, antigen retrieval and immunohistochemistry was performed by use of commercial Ki-67 (MIB-1) and PCNA (PC-10) antibodies and imaging kits (LSAB2, Dako Danmark) according to manufacturer prescription. Statistical analysis included parametric and nonparametric tests. *Results.* According to FAB classification 3 patients had M1 and 18 M2. Seventeen patients had AML M4 and 3 patients M5. One patient had AML M0. Fifteen patients had trilineage dysplasia. Twenty eight patients achieved CR (67%) and 14 were non responders. Mean Ki-67 positivity was 9.05±17.7% (0-82%). In 15/42 patients (35.7%) Ki-67 was absent, and in 38.1% was <10% of leukemic cells. In 11/42 patients (26.2%) Ki-67 was positive in >10% of leukemic cells. Mean PCNA positivity was higher than Ki-67, 34.7±25.1% (0-90%). In only 4/42 patients (9.5%) PCNA was absent and in other 4 (9.5%) was <10%. In 13/42 patients (30.9%) PCNA was positive in >40% of leukemic cells. There was good linear and rank correlation between these two proliferation markers (P<0.05). Patients with trilineage dysplasia had higher Ki-67 positivity (14 *vs.* 6.3%, MWU test P<0.05) but not PCNA positivity. There were no correlation between percentage of Ki-67 or PCNA positive leukemic cells according to morphology type or cytogenetic features. Patients responded to induction chemotherapy (achieved CR) had significantly lower proliferation measured through Ki-67 positivity (CR 4.6 *vs.* 17.9% for NR, MWU P<0.05), but not by PCNA determination (31.2 *vs.* 41%, P>0.05). Patients with lower proliferation, Ki-67 and PCNA labeled leukemic cells <10%, had better survival than others (log rank test for Ki-67 P=0.06, for PCNA P>0.05). *Conclusion.* Our results in a small cohort of patients as pilot trial confirmed that leukemic cells in AML are dormant, in most cases are non proliferative, which is similar to other findings. There is a good correlation between Ki-67 and PCNA proliferation markers. Also, patients with lower proliferation have better treatment outcome (CR achievement) and better survival.

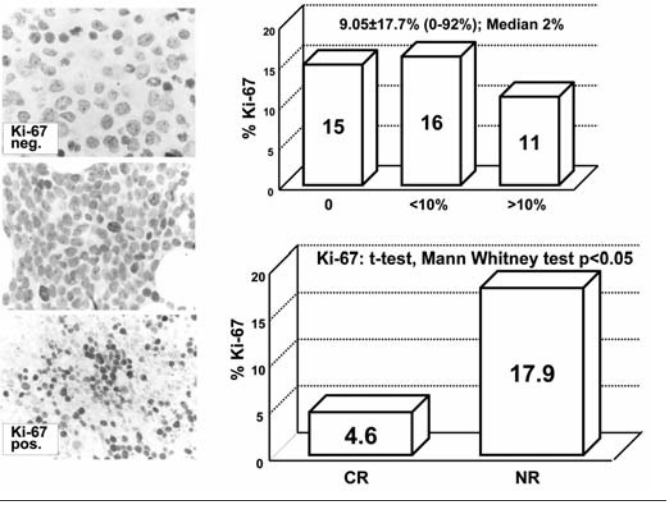

Figure. Proliferation measured by ki-67 and outcome.

MRD MONITORING IN ADULT AML WITH NORMAL KARYOTYPE. COMPARAISON OF WT1 VERSUS NPM1M WHEN BOTH MARKERS ARE PRESENT.

C Pautas,[1] Y Hicheri,[1] JV Malfuson,[2] R Benramdane,[3] F Isnard,[4] L Callas,[1] C Cordonnier,[1] D Borie[1]

[1]Hopital Henri Mondor, Creteil, France; [2]Hopital militaire de percy, Clamart, France; [3]UF hematolgy hopital Rene Dubos, Pontoise, France; [4]Hopital Saint-Antoine, Paris, France

Background. Minimal residual disease (MRD) monitoring has been proved to be useful to guide therapeutic strategies in adult AML. The applicability of MRD monitoring is limited by the presence of a suitable RT-PCR detectable genetic marker. Thus, the over expression of Wilms' tumour gene (Wt1), a transcription factor implicated in neoplasm proliferation, in the majority of adult AML, make it suitable as a commonly used MRD marker. However, Wt1 is expressed at a low level in normal blood and marrow undifferentiated cells. Thus, should we replace the use of more specific markers like mutated NPM1 (NPM1m) by Wt1? *Patients and Methods.* We chose 25 adult AML patients, treated into or according to French multicentre clinical trials (ALFA and GFM) whose molecular screening at diagnosis found a WT1 over expression and a NPM1 mutation. They were 11 males and 14 females, median age 56 years (range: 37 to 71). These patients had a MRD monitoring using in parallel both markers. Quantification of Wt1 and mutated NPM1 was performed according to the ELN recommendations using primers and probes already published (respectively van Dijk, 2002 and Falini, 2005). *Results.* We analysed 143 samples (119

blood samples, 21 bone marrow samples and 3 CSP samples). Quantification was performed at diagnosis and on MRD follow up samples using both markers. On diagnosis samples, there was no correlation between NPM1m expression and Wt1 expression. In most cases (12/25), WT1 was >10% and NPM1m was >10%. In 8/25 cases, WT1 was <10% and NPM1m was >10%. In 4/24 cases, Wt1 was <10% and NPM1m was < 10%. In 1/25 case, Wt1 was >10% and NPM1m was <10%. On MRD samples, however, 91/118 (77%) MRD samples were concordant in term of negativity or positivity of Wt1 and NPM1m expression. 17 /118 (14%) were positive with both markers. 74/118 (63%) were negative for both markers. However, 27/118 (23%) samples were discordant. In 3/118 (2.5%) samples, W1 was considered to be slightly over expressed and NPM1m expression was not detected. But in 24/118 (20%) samples, NPM1m was detected and WT1 was below the threshold of residual positivity (0.045% in blood and 0.28% in bone marrow) observed in normal controls (mean + 2SD). In all these cases, this lack of sensitivity was responsible for either a wrong perception of the decrease of the tumour burden (14/24, 58%), or a delayed haematological relapse anticipation (10/24, 42%). In 6/8 cases of relapse, a slow tumour burden clearance was associated with a relapse and in all these cases, this relapse could have be predicted several months earlier using NPM1m quantification but not using Wt1 quantification. *Conclusion.* Wt1 over expression is a useful marker for MRD detection. However, the presence of a Wt1 normal hematopoietic cell low level of expression decreased its sensitivity and is responsible for a loss of information on the kinetic of the tumour burden evolution. Therefore, if there is a choice, it seems preferable to use a more specific marker like NPM1m.

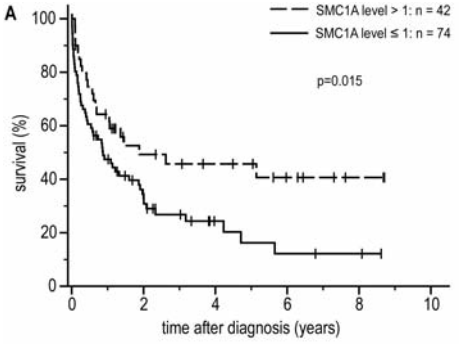
LOW STRUCTURAL MAINTENANCE OF CHROMOSOMES 1A PROTEIN EXPRESSION AT DIAGNOSIS PREDICTS POOR PROGNOSIS IN ACUTE MYELOID LEUKEMIA

O Krug,[1] C Hömme,[1] N Tidow,[1] H Bürger,[2] G Köhler,[1] B Schulte,[1] C Sauerland,[1] T Büchner,[1] W Berdel,[1] S Koschmieder,[1] C Müller-Tidow[1]

[1]University Hospital of Muenster, Muenster, Germany; [2]Institute of Pathology, Paderborn, Germany

Background. Acute myelogenous leukemia is a genetically heterogenous disease with several risk factors implicating a poor prognosis. One of the most important independent risk factor in AML is the age at diagnosis. Older patients with AML generally have a poor prognosis which suggests that the biology of AML in elderly patients differs from AML in younger patients. Little is known about the differential gene expression profile of leukemic cells in elderly *vs.* younger AML patients. *Aims.* The aim of the study was to identify age-related genes in AML and evaluate the impact of the protein expression level of these genes on the prognosis of AML patients. *Methods.* Gene expression profiling was carried out in bone marrow mononuclear cells to identify age related changes in 67 AML patients of different age (range: 17 to 80 years, median: 61 years). Among the genes that correlated with age, SMC1A was selected for protein expression studies. A tissue array was generated containing bone marrow histology samples of 135 patients with newly diagnosed AML of different ages (range: 17 to 84 years, median: 61 years) and probed with an antibody against SMC1A. Protein expression was quantified by the DAKO scoring system.



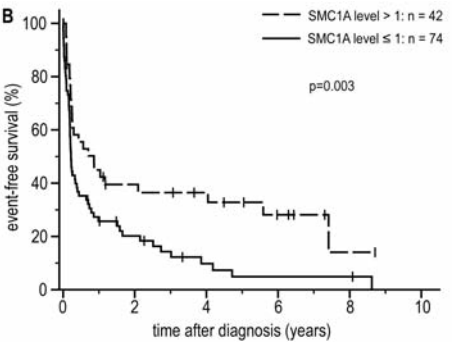


Figure.

Results. 131 genes showed a significant correlation between mRNA expression levels and patient age. Increasing age was associated with significantly decreased mRNA levels of SMC1A. 116 patient samples were evaluable for SMC1A protein expression, and expression of SMC1A protein was low or absent in 74 (64 %) out of 116 AML specimens. On the protein level, SMC1A expression did not correlate with patients' age at diagnosis. Both event free survival (2.6 months *vs.* 10.3 months, P=0.003, Figure) and overall survival (10.4 months *vs.* 22.6 months, P=0.015, Figure) were significantly worse in patients with low or absent SMC1A protein expression. In a multivariate analysis, SMC1A protein expression level remained a significant prognostic factor for event free survival (P=0.014) with a borderline significance for overall survival (P=0.066). *Summary/Conclusions.* We identified 131 genes with putative age-dependent microarray mRNA expression and identified low levels of SMC1A protein expression as a marker for poor prognosis in patients with newly diagnosed acute myeloid leukemia.

SHORT WT1 VARIANT OF WILMS TUMOR GENE IS EXPRESSED IN LEUKEMIC CELL LINES, PATIENTS WITH AML, MDS AND IN CML BLAST CRISIS

T Lopotova, M _ácková, J Polák, H Klamová, J Schwarz, K Machová Poláková, J Moravcová

Institute of Hematology and Blood Transfusion, Prague, Czech Republic

Prognostic significance of total WT1 expression has been proved both for AML and CML, however, the oncogenic effects of WT1 in leukemic cells have not been fully understood yet. In 2004 Dallosso *et al.*. described a short WT1 (sWT1) variant and in 2006 Hossain *et al.*. suggested a connection of sWT1 with leukemias. sWT1 as a part of total WT1 is transcribed from the alternative first exon 1a. Corresponding protein, AWT1 isoform is N-terminally truncated with the lack of transcriptional repression domain, which is supposed to be the cause of its oncogenic properties. To examine sWT1 as novel prognostic marker for leukemic patients and for further understanding the role of sWT1 in leukaemias we have analysed sWT1 and "full length"WT1 expression both on mRNA and protein level in AML, CML and MDS patients. Novel real-time PCR system was established for sWT1 and "full length"WT1 quantification. The two variants were quantified in two separated PCR reactions by combining two different forward primers (one localized on exon 1 and the other on exon 1a) with a common reverse primer and TaqMan probe using GUS as a control gene. Quantification utility was confirmed by high correlation (R^2=0.98) between the sum of sWT1 and full length WT1 with total WT1 measured by standard method according to Kreutzer *et al.,* 2001. Western blot analysis was performed using antibody against the C-terminal region of the WT1 protein. So far, total leukocytes of 41 AML, 5 MDS and 30 CML patient samples were analysed together with K562, CML and JURL cell lines and healthy donors (n=10). Transcript of sWT1 variant was found in K562, CML and JURL cell lines as well as in patient samples but mostly at low levels. We found that sWT1 variant was expressed in CML patients in blast crises but not in patients in chronic phase. Among different AML FAB subtypes, equal levels of sWT1 and WT1 were observed in AML M5b patient, however, sWT1 variant was undetectable in AML M5a patients. MDS patients showed large range of sWT1 expression. High level of full length WT1 was detected in all cell lines and patients samples except of CML patients with major molecular response (<0.1% BCR-ABL), where sWT1 was undetectable. Corresponding results were found at sWT1 and full length WT1 protein lev-

els. In conclusion, sWT1 is expressed at low levels in AML, CML and MDS patients. As sWT1 emerge in AML and in advanced phases of CML, but not in the chronic phase, sWT1 emergence seems to be related to blast cell phenotype. Expression studies of separated cell populations and leukemic progenitor cells are ongoing to examine that idea. Observed differences in sWT1 levels among AML patients tempts to hypothesize prognostic value of sWT1 levels for AML patients. Whether there is any such value and whether such low levels of sWT1 might be of any importance for leukemia pathogenesis remains to be examined. Supported by MZOUHKT2005 and NS 10488-3.

7.1 ANTIBODY REACTS WITH LEUKEMIC CELLS OF ACUTE MYELOID LEUKEMIA BEARING INV(16)

F Mannelli, S Bencini, I Cutini, G Gianfaldoni, B Scappini, A Bosi

Azienda Ospedaliero-Universitaria Careggi, Florence, Italy

Background. Several antigenic patterns have been associated with genotypic aberrancies in acute leukemia. The expression of the human counterpart of mouse NG2 molecule, targeted by 7.1 monoclonal antibody (MoAb), has been demonstrated in association with rearrangement of the mixed lineage leukemia (MLL) gene in acute leukemia. *Aims.* The aim of the study was to investigate the expression of 7.1 MoAb in an unselected cohort of patients with acute myeloid leukemia (AML) in order to establish its correlation with specific genotypic groups. *Methods.* An extensive panel of quadruple combinations of MoAb was applied on a suspension of bone marrow or/and peripheral blood of AML samples at diagnosis. CD45 PerCP was applied in every tube to allow gating of cell populations. The expression of NG2 was assessed using the following staining: CD65-FITC/7.1-PE/CD45-PerCP/CD34-APC. MoAb 7.1 PE was purchased from Beckman-Coulter. 50,000 events per tube were acquired through a FACSCalibur flow cytometer. Analysis of antigen expression was performed through Infinicyt software. NG2 expression was explored on leukemic cells, gated on the basis of CD45 and side scatter, through: i) percentage of 7.1+ cells; ii) mean fluorescence intensity corrected for background fluorescence (MFI) determined by an isotype control; iii) coefficient of variation (CV) of fluorescence intensity. Cytogenetic aberrancies were determined by conventional karyotyping and by FISH for inv(16), t(8;21), t(15;17) and MLL; mutations of NPM1 gene were revealed by immunohistochemical detection of aberrant cytoplasmatic protein localization on trephine biopsy.

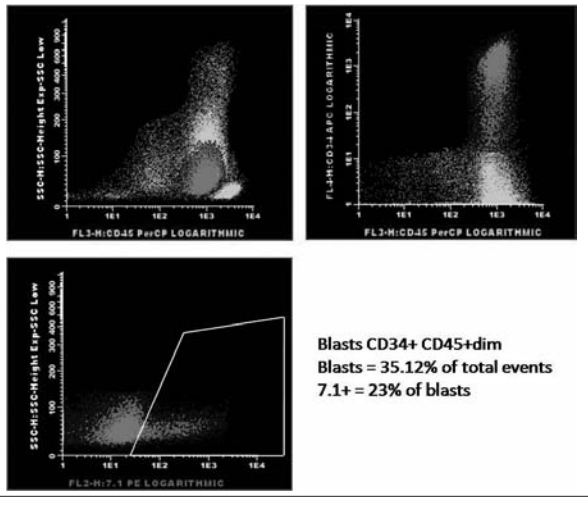

Figure. Expression in a case of AML with inv(16).

Results. Cytogenetics. 64 AML patients were studied. According to genotype, they were subdivided as follows: a) t(15;17) # 6; b) t(8;21) # 4; c) inv(16) # 5; d) normal karyotype # 28, of whom 16 NPM1-wild type and 12 NPM1-mutated. No cases with MLL rearrangements were seen. According to SWOG stratification, 10 and 7 patients had high- and intermediate-risk (other than normal) karyotype respectively. Conventional karyotyping was not possible in 4 cases due to lack of growth. Flow cytometry. Leukemic cells were identified by dim expression of CD45 and low scatter signal; overall, blasts represented a median of 50.78% of global cellularity. No expression of 7.1 was detectable in patients with t(15;17), t(8;21) or other cytogenetic aberrancies. Neither within normal karyotype group, regardless of NPM1 status, 7.1 resulted positive in any case. Of note, we detected a partial expression of 7.1 on blasts from AML with inv(16). Specifically, all 5 patients with such genotype showed 7.1+ cells, with a median percentage of 23% (range 10-28) within blasts. Median MFI was 4.91 (range 3.47-9.86); median CV 275.41 (257.62-291.89). Apart from inv16, expression of 7.1 was seen in an AML case diagnosed as blastic plasmacytic dendritic cell neoplasm according to WHO classification; this finding was not unexpected since Orfao *et al.* (Haematologica 2004) have reported it in this entity. *Summary/Conclusions.* Our study describes the correlation between the expression of 7.1, so far associated with MLL abnormalities, and AML with inv(16). If confirmed within a larger cohort, this phenotypic aberrancy should be deepened for potential prognostic role and minimal residual disease assessment.

BAG-1 IN ACUTE LEUKEMIA: HUNDRED FACES OF A SINGLE PROTEIN

S Aveic, M Pigazzi, G Basso

University of Padua, Padua, Italy

Introduction. Bcl-2 associated athanogene-1 (Bag-1), a founding member of BAG protein family, is a multifunctional protein which has a role in a wide range of cellular processes including apoptosis, cell survival, transcription, cell motility and proliferation. The involvement of Bag-1 in different cellular pathways can be in part examined by the sub-cellular compartmentalisation of the three major Bag-1 isoforms (Bag-1L, Bag-1M and Bag-1S), generated by alternative translation from a single mRNA, and in part by its interaction with a large number of disparate proteins, including Bcl-2, Raf-1, nuclear hormone receptors, subunits of the ubiquitinylation proteasome complex, Hsc70 and Hsp70. *Aims.* The elevated level of Bag-1 protein has been confirmed as a considerable index in several malign diseases. To determine significance Bag-1 might have in the processes of leukemogenesis a sequence of human leukemic cell lines and pediatric bone marrow samples with confirmed acute myeloid leukemia were included in our research. Our goal was to clarify the molecular mechanisms potentially in charge for Bag-1 action, in either leukemic cell lines or primary cell cultures. *Methods. In vitro* studies were based on a small-interfering RNA (siRNA) approach and the results were validated using standard techniques for mRNA and protein expression study. Assays for cell cycle and apoptosis detection were performed. *Results.* The protein study revealed elevated Bag-1 levels in human leukemic cell lines of both myeloid (ML2, THP1, NOMO1, NB4, MV4;11 and HL60) and lymphoid (REH, RS4;11, 697 and JURKAT) origin. A different expression pattern of Bag-1 protein isoforms was noted for two considered groups of patients, AML or ALL, with changes in protein expression profile at different point of the disease. After Bag-1 was knockdown, a modest effect on cell death or cell cycle profile was observed for the human cell lines while primary cultures showed to be more sensitive to Bag-1 silencing. However, significant decrease was confirmed at the expression level of a wide range of proteins, specially the ones involved in the regulation of apoptosis (Bcl-2, PARP, Caspase-3), cell cycle (p27, CDK2, Cyclin D1) and autophagy (LC3, p62), without affecting the mRNA levels. When double silencing experiments of Bag-1 and Bag-3 (a family co-member) were performed, the effect on cell death and cell cycle arrest were found enforced, suggesting a connection between two proteins to be significant for cells faith in leukemia. *Conclusions.* Results indicate that the role of Bag-1 in cell death prevention might be more related to lymphoid leukemia, while it might be considered more significant for cell differentiation in myeloid cells. At the same time, elevated Bag-1 protein expression levels in acute leukemia indicates its possible significance for AML and ALL growth. A different expression profile of Bag-1L, Bag-1M and Bag-1S isoforms in myeloid with respect to lymphoid leukemia could lead to the hypothesis that Bag-1 might play a role in leukemia switch, triggering to either ALL or AML phenotype.

PRIMARY HUMAN AML CELLS CAN EXPRESS CALRETICULIN ON THE CELL SURFACE AND RELEASE HEAT SHOCK PROTEIN 70 (HSP70) AND HSP90 DURING APOPTOSIS

HK Fredly, E Ersvær, Ø Bruserud

Institute of Internal Medicine, Bergen, Norway

Background. Experimental studies strongly suggest that induction of immunogenic apoptosis with exposure of calreticulin on the cancer cell surface is important for induction of anticancer T cell responses. The calreticulin exposure seems essential for uptake and presentation of cancer-associated antigens by dendritic cells. Immunogenic apoptosis is in addition characterized by plasma membrane expression and release of

Heat shock protein (HSP) 70 and HSP90, and these molecules favor cross-presentation of cancer-derived antigens by dendritic cells. Finally, chemotherapeutic drugs seem to differ in their ability to induce immunogenic apoptosis; experimental studies suggest that this phenotype can be induced by anthracyclines but not mitomycin. *Aims.* The aim of the study was to investigate whether induction of apoptosis in primary human AML cells is associated with an immunogenic phenotype including calreticulin exposure and HSP70/HSP90 release. *Methods.* Primary human AML cells derived from 15 consecutive patients were cryopreserved and later thawed and cultured under highly standardized *in vitro* conditions. We used a highly standardized experimental model, and the spontaneous/stress-induced *in vitro* apoptosis that is observed during culture has been characterized in detail previously (Ryningen A, Leuk Res. 2006; 30: 1531-40). Cells were cultured in medium alone and in the presence of daunorubicin, cytarabine, mitomycin, all-trans retinoic acid (ATRA) or valproic acid. Except for mitomycin all these drugs are used in the treatment of AML. AML cell viability and exposure of calreticulin were determined by flow cytometry and HSP70/HSP90 release by ELISA analyses. *Results.* All three cytotoxic drugs caused an extensive *in vitro* apoptosis after 18 hours of incubation. We therefore investigated calreticulin exposure after 4 hours of *in vitro* culture when AML cells generally showed a viability >70% and at the same time an increasing population of dead cells compared with shorter incubations. A dye exclusion assay was used to discriminate between live and dead cells, and these two subsets were analyzed separately with regard to calreticulin exposure. We first investigated stress-induced *in vitro* apoptosis for cells cultured in medium alone, and a wide variation was observed between patients especially for the dead/dye-permeable cell subset (Figure 1). This variation was also detected after exposure to all three cytotoxic drugs, ATRA and valproic acid. Detectable release of HSP70 and especially HSP90 was observed during stress-induced apoptosis and after exposure to cytotoxic drugs, but again a wide variation between patients was observed. Finally, primary AML cells were derived before and during *in vivo* treatment with ATRA plus valproic acid for patients included in a clinical study, and the wide variation in calreticulin exposure and HSP release was maintained during this treatment. *Summary/Conclusions.* Primary human AML cells show calreticulin exposure and release HSP70 and HSP90 during apoptotic cell death. There is a wide variation between patients both with regard to calreticulin exposure and HSP release during spontaneous/stress-induced *in vitro* apoptosis, and this variation is maintained even in the presence of daunorubicin, cytarabine, mitomycin, ATRA and valproic acid. Thus, induction of immunogenic apoptosis in primary human AML cells is strongly influenced by patient-specific biological differences.

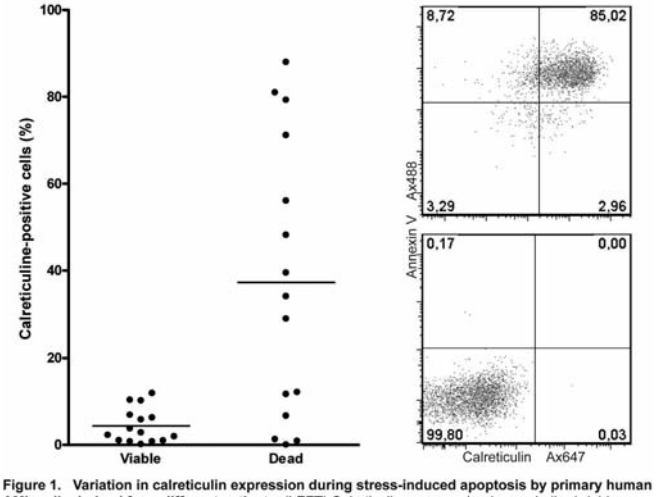

Figure 1. Variation in calreticulin expression during stress-induced apoptosis by primary human AML-cells derived from different patients. (LEFT) Calreticulin-exposure by dye-excluding/ viable and dye-permeable/ dead AML cells derived from 15 patients. (RIGHT) Exposure of calreticulin (x-axis) and Annexin-V (y-axis) by dye-permeable/ dead AML cells derived from two different patients.

INHIBITION OF CELL CYCLE PROGRESSION IN T CELLS AS IMMUNE ESCAPE MECHANISM IN AML

A Franzke, S Alvermann, U Kossatz-Böhlert, S Ukena, P Ivanyi, D Budiwan, N Malek, A Ganser

Hannover Medical School, Hannover, Germany

Background and Aims. Although leukemic blasts express immunogenic tumor-associated antigens, specific T cell responses tend to be severely impaired in acute myeloid leukemia (AML) patients. While contact dependent anergy induction resulting from a lack of costimulation has been previously described, the role of soluble immunosuppressive factors in this disease is less well understood. Here, we analyzed cellular und molecular effects of cell contact independent immune escape mechanisms in AML. *Methods.* $CD4^+$ T cells from healthy donors were cultured in 70% conditioned medium obtained from HL-60 cell cultures supplemented with 30% fresh RPMI medium. PMA and ionomycin were added for mitogenic stimulation. The induced proliferation was evaluated by propidium iodide staining and FACS-based cell cycle analysis was performed. Conditioned medium from a carcinoma cell line (LoVo) was used as a control in subsequent experiments. Expression of positive (i.e., Cdk4, Cyclin E, Cyclin A) and negative (p27Kip1) regulators of cell cycle progression was assessed by western blot analysis. *Results.* Our studies demonstrate that $CD4^+$ T cells cultured in HL-60 conditioned medium show profound alterations in cell cycle regulation with a predominant arrest in G1 phase. Western Blot analyses revealed considerable downregulation of molecules required for G1-S-transition (i.e., Cdk4, Cyclin E, Cyclin A) while no differential regulation was found for Cdk inhibitor p27Kip1. *Conclusion.* AML blasts can induce growth arrest in activated T cells in a cell contact independent manner. The mechanism demonstrated here might contribute to an ineffective antileukemic immunity *in vivo*. While the responsible soluble factors remain to be identified, this study points towards cell cycle regulators as a potential novel target for the optimization immunotherapeutic approaches.

1209

PROMYELOCYTIC LEUKEMIA: MRD DETECTION AND ITS CORRELATION WITH CLINICAL OUTCOME

F Gad alla, T Abdelhamid, E Gafaar, H Raslan

NCI - Egypt, Cairo, Egypt

Background and Objectives. Acute promyelocytic leukemia (APL) is a distinct subtype of acute leukemia characterized by a balanced reciprocal translocation between chromosome 15 and 17 resulting in the chimerical gene encoding PML-RARα protein. Our aim was to study the PML-RARα fusion gene by real-time RT-PCR before and after therapy in a trial to asses its prognostic value and its impact in monitoring MRD to improve therapeutic strategies and decision making. Patients and Method: The study included 41 newly diagnosed APL patients. In addition to the standard work up, cytogenetic and FISH testing were performed at diagnosis and at CR. RT-PCR was done before treatment and after consolidation. We calculated the levels of PML-RAR_ by different *Methods.*1-The number of transcripts. 2-The ratio % which is calculated as: Copy number of PML-RARα /copy number of ABL. 3-The normalized copy number (NCN) which is calculated as: Copy number of PML-RARA/ copy number of ABL x10000. To analyze the different prognostic factors, we correlate them to MRD cut-off values which were for the ratio% (1×10^{-3}), and (NCN=10) for NCN method. Accordingly patients were divided into: Low risk patients: those with ratio% $<10^{-3}$ or NCN<10 and high risk patients: those with ratio% ≥10-3 or NCN>10. Treatment plan: Induction and consolidation regimen included ATRA 45 mg/m^2 P.O. daily and Daunorubicin 60 mg/m^2 I.V. day 1-3 for three courses.Maintenance therapy was given with 6 mercaptopurine and methotrexate with ATRA intermittent courses for two years.Informed consent was signed by all cases. *Results.* Median age was 36 years (18-66) with females to male ratio of 1.2:1. Only 30 patients achieved hematologic remission and followed up for MRD detection while eight cases failed to achieve CR and three cases showed early death.The decrease in expression level of PML-RARα after treatment was highly signficant. During the observation period of 39.1 months (1-56), six cases showed relapse. The time elapsing from the detection of molecular relapse till the appearance of hematological relapse ranged from 1-3 months with most cases clustering in the 3rd month (4patients). The cumulative disease free survival(DFS) was 69.4%. The overall survival(OS) was 76.6% with a mean of 49.85 months with 95%confidence interval of (44.8-54.8). We found significant longer DFS and OS for the low *vs.* high risk patients using the NCN cutoff at post consolidation analysis (P=<0.001 and 0.009 respectively). We found also high statistical significant correlation between log reduction of 2or more after consolidation and longer DFS but not OS. *Conclusions.* PML/RARα NCN method is simple and accurate; its use enables standarization and avoid differences among laboratories. Monitoring patients at short time points is valuable and essential for decision making and choice of proper therapy.

PML/RARA BCR1 AND BCR3 TYPE APL PATIENTS HAVE A DIFFERENT PATTERN OF PRAME, HSP27, S100A4, P21 AND SURVIVIN GENE EXPRESSION

A Misyurin,[1] E Misyurina,[2] M Isakov,[1] A Krutov,[1] I Soldatova,[1] L Kesaeva,[1] K Kaysina,[2] S Markova,[2] E Parovichnikova,[1] V Savchenko[1]

[1]Research Center for Hematology, Moscow, Russian Federation; [2]Research Lab for Molecular Hematology, GeneTechnology LLC, Moscow, Russian Federation

Background. Most frequent cytogenetic hallmark of the acute promyelocytic leukemia (APL) is a translocation t(15;17) that results in the fusion chimeric oncogene PML/RARA. There are 3 different transcriptional variants of PML/RARA: bcr1, bcr2 and bcr3, and they depend on the molecular anatomy of genomic breakpoints. Bcr1 and bcr2 are very similar from the structural point of view. Frequency of bcr1 and bcr3 in adults are rather equal but in different populations there may be a little shift of the balance into the favor of one of them. The frequency of bcr2 in adults is rather low (about 5%). There are contradictory data about the influence of the PML/RARA transcriptional types on the clinical outcome of APL with a few reports showing that patients with bcr3 may be less favorable. We believe that a thorough elucidation and comparison of molecular events that depend on the presence of bcr1 or bcr3 PML/RARA would explain the possible difference in response to treatment in the corresponding APL patients. *Aim.* To study bcr1 and bcr3 PML/RARA positive primary APL patients in order to find a difference among them in expression pattern of genes that may possibly be involved in APL pathogenesis. In this purpose we decided to study an expression level of PRAME, Hsp27, S100A4, p21, WT1, XIAP, survivin and FLT3 genes. *Methods.* To perform this study we have used TaqMan RQ PCR (ABL gene as a housekeeping control gene) and non-parametric methods of statistical analysis of the data obtained. *Results.* We have not found any significant difference of WT1, FLT3 and XIAP gene expression in bcr1 (N=32) and bcr3 (N=45) PML/RARA positive primary patients. On the other hand in these groups of APL patients there was a statistically significant difference in PRAME, Hsp27, S100A4 and survivin gene expression (medians for PRAME(bcr1)=0,034 *vs.* PRAME(bcr3)=0,202, P=0,042; Hsp27(bcr1)=11,69 *vs.* Hsp27(bcr3)=6,42, P=0,0031; S100A4(bcr1)=4,33 *vs.* S100A4(bcr3)=8,86; survivin (bcr1)=1,67 *vs.* survivin(bcr3)=9,19, P=0,0027). *Conclusion.* Our data suggest that in the case of APL there are a number of genes expression of which may depend on the transcriptional type of PML/RARA oncogene. Elevated expression of PRAME, S100A4 and survivin and attenuated expression of Hsp27 in bcr3 cases of APL may be responsible for the less favorable outcome of this type of APL.

1211

ASSOCIATION OF HIGH-LEVEL EXPRESSION OF BCL2L12 GENE WITH ADVERSE OUTCOME IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

S Pavlovic,[1] K Floros,[2] H Thomadaki,[2] N Tosic,[1] D Gourgiotis,[3] M Colovic,[4] A Scorilas[2];

[1]Institute of Molecular Genetics and Genetic Engineering, Belgrade, Serbia; [2]Dep Biochemistry and Molecular Biology, Faculty of Biology, University of Athens, Athens, Greece; [3]University of Athens, School of Medicine, P & A Kyriakou Children's Hospital, Athens, Greece; [4]Institute of Hematology, Clinical Center of Serbia, Belgrade, Serbia

Background. It is well known that changes of the expression level of the main regulators of the apoptosis machinery, such as BCL2, BAD and BAX, contribute to poor outcome in patients with acute myeloid leukemia (AML). BCL2L12 is a novel member of the BCL2 family. Analysis of BCL2L12 mRNA expression in breast and colon cancer, have revealed its involvement in apoptosis in malignancies. However, its role in AML has not been studied yet. *Aims.* In the present study, we investigated the expression profile of the novel apoptosis related gene, BCL2L12, in blood samples of 46 patients with *de novo* AML and 21 samples of healthy controls. We correlated these data with clinical and pathological characteristics, in order to examine potential use of *BCL2L12* mRNA expression as a novel molecular marker in AML. *Methods.* Total RNA was extracted from mononuclear cells and reverse-transcribed into cDNA. We used a highly sensitive semiquantitative real time PCR method based on SYBR Green I chemistry. The internal control gene was *GAPDH.* Relative quantification analysis was performed using delta-delta Ct method. The association of the *BCL2L12* mRNA expression level with clinical and pathological parameters of the disease was evaluated by using chi-square test or the Fisher's exact test, where appropriate. *Results.* In this study the median expression level of *BCL2L12* in 46 *de novo* AML patients was 5.75 while it was 14.82 in 21 healthy individuals. However, this difference was not statistically significant (P=0.14). An optimal cut off value for *BCL2L12* expression of 3.42, equal to the 3rd quartile, was applied to discriminate BCL2L12-positive from BCL2L12-negative cases. Statistically significant relationship was found between *BCL2L12* expression level and CD117 expression (P=0.032), the presence of splenomegaly (P=0.044) and chemotherapy response (P=0.034). Most importantly, we evaluated *BCL2L12* gene expression as a predictor of survival in AML patients. According to univariate data analysis, leukemia patients with positive *BCL2L12* expression status were 3.42 times more likely to relapse (P=0.004) and 3.14 times more likely to die (P=0.007) than patients with negative *BCL2L12* expression status. In multivariate analysis, *BCL2L12* expression was found to be significant prognostic marker for DFS (P=0.014). Kaplan-Meier survival curves demonstrated that BCL2L12-negative patients had substantially longer DFS and OS (P=0.0015 and P=0.0035, respectively), compared to BCL2L12-positive patients, showing that the majority of the leukemia patients who achieved partial or complete response to chemotherapy were BCL2L12-negative. *Conclusions.* Although further investigations are needed to reveal the exact mechanism of *BCL2L12* action and to elucidate its role in AML, our results suggest that *BCL2L12* mRNA expression could be considered as a new independent marker for prognosis and chemotherapy response in AML.

1212

ANTAGONIZATION OF THE MATURATION BLOCK MEDIATED BY THE LEUKEMIA-SPECIFIC FUSION PROTEIN AML1/ETO

ML Solari,[1] J Duque-Afonso,[1] A Cerwenka,[2] M Lübbert[1]

[1]Uniklinik Freiburg, Freiburg, Germany; [2]Deutsches Krebsforschungszentrum, Heidelberg, Germany

Background. The leukemia-specific AML1/ETO fusion gene regulates the gene expression of myeloid cells through different mechanisms, particularly through epigenetic repression of AML1/RUNX1 target genes recruiting histons deacetylases (HDACs) and DNA metyltransferases (DNMTs). The factors contributing to the differentiation block in this leukemia thus probably include also dysregulated AML1/ETO target genes and cooperating oncogenes (e.g. c-kit). *Aims.* To study the contribution of the *in vivo* AML1/ETO target gene LAT2 (an adaptor molecule heavily repress in different AML/ETO positive cells) and the c-kit oncogene to the AML1/ETO-mediated block in differentiation in the t(8;21) positive AML. *Methods.* A Ponasterone-A (PonA) inducible system in the U937 cell line, 9/14/18-U937 was employed. AML1/ETO was induced by adding PonA 5µM to the cell culture. Cells were differentiated for 24 hrs with 10 nM PMA. Flow cytometry for CD11b was performed. Treatment of Kasumi-1 cells: decitabine (DAC) was added in three pulses every 24hrs (changing medium every day). Concentrations used were 50 nM, 100 nM and 200 nM. At 48hrs ATRA 1µM or Vitamin D3 250 ng/mL were added. Medium was changed every day; cell growth and viability were also assessed every day. Dasatinib was added in two pulses, at 0 and 48 hours (after changing medium), at 0.1 nM, 1.5 nM, 10 nM and 100 nM. Viability and cell growth were assessed at 24, 48 and 96 hours. A LAT2 shRNA 'knock-down' model in U937 (Tessarz *et al.* 2007) was treated for 48 hrs with 10nM PMA and multiple other differentiation inducers.

Table. Laboratory data.

	Age y / gender	Latent Period mo	Therapy for CLL	FAB Typ+ MDS/ AML	Cytogenetic	Therapy MDS/ AML	Survival Mo
1	71/M	24	FC(6 cycles)	M5	46,xy,t(3;7)(q26;q21)[23]	Chemo	1
2	54/M	10	CHOP, FMD, FC	M2	46,xy,del 5(q23;q33),-18,+mar(cp2)/46xy,del(5)(q23;q33),-11,-18,+3mar[cp2]/45xy,del(5)(q23;q33),-11,-18,-21,+3mar [14]/46,xy	Chemo	2
3	69/M	5	FC	RAEB2	46,xy,del(5)(q13;q33),t(11;17)(q21;q25),-20,+mar [13]/46,xy [2]	support	8
4	49/F	14	CHOP, FC	M4	43-46,XX,-5,-13,-18,+3mar [cp20]	chemo	4

Results. Conditional expression of AML1/ETO led to a partial decrease in PMA-induced differentiation of U937 cells. The treatment of Kasumi-1 with the DNMT inhibitor DAC resulted in a dose-dependent cell growth inhibition, reduction of viability and partial differentiation (decrease of CD11b expression). An enhancement of this effect

could not be seen with the combined treatment of 5-aza-2'-deoxycytidine (DAC) and 1,25-OH-Vitamin D3 or ATRA, known inducers of differentiation. The functional role of LAT2 in monocytic differentiation was investigated in a LAT2 shRNA "knock-down"model. From nine different differentiation inducers studied, only Phorbolester (PMA, 48 hrs, 10 nM) showed a modest but statistically significant differentiation effect on LAT2-deficient U937 cells when compared to control cells. Treatment of the Kasumi-1 cell line (c-kit-Mutation N822K) with dasatinib showed an inhibition of the autophosphorylation of c-kit, though no clear differentiation of the cells was achieved. *Summary/Conclusions.* Conditional expression of AML/ETO blocks PMA-induced differentiation of 9/14/18 U937 cells. The block in differentiation of the AML1/ETO-positive, LAT2-negative Kasumi-1 cell line could be antagonized through treatment with decitabine, though not with the c-kit inhibitor dasatinib. LAT2 (upregulated during monocytic differentiation) may have a functional role in blocking differentiation of AML cells. These results are being followed by studies in an AML1/ETO-positive, LAT2 negative blasts retrovirally overexpressing LAT2.

PROGNOSTIC IMPACT OF ANGIOPOIETIN-2 (ANG-2) IN ACUTE MYELOID LEUKEMIA

M. Ayoub, M EL-Mogy, N Mostafa, N Nabih

Ain Shams University, Cairo, Egypt

Introduction. Angiogenic factors play an essential role in normal and pathologic angiogenesis. The angiopoietins act as essential regulators in this process. The aim of this study is to detect the expression of angiopoietien -2 (Ang-2) in association with vascular endothelial growth factor A (VEGF-A) in patients with acute myeloid leukemia (AML) and its impact on prognosis and overall survival of patients. *Subjects and Methods.* Forty newly diagnosed AML patients as well as ten normal bone marrow samples were subjected to quantitative real time polymerase chain reaction (RQ-PCR) analysis for detecting the expression of Ang -2 as well as enzyme linked immunosorbant assay (ELISA) for detection of VEGF level. *Results*. This study revealed that high pretreatment levels of Ang-2 and VEGF-A indicate an unfavorable prognosis in AML. Expression of Ang-2 (hazarad ratio 16.8, 95% CI 3.4-82.6 P<0.01) and cytogenetic analysis (hazard ratio 4.5, 95% CI 1.3-15.3, P<0.01) were considered as independent prognostic factors for overall survival, the prognostic significance of Ang -2 expression was more obvious in patients with intermediate risk cytogenetics. In this study, Ang-2 expression was high in 21/40 of AML patients (52.5%) while 19/40 patients (47.5%) had low Ang-2 expression. In the control group, Ang-2 expression was low (<102 copies/mL) and VEGF level was <200 pg/mL. Ang-2 expression was not significantly correlated with any of the clinical or hematological features of AML patients (P>0.05). However, statistically significant association was observed between Ang-2 and CD34, VEGF-A level as well as cytogenetic risk groups. Regarding the clinical outcome of AML patients, out of the 19 patients with low Ang-2 expression group 73.7% showed good response to therapy and achieved CR while 26.3% showed poor response to therapy and failed to achieve CR (relapsed or died). On the other hand, among the 21 patients in the high Ang-2 expression group, 14.3% showed CR while 85.7% showed poor response to therapy and failed to achieve CR. Factors that unfavorably influenced the prognosis were the presence of leukemic burden, positive expression of CD34, high level of VEGF, high Ang-2 mRNA expression as well as cytogenetic risk group. *Conclusion.* high pretreatment levels of Ang-2 predict unfavorable disease outcome in AML. High expression of Ang-2 is associated with high VEGF, supporting the possibility of using angiogenesis inhibitors as an additional novel therapeutic strategy for this disease

1214

HIGH EXPRESSION OF AURKA AND B IS ASSOCIATED WITH UNFAVORABLE CYTOGENETIC ABNORMALITIES IN *DE NOVO* ACUTE MYELOID LEUKEMIA

A Lucena-Araujo, F de Oliveira, G dos Santos, S Leite-Cueva, R Falcao, E Rego

Medical School of Ribeirão Preto, University of São Pualo-USP, Ribeirão Preto, Brazil

Acute myeloid leukemia (AML) is a malignant disease characterized by the excessive proliferation of myeloid precursors in bone marrow. Although chromosomal translocations have been associated with treatment outcome, the relationship between specific chromosomal translocations and pathways regulating mitosis have been not been studied. Aurora kinases play a critical role in regulating of mitosis and cell division, and their overexpression has been observed in many solid tumors, but little is known about their expression in AML. We have investigated AURKA and B expression in 70 cases of *de novo* AML by Real Time PCR. Using an arbitrary cut-off (≥7, for AURKA and <7, for AURK), we observed that 70% of cases with expression higher than the cut-off presented unfavorable cytogenetic abnormalities. No significant differences were found among age, sex and platelets count. However, we detected that the AURKA$^+$ group had 6-fold increase of the risk of presenting high WBC count than AURKA- (OR: 5.6; 95%CI 1.1 to 26.6, P=0.03). This result was not altered after adjustment for age, sex and FLT3-ITD mutations (OR: 7.1; 95%CI 1.22 to 41.2, P=0.02). Similar results were observed in AURKB+ group (OR unadjusted: 4.1; 95%CI 1.16 to 14.61, P=0.02; OR adjusted: 4.7; 95%CI 1.22 to 18.53, P=0.02). Taken together, we provide evidence that overexpression of AURKA and B may correlate with some factors known to be associated with specific translocations which previously have been shown to confer poor prognosis in *de novo* AML.

1215

CORRELATION OF ATP-BINDING CASSETTE (ABC) TRANSPORTERS PGP, BCRP AND ABCB6 EXPRESSION TO RESPONSE TO INDUCTION CHEMOTHERAPY IN ACUTE MYELOID LEUKEMIA PATIENTS

D Palaiologou,[1] G Georgiou,[2] T Vassilakopoulos,[2] G Papanikolaou,[2] N Viniou,[3] E Variami,[3] Y Rombos,[3] E Vervessou,[2] A Mpoula,[4] G Pangalis,[2] P Panayiotidis,[2] N Sakellaropoulos,[3] P Beris,[2] M Angelopoulou[2]

[1]University of Athens, Athens, Greece; [2]Hematology Clinic, Laikon General Hospital, Athens, Greece; [3]1st Department of Internal Medicine, Laikon General Hospital, Athens, Greece; [4]Hematology Clinic, University of Krete, Heraklion, Greece

Background. At least 20% of patients with acute myeloid leukemia (AML) exhibit primary resistance to induction chemotherapy. Classical multidrug resistance (MDR) is caused by upregulation of membrane-resident transporters that efflux chemotherapeutic drugs from tumor cells, like the ABC transporter P-glycoprotein (P-gp, ABCB1), which has been associated with lower remission rates and shorter survival. Other ABC proteins, such as BCRP (ABCG2) may have clinical significance in AML. A recently discovered ABC transporter ABCB6 has also been implicated in MDR development. ABCB6 was overexpressed in a panel of 60 cancer cell lines and has been correlated with increased resistance to chemotherapeutic drugs. No data are so far available about ABCB6 involvement in MDR development in AML. *Aim.* To evaluate the level of Pgp, BCRP and ABCB6 gene expression in bone marrow (BM) samples from AML patients at diagnosis, in relation to response to induction chemotherapy. *Methods.* We studied 34 AML patients admitted to our Department; BM samples at diagnosis were obtained for routine analysis. Non-involved BM samples obtained from Non- or Hodgkin Lymphoma patients for staging purposes were used as control samples. Total RNA was extracted and was reverse transcribed to cDNA. Pgp, BCRP and ABCB6 expression was assessed by quantitative Real Time RT-PCR using SYGR and the Lightcycler Instrument. Gene transcripts were normalized to β-actin and differences in expression were calculated using the ΔΔCT method. Mann Whitney's test was used for statistical analysis. *Results.* Among the 34 patients, 20 were males with a median age of 58 years (range 28-77). Twenty eight patients were *de novo* AML and 6 developed AML after preceding myelodysplastic syndrome (MDS); FLT3-ITD mutations were present in 25% of checked patients. Median value for bone marrow blasts at diagnosis was 78% (range 21-98). Most patients received idarubicin and infusional cytarabine as induction treatment; 22 of them achieved remission, 8 were primary resistant and 4 were not evaluable mostly due to early toxic death. Analysis of Pgp, BCRG and ABCB6 data showed a trend for increased expression in primary resistant patients (median values 8,38, 1,07 and 0,59 respectively) compared to those who achieved remission (median values 1,5, 0,24 and 0,33 respectively), however the differences reached borderline significance, most likely due to the small sample number. We also found a trend for Pgp overexpression in patients who developed AML on a preexisting MDS compared to *de novo* AML patients (median value: 7 and 1,51 respectively), but this difference was of borderline statistical significance as well. The expression levels of the three transporters did not correlate with the percentage of BM blasts at diagnosis. *Conclusions.* The present study is in concordance with the previously reported prognostic significance of Pgp expression on achievement of

complete remission in AML patients. The recently discovered ABCB6 transporter could also be implicated in development of MDR in AML, however we plan to analyse more primary refractory patients in an effort to confirm our hypothesis.

1216

TYROSINE KINASES EXPRESSION PROFILES IN PATIENTS WITH DIFFERENT GENETIC SUBTYPES OF ACUTE MYELOID LEUKEMIA

CY Chen, JH Liu, ZQ Tseng, W Tsay, JL Tang, HF Tien

National Taiwan University Hospital, Taipei, Taiwan

Background. Tyrosine kinase plays an important role in regulation of cell growth, proliferation and survival. *FLT3, KIT, JAK2, JAK3* and *PDGF* have been proved to contribute to leukemogenesis in acute myeloid leukemia (AML). However, the expression levels in most tyrosine kinases are limited in AML. Clarify the gene expression of tyrosine kinases among different genotype of AML may help to know the molecular mechanism of leukemogenesis, and potentially improve the target therapy in the future. *Aims.* Clarify the expression profiles of receptor tyrosine kinases in leukemic blasts in different subtypes of AML. *Patients and Methods.* Patients. Bone marrow specimens were collected from 48 AML patients after inform consent. This study was approved by the Institutional Review Board of National Taiwan University Hospital. Cell line. Cell lines (K562, HL60, U937, Kasumi-1 and THP-1) were cultured with RPMI1640 and 10% fetal calf serum. RNA extraction and RT-PCR RNA extracted from AML patients bone marrow samples with QIAamp RNA Blood Mini Kit, and was treated with DNase and quantitation with NanoDrop® ND-1000 Spectrophotometer, then RNA was converted to cDNA with reverse transcriptase Omniscript RT Kit. Taqman assay was designed based on the genomic sequence. Samples were run in triplicates on a 7500 real-time PCR system (ABI). Nine tyrosine kinases (*DDR1, FLT3, TYRO3, ROR2, INSRR, MATK, MST1R, HCK* and *LYN*) were checked with Taqman RT-PCR technique. Gene expression was normalized to glyceraldehyde phosphate dehydrogenase (*GADPH*) expression and calculated relative to normalized expression in control samples.

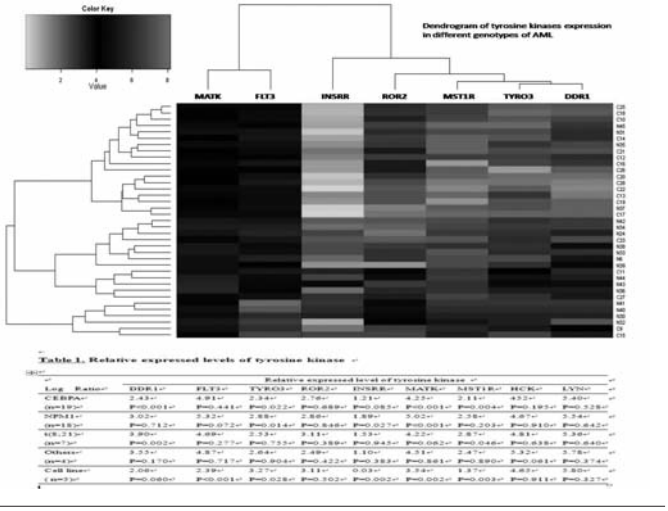

Table 1. Relative expressed levels of tyrosine kinase

	Relative expressed level of tyrosine kinase							
Leg Ratio	DDR1	FLT3	TYRO3	ROR2	INSRR	MATK	MST1R	HCK	LYN
CEBPA (n=19)	2.43 P=0.001	4.91 P=0.441	2.34 P=0.022	2.76 P=0.889	1.23 P=0.085	4.23 P=0.001	2.11 P=0.004	4.32 P=0.195	3.40 P=0.328
NPM1 (n=18)	3.02 P=0.712	2.32 P=0.072	2.88 P=0.014	2.86 P=0.848	1.89 P=0.027	3.02 P=0.001	2.38 P=0.203	4.87 P=0.910	3.34 P=0.842
t(8;21) (n=7)	3.80 P=0.002	4.89 P=.277	2.33 P=0.753	3.11 P=0.389	1.33 P=0.943	4.22 P=0.082	2.87 P=0.046	4.81 P=0.938	3.36 P=0.840

Figure 1. tyrosine kinases expression profiles in AML.

Results. Tyrosine kinase expression in cell lines. Five cell lines (K562, HL60, U937, Kasumi-1 and THP-1) were analyzed for the tyrosine kinase expression. Relatively low expression of FLT3, TYRO3, INSRR, MATK and MST1R was found in cell line samples. Even there were the same cytogenetic changes such as Kasumi-1(AML-ETO) compared with t(8;21) human bone marrow samples, the result also showed significant difference between cell line and bone marrow samples. Tyrosine kinase expression in AML bone marrow samples. There are 48 AML patient (25 men/23 women) enrolled in this study(CEBPA 19, NPM1 18, t(8;21) 7, Other 4). The results were shown as Table 1. The relative expressed levels of tyrosine kinase in cell lines are significantly different from the mononuclear cells in AML patients' bone marrow. The *DDR1* kinase and MST1R kinase are expressed relatively high in the patients with t(8;21), but low in patients with *CEBPA*. *TYRO3* kinase expressed high in NPM1, but low in *CEBPA*. *INSRR* kinase expressed high in *NPM1*. *MATK* kinase expressed high in *CEBPA* and *NPM1*. Expression of *HCK* and *LYN* is no difference among different subtype of leukemia. The expression profile of tyrosine kinases were analysed with cluster analysis, the dendrogram of tyrosine kinases was shown as Figure 1. *Summary/Conclusions.* AML is known with many genetic subtypes which are highly correlated with treatment response and disease survival. Molecular mechanism of AML remains to be investigated. Tyrosine kinase expression profiles in different genetic subtypes potentially help us to explore the complex signal transduction network in the cancer cells.

CONSEQUENCES OF ALTERED DNTP LEVELS FOR GENOME STABILITY IN HEMATOPOIETIC CELLS

I Norrie,[1] O Nielsen,[2] B Porse[1]

[1]BRIC, Copenhagen, Denmark; [2]Institute of Biology, Copenhagen, Denmark

Cells have evolved numerous mechanisms to ensure proper maintenance of their genetic information. These mechanisms are particularly important during cell division, since self-enforcing accumulation of mistakes in the genome is thought to contribute to the development of somatic genetic disorders, particularly cancers. The ribonucleotide reductase (RNR) is a tetramer composed of two non-identical homodimers; R1:R2 or R1:R2b. It catalyzes the *de novo* synthesis of deoxyribonucleotides (dNTPs) to provide a strictly balanced supply of dNTPs required for DNA synthesis and repair. The activity of this enzyme is under exquisite transcriptional and post-transcriptional control to avoid unbalanced dNTP pools that could lead to misincorporation of nucleotides into DNA, mutations, and cell death. Several observations suggest that changes in RNR activity might be an important factor in tumorigenesis (Angus *et al.,* 2002; Fan *et al.,* 1998). In fission yeast it has been demonstrated that the inability to degrade the RNR inhibitor Spd1 results in reduced dNTP pools and elevated mutation rates (Holmberg *et al.,* 2005). Furthermore, fission yeast cells carrying a mutation that relaxes the allosteric feedback inhibition site of RNR exhibit elevated dNTP pools and do also display an increased mutation rate (Olaf Nielsen, unpublished data). In order to investigate whether deregulated levels of nucleotide pools play a role in cancer development, it will be tested to what extend modulation of RNR activity collaborates with various defined genetic lesions in three mouse models of human leukemia. These model systems rests on the ability of retrovirally transduced hematopoietic cells to repopulate the entire hematopoietic system of a lethally irradiated recipient mouse. To test whether modulation of dNTP pools affects tumor latency in any of the two mouse cancer models *Cebpalphap30/p30* or *MLL-AF9,* HSCs/hematopoietic progenitor cells (HPCs) will be transduced with retroviruses aimed at deregulating RNR activity. The deregulation of RNR will be obtained by overexpression of the three different subunits of RNR. To avoid the tight allosteric feedback inhibition of RNR that during overexpression potentially could hamper the increased acitivity of the enzyme a point mutation in the feedback inhibition site of R1 will be introduced. Furthermore, down-regulation of RNR activity in tumor-prone HSCs/HPCs will be achieved in two ways. The activity of R1, R2, and R2b will be down-regulated through expression of shRNAs, but also by expression of the RNR inhibitory yeast proteins Spd1, Sml1, and Dif1. Since RNR subunits are highly conserved, we expect these inhibitors to work across species barriers according to preliminary results. Results thus far shows that mice transplanted with *MLL-AF9* HSCs/HPCs with R1 knockdown lead to a prolonged latency compared to control mice. Since RNR activity may be limiting for progression to and through S-phase, R1 knockdown in *MLL-AF9* HSCs/HPCs might lead to inhibition of proliferation or to a more modest level of dNTP that is not compatible with oncogenic transformation. Both options are in agreement with the increased latency period in MLL-AF9 R1 knockdown transplanted mice.

1219

THE LOW EXPRESSION OF EPH A4 AND B4 HAS NO PROGNOSTIC IMPACT IN AML PATIENTS

T Wrobel,[1] J Pogrzeba,[2] B Jazwiec,[1] E Stefanko,[1] J Dzietczenia,[1] G Mazur,[2] K Kuliczkowski[1]

[1]Wroclaw Medical University, Wroclaw, Poland; [2]Provincial Hospital, Opole, Poland

Background. Eph receptors represent the large subfamily of receptor tyrosine kinases (RTKs), named for its expression in an erythropoietin - pro-

ducing human hepatocellular carcinoma cell line. Both Eph receptors and their ligands-ephrins can be divided into two subclasses, A and B, on the basis of sequence homology, structure, and binding affinity. They play key roles in diverse biological processes: the development of the nervous and vascular system. The up- regulation of Eph receptors has been reported in various solid tumors, including breast, lung, colorectal, and esophageal cancers. This over- expression correlates with tumor invasiveness, vascularization, and metastatic potential. There is very limited data concerning Eph expression in haematological malignancies. *Aim.* This study aimed to investigate the expression of Eph A4, Eph B2, and Eph B4 in non- M3 acute myeloid leukemia (AML) patients, compare the expression levels with normal controls, and determine their prognostic significance. *Methods.* Bone marrow samples from 83 newly diagnosed non- M3 AML patients and 8 controls for comparison were quantified by real time RT- PCR, and the comparative cycle threshold (Ct) method was used to determine the relative expression for Eph A4, Eph B2 , Eph B4 to ABL control gene. All AML patients were treated according to Polish Acute Leukemia Group protocol. *Results.* The total cohort of 83 cases was composed of 49 males and 34 females with a median age of 47.9 years (range: 19-84 years). The relative expression levels of Eph A4 were significantly lower in AML patients as compared to healthy controls (ΔCt 2.871±1.54 *vs.* ΔCt -0.647±0.781, t=6.341, P<0.001 respectively). Comparison between leukemic and normal samples showed that Eph B4 expression was also significantly lower (ΔCt 1.890±1.575 *vs.* ΔCt 0.586±1.023, t=2.289, P=0.024 respectively). Lower expression was also found for Eph B2, but did not reach statistic significance. There was no statistical correlation between the expression of Eph A4, Eph B2, and Eph B4, and patients age, sex, AML subtype according FAB classification, risk group, complete remission rate, and overall survival. *Conclusions.* Our preliminary results showed that in AML patients expression of Eph A4 and Eph B4 was significantly lower than in healthy controls. However in our study low expression of Eph A4 and Eph B4 had no prognostic impact on clinical course of AML.

1220

SOLUTE CARRIER FAMILY 17 MEMBER 1(SLC17A1) IS A NOVEL GENE CONTROLLING ARA-C CYTOTOXICITY

SS Yoon,[1] C Lee,[1] IH Kim,[1] JH Kwon,[2] KS Ahn,[1] DS Lee,[1] HJ Yoon,[3] S Park,[1] BK Kim[1]

[1]Seoul National University College of Medicine, Seoul, South-Korea; [2]Hallym University College of Medicine, Seoul, South-Korea; [3]Kyung Hee University Medical Center, Seoul, South-Korea

Cytosine arabinoside (Ara-C), a structural analogue of deoxycytidine, is a major drug in the treatment of acute myeloid leukemia (AML). Therefore, emergence of resistance to Ara-C is a major problem in AML treatment. To investigate novel genes associated with resistance to Ara-C, whole genome SNP chip analysis was performed. Even though no genes were found that are significantly associated with Ara-C metabolism, 12 regions of loss of heterozygosity (LOH) were found in induction failure group. SLC17 family gene and HIST1H family gene were located in the majority of LOH found in induction failure group. Since SLC29A1, a nucleoside transporter, belonging to solute carrier family genes directly affects Ara-C mediated apoptosis in recent reports, we chose SLC17A1 that has co-transport activity and performed functional analysis of SLC17A1. Its expression levels were examined in 4 AML cell lines (HEL, NB4, KG-1 and ML-1) using RT-PCR. Despite a difference in its expression levels among 4 cell lines, it seemed to be constitutively expressed. To detect changing patterns of SLC17A1 in AML cells surviving Ara-C treatment, 4 cell lines (HEL, NB4, KG-1 and ML-1) underwent on and off treatment of 10^{-8} M of Ara-C for 2 and 4 cycles. Expression of SLC17A1 was decreased more than SLC29A1 expression in the same condition. To examine whether the expression levels of SLC17A1 was associated with Ara-C resistance, Ara-C resistant HEL cell was established *in vitro* and *in vivo* (HEL-R1 and HEL-R1-vivo). SLC17A1 mRNA expression of both resistant cells is decreased or less increased than parental HEL cells with Ara-C treatment. Reduction of SLC17A1 mRNA by shRNA of SLC17A1 effectively suppressed Ara-C mediated apoptosis. Our results suggested that the function of SLC17A1 gene was similar to that of SLC29A1. Taken together, the expression levels of SLC17A1 affected the cytotoxic effects of Ara-C. Thus, our results suggest SLC17A1 as a novel gene controlling Ara-C mediated apoptosis.

1221

GENE EXPRESSION PROFILES IN RESVERATROL APPLIED ACUTE PROMYELOCYTIC LEUKEMIA CELLS

Y Baran,[1] Z Cakir,[1] G Can,[2] G Saydam,[3] F Sahin[4]

[1]Izmir Institute of Technology, Faculty of Science, Dept.of Mol.Biol. & Genetics, Urla Izmir, Turkey; [2]Izmir Institute of Technology, Fac.of Science,Dept.of Mol.Biol.& Genetics, IZMIR, Turkey; [3]Ege University,Faculty of Science, Department of Hematology, Izmir, Turkey; [4]Ege University,Faculty of Science, Department of Biology, Izmir, Turkey

Background. Resveratrol, (3,5,4'-trans-trihydroxystilbene) is a natural product found in plant constitutes such as grape skin. It has shown significant cytotoxic and apoptotic effects on various types of cancer cells with no harm to normal healthy cells. Resveratol inhibits tumor initiation, promotion, and progression. However the mechanisms of resveratrol induced cell death is not well-known. We have previously showed cytotoxic and apoptotic effects of resveratrol on acute premyelocytic leukemia (APL) cells. APL is a hematological malignancy characterized by increased number of clonal population of hematopoietic progenitor cells. *Aims.* In this study, we aimed to show molecular mechanisms of resveratrol induced apoptosis by examining the changes in expression profiles of human cancer signalling pathway genes in HL60 APL cells exposed to resveratrol. *Methods.* Effective concentrations of resveratrol on HL60 cells were determined by XTT cell proliferation assay. Total RNAs were isolated from HL60 cells exposed to 10 and 50 μM resveratrol, converted to cDNA, and changes in expression levels of 84 genes involved in apoptosis, metastasis, angiogenesis, invasion, adhesion, tumor supressors, and transcription factors by PCR array. *Results.* Resveratrol has shown antiproliferative effect on HL60 cells in a dose dependent manner. There were 15 and 45% decreases in cell proliferation in response to 10 and 50 μM resveratrol in HL60 cells as compared to untreated controls, PCR array results demonstrated that there were more than 3-fold increase in expression levels of 24 and 36 genes in HL60 cells treated with the same concentrations of resveratrol as compared to control, respectively. On the other hand, there were 6 genes whose expression levels were decreased more than 4-fold in response to 10 and 50 μM resveratrol, respectively. We observed significant increases in expression levels of p53 in a dose-dependent manner which is not detected in control group. The most significant increases were observed in apoptotic genes (e.g. Bax, Tert), and decreases were observed in antiapoptotic genes (e.g. Bcl-2). Although, there were increases in expression levels of certain growth factor, antiapoptotic and metastatic genes, our whole data demonstrated that these concentrations of resveratrol inhibited cell growth and induced apoptosis in HL60 cells. *Summary/Conclusions.* In this study the mechanisms of resveratrol-induced apoptosis were demonstrated in detail. This *in vitro* data by being supported with clinical data may open the way of the potential use of resveratrol for acute premyelocytic leukemia patients.

This study was supported by Turkish Society of Hematology.

VASCULAR ENDOTHELIAL GROWTH FACTOR-A ACTED AS AN AUTOCRINE GROWTH FACTOR ON SOME OF ACUTE PROMYELOCYTIC LEUKEMIA CASES: RELATIONSHIP TO HYPER-LEUKOCYTOSIS

T Sugao, H Tashiro, Y Oka, Y Shirasaki, N Akiyama, K Kawasugi, N Shiraguji

Teikyo University, Tokyo, Japan

Background. In acute promyelocytic leukemia (M3), a prominent production of vascular endothelial growth factor (VEGF)-A is reported, and an obvious angiogenesis is observed in bone marrow specimens; however, VEGF receptors (VEGFRs) are not expressed in general. We recently reported that an autocrine system of VEGF-A-system was observed in one M3 case (submitted in Leukemia and Lymphoma). *Aims.* In this report we analyzed the expression of VEGF and VEGFRs in our experienced M3 cases to clarify that in what kind of M3 VEGF-A autocrine system was demonstrated. *Patients, materials and Methods.* Patients, administered to our hospital from Nov. 1998 to Nov. 2009 and diagnosed with M3, were eligible. Bone marrow cells were obtained from informed patients, whose mononuclear cells were prepared with density-gradient sedimentation method. Cells were cultured short term for the elimination of an adherent cell-fraction. RNA was extracted from the prepared non-adherent mononuclear cells, and the expression of VEGF-A and VEGFRs was analyzed with reverse transcription-polymerase chain reaction (RT-PCR). When cells expressed VEGFRs with RT-PCR, they were analyzed on the protein level with fluorescent activated cell sorter. VEGF-A levels in

patients' sera and in the conditioned media from the cultured M3 cells were assayed with ELISA kit. When M3 blasts expressed VEGF-A and VEGFRs, a growth-inhibition effect by the administration of anti-VEGF-A-neutralizing antibody was assayed. *Results.* In all 21 cases examined, VEGF-A production was observed. VEGFR-1 and -2 were expressed in 3 cases, in all of which WBC count was above 20,000/μL at the onset of the disease (20,800, 21,500, and 71,400). Statistical significance was demonstrated on WBC count between VEGFRs positive group and negative one. When VEGF-A-neutralizing antibody was added to the blast cell-culture of these three patients, the cell-growth was significantly inhibited. *Conclusion.* These observations indicate that VEGF-A-autocrine system works on proliferation in a few of M3 cases with hyper-leukocytosis.

1223

ANALYSIS OF FLT3 MRNA EXPRESSION LEVEL IN ADULT AML

N Tosic,[1] T Karan-Djurasevic,[1] V Spasovski,[1] T Kostic,[1] N Colovic,[2] M Colovic,[2] S Pavlovic[1]

[1]Institute of molecular genetics and genetic engineering, Belgrade, Serbia; [2]Institute of Hematology, Clinical Center of Serbia, Belgrade, Serbia

Background. Although FLT3 mutations are analyzed in large number of AML patients, and their biological and clinical significance is well known, only a few studies are available regarding FLT3 mRNA expression. *Aims.* The aim of this study was to evaluate expression level of FLT3 gene in 44 adult AML patients (41 *de novo*, and 4 relapsed patients), and in 6 healthy donors. We examined the possible correlations between the FLT3 expression and other clinical characteristic, as well as with FLT3 mutational status. Also in 4 patients we examined the level of FLT3 during the course of the disease. *Methods.* Total mRNA was isolated from PBMCs and cDNA was prepared by reverse transcription. FLT3 expression level was quantified by real-time PCR method, using SYBR Green chemistry. Abl served as a housekeeping gene. Relative quantification analysis was performed using comparative Ct method (2-ΔΔCt), where ΔΔCt = ΔCt(sample) -dCt(healthy(median)). Relative quantity of FLT3 is expressed in relative units (RU). *Results.* FLT3 expression was significantly higher (mean 18,5±2,7, range 1,1-70,0) in AML patients, compared to healthy donors (mean 1,11±0,4, range 0,1-2,6)(P<0.001, U-test). Among patients with different FAB types and different karyotypes, FLT3 expression levels were very heterogeneous, showing no significant difference between groups. We also found no correlation between the level of FLT3 expression and other clinical parameters as age, white blood cell count, percentage of BM blasts and presence of CD34 positive cells. Regarding FLT3 mutational status, we found 4 FLT3/ITD patients and 6 FLT/D835 patients. Neither FLT3/ITD nor FLT3/D835 positive patients showed tendency towards higher level of FLT3 expression. Based on their karyotype, patients were classified into 3 prognostic groups; favorable (t(15/17) (n=18), inv16 (n=3), t(8;21) (n=1)), intermediate (normal karyotype (n=10)), and bad (n=10) prognosis. All 4 relapsed patients were t(15;17) positive, and were observed as a separate prognostic group. After implementation of the cut-off value for FLT3 expression, all of the patients with FLT3 expression above 20,0 RU, were considered to have high FLT3 expression. Significant association between prognosis and high FLT3 expression was found in both favorable and adverse prognostic group (P<0,001), but not among patients with normal karyotype. However, no influence of FLT3 expression on overall survival (OS) was found ((P=0,49; Log Rank), even when t(15;17) positive patients were excluded. Analysis of FLT3 expression levels during the course of the disease in 4 patients, showed rapid decline during CR to the level found in healthy controls. It remained low during continuous CR (2 patients), but increased during the time of relapse (2 patients), back to the level found at the onset of disease. *Conclusion.* Our study shows vide range of FLT3 expression levels and its heterogeneity regarding FAB, karyotype and other clinical parameters. There is also a significant association between high FLT3 expression level and prognosis in favorable and adverse prognostic groups. Although we didn't find association between FLT3 expression level and OS, we found strong association between high/low expression and relapse/complete CR. We suggest that, examination of FLT3 expression level in AML has been wrongly neglected both as prognostic marker and for MRD monitoring.

METALLOPORYPHYRIN CONTROLS THE DIFFERENTIATION OF HUMAN PROMYELOCYTIC LEUKEMIC CELLS

JS Kim,[1] J Park,[2] EM Noh[1]

[1]Chonbuk National University Medical School, Jeonju, South-Korea; [2]Gachon University of Medicine and Science, Incheon, South-Korea

Backgroud. Heme oxygenase -1 (HO-1) is an inducible cytoprotective molecule, which displays antioxidant, anti-apoptotic and anti-inflammatory effects. HO-1 is well induced in leukemia. However, there is no report about role of HO-1 in leukemia.*Aims.* We investigated the involvement of HO-1 in the differentiation of HL-60 cells.*Methods.* HO-1 expression was measured by western blot and realtime PCR. Differentiation of HL-60 cells was determined by CD11b expression through flow cytometric analysis.*Results.* Dimethylsulfoxide (DMSO), a representative differentiation inducer of HL-60 cells, induced completely decrease HO-1 expression in a time-dependent manner, but increase CD11b, indicating that HO-1 might have negative function in DMSO-induced differentiation of HL-60 cells. Zinc protoporphyrin (ZnPP), a strong inhibitor of HO-1, induced differentiation of HL-60 cells, as evidenced by a marked increase in the expression of CD11b following ZnPP treatment. In contrast, treatment with cobalt protoporphyrin (CoPP), an activator of HO-1, decreased CD11b expression. ZnPP induced down-regulation of HO-1 protein expression in HL-60 cells, while CoPP induced up-regulation. In addition, ZnPP treatment caused a decrease in pRb and cyclin D1 expression and an increase in p21 and p27 expression. *Conclusions.* These results suggest that down-regulation of HO-1 might be necessary for DMSO-induced HL-60 differentiation. This study provides the first evidence that HO-1 plays an important role in DMSO-induced differentiation of HL-60 cells.

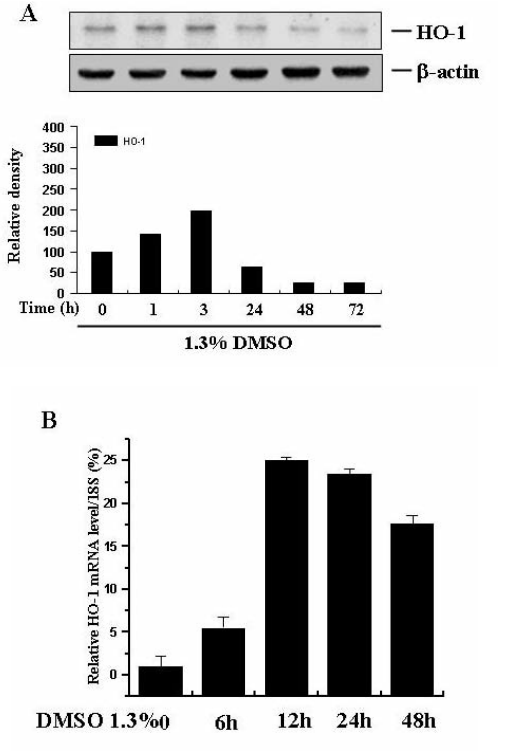

Figure. HO-1 down-regulation by DMSO

EXPRESSION OF MULTIDRUG RESISTANCE GENES MDR1, MRP1, LRP AND BCRP IN CORRELATION TO THE PRESENCE OF FLT3-ITD MUTATION IN ACUTE MYELOID LEUKEMIA- PRELIMINARY RESULTS

B Nasilowska-Adamska, I Solarska, K Warzocha, B Marianska

Institute of Hematology and Transfusion Medicine, Warsaw, Poland

Background. Resistance to chemotherapy in acute myeloid leukemia (AML) is the most important clinical problem and is associated with the expression of the multidrug resistance (MDR) proteins: P-glycoprotein,

multidrug resistant related protein, lung resistance-related protein and breast cancer resistance protein encoded, respectively, by the MDR1, MRP1, LRP and BCRP genes. Moreover some gene mutations e.g. internal tandem duplication (ITD) of FLT3 receptor detected in about 25-35 percent of AML patients portend a poor prognosis. *Aims.* In this retrospective study we estimated expression of the MDR genes and the presence of FLT3-ITD mutation in patients with newly diagnosed, untreated AML. We divided all patients into two groups accordingly to the presence of FLT3-ITD mutation and we compared expression of MDR genes in these groups. We also investigated the relevance of tested genes and FLT3-ITD mutation with other known prognostic factors in AML: age, cytogenetic/molecular aberrations, *de novo*/secondary AML, white blood cell count (WBC), extramedullary involvement and type of AML according to the FAB classification. *Methods.* A total of 46 adult patients (21 women and 25 men) at median age 54 years (range 21-87) with newly diagnosed, untreated AML and 40 healthy donors were included in this study. Diagnosis of AML was based on standard morphological and immunophenotypical criteria according to the WHO classification. There were sixteen FLT3-ITD positive patients (34.7%) and thirty FLT3-ITD negative patients (65.3%). DNA was extracted from bone marrow or peripheral blood samples and used to detect FLT3-ITD mutation with PCR method. RNA was extracted from the same samples and RQ-PCR method was performed for assessment of expression of MDR1, MRP, LRP and BCRP genes. Parameters of RQ-PCR reaction were established based on the Europe Against Cancer protocol. Every tested sample was amplified simultaneously for the presence of control ABL gene for standardization of mRNA level for tested genes. Results of the expression of tested genes were presented as coefficients calculated with an intermediate method according to Pfaffl's rule. *Results.* Significant higher expression of MDR1 gene was found in patients without FLT3-ITD mutation in contrast to the patients with FLT3-ITD mutation (0,1949 *vs.* 0,0701, P=0.002). For MRP, LRP, BCRP genes we did not find significant differences in expression between two groups though we observed much higher expression of BCRP gene in patients without FLT3-ITD. When adjusted for other prognostic factors, only WBC was significantly higher in FLT3-ITD positive group of patients: 3,7-227×10^9/L, median 74 *vs.* 0,5-118×10^9/L, median 11 in FLT3-ITD negative group of patients (P=0,009). We did not observe significant differences in complete remissions and relapses rates and disease free survival and overall survival between groups. *Conclusions.* Significantly higher expression of MDR1 gene was observed in FLT3-ITD negative group of patients. It seems that the presence of FLT3-ITD mutation and high expression of MDR1 gene are independent high risk factors which negatively influence results of AML therapy.

MLL-AF6, A POOR PROGNOSIS FACTOR OF ADULT AML. ROLE OF MRD MONITORING USING QUANTITATIVE REAL TIME PCR

D Bories,[1] Y Hicheri,[1] N Dhedin,[2] JV Malfuson,[3] C Pautas[1]

[1]*Hopital Henri Mondor, Creteil, France;* [2]*Hôpital Pitié-Salpêtrière, Paris, France;* [3]*Hopital Militaire de Percy, Clamart, France*

Background. AML is an heterogeneous disease. Their association to a specific molecular rearrangement allows for a better prognostic stratification. The mixed lineage leukemia (MLL) gene is frequently translocated. MLL is a protooncogene with a transcriptional role that relies on its ability to covalently modify chromatin through its histone H3-K4 methyltransferase activity. Its oncogenic role is associated with deregulated expression of .the master key regulator HOX genes. Indeed, MLL can be fused to more than 50 different partners. In adult AML, AF9 (MLLT3) is the most frequent partner. AF6 (MLLT4) is a rarer partner whose prognosis and role of monitoring are less known. *Patients and Methods.* During the last 10 years, we have monitored in the same laboratory, 9 AML patients with a RT-PCR detectable MLL-AF6 translocation at diagnosis. They were 5 males and 4 females, median age 34 (range 16-56). They were treated into or according to multicenter treatment trails ALFA 9802 (5 pts), ALFA 0702 (1 pt), LAM-EORTC (1 pt) or CHA (3+7) (2 pts). Quantification of MLL-AF6 transcript was performed according to the ELN recommendations for real time quantitative PCR. *Results.* The first patient died of an intracardiac granulocytic sarcoma at D7 post induction therapy. Remission has been obtained for all other patients. A high dose AraC consolidation was performed and well tolerated in all patients except one with severe cerebellitis sequels. The 7 remaining patients underwent an early allogenic HSCT (between M3 and M5) for 5 patients with a geno or pheno identical donor, and a later one (M8 and M15) for the 2 remaining patients for which a donor was difficult to identify. Six out of 8 patients relapsed at M4, M6, M8, M8, M9 and M16 and did not experience any durable second remission although 2 of them underwent a second allogenic HSCT. At the present time, 6 out of the 9 patients are deceased (J7, M14, M16, M19, M25, M47). One is alive and in relapse at M14 post HSCT. Two patients are still in remission, one with a severe HDAC neurologic toxicity. One patient is alive and well at M18. MLL-AF6 transcript quantification was performed according to the ELN recommendation using primers and probes which have already been published (C. Scholl, Haematologica 2005, 90, 1626). Sensitivity was 10^{-5}. For patient monitoring, we have tested 128 serial MRD patient samples. In all cases, a complete molecular response was observed on blood samples. The molecular relapse anticipated the haematological relapse by 2 to 4 months in all cases. None of the patients, who experienced a relapse and a haematological second remission, had a second molecular remission. *Conclusion.* The prognosis of MLL-AF6 adult AML sub-group, in this small series, is poor. Minimal residual disease monitoring of MLL-AF6 transcript allows foreseeing the future of these patients. These observations should incite: 1) to treat patients before haematological relapse, at the stage of a confirmed molecular relapse, 2) to look for targeted therapeutic strategies based on MLL oncogenicity newly acquired knowledge to render MRD monitoring really useful.

1227

CCAAT/ENHANCER BINDING PROTEIN ALPHA (C/EBPA) GENE EXPRESSION LEVELS AS A PROGNOSTIC MARKER IN 49 EGYPTIAN AML PATIENTS

R Abdalreheem,[1] N Salah aldin,[2] A Alshaqanqery,[1] Z Ali[2]

[1]*Kasr Alaini Centre Of Oncology and Radiation (NEMROCK), Cairo, Egypt;* [2]*Depatment of Clinical Pathology, Kasr Elaini, Cairo University, Cairo, Egypt*

Background. The transcription factor CCAAT/enhancer binding protein Alpha (C/EBPA) is a myeloid specific transcription factor that regulates the balance between cell proliferation and differentiation in haematopoietic and non-hematopoietic tissues. C/EBPA plays a major role during the commitment of hematopoietic stem cells towards granulocytic and monocytic differentiation. Impairments in C/EBPA signalling such as reduced mRNA and protein expression are often observed in human myeloid leukemias which may subsequently contribute to leukaemic transformation (Trivedi *et al.*, 2007). In the last few years, various mechanisms have been suggested through which C/EBPA is negatively regulated in certain AML FAB subtypes *Aim.* Studying the heterogeneity of C/EBPA m-RNA expression among different FAB subtypes of newly diagnosed AML patients, as a first step in unraveling the impact of newly discovered genetic abnormalities on the pathophysiology of AML. *Methods.* Fourty nine AML patients were enrolled in the study, 19(38.8%) males, 30(61.2%) females and mean age 32 years (range 2-77). Controls included 20 healthy subjects, 11(55%) males and 9(45%) females with mean age 33 years (range 16-59). The diagnosis of AML was established according to morphology and immunophenotyping (FAB classification). The quantitative assessment of C/EBPA gene expression in AML patients at diagnosis and healthy subjects was performed using RT-PCR *Results.* CEBPA expression levels among the Healthy population and AML patients had an average expression of (1.41±1.14 & 0.52±1.13 respectively, P=0.001). The majority of our study population (40/49) had Low CEBPA expression levels (range 0.001-0.547). Few (6/49) cases showed Intermediate expression levels (range 0.812-1.866) while only 3 cases showed High expression level (range 2.828-5.278). Clinically, Low expressing subgroup had lower DFS and ORS rates than Intermediate and High subgroups with very high statistical significance (P=0.001* and P=<0.001* respectively) *Conclusion.* Using real-time PCR we were capable of defining three prognostic subgroups, that is, high, intermediate and low C/EBPA mRNA expressing patients. Accordingly, C/EBPA expression analysis should be carried out on a larger cohort prior to treatment to predict AML patient's outcome

1228

IMPACT OF CYTOGENETIC ANALYSIS AND MOLECULAR SCREENING ON RISK STRATIFICATION AND FOLLOW- UP IN AML CHILDREN IN SLOVAKIA

M Leitnerová,[1] Z Mikulasova,[1] D Strbova,[1] D Ilencikova,[1] P Novakova,[1] R Ruzbacky,[1] T Slamka,[1] D Sejnova,[2] A Kolenova[2]

[1]*National Cancer Institute, Bratislava, Slovakia;* [2]*University children´s hospital, Bratislava, Slovakia*

Background. AML is aggressive, phenotypically and genetically heterogenous clonal disease of hematopoietic progenitor cells with a great

molecular variability. New WHO classification 2008 divides *de novo* AML according to cytogenetic and molecular prognostic and predictive markers. Recently, it is increasingly possible to identify a subgroup of poorer risk patients among those with normal karyotype AML. *Aims.* The aim of our study was to identify prognostically important molecular markers in children with AML, to stratify patients with normal karyotype and to monitor the disease according the genetic findings. *Methods.* In years 2006-2009 we analysed samples of bone marrow and peripheral blood of 20 children with *de novo* AML by conventional cytogenetic analysis, fluorescence *in situ* hybridisation and arrayCGH. The molecular analysis was performed on the cDNA level, with the restriction analysis of PCR products (FLT3-TKD), conventional PCR (MLL-PTD, NPM1mut, FLT3-ITD) and quantification RT-PCR method (expression of fusion transcripts, BAALC, WT1). *Results.* Samples from 20 children with AML were analysed. With the usage of conventional cytogenetics, FISH and arrayCGH, abnormal karyotype was revealed in 14 patients (70%): t(8;21) in 3/14, t(15;17) in 2/14, t(6;11) in 1/14, t(11;19) in 1/14, inv(16) in 1/14, t(X;11) in 1/14, t(6;9) in 1/14, +8 in 1/14, del(7q) in 1/14, complex karyotype in 2/14 patients. Further analysis revealed FLT3-ITD in 5/20 (25%), FLT3-TKD in 3/20 (15%), NPM1mut in 2/20 (10%) and MLL-PTD in 1/20 (5%), overexpression of WT1 gene in 15/20 (75%) and overexpression of BAALC in 13/20 (65%) patients. *Conclusions.* Wide cytogenetic and molecular screening helped us to find at least one genetic marker in all 20 patients for later follow-up and risk stratification. 6/20 (30%) patients died of the disease progression. These patients revealed following genetic aberrations: a, t(X;11); b, t(6;11); c, inv(16); d, FLT3-ITD and MLL-PTD; e, del(7q) and FLT3-TKD; f, +8 and FLT3-ITD.

1229

COEXISTENCE OF ALTERNATIVE MLL-SEPT9 FUSION TRANSCRIPTS IN AN ACUTE MYELOID LEUKEMIA WITH T(11;17)(Q23;Q25)

J Santos, N Cerveira, C Correia, S Lisboa, L Torres, M Pinheiro, S Bizarro, L Viterbo, J Mariz, M Teixeira

Portuguese Oncology Institute, Porto, Portugal

Abnormalities of 11q23, resulting in fusion of the mixed lineage leukemia (*MLL*) gene with numerous translocation partners, are found in primary acute lymphoblastic leukemia and acute myeloid leukemia, as well as in secondary, topoisomerase II inhibitor-related leukemia To date, more than 50 *MLL* fusion partners have been identified. Five of these, *SEPT2, SEPT5, SEPT6, SEPT9*, and *SEPT11*, code for septins, which are an evolutionarily conserved family of genes with 14 members identified so far. Septins are conserved GTP-binding proteins that assemble into homo- and hetero-oligomers and filaments involved in several processes of cell division and cellular integrity, including polarity establishment, maintenance of membranar dynamics, vesicle trafficking, exocytose, cytoskeleton remodeling, and apoptosis. *SEPT9* (MSF or AF17q25) has previously been cloned as a fusion partner of *MLL* in *AML* with t(11;17)(q23;q25). To our knowledge, *MLL-SEPT9* fusion transcripts have so far been characterized at the molecular level in only nine myeloid neoplasia patients. The *MLL-SEPT9* rearrangements previously reported involve fusions between MLL exon 8 and *SEPT9* exon 3 (type I fusion transcript) (five cases), MLL exon 8 and *SEPT9* exon 2 (type II fusion transcript) (two cases), and MLL exon 7 and *SEPT9* exon 2 (type III fusion transcript) (two cases), with each case presenting only one fusion transcript variant. In this work, we aim to characterize at the RNA level an acute myeloid leukemia patient with a t(11;17)(q23;q25) and a MLL rearrangement demonstrated by FISH. Molecular analysis by RT-PCR led to the identification of two coexistent in-frame *MLL-SEPT9* fusion transcripts (type I and type II), both of them previously described isolated in the literature. The shorter (type I) and longer (type II) transcripts differ by the absence of SEPT9 exon 2 in the former, presumably by alternative splicing. Real-time quantitative RT-PCR analysis of the alternative transcripts showed that the relative expression of the *MLL-SEPT9* type II was 1.88 fold higher than the relative expression of the *MLL-SEPT9* type I. This is the first description of a *MLL-SEPT9* fusion resulting in coexistence of two alternative splicing variants, each of which previously found isolated in myeloid leukemias. Further studies are warranted to evaluate the functional and biological significance f these two distinct variants.

1230

VASCULAR ENDOTHELIAL GROWTH FACTOR-C AND ITS RECEPTOR TYPE-3 WERE EXPRESSED IN TWO CASES OF ACUTE MYELOGENOUS LEUKEMIA WITH T(3;21)(Q26;Q22)

H Tashiro, R Shirasaki, Y Oka, N Akiyama, K Kawasugi, N Shirafuji

Teikyo University School of Medicine, Tokyo, Japan

Background and *Aims.* t(3;21)(q26;q22) is a recurrent chromosomal translocation in acute myelogenous leukemia (AML), in which the fusion molecule of Runx1 and Evi1 plays an important role in leukemogenesis. This chimeric molecule has reported to up-regulate vascular endothelial growth factor-receptor (VEGFR) type-1 and -2. On some cases of AML VEGF-A acts as an autocrine stimulator for the leukemia blast that expresses VEGFR-1 and -2; however, on our knowledge there have been no reports on the relationship of AML and VEGF-C system. VEGF-C and VEGFR-3 play an important role in the formation of systematic lymphatic vessels. They are also reported to work on progression of malignant solid tumor. We analyzed AML blasts with t(3;21)(q26;q22) in point of VEGF-C system. *Materials and Methods.* Blood cells were obtained from two informed AML patients with t(3;21)(q26;q22) as well as other AML patients, whose mononuclear cells were prepared with density-gradient sedimentation method. Cells were cultured short term for the elimination of an adherent cell-fraction. RNA was extracted from the prepared non-adherent mononuclear cells, and the expression of VEGF-C and VEGFR-3 was analyzed with reverse transcription-polymerase chain reaction (RT-PCR). On the protein level, VEGFR-3 was analyzed with fluorescent activated cell sorter, and VEGF-C levels in patients' sera and in the conditioned media from the cultured AML blasts were determined with ELISA kit (R and D Systems, USA). A growth-inhibition effect by the administration of anti-VEGF-C-neutralizing antibody (Sigma, USA) was assayed with Cell-Counting Kit (Dojindo, Japan). *Results and Discussion*. In two cases of t(3;21)(q26;q22), VEGF-C production was observed at RT-PCR level and the protein level. VEGFR-3 was also expressed in two cases, but not other kinds of AML including RUNX1-MTG8 translocation. When anti-VEGF-C-neutralizing antibody was added to the blast cell-cultures of these two patients, the cell-growth was significantly inhibited. These observations indicate that VEGF-C-autocrine system works on proliferation in AML with t(3;21)(q26;q22).

1231

ASSESSMENT OF SERUM VARIATION IN ANTI HSP70 ANTIBODIES DURING ACUTE MYELOID LEUKEMIA INDUCTION THERAPY

J Piszcz,[1] L Bolkun,[2] E Cichocka,[2] K Mazgajska-Barczyk,[2] D Lemancewicz,[2] M Galar,[2] J Kloczko[2]

[1]Medical University, Bialystok, Bialystok, Poland; [2]Medical University, Bialystok, Poland

Background. Heat shock proteins (HSPs) are overexpressed in many kinds of cancers and are implicated in tumor cell proliferation, differentiation, invasion, metastasis, death, and recognition by the immune system. Although HSP levels are not informative at the diagnostic level, they are useful biomarkers for carcinogenesis in some tissues and signal of differentiation and the aggressiveness of some cancers. Furthermore, the reduction in protein expression levels was correlated with an increased susceptibility to drug-induced apoptosis. HSPs were shown highly expressed by acute myeloid leukemia (AML) cells as well as by acute lymphoblastic leukemia (ALL) cells and HSP expressions were correlated with that of differentiation antigens and that of drug-resistance and apoptosis proteins. Additionally lower expression of HSPs is connected with higher rate of complete remission and significantly longer overall survival. *Aim.* The aim of our study was the assessment of the anti Hsp70 antibody concentration in the patients with acute myeloid leukemia before and during the induction therapy. *Material and Methods.* We assessed 25 peripheral blood samples from the patients with newly diagnosed AML (aged 45-56), including 14 males and 11 females. A group of 10 healthy age matched subjects were used as a control group. The patients underwent the seven day induction therapy (cytarabine, doxorubicin, cladribine). The specimens were obtained before, and 7, 14, 21 days after start of the treatment. Quantitative determination of anti-human Hsp70 antibodies in the serum was done using commercial test (anti Hsp70 Elisa Kits, Stressgen). The results are presented as mean±SEM. Statistical analysis was done using Shapiro-Wilk, Mann-Whitney and Spearman's tests. *Results.* There were no significant difference of baseline anti Hsp70 concentration between AML patients and healthy group (276,3±53,3ng/mL and 236,5±61,4ng/mL

respectively). Furthermore no significant changes in the level of anti Hsp70 antibodies were observed during the treatment. In our analysis the parameters such as age, gender and some leukemic features (as leukocytosis, blastosis in bone marrow and peripheral blood) or remission status after induction therapy have no impact on the assessed antibodies. *Conclusions.* Our study revealed no significant variation in the patient antibody level during induction therapy. At that moment there is no significant correlation between the change of the level of anti Hsp70 before and during the induction therapy to complete remission (CR) or overall survival (OS) but the study regards more patients and longer time of observation.

1232

NUCLEOSTEMIN GENE EXPRESSION IN ACUTE PROMYELOCYTIC LEUKEMIA PATIENTS

F Ashrafi,[1] F Nadali,[1] A Ghavamzadeh,[2] K Alimoghaddam,[2] S Rostami[2]

[1]Isfahan University of Medical Sciences, Isfahn, Iran; [2]Hematology/Oncology,BMTResearch Center, Tehran, Iran

Background. Nucleostemin (NS), a novel p53-binding protein has been shown essential for stem and cancer cell proliferation and implicated in oncogenesis. Nucleostemin expression had been shown in gastric cancer (SGC-7901) cells, human hepatocarcinoma (HepG2) cells, human cervical cancer (Hela) cells, human osteosarcoma (OS-732) cells. *Aim.* This work designed to study the NS gene expression in bone marrow cells in acute promyelocytic leukemia (APL) patients and in normal bone marrow specimens. *Materials and Methods.* We examined NS gene expression by Quantitative Real Time PCR in bone marrow specimens of 15 cases of APL patients, before treatment and in 4 bone marrow specimens of healthy donors of bone marrow transplantation. In the same samples of bone marrow aspiration morphology of smears was evaluated. Diagnosis of APL was based on morphology and positive PML/RARA in PCR. RT-PCR used to amplify the NS mRNA, and the GAPDH primer sets used for normalizing .For comparison of NS gene expreesion in 2 groups Mann-Whitney U test was used. *Results.* 15 patients enrolled in this study,11(73%) newly diagnosed APL and 4(27%) relapsed cases. Mean age of patients was 28.67±9.56 year. NS gene expressed in all bone marrow samples of APL patients. NS gene expressed in normal bone marrow specimens too. NS gene expression in bone marrow of APL patients was significantly higher than normal bone marrows(P=0.002) Figure 1. There was no significant difference in NS gene expression between newly diagnosed and relapsed APL cases. *Conclusion.* According to the results of this study it seems that NS gene expressed in normal marrow. NS expression in adult bone marrow hematopoietic stem cells had been reported in previous reports and it had been shown that NS does not express in granulocytes and B lymphocytes. It seems that stem cells and proliferating cells in the normal marrow are the source of NS expression detected in normal marrow. NS expreesion in bone marrow of APL patients was significantly higher than normal marrow. In these patients before treatment marrow is replaced by undifferentiated blasts and promyelocytes. We concluded that NS expression in these cells were high.

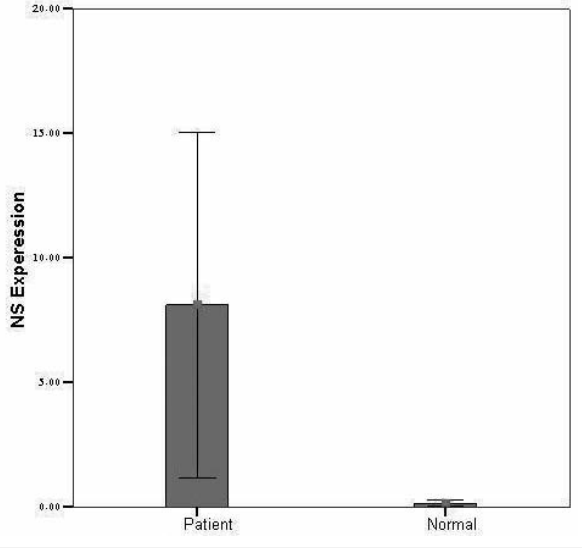

Figure 1. NS gene expression an normal and APL bone marrow.

1233

CYTOKINE PROFILES IN ACUTE LEUKEMIA PATIENTS AT A TIME OF DIAGNOSIS

N Tretyak,[1] N Goryainova,[1] O Kyselova,[1] O Myronova,[2] G Tretyak[1]

[1]Institute of hematology and transfusiology of UAMS, Kyiv, Ukraine; [2]National medical university, Kyiv, Ukraine

Background. As we know, leukemic cells loose the ability to realize the programming cells death - apoptosis. Cytokines produced by healthy immunocompetent cells, blasts and micro environment's cells, consider being an activators and inhibitors of such process. Insufficient knowledge on the role of cytokine's balance (cytokine profile) in acute myeloid leukemia's process formation and following complications of the decease caused our investigation. *Materials and Methods.* 36 acute myeloid leukemia patients (man - 17, woman - 19) were observed in first acute period. According to FAB classification, patients were grouped as follows: M2 - 2 patients, M4 - 24, M5 - 10. All the patients were of 16-65 years. Before chemotherapy, the plasma samples from the patients were collected for cytokine profile analysis: tumor necrosis factor-α (TNFα) and interleukins (IL) - IL-1, IL-2, IL-4, IL-6, IL-8 and IL-10. The reference range of cytokine concentration in plasma samples considered to be: TNF_ - 5,00-30,00 pg/mL, IL-1 - 10,00-50,00 pg/mL, IL-2 - 35,00-190,00 pg/mL, IL-4 - 1,00-35,00 pg/mL, IL-6 - 5,00-50,00 pg/mL, IL-8 - 0-20,00 pg/mL and IL-10 - 1,00-45,00 pg/mL. *Results.* Concentration of IL-2 in plasma of 23 (64%) patients was within the reference level, 39,210±9,14 pg/mL average, but in 13 patients (36%) we observed remarkable decreasing within this parameter - from 0,01 to 7,250 pg/mL. Level of IL-1 (the average level 7.66±3.04 pg/mL in 86% of patients) slightly decreased. No significant changes were disclosed in IL-4 concentration, its average level was 20.550±9.9; however, this parameter's variation was large within the whole group - from 0.1 to186.0 pg/mL. IL-6 increased the most, comparing to the reference range. Being in average 65.74±11.39 pg/mL, it was higher than normal in 4-5 times in some individual cases. IL-8 level was measured in range from 0.01 to 173.20 pg/mL (in average16.570±5.25 pg/mL), but in 50% cases it increased slightly. Investigation of IL-10 didn't show any difference as within the whole group, as comparing to the reference range (average level was 8.560±0.98 pg/mL). Analyzing of TNFα didn't reveal any remarkable deviations; the average level was 5.56±1.97 pg/mL, maximum range of the measured parameter - from 0.10 to 50.77 pg/mL. *Conclusion.* Thereby, our investigation of the cytokine profile in acute myeloid leukemia patients demonstrated the significant increasing in IL-6 level and a trend toward the decreasing in IL-2 and IL-1 levels in most individuals. Further clarifying of these findings is a focus of our future research.

1234

THE EFFECT OF ARSENIC TRIOXIDE TREATMENT ON GENE EXPRESSION OF ACUTE PROMYELOCYTIC LEUKEMIA CELL LINE, NB-4

M Sharifizadeh,[1] H Ghaffari,[2] M Momeny,[2] M Hashemi,[3] K Alimoghaddam,[2] A Ghavamzadeh[2]

[1]Islamic Azad University, Tehran Oloom Tahghighat branch, Tehran, Iran; [2]Shariati Hospital, Tehran, Iran; [3]Islamic Azad University, Medical Campus, Tehran, Iran

Background. APL is the most malignant form of acute leukemia with a fatal course of only weeks which represents 10-15% of AML in adults. Arsenic trioxide as a single agent factor (without chemotherapy) is the treatment of choice for APL patients, but the mechanism by which it induces apoptosis remains poorly understood. *Aims.* Since in Iran arsenic is used as first line treatment, it is worth to investigate its effect on expression of genes involved in apoptosis. *Methods.* In this study, we used the human leukemia (NB4) cell line as a model to evaluate the cytoxicity of arsenic trioxide in APL based on the MTT assay. To study the underlying mechanisms of cell death induction by arsenic, we treated NB4 cell line in a time and dose dependent manner. Extracting RNA and synthesis of cDNA, gene expression of apoptotic genes in mitochondrial pathway including caspase3, Mcl-1 and Bcl-2 was analyzed through Real-Time PCR. *Results.* Data obtained from the MTT assay indicated that arsenic trioxide significantly reduced the viability of NB4 cells and inhibited cell growth with a special emphasis on time- and dose-response relationships. We also found that As2O3-induced cell death was paralleled by reduced expression of the antiapoptotic protein BCL2 in both time and dose dependent treatment, but the expression of Caspase3 and Mcl-1 did not change after arsenic treatment. *Conclusions.* These results suggest that changes in BCL2 gene expression may

be one of the mechanisms of action of arsenic through the induction of apoptosis, while Caspase3 and Mcl-1 are not involved in arsenic induced apoptosis.

1235

P27KIP1 IN ACUTE MYELOID LEUKEMIA

M Sucic,[1] N Hodak,[2] M Markovic-Glamocak,[1] S Ries,[1] K Gjadrov Kuvezdic,[1] B Labar[1]

[1]Zagreb University Hospital Center and School of Medicine, Zagreb, Croatia; [2]Zagreb University Faculty of Pharmacy and Biochemistry, Zagreb, Croatia

Acute leukemia (AL) is clonal proliferation of immature leukemia cells in bone marrow (BM), peripheral blood and other tissue. Uncontrolled clonal cell proliferation caused by malignant transformation of cells is a result of many alterations of cell functions involved in cell proliferation, differentiation and apoptosis. Malignant transformation of leukemic cells is also associated with altered activity of cyclin dependent kinases (CDKs) and cyclin-dependent kinase inhibitors CKIs. CDKs form periodically complexes with cyclins and induce cell cycle progression from G1 to S phase. One of CKIs is p27Kip1 member of KIP (kinase inhibitor proteins) family. Aim of this study was to analyze p27Kip1 immunocytochemical expression of BM hematopoietic cells (HCs) in AML patients before cytostatic therapy and in control group of patients. *Methods.* microscopic analysis of p27Kip1 positive HCs was done after immunocytochemical APAAP staining of BM smears. Analyses were done in 14 AML patients and 11 patients of control group (not suffering of hematological malignant disease). BM analysis in control group was done in course of standard diagnostics and from all patients in both groups informed consent was obtained. *Results.* median (8%) and upper limit (45%) of percentages of p27Kip1 positive HCs in control group were higher than same parameters in AML leukemic cells (median: 2,3%; upper limit 18%). Moreover, percentages of p27Kip1 positive HCs in control group were significantly higher (P<0.001) than in AML patients. In 2 out of 14 AML patients was found higher percentage of p27Kip1 positive HCs (5%, 18%). *Conclusions.* Observations are in relation with known p27Kip1 function acting as CKIs of cell cycle progression and with other studies findings implicating variability of p27Kip1 immunoexpression in leukemic cells.

1236

MYELODYSPLASTIC SYNDROME/ACUTE MYELOID LEUKEMIA IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA TREATED WITH FLUDARABINE

M Colovic

Institute of Hematology, Belgrade, Serbia

Aim. Patients with chronic lymphocytic leukemia (CLL) may have disease transformation to diffuse high grade non-Hodgkin's lymphoma (known as Richter's syndroma) or prolymphocytic leukemia. The development of therapy related myelodysplastic syndrome and therapy related acute myeloid leukemia (t-AML/MDS) is unusual. We report the occurence of acute myeloid leukemia (t-AML) and refractory anaemia with excess of blasts (t-MDS/RAEB2) soon after treatement with fludarabine.

Table 1. Laboratory data.

	Age y / gender	Latent Period mo	Therapy for CLL	FAB Typ+ MDS/ AML	Cytogenetic	Therapy MDS/ AML	Survival Mo
1	71/M	24	FC(6 cycles)	M5	46,xy,t(3,7)(q26;q21)[23]	Chemo	1
2	54/M	10	CHOP, FMD, FC	M2	46,xy,del 5(q23;q33),-18,+mar(cp2)/46xy,del(5)(q23,q33),-11,-18,+3mar[cp2]/45xy,del(5)(q23;q33),-11,-18,-21,+3mar [14]/46,xy	Chemo	2
3	69/M	5	FC	RAEB2	46,xy,del(5)(q13,q33),t(11;17)(q21;q25),-20,+mar [13]/46,xy [2]	support	8
4	49/F	14	CHOP, FC	M4	43-46,XX,-5,-13,-18,+3mar [cp20]	chemo	4

Material and Results. In the period from october 2004 to january 2010 a total of 210 patients (pts) with CLL have been treated with Fludarabine. In the same group we have diagnosed t-AML/MDS in 4 pts (1.9%), with median period of latency of 14 months after treatment with fludarabin. The initial CLL treatment was FC protocol (fludarabine 25 mg/m^2 on days 1 to 3, and 200 mg/m^2 cyclophosphamide on days 1 to 3,) in two patients, CHOP and FC protocol in 2 patients (cyclophosphamide 750 mg/m^2, doxorubicin 50 mg/m^2 i.v. and vincristine 2 mg intravenously on day 1and prednisone 100 mg orally given on days 1 to 5.) and in 1 patient in addition to CHOP, FC and FMD protocol was applied (fludarabine 25 mg/m^2 days 1-3, mitoxantrone 8mg/m^2 day 1, and dexamethasone 20 mg/) There were 3 males, 1 female, with age ranging from 49 to 71 years. According to FAB classification of acute myeloid leukemias there was 1 pts of M5b type, 1 case of M4, 1 case of M2 and 1 of RAEB2 with 17% of blastas in bone marrow. The characteristics of patients at the time of presentation are summarized in Table 1. All pts had cytogenetic abnoramlities commonly seen in therapy related AML, complex karyotype and abnormalities of chromosome 5 in three patients. One patinet had t(3;7)(q29;q21). Three patients were treated with reduced doses of doxorubicin and cytosin/ arabinoside and one patient with RAEB2 with supportive therapy. The patient with M4 achieved a partial response but after second course of chemotherapy developed enterocolitis, ileus and after surgery died. The best survival was in patient with RAEB treated with supportive therapy (8 months). The other three patients survived 2 m, 1 and 4 months respectively. *Conclusion.* Second malignancies occur with increased frequency in patients with CLL, but they may be more frequent and more aggressive after nucleoside analog therapy of CLL.This report may suggest that fludarabin might predispose to secondary malignancies but this preposition needs further evaluation by long term studies.

1237

LACK OF PROGNOSTIC IMPACT OF WT1 MUTATIONS IN NORMAL KARYOTYPE ACUTE MYELOID LEUKEMIA: RESULTS OF THE LAM2003+G-CSF PROTOCOL OF THE CETLAM STUDY GROUP

J Nomdedeu,[1] A Ferrari,[1] C Estivill,[1] M Hoyos,[1] J Esteve,[2] A Domingo,[3] M Tormo,[2] R Guardia,[4] J Bargay,[5] L Florensa,[6] M Queipo,[7] E Bussaglia,[1] M Carricondo,[1] D Gallardo,[4] JM Ribera,[8] S Brunet,[1] A Aventin,[1] J Sierra[1]

[1]Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; [2]Hospital Clinic, Barcelona, Spain; [3]Hospital Universitari Bellvitge, Spain; [4]ICO, Girona, Spain; [5]Hospital Son Llatzer, Mallorca, Spain; [6]Hospital del Mar, Barcelona, Spain; [7]Hospital Virgen de la Victoria, Malaga, Spain; [8]Hospital Germans Trias i Pujol, Badalona, Spain

Background. Wilms tumor 1 (WT1) is a transcription factor which is commonly up regulated in patients with Acute Myeloid Leukemia (AML). Acquired mutations of the WT1 gene have been reported in approximately 10% of normal karyotype (NK) AML and have been associated with a bad outcome. *Methods.* Samples from 165 adult patients with *de novo* NK-AML and included in the LAM2003+G-CSF protocol were analyzed for WT1 mutations. Capillary electrophoresis for exon 7 and direct sequencing for exon 9 were performed for each case using an ABIPRISM 310 Genetic analyzer. NPM1, FLT3-ITD, CEBPA and MLL status was also investigated using well established protocols. WT1 mRNA levels were studied by means real-time PCR following the primers and conditions described by the LeukemiaNet group.*Results.* WT1 mutations were identified in 19 patients (11.5%) and were significantly associated with the presence of CEBPA mutations (P=.021). There was no significant association with NPM (P=.220), FLT3-ITD (P=.449) and MLL (P=.614) mutations. Subset analysis according to the FLT3-ITD status did not reveal any significant impact. Complete remission (CR) rates were not significantly different between patients with WT1 mutations and those with unmutated WT1 (P = .40, 84.2% v 71.9%). There was no difference in disease free survival (DFS; P= .887; 3-year rates, 52.4% v 48%), in overall survival (OS; P=.445; 3 years rate, 40% v 36%) and in refractory disease (P=.705). Patients with WT1 mutations show a trend to statistical significance with regard to the G-CSF use (P=.090). Furthermore, G-CSF use had a favorable impact on OS (P=.013; 3 years-rate, 69% v 30%) (P=.090) and an inverse correlation trend with induction failure (P=.069). *Conclusions.* WT1 mutations were devoid of adverse prognostic meaning in this series of NK-AML. WT1 mutations were significantly associated with CEBPA mutations. G-CSF treatment may play a protective role in patients with WT1 mutations.

1238

CYTARABINE AND AMSACRINE FOR AML SALVAGE THERAPY IN ELDERLY PATIENTS: A SINGLE CENTER RETROSPECTIVE STUDY

PY Dumas, T Leguay, A Pigneux, E Blanchard, R Tabrizi, K Bouabdallah, MS Dilhuydy, S Vigouroux, A Schmitt, G Marit, N Milpied

Hopital Haut Leveque, Pessac, France. *In elderly patients with acute myeloid leukemia (AML) treated intensively, there are little data supporting the efficacy of salvage chemotherapy in patients with refractory or relapse AML*

We performed a retrospective study in 42 patients over 55 years old with the aim to investigate prognostic factors for survival. Salvage chemotherapy consisted in the association of cytarabine 3 g/m_/12 hours D1-D3 (total 5 doses) and amsacrine 150 mg/m^2/day D1-D5. The median age was 64 years (range 58-74). Of these 42 patients, 10 (23.8%) had refractory AML, 18 (42.9%) had a <12 month relapse and 14 (33.3%) a >12 month relapse. There were 3 (7.1%) AML with favorable cytogenetic risk, 29 (69%) AML with intermediate cytogenetic risk and 9 (21.4%) AML with unfavorable cytogenetic risk. Seven patients (16.7%) achieved a complete response (CR), 4 patients (9.5%) achieved a complete response with incomplete blood count recovery (CRi), and 4 patients (9.5%) achieved a partial response (PR). Twenty five patients (59.6%) had a refractory AML, and two patients died within 30 days after D1 chemotherapy. The median time until neutrophil recovery (> 0.5×10^9/L) was 20 days. Febrile neutropenia was universal with 47.6% grade III-IV infection toxicity, 38.1% septicemia and 16.7% invasive fungal infection. After a median follow-up of 4.2 months (range 24 days-7.8 years), median overall survival (OS) was 5 months (range 24 days-7.8 years), median event free survival (EFS) was 51 days (range 18 days-6.8 years) and median relapse free survival (RFS) was 5.9 months (range 31 days-6.7 years). Among 11 patients who achieved CR or CRi, 4 (36.4%) received a consolidation with chemotherapy alone including high-dose cytarabine, 2 patients (18.2%) underwent autologous hematopoietic stem-cell transplantation (HSCT) and 3 (27.3%) allogeneic HSCT. Among 4 patients who achieved PR, 3 received an allograft. Among 8 (19%) patients who underwent HSCT, there were 1 AML with unfavorable cytogenetic risk, 5 AML with intermediate cytogenetic risk and 2 AML with favorable cytogenetic risk. Median OS was 16.5 month (range 6.8 month-7.8 years) for patients who proceeded to transplantation *vs.* 3.5 months (range 24 days-3.3 years) for patients who did not. Median EFS was 5 month (range 1.2 month-6.8 years) for patients who proceeded to transplantation *vs.* 47 days (range 18 days-3.2 years) for patients who did not. In univariate analysis, there is evidence that autologous and allogeneic HSCT (respectively P=0.02 and P=0.0025) could positively affect overall survival among patients over 55 years old. In multivariate analysis, two good prognostic factors affected overall survival: non unfavorable cytogenetic risk evaluated at diagnosis (P=0.02) and consolidation treatment by chemotherapy or HSCT (P<0.001). Our findings suggest that cytarabine-amsacrine offers a reasonnable salvage chemotherapy and that consolidation treatment by HSCT is necessary to sustain the response.

EVALUATION OF PLASMA CYTOKINE LEVELS BY BIOCHIP ARRAY TECHNOLOGY IN ACUTE MYELOID LEUKEMIA PATIENTS. A PILOT STUDY

J Horacek,[1] M Vasatova,[1] M Tichy,[1] R Pudil,[2] L Jebavy,[3] J Maly[2]

[1]*University Hospital Hradec Kralove, Hradec Kralove, Czech Republic;* [2]*Faculty of Medicine Hradec Kralove, Hradec Kralove, Czech Republic;* [3]*Faculty of Military Health Sciences, Hradec Kralove, Czech Republic*

Background. Cytokines and growth factors have been studied as markers of immune system activation in various diseases including hematological malignancies. *Aims.* The aim of our pilot study was to determine plasma levels of multiple cytokines by biochip array technology in acute myeloid leukemia (AML) patients. *Methods.* A total of 15 AML patients (mean age 48.7±12.1 years, median 51.0, 8 males and 7 females) treated with cyclic chemotherapy (3+7, 2+5, HiDAC) alone or in combination with high-dose chemotherapy (preparative regimen Bu/Cy2 or Cy/TBI) followed by autologous hematopoietic cell transplantation were studied. We evaluated plasma levels of the following cytokines: interleukin-1 alpha (IL-1 alpha), interleukin-1 beta (IL-1 beta), interleukin-2 (IL-2), interleukin-4 (IL-4), interleukin-6 (IL-6), interleukin-8 (IL-8), interleukin-10 (IL-10), vascular endothelial growth factor (VEGF), tumor necrosis factor-alpha (TNF-α), interferon-gamma (IFN-γ), epidermal growth factor (EGF), monocyte chemotactic protein-1 (MCP-1). All biomarkers were measured by biochip array technology on Evidence Randox analyzer at the diagnosis of AML (active leukemia) and at 6 months after completion of chemotherapy (durable complete remission in all patients). *Results.* Comparing cytokines levels in active leukemia and in durable complete remission, we found significant decrease in plasma IL-1 β (2.56±3.27 ng/L *vs.* 1.63±2.17 ng/L; P<0.05), IL-6 (46.24±83.14 ng/L *vs.* 2.49±2.51 ng/L; p < 0.05), IL-8 (104.99±167.30 ng/L *vs.* 11.72±4.34 ng/L; p < 0.05), IL-10 (7.58±14.15 ng/L *vs.* 2.22±4.78 ng/L; P<0.05) and TNF-α (4.65±4.27 ng/L *vs.* 2.19±1.13 ng/L; P<0.05). On the other hand, we found significant increase in VEGF (63.93±67.85 ng/L *vs.* 114.39±54.90 ng/L; p < 0.01) and EGF (16.48±33.50 ng/L *vs.* 64.42±35.33 ng/L; P<0.001). Plasma levels of other cytokines (IL-1 α, IL-2, IL-4, INF-γ, MCP-1) were without significant differences. *Conclusions.* Our results indicate that plasma levels of some cytokines and growth factors (EGF, VEGF, IL-1 β, IL-6, IL-10, TNF-α) could serve as useful diagnostic and prognostic parameters for AML patients, showing activity of the disease. Further studies in a larger number of AML patients and comparing cytokine levels with healthy subjects will be needed to define the potential role of these and additional biomarkers in this context.

Background. The outcomes of patients with primary refractory or relapsed after chemotherapy are dismal. Allogeneic hematopoietic stem cell transplantation (allo-HSCT) provides curability for those cases through graft-versus-leukemia effect. *Aims and Methods*. The data of 40 primary refractory to induction chemotherapy and 32 relapsed cases were retrospectively reviewed to investigate the clinical factors that determine the long-term outcomes of allo-HSCT in those cases. *Results.* Primary engraftment failure and veno-occlusive disease occurred in 9 (12.7%) and 12 (16.7%) patients. The 3-year cumulative incidence of chronic graft-versus-host disease (GVHD) and extensive chronic GVHD was 36.0% and 23.5%, respectively. With a median follow-up duration of 5.2 months (range, 0.1-129.4), 5-year overall survival (OS) and disease free survival (DFS) were 18.4% and 14.8%. The causes of death were relapsed-related in 23, GVHD in 10, and infection in 18 patients.

The 5-year cumulative incidence of relapse was 43.0%. The 5-year OS was higher for the patients with chronic GVHD (26.2%) than for those without chronic GVHD (9.0%; P<0.001). Plus, the 5-year OS rate was not significantly different between high WBC index (≥20) and low WBC index (<20) groups (WBC index = WBC (109/L) x [% of marrow blasts/100] at the time of transplantation). In the multivariate analysis, the only variable associated with higher OS was the presence of chronic GVHD (hazard ratio 0.253, 95% confidence interval 0.110-0.582; P<0.001). *Conclusion.* In conclusion, the transplantation outcome of primary refractory or relapsed AML was poor. However, the presence of chronic GVHD indicated favorable outcome in terms of overall survival.

1241

ACUTE PROMYELOCYTIC LEUKEMIA (APL) IN VERY ELDERLY PATIENTS (> 70 YEARS)

R Latagliata, P Finsinger, M Breccia, C Minotti, I Carmosino, L Cannella, P Volpicelli, F Vozella, C Stefanizzi, G Loglisci, G Cimino, R Foà

Ematologia - Università La Sapienza, Rome, Italy

Background. Acute Promyelocytic Leukemia (APL) is a rare subtype of Acute Myeloid Leukemia (AML) which is more common in younger adults, with a median age of 45-50 years at onset. *Aim and Methods.* The use of All-trans Retinoic Acid (ATRA) as tailored treatment has made APL a very curable disease also in patients aged > 60 years; however, there are only few case reports in very elderly APL patients. To address this issue, we revised clinical data and treatment results in 12 patients aged > 70 years with newly diagnosed APL followed at our Institution from 1/91 to 12/2008. *Results.* Clinical characteristics at onset were as follows: M/F 7/5, median age 74.7 years (range 70.0-80.8), M3/M3v 11/1, median WBC 1.3×10^9/L (range 1.0-7.4), median PLTS 53×10^9/L (range 12-302), BCR1/BCR3 6/6. According to Sanz risk score, 7 patients were at low-risk and 5 at intermediate-risk; 6/12 patients had arterial hypertension, 4/12 a concomitant cardiologic disease, 3/12 a cerebrovascular disease and 2/12 a previous neoplasia. Induction therapy consisted of ATRA + Idarubicin in 8 patients (2/8 with reduced Idarubicin dosage) and ATRA alone in 4 patients; in this latter group, however, 2/4 needed to add chemotherapy (CHT) based on Mitoxantrone + AraC due to hyperleukocytosis during ATRA treatment. All patients achieved both morphological and molecular Complete Remission (CR) after a median time of 50 (range 29 - 65) and 105 (range 51 - 239) days, respectively. Infective complications were observed in 10/12 patients (4 episodes of FUO, 6 sepsis, 2 cystitis and 1 oral abscess) while ATRA syndrome occurred in 2/12 patients; in addition, there were 3 episodes of cardiac ischemia and 3 episodes of paroxystic atrial fibrillation. All but one patient received consolidation therapy (based on CHT alone in 7 patients, CHT + ATRA in 3 patients and ATRA alone in 1 patient), followed by maintenance treatment in 8 patients. Four patients had a relapse (hematological in 3 cases and molecular in 1 case) after 8, 11, 35 and 56 months respectively. At present, 6 patients are still alive, 4 died due to disease progression (3) or senectus while in CR (1) and 2 were lost to follow-up while in CR: mean event-free survival and overall survival were 89.2 months (95%CI 52.6 - 125.8) and 99.9 months (95%CI 65.0-134.7), respectively. *Conclusions.* ATRA-based treatment of APL is safe and effective also in very elderly patients, with long-lasting disease-free and overall survival.

1242

INCIDENCE, CLINICAL CHARACTERISTICS AND OUTCOME OF ACUTE MYELOID LEUKEMIA PRESENTING WITH CONCURRENT EXTRAMEDULLARY LEUKEMIC TUMORS: A SINGLE-CENTRE EXPERIENCE

L Marbello, AM Nosari, E Ravano, V Mancini, M Riva, M Nichelatti, S Miqueleiz Alamos, L Paris, E Morra

Ospedale Niguarda Cà Granda, Milano, Italy

Introduction. Acute myeloid leukaemia with extramedullary leukemia (EML) at presentation has been the object of few studies. Most of publications concern case reports. Data about incidence and prognostic impact are variable and conflicting and probably reflect lack of definite criteria. *Materials and Methods.* We examined retrospectively 214 consecutive adults up to 60 years of age with *de novo* AML, admitted to our institution from 1995 to 2009 and uniformly treated. The median age was 45 years (range16-59). There were 103 male and 111 female. Median follow-up was 19,3 months. We found 14 patients (6,5%) with concurrent EML at presentation. Outcome of this subset of patients was compared with patients without extramedullary involvement. *Results*. There were 6 male and 8 female. The median age was 40 years. The anatomical sites affected were: skin (n=4), skin and cervical lymph nodes (n=1), spleen (n=1), central nervous system (n=2), ovary (n=1), parotid gland (n=1), abdominal lymph nodes and kidneys (n=1), cervical lymph nodes (n=1), paraspinal (n=1). Cytologic or hystologic diagnosis of extramedullary localizations were performed in all patients except four (the patients with central nervous system and paraspinal localizations and the patient with skin and cervical lymph nodes involvement). Median of white blood cells (WBC) count at presentation was 83×10^9/L (range 1,3 -180). Median lactate dehydrogenase (LDH) level was 790 U/L. According to FAB classification there were 2 M0, 4 M1, 1 M2, 5 M4, 2 M5. Cytogenetic analysis was performed in 13 patients. They were categorized according to Medical Research Council criteria. Two patients had favourable karyotype and 11 patients had intermediate karyotype (9 patients with normal karyotype and 2 patients with abnormality 11q23/MLL). Data about FLT3 mutations were available for 13 patients: there were 3 FLT3-ITD mutations (23%) and 1 FL-TKD mutation (7%). Age, WBC count, FAB subtype, karyotype, FLT3 mutation did not differ statistically in the two populations. Complete response rate was 50% in patients with EML and 63% in patients without EML (P=0.113). Relapse free survival (RFS) did not significantly differ in the two populations: 14,4 months in the EML group *vs.* 16,1 months (P=0.869). Overall survival (OS) did not significantly differ in the two populations: 19,4 months in the EML group *vs.* 23,5 months (P=0.931). In a Cox multivariate analysis, both OS and RFS were not influenced by presence or absence of extramedullary involvement, even when adjusting by gender, FAB, FLT3, WBC count and karyotype. *Conclusions.* Incidence of AML with EML in our institution was 6,5%. Skin was involved alone or with other tissues in 35% of patients. Fifty per cent of patients had FAB M4 or M5. A normal karyotype was found in 69% of cases. Rate of FLT3 mutations did not differ from that in literature. We did not find a statistical difference in the outcome of this subset of AML.

1243

RELATION BETWEEN PHENOTYPIC FEATURES AND MOLECULAR PROGNOSTIC MARKERS IN ADULT ACUTE MYELOID LEUKEMIA

M Mello, MA Bezerra, F Pereira, D Albuquerque, K Pagnano, F Costa, I Lorand-Metze

Hematology and Hemotherapy Center - University of Campinas, Campinas, Brazil

Background. The FLT3 gene is frequently mutated in acute myeloid leukemia (AML), either by internal tandem duplication (ITD) of the juxta-membrane domain or by activating point mutations in the second tyrosine kinase domain (TKD). Together with nucleophosmin (NPM1) gene mutation, FLT3 alterations are the most frequent molecular changes in AML. FLT3-ITD is related to a poor prognosis of the patients. Mutations in exon 12 of the NPM1 gene are the most frequent genetic abnormality in adult AML, found in 50-60% of patients with normal karyotype and are associated with a better prognosis. Interestingly, this prognostic advantage of NPM1 mutations can only be observed in patients lacking additional FLT3-ITD mutation. *Aims.* We have analyzed the correlations of FLT3 and NPM1 mutations with phenotypic features and karyotype in adult patients with AML diagnosed at our Institution between 2006 and 2009. *Methods.* Diagnosis of the patients was made by bone marrow cytology and karyotype, and classified according to the WHO criteria. Immunophenotyping was made using three-color combinations of monoclonal antibodies. Genomic DNA was extracted by phenol-chloroform. Genotyping was made with the MegaBACE 1000 equipment and analyzed by the software Fragment Profiler v1.2. For detection of the FLT3-TKD mutation, genomic DNA was amplified by PCR followed by restriction analysis. Methylation of p15 and p73 were also analyzed (COBRA and MSP techniques respectively). *Results.* We studied 103 cases. Median age: 52 years (15-97). PB leukocytes: 24.8×10^9/L. In 71 cases the karyotype was available: 15 had t(15;17), 6 had an otherwise low risk karyotype, 33 had a normal, and 17 a high risk karyotype. NPM1 was mutated in 25 cases. All except one had a normal karyotype. However, 44% presented FLT3-ITD. Patients with methylated p15 had a higher frequency of FLT3-TKD and higher leukocyte counts. Those with methylated p73 had a lower frequency of FLT3-ITD as well as lower peripheral leukocytes. Cases without any of the mutations studied had higher hemoglobin (P=0.023) and lower leukocyte counts (P=0.0008). The cases with unmutated NPM1 had lower expression of CD11b (P=0.006) and CD33 (0.028) and a higher expression of CD34 (P=0.01). Patients with FLT3-TKD mutation were

older (P=0.017) and had a higher expression of CD33 (P=0.043). *Conclusions.* Among our patients, NPM1 mutation, although occurring in patients with a normal karyotype, was associated with FLT3-ITD. Besides, in our study there was a high frequency of high risk karyotype. Therefore, several factors influenced the prognosis of the patients. Concerning phenotypic features, the patients with mutated NPM1 had a more mature phenotype. These findings could have important implications for the therapeutic use of anti-CD33 in patients with newly diagnosed AML.

SERUM FERRITIN AS A PROGNOSTIC MARKER IN YOUNG ADULT ACUTE MYELOID LEUKEMIA

M Delia, D Pastore, F Albano, P Carluccio, S Scardino, C Spinosa, C Longo, G Nardelli, V Fesce, V Liso, G Specchia

Hematology-University of Bari, Bari, Italy

Background. Different studies have demonstrated an iron overload contribution to post-transplantation liver toxicity, infectious events and poor survival in patients undergoing hematopoietic stem cell transplantation for haematological malignancies. *Aims.* So far, in the clinical setting of adult acute myeloid leukaemia (AML) there is no evidence of the possible role of iron in response and survival rates. We studied the role as a prognostic factor of pre-treatment serum ferritin in young adult AML. *Methods.* The study sample included 43 consecutive adult *de novo* AML patients (17 males and 26 females, median age 46 years, range 16 to 60 yrs). The serum ferritin level was determined at onset of the disease in each case. According to the FAB criteria the subtypes were: 3 M0, 29 M2, 6 M4, 4 M5, 1 M6. M3 subtypes were excluded from the analysis. NPM, FLT3 and cytogenetic evaluation was performed for all cases. The NPM mutation was present in 16 patients (37%) and 16 (37%) harboured the FLT3 alteration (ITD: 9 (21%); D835: 7 (16%)). Sixteen (37%) patients were in the unfavourable cytogenetic group, 8 (19%) in the favourable group and 19 (44%) presented a normal karyotype (NK). The patients were subdivided into two groups according to serum ferritin values (<800 *vs.* > 800 ng/mL). Student's t-test or the Mann-Whitney test was performed for comparisons of means. Two-tailed Fisher's exact test was used to compare categories. Overall survival (OS) was measured from the time of diagnosis to death or last follow-up visit and was calculated using the Kaplan-Meier method; the log-rank test was used to compare survival curves. Logistic regression was performed for multivariate analysis. Only p values <0.05 were considered statistically significant. *Results.* Seventeen (40%) patients showed a ferritin serum value > 800 ng/mL. Compared with the <800 ng/mL group, patients with serum ferritin > 800 ng/mL were more frequently non responders to chemotherapy (35 *vs.* 73%, P=0.003) and they had a shorter OS (235 *vs.* 657 days, P=0.006). Moreover, patients with serum ferritin >800 ng/mL showed a higher frequency of documented infections during induction treatment (35% *vs.* 4%, P=0.001). At multivariate analysis, FLT3, NPM, Cytogenetic and Ferritin value (<o>800 ng/mL) all showed a statistical correlation with the response rate (P=0.02; P=0.05; P=0.03; P=0.03, respectively). *Conclusions.* The results of our study suggest a link between serum ferritin and AML prognosis. Further studies are needed to confirm the utility of serum ferritin as a prognostic marker in the adult acute myeloid leukaemia setting.

1245

THE EXPRESSION OF BMPS RECEPTORS CORRELATES WITH RESPONSE TO INDUCTION THERAPY AND SURVIVAL IN PATIENTS WITH ACUTE LEUKEMIAS

J Dzietczenia, T Wróbel, G Mazur, B Jazwiec, E Stefanko, K Kuliczkowski

Medical University, Wroclaw, Poland

Background. The pathogenesis of acute leukemias (AL) is related with abnormalities of cells signaling pathways, proliferation and apoptosis. Bone morphogenetic proteins (BMPs) are multifunctional cytokines which belong to the transforming growth factor β (TGFβ) family. They participate in the regulation of growth, differentation and apoptosis in a variety of cell types including hematopoietic lineages. The role of BMPs in pathogenesis of acute leukemias remains unclear. *Aim*. The aim of this study was to evaluate the expression of BMPRIA, BMPRIB and BMPRII on the blast cells and their significance as prognostic factors in patients with acute leukemias. *Materials and Methods.* 70 patients with newly diagnosed AL were evaluated (28 females and 42 males). The median age of patients was 52 years. There were 57 patients (81%) with acute myeloid leukemia (AML) and 13 patients (19%) with acute lymphoblastic leukemia (ALL). The diagnosis was performed according to the FAB criteria for AML patients and EGIL criteria for ALL patients. The healthy control group included 10 age-matched individuals (5 females and 5 males). Bone marrow samples were taken before induction therapy. The mononuclear cells from bone marrow were separated by density-gradient centrifugation. The expression of BMPRIA, BMPRIB and BMPRII was detected by using specific antibodies anti-BMPRIA, anti-BMPRIB and anti-BMPRII (R&D Systems). Leukemic cells were gated based upon their CD45 expression. Two-colour immunofluorescence stainging was performed. The expression of BMPs receptors was analyzed for fluorescence on PAS flow cytometer. The results were statistically analyzed using 'STATISTICA 8,0'. Statistical analysis was performed by means of Mann-Whitney's U-test and P<0,05 indicated a significant difference. The survival of patients was analyzed by the Kaplan-Meier method. *Results*. 38 patients (54%) with AL achieved complete remission (CR) after induction therapy, 6 patients (9%) achieved partial remission (PR) and 26 patients (37%) had no response. The percentage of leukemic cells with expression of BMPRIA, BMPRIB and BMPRII was significant higher in patients with CR than in patients with NR. We observed that expression of BMPRIA, BMPRIB and BMPRII on leukemic cells were significantly lower in patients with early relapse (up to three months after induction therapy) in comparison with patients still being in remission. Patients with the higher percentage of leukemic cells with expression of BMPRIA and BMPRII had the longer survival than patients with the lower BMPRIA and BMPRII expression. The results are shown in Table 1. *Conclusion.* Our results suggest that BMPs receptors could be an independent prognostic factor for response rate and survival after induction therapy in patients with acute leukemias. This observation should be validated by larger study.

Table 1. BMPs receptors and response to treatment.

	CR+PR n=44	NR n=26	Early relapse n=20	Without relapse n=50	p
BMPRIA	39,67±12,51	13,72±6,44	17,54±10,88	27,79±18,27	<0,05
BMPRIB	44,56±7,38	13,45±5,82	19,37±15,35	28,81±17,62	<0,05
BMPRII	44,41±9,62	12,33±3,50	19,58±14,24	28,60±17,89	<0,05

1246

A SIMPLE MOLECULAR PROFILE AT DIAGNOSIS MAY PREDICT THE PROBABILITY OF ACHIEVING COMPLETE REMISSION IN UNTREATED DE NOVO NON-M3 AML PATIENTS

M Miglino,[1] N Colombo,[1] R Grasso,[1] G Pica,[2] M Clavio,[1] G Beltrami,[2] M Bergamaschi,[1] F Ballerini,[1] A Ghiso,[1] L Vignolo,[1] MV Lucchetti,[1] L Mitscheunig,[1] A Cagnetta,[1] S Aquino,[1] C Marani,[1] C Ghiggi,[1] I Pierri,[1] L Canepa,[1] M Sessarego,[1] AM Carella,[2] M Gobbi[1]

[1]Institute of Hematology University of Genoa, Genova, Italy; [2]I Division of Hematology, S Martino Hospital, Genova, Italy

Background. FLT3 mutations and expression of NPM, WT1, BAALC and other genes may exert a relevant role in predicting complete remission and outcome of AML patients. *Aims and Methods.* A molecular profile was performed in 93 consecutive untreated non M3 denovo AML patients receiving induction chemotherapy (standard induction in 38 patients, fludarabine-ara C-idarubicin and low dose gemtuzumab ozogamicin in 65 patients) with the aim of predicting CR rate and long term outcome. Expression levels were obtained by Real-Time-PCR upon normalization on Abl expression. *Results.* 51 patients were younger than 60 years (median age 50) and 42 were older (median age 69). Intermediate or favourable karyotype was detected in 73 patients (78%). Unfavorable karyotype was more frequent in patients older than 60 years, compared with younger ones (31% *vs.* 14%, respectively, p 0.04). FLT3: 20 patients (21%) had ITD and 7 (8%) had exon 20 mutations. WT1: in 24 patients (26%) expression was > 2365 (>75th percentile); in 69 < 2365 (74%); NPM : the gene was mutated in 37 patients (40%) and non mutated in 56 (60%); BAALC: in 47 patients expression was <1000 (51%), in 46>1000 (49%). Molecular profile was similar in the younger and in the older subgroups of patients (p NS). In the entire cohort of patients CR rate was not influenced by the type of induction. CR rate was higher in patients aged 59 or less (P<0.001), in patients with normal or intermediate karyotype (not unfavourable karyotype)

(73% compared with 30% in patients with unfavourable karyotype, p 0.001), in patients with mutated NPM gene (76%, compared with 55% in non mutated NPM; p 0.03), in patients with BAALC expression < 1000 (75% compared with 52 in patients with BAALC expression > 1000, P 0.02) and in patients with WT1 expression > 2365 (79% compared with 56% in patients with WT1 expression < 2365; p 0.05). The presence of FLT3 ITD or FLT3 mutations at exon 20 did not affect CR rate. In the group of 73 patients with not unfavourable karyotype the level of WT1 expression retained a statystical influence on CR rate (90% in patients with WT1 expression > 2365, compared with 65% in patients with WT1 expression < 2365; p 0.03), whereas mutation of NPM gene and BAALC expression had a borderline influence on CR rate (p 0.07 and 0.08, respectively). *Conclusions.* In the whole cohort of denovo AML patients age, karyotype and a simple molecular analysis at diagnosis, including BAALC and WT1 expression and mutational status of NPM gene may predict the probability of achieving CR. In the subgroup of patients with not unfavourable karyotype high (> 2365) WT1 expression was the best positive predictor of CR. A longer observation and further statystical analysis are required to evaluate whether this will be associated with an improved outcome also.

1247

INTERNAL TANDEM DUPLICATION OF FMS-LIKE TYROSINE KINASE-3 DETERMINES A SIGNIFICANT PROGNOSTIC FACTOR ON ACUTE PROMYELOCYTIC LEUKEMIA

H Tashiro, Y Oka, R Shirasaki, T Sugao, M Mizutani-Noguchi, N Akiyama, K Kawasugi, N Shirafuji

Teikyo University School of Medicine, Tokyo, Japan

Background and *Aims.* Internal tandem duplication of fms-like tyrosine kinase-3 (FLT3-ITD) is observed in 20-30_ of the newly diagnosed acute myelogenous leukemia (AML), and that shows significant poor-prognosis in AML with normal karyotype on the response to chemotherapy and over-all duration of the survival. On acute promyelocytic leukemia (APL), it has been still under discussion whether FLT3-ITD is a significant prognostic factor. To clarify this point, we observed FLT3-ITD and clinical outcome of APL prospectively. *Patients, materials and Methods.* We analyzed APL patients (pts), who hospitalized to our institute from Nov. 1998 to Dec. 2009. Bone marrow cells were collected from informed patients, and mononuclear cells were separated with gravity-sedimentation method. After elimination of an adherent cell-fraction, RNA was extracted from the prepared non-adherent mononuclear cells. FLT3-ITD was analyzed with reverse transcription-polymerase chain reaction (40 cycles). *Result.* There were 26 pts (median age 46.5, range 18-74 years) with a diagnosis of APL who were screened for FLT3-ITD. Fifteen pts were male, and 11 were female. Of the 26 pts, 6 (23%) presented with FLT3-ITD. A median WBC counts at the time of diagnosis were 215×10^9/L (range 22-1561×10^9/L) and 16.5×10^9/L in FLT3-ITD positive pts and negative ones, respectively. All pts were treated on Japan Adult Leukemia Study Group APL97 protocol. All cases achieved complete remission. The relapse rates of FLT3-ITD positive pts and negative ones were 100% and 5%, respectively. Among FLT3-ITD positive pts, median duration to 1st relapse from diagnosis was 469 days (range 240-737). The rates of CNS involvement were 50% and 5%, respectively. In FLT3-ITD negative pts group, only one pts had experienced relapse. Interestingly, FLT3-ITD was detected in this pts when bone marrow relapse was demonstrated. *Discussion and Conclusion.* FLT3-ITD plays by itself an important prognostic factor for the relapse and CNS involvement on APL. We should consider an intensive treatment strategy to the FLT3-ITD positive APL pts during maintaining 1st CR.

1248

ACUTE MYELOID LEUKEMIA WITH MYELODYSPLASIA RELATED CHANGE SHOWED A LOWER COMPLETE REMISSION RATE, BUT EQUIVOCAL SURVIVAL COMPARED TO THOSE WITHOUT MYELODYSPLASIA RELATED CHANGE

K Dong Hwan,[1] JH Kong,[1] YW Won,[2] JH Jang,[1] K Kim,[1] HJ Kim,[1] SH Kim,[1] CW Jung[1]

[1]Samsung Medical Center, Seoul, South-Korea; [2]National Center Center, Goyang, South-Korea

Background. Revised World Health Organization (WHO) classification adopted acute myeloid leukemia (AML) with myelodysplasia related change (MRC) as new disease entity. AML with multilineage dysplasia is known to be associated with worse prognosis although it is still in debate. *Aims.* The present study attempted to evaluate the impact of the presence of MRC at the time of diagnosis on the achievement of complete remission (CR), overall (OS) and leukemia free survival (LFS)in patients with AML. *Methods.* The current retrospective study includes AML patients receiving induction chemotherapy between 2001 and 2008 at the Samsung Medical Center, Seoul, Korea, and having available report of marrow morphology data including marrow aspirates and biopsy specimen. According to the presence of MRC in the marrow samples, followings were compared such as patients' demographics, clinical characteristics, CR rate, LFS and OS. *Result.* A total 286 of patients were included, of whom median age was 47 years (15-81). Forty nine patients (20.2%) presented MRC in the marrow samles. The patients with AML-MRC showed characteristics of higher frequency of unfavorable karyotype (P=0.020), and none of them had favorable karyotype. In order to investigate the clinical implication of MRC on CR rate, OS and LFS, 44 patients having favorable karyotype were excluded from the analysis, and finally data of 242 patients with intermediate or unfavorable karyotype were analyzed. Compared to those without MRC, the patients with AML-MRC showed lower WBC counts (P<0.001) and peripheral blast counts (P<0.001), but was not associated with age or gender.. However, those with AML-MRC showed a lower CR rate at 57% compared to those without MRC (79%, P=0.002). Although those without AML-MRC showed higher CR rate, it was not directly translated into better survival: Between those with MRC and without MRC, there was no statistical differences of LFS (P=0.190) or OS (P=0.365). In Cox proportional hazard model, MRC was not identified as an independent prognostic factor for OS (HR 0.952 P=0.834), while an achievement of CR (P<0.001) and cytogenetic risk group (P=0.02) were found to be significant prognostic factors for OS. *Conclusion.* Although CR rate following induction chemotherapy was lower in patients with AML-MRC, they do not seem to have inferior outcomes than those without MRC. It is not necessary to decide different treatment strategy according to the presence of MRC in initial marrow.

1249

COMBINED EPIGENETIC AND SIGNAL TRANSDUCTION THERAPY MODULATE SPECIFIC SIGNAL TRANSDUCTION PATTERNS IN ACUTE MYELOID LEUKEMIA

J Skavland,[1] K Hadziavic,[1] R Hovland,[2] I Jonassen,[1] Ø Bruserud,[2] B Gjertsen[1]

[1]University of Bergen, Bergen, Norway; [2]Haukeland University Hospital, Bergen, Norway

Elderly patients with secondary acute myeloid leukemia (AML) have a limited response to conventional therapy and short survival. The advanced age and comorbidities leads to limited tolerance for intensive chemotherapy. Cell signaling and responses to growth factor stimulation is frequently altered through mutations in key signal nodes of AML. We treated selected elderly AML patients with all-trans retinoic acid (ATRA) for two days alone before adding theophylline and the histone deacetylase inhibitor valproic acid (ClinicalTrials.gov NCT00175812; EudraCT no. 2004-001663-22). Single cell signaling was determined before treatment and during therapy by phospho-flow cytometry in AML cells stimulated with various growth factors and cytokines. A combination of seven different stimuli and phosphorylation of eight signaling proteins (CREB, STAT1/3/5, p38, Erk1/2, Akt and rpS6) indicated perturbations in signal transduction pathways associated with less aggressive growth and differentiation after therapy. AML cellular subsets responded differently to stimuli and were modulated during therapy. Individual signaling profiles together with clinical and hematologic information may identify responders of low toxicity therapy of AML.

1250

EXPRESSION OF GRP78 AND OCT1 IN ACUTE MYELOBLASTIC LEUKEMIAS

E Stefanko,[1] T Wróbel,[2] B Jazwiec,[2] J Dzietczenia,[2] G Mazur,[2] K Kuliczkowski[2]

[1]Department of Hematology, Blood Neoplasms and Bone Marrow Transplantation, Medic, Wroclaw, Poland; [2]Department of Hematology, Blood Neoplasms and Bone Marrow Transplantation, Wroclaw, Poland

Background. Despite continuous progress in therapy of AML, relapses and resistance to chemotherapy remain a challenge for the physician.

GRP78/BiP (glucose regulated protein 78/ immunoglobulin heavy-chain binding protein) and OCT1/SLC22A1 (organic cation transporter 1/ solute carrier family 22, member 1) are linked to drug resistance in solid tumors. There are no data about role of expression of these proteins in AML. *Aims.* The main objective of this study was to compare the expression of GRP78 and OCT1 mRNA between non-M3 AML patients and healthy individuals. *Methods.* Using quantitative reverse transcriptase PCR, the mRNA expression of two genes GRP78 and OCT1 was measured. Bone marrow samples of 83 AML patients (median age 49 years, range 19-84) taken at diagnosis, comprising all subtypes on the basis of FAB classification (without M3 subtype) were assessed. The control group consisted of 8 bone marrow aspirates from healthy individuals. The relative quantitation was indicated by cycle threshold (Ct) values. The Ct value of the target genes was normalized (_Ct) to the Ct value of the ABL gene of the samples. *Results.* GRP78 and OCT1 mRNA were expressed in all samples. A statistically significant (P=0.00001) decrease in OCT1 mRNA expression was observed in AML patients compared with control group (ΔCt 7.382 SD 2.11 *vs.* ΔCt 3.06 SD 1.269 respectively). GRP78 mRNA expression was higher in AML samples than in healthy individuals (ΔCt -4.791 SD 0.75 *vs.* ΔCt -5.097 SD 0.453 respectively), although there was no statistically significant difference (P=0.212). There was also no statistical correlation between the expression levels of GRP78 and OCT1 in AML patients and complete remission rate. *Conclusions.* Our preliminary data indicate differences in expression of GRP78 and OCT1 mRNA in AML patients compared to healthy individuals. Further studies should be undertaken to demonstrate their clinical impact in acute myeloblastic leukemia.

1251

MYELOID SARCOMA: CLINICAL CHARACTERISTICS AND PROGNOSIS

O Baranova, N Falaleeva, S Lunina, A Shirin, A Kovrigina, M Volkova

N.N. Blokhin Cancer Research Center RAMS, Moscow, Russian Federation

Introduction. Myeloid sarcoma (MS) is a rare hematologic neoplasm which was defined by WHO classification as a separate myeloid tumor. Any site of the body other than the bone marrow (BM) can be affected by this tumor. MS may occur *de novo* and as the manifestation of relapse in patients (pts) with previously diagnosed acute myeloid leukemia (AML). The aim of the study was to investigate clinical characteristic and prognosis in pts with *de novo* MS. *Methods.* We observed 121 pts with AML treated at N.N. Blokhin Cancer Research Center RAMS from 2000 to 2010. In this study we included pts with *de novo* MS with extramedullary lesions without BM involvement (according to BM smears and BM biopsies examinations). MS diagnosis was based on histological and immunohistochemical tumor mass studies. Immunohistochemical study was performed with monoclonal antibodies for MPO, lysozyme, CD33, CD13, CD117, CD15, CD68, CD34, TdT, PGM1. *Results.* MSs *de novo* were revealed in 8 pts (6,6%) and as relapse of AML in 2 pts (1,7%). Median age of pts with MSs *de novo* was 39 years (range 26-61). Male: female ratio - 3:5. MSs localizations: 3 cases of genital system lesions (2 - vagina and regional lymph nodes, 1 - uterus, ovary and regional lymph nodes); 1 case - bulky tumor mass in soft tissues of supraclavicular, subclavian, axillary, scapular areas and regional lymph nodes; 1 case - shin bone and soft tissues of this area; 1 case - neck and supraclavicular lymph nodes; 1 case - bulky tumor mass in mediastinum, lesions of pericardium, pleura, lung, mediastinal lymph nodes; 1 case - small bowel (with features of its acute obstruction). Treatment of MS consisted of the regimen for AML: induction therapy "3+7+7"(Idarubicin 12 mg/m^2 d 1-3, Ara-C 200 mg/m^2 d 1-7, Etoposide 75 mg/m^2 d 1-7), 2 cycles of consolidation therapy "HAI"(Idarubicin 12 mg/m^2 d 2, 4 plus Ara-C 3 g/m^2 every 12 hours d 1, 3, 5), 4 cycles of post-consolidation therapy "1+5+5"(Idarubicin 12 mg/m^2 d 1, Ara-C 200 mg/m^2 d 1-5, Etoposide 75 mg/m^2 d 1-5). All pts received intrathecal Mtx + Ara-C + Dexa. In 1 case of small bowel acute obstruction the first step of treatment was surgical. 2 pts received radiotherapy on tumor lesions areas. 1 patient received high-intensity chemotherapy and autologous stem cell transplantation after 2 cycles of consolidation therapy "HAI". Follow-up period was 16 months. Median OS and median RFS were not reached. 1 case of relapse was registered. RFS was 67% at 3 year_s follow-up period. Remission duration ranged from 1+ to 39+ months, life duration ranged from 4+ to 52+ months, all pts are alive at the time of analysis. *Conclusion*. MSs are characterized by various clinical features. Intensive chemotherapy for AML makes it possible to obtain encouraging results in treatment of MSs.

1252

CORRELATING OUTCOMES AND LONG-TERM SURVIVAL FOLLOWING CHEMOTHERAPY IN NORMAL KARYOTYPE AML WITH MOLECULAR RISK - SINGLE CENTRE EXPERIENCE

LC Lim, GF How, Y Loh, GC Wong

Singapore General Hospital, Singapore, Singapore

Background. Patients with normal karyotype AML (NK AML) are a heterogeneous group and assessment for molecular genetic aberrations are important for prognostic differentiation. Presence of mutation involving internal tandem duplication of FLT3 gene (FLT3-ITDmut) is reported in 20-30% NK AML and is associated with poor outlook. In contrast, prognosis is considered good for patients who are FLT3-ITDmut negative but have mutations of NPM1 (NPMmut) or CEBPA (CEBPAmut) genes. *Aims.* We analyse the molecular profile in relation to therapeutic outcomes following chemotherapy in 35patients with NK AML treated between 2003-2007. *Methods.* Only patients less than 65 years old who received induction chemotherapy were included in study. Molecular analyses for mutations of FLT3-ITD, NPM1 and CEBPA were performed on bone marrow samples obtained at diagnosis. Standard induction therapy was idarubicin and cytarabine (IA3+7). Bone marrow assessments were performed on day 14 of induction and also upon recovery of neutrophil and platelet counts. Patients who failed to go into complete remission (CR) with 1 course of induction undergo a second cycle of IA3+7. Subsequent to achieving CR, further chemotherapy was administered with: 1 cycle of IA2+7 and 1 cycle of high dose cytarabine (HDAC). Following this, patients with persistent leukemia or who failed to go into CR after 1 cycle of induction chemotherapy or are FLT3-ITDmut positive undergo allogeneic stem cell transplant (alloSCT) if they have available sibling or match unrelated donors. All others undergo either autologous stem cell transplant (autoSCT), or 2 more cycles of HDAC. *Results.* The median age was 40years (15-63 years) and median follow up 30months (4 to 79months). Of 35 patients, overall rate of CR after 1 cycle of induction chemotherapy (CR1) was 26/35 (74%). Nine patients (26%) required 2 cycles of induction chemotherapy following which 8 achieved remission but 1 remained refractory and died of sepsis. Responses to chemotherapy and outcomes were correlated with presence or absence of the 3 molecular genetic aberrations as indicated in Table 1. Conclusion. In absence of FLT3-ITDmut, NPMmut or CEBPAmut positivity predicts for good responses to induction chemotherapy. Long-term outcomes are excellent following consolidation chemotherapy in this group as 80% remain disease free at 5 years compared with 5-year DFS of 14% for FLT3-ITDmut positive or triple negative patients (P=0.02). AutoSCT for consolidation is a reasonable approach for FLT3-ITDmut negative but NPM1mut or CEBPAmut positive patients.

Table 1.

1253

ACUTE MYELOID LEUKEMIA IN PATIENTS AGED 70 OR OLDER. EXPERIENCE AT A SINGLE CENTRE

JN Rodríguez, E Martin, MV Moreno, A Palma, JA Quesada, A Chacón, MJ Romero, K Gómez, A García-Sola, JC Diéguez, A Amian, A Fernández-Jurado

Hospital Juan Ramón Jiménez, Huelva, Spain

Background. The management of old patients with acute myeloid leukemia remains controversial, specially in those cases affecting very old patients (aged ≥70) in which the dilemma therapeutic abstention *vs.* treatment (with low or high intensity ones) is a major subject. *Aims.*- We present the experience in our centre with this group of patients in the period 1990-2009. *Methods.* During the period of study 85 cases were

diagnosed (relapses and FAB M3 cases were excluded). Patients were divided into 3 groups according to the treatment: supportive treatment, low intensity treatment (low doses Ara-C: 10 mg/m^2/12h s.c. days 1-21) and high intensity treatment (adapted ICE: Idarubicin 10 mg/m^2 days 1 and 3; Ara-C 100 mg/m^2/12h days 1-3; Etoposide 100 mg/m^2 days 1-3). *Results.* The mean age of patients was 76,6 years (70-97); sex distribution was 42 males and 43 females; mean Karnofsky index was 71,9 (30-100); 51 patients received treatment and 34 did not; overall survival was 6,9 months (median 2; 0,03-90+), significant differences were observed in the mean overall survival between the treated and no-treated groups (10 *vs.* 2,2 months respectively; P=0.01). In the low intensity group (31 patients) an overall response of 32,2% (6 CR, 4 PR, 14 NR and 7 not evaluable) was observed while in the high intensity one (20 patients) this overall response was 55% (9 CR, 2 PR, 4 NR and 5 not evaluable); no statistical differences were observed between both groups considering all subgroups of response (P=0,17), however grouping PR+CR *vs.* NR+not evaluable these differences were significant (P<0.01). Considering overall survival, no statistical differences were observed between the low and high intensity groups 7,1 (0,25-90+) *vs.* 14,4 (0,25-76+) months (P=0,15) respectively. *Conclusions.* Overall survival in the treated group is higher than in the non-treated one, differences reached statistical significance (P=0,01). Comparing both arms of treatment statistical differences were observed in the quality of response (PR+CR *vs.* NR+not evaluable), a higher proportion of complete responses were observed in the high intensity group (45% *vs.* 19,3%, respectively), however, if this circumstance will contribute to a longer survival is still unknown. Though no statistical differences have been observed in the overall survival between both groups of treatment, these differences are increasing along time.

1254

ABSOLUTE LYMPHOCYTE COUNT (ALC) IS A POWERFUL PREDICTOR OF OUTCOME IN PATIENTS WITH ACUTE MYELOID LEUKAEMIA (AML) RECEIVING INTENSIVE CHEMOTHERAPY

V Narwani,[1] B Powell,[1] T Corbett,[2] J Duncan,[2] P Hill,[2] R Johnston,[2] T Chevassut[2]

[1]Brighton and Sussex Medical School, Brighton, UK; [2]Haematology, Royal Sussex County Hospital, Brighton, UK

Recent evidence has highlighted the value of the absolute lymphocyte count (ALC) as a useful prognostic indicator of outcome in patients undergoing intensive chemotherapy for treatment of haematological malignancy, notably acute leukaemia. We sought to study the relationship between the ALC and relapse-related mortality in 32 patients who had received intensive chemotherapy for a variety of haematological malignancies from 2005 to 2008 at the Royal Sussex County Hospital in Brighton. In particular, we tested the hypothesis that the ALC is a predictor of survival in acute myeloid leukaemia (AML) which comprised the major disease subgroup. We undertook a retrospective analysis of all level 2 patients treated with intensive chemotherapy at the Royal Sussex County Hospital. The period of study covered three years and included 32 patients, of whom 17 had AML. The ALC was available for all these patients at days 1, 8, 15, 22, 29 following the initiation of induction chemotherapy. We divided the patients with AML into two groups according to whether or not they were still alive at the time of the analysis. The survivors (9/17) had a mean ALC at day 29 of 1020/μL whereas the non-survivors had a mean ALC at day 29 of 430/μL. This was statistically significant using a Student's unpaired t-test (P=0.0067). The mean ALC of all 17 patients was 720/μL with the median value of 800/μL. All 9 survivors had an ALC at day 29 greater than the median of the non-survivors (400/μL). Conversely, all but one of the non-survivors had an ALC at day 29 less than the median of the survivors (900/μL). We also performed a retrospective analysis of 39 patients diagnosed with multiple myeloma to see if the ALC was predictive of outcome in this condition. Our data demonstrates that the ALC is not predictive of outcome in multiple myeloma. We conclude that the day 29 ALC is a simple and statistically powerful measurement of outcome for patients receiving intensive chemotherapy for treatment for AML that can serve as an independent prognostic indicator for improving risk stratification and management decision making in AML. We believe that the ALC reflects the underlying immune status of the patient and are currently investigating the mechanism by which this improves survival.

1255

RELAPSE OR REFRACTORY ACUTE MYELOID LEUKEMIA TRETED WITH AZACITIDINE

A Rosell, R Garcia, M Queipo de Llano, A Campos, G Ramirez, L Entrena, S Del Castillo

Hospital Virgen de la Victoria, Malaga, Spain

Background. Relapsed or refractory acute myeloid leukemia (AML) has a poor overall prognosis, namely in older patientes. Patients with intermediate or poor risk cytogenetics who have relapsed more than once generally have a median survival of less than a year. A number of salvage chemotherapy regimens have been employed in these settings. The hypomethylating agent, azacitidine are generally well tolerated and have been demonstrated to produce responses in a small percentage of patients with relapsed or refractory AML. *Aims.* To investigate the efficacy and toxicity of azacitine in seven patients with relapse or refractory AML *Methods.* From Oct-08 to Dic-2009, 5 patients with refractory or relapse AML, were included. High-risk cytogenetics were found in, Hematological response was assessed according to the International Working Group Criteria for AML. *Results.* At baseline the median age was 67(21-76) years. Male/female ratio 1/4, an ECOG performance status of 0-1 (4 patients; 80%). The most frequent initial dose of AZA applied was 75 mg/m^2 (in whom the dosage schemes applied were: days 1-5 and 8-9 (4 patients) and days 1-5 (1 patients)in every 28 days cycle. AZA were administrated mostly subcutaneously (4 patients). The mean number of cycles administered was X (range 1-15). The overall treatment response was % (IWG 2006 criteria): 40 % partial response and 40 % hematological response, . Nevertheless, 40% achieved a stable disease. AZA was generally well tolerated. Grade 3/grade 4 adverse events documented in these patients, independently of their relationship to the active treatment, were febrile neutropenia (40%), rash (0%), vomiting or nauseas (20%), using antiemetic profilaxis. All patients treated with azacitidine presented burden cytopenias so hematologic adverse events couldn't be analized. Subsequent therapy with allogeneic HSCT in one of these individuals. *Conclusions.* Our results demonstrate that in the community-based setting, patients with relapse or refractory AML response to the treatment with azacitidine. We expect this evidence could offer in the near future evidences for a better prognosis for these patients in our environment prolonging their survival time and offering a better quality of life. Azacitidine is well tolerated in patients with AML and can often be given in an outpatient setting This therapy facilitated allogeneic HSCT as further therapy in responding patients.

Table.

Edad/sexo	Citogenética	Regímenes previos	Recaída/refractario
68/Female	-7	LMA>65; FLAG-IDA	Refractaria
76/Female	-7	CETLAM>70 (3 ciclos)	Refractaria
67/Female	Del 5, +8	CETLAM>70 (completo)	Refractaria
63/Female	Normal	FLAG-IDA+Mylotag 1 ciclo	Recaida refractaria
21/Male	-7	CETLAM<70(induccion); FLAG-IDA	Refractario

1256

CLINICAL AND BIOLOGICAL CHARACTERISTICS OF ADULT BIPHENOTIPIC ACUTE LEUKEMIA (BAL): A SERIE OF 45 ALGERIAN PATIENTS

A Talbi, F Harieche, N Ait Amer, F Tensaout, M Benakli, S Akhrouf, F Boumansour, F Zerhouni, RM Hamladji

Pierre and Marie Curie Center, Algiers, Algeria

Background. BAL display features of both myeloid and lymphoid lineage. It is rare, actually well diagnose thanks to the immunophenotype. We present here the clinical and the biological characteristics and the out come of BAL in our experience. *Design and Methods.* We analysed 45 adult BAL patients (pts),diagnosed between January 2002 and December 2009 according to the European group for the Immunological characterization of leukemia (EGIL), among 429 adult acute leukemia pts diagnosed according to FAB classification. *Results.* During a period of 7 years, of 452 acute leukemia pts, 45 cases of BAL were diagnosed in our unit (10.4%), among them 33 (73.7%) were B lymphoid and myeloid (B/M), and 12 (26,6%) were T lymphoid and myeloid (T/M), no case of B/T or trilineage differenciation. The median age is 27 years old (15-81), the sex ratio is 1,6 (28 M/17 F). The median count of white cells, hemoglobin and platelet is respectively 30, 9 (1,1-239)×10^9/L, 81 (44-159)/L and

64 (9-477)/L, respectively. The median prevalence of blast in bone marrow was 94% (27-100). Nine patients (20%) have extra medullary infiltration, which most commonly affect the mediastinum, the central nervous system was affected in 4pts(8,8%).Lymph nodes was affected in 18pts (40%), spleen in 13pts (28,8%) and both in 11pts(24.4%). The incidence of CD34 antigen expression were 73,3%; 58.3% of them were T/M. Above Fifty patients who has a genetic profil, 3 has t (9-22), 2pts has t(8-21), and 1 a SIL- TAL transcript. The induction regimen was Vincristin, Daunorubicin and L Asparaginase in 42 pts (97,6%) with negative myeloperoxydase coloration, and Daunorubicine - Cytarabine in 3 pts (6,9%) with positive ones, 2 pts do not have any treatment. The complete remission rate was 81,5%.The median follow up is 5 years, twenty(44,4%) patients are still alive, 2 are in relapse, 25pts died (55.5%), 2 before treatement, 7 pts after relapse (16.2%), 7 are refractory (16,2%), 4pts (9.3%) in complete remission and 5 pts (11%) during the induction. The overall survival is 28,8%, The disease free survival is 26,6%. *Conclusion.* The prognostic of BAL pts is poor. They showed a most higher extra medullary infiltration, relapse and resistance to therapy after relapse. In our series the rate of death in complete remission is still too high, because of the remoteness of sanitary structure inducing late treatment of some infectious problems.

1257

BLASTIC PLASMACYTOID DENDRITIC CELL NEOPLASM (BPDCN): REPORT OF A CASE ASSOCIATED WITH CHRONIC MYELOMONOCYTIC LEUKEMIA

M Drera,[1] AM Pelizzari,[2] E Borlenghi,[2] D Marocolo,[2] M Ungari,[2] F Facchetti,[2] G Rossi[2]

[1]Spedali civili di Brescia, Brescia, Italy; [2]Spedali Civili, Brescia, Italy

Background. Blastic plasmacytoid dendritic cell neoplasm (BPDCN) is a rare, aggressive systemic neoplasm originated from plasmacytoid dendritic cells (PDC), a hematopoietic-derived cell implicated in the regulation of innate and adaptive immunity. *Aims.* We describe the clinical and biological characteristics of a case of BPDCN associated with myelomonocytic leukemia. *Methods.* A 73 years old woman presented with cervical lymphadenopathy and nodular erythematous cutaneous lesions, associated with mild anemia (Hb 11.6 g/dL) and thrombocytopenia (120000/mm^3), white blood cell (WBC) count and LDH were normal. On histology, skin, lymph nodes and bone marrow were infiltrated by blastic PDC as defined according to their phenotype ($CD4^+CD56^+CD123^+BDCA2^+TCL1^+CD2AP^+BCL11a^+$, with coexpression of CD2 and CD7, but negativity for B-, T- and myelo-monocytic markers). Diagnosis of BPDCN was made. Cytofluorometric peripheral blood (PB) assay showed 8% of cells expressing CD2, CD4, CD7, CD56, and HLA-DR. Because of rapid progression with fever, organomegaly, disseminated cutaneous lesions and pleural effusion, MICE protocol (mitoxantrone, etoposide and cytarabine) was started. *Results.* Aplastic phase was complicated by Pseudomonas Aeruginosa sepsis and pneumonia resistant to antibiotic therapy; the patient remained febrile despite of the association of antimycotic drugs, with progressively increasing interstitial-alveolar infiltrations and pulmonary insufficiency. During the haematologic recovery she developed significant PB monocytosis (21.496/ mm^3) with 25% of atypical BM monocytoid precursors and 3% of BM blasts. PB and BM cytofluorometry and histology showed cells of monocytic lineage expressing $CD4^+CD56^+$ $CD11c^+CD14^+$, as well as CD123 and CD2AP, but negative for other BPDCN markers. BM dysplastic changes were also obvious. After steroid therapy the clinical conditions improved rapidly and monocytosis resolved, but one month later central nervous system relapse with marked liquoral blastic cell count occurred and patient died. *Conclusion.* In about 15%-20% of cases BPDCN has been reported to be associated with or develops into a myelomonocytic leukemia or acute myeloid leukemia; this study shows that partial sharing of markers between the two neoplastic populations may occur, thus suggesting that the two diseases are more than coincidental and may have a common cellular origin.

1258

ACUTE PROMYELOCYTIC LEUKAEMIA. CLINICO-PATHOLOGICAL PROFILE: EXPERIENCE OF AL-AMAL ONCOLOGY-HAEMATOLOGY CENTER IN QATAR

M Mohamed AbdelDaem Mohamed Yass, F Ibrahim, H Elayoubi

Hamad Medical Corporation Alamal Hospital, Doha, Qatar

Introduction. Acute promyelocytic leukemia (APL) is a subtype of Acute Myeloid Leukemia (AML). It has a characteristics clinical, morphological ,Cytogenetics and molecular pattern. Previously considered as the most devastating subtype of AML now the most treatable of all subtypes. No data has been published about APL in Qatar.

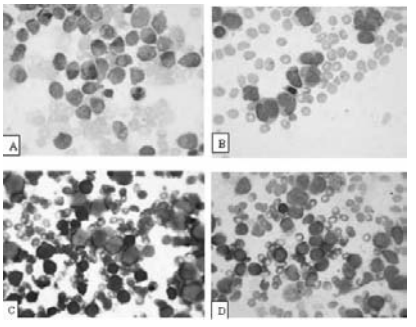

Figure. Classical hypergranular APL (A) microgranular APL variant (B), hyperbasophilic APL variant (C), M3r APL variant (D).

Patients and Methods. This is a retrospective study describe the experience of Al Amal hospital (the adult Oncology/Hematology center in Qatar) with APL patient seen during the period from January 2006 to May 2008 .The diagnosis was established by combined morphological examination, immunophenotyping & cytogenetic studies. *Results.* Out of thirty four AML cases diagnosed, eleven were classified as APL reaching a frequency of (32.2%). DIC was common at presentation (91%). Severe thrombocytopenia seen in 72.7%,leukocytosis in 54.5% and severe anaemia in 45.4%. Only two patients were of the classical hypergranular type. In the remaining nine patients(81.8%) three morphological subtypes were recognized: Microgranular variant in six patients, Hyperbasophilic in two patients and the variant with regular nuclear outline (M3r) in one patient. Translocation (15;17) was detected in 62.5% of the cases analyzed. *Conclusion.* This study shows that APL constitutes a significant proportion of AML in Qatar with significant morphological heterogeneity and predominance of variants APL having unfavorable presenting features.

1259

EVALUATION OF PLASMA LEVEL COPPER,ZINC,CU/ZN,VEGF IN PATIENT WITH AML BEFOR AND AFTER TREATMENT

Z Sanaat, M Nouri, R Dolatkhah, I Asvadi Kermani, J Vaez Gharamaleki, J Eivazi Ziaei, A Nikanfar, A Esfahani, S Chavoshi

Hematology and Oncology Research Center,Tabriz University of Medical Sciences, Tabriz, Iran

Background. Copper and Zinc are the elements that have numerous physiologic activities. Copper has an important role in angiogenesis. The effect of Copper is applied by increasing of VEGF. Serum level of copper increases cancer incidence, progression and recurrence of Hodgkin's lymphoma, sarcoma, leukemia and lung, liver, breast tumors. *Aims.* The aim of this study was measuring blood levels of copper and zinc and the ratio of Cu/Zn, as well as VEGF levels before and after treatment in patients with acute myeloid leukemia. *Methods.* 30 AML newly diagnosed patients in Shahid Ghazi Tabatabai enrolled in this clinical trial. On the first day blood sampled for copper, zinc and VEGF assay and flow cytometry. Treatment protocol was (7×3) ARA-C 100 mg/m^2 for 7 days and Cerubidin 45 mg/m^2 for 3 days. In complete remission blood samples were collected for evaluation of copper, zinc and VEGF and were sent to Biochemistry Laboratory in school of medicine for analysis. *Results.* Of total 30 AML patients 14 (7 / 46%) were female, and 16 (3/53%) were male. patients ranged in aged from 16 to 53 years, with a median age of 9.1±9.35 years. The mean serum level of copper and zinc, before and after treatment showed significant difference ($P<0.05$) ,as well as mean ratio Cu/Zn .There was significant difference between the Mean VEGF level before and after treatment ($P<0.05$). *Conclusions.* In our knowledge based on searching data bases there is not any report indicating copper and zinc serum level correlation before and after treatment in AML patients, and this may be the unique one in this era. We didn't find relationship between copper, zinc serum level, their ratio and VEGF in AML. We expected the increased serum copper noticed by increasing VEGF level that indicates the positive effects of copper in the incidence of malignancies.

1260

BLASTIC PLASMACYTOID DENDRITIC CELL NEOPLASM - DIAGNOSTIC CASE REPORT

D Mikulenkova,[1] I Marinov,[1] V Campr[2]

[1]Institute of Hematology and Blood Transfusion, Prague, Czech Republic; [2]Department of Pathology and Molecular Medicine, University Hospital Motol, Prague, Czech Republic

Blastic plasmacytoid dendritic cell neoplasm (BPDC) formerly known as $CD4^+CD56^+$ hematodermic tumor is a rare hematological neoplasm derived from the precursors of plasmacytoid dendritic cells. A 35 year male patient was examined at our department for unexplained pancytopenia. He had a 3 months history of fatigue and febrile episodes, which required antimicrobial therapy. At the same time the patient noticed a painless 3 cm induration on his right thigh. Blood count investigation revealed leucopenia, thrombocytopenia and mild normocytic anemia: WBC 1.68×10^9/L, Neut 0.53×10^9/L, RBC 3.81×10^{12}/L, HGB 116 g/L, PLT 103×10^9/L. Cytological examination of peripheral blood and bone marrow raised the suspicion of acute myeloid leukemia without maturation (4%, respectively 86% myeloperoxidase negative blast cells). Flow cytometry immunophenotyping of bone marrow aspirate and histological examination of skin biopsy however set the diagnosis of blastic plasmacytoid dendritic cell neoplasm. HAM induction therapy achieved complete hematological remission without complete blood count recovery, followed by I. HAM consolidation and allogeneic hematopoietic stem cell transplantation from unrelated donor. Actually the patient is in hematological remission with detectable minimal residual disease. *Conclusion.* Morphological and cytochemical examination but also extensive immunophenotypic and histological/immunohistochemical analysis is mandatory for definitive diagnosis of BPDC.

1261

LIPOSOMAL CYTARABINE FOR NONLYMPHOBLASTIC MENINGITIS - ROMANIAN WORKING GROUP FOR ADULT ACUTE LEUKEMIA EXPERIENCE

A Moicean,[1] M Brinza1, A Catana,[2] B Ionescu,[1] A Dascalescu[3]

1Fundeni Clinical Institute, Bucharest, Romania; [2]Districtual Hospital, Sibiu, Romania; [3]Sf. Spiridon Hospital, Iasi, Romania

Background. Liposomal cytarabine is an attractive drug for CNS leukemia treatment, given the ability to reduce the frequency and total number of IT treatments. The efficacy of liposomal cytarabine in lymphomatous meningitis prophylaxis and treatment was reported. Central nervous system involvement in acute myeloblastic leukemia is rare and the treatment of meningeal disease remains a challenge. In addition to the standard approach, liposomal cytarabine (Depocyte) permits to decrease the frequency of lumbar punctures, without loss of efficacy, because the intrathecal levels of the drug remain cytotoxic for up to 14 days. *Material and Methods.* We present 3 patients with acute myeloblastic leukemia (M2, M4 and M5 FAB) and SNC leukemia. There were 2 males and 1 female, aged 42, 52 and 65 respectively. The range number of IT administrations was 5 at 14-21 days well tolerated. *Results.* All patients achieve complete liquor blasts clearance after first Depocyte administration. The female, aged 65 years dead with hematological relapse at 12 months after diagnosis. The male 42 year old received related stem cell transplant and is alive in complete remission at 10 months, without CNS leukemia. The third patient is alive at 5 months with high doses systemic chemotherapy without SNC relapse, on the waiting list for unrelated stem cell transplant. *Summary*. Myeloblastic meningitis would be a new indication for liposomal cytarabine 50 mg given IT every 14 days.

1262

DEVELOPMENT OF MULTI-COLOR INTRACELLULAR PANELS IN CHRONIC LYMPHOID LEUKEMIA (CLL) USING ZAP-70 QUANTUM DOT-CONJUGATED ANTIBODIES

N Barteneva,[1] I Sotnikov,[1] M Konopleva,[2] S O'Brien,[2] M Andreeff,[2] G Bortakur,[2] S Jaron,[3] J Hillabrant,[1] K Ketman,[1] D Potashnikova,[4] K Kaplanov,[5] O Kalashnikova,[5] L Tregubova,[5] T Klitochenko,[6] K Demidenko,[5] I Matveeva,[5] N Davidova,[5] B Biderman,[4] A Sudarikov,[4] I Vorobjev[4]

[1]Immune Disease Institute, Harvard Medical School, Boston, USA; [2]MD Anderson Cancer Center, Houston, USA; [3]Life Sciences, Eugene, USA; [4]Hematology Research Center, Moscow, Russian Federation; [5]GUZ Volgograd Regional Clinical Oncology Center, Volgograd, Russian Federation; [6]Guz Volgograd Regional Clinical Oncology Center, Volgograd, Russian Federation

Background. B-cell chronic lymphocytic leukemia (CLL) has a highly variable clinical course. Identified clinically useful prognostic markers include IgVH mutational status, and Zap-70 and CD38 expression. Recent studies have shown that Zap-70 expression may act as a surrogate for IgVH mutational status in CLL. Combined analysis of Zap-70 and CD38 has provided more refined prognostic information. Flow cytometry presents advantages over other methods to detect Zap-70. *Aims.* The goal of this study was to develop and optimize a new methodological approach for intracellular staining with antibodies against Zap-70 conjugated with Quantum dots (QDs) nanoparticles suitable for development of multi-color panels. *Methods.* We analyzed the Zap-70 expression levels in 38 fresh and cryopreserved samples from two groups of patients with newly diagnosed or treated CLL from two outpatient clinics (MD Anderson Cancer Center, Houston, USA and Volgograd Clinical Oncology Center, Volgograd, Russia). The median age of the patients was 65.4 years (range 48÷84). The cohort of CLL patients included 16 untreated and 22 patients on different therapy treatments. The expression of Zap-70 in B-CLL cells was analyzed by flow cytometry using Zap-70 antibodies (clone 1E7.2) conjugated either with QD655 or organic fluorophores (fluorescein) in 3-5 colors combinations with CD19, CD5, CD3, CD38 monoclonal antibodies. % of Zap-70 positive B-cells was calculated using T-lymphocytes from CLL patients as positive controls. Samples were acquired with FACSCanto flow cytometer (BD Bioscience, San Jose, USA). The IgVH mutation status was determined in 23 patients. Shortly, high molecular weight DNA was isolated by phenol-chloroform method. Amplification of VDJH rearrangements was performed, and PCR products were purified and directly sequenced. Germline VH, DH and JH segments from VDJH rearrangements were identified by comparison with database and sequences containing more than 2% deviation from the germline sequence were considered as somatically mutated. Spearman rank correlation was used to analyze correlations and value of $P\leq0.05$ was considered significant for all statistical calculations. *Results.* Out of seven tested commercially available fixation/permeabilization buffers only two present an appropriate combination for the QDs delivery across cell membranes. The percentage of Zap-70 positive B-cells as determined by the QD655-conjugated Zap-70 antibody strongly correlated with the Zap-70 expression levels determined by standard method (Zap-70 conjugated with organic fluorophore)($r=0.593$, $P\leq0.05$) at fresh peripheral blood samples from CLL patients. Combined analysis of QD655-conjugated Zap-70 and IgVH mutational status at CLL patients yielded discordant results in 27.2% cases (vs 33.3 for FITC-Zap-70 antibody panel), whereas 36.3% were concordantly positive and 27.2% concordantly negative. Mean fluorescence intensity (MFI) did not diminish with the increase of fluorophores number in the panel, when QD655-conjugated antibodies were used to detect Zap-70. Positive to negative signal ratio is higher when intracellular QDs nanocrystals were used in comparison to standard fluorophore combination. *Conclusions.* There is a first successful Zap-70 protocol using QD-conjugates for intracellular staining. The QDots conjugated antibodies are advantageous in multiplexing comparing with organic fluorophores, and can be used for evaluation of combination of prognostic markers for leukemia.

1263

AN *IN VITRO* TEST PREDICTIVE OF THE IN VIVO B CELL RITUXIMAB-TRIGGERED DEPLETION, UNDERLINES THE POTENTIAL THERAPEUTIC INTEREST OF A RECOMBINANT ANTI-CD20 IGA IN B-CLL PATIENTS

N Congy,[1] L Ysebaert,[2] P Apoil,[3] G Tiraby,[4] D Drocourt,[4] M Abbal,[5] A Blancher[5]

[1]EA 3033,4 Université Paul Sabatier, Toulouse, France, Toulouse, France; [2]INSERM U563 CHU Purpan, Toulouse, France; [3]EA 3033,4 University Paul Sabatier of Toulouse, Toulouse, France; [4]Cayla-Invivogen, Toulouse, France; [5]EA 3033,4 Université Paul Sabatier, Toulouse, France

Background. Most of therapeutic monoclonal antibodies (thmAb) are built with an IgG1 constant part, in order to trigger complement activation, antibody-dependent cell cytotoxicity (ADCC), and allow long half-life through the interaction with the Neonatal Fc receptor of Ig. One of them, rituximab, targeting the CD20, is widely use to treat lymphomas, auto-immune diseases and B chronic lymphocytic leukaemia (B-CLL). In the latter indication, the rituximab-induced B cell depletion varies greatly from one patient to another. *Aims.* With the aim to predict the *in vivo* efficacy of rituximab in B-CLL patients, we adjusted an *in vitro* test based on the adding of rituximab to whole blood. By means of this whole blood assay, we evaluated the *in vitro* B cell depletion induced by a recombinant anti-CD20 IgA antibody built with variable parts of rituximab, which have been evoked as an alternative isotype. *Methods.* The rituximab or its IgA recombinant homologue, were added to whole blood samples of B-CLL patients (N=50). After three hours of incubation in presence or absence of anti-CD20 antibodies, flow cytometry absolute counts of CD19+CD3- cells allowed to calculate the B-CLL cell depletion. For six patients, we compared the *in vitro* and *in vivo* B cell depletion. *Results.* For six patients, the *in vitro* rituximab induced B-cell depletion revealed by the whole blood assay paralleled the *in vivo* therapeutic effect. The *in vitro* rituximab induced B cell depletion revealed by the whole blood tests with B-CLL blood samples (N=50) did not correlate with the one induced by its IgA counterpart. The *in vitro* B cell depletion induced by the anti-CD20 IgA was either stronger than, weaker than, or equivalent to the RTX-induced depletion for 8, 13 and 29 patients, respectively. *Conclusions.* We demonstrate that the IgA recombinant anti-CD20 antibody is efficient to deplete B-CLL cells *in vitro*. In some cases, the IgA appeared more efficient than the rituximab. Because the *in vitro* test results paralleled the *in vivo* RTX induced B-CLL cells depletion, one can suppose that some B-CLL patients could benefit more from a treatment with the recombinant IgA anti-CD20 than from rituximab.

1264

MONITORING OF NATURAL KILLER (NK) CELLS PHENOTYPE AND ANTITUMORAL ACTIVITY IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

C Veuillen,[1] T Aurran,[2] J Rey,[2] D Coso,[2] F Orlanducci,[2] V Ivanov,[2] R Bouabdallah,[2] AM Stoppa,[2] JM Schiano,[2] D Olive[1]

[1]CRCM INSERM U891 Marseille, France; [2]Institut Paoli-Calmettes, Marseille, France

Background. Chronic lymphocytic leukaemia (CLL) is one of the most common leukaemias in adults in the developed world. Despite advances in anticancers therapeutics, CLL remains incurable. The ability of NK cells to control different haematological malignancies has been demonstrated *in vitro* and *in vivo*. However, alterations of these effector cells have been described in patients with haematological malignancies that might explain an escape from innate immune surveillance.Recently, our group has reported that patients with acute myeloid leukaemia defective interactions receptor-ligand in NK cells possibly due to a defective expression of activating receptors (NKp30 and NKp46) that could represent an immune escape mechanism for leukaemic cells. There is only limited information about the possible defiency of NK cells in CLL. *Aim.*The aim of this work is to evaluate the activating receptors expression in order to determine if it represents an escape mechanism of the immune response in CLL. *Methods.* We investigated the receptor repertoire and measured NK cell activity in peripheral blood of 40 untreated patients with CLL, 30 stage A and 10 stage B/C, and 17 healthy donors (age-matched). The expression of activating receptors (NKRa) that mediate NK cell recognition and lysis of leukemic cells (NKp30, NKp46, NKG2D and DNAM-1) was investigated by flow cytometry. The expression of inhibitory receptors ((NKRi), (KIRs, ILT2, NKG2A)) was also analysed. *Results.* The expression of activating receptor NKp30 was significantly decreased in the patients with stage A (P=0.0005) or with stage B/C CLL (P=0.0097) compared to healthy donors. In CLL NK cells, the expression of NKRi and other NKRa did not differ from healthy donors. However, the cytotoxic activity of NK cells was not significantly different in patients with stage A or stage B/C CLL compared to healthy donors. *Conclusion.* A decreased expression of a major activating receptor NKp30 was observed in CLL independently of the stage. However, this alteration does not affect the lytic activity of CLL NK. In CLL, therapies improving NK functions including monolonal antibody, proteasome inhibitor or immunomodulatory drugs (IMIDs) represents a novel strategy.

1265

TNFRSF4 (OX40) EXPRESSION IN CLL CELLS: EVIDENCES OF A PROGNOSTIC SIGNIFICANCE OF GENE AND PROTEIN OVEREXPRESSION

K von Aprile von Hohenstaufen,[1] U Gianelli,[2] E Bonoldi,[2] V Vaira,[3] I Cortinovis,[4] G Reda,[1] F Maura,[5] M Sciumè,[5] V Ferla,[5] G Gritti,[1] S Lonati,[1] G Lambertenghi Deliliers,[1] S Bosari,[3] A Cortelezzi[1]

[1]Hematology I, Ospedale Maggiore Policlinico Milano, Milano, Italy; [2]Pathology Unit, Ospedale Maggiore Policlinico Milano, Milano, Italy; [3]Pathology Unit , Azienda Ospedaliera S.Paolo, Milano, Italy; [4]Dipartimento di Medicina del Lavoro- Sez. Biometria University of Milan, Milano, Italy; [5]University of Milan Medical School, Milano, Italy

Background. OX40 is an antiapoptotic molecule of activated T lymphocytes. There are not published data reporting OX40 in B-lymphocytes. The presence of high seric levels of OX40 in CLL was thought to be related to the expansion of activated T lymphocytes. However OX40 expression in CLL cells was not tested. *Aims.* to evaluate the expression of OX40 in CLL cells and its prognostic value. *Methods.* OX40 mRNA levels was evaluated by means of real time PCR in $CD19^+$ peripheral blood cells, isolated by magnetic cell separation (Mylteni Biotech, Auburn, CA), in 55 untreated CLL patients characterized for FISH, IGVH mutational status, ZAP70, CD38, need of therapy, and in 10 healthy controls. Ox40 protein expression was assessed by immunohistochemistry (IHC) on bone marrow biopsies performed at diagnosis in a different cohort of 101 CLL cases, in order to analyze retrospectively the relationship between protein expression and outcome. For IHC we employed the previously validated (www.proteinatlas.org) antibody TNFRSF4/OX40 Clone BER-Act35, Santa Cruz Biotechnology, CA, USA. Protein expression were defined according to the following scoring system: percentage of positive proliferation centers (<50% = score 0; > 50% = score1); percentage of positive cells into the proliferation centers (<50% = score 0; > 50% = score 1); positivity of neoplastic cells outside the proliferation centers (none = 0, focal = 1, diffuse = 2). Score 1-2 defined low expression; score 3-4 defined high expression. Patients evaluated for IHC had classic CLL, median age of 60 y (range 31-80); Binet stage A 72%; stage B 20%; stage C 8%. With a median follow-up of 468 days, (range 124-3860), 54/101 patients were treated and 11/101 died. *Results.* OX40 gene was overexpressed in CLL patients in comparison with normal individuals (Fc >2; P<0.01 T test). Between CLL cases having different features, OX40 gene was overexpressed in IGVH unmutated, ZAP 70^+ and $CD38^+$ cases, and in patients requiring therapy (false discovery rate <5%, calculated by means of Significant Analysis of Microarray). OX40 protein high expression relates to Binet Stage B and C (P=0,016). Patients having protein high expression, as compared with patients having low expression, had lower rates of 2 years time to treatment (46% *vs.* 81% P=0.001); and 5 years overall survival (80 and 96 % P=0.058). Summary/*Conclusions.* Over-expression of OX40 is identifiable in CLL cells. OX40 mRNA levels were higher in patients with unfavorable features. Since high levels of OX40 protein expression predicts for poor outcome, IHC for OX40 should be considered in prospectical studies for clinical application. Further investigations are needed to clarify if OX40 in B cells activates the same antiaptotic pathway than in T cells. In such a case OX40 might be considered as a potential target for therapy.

1266

REGULATORY T-CELL NUMBER IS CORRELATED TO FEATURES OF ACTIVE DISEASE IN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS

G D'Arena,[1] L Laurenti,[2] MM Minervini,[1] S Deaglio,[3] L De Martino,[4] L De Padua,[2] N Sinisi,[1] M Tarnani,[2] B Fusco,[4] V De Feo,[4] N Cascavilla[1]

[1]Casa Sollievo della Sofferenza Hospital, San Giovanni Rotondo, Italy; [2]Hematology Chair, Catholic University of Sacred Hearth, Rome, Italy; [3]Laboratoy of Immunogenetics, University of Turin, Turin, Italy; [4]Department of Pharmaceutical Sciences, University of Salerno, Salerno, Italy

Background. Naturally arising $CD4^+CD25^+$ regulatory T-cells (Treg)

actively maintain immunological self-tolerance. A reduction in the number or function of these cells can also elicit tumour immunity. Several studies evidenced that the immune system in patients with chronic lymphocytic leukemia (CLL) is deficient. *Aims.* In the current study we have evaluated, by means of a multiparametric flow cytometric approach, the circulating Treg cell number in 80 patients with previously untreated CLL and in 40 normal subjects. *Methods.* CD4+CD25+high density cells were gated and evaluated for CD127 expression at low or undetectable levels to analyze only Treg cells. *Results.* A lower percentage number of Treg cells was detected in CLL patients (mean number 0.43%, range 0.02-1.2%) than in controls (1.13%, range 0.2-2.1%). On the contrary, when evaluated as absolute number, CLL patients showed a higher number of Treg cells (mean number 70.8/μL, range 3-880/μL) compared to controls (mean number 23.2/μL, range 4.4-41/μL). A correlation of Treg cell absolute number was also found with more advanced Rai clinical stage (P<0.0001), absolute CD38 positive B-cell number (p 0.02), and more elevated LDH levels (p 0.037). No correlation, however, were found with ZAP-70 expression, IgVH mutational status and cytogenetic abnormalities. Only in 2 patients Treg cells were found at very low levels. These patients suffered from a concomitant autoimmune disorder (autoimmune haemolytic anaemia and idiopathic thrombocytopenic purpura) at the moment of analysis. *Conclusions.* Our data showed that Treg cells are higher in CLL patients and correlate with disease status rather than prognostic factors themselves. This subset of T-cells is probably involved in the crucial mechanism of pathogenesis and progression of CLL and a therapeutic intervention targeting these cells need to be explored.

HUMORAL IMMUNE RESPONSES AGAINST THE ROR1-PROTEIN SHOW PROGNOSTIC SIGNIFICANCE IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

M Zeis, S Siegel, S Yousef, N Schmitz

Asklepios Clinic St. Georg, Hamburg, Germany

Background. The receptor tyrosine kinase-like orphan receptor 1 (ROR1) protein is a newly characterized oncofetal antigen in patients with chronic lymphocytic leukemia (CLL). Since a significant proportion of CLL patients never require antitumor therapy, we hypothesized that an autologous tumor-specific immune response is capable of controlling malignant disease. *Aims.* We investigated whether humoral immunity specific for the CLL-associated antigen ROR1 has a prognostic value in CLL. *Methods/Results.* Among sera of 87 untreated patients with CLL, 41 (47.1%) had detectable ROR1-antibodies which were reactive for at least one specific ROR1 epitope. Patients with humoral responses compared to patients with non-reactive sera had a longer progression-free survival (PFS)(P<.001). IgG subclass analyses showed a predominant IgG1 and IgG3 response. ROR1-antibodies were capable of recognizing and selectively killing ROR1-expressing CLL cells in complement-mediated and antibody-dependent cellular cytotoxicity (ADCC) assays. In the analysis of 44 CLL patients after allogeneic hematopoetic stem cell transplantation, twenty-nine showed significant titers of anti-ROR1 antibodies which specifically recognized the extracellular domain of the protein; suggestive for a potential role of anti-ROR1-directed immune responses to the graft-versus-leukemia effect in CLL. *Summary/Conclusions.* Our data suggest that spontaneous tumor-specific humoral immune responses against ROR1 exist in a significant proportion of CLL patients and that superior PFS in those patients could reflect autologous immune control.

1268

CYCLIN D1 EXPRESSION IN B-CELL LYMPHOMAS: A COMPARATIVE STUDY

A Gladkikh, D Potashnikova, E Korneva, O Khudoleeva, I Vorobjev

National Research Center for Hematology, Moscow, Russian Federation

Background. Cyclin D1, an important component of cell cycle machinery and a protein with known oncogenic potential, presents at extremely low level in mature B-lymphocytes. Its overexpression might be important for B-cell oncogenesis. Indeed it happens in mantle cell lymphoma as a result of translocation t(11;14)(q13;q32) and was reported in some cases of CLL. Growing body of evidence demonstrate the possibility that it might occur in other B-cell lymphomas, however, the direct measurement using PCR did not give definite *Results.* One of the reasons for this uncertainty might be insufficient sensitivity of RT-qPCR when using single reference gene. *Aims.* The aim was to determine variations in cyclin D1 expression level in different B-cell lymphomas and to select appropriate reference genes for cyclin D1 validation in lymphoid tissue by RT qPCR. *Methods.* cDNA samples from 100 patients with B -CLL, MCL, CD5-negative B -cell lymphomas were used in this study as well as cDNA from reactive hyperplasia specimens and sorted B cells of 4 healthy volunteers. Diagnoses were established by 3-color flow cytometry and immunohistochemistry. The samples were stained for CD5, CD19, CD23, FMC7, CD45, CD20, CD22, CD38 and κ-/λ- light Ig chains according to the routine protocol. Data on cyclin D1 expression were assessed with real-time quantitive PCR with SYBR Green I. cDNA quantity of cyclin D1 was normalized using the geometric mean of most stable referent genes as normalization factor, and recalculated for tumor cells population using flow cytometry data. *Results.* YWHAS, ubc and HPRT demonstrated high stability in the whole cohort of patients (σ<1.73) and were selected as the primary set of reference genes for evaluating expression level of cyclin D1 in lymphoid tissue. The relative normalized quantity of cyclin D1 cDNA in sorted normal B-cells varied from 0.00003 to 0.0005, normalized cDNA quantity in unsorted specimens ranged from 0.00008 to 0.0009. MCL samples demonstrated high expression level and significant variance of cyclin D1 (n=31, range 0.20 - 23.13, median 0.994). Besides, compared to the reactive lymphoid tissue (n=18, median 0.0003) significant elevation of cyclin D1 was observed in B-CLL (n=33, median 0.014), and even in CD5-negative lymphomas (n=16, median 0.003). Addition of two remaining reference genes (b-actin and GAPDH) to normalization factor led to 10-fold increase in variance among CD5-negative lymphomas' group, and impaired the discrimination between CD5-negative lymphomas and reactive specimens. To allow a closer comparison of our results to others, we recalculated our data using ΔΔCt method with YWHAS as a sole reference gene. The variance in levels of cyclin D1 in all groups increased, and the difference between CD5-negative malignancies and reactive specimens became less significant (P> =0.0004, paired Mann-Whitney test). *Conclusion.* Quantitative RT qPCR allows accurate evaluation of gene expression in malignant B lymphocytes and B cells of reactive hyperplasia when using several reference genes for data normalization. We for the first time demonstrate statistically significant elevation of cyclin D1 expression in a variety of B-cell lymphomas.

1269

CD74 EXPRESSION CORRELATES WITH ZAP70 PROTEIN EXPRESSION BUT NOT WITH CD38 EXPRESSION AND IGVH MUTATIONAL STATUS IN CHRONIC LYMPHOCYTIC LEUKAEMIA PATIENTS

A Butrym,[1] G Mazur,[1] M Majewski,[2] K Kuliczkowski[1]

[1]Wroclaw Medical University, Wroclaw, Poland; [2]Copernicus Hosp., Hematology Dept., Torun, Poland

Background. Chronic lymphocytic leukemia (CLL) is a heterogenous disease with different clinical course. New prognostic markers are still needed to define subgroups of patients with poor prognosis. CD74, known as the invariant chain, is a non-polymorphic glycoprotein with many immunological functions: major histocompatibility complex (MHC) class II chaperone, a receptor for macrophage migration inhibitory factor (MIF) and acts as accessory-signaling molecule involved in malignant B-lymphocytes proliferation and survival. *Aim.* The aim of this study was to determinate expression of CD74 in untreated CLL patient comparing to control healthy group and comparison of expression to already known prognostic factors in CLL, such as expression of ZAP-70 protein, CD38 and immunoglobulin variable heavy chain (IGVH) mutational status. *Methods.* Blood samples from 91 untreated patients with CLL (44 women and 47 men), aged 44-88 year (median age 68) were analyzed comparing to 28 matched healthy controls (15 women and 13 men). The study was provided with dataset of biological and clinical variables of CLL patients. Using flow cytometry the expression of CD74, as well as ZAP70 protein and CD38 was assessed on PBMC isolated from blood taken from patients during routine blood tests. All the samples were also tested using direct sequencing following ERIC recommendations on IGHV gene mutational status analysis in chronic lymphocytic leukemia. Statistical analyses were performed using statistical package EPIINFO Ver. 3.4.3 (Anova, Kruskal-Wallis test). The 'p' values <0.05 were considered statistically significant. *Results.* We observed significantly higher expression of CD74 in chronic lymphocytic leukaemia patients than in control group (mean value 9.4% *vs.* 0.35%; median 7.48% *vs.* 0.24%; SD 9.18 *vs.* 0.312; P<0.00001). There was significant positive correlation between expression of CD74 and ZAP-70 protein (r=0.28, P=0.009). CD74 correlated also with albumins (r=-0.21, P=0.081) and CRP (r=0.38, P=0.001). The expression of CD74 did not correlate with clinical features such as: leukocytosis (r=0.17, P=0,121), hemoglobin level (r=-0.03, P=0.762), platelet level (r=-0.16, P=0.153), lymphocytosis (r=0.1, P=0.393),

bone marrow lymphocytes (r=0.28, P=0.121), LDH (r=-0.02, P=0.886), beta-2-microglobulin (r=0.12, P=0.278). No correlation was found between expression of CD74 and CD38 (r=-0.04, P=0.741). Among the patient with mutated and unmutated status of IGVH there were no differences in CD74 expression (mean 8.62% *vs.* 9.67%, median 7.52% *vs.* 6.86%, SD 8.92 *vs.* 9.54, P=0.608). Expression of CD74 did not influence the need for treatment introducing in CLL patients (r=0.07, P=0.658). *Conclusions.* In our study we showed significantly higher CD74 expression in CLL patients comparing to controls with positive correlation between CD74 and ZAP-70 protein expression. CD74 measurement can help in stratification of patients to risk groups.

1270

HS1 EXPRESSION DOES NOT CORRELATE WITH ZAP70 PROTEIN, CD38 EXPRESSION AND IGVH MUTATIONAL STATUS IN CHRONIC LYMPHOCYTIC LEUKAEMIA PATIENTS

A Butrym,[1] G Mazur,[1] M Majewski,[2] K Kuliczkowski[1]

[1]Wroclaw Medical University, Wroclaw, Poland; [2]Copernicus Hosp., Hematology Dept., Torun, Poland

Background. Chronic lymphocytic leukemia (CLL) is the most common B-cell malignancy in adults and is characterized a heterogeneous clinical course. Although many prognostic markers have been already discovered still further research are conducted to select groups of patients with poorer outcome. Hematopoietic lineage cell-specific protein 1 (HS1). It has been shown to be functionally involved in proliferation and apoptosis of B- and T-cell receptor activation. Different expression of HS1 was observed in CLL patients. *Aim.* The aim of this study was to determinate expression of HS1 protein in untreated CLL-patient comparing to control healthy group and comparison of expression to already known prognostic factors in CLL, such as expression of ZAP-70 protein, CD38 and immunoglobulin variable heavy chain (IGVH) mutational status. *Methods.* Blood samples from 88 untreated patients with CLL (44 women and 44 men), aged 44-88 year (median age 68) were analyzed comparing to 28 matched healthy controls (15 women and 13 men). The study was provided with dataset of biological and clinical variables of CLL patients. We assessed HS1 expression using western-blot analysis. In flow cytometry the expression of ZAP70 protein and CD38 was determined on PBMC isolated from blood taken from patients during routine blood tests. All the samples were also tested using direct sequencing following ERIC recommendations on IGHV gene mutational status analysis in chronic lymphocytic leukaemia. Statistical analyses were performed using statistical package EPIINFO Ver. 3.4.3 (Anova, Kruskal-Wallis test). The 'p' values <0.05 were considered statistically significant and those between 0.05 and 0.1 as indicative of a trend. *Results.* 76 CLL patients expressed HS1 protein comparing to 2 patients from control group. We observed significantly higher expression of HS1 protein in chronic lymphocytic leukaemia patients than in control group (P<0.0000001). We observed strong correlation between HS1 expression and clinical parameters: WBC (r=0.27, P=0.0129), HGB (r=-0.22, P=0.0465), platelets (r=0.-23, P=0.0310), beta-2-microglobulin (r=0.24, P=0.00342). HS1 expression did not influence the need for treatment introducing in CLL patients (r=-0.01, P=0.548). There was no correlation between HS1 and CD38 and ZAP-70 protein expression, but positive trend was observed (r=0.19, P=0.0891 and P=0.0866 for CD38 and ZAP-70 protein respectively). *Conclusions.* In study we showed significantly higher expression of HS1 comparing to control group, but without significant correlation with known prognostic factors.

1271

EPIDEMIOLOGICAL AND GENETICAL ANALYSIS IN A SERIE OF B-CLL PATIENTS: EPIGEN STUDY

P Giraldo,[1] M Abio,[1] V Leon,[2] S Aramberri,[3] G Caballero,[4] C Cortes,[5] F Floristan,[6] N Gonzalez,[7] R Hernández,[8] L López,[9] F Sala,[10] J Marco[11], F Sancho[12], L Perdiguer[12], P Giraldo[1]

[1]Miguel Servet University Hospital, Zaragoza, Spain; [2]University of Zaragoza, Zaragoza, Spain; [3]Basurto Hospital, Bilbao, Spain; [4]San Jorge Hospital, Huesca, Spain; [5]Galdakao Hospital, Bilbao, Spain; [6]Cruces Hospital, Bilbao, Spain; [7]Obispo Polanco Hospital, Teruel, Spain; [8]Txagorritxu Hospital, Vitoria, Spain; [9]Royo Villanova Hospital, Zaragoza, Spain; [10]San Millan y San Pedro Hospital, La Rioja, Spain; [11]Barbastro Hospital, Huesca, Spain; [12]Alcañiz Hospital, Alcañiz, Spain

Background. The B-CLL, is the most common type of leukaemia diagnosed in the West countries (30%), the incidence in Europe is: 0.9-2.4 cases/year/100,000 inhabitants. Immunophenotypic, genetic and molecular markers allow their inclusion in different prognostic groups. OBJECTIVES: To determine the incidence in a year of CLL cases in a geographical area of Northern Spain with 4,686,175 inhabitants. To analyze the demographic, clinical, immunophenotypic and molecular markers and to relate them with gene expression profiles obtained with an oligonucleotide microarray. MATERIAL AND *Methods.* A prospective, descriptive, and analytical and cross section of incidental cases of B-CLL in Aragon, Navarra, Basque Country and Cantabria during the period: 1/09/2007- 31/08/2008. The study involved 13 hospitals that have collected the clinical characteristics at diagnosis and biological samples for DNA, RNA and serum extraction. The study has the approval of the Committee on clinical trials and investigation of Aragon (CEICA) and patients have signed IC. We designed a database for the study where the variables are collected: demographic, staging (Rai / Binet), lymphocyte count, immunophenotyping (IP) (CD38, Zap70), genetic testing (CG) and molecular (Ig VH genes mutation), study of gene expression profiles by the Hematochip platform (539 genes), follow-up to progression, development of primary tumors and response to treatment. *Results.* We collected data from a total of 96 new patients. The preliminary analysis includes 61 cases: men (H) 31 (50.8%) females (M) 31 (50.8%). Average age: 70.8 years (41-91) Males: 63.3 years and Females: 71.6 years. 52.4% were older than 70 years. Staging at diagnosis (Binet and Rai): A0 68.8%, 13.1% AI, AII 3.2%, 1.6% BI, BII 8.1%, BIII 3.2%, 3.2% CIV. 13.1% starts with splenomegaly. 29.5% had no lymph node involvement or extranodal affectation. CG: del13q (18.0%), trisomy 12 (18.0%), del11p (6.5%), del17p (1.6%), normal (45.9%). IP: CD38 positive (22.9%), Zap70 positive (16.3%). Ig VH mutated (21.3%). In 87 samples gene expression profiles have been studied, and differentially expressed genes were observed with statistical significance between different groups: non-mutated IgVH *vs.* mutated, del13q *vs.* normal karyotype, trisomy 12 *vs.* normal karyotype, positive CD38 *vs.* negative and positive Zap70 *vs.* negative. Among these genes, CFL1 has been validated by RT-PCR and found over-expressed in the group of patients with non-mutated IgVH genes. *Conclusions.* 1) The demographic data are similar to the control series and previous studies in greater sample size. We did not find differences by gender. Females were older than males. 2) Diagnosis in early stages (A / 0, A / I). 3) The more common genetic aberrations were: del13q and trisomy 12. Normal kariotype apparently is related to early stages, absence of spleen enlargement and B symptoms, typical morphology and predominance of IgVH gene mutation and CD38 and Zap70 negatives. 4) The analysis of gene expression by Hematochip platform showed differences between the analyzed groups. It is essential to go on studying the prognostic significance of identified genes.

This work has been partially financed by a grant from FEHHA and Gendiag.exe, SL.

1272

IMMUNOPHENOTYPIC PATTERNS IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL): RELATIONSHIP WITH GENETIC FEATURES AND MUTATIONAL STATUS

J Caetano, M Sebastião, L Neto, M Jorge, P Gameiro, M Gomes Da Silva

Portuguese Institute of Oncology, Lisbon, Lisbon, Portugal

Background. CLL has an heterogeneous clinical course. Well-established prognostic factors include genetic, molecular and phenotypic markers. The mutational status of IGVH and use of specific VH segments are important predictors of behavior. Flow cytometry (FC) is the most practical tool for prognostic stratification, including ZAP70 and CD38; recently it has been suggested that different combinations of other phenotypic markers may distinguish between stable and aggressive disease. *Aim.* To investigate a possible association between non typical phenotypes and other prognostic markers we characterized a series of CLL patients using FC, FISH and IGVH sequencing. *Methods.* 123 consecutive patients (47 females, 76 males, median age 66, 36-89 yo), diagnosed according to the 2008 NCI-WG criteria and from whom phenotypic and molecular data were available, were analyzed. FC was performed in 92 peripheral blood (PB) and 31 bone marrow (BM) samples, using various combinations of the following moAb: CD19, CD5, CD20, FMC7, CD79b, CD22 and IgLambda/Kappa. A typical phenotype was defined as strong CD5 and CD23 expression, with a dim surface Ig, CD20 and CD22 and weak or negative CD79b and FMC7. Patients were considered to have atypical phenotypes when the expression of ≥2 of these markers was aberrant. FISH for t(11;14) (LSI IGH/CCND1), performed in 20/25 atypical CLL cases, was negative. FISH for del13q14 (LSI

D13S319), tris12 (CEP12), del11q22 (LSI ATM) and del17p13 (LSI p53) was performed in 93% cases. DNA was extracted from mononuclear cells or whole blood. PCR amplification of IGVH rearrangements was performed with FR1 primers, using the BIOMED-2 strategy. Sequence analysis was done using IMGT data-base, following ERIC group recommendations. *Results.* 25/123 (20%) patients had an atypical phenotype, with a median number of 4 (2-7) aberrations. The most frequent were strong expression of CD22 and CD20 (92%,), strong monoclonal Ig expression (84%), strong CD79b expression (76%) and absence of CD23 (60%). Only 4/25 (16%) cases were heterogeneous/negative for CD5. CD38 expression differed between typical (42%) and atypical (9%) cases (P=0.005). 20/25 atypical cases (80%) were mutated, as compared to 59/98 (60%) typical ones. The incidence of somatic hypermutation was similar between the two groups (P>0,05, Fisher exact test). We further analyzed VH segment usage in 97 pts and found that in typical CLL VH1-69 predominated (16%, 15/97), followed by VH3-30 and VH3-7 (9%, 9/97 cases for each). Interestingly VH1-69, which is known to have an increased frequency among non-mutated cases, was absent from the atypical group. The incidence of cytogenetic abnormalities (46% and 30% for del13q14, 16 % and 35% for tris12, 12% and 4% for del11q22 and 6% and 4% for del17p13 in typical and atypical cases, respectively) was similar between the 2 groups (P>0.05 in all cases). *Summary/Conclusions.* CLL with a typical phenotype do not differ from those with a lymphoma-like pattern in terms of cytogenetic alterations and IGVH mutational status. Interestingly, CD38 expression and VH segment usage may be distinct in these 2 groups. Further studies are needed to confirm these findings and access their significance.

J Caetano, M Sebastião with equal contribution.

1273

ASSESSMENT OF APOPTOSIS CAUSED BY RESVERATROL IN COMBINATION WITH PURINE ANALOGUES IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA.

M Podhorecka, P Klimek, M Kowal, S Chocholska, A Dmoszynska

Medical University of Lublin, Lublin, Poland

Despite many therapeutic regimens introduced recently, CLL is still an incurable disorder. The symptomatic disease can be effectively treated with purine analogues, glucocorticoids, alkylating agents, monoclonal antibodies or combination of these. Some patients, however, with relapsed or refractory disease, have limited therapeutic options. Thus there is an urgent need to discover a novel, less toxic and more effective drugs for CLL patients. Among other options, the use of immunomodulatory drugs or plant-derived substances were reported to improve results of CLL treatment. Resveratrol (trans-3,4',5-trihyrdoxystilbene) is a natural compound present in various plant species and relatively abundant in vine. It has many biological and pharmaceutical properties. Among them the anticancer properties of this naturally occurring substance were widely studied in several human cancer cells including B-cell malignancies. In this study, we attempted to explore whether resveratrol can induce apoptosis of CLL leukemic cells in peripheral blood and bone marrow microenvironments and to assess interactions between resveratrol and two purine analogues - fludarabine and cladribine in terms of their effect on apoptosis of CLL cells. The experiments were performed in 24 h cell cultures of peripheral blood and bone marrow obtained from 25 untreated CLL patients. The cultures were supplemented with resveratrol and resveratrol in combination with cladribine or fludarabine. We analysed the percentage of $CD19^+/CD5^+$ leukemic cells with active caspase 3 expression as a marker of apoptosis with the use of multi-colour flow cytometry technique. Results of our study revealed that resveratrol induced apoptosis of CLL leukemic cells. The percentage of cells with caspase 3 expression in 24 h cultures with resveratrol was significantly higher than the level of spontaneous apoptosis seen in the untreated 24 h parallel control cultures. Such an increase in frequency of resveratrol-induced apoptosis was observed as far as peripheral blood and bone marrow cultures were concerned (18.4±9.3 *vs.* 23.3±9.1 and 19.2±8.4 *vs.* 27.8±10.4), the percentage of apoptotic cells was significantly higher in bone marrow than in peripheral blood (with P=0.006). The frequency of apoptosis in resveratrol+fludarabine treated cultures was significantly higher than in resveratrol treated cultures (28.1±9.2 *vs.* 23.3±9.1, P=0.0003) also than in fludarabine-treated cultures (28.1±9.2 *vs.* 22.3±9.2, P=0.0004). Similarly, a significant increase in apoptosis was observed in resveratrol+cladribine-treated cultures in comparison to both resveratrol cultures and cladribine cultures (32.1±13.3 *vs.* 23.3±9.1, P=0.0004 and 32.1±13.3 *vs.* 25.9±9.1, P= 0.0004, respectively). This pro-apoptotic effect was synergic for resveratrol and fludarabine as well as for resveratrol and cladribine. The obtained results indicate that resveratrol can be used in the treatment of CLL patients as a single agent as well as in combination with purine analogues. This naturally occurring substance may be a good therapeutic option for CLL patients, especially older ones in whom there are some limitations in using aggressive treatment. On the other hand there is a possibility of lowering purine analogues dose used in combination with resveratrol bbecause of their synergic effect.

1274

MUTATION STATUS AND PREFERRED UTILIZATION OF IGVH GENE IN CHRONIC LYMPHOCYTIC LEUKEMIA AND ASSOCIATIONS WITH COMMON BIOLOGIC ABNORMALITIES

WQ Zhao,[1] Y Tang,[1] Y Li,[2] S Long,[1] J Jones,[1] L Andritsos,[1] J Flynn,[1] J Byrd,[1] N Heerema,[1] G Lozanski[1]

[1]The Ohio State University Medical Center, Columbus, USA; [2]The Third Hospital of Xiang-Ya School of Medicine, Changsha, China

Background. Chronic lymphocytic leukemia (CLL) is a clinically heterogeneous disease whose outcome can be partially predicted by the mutational status of immunoglobulin heavy chain variable (IgVH) genes. Moreover, relationships of various clinical manifestations have been reported with specific IgVH genes identified in leukemic cells. Here we investigated the associations between usage of specific IgVH genes and clinical features in CLL. *Aims.* To further characterize the biological features of this disease, we performed IgVH gene mutational status in 231 cases of CLL for gene family preferences and biases, and investigated the mutation status of VH genes against common biologic features of patients and immunophenotype of CLL. *Methods.* cDNA was reversely transcribed from the total RNA extracted from the peripheral blood from consented CLL patients. Polymerase chain reaction (PCR) and cycle sequencing were performed, and analyzed by a Genetic Analyzer. The percentage divergence at the IgVH loci was obtained by matching the resultant sequences to the NCBI Immunoglobulin data base (http://www.ncbi.nlm.nih.gov/igblast). *Results.* The most common gene families were IgVH 1 (26.2%), 2 (2.6%), 3 (45%), 4, (21%), 5 (3.0%), 7 (1.3%), and 9 (0.9%). The most common specific gene above 10% of total events was IgVH 1-69 (16.2% of the total), followed by 3-30 (7.9%), 4-34 (5.7%), 3-23 (5.2%), 4-39(4.8%), 4-59 (4.8%), and 3-7 (4.4%). Somatic hypermutations (>=2%) were present in 46%, and hypomutation (<2%) in 54% of the total CLL. The somatic mutations didn't occur uniformly among subgroups. The hierarchy of hypomutations occured in the order of IgVH 1-69 (27.4%)> 3-30 (6.5%)> 3-48 (5.6%)> 1-3 (4.8%)> 4-39 and 4-59 (4%), and hypermutation as IgVH 4-34 and 3-23 (10.5%)> 3-30 (9.5%) > 3-7(6.7%)> 4-39 and 4-59 (5.7%). We compared the mutation status of HV genes against selected other known biologic features. Positive associations were present between hypomutation and female patients (RR 1.36, 95% CI 1.03-1.80, P<.05), CD38 (>5%) expression (RR 2.36, .95 CI 1.64-3.40), (del)11q22.3 (RR 4.79, 95% CI 2.09-10.98, P<.0001), trisomy 12 (RR 1.84, .95 CI 1.02-3.33) and complex karyotypes (RR 1.31, 95% CI 1.06-1.61, P<.01). The hypermutation status of HV gene was positively associated with 13q- (OR 4.38, 95% CI 2.52-2.7.62, P<.0001). There was no significant association of hypomutation with age. *Conclusion.* Our results confirmed and extended the observations of a biased utilization of HV genes among B-CLL patients. The gene most preferentially used was 1-69 (16.2%) and 92% of CLL patients with this gene were hypomutated. The second most frequently used gene was 3-30, which had no preference to mutation status (55.6% mutated *vs.* 45% unmutated). IgVH 4-34 and 3-23 were frequently seen after IgVH 1-69 and 3-30, and associated with hypermutation, 84.6% and 92%, respectively. The IgVH 4-34/DP 63, encoding an antibody that recognizes autologous determinants of RBC, occured in 5.6% and was one of the most common HV genes with hypermutation (10.5%). The extended studies correlated hypomutation of IgVH to chromosomal abnormalities with prognostic potential such as 11q22.3-, +12, also to female patients, and CD38 overexpression (>5%), while hypermutation correlated to 13q-.

DYNAMIC CHANGE OF SERUM THYMIDINE KINASE LEVELS IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKAEMIA

A Rivkina,[1] M Murovska,[2] G Vitols,[3] S Lejniece[2]

[1]National center of hematology, Riga, Latvia; [2]Riga Stradins University, A.Kirhensteins Institute of Microbiology and Virology,[3] Riga, Latvia; [3]Riga Stradins University, A.Kirhensteins Institute of Microbiology and Virology, Riga, Latvia

Background. Thymidine kinase (TK) is an important enzyme, which reflects cell division and DNA activity. It is known that TK levels are increased in acute leukosis, lymphomas and myeloma . However, nothing is stated about the level of TK in chronic lymphocytic leukemia (CLL). *Aims.* Serum TK levels in newly diagnosed patients with CLL was determined both pre treatment, 6 months and 12 months post initiation of chemo and glucocorticoid therapy. Patients were grouped using the Rai staging system and serum TK levels assessed within each stage. We try to utilize this marker as a prognostic factor in this disease will improve the appropriate selection of more effective treatment. *Methods.* The research group consisted of 120 newly diagnosed CLL patients during the period 2007 to 2009. Since levels of serum TK are low, it is best to use a method based on enzymic activity. In our study the following ELISA technique was used. Serum TK levels in healthy donors is less then 50 ng/L. Latvian Central Ethics Commission approved the research design and all patients enrolled in this investigation had given the informed consent. *Results.* 120 patients were assessed in this study. The patients were divided according to Rai staging system as follows: 7 patients in 0 stage, 38 patients- I stage, 40 - II stage, 19 patients in III stage, and 16 -in IV stage. Serum TK levels was determined as the normal or above the normal (> 0 ng/L) in all patients. Treatment with Chlorambucil had 50 patients. Fludarabinum/Prednisone - 24 patients. COP regimen - 17, mini CHOP regimen - 4, Fludarabinum/Cyclophosphomide - 7 patients, without any therapy - 18 patients. The results showed that 6 months post initiation of therapy serum TK levels were decreased in all treatment groups. (2821±375 ng/L pre therapy, 1557±214 ng/L post therapy P=0.0001)) The 12 month post initiation of therapy group showed a decrease in serum TK levels however the statistical probability was lower than for the 6 month group (2821±375 ng/L pre therapy, 1775±312 ng/L post therapy, P=0.02). We demonstrated a slight positive correlation between the level of serum TK and Rai stage of disease after analysis of all cases (r= + 0,36; P<0.0001). *Conclusions.* TK is increased in the serum of all newly diagnosed CLL patients. Serum TK levels are reduced after initiation of therapy, A highly significant reduction in serum TK levels is seen after 6 months post initiation of therapy (P= 0.0001) however after 12 months post initiation of therapy levels still showed a reduction but not as significant as after 6 months. (P=0.02) When analyzing all patients together, found a weak positive correlation between the level of serum TK and Rai stage (P<0.0001).

HLA-G EXPRESSION IN B CHRONIC LYMPHOCYTIC LEUKEMIA

M Yilmaz Falay,[1] M Yilmaz Falay,[2] G Ozet,[1] S Dagdas,[1] F Ceran,[1] U Ure,[1] G Tokgoz[1]

[1]Ankara Numune Education and Research Hospital, Ankara, Turkey; [2]Haemotology, Ankara, Turkey

B cell chronic lymphocytic leukemia (B-CLL) is the most common adult leukemia in Western countries. It is charactarized by an accumulation of long-lived, functionally inactive, mature-apearing neoplastic B lymphocytes. B-CLL has a variable clinical course. Some patients have an exellent prognosis never requiring treatment, whereas in others the survival is short despite early initiation of therapy. Classical Rai and Binet staging of CLL is being superseded by new prognostic markers. In the last few years, it has been suggested that the involvement of human leukocyte antigen-G (HLA-G) in several tumoral processes and its likely participation as a factor of immune tolerance in malignant cells. Recent studies indicate an ectopic up-regulation in tumor cells that may favor their escape from anti-tumor immune responses. The role of HLA-G in B-CLL has not been defined. For this report, 28 patients suffering from B-CLL were analyzed for the expression of HLA-G by flow cytometry using the anti-HLA-G spesific monoclonal antibody MEM/G9 and its correlation with other prognostic factors, RAI stages, β2-microglobulin, ZAP-70 protein and CD38 ekpression level. We observed low expession of HLA-G on leukemic B cells (1 to 22%). We detected no correlation with Binet staging , CD38 and ZAP-70 .In comparison with the We further observed that the patient group with low HLA-G expression (<10%) had significantly lower levels of IgG than the group with high level of HLA-G (>10%). Hence the 23 patients out of 28 have been followed up without any treatment, the correlation of the progression free survival time evaluation is stil under study.

ROLE OF SECOND GENERATION TYROSINE KINASE INHIBITORS IN OSTEOBLASTOGENESIS

D Tibullo,[1] I Barbagallo,[2] I Giallongo,[3] P La Cava,[3] A Branca,[3] O Di Bartolo,[3] E Spina,[3] P Spina,[3] V Del Fabro,[3] C Conticello,[4] A Romano,[3] G Palumbo,[3] F Di Raimondo[3]

[1]University of Catania, Catania, Italy; [2]Department of Biological Chemistry, Medical Chemistry and Molecular Biology, Catania, Italy; [3]Department of Biomedical Sciences, Division of Hematology, Ospedale Ferrarotto,, Catania, Italy; [4]Department of Experimental Oncology, Mediterranean Institute of Oncology, Via Pe, Catania, Italy

Backgrounds. The BCR-ABL inhibitor imatinib is standard first-line therapy for patients with chronic myeloid leukemia (CML) and has revolutionized treatment of the disease. However, it has been demonstrated that long term treatment of CML patients with IM is associated with altered bone and mineral metabolism with reduction of bone remodeling and increase of bone mineral density. In this perspective, we and others have demonstrated that *in vitro* IM treatment can increase the capacity of hBM-MSCs to differentiate into osteogenic lineage and favour osteoblastogenesis. The mechanisms that are responsible for this effect are not fully understood but an inhibition of PDGF-R_ (Platelet Derived Growth Factor- Receptor beta) axis has been suspected on the basis of some *in vitro* evidences. However, it is not clear whether the effect of IM on osteoblastogenesis may be entirely due to inhibition of PDGF-R signaling. In order to evaluate if stimulation of osteoblastogenesis is a common feature of other tyrosine kinase inhibitors (TKI) approved for the treatment of patients with CML, we evaluate the osteoblatic differentiation of Mesenchymal Stem Cells derived from bone marrow (BM-MSCs) after *in vitro* treatment with Dasatinib (DA) or Nilotinib (NI) or Bosutinib (BO). *Methods.* Mesenchymal stem cells (hBM-MSCs) were obtained from bone marrow samples of normal healthy adults after informed consent, isolated by density gradient (mononuclear fraction) and cultured in standard medium (SM). hBM-MSCs was induced to differentiate in osteoblastic cells by treatment with osteogenic medium (0.2 mM ascorbic acid, 0.1 μm dexamethasone and 10 mM β-glycerophosphate) (OM) with or without DA 2nM or NI 100 nM or BO 5nM. Expression of osteoblast-associated genes such as osteocalcin (OCN), RUNX2 and Bone morphogenetic protein (BMP-2) were evaluated by reverse transcription-polymerase chain reaction (RT-PCR) at 21 days of culture. *Results.* We found that the addition of DA and to a greater extend NI induced expression of osteogenic markers mRNA as compared to cultures with SM or OM only. However, treatment with BO did not induce increase of osteogenic markers as compared to controls. Table 1 indicates RT-PCR fold increase of osteogenic markers compared to cells treated with standard medium only. Conclusion. In conclusion, we showed that besides IM, other TKI such as DA and NI, but not BO, increase osteogenic markers (BMP-2, Runx2 and OCN) mRNA expression in BM-MSCs. Since BO differ from the other TKI because of its low affinity to PDGF-R, these experiments indicate that inhibition of PDGF-R is a major pathway in the induction of osteoblastogenesis by TKI. In this perspective, long term therapy with Bosutinib should not induce perturbation of bone and mineral metabolism and it could represent the treatment of choice for children affected by CML.

Table 1.

	Standard medium	Osteogenic medium (OM)	Dasatinib	Nilotinib	Bosutinib	Dasatinib + OM	Nilotinib + OM	Bosutinib + OM
RUNX2	1	17,7 ± 3,4	17,7 ± 3	20,3 ± 2,8	1,1 ± 1,8	16,5 ±2	28,8±4,3	19 ± 1
OCN	1	6,9 ± 2,3	3,7 ± 2	5,6 ± 1,8	1 ± 0,9	9,8 ± 2,2	12,1 ± 1,9	3,7 ± 1
BMP2	1	11,7 ± 2,4	8,8 ± 3,3	7,7 ± 3,6	0,9 ± 1,6	12,1 ± 4	12,5 ± 2,7	10,9 ± 2

HAIRY CELL LEUKEMIA: RESULTS OF LONG-TERM FOLLOW UP OF 214 PATIENTS

L Al-Radi,[1] A Pivnik,[2] S Kravchenko,[1] A Kremenetsraya[1]

[1]Hematology Research Center, Moscow, Russian Federatio; [2]National Medical-Sergical Senter N.I.Pirogov, Moscow, Russian Federation

We followed up 214 patients (pts) with hairy cell leukemia (HCL) sinse 1995 till 2010(15 yrs). The diagnosis was made according to standard criteria, including routine clinical, radiological, sonography data, blood and bone marrow cytology, TRAP, immunophenotyping, trephine and/or splenic morphology with immunohistology. There was 145 man and 69 women (m:f ratio = 2,1:1). Classical HCL had 159 pts, HCL-variant form 55 (26%) pts. Median age was 51 yrs (range 27-81); patients younger than 45 yrs appeared 53 (25%) pts. 203 pts received a-interferon for 8-12 wks (3 mln Un 3 times per every wk sc) with subsequent cladribin standard prescription in 157 pts with achieving complete remissions for median 7 yrs (range 0.6 - 15) in 85% of them. Thus it was possible to avoid agranulositosis in 95% pts while there were two prolonged such events in initial treatment without preliminary a-IF. The response to this treatment was equal either in classical or variant form of HCL. Relapses happened in 33 (21%) pts after median 4 yrs (range 1.3- 12), most of patients had classical form of HCL. It was noted that from 33 relapsed pts 26 (79%) were younger 45 yrs. Died 18 (8%) pts, aged 31-71 yrs at attendance, 14 pts had classical HCL and 4 pts had HCL-variant form, 9 pts were of 31-45 yrs old. The main cause of death in 6 young pts was HCL progression; 4 old pts died from severe infections at admittance, the last 5 pts - from diseases not linked to HCV. Secondary tumors occurred in 10 (5%) pts aged 62 (46-73) yrs. Tumors were discovered before HCL diagnosis in 2 pts, after 11 (range 2-19) yrs following therapy with a-IF in 4 pts; after 4 (range 0.5-10) yrs following cladribin course in 4 pts. Localization of these 10 secondary tumors were: 3 urogenital (uterus, bladder, prostate), 3 gastrointestinal (gastric cancer, colon), 2 lungs,1 breast, and 1 soft tissues. Among them 4 pts died in complete HCL remission. We propose to intensify initial therapy of HCL in patients younger than 45 yrs with subsequent anti-CD20 monoclonal antibodies.

1279

PROGNOSTIC SIGNIFICANCE OF ABDOMINAL CT SCAN IN CLL PATIENTS IN BINET STAGE A: PRELIMINARY RESULTS OF A PROSPECTIVE, MULTICENTER OBSERVATIONAL-CLL1- GISL STUDY

Background. The Rai and Binet staging systems represent the backbone for assessing prognosis in CLL patients. However the staging systems are not devoid of some limitations, among these there is the lack of evaluation of abdominal lymphadenopathy. Recently, a retrospective study challenged this notion highlighting the importance of prospective validation of abdominal CT before routine inclusion in CLL work-up. *Aims.* We investigated the clinical significance of abdominal CT in the initial work-up of Binet stage A CLL patients, included in the prospective multicenter O-CLL01 GISL study. *Patients & Methods.* To date, 380 patients have been enrolled in the trial started in April 2007 and abdominal CT were available for 127. Median age was 60.5 years (range, 33-70 years) and 61% of patients were male. Ninety-one patients were at low risk and 36 at intermediate risk by Rai classification. LDH was elevated in 11% of cases and B2-microglobulin in 28%. Thirty-six% of cases were IgVH unmutated, 42.5% had a high ZAP-70 expression, 22% were CD38 positive (>30%). FISH data were available for 116/127 cases; the most frequent abnormality was del(13q14) (46%), followed by trisomy 12 (12%), del(11q22.3) (6%) and del(17p13) (3%), 33% of cases were normal. Cytogenetic abnormalities were clustered in 3 risk groups [i.e. low (del(13q14) and normal), intermediate (trisomy 12) and high risk (del(11q22) and del(17p13)]. Abdominal CT was defined as abnormal when ≥1 anomalous lymphnode regions, including spleen enlargement, were observed. *Results.* Fifty-eight of 127 patients (46%) showed an abnormal abdominal CT. Notably, 78% were male, LDH was elevated in 5% of cases and B2-microglobulin in 38%, 48% were IgHV unmutated, 52% had a high ZAP-70 expression, 38% were CD38 positive and 15% showed a high-risk FISH. Male gender (P=0.001), elevated B2-microglobulin level (P=0.036), high CD38 expression (P<0.0001) and IgHV germline status (P=0.016) correlated with an abnormal abdominal CT. At logistic regression analysis only male gen-

der (P=0.013; HR 3.1, CI 1.3-7.7) and high CD38 expression (P=0.008; HR 5.1, CI 1.5-17) remained independently associated with abnormal abdominal CT. Time to progression was significantly shorter in patients with an abnormal CT than in those with a normal CT (2-years TTP probability, 86% *vs.* 100%; P=0.003). According to the Rai classification 35/91 (38.5%) low risk patients showed an abnormal abdominal CT. In this subset of patients male gender and high CD38 expression again correlated with an abnormal abdominal CT at both univariate (P<0.008 and P<0.0001, respectively) and multivariate analysis (P=0.016; HR 3.6, CI 1.3-10.3, P=0.002; HR 6.6, CI 2-21.8, respectively). Patients with an abnormal CT showed a TTP significantly shorter than those with a normal CT (2-years TTP probability, 82.5% *vs.* 100%; P=0.015). *Conclusion.* Our data indicate that abdominal CT allow discrimination among Binet A CLL patients 46% of cases with abdominal lymphadenopathy or splenomegaly. Moreover abnormal CT were associated with bad prognostic parameters as male gender and high CD38 expression. Taken together, abnormal abdominal CT predict disease progression. Similar data are observed in Rai stage 0 patients. Thus the inclusion of abdominal CT in the initial work-up of patients in early stages can provide relevant clinical information.

1280

ENLARGED ABDOMINAL LYMPH NODES AND EARLY RESPONSE ARE NEW FAVORABLE PROGNOSTIC MARKERS IN CLL PATIENTS TREATED WITH FLUDARABIN-CONTAINING REGIMENS

E Stadnik,[1] G Salogub,[1] Y Alexeeva,[2] V Strugov,[2] A Zaritskey[2]

[1]Pavlov State Medical University, Saint-Petersburg, Russian Federation; [2]Federal Almazov Heart, Blood and Endocrinology centre, Saint-Petersburg, Russian Federation

Background. Initial prognosis estimation in CLL can be done by clinical staging (Rai and Binet systems) and a couple of laboratory methods, which are rather labour and time consuming. E. Montserrat *et al.*. showed that CT scans can be used for prognosis prediction. In particular presence of abdominal lymphadenopathy was associated with inferior survival in Rai 0 CLL pts. Fludarabine-containing regimens are widely used as first-line treatment in CLL. We sought to investigate whether interim response after three cycles of such therapy interferes with post-treatment OS and PFS. *Aims.* To evaluate prognostic significance of abdominal lymph nodes enlargement (EALN) and response after three cycles of therapy in CLL pts receiving fludarabine-containing regimens (FC and FCR). *Methods.* 75 untreated CLL pts were included according to intent to treatment by fludarabine containing regimens (41 assigned to FC, 34 to FCR). Informed consent was obtained in each case. Treatment schedules were standard. Lymph nodes were revealed by CT and ultrasound before therapy (available in 71 pts). Lymph nodes >10 mm in diameter were considered abnormal and >100 mm in diameter - bulky. Early response (ER) was defined as PR and CR after 3 cycles of therapy, others were considered non-early responders (nER). CD38 was measured by cytoflow with 30% cut off (available in 57 pts). VH genes were analyzed by cDNA sequencing with 98% threshold (available in 32 pts). CR was defined according to NCI criteria. Statistics were calculated in SPSS17. Cox regression was used for HR estimation. Model included regimen, stage, CD38 status, presence of EALN and ER.

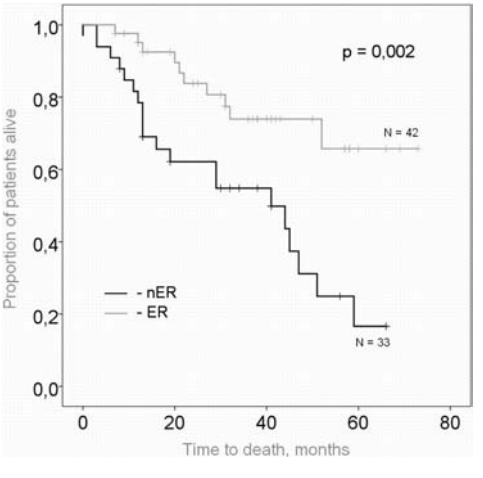

Figure. Overall survival in ER *vs.* nER.

Results. There were 42 pts in ER group and 33 nER. ER pts in comparison to nER had higher median PFS in both FC (28 *vs.* 14 mo., P=0,001) and FCR (58 *vs.* 18 mos., P=0,018) arms. ER pts with standard adverse prognostic factors did better than nER with similar prognostic factors (median PFS in CD38-pos 31 *vs.* 12 mos. P=0,05; UM-CLL 32 *vs.* 18 mos. P=0,03; Stage C 31 *vs.* 9 mos, P=0,001). OS was significantly higher in ER (median OS n.r. *vs.* 41 mos, P=0,002). EALN were present in 41 pts (58%), 16 pts had bulky EAL (23%). PFS was lower in the group of pts with EAL in comparison to pts without EAL (18 *vs.* 48 mos, P=0,001). Difference in PFS has been also revealed in FC and FCR subgroups (16 *vs.* 25 mos, P=0,003 for FC; 22 *vs.* 56 mos, P=0,01 for FCR). Most of the pts with EALN did not reach ER (34,15% *vs.* 89,65% in EALN-group, P<0,01). Interestingly most of the pts with EALN had UM-CLL as opposed to non-EALN group (83,3% *vs.* 43,75%, P=0,054). In Cox regression analysis only presence of EALN and absence of response after three cycles of therapy were significantly associated with decreased PFS (HR 2,679, P=0,013, CI 1,229-5,842 and HR 2,334, P=0,05, CI 0,989-5,513 respectively). *Conclusion.* Presence of EALN appears to be an independent adverse prognostic factor in CLL associated with decreased PFS. Early responding CLL pts form a specific cohort with extremely favorable prognosis.

1281

CHRONIC LYMPHOCYTIC LEUKAEMIA PATIENTS WITH V1-69 GENE REARRANGEMENT HAVE AN UNFAVOURABLE CLINICAL OUTCOME

R Urbanova,[1] V Prochazka,[1] T Papajik,[1] R Plachy,[2] Z Pikalova,[2] M Holzerova,[2] L Schillerova,[2] M Divoka,[2] M Jarosova,[2] K Indrak[1]

[1]University Hospital and Medical Faculty, Palacky University Olomouc, Olomouc, Czech Republic; [2]University Hospital and Medical Faculty, Palacky University, Olomouc, Czech Republic

Background. Mutational status of the immunoglobulin heavy chain variable region (IgVH) gene is a robust and independent predictive factor in patients with B-cell chronic lymphocytic leukaemia (B-CLL). The V1-69 gene is the most frequently rearranged V(H) gene and is almost always unmutated. Nevertheless, the prognostic role of V1-69 gene rearrangement is not clear and the published studies have reported controversial results. *Aim.* To analyze the haematological features, clinical behaviour and outcome of patients with V1-69 gene rearrangement. *Methods.* IgVH mutational status was analyzed in 328 patients with B-CLL who met the NCI-WG diagnostic criteria. IgVH mutational status was analyzed using cDNA transcribed from B-CLL RNA for touch-down reverse transcription polymerase chain reaction (RT-PCR) with degenerate primers for VH1-7 families; IgVH were aligned to the nearest germline using the Ig BLAST database. A sequence homology cutoff of 98% was used to define the IgVH mutational status. The V1-69 gene was clonally rearranged in 44 (13.5%) of 328 cases. All but one (97.7%) patient had unmutated IgVH. Most of the unmutated cases (77.2%) had 100% sequence homology with the nearest germline V(H) gene. The median age at diagnosis was 60 years (36-83) and the M/F ratio was 3.4:1. Binet clinical stages were as follows: A 14%, B 20% and C 10%. FISH analysis was performed in 39 of 44 patients (88.6%); high-risk genetic abnormality (17p, 11q or 6q deletion) was detected in 22 (56%) cases. ZAP-70 was evaluated in 26 of 42 patients - all of the cases were positive. The immunophenotypic profile was aberrant in 18 patients (42.8%). Treatment was initiated in 36/44 patients (82%), with first-line therapy comprising chlorambucil (5/36), fludarabine-based or RFC regimen (26/36) or R-C(H)OP-like regimen (5/36). *Results.* Complete response was achieved in 5 (15%) and partial response in 19 (56%) of 34 patients; the overall response rate after first-line therapy reached 72%. After a median follow-up of 51 months, 17 (38.6%) of 44 patients died. The median overall survival (OS) reached 91.6 months (95% CI 78.4-104.8); the median treatment-free survival (TFS) was 58.0 months (95% CI 40.1-76.0). Both OS and TFS were not significantly different in patients with or without high-risk cytogenetic abnormality (P=0.32 and P=0.09, respectively). Similarly, Binet stage did not influence OS and TFS (P=0.1 and P=0.2, respectively). *Summary.* Patients with V1-69 gene rearrangement almost always have unmutated IgVH, all of the examined patients were ZAP-70 positive and more than half of the patients had a high-risk genetic abnormality. The survival and treatment initiation are not influenced by unfavourable cytogenetics or Binet stage. The overall response to initial therapy is unsatisfactory. The survival is uniformly worse than the published results in unselected patients with unmutated IgVH. Generally, the outcome of the population with V1-69 gene rearrangement is unsatisfying due to an accumulation of unfavourable prognostic factors. *Acknowledgements.* Supported by the grants of the Ministry of Edu-

cation, Youth and Sports (MSM 6198959205) and the Ministry of Health (IGA NR 9484) of the Czech Republic.

THE USE OF GRANULOCYTE COLONY-STIMULATING FACTOR (G-CSF) IN CLL PATIENTS TREATED WITH FLUDARABINE, CYCLOPHOSPHAMIDE AND RITUXIMAB, (FCR) IS ASSOCIATED WITH LONGER PROGRESSION FREE SURVIVAL (PFS)

Medical University of Vienna, Vienna, Austria

Background. Chemoimmunotherapy with fludarabine, cyclophosphamide and rituximab, (FCR) is currently the preferred first or second line treatment for fit patients with chronic lymphocytic leukemia (CLL).With this treatment high overall remission rates of 70 to 90% (CR 25 to 44%) are achieved. Severe neutropenia (CTC grade 3+4: 42 to 62%) and infections (5 to 18%) are the major side effects. Currently, prophylactic use of G-CSF is not recommended for FCR treatment in clinical studies and data on G-CSF are not reported. *Patients & Methods.* We retrospectively analysed the use and impact of G-CSF in a cohort of 32 unselected, consecutive patients with CLL and related entities treated with FCR between 2004 and 2008 in a single center. Twenty-five patients (78,1%) were previously untreated. Patients were older than published cohorts (median age 66 years, range 50 to 82 years, 23 males and 9 females). G-CSF was used for treatment of febrile neutropenia (FN) or infection. G-CSF was also given, when CTC grade 3 neutropenia (ANC 500-1000/uL) occurred, but not for primary prophylaxis. Twenty-three patients (71,8%) received antibiotic prophylaxis with sulfomethoxazole/ trimethoprim. *Results.* The 32 patients received 156 cycles of FCR. Two patients (5%) had febrile neutropenia. CTC grade 3 and 4 neutropenias (ANC 0-500/uL) were observed in 16 patients (50%). Neutropenia predominantly occurred in FCR cycles 1 and 2. G-CSF was administered in 38 (24,6%) of all 156 cycles. The median dose of G-CSF per patient (n=16) was 75 million units (30 to 1.110 million units). Dose reductions for patients receiving G-CSF were recorded in 34 cycles, for patients without G-CSF dose reductions were reported in 48 cycles. Dose reductions were performed according to the rules of the GCLLSG. Dose delays were seen in 10 patients (7 patients with G-CSF and 3 patients without G-CSF). The number of cycles completed in comparison to planned cycles was not different in patients with or without GCSF (patients with G-CSF: 81%, patients without G-CSF 79%). Only 3 patients (7.5%) were hospitalized due to infection or FN (2 before and 1 patient without FN, infection only) currently, 27 of 32 patients are still alive, 5 patients died. The overall response rate in all patients was 84,4% (53% CR). For CLL patients receiving G-CSF the ORR was 93,8% and for patients without G-CSF 75 %. Progression free survival (PFS): only two patients in the G-CSF group had progression. Median PFS at 24 months was 93.75% in patient with G-CSF and 37,5% in patients without G-CSF. (P=0.0001) Overall survival in patients with G-CSF was 93,75% and for patients without G-CSF was 75%. (P=0.221). *Conclusions.* Data suggest that routine use of G-CSF not only to prevent FN but also to increase density may have a positive effect in CLL. Interestingly patients receiving G-CSF had a significantly longer progression free survival (Figure 1). Patients receiving G-CSF have better outcome, progression free survival than patients without G-CSF. Those results warrant a randomized clinical trial of prophylactic use of G-CSF to increase dose densities.

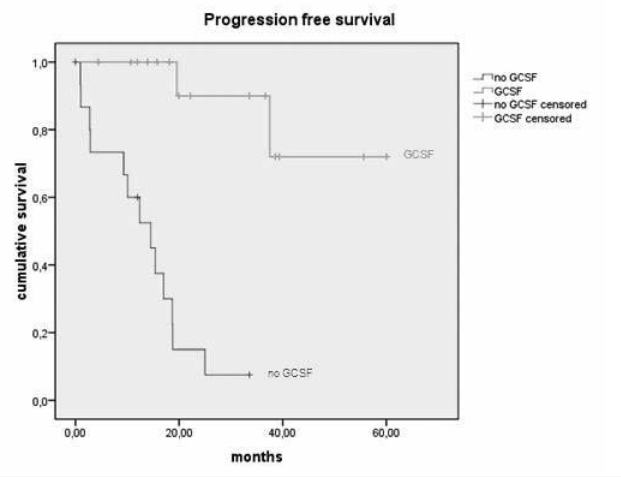

Figure 1. Progression free survival p-value<0.0001.

NON-MALIGNANT B-CELL SUBSETS AS BIOMARKERS FOR THE RISK OF INFECTIONS IN CHEMOTHERAPY -NAÏVE CLL PATIENTS

C Skrabs, K Fleiss, C Einberger, U Jaeger, W Pickl

Medical University of Vienna, Vienna, Austria

Background. Individuals with anatomical or functional asplenia suffer from recurrent infections by encapsulated bacteria (Streptococcus pneumoniae, Haemophilus inluenzae). The impaired immune response to these bacteria is due to the absence of IgM^+ memory B cells, which require the spleen for their generation and/or survival. *Aims.* We here sought to investigate, whether the high incidence of recurrent respiratory infections observed in a subgroup of CLL patients is related to a state of functional asplenia. *Methods.* Sixty-eight patients with chemotherapy-naïve CLL were enrolled in a pilot study. Evaluations consisted of standard laboratory and clinical parameters including type and frequency of infections. Peripheral blood cells were analyzed by multi-parameter flow cytometry. The $CD19^+CD5^-$, non-malignant B cell compartment within the lymphogate was further subdivided by staining for surface IgD and CD27 to discriminate between naïve, marginal zone (MZ) and class switched memory (SM) B-cells, respectively. *Results.* Low numbers (<10 μL) of SM B-lymphocytes were significantly associated with the occurrence of infections (P=0.023; 23/29 *vs.* 20/39), higher age (P=0.0026; 70.7±8.4 *vs.* 63.1±10.7 years), lower leukocyte counts (P=0.041; 28421±21627 *vs.* 52031±58071 μL) and low CD38 expression levels (P=0.0082; 8.7±17.6 *vs.* 26.1±29.6 % CD38+; and P=0.0047; 2/27 *vs.* 15/39 for $CD38^+$ >30%) but not with mutational status or cytogenetic aberrations. Moreover, the occurrence of infections per se was significantly correlated with higher age (P=0.047; 68.3±10.8 *vs.* 63.1±9.0 years), lower hemoglobin levels (P=0.032; 13.4±1.6 *vs.* 14.2±1.3 g/dL) and elevated serum beta2-microglobulin levels (P=0.031; 2.6±1.7 *vs.* 1.8±0.8 mg/L). *Conclusion.* Monitoring of residual, non-malignant CD5-B-lymphocyte subsets in the peripheral blood of chemotherapy-naive CLL patients may represent a novel biomarker to identify CLL patients at risk for frequent respiratory infections. A prospective study relating the above findings with patient morbidity clearly is warranted.

1284

EVALUATION OF MINIMAL RESIDUAL DISEASE IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA BY MULTIPARAMETRIC FLOW CYTOMETRY AND REAL-TIME PCR

O Stehlikova,[1] V Hrabcakova,[2] H Jelinkova,[3] M Doubek,[2] J Mayer,[4] M Klabusay[2]

[1]University Hospital Brno, Brno, Czech Republic; [2]Laboratory of Flow Cytometry and Cellular Therapy, University Hospital Brno, Brno, Czech Republic; [3]Center of Molecular Biology and Gene Therapy, University Hospital Brno, Brno, Czech Republic; [4]Dept. of Internal Medicine, Hematology and Oncology, University Hospital Brno, Brno, Czech Republic

Background. Chronic lymphocytic leukemia (CLL) is the most widespread type of leukemia in adults. Despite significant progress in treatment, chronic lymphocytic leukaemia remains incurable disease. Aim of the therapy in most patients is to achieve a complete remission (CR) of the disease, which is defined by the NCI-WG criteria ("National Cancer Institute - Sponsored Working Group") and is associated with eradication of majority of tumor cells. CR with negative MRD is associated with favorable extension of the remission period, because residual leukemic cells can cause a relapse of the disease. Methods of multicolor flow cytometry and polymerase chain reaction (PCR) enable to detect minimal residual disease (MRD) in patients with CLL, who achieved CR. *Aims.* We have implemented standardized multiparametric flow cytometry protocol for the detection of MRD in CLL (modified according to A. Rawstron, 2007). MRD was also detected by molecular biology approaches with the detection of IgVH specific clones with sensitivity 1:106 cells. Both methods we compared in the group of patients with CLL. *Methods.* A group of 17 patients with diagnosis of CLL, who achieved CR after alogeneic transplantation of peripheral blood stem cells (PBSCT), were included into the observation. Samples of peripheral blood and bone marrow of patients were repeatedly analyzed by flow cytometry. Briefly, samples were analyzed if $CD5^+19^+$ cells represented less then 5% of leukocytes. Samples were incubated with following antibodies directly labeled with fluorochromes FITC, R-PE, PE-Cy5 and PE-Cy7: anti- CD5, CD19, CD20, CD22, CD38, CD43, CD79b, CD81 (Invitrogen, U.S.A.). CD5 and CD19 antibodies were included in each test tube. Erythrocytes were eliminated by hypoosmotic hemolysis according to the standard procedure and samples were analyzed on flow cytometer Cytomics FC500 (Beckman-Coulter, U.S.A.). MRD calculation was performed at web calculator (www.mrd-cll.org). Detection of clonal IgVH was performed by RQ-PCR with LNA probe (Locked Nucleic Acid, TaqMan technology). Universal LNA modified TaqMan probes (TIB MolBiol, Germany) specific for all clones of each VH family were designed to FR3 region. Specific oligonucleotides were designed for each patient, one of those always localized to clonotypic region. Plasmid with cloned patient specific IgVH sequence was prepared for quantification. Albumin was selected as a reference gene. Sensitivity of the method reached 1: 105-106. There were no problems with non-specific amplification (modified protocol, Brüggemann *et al.,* 2000). *Results.* In the cohort 17 of patients who underwent alogeneic PBSCT, 12 of them achieved MRD-negative CR. Five patients had detectable MRD after PBSCT. 11 of these patients were simultaneously evaluated for MRD by both methods. There was a very good correlation between flow cytometry and PCR approaches (r=0,8, in paired samples r=0,93). *Conclusions.* Our results suggest that high-sensitivity flow cytometry method of MRD detection in CLL is applicable to peripheral blood and bone marrow samples of patients after PBSCT and that it is comparable to RQ-PCR technique. Evaluation of MRD in patients with CLL after therapy by high-sensitivity methods has a prognostic importance. It also allows for early detection of relapse and early change of the treatment strategy.*Acknowledgements.* This work was supported by grant IGA MZ CR No. NR9671-4 and MSM 021622430.

DETECTION OF HAIRY CELLS (HC) IN THE BLOOD IS NOT SUFFICIENT TO PREDICT LONG TERM RELAPSE IN HAIRY CELL LEUKAEMIA (HCL)

D Agrefilo, T Cluzeau, JM Karsenti, D Aquaronne, I Sudaka, C Ferrero, A Rosenthal, JG Fuzibet, JP Cassuto, T Ticchioni, N Mounier

CHU Nice, Nice, France

Background. HCL is a lymphoproliferative B-cell malignancy which represents about 2% of all adult leukemia. Purine analogues have transformed its prognosis with a median relapse free survival of 16 years. Overall survival 15 years after the first treatment reaches 95% with pentostatin and 100% with cladribine. However, early relapse may occur with emphazise the need to define new criteria to identify those patients. *Aims.* Detection of HC in the peripheral blood (PB) by flow cytometry at complete remission (CR) as criteria of relapse. *Methods.* Retrospective study of HCL patients treated between 2000 to 2010 with either pentostatin or cladribine. Response evaluation was performed with criteria of the Consensus Resolution and safety evaluation with NCI criteria. Immunophenotyping was performed on peripheral blood using a 6-color panel of antibodies (Ab) with the following combinations: CD43/CD103/CD19/CD25/CD11c/CD45 and IgG/IgG/CD19/IgG/IgG/CD45/. Fifty to one hundred µL of blood was incubated with the different Abs for 10 minutes at room temperature. Red cells were lysed with FACSTM Lysing Solution (BD), then cells were washed and resuspended before analysis on a 6-color flow cytometer . CD19 positive B cells were gated. Hairy cells were identified on the basis of bright coexpression of CD11c and CD103, positivity for CD25 and negativity for CD43. Between 32500 and 235000 cells were routinely acquired . The statistical test Chi-square was used. Kaplan-Meier survival curves were compared using Log-Rank test. *Results.* Twenty two patients were treated and followed between 2000 to 2010. Sisteen patients received pentostatin 4mg/m^2 IV every 2 weeks until maximum response, consolidated with two further doses. Six patients received cladribine by continuous IV infusion (0.1 mg/kg/day) over 7d. A repeated cycle of cladribine was given if CR was not attained after the first cycle. The CR rate was 100%. There was no safety significant difference between cladribine and pentostatin treatment on the following parameters. Regarding infections, we observed 21% grade 1/2 for pentostatin arm; and 19% grade 1/2, 5% grade 3/4 for cladribine arm (P=0.0915). Concerning hepatic toxicity, we detected 5% grade 1/2, 5% grade 3/4 for pentostatin arm; and 0% for cladribine arm (P=0.4416). For skin toxicity, 14% grade 1/2 for pentostatin arm; and 5% grade 1/2 for cladribine arm (P=0.7079) occurred. There was no digestive toxicity . At a median follow up of 2 years, median event free survival (EFS) was 91% without any significant difference between cladribine and pentostatin treatment (94% *vs.* 83%, P=0.7055). Nine patients were evaluable in the PB by flow cytometry. Median hairy cells count was 198 (range 0-24900). Five on nine patients (56%) had a detectable disease, but none of these patients have relapsed to date. *Summary.* Cladribine and Pentostatin are safety treatments for HCL. This disease has a favorable outcome with these treatments but some early relapse occurs. Immunophenotyping evaluation at CR may still detect hairy cells but the correlation with relapse is unclear. It is therefore necessary to validate a cut-off in prospective study to predict the relapse.

1286

LOW DOSE ORAL FLUDARABINE PLUS CYCLOPHOSPHAMIDE IN ELDERLY PATIENTS WITH UNTREATED AND REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA (RETROSPECTIVE STUDY)

H Ionita,[1] I Ionita,[1] DE Nicola,[2] R Pacurar,[2] CO Ionita,[1] M Cheveresan,[2] G Borzak,[2] M Ionita[1]

[1]UMF Victor Babes, Timisoara, Romania; [2]County Clinical Hospital, Timisoara, Romania

Background. Fludarabine plus Cyclophosphamide (FC) at convetional doses is highly effective in Chronic Lymphocytic Leukemia (CLL) and is currently indicated in first line therapy. Oral FC at reduced doses remains highly effective in elderly patients with low-grade non Hodgkin lymphomas other than CLL. *Aims.* To test tolerability and efficacy of oral FC at reduced doses in patients unfit for standard regimens. *Methods.* Thrirty-eight elderly patients with untreated (UT-CLL, n=21) or refractory CLL (R-CLL, n= 17), requiring treatment according tp 1996-NCI criteria, were given oral F (25 mg/m^2/day) and C (120 mg/m^2/day) in an outpatient regimen for 4 consecutive days every 4 weeks for a maximum of 4 cycles. Median age of the whole population was 65

years (range 60-75). Performance status was ≥ 1 in 72% patients. Median time from diagnosis or from prior treatmetn to FC was 21. months (range 1-61). Patients were evaluated after every cycle for toxicity and hematological response. Toxicity and responses were defined according to NCI criteria, with the exception of not repeating bone marrow aspirate after treatment termination in a few cases. Progression, new treatment or death was defined as "event". *Results.* Patients received median 4 cycles (5 in UT-CLL, 4 in R-CLL). 10 patients reduced the number of cycles because of fatigue (1 patient), heart failure (1), idiopathic thrombocytopenic purpura (1) in the UT-CLL (3/21) or infection (2), prolonged isolated thrombocytopenia or pancitopenia (2) and idiopathic thrombocytopenic purpura (2) in R-CLL (6/17). Overall, 35/38 (92,1%) patients obtained a response (15/38 CR, 39,4%; 20/35 PR, 52,6%). Among UT-CLL, all responded to treatment (10/21 CR, 47,6%; 12/21 PR, 57,1%). Among R-CLL, 10/12 (83,5%) responded (5/17 CR, 29,4%; 9/17 PR, 52,9;% and 3/17 NR, 17,6%). With a median follow-up of 20 months, 19/35 patients (54,2%) were event-free and 34/38 (89,4%) were alive. Amoung UT-CLL (median follow-up 12 months) 17/21 (80,9%) were event-free and all were alive. Among R-CLL (median follow-up 23 months), 7/17 (41,1%) were event-free and 14/17 (82,3%) were alive. Deaths occurred in the 2R-CLL that had not responded to treatment, after 2 and 3 years, respectively. *Conclusions.* Low-dose oral FC treatment showed good effciacy both in untreated and refractory/ relapsed CLL. The treatment may be useful in elderly patients who cannot benefit of more aggressive or eradicating strategies and is easy to administer on an outpatient basis.

1287

BENDAMUSTINE IN ASSOCIATION WITH RITUXIMAB AS SALVAGE THERAPY FOR SPLENIC MARGINAL ZONE LYMPHOMA

E Iannitto,[1] S Mancuso,[2] A Augello,[1] G Franco,[1]
E Domingo-Domenech,[3] E Pennese,[4] V Vincenzo[2]

[1]Divisione di Ematologia, AOUP Paolo Giaccone, Palermo, Italy, [2]Chair of Hematology, Palermo, Italy; [3]Hematology Unit. Institut Catala d'Oncologia, Barcellona, Spain; [4]Ematologia, Ospedale Fazi, Lecce, Italy

Background. At present, a prospectively validated treatment for SMZL is lacking. Despite this fact, splenectomy is still deemed to be the best choice for patients requiring treatment. Nevertheless, the high fraction of patients achieving a clinical response following splenectomy eventually relapses or progresses. For such patients, as well as for those who are unfit for splenectomy or unwilling to undergo surgery, systemic treatment may be appropriate. Bendamustine (B) is a purine analogue/alkylator hybrid agent with a unique mechanism of action. Bendamustine has shown a considerable degree of activity as single agent in patients with lymphoid malignancies and there is evidence that its *in vitro* cytotoxic effect may be enhanced by the monoclonal anti-CD20 antibody Rituximab (R). In the setting of several haematological malignancies, the association R-B has proved to be effective and well tolerated. *Purpose.* To asses response rate and toxicity of the R-B association in pre-treated SMZL patients. *Material and Methods.* Clinical data of SMZL patients who received the R-B association as salvage therapy were retrieved. The schedule and dosage of BR was as follows: Bendamustine 80-90 mg/m^2 i.v. days 1-2 and Rituximab 375 mg/m^2 day 1, q28. Presenting features, response rates and toxicities were analysed. *Results.* Six SMZL patients, median age 69 yr (rage 62-82), relapsed after a median of 2 lines of therapy (range 1-3) received R-B treatment. Previous treatments included splenectomy (3 patients), anthracyclines and alkilating agents (all patients), purine-analogues (2 patients), and Rituximab (2 patients). All patients had active disease with peripheral cytopenia and three of them had also B-symptoms and/or symptoms related to huge splenomegaly (spleen tip 7-18 cm below left costal margin). After a median of 4 cycles of therapy (range 2-6), 5 patients attained a CR and one patient, who achieved a complete regression of splenomegaly and bone marrow infiltration, and a 75% reduction of the IgG-k serum monoclonal component, was considered in PR. Haematological toxicity > grade 3 CTC was recorded in two patients (HB: G4; PLT: G3; Neutrophils G4; infection G3). One case of pseudomonas areuginosa bacteremia and one case of febrile neutropenia were recorded in two non-splenectomised patients and both patients recovered after appropriate antibiotic therapy. *Conclusions.* In pre-treated SMZL patients, the association R-B proved to be feasible and induced a high CR rate even in patients with huge splenomegaly. Complete responses were achieved promptly with as low as 4 cycles of therapy but the toxicity observed suggests investigating a dose of Bendamustine lower than 90 mg/m^2. These preliminary results suggest that R-B could represent a potential candidate for replacing splenectomy in the first-line treatment of SMZL patients. Prospective trials aimed to assess toxicity and efficacy of R-B as first line therapy for symptomatic SMZL are warranted.

1288

SERUM LEVEL OF VASCULAR ENDOTHELIAL GROWTH FACTOR (VEGF) AS PROGNOSTIC PARAMETER IN UNTREATED PATIENTS WITH B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA

D Antic,[1] V Cokic,[2] M Dencic Fekete,[1] M Perunicic Jovanovic,[1]
V Milo_evic,[1] N Kraguljac Kurtovic[1]

[1]Clinical Center Serbia, Belgrade, Serbia; [2]Institute for medical research, Belgrade, Serbia

Background. The overall survival of patients with B-cell chronic lymphocytic leukemia (B-CLL) is extremely heterogenous, so novel prognostic factors are being sought in order to identify high-risk patients at the time of diagnosis and to optimize their treatment. Several studies have also shown that in B-CLL there are increased vascularity in bone marrow and increased level of angiogenic cytokines in peripheral blood. *Aim.* In this study, we investigated whether there is an association between serum concentrations of key angiogenic faktor - vascular endothelial growth factor (sVEGF) and mean vascular density (MVD) of bone marrow with conventional prognostic factors (CD38 expression, citogenetic risk, Rai and Binet stage, type of bone marrow infiltration, beta 2 microglobulin) and risk of disease progression in patients with B-CLL. *Material and Methods.* We analyzed 33 Binet untreated stage A patients whose sera were taken at the time of diagnosis and evaluated for the level of sVEGF using ELISA method and whose bone marrow was assessed for MVD using CD34 antibody. *Results.* Serum levels of VEGF positively correlated with Hb level (P=0.027), pletelet number (P=0.007), peripheral blood lymphocytosis (P=0.034) and LDH level (P=0.008). When dealing with MVD only a correlation with CD38 positivity more than 30% (P=0.006) could be found. Different cut-offs of sVEGF level failed to demonstrate any correlation between serum levels of VEGF and time to disease progression. Also, MVD did not correlate with time to disease progression. In univariate and multivariate analyisis the highest prognostic power was obtained when sVEGF and b2-m were examined in combination. Median of progression-free survival of patients who had both sVEGF higher than median value (80pg/mL) and b2-m higher than 3.7mg/mL was only 13 months, while median progression-free survival of patients with one marker increased was 27 months. Patients with both markers below the median experienced the best clinical outcome (median progression-free survival was 48.6 months). *Conclusion.* Only sVEGF in combination with b2-m help us to improve predicts behaviour of disease of stage A patients with B-CLL.

1289

EFFICACY AND SAFETY OF FLUDARABINE AND CYCLOPHOSPHAMIDE REGIME AS FRONT-LINE THERAPY IN PATIENTS AFFECTED BY CHRONIC LYMPHOCYTIC LEUKEMIA WITH LOW RISK BIOLOGICAL PARAMETERS

L Laurenti,[1] L Laurenti,[1] L De Padua,[1] M Tarnani,[1] N Piccirillo,[1]
P Falcucci,[2] G D'Arena,[3] I Innocenti,[1] S Marietti,[1] D Efremov,[4]
P Chiusolo,[1] G Zini,[1] C Rumi,[1] S Sica,[1] G Leone[1]

[1]Policlinico A. Gemelli, Rome, Italy; [2]Ospedale Belcolle, Hematology, Viterbo, Italy; [3]Ospedale San Giovanni Rotondo, Hematology, San Giovanni Rotondo, Italy; [44]Molecular Hematology, ICGEB Monterotondo Outstation, Rome, Italy

Background. The fludarabine plus cyclophosphamide (FC) regime was reported to be superior to chlorambucil or fludarabine alone in terms of complete response, overall response and progression free survival in previously untreated patients with chronic lymphocytic leukemia (CLL) and since has become standard front-line treatment for this disease. The effect of FCR *vs.* FC in terms of OR rate does not introduce a benefit in patients with mutated IgVH and standard risk FISH, suggesting that biological risk stratification may be necessary to determine the optimal first-line treatment in individual patients. *Aims.* We conducted a multicentre retrospective study to evaluate the efficacy and toxicity of FC administered through the oral and intraveneous route and to assess the influence of immunoglobulin variable region heavy chain (IgVH) gene mutation status, interphase cytogenetic abnormalities, expression of ZAP70 and CD38 on the clinical outcome. *Methods.* We enroled 65 CLL patients treated front-line with oral fludarabine (30 mg/m^2) and oral cyclophosphamide (250 mg/m^2) (38 patients) or intravenous fludarabine (25 mg/m^2) and intravenous cyclophosphamide (250 mg/m^2), administered for three consecutive days every 4 weeks for six

cycles. *Results.* No statistical differences were noticed between the ywo route of administration in terms of overall response (OR), progression free survival (PFS), time to retreatment (TTR) and overall survival (OS). Among the 58 evaluable patients, 31 (53%) achieved a complete response and 18 (31%) a partial response. The median progression-free survival (PFS) was 35 months, median time to re-treatment (TTR) was 42 months and median overall survival (OS) was not reached after 45 months. Haematological toxicity consisted of neutropenia grade III/IV detected in 33 patients and resolved with G-CSF while three patients experienced autoimmune phenomena. Two patients died for infection complications and one due to cardiac death. A significantly lower overall response rate was noticed in the high risk cytogenetic abnormalities group; no statistical differences were detected for the IgVH, ZAP70 and CD38 categories. Response to treatment, high risk cytogenetic abnormalities and unmutated IgVH genes were independent predictors of TTR. Biological parameters were not significant predictors of PFS or OS. *Conclusion.* These results underline the importance of biological stratifications in the front-line treatment of CLL patients. We confirm that the combination of fludarabine and cyclophosphamide is an effective regimen, with mild toxicities that would be especially appropriate in patients with low risk biological parameters who represent in our experience about 30% of patients, in which the association of immunotherapy to FC would not be recommended because of haematological and extra haematological toxicity.

1290

SPONTANEOUS SECRETION OF SERUM INTERLEUKINS IN PATIENTS WITH B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA

T Shlyahtichenko, J Minchenko, I Dyagil

Research Centre of Radiation Medicine AMS of Ukraine, Kiev, Ukraine

Introduction. Variation of spontaneous interleukins (IL) production at the malignant diseases of lymphoid system has an important value. Tumor progression at chronic lymphocytic leukemia (CLL) mediately related to the activity of the organism immunocompetent cells. *Aims.* To determine of immunological component influence on a clinical course and therapy response in patients with B-cell CLL. *Methods.* Estimation of interleukins-1β,2,4, tumor necrosis factor α (TNF-α) and interferon-γ (IFN-γ) concentration was conducted for 32 patients with b-cell chronic lymphocytic leukemia (B-CLL) on the different stages of clinical course and treatment. All patients were divided on two groups: group I was composed by 17 patients with B-CLL who had low risk of therapy resistance progress, group II was formed by 15 patients with B-CLL who had high risk of therapy resistance progress. 28 healthy donors represented a control group. *Results.* We revealed the higher concentration of IL-1β in the blood serum in patients with B-CLL in comparison with a control group. It should be noted that in the group II level of IL-1β spontaneous secretion was the highest (38.84±5.9 pg/L). Suppression of IL-2 and IL-4 spontaneous secretion by immunocompetent cells is clearly marked during disease progression. Low level of these cytokines (IL-2 9.63 ±2.3 pg/L, IL-4 1.86±0.3 pg/L) was detected for patients with the high risk of therapy resistant progress. Concentration of TNF-α in the blood serum of the patients with B-CLL correlated with the clinical course and rate therapy resistance. Since TNF-α has the vectored cytotoxic effect on the cells of tumor clone and also immunomodulatory, anti-inflammatory effect, so the increase of this factor quantity testifies to activation of acute phase proteins and possibility of septic complications for patients in the stage of clinical progression. The considerable reduction of IFN-γ concentration in the serum was marked also for patients from both clinical groups, irrespective of clinical course. *Conclusions.* In the patients with B-CLL in stage of clinical progression and high risk of therapy resistance progress high level of IL-1β spontaneous secretion and low level of IL-2, IL-4 and IFN-γ in the blood serum testifies to the unfavorable clinical course. Study of serum interleukines allows to estimate influence of immunological component on the CLL clinical course and also to predict the development of septic complications for patients with CLL.

1291

PROGNOSTIC FACTORS IN CHRONIC LYMPHATIC LEUKAEMIA. WHAT DO THEY REPORT?

K Bauer, C Herbst, I Monsef, T Elter, M Hallek, A Engert

University Hospital of Cologne, Cologne, Germany

Introduction. Chronic lymphatic leukaemia (CLL) is one of the most common lymphatic malignancies. The disease is characterised by a highly variable clinical course and prognosis. Newly evaluated biological and cytogenetic markers may allow more precise prediction of the clinical course, however, it is often difficult to judge their impact for the prognosis of the disease from the available literature. The REMARK guidelines developed to improve and guide publication of tumour markers in prognostic studies in a standardized fashion were applied to the currently available CLL literature. *Methods.* We performed a systematic search in MEDLINE, EMBASE and Cochrane CENTRAL with the following inclusion criteria: CLL, at least one new prognostic factor (i.e. IgVH, ZAP70, p53, CD38, del 17p, del 13q, trisomie 12, del 6q or del 11q), one therapy for all patients (or randomised controlled trial), reporting of at least one clinical relevant outcome (e.g. overall survival, response) and a standardised time point of testing the factor (e.g. at diagnosis, at start of treatment). A standardised time point of testing the factor is important because cytogenetic factors may change due to the progress of disease or therapy. We designed a data extraction sheet based on the items of the REMARK guidelines to check the completeness of the eligible publications. *Results.* We screened 5585 abstracts and titles. From 1002 potentially interesting publications, 9 randomised and 5 non-randomised studies were eligible. Most of these articles reported the inclusion criteria of the study and the patient characteristics well (10 of 14 studies). The specimen characteristics and assay methods were not always reported, but 3 of 14 studies gave a complete or partial description of these issues. Survival curves of several factors were shown in 5 of 14 studies. Only 1 of 14 studies reported hazard ratios (HR) at least for one factor. *Summary/Conclusion.* The reporting of new prognostic factors for CLL is often incomplete. Therefore, the reports of these prospective studies do not provide sufficient evidence to judge (e.g. meta-analyse) the impact of new prognostic factors for patients with CLL with respect to overall survival, tumour control or response.

1292

EFFICACY OF BENDAMUSTINE IN COMBINATION WITH RITUXIMAB IN THE TREATMENT OF ADVANCED STAGE, HEAVILY PRE-TREATED CHRONIC LYMPHOCYTIC LEUKAEMIA

S Khan, P Thornton

Mater Misericordiae Hospital, Dublin, Ireland

Background. Bendamustine is a unique chemotherapeutic agent, which resembles anti-metabolites and purine analogues in structure. *in vitro* studies have shown that bendamustine activates DNA-damage stress responses and apoptosis, as well as mitotic catastrophe, a form of necrotic cell death distinct from apoptosis. Bendamustine shows in-vitro synergism with Rituximab, and this combination has been found to be highly effective *in vivo*, with response rates of up to ninety percent in patients with indolent lymphomas. Patients with relapsed and refractory chronic lymphocytic leukaemia have had response rates of 67% with this combination, in a large multi-centre trial. *Aims.* We aim to assess the efficacy and tolerability of Bendamustine and Rituximab in treatment of a small cohort of heavily pre-treated CLL patients, with advanced stage disease, and poor risk cytogenetics in over half the cases. *Methods.* A retrospective analysis was carried out on all patients who received Bendamustine in our institution to date. The medical records of the eligible patients were obtained. Data was gathered regarding age, sex, performance status, stage of CLL, prognostic markers, lines of previous chemotherapy, relapsed *vs.* refractory disease, the number of cycles of Bendamustine and Rituximab received to date, complications of treatment, response rates and duration of follow-up. *Results.* Eight patients were included in the analysis. Five patients have completed treatment, with three patients still receiving treatment. The average age of patients at the start of treatment was 66. All patients had stage C disease. One patient had 17p deletion, three patients had 11q23 deletion and one patient had trisomy 12. Most patients were heavily pre-treated. All had prior exposure to Rituximab, seven to fludarabine, seven to high dose methyprednisolone and two had recieved alemtuzumab. Four patients had relapsed disease, while four patients had refractory disease. Of the eight patients one achieved CR u, four had a partial response, one had stable disease and two had progressive disease, giving an overall response rate of 62.5%. All three non-responding patients had adverse cytogenetics, and had been refractory to previous chemotherapy. The treatment was well tolerated with the most frequent complication being infection, which occurred in five of eight patients, and treatment related cytopaenias in four out of eight patients. Three patients required inpatient admission for treatment of infections. *Conclusions.* In this cohort of heavily pre-treated patients, the overall response rate of 62.5% suggests that Bendamustine and Rituximab can be an effective treatment in relapsed, advanced stage CLL, including those with 11q23 dele-

tion. Treatment was well tolerated in older pateints with marrow failure. We did not find satisfactory response in our patient with a p53 deletion. Although our conclusions are limited by the relatively small numbers of patients available for inclusion in this analysis, our data suggests that larger studies to assess the impact of adverse risk cytogenetics on treatment response are needed.

Table.

Age	Sex	ECOG PS**	No. of Prior Treatments	Cytogenetics	No. of B+R*** cycles to date	Response*	Follow up Period (months)
86	M	1	4	Normal	4	CR (u)	7
64	M	0	8	11q23-	4	PD	2
76	M	1	3	13q14-	6	PR	1

CLINICAL AND IMMUNOLOGICAL CHARACTERISTIC OF ZAP-70POSSITIVE AND ZAP-70 NEGATIVE PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

E Wasik-Szczepanek, A Bojarska-Junak, D Koczkodaj, I Hus, I Hus, A Dmoszynska, M Wach, D Szczepanek, M Adamczyk-Cioch

Hematooncology, Lublin, Poland

The clinical course of B-cell chronic lymphocytic leukemia is far from being uniform. Some patients have indolent disease with long survival and not require treatment for many years but others have aggressive form of the leukaemia and progress quickly from the initial diagnosis to death within a short time. Several clinical and biological markers each can segregate patients into subgroups with different rates of disease progression. Interest in ZAP-70 has grown since it has been shown, that it is expressed in a subset of cases of chronic lymphocytic leukemia and is associated with aggressive form of disease. We performed analysis of 203 untreated patients with CLL presenting typical morphology and immunophenotype. The mediane age at diagnosis of the patients who participated in our study was 67 years (range 34-86 years). The distribution of patients with Rai stage eg. low-risk (stage 0), intermediate-risk (stage 1 and 2) or high-risk (stage 3 and 4) was 26.6%, 54.19% 19.21% respectively. Patients we segregated by CLL-cell expression of ZAP-70 into two group: ZAP-70 possitive and ZAP-70 negative. Sample analysis included CD38 and ZAP-70 stainings, fluorescence *in situ* hybridization (FISH) for chromosomes 11, 12, 13 and 17, level of bFGF, VEGF and TNF. Patient's samples were obtained after informed consent. In ZAP-70 possitive patients we observed statistically significant increase serum level of TNF, LDH; TTM, percentage of $CD38^+$ cells in peripheral blood and bone marrow and cells with 11q23 deletion. We also found statistically significant short time interval from diagnosis to initial therapy, overall survival, low level of PLT and percentage of $CD4^+$ cells. In all group of patients (ZAP-70 possitive and negative) negative correlation overall survival and time to treatment with percentage of ZAP-70 possitive cells was observed. The percentage of ZAP-70 possitive cell was also statistically significant higher in patients which needed treatment at time of diagnosis. Compare to $ZAP\text{-}70^+/CD38^+$ group, $ZAP\text{-}70^-/CD38^-$ patients showed longer overall survival.

1294

FLUDARABINE, CYCLOPHOSPHAMIDE AND RITUXIMAB IN FIRST-LINE TREATMENT OF PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA (CLL): RETROSPECTIVE STUDY

H Ionita,[1] I Ionita,[1] M Cheveresan,[2] M Ionita,[1] D Calamar,[1] CO Ionita,[1] D Oros[1]

[1]UMF Victor Babes, Timisoara, Romania; [2]County Clinical Hospital, Timisoara, Romania

Background. Combination of fludarabine, cyclophosphamide and rituximab (FCR) is currently considered the first-line treatment of choice in physically fit patients (pts) with chronic lymphocytic leukemia (CLL). There is a very limited amount of data regarding the use of FCR in real practice. *Aims.* To perform a retrospective efficacy and safety analysis of FCR regimen used as routine first-line treatment in CLL. *Methods.* We treated 37 pts with active CLL (63% males, median age 58 years [range 37-75]) by FCR regimen as first-line therapy. Diagnosis of CLL, indication for treatment and assessment of response to therapy followed NCI-WG criteria. Patients received standard doses of Fludarabine (25 mg/m^2/i.v. or 40 mg/m^2 p.o d 1-3) and cyclophosphamide (250 mg/m^2 i.v. or p.o. d1-3). Rituximab was administrated i.v. on day 1 of each cycle at the dose of 375 mg/m^2 in all cycles (n=87) or 500 mg/m^2 from 2nd cycle (n=20). Treatment was repeated every 4 weeks. Antimicrobial prophylaxis and growth factors were routinely used. Low/intermediate/high risk according to modified Rai staging was present in 2/62/36%. *Results.* At the time of analysis, the median observation time was 18,3 months (mo).Median number of FCR cycles was 5. The overall response rate/complete response rates were 89/37. Median PFS was 26 mo; median overall survival (OS) was not reached. Grade III/IV neutropenia occurred in 28,17% of cycles and thrombocytopenia grade III/IV in 5,3% of cycles. Serious infections occurred in 3% of cycles. G-CSF was administrated in 54% and recombinant erythropoietin in 23% of pts. *Conclusions.* Treatment of CLL patients in first line with Fludarabine, cyclophosphamide and rituximab resulted in high number of overall and complete responses despite unfavourable prognostic factors present in the majority of pts. Toxicity was acceptable and manageable.

1295

DASATINIB INDUCES COMPLETE REMISSION OF CHRONIC LYMPHOCYTIC LEUKEMIA IN A PATIENT WITH PRIMARY CNS MANIFESTATION

G Ruβwurm, A Giagounidis, M Heinsch, R Erlemann, R Radkowski, C Aul

St. Johannes Hospital, Duisburg, Germany

Background. Treatment options for central nervous system lymphoma are very limited since the blood-brain barrier prevents free drug penetration and is even less permeable to antibodies. Chronic lymphocytic leukemia (CLL) rarely causes involvement of the central nervous system (CNS). *Case.* We were presented with a case of a 68 year old male who was initially treated for multiple sclerosis without signs of clinical improvement. Further testing revealed a CLL with primary manifestation in the CNS. After initial therapy with MTX/Ifosfamide the patient relapsed and was subsequently treated with high dose Cytosinarabinoside/Mitoxantrone/MTX. Upon disease progression we were able to induce a long lasting complete remission (8 months+) with Dasatinib. *Conclusion.* Among the substances primarily used for treatment of CLL only Cyclophosfamide/Ifosfamide are known to cross the blood brain barrier. Deprived of these options we chose to use Dasatinib as a salvage therapy. Dasatinib is a widely acting tyrosine kinase inhibitor that has recently been demonstrated to be effective in CLL and was shown to pass the blood brain barrier in an animal model. This highly unusual case demonstrates activity of Dasatinib monotherapy in primary CNS-CLL.

1296

STUDY CONCERNING THE ASSOCIATION BETWEEN CHRONIC LYMPHOCYTIC LEUKEMIA AND DYSLIPIDEMIA

RG Mihaila,[1] G Cocisiu,[2] L Bera,[1] A Catana,[2] O Flucus,[2] E Rezi,[2] RG Mihaila,[3] D Ciuta[1]

[1]Lucian Blaga University of Sibiu, Sibiu, Romania; [2]Emergency County Clinical Hospital, Sibiu, Romania; [3]Public Health Direction, Sibiu, Romania

Background. It is known that the metabolic pathways, namely cholesterol synthesis and adipogenesis are enhanced by CD5 and CD5

expression which is a feature of chronic lymphocytic leukemia. In addition, in previous studies, we have found that there is an association between the metabolic syndrome (which often includes hypertriglyceridemia) and neoplasms. *Aims.* We aimed to study whether the patients with chronic lymphocytic leukemia associate more frequently hypercholesterolemia and hypertriglyceridemia compared to a control group. *Methods.* We have conducted a cross-sectional study that included all patients with chronic lymphocytic leukemia who existed in the records of the Hematology Department of the Emergency County Clinical Hospital from Sibiu in November 2009 and who agreed to participate (group A) and a group of volunteers from the medical staff of the clinics from the same hospital (without neoplasic pathology) (group B). In all subjects a sample from the peripheral blood was taken for determination of hemoleucogram, cholesterol, triglycerides and glucose. The 2 groups were compared and the results were statistically analyzed. *Results.* Group A included 43 patients with a mean age of 69.16±7.74 years; the gender distribution was: 16 women and 27 men. Group B was composed of 34 subjects with the mean age of 32.64±9.88 years; the gender distribution was: 26 women and 8 men. The mean cholesterol level in group A was 203.33±47.76 mg/dL, and in group B - 183.15±40.15 mg/dL (P=0.048); the triglycerides level was in average, in group A 180.73±106 mg/dL and in group B - 81.09±53.33 mg/dL (P<0.00001), the average blood glucose level was in group A 108.12±27.47 mg/dL, and in group B - 92.74±26.36 mg/dL (P=0.015). The cholesterol levels did not correlate with age (P>0.05) or gender (P>0.05), so the difference between the two groups is statistically significant. The triglycerides levels correlated with age (P<0.005) and gender (P=0.016); after adjusting the results by age and gender differences between the two groups remain also statistically significant. Because the glucose level is correlated with age (P<0.05) and gender (P=0.04), the difference between the two groups is not statistically significant. *Conclusions.* Hypertriglyceridemia presented at the patients with chronic lymphocytic leukemia from our study argues for a possible association between the metabolic syndrome and chronic lymphoproliferative syndromes. Hypercholesterolemia presented at the patients with chronic lymphocytic leukemia may have implications in the multiple drug resistance, which is worth studying.

1297

THE EFFICACY OF FLUDARABINE AND CYCLOPHOSPHAMIDE COMBINATION IN UNTREATED VS PRETREATED PATIENTS WITH B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA

V Miloševic, M Bogunovic, S Jankovic, D Antic, D Tomin, M Todorovic, N Kraguljac Kurtovic, M Perunicic Jovanovic, A Bogdanovic, B Mihaljevic, M Gotic

Clinical Center Serbia, Belgrade, Serbia

Background. B-cell chronic lymphocytic leukemia (B-CLL) is a heterogenous disease with an extremely variable course and chemotherapy is ussually not indicated in early and stable disease. Treatment is needed if the progressive form of leukemia started. The combination of fludarabine and cyclophosphamide (FC) is an effective regimen for patients (pts) with B-CLL. *Aim.* The purpose of this study was to analyse the efficacy of fludarabine and cyclophosphamide combination as a first, second and third-line therapy in pts with B-CLL.Treatment outcome was correlated with clinical and biological variables. Matherial and methods. This study included 120 pts with B-CLL who were treated with FC combination between January 2004 and December 2008 in the Institute of Hematology CCS, Belgrade. The diagnosis of CLL was confirmed in all pts using immunophenotyping of pheripheral blood cells. Score 5 (Matutes E) was present in 90% of pts and Score 4 in 10% of pts. Median age was 60 years (range, 30-76) with 78 males and 42 females. 30 pts (25%) were classified as Binet Stage A, 64 pts (53%) as Binet Stage B and 26 pts (22%) as Binet C. Pts received six cycles of fludarabine 25 mg/m^2 i.v x 3 days and cyclophosphamide 250 mg/m^{2}x3 days, every 28 days. FC combination was administrated in 63 pts (52%) as a first line, in 38 pts (32%) as a second- line and in 19 pts (16%) as a third-line therapy. *Results.* The overall response rate (ORR) was 83%. Complete remission (CR) was achieved in 51 pts (42%), very good partial remission in (vGPR) in 15 pts (12%) and partial remission (PR) in 34 pts (28%). The comparasion of response in untreated and pretreated pts shown that CR was achieved in 34 pts (67%) when FC combination was used as first-line therapy, in 11 pts (22%) as a second and in 6 pts (12%) as a third-line therapy. The median duration of remission was 22 months (range, 20-66). The median survival was 52 months (range, 8-120). Fiftyseven pts (58%) who achieved remission had CD 38 expression>30% and shorter overall survival. Lymphocyte doubling time (LyDT) <12 months was present in 57% pts and this was not statistically significant. FC combination caused additional hematological toxicity. Prolonged thrombocytopenia (28% of pts), neutropenia (28% of pts) and anaemia (40% of pts) were observed especially after multiple courses of therapy and in heavily pretreated pts. *Conclusion.* Treatment with fludarabine and cyclophosphamide was associated with a significantly higher CR and ORR in pts with previously untreated CLL and was not associated with increase in episodes of infections.

1298

THE COMBINATION OF LOW DOSES FLUDARABINE & CYCLOPHOSPHAMIDE AS FRONTLINE TREATMENT FOR ELDERLY PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA.

I Pierri, F Olcese, A Cagnetta, M Bergamaschi, M Gobbi

University of Genoa, Genova, Italy

Background. Fludarabine (Flu) was the first purine analogue with an oral formulation available for clinical use . Some recent clinical trials, showed that oral-flu was effective and well tolerated, suggesting its convenience in the outpatient setting. It has been previously demonstrated that a combination of reduced doses of flu and cyclophosphamide (Cy), given orally in elderly patients with indolent non Hodgikin lynphoma, showed good efficacy and was simple to administer to patients unfit for more aggressive treatments. *Methods.* Between April 2005 and June 2009, 8 elderly untreated patients (mean age 75, range 68-81) with treatment requiring "B-CLL"(according to ESMO guidelines working group) underwent therapy with low dose of oral fludarabine (25 mg/mq/die) and cyclophosphamide (150 mg/mq/die) both from days 1 to 3 in two dailly administrations. Treatment schedule consisted of 6 cycles repeated at 4 weeks intervals. Patients received antibiotic prophylaxis with trimethoprim/sulphamethoxazole (160/800 mg twice a day, 2 times a week) and allopurinole (300 mg once a day from days 0 to 4) (range 2-6). Performance status was WHO ≤1 in all patients. Comorbidities, which included diabetes, hypertension and chronic heart desease, were present in 7 patients. Biological prognostic factors were assessed at diagnosis and before treatment. ZAP70 and CD38 were independently expressed in 5 and 6 respectively cases. The IgVh sequences were unmutated in 4 patients. Beta2microglobuline mean was 3.2 mg/dL (range 1.6-4.7). The mean of cycles performed was 4 with range 2-6. No patients reduced dose and number of cycle because of haematologic and extra-haematologic toxicities. Specifically 4/8 patients experienced anemia (grade II) but only 2 required epoetin support. Nausea and diarrhea (grade I) were observed in 2 patients. Definition of response was reviewed according to the updated IWCLL-NCI 2008 international general practice criteria. 6 of 8 (OR rate 75%) obtained a response, with 3 molecular complete (CR) and 3 partial response (PR). 3 patients with CR were: CD38$^+$/ZAP70$^+$/IgVH mutated, CD38$^+$/ZAP70$^+$/IgVH unmutated, CD38$^-$/ZAP70$^-$/IgVH mutated. All responder patients are alive and manteined response after mean follow-up of 24 months (range 13-44). *Conclusions.* Based on our studies results, we believe that this regimen could be effective and well tolerated for elderly patients with untreated CLL unfit for more aggressive treatments. In fact although some patients relapsed or progress, most of them do not experience severe toxic side effects or required hospitalisations, obtaining satisfactory quality of life and survival

1299

EFFICACY OF RITUXIMAB-THERAPY IN RELAPSED OR REFRACTORY HAIRY CELL LEUKEMIA

L Cheveresan,[1] M Cheveresan,[2] H Ionta,[1] D Nicola,[2] D Calamar[1]

[1]*University of Medicine and Pharmacy Victor Babes Timisoara, Timisoara, Romania;* [2]*City Hospital, Timisoara, Romania*

Hairy cell leukemia (HCL) is an indolent B-cell neoplasm, strongly expressing the pan B-cell antigen CD20. Alltough high response rates are achieved following 2-chlorodeoxyadenosine (CDA), with longer follow-up relapses are common. We investigated efficacy of Rituximab in 7 patients (pts) (5 males and 2 females) with relapsed or primary refractory HCL after 2-CDA therapy. Rituximab was administered intravenously at a dose of 375 mg/m^2 weekly for 8 weeks. Overall response rate was 75.7%, 3 pts (42.8%) achieved CR, 3 pts (42.8%) achieved a partial response and 1 pts failed to respond. Of the 6 responders followed for a median of 34 months (11-59+) 4 pts (57%) relapsed after 10,17,23 and 36 months. Toxicity was minimal, with no infectious episodes observed. Due to its minimal toxicity and significant efficacy Rituximab is an indication for relapsed or refractory HCL patients after 2-CDA therapy.

1300

IMATINIB (IMA) PLASMA CONCENTRATION (PC) MONITORING AND ITS CORRELATION WITH TREATMENT RESPONSE IN CHRONIC MYELOGENOUS LEUKEMIA (CML): A SINGLE CENTRE EXPERIENCE

Z Zdenek,[1] L Malaskova,[1] M Vyskocilova,[1] F Razga,[1] L Buresova,[2] D Zackova,[3] J Mayer[1]

[1]Masaryk University and University Hospital Brno, Brno, Czech Republic; [2]Masaryk University, Brno, Czech Republic; [3]Dept. of Internal Medicine and Hemato-Oncology, Univ. Hospital and Masaryk Univ., Brno, Czech Republic

Background. Correlation between the probability of therapeutic response in patients with CML treated with IMA and IMA PC was recently described, suggesting that IMA trough PC levels should be above 1.04 ng/mL. However data from large group of "real-life" CML patients (out of clinical trials), where IMA PC monitoring is performed, are still lacking. *Aims.* To evaluate correlation of IMA trough PC with daily IMA dose, treatment response and influence of alfa1-acid glycoprotein (AGP) on IMA PC in "real-life" group of CML pts. *Methods.* HPLC was used for IMA trough PC monitoring. Pts. charts were assessed for evaluation of treatment response and AGP concentration results. *Results.* Between 9/2008 and 1/2010 IMA PC have been detected in 397 samples from 108 pts. (median: 3 samples/ pt., range: 1-22). Median IMA daily dose at the time of monitoring was 400 mg (range: 150-800 mg). Median duration of IMA treatment at the time of sampling was 28 months (range: 0.5-99). Median IMA PC for pts. with 24 h. IMA dosing was 830 ng/mL (n=83 pts.) and for 12 h. dosing 1450 ng/mL (n=14 pts.). Mean inter-patient and intra-patient variability of IMA PC was 31% and 17%. There was a clear correlation between daily dose of IMA and IMA PC (Figure). IMA PC below suggested level 1.0 ng/mL was measured in 57% of samples and this percentage decreased with increasing daily dose of IMA (65% in 300 mg/day group, 60% in 400 mg/day, 10% in 600 mg/day and 0% in 800 mg/day group). 67 pts. with IMA as first line therapy were further analyzed regarding correlation of their IMA PC and achieved cytogenetic response. Medians of all samples obtained from single pt. were used for analysis. Any significant difference was found between medians of IMA PC in pts. with and without CCyR - 0.938 ng/mL *vs.* 0.836 (P=0.560, Mann-Whitney test). Finally our analysis found statistically significant correlation between IMA PC and AGP plasma concentration at the time of sampling - for different ranges of AGP concentrations the medians of IMA PC were as follows: AGP < 0.5 mg/mL - IMA PC 0.780 ng/mL, AGP 0.5 to 1.0 mg/mL - IMA PC 0.940 ng/mL, AGP 1.0 to 1.5 mg/mL - IMA PC 1.10 ng/mL, AGP > 1.5 mg/mL - IMA PC 1.24 ng/mL (P<0.001) (Kruskal-Wallis ANOVA). *Summary/Conclusions.* Our analysis did not find any correlation between IMA PC and cytogenetic response in patients with CML treated with IMA as first line therapy. On the contrary, our analysis showed that the resulting PC IMA strongly depends on the current administered dose of IMA and the current AGP concentrations at the time of sampling.

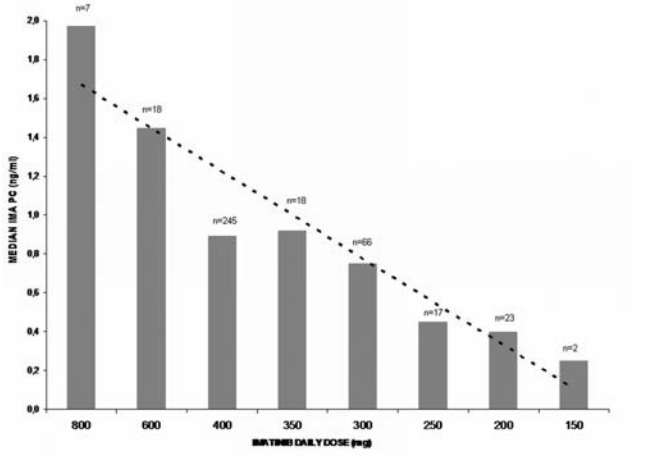

Figure. Correlation of IMA PC and daily dose of IMA.

1301

A NOVEL MECHANISM OF NILOTINIB-INDUCED APOPTOSIS; BIOACTIVE SPHINGOLIPIDS

Y Baran,[1] A Camgoz,[2] E Gencer,[2] A Ural,[3] F Avcu[3]

[1]Izmir Institute of Technology, Faculty of Science, Dept.of Mol.Biol. & Genetics, Urla Izmir, Turkey; [2]Izmir Institute of Technology, Faculty of Science,Dept.of Mol.Biol. & Genetics, Izmir, Turkey; [3]Gulhane Medical School, Faculty of Medicine, Department of Hematology, Ankara, Turkey

Background. Chronic myeloid leukemia (CML) is a hematological malignancy resulting from the reciprocal translocation of chromosomes 9 and 22 that generates BCR/ABL oncogene. Nilotinib is a rationally designed, specific BCR/ABL tyrosine kinase inhibitor. Ceramide is a novel regulator of cell growth and proliferation, differentiation, senescence, cell cycle, and also acts as a strong apoptotic molecule while its conversion to antiapoptotoic glucosyleceramide (GC) and sphingosine-1-phosphate (S1P) by glucosyle ceramde synthase (GCS) and sphingosine kinase-1 (SK-1) enzymes result in more aggressive and resistant cancers. *Aim.* In this study, we examined the roles of ceramide generating and ceramide clearence genes in nilotinib induced apoptosis and possibility of increasing the sensitivity of BCR/ABL positive K562 and Meg-01 cells to nilotinib through targeting ceramide metabolism. *Methods.* Expression levels of ceramide synthase (LASS1-6) genes, SK-1, and GCS genes in response to increasing concentrations of nilotinib in K562 and Meg-01 cells were examined by RT-PCR. The antiproliferative effects of nilotinib, ceramide analog, GCS and SK-1 inhibitors were conducted by XTT cell proliferation assay. The changes in caspase-3 enzyme activity and loss of mitochondrial membrane potential (MMP) were measured by caspase-3 colorimetric assay and JC-1 MMP detection kit, respectively. *Results.* Importantly, RT-PCR results demonstrated that there were significant decreases in expression levels of SK-1 and increases in expression levels of Lass1, Lass2, Lass4, Lass5, and Lass6 ceramide synthase genes in response to nilotinib in a dose dependent manner as compared to untreated controls in both K562 and Meg-01 cells. On the other hand, application of ceramide analogs/mimetics and inhibitors of GCS and SK-1 enzymes inhibited cell proliferation and induced apoptosis in a dose dependent manner. Our results also revealed that combination of even very low doses of nilotinib with these bioactive sphingolipids targeting chemicals resulted in synergistic apoptosis in both cells, as compared to any agent alone. The highest apoptotic rates were observed in combination of nilotinib with ceramide analog, C8:ceramide. *Summary/Conclusion.* It was shown for the first time by this study that nilotinib triggers apoptosis by regulating intracellular concentrations of bioactive sphingolipids in addition to inhibition of BCR/ABL in K562 and Meg-01 CML cells. Increasing endogenous ceramide in addition to inhibition of BCR/ABL could be an effective treatment method to regulate CML cell growth.

This study was supported by The Scientific and Technological Council of Turkey.

NILOTINIB SYNERGIZES WITH DASATINIB IN PRODUCING GROWTH-INHIBITION IN CML CELLS, INCLUDING BCR/ABL T315I+ CELLS

K Gleixner, K Schuch, W Pickl, C Sillaber, P Valent

Medical University of Vienna, Vienna, Austria

In most patients with chronic myeloid leukemia (CML), complete cytogenetic remission can be achieved with the BCR/ABL tyrosine kinase inhibitor (TKI) imatinib. However, unfortunately, not all CML patients are long-term responders. Acquired resistance against imatinib is often caused by BCR/ABL mutations. In most of these patients, a second generation TKI is prescribed. However, the T315I mutant of BCR/ABL introduces resistance against most TKI, including nilotinib and dasatinib. One approach to overcome drug resistance in BCR/ABL T315I$^+$ CML cells may be to apply drug combinations. Recent data suggest that the mechanisms through which dasatinib and nilotinib act on BCR/ABL differ from each other and that both drugs may elicit mild residual activity on most BCR/ABL mutants including T315I. Moreover, it has been described that both drugs act on multiple additional targets in CML cells. We here show that dasatinib and nilotinib cooperate with each other in producing growth inhibition in BCR/ABL T315I$^+$ CML cells. Strong cooperative or even synergistic effects were observed in primary T315I$^+$ CML cells in 3 of 3 patients tested (chronic phase, n=1; blast phase n=2) as well as in Ba/F3 cells exhibiting BCR/ABL T315I. Synergism was demonstrable at pharmacologic drug concentrations (<1 μM) and was also seen in freshly diagnosed patients

with CML (wt BCR/ABL+ leukemic cells) and in all other BCR/ABL mutants tested, suggesting that the drug combination acts suppressive on most if not all CML subclones. Synergistic effects of dasatinib and nilotinib may be explained by direct effects on BCR/ABL including residual effects on BCR/ABL T315I, and additional drug targets in CML cells. Notably, the target kinase spectrum for Nilotinib in primary CML cells was found to differ significantly from the target kinase spectrum of Dasatinib. Together, our data show that two second generation BCR/ABL TKI, Dasatinib and Nilotinib, produce synergistic drug effects on TKI-resistant CML cells including leukemic cells exhibiting BCR/ABL T315I. These drug-combination effects occur at drug concentrations that can be reached *in vivo* and may thus represent an interesting new pharmacologic concept to treat patients with TKI-resistant CML.

1303

CORRELATION BETWEEN PRAME, WT1 AND BCR-ABL EXPRESSION AND RESPONSE TO THE THERAPY AT CML

E Aksenova, A Krutov, A Misiurin, I Soldatova, L Kesaeva, A Turkina, N Khoroshko

Research Centre for Hematology, Moscow, Russian Federation

Background. It was shown that WT1 and Prame genes are expressed at CML. The data about correlation between WT1 and BCR-ABL expression and the role of WT1 in relapse prediction are contradictory. It is suggested that Prame expression increases during disease progression of CML, correlation was shown between Prame expression and response to nilotinib therapy. The question of interaction between Prame, WT1 and BCR-ABL during disease development and degree of significance WT1 and Prame as markers of response to the therapy remains open. Aim. To analyze Prame, WT1 and BCR-ABL expression, the correlation of expression with the response to the therapy CML patients at different timepoints. *Methods.* 92 patients were included: 26 primary patients, 36 at the point of 12 month and 30 at the point of 18 month of imatinib therapy. RQ-PCR testing was used for genes expression definition. The patients were divided into 4 group depending of the response to the therapy during the next 12-24 month from this timepoint: 1) resistant/bad response; 2) secondary resistant; 3) suboptimal response; 4) good response. In each timepoint the patients were divided also into 2 groups: patients having achieved major molecular response (MMR) on imatinib therapy and not achieved. Spearman's rank correlation and Pearson's chi-square test for contingency tables was used for statistical analysis. *Results.*There was not significant dependence between response to the therapy and Prame, WT1 and BCR-ABL expression, and dependence of Prame and WT1 expression with BCR-ABL expression in primary patients, but there was strict correlation between Prame and WT1 expression (Rs_corr=0,44, P<0,05). At the point 12 month of therapy there was significant dependence between BCR-ABL and Prame expression (Rs_corr=0,36, P<0,05), BCR-ABL and WT1 expression (Rs_corr=0,52, P<0,001), between BCR-ABL expression and response (Rs_corr=0,84, P<0,001), Prame expression and response (Rs_corr=0,34, P<0,05), WT1 expression and response (Rs_corr=0,54, P<0,001). The correlation between level of WT1 expression and achievement of MMR was also significant (P<0,05), such correlation was not proved for Prame expression. At the point 18 month of therapy there was significant dependence between BCR-ABL and WT1 expression (Rs_corr=0,66, P<0,001), between BCR-ABL expression and response (Rs_corr=0,78, P<0,001), WT1 expression and response (Rs_corr=0,39, P<0,05), correlation between level of WT1 expression and achievement of MMR (P<0,05). Significant correlation was not found between BCR-ABL and Prame expression, Prame expression and response, Prame expression and achievement of MMR. *Conclusion.*The dependence between expression of Prame, WT1, BCR-ABL and between expression of these genes and response to the therapy is changing during CML development and treatment. Correlation between BCR-ABL and WT1 expression, WT1 expression and response to the therapy is more strict and renewed than the same markers for Prame.

1304

DOWNREGULATION OF ANTIAPOPTOTIC GENES INDUCED BY IMATINIB/MELPHALAN COMBINATION INCREASES KILLING OF CHRONIC MYELOID LEUKEMIA CELLS

C Giallongo,[1] P La Cava,[1] D Tibullo,[1] N Parrinello,[1] I Barbagallo,[2] A Branca,[1] P Spina,[1] E Spina,[1] O Di Bartolo,[1] V Del Fabro,[1] A Romano,[1] C C Conticello,[3] G Palumbo,[1] F Di Raimondo[1]

Imatinib (IM) has become the drug of choice for first line therapy in the treatment of chronic myeloid leukemia (CML). However, a relatively small percentage of CML patients develop resistance to IM and there is a need for alternative strategies. In this perspective, we have already demonstrated that a sequential exposure of K562 cells to IM followed by Melphalan (MEL), induces a greater cell death than each drug alone. This synergistic activity was also confirmed in primary cells from bone marrow of 6 CML patients at diagnosis. The IM/MEL combination was the most effective treatment in reducing the total number of CFU-GM and BFU-E colonies (P<0.05 *vs.* IM alone) and especially the number of BCR/ABL copies (P<0.01 *vs.* IM). (Giallongo C. *et al.,* submitted). In order to evaluate the possible mechanism of action and the superior efficacy of the combination, we analyzed several apoptotic pathways on K562 cells by TaqMan Low Density Arrays. Treatment with MEL alone induced expression of FASL, FAS and FADD (respectively of 1000, 400 and 40 fold), that leads to caspase-8 activation. APAF and PYCARD (20 and 75 fold) observed over-expression could also activate caspase-9. Furthermore, MEL-induced activation of mitochondrial apoptotic pathway by BAD, BAK1 and BAX (7×10^6, 40 and 40 fold) was counterbalanced by BCL2, BCL-xL and BIRC8 (80, 12 and 50 fold) expression. In addition, MEL activated BIRC1 (1500 fold), BIRC3 (3000 fold) and, especially, BIRC7 (>109 fold). MEL alone also induces over-expression of genes involved in NFkB activity such as NFKB1, NFKB2, IKBKE and RELB (7, 50, 150 and 800 fold). In the TNF superfamily system MEL both up-regulated an apoptotic pathway, TRAIL (1600 fold) and its receptors DR4 and DR5 (30 and 25 fold) with consequent activation of caspase-8, and an anti-apoptotic one, TNFβ gene (800 fold) and its receptor TNFR2 (20 fold), leading to activation of NFKB. IM alone is able to down-regulate all above mentioned anti-apoptotic genes. Unexpectedly, IM/MEL combination did not dramatically increase expression of apoptotic genes, rather, the association silenced the anti-apoptotic signaling induced by MEL alone. In conclusion, the greater cytotoxic effect observed with IM/MEL combination is probably due to a shift towards the pro-apoptotic gene expression profile. In fact, MEL alone induces both pro- and anti-apoptotic genes while IM alone is able to down-regulate anti-apoptotic pathways. IM/MEL association keeps the ability to cause apoptosis and switches off the anti-apoptotic defensive signal induced by MEL alone.

THE RATE OF BCR-ABL KINASE DOMAIN MUTATIONS IN CML PATIENTS RESISTANT TO TYROSINE KINASE INHIBITOR TREATMENT IN SOUTH AFRICA, UNUSUAL FINDINGS

D Schnugh,[1] W Pascale[2]

[1]National Health Laboratory Service, Johannesburg, South Africa; [2]University of the Witwatersrand and the National Health Laboratory Service, Johannesburg, South Africa

Background. Imatinib Mesylate, the standard first line tyrosine kinase inhibitor treatment, has revolutionized the management of chronic myeloid leukemia (CML) patients. Nonetheless a minority of patients either fail to respond or develop resistance to treatment. BCR-ABL kinase domain and p-loop mutations are the best understood cause of resistance. *Aims.* The aim of this study was to ascertain the frequencies and types of mutations occurring in South African CML patients treated with Imatinib. *Methods.* The levels of BCR/ABL were monitored via quantitative real time PCR (RQ-PCR) in CML patients receiving TKI therapy from nine centers across South Africa. The BCR-ABL gene was sequenced in 147 patients, on request of the treating physician. A semi-nested reverse transcription polymerase chain reaction (RT-PCR) was performed to selectively amplify exons 4-7 of the ABL kinase domain that was subsequently sequenced using direct sequencing. To analyze these results, patients were divided into three groups based on their response to TKI treatment. First, responders who became resistant to treatment (increased

levels of BCR-ABL above the 3 log level in two consecutive assays), Second patients who failed to respond and had primary resistance (failure to obtain a CCR at 18 months) and third patients for whom we did not have further information on their response to therapy. *Results.* Among forty patients with acquired resistance, 42.9% showed a BCR-ABL gene mutation. The most common mutations were M244V (17.4%), E255K (13%) and Y253H (13%), with nine different mutations accounting for the remaining 56.6%. Forty one patients failed to respond to therapy, and the mutation rate in this group was 29.3% with the T315I (28.6%) being the most frequently observed. No detailed information was available for 63 TKI resistant CML patients. In this group, the mutation rate was 28.6% with the T315I (20%) and E255K (20%) being the most frequent mutations, followed by M244V (15%). Overall, among the 147 patients, the mutation rate was 36.77%. The T315I (17.5%), M244V (12.3%) and E255K (12.3) were the most frequently detected mutations, with 22 other mutations being detected. *Summary/Conclusions.* While the mutation rate in patients who acquired resistance to Imatinib was comparable to those observed in other studies, mutations in the BCR-ABL gene only accounted for 29% of patients with primary resistance. This finding warrant further investigations as to other reasons for primary resistance which are likely to be multi-factorial. Overall, the most frequent mutation was the T315I (17.5%). Our results have set a base line for the types of mutations which may be expected in South African CML patients. Fifty two percent of the mutations detected resulted in full resistance to TKI therapy, which poses a large problem for the future management of patients in an already over burdened public health system.

COMPARATIVE ANALYSIS OF DIFFERENTIAL GENES EXPRESSION OF CHRONIC MYELOID LEUKEMIA BETWEEN CHRONIC AND BLAST PHASE WITH CDNA MICROARRAY

S Gao,[1] Y Tan,[1] X Zhu,[2] C Yao,[1] W Li,[1] G Wang[1]

[1]First Hospital of Jilin University, Changchun, China; [2]College of Basic Medical Science of Jilin University, Changchun, China

Background. Chronic myeloid leukemia (CML) is characterized by the clonal expansion of hematopoietic stem cells (HSCs). The natural history of CML progresses from a relatively benign chronic phase into a fatal blast crisis, which is incurable by chemotherapy. Despite recent success in the treatment of early-stage disease (chronic phase, CP), blastic phase (BP) of chronic myeloid leukemia remains a therapeutic challenge. The better understanding of the molecular mechanisms underlying disease progression constitutes the most important problem in predicting and detecting patients involved into advanced disease and in alternating therapeutic strategies. *Aims.* The aim of this study was to explore the mechanism underlying the acute transformation of CML by comparing the differential genes expression in CP and BP. *Methods.* Analysis of gene expression profiles of 4 pairs of Chinese chronic myeloid leukemia patients (4 CP patients *vs.* 4 BP patients, Appropriate consent for bone marrow samples from each individual was obtained) was carried out by using cDNA microarray represented with 4096 genes. *Results.* 74 differential expression genes were identified in at least 3 pairs of CML patients, in which 52 genes were down-regulated and 22 genes were up -regulated in BP patients. Only 5 genes (FCN1_TPX1_ANXA3_BTG2_HCLS1) which down-regulated in BP were identified consistently in all 4 pairs of patients. The expression of selected genes was validated by semi-quantitative RT-PCR. The functions of the differential genes were involved in cell structure/mobility, signal transduction, gene transcription, related immunity, metabolism, cell cycle, protein translation/synthesis and other unknown functions. *Conclusions.* Our results showed that significant difference of gene expression profile existed between chronic and blastic phases of CML. The different genes were concerned with cell signal transduction cell cycle regulation, cell differentiation and related immunity, and might be the critical genes for chronic myeloid leukemia blast crisis transformation.

1307

TRIPLE POINT MUTATIONS, WITH TWO WITHIN THE SAME CODON IN A CML PATIENT RESISTANT TO TYROSINE KINASE INHIBITOR THERAPY

A Walton,[1] D Schnugh,[1] M Patel,[2] P Willem[1]

[1]National Health Laboratory Service, Johannesburg, South Africa; [2]Clinical Haematology, Department of Medicine, Chris Hani Baragwanath Hospital, Johannesburg, South Africa

Background. In chronic myeloid leukemia (CML) patients, resistance to the tyrosine kinase inhibitor (TKI), Imatinib, is often due to point mutations in the ABL kinase domain of the BCR-ABL gene. From studies performed to date, only a small number of patients with multiple point mutations have been identified. As the position and nature of these mutations can influence drug resistance, revised patient-specific treatment strategies, including combination TKI therapy may prove beneficial in treating patients with multiple mutations. We report on the occurrence of multiple mutations in Imatinib-resistant CML patients and describe findings on a patient with three mutations in the ABL kinase domain. Although previous studies have detected three or more mutations, this is the first study to report on two mutations occurring at different nucleotides within the same codon, in addition to another third mutation. *Aims.* To determine the frequency of multiple point mutations in the ABL kinase domain in a cohort of South African Imatinib-resistant CML patients and to characterize the type and location of mutations in a patient with a triple mutation. This will emphasize the need to optimize treatment strategies in patients with multiple mutations. *Methods.* Samples from 155 Imatinib-resistant CML patients were analyzed by direct sequencing of the ABL kinase domain. Resistance was suspected on the basis of two consecutive increased levels of BCR-ABL using real-time quantitative polymerase chain reaction results or failure to obtain a major cytogenetic response within 18 months. In the patient harboring the triple mutation, samples were analyzed at 40, 46, 49 and 55 months to determine the levels of BCR-ABL and to detect any kinase domain mutations. Drug efficacy for each mutation was determined from reported data. *Results.* Of the patients sequenced, 56 (36.1%) had detectable point mutations at 25 different residues. Seven of these 56 patients (12.5%) had double mutations and one patient (1.8 %) had three mutations. Despite dose escalation, the triple mutation patient showed no response to Imatinib. Mutational analysis forty months after diagnosis showed that two of these mutations (G to A and A to T) occurred at adjacent nucleotide positions within codon 255. This could result in the substitution of Glutamic acid with either a Methionine, Valine or Lysine. The third mutation substituted a Glutamine with a Histidine at codon 252 (Q252H). These three mutations were all previously reported to be fully resistant to Imatinib and partially sensitive to Dasatinib and Nilotinib. The patient then rapidly transformed in blastic phase, was given Nilotinib, but after a poor response this was withdrawn. However, sequencing analysis after Nilotinib therapy showed that although the Q252H mutation was undetectable, the two mutations in codon 255 still remained, suggesting that the Q252H mutation was more sensitive to treatment. *Summary/Conclusions.* The findings of this study highlight the importance of testing for kinase domain mutations in therapy resistant CML patients and that multiple mutations, although rare, can occur. It also emphasizes the value of patient-specific optimized treatment strategies dependant on the location and nature of any mutations present.

1308

BCR-ABL SEQUENCING AND MUTATIONAL STATUS IN CHRONIC MYELOID LEUKEMIA: DESCRIPTION OF ATYPICAL MUTATIONS AND RELATIONSHIP WITH RESPONSE TO IMATINIB AS A PRELIMINARY ANALYSIS OF A SINGLE CENTER STUDY

I Montero, V Aquino, R García-Lozano, R Morales, I Espigado

Hospital Virgen del Rocío, Seville, Spain

Background. The clinical significance of mutations of bcr-abl at diagnosis of chronic myeloid leukemia and during its clinical course is not well established except in well-studied mutations and unresponsive to tyrosine kinase inhibitors such as T315I, being controversial the utility of mutational analysis for therapeutic decisions. We present preliminary results of a study of mutation by directing sequencing analysis in CML patients with alterations in the detection of exons 7, 8 and 9. *Aims.* To analyze the mutational status by sequencing a group of CML patients by establishing correlation with response to treatment with imatinib. *Methods.* In January of 2009 it began in the Hematology Department of the Hospital Virgen del Rocío de Sevilla a study of bcr-abl mutations in CML patients at diagnosis and, in retrospect, in those treated with imatinib who presented still detect bcr-abl transcripts using real-time PCR. All patients were treated with imatinib after diagnostic doses of 400 mg daily, with subsequent monitoring as recommended by the European Network of Leukemia (2006). The mutational study was performed by extracting RNA from peripheral blood samples, reverse transcription to cDNA, gene amplification by nested PCR and subsequent direct sequencing. We conducted a subanalysis of the first 10 patients included correlating the results with response to imatinib. *Results.* Four out of each studied patients submitted mutations. Three of them consisted of a deletion of exon 7 and one in an insertion between exons 8 and 9. These two types of mutations may potential-

ly alter the conformation of the kinase domain of BCR-ABL protein. Three of the mutated patients (75%) had a suboptimal response to treatment with imatinib, without greater molecular response achieved after 18 months of follow up, leading to an increase in dose or change to second inhibitor (nilotinib or dasatinib) without intolerance. One patient with deletion of exon 7 shows a complete hematologic and cytogenetic response transcripts persisted over follow-up of 0.1% with less than 18 months. *Conclusions.* 1) Mutations in the bcr-abl kinase domain of exon 7 deletion type and insertion between exons 8 and 9, rarely reported in literature, determined in our series poorer response to treatment with imatinib in a 75% CML patients. The value of its presence at the time of diagnosis must be confirmed after further recruitment and monitoring of patients in the study. 2) The use in our study of the direct sequencing method in the analysis to detect mutations more rarely described and that might go unnoticed by other methods.

PROGNOSTIC SIGNIFICANCE OF CHROMOSOMAL REARRANGEMENTS IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA TREATED WITH IMATINIB

C Gug,[1] H Ionita,[1] R Mihaescu,[1] L Cheveresan,[1] A Anghel,[1] C Cotoraci,[2] M Ioana[3]

[1]University of Medicine and Pharmacy Victor Babes, Timisoara, Romania; [2]West University Vasile Goldis, Arad, Romania; [3]University of Medicine and Pharmacy, Craiova, Romania

Background. The Philadelphia chromosome (Ph1) is the hallmark of chronic myeloid leukemia (CML) and results from the reciprocal translocation t(9;22)(q34;q11). Glivec (Imatinib mesylate) is included on the orphan drugs list, works on a molecular level. CML treatment is guided by monitoring cytogenetic and molecular therapy response. Complex chromosomal rearrangements developing during progression of CML are rather rare and significance and frequency of different anomalies are poorly understood. *Method.* The study was conducted between January 2002 and January 2010. The study group included 35 patients: 19 males and 16 females. The average age was 38,11 years. All the patients received a daily dose of 400 mg Imatinib. The cytogenetic studies were made on hematopoietic bone marrow using culture for 24-48 hours on a culture medium dedicated for hematopoietic cells, followed by standard cytogenetic exam, GTG banding and karyotyping. The haematologic and cytogentic evaluation of patients were monitored during the treatment. The patients were classified on the basis of the response to treatment (% of Ph^+ cells) in 5 categories: complete cytogenetic response (0% Ph^+ cells), major cytogenetic response (<35% Ph^+ cells), partial response (1% to 34% Ph^+ cells), minor cytogenetic response (35% to 90% Ph^+ cells) and without cytogenetic response.

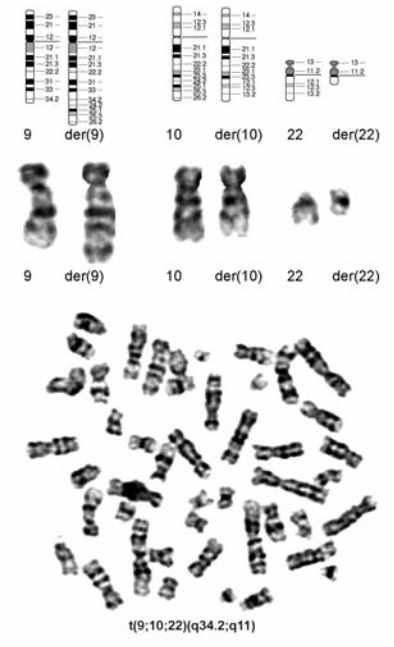

Figure.

Results. The average time for the treatment was 20,8 months with limits between 4 and 65 months. At 6 months of treatment 85,71% obtained CCR and 14,29% mCR. At the last evaluation, CCR was obtained by 67,85% patients, MCR by 10,71% and mCR by 21,42%. Several patients acquired additional clonal cytogenetic abnormalities during therapy, a finding with significant implications for prognosis and laboratory monitoring. The majority of structural changes were unbalanced. Variant Ph translocation (involving chromosome 9, 22 and one or more other chromosome) were found in 3 patients, the rest of the cohort had a classical Ph translocation associated with additional structural aberrations. *Conclusions.* Glivec is a revolutionary drug which grew the life expectance of patients with CML. Complex chromosomal rearrangements are associated with rather poor prognosis and respond poorly to antileukemic treatment. Identification of complex chromosomal aberrations may provide information of genetic mechanisms playng role in disease progression.

1310

MOLECULAR MONITORING OF CHRONIC MYELOCYTIC LEUKAEMIA (CML) IN A PATIENT POPULATION OF THE STATE OF QATAR ON IMATINIB MESYLATE (IM) TREATMENT

I Al-Dewik,[1] P Jewell,[2] R Elayoubi,[1] M Morsi[3]

[1]Hmc-Al Amal Oncology Center, Doha, Qatar; [2]Kingston University and St Georges University of London, London, UK; [3]Research and Education Department, Aquamed ME, Doha, Qatar

Background. Most cases of CML are associated with presence of BCR-ABL fusion gene; this molecular anomaly enabled the development of the drug Imatinib that selectively target diseased cells. The success of the rationally designed Imatinib therapy is tempered, however, by the problem of disease persistence and resistance. Internationally, around 10% of CML patients develop resistance to Imatinib. In comparison the rate of resistance in Qatar was noticed to be higher; as 40-50% of patient's progress from chronic phase to accelerated or blastic crisis phase within the 1st year of treatment. *Aim.* To monitor the molecular response of CML patients in the state of Qatar using Real Time PCR (RQ-PCR) in order to provide an early indication of emerging drug resistance. *Materials.* CML PB and BM samples were analysed using RQ-PCR as per the European against Cancer (EAC) protocol. *Results.* Over a period of three years, a total of 113 samples (61 PB and 52 BM) from 24 CML patients receiving Imatinib underwent molecular analysis, via serial real-time-polymerase chain reaction (RQ-PCR) to monitor the ratio of BCR-ABL to normal ABL transcripts. According to European Leukemia Net (ELN) a BCR-ABL/ABL ratio of 0.1% or less represents major molecular response (MMR), BCR-ABL/ABL ratio of (0.1% to 1%) represents minor molecular response (MiMR), BCR-ABL/ABL ratio of more than 1% suggested a resistant or relapsed case. As recommended by ELN, major molecular response (MMR) has to be achieved at 18 months after diagnosis. The rate of resistance in our patients was found to be as high as 45%.8/24 patients (33%) showed resistance within 6-39 months (mean & median = 13 months).3 patients (12%) developed additional chromosomal abnormalities (ACA) +8, +14, +17, +19. One patient of the three developed AML at 21 months and died, the other developed ALL and died at 9 months, and the third kept showing fluctuating results. On the other hand, 2 patients (9%) showed an initial response after 6 months (mean & median = 18 months) one still in remission and the other in (MiMR), 1 patient (4%) showed initial response after 15 month and still in remission, 2 (9%) patients achieved MMR at 18 and 21 months. 8 patients (33%) enrolled recently into the study and are still too early to yield any significant results at the time of writing this abstract. *Summary/Conclusion.* Our results confirmed the higher resistance rate of Qatari patient's population in comparison to European and international counterparts. 45% Qatar: 10-15% Europeans. We noticed that patients responding early to treatment had a good chance to achieve MMR and disease-free survival (DFS); while patients not achieving any molecular response during the 1st year were more likely resist to Imatinib treatment. Although the recommendation of ELN is to monitor molecular response at 12 months of treatment (not earlier), however, in areas with high resistance rate other monitoring guidelines are needed. We thus suggest incorporating molecular response at ELN criteria as an essential early monitoring test at 6, 9 months to allow early prediction of resisting / relapsing patients.

1311

THE CLINICAL IMPACT OF THE IMATINIB BLOOD LEVEL TESTING FOR CML: SINGLE CENTER EXPERIENCE OF FUNDENI HEMATOLOGY DEPARTMENT IN COLLABORATION WITH BORDEAUX'S PHARMACOLOGY AND TOXICOLOGY LABORATORY

M Crisan,[2] D Coriu,[1] ,[2] M Molimard,[3] F-X Mahon,[3] R Talmaci,[1] A Colita,[2] S Badelita,[1]

[1]University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania; [2] Department of Hematology, Fundeni Clinical Institute, Bucharest, Romania; [3]University Victor Segalen,Bordeaux, France

The patients with chronic myeloid leukemia (CML) in chronic phase who receive Imatinib from diagnosis have a very good prognosis, but, despite of this, cases of treatment failure or suboptimal response have been reported. Achieving maximum benefit with Imatinib therapy may require optimal dosing as well as adherence to therapy. To look for these, Imatinib Blood Level Testing (BLT) had been done for some of our patients with CML. In the last three years, we sampled 40 probes which were send to Department of Clinical Pharmacology and Toxicology, Centre Hospitalier Universitaire (CHU) de Bordeaux. According to ELN recommendations, the indications for Imatinib BLT were: insufficient response for thirty two patients (80%), suspicion of non-adherence to treatment for five patients (12,5%) and adverse events for three patients (7,5%). The median time from the beginning of Imatinib treatment of those patients is 65,7 months (raging from 12-96 months). In the moment of sampling, the molecular monitoring showed that six patients (15%) were in complete remission and thirty four patients (85%) were in partial remission and progresive disease. Compared to the medium value, recommended by Bordeaux lab (1002 ng/mL), the results of Imatinib BLT were high in twenty five patients (62,5%), low in twelve patients (30%) and normal in three patients (7,5%). After the results had been received, twenty patients (50%) were tested for mutations in BCR-ABL- kinase domain. For nineteen patients (47,5%) the Imatinib dose was escalated, and one patient (2,5%) had been retested after confessing non-adherence to therapy. In CML patients with suboptimal response to Imatinib at 400 mg per day, monitoring blood levels of Imatinib would be most helpful to physicians in determining if the dose should be increased, or whether, in the case of imatinib failure, alternative therapies should be considered.

This work was partially supported by the grant PN 41-087 from the Romanian Ministry of Research and Technology. The authors express their gratitude to European Leukemia Net / EUTOS for their permanent support.

1312

DETECTION OF ABL KINASE DOMAIN POINT MUTATIONS IN 11 CHRONIC MYELOID LEUKEMIA PATIENTS RESISTANT TO IMATINIB TREATMENT

A Bennour,[1] N Beaufils,[2] J Gabert,[2] M Laatiri,[3] M Elloumi,[4] B Meddeb,[5] A Khelif,[1] H Sennana,[1] A Saad[1]

[1]Farhat Hached Hospital, Sousse, Tunisia; [2]Hopital Nord, Marseille, France; [3]Fattouma Bourguiba Hospital, Monastir, Tunisia; [4]Hedi Chaker Hospital, Sfax, Tunisia; [5]Aziza Othmana Hospital, Tunis, Tunisia

The Philadelphia (Ph1) chromosome which characterizes the chronic myeloid leukemia (CML) is generated by a balanced reciprocal translocation t(9;22)(q34;q11), in which the ABL and BCR genes are disrupted, to form a BCR-ABL fusion gene. Most CML patients express the BCR-ABL transcript with β2α2 or β3α2 junction. A few CML patients express a shortened BCR-ABL transcript with an e1a2 junction (m-bcr) and only sporadic cases have a BCR breakpoint located in the μ-bcr region and express the rare junction e19a2. The recent introduction of tyrosine kinase inhibitors such as imatinib represents a major therapeutic advance in the management of CML. However, resistance to imatinib due to point mutations in Bcr-Abl kinase domain is an emerging problem. This study was purposed to evaluate ABL tyrosine kinase point mutations in 11 chronic myeloid leukemia (CML) patients showing resistance to imatinib. All the patients disclosed the Ph1 chromosome revealed by R-banding karyotype. Multiplexed reverse transcription polymerase chain reaction (RT-PCR) was performed to discover the BCR/ABL subtype. We have identified 6 patients with β3α2 rearrangement, 4 patients with β2α2 rearrangements and one patient carried the e19a2 transcript. A cytogenetic follow-up during imatinib treatment was done and none of the 11 patients achieved complete cytogenetic response throughout a mean duration of 21 months. A search for a mutation on ABL gene exons 4-9 was done by sequencing cDNA for the BCR-ABL fusion transcript. The results showed that the point mutations were found in 2 of 11 patients. One patient showed E355G mutation. This one was detected in the majority of alleles. It has been recognized that E355G is a point mutation in the exon 6 of BCR-ABL gene that alters the conformation of the kinase domain required for imatinib binding and therefore, decreased sensitivity to imatinib. This is, to our knowledge, the first report of CML with e19a2 transcript and E355G mutation arising during imatinib treatment. In the second patient, two point mutations have been identified: L376S and K467R which probably cause resistance to imatinib, the mechanisms by which resistance is induced, are discussed. These findings indicate that E355G induces imatinib resistance also in CML patients carrying the e19a2 transcript. We speculate that DNA instability in this type of CML may not differ significantly from that in the M-BCR-ABL type, and that blastic transformation with clonal evolution eventually occurs unless suitable therapy is administrated. We have identified two point mutations that have not been described previously in the literature, and induce resistance to imatinib therapy. It is concluded that ABL kinase point mutation is an important mechanism of imatinib resistance, monitoring the ABL kinase domain point mutation is helpful to estimating the prognosis and adjusting the therapeutic strategy.

1313

ABSENCE OF BCR-ABL KINASE DOMAIN MUTATIONS IN CHRONIC MYELOCYTIC LEUKEMIA (CML) QATARI PATIENTS ON IMATINIB MESYLATE (IM) TREATMENT

I Al-Dewik,[1] P Jewell,[2] R Elayoubi,[1] M Morsi[3]

[1]Hmc-Al Amal Oncology Center, Doha, Qatar; [2]Kingston University and St Georges University of London, London, UK. [3]Research and Education Department, Aquamed ME, Doha, Qatar

Background. More than 45% of CML patients in Qatar resist the first line of Imatinib treatment; we thus investigated the role ABL mutations might play in this resistance. *Aim.* To investigate the role of ABL mutation in resistance of CML patients to treatment in Qatar. *Materials & Methods.* CML PB and BM samples were collected from 21 patients; total RNA was extracted using QIAamp RNA Blood Mini Kit, cDNA synthesis was performed using RT-Dx, cDNA was amplified using Semi-nested PCR, the 863 bp PCR product was directly sequenced in the forward and reverse directions using ABI PRISMA 3130 Genetic analyzer. *Results.* Over a period of three years, 57 samples (33 PB and 24 BM) for 21 patients receiving Imatinib were studied for ABL mutations prior to treatment, and at the time of resistance (failure and suboptimal response as defined by European Leukaemia Net (ELN)). Initially, sequencing was performed on 412 bp of ABL gene alone using ABL forward and reverse primers, the results didn't show any mutations in ABL kinase domain at C helix, SH3 contact, IM binding site, SH2 contact, kinase catalytic domain and Activation loop. In order to avoid wild type ABL amplifications and cover the whole ABL kinase domain that is fused to BCR, we resequenced the 57 samples using two new sets of primers that amplified BCR-ABL fusion gene followed by semi-nested PCR that amplified the whole ABL kinase domain (863 bp). We could find no evidence of ABL gene mutations at P-loop, C helix, SH3 contact, IM binding site, SH2 contact, kinase catalytic domain, Activation loop, C-terminal loop. To confirm the absence of any novel mutation we compared the resulted sequence data with ABL kinase domain reference sequence (GenBank accession no. M14752) using www.ncbi.nlm.nih.gov/blast. *Summary/Conclusion.* Due to high rate of resistance of Qatari CML patients to Imatinib, we tested our patients for BCR-ABL mutation. Internationally, ABL mutations are the most common cause of Imatinib resistance. Despite of the high resistance in our patient's population, our study didn't reveal any of the known imatinib resistant ABL kinase domain mutations. Our results suggest that the observed high rate of resistance in our patients is not due to ABL kinase mutations. However, it must be kept in mind that direct sequencing has a limited sensitivity and if the mutated ABL is less than 30% of the total ABL domain then a low level mutation could have been missed. An alternative approach such as High Resolution Melting (HRM) technology accompanied with sequencing, single nucleotide polymorphisms (SNPs) assay to detect and quantify low level mutations is needed to confirm their absence and to rule in/out the existence of mutations or SNPs that might be uniquely contributing to our patients resistance to Imatinib. If absence of mutations proves to be true, then other contributing mechanism(s) should be sought, such as BCR-ABL over expression, increased levels of P-glycoprotein (Pgp), up regulation of plasma protein alpha1 acid glycoprotein (AGP) and/or the existence of intrinsic factors that reduce the bioavailability of Imatinib.

1314

PROGNOSTIC VALUE OF CYTOGENETIC ABNORMALITIES ASSOCIATED TO PHILADELPHIA CHROMOSOME IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA TREATED WITH TYROSINE KINASE INHIBITORS

M Jimenez-Rolando, JV García-Gutiérrez, P Herrera, J López, M Calbacho, MJ Blanchard, A Chinea, I Delgado, JM Alonso, D Velasco, J Odriozola

Ramón y Cajal Hospital, Madrid, Spain

Background. Prognosis of chronic myeloid leukemia (CML) has changed dramatically in the last decade since the introduction of tyrosine kinase inhibitors (TKI). However, there are still an important number of patients with unsatisfactory response to this therapy. Cytogenetic abnormalities associated to Ph chromosome have been classically considered as a worse prognosis indicator. Their importance in CML patients with TKI therapy must be further investigated, e.g. the expert board of the European LeukemiaNet (ELN) has dropped off the presence of $9q^+$ at the time of diagnosis as an adverse prognosis marker, but on the other hand has considered the appearance of clonal chromosome abnormalities in Ph^+(CCA/Ph^+) in the follow-up a therapy failure. *Aims.* To analyze the prognostic value of cytogenetic abnormalities associated to Ph chromosome in patients with CML treated with TKI. *Methods.* We analyzed the response to Imatinib 400 mg in 76 patients attended in our center (50% in first line, 50% in second or more lines). Sokal index at diagnosis was low in 47%, intermediate in 43% and high in 10% of patients. All patients underwent bone marrow karyotyping at diagnosis and at the 3th, 6th, 12th, and 18th month, and yearly after this point in patients that maintained complete cytogenetic response. Clonal evolution (CE) is definite as the development of non-random chromosomal abnormalities (CCA) in addition to the Ph chromosome. BCR-ABL transcripts were quantified by rt-PCR every 3 months in peripheral blood. In those patients with an inadequate response, we examined the Ph chromosome mutations as well as the plasmatic levels of Imatinib. *Results.* The responses according to ELN criteria were: failure in 21%, suboptimal response in 17% and optimal response in 62% of patients. The frequency of CCA at the time of diagnosis was 9%. In the follow-up CE was developed in 18%. The frequency of therapeutic failure was similar in patients with and without CCA at the time of diagnosis (29% *vs.* 39%; RR 0.85, 95% CI=0.51 to 1.41), but the development of CE was associated to a higher percentage of therapeutic failure in the complete cohort (71% *vs.* 31%; RR 2.42, 95% CI=1.04-5.65). Development of CCA in patients who achieved a major molecular response (MMR) in the firsts 6 and 12 months after diagnosis was low (0 and 16% respectively). Nevertheless, these subgroups were too small to obtain statistical significances (RR for CCA at 12th month 0.83, 95% CI=0.69-1.00). *Conclusions.* The prognosis impact of cytogenetic abnormalities is still an ongoing issue. In our series, CCA is not a prognosis marker at the time of diagnosis but implies a worse prognosis when it develops in the follow-up time. There is a tendency against the development of CCA when the MMR is achieved in the firsts 6 and 12 months after diagnosis.

UNFAVOURABLE OUTCOME OF CML PATIENTS CARRYING COMPLEX VARIANT CHROMOSOMAL TRANSLOCATIONS TREATED WITH TYROSINE KINASE INHIBITORS

F Stagno,[1] P Vigneri,[2] V Del Fabro,[1] S Stella,[2] A Cupri,[1] M Massimino,[2] C Consoli,[1] L Tambè,[1] ML Consoli,[2] A Antolino,[3] E Spina,[1] F Di Raimondo[1]

[1]Hematology Section, Ferrarotto Hospital, Catania, Italy; [2]General Pathology Section, Dept.of Biomedical Sciences, Catania, Italy; [3]Department of Transfusional Medicine, Ragusa, Italy

Background and Aims. Cytogenetic variants of the Philadelphia (Ph) chromosome can be observed in 5-8% of patients diagnosed with Chronic Myeloid Leukemia (CML), and usually involve at least one chromosome other than 9 and 22. Despite the genetically heterogeneous nature of these alterations, available data indicate that CML patients displaying complex variant translocations (CVTs) do not exhibit a less favorable outcome as compared to individuals presenting conventional Ph-positive CML. *Patients and Methods.* We report our experience with 10 CML patients carrying CVTs among 153 newly diagnosed cases followed at our Institution between January 2003 and June 2009. All patients included in this series were diagnosed as CML in chronic-phase and their main clinical characteristics are listed in Table. Clinical, cytogenetic and molecular responses to TKIs were rated according to the European LeukemiaNet (ELN) 2006 guidelines. Peripheral blood samples were used for BCR-ABL determination by quantitative real-time polymerase chain reaction according to the suggested recommendations and all BCR-ABL transcripts were measured according to the International standardized Scale (IS). Cytogenetic responses (CyR) were evaluated on no less than 20 marrow cell metaphases with standard G-banding techniques. *Results.* In our series only two CML patients exhibiting CVTs achieved an optimal response to tyrosine kinase inhibitors (TKI) treatment. The remaining eight patients obtained either a suboptimal response or failed TKIs therapy. Statistical analysis revealed that patients carrying CVTs at diagnosis exhibited a poor clinical outcome as compared to CML patients without CVTs (P=0.02). *Conclusions.* These findings suggest that the presence of CVTs at diagnosis might confer an unfavorable clinical outcome as these genetic alterations might be markers of genomic instability and indicate a higher likelihood of disease progression.

Table.

1316

PRE-EXISTING AND ACQUIRED MORE FREQUENT KD MUTATIONS OF BCR-ABL IN PRIMARY AND SECONDARY RESISTANT IMATINIB-TREATED CML PATIENTS

M Marusic Vrsalovic, I Duic, R Ajdukovic, V Haris, V Pejša, O Jaksic, R Kusec

Dubrava University Hospital, Zagreb, Croatia

Background. Mutations of the BCR-ABL tyrosine kinase domain are the major cause of resistance to imatinib in patients with chronic myeloid leukemia. However, the incidence of KD mutations in imatinib-naive patients is unknown. It is not known whether KD mutant clones that are detectable prior to therapy are selected in the presence of imatinib, and whether they may predict for therapy outcome. *Aims.* We sought to investigate the occurrence and dynamics of 5 common KD mutations (T315I, F311L, M351T, E255K, E255V) in imatinib-treated patients lacking predicted therapy respone (by ELN criteria). *Materials and Methods.* Out of 34 imatinib treated CML patients at our institution, 8 of them showed primary resistance to imatinib with inadequate CgR and consistently high levels of BCR-ABL transcripts monitored by real-time PCR. Two patients showed secondary resistance with loss of CCgR and loss of MMolR. All patients had intermediate or high Sokal score at diagnosis. Using ASO-PCR we investigated the prevalence and the evolution of 5 common BCR-ABL KD mutations in pretherapeutic leukemic samples and follow-up samples collected throughout imatinib therapy of those patients. *Results.* In all patients with primary resistance KD mutation was detected in imatinib-naive pretherapeutic leukemic samples. F311L was detected in 3/8 (37.5%) and M351T in 6/8 (75%) patients, with 2 of them harboring dual mutation F311L/ M351T. One patient had no detectable mutations, but acquired M351T after 3 months of imatinib. After 24 months of imatinib therapy identical mutation status was identified in 4/8 patients (50%). Three patients acquired additional mutation (F311L, E255K, E255V, one each). Patients harboring dual mutations (n=4) had approximately 10 times higher BCR-ABL transcripts compared to patients with single KD mutation. Two patients with secondary resistance showed no mutations at the time of diagnosis. At the time of loss of MMolR, they both showed M351T. With the increase of the imatinib dose, one of them achieved MMolR again. T315I mutation was not detected in any patient. *Conclusions.* We conclude that: (1) in patients with primary resistance KD mutations occur prior to imatinib therapy, and are selected during therapy, indicating that the mechanism of resistance was in operation since the beginning of therapy, (2) mutations may also be acquired during disease progression and imatinib therapy through associated genetic instability, (3) mutation (e.g. M351T in

our patient) is accompanied by molecular progression of the disease, (4) the sensitive detection of mutated clones may provide clinical benefit leading to early therapeutic modifications.

1317

NILOTINIB SAFETY AND RESPONSES ANALYSIS IN RUSSIAN PATIENTS WITH CHRONIC MYELOID LEUKEMIA (CML) FROM ENACT(EXPANDING NILOTINIB ACCESS IN CLINICAL TRIALS) STUDY

A Turkina,[1] N Khoroshko,[1] A Bakirov,[2] A Korobkin,[3] T Pospelova,[4] V Rossiev,[5] Y Shatokhin,[6] A Silin,[7] A Zaritsky,[8] E Kravchenko[9]

[1]National Research Center for Hematology RAMS, Moscow, Russian Federation, Moscow, Russian Federation; [2]Republican clinical Hospital, Ufa, Russian Federation; [3]Chelyabinsk Regional Clinical hospital, Chelyabinsk, Russian Federation; [4]Novosibirsk City Clinical Hospital , [2]Novosibirsk, Russian Federation; [5]Samara Regional Clinical hospital, Samara, Russian Federation; [6]Rostov State Medical University, Rostov-on-Don, Russian Federation; [7]Irkutsk Regional clinical Hospital, Irkutsk, Russian Federation; [8]City Clinical Hospital #31, Saint Petersburg, Russian Federation; [9]Novartis Pharma, Moscow, Russian Federation

Background. Nilotinib is a potent and highly selective BCR-ABL kinase inhibitor, approved for the treatment of patients (pts) with Philadelphia chromosome-positive chronic myelogeneous leukemia (Ph^+ CML) in chronic phase (CP) and accelerated phase (AP) who are resistant or intolerant to prior therapy, including imatinib. ENACT study was initiated as a global expanded access program to obtain additional safety information in CML pts in a clinical practice setting outside of a registration study. This report focuses on a subset of patients enrolled in Russian Federation. *Methods.* Adult patients with imatinib resistant or -intolerant Ph^+ CML-CP, AP or BC were admitted to the study. Pts received nilotinib 400 mg twice daily (BID). Pts who required dose reduction to 400 mg once daily due to toxicity were allowed to have a dose re-escalation to 400 mg BID after resolution of the adverse events (AEs). *Results.* A total of 130 pts were enrolled in the ENACT study between 01/2006 and 10/2008, including 102 CP pts (79%), 20 AP pts (15%) and 8 BC pts (6%). The median age of all pts was 46 years; 71% were imatinib-resistant, and 29% were imatinib-intolerant. The most common prior antineoplastic therapy (other than imatinib) was hydroxyurea, interferons, cytarabine. At study completion, 72 pts (71%) at CP, 11 pts (55%) in AP and 0 pts were continuing on nilotinib; 30 pts(29%), 9(45%) and 8(100%) discontinued treatment, 18 (18%) CP pts, 6 (30%) AP pts, and 6 (75%) BC pts discontinued due to disease progression. There is a total of 1 (1%) death during the study. Median (range) duration of nilotinib exposure was 212 (9-693) days for CP pts, 199 (24-679) days for AP pts, and 61 (19-101) days for BC pts; median average dose intensity was 785, 743 and 786 mg/day, respectively. 29 CP pts (28%), 5 AP pts (25%) and 1 BC pts (13%) had their dose reduced due to AE, while 51 CP pts (50%), 11 AP pts (55%), and 4 BC pts (59%) had their dose interrupted due to AE. Median duration of dose interruption due to AE was short (13 days for CP, days for AP and 5 days for BC pts). The most common grade 3/4 hematologic AEs suspected of being drug related were thrombocytopenia (24%, 35%, 38%) and neutropenia (20%, 17% ,38%) in CP, AP and BC pts. The most frequent non hematologic all grades AEs or lab abnormalities included rash, headache, nausea, fatigue and hyperbilirubinaemia, and all were slightly lower in Russian patients compared with the overall ENACT population. No patients discontinued treatment due to pleural effusion and there was no incidence of QTcF prolongation > 500 msec. Overall, complete hematological responses (CHR) rates were 55% in CP, 35% in AP and 0% in BC pts while major cytogenetic responses (MCyR) rates were 31% in CP, 20% in AP and 13% in BC pts. *Conclusions.* Analysis of Russian patients' sub-population demonstrated what nilotinib is well tolerated and effective in heavily pretreated CML patients.

Table. Patient disposition (n = 130).

	CML-CP n = 102 n(%)	CML-AP n = 20 n(%)	CML-BC n = 9 n (%)
Patients continuing nilotinib at the end of protocol treatment	72 (71)	11 (55)	0
Discontinued	30 (29)	9 (45)	8 (100)
Progression	18 (18)	6 (30)	6 (75)
Adverse event	10 (10)	2 (10)	1 (13)
Death	1 (1)	0	0
Others*	1 (1)	1 (5)	1(13)

* Includes patients who withdrew consent and abnormal laboratory value(s).

DETERMINATION OF BCR-ABL ELEVATION LEVEL THAT CORRESPONDS TO MUTATION DETECTION IN CHRONIC MYELOID LEUKEMIA PATIENTS TREATED WITH TYROSINE KINASE INHIBITORS

A Tsaur,[1] A Ivanova,[1] A Popov,[2] Y Yakovleva,[2] T Riger,[2] O Plekhanova,[2] A Misyurin,[3] M Suchkova,[3] L Saveliev,[4] L Fechina[2]

[1]Research Institute of Cell Technologies, Ekaterinburg, Russian Federation; [2]Regional Children's Hospital, Ekaterinburg, Russian Federation; [3]National research center for Hematology, Moscow, Russian Federation; [4]Ural State Medical Academy, Ekaterinburg, Russian Federation

Background. BCR-ABL mutations are known to be one of the most frequent causes of acquired resistance to tyrosine kinase inhibitors (TKI). In some cases they lead to the treatment failure. Aim. To evaluate *BCR-ABL/ABL* threshold rising level that clearly predicts presence of *BCR-ABL* mutation. *Methods.* In current study 48 patients (pts) with suboptimal response or treatment failure according to the European LuekemiaNet criteria (M. Baccarani *et al.*, 2009) were included. Conventional cytogenetic analysis was performed every 6 months. Quantitative measurement by real-time PCR of *BCR/ABL* transcript level was done every 3 to 6 months after first year of therapy. 28 pts (58.3%) had lack of complete cytogenetic response (CCyR) by 12 months of IM therapy. Loss of response was detected in 12 pts (25.0%) achieved CCyR only and in 8 pts (16.7%) achieved both CCyR and major molecular response (MMR). mRNA was isolated from peripheral blood leukocytes and analyzed for point mutations in the *BCR-ABL* kinase domain by reverse transcription-polymerase chain reaction and direct sequencing at ABI Prism 3130 genetic analyzer. Our primers covered area spanning from a3 to a11 ABL exons of BCR-ABL gene, including the whole *BCR-ABL* kinase domain and flanking regions. Elevation of *BCR-ABL/ABL* was calculated by subtraction of *BCR-ABL/ABL* value at the time point (TP) prior to mutation screening to the *BCR-ABL/ABL* value at TP where mutation was detected. Threshold level was defined by ROC curve analysis. Positive and negative predictive values (PPV, NPV), sensitivity, specificity and overall correct prediction (OCP) were calculated. *Results.* Mutations in *BCR-ABL* gene were detected in 17 of 48 cases, including 3 different point mutations in P-loop, 3 mutations in imatinib-binding site, 2 mutations in A-loop, and 1 mutation outside the tyrosine kinase domain (TKD). Number of pts and mutations are shown in table. 14 (82.4%) out of 17 pts did not achieve CCyR. Median time from imatinib treatment start to mutation detection was 29 months (range 4-48 months). ROC curve analysis determined that increasing of *BCR-ABL/ABL* level in 5.5 times corresponds to 100% of NPV. In spite of excellent specificity (100%) other parameter of diagnostic performance such as sensitivity, PPV and OCP were relatively low (30.8%, 35.7%, 50% respectively). *Conclusions.* Mutation detection can be concerned as screening methods where NPV is the most valuable parameter. Thus *BCR-ABL/ABL* elevation in 5.5 times helps not to omit every single patient with *BCR-ABL* mutations.

Table. Number and localization of detected mutation.

Mutation localization		Number
P-loop	M244V	3
	G251A	1
	Y253H	4

SURVIVAL, CYTOGENETIC AND MOLECULAR RESPONSES IN CHRONIC MYELOID LEUKEMIA CHRONIC PHASE PATIENTS TREATED BY IMATINIB: 9-YEAR FOLLOW-UP DATA FROM POPULATION ST-PETERSBURG AND LENINGRAD REGION DATABASE

K Abdulkadyrov,[1] E Lomaia,[2] V Shuvaev,[1] A Abdulkadyrova,[1] V Udalieva,[1] E Usacheva,[1] D Shikhbabava,[1] E Machulaitene,[3] I Zotova,[1] M Ivanova,[3] E Poznyak,[3] E Koryagina,[4] N Ilina,[4] T Shneider,[5] E Romanova,[2] E Salamatova,[3] N Lazorko,[2] I Martinkevich,[1] A Zaritskey[2]

[1]Russian Research Institute of Hematology and Transfusiology, St-Petersburg, Russian Federation; [2]Federal Centre for Heart Blood & Endocrinology, St-Petersburg, Russian Federation; [3]State Pavlov's Medical University, St-Petersburg, Russian Federation; [4]City Hospital #1, St-Petersburg, Russian Federation; [5]Clinical hospital of Leningrad region, St-Petersburg, Russian Federation

Background. During the last decade Imatinib (IM) become the first line treatment for Chronic Myeloid Leukemia (CML) patients. There are few data about the efficacy of IM beyond clinical trials without patient selection based on strict eligibility criteria. *Aims.* The aim of this study was to analyze survival, cytogenetic and molecular responses in CML chronic phase (CP) patients treated by IM in different centers in Saint-Petersburg and the Leningrad region in 9 years follow-up period. *Patients and methods.* In our database there are 234 CML CP (ELN criteria) pts, who have been treated with IM since 2001. Before IM the pts were pretreated with hydroxyurea (79.5%), interferon-alfa with or without hydroxyurea (48.3%) and busulfan (6.8%). There were 133 (56.8%) pts in early CML CP (disease duration before IM ≤12 months) and 101 (43.2%) in late CP (>12 months). *Results.* The median time before IM for the whole group was 6.75 months (3 days - 243 months), for early and late CP patients it was 1.7 months (3 days - 12 months) and 38 months (13.3 - 243 months) respectively. The median time of IM therapy was 32 months (0.33 - 85 months) for the whole group, 28 months (1-82 months) in early and 41 months (0.33 - 85 months) in late CP patients respectively. The estimated overall survival (excluding CML unrelated deaths) by 9 years was 85%. The rate of CML related death was 8.3% (19/229). The probability of complete cytogenetic response (CCyR) in the whole group was 82%. In early CP the probability of CCyR was definitely higher, than in the late phase: 92% *vs.* 75%, P=0,003. There was no difference between patients who had been pretreated by interferon and those who had not (83% and 83%, P>0.5). No significant differences between the probability of CCyR in patients with or without clonal evolution before imatinib therapy (86% *vs.* 68%, P>0.5) was found. The rate of CCyR loss was 29.7%. It was equal in patients treated with or without interferon before IM (29% *vs.* 30%, P>0.5). The rate of major (MMR) and complete (CMR) molecular response was 50% (59/117) and 37% (45/117) respectively. It depended on time to CHR and CCyR. The probability of MMR by 5 years was 64% *vs.* 0% with or without CHR by 3 months (P<0.05), 64% *vs.* 48% (P<0.05) with or without CCyR by 12 months. Imatinib therapy was stopped in 34.2% (80/234) of patients. The reasons for discontinuation were: resistance - 66.25% (53/80), intolerance -15% (12/80), death from causes other than CML - 6.25% (5/80), stem cells transplantation - 1.25% (1/80), 3.75% (3/80) - patient decision, 7.5% (6/80) - unknown reason/loss to follow-up. *Conclusions.* IM therapy was very effective in patients, treated in outpatients departments of Saint-Petersburg and the Leningrad region. The most patients are alive and still on IM therapy. No significant difference in achievement or loss of CCyR for patients who were and who were not pretreated by interferon was revealed. The probability of MMR was higher in patients with early CHR and CCyR.

1320

IMATINIB IN CLINICAL PRACTICE IN TREATMENT OF PATIENTS WITH CML. RESULTS OF LARGE COHORT FROM SINGLE UNIVERSITY CENTER IN SOUTHERN EUROPE

A Bogdanovic,[1] V Djordjevic,[1] V Miloševic,[1] J Jovanovic,[1] M Mitrovic,[1] M. Dencic Fekete,[1] B Todoric-Živanovic,[2] G Jankovic,[1] M Gotic,[1] D Boskovic[1]

[1]Inst of Hematology CCS Belgrade, Belgrade, Serbia; [2]Center for Pathology& Forensic Medicine, Military Medical Academy, Belgrade, Serbia

Prospective trials showed high efficacy of imatinib in treatment of CML, but few data are available about non trial clinical patients. We analyze efficacy of IM in treatment of large cohort of CML patients from 2002 to 2009, from database of Clinical Center of Serbia. *Patients.* In the period of >7 years, 90 patients with CML was treated by regular IM (health insurance), and 32 patients were enrolled in CELSG "ISTAHIT" trial between 2004-2006. *Results.* Mean age was 47.4 yrs (17-76). Mean follow up was 35 mths (9-170). Four patients were treated in BC-CML, with poor outcome. 86 patients were treated either as 1st line IM (63 pts, 70%) or 2nd line chronic phase, CP (14), or accelerated phase AP (9 pts). We found high proportion of high Sokal (39%) and Hasford (12%) scores. We had 3 Ph-, bcr-abl+ patients (3%). All patients started with 400mg IM with subsequent escalation in non optimal response according to National guidelines based on ELN 2006&NCCN 2007. Only 3/9 patients in AP achieved major CgR at 6m, but 2/9 achieved CCgR at 12 and 24m. From patients treated in CP, 12/13 patients achieved at least MCgR at 6m with 2nd line IM, and 53/61 evaluated (86%) achieved at least MCgR at 6m, with 70% of CCgR with 1st line IM. At 12 months, all 12/13 pts treated with 2nd line IM achieved CCgR, and 41/47 patients evaluated (87%) were in CCgR on 1st line IM. 2 of 3 Ph negative pts achieved MMR. There was no significant difference between 1st and 2nd line IM treatment. Seven patients (9%) in CP had treatment failure or progression (events), and 5 (6%) experienced toxicity resulting in IM withdrawal. Concerning survival, 2 pts in AP with CCgR continues IM like CP patients, 2 patients were transplanted, and 5 died due to progression. From patients in CP, 74 (96%) is alive, with OS5y 97%, with no difference between 1st and 2nd line IM. Concerning progression free survival, PFS, we have found difference between 1st and 2nd line IM treatment but it would be worth to note that 2nd line IM treatment group was small, and also had at least 1.5 year of stabile chronic phase before IM treatment. We have not found significant difference in survival of CP patients concerning Sokal risk but in general patients with high risk did slightly worse (OS5y 93%) than low and particularly intermediate risk (OS5y 100%). There was a slight difference in PFS with PFS5y for Sokal low risk 95%, and 70% for intermediate and high risk group. We have not found that difference concerning Hasford score. *Conclusion.* Our results are in concordance with previous published data from clinical trials and also some cohort data. Introduction of National guidelines based on ELN proposals, positively affect CML treatment and IM has proven to be efficient treatment for all patients in CP, but for patients in AP it would be necessary to find different strategies.

1321

HIGHTROUGHPUT BLOOD LEVEL TESTING OF IMATINIB BY FLOW INJECTION ANALYSIS - TANDEM MASS SPECTROMETRY

D David, E Faber, K Micova, K Indrak, T Adam

Palacky University in Olomouc, Olomouc, Czech Republic

Background. Imatinib (Glivec) is a selective tyrosine kinase inhibitor currently used for the treatment of Philadelphia chromosome-positive chronic myeloid leukemia (CML) and for other malignant pathologies. Usually it is determinated by liquid chromatography coupled with (tandem) mass spectrometry, but the analyses are time consuming. *Aims.* The aim of this work was to develope of new rapid and sensitive flow injection analysis with tandem mass spectrometry detection for determination of imatinib (IM) in plasma. *Methods.* Plasma was deproteinated by methanol with added internal standard (D8-deuterated imatinib), shaken, freezed and centrifugated. Imatinib plasma levels were measured using UHPLC UltiMate 3000 RS (Dionex) coupled with the API 4000 tandem mass spectrometer (Applied Biosystems). Mobile phase consisted of methanol and 0.1% formic acid. A triple quadrupole detector with electrospray ionization was operated in multiple-reaction monitoring mode (m/z transitions for IM 494=>394, D8-IM 502=>394; dwell time 200 ms). Our method was compared with currently accepted method (Titier K, Blood, 2005), where chromatographic separation on a reverse phase analytical column Acquity UPLC® BEH C18 1.7 µm (2.1 ×50 mm; Waters) we used. *Results.* Total analysis time of our method (45 s) was 10 times faster compared to Titier's original method. The method was fully validated and tested on plasma samples from 120 patients treated with IM. All evaluated parameters (recovery, imprecision, accuracy), Bland-Altman plot (mean difference -1.5 and SD 29.0 ng/mL) and regression analysis (y = 0.995x + 3.295; r2 = 0.997) revealed agreement of tested methods. *Conclusions.* This method is simple and high throughput, adapted to routine application and it is suitable for therapeutic monitoring of imatinib. It provides comparable results with commonly used liquid chromatography-mass spectrometry method but it is much faster and cheaper. *Acknowledgement.* The work was supported by grants NS9627-3 (Ministry of Health, the Czech Republic), MSM 6198959205 (Ministry of Education, Youth and Sports, the Czech Republic).

1322

RELATIONSHIP BETWEEN AN EFFECTIVE DOSE OF IMATINIB AND TROUGH LEVEL IN KOREAN CHRONIC-PHASE CML WITH REDUCED DOSE

SR Lee,[1] JS Ahn,[2] Y Park,[3] HJ Sung,[3] YK Kim,[2] CW Choi,[3] HJ Kim,[2] BS Kim[3]

[1]Korea University Anam Hospital, Seoul, South-Korea; [2]Department of Hematology-Oncology, Chonnam National University Hwasun Hospital, Jeollanam-do, South-Korea; [3]Departement of Hematology/Oncology, Korea University Medical Center, Seoul, South-Korea

Background. Some patients in chronic-phase chronic myeloid leukemia (CML) receive reduced doses of imatinib due to some adverse effects in practical setting. Their clinical response was comparable with the data of other reports including the IRIS study despite low dose of imatinib. Recently, the effective trough levels of imatinib were demonstrated in some studies. *Aims.* In this study, we tried to verify the relationship between effective dose of imatinib and the trough level in Korean chronic-phase CML with reduced dose. *Methods.* Forty-eight patients having record of BSA from 2 University Hospital in Korea (Korea University Medical Center and Chonnam National University Hwasun Hospital) who treated with reduced dose of imatinib were retrospectively analyzed. Informed consent was obtained from 23 of 48 patients to measure the trough level of imatinib. This study was approved by the Ethic Committees of the participating hospitals. *Result.* Thirty-three patients (68.8%) were reduced dose to 300 mg/day within six months after starting imatinib therapy with 400 mg/day. The main reasons for dose reduction were severe neutropenia or thrombocytopenia (grade 3 or 4) (62.9%). The cumulative complete cytogenetic response (CCR) at 12 months was 62.5%. After median follow-up period of 38.6 months (7.2~88.6), 36 patients (75.0%) have sustained CCR. The mean dose of imatinib/day of all patients were 328.6±34.2 mg (208.0 ~ 394.2). The mean BSA was 1.58±0.16 (1.28~1.97) with significant difference by gender (P<0.001)(male; 1.70±0.13 *vs.* female; 1.49±0.12). Also, the mean dose of imatinib/BSA of male patients was significantly lower than female patients with low BSA (P = 0.034) (male; 199.6±18.5 mg/m^2 *vs.* female; 216.3±30.1 mg/m^2). The mean dose of imatinib/BSA was significantly higher in patients achieving cumulative CCR at 12 months compared with those couldn't achieving efficacy (P<0.032)(215.2±23.6 mg/m^2 *vs.* 196.5±31.4 mg/m^2), although the gender, the mean dose of imatinib and BSA didn't show the difference. We measured the trough level of imatinib among 23 patients. The cumulative complete cytogenetic response (CCR) at 12 months was 73.9%. The mean trough levels of imatinib were 1370±708 ng/×(585~3940) with the mean dose of imatinib/day, 333.5±23.4 mg. The trough levels of imatinib have a significant correlation with the dose of imatinib/BSA (r2 = 0.268). The mean trough level of imatinib in patients with cumulative CCR at 12 months was relatively higher without statistically significance (P=0.097). After median follow-up period of 35.2 months (7.2~88.6), 20 patients (87.7%) have sustained CCR. *Conclusion.* The mean dose of imatinib/BSA was associated with the efficacy of reduced dose of imatinib in Korean chronic-phase CML. Although we didn't show that significant relationship between the trough levels of imatinib and effective outcomes, the trough levels of imatinib have a significant correlation with the mean dose of imatinib/BSA. Considering the smaller BSA of Korean patients, this result suggest that the reduced dose of imatinib could maintain effective trough level and excellent clinical outcomes for the threatment of chronic-phase CML in Korea.

HEMATOLOGIC AND MOLECULAR RESPONSE EVALUATION OF PATIENTS WITH CHRONIC MYELOID LEUKEMIA TREATING WITH INDIAN GENERIC TYPE OF IMATINIB

F Razmkhah, M Razavi, F Zaker, A Kazemi, P Rasighaemi, V Pazhakh

Iran University of Medical Sciences, Tehran, Iran

Background. Imatinib mesylate is used in chronic phase of chronic myeloid leukemia patients to induce apoptosis and inhibit cell proliferation. *Aims.* Hematologic and molecular responses of these patients to Indian generic type (Imatib) were studied, since 95% of Iranian CML patients use this drug as a first-line therapy due to it's cheaper price (about 12 times cheaper). *Methods.* Thirty patients with chronic myeloid leukemia who were treated with Imatib were analyzed in this investigation (informed consent was obtained). Physical examination, CBC test and peripheral blood smear observation was used for hematologic response determination. Molecular response was also examined through quantitative assessment of BCR-ABL fusion gene expression by Real Time RT-PCR. Also, the correlation of molecular and hematologic responses with patient's age and sex, dose and duration of Imatib consumption was analysed statistically. *Results.* 90% of patients showed hematologic response which did not have any significant correlation with patient's age and sex , dose and duration of Imatib consumption (P>0.05). While, 46.7% of patients showed complete molecular response, 43.3% of patients showed partial molecular response and 10% of patients showed no molecular response to Imatib. A significant reverse correlation between molecular response type and age (P<0.05) was observed. In contrast, there was no significant correlation between molecular response type and patient's sex, dose and duration of Imatib consumption (P>0.05). *Conclusions.* In this cross sectional study, results of molecular and hematologic responses to Imatib which is comparable to more expensive Gleevec, was good and acceptable. Also, More accuracy and integrity of patient's molecular response due to higher sensitivity of Real Time RT-PCR technique, shows the necessity of molecular response determination in addition to hematologic response for better assessment of patient therapeutic situation.

1324

CHRONIC MYELOID LEUKEMIA IN THE IMATINIB ERA: THE PREDICTIVE VALUE OF OPTIMAL RESPONSE AT 12 MONTHS OF THERAPY ON ACHIEVING MOLECULAR RESPONSE AND DISEASE PROGRESSION

P Santos-Sousa,[1] L Guerra,[1] B Gomez,[1] S Valle,[1] C Lopes,[1] J Raposo,[1] C Martins,[1] MJ Costa,[1] G Esteves,[1] J Fajardo,[1] J Forjaz Lacerda,[1] S Matos,[2] S Santos,[2] J Alves do Carmo[1]

[1]Hospital de Santa Maria - Centro Hospitalar Lisboa Norte, EPE, Lisboa, Portugal; [2]Genomed - Diagnósticos de Medicina Molecular, IMM, FML, Lisboa, Portugal

Background. Imatinib as first line treatment for chronic myeloid leukemia (CML) has improved significantly the overall survival, progression free survival and event free survival of these patients. Achieving complete cytogenetic response (CCyR) is nowadays one the primary objectives of the therapy. *Aims.* Compare the evolution of patients with CML who achieved CCyR at 12 months of therapy (optimal responders) with those with those with less than this response (non-optimal responders).

	Optimal responders (n=46)	Non-optimal responders (n=28)
CHR Median time to CHR	46 (100%) 1 mths (1-4)	28 (100%) 1.5 mths (1-4)
CCyR Median time to CCyR	44 (95.7%) 6 mths (3-12)	11 (39.3%) 16 mths (13-24)
MMR Median time to MMR	33 (71.7%) 16 mths (5-48)	10 (35.7%) 38.5 mths (24-61)
CMR Median time to CMR	16 (34.8%) 25.5 mths (12-63)	2 (7.1%) 39 mths (30-48)
Disease progression	0	2 (7.1%)
Therapeutic discontinuation (switch to 2nd generation TKI)	1 (intolerance)	9 (intolerance/resistance)
Mortality	0	3 (10.7%)

CHR: complete hematologic response; CCyR: complete cytogenetic response; MMR: major molecular response; CMR: complete molecular response; TKI: tyrosine kinase inhibitor

Methods. From May 2001 to March 2010, 88 patients with the diagnosis of CML were treated with Imatinib at our institution. Of these, 74 had a follow-up period longer than 12 months (median = 49 months), with a median age of 58.5 years (20-88). 10 patients were at late chronic phase, with a median time from diagnosis to start of Imatinib of 42,5 months (15-197). Imatinib dosage: 400mg (chronic phase), 600-800mg (accelerated/blastic phase). *Population characterization.* - optimal responders (n=46) - median age at diagnosis 53.5 years (14-78), 23 male/23 female, 42 (91.3%) in chronic phase (Sokal score: low risk 50.0%, intermediate risk 35.7%, high risk 14.3%), 2 (4.3%) in accelerated phase, 2 (4.3%) in blastic phase. 2 patients were in late chronic phase, with a median time from diagnosis to start of Imatinib of 50 months (22-78). Median follow-up 42.5 months (12-105). - non-optimal responders (n=28) - median age at diagnosis 53.5 years (19-81), 14 male/14 female, 26 (92.9%) in chronic phase (Sokal score: low risk 23.1%, intermediate risk 46.1%, high risk 30.8%). 8 patients were in late chronic phase, with a median time from diagnosis to start of Imatinib of 42,5 months (15-197). Median follow-up 60 months (14-105).

The hematologic, cytogenetic and molecular responses were evaluated according to the European LeukeamiaNet recommendations, as well as the development of intolerance/resistance to Imatinib, disease progression and mortality. *Results.* Figure 1. *Conclusions.* The achievement of cytogenetic and molecular responses is associated with an improved event free survival and progression free survival. Patients who fail to have CCyR at 12 months of therapy with Imatinib are less likely to achieve MMR, and have a higher risk of losing their response and of progression to advanced stages of the disease. These results verify the predictive value of obtaining an optimal response at 12 months.

CUPLIKE NUCLEI IN ACUTE MYELOID LEUKEMIA: A SPECIFIC ENTITY WITH INCREASED FLT3 ITD AND NPM1 MUTATION

A Al-Kali, H Kantarjian, C Bueso-Ramos, S Konoplev, A Al-Ameri, S Pierce, M Brendt, E Jabbour, A Quintás-Cardama, S O'Brien, J Cortes

UT MD Anderson Cancer Center, Houston, USA

Background. Cuplike Nuclei blasts have been reported in a small portion of patients (pts) presenting with acute myeloid leukemia (AML). Recent reports showed the close relationship with molecular abnormalities including the gain of FLT3 ITD and NPM1 mutation in a higher percentage than other subtypes. There is little data on the clinical features and outcome of patients with this entity. *Aims.* Describe the clinical outcome of patients with cuplike nuclei blasts. *Methods.* We searched the UT MDACC database for patients with myeloid malignancies with cuplike nuclei morphology (ie, ≥10% blasts with nuclear invagination in ≥25% of nuclear size). Pts were divided into two groups: *de novo* AML (group 1) and relapsed AML or MDS (group 2). Three- or 4-color flow cytometry immunophenotypic analysis was performed on BM aspirates. FLT3 and NPM1 mutations were investigated by polymerase chain reaction followed by sequencing on an ABI Prism 3100 or 3130 Genetic Analyzer. Kaplan-Meier method was used to estimate survival using Statistica 6 software. All patients signed an approved consent. *Results.* Forty-eight pts and 16 pts were identified at UTMDACC between 1998-2009 in groups 1 and 2, respectively. Group 1 had a median age 60 years (range 17-81), 56% were female, and more frequent of M1 morphology (44 pts, 92%). Group 2 had a median age of 62 years (25-76), slight female predominance (56%) and all AML pts classified as M1; 2 pts had a diagnosis of MDS (RAEB). Diploid cytogenetics was more frequent in group 1 *vs.* group 2 (65% *vs.* 44%). Both groups had elevated WBC (median, 44.1 and 35×10^9/L×10^9/L), D-Dimer (2001 and 892) and peripheral blasts percentage (86% and 88%) at start of therapy. In group 1, 27 (56%) pts lacked CD34 expression and 16 (33%) lacked HLA-DR. Ninety four percent of pts with no HLA-DR expression lacked CD34 too. Among evaluable pts, 21/36 (58%) in group 1 and 7/9 (78%) in group 2 had FLT3 ITD. Four out of 36 pts in group 1 and none in group 2 had FLT3 TKD mutation. NPM1 mutation was found in 9/11 (82%) in group 1, 8 (89%) of them with concomitant FLT3 ITD/TKD. CR was achieved in 55% and 60% in groups 1 and 2, respectively. IA based chemotherapy resulted in CR in 16/21 (76%) in group 1 and 8/9 (89%) in group 2. Median overall survival was 275 days for pts in group 1 and not reached in group 2. Of 12 pts who died within 35 days, 7 had molecular testing, and all had FLT3-ITD. *Conclusions.* Cuplike nuclei AML is characterized by frequent association with mutated NPM1 and FLT3 ITD/TKD, absence of both CD34 and HLA-DR, and a high frequency of FAB M1 morphology. This entity is characterized by a poor outcome.

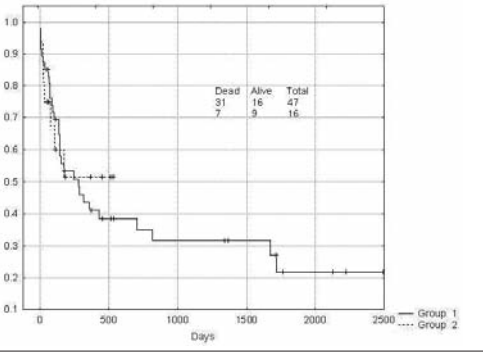

Figure. Overall Survival for group 1, 2.

MANAGEMENT AND OUTCOME OF CML PATIENTS: A TUNISIAN MULTI-CENTER STUDY ABOUT 116 CASES

R Ben Amor,[1] R Ben Lakhal,[2] H Ghedira,[2] H Belaaj,[3] M Laatiri,[4] Y Ben Youssef,[5] N Ben Romdhane,[6] F M'Saddek,[7] S Menif,[8] M Elloumi,[3] A Khelif,[5] B Meddeb[2]

[1]Hospital, Tunis, Tunisia; [2]Aziza Othmana, Tunis, Tunisia; [3]Hedi Chaker Hospital, Sfax, Tunisia; [4]Fattouma Bourguiba, Monastir, Tunisia; [5]Farhat Hached Hospital, Sousse, Tunisia; [6]La Rabta, Tunis, Tunisia; [7]Military Hospital, Tunis, Tunisia; [8]Institut Pasteur, Tunis, Tunisia

Aims. Imatinib was the first treatment for chronic myeloid leukemia (CML) that specifically targeted the causative BCR-ABL transcript, producing high response rates in most patients. In this multicentre study, we retrospectively evaluate cytogenetic and molecular response to Imatinib and analyze the predictive resistance factors and their impact on event free survival (EFS) and overall survival (OS). *Methods.* From July 2002 to June 2009, 116 CML patients were included: 104 in chronic phase (CP) and 12 in accelerated phase (AP). Median age was 44 years (13 - 76 years). Sokal score, calculated in 110 cases, was high in 21 patients (18%), Intermediate in 53 patients (46%) and low in 36 patients (31%). First-line treatment in all patients was Imatinib 400mg/day, initiated at median time of 3 months (1-12months). ELN criteria were used for response evaluation. *Results.* Complete cytogenetic response (CCyR) was achieved in 76% of cases (n=88) with a median of 12 months (3-36 months). Molecular monitoring was performed in 80% of patients (n=93). Major molecular response (MMR) was achieved in 62% of them (n=58) with a median of 18 months (6-48 months). 33% of patients (n=38) were in optimal response (OpR), 46 % (n=53) in suboptimal response (SubOpR) and 21% (n=25) in primary resistance (PR). Imatinib dose escalation benefit to 72% of patients in PR (18/25), only five of them did achieve a CCyR. 11% (n=13) of patients had a secondary resistance and 85% (11/13) of them benefit of dose escalation. No other patient eligible for escalation (SubOpR: n=53) did benefit of IM increase. Predictive factors of CCyR were Sokal score and treatment discontinuation (toxicity or non adherence). Sokal score was the only predictive factor of MMR. The 5 years EFS was 79%. EFS varied according to the CCyR at 6 months (92% *vs.* 58%, P=.00001), the initial disease status (CP: 87% *vs.* AP: 58%; P= .002) and the initial response (PR: 87% *vs.* OpR-SubOpR 68%; P=.008).The 5 years OS was 88%. Only CCyR had a significant impact on OS. MMR had no significant impact on EFS or OS. *Conclusions.* In our study we note that management of resistances and suboptimal responses was not harmonized between the different centers. Despite this difficulty and even in lack of second generation TKI: EFS, OS and rate of CCyR are hopeful and may be compared to those reported in the different publications.

1327

ANALYSIS OF BCR-ABL KINASE DOMAIN MUTATIONS IN HUNGARIAN PATIENTS WITH IMATINIB RESISTANT CHRONIC MYELOID LEUKEMIA AND PHILADELPHIA POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA

N Meggyesi,[1] A Bors,[1] G Halm,[2] S Nahajevszky,[2] A Barta,[2] S Lueff,[2] Á Bátai,[2] P Reményi,[2] T Masszi,[2] S Fekete,[2] G Ujj,[3] A Tordai,[1] H Andrikovics[1]

[1]Hungarian National Blood Transfusion Service, Budapest, Hungary; [2]St. Istvan and St. Laszlo Hospital, Budapest, Hungary; [3]Hetenyi Geza Hospital, Szolnok, Hungary

Background. Standard therapy of Philadelphia (Ph) positive chronic myeloid leukemia (CML) and acute lymphoblastic leukemia (ALL) is the targeted BCR-ABL tyrosine kinase inhibitor (TKI) imatinib mesylate, but mutations in the BCR-ABL tyrosine kinase domain (TKD) may cause imatinib resistance. The second-generation TKIs, dasatinib and nilotinib offer high likelihood of therapeutical success for imatinib resistant patients. *Methods.* We performed mutation analysis of 69 imatinib resistant CML and 2 ALL patients with direct sequencing of BCR-ABL TKD after a two-step nested PCR. In addition to imatinib, 49 of 71 patients also received second generation TKI, nilotinib or dasatinib. Mutation analysis was performed in nilotinib and dasatinib resistance as well. *Results.* In case of 21/71 (30%) imatinib resistant patients 12 BCR-ABL TKD mutations (aa. change M244V, G250E, Y253H, E255V, D276G, E279K, T315I, M351T, F359I/V, L384M, L387M) were detected, with two patients having double mutation. Mutations were found in 32% of chronic-phase (CP) patients, 36% of accelerated-phase (AP) patients and 80% of blast crisis (BC) patients. In CP patients treated with imatinib, frontline mutations were less frequent compared to CP patients treated with imatinib post-IFN failure (10% *vs.* 42%, respectively). T315I mutation was detected only in ALL, but not in CML CP in imatinib resistant patients.The reduction of BCR-ABL/ABL ratio during nilotinib treatment (n=29) did not differ between imatinib-resistant patients with or without mutation on imatinib (baseline mutation), except for cases with mutations E255V, Y253H and F359V/I. In our series, F359I mutation proved to be imatinib resistant similarly to F359V/C. There were not enough cases with baseline mutation among dasatinib treated patients (n=20) to perform this comparison. In case of second generation TKI resistance, the spectra of mutations has changed and less types of mutations were detected. In cases of 7/15 nilotinib-resistant patients, the following new mutations occured: Y253H, T315I, F359V and the following mutations persisted: Y253H, M351T, F359I; one patient had double mutation: Y253H+F359V. 2/14 dasatinib-resistant patients developed new mutations (T315I and T315+E279K). During second generation TKI treatment, the T315I mutation emerged not only in BC but in CP and AP. *Conclusions.* The frequency and type of TKD mutation depends on disease phase and TKI applied. Screening for BCR-ABL TKD mutations is recommended in TKI resistance before changing TKI, because the presence of different mutations may influence the selection of TKI and the therapeutic response.

1328

EFFICACY OF NILOTINIB VERSUS IMATINIB IN ADULT PATIENTS WITH PH+ CHRONIC MYELOID LEUKEMIA IN EARLY CP WHO HAVE A SUBOPTIMAL MOLECULAR RESPONSE TO IMATINIB (RE-NICE MULTICENTER STUDY)

HG Goh,[1] D Kim,[2] SY Choi,[2] SH Kim,[2] JY Kim,[2] S Park,[2] MS Kim,[2] EJ Jang,[2] R Woodman,[3] T Szczudlo,[3] HJ Kim,[3] S Jootar,[4] HJ Kim,[5] SK Sohn,[6] JS Park,[7] SH Kim,[8] DY Zang,[9] SJ Oh,[10] DW Kim[11]

Background. Achievement of major molecular response (MMR) is important in imatinib therapy as it appears to predict for long-term progression-free survival. In IRIS study, progression-free survival was higher for patients who achieved both complete cytogenetic response (CCyR) and MMR, compared to patients who had CCyR but no MMR and patients who did not achieve CCyR. Compared to standard dose of imatinib, higher doses of imatinib are expected to yield higher CCyR and MMR rates, and nilotinib also produces high CCyR and MMR rates in patients with chronic phase (CP) CML who are resistant to imatinib. *Aims.* In this study, the efficacy of nilotinib at 400 mg BID was compared with imatinib at 400 mg BID in suboptimal molecular response patients who received first line imatinib therapy at a daily dose of 400 mg. *Methods.* Adult patients with Ph^+ CML early CP who have achieved a CCyR but no MMR after at least 18 months and up to 24 months (≥18 to ≤24 months) on first line imatinib therapy at a daily dose of 400 mg were enrolled. In nilotinib arm, patients received oral dose of 400 mg BID (800 mg/day), and patients received 800 mg/day administrated as 400 mg BID in imatinib dose-escalation arm. Informed consent was obtained prior to participation in this clinical trial. Primary endpoint is to evaluate the cumulative rate of MMR at 12 months, and secondary endpoints are to evaluate the cumulative rate of CMR and time to and duration of MMR and CMR. Progression-free survival and safety profiles will also be assessed as secondary endpoints. To assess the drug efficacy, cytogenetics and RQ-PCR analysis were performed at regular intervals. Baseline mutational analysis was also performed for every patient, and subsequent mutational analysis was performed in patients demonstrating either lack of response, or disease progression. *Results.* A total of 8 patients were randomized into nilotinib arm (n=4) or imatinib arm (n=4). With a median follow-up of 6 months (range, 1-9 months), all patients have maintained CCyR, and progressive decrease in BCR-ABL transcript level was observed in 7 patients except 1 patient in imatinib arm. (Figure 1). In 1 patient who showed unchanged BCR-ABL transcript level, BCR-ABL (IS%) was 0.24 at baseline and 0.25 at C9D28. Patients treated with nilotinib showed a greater depth of molecular response compared to the patients in imatinib dose-escalation arm, with 1 patient achieving MMR after 1 month of nilotinib therapy. Although toxicity was observed more frequently in imatinib dose-escalation arm, no patient required dose reduction or discontinuation of therapy due to toxicities in both randomized groups. *Conclusions.* These data show that both nilotinib and imatinib are generally well tolerated at a daily dose of 800 mg. This promising preliminary results demonstrating progressive decrease in BCR-ABL transcript level, support the potential of further clinical investigation in which the efficacy of early intervention of suboptimal molecular response using nilotinib or dose escalation of imatinib will be assessed on a large patient population and longer period of observation.

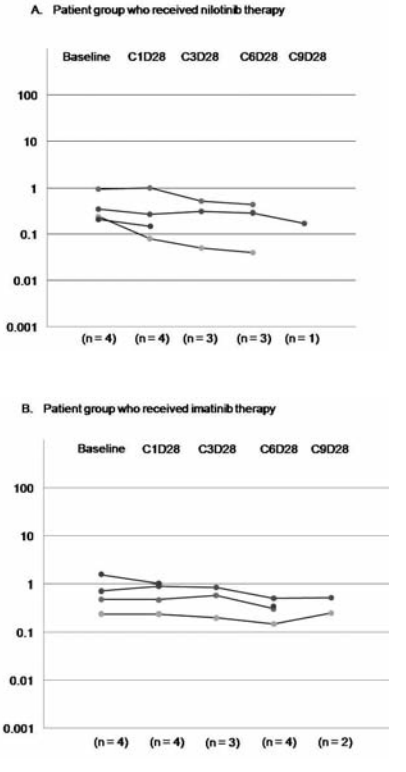

Figure 1. RQ-PCR follow-up.

USING OF DASATINIB FOR TREATMENT IMATINIB-RESISTANT AND IMATINIB-INTOLERANT PATIENTS WITH CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE. RUSSIAN EXPERIENCE OF DASATINIB TREATMENT

N Khoroshko, O Vinogradova, A Turkina, A Voroncova, E Chelysheva, G Gusarova, S Kuznetsov, S Gorjacheva, M Sokolova, E Abakumov, O Lazareva, E Domracheva, A Misyurin

National Research Center for Hematology RAMS, Moscow, Russian Federation, Moscow, Russian Federation

Objectives. Resistance to imatinib therapy is an unmet medical need in CML treatment. The one of pathway for decision this problem is in using of second line of TKI. The aims of this article are to describe the subanalysis and representation of subanalysis data covering dasatinib efficacy and tolerability from Russian patients who did participate in the international randomized trials Dasatinib 140 mg *vs.* imatinib 800 mg (START-R) and the dose optimization study 034. Totally there were 101 patients with dasatinib treatment in the Start-R international randomize trial and 670 patients in the 034 international dose optimization study. *Materials.* In the Russian Hematology Research Center we treated 36 (7 patients from START-R, 11 patients from 034 study and 11 patients from compassion use) adult patients with chronic phase CML with dasatinib. Median of age was 52 years (range 17-72). Median time from diagnosis to dasatinib treatment was 63 months (range 16-241). Patient was treated with hydrea, a-interferon and imatinib. Median of imatinib treatment was 0,5 months (range 0,3-33). *Results.* Duration of dasatinib treatment until March 2009 was 28 months (range 2-44). There were no cases of death during dasatinib treatment. Two patients died after discontinuing dasatinib, due to progression of CML. Complete hematological response were observed in 89% patients receiving dasatinib, major cytogenetic response in 57% patients, complete cytogenetic response in 43%, major molecular response in 25%, complete molecular response in 16%. Three patients were resistant and one patient had intolerance. Hematological toxicity 3-4 grade was described in 12(33%) patients. Non-hematological toxicity 3-4 grade was in 7 (19%) patients. Pleural effusion was diagnosed in 6(17%) patients. Dose interruptions of dasatinib were required in 15(42%) and dose reductions were noted in 15(42%) patients. The patients who had a dose reduction or a dose interruption have restarted their treatment in initial dose. Dasatinib treatment was discontinued for one patient with pleural effusion and complete molecular response is remaining during one year without any treatment. 26 (66%) patients continue therapy with dasatinib. *Conclusion.* Results from trials in Russian Hematology Research Center are the same as in international study. Dasatinib is effective and well tolerated therapeutic option for imatinib-resistant patients with chronic phase of CML.

1330

RENAL FAILURE ASSOCIATED TO TYROSINE KINASE INHIBITORS

L Luciano,[1] C Cerchione,[2] R Ciancia,[1] F Pane[1]

[1]University Federico II, Naples, Italy; [2]Hematology DBBM, Naples, Italy

Some studies suggest that tyrosine kinase inhibitors may cause renal failure, as rare side effect of this treatment. We report here cases of seven patients, four male and three female, who developed subacute or acute renal failure in our Department during tyrosine kinase inhibitors treatment. The significant biochemical data of the patients are summarized on Table 1. Of seven patients, two patients showed mild renal failure at diagnosis, one patient developed severe renal failure after seven years of Imatinib therapy, four patient showed mild renal failure during TKIs therapy. In detail, the two patients (PA and PC) who showed mild renal failure at the time of diagnosis of CML were 71yo and 68yo respectively. Both patients received Imatinib therapy for 10 years and 5 years, respectively. They showed a gradual worsening of their renal failure during the time, until now, with needed of eritropoietin support and aproteic diet. In one of two, the renal failure didn't solve after switch to Dasatinib (April 2007) when there was the worsening of renal failure, neither with Nilotinib. They are now in CHR, CCyr and MMR. The only one patient who died (AC), received diagnosis in 1999 and he started Imatinib in 2002; he showed severe renal failure in 2009 after seven years of Imatinib therapy. He died after two months for acute renal failure. The remaining 4 patients had a median age at diagnosis of 69.7 yo (66-77). All of them received imatinib therapy for a median period of 4.5 years (3-7) at the first signs of renal failure; one of them showed mild renal failure after 6 month to switching to Dasatinib for secondary resistance to Imatinib. In this case, the renal failure didn't solve neither after the switch to Nilotinib (May 2009) for appearance of F317L mutation. All 4 patients are at moment in CHR, CCyR and in suboptimal molecular response, with mild signs of renal failure, continuing three Imatinib and one Nilotinib therapy with good compliance. Renal failure can be considered as an extremely rare adverse event of TKIs. In our cases the renal failure developed gradually, and the patients with pre-existing renal disease showed a slight worsening. It is not really clear what is the real role of TKIs in renal failure onset. Some reports suggest the role of the TKIs in inhibiting signalling pathways which may play a role in renal injury. The responsible mechanism could be the inhibition of other tyrosine kinase receptors expressed in the kidney, with a consequent tubular disfunction. The alterated metabolism of Calcium and Phosphorous might be another possible cause, as suggested by some reports. All these mechanisms could have a role when predisposing factors (age, diabetes, hypertension) or pre-existing renal failure are present. In conclusion, TKIs-related nephrotoxicity may be a relatively rare side effect in CML patients. An accurate biochemical follow-up, especially in older patients and in patients with predisposing factors, it would be useful before the treatment and during the follow up of the disease.

PREVALENCE OF BCR-ABL IMATINIB RESISTANT MUTATIONS IN PORTUGUESE CHRONIC MYELOID LEUKAEMIA (CML) PATIENTS

A Palmeiro, F Torres, R Lemos, M Teixeira, H Gabriel, P Rendeiro, M Tavares

CGC Genetics, Porto, Portugal

Background. The Tyrosine Kinase inhibitor Imatinib Mesylate (IM) is the current standard treatment in patients with in Chronic Myeloid Leukemia (CML). However, there are patients who do not respond to Imatinib or, after an initial response, develop resistance. There are several resistance mechanisms that can either be BCR-ABL dependent (genomic amplification and point mutations in BCR-ABL fusion gene) which are the main mechanism of acquired resistance or BCR-ABL independent. In these patients Dasatinb has proved to be an efficient therapeutic alternative. *Aims.* To identify the mutation frequency and mutation pattern in ninety (90) CML patients filling criteria for acquired resistance to imatinib therapy. *Methods.* BCR-ABL quantification was done according to EAC protocol. Mutation screening was done by automatic sequencing of a RT-PCR-amplified segment including the BCR-ABL Tyrosine Kinase domain. Karyotype was performed according to standard procedures. *Results.* BCR/ABL mutations were identified in thirty five patients (38.9%). In this cohort a total of 20 different IM resistant mutations (18 known and 2 new), 1 polymorphism and 1 unknown variant were identified. Seven patients had more than one BCR/ABL mutation. In the remaining fifty five (61.1%) some had complex karyotypes with complex Philadelphia variants or additional cytogenetic abnormalities (30%) and the remaining (31.1%) showed no alterations. *Summary/Conclusions.* The distribution of the mutations was: D276G in 5 cases, G250E, E255K, T315I, M351T and H396R in 4 cases, Y253H, E255V, F317L and L387M in 2 cases and mutations M244V, F359I, M388L, A397V, F416S, S438C, E450K, E453K, E459K and F486S in 1 case each. Although these results are according with the most frequently mutated amino acids reported, there are some differences such as for the D276G mutation, that in this cohort has the highest frequency and for F359 variants, which in this cohort are less represented. The polymorphism K247R was identified once, as well as the variation G383G. This last variant hasn't been described yet and was found together with the mutations H396R and A397V. This data indicate a possible variability among different populations and emphasize the fact that patients who fail IM therapy should undergo mutational analysis to define a more efficient treatment.

1332

THE IMPACT OF AGE ON THE EFICACY AND TOXICITY OF IMATINIB TREATMENT IN CHRONIC MYELOID LEUKEMIA

P Santos-Sousa, L Guerra, B Gomez, S Valle, C Lopes, J Raposo, C Martins, MJ Costa, G Esteves, J Fajardo, J Forjaz Lacerda, J Alves do Carmo

Hospital de Santa Maria - Centro Hospitalar Lisboa Norte, EPE, Lisboa, Portugal

Background. Imatinib has become the gold standard in general practice for chronic myeloid leukemia (CML). Old age has been classically considered a feature of bad prognosis for CML. Imatinib has changed dramatically the course of the disease and is forcing the clinicians to reassess the importance of previously considered indicators of prognosis. *Aims.* Evaluate the efficacy and tolerability profile of Imatinib in elderly patients (≥ 65 years) with CML, in comparison to younger patients (< 65 years). *Methods.* This is a retrospective study, including all patients treated with Imatinib in our institution, from May 2001 to March 2010 (n=88 patients). *Population characterization.* - elderly patients (n=22) - median age at diagnosis 71.5 years (65-86), 11 male/11 female, 21 (95.5%) in chronic phase (Sokal score: low risk 52.3%, intermediate risk 28.6%, high risk 19.1%), 1 (4.5%) in accelerated phase. Median follow-up 49.5 months (6-87). - younger patients (n=66) - median age at diagnosis 47 years (14-64), 32 male/34 female, 60 (90.9%) in chronic phase (Sokal score: low risk 33.3%, intermediate risk 41.7%, high risk 25.0%), 4 (6.1%) in accelerated phase, 2 (3.0%) in blastic phas. Median follow-up 38.5 months (3-105). *Therapeutic regimen.* Imatinib 400mg (chronic phase), 600-800 mg (accelerated/blastic phase). The hematologic, cytogenetic and molecular responses were evaluated according to the European LeukeamiaNet recommendations, as well as the therapy associated toxicity, the disease progression and the mortality.

	Younger patients (n=66)	Elderly patients (n=22)
CHR	66 (100%)	22 (100%)
Median time to CHR	1 mths (1-4)	2 mths (1-4)
CCyR	45 (68.2%)	15 (68.1%)
Median time to CCyR	6 mths (3-23)	8 mths (3-24)
MMR	32 (48.5%)	10 (45.5%)
Median time to MMR	18 mths (4-57)	18 mths (6-50)
CMR	13 (19.7%)	5 (22.7%)
Median time to CMR	27 mths (12-63)	30 mths (12-36)
Disease progression	2 (3.0%)	0
Hematologic toxicity (grade≥3)	4 (6.1%)	2 (9.1%)
Non hematologic toxicity (grade≥3)	3 (4.5%) - hepatic	1 (4.5%) -hepatic
Therapeutic discontinuation (switch to 2nd generation TKI)	10 (15.2%) (intolerance/resistance)	2 (9.1%) (intolerance/resistance)
Mortality	4 (6.1%)	1 (4.5%)

CHR: complete hematologic response; CCyR: complete cytogenetic response; MMR: major molecular response; CMR: complete molecular response; TKI: tyrosine kinase inhibitor

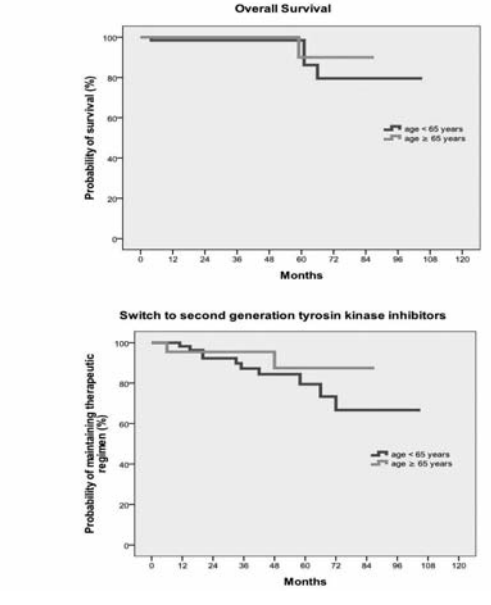

Figure 1.

Results. Figure 1. *Conclusions.* The results suggest that Imatinib treatment is equally effective in young and in elderly patients, having the same toxicity profile. The establishment of tyrosine kinase inhibitors as the standard first line therapy in CML has lessened the negative impact of age on the prognosis of CML.

1333

MUTATIONS OF THE BCR-ABL- KINASE DOMAIN EXPLAIN THE IMATINIB FAILURE ONLY IN A MINORITY OF PATIENTS WITH CHRONIC MYELOID LEUKEMIA

D Jardan,[1] R Talmaci,[1] D Coriu,[2] M Dragomir,[2] I Ursuleac[1]

[1]*University of Medicine and Pharmacy Carol Davila, Bucharest, Romania;* [2]*Fundeni Clinical Institute, Bucharest, Romania*

Background. The tyrosine kinase inhibitor Imatinib have opened a new era in CML treatment by allowing a targeted disruption of a signalling pathway believed to be crucial for leukemia maintenance. However, soon it was realized that point mutations in ABL kinase domain are responsible for aquired resistance and poor outcome especially for patients with mutations affecting P-loop domain. Clinical impact of imatinib-resistance mutations in CML is still elusive due to controversial reports in literature. *Aims.* our aim was to asses the importance of mutational status for patients with failure or suboptimal response to imatinib. *Methods.* we used a semi-nested PCR for the amplification of the kinase domain of BCR-ABL fusion gene, followed by direct sequencing (Sanger method). This method allows identification of mutations when mutated clone have reached an abundance threshold of ~20-25%. *Results.* from 230 patients in monitoring in our center 35 were referred for mutation detections due to failure or suboptimal response to imatinib. The following mutations were identified: E450K, E459K, F359V, M244V, E255K, L387M, E450A, Q252H in seven patients. Five patients presented single mutation in ABL kinase domain and two patients presented two mutations. Patients with two mutations presented L387M + M244V and respectively, E450A+Q252H. For these seven patients clinical evolution of disease was evaluated: five patients have better clinical evolution after changing treatment to second generation TKIs (nilotinib for two patients and dasatinib for three patients) and two patients died with progressive disease despite changing the therapy to dasatinib. *Summary.* identification of the ABL kinase domain mutations is an important prognostic factor for clinical outcome of patients presenting failure or suboptimal response to imatinib treatment, but presence of these mutations can explain unsatisfactory response only in some patients (seven of thirty-five). For better clinical management, we need new tools able to give us, in real time, a comprehensive information about TKIs efficiency.

This work was supported by the grant PN 41-087 from the Romanian Ministry of Research and Technology. The authors express their gratitude to European LeukemiaNet for their permanent support.

REFRACTORINESS TO IMATINIB - A SINGLE CENTRE EXPERIENCE

J Diamond, M Tomé, A Parreira, A Almeida

Portuguese Institute of Cancer, Lisbon, Portugal

Background. Imatinib (IM) is the first line drug therapy for patients (pts) with chronic myeloid leukemia (CML). While the efficacy of IM is unquestioned, persistence of minimal residual disease and the development of resistance had a significant impact on the clinical management of CML. The mechanisms of resistance have been extensively studied and the search for more efficacious agents to overcome Imatinib failure is still on going 1. *Aim.* To assess the incidence of tyrosine kinase inhibitor (TKI) resistance in CML pts treated in our centre and estimate the mutational rate in this group of pts. *Methods and Results.* 63 pts with a medium follow-up of 46 months (mo) on conventional dose IM therapy were serially monitored by RQ-PCR for BCR-ABL transcripts in peripheral blood samples according to Leukemianet guidelines. Screening of BCR-ABL mutations was performed by direct sequencing covering the entire tyrosine kinase domain (KD). Forty (63%) pts responded to IM (mean follow-up 52 mo). IM was first line therapy in 23/40 (57%). The others received IFN-alfa (36%) or BMT (7%) prior to IM therapy. MMR was obtained after a medium time of 12 mo. Five pts achieved sustained CMR . Twenty three (37%) failed IM therapy after a mean follow-up of 31 mo. Kinase domain (KD) mutations were detected in 7 pts (30%): F317L, E459K, E255K, E255V, M351T, T315I and one pt bearing two mutations L387 (++)/ D276G(+). Five IM resistant pts died, four with disease progression. KD mutations were detected in three pts

after a median follow-up time of 10 mo (range 4-61): F317L, E459K and E255K. Pts bearing F317L and E459K died in myeloid blast crisis and E255K pt in lymphoid blast crisis. The three pts with mutations were treated with Dasatinib but CCyR was never achieved. The remaining 18/23 IM resistant pts received IM during a mean time of 34 mo. None had disease progression and KD mutations were detected in four pts: E255V, M351T, T315I and one pt bearing two mutations L387 (++)/ D276G(+). Fourteen pts (14/23, 22%) with IM failure received Dasatinib therapy for a mean time of 16 mo (range 40-2), of which only two obtained MMR, one with M351T and one with primary resistance and no mutations. Of the Dasatinib refractory pts, one is on HU awaiting BMT and four were switched to Nilotinib. Following a mean time of 11 mo (range 27-16), no major molecular responses were observed in the latter group. *Conclusions.* Careful molecular monitoring according to European Leukemianet Guidelines2 allow early detection of resistance and optimal disease management. The long-term efficacy of second-generation TKIs may also be related to specific BCR-ABL mutations3. We highlight that in our experience only 7/23 pts with IM failure developed KD mutations and that BCR-ABL over expression, drug efflux an influx transporters and BCR-ABL independent mechanisms of resistance may also play a role in IM performance. Choice of therapy should be guided by multiple factors, including mutational analysis, disease phase, patient characteristics, and the safety profile of the agents.

1335

A CASE REPORT WITH E6A2 BCR-ABL FUSION TRANSCRIPT WITH MARKED BASOPHILIA AND HIGH ACTIVATION OF SRC KINASES DOWNSTREAM BCR-ABL

M Divoka,[1] P Rohon,[2] L Calabkova,[3] R Mojzikova,[3] A Novosadova,[2] E Faber,[2] M Jarosova,[2] M Holzerova,[2] K Indrak,[2] V Divoky[3]

[1]Faculty Hospital, Olomouc, Czech Republic; [2]Hemato-Oncology, University Hospital and Faculty of Medicine, Olomouc, Czech Republic; [3]Biology, Faculty of Medicine Palacky University, Olomouc, Czech Republic

Background. Most cases of chronic myeloid leukemia (CML) carry *BCR-ABL* fusion transcripts β2α2 or β3α2 in major BCR region, other fusion transcripts are rare. Until now, *BCR-ABL* fusion transcript e6a2 with breakpoint in intron 6 of the *BCR* gene was detected only in a few CML cases. *Methods.* RT-PCR and sequencing were used to detect the type of *BCR-ABL* transcript. *BCR-ABL* mutational status was assessed by sequencing of the RT-PCR products. The *in vitro* test of sensitivity to TKIs was based on detection of inhibition of phosphorylation of Crkl and Src family kinases (SFK, Tyr416) using immunoblotting. *Features at presentation.* A 51-year-old man presented in January 2010 with 3-week symptoms linked to marked splenomegaly. *Laboratory results.* HGB 7.3 g/dL, WBC 150.3×10^9/L (neutrophils 18%; lymphocytes 2%; eosinophils 18%; basophils 45%; metamyelocytes 4%; myelocytes 5%, promyelocytes 6%, blasts 2%) and PLT 36×10^9/L. Severe anemia and trombopenia were asymptomatic. Cytogenetics revealed 90% of Ph+ cells in the bone marrow (iFISH 278/308 BCR-ABL+ nuclei) with no additional clonal chromosomal abnormalities. Laboratory results implied CML in accelerated phase. Sokal risk was intermediate. Sequencing analysis of amplified BCR-ABL transcript revealed a rare e6a2 fusion, with no evidence for Bcr-Abl kinase domain mutation. Western blot analysis revealed high activation (phosphorylation) of Crkl and the Src family of kinases (P-SFK) in the patients' sample. *In vitro* test of sensitivity of the patients' leukemic cells to imatinib showed sensitivity of Bcr-Abl tyrosine kinase to imatinib (as assessed from P-Crkl monitoring), and a complete elimination of P-SFK, suggesting, that P-SFK represents only Bcr-Abl-dependent SFK activity. *Treatment results.* Cytoreduction was performed with hydroxyurea. Dose of imatinib was 400mg daily. After 2 weeks of imatinib further drop in platelets demanded transfusion of packed platelets. Moreover, G-CSF was indicated for severe neutropenia, while the imatinib dosage was reduced to 400 mg 5 days weekly. At 3 weeks of imatinib therapy (a week after G-CSF) complete resolution of splenomegaly and marked laboratory improvement was observed: HGB 9.6 g/dL, WBC 9.8×10^9/L (eosinophils 1%; basophils 14%), PLT 425×10^9/L. A search for voluntary hematopoietic stem cell donor was started. *Conclusions.* A higher frequency of advanced CML phases has been suggested for the patients with e6a2 rearrangement, but with good initial responses to imatinib. The patient presented here adds additional knowledge to the e6a2 patients: he presented marked splenomegaly, basophilia, severe trombopenia and anemia and a high activation of SFK downstream Bcr-Abl. Further follow-up of the patient should bring novel insights into prognosis of patients with rare e6a2 BCR-ABL transcript variant encoding for Bcr-Abl kinase with possibly enhanced oncogenic potential. *Acknowledgement.* Supported by grants NS9949-3 (Ministry of Health) and MSM 6198959205 (Ministry of Education, Youth and Sports) of the Czech Republic.

SUCCESSFUL PREGNANCIES IN CHRONIC MYELOID LEUKAEMIA MALE PATIENTS ON IMATINIB THERAPY.

L Luciano,[1] C Cerchione,[2] R Ciancia,[1] F Pane[1]

[1]University Federico II, Naples, Italy; [2]Hematology DBBM, Naples, Italy

Imatinib represents the first line management in chronic myeloid leukemia (CML).This therapy has changed the natural history of disease, so that the management of disease must now to adapt to the patient's lifestyle. So, it is not unusual that some patients may hope to have a child. Otherwise, we know that Imatinib therapy has potential teratogenicity in animal, but the effect during conception and pregnancy in human is not clear so far. We report here on 4 healthy pregnancies conceived from four male patients on long-term imatinib therapy. The first patient received CML diagnosis in 1990 at the age of 27y. After interferon therapy, he underwent to stem cell auto transplantation in 1998; in march 2000 he started imatinib at full dose. In October 2006 the patient showed BP of CML and he switched to Dasatinib. Then, for not compliance to therapy, he switched to Nilotinib until July 2008, when he showed a new BP of CML and he died in September 2008. During Imatinib therapy the patient underwent to sperm criopreservation; in 2007 the wife began pregnant and in 2008 and she delivered three healthy babies. The other patient, after a CML diagnosis in May 2002, when he was 34 yo, started imatinib in May 2003. In May 2005 he showed AP of CML and during this period the partner began pregnant and after 34 weeks she delivered an healthy baby. The patient switched to Dasatinib in July 2005 and he is already treated with that drug in complete cytogenetic and major molecular response. The third patient had CML diagnosis in February 2006 at age of 39y, starting Imatinib therapy in march 2006. The patient's partner had an history of recurrent spontaneous abortions, but she began pregnant in 2008 while the partner was receiving Imatinib. They had an healthy baby after 34 weeks of pregnancy. The last patient received CML diagnosis in March 2004 when he was 26yo, starting Imatinib at full dose. This treatment led to complete cytogenetic response after one year with major molecular response in 24 months. The patient's partner conceived in 2009 during Imatinib treatment. After 34 weeks, she delivered an healthy baby. In this report all patients were on prolonged Imatinib treatment. In all the babies were not observed structural malformations and they all have normal growth and development until now. There is an increasing evidence that children born to men who were taking Imatinib at time of conception do not have an increased risk of congenital malformations or increased risk of pregnancy associated complications. It is useful anyway to be advised patients in Imatinib therapy to practice adequate contraception, even if for male patients fathering children can be achieved without interruption of treatment.

1337

PRIOR THERAPY WITH INTERFERON IMPROVES THE RESULTS OF SECOND-LINE TREATMENT OF CHRONIC MYELOID LEUKEMIA WITH IMATINIB

K Kotlyarchuk,[1] A Lukjanova,[1] L Lukavetskyy,[1] Y Karol,[1] O Danysh,[1] M Lozynska,[2] Z Maslyak[1]

[1]SI Institute of Blood Pathology and Transfusion Medicine, UAMS, Lviv, Ukraine; [2]SI Institute of Hereditary Pathology, UAMS, Lviv, Ukraine

Background. Treatment of chronic myeloid leukemia (CML) with imatinib mesylate (IM) administered frontline covers only about 50% of all patients in Ukraine due to certain reasons. Therefore the issue of adequate treatment of these patients for the time they are on a waiting list for the drug, which may last from 6 to 12 months, is of current importance in our country. *Methods.* The group of 77 patients with CML treated with imatinib for 2-4 years was analyzed for treatment efficacy. Among these patients 16 took the drug frontline (group 1); 35 patients were treated with imatinib after prior therapy with interferon alfa (group 2); another 26 patients were pretreated with hydroxyurea and in more rare cases - with busulfan (group 3). The dose of imatinib was 400-800 mg daily. *Results.* In the first group of patients major cytogenetic response (MCyR) was achieved in 64% of patients at 6 months and in 68% of patients at 12 months. Two of these patients (12%) developed blast crisis in 3 and 4 months after imatinib introduction. Both of them were qualified as high risk group, their daily dose of imatinib was 600 mg. All the other patients developed complete cytogenetic response

(CCyR) at 24 months. In the second group of patients mean duration of interferon alfa treatment prescribed for the chronic phase of CML was 21,2 months before imatinib initiation. Similarly to the first group MCyR was achieved in 62% of patients at 6 months and in 71% - at 12 months. Blast crisis was diagnosed in 5 patients (14.3%). Complete CyR was achieved and remained stable in 66% of patients at 24 months. Among the patients of the third group MCyR was achieved only in 15 % of patients at 6 months and minor cytogenetic response - in 35% of patients at the same time point. Rest of the patients in this group had no cytogenetic response at all. The proportion of patients expressing major cytogenetic response increased to 19% at 12 months and subsequently to 23% - at 24 months. Blast crisis was diagnosed in 7 of 26 patients (27%); 5 of them were pretreated with busulfan. *Conclusions.* The results of this study show that the level of cytogenetic response and rate of transformation to the blast crisis were similar in patients taking imatinib frontline and in those who took the drug as second-line treatment after prior therapy with interferon alfa. Significantly worse results were revealed in patients pretreated with hydroxyurea and busulfan for the long period of time. One may conclude that in treatment naïve patients and in patients pretreated with interferon there may remain preserved a pool of Ph-negative hemopoietic cells able to replace the leukemic clone in bone marrow after treatment with imatinib. Therefore in case there is no possibility to administer imatinib frontline due to various reasons, initial treatment with interferon alfa is probably an optimal option for patients with CML as pretreatment with other cytostatic drugs can significantly reduce the response rate for subsequent treatment with imatinib.

RESULTS OF CHRONIC MYELOID LEUKEMIA TREATMENT BY IMATINIB IN UKRAINE

I Dyagil,[1] I Dmytrenko,[1] J Minchenko,[1] T Perekhrestenko,[2] N Tretyak,[2] V Fedorenko,[1] Z Martina,[1] N Babkina,[1] V Bebeshko[1]

[1]Research Centre of Radiation Medicine AMS of Ukraine, Kiev, Ukraine; [2]Institute Hematology and Transfusiology AMS of Ukraine, Kiev, Ukraine

Background. Up-to-date therapy of chronic phase of chronic myeloid leukemia (CML) is based on using of tyrosine kinase inhibitors. The application of imatinib for treatment of CML in Ukraine have been actively started since 2008. *Aims.* To estimate the efficiency of imatinib application in CML patients after 12 months of treatment . Here, we present a restricted analysis of Ukraine cohort of CML patients. *Methods.* In research we included 558 patients with the chronic phase CML in age from 18 to 80 years old. Clinical data were collected at most recent visit and retrospectively through clinical chart review and Sokal Score. Diagnostics and monitoring of CML was conducted on the basis of cytogenetic examination of bone marrow cells by G - banding, and also molecular-genetic research of bone marrow and peripheral blood cells by the RT - PCR. 35% patients have got imatinib as the first line therapy and 65% patients have taken other medicinal preparations before (hydroxyurea, busulfan, interferons). Duration of prior treatment was 4-120 months. *Results.* Results of CML patients monitoring were estimated after 12 months of imatinib treatment according to recommendations of ELNet 2010. A complete cytogenetic response was got for 35% patients, partial cytogenetic response with level of Ph-chromosome <35% was revealed in 25% patients. 40% patients had more than 35% Ph-positive cells in bone marrow after 1 year of imatinib taking. The hematological toxicity during the imatinib reception developed as anaemia (Hb<80 g/L) in 3% patients, leukocytopenia ($<2\times10^9$/L) - 4% patients, thrombocytopenia ($<50\times10^9$/L) - in 7% patients. 2% patients discontinued imatinib during the follow-up period because of hematological and unhematological toxicity of preparation. For patients who have got imatinib as the first line therapy, frequency of complete cytogenetic response was significantly higher, than for the pre-treated patients (P<0.05). The least level of complete cytogenetic response was among patients getting busulfan before in comparison with patients who were pre-treated by other preparations (P<0,05). *Conclusions.* Treatment of chronic phase CML by imatinib is the most effective as the first line therapy in comparison with pre-treated patients, especially patients, who have taken busulfan.

1339

SEQUENTIAL CHRONIC MYELOGENOUS LEUKEMIA (CML) AND CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) - 3 CASE REPORTS

I Skoumalova,[1] R Urbanova,[2] P Rohon,[2] E Faber,[2] M Divoka,[2] Z Pikalova,[2] M Jarosova,[2] K Indrak[2]

[1]University Hospital, Olomouc, Czech Republic; [2]Department of Hemato-Oncology, University Hospital and Faculty of Medicine, Olomouc, Czech Republic

Background. Incidence of second malignancies in CLL is well-known. Coincidence of CLL and CML is a rare event. We report three patients in whom CLL and CML were diagnosed sequentially. The possibility that both diseases may arise from the same clone may have important implications for pathogenesis and clinical management. *Results.* CASE 1. A 57-year-old man was diagnosed with B-CLL by immunophenotyping indicated due to non-symptomatic lymphocytosis in October 2007. Clinical stage was Binet A, karyotype +12, IgVH gene unmutated. Due to short lymphocyte doubling time one cycle of fludarabine and cyclophosphamide was given. After recovery leukocytosis with immature granulocytes was observed and Ph-positive CML with $\alpha2\beta3$ BCR-ABL was diagnosed in August 2008 (Sokal risk intermediate). Patient started treatment with imatinib 400 mg daily in September 2008 and achieved complete cytogenetic response (CR) in May 2009 and major molecular response (MR) in January 2010. Curiously a third malignancy - lung adenocarcinoma (clinical stage IV, T1N3M1 with spread to mediastinal lymph nodes and blade bone) was diagnosed in June 2008. While imatinib treatment was ongoing, gemcitabine was added. The patient is currently alive in satisfactory condition. CASE 2. A 57-year-old man was diagnosed with Ph-positive $\alpha2\beta3$ BCR-ABL CML in July 2009 due to non-symptomatic leukocytosis (Sokal high risk). He started therapy with imatinib 400 mg daily in August 2009 and achieved major CR in January 2010. In February 2010 absolute lymphocytosis and thrombopenia were observed. Immunophenotyping confirmed B-CLL; ZAP 70 was negative, IgVH gene unmutated. Clinical stage was Binet A and no treatment for CLL was indicated. However, acceleration of CML with 30 % of basophiles was observed the same month. Patient was converted to dasatinib and the possibility of allogeneic stem cell transplantation has been discussed. CASE 3. A 71-year-old man was diagnosed with Ph-positive $\alpha2\beta2$ BCR-ABL CML in December 1999. He was treated with interferon alfa and oral AraC. No CR was achieved and because interferon toxicity, patient was assigned to imatinib 400 mg per day in July 2001. Complete CR was achieved in January 2006, major MR was not achieved. Due to absolute lymphocytosis immunophenotyping was indicated and B-CLL (clinical stage Binet A, karyotype with deletion 13q14, IgVH gene mutated) confirmed in September 2004. No therapy was required until February 2009, when chlorambucil and prednisone was given for anemia and short lymphocyte doubling time. Imatinib was interrupted during CLL therapy and cytogenetic progression was observed. Despite reintroduction of imatinib hematologic progression with thrombocytemia and F311L mutation of tyrosine kinase domain developed and patient is now assigned to 2nd generation tyrosine kinase inhibitor. *Conclusions.* In neither of abovementioned cases common origin of CLL and CML was demonstrated. Sequential occurrence of CML and CLL due to the prolongation of patients´ survival might be a more frequent event in the future. Clinical management of these patients may be challenging. *Acknowledgement.* This work was supported by the grants NS9949-3 (Ministry of Health) and MSM 6198959205 (Ministry of Education, Youth and Sports) of the Czech Republic.

DASATINIB IS A POTENT AGENT IN SECOND LINE TREATMENT FOR CHRONIC PHASE CHRONIC MYELOID LEUKEMIA PATIENTS - SINGLE CENTER EXPERIENCE

J Dybko, E Medras, O Haus, J Jazwiec, E Duszenko, A Jaskowiec, M Chmielewska, K Kuliczkowski

Wroclaw Medical University, Wroclaw, Poland

Background. Dasatinib 100 mg once daily is approved for chronic-phase chronic myeloid leukemia patients resistant or intolerant to Imatinib. According to European Leukemia Net recommendations failure to Imatinib first-line in early chronic phase is defined as less than complete cytogenetic response (CCyR) after 12 months of treatment or loss of CCyR at any time during treatment. We tried Dasatinib efficacy with a 6 months minimum follow-up in 16 patients resistant to Imatinib.

Patients. All 82 patients of our center with Philadelphia chromosome (Ph) - positive chronic myeloid leukemia in first chronic phase were initially treated with Imatinib in standard dose 400 mg once daily. In the first group of 12 patients of this front-line treatment failed in one-year observation - they did not achieve any cytogenetic response. In one case E450Q mutation was detected and reported to be sensitive to Dasatinib. The second group consisted of 4 patients who lost CCyR in a median period of 40 months since the start of Imatinib. No mutations were detected in this group. All 16 patients were switched to Dasatinib 100 mg once daily. *Results.* Among these 16 patients observed for at least 6 months, 11 patients (69%) achieved CCyR and 8 patients (50%) achieved a major molecular response (MMR). There were differences in response rate by groups. In the first group of 12 patients primary resistant to Imatinib CCyR and MMR were achieved by 7 (58%) and 4 (33%) patients respectively. All patients in the second group achieved CCyR and MMR by 6 months. Grade 3 or higher neutropenia and thrombocytopenia occurred in 31% and 25% of patients respectively. Nonhematologic toxicity was grade 1 or 2. All patients are alive and all Dasatinib responders are still maintaining CCyR. 3 of 5 patients who failed Dasatinib therapy were eligible for allogeneic bone marrow transplantation. *Conclusions.* In our center experience Dasatinib as a second line therapy for first chronic phase myeloid leukemia patients resistant to Imatinib produces high rates of CCyR and MMR with an acceptable toxicity profile.

1341

TRABECULAR BONE DENSITY INCREMENT IN CML PATIENTS UNDERGOING IMATINIB THERAPY

J Groiss Buiza,[1] I Rangel Bravo,[2] R Ramos Fernandez de Soria,[2] E Delgado Casado,[1] A Blesa Sierra,[1] A Corbacho Hernandez,[1] C Lopez-Santamaria,[1] J Benitez Rodriguez,[3] R Bajo Gómez[1]

[1]Infanta Cristina Hospital, Badajoz, Spain; [2]Mérida Hospital, Mérida, Spain; [3]Facultad de Medicina, Badajoz, Spain

Background. Several studies have demonstrated that Imatinib, a tyrosine kinases inhibitor, alters calcium and phosphate metabolism. 1. We evaluated if these alterations are related to a bone-metabolic disbalance. 2. We propose a possible explanation for the abnormalities in bone and mineral metabolism. *Methods.* Transversal analysis of CML patients treated with Imatinib from April 2006 to february 2010: 18 patients, 8 male (44.4%) and 10 female (55.6%), with a median age of 56 years (25-83), in treatment with a median daily Imatinib dose of 511 mg (400-800), for a median period of 41 months (1-83). Twenty one patients with myeloproliferative sindromes Philadelphia chromosome negative served as internal controls: 10 male (47,6%) and 11 female (52,4%), with a median age of 54 years (28-80). We evaluated bone mineral density (BMD) by fotonic dual absorciometry at the beginning of the study, 24 and 48 months later. Trabecular bone volume (TBV) was determined in patients and controls by microscopic study of bone marrow biopsies with an ocular-mounted Weibel II graticule (40x). We calculated the bone percentage of all bone marrow. *Results.* BMD was higher in 29 of the 44 determined (66%), although the median values din´t differ significantly between the first determination, second (two years later, P=1) and third (four years later, P=1). However, the percentage of TBV after Imatinib therapy was significantly higher than this for the control group (31.5 *vs.* 15.3 % P=0.002). *Conclusions.* 1. Trabecular bone volume is increased in patients receiving Imatinib. 2. This alteration could appear soon in early Imatinib therapy and stabilce through the treatment, since BMD didn´t change after two years of monitoring. 3. Imatinib could interfere with osteoblasts and osteoclasts functions by inhibiting alpha and beta PDGF receptors.

No Conflict of Interest. Informed consent was obtained.

MEGAKARYOCYTIC MATURATION IN PERIPHERAL BLOOD SMEAR IN CHRONIC MYELOID LEUKEMIA

R Kumar, M Anand, S Singh, A Chopra, V Raina, A Sharma

All India Institute of Medical Sciences, New Delhi, New Delhi, India

Background. Knowledge about how megakaryocytes mature and platelets form, has come chiefly from direct observations on bone marrow, or from studies on megakaryocytic cells grown in culture, and less from direct observations on the peripheral blood (PB). Circulating megakaryocytic cells, abundant in all phases of chronic myeloid leukemia (CML) in India, seem, however, to point to an alternative viewpoint. *Aims.* To evaluate how megakaryocytes mature and platelets form in the PB in CML. *Methods.* Romanowsky-stained PB of 1200 patients of CML in the 3 phases of the disease was evaluated to assess the type of morphologically identifiable Mk cells. Immunocytochemistry (APAAP) for megakaryocytes was done in selected cases. *Results.* The most dramatic features are seen in the blastic and accelerated phases. There is a continuum of megakaryocytic maturation that begins with a megakaryoblast differentiating abnormally, and ends with a mature, functioning micromegakaryocyte. Blasts otherwise undifferentiated, reveal their lineage unequivocally by putting out into the circulation, dysplastic platelets / megakaryocytic cytoplasmic fragments that arise from a localized zone of the cell membrane. While the periphery continues to be engaged in abortive and tentative attempts at successful platelet formation, cytoplasmic granules appear, heralding shift towards normal maturation. The process culminates in a small mature micromegakaryocyte, which continues to form normal platelets. *Conclusions.* 1. Megakaryoblasts are capable of platelet production without undergoing normal maturation. This unproductive effort, that yields dysplastic platelets, corrects itself as the cell matures further. 2. The familiar mature micromegakaryocyte is not a dyspoietic cell but one that actively contributes to platelet formation. 3. Large dysplastic platelet masses in the PB in CML arise largely from the PB megakaryocytic cells. 4. Study of PB Mk cells allows one to see megakaryocytic cells in a new perspective and opens vistas for further study.

1343

PSYCHOLOGICAL PROFILE OF CHRONIC MYELOGENOUS LEUKEMIA (CML) PATIENTS

P Bajenova,[1] E Lomaia,[2] A Zaritskey,[3] O Schelkova[1]

[1]St.-Petersburg State University, Saint-Petersburg, Russian Federation; [2]Federal Almazov Heart, Blood and Endocrinology Centre, Saint-Petersburg, Russian Federation; [3]Federal Almazov heart, blood and endocrinology centre, Saint-Petersburg, Russian Federation

Background. The studies of the psychological peculiarities of personality of CML patients are absent. *Aims.* 1. To study conceptual and dynamic peculiarities of mental activity (temperament structure). 2. To study individual and typological peculiarities of a personality. 3. To determine dominant emotional state during the treatment process. 4. To study peculiarities of axiological and conative spheres. *Methods.* 25 CP CML pts (12 men and 13 women) on TKI treatment were studied. "Questionnaire of temperament structure"(Rusalov V. 2007), "Individual and typological questionnaire"(Sobchik L. 2008), "Method of dominant state determination"(DS) (Kulikov L. 2002), "Life orientations"(LO) (Crumbaugh G., Maholick L., 1981; Leontyev D. 2000) were used. This complex of methods is aimed to study psychological profile in interrelations of different levels and substructures of personality-biologically determined, constitutional, individual-typological, emotional-affective, volitional as well as value-motivational peculiaraties formed during socialization. Healthy people were used as controls. *Results and discussion.* Temperament study revealed differences (P<0.01) in the "rate of psychomotor action"parameter. CML pts are closer to low emotional and passive type (using classical terminology - close to phlegmatic type). It seems that feature of weakness of ego is the main in the personality, whereas overestimation is compensatory. It was shown that accentuated personality traits of CML patients are: spontaneity (increased self-esteem and striving to lead), constriction (inflexibility, inability to change the line of behaviour following the change of real-life situation), vulnerability (sensitivity and anxiety). Such combination of accentuated personality traits is disharmonious and creates obstacles for social and psychological adaptation. Dominant emotional state is characterized by the following parameters: "Passive attitude to life situation"(P<0.001), "Calmness" (P<0.05), "Satisfaction with life" (P<0.01). The obtained result reflects the patients' compensative striving to show externally that they are successful, satisfied with their self-realization, able to take over the responsibility, make their choice and overcome difficulties while implementing it. In axiological and conative studies there were differences in regard to the following scales: "Life purpose" (P<0.001), "Life productivity or satisfaction with self-actualization" (P<0.05) and "I am the locus of control" (P<0.05). In each of these cases the patients' indicators exceeded normal data. This proves that self-consciousness of patients with CML reflects the aims, which make their life meaningful and fill temporary prospects. At the same time the plans that are formed do not have a real ground in the present and are not supported by personal responsibility for their realization. *Conclusions.* In terms of their temperament characteristics CML pts have on average the low emotional and passive type. There is a disharmonious combination of accentuated features of spontaneity, rigidity, vulnerability in patients with CML. A combination of passive attitude to life, satisfaction and reduced level of concern with the actual life situations can be seen in the emotion-

al structure of the patients. In axiological and conative spheres of patients with CML prevails satisfaction with the results of life. The data obtained can be used for psychological support of the therapeutic process.

1344

CHRONIC MYELOID LEUKEMIA TREATMENT IN BLASTIC PHASE WITH IMATINIB 600 MG

H Ionita,[1] I Ionita,[1] R Pacurar,[2] L Cheveresan,[1] CO Ionita,[1] M Cheveresan,[2] DE Nicola,[2] M Ionita,[1] D Oros[1]

[1]UMF Victor Babes, Timisoara, Romania; [2]County Clinical Hospital, Timisoara, Romania

Background. Management of Blast crisis Chronic Myeloid Leukemia (BC-CML) is the most challenging entity in the treatment of chronic myeloproliferative disorders. In 2000, the introduction of Imatinib mesylate (IM) has opened a new option in the treatment of BC-CML. Early results have shown the superiority of IM compared to conventional chemotherapy. *Aims.* To investigate the long-term effects of IM in BC-CML patients, treated with IM 600 mg daily. *Methods.* Twenty-five patients were enrolled. After a 3 year follow-up, we assessed the IM long-term efficacy, response duration and survival, and we characterized the prognostic factors associated with a favorable outcome. Patients were monitored for hematologic and cytogenetic response at 1-3 months intervals. A complete hematologic response (CHR) required the normalization of platelet and white cell differential count and absence of extramedullary involvement. The definition of return to chronic phase (RTC) required less than 15% blasts and less than 30% blasts plus promyelocytes in blood or bone marrow and less than 20% peripheral basophils. Cytogenetic analysis was performed with standard banding techniques and the response was rated as usual. *Results.* Thirteen patients had a sustained RTC, and 8 patients achieved a CHR. RTC was subsequently lost by 7 patients for a median duration of a second CP of 9 months (range 1-32). Four patients lost the CHR, for a median duration of the CHR of 6 months (range 1-23). Six patients had a cytogenetic response (2 complete, 1 partial, and 3 minor or minimal). The Kaplan-Meier median survival time was 6 months, and the survival rated were 43% at 6 months, 19% at 12 months, 13% at 18 months and 15% at 36 months. Conclusion. We confirm that IM as monotherapy was valuable and safe in the short-term, but relapse rate was high and the longer term clinical outcome was not significantly influenced.

1345

CHRONIC MYELOID LEUKEMIA (CML) TREATMENT EXPERIENCE AT HOSPITAL J.M. RAMOS MEJIA (HRM). A DESCRIPTIVE STUDY FROM ARGENTINA

A Varela, IS Otero, T Zarate, M Lluesma Goñalons, MC Ardaiz, B Moiraghi

Hospital Ramos Mejia, Buenos Aires, Argentina

Background. The rate of complete cytogenetic response (CCyR) in patients with chronic phase CML treated with imatinib mesylate is 87%. Data in our country is limmited. *Aims.* to describe demographic, clinical presentation and treatment characteristics and outcome of CML patients treated at HRM. *Methods.* data of patients with CML diagnosis since 2000 was collected from medical charts: demographic characteristics, clinical presentation, type of treatment and outcome. The rate of cytogenetic response to tyrosin kynase inhibitors (TKIs) at 6, 12 and 24 months of patients treated with imatinib mesylate and second generation TKIs(2° TKI), nilotinib and dasatinib, as initial treatment is reported. *Results.* Data of 96 patients was analysed with a median follow-up of 35 months (IQR: 13-59). Median age was 42 years (range 5-79) and male sex 52% (50/96). Sokal risk score was calculated in 86% of patients (83/96) with 19% (16/83) low risk, 28% (23/83) intermediate risk and 53%(44/83) in the high risk group. 93% (87/96) of patients were diagnosed in chronic phase, 2% (2/96) in accelerated phase and 5% (5/5) in blast crisis. 26% (25/96) of patients had received Interferon prior to TKI treatment. First line TKI was imatinib in 75%(n=72) of patients, nilotinib in 4%(n=4), dasatinib in 10%(n=10) and 2 (2%) received allogeneic bone marrow transplantation. 8 patients (8%) were lost to follow-up. Data of patients treated with imatinib and with dasatinib is described in Table 1. 29% (25/86) of the patients required second generation TKIs, 28%(24/86) because of failure to achieve response and 6%(5/86) for intolerance. Mortality rate was 14%, in 10 cases related to CML and in 4 patients not related. *Summary.* A cohort of patients treated in a Public Hospital in Argentina is described. Results show 53% rate of complete cytogenetic response in CML chronic phase patients treated with first line imatinib. More studies are necessary to confirm this outcome and to identify the variables that have influence on these results.

Table 1.

Table 1	Age	Male (%)	SOKAL RISK SCORE (%)			% CCyR			Mortality (%)
			1	2	3	6 months	12 months	24 months	
Imatinib	41	50(36/72)	19(14/72)	31(23/72)	34(25/72)	31(17/55)	47(27/57)	53(31/59)	8(13/72)
2ª TKI	45	50(7/14)	0	0	100(14/14)	71(10/14)	79(11/14)	NA	14(2/14)

BUSULFAN, AND NOT DURATION OF DISEASE, RESULTS IN DECREASE OF RESPONSE TO IMATINIB IN VERY LATE CHRONIC PHASE OF CHRONIC MYELOID LEUKEMIA (CML)

A Zaritskey,[1] I Martinkevich,[2] V Shuvaev,[2] A Abdulkadyrova,[2] V Udalieva,[2] E Usacheva,[2] D Shikhbabava,[2] M Golubeva,[3] S Meresii,[3] E Machulaitene,[4] I Zotova,[2] E Poznyak,[4] E Koryagina,[5] N Ilina,[5] T Shneider,[6] E Romanova,[1] E Salamatova,[4] N Lazorko,[1] E Lomaia,[1] K Abdulkadyrov[2]

[1]Federal Centre for Heart Blood & Endocrinology, St-Petersburg, Russian Federation; [2]Russian Research Institute of Hematology and Transfusiology, St-Petersburg, Russian Federation; [3]Perm City Hospital, Perm, Russian Federation; [4]State Pavlov's Medical University, St-Petersburg, Russian Federation; [5]City Hospital #15, St-Petersburg, Russian Federation; [6]Leningrad Region Hospital, St-Petersburg, Russian Federation

Background. Imatinib (IM) is very effective in CML in its early chronic phase (CP) whereas the results of therapy are much lower in patients in late CP. Few data are available about outcome of patients in very late CML CP (disease duration ≥5 years) and pretreated by busulfan. *Aims.* The aim of this study was to analyze the efficacy of Glivec in busulfan pretreated CML CP patients with long history of the disease. *Patients and methods.* In our database there are 14 patients with very late CML CP treated by busulfan before IM. The efficacy of IM in this group was compared to 19 pts with very late CML CP, who have never been treated with busulfan. At the start of Glivec the median age for pts treated with or without busulfan was 58.7 yrs (range 24-84) and 51 yrs (range 41-78.5). The median time before Imatinib was 90 mos (range 64-243) and 76 mos (range 61-122 mos) for busulfan and non-busulfan group respectively. Median time of Imatinib therapy was 33 mos (range 5-72 mos) and 35.5 (range 2-83mos) in pts pretreated or did not pretreated by busulfan respectively. There was another control group of pts with disease duration less than 60 mos before Imatinib (early late CP). *Results.* The rate of CCyR was 64% (41/64) in early late CP, 50% (8/16) in non-busulfan group and only 14% (2/14) in busulfan group of pts. Probability of 5-years of overall survival (excluding CML unrelated death) was 88%, 83.5% and 68% for pts in early late CP, with or without pretreatment with busulfan. The rate of CML related death was higher in pts pretreated with busulfan (27%) than other groups - 9% and 16% in early late CP and busulfan naïve pts in very late CP group. Glivec related toxicity led to dose interruption or treatment discontinuation in 28% (4/14) and 21% (4/19) pts with or without busulfan therapy (p>0,05). Some of busulfan pretreated patints resistant to imatinib responded to another TKIs. *Conclusions.* The rate of CCyR and overall survival were comparable in pts with early late CP and very late CP pts without experience of busulfan therapy. Thus, long-term duration before imatinib treatment does not result in decrease of sensitivity to Imatinib and in contrast to widely accepted opinion about accumulation of mutations leading to insensitivity to imatinib Busulfan pretreatment results in decrease of sensitivity to imatinib, although not spread to another TKIs.

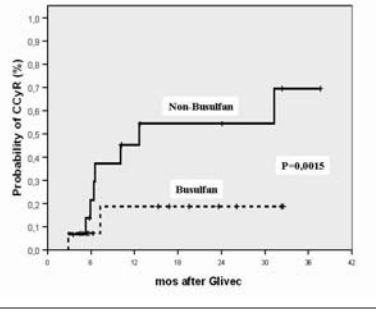

Figure. CCyR on IM in pts pretreated or not with busulfan.

1347

COMPLETE CYTOGENETIC RESPONSE ON LOW DOSE CHEMOTHERAPY AND 2ND GENERATION TKI NILOTINIB IN A MULTI-TREATED CML PATIENT ONE YEAR AFTER LYMPHOID BLAST CRISIS

A Andreoli,[1] V Durrand,[2] C Gourmel,[3] V Eclache,[4] L Joseph,[5] JM Zini[5]

[1]Hématologie Clinique - GH Lariboisière/St Louis, Paris, France, Paris, France; [2]Hématologie Biologique - Hôpital Saint Antoine, Paris, France; [3]Hématologie biologique - Hôpital Lariboisière, Paris, France; [4]Laboratoire d'Hématologie, Paris, France, Paris, France; [5]Hématologie Clinique - GH Lariboisière/St Louis, Paris, France

Background. Chronic myeloid leukaemia (CML) is nowadays a highly curable disease in its chronic phase (CP), and sustained complete response (CR) - most often cytogenetic (CCyR) - can be obtained with first-line imatinib treatment. CML blast crisis (BC) is fatal within few months unless a second CR is achieved (most often with acute leukaemia regimens) and bone marrow transplantation (BMT) can be performed. Elderly, unfit patients do not usually benefit of this kind of approach. Tyrosin-kinase inhibitors (TKI) can safely be administered to the vast majority of patients, and have been proved useful in resistant cases in the chronic and accelerated phase. Mutational analysis can drive the choice of 2nd generation TKI when a first line of treatment with imatinib is no longer effective. *Aim.* to describe the case of Mr S., a 72-year-old man suffering from CML, who suddenly developed lymphoid BC, B-cell type, while on dasatinib. *Case report.* Mr S. was 60 when he was diagnosed with CML-CP. Caryotype showed t(9; 22). Sokal score was high. Older age and the first signs of chronic obstructive pulmonary disease made him unfit for BMT. After a few months of interferon and Ara-C, he was switched to hydroxyurea because of unacceptable toxicity (namely, psychiatric). In 2002, loss of hematologic response and availability of the first TKI resulted in a therapeutic change (imatinib 400 mg/day) leading to CCyR 6 months later. Imatinib was continued at 400 mg until 4 years later, when cytogenetic relapse was documented, accompanied by t (12;15) additional mutation. 6 month later, despite dose-increase and adequate imatinib plasma levels, no response was obtained. Mutational analysis showed bcr-abl H396L mutation. Dasatinib 140 mg/d was then started, and Mr S. could again, 6 months later, obtain CCyR. Response was short-lived, and 10 months after dasatinib was started, lymphoid BC, B-cell lineage was documented in the peripheral blood (PB) and the bone marrow (BM blasts >90%), harbouring a complex caryotype and a new mutation (V299L) in addition to the known cytogenetic and molecular abnormalities. High dose steroids and weekly vincristine led to PB blast clearance by day 8, but no effect was found on BM. At day 21, Mr S. wished to go back to his native country, and he left with a palliative treatment (oral 6-mercaptopurine 50 mg/day, oral prednisone 100 mg/day, IM Methotrexate 25 mg/week). He unexpectedly came back 8 months later, and both PB and BM examination confirmed morphological CR of lymphoid BC. Cytogenetic study of BM showed major cytogenetic response (2/22 metaphases were positive for t(9;22)). Nilotinib was started at 800 mg/day. Complete cytogenetic response was obtained one month later and remission was confirmed 3 months afterwards. *Conclusion.* low dose chemotherapy and nilotinib have been effective in obtaining cytogenetic remission one year after lymphoid blast crisis on dasatinib in an elderly patient not fit for BMT. Hypothetically, associating low-dose chemotherapy and 2nd generation TKI could be more effective than using either treatment alone. Mutational analysis could be used in this context to drive TKI choice.

1348

A RETROSPECTIVE ANALYSIS OF IMATINIB MESYLATE RESPONSES IN CHRONIC MYELOID LEUKEMIA PATIENTS IN THE DEVELOPING WORLD

E Gurkan, S Paydas

Cukurova University, Adana, Turkey

The introduction of imatinib mesylate made a remarkable contribution to the management of patients with CML in chronic phase and this drug has now become the standart treatment for adult patients throughout the world. However, access to STI571 treatment became available in a delayed manner in many parts of the world. We assessed the long-term efficacy of imatinib exposure in patients with chronic myeloid leukemia in chronic phase according to European recommendations. Approximately half of the patients (43.6%) had prior history of interferon therapy. The median time from diagnosis to imatinib therapy was 7 months (range, 0-132 months). Of the 94 patients complete cytogenetic responses were achieved in 39.4% of patients; 21.3% had cytogenetic failure and 5.3% without any hematological response. Treatment was tolerated well and 54% of patients with a median follow-up of 60 months (range, 3-168 months) continued to receive imatinib at the intended dose. This study demonstrated that imatinib treatment in chronic phase CML patients is highly efficacious even if applied as an second-line option.

1349

CHRONIC MYELOID LEUKEMIA IN REUNION ISLAND

C Le Roux,[1] P Agape,[2] C Lemmonier,[3] A Clabe,[3] B Ghazi,[3] AM Pequin,[4] JC Saly,[4] I Belkaid,[2] T Henni,[2] A Mimoun,[4] H Wille,[2] E Perez,[5] A Lam Kam Sang,[5] S Berg,[6] G Marit,[7] P Zunic[5]

[1]CHR Reunion, Saint-Pierre, Reunion; [2]Service Hématologie Oncologie, CHR-CHFG, Saint Denis, Saint-Denis, Reunion; [3]Laboratoire d'Hématologie, CHR-GHSR, Saint Pierre, Saint-Pierre, Reunion; [4]Laboratoire d'Hématologie, CHR CHFG, Saint-Denis, Saint-Denis, Reunion; [5]Service d'Hématologie Clinique, CHR-GHSR Saint Pierre, Saint-Pierre, Reunion; [6]Laboratoire de Génétique, CHR-CHFG, Saint-Denis, Saint-Denis, Reunion; [7]Service d' Hématologie Clinique et Thérapie Cellulaire, Bordeaux, France

Background. The Epidemiology of Chronic Myeloid Leukemia (CML) in Reunion has not been studied to date. *Aims.* The purpose of this study is to assess the epidemiological and therapeutical aspects of the disease in Reunion, an island where the population has the following characteristics: mixed racial origins: Europe, Asia, Africa, Madagascar (INSEE 2008 data), two main age-groups: young and ageing. *Methods.* This is a retrospective study based on computer data originating from the hematology laboratories of the two centers of the regional hospital complex: Saint-Pierre and Saint-Denis, where all CML patients are supposed to be managed. The time span of the study is 10 years : 01/01/1998 - 12/31/2008 (n=65). Criteria for diagnosis have been the presence of the Philadelphia (Ph) chromosome and/or BCR-ABL transcripts. *Results.* Epidemiological aspects: crude annual incidence is 0.78 per 100,000 (1-2 in mainland France). The average age at diagnosis is 51 (54). The male to female ratio is 0.9 (1.4). At diagnosis, 97% of patients are in chronic phase, 3% are in accelerated phase and 0% are in blast crisis. The Sokal score at diagnosis is low (<0.8) for 35% of the patients, high (>1.2) for 27% and intermediate (0.8-1.2) for 39%. Most of the patients (94%) are Ph positive and 18% of them have related cytogenetic abnormalities. *Therapeutical aspects.* In Reunion, there is a national healthcare insurance system who can cover for medicine and hospitalization. Prior to the introduction of IMATINIB (IM) in Reunion (2002), most of the patients (71%), were treated with INF±Aracytine. Since 2002, 86% have received IM. Among these patients, 61% (n=23) received IM as first-line treatment, 34% (n=13) as second-line and 5% (n=2) as third or fourth line treatment. Causes for therapeutical change under IM are as follows: accelerated phase (n=12), blast crisis on myeloid (n=2) or lymphoid mode (n=1), intolerance (n=5): hematological (n=3), hepatic or other (n=2). Three BCR-ABL mutations have been observed (T315I, G250E, L248V). Eight patients received DASATINIB. One patient received NILOTINIB. Three patients received allogenic transplants (one of whom from placental blood). Two IM-treated patients developed other forms of cancer (urothelial, digestive). At 18 months, the estimated rate of freedom from progression to accelerated-phase or blast crisis was 90% (96.7% in IRIS trial). *Conclusion.* Our study shows that it seems that there are epidemiological specificities to CML in Reunion as compared to mainland France, in particular it seems that it is less frequent and that it affects women more than men. However, since it seems to show the same initial clinical presentation and therapeutic response as it does in metropolitan France "in particular in the case of tyrosine kinase inhibitors" we feel encouraged to suggest that our patients take part in the available clinical trials.

1350

IMATINIB MESYLATE INDUCED HEPATOTOXICITY IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA (CML)

V Miloševic, A Bogdanovic, V Djordjevic, M Dencic Fekete, B Mihaljevic, M Gotic

Clinical Center Serbia, Belgrade, Serbia

Background. Imatinib Mesylate (IM) is current standard treatment for newely diagnosed patients (pts) with CML.Treatment with IM is generally well tolerated, and the risk for severe adverse events is low. Liver toxicity has been observed in 1-5% of CML pts treated with IM in various reports, but in general, liver dysfunction resolves ether with

dose reduction or IM discontinuation. *Aim.* The aim of our study was to analyse pts who developed liver toxicity during IM treatment, from the large cohort of our CML pts. Patient: Between 2002 and 2009, 90 pts with CML were treated with IM in our institution. In five pts liver toxicity occured between 4 to 40 months after IM treatment was started. Pts were closely followed with laboratory monitoring once weekly and later on every 2 weeks. *Results.* We analysed 2 males and 3 females with mean age of 46 years (range, 35-59 yrs). All pts had chronic phase CML, 2 pts had low risk Sokal score, one pt intermediate and 2 pts high risk. Before the introduction of IM treatment all pts had normal values of liver enzymes, normal liver function and were seronegative for hepatotropic viruses HCV and HBsAg. IM therapy was commenced in a dose of 400 mg/d. Liver function tests performed during the first three months of treatment were normal. Liver toxicity developed in our patients after 4-40 months of IM treatment (median 14). Aminotransferases (AST and ALT) values increased up to CTC Grade 2 in 3 pts and CTC Grade 3 in 2 pts. There were no signs of cholestasis and hepatic synthesis was not affected. In one pt, whom the manifestation of Grade 3 hepatoxicity occurred after 12 months of IM treatment, HBsAg was detected, with negative HBeAg but with anti-HBe antibodies present, suggesting reactivation of unapparent HBV.The pt was treated with lamivudine and later on with interferon alpha. In all other pts, IM treatment was withheld until grade 1 toxicity was reached and then restarted. In one pt IM treatment was discontinued definitively due to recidivant toxicity, so the pts continued treatment with nilotinib..*Conclusion.* IM have many adverse events but the incidence and management of hepatotoxicity has been rarely reported. Liver function tests should be carefully monitor during treatment and if they continue to be elevated, treatment have to be discontinued and reassessment for viral reactivation should be done. Continuation of IM in pts with viral reactivation is doubtful and possess a risk, so, introduction of interferon alpha as maintenance therapy could be of great help in preserving good cytogenetic response already achieved with IM.

1351

EARLY DEVELOPMENT OF SECONDARY HYPERPARATIROIDISM AFTER STARTING IMATINIB THERAPY IN MCL

J Groiss Buiza,[1] I Rangel Bravo,[2] R Ramos Fernandez de Soria,[2] C Lopez-Santamaria,[1] E Delgado Casado,[1] A Blesa Sierra,[1] A Corbacho Hernandez,[1] J Benitez Rodriguez,[3] R Bajo Gómez[1]

[1]Infanta Cristina Hospital, Badajoz, Spain; [2]Mérida Hospital, Mérida, Spain; [3]Facultad de Medicina, Badajoz, Spain

Background. The tyrosine kinase inhibitor Imatinib Mesylate has an established role in the management of chronic myeloid leukemia by inhibition Bcr/Abl fussion protein, but some other tyrosine kinases may also be inhibited: PDGFR and C-Kit. Several studies, included ours, have demonstrated that Imatinib theraphy causes anomalies in calcium and phosphate metabolism, such as hypocalcemia, hypophosphatemia and hyperparatiroidism. *Objetive.* To specify in which moment of the treatment the mentioned alterations appear. *Methods.* Prospective study of CML patients treated with Imatinib from July 2006 to June 2009: 9 patients, 5 male (55,6%) and 4 female (44,4%), with a median age of 62 years (29-83), in treatment with a daily Imatinib dose of 400 mg. Serum levels of calcium, phosphate and parathyroid hormone were determined before the beginning of Imatinib treatment, and then monthly until observing a significant difference with regard to the initial determinations. The statistical analysis of the results was performed by Wilcoxon test. *Results.* Significant differences were detected for all the parameters measured after one month of treatment with Imatinib: calcium (8,76 *vs.* 9,52 mg/dL; P= 0,008), phosphate (2,84 *vs.* 3,87 mg/dL; P=0,011) and parathyroid hormone (114,38 *vs.* 56,89 pg/mL; P= 0,008). *Discussion.* Patients taking Imatinib develop an increase in bone matrix mineralization, secondary to a decrease in calcium mobilization from bone (probably by PDGFR inhibition and the consequent aboliton of osteoclast activation). It results in hypocalcemia, hypophosphatemia and in a long lasting secondary hyperparatiroidism. This work is carried out in order to determine when they appear. We note that these analytical changes turn up as soon as after one moth of treatment *Conclusion.* Disorders of calcium and phosphate metabolism appear early after starting Imatinib therapy.

Informed consent was obtained.

1352

THE IMPORTANCE OF T315I, T317L, E255K AND Y253H BCR-ABL GENE MUTATIONS IN THE PATIENTS OF CHRONIC MYELOID LEUKEMIA WHO TREATED BY IMATINIB

C Kis,[1] M Pehlivan,[2] S Pehlivan,[3] B Eser,[4] T Sever,[3] M Yilmaz,[2] L Kaynar,[4] F Altuntas,[4] S Oguzkan Balci,[3] M Cetin[4]

[1]Gaziantep University, Faculty of Medicine,, Gaziantep, Turkey; [2]Gaziantep University, Faculty of Medicine, Section of Adult Hematology, Gaziantep, Turkey; [3]Gaziantep University, Faculty of Medicine, Department of Med Biol and Genetics, Gaziantep, Turkey; [4]Erciyes University, Faculty of Medicine, Section of Adult Hematology, Kayseri, Turkey

Aims. In spite of Imatinib is an effective treatment for CML, the important problem that is seen by at the patients is primary and secondary resistance. *Methods.* In this study, the 54 chronic phase CML patients observed in two centre between 2000-2008, mostly observed T315I, F317L, Y253H gene and E255K mutations in BCR-ABL gene are scanned by ASO-PCR method. *Results.* Twenty of patients are men and 42 of patients are women and the median age of the patients are 44.5(19-78). According to the Sokol classification in diagnosis; 12 of patients are low risky, 26 of them are middle risky and 16 of them are in high risky group. Median imatinib usage time is 1.8(0.3-7) year. When imatinib treatment response is evaluated; the 24 of the patients are optimal response, 10 of the patients are suboptimal response and 20 of them have resistance. Expected values in 7 years are found as 96% for Median Overall Survival(OS) and 80% for Progression Free Survival(PFS). Scanned mutations are observed in 18 of the patients and T315I and F317L are observed in 2 patients together. Mutations are determined in 60% of the resistance patients(P=0.004). Seven years PFS is found as 62% in mutation determined patients and 90% in undetermined patients(P=0.041). While T3151 mutation observed patients guided to AKIT, F317L mutation observed patients are started to nilotinib and dasatinib treatment. *Conclusion.* To determine the optimal treatment type; resistance should be identified in early stages in CML patients, rational treatment type should be planned according to the determined mutation type.

1353

THE CORRELATION BETWEEN THE MEDIUM ERYTHROCITARY VOLUME AND THE BCR-ABL/ABL RATIO IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA

RG Mihaila,[1] A Catana,[2] E Rezi,[2] S Mitea,[2] RG Mihaila[3]

[1]Lucian Blaga University of Sibiu, Sibiu, Romania; [2]Emergency County Clinical Hospital, Sibiu, Romania; [3]Public Health Direction, Sibiu, Romania

Background. Even if imatinib mesylate is not acting on leukemic stem cells, which are commonly found in the quiescent state, its administration permits in most cases of chronic myeloid leukemia to obtain the disease control, which means a significant decrease in leukemic cell mass, reflected at the monitoring by RT-PCR by lowering the BCR-ABL/ABL ratio to less than 0.1% and sometimes even to the absence of its detection. *Aim.* We aimed to study which parameters of the patients with chronic myeloid leukemia who are in their first months of treatment with imatinib mesylate correlate with the lowest BCR-ABL/ABL ratio they can obtain, parameters which in their turn could constitute prognostic factors for the response at the treatment with imatinib mesylate. *Methods.* We conducted a retrospective study which included all patients with chronic granulocytic leukemia who are in the records of the Hematology Department of the Emergency County Clinical Hospital from Sibiu who were treated with imatinib mesylate, at whom we have analyzed the following parameters: gender, age at diagnosis, the disease duration, the duration of treatment with imatinib mesylate, the hemoleucogram and the erythrocytes medium volume after 2-3 months and the lowest BCR-ABL/ABL ratio obtained by each patient, thereafter, during the treatment. We have compared each of the parameters mentioned with the BCR-ABL/ABL ratio, using the Pearson test. *Results.* The study included 21 patients with the mean age of 49.35±16.18 years. The women/men ratio was 8/13. The lowest average BCR-ABL/ABL ratio obtained over time was 0.60±1.27%. We have found a statistically significant inverse correlation between this ratio and the erythrocytes medium volume (93.41±7.63 fl) (r=-0.598). In other words, the higher the erythrocytes medium volume is in the first 2-3 months of administration of imatinib mesylate, there are more chances for the BCR-ABL/ABL ratio to reach a low value, in dynamics. There was also found a direct correlation between the mentioned ratio

and the platelet count (212904.8±171212.6/mm^3) (r=0.346) and between that ratio and age (r=0.334). So, as the platelet count is higher in the first 2-3 months of administration of imatinib mesylate, the chances are higher for the BCR-ABL/ABL ratio to remains high, in dynamics. Patients with advanced ages have more often a high BCR-ABL/ABL ratio. The BCR-ABL/ABL ratio did not correlate with gender, disease duration, the duration of treatment with imatinib mesylate or with the parameters of the hemoleucogram, except platelets. *Conclusions.* The increased erythrocytes medium volume in the first months of imatinib mesylate administration correlates with a future low BCR-ABL/ABL ratio, suggesting that it could be a positive prognostic factor for obtaining, in dynamics, the molecular response. Conversely, a large number of platelets in the first months of administration of imatinib mesylate are correlated with a future high BCR-ABL/ABL ratio, suggesting that it could be a negative prognostic factor for obtaining subsequent molecular response.

1354

THE EFFICACY OF IMATINIB MESYLATE TREATMENT PATIENTS WITH CHRONIC MYELOGENOUS LEUKEMIA PH' POSITIVE (CML) REFRACTORY TO PREVIOUSLY INTERFERON THERAPY (CML) - THE FOLLOW UP OF OWN STUDY REPORT

B Ceglarek, A Sikorska, L Konopka, K Warzocha

Institute of Hematology and Blood Transfusion, Warsaw, Poland

Imatinib Mesylate is the selective inhibitor of BCR / ABL tyrosine kinase of first generation presented at the most patients with CML. *The aim of study.* analysis of efficacy and safety Gleevec therapy in 112 CML Ph' positive patients resistant to previously given therapy i.e. Interferon and others (Hydrea, Mercaptopurine, ARA-C, Vincristine, Epirubicine, relapse after BMT). *Methods.* 112 patients were eligible for the 96 months study: - 108 patients in chronic phase-CP of CML, - 04 patients in accelerated phase-AP of CML. The patients received Gleevec in a daily oral dose of 400 mg in CP and 600 mg in AP of CML . Doses were modified (400-600mg daily) in a case of side effects or an incomplete achieved hematologic response. *Results.* Complete hematologic responces were reported for 97% evaluated CML treated patients after 2-3 months therapy and complete cytogenetic responses for 41.1% (46/112) CP-CML patients after 8-14 months has been lasting 34 months. There were maintained the primary hematologic resistance in 2.6% (3/112) patients, and the cytogenetic ones in 20.5% (23/112). The acquired hematologic resistance were in 5.3% (6/112) pts., and cytogenetic ones in 60.7% (68/112) patients. During study partial cytogenetic response (PCR) was observed in 15.2% (17/112) after 4.5 -37.0 mo (median 8.1 mo), which has been lasting 14.0 - 71.0 mo (median 22.3 mo+). Minimal cytogenetic response lasting median 4.0 mo was received in 43.8 % pts.(49/112) after 6.0 mo Imatinib therapy. Gleevec is well tolerated. Side effects (1-4o WHO) were observed at 23.2 % (26/112) patients : leucopenia, neutropenia, rash, hypoplasia medullae ossium, thrombocytopenia, bone and abdomen pain, increased AST/ALT level, allergic reactions, fever, hiperhidrosis. Survival time since Imatinib mesylate therapy is 27.5 -116.0 months for CML-CP patients.

1355

THE EFFICACY OF NILOTINIB TREATMENT PATIENTS WITH CHRONIC MYELOGENOUS LEUKEMIA PH' POSITIVE (CML) REFRACTORY TO PREVIOUSLY IMATINIB MESYLATE THERAPY - THE OWN STUDY REPORT

B Ceglarek, L Konopka, A Sikorska, K Warzocha

Institute of Hematology and Blood Transfusion, Warsaw, Poland

Nilotinib is the selective inhibitor of BCR / ABL tyrosine kinase of second generation which can be used at the treatment CML patients refractory to previously Imatinib mesylate with CML. *The aim of study.* analysis of efficacy and safety Nilotinib therapy in 30 CML Ph' positive patients resistant to previously given therapy i.e. Gleevec or Dasaninib. *Methods.* 30 patients were eligible for the 36 months study: - 28 patients in chronic phase-CP of CML, - 02 patients in accelerated phase-AP of CML. The patients received Nilotinib in a daily oral dose of 800 mg in CP and AP of CML . Doses were modified (800-400mg daily) in a case of side effects. *Results.* Complete hematologic responces were reported for 90% (27/30) evaluated CML treated patients after 1-2 months therapy and complete cytogenetic responses for 16.7% (5/30) CP-CML patients after 6-12 months has been lasting 24.8+months. There were maintained the primary hematologic resistance in 6.7% (2/30) patients, and the cytogenetic ones in 3.3% (1/30). The acquired hematologic resistance were in 0.1% (3/30) pts., and cytogenetic ones in 3.3% (1/30) patients. Major molecular response (CMR+PMR) were maintained at 3.3% (1/30) patients. During study partial cytogenetic response (PCR) was observed in 16.7% (5/30) after 6.0 mo (median 8.1 mo), which has been lasting 6 - 27 mo (median 16.5 mo+). Minimal cytogenetic response lasting median 4.0 mo was received in 33.3 % pts.(10/30) after 6.0 mo Nilotinib therapy. Nilotinib is good tolerated. Observed side effects At 20% patients (6/30): neutropenia, thrombocytopenia, increased AST/ALT level, allergic reactions. Survival time since Nilotinib therapy is 2.0 -35.0 months for CML-CP patients.

1356

IS THERE ASSOCIATION BETWEEN GASTROINTESTINAL STROMAL TUMORS AND CHRONIC MYELOID LEUKEMIA? EXTRAORDINARY EFFICACY OF IMATINIB IN BOTH DISEASES

MD De Miguel, IM Garcia Castro, MI Lopez San Roman, N Golbano, M Diaz Morfa, D Morales, J Arbeteta, B Pinedo

Hospital Universitario de Guadalajara, Guadalajara, Spain

Background. Gastrointestinal stromal tumors (GISTs) are KIT-positive mesenchymal tumors of the gastrointestinal tract that are driven by activated KIT-signalling or platelet-derived growth factor receptor-alpha (PDGFR) signaling. These tumors most commonly occur in the stomach and small intestine and encompass a clinical spectrum from benign to malignant. In Targeting constitutively activated tyrosine kinases, such as BCR-ABL, in chronic myeloid leukaemia (CML) and c-KIT in GIST has substantially changed the clinical management of both diseases. The introduction of imatinib, a tyrosine kinase inhibitor mainly targeting BCR-ABL, c-KIT and PDGFR, has profoundly improved the prognosis of both entities. Imatinib induces cytogenetic and molecular responses in CML and also has substantial activity in GIST patients. Thus, in view of the low rates of severe toxicities and the extraordinary efficacy of the drug in both diseases, imatinib represents an oral drug with a high benefit-risk ratio for the treatment of CML and GIST. We report the unusual case of a patient who was diagnosed simultaneously two tumors whose common treatment is Imatinib. We conducted a review of the literature and found that there is an association, between GIST and CML (not statistically significant). *Matherial and Methods.* We reported the following case: a 63-year-old man patient that developed simultaneously CML and small intestine GIST. Patient with a history of arterial hypertension and hypothyroidism. In an analytical performed as preoperative presented: WBC 23960 (mielemia and basophilia) 12.4 g/dL hemoglobin 495000/mm^3 platelets. The bone marrow biopsy was compatible with chronic myeloproliferative syndrome, type CML. The patient was operated of a retroperitoneal mass of 18×15×9 cm, attached the inferior vena cava, right kidney and duodenum. Retroperitoneal GIST diagnosis is high grade malignancy. After diagnosed as high risk GIST, the patient was treated with imatinib at a dose of 400 mg/day, and the tumor was controlled. Follow up during 7 months, patient is alive, good performance status, and chronic phase CML with mayor molecular response. *Review of literature.* Miettinen M. *et al*. (Cancer. 2008;112: 645-9) examined long-term follow-up data of 1892 GIST patients. Nine patients (2 with gastric GISTs and 7 with GISTs of the small intestine) developed myeloid leukemia. There were 6 patients with AML, including 1 case of promyelocytic and 1 case of myelomonocytic leukemia, and 3 patients with CML. The leukemias developed 1.7 to 21 years after the GIST (median interval, 6 years). None of the GIST patients had received radiotherapy or chemotherapy prior to the leukemia diagnosis. Eight of 9 patients died of leukemia, and none died of GIST. In GIST patients, the risk of AML was found to be significantly higher for women and overall. There was a slightly increased risk for CML, but this was not statistically significant. *Conclusions.* Additional epidemiologic, clinical, and pathogenetic studies are needed to understand the apparent nonrandom association between GIST and myeloid leukemia. In this moment, therapy of both entities has successfully changed.

1357

COMPLETE MOLECULAR REMISSION WITH PLATELETS NUMBER NORMALIZATION AFTER DASATINIB THERAPY IN PATIENT WITH CML COMPLICATED BY THROMBOCYTOPENIA AND RESISTANT TO IMATINIB DUE TO AN E459K MUTATION

M Cioch,[1] K Lewandowski,[2] M Gniot,[2] A Dmoszynska[1]

[1]Medical University in Lublin, Lublin, Poland; [2]Poznan University of Medical Science, Poznan, Poland

Imatinib mesylate, an inhibitor of BCR-ABL tyrosine kinase at a dai-

ly dose 400 mg is a gold standard of first line treatment in patients with chronic myeloid leukemia (CML). This therapy is generally well tolerated, but in 20-50% myelosupression including thrombocytopenia is observed. These events are associated with temporary dose reduction or drug discontinuation, what may be cause of disease progression and promotion of leucaemic clone with BCR-ABL kinase domain mutation. The hope on effective therapy in such cases gives us the second generation of tyrosine kinase inhibitors. We present a patient (pt) with CML complicated by thrombocytopenia after imatinib therapy and disease progression because of E459K mutation successfully treated with dasatinib. *Case report.* A 61 year-old man with Ph-positive CML was treated with imatinib at 400 mg daily after a 5-months period of hydroxycarbamide therapy. After 3 weeks of such therapy thrombocytopenia in grade 3 acc. WHO (42×10^9/L) was developed. The dose of imatinib was decreased to 300 mg. The lower dose (200 mg) was also applied temporary due to thrombocytopenia intensification (35×10^9/L). The cytogenetic analysis of bone marrow after 6 and 12 months of imatinib therapy revealed 40% and 10% of Ph-positive metaphases, respectively. Such level of cytogenetic response (Ph 10-15%) was maintained during 3 years, when progression with increase of Ph-positive metaphases to 45% was detected. Direct sequencing of BCR-ABL kinase domain displied an E459K point mutation. Therefore the decision to change of therapy on dasatinib was made. The initially dose of dasatinib was low (40 mg daily) and was increased gradually to 100 mg. That was possible because platelet number was increasing systematically to complete normalization after 6 months of such therapy. In that time cytogenetic analysis revealed complete response. After 12 months of dasatinib therapy complete molecular response in RT-PCR analysis was achieved. *Conclusions.* The BCR-ABL kinase domain mutations are the most frequent causes of resistance to first-line imatinib therapy. Sensitivity of mutated leucaemic clone on dasatinib or nilotinib was established on basis of *in vitro* analysis. There are only a few reports concerning the clinical outcome of pts with mutations treated by second generation of TKI. Our case presents high sensitivity of leucaemic BCR-ABL-positive clone with E459K mutation on dasatinib, which additionally overcome thrombocytopenia after imatinib therapy.

IMATINIB MESYLATE IN NEWLY DIAGNOSED CHRONIC MYELOID LEUKEMIA (CML) PATIENTS

H Ionita,[1] I Ionita,[1] M Cheveresan,[2] M Iordache,[1] L Cheveresan,[1] M Ionita,[1] G Borzak,[2] CO Ionita,[1] A Pascalau,[2] D Calamar,[1] D Oros[1]

[1]UMF Victor Babes, Timisoara, Romania; [2]County Clinical Hospital, Timisoara, Romania

Background. Imatinib Mesylate (IM) is a powerful and selective p210 Bcr-Abl tyrosine kinase inhibitor that has been demonstrated to be effective for the treatment of CML. *Aims.* The study was performed to investigate the safety, efficacy, tolerance and compliance of IM in newly diagnosed CML patients. *Methods.* From June 2004-June 2008 we collected 62 untreated Ph^+ CML patients. They received Imatinib at diagnosis at a dose of 400 mg orally per day. 35 were male and 27 female with a median age of 45 (range 23-70 years) Sokal risk low 32,4%, intermediate 47.5% and high 20.1%. *Results.* Complete hematological remission was achieved in 95% patients. The estimated rate of complete cytogenetic remission (CCR) was 75,7% after 12 months. The most commonly reported adverse events after IM were edema (including peripheral and periorbital edema) (55 %); muscle cramps (29.7%); diarheea (25.5%); fatigue (31.8%); moreover in 4,2% patients with grade 3-4 events were observed consisting of pancitopenia and/or elevated liver enzymes. Four patients died: 1 patient of cardiac infarction, 1 patient of metastatic colon cancer and 2 patients of blastic crisis. In summary, at 84 months, 96% patients are alive and 83% of them are still receiving IM. 13 patients discontinued Imatinib: 7 patients for adverse events grade 3-4 and 6 patients for progressive disease. *Conclusions.* These data confirm the safety and efficacy of IM in newly diagnosed patients.

1359

THIRD LINE THERAPY WITH NILOTINIB INDUCED FIRST MAJOR MOLECULAR RESPONSE (MMR) IN A PATIENT WITH CHRONIC MYELOID LEUKAEMIA AND F317L MUTATION

A Abbadessa, M Iovine, S Iaccarino, E Attingenti, ML Vigliotti, G Monaco

S. Anna e S. Sebastiano Hospital, Caserta, Italy

Introduction. This report describes the case of a patient affected by chronic myeloid leukaemia (CML) with F317L mutation of the Bcr-Abl domain, responding to nilotinib after acquiring resistance to imatinib and dasatinib. *Case report.* In 1996, a forty-three years old woman was diagnosed with CML and treated with alfa-Interferon (alfa-IFN), achieving complete haematological response (CHR). Three years later, patient was switched to hydroxiurea due to thyroid toxicity. For logistic reasons, therapy with imatinib (400 mg/die) was initiated only in 2003, obtaining complete cytogenetic response (CCyR) and suboptimal molecular response in twelve months. CCyR and CHR were then lost three years later. Doubling imatinib dose to 800mg/die gave no positive *Results.* Mutational analysis performed in September 2007 showed F317L point mutation of the Bcr-Abl kinase domain. In October 2007 dasatinib was started and in April 2008 CCyR was reached with suboptimal molecular response. In March 2009 Bcr-Abl transcript progressively increased, and in August 2009 cytogenetic analysis showed loss of CCyR. In the same month, therapy with Nilotinib 800mg/die was started, and in October 2009 the patient obtained MMR. *Discussion.* The reported case shows successful third-line treatment with nilotinib in a CML patient proven to bear the F317L mutation after developing resistance to imatinib. In particular, patient had never obtained MMR before receiving nilotinib. Bcr-Abl kinase-domain point mutations, acquired during first line therapy, are a common cause of resistance to tyrosine kinase inhbitors (TKIs). While several Bcr-Abl mutations have been identified, involvement of codon 317 has been reported in the literature following treatment with imatinib and dasatinib. A study by Jabbour *et al*. described incidence, prognosis and response to therapy in F317L mutated patients. Prognosis seems to be independent from the type of mutation, and rather dictated by CML phase and response to salvage therapy. (Jabbour *et al.*, Blood 2008,210:4839-4842). Moreover, *in vitro* studies show high sensitivity of F317L mutated cells to nilotinib (O'Hare T, *et al.* Blood 2007;110: 2242-2249). *Conclusion.* Nilotinib has significant clinical activity in patients who failed therapy with other TKIs; mutational analysis of Bcr-Abl kinase-domain can help choosing effective TKIs and overcoming resistance.

1360

CHRONIC EOSINOPHILIC LEUKEMIA

D Ozbalci,[1] U Ergene,[1] H Yazgan[2]

[1]School of Medicine, Manisa, Turkey; [2]Celal Bayar University School of Medicine Department of Internal Medicine, Manisa, Turkey

Background. Chronic Eosinophilic Leukaemia (CEL), a rare entity, is a myeloproliferative variant of Hypereosinophilic Syndrome defined by FIP1L1 gene rearrangements. Increased number of eosinophils are thought to mediate an inflammatory response by releasing contents of its secondary granules and hence responsible for the pathogenesis. Hepatosplenomegaly, eosinophilia with systemic disturbances, anaemia or thrombocytopenia and especially cardiac involvement are major components of the disease. In the past, prognosis was grave and most of the patients died especially from cardiac involvement but detection of gene rearrangements and their susceptibility to tyrosine kinase inhibitors has made a revolutionary change in prognosis and life expectancy of these patients. *Case report.* A thirty-two year old man who had been in good state of health previously was referred to our clinic with leucocytosis and high eosinophil count. He had fatigue, blurred vision, non-productive cough and sore throat for ten days; his physical examination revealed splenomegaly 10 cm below costal margin and eye examination revealed segmentation and dilatation of capillaries around the optic disc. His hemogram revealed the following; Hg:9.2 gr/dL, WBC:50000/μL Plt:98000/μL and eosinophil 21100/μL and on peripheral blood smear eosinophil 62 %, neutrophil 23 %, lymphocyte 10 %, metamyelocytes 3 % and myelocytes 2 %. In bone marrow aspiration, more than 50 % myeloid cells were eosinophils and blast ratio is below 3%. T (9; 22) with fluoresan *in situ* hybridisation method was 100% negative. Tests for BCR-ABL and FIP1L1-PDGFRA rearrangement with real time PCR were performed. Parasite tests for eosinophilia were negative. CT of the thorax and abdomen revealed splenomegaly and hepatomegaly. On follow-up, hypotensive attacks with dynamic electrocardiographic (ECG) changes were observed and methylprednisolon 1 mg/kg/day therapy started when pericardial effusion was seen on USG. Despite steroid therapy, his eosinophil count did not change as expected but hypotensive attacks and ECG changes were not seen again and pericardial effusion resolved. Erythrocyte and thrombocyte transfusions were needed on follow-up. BCR-ABL rearrangement was found negative however; FIPL1-PDGFRA rearrangement for RNA was found to be positive so Imatinib 100 mg/day began and steroid therapy quickly stopped. His medical condition quickly

improved, eosinophilia disappeared, vision improved and he was free of transfusions. He was discharged with good state of health and on his last outpatient visit, his Hg: 12.3 gr/dL, WBC: 5600/μL Plt: 148000/μL and eosinophil 0.4%. *Discussion and conclusion.* CEL, once disease with a poor prognosis, is now a manageable disease with a good quality of life with tyrosine kinase inhibitors. FIP1L1-PDGFRA fusion gene was found to be 50 fold more sensitive to Imatinib, a tyrosine kinase inhibitor, than BCR-ABL so lower doses of the drug (100 mg/day) had been found to be mostly successful in achieving hematologic and molecular response quickly. Our patient depended on transfusions and he had vision loss attributed to eosinophilia but after the start of Imatinib therapy, his medical and hematologic condition quickly improved. Here, we report our case presented with non specific symptomatology and rapid disease progression but good response to therapy in the end.

1361

CALCIUM AND PHOSPHATE METABOLISM WAS ALTERED IN CML PATIENTS RECEIVING DASATINIB

J Groiss Buiza,[1] I Rangel Bravo,[2] C Lopez-Santamaria,[1] E Delgado Casado,[1] A Corbacho Hernandez,[1] R Bajo Gómez,[1] J Benitez Rodriguez[3]

[1]Infanta Cristina Hospital, Badajoz, Spain; [2]Mérida Hospital, Mérida, Spain; [3]Facultad de Medicina, Badajoz, Spain

Background. Dasatinib is an inhibitor of BCR-ABL and SRC-family kinases for patients with Imatinib-resistant or -intolerant chronic myelogenous leukaemia (CML). Recent studies have demonstrated that patients taking Imatinib had indicators of altered bone and mineral metabolism. We evaluated if Dasatinib therapy may also produce these adverse events. *Methods.* Transversal analysis of CML patients treated with Dasatinib from April 2007 to April 2008: 4 patients, with a median age of 57 years, in treatment with a median daily Dasatinib dose of 112 mg. All four patients were previously treated with Imatinib for a median period of 37 months. Serum levels of calcium, phosphate (nephelometry) and parathyroid hormone (quimioluminiscence) were determined. Eleven patients (median age: 58 years) with myeloproliferative sindromes Philadelphia chromosome negative served as internal controls. Qualitative variables were analyzed by Chi-squared or Fisher's Exact and quantitative variables by Mann-Whitney test. *Results.* Among the 4 patients receiving Dasatinib, one of them developed hypophosphatemia (P=0,011), another one hypocalcemia (P=0,01) and 3 of them hyperparatiroidism (P=0,004). In the same way, median values also differ significantly from those in the control group: phosphate (2,7 *vs.*3,5 mg/dL, P= 0,01), calcium (8,8 *vs.* 9,5 mg/dL, P= 0,01) and paratohormone (109 *vs.* 47 pg/mL, P= 0,01). One of the four patient didn´t show any anomalies. *Conclusions.* 1. Dasatinib therapy develops calcium and phosphate metabolism alterations. 2. Futher studies are necessary to investigate the effect of Dasatinib on bone and mineral metabolism.

No Conflict of Interest. Informed consent was obtained.

CLINICAL OUTCOME AND PRESENTING FEATURES OF CD20 POSITIVE REED-STERNBERG CELLS CLASSICAL HODGKIN'S LYMPHOMA

F Gaudio,[1] T Perrone,[1] A Giordano,[1] C De Risi,[1] A Spina,[1] F Laddaga,[1] A Fanetti,[1] A Gentile,[2] E Maiorano,[2] V Liso,[1] G Specchia[1]

[1]Hematology, Bari, Italy; [2]Pathology, Bari, Italy

Background. Hodgkin and Reed-Sternberg cells (HRS) cells are the neoplastic population in classical Hodgkin's lymphoma (cHL). Recent immunological and molecular studies have shown that HRS cells originate from mature germinal centre B cells. Although cHL is genotypically considered a B-cell lymphoma, the classical B-cell marker CD20 is expressed with reported frequencies of 5-58%. The prognostic significance of CD20 expression in HRS cells of cHL is still controversial. *Aims and Methods.* To further assess the presenting features and the prognostic significance of CD20 expression in cHL, we performed a retrospective single institution study of 87 cases with a mean clinical follow-up of 12 years. The mean ages were 40.4 years (range, 14-83 years) for the men and 34.3 years (range, 16-77 years) for the women. Sixty-five (74.7%) of the 87 patients (pts) were younger than 45 years of age. The histology was nodular sclerosis in 75, mixed cellularity in 10, lymphocyte rich cHL in 1, and lymphocyte-depleted in 1. Stages III+IV were present in 57 pts (65.5%), bulky disease in 34 pts (39.1%), extranodal disease in 16 (18.4%), 51 pts (58.6%) had an IPS score 0-2 (low-risk) and 36 (41.4%) had a score of ³3 (intermediate-high-risk). Combined radiochemotherapy was administered in 57 pts (65.5%) and chemotherapy alone in 30 (34.5%); 24 pts (27.6%) received the MOPP/ABVD, 16 (18.4%) the BEACOPP, and 47 (54%) the ABVD chemotherapy regimen. *Results.* HRC expressed CD20 in 27 pts (31% of cases). The negative rate of CD20 was significantly higher in patients with B-symptoms (54% *vs.* 32.2%, P=0.046) and with bulky disease (49.4% *vs.* 22.9%, P=0.035). There was no statistically significant difference in CD20 expression between the groups with other different clinical parameters. No significant difference in terms of response rate (82% *vs.* 85%) was found between CD20 positive and negative cHL. The 5-year progression free survival (PFS) rates were 76.2% in CD20-positive patients and 82.2% in CD20-negative patients (P=n.s.; Figure 1). The 5-year overall survival (OS) rates were 91.4% in CD20-positive patients and 92.5% in CD20-negative patients (P=n.s.). *Conclusions.* CD20 is expressed by HRS cells in 31% of patients with cHL; it is higher in patients without bulky disease and B symptoms. However, according to our results, the expression of CD20 is not an independent prognostic factor for PFS and OS of naive cHL patients.

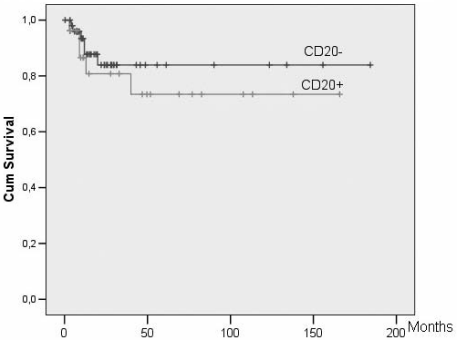

Figure 1. PFS in pts with cHL according to CD20 expression in HRS.

THE TEI-INDEX EVALUATION: A MORE EFFECTIVE ECHOCARDIOGRAPHY MONITORING IN PATIENTS WITH HODGKIN'S AND NON-HODGKIN'S LYMPHOMA

A Guarini, S Oliva, A Iacobazzi, A Lapietra, A Rana, C Minoia, A Fioretti, M Giannoccaro

NTL Cancer Institute Giovanni Paolo II, Bari, Italy

Background. Anthracyclines are widely employed in lymphoma's chemotherapy and has been shown to induce heart failure. To monitor this toxic damage, echocardiographic parameters of left ventricular (LV) systolic function are usually used. *Aims.* of this study was to evaluate in lymphoma's patients the reliability of echocardiographic data in comparison with a LV systo-diastolic parameter function: the Tei-Index. *Methods.* Twenty-nine pts (10 males, 19 females, mean age: 49 yrs) suffering from Hodgkin's and non Hodgkin's lymphoma respectively treated with ABVD or R-CHOP at standard dose. We performed a two-dimensional doppler echocardiography before the first and the fourth chemotherapy cycle, calculating in apical 4 chamber view: LV end-diastolic volume (EDV), end-systolic volume (ESV), ejection fraction (EF) and stroke volume (SV). During mitral and aortic pulse doppler flow, we evaluated the Tei-Index, according to the next formula: Tei-Index = (isovolumetric relaxation time + isometric contraction time)/ejection time. *Results.* We divided the patients in two groups, according to the presence (Tei+, 9 pts) or the absence (Tei-, 20 pts) of a Tei-Index increase (cut off: 0.1). EF did not change in either group (Tei: 63.35% *vs.* 62.34% P=.0809; Tei+: 63.02% *vs.* 64.78% P=.2638). In Tei- group EDV, ESV and SV increased from the first to the fourth cycle (EDV: 63.23 mL *vs.* 70.88 mL P=.0172; ESV: 23.55 ml *vs.* 26.92 ml P=.0012; SV: +10.78% P=.0809). In Tei+ group EDV and ESV did not change (EDV: 73.16 ml *vs.* 68.59 mL P=.2426; ESV: 27.35 ml *vs.* 24.34 mL P=.2177) and we did not observed a significantly reduction of SV (-7.47%; P=.3666). *Conclusion.* According to our data, it seems that SV increase in Tei- pts by increasing the LV volumes. This phenomenon could be explained by early "positive"LV remodelling. On the contrary, Tei+ pts seem not able to counterbalance at the same way and SV reduces, in spite of an unchanged EF. We believe that Tei-Index could be a useful parameter to diagnose the compensative ability of the heart muscle to toxic damage by anthracycline, earlier than EF. Nevertheless, we still have to understand if the remodelling phenomenon observed in Tei- pts could lead to a better prognosis during the follow-up.

1364

EXPRESSION OF CANCER-TESTIS ANTIGENS IN HODGKIN'S LYMPHOMAS USING TISSUE MICROARRAY

R Inaoka,[1] A Jungbluth,[2] F Carvalho,[1] O Boiocchi,[1] M Assis,[1] J Oliveira,[1] A Alves,[1] G Colleoni[1]

[1]Federal University of Sao Paulo, Sao Paulo-SP, Brazil; [2]Ludwig Institute for Cancer Research, New York, USA

Background. Cancer-testis (CT) antigens are expressed in a variety of malignant tumors and in normal adult tissues solely in testicular germ cells. Owing to this tumor-associated expression pattern, these antigens are potential targets for immunotherapy. *Aims.* To analyze the expression of CT antigens in Hodgkin's lymphomas (HL) using tissue microarray (TMA), and to correlate their expression with histologic subtypes, clinical parameters such as gender, disease stage, EBV status and treatment response. *Methods.* Formalin-fixed paraffin-embedded tissues of 38 HL cases were obtained from the archives of the Department of Pathology, Federal University of São Paulo, Brazil. All cases were classical HL, of the following subtypes: 25 (65.8%) nodular sclerosis, 9 (23.7%) mixed cellularity, 2 (5.2%) lymphocyte-rich and 2 (5.2%) not specified. 20 patients were male, 18 female; EBV was detected in 17 patients. A TMA block was constructed including two cores of each tumor sample, and the following monoclonal antibodies (mAbs) were used for immunohistochemical stainings: "MAGE-A cocktail"consisting of mAbs MA454, M3H67, 57B and 6C1, to allow screening for MAGE-A1, MAGE-A2, MAGE-A3, MAGE-A4, MAGE-A6 MAGE-A10 and MAGE-A12; mAb CT7-33 (to CT7/MAGE-C1), mAb CT10#5 (to CT10/MAGE-C2), mAb E978 (to NY-ESO-1) and mAb #26 (to GAGE-family antigens). Staining was carried out using the avidin-biotin peroxidase complex, and two independent observers scored all slides. *Results.* Eight (21.1%) of 38 HL cases expressed at least one CT antigen, which were 6/25 nodular sclerosis and 2/9 mixed cellularity. Among the 8 positive cases, 6/20 were female and 2/18 male. According to Ann Arbor stage, 6/21 advanced stage (III or IV) and 2/17 early stage (I or II) patients were CT antigen positive. Of 17 EBV-positive cases, 4 were showed CT antigen expression, and 4/21 EBV-negative cases were also CT antigen positive. CT antigen expression were observed in 6/30 patients who achieved complete response and in 2/8 who had refractory disease. Among the tested CT antigens, MAGE-A and CT7 were the most frequently expressed in HL, being present in 7/38 (18.4%) and 5/38 (13.2%) respectively. *Conclusions.* Using a panel of antibodies to detect the expression of MAGE-A, CT7, CT10, NY-ESO-1 and GAGE antigens, we found that 21.1% of HL cases express at least one CT antigen. Interestingly, in the present series CT antigen expression appears to be higher in advanced stage disease than in early stage disease. MAGE-A family and CT7 were the most frequently expressed CT antigens in HL. Our data suggest that CT antigens could serve as diagnostic markers and/or potential therapeutic targets in a proportion of classical Hodgkin's lymphomas.

ASSOCIATION OF EPSTEIN-BARR VIRUS AND HODGKIN'S LYMPHOMA: PREVALENCE AND LONG TERM SURVIVAL

M Belkaid,[1] F Zerhouni,[2] J Briere,[3] JM Andrieu,[4] T Henni,[1] W Assouak,[2] RM Hamladji,[2] P Colonna[4]

[1]CHR Reunion, Saint Denis, Reunion; [2]Centre Pierre et Marie Curie, Algiers, Algeria; [3]Groupement Hospitalier Universitaire Nord, Paris, France; [4]Hopital Europeen Georges Pompidou, Paris, France

The association of Epstein-Barr virus (EBV) with Hodgkin's lymphoma (HL) has been investigated over the last few years. The impact of EBV on clinical outcome is still controversial, however. In this study, we investigated the effect of EBV status on clinical outcome of Algerian HL patients (Pts). This study included sixty-eight Pts with HL (33 females, 35 males), all clinically staged during 1990-1992. Median age was 25 years (6"70). Histological subtypes included lymphocytic predominance (LP) 3; nodular sclerosis (NS) 33; mixed cellularity (MC) 30 and lymphocytic depletion (LD) 2. According clinical staging, 47% where localized forms (IA, IIB). EBV markers examined included expression of latent membrane protein (LMP) in Reed-Sternberg and Hodgkin cells (RSC) by immunochemistry. The LMP was expressed RSC in 26 Pts. LMP was significantly associated with MC subtype (1 LP, 8 SN and 17 MC). The viral expression was more frequent in the localized forms of HL. The LMP was expressed in respectively 50% and 28% of IA-IIB and IIIA-IVB stages. The ten years overall survival was respectively 81% and 62% for HL LMP positive and HL LMP negative (P=0.003). EBV infection may be involved in the pathogenesis of HL in our Algerian study cohort and it does significantly affect therapeutic results and overall survival of HL Pts.

1366

BEACOPP-14 VS BEACOPP-ESC IN PATIENTS WITH HODGKIN'S LYMPHOMA FROM POOR-PROGNOSIS GROUP: PRELIMINARY RESULTS OF PROSPECTIVE RANDOMIZED MULTYCENTER STUDY

I Kriachok, I Titorenko, K Filonenko, E Aleksik, O Novosad, T Kadnikova, E Kushchevoy, A Martinchik, Y Pastushenko

National Cancer Institute, Kyiv, Ukraine

Background. At the moment, it is unclear which of therapy approach is optimal for patients with high risk Hodgkin lymphoma (HL). For this reason many clinical trials undergo comparing different chemotherapy and radiotherapy regimens. Promising results demonstrates of BEACOPP-14 regimen. The prospective randomized multicenter study comparing two regimens in patients with high risk HL was started in Ukraine. The aim of study: compare the treatment efficacy and toxicity BEACOPP-14 and BEACOPP -esc. regimens in patients with high risk HL. *Methods.* from September 2008 until now 65 patients from 18 to 65 years old (median 29 year), 26 male and 39 female with stage IIB with more than one unfavorable factor and stage III-IV were included in the study. All patients were randomized to receive BEACOPP-14 (31 patient, totally received 185 cycles, 6,02±1,08 cycles per patient) and BEACOPP-esc (31 patient, totally received 206 cycles, 5,96±1,08 cycles per patient). The treatment efficacy in both groups was evaluated after 4, 6 and 8 cycles by Cheson criterias (1999). For patients who achieved complete response after 4 cycles, maximum 6 cycles was done. Toxicity rate was evaluated with NCI-CTC V.3.0. Chemotherapy in patients with initial sites >5 cm, residual lymph nodes >2 cm and/or PET-positive sites was followed by radiotherapy (30-36 Gy). *Results.* completion of overall response after 4, 6 and 8 cycles of chemotherapy is presented on the diagram. The treatment of patients from high risk HL with BEACOPP-14 and BEACOPP-esc is highly efficient. The rate of complete response after 4 cycles of BEACOPP-14 was higher (66,6%) than after the 4 cycles of BEACOPP-esc (52%) (P>0,05); after 6 cycles (81,25% and 64,7%, respectively) (P>0,05). After 8 cycles 100 % overall response rate was reached in both groups), complete response rate was equal (88,8 % and 87,5%, respectively) (P>0,05). Maximal observation period is 12 months. Positive response is keept in all patients, cases of disease progression were not detected. The main toxicity was haematological toxicity of different stages, that was detected in 69,3% of chemotherapy cycles totally (67,55% during the treatment with BEACOPP-esc in comparison with 72,8% during the treatment with BEACOPP-14, P>0,05). Anemia was detected in 69,29% cases (BEACOPP-esc - 57,74%, and BEACOPP-14 - 82,1%) (P<0,05). Neutropenia was detected in 67,51% cases (BEACOPP-esc - 64,4 %, BEACOPP-14 - 70,7%) (P<0,05). Febrile neutropenia was detected in 10,1 % cases (BEACOPP-esc - 10,1 %, BEACOPP-14 - 8,6%). Thrombocytopenia was detected in 31,45 % cases (BEACOPP-esc - 33,49%,BEACOPP-14 - 29,18%) (P<0,05). The most frequent non-hematologic toxicity were nausea and vomiting, that were detected in 44,85 % of patients (BEACOPP-esc - 54,5%, BEACOPP-14 - 35,2%). Mucositis was detected in 18,8% cases during the treatment with BEACOPP-esc and in 19,3% during the treatment with BEACOPP-14. *Conclusion.* Both comparative regimens BEACOPP-esc and BEACOPP-14, are effective (100% overall response after 6-8 cycles) and showed equal toxicity rate. However, the results are preliminary and should be confirmed in larger number of patients and with a longer follow-up.

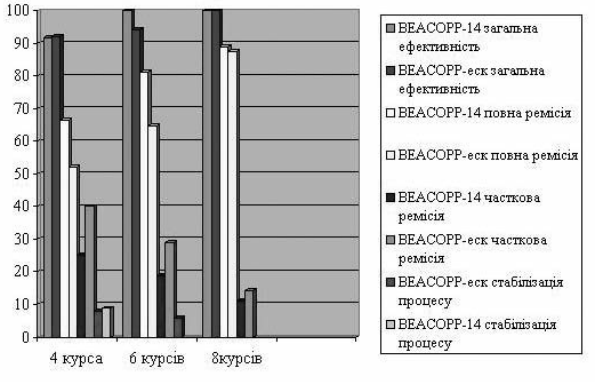

Figure. Completion of overall response.

HIGH-DOSE THERAPY IN CHEMOREFRACTORY HODGKIN'S LYMPHOMA PATIENTS

E Karamanesht, Y Shestovska, S Korenkova, L Dushko, K Reztsova, E Makovey, N Kostyukova, E Turchanovskiy

Kiev BMT Center, Kiev, Ukraine

It has been shown that patients (pts) with chemosensitive relapsed and refractory Hodgkin's lymphoma (HD) were more likely to remain progression-free after high-dose therapy (HDT) and autologous stem cell transplantation (auto-SCT). We report here retrospective analysis evaluating the outcomes of 45 pts who didn't response to salvage therapy or progressed before HDT. Indication to HDT is controversial in this chemorefractory group but it corresponds with our transplant program. *Patient and Methods.* In total 22 male (48.9%) and 23 (51.1%) female with progressive HD were treated with HDT and auto-SCT from February 2001 to October 2009. The median patient age was 28.9 years (range 13-54). The primary-refractory before salvage were 26 pts (57.8%), others - relapsed. The average number cycles of previous therapy were 9 (range 3 - 30), by radiotherapy treated 35 pts (77.8%). Pts who received badly standardized previous therapy (inadequate estimation of responses, extended treatment intervals, reduced doses and so on) - 18 (40%). Were performed 51 auto-SCT and one allo-SCT. Median numbers of CD 34^+ cells reinfused were 6.6×10^6/kg (range 1.97-18.8×10^6/kg). Salvage regimens were mainly platinum-based, they were received by 42 pts (93.3%). More than one line pretransplant salvage therapy received 15 pts (33.3%). Preparative HDT mainly was CEAM (lomustin 400 mg/m^2 instead carmustin) - 35 pts (68.6%). *Results.* After a median follow-up of 19.3 months (range 2.2 - 99.9) the overall survival (OS) is 65,4% (CI 95% 50,6%-80,2%), and progression free survival (PFS) is 43,5% (CI 95% 28,3%-58,7%). The most frequent causes of death were disease progression - 76.2% of cases. TRM in estimated group was 6.67%, while in chemosensitive group was 2.7%. Our assumption was that the worst results will in group of initially inadequately treated patients, but we have not found difference in OS and PFS. Significantly better (P=.00521) survival (OS and PFS) was observed in part of patients which was reinfused more than 10.0×10^6/kg CD 34^+ cells in comparison with less 5.0×10^6/kg. *Conclusions.* This prognostic unfavorable category of patient also must be included in transplant programs. Number of infused stem cells can influence an outcome.

CUTANEOUS HODGKIN'S DISEASE: A RARE ENTITY

G Giglio,[1] A Antuzzi,[2] M Musacchio,[2] C Carrozza,[2] G Grivet Fojaja,[3] P Pollio,[4] A Antrilli[5]

[1]Hematology Unit A. Cardarelli Hospital - ASREM, Campobasso, Italy; [2]Hematology Unit - A. Cardarelli Hospital - ASREM, Campobasso, Italy; [3]Nuclear Medicine Unit - A. Cardarelli Hospital, ASREM, Campobasso, Italy; [4]Pathology Unit - A. Cardarelli Hospital, ASREM, Campobasso, Italy; [5]Dermatology Unit - A. Cardarelli Hospital - ASREM, Campobasso, Italy

Introduction. Hodgkin's disease involving the skin is an unusual occurrence and usually occurs late in the course of Hodgkin's lymphoma. This rare condition is thought to have decreased in incidence in recent decades, likely owing to improved treatment of patients with Hodgkin's disease, who are receiving improved chemotherapy and radiation therapy, and the advent of peripheral blood stem cell transplantation. The most common clinical presentation is of single or multiple dermal or subcutaneous nodules. Direct extension from an underlying nodal focus, hematogenous dissemination, and most often, retrograde lymphatic spread, distal to involved lymph nodes, are the mechanisms usually implicated. We report the case of a patient with Hodgkin's disease who presented with skin involvement at diagnosis. *Case report.* we present a case of an 85 years old woman who developed Hodgkin's lymphoma with cutaneous involvement. She accused malaise, fatigue and loss of weight. On physical examination the unilateral supraclavicular lymph node was found (diameter 2.0 cm) and ulcerated lesion of the neck of 5 cm diameter. The remaining of physical finding was normal. Laboratory data revealed: RBC $4,8\times10^6$/μL, Hgb 13.5 g/dL, WBC $6,2\times10^3$/μL, PLT 242×10^3/μL; renal functions, Beta 2 microglobulin, Ves, copper, fibrinogen and ferritin were normal. LDH was high: 679 UI/L (v.n.300-600). Total body scan was negative. The biopsy of lymph node was performed and the histology reveled Hodgkin's lymphoma, mixed cellularity subtype. The PET total body after node biopsy showed a single area with excavation at the canter at the level of subcutaneous tissue in the left occipital (SUV max 5.9). The skin biopsy pointed a dermal localization of Hodgkin's lymphoma, $CD30^+$ and $CD15^+$. Histology of bone marrow was normal. The patient was considered in clinical stage II AE. Chemotherapy with VEPEMB protocol (Vinblastina,procarbazina,prednisone,etoposide,mitoxantrone, bleomicina) was started; the patient received 3 full cycles obtained a complete remission, proved by clinical, biochemistry, and PET/TC imaging techniques. After chemotherapy RT/IF was performed. Discussion: Primary cutaneous HD is very unusual and usually represents a rare late manifestation of dissemination of the disease heralding a grave prognosis. Specific skin lesions were described in 3.4-7.6% from all cases of HD and have been categorized as papules, nodules, plaques or infiltration, ulcerative lesions, a combination of these, and erythroderma and often are accompanied by pruritus. The skin of the chest seems to be most frequently involved. Many cases of coutaneous HD can be excluded from other cutaneous granuloma by the immunohistochemistry criteria for this disease. More recently, cutaneous HD has been described in patient with human immunodeficiency virus (HIV) infection, advanced clinical stage, and aggressive clinical course, suggesting that alteration in immune system function is important for disease appearance and spread. EBV positively has been previously described in cutaneous HD in only one case. *Conclusion.* Cutaneous involvement usually represents, or accompanies, Stage IV Hodgkin's disease, and often portends an ominous prognosis. Nevertheless, it also might follow a relatively benign course, and more and more intensive systemic chemotherapy sometimes is effective in such cases.

1369

HODGKIN'S LYMPHOMA IN HONG KONG CHINESE

MF Law, SF Yip, YM Yeung

Tuen Mun Hospital, Hong Kong, Hong Kong

Hodgkin's lymphoma constitutes about 30% of all cases of lymphoma in Caucasian population.[1] However, a lower incidence of 6.1% was found in Hong Kong adult patients.[2] An analysis of patient characteristics, clinical course and treatment outcome of Hong Kong Chinese patients in a local hospital was done. *Methods.* It was a retrospective study of Hodgkin's lymphoma patients in a local hospital from 1991 to 2009. Data were collected from old notes and hospital computer file. Patients were staged according to Ann Arbor Staging system. The response rate and overall survival were assessed and the overall survival was calculated by Kaplan-Meier method. *Results.* Sixty-six Chinese patients with Hodgkin's lymphoma were reviewed. There were 37 males and 29 females and the median age was 37 (range 19-81 years). Most of the patients had the histology subtypes of nodular sclerosis (52%), followed by mixed cellularity (39%), nodular lymphocyte predominant Hodgkin's lymphoma (7.6%) and lymphocyte rich (1.5%). There was no case of lymphocyte depleted histology. There were 26% of patients with stage I disease, 41% with stage II, 24% with stage III and 9% with stage IV disease. There was a bimodal age distribution with peak incidence at 21-30 and 61-70 years of age. A variety of treatments were given to these patients (chemotherapy alone, radiotherapy alone and combined treatment). Patients also received various chemotherapy regimes including ABVD, ChlVPP, stanford V, escalated BEACOPP. ABVD was the most commonly used regimen (68%). Radio-

therapy alone was also given to some patients with early stage disease. The complete remission rate was 80% and the advanced stage had a lower CR rate (33% for stage IV, 56% for stage III, 93% for stage II and 100% for stage I disease). The 5-year overall survival for the patients was 85%. Age and advanced stage (III/IV) are independent variable significantly affecting the overall survival. Sex of patient is not a significant factor for the survival. *Discussion.* The relatively low incidence of Hodgkin's lymphoma has been a consistent finding. Orientals may have a relatively high incidence of T-cell lymphoma, especially NK-T cell lymphoma. The distribution of histologic subtypes was quite similar to the pattern found in Caucasians with nodular sclerosis being the commonest histology. The incidence was higher in male patients. There was also an early peak in young adults and another peak at advanced age. The treatment regimen was changing. Combined modality treatment incorporating chemotherapy especially ABVD with or without radiation was used for most patients. The complete remission rates and overall survival in this study were satisfactory. The major cause of death of the patients was refractory lymphoma. *Conclusion.* Hodgkin's lymphoma has a lower incidence in Hong Kong Chinese than in Caucasians. Nodular sclerosis and mixed cellularity are the commonest histologic subtypes. Age and staging were independent variables affecting the overall survival.

DISEASE CHARACTERISTICS AND TREATMENT APPROACH AS PREDICTIVE FACTORS IN HODGKIN'S DISEASE

O Karanfilski,[1] A Stojanovic,[1] S Trpkovska-Terzieva,[1] S Trajkova,[1] T Sotirova,[1] A Latifi,[2] D Dukovski[1]

[1]University Clinic for Hematology, Skopje, Macedonia; [2]Clinical Hospital, Kumanovo, Macedonia

Labeling Hodgkin's disease (HD) as one of the curable neoplastic diseases, motivates hematologists to define the basis on which this contemporary medical achievement is accomplished. Our study is a contributing attempt in this direction. At our Clinic we have been managing more than 500 HD patients over a 25-year period. We have studied the prognostic impact that disease onset manifestations, mostly included in the IPI scoring system, but alongside with and across different treatment approaches, and the impact that both have on the disease course and its outcome. Of a total of 473 HD evaluable patients, 119 were with clinical stages 1-2A, and were analyzed regardless of the disease mass (bulk). Evaluable advanced stage patients, with clinical stages 2B-4, also irrespective of tumor mass size, were 348 of them. Multivariate statistical analyses show that of the seven IPI parameters, only the scoring system backbone still retains its prognostic significance: Hb and Alb levels. Patient's gender, and a modified range for age and clinical stage of the disease, also remain important factors. Selective statistics reveal that this importance is valid mostly due to factor's impact on advanced stages of HD, whereas the prognosis of early stage HD patients does not seem to be affected by these parameters. The values for the chi-square tests are 45.9023 and 24.5866 for 3 degrees of freedom (gender, Hb, Alb) for the whole population and the advanced disease subset respectively, and the p-values are highly significant (0.00000 and 0.00002), when the analysis is performed on standard IPI values. Modified values achieve even higher significance and incorporate more parameters. Following our assessment that onset manifestations do not have statistical influence on the outcome of early stage disease patients, we extended the analysis to the post-diagnostic period. Analyzing different types of treatment engaged, as well as similar approaches, it is clearly evident that these patients benefit from treatment modalities containing the gold standard and the increasingly competitive newer chemotherapy regimen: ABVD and BEACOPP. Interestingly enough, and possibly due to the low number of entries, combined modality treatment did not show significant advantage over chemotherapy alone in these early stage patients. On the other hand, advanced stage disease course could not be significantly altered by employing even more aggressive treatment approaches. Rough grouping of the originally and contemporarily treated subsets, show an evident difference of 25-40% in overall survival ($P<0.001$). Both observations clearly imply that rapid diagnosis, diminishing the possibility of disease advancement, and utilization of contemporary and aggressive treatment options in the first instance, speculating that the appreciated effect is mostly attributable to the potential of doxorubicin and very possibly etoposide, are the milestones on which the successful story of HD management has been created and confirmed.

1371

RETROSPECTIVE STUDY OF HODGKIN LYMPHOMA IN A 10-YEAR PERIOD AT A COMMUNITY HOSPITAL

E Ramila,[1] G Navarro,[2] S Piernas,[2] JA Soler,[2] M Gómez,[2] I Roig[2]

[1]Hospital Parc Tauli, Sabadell, Spain; [2]Hospital Parc Taulí, Sabadell, Spain

Background. Hodgkin's Lymphoma (HL) affects mostly young people. Old people and patients in advanced stage have a worse outcome. *Aims.* To analyze the clinical data, outcome and treatment toxicity of HL patients during a 10-year period at a 450-bed hospital. *Patients and Methods.* Retrospective analysis of the clinical features, therapy and outcome of patients with HL treated between January 1999 to October 2009. *Results.* Seventy one patients were identified. They were 45 (63%) male and 26 (37%) women; median age was 42 years (range 17-89) and seventy five % were younger than 45 years. Histology was: 41 (58%) nodular sclerosis, 14 (20%) unspecified HL, 7 (10%) nodular lymphocyte predominant HL, 6 (8%) mixed-cellularity and 3 (4%) lymphocyte-rich. Characteristics of the disease at diagnosis were as follows: early stage 39 (55%), advanced stage 32 (45%). Seven patients (7%) had Bulky disease, 33 (46%) had B symptoms and performance status measured by ECOG scale was 0-1 in 63 (89%). Thirty eight (97%) of the 39 patients in early stage received treatment: 27 (69%) combined modality (ABVD plus Radiotherapy), 10 (26%) AVBD alone and 1 (2.5%) Radiotherapy alone. After therapy, responses were as follows: 35 (92%) complete response, 1 (3%) partial response and progression in 2 (5%) patients. Among patients in advanced stage (32), 30 received chemotherapy (28 AVBD, 1 BEACOPP and 1 DHAP); four patients received also radiotherapy. In this group 25 patients (83%) achieved a complete response, 2 (7%) partial response and 3 were not evaluables (1 was lost of follow-up and 1 died respectively before evaluation and 1 patient was already in course of treatment at the moment of analysis). In terms of toxicity, grade 3-4 neutropenia was observed in 19 (28%) of patients and grade 3-4 infections in 6 (9%): 4 patients with febrile neutropenia, 1 fungal pneumonia and 1 patient suffered an acute hepatitis B reactivation. In 6 (9%) patients pulmonary-toxicity was observed (grade 1-2 in 2 and grade 3-4-5 in 4 patients). Three patients developed grade 3-4 cardiac toxicity. One patient presented a second malignancy (breast cancer). Nine patients relapsed/progressed and required new line of treatment. Among those, 5 were in advanced stage and 4 in early stages (all of them had any unfavourable risk factor according the EORTC). No relapses were observed in the early favourable-stage group). Eleven (15%) patients died and the causes of death were as follows: 6 (8.5%) disease progression, 3 (4%) toxicity (1 pneumonia and 2 pulmonary toxicity; all of them were older than 70 years) and 2 patients died for others reasons (1 patient aged 92 years for pneumonia after remaining 5 years in complete response, and 1 presented a sudden death). With a median follow-up of 41.5 months (range 1-123) overall survival in the Kaplan Meier's curves was 100% in early favourable-stage, 80% in early unfavourable-stage and 78% in advanced stage. *Summary.* In our cohort of HL patients the responses were according to the previously described in the literature. Old people presented the more severe toxicity.

1372

THE LEVEL OF ADENINE NUCLEOTIDES AT HODGKIN LYMPHOMA BEFORE AND AFTER CHEMOTHERAPY

S Daghbashyan, A Pepanyan, P Ghazaryan, A Asoyan

Center of Haematology, Yerevan, Armenia

Considering the significance of adenine nucleotides (AN) and adenosine in proliferation and differentiation of immune cells we have studied AN metabolism in patients with Hodgkin lymphoma before and after chemotherapy. The aim of the work was to study AN pool and the state of the processes of their decay (activity of 5'-nucleotidase) in peripheral blood lymphocytes at Hodgkin lymphoma before and after the therapy. The AN content was studied by the method of thin-layer chromatography, and the activity of ecto-5'-nucleotidase - by spectrofotometric method. An acute (almost 2 fold) decrease in ecto-5'-nucleotidese activity was found in lymphocytes, accompanied by a significant (1,3 fold) rise of AMP level on the background of some ($P<0.01$) decrease in ADP quantity and stable level of ATP. The qualitative and

quantitative interchanges of the components of adenylic system led to a marked decrease in the ATP/AMP and increase in ATP/ADP ratios (P<0,01), while the energetic charge (EC) of the cells did not undergo any deviations. Thus, at Hodgkin's lymphoma despite the stability of EC, marked alteration of ATP/AMP and ATP/ADP ratios is observed probably due to the disturbance of ecto-5'-nucleotidase activity. After chemotherapy a definite normalization of the studied indices occurs. The question of informativity of the indices of the exchange of ecto-5'-nucleotidase activity and metabolites of adenylic system at Hodgkin lymphoma is discussed, as of additional prognostic criteria and for assessment of the conducted treatment efficiency.

1373

PLATINUM-BASED PROTOCOLS IN THE TREATMENT OF RELAPSED OR REFRACTORY HODGKIN'S DISEASE

JN Rodríguez, JA Quesada, A Palma, E Martin, MV Moreno, A Chacón, MJ Romero, K Gómez, A García-Sola, A Amian, JC Diéguez, A Fernández-Jurado

Hospital Juan Ramón Jiménez, Huelva, Spain

Background. The platinum-based protocols (ESHAP or EDHAP) have been widely used in relapsed or refractory cases of non-Hodgkin lymphoma (NHL) or as a conditioning regimen prior to transplantation as well. In contrast to these data, their use in Hodgkin disease is scanty. *Aims.*- We present our experience in 18 patients with relapsed or refractory Hodgkin disease treated with these protocols, sixteen of them prior to transplantation. *Methods.* Eighteen patients (8 males, 10 females), mean age 32 years (17-58) are presented. Histologic subtypes included 3 lymphocyte predominance, 12 nodular sclerosis and 3 mixed cellularity. Eight cases were relapsed and 10 resistant to previous therapies. Fifteen patients were treated with ESHAP cycles and only one with EDHAP. No modifications on the conventional doses or schedule of these protocols were made. In another two cases with lymphocyte predominance histology Rituximab (375 mg/m^2, day 1) was added to the conventional protocol (ESHAP and DHAP, one each). *Results.* A total of 57 cycles were administered, mean number of cycles was 3,2 (2-5). Seventeen patients received complete doses and in only one case corticosteroids were reduced 50% due to previous hypertension. No delayed administration of cycles was observed. Toxicity included: Anemia in 15 cases (83,3%), mean grade 1,9 (1-4); neutropenia in 11 (61,1%), mean grade 3,7 (2-4); thrombocytopenia in 12 (66,7%), mean grade 2,8 (1-4); mild increases of creatinine levels in 3 (16,7%); hypomagnesemia in 6 (33,3%); febrile syndrome in 1 (5,5%); emetic syndrome in 5 (27,7%). Response was observed in 14 cases (77,7%) (5 CR and 9 PR). Sixteen patients received an hematopoietic progenitors transplantation post-platinum treatment: Fifteen autologous transplantation, and the other a non-myeloablative allogenic one from his sister. In those cases of autologous procedures enough number of CD34$^+$ cells (data from 14 patients: mean 8,3×10^6/Kg; 38-18) could be obtained from peripheral blood (13 cases) or bone marrow (1 case) without significative problems, mean number of aphereses 1,48 (1-2). Two patients (autograft) have relapsed after transplantation (one patient is now being transplanted). *Conclusions.* In our experience, platinum-based protocols could be a safe, generally well tolerated and worthwhile option for the treatment of patients with refractory or relapsed Hodgkin disease. Toxicity is mainly related to cytopenias and mild renal failure. These protocols do not seem to affect the number of CD34$^+$ cells collected in cases of autologous transplantation.

1374

THE 'BATTLE' FOR THE GOLD STANDARD IN HODGKIN'S DISEASE: EVIDENCE FOR SUPERIORITY OF ABVD IN THE PRE-BEACOPP ERA

O Karanfilski,[1] A Stojanovic,[1] T Sotirova,[1] M Pavkovic,[1] S Trajkova,[1] S Trpkovska-Terzieva,[1] A Latifi,[2] D Dukovski[1]

[1]University Clinic for Hematology, Skopje, Macedonia; [2]Clinical Hospital, Kumanovo, Macedonia

Different treatment approaches were available and utilized over time for patients with HD. Even today, different centers and schools use different treatment modalities as standard. Efforts are directed towards tailoring the optimal treatment method for different risk stages. Nevertheless, in the segment of chemotherapy, most researchers still accept the ABVD regimen as the present and valid 'gold' standard for treating all stages and types of HD, in combination or without adjuvant radiotherapy. In a single-center study, on a population of more than 500 HD patients, treated at our Clinic over a longer than 25-year period, we attempted to define points where ABVD has shown superiority over earlier chemotherapy option(s), the sustainability of prognostic models for HD patients when analyzed separately according to treatment protocol, as well as the benefit it implies, evaluated by patient longevity and quality of life. Univariant statistical analyses were performed on a number of patient characteristics, disease manifestations and treatment modalities and their outcomes, and compared in patients grouped according to treatment protocol, meaning also according to the period when they were observed and/or treated at our Clinic. Special attention was placed on the subgroup of HD patients in whom the ABVD chemotherapy protocol was the principal one. Multivariate analyses were performed in order to define whether known predictive factors, certainly the ones incorporated in the IPI, and others, sustain prognostic significance within the 'newer' subpopulation of HD patients, treated initially with the present gold chemotherapy standard. The most obvious advantage of ABVD treated patients was observed in the field of life expectancy. Overall survival was above 85% at 10 years, reaching its plateau shortly after year 2, as opposed to a near 55% for MOPP-based treated patients. EFS followed this line of *Conclusions.* Chance for relapse was also markedly low. Patients treated with the hybrid MOPP/ABV(D) were not evaluable for the analyses, since when this treatment option first became available, it was widely used for poor risk HD patients, thus diminishing their chances for a privileged outcome. In the segment of univariate statistical analyses, most of the parameters maintained their prognostic significance, although with slightly higher p-values. This applies to the IPI parameters also, both with the original settings, as well as under our dichotomization criteria (slightly altered points derived from population and disease characteristics). Nevertheless, in multivariate analyses, ABVD treated patients manifest no outcome affection by the known predictive parameters, except for a couple: one patient characteristic - age, and one disease manifestation - symptom presence. Therefore, HD patients treated with ABVD chemotherapy as their underlying regimen, still remain with significantly greater outcome expectations and very high reliability for achieving definite disease control. In that process not many patient characteristics, nor disease manifestations can influence their favorable prognosis, which is why this chemotherapy protocol is applicable to patients with different age and gender, with disease of different type or extent, with comparably similar favorable effect. The evidently lower incidence of undesired late effects is also a fact deserving respect and a confidence vote.

EFFECTIVENESS OF DECITABINE IN CHRONIC MYELOMONOCYTIC LEUKEMIA PATIENTS. INTERNATIONAL COOPERATIVE MULTI-CENTER STUDY

JH Jang,[1] M Iastrebner,[2] G Taborda,[3] J Arbelbide,[4] F Sackmann,[5] G Klein,[6] H Bernard,[7] C Jozami,[8] K Kim,[1] D Kim,[1] C Jung[1]

[1]Samsung Medical Center, Seoul, South-Korea; [2]San Luis Medical Center, Buenos Aires, Argentina; [3]Policlinico Modelo, Cipoletti, Argentina; [4]Hospital Italiano, Buenos Aires, Argentina; [5]Fundaleu, Buenos Aires, Argentina; [6]Hospital Rossi Cucaiba, La Plata, Argentina; [7]Ramón Madariaga, Posadas, Argentina; [8]Hospital de Clínicas, Buenos Aires, Argentina

Background. Epigenetic therapy with hypomethylating agents has recently been approved for the treatment of myelodysplastic syndromes (MDS) and chronic myelomonocytic leukemia (CMML) in South Korea and Argentina. CMML is a heterogeneous disorder sharing features of MDS and Chronic Myeloproliferative disorders. It has recently been reported that decitabine (DACOGEN, Janssen Cilag Farmaceutica S.A. and Eisai Inc.) is effective in the management of CMML. *Aims.* To describe the clinical and hematological improvement with decitabine among patients with CMML on a 'real world program'. *Methods.* This field investigation was based on data collection from patients with CMML who received decitabine at different centers of South Korea and Argentina between July 2007 and December 2009. Inform consent has been signed according to the regulations of each institution. A report prepared ad hoc was completed. We took into account WHO classification, as well as performance status by ECOG, co-morbidities, previous treatments and IWG 2006 criteria. Efficacy was evaluated with at least 2 cycles. Inclusion criteria were 18 years of age and confirmed diagnosis of CMML type 1 or type 2. Exclusion criteria were diagnosis of acute myeloid leukemia (AML) or other progressive malignant disease. Patients with prior therapy were not excluded. All patients received decitabine 20 mg/m^2 IV over 1 hour once daily for 5 consecutive days repeating every 4 weeks. We evaluated the overall improvement rate (complete response + marrow complete response + partial

response + hematologic improvement) and rate of stable disease or better. *Results.* The study population included 33 CMML patients (M/F: 24/9 ; median age 67, range 23-82). CMML Type-1 63.6 (21) %, Type-2 36.4(12) %. Karyotype was normal 75.8% (n=25), isolated -7/7q- 6.1% (n=2), +8 6.1% (n=2), del3q/der3 3.0% (n=1), tY/1 3.0% (n=1), complex 3.0% (n=1) and no metaphases 3.0% (n=1). The median interval from diagnosis to treatment was 3 months (R 0 - 35); The median number of cycles received was 5 (R 1-12) with a median follow-up of 14 months. According to IWG 2006 criteria, the overall response rate (ORR) was 43%, including CR in 8 (26.7%), marrow CR (mCR) in 1 (3.3%), PR in 0 (0 %), stable disease (SD) in 5 (16.7%), HI in 4 (13.3%), and progression in 9 (30%). Clinical and Hematological response are summarized in Table. Most of the patients remained alive during the first year of follow-up. 2 patientS received allogeneic stem cell transplant without additional toxicity. *Conclusions.* Decitabine is an effective and generally well tolerated treatment in CMML. This treatment strategy allows relatively young patients to be transplanted in a better clinical condition and can be the best option for older patients.

Table.

Treatment response	
Complete response (CR)	8 (26.7%)
Partial response (PR)	0 (0%)
Marrow complete response (mCR)	1 (3.3%)
Hematologic improvement (HI)	4 (13.3%)
Stable disease (SD)	5 (16.7%)
Overall improvement rate (CR+PR+mCR+HI)	13 (43%)
Rate of stable disease or better	18 (60%)
AML development	9 (30%)
Failure	12 (40%)

PTPN11 MUTATIONS WERE RARE IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES AND CHRONIC MYELOMONOCYTIC LEUKEMIA

TL Lin,[1] LY Shih,[2] P Dunn,[2] PN Wang,[1] JH Wu,[1] MC Kuo,[1] TC Tang,[1] H Chang,[1] YS Hung,[1] YS Hung[1]

[1]*Chang Gung Memorial Hospital, Taipei, Taiwan;* [2]*Chang Gung Memorial and Chang Gung University, Taipei, Taiwan*

Background. PTPN11 gene, encoding SHP-2, is the disease gene of Noonan syndrome. Mutations of PTPN11 have been described in children with juvenile myelomonocytic leukemia, myelodysplastic syndromes (MDS) and acute leukemia. It is not known that the role of PTPN11 in adult MDS and chronic myelomonocytic leukemia (CMML) and the role in disease progression to acute myeloid leukemia (AML). *Aims.* The aims of this study are (1) to determine the prevalence of PTPN11, N-Ras, K-Ras mutations in adult MDS and CMML; (2) to correlate these mutations with time to progression to AML and overall survival (OS). *Methods.* Bone marrow samples from patients with MDS and CMML at diagnosis and at AML transformation were examined for N-Ras, K-Ras and PTPN11 mutations. Analysis of N-Ras and K-Ras mutations were performed by genomic DNA or cDNA PCR followed by direct sequencing. Analysis of PTPN11 mutations was performed by cDNA PCR followed by direct sequencing. *Results.* One hundred and twenty-one patients with MDS and 92 patients with CMML at diagnosis were available for analysis. Eighty-one patients with MDS and 38 patients with CMML also had samples at AML phase available for analysis. Among patients with MDS, three had N-Ras mutations at diagnosis and 8 had N-Ras mutations at AML phase. None had K-Ras mutations at diagnosis but 3 acquired the mutations at AML phase. None had PTPN11 mutations at diagnosis and at AML phase. The time to AML transformation and OS were not statistically different between patients with and without N-Ras, K-Ras, or PTPN11 mutations. Among patients with CMML, sixteen had N-Ras mutations at diagnosis and 9 at AML phase (3 of them did not have mutations at diagnosis). Three patients harbored K-Ras mutations at diagnosis. One patient gained K-Ras mutation at AML phase. Four patients (4.3%) had PTPN11 mutations at diagnosis and 2 of them retained the same mutations at AML phase. The time to AML transformation and overall survival (OS) were not statistically different between patients with and without N-Ras, K-Ras, or PTPN11 mutations. However, CMML patients with N-Ras mutations had the trend of inferior OS than those without the mutations (P=0.068). We found that N-Ras, K-Ras, and PTPN11 mutations were mutually exclusive in patients with MDS or CMML. *Conclusions.* Our results showed that N-Ras mutation played a role in the AML transformation and no patients had PTPN11 mutations at diagnosis and at AML phase in patients with MDS. PTPN11 mutations were rare in patients with CMML. There was no statistical difference in term of time to AML transformation and OS according to the status of N-Ras, K-Ras, and PTPN11 mutations in patients with MDS and CMML.

COMPARING THE PROGNOSTIC VALUE OF DIFFERENT TYPES OF PHENOTYPIC ABNORMALITIES OF HEMOPOIETIC PRECURSORS IN MYELODYSPLASTIC SYNDROMES

I Lorand-Metze, C Reis-Alves, F Traina, S Saad, K Metze

State University of Campinas, Campinas, Brazil

Background. several phenotypic alterations of bone marrow (BM) hemopoietic precursors have been described in myelodysplastic syndromes (MDS). Increase and abnormal phenotypes of $CD34^+$ cells have been associated with a worse outcome of the patients. *Aim.* to compare the influence on survival of several kinds of phenotypic abnormalities with that of peripheral cytopenias and IPSS. *Methods.* BM of newly diagnosed patients with MDS was examined by multiparametric flow cytometry examining the myelomonocytic lineage and the hemopoietic progenitors in four-color combinations. The influence on overall survival of age, PB counts, IPSS, total number of phenotypic abnormalities, abnormalities of granulocytic and monocytic precursors as well as BM percentage of blasts in cytology and subsets of $CD34^+$ cells were analyzed using the Cox model. *Results.* We analyzed 55 cases: 6 RA, 2 RARS, 30 RCMD and 17 RAEB. IPSS: 22 cases were low risk, 20 intermediate-1, 7 of intermediate-2 and 6 were high risk. Median follow-up time: 23 months (1-43). In the univariate analysis, the following variables were associated with a shorter survival: aggressive WHO type (P=0.001), a higher IPSS score (P=0.004), the degree of anemia (P=0.007), a higher BM blast percentage in cytology (P<0.0005), but not age, PB neutrophils and platelets. Among the flow cytometric variables, the total number of phenotypic abnormalities (P=0.004) and that of $CD34^+$ cells (P=0.002), as well as the percentage of $CD34^+$ cells (P<0.0005), $CD34^+/CD13^+$ (P=0.0006) and $CD34^+/CD13^-$ cells (P=0.0002), besides $CD34^+/CD19^+$ cells among all nucleated cells (P=0.05). The number of granulocytic aberrancies and the number of dendritic cell precursors had no influence on survival. In the multivariate Cox regression comparing IPSS with PB counts and phenotypic abnormalities, only IPSS and the number of abnormalities of $CD34^+$ cells were independent risk factors. In a model comparing only the percentage of blasts in cytology and each single abnormality of $CD34^+$ cells stratified by WHO type, only the percentage of blasts in cytology and the increase of $CD34^+/CD13^-$ cells were independent risk factors for a shorter survival. *Conclusions.* specific phenotypic changes in MDS, rather than their total number are important risk factors in MDS. Among them, the most important were the changes in $CD34^+$ cells which reflect the degree of genetic disarrangement of hemopoietic precursors producing a maturation block of the abnormal clone.

FAK EXPRESSION IN MYELODYSPLASTIC SYNDROME AND ACUTE LEUKEMIA

J Machado-Neto, M Lazarini, B Mendes-Silva, L Fröhlich-Archangelo, C Bigarella, F Costa, S Saad, F Traina

Faculty of Medical Sciences, University of Campinas, Campinas, Brazil

Background. Myelodysplastic syndrome (MDS) encompasses a heterogeneous group of clonal hematopoietic stem cell disorders characterized by ineffective hematopoiesis, refractory cytopenia and a tendency to progress towards acute myeloid leukemia (AML). The occurrence of acute leukemia results from a combination of mutations and changes in protein functions that confer the ability of proliferation, defects in cell differentiation and apoptosis. The identification of cellular signaling pathways responsible for the increase in survival and reduction in cellular differentiation of myelodysplastic cells is of great importance, because these signaling pathways may represent therapeutic targets in an attempt to prevent progression to AML. Focal Adhesion Kinase (FAK) is a key mediator of signaling induced by inte-

grins and plays an instrumental role in cell survival and proliferation. Increased FAK expression in acute leukemia was associated with resistance to Danorrubicina therapy and poor prognosis, however, no study of the expression or function of FAK in MDS has been performed. *Aims.* The aim of the present study was to investigate the gene and protein expression of FAK in MDS, AML and ALL patients and to correlate the level of expression with low risk *vs.* high risk MDS according to FAB. *Methods.* We studied 09 healthy donors, 27 patients with MDS (18 low risk [RA/RARS] and 09 high risk [RAEB/RAEBt] according to FAB classification), 14 patients with AML (07 M2, 01 M3, 03 M4, 02 M5, 01 M6, according to FAB classification) and 10 patients with ALL (5 T ALL and 5 Pre B ALL). Samples were obtained from total cell of bone marrow. Gene expression was evaluated by real time RT-PCR in total cells. Western blot of mononuclear cell of bone marrow (patients) or 34^+ cell of peripheral blood (healthy donors) was performed for protein expression *Results.* Real time RT-PCR demonstrated a significant decrease in FAK expression of AML cells compared with normal haematopoietic cells (0.10 [1.22-0.005] *vs.* 0.29 [1.00-0.08], P=0.04) or with low risk MDS cells (0.10 [1.22-0.005] *vs.* 0.36 [1.42-0.01], P=0.01); no differences in FAK expression was detected between low and high risk MDS cells (0.36 [1.42-0.01] *vs.* 0.16 [2.39-0.01], P=0.19) and when comparing high risk MDS cells or ALL cells with normal haematopoietic cells (0.16 [2.39-0.01], P=0.34 or 0.10 [1.16-0.01], P=0.13 *vs.* 0.29 [1.00-0.08], respectively). Western blot analysis revealed absence of FAK expression in AML samples, but a positive expression was detected in $CD34^+$ cells as well as in ALL patient samples, confirming real-time *Results. Conclusion.* FAK is down-regulated in AML cells. The inclusion of a higher number of high risk MDS would be necessary in order to point out the involvement of FAK in disease progression of MDS towards AML. Background. Myelodysplastic syndrome (MDS) is a hematological malignancy characterized by dysplasia and ineffective hematopoiesis. The lineage affected in this pathology is the myeloid one. Plasma cells disorders (PCD) affect B-cells derivates, producer of immunoglobulines, the most common being monoclonal gammopathy of undetermined significance (MGUS) and; the most classic, the multiple myeloma (MM). The coexistence of both pathologies is a rare event, although, the appearance of a MDS following plasma cells pathology is more frequent. In this study, we describe the cytogenetic characteristics of a series of 15 preliminary cases with the coexistence of both MDS and a PCD at presentation. *Patients and methods.* Reviewing cases with the diagnosis of PCD and MDS from centers belonging to the Spanish Hematological Cytogenetics Working Group (GCECGH) and to the MDS International Cytogenetics Working Group, we recruited 42 cases. Among them, 27 presented a MDS during the evolution of the PCD, and 15 presented a coexistence of PCD and MDS at diagnosis time. We have collected cytogenetic information: conventional cytogenetics in short term culture and FISH 5q result (in case it was performed). In some cases in which the FISH was performed on plasma cells, have been also reported. Results. The following table shows the diagnoses, conventional cytogenetic and FISH (Fluorescence *in situ* Hybridization) information from our series of 15 patients. *Conclusions.* The following preliminary conclusions can be highlighted: 1- The short term culture showed in all cases karyotype corresponding to MDS, but one case with a complex karyotype (more close to the PCD). 2- MDS karyotype presented similar findings and incidence of chromosomal abnormalities than cases with *de novo* MDS, although in two cases trisomy 8 and deletion 20q were observed. 3- From eight patients in whom the FISH analysis on 5q was performed, half of them revealed aberrations of chromosome 5, not previously observed by conventional cytogenetics. However, trisomies are more typical of PCD, suggesting hyperdiploidy. This work is presented on behalf of the Grupo Cooperativo Español de Citogenética Hematológica (GCECGH), and the International Working Group on MDS Cytogenetics of the MDS Foundation. *Acknowledgements.* This work has been partially supported by grants from Instituto de Salud Carlos III, Ministerio de Sanidad y Consumo, Spain: FI07/00107.

FLOW CYTOMETRY COUNTING AND ANALYSIS OF MYELOID AND NUCLEATED ERYTHROID CELLS WITH IRREGULAR ANTIGENIC PROPERTIES IN MYELODYSPLASTIC SYNDROME

O Pikovsky, I Levy, T Sidortsov, T Shimon, E Madar, I Dulman, M Kafka, G Shubinsky

Soroka University Medical Center, Beer Sheva, Israel

Background. Myelodysplastic syndrome (MDS) is a group of clonal stem cell disorders hallmarked by refractory cytopenia and blood cell dysplasia. Flow cytometry (FC) is a useful method to study hematopoiesis and detect myelodysplasia. The analysis of myelopoesis is the most informative part of FC analysis in MDS, particularly when the results of morphology or cytogenetic testing are ambiguous. FC finding of dysplastic myeloid cells in bone marrow is currently documented by abnormal distribution of cells with myeloid markers in different fluorescent dot plots. Unsatisfactory level of standardization and difficulty in interpretation of results limit the utility of FC in diagnosis of MDS. The identification and enumeration of dysplastic cells by FC in suspected MDS may help to standardize and simplify the diagnostic work-up. This approach to FC analysis of patients with MDS has not been tested, and its clinical significance remains unknown. *Study aim.* The present study was performed to evaluate the diagnostic significance of FC count of dysplastic myeloid and erythroid cells in MDS. *Methods.* The patient's cohort enrolled in this study consisted of 47 cases of MDS and joined control group composed of 10 cases of idiopathic cytopenia of undetermined significance (ISUS), 56 cases of disorders distinct from MDS and ICUS but with potential impact on bone marrow hematopoiesis (pathological controls), and 15 patients with normal BM (normal controls). Bone marrow myelopoiesis was studied using multicolor staining and specially designed analysis templates. The cells failed to pass the gates collecting normal cells, were classified as myeloid or erythroid cells with undetermined (irregular) antigenic characteristics (MUC/NEUC). These cells were collected and counted using logical (Boolean) gate. The ratio between myeloid and lymphoid progenitors, $CD117^+$ cell count and B-cell maturation index were the additional FC parameters measured in patients. *Results.* Cell analysis revealed an elevated number of MUC in 84% patients with MDS, comparing to

30% patients in joined control group (P<0.0001, Fisher's exact test). The specificity of MUC count was 78%, the sensitivity was 83% with negative predictive value 91%. Increased number of NEUC was found in 69% patients with MDS and in 40% of controls (P<0.02). The combination of these two tests for diagnosing MDS showed the precision rate of 89% and negative predictive value of 94%. The finding of elevated MUC number together with abnormal values of any two additional FC parameters had a significantly increased specificity of the test. *Conclusion.* The study demonstrated that FC may be used for detection and count of myeloid and nucleated erythroid cells with abnormal antigenic characteristics in MDS. The enumeration of dysplastic cells may simplify FC criteria for the diagnosis of MDS and facilitate diagnostic procedure in patients suspected for having MDS.

Seragnoli, Bologna, Italy; [10]Chair of Haematology, Unit of Blood Diseases and Cell Therapies, Brescia, Italy

Background. Nucleoside 5-Azacitidine (5-Aza) in high risk MDS patients (pts) at a dose of 75mg/mq/day subcutaneously for 7 days, every 28 days, induces high hematologic response rates (hematologic improvement (HI) 50-60%, complete remission (CR) 10-30%) and prolongation of survival (at 2 years 50,8%). *Aim.* The role of 5-Aza in low-risk MDS patients is not well defined but its use in the earlier phases of disease could be more effective and useful to control the expansion of MDS clone and disease progression. In our phase II, prospective, multicentric trial a low-dose schedule of 5-Aza (75 mg/mq daily for 5 consecutive days every 28 days) was given to low-risk MDS pts in order to evaluate its efficacy and tolerability and to identify biological markers to predict the response. *Methods.* From September 2008 to February 2010, 34 patients were enrolled into the study. Fifteen patients had refractory anemia (RA), 5 patients refractory anemia with ringed sideroblasts (RARS), 7 patients refractory cytopenia with multilineage dysplasia (RCMD) and 7 patients refractory anemia with excess blasts-1 (RAEB-1). All patients failed previously EPO therapy and were in chronic red blood cell (RBC) supportive care with a median transfusions requirement of 4 units/monthly. The response treatment criteria was according to IWG 2006. *Results.* At present time 31 out of 34 pts are evaluable: 12/31 pts (39%) completed the treatment plan (8 courses), 7/31 pts (22%) performed the first 4 courses, 8/31 (26%) made 1 to 3 courses and 4/31 (13%) died during the treatment period. Out of 12 pts who completed the 8 courses of therapy 10 (83%) obtained an HI, 2/12 (17%) maintained a stable disease. Out of 10 pts who obtained HI, 4 pts (40%) achieved a CR. Generally the drug was very well tolerated. The most commonly reported hematologic toxicities were neutropenia (55%) and thrombocytopenia (19%) but they were transitory and usually no delay of treatment was necessary. 2/4 pts died early after the 1th cycle for septic shock and gastrointestinal hemorrage respectively whereas 2/4 pts died in a condition of stable disease after the 4th cycle for pneumonia and respiratory distress. Samples for biologic studies have been collected from the pts before starting the therapy and at the end of 4th and 8th course. Preliminary data on the lipid signalling pathways suggested a direct correlation between PI-PLC-β1 gene expression and 5-Aza responsiveness. *Conclusion.* Interim analysis of our study based on the small number of cases who completed the treatment program, shows that 83% of pts obtain an HI and 40% obtain a CR. 4 patients died during the treatment and even if the causes were reported as no related to the therapy it has been considered that caution has to be reserved in given 5-Aza in these pts who are elderly and frail. Preliminary data of PI-PLC-β1 gene expression suggest that this and probably other biological markers could help us to know a priori who are the patients who have more chances to respond. *Acknowledgments.* this work was supported by MIUR 2008.

ISOCHROMOSOME 17q AND DELETION 17p AS MARKERS OF GOOD CLINICAL RESPONSE TO DECITABINE IN MYELODYSPLASTIC SYNDROMES

M Iastrebner,[1] JH Jang,[2] S Benasayag,[3] D Fassi,[4] G Saidon,[5] G Garay,[6] A De Leon Bustamante,[7] D Caviglia,[8] M Gonzalez[5]

[1]San Luis Medical Center, Buenos Aires, Argentina; [2]Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Seoul, South-Korea; [3]Fundagen, Buenos Aires, Argentina; [4]Hospital Universitario de la UAI, Buenos Aires, Argentina; [5]OSECAC, Buenos Aires, Argentina; [6]Cemic, Buenos Aires, Argentina; [7]Hospital Aeronático, Córdoba, Argentina; [8]Hospital Aeronáutico, Buenos Aires, Argentina

Background. Isochromosome 17q or *<i17q)* plays a presumably important pathogenetic role both in leukemia development and myelodysplastic syndrome (MDS) progression. p53 gene aberrations can result from an *<i17q)* or *del(17p)* in MDS patients with poor risk prognosis. MDS rarely displays a p53 mutation. The deoxycytidine analog decitabine not only is thought to reflect its ability to reactivate methylation-silenced genes, but also is known to induce a ribonucleotide reductase (p53R2/RRM2B), a robust transcriptional target, that correlates with good clinical response (Petra A Link, Cancer Res, 2008;8, 9358). *Aims.* To report clinical response to decitabine in MDS patients displaying *<i17q)* or *del(17p)*. *Methods.* Patients with *<i17q)* or *del(17p)* were analyzed from our international database made up of 99 MDS patients treated with decitabine as from July 2007 through December 2009. These patients displayed *<i17q*) or *del(17p)* as an isolate aberration or combined with at least 2 chromosomal alterations. We ruled out complex karyotypes (more than 3 cytogenetic abnormalities), and correlated chromosome findings with clinical response to decitabine that was infused at a dose of 20 mg/m^2/day in an outpatient setting. This study took into account WHO classification, International Prognosis Score System (IPSS) and International Working Group (IWG) 2006. *Results.* Four out of the 99 patients displayed *<i17q)*, in two cases as an isolate finding (patient #1 and #2), in another case (patient #3) combined with *del(5q)* and *del(7q)*; and patient #4 presented *del(17p)* combined with *del(11q)*. Baseline patient characteristics and clinical response are described in the Table below. All patients presented primary MDS, required transfusions before decitabine therapy, and had not received previous chemotherapy. Patient #1 and #2 had received erythropoietin and patient #4 had been treated with Thalidomide. There were no comorbidities except for patient #1, who suffered from ulcerative colitis. According to IPSS, patient #2 and #4 belonged in the high risk group, patient #3 in INT-2, and patient #1 in INT-1. Patient #1 achieved cytogenetic remission and is waiting for an unrelated bone marrow transplant. *Summary.* The *<i17q)* or *del(17p)* correlated *in vivo* with good clinical response in MDS patients under decitabine as it was described by literature mentioned above. This data highlights and guarantees further studies.

Table.

Patient	Age/ Sex	MDS Subtype	Karyotype	Nº cycles	Clinical Response
# 1	52M	RCMD	46,XY,i(17)(q10)[11]	7	Complete Response
# 2	64F	RAEB 2	46,XX,i(17)(q10)[20]	5	Stable Disease
# 3	71M	RAEB 2	46,XY,i(17)(q10), del(5q),del(7q)[9]	3	Hematology Improvement
# 4	79F	RAEB 2	46XX,del(17p),del(11q)[8]	8	Complete Response

RISK ASSESSMENT IN MYELODYSPLASTIC SYNDROMES (MDS)

S Improta, A Gagliardi, A Lucania, P Della Cioppa, MR Villa, M Esposito, A Quirino, L Mastrullo

ASL Na[1] Centro, Naples, Italy

Background. Myelodysplastic Syndromes (MDS) are clonal hematopoi-

etic stem-cell disorders characterized by ineffective dysplastic hematopoiesis involving one or more cell lineages, by peripheral-blood cytopenias and a high risk of progression to acute myeloid leukemia (AML). The slowly evolving process of neoplastic transformation explains the clinical, morphological and prognostic heterogeneity which is not sufficiently addressed even in current classification systems. *Aims.* We investigated the role of WT1 gene expression and its association with the expression of the chemokine receptor CXCR4 on bone marrow $CD34^+$ cells of MDS patients. *Methods.* BM samples from 46 MDS patients (according to WHO classification: 21 RA, 7 RAEB I, 4 RAEB II, 9 RARS, 3 deletion of 5q, 2 MDS unclass) were tested for WT1 expression at diagnosis and every 6 months. WT1 gene expression was evaluated by methods of real-time quantitative PCR (RQ-PCR). Surface CXCR4 expression were measured flow cytometrically. *Results.* At diagnosis, 22BM samples (10 RA, 6 RAEB I, 4 RAEB II, 1 RARS, 1 MDS unclass) expressed WT1 transcript amounts greater than the ranges level. The degree of WT1 expression was highly correlated with the type of MDS, was much higher in RAEB I and II compared with RA, and other types, and increased during disease progression. Moreover, a significant correlation was found between WT1 expression levels, blast cell percentage and CXCR4 over-expression on blast cells (as defined by CXCR4 mean fluorescence intensity ratio thresholds of more than 5). The patients received only a supportive therapy if necessary. After 6 months, 9 patients (2 RA, 5 RAEB I, 2 RAEB II) converted to AML. All of these patients showed at diagnosis an high WT1 and CXCR4 expression and a further elevation of WT1 expression level after 6 months. *Conclusions.* WT1 expression has been previously reported to be increased also in myelodysplastic syndromes. In this study, the data obtained show that in most MDS, including a large percentage of RA and almost the total number of RAEB I and II, WT1 is expressed above the range observed in normal controls in BM and that its expression is directly correlated with the type of MDS. A strong association is present between the level of WT1 expression and the blast percentage and the CXCR4 over-expression. The identification of a molecular marker so able to establish the tendency of MDS to progression can be of great help in decision making for MDS patients. Our results justify further investigation into the role of CXCR4 in MDS and suggest that WT1 and CXCR4 should be incorporated into the risk assessment of MDS patients.

'STANDARD' DOSES OF RH-EPO ARE HIGHTLY EFFECTIVE IN IMPROVING ANEMIA IN SELECTED 'LOW-RISK' MYELODYSPLASTIC PATIENTS

E Balleari,[1] M Clavio,[1] E Arboscello,[1] A Bellodi,[1] A Bruzzone,[1] M Cavalleri,[1] E Cenni,[1] L Del Corso,[1] M Laura,[2] M Lucchetti,[1] C Passalia,[1] I Pierri,[1] I Ponassi,[1] F Olcese,[1] C Oneto,[1] O Racchi,[3] V Sicbaldi,[1] S Timitilli,[4] L Vignolo,[1] M Scudeletti,[4] M Sessarego,[1] M Gobbi,[1] R Ghio[1]

*[1]University of Genoa, Genova, Italy; [2]*Sanremo Hospital ASL,[1] Sanremo, Italy; [3]Villa Scassi Hospital ASL,[3] Genova, Italy; [4]°Sestri Levante Hospital ASL,[4] Sestri Levante, Italy*

Background. Since more than twenty years recombinant human erythropoietin (rhEPO) has been widely used to correct anemia in patients with myelodysplastic syndromes (MDS). While first clinical trials -usually conducted with relatively low doses of rhEPO (ranging from 12.000 to 30.000 U per week)- showed favourable responses to rhEPO in no more than 15-20% of such population as a whole, in the last decade a better selection of MDS patients - i.e. reserving treatment to patients with low/intermediate-risk MDS - allowed for a relevant increase of the response-rate, ranging around the 40% of treated individuals; more recently, several studies demonstrated a favourable clinical response in an even higher percentage of low-risk MDS patients (proximally 50 to 65 %) using high-doses (up to 80.000 U weekly) of rhEPO. These treatments, however, are costly and not easily affordable in the long time. *Aims.* In order to verify if an accurate selection of MDS patients could results in a satisfying response-rate with a less expensive schedule of rhEPO, we prospectively explored the effects of "standard"doses of rhEPO in a cohort of anemic "low-risk"MDS patients. *Methods.* From January 2005 to December 2009 a total of 55 anemic (Hb <10 g/dL) consecutive patients (29 males; 26 females; median age 78 years) with low/intermediate-1-risk MDS (IPSS 0 -1) were treated after informed consent with rhEPO-alpha 40.000 U per week subcutaneously for at least 3 months; at the end of this period hematologic response was assessed; only patients achieving an hematologic response were allowed to continue treatment indefinitely; safety and efficacy of the treatment was recorded along the entire duration of the study. *Results.* According to IWG 2006 criteria, after 3 months of treatment 36 out of 55 (65.5%) patients achieved a favourable response to rhEPO; while the percentage of responders did not significantly differed according to different IPSS scores (67,7% with IPSS score 0 *vs.* 62,5% with IPSS score 0,5-1) response to rhEPO was significantly correlated with lower WPSS scores (90%, 53% and 42% of responders for WPSS 0, 1 and 2-3 scores, respectively). Treatment was discontinued because of unmanageable side effects in only one patient. Among the 36 responders, after a median follow-up of 38 months, 28 (77%) still maintain a hematologic response and continue the treatment. Progression to high-risk MDS or acute leukemia was observed in 7 out of the 55 patients after a median of 26 months. *Conclusions.* In summary, our study indicate that "standard"doses of rhEPO are at least equally effective as higher doses to induce durable hematological improvement in anemic patients with low-risk/intermediate 1 MDS; in this clinical setting, this schedule allows for a consistent reduction of costs of the treatment without precluding the achievement of potential benefit from a challenge with rhEPO.

Background. The myelodysplastic syndrome (MDS) associated with isolated 5q- and restricted with marrow blasts less than 5% was called '5q- syndrome'. This unique subtype of low-risk MDS with favorable prognosis is known as good responder of lenalidomide recently and occurs predominantly but not exclusively in middle age to older women in Western countries. In contrast, the patients with other abnormalities in chromosome 5 showed quite different clinical features from those with '5q- syndrome'. *Aims.* The aim of this study was a retrospective evaluation of clinical characteristics and prognostic impact of various factors in Korean patients with abnormalities in chromosome 5 including '5q- syndrome'. *Methods.* Among 456 patients with MDS diagnosed at 16 hospitals in Korea between 1996 and 2006, 370 patients with available cytogenetic data entered the study. Univariate and multivariate analysis including various prognostic factors were performed. *Results.* On the basis of chromosomal analysis, 93 out of 370 patients (25.1%) showed abnormalities in chromosome 5. The '5q-syndorme' was documented only in 10 patients (2.7%). The deletion of 5q was interstitial, of variable size, but with a predominance for 5q13-33 deletions (34.8%). The female predominance (P=0.029) was documented similar to Western country. The anemia was more prominent (P=0.003) and macrocytic (P<0.001) in '5q- syndrome' than other MDS patients. The erythroid hypoplasia in marrow seemed to be prominent in '5q- syndrome' (P=0.149). None of '5q- syndrome' was transformed to leukemia and overall survival was significantly better than other patients. (P=0.036). Thirty nine patients (41.9%) had various abnormalities in chromosome other than 5q deletion such as translocation with other chromosome or 5 monosomy. They didn't share the clinical features with '5q- syndrome'. The patients with mosaic chromosomes with isolated 5q- and normal chromosome also showed different clinical outcomes with '5q- syndrome'. *Summary/Conclusions.* The incidence of '5q- syndrome' in Korea was lower than that reported in Western countries. The favorable clinical features of '5q- syndrome' were also documented in Korean patients. Patients with isolated 5q- and excess blast (>5%), other abnormalities than isolated 5q-, or mosaic chromosome with isolated 5q- and normal chromosome didn't share the clinical features such as lower rate of leukemic transformation and long survival.

DIAGNOSTIC UTILITY OF FLOWCYTOMETRY IN MYELODYSPLASTIC SYNDROME: A FIRST STUDY FROM INDIA

A Chopra, R Kumar, H Pati, M Mahapatra, P Mishra, T Seth, S Singh

All India Institute of Medical Sciences, New Delhi, India

Background. Flow cytometry is now being increasingly evaluated to define its apparently promising role in the diagnosis of myelodysplastic syndrome (MDS). Expert recommendations emphasize the need for further validation and standardization, including flow cytometric (FCM) evaluation of secondary myelodysplasia. In this first study from India we have used 5 - color flow cytometry to evaluate patients with MDS. *Aim.* To evaluate the role of flow cytometric immunophenotyping in diagnosis of myelodysplastic syndrome. *Methods.* Thirty four cases with unexplained cytopenias and suspected MDS were prospectively studied. Five - color analysis using Coulter FC500 was done on bone marrow (BM) samples without knowing the morphological diagnosis. These subjects were compared with normal controls (no leukemia or MDS) using primary gating of blasts, myeloid cells and monocytes according to CD45 expression and side scatter. Normal fluorescence intensity and maturation pattern was collected from 31 control BM: 3 hypersplenism, 17 idiopathic thrombocytopenic purpura, 4 lymphoma staging marrow, 6 post-chemotherapy regenerating marrows and 1 peripheral blood sample from donor of peripheral blood stem cell transplantation. A large panel using antibodies reported in the literature was employed including CD34, CD45, HLA-DR, CD38, CD117, CD33, CD13, CD64, CD14, CD11b, CD16, CD15, CD56, CD10, CD71, CD235a, CD36, CD7, CD2, CD5, and CD19. Cases were placed into "positive", "intermediate"and "negative"flow cytometric categories based upon numerical and antigenic aberrancies observed on blasts and myelomonocytic cells. Flow results were correlated with morphological diagnosis and cytogenetics. *Results.* Of the 34 cases, 22 (64.71%) had MDS by morphology while 11 (32.3%) exhibited no myelodysplasia. The remaining single case had dysplastic megakaryocytes only on BM biopsy. Of the 22 cases with MDS (8 RCUD, 7 RCMD, 1 RAEB-1, 4 RAEB-2 and 2 MDS-U), 19 (86.36%), 3(13.64%), and 0 (0.0%) cases were FCM positive, intermediate and negative, respectively. The patient with dysplastic megakaryocytes only, had abnormal flow pattern but responded to hematinics and hence was considered false positive for flow. The most common abnormality in the blastic population was abnormal expression of lymphoid antigens (CD2, CD5, CD7, CD19 or CD56) (n=12) while the commonest abnormalities in the maturation pattern were discernible with the following antibody combinations: CD34/CD38 (16/22; 72.7%), CD16/HLA-DR (13/22; 59.1%), CD13/HLA-DR (13/22; 59.1%), CD11b/CD15 (13/22; 59.1%) and CD13/CD16 (13/22; 59.1%). The overall sensitivity was 91.67% and overall specificity 86.36% and 100%, respectively, depending on whether the intermediate category was excluded or included as an indicator of MDS. In all patients with low grade MDS (n=17), PNH test was negative and therapeutic trial with vitamin B12 and folic acid had failed. Serum iron studies, serum vitamin B12 and folate levels were normal. Cytogenetics was normal in 21/22 (95.45%) and trisomy 8 was found in one patient. *Conclusion.* FCM is a very sensitive and useful tool for diagnosis of MDS. Abnormalities in blast segment and the maturation pattern of myeloid and monocytic cells of the BM are very informative. The small but significant number of cases that give false positive result, warrant analysis of normal controls and cases with secondary dysplasia using multicolor immunophenotyping.

EVALUATION OF GENE METHYLATION STATUS AND FOLATE METABOLISM IN PATIENTS WITH MYELODYSPLASTIC SYNDROME

E Cortesão,[1] A Gonçalves,[2] M Sousa,[3] C Moucho,[1] L Rito,[1] E Magalhães,[1] A Espadana,[1] M Pereira,[4] A Teixeira,[1] J Nascimento Costa,[1] AB Sarmento Ribeiro[2]

[1]University Hospitals of Coimbra, Coimbra, Portugal; [2]Faculty of Medicine and Center of Investigation in Environment Genetics and O, Coimbra, Portugal; [3]1. University Hospital of Coimbra, Coimbra, Portugal; [4]Distrital Hospital of Figueira da Foz, Figueira da Foz, Portugal

Aberrant methylation patterns are common mechanisms in human neoplasia, especially in hematopoietic neoplasms. Many genes may be involved; cell cycle regulators, as the tumor suppressor gene p15, are frequently inactivated in MDS by aberrant methylation and have been correlated with the risk of evolution toward AML and poor prognosis. Several studies suggest that folate intake/status modulates DNA methylation. Functional polymorphisms in key genes may also influence DNA methylation namely those related with MTHFR. A common MTHFR gene polymorphism involving a C-T transition at codon 677 is associated with reduced methylation of CpG DNA in human lymphocytes under conditions of low folate status. Less is known about the A1298C polymorphism, but most studies have failed to show a relationship between this polymorphism and aberrant methylation. The aims of this study are the evaluation of the methylation patterns of genes involved in MDS, p15/p16, and its relationship with folate/vitamin B12 levels. We hope to contribute for the identification of molecular risk markers: the role of epigenetic gene modulation and its interference with prognosis, evolution to AML and therapeutic approach in MDS patients. We examined the methylation status of the cell cycle regulators p15/p16 in CD34 bone marrow cells populations collected at diagnosis from 26 patients with MDS and in 8 non-malignant controls(Immune Thrombocytopenic Purpura,ITP), using a methylation specific-PCR. We also evaluated the folate/vitamin B12 serum levels, by a commercial radioimmunoassay kit, and the MTHFR polymorphisms, C677T and A1298C, by PCR-RFLP, in patients and in 289 healthy controls. The median SMD patients age is 74 years(33-84), gender M/F=14/12, the distribution according WHO-subtypes is: RCMD(n=9), RA(n=5), RAEB-1(n=3), RAEB-2(n=5), CMML(n=3), 5q-syndrome(n=1) and according IPSS is: low(n=7), intermediate-1(n=13) and intermediate-2(n=6). Seven patients (6-RAEB and 1-CMML,IPSS intermediate-1 and -2) evolve to AML, with a median follow-up of 28 months(16-71). Our preliminary results show that 74% of cases of MDS have at least one methylated gene. p15 methylation occurred in 39% MDS patients, while p16 methylation occurred in 37%. p15 methylation was present in all the RA and 5q- syndrome patients and in 25% of patients with the RCDM subtype. On the other hand, p16 methylation was observed in all subtypes expect RAEB-2 and CMML (75%-RA and RCDM;100%-5q- syndrome and RAEB-1). Only 2 of the 7 patients who evolve to AML show aberrant methylation. The levels of folate/B12 seem to influence methylation, since low levels are associated with methylation, especially of p16. Twenty patients, mainly RCDM, have the polymorphism C677T, and this may be a risk factor for the disease (OR-3,982). However, the polymorphism A1298C also predominates in this population. This study suggest that p15 and p16 seem to be an event in the MDS development and serum folate/vitamin B12 low concentrations might be associated with the risk of promoter methylation in tumor-specific genes, especially p16 gene. On the other hand, in MDS patients, the MTHFR polymorphisms CT(C677T) and AC(A1298C) predominate, being the first one a risk factor for this disease. Surprisingly, in the majority of patients who evolve to AML, we didn't found aberrant gene methylation.

1388

THROMBOCYTOPENIA IN MYELODYSPLASTIC SYNDROME BASED ON THE DATA OF A SINGLE-CENTER ROMANIAN REGISTRY

R Gologan

Fundeni Clinical Institute, Bucharest, Romania

Introduction. Thrombocytopenia is a challenging finding in myelodysplastic syndrome (MDS) patients because, when severe, it is an important cause of death by life-threatening bleedings, and also it is difficult to manage because no approved specific pharmacologic therapy exists yet. The interest in MDS-related thrombocytopenia increased recently due to the promising results obtained with some specific drugs. *Material and Methods.* The patients recruited between 1982 and 2004 constituted the database of the MDS Registry comprising 403 primary adult cases. The registration form was kindly provided by the MDS Foundation (USA) and the diagnosis of MDS was based on well-accepted FAB minimal diagnosis criteria. Thrombocytopenia was defined as a platelet count ≤100,000/mcL and was divided in three subgroups of severity: mild (100,000-51,000), moderate (50,000-21,000) and severe (≤20,000). The parameters age, sex, rural/urban location, temporal trend and distribution by FAB subtypes were analysed comparatively in thrombopenic and non-thrombopenic MDS cases. The frequency, type and severity of hemorrhagic complications and of their implications on survival and clinical practice are also analyzed. *Results.* A retrospective review of thrombopenic patients at referral identified 182 cases (45%). The isolated thrombopenia represented 1% in the MDS registry and 2% in the thrombopenic cohort. There were 43% cases in the mild, 34% cases in the moderate and 23% cases in the severe group with a median platelet count of 77,000/mcl, 39,000/mcl and 14,000/mcl, respectively, with no differences among the age subgroups. No signif-

icant difference between the thrombopenic and non-thrombopenic cases concerning the epidemiological characteristics was found. The temporal trend of the thrombopenic cases was significantly higher in the group ≥60 years compared to ≤50 years, similarly with the trend found in the whole cohort of MDS patients of our registry. A significant predominance of the thrombopenic cases in the high-grade FAB subtypes was found. *Conclusions.* To our knowledge, this is the first epidemiological study on the MDS patients with thrombocytopenia in Europe and the presented findings are close to those reported in a similar study by the MD Anderson Cancer Center (USA) in 2007. However, the percentage of thrombopenic MDS patients appears significantly lower in the present study, reflecting the inherent difference in referral between a hematooncological center with a MDS specialized unit and a large but ordinary hematological department where bone marrow transplantation was not available.

1389

MNSOD ALA(16)VAL POLYMORFISM AS A RISK MARKER FOR MYELODYSPLASTIC SYNDROME?

AC Gonçalves,[1] E Cortesão,[2] AI Espadana,[3] L Rito,[3] E Magalhães,[3] MJ Lobão,[4] A Pereira,[4] I Sousa,[3] A Teixeira,[3] AB Sarmento-Ribeiro[5]

[1]Faculty of Medicine, University of Coimbra, Coimbra, Portugal; [2]Clinical Hematology Service, University Hospital of Coimbra (HUC) and CIMAGO, Coimbra, Portugal; [3]Clinical Hematology Service, University Hospital of Coimbra (HUC), Coimbra, Portugal; [4]Distrital Hospital of Figueira da Foz, Figueira da Foz, Portugal; [5]Faculty of Medicine, CIMAGO, CNC, University of Coimbra, Coimbra, Portugal

Myelodysplastic syndrome (MDS) is a heterogeneous stem cell bone marrow disorder characterized by the underproduction of one or more blood cells types, due to haematopoiesis dysfunction, and higher risk of leukemic transformation. The aetiology and pathogenesis of MDS remain poorly characterized and may arise *de novo* or be secondary to treatment with chemotherapy or radiation therapy. Indirect evidences suggest a role for oxidative stress (OS) in MDS aetiology and pathogenesis. OS, resulting from an imbalance between Reactive Oxygen Species (ROS) production and antioxidant defences, contributes to cell damage, apoptosis and ineffective haematopoiesis. A genetic polymorphism in the mitochondria targeting sequence of the MnSOD gene, resulting in a substitution of valine (Val) to alanine (Ala) at amino acid 16, leads to a defective localization of the antioxidant enzyme to the inner mitochondrial membrane. This polymorphism has been associated with an increase in breast, prostate and colorectal carcinoma cancer risk. However scanty studies are done in haematological neoplasias, namely in MDS. In the present study we set to investigate the influence of Val16Ala MnSOD polymorphism as a risk factor of MDS development and as a prognostic risk marker in MDS patients. For this purpose we analyzed MnSOD polymorphisms by PCR followed by restriction digestion in 33 MDS patients and 62 controls from the same geographical area, ethnic background and approximately similar age. The patient group median age was 79 years (33-84), gender M/F=18/15, WHO subtypes: RCMD (n=9), RA (n=9), RAEB-1 (n=3), RAEB-2 (n=7), 5q- syndrome (n=2) and IPSS: low (n=8), intermediate-1 (n=14) and intermediate-2 (n=6). Allele frequencies were determined by direct count of the alleles. Departures from Hardy-Weinberg equilibrium and differences between groups were evaluated by the chi-square test. ORs and 95% CIs were determined by using Fisher's exact Test and Kaplan-Meier survival analysis were used to investigate the prognostic importance of MnSOD polymorphism. Our preliminary results show a higher C allelic frequency in MDS patients (75%) while controls present a higher T allelic frequency (55%). In MDS patients the frequency of TT, CT and CC genotype was 6%, 54% and 40%, respectively, Besides that, individuals with CC genotype have an increase risk for MDS about 3,014-fold (CI95% 1,159-7,834; P=0,0269). On the other hand, the TT genotype might be a protective factor (OR=0,2022; CI95% 0,04317-0,9466; P=0,0464). Our results also show that MnSOD genetic polymorphism might be related with MDS subtype and prognosis, since we observed differences in MDS overall survival between genotypes (without significance). However, we are currently being tested this observation in a large cohort of samples. This study indicate that MnSOD polymorphisms may confer susceptibility to the development of MDS, since individuals with MnSOD CC genotype have an increase risk 3-fold, and may also be related with the subtype, prognostic and survival of MDS patients.

ROLE OF WT1 IN JUVENILE MYELOMONOCYTIC LEUKEMIA

A de Vries,[1] C Zwaan,[1] P Bader,[2] A Willasch,[2] M Aalders,[3] O Haas,[4] V de Haas,[5] C Niemeyer,[6] M van den Heuvel-Eibrink[1]

[1]Erasmus MC, Sophia Children's Hospital, Rotterdam, Netherlands; [2]Wolfgang University of Frankfurt, Division of Pediatric Hematology and Oncology, Frankfurt, Germany; [3]University of Amsterdam, Amsterdam, Netherlands; [4]Children's Cancer Research Institute, Vienna, Austria; [5]Dutch Childhood Oncology Group, The Hague, Netherlands; [6]Department of Pediatric Oncology, University of Freiburg, Freiburg, Germany

Background. Approximately 75% of patients with juvenile myelomonocytic leukemia (JMML) harbour mutations in PTPN11, NF1 and RAS genes. Recently mutations in c-CBL were identified playing a role in the pathogenesis of JMML. Still, in about 15% of the cases no mutations are found. In adult patients with acute leukemia and MDS increased levels of WT1 expression are reported. In these patients determination of WT1 expression is considered to be a suitable technique for the monitoring of minimal residual disease. Furthermore, WT1 mutations predict poor outcome in adult and childhood acute myeloid leukemia (AML). In JMML WT1 expression levels in bone marrow have been reported to be significantly higher than in normal bone marrow. *Aims.* To investigate if the higher WT1 expression is caused by mutations in the WT1 gene and whether they play a role in the hyperproliferation in JMML. *Methods.* In 48 JMML patients screening for mutations in the whole WT1 gene was performed (exon 1-10) on DNA by PCR and direct sequencing. Quantitative expression analysis of WT1 was performed by qRT-PCR. *Results.* In only one patient a mutation was found in exon 1 of the WT1 gene. Mean expression levels were higher as compared to normal bone marrow, but lower as compared to acute myeloid leukemia. Expression levels were not correlated to mutation status, white blood cell count, blast count or absolute monocyte count. *Conclusion.* In JMML patients the expression of WT1 is higher as compared to normal bone marrow. This higher expression is not caused by mutations in the WT1 gene.

1391

SYSTEMIC AND IMMUNE MANIFESTATIONS IN MYELODYSPLASIA. A MULTICENTRIC RETROSPECTIVE STUDY.

C Belizna,[1] C Belizna,[1] M Hamidou,[2] H Lévesque[3]

[1]CHU Angers, Angers, France; [2]CHU Nantes, Nantes, France; [3]CHU Rouen, Rouen, France

The presence of systemic and/or immune manifestations in myelodysplasia is classical, even thought rarely presenting as initial clinical event. *Purpose.* We present a multicentric retrospective study (2002-2009) with systemic and/or immune manifestations dominating the clinical presentation. *Patients et methods.* 46 patients with a formal diagnosis of myelodysplasia, presenting systemic and/or immune manifestations have been studied during a eight year period (2002-2009). The clinical picture in these cases consisted in transient fever, not related to infections. (17%), arthralgia or arthritis (12%), and especially cutaneous (purpura 25%, nodular 12%, papular 7%, and necrotic lesions 6%) related to cutaneous lymphocytary and/or leucocytoclasic vasculitis. In 8% of the cases this leucocytoclasic vasculitis was mainly present in muscular vessels, evoking panarteritis. Lung symptoms were occasional (4% of cases), the same as renal manifestations (4% of cases). Even though infrequently, some rare cases of systemic vasculitis have been reported in our series (one panarteritis 2%, one cas of Wegener granulomatosis, one cas of microscopic polyangeitis et one cas of Churg-Strauss syndrome). Immune anomalies were recorded in 29% of the cases (antinuclear antibodies 22%, ANCA 4%, rheumatoid factor 8%). A corticosteroid treatment was efficient in 92% of the cases. The presence of vasculitis during myelodysplasia has been reported in 63% of the cases, and represented a marker of acutisation (relapse) in 49% of the cases. A vasculitis initial clinical presentation has been found in myelodysplasia in 37% of the cases in our series (and preceded myelodysplasia with a mean period of 6 months). *Discussion and conclusion.* The association between myelodysplasic syndromes with systemic and immune manifestations seems to not be occasional and suggest the eventuality of a potential common primary immune disorder.

1392

HEMATOLOGIC RESPONSE TO AN ALTERNATIVE DOSING SCHEDULE OF AZACITIDINE IN HIGH-RISK MYELODYSPLASTIC SYNDROMES

C Finelli,[1] C Clissa,[1] M y Follo,[2] A Curti,[1] S Paolini,[1] C Papayannidis,[1] N Testoni,[1] E Ottaviani,[1] S Parisi,[1] G Martinelli,[1] L Cocco,[2] M Baccarani[1]

[1]Istituto di Ematologia Seràgnoli, Bologna, Italy; [2]Istituto di Anatomia, Bologna, Italy

Background. Azacitidine (AZA) has proven effective in Myelodysplastic Syndromes (MDS), as it has been shown to induce: a) significant reduction of transfusion dependence; b) decreased risk of evolution into acute myeloid leukemia (AML); c) improvement of quality of life; d) significant increase of overall survival, as compared to conventional care regimens, in high risk patients (pts.) (Silverman LR, J Clin Oncol 2002; Fenaux P, Lancet Oncol 2009). The currently approved AZA regimen is 75 mg/sqm/die subcutaneously (SC) or intravenously (IV) for 7 days every 28 days. Recently 3 different AZA dosing regimens, which avoid week-end dosing, have shown to induce therapeutic responses consistent with the currently approved schedule (Lyons RM, J Clin Oncol 2009). In particular, one of them, i.e. the AZA 5-2-5 regimen (50 mg/m^2/d subcutaneously for 5 days, followed by 2 days no treatment, then 50 mg/m^2/d for 5 days) allows the administration of a nearly equivalent monthly total dose of AZA, saving 4 vials/month (28% of the actual cost). Moreover, some data suggest the possibility that prolonged exposure to lower doses of AZA may increase the response rate (Gore SD, Cancer Res 2006). However, the community-based study of Lyons mainly involved lower-risk MDS pts. *Aims.* These data prompted us to investigate the therapeutic effect of the more convenient and less expensive AZA 5-2-5 regimen in higher-risk MDS patients (i.e.: IPSS risk: high or intermediate-2). *Methods.* From December 2007, in our Institution, 10 consecutive MDS pts. (6 males), with a median age of 69 (52-79) yrs, were treated with the AZA 5-2-5 regimen. IPSS risk was high (2 pts) or intermediate-2 (8 pts). IPSS-based cytogenetic risk was: high (2 pts), intermediate (3 pts), low (5 pts). *Results.* The pts received a median number of 7 (3-10) AZA cycles. 7 pts. (70%) showed a favourable response, following IWG criteria (Cheson BD, Blood 2006): 1 Complete Remission (CR), and 6 Hematologic Improvement (HI). Among them, erythroid response was observed in 2 pts, platelet response in 5 pts and neutrophil response in 3 pts. 1st response occurred after a median of 3 (3-6) cycles. The 3 non-responder pts maintained a stable disease (SD) during treatment. 2 of them received at least 6 cycles of AZA, 1 pt stopped treatment after the 4th course because of worsening of clinical condition. 2/3 non-responder pts died, 1 following evolution into AML, 1 because of infection. 1 responder pt stopped treatment after the 8th cycle because of disease progression (AML), and is still alive. Summary/*Conclusions.* Our data seem to confirm, in a population of higher risk MDS pts, the favourable results obtained by Lyon with the 5+2+5 AZA regimen in lower risk pts. These results need to be supported by larger studies, and the effect of this alternative dosing schedule on survival also needs to be assessed.

TREATMENT WITH AZACITIDINE IN THERAPY-INDUCED MSD. PRELIMINARY DATA FROM THE SPANISH AZACITIDINE COMPASSIONATE USE REGISTRY

R Garcia,[1] L Entrena,[1] G Sanz,[2] MD De Miguel,[3] M Amutio,[4] T Bernal,[5] J Besalduch,[6] S Brunet,[7] A Bailen,[8] J Guzman,[9] J Sanchez,[10] C Martinez,[11] H Garcia-Quiroga,[12] M Garcia-Talavera,[13] J Falantes,[14] R Garrido,[15] M Romero[16]

[1]Hospital Virgen de la Victoria, Malaga, Spain; [2]Hospital La Fe, Valencia, Spain; [3]Hospital de Guadalajara, Malaga, Spain; [4]Hospital de Cruces, Bilbao, Spain; [5]Hospital central de asturias, Oviedo, Spain; [6]Hospital de Son Dureta, Mallorca, Spain; [7]Hospital San Pau, Barcelona, Spain; [8]Hospital Carlos Haya, Malaga, Spain; [9]Hospital Jerez de la Frontera, Jerez, Spain; [10]Hospital Reina Sofia, Cordoba, Spain; [11]Hospital clinic, Barcelona, Spain; [12]Hospital Xeral, Lugo, Spain; [13]Nuestra Señora de la Candelaria, Tenerife, Spain; [14]Hospital Virgen del Rocio, Sevilla, Spain; [15]Hospital La Paz, Madrid, Spain; [16]Hospital del Mar, Barcelona, Spain

Background. Therapy-related Myelodysplastic Syndromes/Acute Myeloid Leukemias (t-MDS/AML) are one of the most compelling long term adverse events occurring in cancer survivors treated with chemoradiotherapy regimes. Beside several well-described genetic lesions, a growing amount of data suggests that abnormalities in DNA methylation profile contribute to multistep secondary leukemogenesis. Cytotoxic drugs and radiation have been shown to affect tissue DNA methylation profile. In general, patients with therapy-induced MDS have a poorer prognosis then patients with *de novo* MDS. Azacitidine (AZA) is a hypomethylating agent recently approved in Europe for the treatment of MDS. AZA was available in Spain under compassionate use before its commercial approval in May 2009. *Material and Methods.* We present the preliminary analysis of the clinical data from a longitudinal, multicenter Spanish patient registry. Data on the disease course and management of patients with MDS treated with AZA under compassionate use conditions were retrospectively collected from community-based hematology clinics. As of Febrary 1, 2010, 30 patients with intermediate-2/high IPSS-risk therapy-induced MDS diagnosed according to WHO criteria had been included. *Results.* At baseline the median age was 76 years, the male/female ratio was 13/17 with an ECOG performance status of 0-1 60%. The most frequent initial dose of AZA applied was 75 mg/m^2 AZA was administered mostly subcutaneously (80%). The mean number of cycles administered was 6. The overall treatment response was 46,6% (International Working Group 2006 criteria): 16% complete response, 3,3% complete bone marrow response, 6,6% partial response and 20% hematological response. In addition, 23,3% achieved stable disease. AZA was generally well tolerated. The grade 3/4 adverse events documented in these patients, regardless of their relationship to active treatment, were neutropenia (26%), thrombocytopenia (33%), anemia (20%), febrile neutropenia (3%), rash (6%), colicky lumbar pain (3%) and subcutaneos zone reaction (6%).Similar response rates were observed in patients with MDS secondary that in primary ones. *Conclusion.* Our results demonstrate that in a community-based setting, patients with intermediate-2/high-risk therapy-induced MDS respond to treatment with AZA. These favorable results suggest that patients with secondary MDS may benefit of 5-AZA. More data coming from this registry and from the clinical trials are awaited.

PRELIMINARY SAFETY ANALYSIS OF AN EXPANDED ACCESS PROGRAM FOR DECITABINE IN SUBJECTS WITH MYELODYSPLASTIC SYNDROME (MDS)

J Pereira,[1] J Vaz,[2] A Apa,[3] I Lorand-Metze,[4] L Niero Melo,[5] MA Zanichelli,[6] S Magalhães,[7] ML Chauffaille,[8] TC Bortolheiro,[9] R Uehara,[10] P Novita,[10] AP Navarrette Lotito[10]

[1]Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, Sao Paulo, Brazil; [2]Centro de Tratamento Oncológico, Brasília, Brazil; [3]Instituto Nacional do Câncer (INCA), Rio de Janeiro, Brazil; [4]Hemocentro da Universidade de Campinas (UNICAMP), Campinas, Brazil; [5]Universidade Estadual Paulista Júlio de Mesquita Neto (UNESP), Botucatu, Brazil; [6]Hospital Brigadeiro, São Paulo, Brazil; [7]Hospital Universitário Walter Cantídio (HEMOCE), Fortaleza, Brazil; [8]Universidade Federal de São Paulo (UNIFESP), São Paulo, Brazil; [9]Santa Casa de Misericórdia de São Paulo, São Paulo, Brazil; [10]Janssen Cilag Brazil, São Paulo, Brazil

Background. Decitabine is a hypomethylating agent, approved by the FDA for treating MDS. In 2008 an expanded access program was established in Brazil to make decitabine available to subjects with MDS. *Aims.* To present the results of an interim analysis, regarding the patient's baseline characteristics and safety profile. *Methods.* Between August 2008 and June 2009, 30 Brazilian patients diagnosed with *de novo* MDS were enrolled for treatment with decitabine in 9 different centers. The decitabine schedule used in all the subjects was 20 mg/m^2/day for 5 days, in a four-week cycle for four cycles. To associate some baseline characteristics to the occurrence of adverse events during the course of treatment we underwent an analysis using the chi-square test. *Results.* The median age was 65.5 (range 30-80), most of the patients were men (60%) and had a good Performance Status (ECOG 0+1: 86.7%, ECOG 2: 13.3%). Regarding IPSS, 19 patients (63.3%) were Int-1, 7 were Int-2 (23.3%) and 4 (13.3%) were High risk. All the patients had anemia, 63.4% were neutropenic and 60% were thrombocytopenic before starting the treatment. Regarding the cytogenetics, most of the patients (66.7%) had a good prognosis karyotype. Eighty percent were at transfusion support, mostly with RBC transfusions. The most frequent hematologic adverse events related to decitabine were: neutropenia (63.3%), thrombocytopenia (53.3%) and anemia (36.7%). Febrile neutropenia related to the treatment occurred in 43.3% of the patients and infections were detected in 12 (40%). Dose reductions and dose delays were performed mostly after the first cycle (12% and 71.8%, respectively), mostly due to hematologic toxicity. The transfusion need had a small increase after the first cycle (80-86.7%), but decreased progres-

sively until the fourth cycle (45%). During the treatment with decitabine, 80% of the patients required antibiotics, either prophylactic or therapeutic. In an association analysis, it was observed that the patients with ECOG Performance Status 2 were at a higher risk of developing infection (P=0.016), hemorrhage (P=0.031) and constipation (P=0.031). No statistically significant difference was found among the FAB classification and IPSS score groups regarding the occurrence of adverse events. We also observed that patients from the age group 60-75 years had a higher percentage of neutropenia than the group older than 75 years (P=0.018). In the sample of 30 patients, 9 (30%) died most deaths related to infections, and 3% discontinued the study medication during the four cycles. *Conclusion.* In this sample, the FAB classification and IPSS had no statistically significance in the risk of development infection, hemorrhage or constipation. Patients with ECOG 2 were at higher risk of developing these adverse events.

1395

DECREASED EXPRESSION OF RIZ1 AND ITS CORRELATION WITH RISK STRATIFICATION IN MDS PATIENTS

W Xie,[1] XQ Li,[1] XJ Chen,[1] S Huang,[2] SA Huang[1]

[1]Union Hospital of Tongji Medical College, Wuhan, China; [2]The Burnham Institute for Medical Research, La Jolla, USA

Background. RIZ1, the retinoblastoma protein-interacting zinc finger gene, is now considered to be a candidate tumor suppressor in many types of human cancers. Expression of RIZ1 is reduced in a variety of human solid tumors including breast cancer, liver cancer, colon cancer, neuroblastoma, melanoma, lung cancer, and osteosarcoma. Suppression of RIZ1 expression is also found in a few of neoplastic hematologic disorders such as acute myeloid leukemia (AML), chronic myeloid leukemia (CML) and lymphomas, indicating that downregulated expression of RIZ1 may play an important role in leukemogenesis and disease progression. However, alteration of RIZ1 gene expression in myelodysplastic syndrome (MDS) has not been reported to date. *Aims.* To investigate the expression of RIZ1 and its correlation to development, disease progression and risk stratification in human MDS. *Methods.* We analyzed the expression of RIZ1 by quantitative real-time reverse-transcription polymerase chain reaction assay in 22 untreated MDS patients and in 6 patients with nonneoplastic hematologic diseases as control. Results were expressed as a ratio between the RIZ1 mRNA expressed in MDS and normal bone marrow cells. Values that differed from normal cell values by 2 standard deviation (SD) units were considered significant. *Results.* The expression of RIZ1 was significantly decreased in MDS group (0.59±0.27 *vs.* 1.00±0.19, P<0.05, compared with control group) in 15 of 21 (71%) patients. When compared with noncancerous patients, MDS patients of RA subtype (0.84±0.36) owned the statistically same expression of RIZ1 (P>0.05), but patients of RCMD (0.29±0.05), RAEB-1 (0.64±0.15) and RAEB-2 (0.31±0.09) subtypes showed a significantly decreased expression of RIZ1 (P<0.05). Likewise, RIZ1 mRNA level decreased obviously in high risk group (including RAEB-1 and RAEB-2 subtypes; 0.49±0.18, P<0.05), but had no statistical change in low risk group (including RA, RCMD and 5q- subtypes; 0.70±0.35, P>0.05). The RIZ1 expression of high risk group tended to be lower than that of low risk group, but the difference was not statistically significant. *Summary.* Decreased gene expression of RIZ1 is very common in human MDS and its level alters among WHO subtypes or risk groups. The expression of RIZ1 may contribute to the evaluation of development, progression and risk-stratification in MDS.

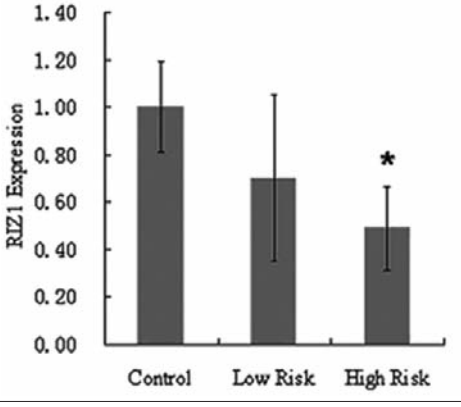

Figure. RIZ1 expression in MDS patients. *P<0.05.

IMPACT ON THE SURVIVAL OF PROLIFERATIVE TYPE MYELOMONOCYTIC LEUKEMIA DIAGNOSED PATIENTS

B Moreno de Gusmao,[1] E Perez-Persona,[1] J Guinea,[1] M Ardanaz,[1] A Mendizabal,[1] C Menchaca,[1] J Feliu,[2] J Calavia[3]

[1]Hospital Txagorritxu, Vitoria-Gasteiz, Spain; [2]Hospital San Pedro, Logrono, Spain; [3]Hospital Reina Sofia, Tudela, Spain

Background. Chronic myelomonocytic leukemia (CMML) is characterized by its extensive heterogeneity clinical and evolutionary, behaving as a mielosdisplastic syndrome (MDS) with defective and ineffective clonal cell proliferation or features of mieloprolyferative chronic disorders (cMPD) with Leukocytosis, monocytosis, organ involvement (eg.splenomegaly) and hypermetabolism. The scores used in the MDS are not reproducible to predict its evolution, and there are no studies that indicate the start of an active treatment based on prognostic factors. *Aims.* The study aimed to identify the variables to the diagnosis of cmml with impact on the risk of transformation in acute myeloid leukemia (AML) and overall survival (OS) and propose a new prognostic score index to identify high-risk patients and treated early. *Patients and Methods.* They have been revised as retrospective features 44 cmml criteria the FAB and between the years 1978-2010 WHO diagnosed patients. The median age was 80 years old and 37 were men (84,1%). According to the criteria of the FAB 26 patients have the MDS and 18 cMPD and according to the WHO clasification 86.4% (N = 38) were CMML-1 (blasts <10% in bone marrow and <5% in blood) y 13,6% (n=6) were cmml-2. They valued the alterations in the karyotype of 38 patients (altered 12) and find the presence of organomegaly in 29.5% (n = 13) patients. With a point cut of Hb 10 g/dL, 15 patients showed lower figures and the number of LDH > 400 U/L observed in 69,2% (N = 27) of patients. β-2 microglobulin (>4mg/L) was studied in 27 patients and were abnormal in 47% of patients. Having identified these variables from poor prognosis, we evaluated the OS curves built with KAPLAN-MEIER method. *Results.* In the sample we have evaluated the wrong variables forecast and its impact on survival. The organomegaly was present at 61.5% of the cMPD-CMML (P=0.07), 66.7% of patients with abnormal karyotype was proliferative type and the LDH > 400 U/L was mostly in these patients. 27 Patients studied β-2 microglobulin 69,2% (P=0, 35) were myeloproliferative-CMML and moving those variables to survival curves,patients with cMPD-CMML have a 4.7 months *vs.* 28.3 survival in patients that no presented. It was noted the value separately as well as in conjunction with significant decrease in survival. *Conclusions.* The results of our study confirm the poor prognosis of patients of CMML associated with other variables such as alterations in the karyotype, proliferative type, Hb<10 g/dL, levels of β-2 microglobulin >4 mg/L. A clinical trial with new drugs is needed to assess the effectiveness of early treatment in high-risk patients.

1397

FREQUENCY OF H63D MUTATION IN THE HFE GENE IN ADULT PATIENTS WITH MYELODYSPLASTIC SYNDROMES

F Ferrara,[1] L Pagano,[2] R D'Elia,[1] M Celentano,[1] F Pollio,[3] D Laudati,[3] A Viola[3]

[1]Hematology and stem cell tranplantation unit, Naples, Italy; [2]Center for Hemoglobinopathies, Cardarelli Hospital, Naples, Italy; [3]Hematology and Stem Cell Tranplantation Unit, Naples, Italy

Background. The Hereditary hemochromatosis gene (HFE) plays a pivotal role in iron homeostasis. An increased incidence of HFE gene mutations has been described in hematologic malignancies, including acute leukemias and lymphoproliferative disorders. On the contrary, few data are available in patients with myelodysplastic syndromes (MDS), in which HFE mutations could have major clinical relevance, by interfering with iron overload due to transfusion dependence. Among general population, the allelic frequencies of C282Y and H63D, which is the more frequent mutations of HFE gene in Italy, are 0.037 and 0.16 in the Northern regions and 0.015 and 0.16 in the Southern regions. *Aims.* To investigate the allelic frequency of HFE gene mutations in 51 adult patients with MDS, diagnosed according to the current WHO criteria; 25 patients had refractory anemia (RA), 21 refractory anemia with blast excess (RAEB1= 9, RAEB2= 12) and 5 as refractory cytopenia with multilineage dysplasia (RCMD); MDS data were compared to those deriving from 230 healthy blood donors. In addition, data were also compared with those from a series of 107 patients with acute myeloid leukemia (AML) other than acute promyelocytic leukemia. We did specifically focus on H63D mutation, which either in the study group

or in the controls was the most frequent. *Methods.* HFE genotyping was performed by a polymerase chain reaction (PCR) method using sequence-specific-primers, and the products were analyzed on agarose gel and by Reverse Dot Blot. Statistical differences between the prevalence of HFE genotypes in the patients and controls as well as between different diseases and subtype of disease were assessed using the chi square test. P values were considered as statistically significant at a value <0.05. In addition, for any difference Odd's ratio and confidence intervals (CI) were also calculated. *Results.* The median age was 75 years for MDS patients (range 24-92), 40 years for blood healthy donors (19-55) and 55 years for AML patients (14-90). The allelic frequency of H63D mutation was 21 % in MDS patients and 25% in the healthy controls (P=0.58; odds ratio = 1.20; 95% CI=0.77 to 1.93). Furthermore, no significant difference was found between MDS and AML patients (21% *vs.* 29%, P=0.20; odds ratio = 1.37; 95% CI = 1.05 to 5.36). Finally, no statistically significant difference was found among the two main MDS subtypes (16% for RA *vs.* 24 % RAEB, p: 0.43; odds ratio = 1.20; 95% CI = 0.78 to 4.35). *Conclusions.* Our data demonstrate the absence of correlation between the presence of H63D mutation and the occurrence of MDS as opposed to normal population. In addition, no difference exists in the allelic frequency of the mutation between MDS and AML as well as between early and late MDS.

1398

ROLE OF ANTIAPOPTOTIC AND PROANGIOGENIC CYTOKINES IN THE COURSE OF DIFFERENT SUBTYPES OF MYELODYSPLASTIC SYNDROME

O Bojko, O Danysh, M Simonova, K Kotlyarchuk, Y Vyhovska, A Mazurok, Z Maslyak

SI Institute of Blood Pathology and Transfusion Medicine, UAMS, Lviv, Ukraine

Background. Significant importance in pathogenesis of myelodysplastic syndrome (MDS) belongs to the process of angiogenesis stimulated mainly by vascular endothelial growth factor (VEGF), however, some other cytokines, particularly transforming growth factor-β (TGF-β), also show certain angiogenic activity. Aim of this study was to determine the role of antiapoptotic and proangiogenic cytokines in the course of certain MDS subtypes with different levels of malignancy (refractory anemia (RA), refractory anemia with excess of blasts (RAEB)). *Methods.* Twenty one patients with MDS RA (mean age of 49,10±3,80) and 6 patients with MDS RAEB (mean age of 69,67±2,68) were investigated. The control group included 27 healthy volunteers with their age ranging from 20 to 54. TGF-β and VEGF levels were determined in blood serum by immune-enzyme analysis using the standard BIOSOURSE kits, USA. *Results.* Level of the antiapoptotic cytokine TGF-β was higher in patients with MDS RAEB. Three of RA patients had TGF-β levels higher, than the control group and other 18 showed the same levels as the healthy volunteers or even lower. Serum level of the proangiogenic cytokine VEGF was quite variable in patients with RA ranging from 15,43 to 183,21 pg/mL. In 5 RA patients it was considerably lower than the control value (114,44±11,08 pg/mL) and only in one case its level was twice as high as the controls. Among 6 patients with RAEB three had serum VEGF levels 2,5 times higher than the controls, whereas in other three patients its values were 4 times lower than in the control group. Blood and bone marrow investigations of the RAEB patients showing higher VEGF levels revealed prevalence of proliferative activity (increased level of peripheral blood leukocytes, hypercellular bone marrow); at the same time patients with lower levels of VEGF showed peripheral blood leucopenia and bone marrow hypocellularity. The course of MDS was quite stable in the latter group of patients; none of them developed transformation to acute leukemia during one year, despite persistent anemia, thrombocytopenia, increased blast counts. On the contrary, two of the three patients showing high VEGF levels progressed to acute leukemia 8 and 10 months after the first diagnosis respectively. There was a tendency observed that patients with low VEGF levels showed also low values of TGF-β, whereas patients with progressive disease had levels of both cytokines increased. *Conclusions.* Analysis of data obtained show that certain role in development of leukemic transformation of MDS belongs not only to the pro- and antiapoptotic cytokines but also to the process of angiogenesis. Relatively stable disease without progression in patients with MDS RA may result from the low TGF-β and VEGF production and increased apoptosis of hemopoietic cells. Elevation of TGF-β causes increase of proliferative potential and apoptosis inhibition, which along with activated angiogenesis induces disease transformation. Impaired angiogenesis (probably due to fibrotic changes in the bone marrow) even in condition of elevated TGF-β may contribute to disease stabilization. This data may explain certain success achieved by administration of antiangiogenic and proapoptotic medications in MDS patients.

1399

IMMUNOBIOLOGY AND IMMUNOPHENOTYPE OF PERIPHERAL BLOOD MONOCYTES IN CHRONIC MYELOMONOCYTIC LEUKAEMIA

Y Hayman,[1] S Ali,[2] J Greenman,[3] C Carter[2]

[1]Hull University, Hull, UK; [2]Queens Oncology and Haematology Department, Hull, UK; [3]The University of Hull, Hull, UK

Chronic Myelomonocytic Leukemia (CMML) is a clonal disorder of the bone marrow resulting in monocytosis coupled with dysplasia in one or more myeloid cell lineage. Although classified as a separate disease CMML shows similarities with both myelodysplastic syndrome (MDS) and myeloproliferative disorder (MPD). Previous studies have shown excessive apoptosis in the bone marrow of MDS patients in addition to increased levels of Bcl-2 whilst in MPD, proliferation predominates. Using flow cytometric techniques peripheral blood $CD14^+$ monocytes were analysed for markers of proliferation (Ki-67) and apoptosis (Annexin V/Propidium Iodide) in addition to intracellular apoptosis regulatory proteins Bcl-2 and BID. Investigations were also carried out into the cell surface immunophenotype of CMML circulating monocytes. A tendency towards proliferation over apoptosis was observed in CMML compared with controls. Significant findings were reduced expression of both Bcl-2 and BID (P=0.015 and P=0.009 respectively), Bcl-2 expression correlating with haemoglobin levels and white blood cell count. Further correlations were seen between BID and both haemoglobin level and bone marrow blast cell count. Significant increased expression of CD56 on $CD14^+$ monocytes was observed along with decreased expression of CD3 and CD4 on lymphocytes. Correlations were found between CD56 and both Bcl-2 expression and bone marrow blast count. These findings, although preliminary, show that CMML may be more closely related to MPD, rather than MDS. Also a distinct lack of BID contributes to the pathogenesis of CMML and that CD56 expression may be used as a favourable prognostic marker.

1400

CIRCULATING MALIGNANT CLONAL CELLS IN PERIPHERAL BLOOD IN MDS: VERIFICATION USING INTERPHASE FLUORESCENT *IN SITU* HYBRIDIZATION AND ITS CORRELATION WITH BONE MARROW CLONAL CELLS

M Kim,[1] S Kim,[1] SM Hwang,[1] CJ She,[1] B Oh,[2] TY Kim,[2] SS Yoon,[1] DS Lee[1]

[1]Seoul National University Hospital, Seoul, South-Korea; [2]Seoul National University College of Medicine, Seoul, South-Korea

Background and Aims. Bone marrow (BM) cells are believed to be the source of neoplasm in the myelodysplastic syndromes (MDS). We investigated whether the clonal proliferating pattern of peripheral blood truly reflects that of bone marrow. *Methods.* Interphase fluorescence *in situ* hybridization (iFISH) was performed on peripheral blood mononuclear cells from 9 MDS patients who had showed clonal abnormalities in the bone marrow at the initial diagnosis. Collection time of the peripheral blood sample, bone marrow diagnosis, type of clonal abnormality detected in bone marrow at the initial diagnosis, and the quantity of the clonal abnormality are as follows: patient 1 - initial diagnosis, RCMD, del(5q), 86.0%; patient 2 - initial diagnosis, RAEB-1, del(5q), 80.0%; patient 3 - initial diagnosis, RCUD (RN), tetrasomy 1q, 66.5%; patient 4 - follow up without stem cell transplantation (SCT), RAEB-2 progressed from RAEB-1, monosomy 7, 90.5%; patient 5 - follow up without stem cell transplantation SCT, RCUD (RA) sustained from RCUD (RA), del(5q), 45.0%; patient 6 - follow up after SCT, no engraftment after SCT in RCUD (RA), trisomy 1q, 5.0%; patient 7 - follow up after SCT, complete response after SCT in RAEB-1, trisomy 1q, 31.0%; patient 8 - follow up after SCT, complete response after SCT in RAEB-2, trisomy 1q, 64.5%; patient 9 - follow up after SCT without follow up bone marrow study (peripheral blood study only), RCUD (RA) at the initial diagnosis, trisomy 8, 69.0%. Probes (Vysis Inc.) were used to detect 5q, 7q, 8 and 1q abnormalities. The results were compared with iFISH results of bone marrow at the initial diagnosis and at the follow up. *Results.* The same types of clonal abnormalities were detected in similar quantity in the initial bone marrow, the follow-up bone marrow and the peripheral blood mononuclear cells in patients 1, 2, 3, 4 and 5. Patients 6, 7 and 8 showed no clonal abnormalities in peripheral blood and bone marrow at the follow up. Patient 9 showed the same clonal abnormality (trisomy 8) in peripheral

blood at the follow up as in the bone marrow at the initial diagnosis in a reduced dose (69.0% *vs.* 2.5%). *Conclusions.* We concluded that the types and the quantities of clonal abnormalities in the peripheral blood mononuclear cells well reflect those of bone marrow. Our results suggest the potential use of peripheral blood cells in the disease monitoring of the MDS patients without invasive bone marrow study.

Table. Profiles of the patients and the samples.

Patient No.	Initial BM/Follow up BM	SCT*	PB collection time	Initial BM FISH/ Follow up BM FISH/ PB FISH
1	RCMD/-	No	Initial Dx.	deletion 5q (86.0%/-[1]/75.5%)
2	RAEB-1/-	No	Initial Dx.	deletion 5q (80.0%/-/77.0%)
3	RCUD (RN)/-	No	Initial Dx.	tetrasomy 1q (66.5%/-/25.0%)

CURRENT MANAGEMENT AND SURVIVAL OF IRISH PATIENTS WITH MYELODYSPLASTIC SYNDROME.

C Mchale, N O'Connell, H Enright

Adelaide and Meath, Incorporating the national childrens' hospital, Dublin, Ireland

Background. Myelodysplastic Syndromes (MDS) is commonly associated with a poor prognosis in high risk patients, and an indolent course in low risk patients. As a result, patients may not be eligible for active treatment. *Aims.* To examine the management strategies and survival of MDS in an Irish patient population. *Methods.* We prospectively collected data regarding management and survival for MDS patients from our own database (1999-2009) and those registered with the National MDS Registry. *Results.* Data is presented for 220 patients. Median age was 73 years (range 15-94 years). Where data is available regarding WHO categorisation, 153 (69%) patients had RA, RCMD, RARS or RCMD-RS and 67 (30%) had RAEB or CMML. 152 patients (69 %) required transfusion. 34 (15%) received transfusion therapy alone; only 87 received Erythropoietin (39%). Four patients received iron chelation therapy. Thirty seven (16.8%) patients were treated with GCSF. 25 (11%) patients received both Erythropoietin and GCSF therapy. Forty nine patients (22%) received low dose chemotherapy, 15 were treated with Azacytadine and 30 with Hydroxyurea - 4 patients received both. 4 were treated with Thalidomide and 6 received Lenalidomide. Twenty one patients received AML induction-type therapy and 8 patients remain alive. Eight patients were transplanted (one autograft and 7 allografts). Of the patients where follow-up information is available, 110 remain alive and 90 have died. The median survival for the entire group was 22 months, 25 months for the 135 patients with data from the low grade MDS and 17 months and for the 65 with data from high grade group. *Summary/Conclusions.* MDS remains a disease that is not always actively managed although management options have improved with the onset of new medications such as Azacytadine. 39 (17%) received no treatment either in the form of medication or transfusion. Less than half of transfusion-dependent patients receive Erythropoietin therapy and very few are treated with iron chelation therapy. A small number receive aggressive chemotherapy. Most patients with MDS die as a result of their disease, and long-term survival is rare in high-risk disease.

1402

EFFICACY AND TOLERABILITY OF 5-DAY AZACYTIDINE DOSE INTENSIFIED REGIMEN IN HIGHER RISK MYELODYSPLASTIC SYNDROMES

F Pierdomenico, A Parreira, A Almeida

Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisbon, Portugal

Background. Azacitidine is a hypomethylating agent indicated for treatment of higher risk Myelodysplastic Syndromes (MDS). A recently published phase III trial demonstrated improved overall survival (OS) of MDS patients treated with azacitidine compared to those receiving conventional care regimens, thus establishing this treatment option as first line therapy in those patients for whom bone marrow transplantation is not an option. The recommended azacitidine dosing regimen is 75 mg/m^2/day subcutaneously for 7 days every 4 weeks. Three alternative dosing were recently compared, achieving similar results to the approved schedule. Limited resources and patient comfort would favour a five day regimen if this was equally effective. *Aims.* Evaluate the efficacy of a 5-day dose intensified azacitidine regimen in terms of transfusion independence (TI), overall response (OR), time to Acute Myeloid Leukemia (AML) transformation and tolerability in patients with higher risk MDS and AML with 20-30% blasts. *Methods.* Higher risk (International Prognostic Scoring System - IPSS intermediate-2 and high risk) MDS patients were treated with the 5-day intensified azacitidine schedule (100 mg/m^2/day subcutaneously for 5 days every 4 weeks) in our institution. OR, including complete response (CR), partial response (PR) and haematological improvement (HI), defined according to the 2000 International Working Group Criteria (IWG), were assessed by blood and bone marrow examination after the sixth cycle. Treatment cycles were repeated until toxicity or disease progression. *Results.* A total of 13 patients were treated: nine patients with refractory anaemia with excess blasts (RAEB), two with AML with 20-30% blasts and two with chronic myelomonocytic leukaemia (CMML). The average age was 71 years old (range 33-85) and 77% were men. Most patients were high risk according to IPSS scoring (77%). Azacytidine was used as first line therapy in 42%. An average of 7,5 cycles (1-18) per patient were administered. Four patients interrupted treatment following the first cycle, one due to disease progression and three due to patient refusal following admissions with pneumonias. The average follow-up period was 21 months. The overall response rate was of 53%, all of whom became TI, with average response duration of 11 months. Marrow responses were obtained in 2 patients (15%) (1 CR and 1 PR) both of which had good risk cytogenetics. During the follow-up period, nine patients died with average interval between diagnosis and death of 25 months. Six deaths were due disease progression whilst three were due to acute pneumonia in the absence of disease progression. Ten patients (77%) had Grade III haematological toxicity and three (23%) suffered Grade IV haematological toxicity. Grades I and II gastrointestinal and skin toxicity were recorded in all patients. *Conclusions.* The efficacy of Azacitidine in achieving TI and prolonging survival in MDS is well recognized. However, the recommended 7 day regimen is often difficult due to limited resources. In this small cohort a 5 day dose intensified azacitidine schedule was well tolerated and achieved similar response rates to those published. Larger studies would be necessary to validate this regimen.

1403

HIGH-RESOLUTION SNP ARRAYS AS AN ADDITIONAL TOOL TO SEARCH FOR GENETIC DEFECTS INVOLVED IN PROGRESSION FROM MYELODYSPLASTIC SINDROME TO ACUTE LEUKEMIA

G Palumbo,[1] V Barresi,[2] C Capizzi,[2] N Musso,[2] C Consoli,[1] C Meli,[1] A Romano,[2] F Di Raimondo,[1] D Condorelli[2]

[1]Biomedical Sciences Department - Haematology Section - University of Catania, Catania, Italy; [2]Laboratorio sui Sistemi Complessi, Scuola Superiore Università di Catania, Catania, Italy

Myelodysplastic syndromes (MDS) often progress to acute myeloid leukemia (AML), but the molecular basis of this transformation are not fully known. In order to find clues to identify genes involved in progression, we studied a high-risk MDS patient with high resolution SNP arrays (molecular cytogenetics) at different stages of the disease. This technique can detect lesions between 1-10 Mb and map two different genetic alterations: copy number variants (CNVs) and copy neutral-loss of heterozygosity (CN-LOH). CNVs comprise submicroscopic variants of 1 kb or larger, which include deletions, duplications, insertions, inversions and traslocations not present in a reference genome while CN-LOHs represent extended tracts of homozygosity occuring without concurrent changes in the gene copy number (CN). We report of a 70y man presented with mild anemia, neutropenia and thrombocytopenia. A diagnosis of MDS AREB2, Intermediate-2 IPSS, was done on the basis of bone marrow (BM) analysis (trilineage displasia with 15% blasts) and cytogenetics (complex karyotype with 3 unrelated aberrations including -7). Therapy with rhuEPO was started with no benefit. Four months after diagnosis cytopenias worsened and BM blasts raised to 20%. RBC transfusions and therapy with 5-azacytidine (5-AZA) were started. After 2 cycles we observed a striking improvement of Hb and

PLT and, after 4 cycles, in WBC too. BM biopsy showed no blasts, karyotype was normal except 45X, -Y in 3/20 metaphases. After 11 cycles a decrease in PLT levels was noticed and 18% blasts reappeared in BM. The complex karyotype reappeared with additional chromosome abnormalities. 5-AZA was stopped and lenalidomide was started, with significant benefits already after the first cycle. However, after the 2nd cycle both WBC and PLT worsened again. Therapy was continued for 2 more cycles, when BM analysis (80% blasts) and cytogenetics (100% complex karyotype) were repeated leading to a diagnosis of overt AML secondary to MDS. The patient soon died for multiorgan failure due to disease progression. Compared to conventional cytogenetics, molecular cytogenetics identified a conversion of the partial trisomy to partial tetrasomy 8 that occurred during the progression of the disease due to the addition of an extra copy of the whole chromosome 8 and a CN-LOH on the q-arm of chromosome 11. SNP array analysis in different phases of the disease provided information also on the temporal order of appearance of the various abnormalities. Both partial chromosome 8 tetrasomy and 11q CN-LOH were late events during the progression of the disease, thus not to be considered primary genetic defects initiating MDS. We then searched for point mutations in 11q genes to pinpoint eventual homozygous mutations that could have played a role in the pathogenesis of MDS/AML and found a novel mutation in c-Cbl gene (K382E). The mutation appeared in a subclone at diagnosis and became predominant at late relapse. Serial application of conventional and novel molecular cytogenetics techniques provided new hints on the possible involvement of novel genes in the leukemogenic process. SNP arrays revealed not otherwise observed genetic defects and quantified the enrichment of cells bearing chromosomal abnormalities during disease progression.

LENALIDOMIDE IN LOW RISK MYELODYSPLASTIC SYNDROME: SINGLE CENTRE EXPERIENCE

N Gupta, R Kapoor, M Mahapatra, H Pati, P Mishra, T Seth

All India Institute of Medical Sciences, New Delhi, India

Background. Low risk myelodysplastic syndrome (MDS) is characterized by transfusion dependent anemia and lower propensity to progression to acute myeloid leukemia. Lenalidomide, an immun-modulatory agent has been shown to be effective in treatment of low risk MDS associated with 5q del abnormality. Responses in transfusion-dependent non-5q del MDS appears to be significantly lower, with approximately 21% becoming transfusion independent. *Aims.* Prospective study to evaluate safety and efficacy of lenalidomide in the treatment of low risk myelodysplastic syndrome was carried out from July 2008 to Dec 2009. *Methods.* All the patients with low risk *de novo* MDS (IPSS low & int-1), with transfusion dependent anemia were included in study. Patients with a base line platelet count <50×10^9/L, absolute neutrophil count (ANC) <1×10^9/L were excluded. Lenalidomide starting dose -10mg/day with modification for cytopenias. Minimum period of study period was 4 months with the drug to be continued in the responding patients. All the patients were monitored for response (IWG criteria) and toxicity. Institutional ethics committee approval and patient's consent was taken before starting therapy. *Results.* Fifteen patients were prospectively enrolled for lenalidomide therapy, out of which 14 (Male: female: 6:8) have completed 4 months of therapy while one patient was lost to follow up. Mean age was 46.7years (27-72years). WHO types: RA-4, RARS-1, RCMD-3, RAEB1-2, MDSU-1, MDS with 5q del3 (RAEB2-1, RA-2). In twelve patients cytogenetics data was available (normal- 8, 5q del-3, 44xy with del2 & del18-1). Serum EPO level was more than 500 mIu/mL in all patients. Base line mean hemoglobin was 5.2gm% (3-6.7), ANC 2.8×10^9/L (1.4-5.4), platelet count 171×10^9/L (51-740). Five patients became transfusion independent (overall response 5/14 (35.7%)- two of the three (66%) patients with 5q del & three of the eleven patients without 5q del (27.7%) responded while 9 patients did not show any improvement. Median time to response was 8 weeks (4-12 weeks) with a mean rise in hemoglobin of 5.3gm%, and median follow up of 12 months (2-15 months). Early myelosuppression was the predominant drug toxicity, occurred in 11/14 (78.5) % of patients, however grade 3/4 neutropenia & thrombocytopenia occurred in 9/14 (56%) patients requiring temporary drug interruption. At the end of 4 months 9/14 patients were on 5 mg/day dose of lenalidomide. Two patients required hospitalization for neutropenic fever and platelet transfusion support. Renal and liver dysfunction was seen in none but one patient had skin allergic reaction requiring antihistaminics. All responding patients are still on treatment & transfusion independent (one-10 mg/day, three- 5 mg/day, one- 5 mg/alternate days). *Conclusion.* In our study lenalidomide was found to effective in low risk MDS with 35% response rate irrespective of cytogenetic abnormality. Predominant toxicity is myelosuppression necessitating frequent monitoring, dose modification & supportive treatment. A lower dose of 5 mg/day appears to be effective and better tolerated in low risk MDS patients. A further large multicentre trial of low dose lenalidomide is warranted to validate this approach.

1405

EFFICACY OF 5-AZACITIDINE IN THE TREATMENT OF HIGHER-RISK MYELODISPLASTIC SYNDROMES, ACUTE MYELOID LEUKEMIA AND CHRONIC MYELOMONOCYTIC LEUKEMIA: EXPERIENCE AT A SINGLE CENTER

H Hernández Vázquez, E Amutio Díez, I Olazabal Eizaguirre, A Balerdi Malcorra, I Etxeguren Urkixo, A Uresandi Iruin, M Puente Pomposo, M Dueñas Usategui, J Mateos Mazón, A Iglesias Perez, A Moretó Quintana, MA Piñan Frances, F Floristan Goñi, MC Alvarez Martinez, I Hernandez Ontoria, JC García-Ruíz

Hospital de Cruces, Barakaldo, Spain

Introduction. The AZA-001 trial established 5-Azacitidine (5-AZA) as the first drug treatment to significantly extend overall survival (OS) in patients with myelodysplastic syndromes (MDS) compared with conventional care regimens (CCR) and showed a significantly haematological improvement (HI) of 49% of patients with 5-AZA *vs.* 29% with CCR. The role of 5-AZA as maintenance therapy is currently being investigated, after intensive chemotherapy, in patients with high risk MDS (HR-MDS) or acute myeloid leukemia (AML), not eligible for stem cell transplantation. *Aims.* 1- To assess the global haematological response (transfusion independence) and the tolerance with 5-AZA treatment in higher-risk MDS and CMML. 2- To assess the role of 5-AZA as maintenance therapy in patients with AML not eligible for stem cell transplantation. *Methods.* Patients have received 5-AZA at a starting dose of 75 mg/m^2 for five days of 28-day cycle. Table 1. *Results.* Between April , 2008, and February, 2010, 17 patients have been treated, with a median 10 months monitoring (3-23). We have defined haematological response as the achievement of transfusion independence and the maintenance of that independence. About 47% of patients have obtained haematological response with a median first response after 2 cycles (1 to 7) and highest response after 3 cycles (1 to 16). The most common side effects have been neutropenia (47%) and thrombocytopenia (30%). About 41% of patients have been hospitalized because of intravenous antimicrobial requiring infections and 23% have required G-CSF along the treatment. We have made subgroup analysis among patients treated previously with intensive chemotherapy. About 83% have obtained haematological response; toxicity has been comparable to the global analysis and only 2 of 6 have required intravenous antimicrobial treatment. Only one of these patients was transfusion dependent at the beginning of 5-AZA treatment. Death has occurred in 2 patients due to progression to acute myeloid leukemia, nevertheless, one of the patients has progressed 6 months after 5-AZA discontinuation (discontinued because non-related comorbidities: ischemic cardiopathy, temporal arteritis).

Table 1.

		AGE (Mean years)	TRANSFUSION DEPENDENCE BEFORE 5-AZA (Patients)	MEDIAN CYCLES
PATIENTS (TOTAL)	**17**	**71**	**7/17**	**4**
HR-MDS	3	68	2/3	3
CMML	6	71,5	2/6	4
AML	8	71	3/8	7
•Previous chemotherapy	**6**	**68,5**	**1/6**	**9**
•Not chemotherapy	2	76,5	2/2	4,5

Conclusions. The haematological responses obtained with 5-AZA treatment in our group of patients are comparable to AZA-001 trials results, with lower dose of 5-AZA (75 m/m^2/5 days of 28 days *vs.* 7 days of 28). In the previously intensive chemotherapy treated subgroup (initially poor prognosis subgroup not elegible for TPH), 5-AZA has been effective at achievement and keeping transfusion independence without an increase of toxicity. The time of monitoring is not enough to obtain conclusions about extend of overall survival, nevertheless, in our group of previously chemotherapy treated patients, about 66%

remain still alive with haematological response with a median of monitoring time of 9 months. These data suggest 5-AZA as a good maintenance therapy in these patients.

1406

ELEVATED FERRITIN VALUES ARE COMMON AT PRESENTATION IN IRISH PATIENTS WITH MYELODYSPLASTIC SYNDROME

C O'Rafferty, C McHale, N O'Connell, H Enright

Adelaide and Meath Incorporating the National Children's Hospital, Dublin, Ireland

Background. Myelodysplastic syndromes (MDS) are clonal disorders of the marrow resulting in ineffective haematopoiesis, with premature intramedullary destruction of abnormal precursor cells and peripheral cytopenias. Morbidity and mortality in MDS results mainly from the complications of pancytopenia; specifically anaemia, haemorrhage and infection or from transformation to Acute Myeloid Leukaemia. More recently, it has been recognised that multiply-transfused patients with MDS develop iron-overload which may contribute considerably to morbidity and mortality, especially in lower risk subgroups who tend to have a longer life expectancy. Despite the recognition of iron overload due to transfusion in MDS patients, and evidence that ineffective haematopoiesis may result in defective utilization of iron, there is little data in the literature concerning iron accumulation already present at diagnosis. *Aims.* We sought to investigate ferritin levels in patients at presentation of MDS as a marker of iron overload. *Methods.* We performed a retrospective analysis of all patients presenting to our haematology service with a new diagnosis of MDS between 1996 and 2009. We recorded date of diagnosis, WHO 2008 Classification, ferritin value at diagnosis, transfusion status at diagnosis and cause of death for each patient. *Results.* Of 114 new diagnoses of MDS between 1996 and 2009, ferritin values were available for 82. The range of ferritin values at presentation was 3-5000ng/mL (normal range 15-200 ng/mL). Mean ferritin was 481ng/mL. Forty four patients (53%) had a ferritin level greater than the upper limit of normal (>200ng/mL). Of these 44 patients with elevated ferritin, only 6 had received prior transfusions (14%) with only 4 patients having received >5 units (9%). The cause of death for all patients who died was identified - only one heavily transfused patient died from cardiac failure due to iron overload. *Summary/Conclusions.* We speculate that high ferritin levels at diagnosis in MDS results partially from increased gastrointestinal iron absorption as a result of ineffective haematopoiesis. However, in the Irish population, it may also relate to the high prevalence of heterozygosity and homozygosity for the common haemochromatosis mutations. Excessive alcohol consumption may also contribute towards a higher baseline ferritin in this population. Cultural trends and genetic background may influence the risk of iron overload in different MDS patient populations. Iron chelation therapy (ICT) has been shown to reduce ferritin levels and may improve survival in patients with low- or intermediate-1 International Prognostic Scoring System scores. It has also been shown to improve cytopaenias. ICT has been recommended for low- and intermediate-1 risk patients who have received more than 20-30 packed red cell transfusions, for whom ongoing transfusions are anticipated and for those with serum Ferritin >2500 ng/mL. For Irish patients, and possibly for other patients of Celtic origin, where there is a high prevalence of haemochromatosis gene mutations, it may be useful to consider ICT earlier in the disease course.

1407

MYELODYSPLASTIC CHANGES AFTER ALEMTUZUMAB TREATMENT: MONOCLONAL ANTIBODY-INDUCED?

A Braester,[1] L Akria,[2] R Nitzan-Inbar,[2] E Mishchenko,[3] I Cohen[2]

[1]Western Galilee Hospital, Nahariya, Israel; [2]Western galilee hospital, Nahariya, Israel; [3]Bnai Zion Hospital, Haifa, Israel

Background. The myelodysplastic syndromes (MDS) comprise a heterogeneous group of malignant stem cell disorders characterized by dysplastic and ineffective blood cell production with a variable risk of transformation to acute leukemia. These disorders may occur *de novo* or arise between one and 5 years after exposure to potentially mutagenic therapy, named t-MDS (radiation exposure or after chemotherapy - alkylating agents or topoisomerase II inhibitors in most of the cases, but also purine analogs, like Fludarabine, a well known agent used in Chronic Lymphocytic Leukemia [CLL] treatment). Myelodysplastic changes after immunotherapy (i-MDS) are reported in the literature sporadically. Alemtuzumab (Campath-1H) is a therapeutic monoclonal antibody (Mab) that recognizes the CD52 antigen. CD52, a cell surface glycopeptide, is expressed on virtually all human lymphocytes. The highest expression is on CLL cells and the lowest on normal B cells. CD52 is expressed on all CLL cells. In CLL cells Alemtuzumab induces apoptosis. It is able to eradicate minimal residual disease (MRD) and achieve clinical response in high-risk relapsed patients. Adverse events related to alemtuzumab include acute first-dose reactions, infectious complications and rare hematologic toxicity. Prolonged lymphopenia is well known, but myeloid toxicities are less known. *Methods.* We treated five patients with relapsed CLL by Alemtuzumab (as second or third line of treatment). *Results.* In two patients there was a complete response, but myelodysplastic changes, which were not present before this treatment (when a massive infiltration by small lymphocytes occupied up to 90% of the bone marrow) were present post-treatment, especially in myeloid cells. These two patients developed serious infections and died in a short time. Myelodysplasia post Mab treatment is very rare. *Conclusion.* Myelodysplastic features post alemtuzumab treatment (Mab) are an even more rare event. The mechanism is unknown. It is not clear if this myelotoxicity is linked directly to Mab treatment or if it was present earlier, linked to Fludarabine or Cyclophosphamide, but expressed mainly in the progenitors cells, which were inhibited by the small lymphocytes and only after lymphocyte infiltration eradication expanded to all cells. Only three cases were described previously, not in CLL patients (in T-cell lymphoma). It is too early to establish a new medical term: i-MDS.

1408

LENALIDOMIDE IN A COHORT OF VERY ELDERLY PATIENTS WITH MYELODYSPLASIA AND DEL(5Q): A SINGLE CENTRE EXPERIENCE

I Capodanno,[1] P Avanzini,[2] F Franchi,[3] F Merli[2]

[1]Dept. of Hematology, Azienda Ospedaliera Santa Maria Nuova Reggio Emilia, Italy, Reggio Emilia, Italy; [2]Azienda Ospedaliera Santa Maria Nuova, Department of Hematology, Reggio Emilia, Italy; [3]Azienda Ospedaliera Santa Maria Nuova, Laboratory of Cytogenetic, Reggio Emilia, Italy

Background. Lenalidomide is a well-established treatment for myelodysplastic syndromes with del(5q) isolated or associated with other abnormal karyotypes. Little is known about the use of Lenalidomide in patients older than 75 years old (hereafter we referred to as very elderly patients). *Aims.* The aim of our retrospective analysis was to evaluate the efficacy and the feasibility of lenalidomide therapy even in very elderly patients, who often present comorbidities and low tolerance to anaemia, and for whom no alternative therapy is available. *Methods.* From November 2008 to date we treated four very elderly patients (median age: 81 years old, range 76-88) with a diagnosis of myelodysplasia and del(5q) and a low-int-1 IPSS risk score with Lenalidomide. Three patients received a diagnosis of "5q- syndrome", while another patient had a del(16)(q22) together with del(5q-). All the patients were transfusion-dependent at the time we started treatment (median transfusion requirement: 4 units/month, range 2-6). *Results.*In all four patients we observed a complete erythroid response according to IWG criteria (2006) and the median time to achieve the response was 7.5 weeks (range 4-10 weeks). Transfusion-independence had a variable duration (from 24 to over 65 weeks). All the patients achieved a partial cytogenetic response. In Patients 1 and 2 Lenalidomide treatment (10 mg/day for 21 days every 4 weeks) was well tolerated and is still ongoing. In Patient 3 treatment was stopped after 10 days due to the onset of serious agitation and panic attacks; regardless this patient had a transfusion-independence of 6 months. When anaemia worsened she started treatment again and had the same toxicity, so she stopped the drug after 15 days and had another 6 months of transfusion-independence. In Patient 4 Lenalidomide was stopped after 15 days despite a good tolerance due to a worsening of clinical conditions, but 4 weeks after treatment discontinuation she achieved a complete erythroid response. She remained in good clinical condition and transfusion-free for one year. *Toxicity.* as reported in the literature, we observed haematologic toxicity in 50% of patients, however in all cases there was a spontaneous recovery without severe infectious and hemorrhagic complications. Only in one patient the use of G-CSF was required. In one case treatment was stopped due to the onset of psychiatric complications. *Conclusions.* Lenalidomide therapy was effective and well-tolerated in this small cohort of very elderly patients. We observed a time of onset of the response longer than that reported in literature (7.5 weeks *vs.* 4.7 weeks) and a durable response in patients who continued the therapy without interruption (50% of cases); the other 2 patients had a delayed, yet durable erythroid response. Al the patients had a partial cytogenetic response. Lenalidomide therapy is feasible and effective

even in very elderly patients with myelodysplasia with del(5q) and/or other abnormal karyotypes.

1409

OXIDATIVE STRESS IN BLOOD PLASMA OF PATIENTS WITH MYELODYSPLASTIC SYNDROMES

J Suttnar, L Chrastinova, K Pimkova, P Majek, J Cermak, J Dyr

Institute of Hematology and Blood Transfusion, Prague, Czech Republic

The myelodysplastic syndromes (MDS) constitute a heterogeneous group of clonal stem cell disorders characterized by ineffective hematopoesis, associated with cytopenias, leading to serious morbidity plus the additional risk of leukemic transformation. MDS are associated both with autoimmunity and increased oxidative stress. Inducible NO synthase is expressed in MDS patients. Autoimmune diseases with hyperhomocysteinemia may mediate oxidative cell damage by reactive oxygen species (ROS) production. We estimated concentrations of nitrites and nitrates and the presence of S-nitrosocompounds in plasma of MDS patients. To evaluate ROS production and its influence on plasma proteins we investigated their oxidative changes, plasma levels of homocysteine, other low-molecular weight thiols and malondialdehyde (MDA). Blood was collected into EDTA-coated tubes and plasma was obtained by centrifugation. Oxidized proteins in both MDS patients and control plasma were identified using biotin-avidin technology and mass spectrometry. Plasma levels of low molecular weight thiols or malondialdehyde were analyzed using HPLC of fluorescent derivatives. The concentrations of nitrites and S-nitrosothiols in plasma were estimated using HPLC of fluorescent 1-[H]-naphthotriazole produced by reaction with 2,3-diaminonaphtalene. S-nitrosoproteins in both MDS patients and control plasma were identified using biotin-switch method and mass spectrometry. We found increased concentration of homocysteine and MDA in patients plasma with MDS. Slightly increased concentrations of nitrites and S-nitrosothiols as compared with control samples were also found in plasma of patients with MDS. In our previous work we found changed platelet responses to various stimulants at the presence of either prooxidant or antioxidant species. It seems that the oxidation stress can contribute to the described defective platelet aggregation in MDS. *Acknowledgement.* This study was supported by Grants NS10633-3/2009 and MZ 02373601 from the Ministry of Health, Czech Republic, by Grant KAN200670701 from the Academy of Sciences, Czech Republic, and by Baxter, Czech Republic.

1410

IRON-CHELATION THERAPY IN MDS/IMF PATIENTS: DOES IT REALLY IMPACT ON TRANSFUSION REQUIREMENT?

A Molteni,[1] M Riva,[1] V Speziale,[1] E Morra,[1] MD Cappellini[2]

[1]A.O. Ospedale Niguarda Ca' Granda, Milano, Italy; [2]Università di Milano, Policlinico Foundation IRCCS, Milano, Italy

Background. Hematological improvements in MDS (myelodysplastic syndromes) or IMF (idiopathic myelofibrosis) transfusions dependent patients during iron-chelation therapy have been sporadically reported. However actual incidence, impact and potential predictive clinical factors of this phenomenon are still unknown. *Aims.* To extimate the actual impact of iron-chelation therapy on transfusion requirement or on other hematological parameters in MDS/IMF patients. *Methods.* A retrospective analysis was performed in MDS/IMF transfusion dependent patients to evaluate possible hematological improvement during iron-chelation. Transfusion requirement was defined as number of RBC units transfused every three months during the iron chelation period and compared with baseline requirement, for an overall period of one year. Platelets counts were also recorded every three months from beginning of iron chelation and compared to baseline ones. According to IWG criteria, erithroid response was defined "major"in case of transfusion independence; "minor"in case of 50% decrease in transfusion requirements. In thrombocytopenic patients (plt <100.000/mm^3) a "major"platelet response was defined as absolute increase of 30.000/mm^3 (for platelet transfusion-dependent patients, as stabilization of platelet counts and platelet transfusion independence); a "minor"platelet response was defined as 50% or more increase in platelet count with a net increase greater than 10.000/mm^3 but less than 30.000/mm^3. *Results.* From November 2007, eleven patients (10 low-risk MDS and 1 IMF) underwent to iron-chelation therapy in our institution. Only 8 of them had a follow-up sufficient for evaluation. They were treated with Deferasirox (7 cases; from 5 to 20 mg/kg/die) or Deferoxiamine (1 case; 30 mg/kg s.c. for 3-4 times/week). Average baseline ferritin level was 1837 ng/mL (SD 1433); after 9 months of chelation-therapy it was reduced to 1323 ng/mL (SD 897). No "major"erithroid responses were observed. "Minor"erithroid response (50% reduction of RBC units transfused) was reached after 6 months in one patient, after 9 months in two patients and after 12 months in two patients. Three patients had no improvement in transfusion burden. Only one patient was thrombocytopenic. He had a major platelet response after 3 months. Loss of erithroid response was observed in one patient after six months from time of response. The only platelet response was enduring at end of observation. All responders were affected by MDS and treated with Deferasirox. These preliminary results do not allow to identify clinical factors that can predict hematological improvement. *Conclusion.* Hematological improvement during iron chelation therapy was described, but currently considered as an infrequent phenomenon. In this small cohort, the impact of the erithroid response, even if "minor", seems to be relevant (about 60%) in MDS patients on Deferasirox treatment. Platelet response was also observed in a thrombocytopenic patient. Hematological improvements can occur as early as after 3 months of iron chelation. This interesting effect of iron chelation therapy in MDS/IMF deserves to be further investigated in a larger group of patients in order to explore possible predictive factors. In addition, a longer period of observation is required to evaluate the endurance of hematological benefits.

1411

RECOMBINANT HUMAN ERYTHROPOIETIN ALFA IN PATIENTS WITH LOW-RISK MYELODYSPLASTIC SYNDROMES, SELECTED ON THE BASIS OF A LOW PRETREATMENT SERUM ERYTHROPOIETIN CONCENTRATION

E Vigna,[1] M Gentile,[1] AG Recchia,[1] R Morelli,[2] C Mazzone,[1] E Lucia,[1] P Servillo,[1] S Bossio,[1] N Caruso,[1] V Gigliotti,[1] A Madeo,[1] MG Bisconte,[1] S Franzese,[1] C Gentile,[1] F Morabito[1]

[1]UOC Ematologia, AO Annunziata Cosenza, Cosenza, Italy; [2]UOC Medicina Nucleare, AO Cosenza, Cosenza, Italy

Background. Epoetin alpha (EPO) continues to be the initial treatment of choice for most anemic patients with myelodysplastic syndromes (MDS). Subcutaneously, at a dosage of 80.000 U/week, has proven effective in relieving symptomatic anemia in 20-30% of patients (pts) with MDS. A low or intermediate-low risk score, according to International Prognostic Score System (IPSS) (Greenberg *et al.*, 1997) and low pre-treatment serum EPO levels are both associated with a higher probability of response. *Aims.* As rHuEPO is expensive, and the percentage of responder MDS pts is low, an attempt to select. MDS pts on the basis of basal serum EPO levels and IPSS score, is justified. *Methods.* From September 2005, 33 pts (27 males, median age: 66, range 48-84 yrs) with low- or intermediate risk MDS were treated with rHuEPO alpha for symptomatic anemia (Hb <10 g/dL). The pts received a high dose rHuEPO regimen: 40.000 U twice weekly, for the first month, followed by a single weekly dose of 40.000 as maintenance treatment, for at least 24 weeks. Only pts with a pre-treatment serum EPO <200 U/L were selected for rHuEPO treatment. *Results.* 27/33 pts (81.8%) showed a favourable response. 8 pts were transfusion-dependent. Among them, 6 showed a >50% decrease of their transfusion need. All the remaining 19 pts, with less severe anemia, not requiring transfusions, showed a clinical significant response (i.e. a >1g/dL increase of Hb). The median duration of response was of 13 (2-45) months, and 19 pts are still maintaining response under maintenance treatment. *Summary/Conclusions.* Although only 20-30% of MDS pts show a clinical significant response to rHuEPO, if pts are carefully selected on the basis of a low risk score (following IPSS) and a low (<200 U/L) pre treatment serum EPO level, the percentage of responses is higher (81.8%), this however does not exclude the use of EPO in other categories of MDS patients (Int-1 or EPO>200 U/L). Considering the high cost of EPO therapy, a selection of a cohort of low risk MDS patients with low serum EPO levels is necessary to maximize the cost-benefits ratio of therapy.

1412

PRECOCIOUS SECONDARY MYELODISPLASIA PRESENTING AS A CHRONIC MYELOMONOCYTIC LEUKEMIA IN A SEVERE CONGENITAL NEUTROPENIA YOUNG PATIENT

A Catala, S Rives, M Camos, T Toll, R Berrueco, M Torrebadell, J Estella

Hospital Sant Joan de Deu, Barcelona, Spain

Background. Severe congenital neutropenia (SCN) is a bone marrow failure with a clinical picture of early severe neutropenia and life-threatening bacterial infections. Maintenance treatment with recombinant

humanized G-CSF (rHuG-CSF) has changed the outcome and the quality of life of these patients. However a significant number of them will be affected by haematological cancer: acute myeloid leukemia (AML) and myelodisplasia (MDS). *Aim.* To present an interesting patient with severe congenital neutropenia and a novel ELA2 gene mutation and precocious development of secondary myelodisplasia. *Case.* A 6 month old boy was referred to our institution to study a severe neutropenia (0.3×10^9/L ANC) in the context of severe infection. His physical examination was normal with no growth impairment. The bone marrow aspirate showed maturation arrest at the promyelocyte/myelocyte stage, with no dysplastic signs neither other features. Cytogenetic analyses were consistently normal. Metabolic disorders, viral infections were ruled out. ELA 2 mutational status revealed a novel mutation (ELA2/ V36D). He started G-CSF (lenograstim) at 5mcg/Kg/day and was increased to 10 mcg/kg/day in order to maintain him around 1×10^9/L ANC. During follow up he presented several otitis and chickenpox. At 2 years old was admitted for a large splenomegaly (8 cm), anemia (64 g/L), thrombocytopenia (26×10^9/L) and monocytosis (5.6×10^9/L) and cutaneuos nodules in the scalp. The bone marrow showed moderate dysplastic changes in the erythroid and myeloid comparments and monocytosis. Cytogenetic analysis revealed monosomy 7 and KRAS mutation in the molecular analysis. *Discussion.* Since the introduction of rHu-G-CSF in SCN, AML and MDS have become the major events in these patients. Some works have correlated mutational ELA2 status with more severe phenotype and increased risk of hematological malignancies however further studies are needed. This patient shows the typical picture of secondary MDS presenting as chronic myelomonocytic leukemia. Bone marrow transplantation is advised in such patients. Open trials are evaluating the benefit of demethylating agents.

1413

RESPONSE TO 5-AZACITIDINE IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES AND SECUNDARY AML: RESULTS FROM UNIQUE HOSPITAL

MD De Miguel, N Golbano, MI Lopez San Roman, M Diaz Morfa, J Arbeteta, D Morales, B Pinedo

Hospital Universitario de Guadalajara, Guadalajara, Spain

Background. 5-azacitidine (AZA) significantly prolonged overall survival in higher-risk patients with myelodysplastic syndromes (MDS) in international phase III trial (AZA-001). However, data about efficacy of AZA in lower risk MDS are less consistent and only few studies have addressed this topic. Recently, FDA has approved AZA in all categories MDS, but EMEA has approved in high risk MDS. *Material and Methods.* we evaluate the efficacy and safety in all MDS groups and patients with secondary AML, non candidates to aggressive therapy. *Results.* In our institution, a total of 21 patients were treated with AZA since 2006. We evaluated 13 patients diagnosed according to WHO criteria as low/intermediate-1 International Prognostic Scoring System (IPSS) risk MDS, 4 patients as high/int-2 IPSS risk MDS and 4 secondary AML diagnosed patients. At baseline, the median age was 71.9 years (range 46-86), the male/female ratio 13/8. According to WHO classification, there were 1 RA, 6 RARS, 4 RAEB-1, 4 RAEB-2 and 1 MDS unclassified. Median time from diagnosis was 48 months (range 5-192). 85% patients were transfusion-dependent, 89% had received a prior treatment (rhu-EPO+G-CSF 55%, only rhu-EPO 34%). AZA was administered as single agent in 15 patients. Out of patients received a "standard"AZA dose of 75 mg/sqm/d subcutaneously during days 1-7, in a 28-day cycle. The median number of monthly cycles was 8.6 (range 2-26), and 61.9% completed at least 6 cycles. Grade 3-4 adverse events documented in these patients were myelosupression (20%), and injection site reaction (10%).

Hb pre-AZA	Hb max. post-AZA	Time to response months
6.9 (5.5-11.5)	10.7 (8.2-15)	3 (2-5)

Number Cycles Max. response	Number Cycles Lost response
5.3 (2-10)	11.8 (4-16)

Response	TI	PR	NR
	60%	30%	10%

TI: transfusion independence; PR: partial response; NR: non-response.

Response duration ranged from 1 to 8 months. There were no significant differences in response rate according to age, previous treatment, transfusion requirements, basal EPO and Hb pre-AZA. 2 patients were transformed to AML. 42.8% patients are death at moment of write this abstract. *Conclusions.* 1.- 90% patients achieved a hematologic response. 2.- Time to response is early (3months), although some patients response later (5 cycles or more). 3.- Efficacy and safety of AZA treatment is a valid alternative in low/int-1 risk MDS patients, although more studies are necessary. 4.- In secondary AML patients, AZA is a excellent alternative therapy in patients with co-morbidity and poor performance status.

1414

MYELODISPLASTIC SYNDROME WITH ADVERSE CYTOGENETIC ABNORMALITY IN CHILDHOOD: GOOD RESULTS OF ALLOGENIC HSCT

V Fernández Cisneros, I Pérez de Soto, JM Pérez Hurtado, R Parody Porras, J Sánchez, R Morales Camacho, A Urbano Ispizua

Virgen del Rocío Hospital, Seville, Spain

Introduction. Myelodisplastic syndrome (MDS) is the most common hematopoietic malignancy in adults, but it is a very uncommon disorder in children and adolescents. The most frecquent MDS subtype in children is refractory cytopenia (RC). Allogeneic hematopoietic stem cell transplantation (alloHSCT) is the only potentially curative treatment, mainly when an adverse kariotype is present. However, scarce literature have been reported in alloHSCT and MDS with cytogenetic abnormalities. Monosomy 7 is the only chromosomal abnormality strongly suggestive of MDS in children. *Objectives.* We report our experience in all cases of MDS with adverse cytogenetic abnormality in children who were submitted to allogeneic HSCT in our hospital from 1999 to 2009. *Patients, materials and Methods.* A total of 4 MDS associated with an adverse cytogenetic abnormality have been diagnosed. All 4 patients were female, with a median age of 11.5 years old (10-14 years old). MDS were primary in 3 patients (1 refractory cytopenia with multilineage dysplasia [RCMD], 1 refractory anemia with excess of blasts type 2 [REAB-2] and 1 refractory anemia with excess of blasts type 1 [REAB-1]) and secondary in the remaining one (1 case of chemotherapy-related secondary REAB-1). Discovered karyotypes were t(X;20)(q13.1q13.3) [this karyotype had not ever been reported in children with MDS, as far as we know]; 47,XX(+8) y 45,XX(-7). The secondary case had got a complex karyotype with 2 cellular populations: 46, XX, del (5)(q14), -9, -18, -21q / 44, XX , del (5)(q14), -9, 17p-, -18, -21, 21q-, -22. The 2 fist cases received treatment with Cyclosporine A (CsA) and acute mieloblastic leukaemia (AML) intensive chemotherapy regimen before allogenic HSCT, without any response. The other two patients received allogenic HSCT as a first line of treatment. 2 patients received unrelated donor allogenic HSTC and 2 patients received HLA identical sibling related donor allogenic HSTC. In 2 cases, bone marrow was the source of HSC and peripheral blood was the source of HSC in the other 2 cases. Conditioning regimen was busulfan / cyclophosphamide in all cases. The Graft *vs.* host disease (GVHD) prophylaxis was made by CsA in 2 cases and by CsA and methotrexate in the other 2 patients. 3 patients developed acute GVHD (2 patients developed cutaneous acute GVHD and the other one developed cutaneous and intestinal acute GVHD). All of patients remain alive in a complete remission with a median follow up of 9.5 months (2-120 months) post-allogenic HSCT. Discussion: The karyotype is the main prognostic factor of MDS in childhood. Monosomy 7 and complex karyotype are strongly suggestive of adverse prognosis and high probability of progression to acute mieloblastic leukaemia. In contrast to monosomy 7, patients with trisomy 8 or normal karyotype may experience a long stable course of their disease. Allogenic HSTC is the only curative therapy and is the treatment of choice for patients with monosomy 7 or complex karyotypes early in the course of their disease. Immunosupresive therapy could be a successful initial strategy for children with other karyotipes. Responses are better in children with a normal karyotype. *Conclusions.* - MDS is a very uncommon diagnosis in childhood. - Cytogenetic analysis is essential in diagnosis and treatment of this type of patients. - Our report proves successful results of the allogenic HSCT in patients with adverse cytogenetic abnormalities. That should be indicated as first line therapy when a donor is available. - Immunosupresive therapy and myeloid acute leukaemia chemoteraphy are not effectives in our patients. Its benefit before alloHSCT must be clarified.

MULTIDIMENSIONAL FLOW CYTOMETRY (MDF) TO IDENTIFY NORMAL AND ABNORMAL MYELOID, MONOCYTOID, ERITROID AND BLASTS POPULATIONS IN MYELOPROLIFERATIVE DISORDERS (MPDS) AND MYELODYSPLASTIC SYNDROMES (MDSS)

F Gervasi

Hematology Unit, Arnas Civico, Palermo, Italy

Background. in our opinion MDF represents a highly reproducible and objective way of assessing the antigen expression in myeloid or monocytoid maturation as well as in benign reactive or malign proliferation or in normal marrow regeneration through analysis expression of multiple antigens on a single cell to identify normal or abnormal patterns of proliferation. The aim of this study is to correlate the normal antigen expression during haematopoietic development as determined by MDF with the dysregulation of haematopoiesis observed in MDS and MPDs. *Methods.* We have elaborated a multidimensional immunofluorescence protocol; forward scatter (FSC) and side scatter (SSC) were collected along with 7-8-color antibodies combination to generate 9-10 parameters per cellular event. multicolor flow cytometric immunophenotyping was performed on cytometer: Cyan ADPTM (Beckman Coulter). The following panel of antibodies was used in all of the cases: CD66b-Fitc/CD33-Pe/CD45-AmCyan/CD11b-Pe-Cy5/CD13-Pe-Cy7/CD10-APC/CD16-APC-Cy7/CD19PB; CD3-Fitc/CD16+CD56-Pe/CD45PerCp/CD4-Pe-Cy7/CD19-APC/CD8-APC-Cy7; CD64-Fitc/CD56-Pe/CD45-AmCyan/CD11b-Pe-Cy5 /HLADR-APC/CD14-APC-Cy7; TdT-Fitc/CD33-Pe/CD45-AmCyan/CD34-PerCpCD38-Pe-Cy7/Mpo-APC; CD36-Fitc/CD235-PE/CD45-AmCyan/CD71-APC. *Results.* We have been able to design combinations of antibodies to distinguish normal from abnormal maturation and the expression patterns of CD10, CD16, CD13, CD33, CD64, CD66b, and CD11b which we observe in MDSs are able to identify maturational anomalies and asincronous antigen expression. *Conclusion.* Our results indicate that multicolor flow cytometry allows to distinguish normal from abnormal myelopoiesis and also aberrant immunophenotype ($CD10^+$, $CD34^+$, $CD56^+$etc) is particularly useful in detecting and distinguishing leukemic from normal recovery blasts with high sensitivity and specificity respect to the patterns described in literature with three or four color flow cytometry.

1416

CLINICAL-BIOLOGICAL PROFILE OF A GROUP OF PATIENTS WITH PLASMACYTOMAS: A REVIEW OF HOMING BEHAVIOUR IN 68 PATIENTS WITH MULTIPLE MYELOMA

C Calderón, I Montero, A Vallejo, J Martín, M Martino

Hospital Universitario Virgen del Rocío, Sevilla, Spain

Background. Extramedullary infiltration at diagnosis or throughout the disease course of patients with multiple myeloma affects the therapeutic strategy and often shadows prognosis. There are numerous studies linking homing behaviour of plasma cell to stage, antigen expression and treatments received, so far without any parameter that allows us to predict this behaviour. *Aims.* 1. To set extramedullary infiltration rate over the hospitalization events in patients with multiple myeloma at our center. 2. Analysis of type of myeloma, Salmon and Durie stage, inmunophenotype and treatments received in these patients. 3. To correlate these results with the group of patients without plasmacytomas. 4. To develop a possible profile of patients with myeloma which present or would be able to present extramedullary involvement in future. *Methods.* Sixty-eight patients with multiple myeloma diagnosed between 2006 and 2008 in our hospital were reviewed. We analyzed presentation of plasmacytomas at diagnosis or during clinical course, age, sex, type of myeloma, inmunophenotype (CD56, CD38++) and treatment on each group. We compared this group with the one without extramedullary infiltration using stadistic software SPSS (version 17.0). *Results.* Patients with extramedullary infiltration were 22 (32%) and at diagnosis 11 (16%) of total. In this group the proportion male to female was 12:10 and median age 59.2 years. The distribution of isotypes was IgG 13 (59%), 5 kappa and 8 lambda; IgA 6 (27%), 3 kappa and 3 lambda; Bence Jones 3 (13%), 1 kappa and 2 lambda. Salmon and Durie stages were IIA 8 (36%), IIA 6 (27%), IIB 2 (9%), IIIB 6 (27%). Inmunophenotypes: CD 56^+ 13 (68%) and CD56- 6 (32%). Four of them were $CD38^{++}$ (3 not analyzed). Treatments received were Thalidomide 11 (50%), Bortezomib 17 (77%), Lenalidomide 3 (13%), autolog stem cell transplantation 3 (13%). In the group without plasmacytomas (68%) proportion male/female was 23:23 and median age 56.8 years. IgG 31 (67.3%), 24 kappa and 7 lambda; IgA 10 (21.7%) 8 kappa and 2 lambda; Bence Jones 5 (10.8%) 3 kappa and 2 lambda. Stages: IA 2 (4.3%), IIA 21 (45.6%), IIIA 14 (30.4%), IB 1 (2.1%), IIB 1 (2.1%), IIIB 6 (13%). Analyzed inmunophenotypes (15 not available): 29 patients were $CD56^+$ (93%), 2 CD56- (6.4%) and 7 CD 38++ (22.5%). Treatments in this group were Thalidomide 22 (47%), Bortezomib 34 (73%), Lenalidomide 4 (85%) and autolog stem cell transplantation 23 (50%). There was significative difference in stadistic analysis between groups with extramedullary infiltration and without it in type of myeloma and CD56 expression (lambda/CD56: 59.1%/27.3% *vs.* 23.9%/4.3%, $P<0.05$). *Conclusions.* 1. Incidence of extramedullary infiltration observed in patients with multiple myeloma was high (one-third part). 2. There was no association between extramedullary infiltration in myeloma and sex, age or influence of treatment received, but this group presented more renal disease associated. 3. Patients with lambda myelomas and without CD 56 expression had more frequently plasmacytomas in our series and this could be related to homing behaviour. 4. Extramedullary infiltration carried a worse prognosis and lower possibilities of reaching an autolog stem cell transplantation.

1417

FUNCTIONAL ANALYSIS OF CYTOPLASMIC YB-1 IN MULTIPLE MYELOMA: TRANSLATIONAL CONTROL OF ANTI-APOPTOTIC PROTEINS

M Effenberger,[1] E Leich,[2] R Bargou,[1] K Bommert[1]

[1]University Medical Center Wuerzburg, Medical Clinic & Policlinic II, Wuerzburg, Germany; [2]Institute of Pathology, University of Wuerzburg, Wuerzburg, Germany

The Y-box Binding Protein-1 (YB-1) is an oncogenic transcription/translation factor belonging to the evolutionarily highly conserved family of cold-shock domain proteins. YB-1 binds to DNA as well as RNA and fulfils pleiotropic cellular functions, including the regulation of proteins involved in cellular growth, survival and stress response. In transgenic mice, mammary gland specific over-expression of human YB-1 provokes breast cancer with a 100 % penetrance. YB-1 knockout experiments in mice showed that a homozygous deletion is lethal and a heterozygous YB-1 deletion is accompanied with an increased sensitivity to cisplatin and mitomycin C. YB-1 over-expression can be detected in many human malignancies including colorectal carcinoma, prostate cancer, osteosarcoma, breast cancer and multiple myeloma (MM). Compared to normal plasma cells YB-1 is strongly expressed in 30-50 % of primary MM samples. Over-expression of the protein was seen in a proliferative subset of primary MM cells, which are characterized by Ki67. Although eukaryotic Y-box binding proteins were originally identified as transcription factors binding to Y-box sequences in promoters of a variety of genes, the protein itself is predominantly localized in the cytoplasm of primary multiple myeloma cells and MM cell lines. To improve the understanding of YB-1 function in the cytoplasm we performed immunoprecipitation of YB-1 and subsequent analysis of the YB-1 bound mRNAs using gene expression arrays. Here we present the data of identified mRNAs bound to YB-1 in different MM cell lines and the adjacent functional analysis of promising protein candidates, like Mcl-1 and TCTP in multiple myeloma. This was accomplished by immunohistochemical investigation of primary samples, protein knockdown-/over-expression in MM cell lines, western blot analysis, the detection of mitochondrial membrane potential and caspase activation. The knockdown of YB-1 in MM cell lines led to a strong decrease of the protein level of the tested candidates while the mRNA level remained unaffected, validating their accuracy. The translational down regulation of these anti-apoptotic proteins caused the induction of apoptosis with subsequent activation of effector caspases, like caspase 3. In conclusion we state, that YB-1 can function as a RNA-chaperone in multiple myeloma stabilizing or enhancing the translation of anti-apoptotic proteins, thus assuring the pro-survival phenotype of MM cells.

1418

HETEROGENEOUS EFFECTS OF CXCR4 ANTAGONISTS ON THE PROLIFERATION OF MYELOMA CELLS

HY Kim,[1] SW Kim,[1] JY Hwang,[1] HJ Lee,[2] HJ Yun,[3] S Kim,[3] DY Jo[3]

[1]School of Medicine, Chungnam National University, Daejeon, South-Korea; [2]Chungnam National University Hospital, Daejeon, South-Korea; [3]Cancer Research Institute, Chungnam National University, Daejeon, South-Korea

Background. AMD3100, an antagonist for chemokine receptor CXCR4, induces the peripheral mobilization of haematopoietic stem cells. It also induces the segregation of myeloma cells in the bone marrow microenvironment, which should enhance the chemosensitivity of the cells. Based on these observations, AMD3100 is being considered for clinical

use. We have previously shown that AMD3100 induced the proliferation of myeloma cells in a short-term culture. *Aim.* We explored whether the proliferation-enhancing effect of AMD3100 is common to all the CXCR4 antagonists. *Methods.* Myeloma cell lines (RPMI8226 and U266) and CD138+ primary myeloma cells were incubated in serum-free medium with or without three CXCR4 antagonists (AMD3100, T140 and T22) at the concentrations of 0.1 μM to 10 μM for up to 14 days. Cell proliferation was measured by a modified MTT assay and cell apoptosis was analyzed by flow cytometry using annexin V. *Results.* All the CXCR4 antagonists markedly inhibited the stromal cell-derived factor-1 (SDF-1)-induced chemotaxis of myeloma cells. In addition to CXCX4, myeloma cells expressed CXCR7 to various degrees. All the antagonists induced internalization of CXCR4. However, AMD3100, but not T140 and T22, induced internalization of CXCR7 in these cells, indicating that only AMD3100 binds to CXCR7. SDF-1 or I-TAC, a ligand for CXCR7, on its own did not stimulate the proliferation of these myeloma cells, nor did it rescue the cells from apoptosis induced by serum deprivation. In 3-day cultures, AMD3100 (10uM) increased the number of cells up to 2-folds compared to controls, which was not abrogated by pretreating the cells with pertussis toxin. In contrast, T22 (1 μM-10 μM) decreased the number of cells by up to 35%, and abrogated the AMD3100-induced early proliferation enhancement. T140 (0.1 μM - 10 μM) did not affect the cell proliferation or apoptosis at all. In extended cultures of these cells for up to 14 days, AMD3100, but not T140 or T22, induced a marked decrease in the number of cells after 5-7 days. Taken together, AMD3100 exerts dual effects, initially enhancing and subsequently inhibiting the survival and proliferation of the cells. Adding SDF-1 at the beginning and middle of the incubation did not affect the early increase or later decrease in the number of cells induced by AMD3100, whereas it diminished the early inhibition of the cell proliferation induced by T22. T140 or T22 did not affect the cell proliferation after 5 to 7 days of cultures. The initial proliferation-enhancing effects of AMD3100 were not changed by knocking-down CXCR4 using the siRNA technique, whereas knocking-down CXCR7 significantly delayed the enhanced proliferation. In contrast, knocking-down CXCR4, but not CXCR7, partially restored the T22-induced decrease in cell proliferation. *Conclusions.* The effects of CXCR4 antagonists on the proliferation of myeloma cells are not uniform. Given that AMD3100 exerts dual effects, early enhancing and later inhibiting myeloma cell proliferation, whereas T22 exerts only early inhibition *in vitro*, combination of these two antagonists might be helpful in clinical use in myeloma patients.

1419

NONSECRETORY MYELOMA - SECRETORY POTENTIAL & CYTOGENETIC CHANGES

T Pika,[1] J Balcarkova,[2] P Lochman,[3] J Minarik,[4] P Mikula,[5] J Zmolikova,[6] J Bacovsky,[4] M Jarosova,[2] V Scudla[4]

[1]Faculty Hospital Olomouc, Olomouc, Czech Republic; [2]Department of Haematooncology, Faculty Hospital, Olomouc, Czech Republic; [3]Department of Clinical Biochemistry, Faculty Hospital, Olomouc, Czech Republic; [4,3]rd Department of Internal Medicine, Faculty Hospital, Olomouc, Czech Republic; [5]Department of Haematology, Havirov Hospital, Havirov, Czech Republic; [6]CGB laboratory Inc., Ostrava, Czech Republic

Background. A rare variant of multiple myeloma is the nonsecretory form (NSMM), characterised by the absence of the detectable M-component in the serum and/or urine, with the related difficulties by diagnosing and the subsequent monitoring of the disease progress, which tends to be the reason why such patients are eliminated from clinical research studies. *Aims.* The study aimed at assessing the benefit of determining the serum levels of free light chains (FLC) in a group of NSMM patients, and evaluating the present cytogenetic changes. *Methods.* The examined group consisted of 8 patients who met the NSMM criteria of the International Myeloma Working Group. The serum levels of free light chains were determined by means of the FreeliteTM system. To determine the chromosomal changes, classic cytogenetic analysis and FICTION method were used with locus-specific probes 1q21/1p36 (Kreatech, MP Biomedicals, CA, USA), IgH, RB1, t(4;14), t(11;14) and centromeric probes for chromosomes 7, 9, 11, 15 and 17 (Abbott-Vysis, Downers Grove, IL, USA). *Results.* Pathological serum levels of free light chains κ or λ and their mutual ratio - κ/λ ratio were detected by 4 patients, namely in a quantity allowing for regular monitoring of the disease progress by means of the FreeliteTM system, whereas 2 patients revealed serum levels of FLC within the standard range, and a decrease in both FLC below the standard range was recorded in 2 cases. RB1 gene deletion was found by 6 patients together with translocation t(11;14), while this change was by all real, purely non-secreting forms. In addition, 2 of those patients revealed gain of 1q21 region. In one patient polyploidy and trisomy of chromosome 15 was detected. In one patient the cytogenetic analysis could not be made, due to multifocal character of the disease. *Conclusions.* Determining the serum levels of free light chains allows the additional detection of the secretion of light chains by part of the NSMM patients, leading to a reclassification of NSMM to an illness of κ or λ light chains. Consequently, this becomes an irreplaceable examination for monitoring the disease progress. Translocation t(11;14) and RB1 gene deletion seems to be the dominant cytogenetic changes by NSMM.

With the support of the Research project VVZ MSM 619895205.

CD40 LIGAND LEVELS IN THE SERUM OF PATIENTS WITH MULTIPLE MYELOMA CONSTITUTE A MARKER OF BONE MARROW PROLIFERATIVE ACTIVITY

G Tsirakis,[1] M Fragioudaki,[2] P Kanellou,[2] D Liapi,[3] M Stratinaki,[2] A Hatzivassili,[3] K Sfyridaki,[3] M Alexandrakis[2]

[1]General Hospital Chania, Chania, Greece; [2]University Hospital of Crete, Heraklion, Greece; [3]Venizeleion Hospital, Heraklion, Greece

Background. The CD40 is a member of the TNF receptors superfamily expressed on antigen presenting cells such as B cells. Activation of CD40 by its ligand (CD40L) causes activation of B cells that leads to proliferation, switch and plasma cell differentiation. In malignant plasma cells, its activation is associated with increased aggression and proliferative capacity of the disease. CD40L is primarily expressed on activated CD4 (+) T cells. There is evidence that it promotes the adhesion and hence growth of myeloma cells. It has been shown that CD40L competitors have significant anti-myelomatic action. *Aim.* The purpose of this study was to measure soluble levels of CD40L in myeloma patients and to assess whether these could be an indicator of proliferative activity of multiple myeloma as expressed by the cell proliferation marker Ki67 and the secretion of growth factor hepatocyte growth factor (HGF). *Methods.* 43 patients with multiple myeloma and 15 healthy controls were studied. Patients were staged by Durie-Salmon system. Serum samples were collected from all patients at the diagnosis. We have also performed bone marrow biopsies prior to treatment, which assessed the expression of proliferation marker Ki-67 in plasma cells. Serum levels of CD40L and HGF were measured by ELISA. The percentage of Ki67 expression on plasma cells in bone marrow was measured by immunohistochemistry. For the statistical analysis of results we used the non parametric method (Mann Whitney and Wilcoxon) for comparison between patients and healthy controls and between different stages. The statistical correlation Spearman's rho was used to compare the identified factors. *Results.* CD40L and HGF serum levels as well the percentage of Ki67 positive plasma cells were significantly higher in the myeloma patients compared to controls (P<0.001). Serum HGF and CD40L levels and the percentage of Ki67 positive plasma cells were proportionally increased in accordance with the disease progression (CD40L: 505± 408pg/mL for stage I, 689±469pg/mL for stage II and 1471±651pg/mL for stage III and 242±99pg/mL for controls, P<0.001), (HGF: 821±372pg/mL for stage I, 1579±445pg/mL for stage II, 2608±1513 pg/mL for stage III and 471±128pg/mL for the controls, P<0.001). Serum CD40L levels in myeloma patients showed good correlation with HGF (r: 0.51, p 0.001) and Ki-67 expression in plasma cells. *Conclusions.* Our results demonstrate that CD40L plays an important role in the development of multiple myeloma as it is closely linked to the expression of the proliferation index of malignant plasma cells, Ki67 and the angiogenic index HGF. Given the contribution of HGF to promote angiogenesis in myeloma bone marrow, we support that the expression of CD40L could be an indirect marker of the angiogenic process. This is consistent with *in vitro* data in which activation of CD40 leads to secretion of angiogenic factor VEGF by malignant plasma cells.

STROMAL MICROENVIRONMENT AND STEM CELLS NICHES IN MULTIPLE MYELOMA

S Bessmeltsev, V Rugal

Russian Research Institute of Hematology and Transfusiology, St-Petersburg, Russian Federation

Background. Bone marrow stroma has a microenvironment which organized into bone and vascular niches of hematopoetic stem cells

(HSC). In multiple myeloma (MM), bone lesions and vascular rear-rangements determine HSC niche involvement into MM pathogenesis. *Aims.* The study described here examined the microenvironment of intramedullar stromal bone marrow in patients with MM. The emphasis was on the osteogenic cells role in the endosteal zone of trabecular bones and sinusoidal vessels. *Methods.* Stromal and hematopoetic tissue was sampled from the ilium for 79 patients with MM. The samples were examined for morphology/morphometric parameters and by electron microscopy. Proliferative activity of mesenchymal stem cells was evaluated using our proprietary *in vitro* cultivation method. Angiogenesis activity was evaluated using the microvessel density index (MDI). All patients were treated with bortezomib-containing combinations (BCC). *Results.* During the MM active phase, there was a reduction in adipocytes; reticular cell number in-creased; phagocyte activityof reticular cells increased; and local reticular sclerosis could be seen in the bone marrow. Centers of bone trabecular resorption were identified and the structure of endosteal colla-gen was disrupted in these centers. The banding of transverse collagen fibers was difficult to detect and some fiber banding disappeared completely and was replaced by extracellular matrix clumps. Both the number and the structure of endosteal osteogenic cells changed. The number of spindle-shaped osteob-lasts increased ($P<0.05$). Increased functional cell activity was confirmed by the appearance of cytop-lasmic organelles and the state of the nuclear chromatin. Increased proliferative activity of endosteal cells was also detected. The number of bone trabeculae was slightly reduced, but this reduction was not sta-tistically significant ($P>0.005$). The number of sinusoidal vessels was increased ($P<0.05$). MDI was also significantly increased. In patients treated with 6-8 cycles of BCC and achieved CR, bone marrow stroma samples showed decreased number of endosteum osteogenic cells and decreased destruction of collagen fibers. The MDI was significantly decreased. The sinusoid volume index did not differ from the index in healthy individuals. *Conclusion.* The results demonstrated significant changes of intramedullary stroma status and HSC nich-es in MM. The endostal osteogenic cells have two main functions: to maintain the HSC and bones. This functional ability is changed during MM. Decrease in bone tissue volume is related to both increased os-teoclast activity and abnormal bone formation function of endosteal cells. It is also possible that the he-mopoesis-inducing activity of endosteal cells is enhanced, which would support extension of the myeloma cell clones. Intensive angiogenesis and sinusoid changes were evidence of functional rearrangements in the vascular niche. Bortezomib regulates protein degradation, directly influencing stromal microenvironment cells, myeloma cell clones, and osteoclast activity. Endosteal zone status and blood flow were improved in patients with MM treated with bortezomib and achieved CR. This confirms the importance of bone and vascular niches in MM pathogenesis. Therefore, new drugs should target not just the myeloma cells themselves but also the activity of the bone and vascular niches. The status of the HSC niches is an important prognostic criterion for transplantation outcome.

ROLE OF SEROTONIN REGULATION IN OSTEOLYTIC LESIONS OF PATIENTS WITH MULTIPLE MYELOMA

A Romano,[1] A. Chiechi,[2] A Van Meter,[3] G Orloff,[4] P Patel,[4] A Spira,[4] C Walker,[5] F Di Raimondo,[1] E Petricoin,[3] L Liotta,[3] V Espina[3]

[1]Ospedale Ferrarotto, Università di Catania, Catania, Italy; [2]Laboratorio di Oncologia Sperimentale, Istituto Ortopedico Rizzoli, Bologna, Italy; [3]George Mason University, Manassas,VA, USA; [4]Northern Virginia Hematology & Oncology, Fairfax, VA, USA; [5]Walker & Company, Reston, VA, USA

Background. The biologic mechanisms involved in the pathogenesis of multiple myeloma (MM)-induced osteolytic bone disease are poorly understood. Physiological interactions between the serotoninergic and skeletal systems are implicated by clinical observations.[1-3] MM patients with evidence of osteolytic lesions exhibited an increase in the concentration of serum tryptophan and serotonin,[3] while that of tyrosine, dopamine, and noradrenaline was decreased.[3] We hypothesize a direct role of serotonin signaling in myeloma bone disease. The monoamine serotonin [5-hydroxytryptamine (5- HT)] has previously been investigated as a neurotransmitter, synthesized by a two-step pathway in which tryptophan hydroxylase is the rate-limiting enzyme. The brainstem-derived serotonin (BDS) positively regulates bone mass following binding to 5-HT2C receptors on ventromedial hypothalamic neurons. This is opposed by platelet-derived serotonin (PDS) which induces bone lysis and osteoclast activation. Circulating 5-HT is principally stored in platelet-dense granules. Immunoglobulins have been shown to induce platelet release a) when participating in immune reactions as antigen-antibody complexes or b) by nonimmune mechanisms such as coating of glass or polymethylmethacrylate beads. Aggregated immunoglobulins derived from all the IgG subclasses, isolated from healthy controls or myeloma patients, induce platelet granules to release serotonin (in the absence of antigen or particulate matter) in a dose dependent manner.[2] *Aims.* Increased circulating-serotonin levels released from platelets by immunoglobulin complexes may alter the RANK/RANKL ratio in the BM environment and promote MM osteolytic lesion. *Methods.* We explored the role of serotonin in MM bone disease by examining the levels of serotonin and a range of 20 cell signaling proteins in bone marrow core biopsies. We also measured circulating serotonin levels by HPLC in a pilot set of MM patients (n=5). We retrospectively examined 15 bone marrow core biopsies from patients with different clinical stages, using reverse-phase protein microarray (RPMA). RPMA is a reproducible, high-throughput system for protein signal pathway profiling, providing direct information about receptor phosphorylation and consequent activated network . *Results.* We evaluated the association of serotonin and adrenergic receptor levels with DKK1 and RANK which participate in bone loss, as well as with a variety of hormone and cytokine receptors, and a series of phosphorylated signaling proteins. 4 out of 5 samples in patients with osteolytic lesions had detectable serotonin. Positive correlations were noted between DKK1, Ezrin Thr567, Deptor, and serotonin in patients with osteolytic disease. *Summary.* These data suggest that the 5-HT system plays an important role in bone homeostasis through effects on osteoclast differentiation and can support the hypothesis that the serotonin system is involved in the pathogenesis of MM-induced bone disease. This insight could provide strategies for reducing osteolysis using agents which regulate circulating serotonin.

Background. Multiple myeloma (MM) is the second most common hematological malignancy. It is caused by clonal proliferation of terminally differentiated cells of B-lineage. Morphology assessment including the determination of plasma cell percentage in the bone marrow remains one of the basic diagnostic procedures even in the era of genomics. The objective of this study was to evaluate the prognostic impact of the presence of different plasma cell morphological subtypes on overall treatment response and long-term survival. We also analyzed whether this parameter can be correlated to other conventional prognostic/predictive markers. *Patients and Methods.* Our cohort consisted of 139 newly diagnosed MM patients (pts) who subsequently underwent autologous transplantation (AT) within the 4W and CMG 2002 clinical trials in a single center. Percentage of plasma cell subtypes in the bone marrow was evaluated based on the progressive nucleolus analysis, assessment of nuclear chromatin, and the nucleus/cytoplasm (N/C) ratio. A combination of these elements permits differentiation of eight subtypes P000-P111 and four subclassifications. *Results.* Mature plasma cells (P000, P001) were found in 42.4% of patients; type I proplasmocytes (P010,P011,P100) in 38.1% of patients; and type II proplasmocytes (P101,P110) in 19.4% of patients. For patient undergoing AT, group of pts with overall therapeutic response ORR has lower number of mature plasma cell P000 group than pts without treatment response (median 24.0% *vs.* 36.0%; P=0,032). Patients with bone marrow infiltration by mature plasmocytes (P000 subtype) <10% had shorter overall survival compared to pts with P000 ≥37% (median 46.8 months *vs.* 77.8 months; P=0.020). The presence of proplasmocytes (P110 subtype) <3% was associated with longer time to progression compared to P110 ≥31% (median 54.6 months *vs.* 22.4 months; P=0.045). Patients with ISS stage 1 or 2 had lower percentage of P010 (type I) proplasmocytes than stage 3 patients (11.5% *vs.* 23.0%; P=0.030). In contrast, higher infiltration with P100 (type I) proplasmocytes and P101 (type II) proplasmocytes

was observed in ISS stage 1-2 patients compared with stage 3 patients (12.0% *vs.* 6.5%; P=0,015 for P100 a 1.0% *vs.* 0,0%;P=0,046 for P101). Patients without 13q14 deletion have had higher bone marrow percentage of mature P000 plasmocytes than patients with del 13q14 (35% *vs.* 13%; P=0.014). Del13q14 was also associated with lower counts of type II P110 proplasmocytes (36,5% *vs.* 6,0%; P=0,012). There was found no other association with evaluated chromosomal abnormalities including 1q21 gain, del(13)(q14), del(17)(p13), t(4;14)(p16.3;q32), and t(11;14)(q13;q32). *Conclusion.* Despite advances in high-tech genomic technologies, evaluation of plasmocyte infiltration of the bone marrow still belongs to basic diagnostic procedures in MM and further morphological subtyping of plasmocytes provides important prognostic information in MM patients treated with autologous stem cell transplantation.

SERUM PROINFLAMMATORY CYTOKINES PROFILE IN MULTIPLE MYELOMA RELATED TO PATHOGENESIS OF BONE DISEASE

J Gervas-Arruga, M Pocovi, P Giraldo

I+CS, Zaragoza, Spain

Background. Bone disease is one of the most frequent complications in Multiple Myeloma (MM), and as consequence produce irreversible and invaliding lesions. The pathogenesis of bone disease is not completely known. There are several publications about the influence of different cytokines in the bone remodelling, by break the balance between osteoclastic/osteoblastic activities. Aims of the study: to analyze a cytokine panel in a group of consecutive patients diagnosed as MM according the International Myeloma Working Group, 2003 criteria and to compare the results between patients with an without overt bone disease and to study the profile change related to therapy response. *Patients and Methods.* Between June 2008-June 2009, a total of 40 consecutively MM patients were studied (46.0% females) in Haematology Department of Miguel Servet University Hospital; mean age: 70.2 (range: 66.3-74.0). According subtypes distribution: Light Chain: 6 (15.0%) IgG: 21 (52.5%); IgA 11(27.5%), double MC 2 (5.0%); the ISS (1: 9, 22.5%, 2: 21 52.5%, 3: 10 25.0%). Four different degrees of bone disease was established: 17 normal (48.58%); 6 osteopenia (17.14%); 1 osteoporosis (2.86%); 5 Lytic lesions (14.28%); 6 fractures (17.14%). The cytokine assay was performed in serum samples stored at -80ºC at diagnosis and the end of therapy, using Millipore human cytokines Kit according the established protocol by Luminex®100 platform. The profile cytokine panel used were: IL-4, IL6, IL-7, IL-10, IL-13, MIP-1α,MIP-1β, TNFα and RANKL. Previously we had compared the cytokine profile with a group of healthy population (n=36) and MGUS (n=36) group matched by age and gender. The results of the cytokine panel were compared between group's control/MGUS/MM, bone disease, immunochemical subtypes and ISS stage, haemoglobine, β2 microglobuline concentration, free light chain ratio in the MM group. Descriptive analysis and non-parametric test was performed using SPSS 15.0 and STATA SE v.10. *Results.* The cytokine profile of control/MGUS/MM was significant different for IL-4 (P=0.02), IL-13 (P=0.001), MIP-1α(P=0.03), MIP-1β(P=0.001) and TNFα(P=0.003). Considering only MM group the comparative analysis of profiles according ISS classification showed significant differences for MIP-1α(P=0.04), IL-13(P=0.02) and β2microglobuline *vs.* TNFα (P=0.002). No significant differences were observed for immunochemicals subtypes, free κ/λ ratio and haemoglobine. *Conclusions.* In our experience Luminex®100 technology is a sensible and accurate technique useful to determine cytokine profile in serum. A different significant cytokine profile was observed between control/MGUS MM and in MM group: β2microglobuline and ISS. It is necessary to perform more studies with more patients in order to confirm these results.

This work has been partially sponsored by a grant from CIBERER.

AN INTERIM STUDY REPORT OF CD44 STANDARD MOLECULE AND ITS VARIANT ISOFORM EXPRESSION IN MGUS AND MM

K Muthu Raja, I Buresova, L Kovarova, J Stossova, R Hajek

Babak Research Institute, Brno, Czech Republic

Background. Multiple myeloma (MM) is a neoplastic plasma cell (PC) disorder in which the malignant PCs accumulate in the bone marrow (BM); this has been defined by regulation of various adhesion molecules. Expression of adhesion molecules such as CD56 and CD138 prominently represented as a tool for PC identification and characterization in PC disorders. CD44 or CD44 standard molecule (CD44s) is restricted on haematopoietic cells and involved in various adhesive functions such as cell-cell interaction, binding to matrix and homing to inflammatory sites. Few studies documented the CD44s and CD44 variant (CD44v) isoforms expression in MM. We made an attempt to renew the interest of CD44s, CD44v4 and CD44v6 expression in MM. *Aims.* To evaluate the differential expression of CD44s, CD44v4 and CD44v6 in BM $CD19^+$ cells and BMPCs of MGUS and MM patients (pts). To analyze the clinical features that influence expression of CD44s and CD44v isoform in MM. *Methods.* In this pilot study a total of 43 pts were enrolled and diagnosed as 9/43 with MGUS, 14/43 with symptomatic MM and 20/43 with relapse. Five-color flow cytometric immunophenotyping was applied to screen CD44s, CD44v4 and CD44v6 expression in BMPCs and PC excluded $CD19^+$ cells. Following 5 color combination of MoAbs were used for phenotyping: CD44s/CD44v4/$CD44v6^-$FITC/$CD19^-$PE/$CD138^-$PercpCy5.5/CD56-PE-Cy7/CD38-APC. Estimation of statistical significance (P<0.05) between groups were performed using Mann-Whitney U test and correlation analysis was done by Spearman Rank Order correlations. *Results.* PCs were identified on the basis of $CD138^{++}CD38^+$ expression and PC excluded CD19+ cells were characterized as $CD138^-$ $CD38^-CD19^+$. Expression of CD44s and CD44v molecules in PCs and $CD19^+$ cells has been summarized in Table 1. In MGUS, MM and relapsed cases overall differential expression of CD44s, CD44v4 and CD44v6 in PCs and $CD19^+$ cells were observed; however it did not reach statistical significant difference. In accordance with several reports, statistically significant difference in the BMPCs of MGUS *vs.* MM (P=0.009) and MGUS *vs.* relapsed cases (P=0.017) were found. Notably for CD44s molecule, BM $CD19^+$ cells had higher frequency of CD44s expression compared to BMPCs (P<0.001). In univariate analysis, ≥ 3.5 mg/L of β2M (P=0.040) was found to be the influential factor for BM $CD19^+CD44s^+$ cells. Features such as <10% of BMPCs (P<0.01) and <30g/L of M-protein (P<0.01) were chosen as most influential factor for $CD44v4^+$ expression in BMPCs. More interestingly, inverse correlation had been observed between $CD44v4^+$ *vs.* BMPCs (R= -0.44; P=0.003) and $CD44v6^+$ *vs.* BMPCs (R= -0.34; P=0.021). *Summary.* This interim report revealed that there is no significant influence of CD44s, CD44v4 and CD44v6 expression with regard to distinguishing MGUS and MM. The unique finding from this study is inverse correlation between CD44v isoforms and BMPCs. We are expecting CD44v4 and CD44v6 isoform could serve as a prognostic marker in MM and moreover this should be confirmed in large cohort of pts.

This study has been supported by grants: GACR P304/10/1395, LC06027 and MSM 0021622434.

Table 1. Expression of CD44s, CD44v4 and v6 in MGUS and MM.

Group	BM $CD19^+$cells/Leukocytes %Median (range)	$CD19^+CD44s^+$ %Median (range)	$CD19^+CD44V4^+$ %Median (range)	$CD19^+CD44V6^+$ %Median(range)
MGUS	1.62 (0.7-4.61)	98.7(92.02-99.8)	2.61(0.95-4.72)	6.75 (1.55-15.16)
MM	1.08 (0.48-4.07)	98.5(90.5-99.6)	3.45(0.5-10.48)	8.19 (0.68-44.57)
Relapsed MM	2.28(0.15-10.13)	97.8(88.2-100)	5.31(1.03-18.54)	10.45(3.6-24.5)

Group	BMPCs/Leukocytes %Median (range)	PCs $CD44s^+$ %Median (range)	PCs $CD44V4^+$ %Median (range)	PCs $CD44V6^+$ %Median(range)
MGUS	0.49 (0.03-1.9)	96.38(81.7-98.8)	5.58(1.33-11.76)	13.18(2.13-22.25)
MM	3.6 (0.02-26.43)	92.7(17.5-99.3)	6.03(0.2-29.45)	9.4(1.64-53.57)

MATRIX METALLOPROTEINASES -2 (MMP-2) AND -9 (MMP-2), TISSUE INHIBITOR OF METALLOPROTEINASE - 1 (TIMP-1) AND-2 (TIMP-2) PRODUCTION AND EMMPRIN (CD147) EXPRESSION ARE INCREASED IN PATIENTS WITH MYELOMA MULTIPLEX AND DISPLAY CORRELATION WITH ADVANCED STAGE

D Urbaniak-Kujda, K Kapelko-Slowik, I Prajs, J Dybko, M Kielbinski, D Wolowiec, J Jakubaszko, I Frydecka, K Kuliczkowski

Wroclaw Medical University, Wroclaw, Poland

Introduction. Matrix metalloproteinases (MMPs) are a family of zinc-dependent endopeptidases characterized by the activity to degrade of the extracellular matrix. Gelatinases : MMP-2 (gelatinase A) and MMP-9 (gelatinase B) are members of MMP family involved in tumor initiation growth and metastasis. The activity of MMPs is controlled by their interaction with tissue inhibitors of metalloproteinases (TIMPs). Myeloma multiplex (MM) is a B-cell malignancy with the excessive bone resorption and the tumor invasion process inside and outside the bone

marrow. There is a little data about concentration of MMP-2 and MMP-9, their tissue inhibitors (TIMP-1, TIMP-2) and an activator emmprin in myeloma patients. *Aim.* The aim of our study was to estimate the bone marrow concentration of MMP-2, MMP-9, TIMP-1, TIMP-2 and emmprin expression in MM patients and whether these parameters are connected with the disease`s advanced stage. *Patient and Methods.* Forty -four patients: 27 men and 17 women, aged 48- 81 mean: 52.4 years with newly diagnosed MM were enrolled in the study. According to Durie and Salmon staging system 4 patients were in I stage, 10 in II stage and 30 in III stage. The control group enclosed 17 healthy subjects matched sex and age. Bone marrow samples were obtained at presentation. The bone marrow stromal cells (BMSCs), CD166 positive, were incubated in Mesencult. Supernatans were collected and stored at -80°C until measurement. Concentration of MMP-2 and TIMP-2 in supernatants was assessed by ELISA method. MMP-9 and TIMP-1 were assessed in bone marrow before culture by ELISA method. Expression of CD147 on CD166 positive cells was assessed by flow cytometry. *Results.* Mean concentrations of MMP-9, MMP-2 , TIMP-1 and TIPM-2 were significantly higher in MM patients than in normals. The MMP-9/TIMP-1 and MMP-2/TIMP-2 ratios were significantly higher in MM group than in the control. Moreover we revealed the positive correlation between concentration of MMP-2 and MMP-9 with advanced stage of MM according to Durie-Salmon staging system and number of bone osteolytic lesions. Expression of CD147 on BMSCs obtained from MM patients were significantly higher than on BMSCs in normal group. *Conclusion.* Our study revealed increased concentration of MMP-2, MMP-9, TIMP-1 and TIMP-2 in bone marrow of patients with MM and positive correlation with the disease advanced stage and a number of osteolytic lesions.

1428

STEM CELL MARKER NESTIN IS EXPRESSED IN PLASMA CELLS OF PATIENTS WITH MONOCLONAL GAMMOPATHIES

H Svachova,[1] L Pour,[2] L Kovarova,[1] I Buresova,[1] K Muthu Raja,[1] R Hajek[1]

[1]Babak Research Institut, Brno, Czech Republic; [2]Department of Internal Medicine and Hematooncology, The Faculty Hospital, Brno, Czech Republic

Backround. Nestin, an intermediate filament protein is known to be a stem cell marker expressed in various embryonic and fetal tissues. Nestin expression is downregulated in adult terminally differentiated tissues. Currently, nestin expression has been detected in many tumors including multiple myeloma (MM). Nestin is supposed to be a cancer stem cell marker; its overexpression is related to malignancy and plays a crucial role in aggressive behaviour, migration and proliferation of several solid tumors. *Aims.* The aim of this study was to confirm nestin expression in plasma cells (PCs) of patients with monoclonal gammopathies (GMs). *Methods.* A total number of 37 MG patients (23M/14F; median age 68 years) represented by 92% (34/37) of MM patients, 5% (2/37) of MGUS patients and 3% (1/37) of non-secretory MM patients were included in this pilot study. Five patients without monoclonal gammopathy served as a control group. Bone marrow mononuclear cells were analysed by 3-color flow cytometry, and PCs were identified as $CD38^+CD138^+$ followed by direct staining for intracellular nestin. Nestin expression was assessed based on percentage of PCs showing positivity for nestin (Nes+PC) and median fluorescence intensity of nestin expression in PCs. Nestin expression was verified in 8% of MG patients (3/37) by immunocytochemistry and in 24% of samples (9/37) by western blots. *Results.* The whole group of MG patients had the median percentage of Nes+PC 31.3% (range, 0%-95.4%). In the control group, the median percentage of nes+PC did not exceed 1.5% (range, 0.3-2.7%). The median fluorescence intensity of nestin expression in PC was 4.2×10^2 (range, 0-6.8×10^3). Immunocytochemistry demonstrated nestin immunoreactivity in all analysed samples (3/3) as the network of nestin filaments or the diffused signal in the cytoplasm of PC. Western blot analyses confirmed nestin expression in 78% (7/9) of MM cases. *Conclusion.* Our results clearly confirmed nestin expression in PCs of MG patients. The percentage of nestin-positive PC and the median fluorescence intensity of expression ranged between patients. Prognostic/predictive significance of these differences requires an evaluation on a larger number of patients and correlation to clinical data. Based on current reports, we hypothesise that nestin could be a prospective marker of myeloma stem cells and a possible target of anticancer therapy. Further studies are required to confirm our hypothesis.

A PRELIMINARY STUDY REPORT OF T REGULATORY CELLS IN PRE AND POST TREATED MYELOMA PATIENTS

K Muthu Raja, L Zahradova, Z Mikulkova, M Cibulka, I Buresova, L Kovarova, R Hajek, J Michalek

Babak Research Institute, Brno, Czech Republic

Background. T regulatory (Treg) cells play an important role in modulation and maintenance of overall immune response against infectious disorders and tumors. In various cancers including solid and hematological malignancies clinical anti tumour response has been degenerated due to expansion of Treg cells. Immune dysfunctions were also described well in multiple myeloma (MM) and now it is obvious to exploit the Treg cells in MM. *Aims.* The proposed concept of this study is to compare the frequency of $CD4^+$ Treg cells in newly diagnosed and treated/transplanted MM patients (pts). Evaluation of possible association of Treg cells to clinical features of MM. *Methods.* A total of 51 newly diagnosed MM pts were enrolled in this study after signing informed consent. Patients were clinically represented with different stages of MM (International Staging System: ISS 1=17%, ISS 2=39% and ISS 3=44%). A uniform treatment including thalidomide in combination with cyclophosphomide and dexamethasone (CTD) was given in four and eight cycles, respectively for younger (<65 years= 41%) and elderly (≥65 years= 59%) pts. Followed by 4 cycles of CTD regimen, autologus stem cell transplantation (ASCT) was offered to younger pts. $CD4^+$ Treg cells had been quantified based on four-color flow cytometric phenotyping for antigens CD4, CD25, CD127 and FoxP3. All pts peripheral blood (PB) and bone marrow (BM) samples were analyzed for $CD4^+$ Treg cells during diagnosis, as well for 17 treated and 8 transplanted pts. As a control group 20 healthy individuals PB $CD4^+$ Treg cells were also analyzed. *Results.* Immunophenotypisation revealed $CD4^+$ Treg cells as $CD4^+$ $CD25hi^+$ CD127dim/- $FoxP3^+$. Enumeration of Treg cells were performed on the basis of $CD4^+$ $CD25hi^+$ $FoxP3^+$ phenotype. Our results shown a paradigm of statistically significant increased frequency of PB Treg cells in MM pts compared to control group (median=5.48% *vs.* 3.82%; P<0.0001). Quantified PB and BM Treg cells of MM pts had shown significant positive correlation (R=0.70; P<0.0001). A pattern of reduction in the PB Treg cell frequencies were observed after eight cycles of CTD regimen, compared to pre-treatment (median=4.61% *vs.* 5.71%; P>0.05 [not significant]). Proportionately, PB Treg cell frequencies in transplanted pts were also found to be reduced than prior to transplantation (median=3.4% *vs.* 5.94%; P>0.05). Whereas, BM showed increased number of Treg cells in transplanted pts than at the time of diagnosis (median= 5.59% *vs.* 4.35%; P>0.05). In univariate analysis clinical parameters such as ≥ 30 g/L of M-protein and ≥ 3.5 mg/L of β2- microglobulin were chosen for increased frequency of PB and BM Treg cells, although it did not reach the statistical significance. *Summary.* As anticipated, CD4+ Treg cells were found to be increased more prominently in MM pts. From this preliminary study report no strong conclusion can be drawn but a paradigm of reduction in Treg cells was documented in post treated and transplanted pts. Therefore, the impact of Treg cells in pre and post treated MM pts must be acknowledged in large series of pts.

CD45 EXPRESSION BY BONE MARROW PLASMA CELLS AT DIAGNOSIS IN MULTIPLE MYELOMA: CORRELATION WITH MINIMAL RESIDUAL DISEASE

I Safra,[1] A Lakhal,[2] S Ladeb,[2] L Torjemane,[2] R Ben Jemaa,[1] A Ben Abdeladhim,[2] T Ben Othman[2]

[1]Institut Pasteur Tunis, TUNIS, Tunisia; [2]Centre de Greffe de Moelle Osseuse, Tunis, Tunisia

Background. Multiple myeloma (MM) is characterized by accumulation of clonal plasma cells (PCs) in bone marrow. CD45, a key regulator of antigen-mediated signalling and activation in lymphocytes, is present in early stages of PCs development. CD45 is now established as a critical component of the signal transduction machinery of lymphocytes. *Aims.* In the present work we are interested in tracking the pattern of expression of CD 45 by malignant plasma cells at diagnosis in comparison with the degree of minimal residual disease after induction by Thalidomide and Dexamethasone. *Methods.* CD45 expression on multiple myeloma plasma cells and minimal residual disease quantification were studied by flow cytometry (FCM). A total of 14 patients (13 H, 1F) were studied at diagnosis and after first line therapy. Inten-

sity of expression and the percentage of plasma cells are taken into account when determining the expression profile of CD45. Samples were considered $CD45^+$, if they present more than 20% of plasma cells with bright CD45 expression (>102). Response to treatment was evaluated by quantification of CD38 high $CD138^+$ $CD56^+$ cells. A lower threshold of 10-2 was considered as a good response. *Results.* At diagnosis, the average of plasma cell bone marrow infiltration was 35% by cytology and 25% by FCM. There is a correlation between the percentage of plasma cells estimated by cytology and FCM with a significant value (P=0.005). The expression of CD 45 was predominantly negative in 9 (64%) of 14 samples. Minimal residual disease separate two groups of patients: The first group: 6 patients with MRD>10^{-2} and a profile CD 45 predominantly negative (only one sample was CD45 positive) and a second group: 8 patients with MRD<10^{-2} with five samples CD45 positive. Negative expression of CD45 is correlated with bad response to treatment (P=0.05). *Conclusion.* In this study, we report a positive correlation between the expression of CD 45 and the therapeutic response. Further prospective studies are necessary to confirm this concept.

DOES CD117 HAVE AN INDEPENDENT PROGNOSTIC VALUE IN PATIENTS WITH MULTIPLE MYELOMA?

M Begu,[1] H Bumbea,[1] AM Vladareanu,[1] A Vintilescu,[1] M Onisai,[1] C Baluta,[1] O Cazaceanu,[1] A Ichim,[1] S Radesi,[1] I Voican,[1] D Cisleanu,[1] VM Popov,[2] C Marinescu,[1] M Gaman,[1] C Ciufu,[1] A Nicolescu,[1] D Vasile,[1] L Barsan[1]

[1]Emergency University Hospital Bucharest, Bucharest, Romania; [2]County Hospital, Pitesti, Romania

Background. Immunophenotyping by flowcytometry is known as a useful method in diagnosis and prognosis of multiple myeloma. Guidelines of European Myeloma Network (EMN) recommend a few markers to be assessed for prognosis, such as CD56, CD117, CD20, CD27, CD28. *Aim.* to assess prognosis value of CD117 and association with other biological features in patients with multiple myeloma. *Methods.* We have studied 22 consecutive, new diagnosed myeloma patients. Immunophenotyping analysis was performed on 4 colors BD FACS Calibur flowcytometer. For statistical analysis we used SPSS software. Mandatory panel recommended by EMN was used for diagnosis by flowcytometry, gating the CD38 and CD138 positive plasma cells; prognosis markers were considered CD20, CD56, CD117, CD45. *Results.* Sex ratio: 7 females, 15 males; average age=60 years. Durie-Salmon staging was as follows: stage II(60%); stage I(20%) stage III(19%), 1% smoldering myeloma. Regarding CD117 expression, we divided the patients in 2 groups: 11/22 patients (3 females, 8 males; average age=70 years) had poor prognostic immunophenotypic profile: CD117 positive, CD56 positive in 9/11cases; the other half - 11/22 patients (4 female, 7 male; average age - 57 years) had favorable prognosis profile: CD117 negative, $CD56^+$. Percentage of myeloma plasma cells existent in bone marrow is not different between the two groups of patients (ranging between 20-80%). We found a possible correlation of low expression of CD45 with low expression of CD56 on myeloma cells, and an unusual high expression of CD45 and $CD56^+$ on malignant myeloma cells and with good clinical outcome, also(P=0.05). In both groups, the most restriction was with kappa light chains (CD117 positive: kappa/lambda ratio - 10/1; CD117 negative: kappa/lambda ratio - 9/2). Immunoglobulin G was most frequently encountered in both groups (CD117 positive patients: 7 patients with IgG, 2 patients with IgM and 2 patients with IgA; CD117 negative group - 6 patients with IgG, 3 patients with IgE). Considering evolution, patients with positive expression of CD117 had mostly unfavorable outcome (7/11); from CD117 negative patients, 6/11 went worse. *Conclusions.* Our results on preliminary data suggest that CD117 has not a particular prognosis value as independent parameter in multiple myeloma.

TUMOR NECROSIS FACTOR-ALPHA AND OTHER PROINFLAMMATORY CYTOKINES IN MULTIPLE MYELOMA

I Ionita, RG Cioaca, CO Ionita, H Ionita

UMF Victor Babes, Timisoara, Romania

Background. Excessive or inadequate expression of proinflammatory cytokines during the immune response may produce autoimmune phenomena at the inflammatory site by tissue destruction, consequently maintained by complex mechanisms in with the proinflammatory cytokines play a critical role. Multiple myeloma represents a disorders characterized by the presence of general inflammatory processes. Studies on peripheral bllod proved the presence of numerous proinflammatory cytokines (TNF-α, IL-1 and IL-6). *Aims.* We tried to assess the serum concentration of the proinflammatory cytokines: TNF-α, IL-1 and IL-6 as a mirror of type 1 response. *Methods.* We studied 28 multiple myeloma patients in a progressive stage of the disease, without any other autoimmune disease, other tumor or sistemic infection compared with a group of 28 healthy individuals, with a median age of 30 years. We performed immunoenzimatic determinations by ELISA technique, following the working protocol Quantikine, R and D System, Minneapolis, USA for the TNF-α and Endogen, Woburg, MA, USA for the IL-1 and IL-6 . We have determined the serum level of some proinflammatory cytokines (IL-1 α, IL-6 and TNF-α) in multiple myeloma comparing to healthy controls, in order to identify possible significant changes of cytokines concentration. *Results.* Our study showed a significantly increased level of TNF-α in the peripheral blood of multiple myeloma patients (28.21±17.08 pg/mL) compared with those obtained in healthy controls (4.6±14.6 pg/mL) (P<0.05). IL-1 and IL-6 proinflammatory cytokines were found in all multiple myeloma patient's serum and the value were higher than in healthy controls. IL-6 in multiple myeloma patients serum was 22.3±10.7 pg/mL compared with the healthy group 6.76±3.78 pg/mL (P<0.05), and IL-1 was 4.9±2.3 pg/mL in multiple myeloma *vs.* 2.24±0.94 pg/mL in healthy patients. *Conclusions.* Our study results show that IL-1 and IL-6 are involved in the multiple myeloma pathogenesis and argue for the existence of a systemic inflammatory response. TNF-α cytokine is constantly present in the peripheral blood of multiple myeloma patients.

THROMBOPHILIA STUDY IN MULTIPLE MYELOMA (MM) PATIENTS

E Papakonstantinou,[1] E Yfantis,[1] A Theofani,[1] E Sini,[2] A Hepetary,[2] A Maris,[2] A Filiotou,[2] C Manti[1]

[1]Thriassion Hospital, Agia Paraskevi, Greece; [2]Ippokration Hospital, Athens, Greece

Background. Thrombosis correlates significantly with MM. The role played by coagulation system in MM thrombosis is unclear. This may partly be due to lack of tests that truly reflect the balance between mechanisms that promote or inhibit the coagulation *in vivo*. Recently, a test is available for routine measurement of total thrombin potential (ETP) from Dade Behring. *Aim.* Comparison of ETP parameters with other coagulation markers like: - Antithrombin III, protein C, protein S, lupus anticoagulant, plasminogen, a2-antiplasmin, APCR, homocystein- between controls and MM patients. *Methods.* 18 consecutive samples of MM patients (7 men, 38.9% and 11 women 61.1%) and 30 control group samples were studied for ETP parameters, Antithrombin III, protein C, protein S, lupus anticoagulant, plasminogen, a2-antiplasmin, APCR, homocystein. We used the chromogenic method on the fully automated Behring Coagulation System (BCS) for the measurement of thrombin generation parameters. It should be noted that no patient received thalidomide for which is known to increase the likehood of thrombosis in MM patients. *Results.* Table. *Conclusions.* 1.ETP had not statistical significance between the control group and MM patients. 2.Acquired APCR is known to be a predisposing factor for thrombosis but was found in just one case. The ATIII, protein S, the LA and homocysteine had statistically significant differences between MM patients and controls. 3.Thrombophilic alterations in coagulation were not found in ETP parameters of our study. Despite that, ETP measurements may be useful as a simple method to identify patient of MM at risk for thrombosis and in whom the prophylactic anticoagulation may be necessary in conjunction with therapies such as thalidomide, which increase the risk of thrombosis.

Table.

Parameters	Controls	Patients	*P* Value

DIFFERENCE IN SERUM CYTOKINES PATTERN BETWEEN SYSTEMIC AND LOCALIZED AL AMYLOIDOSIS

F Saltarelli,[1] A Moscetti,[2] MP Bianchi,[2] G. Bruno,[3] G Salerno,[4] G Ferranti,[4] MT Corsetti,[4] P Cardelli,[4] G La Verde[2]

[1]Az. Ospedaliera Sant'Andrea, Università Sapienza, Roma, Italy; [2]UOC Ematologia Az.Ospedaliera Sant'Andrea, Università Sapienza, Roma, Italy; [3]UOC Medicina Generale I, Az.Ospedaliera Sant'Andrea,Università Sapienza, Roma, Italy; [4]UOC Diagnostica di Laboratorio,Az.Ospedaliera Sant'Andrea,Università Sapienza, Roma, Italy

Background. AL amyloidosis, a plasmacellular discrasia, is characterized by the deposition of proteic fibrils that infiltrate tissues leading to organ failure. Amyloid deposition can be systemic, affecting many different organ systems, or organ-specific. *Aims.* The aim of this study is to evaluate serum cytokines levels in patients with systemic or localized AL amyloidosis at presentation to find out potential differences. *Methods.* Blood samples were collected from 6 patients with systemic amyloidosis and from 4 patients with localized amyloidosis. Cytokine panel used included IL-10 and VEGF. Mann-Whitney test was used to compared results. IL-10 and VEGF were also tested in a group of healthy people as control. *Results.* Results showed that IL-10 level was significantly higher in the serum of patients with localized disease compared to the group of patients with systemic amyloid involment (P=0.006), VEGF was instead significantly increased in systemic disease group (P=0.027). *Conclusions.* Results seems to suggest a difference in serum cytokine pattern between AL systemic and localized amyloidosis. In particular, in localized disease T-regulators activity seems to be more efficient then in the systemic form in which we observed an increase in VEGF values maybe related to a more advanced neoplastic neoangiogenesis.

THE COMPARISON OF SERUM AND PLASMATIC LEVELS OF SELECTED BIOMARKERS IN MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE AND MULTIPLE MYELOMA.

S Piano, G Farina, T Grafone, C Nicci, V Fraticelli, C Gasbarrino, G Giordano, M Petrilli, S Storti

Catholic University, Campobasso, Italy

Background. Multiple myeloma (MM) is characterized by proliferation of malignant plasma cells that accumulate in the bone marrow and often produce a monoclonal immunoglobulin. Angiogenesis activators include vascular endothelial growth factor (VEGF) and plasma concentrations of cytokines such as Tnf-a and Il-6 play a role in MM pathogenesis. They have been shown to stimulate the proliferation of malignant plasma cells as well as nonmalignant stromal cells. *Aims.* The aim of our study was to evaluate different expression of serum and plasmatic concentration of Tnf-α, Il-6 and VEGF in MM and MGUS patients. *Methods.* The levels of VEGF, TNF-α and Il-6 were detectable in 44 MM patients,48 MGUS patients and 14 healthy controls from 2004 today. The detection of the cytokine levels was performed by ELISA technique. Statistical analysis was perfomed using STATA program, t-test and Spearmen test. *Results.* M/F was 21/23 in MM patients, their median age was 69.5 yr (range 41-88). 18/44 (41%) patients showed a monoclonal component IgG/k, 11/44(25%) IgG/l, 4/44(9%) IgA/k, 7/44(16%) IgA/l; 4/44(9%) micromolecular type. 29/44(65%) patients presented comorbidities. The most was in advanced disease (Salmon and Durie stage III). Median concentration of B2 microglobuline was 3.5 mg/dL (range 1-16). 15/44(34%) patients presented abnormal cariotype. 24/39(62%) patients were in first; 10/39(25%) in second and 5/39(13%) in third/fourth lines therapy. M/F was 27/21 in MGUS patients, their median age was 68 yr (range 39-85). 5/48(10%) patients showed a monoclonal component IgA/k, 2/48(4%) IgA/l, 19/48(40%) IgG/k, 15/48(15%) IgG/l; 6/48(13%) IgM/k, 1/48(2%) IgM/l. 39% of this group had comorbidities. There weren't different expression of serum and plasmatic TNF-α and Il-6 between MM and MGUS patients. Only VEGF serum concentration was statistically significant into two study groups (P=0.012). Il-6 levels showed a progressive increase from healthly controls to MM patients. In MM patients we found statistically significance differences between serum and plasmatic medium concentration of VEGF (P<0.001), TNF-α (P<0.02) and Il-6 (P<0.005). We found a significant correlation between the concentration of VEGF and Il-6 and the number of platelets in those patients analyzed. *Conclusions.* Plasma and serum concentrations of these cytokines are not conclusive as to their relative importance in pathogenesis and progression from MGUS to MM. Since median concentration of all cytokines were bigger in serum, we think that this analysis could be more sensibility. Neverthless these data need confermation on a larger cohort of patients.

1436

THE INTRODUCTION OF SERUM FREE LIGHT CHAINS ASSAY ON THE DIAGNOSIS AND SCREENING PROTOCOLS FOR MONOCLONAL GAMMOPATHIES IS ESSENTIAL TO AN EARLY DIAGNOSIS

J Jimenez Jimenez,[1] N Barbosa de Carvalho,[2] C Hernando de Larramendi[1]

[1]Hospital Severo Ochoa, Leganes. Madrid, Spain; [2]The Binding Site, Birmingham, UK

Background. Monoclonal free light chains are homogeneous populations of kappa (κ) or lambda (λ) immunoglobulin light chain molecules produced by malignant B-cells clones. They are important tumour markers for identifying and monitoring patients with monoclonal gammopathies like multiple myeloma (MM), solitary plasmacytoma, monoclonal gammopathy of undetermined significance (MGUS) and smoldering multiple myeloma. The identification and quantification of monoclonal immunoglobulin in plasma cell disorders is based on electrophoresis, immunofixation and nephelometric measurement of immunoglobulins. The use of serum κ/λ FLC ratio is an emergent method that is becoming very important for the diagnosis of a plasma cell dyscrasia. An altered serum κ/λ ratio is a marker of monoclonality. *Aims.* We present a case that only serum protein electrophoresis (SPE) and free light chain (FLC) tests was necessary for efficient and quickly inicial diagnostic screen for monoclonal gammophaty. *Methods.* Serum free light chains (Freelite. The Binding Site) and immunoglobulins were measured by nephelometry in a BNII (Siemens). Serum and urine electrophoresis and serum and urine inmunofixation (SEBIA). *Results.* This case reports a 41 years old male who was admitted to the rheumatology services of hospital with a strong thoracic pain. He presented four vertebral fractures in dorsal region. Due to these lesions and to low total proteins and immunoglobulins (Total proteins: 6.0 g/dL and IgG = 307 mg/L; IgA = 30,4 mg/L; IgM = 10,1 mg/L) a MG (monoclonal gammopathy) suspicion was raised even he was a young patient. SPE not present monoclonal component. Even if the SPE was negative the results from the radiologic studies and immunoglobulins could induce the clinician to the suspect of a multiple myeloma or other monoclonal gammopathy. sFLC were requested and extremely high values were found (κ = 2710 mg/L; λ = 0,35 mg/L ratio κ/λ = 7742,86). Serum and urine immunfixation were then performed and a weak free K light chain was detected in both serum and urine IFE corresponding to the sFLC *Results.* After these results a bone marrow biopsy was requested and a 61% of plasma cells infiltration was found. Phatologic immunophenotype ($CD56^+/CD19^-$) compatible with MM. *Conclusions.* Even if SPE is the gold standard for the screening of monoclonal gammopathies, the sFLC measurement together with the ratio allows us to suspect a monoclonal gammopathy without recurring to expensive and invasive techniques for the patient achieving a quick and effective diagnosis. The high specificity and sensibility of serum free light chains allow us an early detection of monoclonal gammopathy or the exclusion of pathology.

1437

MULTIPLE MYELOMA PRESENTING AS SEVERE RENAL FAILURE: RELATED AND PROGNOSTIC VARIABLES IN A COHORT OF 391 PATIENTES

A Canovas, J Alonso, G Barreiro

Hospital de Cruces, Baracaldo (Vizcaya), Spain

Background. The multiple myeloma (MM) presenting as severe renal failure (SRF) has reduced the chances of treatment and survival. The detection of prognostic variables can provide decision-making but may vary by study population. *Aims.* To assess variables associated whit SRF and its prognostic utility regarding recovery of renal function in newly MM diagnosed patients. *Methods.* We retrospectively evaluated from the cohort of MM patients diagnosed in our department (1980-Jaunary to 2008-Mars) those affected by concomitant SRF defined as serum creatinine equal o superior to 5 mg/dL. We assessed the variables usually considered in this context for the remaining patients, and within the IRS group, the prognostic variables of renal function recovery. Diagnostic criteria for MM and response: those the Chronic Leukemia-Myeloma Task Force. Statistical *Methods.* univariate analysis using chi-square, Student t test and multivariate analysis by Cox binary logistic regression. *Results.* There were 376 patients with symptomatic MM; median age 68 years (31-93); monoclonal component (MC) (%): G (47), A(31), light

chains /others (57%); urinary MC present in 60%. Durie-Salmon stage (DS) (%): 1(15), 2 (25), 3 (60). DS A: 75%; B: 25%. ISS in 202 patients(%): 1 (29); 2 (36,5); 3 (35,5). Thirty-three patients (8,8%) had IRF at diagnosis; median creatinine 7,78 mg/dL (5-20). Urinary MC was detected in 88%; There were 13 (39%) light chains MM. In the univariate analysis, significant variables in relation to SRF were: ISS, MM, light chains MM, performance status, Hb, bone marrow plasmacytosis , amount of serum MC, calcemia and b-2 microglobulin. In multivariate analysis, however, the only variable that was significantly associated with SRF was hemoglobin. Eleven of the 33 patients required hemodialysis. First line chemotherapy was: MP(melphalan-prednisone) (6); VAD(vincristine-doxorrubicin-dexametasone) (16); other chemotherapy (11). In relapse or progression were used too, from 2003, thalidomide and from 2004 and 2006, bortezomib and lenalidomide respectively. The response rate was 28% (1 RO IF-, 7 RP); no response 21 (72%)patients, not evaluable 4 (12%). Fifteen patients (45%) recovered renal function (creatinine <2,5 mg/dL) at 3 months and 12 (36%) died within three months. Seven(21%) lived more than 2 years and two patients are living more than 7 years. We finally assessed the variables related to recovery of renal function or death before three months. In the univariate analysis was significant only hemoglobin and ISS and urinary MC were in the borderline. In multivariante analysis, hemoglobin was also the only significant variable.*Conclusions.* Our resuts confirm the poor prognosis of the SRF concomitant with the diagnosis of MM, although a subset of these patients can achieve long survival. The fact that hemoglobin has probed the only significant variable both in relation to the frequency of SRF and its reversibility could be explained because it is related to the MM and the severity and previous duration of renal failure.

1438

LIGHT CHAIN DEPOSITION DISEASE (LCDD) VERSUS AL AMYLOIDOSIS: DIFFERENCES IN NATURAL HISTORY AND TREATMENT?

S Gibbs, J Pinney, P Sattianayagam, T Lane, D Rowczenio, A Wechalekar, T Hunt, J Gilbertson, P Hawkins, J Gillmore, H Lachmann

National Amyloidosis Centre, London, UK

Background. LCDD is characterized by granular deposition of monoclonal immunoglobulin light chains and clinical presentation can mimic AL amyloidosis. Published descriptions of the natural history and treatment of LCDD are scanty. *Aims.* We wished to gain a better understanding of the differences between LCDD and AL amyloidosis, including natural history, response to treatment and overall survival. *Methods.* We conducted a retrospecive analysis of our experience at a single centre of LCDD, focusing on organ involvement, types of and responses to treatment and overall survival. *Results.* 24 patients had a histological diagnosis of LCDD. Another 6 patients with presumed LCDD were excluded from analysis as electron microscopy was not performed or unsuccessful. Males outnumbered females 2.4:1, and deposits were kappa class in 79% (19/24). Median age at diagnosis was 55 years (range 36-72). 2 patients had a bone marrow plasmacytosis >30%, and 5 patients had concomitant AL amyloidosis. All patients presented with renal involvement, and diagnosis was made on renal biopsy in 96%. At presentation all had haematuria, 50% with nephrotic range proteinuria, and 96% had marked hypertension. 7 patients had endstage renal failure (ESRF) at diagnosis. There was clinical evidence of cardiac, liver, gastrointestinal and skin involvement in 4, 4, 3, and 1 cases respectively. One patient had a factor X deficiency. Chemotherapy was administered to 96% of patients, including high dose steroids in 22 patients, CTD(a) in 14, ASCT in 5, VAD in 3, Mel Dex in 3, and bortezomib/dex in 2. Complete clonal responses (CR) were achieved in 3, and partial responses in 9 out of 19 evaluable patients. Median follow up was 40 months (range 1-91) with 18 patients alive at censor. 7 patients progressed to ESRF in a median of 47 months. Improvement in renal function was seen in 5 patients, defined as improvement by a CKD grade for >6 months (4 patients CKD V to IV; one CKD III to II) including 2 patients treated with short courses of steroids only - all had >90% reduction in light chain values. One patient, in CR post-ASCT, had a kidney transplant with good graft function at 10 months. Median projected overall survival was 7.5 years. Adverse prognostic features were heart or liver involvement and poor response to chemotherapy. *Conclusions.* LCDD patients are younger, with more kappa light chain involvement, hypertension and haematuria than patients with renal AL amyloidosis. Prolonged stabilisation or even improvement of renal disease can be seen when clonal disease is suppressed. An international registry would help determine optimal treatment and the role of renal transplantation.

1439

EFFICACY OF THALIDOMIDE-BASED AND BORTEZOMIB-BASED REGIMENS IN THE FIRST RELAPSE OF 146 MULTIPLE MYELOMA PATIENTS: A SINGLE CENTRE EXPERIENCE

M Krejci, Z Adam, A Krivanova, L Pour, L Zahradova, J Mayer, J Vorlicek, R Hajek

University Hospital Brno, Brno, Czech Republic

Background. The introduction of novel agents, such as immunomodulatory drugs and proteasome inhibitors, has substantially changed the treatment paradigm of multiple myeloma (MM). *Aims.* In this report, we describe the outcome of a cohort of 146 patients (pts) with the first relapse of MM treated with thalidomide-based and bortezomib-based regimens with aims to compare the efficacy of these therapies. *Methods.* Eighty-two percent of pts (119/146) had stage III according to DS, 17% (26/146) II and 1% (1/146) I, clinical stages according to ISS were the following: stage 1 in 44% of pts (64/142), stage 2 in 31% of pts (44/142) and stage 3 in 24% of pts (34/142). Renal insufficiency was presented in 14% of pts (19/146). Median age was 63 years (range: 33-84). Thalidomide-based (T) regimens were used in 99 pts; thalidomide + alkylating agent + dexamethasone: 86 cases (86%), thalidomide + dexamethasone: 5 cases (5%), alone thalidomide: 8 cases (8%). The daily dose of thalidomide was 100-200 mg. Bortezomib-based (B) regimens were used in 47 pts; bortezomib + alkylating agent + dexamethasone: 20 cases (42%), bortezomib+alkylating agent: 21 cases (45%), alone bortezomib: 6 cases (13%). Bortezomib was used in standard dose 1.3 mg/m^2 intravenously on days 1, 4, 8, 15. The cycle was repeated on day 21-28 for up to 8 cycles or until progression. Median of T and B treament cycles was 5, range 1-8. No statistically significant differences were observed between the T and B groups in baseline clinical parameters including age, clinical stages according to ISS and DS staging systems, the type of M-protein and presence of renal impairment. The first-line therapy was comparable for both T and B groups and it is not include novel agents. *Results.* In T group, overall response rate (ORR) was 56% (52/93), 12% of pts (11/93) achieved the complete response (CR), 20% of pts (19/93) were in very good partial response (VGPR), 24% of pts (22/93) in partial response (PR), 6% of pts (6/93) had minimal response (MR) or stable disease (SD) and 38% of pts (35/93) had progression of disease. Median time to progression (TTP) from the start of relapse treatment was 15.1 months, median overall survival (OS) was 30.5 months. In B group, ORR was 45% (17/38), 5% of pts (2/38) were in CR, 16% of pts (6/38) were in VGPR, 24% of pts (9/38) in PR, 18% of pts (7/38) had MR or SD and 37% of pts (14/38) had progression of disease. Median TTP from start of relapse treatment was 14.5 months, median OS was 34.4 months. *Conclusion.* The thalidomide-based and bortezomib-based regimens are effective in treatment of the first relapse MM with ORR 45-56%. Medians of TTP and OS are similar for both treatment groups, combination of novel agent with other drugs (dexamethason and/or alkylating agent) seems to be very useful. However, the significance part of patients (37-38%) had progression on this treatment and other treatment strategies are needed.

1440

ANALYSIS OF HEAVY/LIGHT CHAINS PROVIDES A RAPID, SENSITIVE AND ACCURATE ALTERNATIVE TO SERUM PROTEIN ELECTROPHORESIS AND IMMUNOFIXATION FOR PARAPROTEIN DETECTION AND QUANTIFICATION

H Ludwig,[1] L Mirbahai,[2] N Zojer,[3] A Bradwell,[4] S Harding[2]

Wilhelminenspital, Vienna, Austria; [2]The Binding Site Group Ltd, Birmingham, UK; [3]Wilhelminenspital, Vienna, Austria; [4]The Department of Immunology, Medical School, University of Birmingham, Birmingham, UK

Introduction. Detection and quantification of monoclonal serum proteins by traditional serum protein electrophoresis (SPE) can be difficult and requires skilful interpretation. This is particularly true for IgA monoclonal proteins whose migration on the gel can often be obscured by co-migrating proteins. Immunofixation (IFE) can alleviate some of these issues, however it is non quantitative and can be time consuming. Serum free light chain (FLC) analysis can be useful, although international guidelines recommended a concentration of greater than 100mg/L for patient monitoring. Novel nephelometric assays have now been produced which quantify IgAκ and IgAλ in serum. Quantification of these proteins enables the calculation of an IgAκ / IgAλ (HLC) ratio which has been reported to have a greater sensitivity than IFE. Here we report the evaluation of these reagents in monitoring a cohort of IgA patients through the course of their disease and compare their utility to SPE, IFE and FLC measurements. *Materials and Methods.* Sequential samples from 53 IgA (29 IgAk / 24IgAl)

multiple myeloma patients were analysed (mean number of patient samples= 4, range 1-12). SPE and IFE were performed using SEBIA Hydrasys according to manufacturer's instruction. FLC and heavy/light chain analysis was performed on a Siemens Dade Behring BN™II analyser. *Results/Discussion.* 29/53 patients had presentation samples available; in 29/29 cases an abnormal HLC ratio correctly identified the monoclonal protein, matching IFE *Results.* In 14/53 patients the monoclonal protein was obscured by other proteins and accurate quantification was not possible; the HLC ratio could be used to monitor the patients through the course of their disease in all cases. In an additional 10/53 patients HLC ratios identified monoclonal disease which was below the sensitivity of SPE in 5/10 patients HLC identified monoclonal proteins below the sensitivity of IFE. 23/53 patients had FLC levels greater than 100 mg/L. In 3/23 patients the HLC ratio remained abnormal after the FLC ratio had normalised, conversely in 4/23 patients the FLC ratio remained abnormal after the HLC ratio had normalised. In 16/23 patients both assays had similar sensitivities. At relapse 5/53 patients the HLC ratios became abnormal before any other test, in 3/5 cases the abnormal ratio correctly identified early disease progression (75-282d). In 2/5 patients the disease progression occurred >1000d after the ratio had become abnormal. *Conclusions.* Abnormal HLC ratios correctly identified monoclonal proteins at presentation. Furthermore, HLC ratios quantified monoclonal proteins, even when they were obscured by other proteins on SPE. It is necessary to use both FLC and HLC in patient monitoring. Further work is needed to clarify what constitutes disease progression using the HLC ratios.

1441

THE EFFICACY OF BORTEZOMIB AND BORTEZOMIB-CONTAINING REGIMENS FOR TREATMENT OF RELAPSED/REFRACTORY MULTIPLE MYELOMA IN REAL CLINICAL PRACTICE

T Mitina, A Golenkov, E Kataeva, T Lutskaya, E Trifonova, E Klinushkina

The M. F. Vladimirsky Moscow Regional Research Clinical Institute, Moscow, Russian Federation

Background. Bortezomib is currently considered as the standard of care for patients with relapsed/refractory multiple myeloma (R/R MM). However, there are few reports of outcomes with bortezomib treatment in regular clinical practice. *Aim.* To assess the efficacy of bortezomib alone and in combination regimens for treatment of patients with R/R MM at the Moscow Regional Research Clinical Institute. *Methods.* The study involved 101 patients with R/R MM (48 male and 53 female) aged from 34 to 77 years (average, 54 years). The average pretreatment time was 22.1 months and the average number of previous treatment cycles was 8.2 (MP; M-2; VAD). The study included 51 patients (50.4%) who had other pathologies: chronic renal failure and dependence upon hemodialysis, intraspinal plasmacytoma, lower extremity paresis, refractory anemia, or leukemic myeloma. Patients were randomized into four groups (V1-V4) to receive a bortezomib-containing regimen with reduced intensity of induction treatment: V1, (n=27) bortezomib-1.3 mg/m^2 on days 1, 4, 8 and11 of 31-d cycle; V2, (n=22) bortezomib-1.3 mg/m^2 on days 1, 4, 8 and 11; melphalan 20 mg/m^2 orally on the 2nd day of 56-d cycle; V3, (n=20) bortezomib-1.3 mg/m^2 on days 1, 4, 8 and 11; melphalan 9 mg/m^2 orally on days 1-4; prednisone 60 mg/m^2 on days 1-4 of 56-d cycle; V4, (n=32) bortezomib-1.3 mg/m^2 on days 1, 4, 8 and 11; melphalan 9 mg/m^2 orally on days 1-4; cyclophosphan i.v. 250 mg/m^2 on days 1-7; prednisone 60 mg/m^2 orally on days 1-4 of 60-d cycle. Treatment efficacy was assessed using the European Bone Marrow Transplantation (EBMT) criteria: time to progression; overall response rate (ORR=CR+nCR+PR); and overall survival (OS). *Results.* Patients received an average of 6.5 induction cycles. The following results were obtained: V1, ORR = 70.3% (CR 18.5%; nCR 14.8%; PR 37%); V2, ORR = 67.4% (CR 9.0%; nCR 13.0%; PR 45.4%); V3, ORR = 90.0% (CR 10.0%; nCR 0%; PR 80.0%); and V4, ORR = 62.3% (CR 21.8%; nCR 21.8%; PR 18.7%). There was no significant difference in OS between the four regimens. Since bortezomib was used in all four regimens, treatment efficacy was also assessed for the whole group of 101 patients. An objective response was obtained in 71.1% (CR 15.8%; nCR 13.8%). Progression was observed in 7.9% of patients within 6 months, and in 20.7% of patients within 20 months. Median OS estimated with the Kaplan-Meier method was 8.6 years (n=101). No cases of myelotoxicity grade III/IV were registered. Grade III polyneuropathy was observed in two patients. *Conclusions.* This study showed high efficacy and acceptable toxicity for bortezomib-containing reduced intensity regimens when used in a daily clinical practice for patients with R/R MM, including those who had been heavily pretreated or who had complicated comorbidities.

CLINICAL CHARACTERISTICS OF BICLONAL GAMMOPATHIES REVIEW OF 101 CASES

A Piccioni,[1] L Annino,[2] A Andriani,[3] V Bongarzoni,[4] V De Stefano,[5] F Gentilini,[6] G La Verde,[7] S Leonetti Crescenzi,[1] M Petrucci,[6] F Pisani,[8] F Saltarelli,[7] A Scardocci,[1] N Villivà,[3] T Za,[5] A Bagnato[1]

[1]Sandro Pertini Hospital, Rome, Italy; [2]Hematology S Giovanni Hospital, Rome, Italy; [3]Hematology Nuovo Regina Margherita, Rome, Italy; [4]S Giovanni Hospital, Rome, Italy; [5]Hematology Catholic University Gemelli Hospital, Rome, Italy; [6]Hematology La Sapienza University, Rome, Italy; [7]Hematology S Andrea Hospital, Rome, Italy; [8]Hematology IFO, Rome, Italy

Introduction. Biclonal Gammopathy of Undetermined Significance (BGUS) is characterized by the simultaneous appearance of two narrow peaks, suggesting the existence of two monoclonal antibodies. The incidence is about 1% of all monoclonal gammopathies. The pathogenesis of BGUS is unknown, but several possibly related environmental factors have been identified. The type of monoclonal component (MC), level of uninvolved immunoglobulins (UI), Bence Jones proteinuria, light chains isotype, erytrosedimentation rate (ESR), percentage of bone marrow plasma cells are prognostic factors mentioned in the literature for the monoclonal gammopathies in defining the risk of malignant transformation. This study was performed in order to evaluate the baseline characteristics of a BGUS population and to determine the role of the same prognostic factors for the biclonal gammopathies's progression to myeloma. *Patients and Methods.* We performed a retrospective study of 101 consecutive patients observed between 1999 and 2009. Males were 53 (52 %) and females were 48 (48 %). Patients were divided in three groups of age: younger than 50 years (5 %, median 46y, range 38-49y), between 50-70 years (42 %, median 65y, range 53-70y) and older than 70 years (53 %, median 79y, range 71-92y). Clinical and laboratory features was selected for primitive BGUS so lymphoproliferative disorders, infections and solid tumors were excluded. Patients' characteristics baseline are shown in Table 1.

Table 1.BGUS patients' beseline characteristics (n=101).

Variable		N. (%)	Variable				N. (%)		
Gender	M / F	48(48) / 53(52)	Type of light chains			k/λ	50 (49)		
Age (y)	<50	5 (5)				k/k	33 (33)		
	50-70	42 (42)				λ/ λ	18 (18)		
	>70	54 (53)	Bence Jones	negative	positive	NE	84(83)	13(13)	4(4)
Isotype	IgG/IgA	38 (38)	[UI] (mg/dL)	normal	reduced	NE	41(41)	26(26)	34(33)
	IgG/IgM	28 (27)	PC (%)	≤ 5	>5	NE	22(22)	17(17)	62(61)
	IgG/IgG	17 (17)	Albumin (g/dL)	≥ 3.5	<3.5	NE	91(90)	10(10)	0

	IgM/IgM	8 (8)	ESR (mm/h)	≤ 15	> 15	NE	34(33)	46(46)	21(21)
	IgA/IgA	2 (2)	UI = uninvolved immunoglobulins; PC = plasmacells in bone marrow; ESR = erytrosedimentation rate NE= no evaluated						
	IgM/k free	2 (2)							

The median follow-up in no developed no complicated BGUS was 47 months (range 1-210). Two patients was excluded for the cancer appearance after a 24 and 29 months follow-up (lung and prostate respectively).Three patients (3 %) progressed to myeloma and their characteristics are shown in Table 2. The median follow-up was 252 months. *Conclusions.* Although the clinical features of biclonal gammopathies are similar to those of monoclonal gammopathy, this subject is of importance because of the lack of clinical data in the literature. Three progressed BGUS aren't many for conclusions so further a long term studies are ongoing to examine the natural history of BGUS using a prospective approach and a larger patients' cohort to identify variables associated with the progression, the rate of progression, the progression free survival, the overall survival and the type of myeloma evolution (monoclonal or biclonal myeloma).

Table 2. MM patients' characteristics (n=3).

Variable		N. (%)	Variable				N. (%)

CLINICAL VALUE OF ABSOLUTE LYMPHOCYTE COUNTS BEFORE BORTEZOMIB-DEXAMETHASONE THERAPY IN RELAPSED MULTIPLE MYELOMA PATIENTS

MK Song,[1] JS Chung,[1] HJ Shin,[1] YM Seol,[1] YJ Choi,[1] GJ Cho,[1] SG Kim,[1] SH Kim,[2] GW Lee,[3] HS Lee,[4] SM Lee[5]

[1]Pusan National University Hospital, Busan, South-Korea; [2]Dong-A Medical center, Busan, South-Korea; [3]Gyeongsang National University Hospital, Jinju, South-Korea; [4]Kosin University Gospel Hospital, Busan, South-Korea; [5]Inje University Busan Paik Hospital, Busan, South-Korea

Background. High absolute lymphocyte count (ALC) at diagnosis is known as a surrogate marker of host-immunity with favorable prognosis in newly diagnosed Multiple myeloma. Bortezomib is an effective proteasome inhibitor in relapsed multiple myeloma (MM). Recent studies have shown tumor sensitization and enhanced cytotoxicity of bortezomib. *Aims.* To evaluate whether high ALC before bortezomib treatment would contribute to tumor sensitization and activated cytotoxicity of bortezomib in relapsed MM. *Methods.* Ninety-seven relapsed MM patients who were treated with bortezomib-dexamethasone (Vel-Dex) therapy were analyzed in the present study. Median follow up duration was 21 months and median age was 61 years. *Results.* Complete response (CR) and very good partial response (VGPR) after 2 cycles of Vel-Dex therapy were higher in the high ALC group (≥ 1.1×10^9/L) than in the low ALC group (CR+VGPR, 50.0 % in the high ALC group *vs.* 10.4 % in the low ALC group, P=0.001), and stable (SD) was lower in the high ALC group than in the low ALC group (SD, 11.8 % in the high ALC group *vs.* 44.8 % in the low ALC group, P<0.001). In univarate analysis, the low ALC group before therapy was associated with shorter PFS (HR, 2.780; 95% CI, 1.703-4.536, P<0.001). Multivariate analysis revealed that the low ALC group before therapy represented an independent predictive factor for PFS (HR, 1.937, 95%CI, 1.168-3.212, P=0.010). *Conclusion.* Low ALC just before Vel-Dex therapy was associated with poor prognosis for the patient with relapsed MM.

LONG SURVIVAL RELATED VARIABLES IN A COHORT OF 391 PATIENTS WITH MULTIPLE MYELOMA

J Alonso, A Cánovas

Hospital de Cruces, Baracaldo (Vizcaya), Spain

Background. It is known that a low rate of patients with Multiple Myeloma (MM) reach a long survival, not conditioned to a specific type of therapy.The factors related to it can vary depending on the environment for recruitment of the patients. *Aims.* To asses in a series of unselected patients with symptomatic MM treated with chemotherapy(CHT), the existence of initial variables related to long survival, together with the impact of response rate at 3 and 12 months of starting treatment. *Methods.* Retrospective study of the MM patients cohort treated in our Unit (1980-January to 2008-Mars). Length of observation time(OT): since the start of chemotherapy until death or 2010-January. Assessed groups: patients with more than 10 years survival or diyng before that interval. Diagnostic and response criteria according to Chronic Leukemia-Myeloma Task Force. Staging by Durie-Salmon and ISS.Delivered CHT was variable, depending on periods(MP; VMCP-VCAP/VBAP; M2 ; VAD).ASCT was performed since 1994. Thalidomide, bortezomib or lenalidomide had been recently incorporated as salvage. Initial clinical and analytical variables were compared between both groups; and moreover the rate of at least partial response at three months and progression earlier than 12 months. *Statistical methods.* Chi-square, Fisher exact test, Student t and Cox binary logistic regression meodel. *Results.* 327 of 391 patients were included in the study by exclusion of asymptomatic and treated patients with less than 10 years of survival. Median age: 68 (31-93) years.Gender(M/F): 170/157. Types of monoclonal component(MC)(%): G (46); A (31); light chain and other(23). Median serum MC: 3.6 g / dl (0,3-10); urinary MC present in 60%. Durie-Salmon staging (%): I (13), II (23), III (64); A/B: 75/25. ISS (154 patients)(%): 1 (21), 2 (40) 3 (39). Median β-2 microglobulin(B2M): 4 mg / L (0,8-70). Median bone marrow plasmocytosis(BMP): 40% (3-100). 23 patients (7%) survived 10 or more years with median OT of 12 years (10-24). The remainder of patients died with median survival of 1.6 years (0.02-9.6). ASCT were performed in 44 patients (double in 12), 9 of them in the long survival group (double in 4). In the long survival group it was significantly more frequent: good performance, favorable ISS and DS A stage; on the other side, age, BMP, calcemia and serum MC were significantly lower; on the contrary hemoglobin and serum albumin were higher.We did not find significant difference in the proportion of patients with three months at least partial response, but progression at 12 months was lower in the long survival group (P:0.0015). However, in multivariate analysis the only significant variables were younger age (P:0.0008), lower serum MC (P:0.03) and BMP (P=0.01) in long survival group.Conclusion. Survival over 10 years in our symptomatic MM is significantly associated with younger age, and lower plasmacytosis and serum CM. These results can be interpreted as the consequence of tumor burden (BMP and serum MC) and the better tolerance and available treatments in younger patients.

1445

THALIDOMIDE AND LOVASTATIN AS A SALVAGE IMMUNOMODULATORY THERAPY IN PATIENTS WITH RELAPSED MULTIPLE MYELOMA

M Hus,[1] M Adamczyk-Cioch,[2] D Jawniak,[2] N Grzasko,[2] M Morawska,[2] J Kozicka,[2] M Szostek,[3] G Helbig[4]

[1]Medical University of Lublin, Lublin, Poland; [2]Deparment of Haematology and Bone Marrow Transplantation Medical University, Lublin, Poland; [3]Department of Haematology Collegium Medicum Jagiellonian University, Cracow, Poland, [4]Silesian Medical University, Katowice, Poland

Background. Lovastatin (LOV) and other inhibitors of HMG-CoA reductase, the rate-limiting enzyme of the mevalonate pathway, have been demonstrated to exhibit antineoplasmatic and proapoptotic properties in numerous *in vitro* studies involving myeloma cell lines including our own experiments. *Aims.* The aim of the study was to assess the influence of lovastatin addition on the treatment effects in patients with relapsed and refractory MM. *Methods.* We have treated 49 patients with TAL+DEX (TD) regimen and 42 patients with TAL+LOV+DEX (TLD) regimen. Patients received drugs orally in 28-day cycles. TAL was given from day 1 to day 28 each cycle of dose 100 mg daily. DEX was administered at dose of 20 mg daily in days 1-4 of each cycle. LOV was administered at a dose of 2 mg /kg in days 1-5 and 8-12 and at a dose of 0.5 mg/kg in days 15-28 of each cycle. Patients characteristics before treatment were as follows: the median age 59.3 years in TLD and 62.4 years in TD . All of them were ISS 2. 61% of patients IGG, 26% IGA, 7% light chain and 6% others. 76% were light chain kappa and 24% lambda. Median serum M protein level was 4.2 g/dL, bone marrow plasma cells 47%. *Results.* A clinical response, defined as a reduction of M-protein by 50% or more, was observed in 32 % of patients in TD group and 44 % in TLD group. CR and NCR were observed in TD 5% and 11% TLD respectively. In 47.9% TLD and 14.6% TD patients successful stem cell harvest was performed and mean amount of collected $CD34^+$ cells was 6.76×10^6 in TD and 8.26×10^6 in TLD. Successful autologous transplantation was performed in 3 patients of TD and 11 TLD. Overall survival (OS) in TLD group (median 53 months) was significantly longer than TD group (39 months). Similarly event free survival (EFS) was longer in TLD (median 27 months) than in TD group (23 months). We observed significant negative correlation between response and bone marrow infiltration (P<0.005). Short time to reduction of M-protein by 50% was connected with better response. Common side effects such as somnolence, fatigue and constipation were observed in about 18 patients in TLD and TD group. In 2 TLD and 1 TD patients we diagnosed deep vein thrombosis. In 5 five TLD patients moderate hypertransaminazemia was observed. No TLD treated patients were observed with the rise of myoglobine and troponine in the control blood examinations. In 2 TLD patients sinus bradykardia was observed. *Summary/Conclusions.* Our results suggest that addition of LOV to TAL and DEX improves the response rate as well as OS and EFS in patients with relapsed or refractory MM. Moreover it is possible to harvest stem cells and perform autologous stem cell graft in patients with relapsed or refractory MM treated with such regimen. The addition of lovastatin during the salvage therapy in the relapsed or refractory form of MM seems to be a very efficient and nontoxic.

1446

COMPARISON OF HUMORAL IMMUNE STATUS IN ELDERLY PATIENTS WITH MULTIPLE MYELOMA, WALDENSTROM'S MACROGLOBULINEMIA AND MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE

J Karlsson,[1] B Andréasson,[2] N Kondori,[3] H Hogevik,[4] C Wennerås[5]

[1]Dept of Infectious Diseases, NU Hospital Organization, Trollhättan/Uddevalla, Sweden; [2]Dept of Hematology/Internal Medicine, NU Hospital Organization, Trollhättan/Uddevalla, Sweden; [3]Dept of Clinical Bacteriology, Sahlgrenska University Hospital, Göteborg, Sweden; [4]MD, PhD, NU Hospital Organization, Trollhättan/Uddevalla, Sweden; [5]Dept of Hematology and Coagulation, Sahlgrenska University Hospital, Göteborg, Sweden

Background. It is well known that patients with multiple myeloma (MM) have impaired humoral immunity, but the immune status of patients with Waldenstrom's macroglobulinemia (WM) and monoclonal gammopathy of undetermined significance (MGUS) has been less studied. *Aim.* The aim of this study was to compare humoral immunity to various common pathogens in elderly patients with these B-cell disorders. *Methods.* Seventy-nine persons ≥ 60 years of age were studied, with a diagnosis of MM (n=25), WM (n=16), MGUS (n=18) and healthy controls (n=20). Patients who had undergone stem cell transplantation were excluded. Serum samples were analyzed for antibodies to in total 26 bacterial, viral, fungal and protozoan pathogens. *Results.* A stepwise pattern of antibody levels was seen for staphylococci, pneumococci, tetanus and diphtheria with the lowest titres observed in the MM group followed by, in increasing order, WM, MGUS and healthy controls (P<0.001 for MM *vs.* controls). Whereas 65% of healthy controls were immune to tetanus, a mere 8% of MM patients had protective antibody levels despite previous immunization being reported by 56% to 83% of all study subjects. Long-term immunity to diphtheria was absent in all studied subjects (n=79) including healthy controls although 35% reported previous immunization. As to viral pathogens, a stepwise antibody pattern was seen for measles, mumps, rubella, and was most pronounced for varicella (P<0.0001 for MM *vs.* controls), with the lowest antibody titres seen among MM patients. Analyses of antibodies to the other Herpes viruses (HSV-1, HSV-2, CMV, EBV and HHV-6) on the other hand, revealed no differences between the study groups, and except for HSV-2, high levels of protection were seen. Antibody titres to Candida albicans, Aspergillus fumigatus and Toxoplasma gondii were particularly depressed in the MM group. The analysis of IgG antibodies to Borrelia burgdorferi revealed a strikingly high prevalence with 21 (27%) of the study persons defined as seropositive and no differences seen between the study groups. *Summary.* In conclusion, the multiple myeloma patients displayed by far the most suppressed humoral immunity among the patient groups studied. However, depressed humoral immunity against many infectious agents was also seen in patients with Waldenstrom's macroglobulinemia and monoclonal gammopathy of undetermined significance as compared to healthy controls. The most obvious immune impairment was found towards Staphylococcus aureus, pneumococci and varicella, while seroprotection to other Herpes viruses seemed to be retained in patients with these B-cell disorders.

1447

BIGGER IS NOT BETTER IN PBSC MOBILIZATION WITH CYCLOPHOSPHAMIDE FOR AUTOLOGOUS STEM CELL TRANSPLANT IN MYELOMA: A RETROSPECTIVE SINGLE-CENTRE AUDIT OF 1.5G/M² VS 3G/M² CYCLOPHOSPHAMIDE WITH G-CSF

G Loudon,[1] R Soutar,[1] A Clark,[1] K Douglas[2]

[1]Beatson West of Scotland Cancer Centre, Glasgow, UK; [2]Scottish National Blood Transfusion Service, Glasgow, UK

Background. High dose chemotherapy followed by autologous stem cell transplant in first CR is the standard of care for myeloma patients fit enough to undergo the procedure. However, mobilization methods vary with no generally accepted consensus. Cyclophosphamide with G-CSF is the most frequent mobilization chemotherapy in the West of Scotland: however, dose administered varies between 1.5 and 3 g/m² dependent on preference of referring physician. Only one previous relevant comparative study has been published (Hiwase *et al.,* Cytotherapy 9:539-547,2007), which suggested better mobilization efficacy with 3-4 g/m² cyclophosphamide compared with 1-2 g/m². However, due to a local impression of increased toxicity with 3 g/m² of cyclophosphamide without much difference in mobilization efficacy, we felt that a single-centre audit of our own experience would be useful. *Aims.* To compare mobilization failure rate and total CD34 dose collected following cyclophosphamide 1.5 g/m² *vs.* 3 g/m² both with G-CSF 5mcg/kg. *Methods.* All myeloma patients referred to BWOSCC clinical apheresis unit for collection of autologous stem cell collection over the period January 2007 to November 2009 were assessed. 83 patients received cyclophosphamide and G-CSF. Dose of stem cells collected, number of apheresis procedures per mobilization episode, and failure to achieve a good enough peripheral CD34 count to undergo apheresis were recorded. The Chi-Square and Mann-Whitney U statistical tests were used to determine significance. *Results.* See Table. There was a significant increase in complete mobilization failure (failure to undergo any apheresis) in the 3g/m² group. There was no significant difference between number of procedures required to collect stem cells in either group. The number of patients achieving a total dose sufficient for 2 transplants was similar in each group and there was no significant difference in the number of patients unable to collect enough stem cells for at least one transplant in either group. There were 5 patients in each group who developed neutropenic fever requiring admission and antibiotics, which was associated with subsequent failed PBSC mobilization in 4 of the 3 g/m² patients and 1 of the 1.5 g/m² patients. Neutropenic fever appeared more severe and prolonged in the 3 g/m² group, and we believe this to be the likely cause of the significantly higher rate of complete mobilization failure in this group. *Conclusion.* Contrary to the findings of Hiwase *et al.,* we found cyclophosphamide 1.5 g/m² with G-CSF as effective as 3g/m² in mobilizing enough cells for tandem transplant, and a significantly higher rate of complete mobilization failure in the 3g/m² group, associated with more severe toxicity in the form of neutropenic fever. In view of these results, we now recommend 1.5g/m² as the standard dose for our myeloma patients, particularly given the availability of non-chemotherapeutic stem cell mobilizing agents such as plerixafor for patients failing initial chemotherapy-based mobilization.

Table.

	3g/m2	1.5g/m2	
No of Patients	30	53	
Failed Mobilization	5	1	P<0.02
Median no. Procedures (Range)	2 (1-3)	2 (1-3)	
CD34 dose >6 (%)	18 (60)	34 (64)	
CD34 dose <2 (%)	4 (13.3)	4 (7.5)	
CD34 dose 2-6 (%)	3 (10)	13 (24.5)	
Neutropenic Fever (No of failures)	5 (4)	5 (1)

HIGH-DOSE OR INTERMEDIATE-DOSE CYCLOPHOSPHAMIDE PLUS GRANULOCYTE COLONY-STIMULATING FACTOR FOR PROGENITOR CELL MOBILIZATION IN PATIENTS WITH MULTIPLE MYELOMA

O Pokrovskaya, L Mendeleeva, E Urnova, I Alekseeva, E Gribanova, E Gretsov, A Panteleev, V Savchenko

Research Center for Hematology, Moscow, Russian Federation

Autologous PBSC transplantation is the standard care for patients with multiple myeloma (MM). Cyclophosphamide (CY) combined with granulocyte colony-stimulating factor (G-CSF) is commonly used to mobilize blood progenitor cells to support high-dose therapy in patients with MM. The optimal dose of CY in this setting is unknown. *Methods.* We have analyzed mobilization efficiency and need for supportive care in 81 patients (pts) with newly diagnosed myeloma previously treated with VAD or bortezomib-containing courses. The patients were mobilized either with high-dose CY (HD-CY, 6 g/m²) (n=61) or intermediate-dose CY (ID-CY, 4 g/m²) (n=20) plus G-CSF 5 mcg/kg/day. *Results.* Both regimens proved to be effective in the progenitor cell mobilization. In the HD-CY group, 30,5 (1,1-10⁶)×10⁶ CD34⁺ cells/kg, and in the ID-CY group 17,6 (2,5-22,7)×10⁶ CD34⁺ cells/kg (P=0,0001), were collected. At least 2×10⁶ CD34⁺ cells/kg were collected from 90,2% and 85% of the patients with a first apheresis respectively. Patients who are to have tandem autologous PBSC transplants require at least 4×10⁶ CD34⁺ cells/kg. This was achieved in 96,7% pts in the HD-CY group and in 95% pts in the ID-CY group. Only two pts in the HD-CY group (3,3%) failed to mobilize *vs.* none in the ID-CY group. The highest yield of peripheral

blood CD34+ cell was reached in the HD-CY group. The median number of aphereses performed in each group was 2 (range 1-6). The first day post CY infusion of first leukapheresis was between day 12 and day 20 (median day 15 in HD-CY group and 14,5 in ID-CY group). Pts mobilized with ID-CY plus G-CSF had less toxicity: lower frequency of febrile episodes (35 *vs.* 49,3%) and less need for supportive care including parenteral antibiotics (35 *vs.* 49,3%), platelet transfusions (25 *vs.* 59%, P=0,01). Also, nausea and vomiting were less frequent and less severe in patients receiving ID-CY. *Discussion.* While these regimens seem to be equally effective in terms to collect a total CD34+ cell number adequate for tandem autologous PBSC transplantation in newly diagnosed patients with MM, ID-CY+G-CSF is preferential because of more optimal resource utilization and more favorable toxicity profile.

SOLUBLE UROKINASE-TYPE PLASMINOGEN ACTIVATOR RECEPTOR (SUPAR) IN PATIENTS WITH MULTIPLE MYELOMA (MM). RELATIONSHIP TO AMYLOIDOSIS, RENAL FUNCTION AND CLINICAL COURSE

W Usnarska-Zubkiewicz,[1] J Holojda,[2] S Potoczek,[1] K Kuliczkowski[1]

[1]Wroclaw Medical University, Wroclaw, Poland; [2]District Specialist Hospital, Legnica, Poland

The urokinase-type plasminogen activator (uPA) system has been shown to be involved in tumour cell migration, angiogenesis and tissue remodeling. The expression of uPAR by malignant plasma cells and its soluble form (suPAR) may play a relevant role in plasma cells invasion, homing and clinical evolution. The study was undertaken to evaluate the serum concentration of suPAR in patients with MM in order to assess its relation to the amyloidosis, renal function and clinical course of the disease. We analyzed 70 patients treated in the Hematology Department of District Specialist Hospital of Legnica and Dept. of Haematology, Blood Neoplasms and Bone Marrow Transplantation, Wroc_aw Medical University, from 2007 to 2009. The group consisted of 40 females and 30 males aged 28-83 years (x=62,1), 37 (52,9%) recently diagnosed (group I) and 33 (47,7%) in the progression of the disease (group II), 6 pts of group I and 12 of the group II had amyloidosis. Renal failure developed in 15 pts. The control group comprised 10 healthy donors. Written informed consent was obtained. Blood samples (5 ml) for analysis were taken at diagnosis, or at the time of progression, the serum concentration of suPAR was determined by ELISA and expressed in pg/mL. Diagnosis of AL was based on finding in the biopsy of adipose tissue, deposits showing a typical green birefringence under polarized light. The serum concentration of suPAR in patients with MM ranged from 1450 to 22602, x= 3813, SD= 2949 and was significantly higher (P=0.0002) than in the control group: 1783-2732, x=2211, SD=345, the highest in 6 pts with LCD: 2399-22602, x=7453, SD=7659. In patients before chemotherapy suPAR concentration was insignificantly lower than those with progression of the disease: x=3567, SD=2027, and x=4577, SD= 4828, respectively. suPAR concentrations did not differ between patients with clinical stage I, II and III however patients with stage III revealed a tendency to higher suPAR concentration (P=0.06). In patients with renal failure suPAR concentration was significantly higher (P=0.01) than in patients with normal renal function, and were as follows: 1749-5922, x=4593, SD=2848 and 1449-22602, x=3600, SD=2965. In MM pts with amyloidosis, suPAR concentration was significantly higher than in group without this complicantion : 1449-22602 x= 5211, SD= 4784 and 1552 -11686, x=3328, SD=1170, P=0,0047. There were positive correlations between suPAR concentrations and number of plasma cells in bone marrow as well as serum free light chain and β-2-m concentrations and negative correlation between suPAR and albumin level (P=0,005). These results suggest that suPAR might provide additional information related to a more aggressive course disease and development of amyloidosis.

NORMAL SERUM FREE LIGHT CHAIN RATIO AT PRESENTATION IS MORE COMMON IN IGA- κ MULTIPLE MYELOMA: A SINGLE CENTRE OBSERVATIONAL STUDY

H Ahmed, S Simpson, A Roy

Basingstoke and North Hampshire NHS Foundation Trust, Basingstoke, UK

Background. Several studies have shown that baseline serum free light chain ratio (sFLCR) is an independent prognostic factor in patients with multiple myeloma and other plasma cell disorders. Baseline serum free light chain correlated with serum creatinine, lactate dehydrogenase, marrow infiltration by plasma cells and light chain type multiple myeloma in some studies. The relationship between baseline sFLCR at diagnosis and the different subtypes of multiple myeloma has not been reported to date. *Aims.* To analyse the baseline sFLCR in relation to the different subtypes of multiple myeloma and to assess the relationship between the baseline sFLCR and parameters of disease activity. *Methods.* All newly diagnosed multiple myeloma patients in our centre between June 2005 and January 2010 were included. The serum free light chain measurement was performed by immunonephelometry (Freelite assay; The Binding Site Ltd., Birmingham, UK). sFLCR was calculated as κ/λ (normal range 0.26-1.65). Clinical and laboratory parameters at the time of diagnosis were recorded. *Results.* 48 patients were included in this study. The male to female ratio was 1.4:1 with a median age of 73 years (range 45- 94 years). The majority of the patients (56%) had IgG multiple myeloma, 31% had IgA multiple myeloma and 13% were light chain only subtype. 44 patients had their sFLCR measured at diagnosis. All patients with IgG and light chain only multiple myeloma had an abnormal sFLCR at presentation. Interestingly 33% of IgA multiple myeloma patients in our study showed an absolutely normal sFLCR with a further 20% of patients showing only mild elevation in monoclonal light chain. Normal sFLCR correlated with negative Bence Jones proteinuria, heavy bone marrow infiltration (>45% plasma cell infiltration), and the ISS stage II - III. However, there was no observed relation of the baseline sFLCR to serum creatinine, calcium level or serum albumin. The median baseline sFLCR in IgA-κ group was 1.79 (range 0.5 - 310.6) in comparison to 31.34 (range 1.74 - 1791.75) in IgG-κ group. In contrast, IgA-λ and IgG-λ groups showed no difference in the median baseline sFLCR. *Conclusion.* Our study has shown, for the first time, that IgA-κ multiple myeloma patients commonly present with normal sFLCR. Our data suggests that sFLCR at presentation may be of less prognostic value in IgA-κ multiple myeloma subtype. This might also have an implication in the assessment of stringent complete response in this group of patients. Further analysis is required to assess the clinical course in this group of patients.

1451

BALANCING EFFICACY AND TOXICITY BY OBJECTIVE CHARACTERISTICS IN PATIENTS WITH MULTIPLE MYELOMA TREATED WITH NEW-DRUG COMBINATIONS

M Offidani,[1] L Corvatta,[2] S Gentili,[1] C Polloni,[1] P Galieni,[2] M Catarini,[2] F Alesiani,[2] M Brunori,[2] G Visani,[2] A Mele,[2] M Ferranti,[2] M Burattini,[2] P Fraticelli,[2] A Samori,[2] P Leoni[1]

[1]Clinica di Ematologia Azienda Ospedaliero Universitaria Ospedali Riuniti ANCONA, Ancona, Italy; [2]GEMaMM, Fabriano, Italy

Background. New-drug combinations have changed the outcome of Multiple Myeloma (MM) but their administration frequently induce severe complications leading possibly to early death and often prevent therapy continuation particularly in elderly patients. Therapy withdrawal with new-drug combinations (until 30-40%) and early mortality actually represent the major cause of unsatisfactory outcome in MM patients. In order to adapt treatment schedule, age, performance status and comorbidities are empirically considered. However, there is no objective methods to identify MM patients who will develop severe complications or will die because of induction therapy with novel-drug combinations. *Aim.* To assess the potential of objective factors in predicting complications in MM patients treated with new-drug combinations. *Methods.* Patient, disease and treatment related characteristics of the 29 patients who developed severe complications such as grade 3-4 infections, deep venous thrombosis (DVT), any other adverse event preventing therapy continuation or who died because of induction therapy were compared to those of 98 patients who did not. One hundred and twenty seven *de novo* MM patients enrolled in phase II and III prospective, controlled trials were included in this study. Patients were treated with thalidomide (83%), bortezomib (17%) or both (14%) in combination with steroids and chemotherapy. Median age was 71 years (range 45-71), 70% of patients were older than 65 years and 25% aged 75 years or above. Twenty eight percent of patients presented ECOG PS ≥2,21% IgA myeloma, 70% 2-3 ISS stage, 20% renal failure and 30% had at least one comorbidity. All patients received antibiotic and antithrombotic prophylaxis. *Results.* An event, such as above defined, occurred in 29 patients. Thirteen patients (10%) had an infection, 11 (8.5%) had DVT, 3 (2.5%) had infection and DVT, 3 (2.5%) died early and 7 (5.5%) discontinued therapy because of severe toxicity. Probability of severe complication was 23%. Univariate analysis selected age ≥75 years (P= 0.072), IgA myeloma (P= 0.021), monoclonal component >3 g/dL (P= 0.059), ISS stage (P= 0.088), β-2 microglobulin ≥3.5 mg/dL (P= 0.133), albumin <3.5 g/dL (P= 0.021), CRP > 3 mg/dL (P= 0.153) and platelets <130.000/μL (P=0.027) as predictive

factors of severe complications whereas PS, comorbidities, D-S staging, bone disease, renal failure, and therapy regimens were not predictive. Multivariate Cox regression analysis selected monoclonal component >3 g/dL plus platelets ≤130.000/μL (HR= 3.0; P= 0.004) and IgA myeloma (HR= 2.3; P= 0.032) as factors associated with an increased risk of severe complications. *Summary.* This retrospective study suggests that in MM patients disease characteristics, rather than those patient- or therapy-related should be taken in account to balance efficacy and toxicity when treatment with new-drug combinations is planned.

1452

PRECLINICAL AND PHASE I EVALUATION OF THE PHARMACOKINETICS, METABOLISM, SAFETY AND EFFICACY OF A 30-MINUTE INFUSION OF CARFILZOMIB

K Papadopoulos,[1] P Lee,[2] J Infante,[3] E Sausville,[4] M Gordon,[5] A Patnaik,[1] H Burris III,[3] D Mendelson,[5] A Wong,[6] Z Wang,[6] C Kirk,[6] M Bennett,[6] T Woo,[6] L Bui,[6] A Tolcher,[1] P Rosen[2]

[1]The START Center for Cancer Care, San Antonio, TX, USA; [2]Tower Cancer Research Foundation, Beverly Hills, CA, USA; [3]Sarah Cannon Research Institute, Nashville, TN, USA; [4]Greenebaum Cancer Center, Baltimore, MD, USA; [5]Premiere Oncology of Arizona, Scottsdale, AZ, USA; [6]Onyx Pharmaceuticals, Emeryville, CA, USA

Background. Carfilzomib (CFZ) is a novel, highly selective, irreversible tetrapeptide epoxyketone proteasome inhibitor. In Ph I-II trials single-agent bolus CFZ is active at 20-27 mg/ m^2 and well-tolerated in patients with relapsed and/or refractory (R/R) multiple myeloma (MM). *Aims.* Preclinical studies in Sprague-Dawley rats were conducted in order to characterize the pharmacokinetics (PK), pharmacodynamics (PD), and toxicity of CFZ administered as an intravenous (IV) bolus or 30 minute infusion. The effect of IV infusion of CFZ is also being evaluated in a Phase Ib/II study in patients with R/R MM to determine the maximum recommended dose, safety, efficacy, PK and PD. *Methods.* In rats, a dose of 8 mg/kg (48 mg/m^2) was administered as an IV bolus (~20 sec) or a 30 minute infusion. Plasma samples were taken for PK and whole blood and tissue (adrenal, heart, liver) samples were collected to determine the extent of proteasome inhibition. PK parameters were calculated using non-compartmental analysis and proteasome activity was measured using fluorogenic substrates. The Phase I trial is enrolling patients with R/R MM after ≥2 prior treatment failures or following induction and transplantation. CFZ is given as a 30 minute IV infusion on days (D) 1, 2, 8, 9, 15, and 16 of a 28-day cycle (C) until disease progression. Dosing in all cohorts is 20 mg/m^2 for C1 D1, D2 with subsequent escalation to 36, 45, or 56 mg/m^2. Responses by IURC are measured every C.

Table.

Best Response	Dose (mg/m^2)[a]	Prior Regimens	Time on Study (months)
VGPR	36	1	7+
PR	45	4	4.5+
MR	36	6	5
SD	36	1	5.4
	45	4	2.4+

[a] Patients received 20 mg/m^2 on C1, D1 and D2, with subsequent dose escalation to the dose specified.

Results. Despite a >10 fold decrease in maximum concentration, infusion of CFZ in rats resulted in equivalent levels of proteasome inhibition in blood and tissues (>80%), suggesting widespread tissue distribution. IV bolus administration of CFZ at 8 mg/kg resulted in 50% mortality and elevated blood urea nitrogen and creatinine levels in the surviving animals. Infusion of this dose did not cause mortality or significant changes in renal function. To date, 7 pts with R/R MM are enrolled in the Phase 1b infusion study; 4 remain active. Pts remain on study a median of 136 days (range 32-213). They received a median of 4.9 cycles of CFZ (range 1.1-7.6). Preliminary data show that CFZ is well-tolerated and has anti-tumor activity when administered as an infusion. Efficacy data are detailed in the Table. Common adverse events (AEs) with infusional CFZ included fatigue, headache, diarrhea, nausea, and constipation. There has been no worsening of baseline peripheral neuropathy, severe hematologic toxicities, or hepatotoxicity. Updated results will be presented. *Conclusions.* In rats, infusion of high dose CFZ is substantially better tolerated than IV bolus and resulted in similar levels of proteasome inhibition. In patients with R/R MM, single-agent CFZ as 30 minute IV infusion is both active and well-tolerated at doses ≥ 36 mg/m^2, with documented PRs achieved, early in the course of therapy. These data support ongoing evaluation of CFZ infusion in patients with MM, and dose escalation beyond 45 mg/m^2 has been initiated.

1453

CLINICAL CHARACTERISTICS AND PROGNOSTIC SIGNIFICANCE OF HEPATITIS VIRUS INFECTION IN PATIENTS WITH MULTIPLE MYELOMA AND ITS ASSOCIATION WITH CYTOGENETIC ABNORMALITIES

CJ Teng, YB Yu, HT Liu, CY Liu, YC Hong, LT Hsiao, JP Gau, JH Liu, TJ Chiou, PM Chen, CH Tzeng

Taipei Veterans General Hospital, Taipei, Taiwan

Background. Long-term steroid treatment may lead to reactivation of hepatitis virus infection and therefore probably affect the treatment outcome of patients with multiple myeloma. However, reports regarding the impact of hepatitis virus infection in myeloma are limited. *Aims.* We assessed the prevalence and prognostic significance of viral hepatitis in myeloma patients. *Methods.* From January 2003 to December 2008, patients with confirmed diagnosis of multiple myeloma at Taipei Veterans General Hospital were consecutively enrolled. Hepatitis virus infection was determined by serology tests for hepatitis B and C virus. Clinical characteristics were recorded via chart review, and univariate and multivariate analysis were performed to investigate the significance of relevant parameters. *Results.* Totally 222 patients were enrolled and 68.9% (153/222) of them had completed studies for hepatitis virus. The estimated prevalence of hepatitis B and C virus infection was 11.1% (n=17) and 9.3% (n=14) respectively. Median age at diagnosis was 69.0 years (range, 29-91) and median follow-up was 19.3 months (range, 0.2-83.9). The characteristics of patients with or without hepatitis virus infection were similar, but viral hepatitis carriers were strongly associated with the occurrence of cytogenetic abnormalities (P=0.005). Hepatic adverse events did not differ in 2 groups except that one patient with chronic hepatitis B died of fulminant hepatitis. Overall survival of patients with hepatitis virus infection was significantly worse than that of whom without the infection (42.4 *vs.* 16 months, P=0.023). In multivariate analysis, older age, cytogenetic abnormalities, and beta-2-microglobulin of more than 3.5 μg/mL at diagnosis were independently correlated with shorter overall survival. *Conclusions.* Hepatitis virus infection exerts a poor survival impact on patients with multiple myeloma, which might be resulted from the association with cytogenetic abnormalities. Further studies to elucidate the relationship between viral hepatitis and chromosomal abnormalities in myeloma appear to be warranted.

1454

AGGRESSIVE APPROACH WITH BORTEZOMIB AND CYCLOPHOSFAMIDE, FOLLOWED BY AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT) AND THALIDOMIDE CONSOLIDATION, IS FEASIBLE IN OLDER PATIENTS WITH MULTIPLE MYELOMA AND CAN ACHIEVE A MYELOMA-FREE HARVEST

I Attolico,[1] R Nuccorini,[1] G Discepoli,[2] A Fragasso,[3] D Vertone,[1] N Filardi,[1] M Pizzuti,[1] M Poggiaspalla,[1] A Amendola,[1] A Olivieri[1]

[1]Ospedale San Carlo, Potenza, Ital; [2]Ospedale G.Salesi, Laboratorio di Citogenetica e Genetica Molec, Ancona, Italy; [3]U.S. Ematologia, Ospedale Madonna delle Grazie, Matera, Italy

Background. Bortezomib (BOR) and Cyclophosphamide (CY) have been recently associated in young patients with Multiple Myeloma (MM), achieving a high response rate, with good safety profile; moreover this schedule does not affect PBSC collection. Recently BOR has also been combined with High Dose Melphalan (HD-MEL), without affecting the engraftment and the morbidity after ASCT; Thalidomide (Thal) is active and well tolerated as consolidation after chemotherapy or ASCT. *Aims.* We started a pilot study in high risk MM elderly patients, fit for ASCT, combining BOR, CY and dexamethasone (DEX) as induction and mobilizing therapy (CY-BOR), followed by ASCT with supplemented BOR-HD-MEL. The main end point was the depth of response (percentage of CR) after the whole program; secondary end points were: percentage of clearance of Minimal Residual Disease (MRD) assessed by flow cytometry, both in the harvest and *in vivo* (in bone marrow before and after ASCT and after thalidomide), safety, PFS and OS. *Methods.* Patients received four 3 weeks courses of BOR 1.3 mg/m^2 and DEX 40 mg/day i.v. (days 1,4,8,11) and CY i.v. 300 mg/m^2 (days 1,8,15). Patients achieving at least PR, were mobilized after BOR and DEX standard dose (days 1,4,8,11) with CY 3 g/m^2 (day 8); GCS-F was started at day 9. Patients collecting an adequate PBSC amount underwent ASCT with HD-MEL (day -1) combined with BOR (1.3

mg/m^2 on days -6, -3, +1, +4). Three months after ASCT, patients not in CR or in CR but with evidence of MRD (by flow cytometry), received thalidomide 100 mg/day until progression or unacceptable toxicity. *Results.* 26 patients (median age: 66, range 52-77) were enrolled: 22 were evaluable for response before PBSC harvest: 18 responded to induction therapy (82%), 2 achieving PR (9%), 10 VGPR (46%), 4 nCR (18%), 2 CR (9%); 4 patients had resistant disease (18%). 17/22 patients were mobilized: in 14 we collected PBSC (median 5.5; range 2.5-11.2×10^6 CD34$^+$ cells/kg) and performed ASCT. Conditioning was well tolerated and followed by quick and complete engraftment, without major toxicities. With a minimum follow-up of 100 days after ASCT, all pts are alive, maintaining or improving the response: 5 VGPR, 2 CR, 7 nCR; 9 of them started the consolidation with thalidomide and only one relapsed. With a median follow up of 400 days (range: 74-753) all 26 pts are alive. We did not observe thromboembolic events; 3 pts experienced grade 3 neurotoxicity, requiring reduction of dose of BOR. MRD evaluation, by flow cytometry analysis, shows complete clearance of clonal plasmacells in 73% of PBSC harvests and in 29% of patients evaluated, before and after ASCT. *Conclusions.* These preliminary data show that this aggressive approach in fit elderly patients with MM is feasible, allowing to achieve a rapid and deep response, with a clonal plasmacells free harvest in the majority of cases (73%). Whether this will also translate in an *in vivo* MRD clearance, evaluated by Quantitative Real Time PCR with patients' specific probes (which is still ongoing), it has to be confirmed by a longer follow up.

1455

BORTEZOMIB - MAINTENANCE POST AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT) IMPROVES REMISSION DURATION AND QUALITY OF RESPONSE IN ADULT (< 65 Y) MULTIPLE MYELOMA (MM) PATIENTS: AN UPDATE

V Bongarzoni,[1] R Greco,[2] B Anaclerico,[1] B Ronci,[1] S Fenu,[1] A Chierichini,[1] P Anticoli Borza,[1] S Angelini,[3] P Iacovino,[1] M Cedrone,[1] S Cortese,[1] R Bruno,[1] G Avvisati,[4] L Annino[1]

[1]Azienda Ospedaliera San Giovanni, Rome, Italy; [2]Ospedale Niguarda Ca' Granda, Milano, Italy; [3]Policlinico Torvergata, Rome, Italy; [4]Università Campus Biomedico, Rome, Italy

Background. ASCT is the standard approach in adult MM patients (pts), however post ASCT disease progression may occur. *Aims.* In December 2007 we activated a single center study to assess the impact of Bortezomib maintenance a) on time to progression (TTP) and time to next treatment (TNT) b) the feasibility and toxicity. *Methods.* Between October 2002 and July 2008, at our Unit, 25 newly diagnosed MM pts (median age 59.5y, range 38-67) underwent single (9), or tandem (16) ASCT. Of these, 13 pts autotransplanted (8 single and 5 tandem) not receiving any treatment post-ASCT, were considered as control group (CG), while the remaining 12 transplanted from December 2007 to September 2008, received Bortezomib maintenance. (BG). Maintenance schedule consisted of Bortezomib as single agent given at dosage 1.5 mg every 15 days until progression. Response was evaluated according to the International Myeloma Working Group criteria, minimal residual disease (MRD) was assessed every 3 months on bone marrow (BM) samples by 6-colour BDFACS CANTO II. Abnormal plasma cells were identified as CD38, CD138, CD19, CD20, CD45, CD56, CD117, CD28, CD200 positive with a sensitivity level ≤ 1×10^{-5} (<0.01). Peripheral neuropathy (PN) was monitored before maintenance start, then every 3 mo by neurophysiologic motor and sensory conducting tests.

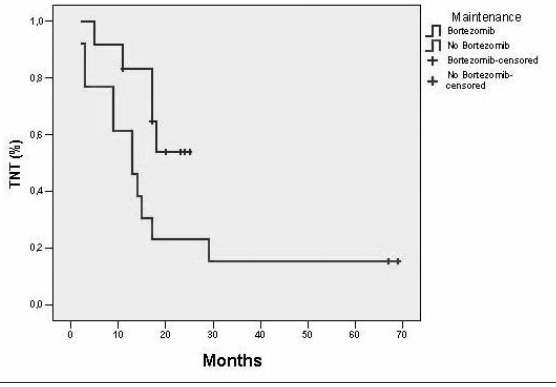

Figure. Time to next treatment.

Results. In the BG maintenance was started in a median time of 3.1 mo (range 1.7-13.7), post ASCT, 6 pts were in CR orVGPR, 4 PR, and 2 SD; the overall response rate was 83%, with 50% CR+VGPR. As of February 2010, after a median maintenance of 19.5 mo (range 4.1 -24), all 12 pts are alive. 6 (50%) in CR or VGPR (2 of these in sCR), 1 PR, 1 SD, 2 progressive disease and 2 pts who relapsed with an isolated extramedullary disease after 17 and 18 mos of maintenance, respectively. It is surprising that FISH analysis in 4/5 progressive-relapsed disease during maintenance had 13q- abnormality at diagnosis. Since not all pts underwent 2nd ASCT, TTP and TNT was evaluated from 1st ASCT. In the BG median TTP is 33 mo, whereas in the CG median TTP is 12 mo (P=0.01). Median TNT in BG has not yet been reached, whereas in the CG median TNT is 13 mo (P= 0.04). At median follow up of 40 mo (19-47) median OS has not yet been reached in BG, In CG at median follow up of 70 mo (31-96) median OS is 58 mo (P=0.023). Finally, none of pts in the BG experienced grade 3 or 4 haematologic toxicity and/or PN requiring dose reduction or drug discontinuation. *Summary and conclusions.* The preliminary results, even in a limited cohort of pts, suggest that Bortezomib as single agent in post-ASCT is active and safe to prolong TTP, TNT and able to improve response quality. However these preliminary results need to be confirmed by a longer follow-up and a randomized multicenter study.

1456

THALIDOMIDE DOES NOT AFFECT STEM CELL MOBILISATION IN PATIENTS WITH MULTIPLE MYELOMA

O Chowdhury,[1] J Smythe,[2] S Clarke,[2] R Aitchison,[3] E Wilson,[2] S Benjamin,[2] R Pawson[2]

[1]Oxford Radcliffe Trust, Oxford, UK; [2]NHS Blood and Transplant, Oxford, UK; [3]Wycombe Hospital, High Wycombe, UK

Background. Over the past decade, thalidomide-containing regimes such as Cyclophosphamide, Thalidomide and Dexamethasone (CTD) have become first line therapy for patients fit enough for autologous stem cell transplantation. It is therefore essential that thalidomide does not have a detrimental effect on mobilisation of peripheral blood stem cells (PBSCs). A recent retrospective analysis (Auner *et al.* ASH abstract 2147, 2009) comparing CTD to regimes not containing thalidomide suggested a lower yield of CD34$^+$ PBSCs and a higher rate of mobilisation failures in the CTD group. *Aims.* Our aim was to see if introducing thalidomide-containing regimes such as CTD as first line chemotherapy has had an impact on the success of mobilisation of PBSCs in myeloma patients at our institution. *Methods.* We retrospectively analysed data on 121 consecutive patients with multiple myeloma who underwent PBSC harvest between 2004 and 2009. 73 patients treated with CTD were compared to 48 control patients receiving regimes not containing thalidomide: VAD (Vincristine, Adriamycin and Dexamethasone; n=35), ZDEX (Idarubicin and Dexamethasone; n=.10) or Velcade/Dexamethasone (n=3). The majority of patients were primed with cyclophosphamide 1.5 g/m^2 and either 5 or 10 mcg/kg GCSF but four patients received ESHAP (Etoposide, Methylprednisolone, Cytarabine and Cisplatin)chemotherapy and two patients received GCSF alone. Apheresis was performed when the peripheral blood human progenitor cell (HPC) count on a Sysmex SE2100 haematology analyser was > 0.045/μl or a peripheral blood CD34 count was >8×10^3 mL. If neither of these targets were reached, the patient was not apheresed. The harvest target was 4 - 6×10^6 CD34$^+$ cells/kg with a minimum of 2×10^6 CD34 + cells/kg. We compared the yield of CD34$^+$ stem cells, the number of apheresis days and the rate of failed mobilisation (no collection or yield <2×10^6 CD34$^+$ cells/kg) in the CTD patients and the control group. *Results.* Patients had received between 3 and 8 courses of CTD (5.2±1.5) and between 4 and 8 (5.2±0.98) of regimes without thalidomide. There was no significant difference between the two groups in the number of patients who failed to mobilise sufficient PBSCs (CTD 8.2±28% *vs.* controls 10±31%, P=0.35). The yield of CD34$^+$ cells/kg in the CTD patients was similar to the control group (CTD 6.73±3.84 *vs.* control 6.94±3.80, P=0.68). The mean duration of apheresis in the CTD arm was 1.64 ±0.69 *vs.* 1.70±0.64 days in the control arm (P=0.67). *Conclusions.* These results suggest that the use of CTD at induction in patients with myeloma has no adverse effect on PBSC mobilisation and so does not impact on the ability to proceed to autologous stem cell transplantation. Differences between our findings and those of other groups may relate to priming regimes used or patient factors such as prior radiotherapy.

1457

CIRCULATING LEVELS OF VISFATIN AND HIGH MOLECULAR WEIGHT ADIPONECTIN IN MULTIPLE MYELOMA: A CASE-CONTROL STUDY

M Dalamaga,[1] K Karmaniolas,[2] M Triantafilli,[2] A Panagiotou,[3] E Papadavid,[3] G Sotiropoulos,[2] C Dimas,[3] A Lekka[2]

[1]Attikon University General Hospital, Agia Paraskevi-Athens, Greece; [2]NIMTS General Hospital, Athens, Greece; [3]Attikon General University Hospital, Athens, Greece

Background/Aim. Recent evidence suggests that obesity may be implicated in the etiology of multiple myeloma (MM). A novel hormone of the adipose tissue, visfatin (known as pre-B cell colony-enhancing factor) is a cytokine which is expressed in visceral fat exerting insulin mimicking effects and correlating with obesity. We thus attempted to explore whether altered secretion of the visfatin and high molecular weight (HMW) adiponectin, an adipokine linked with several obesity and insulin resistance associated malignancies including leukemia, may underlie this association. We have designed a case-control study to investigate the role of serum visfatin and HMW adiponectin in the etiopathogenesis of MM after adjusting for a potential confounding effect of age, gender, body mass index (BMI), and other adipokines. We also explored associations between visfatin and HMW adiponectin with prognostic factors of MM. *Methods.* Blood samples were collected from seventy three patients with incident, histologically confirmed MM and from an equal number of hospital controls admitted for non-neoplastic, non-infectious conditions and matched on gender, age (±5 years) and year/month of diagnosis (±1 month) between 2001 and 2009. Serum visfatin and HMW adiponectin concentrations were measured using ELISA (Phoenix Pharmaceuticals, Burlingame, CA, USA and ALPCO Diagnostics, Salem, USA respectively). MM prognostic parameters such as C-Reactive Protein (CRP), LDH, calcium, β-2 microglobulin (BMG) and erythrocyte sedimentation rate (ESR) were determined. Statistical analysis of the data was performed using univariate and multivariate analyses with SPSS version 17 for Windows. *Results.* Cases presented significantly higher body mass index (BMI) and elevated levels of serologic prognostic parameters of MM than controls. Cases had significantly lower serum levels of visfatin (mean±SD: 15.6 ng/mL±8.6) than controls (mean± SD: 28.7 ng/mL±15.9, P<0.001). Also, cases presented significantly lower serum levels of HMW adiponectin (mean±SD: 8.5 μg/mL±6.6) than controls (mean± SD: 14 μg/mL±9.6, P<0.001). Hypoadiponectinemia was associated with higher risk of MM after adjusting for age, gender, time at diagnosis, BMI and serum levels of other adipokines (P=0.002). Although, total and HMW adiponectin were both significantly inversely associated with MM when modeled either in quartiles or continuously, HMW didn't offer any substantial additional predictive value over total adiponectin (OR=0.92 *vs.* 0.91 for a 1 μg/mL change, respectively). Adjusting for the previous factors, lower levels of visfatin were found to be associated with significantly higher risk for MM (OR=0.89 and 95% Confidence Intervals: 0.85-0.94). No significantly different HMW adiponectin levels were found among different paraprotein classes and MM stages. In MM patients, serum visfatin was significantly positively associated with CRP, LDH, BMG, and ESR. Visfatin was significantly different among multiple myeloma stages with higher stages presenting higher visfatin levels (P<0.001). No significantly different visfatin levels were found among different paraprotein classes (P=0.65). *Conclusion.* HMW adiponectin may present a protective role in MM, whereas serum visfatin levels may be decreased via a compensatory response to the upregulation of other inflammatory parameters etiologically linked to MM such as IL-6. These observations need to be replicated and warrant further investigation.

1458

UNUSUAL EXTRAMEDULLARY PLASMACYTOMAS APPEARING DURING LONG-LASTING LENALIDOMIDE TREATMENT IN MULTIPLE MYELOMA: MUCH MORE THAN A CASUAL CLINICAL OBSERVATION?

JJ Gil-Fernandez,[1] H Guillen,[1] M Fernandez-Pacheco,[1] J Garcia-Suarez,[1] Y Martin,[2] M Callejas,[1] T Pascual,[1] E Magro,[1] MA Calero,[2] M Lopez-Rubio,[1] C Burgaleta[1]

[1]Hospital Universitario Principe de Asturias, Alcala de Henares, Madrid, Spain; [2]Hospital Universitario Príncipe de Asturias, Alcalá de Henares, Madrid, Spain

Background. The efficacy and safety of oral Lenalidomide plus High-Dose Dexamethasone (LD) in patients with relapsed-refractory MM was investigated in two Phase III large, randomized, multicenter, double-blind, placebo-controlled studies: the North American trial, MM-009 (n=354) and the European/Australian trial, MM-010 trial (n=351); [Dimopoulus *et al.*, Haematologica 2005; 80: 160]. As a result of MM-009 and MM-010 trials, LD reached an ORR of 61, 2- 58%, a CRR of 26, 5- 13,6% and a median TTP of 15 and 13,3 months, respectively. Recent publications has reported an increased risk of relapse as extramedullary plasmacytomas in MM treated with thalidomide containing regimens [E. Katodritoua *et al.*, Leukemia Research 2009; 33: 1137]. *Aims.* To review our recent clinical experience with the combination of LD in relapsing/ refractory MM and to describe the relapses after LD or the progressions during long-lasting continuous treatment with LD. *Patients and Methods.* We did a retrospective study from June 2007 to February 2010. We obtained efficacy and safety data by reviewing medical records from MM patients receiving treatment with LD and Data dispensing were collected from Landtools ® software.

Figure.

Results. We identified 19 consecutive patients MM treated with LD (12 males and 7 females with a median age at the beginning of LD of 60 (22-82) years. Patients received a median of 5 (1- 21) cycles of LD. The median daily dose of Lenalidomide was 15 (5- 25) milligrams. Up to 15 patients were evaluable for response; 12 of 15 achieved an Objective Response (80%). There were 7 of 12 responding patients who did not exhibit progressive disease (1 submitted to autologous transplantation, 3 submitted to allogeneic transplantation, 3 showed a sensitive relapse after autologous transplantation). The other 5 Lenalidomide-responding patients displayed progressive disease, showing extramedullary plasmacytomas without evidence of bone marrow disease progression, as follows: 4 patients during the course of Lenalidomide-treatment exhibited extramedullary disease (a giant right pelvic plasmacytoma of 9×5 cms, a right iliac bone plasmacytoma, a neuromeningeal plasmocellular infiltration and a right mandibular plasmacytoma associated to an area of mandibular osteonecrosis due to zolendronate), diagnosed after 12, 11, 3 and 9 cycles respectively; the remaining patient suffered from a brain mass located in the right cerebellar hemisphere 14 months after receiving treatment with 6 cycles of LD, he underwent a tumoral biopsy that disclosed an extramedullary neoplasia of highly prolifferative plasmoblastic cells and die in the immediate post-surgical period. *Conclusions.* We have observed an unexpectedly high incidence (41%) of extramedullary disease among MM patients with sensitive to Lenalidomide-therapy disease. Lenalidomide combinations might offer a good control of the disease in relapsing/ refractory MM, but physicians should be alert of extramedullary relapses ("escape phenomenon") which confer a poor prognosis in MM.

1459

CD56 EXPRESSION AND TREATMENT OUTCOME WITH BORTEZOMIB THERAPY IN PATIENTS WITH RELAPSED PLASMA CELL MYELOMA

O Ahmed,[1] C Lentaigne,[2] F Wright,[2] D McAleese,[2] F Dangwa,[2] A Wechalekar,[3] D Hughes,[4] A Mehta,[4] C McNamara[2]

[1]Royal Free Hospital, London, UK; [2]Dept. of Haematology, Royal Free Hospital, London, UK; [3]National Amyloidosis Centre, University College London Medical School, London, UK; [4]Dept. of Academic Haematology Royal Free Hospital and University College London, London, UK

Background. Approximately 67-79% of cases of plasma cell myeloma

aberrantly express CD56. It has been postulated that CD56 negative (CD56-) myeloma may develop from a less mature plasma cell and be associated with a worse outcome, though the evidence for this has been conflicting. Bortezomib is a peptide boronate inhibitor of the proteasome and is a highly effective therapy in relapsed and refractory myeloma. *in vitro* studies suggest that bortezomib therapy targets only $CD138^+CD56^+$ plasma cells.[1] *Aims.* We hypothesised that the presence or absence of CD56 may predict response to bortezomib therapy in the clinical setting in relapsed and refractory patients. *Methods.* We retrospectively analysed 25 patients (12 M: 13 F) with relapsed myeloma on whom diagnostic bone marrow immunophenotyping results were available. The median age of the cohort was 62 years (range 32-81). They had received a median of 2 previous lines of therapies, the most common being cyclophosphamide, dexamethasone and thalidomide (16/25). Four patients (4/25, 16%) has received a prior autograft. CD56 expression was assessed, prior to any therapy, by flow cytometry (FacsCantoII, Becton-Dickinson) utilising a CD138 live-gating strategy on bone marrow. A response to therapy was assessed according to published guidelines after 4 cycles of bortezomib. *Results.* Fifteen of 25 patients aberrantly expressed CD56. In the $CD56^+$ group, a partial response was seen in 11/15 (73%) patients. In the CD56- group, a partial response was seen in 4/10 (40%) of patients and a very good partial response in 1/10 (10%). Overall responses in the $CD56^+$ *vs.* $CD56^-$ group were 73% *vs.* 50% (Fisher's exact test, P=0.22). The median estimated survival in the $CD56^-$ group was 61 months; median survival was not reached in the $CD56^+$ group (log rank P=0.09). *Conclusion.* Though there appeared to be a trend towards higher responses in $CD56^+$ patients, who also appeared to have a trend towards better overall survival, however, given the relatively small sample size, neither reached statistical significance. These interesting observations suggest a need for further studies to assess the impact of CD56 status on patients treated with bortezomib, and these may elucidate whether CD56 expression could influence the decision of treating relapsed patients with bortezomib or other novel agents.

THE MAINTENANCE THERAPY WITH THALIDOMIDE IN ELDERLY PATIENTS WITH MULTIPLE MYELOMA

J Bila, D Lekovic, M Smiljanic, A Sretenovic, B Andjelic, A Vidovic, M Todorovic, I Elezovic, D Tomin, M Gotic, B Mihaljevic

Institute of Hematology, Belgrade, Serbia

Background. Current treatment approach to the newly diagnosed patients (pts) with multiple myeloma (MM) is based on two elements: age and risk factors. Main goals of treatment of elderly patients are prolongation of survival accompanied with maintenance of good performance and hospitalization independence. The aim of study was to analyse results of the thalidomide maintenance in elderly (>65yrs) MM pts. *Patients and methods.* The study included 80 newly diagnosed MM pts (45 male/35 female, mean age 68 yrs, range 66-83yrs). IgG myeloma was diagnosed in 47pts, IgA in 17pts, light chains in 15pts and non-secretory in 1pts. According to the clinical stage (CS, Durie-Salmon), patients were distributed as follows: II 37pts; III 43pts. Regarding ISS score, the group included: ISS1 23pts; ISS2 22pts; ISS3 35pts. Renal impairment was present in 15pts. The study included 3 arms of induction treatment according to the regimens: a) MP (30/80pts, 37,5%); b) MPT (35/80, 43,7%); and c) Thal-Dex (15/80, 18,7%). Maintenance therapy with Alfa-Interferon (aIFN) was applied in 30pts treated with MP chemotherapy. Thalidomide maintenance (100 mg/day) was applied in 50/80pts (62,5%) treated with MPT/Thal-Dex induction with median duration 16m (range 4-28m). Routine thromboprophylaxis was applied in all pts receiving thalidomide. *Results.* In the group of pts treated with MP, PR (IMWG criteria) was achieved in 12/30pts (40%). The overall response rate were significantly higher (P<0,001) in pts treated with MPT (CR/VGPR/PR: 27/35pts; 77,3%) and Thal-Dex (CR/VGPR/PR: 10/15pts; 66,7%). Median follow-up was 34 m (18-60 m). The 3-yrs probability of event-free and progression-free survival was significantly improved in the group treated with MPT/Thal-Dex induction and thalidomide maintenance (MP+aIFN: EFS 20%, PFS 25% *vs.* MPT+Thal: EFS 40%, PFS 54% *vs.* Thal-Dex +Thal: EFS 46%, PFS 50%, P< 0,003). Furthermore, according to the analysis of 3-yrs probability, pts treated with thalidomide maintenance had a significantly longer overall survival (MP+aIFN: 29% *vs.* MPT+Thal: 48% *vs.* Thal-Dex +Thal: 51%, P< 0,0025). The main reason for thalidomide discontinuation was peripheral neuropathy recorded in 37/50pts (74%) with occurrence of grade 3-4 toxicity in 6/37pts. Thrombosis was recorded in 4/50 treated with thalidomide maintenance. *Conclusion.* Application of the thalidomide maintenance resulted with improvement in the quality of response, its duration and overall survival of the elderly myeloma patients. Still, limitations of thalidomide maintenance mainly due to the toxic effects and possibility to induce more resistant relapse, indicates further studies of such therapy in terms of recommended duration and dosage.

SERUM FREE LIGHT CHAINS ASSAY IN DIAGNOSIS OF MONOCLONAL PLASMA CELL DISORDERS - SINGLE CENTER EXPERIENCE

M Dogaru, D Coriu, S Badelita, M Crisan

Fundeni Clinical Institute, Bucharest, Romania

Serum Free Light Chains are important markers for diagnosis and monitoring patients with monoclonal plasma cell disorders (PCDs). Automated immunoassay that measures serum free light chains (FLCs) has been recently introduced in our lab and this report present our experience. *Aims.* to evaluate the utility and efficiency of FLCs along with immunofixation electrophoresis (IFE) and serum protein electrophoresis (SPEP) in diagnosis of patients with monoclonal plasma cell disorders and for monitoring response to treatment. *Methods.* We analyzed samples from 182 patients with diagnosis or suspicious of PCDs. The FLC assay (FREELITETM; Binding Site) was performed on a Dade Behring, BN ProSpec automated nephelometer. The FLC κ/λ ratio was used to determine a positive or negative test and data was analyzed based on previously established normal ranges. A κ/λ ratio less than 0.26 (positive for λ FLC) or greater than 1.65 (positive for κ FLC) were considered positive. In the same time, for each patient were performed SPEP and IFE at the patient's initial presentation and during follow- up. *Results.* In this study we identified: 122 patients with intact immunoglobulin multiple myeloma (IIMM); 13 patients with light chain multiple myeloma(LCMM); 2 patients with nonsecretory multiple myeloma (NSMM); 2 patients with smoldering multiple myeloma (SMM); 8 patients with monoclonal gammopathies of undetermined significance (MGUS), 6 patients with solitary plasmocytoma(SP), 4 patients with lymphoplasmcytic lymphoma (LPL), 22 patients with primary systemic amyloidosis (AL), and 3 patients with Waldenstrom disease (WD). The monoclonal protein were similarly identified by FLCs assay, IFE and SPE in all patients with IIMM, SMM, MGUS, WD. For patients with LCMM classical IFE and SPE failed to demonstrate monoclonal protein in 11 cases. FLC assay help us to identified the monoclonal light chain in all of these cases. Among the 22 AL patients at the initial presentation 16 of them showed high levels of κ or λ light chains, but IFE were positive only for 8 patients. The serum FLC κ/ λ ratio was abnormal in 90.9% of patients with IIMM, 84.6% of patients with LCMM, 50% of patients with NSMM, 62.5% of patients with MGUS, 66.6% of patients with SP, 75% of patients with LPL, 100% of patients with WD and 72.7% of patients with AL. The most important fact of using FLC assay in our patients with PCDs is the clinical relevance of early FLC "response"after therapy or "relapse"in patients with measurable serum immunoglobulin free light chains, specifically in IIMM, AL and MGUS. *Conclusions.* The FLC assay is complementary to IFE and SPE in detecting the monoclonal protein in patients with PCDs, but, in addition, the sFLC assay has shown significant clinical application for monitoring response to therapy. FLCs assay has proven to be more sensitive than IFE in the diagnosis of patients with LCMM and AL.

THE IMPACT OF FRONTLINE TREATMENT ON SURVIVAL OUTCOMES IN MULTIPLE MYELOMA (RETROSPECTIVE STUDY)

I Ionita,[1] M Iordache,[1] CO Ionita,[1] D Calamar,[1] RG Cioaca,[1] M Ionita,[1] A Pascalau,[2] H Ionita[1]

[1]UMF Victor Babes, Timisoara, Romania; [2]County Clinical Hospital, Timisoara, Romania

Background. Multiple myeloma (MM) is a plasma cell malignancy characterized by an indolent clinical course with recurrent remission and relapses. The significance of attaining a complete remission (CR) rather than a partial response after frontline treatment, and its impact on overall survival (OS) remains controversial. *Aims.* We evaluate the effectiveness of the various frontline regimens used and whether best responses

to frontline therapy are good surrogates for OS. *Methods.* Previously untreated MM patients diagnosed from 2000-2007 with complete clinical data were included. Criteria for partial response (PR) required reduction of serum myeloma protein level by >50%, while a complete remission (CR) was defined by negative findings on immunofixation. OS curves were estimated by the Kaplan-Meier method. *Results.* 110 patients with complete treatment data were available for review. The median age was 62 years. 22 (20%), 31 (28.1%) and 47 (42.7%) patients presented with ISS stage I, II and III disease respectively. The induction therapy received was alkylating agents - 15 (13.7%), VAD based - 42 (40.9%), Melphalan Based - 23 (20.9%) and Bortezomib Based therapy - 27 (24.5 %) respectively. 33(30%) and 67 (60.9%) patients attained CR and PR respectively after frontline treatment. The median progression free survival was 2,8 years and independent of response status. Patients who attained CR however, had a significantly better median OS at 6,7 years compared to those who achieved PR at 4,3 years. No significant differences were observed in the response rate among the different frontline regimes, although bortezomib-based induction showed a trend towards more rapid reduction of M-band. *Conclusions.* Achievement of CR seems to confer a more favorable survival. Survival analysis is important for better understanding the contributions of treatment, particularly bortezomib and transplant, as well as other factors in these patients.

VALUE OF MAGNETIC RESONANCE (MR) AND POSITRON EMISSION TOMOGRAPHY (PET) FOR DIAGNOSIS AND FOLLOW UP OF BONE LESIONS IN MULTIPLE MYELOMA (MM)

MJ Moreno,[1] F De Arriba,[1] A Blanco,[1] JF Contreras,[2] M Martinez,[1] L Frutos,[2] C Castilla,[1] ML Amigo,[1] V Vicente[1]

[1]Hospital Morales Meseguer, Murcia, Spain; [2]Hospital Virgen Arrixaca, Murcia, Spain

Up to 90% of symtomatic MM patients develop osteolytic lesions during the course of the disease. The lesions rarely heal even when patients achieve complete remission (CR). Conventional radiography (X-rays), computed tomography (CT) and MR are all used to diagnose the extent of bone disease but they are limited for the follow-up of the disease. During last decade, PET-CT has proved to be useful for staging and monitoring response to treatment in solid tumours and lymphomas. Moreover, five MR imaging patterns of marrow involvement in MM have been described and they can be related with tumor burden. The aim of this study was to analyze the ability of PET-CT and MR to evaluate bone disease in MM at diagnosis and during the course of the disease. In addition to biological and clinical assessment, each patient underwent X-rays, spine and pelvis MR and PET-CT studies. We studied a total of 17 patients in different moments: 10 at the moment of diagnosis MM, and 11 when CR was reached (so 4 of them could be studied before and after treatment). From the group 10 patients studied at the moment of diagnosis of symtomatic MM: there was concordance between PET-CT and X-rays in 5 patients, and there was discordance in the other 5 patients (2 PET-CT positive but X-rays negative, 2 X-rays positive and PET-CT negative, and 1 patient positive in both studies, but affecting different regions). The marrow patterns by MR were abnormal in all the 10 patients. In five of the 10 patients a new evaluation was performed after achieving any treatment response (4 CR and 1 partial response); while the PET-CT scan was normal in all cases after the therapy, the pattern of marrow involvement by MR remained pathological. Finally, we studied another group of patients that were in CR (negative immunofixation) after treatment (n=11). Four cases showed a normal marrow pattern by MR and PET-CT was negative in 9 cases. Conclusion. The pattern of marrow involvement seen with MR in symptomatic MM patients, can return to normal in patients achieving CR; our study suggests that the normal pattern of medullar signal by MR would occur with some delay after reaching CR. PET-CT needs of other radiological techniques for the correct assessment of bone disease in patients with MM at the time of diagnosis, but is able to detect resolution of lesions when CR is obtein. Nevertheless, the value of PET-CT + in patients with complete response (IF-) needs further evaluation.

1464

PREDICTIVE VALUE FOR SURVIVAL OF POST-TRANSPLANT DAY+14 BONE MARROW PLASMA CELL PERCENT IN MULTIPLE MYELOMA PATIENTS WHO UNDERGONE SINGLE AUTOLOGOUS TRANSPLANTATION

MK Song, JS Chung, HJ Shin, YM Seol, YJ Choi, GJ Cho, SG Kim

Pusan National University Hospital, Busan, South-Korea

Backgrounds. Autologous stem cell transplantation (ASCT) has become the treatment of choice for eligible patients with multiple myeloma (MM).In recent studies, pre- and post-transplant response after ASCT were reported to predict the outcome in MM patients. *Aims.* We analyzed retrospectively the prognostic influence of post-transplant day+14 bone marrow plasma cell percent (BMPCp) and other pre-transplant characteristics on progression-free survival (PFS) and overall survival (OS) in 39 MM patients received ASCT between 2003 and 2008. *Methods.* All patients received induction chemotherapy with vincristine, adriamycin and dexamethasone (VAD) and ASCT after high dose melphalan alone conditioning therapy. We evaluated the influence of post-transplant day+14 BMPCp (≥2% *vs.* <2%), ISS stage (II *vs.* III), response after 3 cycle of VAD therapy (complete response (CR) *vs.* non-CR), deletion of chromosome 13q (del(13q)) (presence of the abnormality *vs.* absence) and BMPCp at diagnosis (≥50% *vs.* <50%) on PFS and OS. *Results.* Median follow-up duration was 28.0 months. International staging system (ISS) at diagnosis were stage II (n=25) and stage III (n=14). The type of M protein were IgG (n=23), IgA (n=12) and others (n=4). Median BMPCp at diagnosis was 43.0 % (range, 11-57%) and chromosomal abnormalities at conventional cytogenetic study were found in 15 patients. Deletion of chromosome 13 by FISH was found in 8 patients. After induction VAD therapy, 12 patients achieved complete response (CR). Infused mean CD 34^+ stem cell dose was 4.1×10^6/kg (range, $2.1\text{-}6.1\times10^6$/kg). Median BMPCp at post-transplant day+14 was 0.7% (ran! ge, 0-4.0%). Analysis of different cut-off levels between the 25% and 75% quartile (0.2-2.2%) using the log-rank test determined that BMPCP=2% as the cut-off point yielded the highest difference in PFS and OS, which was used as cut-off level in statistical analysis. Comparing to baseline characteristics between the two groups (BMPCp ≥2% *vs.* <2%). In univariate analysis, the five prognostic factors (post-transplant BMPCp, del(13q), CR after 3 cycles after VAD therapy, ISS fatge III and BMPCp at diagnosis) were significantly correlated with PFS and OS. Multivariate analysis revealed that post-transplant day+14 BMPCp ≥ 2% (PFS, HR=4.426, P=0.008; OS, HR=3.545, P=0.038) and CR after 3 cycle of VAD therapy (PFS, HR=0.072, P=0.014; OS, HR=0.055, P=0.015) were independent prognostic parameters on RFS and OS compared with other characteristics. *Conclusions.* It appears that post-transplant day+14 BMPCp would be an important and useful parameter predicting the outcome for the patients with MM received ASCT.

VASCULAR ENDOTHELIAL GROWTH FACTOR AS PROGNOSTIC FACTOR OF CLINICAL COURSE OF MULTIPLE MYELOMA

T Tsyapka, O Danysh, M Simonova, O Bojko, K Kotlyarchuk, N Serafyn, Z Maslyak

Institute of Blood Pathology and Transfusion Medicine of AMS of Ukraine, Lviv, Ukraine

Background. Despite generally low overall survival of patients with multiple myeloma (MM) certain group of patients live more than 10 years even being treated with conventional therapy. This fact can be explained by considerable prognostic heterogeneity of multiple myeloma. Introduction of the new highly effective therapeutic methods significantly improves treatment outcomes irrespective of prognostic factors. Therefore the issue of searching for the new and independent prognostic factors for multiple myeloma is currently important. *Aims and methods.* Serum levels of β-2 microglobulin and vascular endothelial growth factor (VEGF) were studied in 31 patients with MM during the course of treatment. Serum levels of VEGF and β-2 microglobulin were determined by immune-enzyme analysis using standard laboratory kits "Human VEGF"(BIOSOURCE, USA) and "β-2 microglobulin"(DAI, USA). According to the results obtained, all the patients were divided into 2 groups: group 1 - with lower (< 5,5 mg/L) and group 2 - with higher (>5,5 mg/L) levels of β-2 microglobulin. Patients of both groups were evaluated for treatment response, according to which each group was further subdivided into 2 subgroups - first one included non-responders (NR) and those who achieved any response (complete, partial or minimal response) were assigned to the second subgroup. Levels of β-2 microglobulin and VEGF were determined during the course of treatment. *Results.* In the first group of patients with low baseline values of β-2 microglobulin its level was 2,37 mg/L in 14 responding subjects and 1,64 mg/L in 6 non-responders. In the course of treatment this parameter tended to decrease irrespective of treatment efficacy. However, this decrease was much more significant in patients of the second subgroup who achieved response, whereas in non-responders the level of β-2 microglobulin was found to reduce only by half. As for VEGF, its baseline levels in patients of the first group were higher in responders compared to non-responding subjects and equaled 280,87 pg/mL and 205,80 pg/mL respectively. During the course of disease serum levels of this cytokine became almost normal in patients with the positive treatment results, at the same time non-responding patients were found to show increase of serum VEGF. The levels of VEGF at baseline in patients of the second group with high β-2 microglobulin values (high risk group) differed between the two subgroups depending on the treatment efficacy and were 196,70 pg/mL and 341,18 pg/mL in responding subgroup and non-responders respectively. After anti-myeloma therapy this parameter showed certain elevation in responders whereas in non-responding subgroup of patients, although decreasing, it remained two times higher than VEGF levels of healthy volunteers. This tendency may be considered as predicting factor of disease progression in this group of patients. Conclusion. The results of this study suggest that combined evaluation of serum levels of β-2 microglobulin and VEGF at baseline and at different time points during the anti-myeloma treatment may serve as prognostic criteria in patients with multiple myeloma.

1466

BENEFITS OF NOVEL AGENTS ON MOBILIZATION AND ENGRAFTMENT IN AUTOLOGOUS STEM CELL TRANSPLANTATION FOR MULTIPLE MYELOMA PATIENTS

M Bastos Oreiro,[1] M Canales,[2] A Lopez de la Guia,[2] K Humala,[2] M Gasior,[2] R Arrieta,[2] A Rodriguez de la Rua[2]

[1]Hospital la Paz, Madrid, Spain; [2]Hospital La Paz, Madrid, Spain

Background. The introduction of novel agents (NA), such as proteasome inhibitors and IMIDs, in recent years has improved the outcomes for multiple myeloma (MM) patients. Autologous stem cell transplantation (ASCT) is actually recommended as initial therapy in younger patients but there are contradictory data about influence of NA on mobilization as well as time of engraftment. *Aims.* To evaluate the influence of the NA on mobilization and time to the engraftment in consecutively treated MM patients who underwent ASCT in University Hospital La Paz, Madrid. *Methods.* We searched in our computerized database and reviewed the medical records of MM patients who underwent ASCT between 2003 and 2008 in our centre. Patients were divided in two groups: those who received NA as induction therapy and those who received conventional drugs (CD). Those patients who received lenalidomide as induction therapy were excluded for the analysis. Data were analyzed with the software SPSS 15.5 for Windows. *Results.* We have included 41 patients (18 men). Mean age was 59 y/o (r: 41-65) with the following type of MM: IgG / IgA / light chains / IgD / non-secretory: 20%, 13%, 6%, 1%, and 1% respectively. Induction regimen used was VAD in 10 patients, VBCMP/VBAD in 4, melphalan alone or melphalan + dexametasone in 5, cyclophosphamide + dexametasone in 6, bortezomib + dexametasone in 6, thalidomide, bortezomib, dexametasone in 6, and thalidomide + dexametasone in 4 patients. Twenty-three patients received autologous transplant as first line of treatment; 12 in 2nd line, 6 in 3rd line. Ten patients in 1st line received NA and 12 CD. Five patients in 2nd line received NA and 8 CD. Twelve patients required one apheresis (9 NA, 3 CD); 27, two apheresis (5 NA, 22 CD) and 2 patients needed three apheresis. In one patient treated with CD mobilization with cyclophosphamide was necessary. The median number of CD34×10^6/kg obtained was 5,3 (r: 3,5-6,3) for the NA group and 3,3 (r: 2,7- 4,9) for the CD group (p 0,036). The median of transfused red cells units was 2 (r: 0-3) in the NA group and 4 (r:2-6) in the CD group (P≤0,05). The median of platelets pool transfused was 2 (r: 2-4) and 6 (r: 3-7) respectively. The median of days with thrombocytopenia was 10 and 14 days and of neutropenia was 12 and 14.5 days in both groups respectively (P≤0.002). In the multivariable analysis, the NA had a direct effect over the reduction in the aplasia time post-transplant in 2 days (P:0.025, IC95%: 3.7-0.25) regardless the number of CD34 cells infused. *Conclusions.* In our series, the NA used for the MM induction treatment, excluding lenalidomide, are associated with an improvement in stem cell mobilization, as well as a reduction in the transfusion requirements and the engraftment after transplant.

POLYMORPHISMS OF DNA REPAIR GENES IN MULTIPLE MYELOMA; NO ASSOCIATION WITH XRCC1(399) POLYMORPHISM, BUT THE XRCC4 (VNTR IN INTRON 3 AND 1394) AND XPD (751) POLYMORPHISMS IN ASSOCIATION WITH THE DISEASE IN TURKISH PATIENTS

S Ciftci,[1] M Yilmaz,[2] M Pehlivan,[2] T Sever,[3] V Okan,[2] S Pehlivan[3]

[1]Gaziantep University, Medical School, Gaziantep, Turkey; [2]Gaziantep University Medical School Hematology Department, Gaziantep, Turkey; [3]Gaziantep University Medical School Deartment of Medical Biology and Genetics, Gaziantep, Turkey

Background. Genetic polymorphisms of DNA repair genes seem to determine the DNA repair capacity, which in turn may affect the risk of Multiple myeloma (MM). *Aim.* This study aims to investigate the association between the polymorphisms in DNA repair genes (XPD, XRCC1, XRCC4) and clinical parameters in patients with MM, their effects on prognosis and their roles in susceptibility to MM. *Methods.* Some 60 patients, diagnosed with MM in the Section of Hematology at the Department of Internal Medicine in the Faculty of Medicine at Gaziantep University, and some 70 individuals as the healthy control group were included in the study. DNA isolation was performed using 2 cc of blood sample in tubes with EDTA for the control group and using bone marrow smear preparations for the patient group. Gene polymorphisms were detected with the PCR and/or PCR-RFLP method. The obtained results were compared both among each other and with clinical parameters. *Results.*When the genotype frequencies of XPD (751) and XRCC1 (399) genes were examined in terms of patient and control groups, no significant difference was detected, while a significant association was detected in XRCC4 (VNTR in intron 3 and 1394) polymorphisms in terms of genotype frequency. In terms of XPD (751) gene polymorphism, a significant association was found in MM patient group in terms of AA genotype and event-free survival (EFS) (P=0.047). When XRCC4 VNTR intron 3 polymorphism was compared in terms of genotype frequency, DD genotype was determined to be significantly low (P=0.012) in the MM patient group, whereas GG and TT genotypes were detected to be significantly low in the patient group in terms of the genotype frequency of XRCC4 (1394) polymorphism when compared to the healthy control group (P=0.015, P=0.010, respectively). *Conclusions.* These data provide support for the hypothesis that common variation in the genes encoding XRCC4 DNA repair proteins contributes to susceptibility to myeloma. These findings require further validation in independent populations.

ASSOCIATION OF SERUM LEPTIN AND RESISTIN LEVELS WITH MULTIPLE MYELOMA RISK

M Dalamaga,[1] A Lekka,[2] M Triantafilli,[2] K Karmaniolas,[2] A Hsi,[3] E Papadavid,[4] A Panagiotou,[4] C Dimas,[4] C Mantzoros[3]

[1]Attikon University General Hospital, Agia Paraskevi-Athens, Greece; [2]NIMTS General Hospital, Athens, Greece; [3]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, USA; [4]Attikon General University Hospital, Athens, Greece

Background/Aim. The adipose tissue is currently considered an active endocrine organ participating in the modulation of insulin sensitivity and resistance, energy homeostasis, bone metabolism, inflammation, hematopoiesis, immunity and angiogenesis. Accumulating evidence supports a role for obesity in the etiology of multiple myeloma (MM). The distinct possibility exists that obesity may be linked to MM through altered adipokine secretion. Whether circulating leptin or leptin produced by bone marrow adipocytes and stromal cells, and its receptor OB-R may function as a growth factor/receptor-ligand system in malignant plasma cells acting in a paracrine fashion remains to be demonstrated. In this case-control study we investigated the role of serum leptin and resistin in the etiopathogenesis of MM and we explored their association with several established prognostic factors. *Methods.* Between 2001 and 2009, blood samples were collected from seventy three patients with incident, histologically confirmed MM and from an equal number of hospital controls admitted for non-neoplastic and non-infectious conditions and matched on gender, age (±5 years) and date of diagnosis with cases. Serum leptin and resistin concentrations were measured using ELISA (Avibion Human Elisa, Orgenium Laboratories, Helsinki, Finland and Phoenix Pharmaceuticals, Inc, Burlingame, CA 94010, USA, respectively). MM prognostic parameters such as C-Reactive Protein (CRP), LDH, calcium, β-2 microglobulin and erythrocyte sedimentation rate were determined. Statistical analysis of the data was performed using univariate and multivariate analyses with SPSS version 17 for Windows. *Results.* Patients had significantly higher height, weight and body mass index (BMI) as well as higher levels of serologic prognostic parameters of MM than control subjects. In univariate analysis, cases presented significantly lower serum levels of resistin (mean±standard deviation: 9.4 ng/mL±5) than controls (mean±standard deviation: 15.9 ng/mL±6.8, P<0.001). Also, patients presented significantly higher serum levels of leptin (mean±standard deviation: 27.5 ng/mL±17.6) than hospital controls (mean±standard deviation: 21.9 ng/mL±9.5, P=0.02). Adjusting for age, gender, date of diagnosis, BMI and serum levels of adipokines, higher levels of resistin were found to be associated with significantly lower risk for MM (P<0.001). In contrast to resistin, leptin showed no significant association with risk for multiple myeloma after adjustment with the previous variables (P=0.18). Amid cases, only leptin tended to be positively associated with CRP, LDH and calcium, and negatively with adiponectin. Furthermore, serum leptin was significantly different among multiple myeloma stages with higher stages presenting increased leptin levels (P=0.01). No significantly different leptin or resistin levels were found among different paraprotein classes. *Conclusion.* The results of our study don't provide support that leptin, a reflection of the degree of obesity, is independently associated with risk for multiple myeloma. The decreased resistin levels in MM patients could be associated with the upregulation of other adipokines or cytokines involved in MM. Further studies are needed to confirm these associations and to explore the mechanisms underlying leptin and resistin implications in MM and plasma cell dyscrasias.

1469

BORTEZOMIB TREATMENT AT HOME DOES NOT DECREASE EFFICACY, TOLERABILITY AND COMPLIANCE COMPARED WITH IN-HOSPITAL ADMINISTRATION

M Delforge,[1] G Bries,[2] R De Bock,[3] H De Samblanx,[4] J van Droogenbroeck,[5] G Kuijten-Celzo,[6] J Diels,[7] R Ganguly,[7] R Dhawan[7]

[1]UZ Leuven, Leuven, Belgium; [2]AZ Turnhout, Turnhout, Belgium; [3]ZNA Middelheim, Antwerp, Belgium; [4]AZ St.-Dimpna, Geel, Belgium; [5]AZ Sint-Jan Brugge, Brugge, Belgium; [6]Janssen-Cilag NV, Berchem, Belgium; [7]Johnson&Johnson, Beerse, Belgium

Background. In Belgium in 2008 the MyCare@home® project was started, making it possible to treat multiple myeloma (MM) patients receiving bortezomib at home. Patients generally receive the first cycle and the first injection of subsequent cycles at the hospital. Trained nurses provide the administration at home after assessing the patient's health status and possible adverse reactions and consulting with the hematologist. To date, the service has been used for 117 patients in 23 centers, with no major infusion related reactions reported. eVOBS is an observational study in 7 countries designed to assess bortezomib treatment in daily practice. Some of the MyCare® patients were enrolled in eVOBS, allowing for subgroup analysis. *Aim.* Primary objectives were efficacy and tolerability. Secondary objectives included treatment and dose schedule, use of co-medications, and (in Belgium), quality of life (QoL). Aim of this analysis is to describe these parameters in the homecare population, and compare with a matched group. *Methods.* Adults were eligible if treated with bortezomib within approved indication. All bortezomib dosages and co-medications were permitted, except investigational therapies. Due to the non-interventional nature of the study, no predefined response criteria were mandated; these could include M-protein, EBMT, SWOG, or other. All patients signed informed consent. QoL assessment was conducted using the EORTC QLQ-C30, administered at the start of each treatment cycle. For comparison of safety and efficacy results, the homecare patients were matched with 17 hospital treated patients for age, line of treatment, disease stage and presence of pre-existing neuropathy. Because very few patients in the matched group completed the QoL questionnaires, for QoL results only homecare patients were compared with all hospital patients (N=138). *Results.* 155 Belgian patients were enrolled in eVOBS, of whom 17 received treatment at home. Reasons for the physician to choose home care were: patient mobility and transport difficulties, patient comfort and overburdened day clinic. Table shows baseline parameters and efficacy *Results.* In the matched group AEs were most frequent reason for discontinuation of treatment (53% *vs.* 20% in home group). Most frequent AEs - presented as all grades (gr.3-4 if present), home *vs.* matched - were: new onset neuropathy 57% (14% gr.3) *vs.* 58% (33% gr.3), fatigue 12 *vs.* 47%, nausea 24 *vs.* 24%, thrombocytopenia 18 *vs.* 24% (6% gr.3-4). On all subscales of the EORTC QLQ-C30, home patients had scores similar or slightly better than the total hospital group. *Conclusion.* Although the number of patients is limited, these results suggest that bortezomib treatment at home, in a controlled setting, is of at least comparable efficacy and tolerability as a treatment completed in the hospital. Aside from the potential benefit to the patient, this could also result in reduced costs.

Table. Baseline parameters and efficacy results.

Baseline parameters/ results	Homecare patients (N=17)	Matched group (N=17)
Age (years)	69.4	70
Time since diagnosis (yrs)	3.5	1.5
≥3rd line therapy	30%	30%
Median cycles given	5	5
ORR/CR/nCR (%)	59/18/6	59/6/6
PFS (months)	10.7	7.1

SMALL BUT SIGNIFICANT OVERLAP IN SERUM FREE LIGHT CHAIN PARAMETERS IN INDIAN NON - MYELOMA AND MYELOMA SUBJECTS

R Kumar,[1] V Raina,[1] S Singh,[1] A Pandey,[1] A Chopra,[1] S Agarwal,[1] U Kumar,[1] M Irshad,[1] D Behera[2]

[1]All India Institute of Medical Sciences, New Delhi, New Delhi, India; [2]LRS Institute of Tuberculosis, New Delhi, India

Background. Serum free light chain (sFLC) analysis for detection and monitoring of monoclonal gammopathies has been validated by several studies but none from India. We undertook this study to determine if sFLC parameters could clearly distinguish between myeloma patients and non-myeloma subjects in India who might be expected to be having higher sFLC on account of greater incidence of sub-clinical infec-

tions. *Methods.* Serum samples from 135 healthy subjects, 50 patients with active pulmonary tuberculosis , 25 with autoimmune disorders, 25 cases of CRF(chronic renal failure) and 51 myeloma patients were analyzed using serum protein electrophoresis , immunofixation when indicated and estimation of sFLC , the latter using FREELITE reagent kit and Hitachi autoanalyzer. Parameters analyzed were κ and λ levels, κ/λ ratios. *Results.* Median age of healthy subjects (115 males, 20 females) was 39.5 years (range 19-58), tuberculosis patients (50 males) 48 years (range 21-75), patients with auto immune disorders (13 males, 12 females) 36.5 years (range 17-60 years), patients with CRF (20 males, 5 females) 50 years (range 19-85 years) and myeloma patients (37 males, 14 females) 55 years (range 27-79 years). Serum k levels ranged from 6.8 - 70.7 mg/L in healthy donors, 19. 6 - 65.0 mg/L in tuberculosis, 8.9 - 68.3 mg/L in autoimmune disorders, 11.7-77.7 mg/L in CRF and 5.9-5420.0 mg/L in myeloma patients. Serum λ levels ranged from 3.3-66.7 mg/L in healthy subjects, 14.9-93.5 mg/L in tuberculosis, 4.3-90.8 mg/L in autoimmune disorders patients, 14.9 - 125.3 in CRF and 5. 4 - 7,700.0 mg/L in myeloma. The κ/λ ratio was 0.6-3.0 in healthy donors, 0.5-2.9 in tuberculosis, 0.4-1.1 in autoimmune disorders, 0.6-6.9 in CRF and 0.002-669.1 in myeloma patients. Ten of the 51 (19.6%) myeloma patients had low κ/λ ratio that overlapped with the non-myeloma subjects,especially the CRF cases. *Conclusions.* Indian individuals not having myeloma have higher κ and λ values and also higher κ/λ ratio than reported, possibly because of greater incidence of subclinical infections, a conclusion supported by the findings in tuberculosis patients. As the higher values of κ/λ ratio in non-myeloma subjects overlap with a small but significant number of myeloma patients, the distinction between the two groups, especially in Indian subjects, must often require correlation of multiple parameters. Though the κ/λ ratio is reported to be very sensitive for myeloma detection, study of a larger cohort of patients and healthy Indian subjects is needed to validate our findings.

A MULTICENTER, OPEN LABEL STUDY OF VELCADE, MELPHALAN AND PREDNISONE IN RELAPSED/REFRACTORY MULTIPLE MYELOMA PATIENTS

MT Petrucci,[1] F Gentilini,[1] S Bringhen,[2] S Scotti,[1] A Levi,[1] A Siniscalchi,[3] A Larocca,[2] E Calabrese,[1] R Foà,[1] A Palumbo[2]

[1]Haematology, Sapienza University of Rome, Roma, Italy; [2]University of Turin Division of Hematology, Torino, Italy; [3]Hematology, S. Eugenio Hospital, Roma, Italy

Background. Velcade has shown significant anti-myeloma activity in clinical studies. In newly diagnosed elderly patients (pts) the addition of Velcade to the standard oral Melphalan and Prednisone (MP) significantly increases response rate and event free-survival compared to MP. In this multicenter open label phase I/II trial we assessed dosing, efficacy and safety of MP plus Velcade (MPV) as salvage treatment for multiple myeloma (MM) pts. *Patients and Methods.* In order to assess the maximum tolerated dose (MTD), 19 MM pts in relapse or refractory, after one or two lines of treatment, including high-dose chemotherapy with stem cell support, conventional chemotherapy, Thalidomide, Velcade and Melphalan-based regimens, entered the first phase of the study. They were treated with Melphalan 24 mg/28 days (2 mg on Monday, Wednesday and Friday every week), Velcade 1.3 mg/m^2 as a bolus intravenous (IV) injection on days 1, 8, 15, 22 and Prednisone at the dose of 50 mg every other day, for a total of 9 cycles. The MTD will be evaluated after the first 3 VMP cycles. The MTD dose was defined by two parameters: the number of responses (at least 5 partial responses: PR) and the number (<10) of pts presenting the following toxicities: grade 4 neutropenia >4 weeks or grade 4 hematological toxicity except neutropenia or any grade 3 non-hematological toxicity. At the end of the first phase, a further series of 23 pts was enrolled. All (total=42) pts received acyclovir as prophylaxis. *Results.* Between March 2008 and March 2009, 19 pts were treated and 12 (60%) achieved at least a PR; 7 presented the following toxicities: 3 pts grade 4 thrombocytopenia and 6 pts grade 3 non-hematological toxicity (4 infections, 1 peripheral edema and 1 diarrhea). Based on these results and according to the study design, between March 2009 and January 2010 23 further pts were treated with the same schedule. At the time of writing, 10 pts have completed the study and 19 are ongoing, while 13 have dropped out of the study (11 due to progression of disease, PD, 1 consent withdrawal and 1 SAE). 31/42 pts received at least 2 cycles and were considered for response. 17/31 (55%) obtained at least a PR: 6 pts reached a near complete remission (nCR), 1 achieved a very good partial response (VGPR), 10 showed a PR. In addition, 2 pts showed a minimal response, 1 stable disease and 11 PD. Toxicity was observed, more frequently during the early cycles, in 12/42 pts (28%) and it was manageable. Major grade 4 hematological toxicities consisted of thrombocytopenia (4 pts). Major grade 3-4 non-hematological toxicities were infections (5), diarrhea (2), neuropathy (1), hepatic toxicity (1), peripheral edema (1). *Conclusions.* The weekly infusion of Velcade + MP induced a high proportion of responses and was well tolerated in relapsed/refractory MM pts. An update of these data will be presented at the meeting.

PERIPHERAL NEUROPATHY CLINICAL COURSE DURING LENALIDOMIDE THERAPY FOR RELAPSED/REFRACTORY MULTIPLE MYELOMA: A SINGLE-CENTRE PROSPECTIVE NON INTERVENTIONAL STUDY

R Zambello, T Berno, C Dalla Torre, L Candiotto, M Lucchetta, M Campagnolo, L Trentin, C Briani, G Semenzato

Padua University School of Medicine, Padova, Italy

In recent years, proteasome inhibitors and immunomodulatory drugs (IMiDs) have provided invaluable advantage in the therapy of multiple myeloma (MM) in terms of disease free survival and, to some extent, overall survival. However the benefits have sometimes been blunted by the occurrence of adverse effects which strongly impact patients'quality of life. Among them, chemotherapy-induced peripheral neuropathy (CIPN) represents one of the most disabling and often dose-limiting side effect. Lenalidomide, a second generation IMiD and structural analogue of thalidomide, has been claimed to have low toxicity on peripheral nervous system. In a single-centre prospective study we evaluated the natural history of CIPN in consecutive patients previously treated with bortezomib and/or thalidomide, who shifted to lenalidomide for relapsed or refractory MM. The aim was to evaluate the clinical course of CIPN during lenalidomide therapy. *Patients and methods.* 34 consecutive patients previously treated with bortezomib and/or thalidomide were treated with lenalidomide (25 mg daily for 21 day cycle) alone or associated with low dose dexametasone for relapsed/refractory MM. Patients previously treated with bortezomib and/or thalidomide, who developed a CIPN and whose MM was still in remission, were included as control. Neurological evaluation was planned at baseline, after 6 and 12 months from the beginning of lenalidomide therapy. Patients were assessed with the Total Neuropathy Score clinical version (TNSc); pain was assessed with the Numeric Rating Scale (NRS) Nerve conduction studies were performed at the beginning of the treatment and regularly during follow up. Lack of chemotherapy-induced PN at baseline was not an exclusion criteria, as well as progression of myeloma during lenalidomide treatment. *Results.* Of the 34 patient in lenalidomide therapy, 19 (mean age 66 yrs + 8) were available for evaluation with at least six months follow up, 12 of whom at one year. Fifteen patients presented chemotherapy-induced PN at baseline, confirmed also by neurophysiological studies. Four patients had no CIPN at baseline (TNSc: 0) despite previous exposure to bortezomib in three cases, and bortezomib and thalidomide in one case. The majority of evaluable patients (75%) had a TNSc >2 at baseline (median = 6.5, SD ±3.4, range 3-15). At six months, haematological response was documented in 17/19 patients, whereas two patients were in disease progression; at one year all 12 patients showed haematological response. Neurological evaluation revealed improvement (7 patients) or stability (11 patients) of symptoms and TNSc after six months, that persisted unchanged in 11/12 patients at one year. The only patient whose TNSc had worsened at six months, improved to baseline value after 12 months. The improvement of symptoms was more evident in patients with the highest baseline TNSc. All patients with TNSc score 0 at baseline, remained unchanged after six months (3 cases) and 1 year (one case) of lenalidomide therapy. Electrophysiological findings not always paralleled clinical improvement. NRS and ECOG performance status did not change during lenalidomide therapy. *Conclusions.* Using validated clinical tools, the preliminary results of our prospective study suggest that lenalidomide therapy does not worsen and in selected cases may improve CIPN, regardless of MM response.

1473

ACTIVATED PROTEIN C RESISTANCE (APC-R) ANALYZED AS A CONTINUOUS VARIABLE IS DECREASE IN PATIENTS WITH MULTIPLE MYELOMA (MM) AND BENIGN MONOCLONAL GAMMOPATHIES (MGUS) COMPARED TO NORMAL INDIVIDUALS

M Zangari,[1] K Boucher,[1] F Zhan,[1] S Sana,[1] L Fink,[2] C Torres,[1] G Tricot[1]

[1]University of Utah, Salt Lake City, USA; [2]Nevada Cancer Institute, Las Vegas, USA

Background. Multiple myeloma (MM) patients have an increased risk

of venous thromboembolism (VTE), particularly when exposed to immunomodulatory drugs. Large epidemiological studies have recently showed that patients with MGUS also have an increased risk of VTE compared with normal subjects. Acquired activated protein C resistance (APC-R) is a significant independent risk factor for VTE in hematologic malignancies. *Methods.* We reviewed the records of patients with MM and MGUS for APC resistance by prefakit APC-R test. Patients with documented Factor V Leiden mutation were not included in this analysis. The Prefakit APC-R is a plasma-based functional clotting assay reported as a ratio of patient clotting time with and without APC which is standardized and reported as normalized ratio (normalized to results obtained on pooled normal plasma which is performed on each run). *Results.* APC-R results from 23 MGUS and 73 MM patients were compared with 39 normal subjects. The median APC-R for MM, MGUS and normal subjects were 0.99, 0.90 and 1.1 respectively. MM patients compared to normal subjects, had significantly lower APC-R (P=0.0007). MGUS also showed lower APCR when compared to normal subjects (0.0009). No significant difference was observed between and MM and MGUS (P=0.47) (Figure 1). Baseline characteristics from the three groups were similar in terms of age, sex, and performance status. *Conclusion.* APC-R measured as continuous variable shows a statistically significant decrement in patients with paraproteinemias compared to normal subject and correlates to the underline hypercoagulability observed in patients with MGUS and MM.

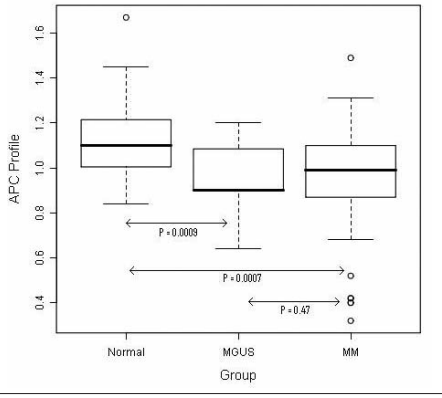

Figure.

1474

EFFICACY AND SAFETY OF LENALIDOMIDE IN PATIENTS WITH MULTIPLE MYELOMA COMPLICATED BY EXTRAMEDULLARY PLASMACYTOMAS

JM Calvo,[1] A Alegre,[2] R García-Sánchez,[3] MT Hernández,[4] P Giraldo,[5] M Zudaire,[6] B Gusmao,[7] JN Rodríguez,[8] C Calle,[9] G Ramírez,[3] B Íñigo,[10] J Martínez[1,1] A Oriol[12]

[1]Hospital Doctor Jose Molina Orosa, Arrecife de Lanzarote (Las Palmas), Spain; [2]Hospital Universitario La Princesa, Madrid, Spain; [3]Hospital Virgen de la Victoria, Málaga, Spain; [4]Hospital Universitario de Canarias, Tenerife, Spain; [5]Hospital Miguel Servet, Zaragoza, Spain; [6]Hospital de Navarra, Navarra, Spain; [7]Hosptial San Pedro, Logroño, Spain; [8]Hospital Juan Ramón Jiménez, Huelva, Spain; [9]Hospital General de Ciudad Real, Ciudad Real, Spain; [10]Hospital Clínico Universitario San Carlos, Madrid, Spain; [11]Hospital [12] de Octubre, Madrid, Spain; [12]Hospital Germans Trias i Pujol, Barcelona, Spain

Background. The role of lenalidomide for the treatment of multiple myeloma (MM) with extramedullary myeloma (EM) is still under investigation. *Aims.* This multicenter retrospective study evaluated the response rate and toxicity profile of lenalidomide-based regimens in myeloma patients with extramedullary involvement at relapse or progression. *Methods.* We reviewed the records of patients treated with lenalidomide-based regimens from October 2007 to February 2010 (n=17, median age 67 years; range 54-87; 8 women). The response of MM was evaluated according to international criteria and the response of EM was evaluated as size changes by physical examination, CT scan or MR imaging. Adverse events were graded with the WHO toxicity scale. The M-protein type was IgG in 9 cases, IgA in 6 and light chain in 2. The type of light chain was lambda in 10 patients and kappa in 7. In 9 patients soft-tissue plasmacytomas developed from underlying bone lesions in the skull (n=3), rib cage (n=4) and paravertebral sites (n=2). Two patients had subcutaneous nodules and 6 had visceral involvement in the liver (n=2), lung and kidney (n=1), periorbital tissue (n=1), cavum (n=1) and pleura (n=1). Multiple localizations were present in 6 patients (35.3%). The median number of prior chemotherapy regimens was 3 (range 1-8), including autologous stem cell transplantation in 3 patients, bortezomib-containing regimens in 16 (94.4%) and exposure to thalidomide in 1. Twelve patients received a standard lenalidomide dose (25 mg/day every 4 weeks) plus dexamethasone (40 mg/d p.o., 1 to 12 doses/cycle) every 3 weeks, and 5 received different schedules. Involved-field radiotherapy was given in 4 cases. 29.4% of patients required lenalidomide dose reduction because of toxicity or intolerance. *Results.* Median duration of lenalidomide treatment was 3.2 months (range 1-15). One case was not evaluable for response because of early death. MM responded to lenalidomide in 11 out of 16 evaluable patients (68.7%). Complete response occurred in 4 (25%) and partial response in 7 (43.7%). Median time to response was 46 days (range 19-363). Regarding EM, tumor size decreased in 11 patients and complete disappearance occurred in 8 (47%) of these. Response of EM was also achieved in 73.3% of patients previously exposed to bortezomib. Median follow-up was 121 days (range 30-474). Median overall survival from the start of lenalidomide therapy has not yet reached; at the time of writing 13 patients (76.4%) are alive and 10 are still on therapy. Only 1 of the 11 responding patients has relapsed. Toxicity profile (grade 3/4) was: thrombocytopenia, 5 (29.4%); anemia, 5 (29.4%); neutropenia, 5 (29.4%); neutropenic fever, 1 (5.8%); others, 3 (11.8%). No deep venous thrombosis was reported but thrombosis prophylaxis was used in most cases (94.1%). *Conclusions.* Results from one of the first studies to specifically evaluate the activity of lenalidomide in EM suggest that lenalidomide-based regimens may be a promising alternative in heavily treated MM patients with extramedullary disease. Further analyses and longer follow-up times are needed to determine the duration of response and the best regimen or combination.

1475

A RANDOMISED CONTROLLED TRIAL OF AN EDUCATIONAL BOOKLET FOR MULTIPLE MYELOMA PATIENTS WITH PERIPHERAL NEUROPATHY

H Clarke, R Gillibrand

University of the West of England, Bristol, UK

Background. As overall survival improves in multiple myeloma (MM) patients, quality of life and symptom management are becoming paramount. Peripheral neuropathy (PN) is a debilitating side effect of MM and its treatment but can be managed by monitoring symptoms and changing medication. *Aims.* Improve patient understanding and management of PN in MM patients using an educational booklet. *Methods.* MM patients diagnosed for at least 1-year were randomised (1:1:1) to three treatment groups; Group 1 (control) received no information on PN. Group 2 and 3 received an educational booklet designed specifically for this research project providing in-depth information on PN. Questionnaires were completed at 0, 4, 8 and 12-months to assess impact of educational booklet. Groups 1 and 2 completed the questionnaires themselves and group 3 had the questionnaire completed as part of a telephone interview. Due to a high drop rate, groups 2 and 3 were combined for the analysis. *Results.* 58 patients were enrolled (19 group 1, 39 group 2 and 3). 63% of patients were male, 67% aged >60years and 51% received ≥3 prior lines of therapy with 38-43% of patients on active treatment at any time point. Only 11% had a resolution of their PN over the course of the study but the percentage of patients discussing PN declined by 35%. At baseline, 35% of patients had nothing done to their MM treatment to manage their PN, this increased to 75% at 12-months. In addition, 46% were still not receiving any treatment recommendations to manage their PN symptoms. 46% of patients found it a lot more or somewhat more difficult to be optimistic or hopeful about their progress and survival when they have PN. The educational booklet was reported as good/very good by virtually all the patients, with at least 50% referring to it between 1-3 times at each time point. All patients reported the booklet as easy to understand and the most useful section was on the treatment of PN. 60% of patients think a booklet on PN should be available at diagnosis or at the beginning of their MM treatment with the majority (93%) of patients stating that it should be provided by their Dr or nurse. Over the course of the study, level of knowledge of PN as measured by the correct identification of symptoms associated with PN did not significantly increase. At 12-months, 7% believe that PN is reversible and a further 46% reported that the reversibility of PN depends on the MM treatment that caused the PN. Consequently, 46% of patients stated that PN is not reversible and once you have the symptoms that they will not disappear. *Summary/Conclusions.* Results show that MM patients have a relatively high level of knowledge of the symptoms but not the management of PN,

which was not impacted by the educational booklet. This study shows that PN is impacting on MM patients lives and it is not being managed effectively either through modification of the patients MM therapy or additional treatment recommendations.

1476

SECOND AUTOLOGOUS STEM CELL TRANSPLANTATION AS SALVAGE THERAPY IN RELAPSED MULTIPLE MYELOMA: EXPERIENCE FROM A SINGLE INSTITUTION COHORT OF 28 PATIENTS

F Ferrara,[1] M Celentano,[1] B Pocali,[2] F Pollio,[2] C Riccardi,[1] A Viola,[2] C Falco,[3] G Mele,[2] S Palmieri[1]

[1]Hematology and stem cell tranpslantation unit, Naples, Italy; [2]Hematology and Stem Cell Tranpslantation Unit, Naples, Italy; [3]Service of Transfusion Medicine, Cardarelli Hospital, Naples, Italy

Background. Double autologous stem cell transplantation (ASCT) is widely used as part of the multi-step first-line treatment in multiple myeloma (MM). On the contrary, few data are available as long as the potential utility of second ASCT as salvage for relapsed MM is concerned. *Aims.* To retrospectively investigate therapeutic results from a series of 28 patients in whom second ASCT was used as treatment for relapsed MM. *Methods.* Twenty-eight MM relapsed patients (M/F= 18/10), median age 55 years (range 37-70), received a second ASCT. All but 2 patients of this series were in first relapse. In 23 cases ASCT was performed after a previous salvage regimen (which depended on first line therapy and on the period of relapse, and included chemotherapy, radiotherapy, thalidomide or bortezomib based combinations in 10, 2, 6 and 5 cases, respectively), while 5 patients with a long duration of previous remission were given ASCT as upfront salvage therapy. Between the 23 patients salvaged before second ASCT, status at transplantation was complete remission (CR) in 10/23 cases, partial remission in 12/23, and no response in 1/23. Median duration of previous remission was 24 (3-57), median interval between the two transplants was 25 months (6-65). Median number of $CD34^+$ cells$\times10^6$/kg infused was 5,4 (2,5-23,65) and they had been collected in the mobilization for the first ASCT in 26/28 cases. Conditioning regimen was Melphalan 200, Melphalan 140, and BEAM in 9, 11, and 8 cases, respectively. *Results.* There was no transplant related mortality. All patients were given G-CSF in order to shorten the period of aplasia (one dose of peg-filgrastin in 15 cases, filgrastim for a median of 8 days in 13 cases). Median days to neutrophil $>0,5\times10^9$/L (all patients) and platelet $>20\times10^9$/L (19 patients) were 11 (8-18) and 12 (9-21), respectively. Six patient experienced FUO requiring intravenous antibiotic therapy for a median of 4 days, while there were no case of documented infections. Oral mucositis represented the only relevant extra-hematologic toxicity, requiring total parenteral nutrition in the 5 patients with WHO grade 3 stomatitis. After ASCT, a further improvement of therapeutic results was observed in 13 patients in partial remission (PR); more in detail, 5 patients achieved CR, while 8 ameliorated the degree of PR. In 2 patients a maintenance with thalidomide was started. With a median follow up of 25 months (6-81) after ASCT, 21 patients have progressed, median progression free survival (PFS) 15 months (Figure 1).

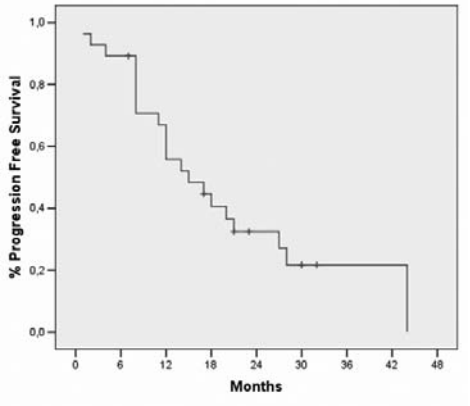

Figure 1.

At the time of writing, 13 patients are alive, while 15 patients died, all of progressive disease; the median overall survival (OS) from second ASCT is 32 months. Duration of previous PFS and interval between the two transplants more or less than 24 months were related to duration of second PFS (P=0.05 and 0.03, respectively). *Conclusions.* Second ASCT is an effective treatment in relapsed MM. Toxicity is similar to that observed when ASCT is executed as first line treatment. Best results are achieved in patients with a duration of previous remission longer than 2 years.

CONVENTIONAL RADIOGRAPHIC SKELETAL SURVEY VS WHOLE BODY MAGNETIC RESONANCE IN MULTIPLE MYELOMA PATIENTS. EXPERIENCE OF A SINGLE INSTITUTION

T Gimenez, E Abella, J Ares, A Solano, C Pedro, B Sanchez, J Tena, S Saumell, E Gimeno, C Besses

Hospital del Mar, Barcelona, Spain

Introduction. Conventional radiographic skeletal survey (SS) has been considered the gold standard test for detection of bone lytic lesions in Multiple Myeloma (MM). New imaging techniques as whole body magnetic resonance (WB-MR), have been introduced in the staging of MM because of increased sensivity and specificity of bone lesions. The new updated Durie/Salmon plus system uses MR imaging for a more accurate diagnosis and staging of MM patients. *Aim.* To compare SS and WB-MR images in patients diagnosed of MM in our single institution. *Materials and methods.* A descriptive and retrospective study was performed in 15 patients with MM diagnosed in different Durie/Salmon stages (stage I: 7 patients, stage II: 2 patients, stage III: 5 patients and 1 patient with plasmatic cells leukemia) in our institution from 2001 to 2009. 12/15 patients were chemotherapy-naive. SS and WB-MR were carried out simultaneously for every patient. *Results.* The SS and WB-MR were concomitantly positive for bone lesions in 8/15 patients and were normal in 3/15 patients. In 6 patients with pathological images, WB-MR detected more bone lesions than SS and in 2 patients, WB-MR showed medullary and extramedullary plasmacytomas that SS hadn't detected. In four patients, SS and WB-MR provided discordant results; WB-MR of 2 patients revealed myelomatous lesions in areas where SS was normal leading then to treatment because of stage's change. In the other two patients, WB-MR results indicated a non-myelomatous origin of observed SS lesions. *Conclusion.* Although SS still remains the gold standard imaging technique in the staging of MM patients, WB-MR adds useful new information for staging and treatment decisions. In our experience, 74% of results of both techniques were comparable but WB-MR was superior to SS for detecting more bone lytic and extramedullary lesions.

1478

BORTEZOMIB, MELPHALAN AND DEXAMETHASONE (VM-DEX) IS A SAFE AND EFFECTIVE THERAPY FOR NEWLY DIAGNOSED ELDERLY PATIENTS WITH MULTIPLE MYELOMA

A Gozzetti, M Defina, M Bocchia, A Fabbri, E Marchini, I Chitarrelli, F Lauria

University of Siena, Italy, Siena, Italy

Background. The VISTA trial showed great efficacy and superiority of VMP (bortezomib, melphalan and prednisone) *vs.* MP (melphalan, prednisone) in patients ineligible for high dose therapy. Since bortezomib (V) is usually administered with dexamethasone (Dex) in many combination treatments for myeloma, with additive efficacy, the rationale of combining V with Dex and melphalan (M) is immediate and it was tested in elderly MM patients at diagnosis. Although in the past M-Dex was compared with MP resulting in an unacceptable rate of extra-hematological toxicity (mainly pyogenic infections), the rate of complete responses was strikingly superior with M-Dex compared to MP (22% *vs.* 5%). Aim of this study was to test safety of VM-Dex by reducing Dex doses and related toxicity, nonetheless to investigate efficacy of VM-Dex based on this novel combination. *Patients and methods.* In this study 15 patients with a median age of 70 years have been treated with V at usual doses of 1,3mg/m^2 day 1,4,8,11,22,25,29,32 every 42 days - cycle (cycles 1-4) , and day 1,8,22,29 (cycles 5-9). Melphalan was given at 9 mg/m^2 day 1-4 every 42 days- cycle. Dexamethasone was given iv 20 mg on V administration days. *Results.* Thirteen/15 patients completed the treatment. The median number of cycles received was 8. Median follow up is 11 months. VM-Dex therapy resulted in 13/15 objective responses for an overall response rate (ORR) of 86% (CR 7, 47%; VGPR 2, 13,5%; PR 4, 26%). Grade 3-4 hematological toxicities were present in 15% of the patients; more importantly no one experienced bacterial infections/pneumonia. *Conclusions.* VM-Dex combination is a safe and extremely effective combination in elderly untreated MM patients. Larger phase III trials are needed to confirm these data.

1479

DE NOVO EXTRAMEDULLARY PLASMACYTOMA DURING THE COURSE OF MULTIPLE MYELOMA, A KOREAN SINGLE CENTER EXPERIENCE

J Jo, C Yoo, S Park, Y Ahn, S Jang, C Park, HS Chi, CW Suh

Asan Medical Center, Seoul, South-Korea

Background. Extramedullary plasmacytoma (EMP), solitary plasmacytoma of bone and multiple myeloma (MM) are identifiable as separate entities by distinct clinical features and natural histories. However, some MM patients who had no plasmacytoma at diagnosis would develop *de novo* EMP during the disease course. Few reports have shown the clinical features of this *de novo* secondary EMP. *Aims.* We aimed to investigate the clinical characteristics and prognosis of the MM patients who developed *de novo* secondary EMP during the clinical course. *Methods.* The records of MM patient registry in Asan Medical Center were reviewed. Between March, 1998 and August, 2008, 31 out of 415 patients (7.5%) with MM who met the criteria of *de novo* secondary EMP were found. None had plasmacytoma at diagnosis. *de novo* secondary EMP was detected by imaging techniques (CT, MRI or PET), and when possible confirmed by histologic study. *Results.* The study cohort of 31 patients showed median age of 51 years (range 33-77 years) at MM diagnosis. Eighteen patients were males. The M-protein isotype were IgG 14, IgA 5, IgD 5, free kappa 4, and free lambda 2. The ISS stage was I in 9 patinets, II in 14 patients, and III in 8. The median number of treatment regimen before EMP was one (range 0-4) and 24 patients received VAD chemotherapy as the first-line chemotherapy. Twenty-two patients (71%) underwent single or tandem autologous stem cell transplantation before EMP development. The site of plasmacytoma included various bones, nasal cavity, obit, stomach, liver, and lung with the most common site of spine. Seven patients (22.6%) had involved multiple sites. The median time from MM diagnosis to EMP development was 31.9 months (range 6.5-75.7 months) At EMP detection, only 6 patients had >25% increase in paraprotein levels. Following *de novo* secondary EMP, 14 patients were treated with local radiotherapy, 9 patients received chemotherapy, and 5 patients received combination of radiotherapy and chemotherapy. Other 3 patients got supportive care. Systemic therapy regimens were VAD in 6 patients, thalidomide in 4, velcade in 2 and others in two. In study cohort, the median overall survival (OS) from MM diagnosis was 39.3 months (95% CI, 28.0-50.5 months) The median OS from secondary EMP was 5.1 months (95% CI, 4.0-6.2 months) and the median progression free survival (PFS) from EMP was 3.5 months (95% CI, 2.8-4.2 months). In the radiotherapy and chemotherapy group, the median OS from EMP was 4.5 and 6.0 months (P=0.535) and median PFS from EMP was 3.0, 3.7 months (P=0.598). Survival was not different among various systemic therapy modalities. *Summary/Conclusions. De novo* secondary EMP would develop in MM patients during their disease course not infrequently (around 8%). The median time to secondary EMP was 32 months following initial diagnosis. The prognosis following *de novo* secondary EMP was very poor regardless of treatment modalities. Novel therapeutic approaches should be explored to improve the outcome of *de novo* secondary EMP.

1480

DEVELOPMENT OF HIGH-GRADE B-CELL NEOPLASMS AND EXTRAMEDULLARY MYELOMA MANIFESTATIONS FOLLOWING THALIDOMIDE THERAPY

M Kraj, R Poglod, B Ceglarek, R Tronina, K Warzocha

Institute of Hematology and Transfusion Medicine, Warsaw, Poland

Thalidomide targets marrow stromal cells, alters IL-6 and TNF-α production and decreases adhesion of malignant plasma cells. Due to modified cell-to-cell contacts and interactions within marrow microenvironment, malignant plasma cells may become resistant to therapy and tend to disseminate and infiltrate other peripheral tissues. Of 93 multiple myeloma patients on thalidomide 7 developed extramedullary symptoms of plasmocyte proliferation: 1st. A 54-year-old man, with IgGκ myeloma from 2004. VAD and EDAP resulted in partial remission. He received thalidomide 100-400 mg/d from April to September 2006, when submandibular lymph node enlargement appeared, composed of blastic $CD38^+$, $CD20^-$, $CD3^-$, $CD79a^-$, $CD56^-$, cyclin $D1^-$ plasmocyte infiltrates with high 90%MIB1. Marrow plasmacytosis was 0.5%, M-protein- 2.63 g/dL. In November 2006 M-protein increased to 4.9 g/dL. He progressed and died in January 2007. 2nd. A 43-year-old man with IgAλ myeloma IIIA. Since December 2008 to September 2009, he received thalidomide 100 mg/d (8 CTD) with partial response. In September 2009 disease progressed and manifested by osteolysis progression, M-protein increase, β2M-6.7mg/L, 98% marrow plasmacytosis (atypical plasmocytes), chest soft tissue tumors composed of large anaplastic cells with acidophil nucleoli and sparse, very large mononuclear or multisegmented-nuclei cells. These *vs.* $CD38c^+$cells were $PAX^{+/-}$, $CD138^-$, $CD56^-$, LCA^-, $CD20^-$, $CD79a^-$, with 10% MIB1. PAD, MP, EDAP were ineffective; patient died in January 2010. 3rd. A 60-year-old IgGκ myeloma patient, from December 2001 treated with VAD, VMCP, VBAP, followed by thalidomide (CTD; May-August 2006), without response. In January 2007 disease progressed, with cutaneous plasmacytomas formation (histopathologically: atypical plasmocytes). 4th. A 62-year-old man with IgGλ myeloma (90% BM plasmacytosis, IgGλ 6.7 g/dL, osteolysis). Thalidomide (4 CTD; December 2008 -April 2009) resulted in partial response. In April 2009, extramedullary disease progression with chest soft tissue tumors was treated with PAD. In June 2009, patient progressed (IgGλ 0.9 g/dL, WBC 55×10^9/L, renal failure) and died. 5th. A 57-year-old IgAλ myeloma woman, on thalidomide (6 CTD; January-August 2009) with partial response, in 8th therapy month developed fulminant plasma cell leukemia (PCL) (4.3×10^9/L of $CD38^{++}$, $CD138^+$, $CD56^+$, $CD54^+$, $CD49^+$, $CD29^+$, $CD126^+$, $CD11a^-$, $CD18^-$ plasmocytes in blood; 70% marrow blast cells with identical immunophenotype) with cutaneous plasmacytomas, renal failure and 1.0 g/dL -13 g/24h urine BJλ. 6th. A 71-year-old man with BJλ-myeloma from April 2005. VAD, melphalan, VMBCP resulted only in disease stabilization. On thalidomide 100-300 mg/d (March-August 2006), he developed PCL in 6th therapy month (26% $CD38^{++}$, $CD138^+$, $CD56^-$ plasmocytes in blood) with hypercalcemia, kidney failure and 3.25 g/dL urine BJλ. Mixed aplastic/hypercellular marrow, was heavily (80%) infiltrated by $CD138^+$ plasmocytes. 7th. A 50-year-old man with IgGκ myeloma infiltrating Th3 vertebra, from June 2004. No remission was achieved after laminectomy, spine irradiation, VAD and EDAP. On thalidomide (200-400 mg/d; May-November 2006), after 2 months, marrow plasmacytosis decreased from 93% to 4% and M protein from 4.7 g/dL to 2,0 g/dL. In November 2006 PCL developed (blood: 40% $CD138^+$, $CD56^+$ plasmocytes; marrow: 83% plasmacytosis. Our findings suggest, thalidomide is effective in initial reducing more mature plasmocytes confined to marrow and allows relatively immature myeloma cells to escape marrow microenvironment.

ANTITUMOR ACTIVITY OF BORTEZOMIB RETREATMENT IN RELAPSED OR REFRACTORY MULTIPLE MYELOMA PATIENTS

N Skvortsova,[1] T Pospelova,[1] I Nechunaeva[2]

[1]State Medical University, Novosibirsk, Russian Federation; [2]City Hematological Center, Novosibirsk, Russian Federation

Background. Bortezomib is a proteasome inhibitor with multiple effects on myeloma cells and bone marrow microenvironment. Bortezomib therapy has become an important part of the standard of care for patients with relapsed/refractory multiple myeloma. Additionally clinical evidences suggest that bortezomib retreatment in patients previously treated with the drug may prolong disease control. Objective. The aim of this retrospective study was to describe patterns and response on retreatment with bortezomib-based regimens on patients with multiple myeloma (MM). *Methods.* Data were retrospectively extracted from the medical records of patients treated in Russia Novosibirsk Hematology Center, who were subsequently retreated off protocol with bortezomib-based therapy. Analyzed patients had 60 or more days between treatments and ≥ 4 bortezomib cycles during initial treatment. Response was evaluated as very good partial response (VGPR) in case ≥ 90% M-protein decrease; partial response (PR) in case 50%-89% M-protein decrease; and minimal response (MR) in case M-protein decrease was less than 50%. *Results.* Retreatment response data were available for 26 patients: 3 (12%) had VGPR, 6 (23%) had PR, 8 (31%) had MR, 7 (27%) had diseases progression and 2 (7%) died. Thus, the overall response rate for bortezomib retreatment was 64%. During retreatment, 15 (58%) patients received bortezomib in combination with another antineoplastic agent, 11 (42%) patients received bortezomib as monotherapy. Median time between bortezomib treatments was 7.9 months; 31% of patients received non-bortezomib maintenance therapy between treatments. Toxicity was a reason for retreatment discontinuation in 27% of patients; the majority of cases (15%) were connected with neuropathy. *Conclusion.* Thus, bortezomib retreatment appears to be safe and effective. Favorable observed response rates with bortezomib retreatment suggest that it may be a viable option for relapsed/refractory multiple myeloma treatment, even in patients previously exposed to bortezomib.

1482

EFFICACY AND SAFETY OF DARBEPOETIN ALPHA IN KOREAN PATIENTS WITH MULTIPLE MYELOMA WHO ARE UNDERGOING CHEMOTHERAPY: A RETROSPECTIVE MULTICENTER STUDY

JH Kwon,[1] CK Min,[2] JH Lee,[3] YC Mun,[4] HJ Kang,[5] KH Kim,[6] SM Bang,[7] SH Bae,[8] SS Yoon,[9] K KMMWP[10]

[1]Kangdong sacred heart hospital, hallym univertisy, Seoul, South-Korea; [2]Seoul St. Mary's hospital, the Catholic University of Korea, Seoul, South-Korea; [3]Gachon University Gil Medical Center, Incheon, South-Korea; [4]Ewha Womans University School of Medicine, Seoul, South-Korea; [5]Korea Cancer Center Hospital, Seoul, South-Korea; [6]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South-Korea; [7]Seoul National University Bundang Hospital, Seoul National University, Bungdang, South-Korea; [8]Daegu Catholic University Medical Center, Daegu, South-Korea; [9]Seoul National University Hospital, Seoul, South-Korea; [10]Korean Myeloma Working Party, Seoul, South-Korea

Background. Anemia is one of the common symptoms in multiple myeloma patients that determine the quality of life and compliance to chemotherapy. Darbepoetin alpha is a unique erythropoietin with a longer half life and greater biologic activity than other erythropoietin agents. *Aims.* We decided to evaluate the efficacy and toxicity of darbepoetin alpha in patients with multiple myeloma who are undergoing chemotherapy in clinical practice. *Methods.* We reviewed the clinical data of patients with multiple myeloma who received recombinant erythropoietin during his/her chemotherapy. Efficacy of treatment was assessed using the hemoglobin level and the frequency of transfusion. After 4 weeks of administration of darbepoetin alpha, the increment of hemoglobin more than 2 g/dL from the baseline in the absence of RBC transfusion was defined as the complete response and increment of hemoglobin between 1 g/dL and 2 g/dL or no more transfusions were defined as partial response. Adverse events during the treatment were evaluated by descriptive manner. *Results.* 59 patients were enrolled from 9 centers in South Korea. Of these, 23 were males and 36 females, median age was 67 years (range, 34-85). 5 patients had stage IIA, 1 had IIB, 44 had stage IIIA, and 9 had stage IIIB disease by Durie-Salmon (DS) stage. 44 of 59 patients had heavy chain and others had light chain disease as DS stage system. 36 patients received darbepoetin alpha with their first line of chemotherapy. Responses to the chemotherapy were evaluable in 57 patients. Median dose of darbepoetin alpha was 2.00 ug/kg/week (range 0.88-4.0; 95% confidence interval 1.78-2.01). 36 patients achieved complete response and 9 patients had partial response giving a total response rate of 76.3%. The dose of darbepoetin alpha was not correlated with the degree of hemoglobin increment (P=0.439). Sex, stage at diagnosis, response to concomitant chemotherapy, and previous history of radiation therapy had no effect on the correction of anemia by darbepoetin alpha. Side effects were minimal. Diarrhea and hypertension were reported in 2 patients, respectively, and thrombotic event developed in only 1 patient and resulted in the interruption of administration of darbepoetin alpha. *Conclusions.* Darbepoetin alpha significantly increased hemoglobin and reduced red blood cell transfusions in patients with multiple myeloma receiving chemotherapy with a favorable safety profile. We need to determine the optimal dose of darbepoetin alpha in our patient population by prospective study to avoid unnecessary overdosing.

1483

THE SIGNIFICANCE OF TWO DIFFERENT FREE LIGHT CHAIN IMMUNOASSAYS FOR MONITORING OF DISEASE ACTIVITY IN MULTIPLE MYELOMA PATIENTS

V Maisnar,[1] J Vavrova,[1] K Machalkova,[1] M Tichy,[1] J Radocha,[1] B Friedecky,[1] R Hajek,[2] V Palicka,[1] J Maly[1]

[1]Charles University Hospital, Hradec Kralove, Czech Republic; [2]University Hospital Brno-Bohunice, Brno, Czech Republic

Background. Quantification of monoclonal immunoglobulin light chains (FLCs) in the serum is increasingly used in the clinical practice for the diagnosis, prognostic assessment, and also for treatment monitoring of monoclonal gammopathies as an adjunct to standard serum protein electrophoresis and immunofixation. This method is based on the binding of monoclonal antibodies to FLC epitopes that are only exposed if the light chain is not bound within a complete monoclonal immunoglobulin (M-Ig) molecule. It was published that serum FLC assays can be used to follow the disease course in nearly all multiple myeloma patients (Mead *et al.*, 2004). *Aims.* The main purpose of our study was to check the significance of free light chains determination for monitoring of disease activity in multiple myeloma patients. The second aim was comparison of two different FLC immunoassays in this setting. *Methods.* All serum test samples were obtained from our MM patients after receiving their written information consent. Serum M-Ig concentration we measured using electrophoresis gel densitometry or capillary electrophoresis. For determination of free light chains we used immunoturbidimetric measurement by the FreeLite kit and also the new ELISA method performed by kit BioVendor. Manufacturers' instructions were followed without modifications. *Results.* We present several examples of disease monitoring using serum M-Ig and FLCs determination together. In some cases we obtained different information which we had to correlate with other laboratory markers of disease activity and clinical status. A theoretical advantage of serum FLC monitoring is the short serum half-life of FLC compared to intact immunoglobulins. This is the reason for possible use of FLCs determination for detection of early response to therapy which we demonstrate in some our patients. In responding patients FLC levels rapidly fall and stabilise within the normal range. Nevertheless, the reliable measurement of FLC concentration is always hampered by several factors, including crossreactivity of antisera against FLCs, lack of standardisation of FLC quantification and occasional false negativity of FLC measurement despite of positive immunofixation electrophoresis. The results obtained using two different immunoassays for FLCs determination were similar. *Conclusions.* For most patients with a monoclonal immunoglobulin, measuring FLC is unlikely to have additional benefit for monitoring of disease activity with the notable exception of those with nonsecretory/oligosecretory myeloma. FLCs monitoring could identify patients with resistance to current therapy regimens more quickly than M-Ig determination. Conversely the most rapidly responding patients may have a worse outcome. FLCs measurement can help us also in patients with early relapse still on chemotherapy or in case of free light chains escape phenomenon. Because of the kappa/lambda FLC ratio calculation is strongly influenced by measurement errors, therefore we recommend the preferential use of relevant FLC concentration values.

RELATIONSHIPS OF CLINICAL PARAMETERS AND EFFECTS ON PROGNOSIS OF GENOMIC POLYMORPHISMS IN NOS3, TNF-α AND MDR1 IN PATIENTS WITH MULTIPLE MYELOMA

M Pehlivan, T Sever, S Pehlivan, V Okan, M Yilmaz, S Oguzkan Balci

Gaziantep University, Faculty of Medicine, Gaziantep, Turkey

In this study, relationships of clinic parameters and effects on prognosis of genomic polymorphisms in NOS3 (+894, VNTR), TNFα (-308, -238 and -857) and MDR1 (C3435T) were assessed in patients with multiple myeloma. Seventy-seven patients with multiple myeloma in the Section of Hematology at the Department of Internal Medicine at Gaziantep University Hospital were included. 77 healthy people without any hematological malignancies were included as control group. We studied these polymorphisms using the PCR and/or PCR-RFLP method. No significant relationship was found between TNFα (-238 and -857) and MDR1 (C3435T) gene polymorphisms and MM. GG genotype in TNFα (-308) gene polymorphism (P=0.012) and TT genotype in NOS3 (+894) gene polymorphism (P=0.004) were significantly increased in patients with MM in comparison with the control group. However, AA genotype in NOS3 (VNTR) gene polymorphism (P=0.007) and GG genotype in NOS3 (+894) gene polymorphism (P=0.004) were significantly decreased in patients with MM in comparison with the control group. In conclusion, TT genotype in NOS (+894) polymorphism and GG genotype in TNFα (-308) polymorphism, which are related to decreased expression, are increased in patients with MM. Thus, this may play a role in the etiopathogenesis of multiple myeloma. Moreover, GG genotype in TNFα (-238) gene is not affected whatever the first-line therapy (OPKHT, bortozomibe, thalidomide) is, but related with early progression not affecting total survival.

1485

CARDIAC IMPAIRMENT BY AL-AMYLOIDOSIS

T Pika,[1] J Vymetal,[2] R Metelka,[2] J Kozak,[3] P Lochman,[4] J Minarik,[2] J Bacovsky,[2] V Scudla[2]

[1]Faculty Hospital Olomouc, Olomouc, Czech Republic; [2]3rd Department of Internal Medicine, Faculty Hospital, Olomouc, Czech Republic; [3]Department of Radiology, Faculty Hospital, Olomouc, Czech Republic; [4]Department of Clinical Biochemistry, Faculty Hospital, Olomouc, Czech Republic

Background. The primary systemic (AL) amyloidosis is a systemic haematological disease belonging to the group of monoclonal gammopathies, characterised by the extracellular deposition of insoluble fibrils which are formed by the fragments or complete molecules of immunoglobulin light chains produced by the clonal plasma cell population, resulting in tissue disorganization and malfunction of the affected organs. Cardiac impairment is usually present by more than a half of the patients and represents the most significant prognostic indicator of this disease. *Aims.* The study aimed at detecting the presence of cardiac impairment by means of laboratory and non-invasive paraclinical methods by patients with AL amyloidosis examined at the time of the diagnosis. *Methods.* The group consisted of 14 patients with the histologically verified AL systemic amyloidosis (12x AL, 2x associated with multiple myeloma), all patients were examined using ECG, echocardiography, levels of NT-proBNP and Troponin T were determined, and some of the patients underwent myocardial magnetic resonance (MRI). *Results.* 10 (70%) out of 14 patients met the criteria of the International Society for Amyloidosis (ISA) for cardiac impairment caused by amyloidosis according to echocardiography; all the patients revealed diastolic impairment and also the electrocardiographic examination showed the characteristic features - namely a decreased voltage in limb leads and QS image in V1-3; an increased level of Troponin T in the serum was recorded in 9 out of those patients. Levels of NT-proBNP were higher by 13 patients, whereas 9 of the patients exceeded 1000ng/l. MRI examination of the heart was positive by 6 out of 8 examined patients who, however, had already shown echocardiographic signs of cardiac impairment. By 2 patients with a negative MRI finding, no ECG or echocardiographic sings of cardiac impairment were detected. *Conclusions.* Preliminary experience confirms the very positive benefit of the implemented examination algorithm of patients with AL amyloidosis, which lies in a combination of imaging methods, heart biomarkers, and together with the ISA criteria, it seems to be the optimum approach in the diagnostics of amyloid cardiomyopathy.

MULTIPLE MYELOMA IN A 10-YEAR-OLD BOY: A CASE REPORT

S Auger, G Margueritte, P Quittet, R Tichit, N Fegueux, JF Rossi

CHU Montpellier, Montpellier, France

Multiple myeloma (MM), a disease of the elderly, is exceedingly rare below 30 years of age. We present a case of MM in a 10-year-old boy who has been admitted in September 2007 in paediatric unit for a fracture of his left femoral bone during playing rugby. In his history, he's presented a juvenil myelomonocytic leukaemia (JMML) when he was four months old in December 1998. He's treated by aracytine and hydroxyurea during 4 years and he's still in complete response since July 2005. At admission, surprisingly the radiography shows two lytic bone lesions. The RMI finds proximal and distal medullar metaphyso-diaphysairy spreading with broken while previously he had no pain, no symptom. The histology of the two tissue biopsy of the lesion shows some large dystrophic plasma cells, MI 15 positive with no evidence of monoclonal light chains. The bone marrow biopsy shows an interstitial infiltrate of dystrophic plasma cells, with lambda light chain expression. The bone marrow smears finds 5% of dystrophic plasma cells. The monoclonal component IgG Lamda is at 3.56 g/dL, kappa and lambda light chain respectively at 5.65 mg/L and 766 mg/L, the kappa lambda ratio is less than 0.01. There is a proteinuria at 0.64 G per day, haemoglobin at 106 G/L, and Beta2 microglobulin at 2.6mg/L. There is no hypercalcaemia and serum albumin is normal. Plasma Cells Labelling Index is 1,16 % and 6,6 circulating plasma cells/µL in blood. The gene expression profiling can't be made. The PETscanner find multiple uptakes in femoral, vertebral costal and sternal bone. So this boy presents a multiple myeloma with stage 3A Salmon Durie, ISS 1. He undergoes nine cycles of bortezomib (1.3 mg/m^2 D1, D4, D8, D11) and dexamethazone (40 mg/D, D1 to D4) to reach a complete response. An allogenic stem cell transplantation was performed with his sister in the 11th September 2008, with a regimen based cyclophosphamide (60 mg/Kg) and TBI 12Gy, the immunosuppressive regimen is methotrexate (D3, D8, D11) and cyclosporine. He receives a graft containing 3×10^6 CMN/Kg. At Day 120, the chimerism is less than 1% recipient cells, without GVHd, but the monoclonal component reappears. Although he receives only a single cycle of Bortezomib Dexamethazone because of severe neuropathy and gastro-intestinal intolerance, a 2nd response complete has been obtained in June 2009. We report a case of MM during the childhood that is extremely rare. Only very few cases are reported in the literature. In this particular case the boy has been also treated for a JMML that have no relationship with the MM. Infortunaly no cytogenetic or DNA profiling has been made to highlight this feature. At our knowledge it is the first time that such feature is reported. The OS reported by Mayo clinic in a serial of 10 child is 87 months suggesting a better OS that compared in adults.

BORTEZOMIB PLUS MELPHALAN AND PREDNISONE IN UNTREATED PATIENS WITH MULTIPLE MYELOMA INELIGIBLE FOR STEM CELL TRASPLANTATION

R Garcia Sanchez,[1] L Entrena,[1] A Hernandez,[2] P Gonzalez,[3] JM Puerta,[2] A Pascual,[4] M Castellanos,[5] E Morales,[5] M Casanova,[6] A Bailen,[7] S Duran,[3] M Almagro,[2] G Ramirez,[1] S Del Castillo[1]

[1]Hospital Virgen de la Victoria, Málaga, Spain; [2]Hospital Virgen de las Nieves, Granada, Spain; [3]Hospital de Jaen, Jaen, Spain; [4]Hospital de Ubeda, Jaen, Spain; [5]Hospital Torrecardenas, Almeria, Spain; [6]Hospital Costa del Sol, Marbella, Spain; [7]Hospital Carlos Haya, Malaga, Spain

Background. The latest studies prove that Bortezomib plus Melphalan-Prednisone (VMP) is superior to Melphalan-Prednisone in newly diagnosed patients with multiple myeloma (MM) ineligible for stem cell transplantation, across all efficacy end points, including response rates, time to progression, time to subsequent therapy and overall survival. *Aims.* To evaluate the efficacy and safety of VMP regimen for previously untreated patients with MM who were ineligible for high-dose therapy, in the diary clinical practice. *Patients and methods.* We treated 31 newly diagnosed MM patients from seven eastern andalusian centers with nine 6-week cycles of VMP: bortezomib (1.3mg/m^2 on days 1,4,8,11,22, 25,29 and 32, cycles 1 to 4, and on days 1, 8, 22 and 29,cycles 5 to 9) plus melphalan (9mg/m^2) and prednisone (60mg/m^2) on days 1 to 4, cycles 1 to 9, giving a total of 49 weeks of treatment. Among the study patients, the median age was 71 years (range 59-85) and included 11 male (36%). Disease characteristics at the time of diagnosis were: International Staging System (I 32%, II 45%, III 23%), ECOG performance status <3 (84%), median of plasma cells in bone marrow (20%) and impaired renal function (32%). We assessed the response to treatment using criteria of the European Group for Blood and Marrow Transplantation (EBMT). Adverse events were graded with the use of the National Cancer Institute's Common Terminology Criteria for Adverse Events, version 3.0. *Results.* After a median follow-up of 8 months (1-31) the response rates could be evaluated in 21 patients with a median of cycles administered of 4 (24 weeks). Overall response was achieved by 95% (33% complete response and 62% partial response) and progression 5%.At the data cutoff point, 14 patients (45%) were still receiving the therapy. Toxicity profile was evaluated in all the patients. Adverse events grade 3-4 observed were neutropenia (10%), thrombocytopenia (7%) and gastrointestinal symptoms (13%). Peripheral sensory neuropathy was reported in 51%, including grade 1 neuropathy in 19%, grade 2 in 26% and grade 3 in 7%. 55% of patients required dose reduction of bortezomib, 26% and 11% of melphalan and prednisone, respectively. Ten patients (32%) discontinued treatment because adverse events in 29% and progression in 3%. Time to progression has not reached. The overall survival was 90%. *Conclusion.* VMP is an effective treatment with acceptable toxicity for elderly untreated patients with MM. The response rates and overall survival in our series are similar to data described in previous studies, although a longer follow up is needed in order to confirm these results. The adverse events reported were consistent with established toxicity profiles for both bortezomib and melphalan-prednisone. Therefore, VMP can be considered the standard care in patients who are 65 years of age or older and cannot receive more aggressive treatment.

1488

AUDIT ON THE USE OF BORTEZOMIB IN CASES OF RELAPSED MYELOMA AT SOUTHAMPTON GENERAL HOSPITAL

H Ahmed,[1] A Smith,[2] S Croft[2]

[1]*Basingstoke and North Hampshire NHS Foundation Trust, Basingstoke, UK;* [2]*Southampton University Hospital Trust, Southampton, UK*

Introduction. Bortezomib is a novel first-in-Class proteasome inhibitor that causes down-regulation of tumour growth and up-regulation of proapoptotic pathways. It also has an anti-angiogenic effect and improves survival in murine models of multiple myeloma. It has been approved for the treatment of relapsed or refractory myeloma by US FDA in May 2003. Since then, it has been recommended as third line therapy in patients with reasonable performance status and organ function and reasonable life expectancy and as an option for the treatment of progressive myeloma in patients who are at first relapse i.e. those who have received one prior therapy and have undergone, or found unsuitable for bone marrow transplantation. *Aims and objectives*. 1) To assess the response of our patients to Bortezomib. 2) To assess the common side effects experienced, in comparison to those reported in the current literature. 3) To assess the survival benefits for patients receiving Bortezomib for relapsed or refractory myeloma. *Methods.* We retrospectively analysed patient notes, e-documents, masterlab- results and pharmacy records looking at patients who received Bortezomib for relapsed or refractory myeloma. *Results.* We identified a total of forty one patients, but three were excluded as they were still receiving ongoing therapy. There was a total of 26 males (68%) and 12 females (32%) with a median age of 62 years (42-62). Their paraprotein profile was IgG in 22 cases, IgA in 6 and light chains only in 8. Most patients (84%) received Bortezomib as a 3rd or 4th line therapy. Eleven patients (29%) required initial dose reduction with a further 10 requiring subsequent dose modifications due to renal impairment, thrombocytopenia and worsening peripheral neuropathy. Nine patients had their treatment interrupted due to herpes zoster in 4, troublesome diarrhoea in 2, a further 2 with pneumonia and one with renal failure. The number of cycles given was more than 4 in 23(60%) patients and less than two in 7(18%). Patients who have shown a good response rate (PP >50% reduction) were 23 (72%) in those who completed at least 2 cycles and 14 (61%) in those who received more than 4 cycles. The overall survival was <6 months in 9 patients (24%), 6 to 12 months in 8 (21%) and 12 to 48 in 2 (5%) *Conclusions.* Limited by its costs, the majority of our patients received Bortezomib as 3rd or 4th line therapy. It was found to be efficacious with reasonable response rates. Its side effects were comparable in our group to those reported but the survival assessment was limited due to the small numbers of patients and short time frame post therapy.

1489

A STAGED APPROACH WITH VINCRISTINE, ADRIAMYCIN AND DEXAMETHASONE FOLLOWED BY BORTEZOMIB, THALIDOMIDE AND DEXAMETHASONE BEFORE AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION IN THE TREATMENT OF NEWLY DIAGNOSED MULTIPLE MYELOMA

C Chim, AK Lie, EY Chan, YY Leung, SC Cheung, SY Chan, R Liang, YL Kwong

Queen Mary Hospital, Hong Kong, China

Bortezomib-based regimens have significant activities in multiple myeloma (MM). In this study, we tested the efficacy of a total therapy with a staged approach, where newly diagnosed MM patients received vincristine/adriamycin/dexamethsone (VAD). VAD-sensitive patients (≥75% paraprotein reduction) received autologous hematopoietic stem cell transplantation (auto-HSCT), whereas less VAD-sensitive patients (<75% paraprotein reduction) received bortezomib/thalidomide/dexamethasone (VTD) for further cytoreduction prior to auto-HSCT. On an intention-to treat analysis, a progressive increase of complete remission (CR) rates was observed, with cumulative CR rates of 48% after HSCT. Seven patients progressed leading to three fatalities, of which two had central nervous system disease. The 3-year overall-survival and event-free-survival (EFS) were 75.1% and 48.3%. Six patients developed oligoclonal reconstitution with new paraproteins. In the absence of anti-coagulant prophylaxis, no patients developed deep vein thrombosis. The staged application of VAD+/-VTD/auto-HSCT resulted in an appreciable response rate and promising survivals. Our approach reduced the use of bortezomib without compromising the ultimate CR rate, and is of financial significance for less affluent communities.

1490

LENALIDOMIDE AS CONSOLIDATION/MAINTENANCE THERAPY IN MULTIPLE MYELOMA PATIENTS

A Gagliardi, P Della Cioppa, A Lucania, MR Villa, M Esposito, S Improta, G Nitrato Izzo, L Mastrullo

ASL Na[1] Centro, Naples, Italy

Background. Lenalidomide is a new immunomodulatory drug with a potent biologic activity. It represents an important treatment option for multiple myeloma patient either as first line therapy, either in resistant/refractory disease or consolidation/maintenance therapy. In this way Lenalidomide increases the available treatment options. *Aims.* According to several studies which evaluated lenalidomide in the treatment of multiple myeloma, in our department, lenalidomide was administered in resistant/relapsing myeloma patients and as consolidation/maintenance therapy in elderly myeloma patients with stable disease (partial remission) after induction therapy or more lines of chemotherapy. *Methods.* We treated 20 patients (11M and 9F) with median age of 70 years (range 66-80). Patients completed almost 12 months of therapy with variable doses of Lenalidomide (5-25 mg/die p.o., according to tolerability of each patient, for 21 days every 28 days), in association of very low doses of dexametasone (10 mg/die p.o. days 1,2,3,4) or alone. We used Enoxaparin for prophylaxis of venous thromboembolisms. Clinical restaging was performed after three, six and twelve months, in course of therapy. *Results.* At the present we didn't observe any progression of disease and in 15 cases we observed a good impact on monoclonal component. In all patients the therapy was well tolerated and were not found significant adverse events. *Conclusions.* Exists a role for lenalidomide with dexametasone or alone for consolidation/maintenance therapy in previously treated elderly myeloma patients. This therapy seems to lead an improvement in prognosis of these patients, without causing severe complications.

1491

REVERSIBILITY OF RENAL FAILURE IN MULTIPLE MYELOMA PATIENTS TREATED WITH BORTEZOMIB-BASED REGIMENS: A SINGLE CENTRE EXPERIENCE

Z Stefanikova, L Roziakova

Nemocnica Sv. Cyrila a Metoda, Bratislava, Slovakia

Background. Renal failure is a common complication in patients with multiple myeloma (MM). The two major causes of renal insufficiency in MM are myeloma kidney and hypercalcemia. Bortezomib is the first in a new class of pharmacologic agents that inhibit the proteasome. *Aims.* We designed this retrospective analysis to show reversal of renal impairment by bortezomib-based therapy. *Methods.* In this study, eight previously treated patients with acute myeloma induced kidney failure have been evaluated. The median age was 62 years. All patients received bortezomib at a dose l,3mg/m^2 with dexamethasone or in combination with other agents (doxorubicin or melphalan). Two patients required dialysis support at the time of bortezomib administration. *Results.* Three out of the 8 patients (37%) with acute myeloma induced kidney failure experienced reversal of renal failure (complete renal response) and the median time to reversal was 31 days. A partial renal response was documented in two (25%) of patients with the median time to rensponse 48 days. The objective tumor response rate was 75%. All patients who required dialysis became dialysis independent. Toxicities were similar to those seen in myeloma patients without renal failure. *Conclusions.* Bortezomib-based regimens has been shown to be highly effective and to rapidly induce tumor response in patients with multiple myeloma who have renal failure, including those requiring dialysis.

1492

SEQUENTIAL THERAPY WITH VAPLD AND BORTEZOMIB AS INDUCTION THERAPY FOR MULTIPLE MYELOMA: A PHARMACOLOGIC COMBINATION TO ACHIEVE COMPLETE REMISSION BEFORE STEM CELL MOBILIZATION

L Franceschini,[1] M Postorino,[2] M Rizzo,[2] L Pupo,[2] L Inchiappa,[2] S Vaccarini,[2] D Renzi,[2] M Quaresima,[2] S Gumenyuk,[2] C Ditto,[2] V Botteri,[2] M Mirabile,[2] D Venditti,[2] G De Angelis,[2] L Gianni',[2] M Cantonetti[2]

[1]*Policlinico Tor Vergata, Rome, Italy;* [2]*Unita'Operativa Oncoematologia, Policlinico Tor Vergata, Rome, Italy*

Background. Multiple Myeloma remains an incurable disease despite intensive therapy such as high-dose Melphalan and autologous stem cell

transplantation (ASCT), that remains the gold standard therapy. In multivariate analysis achieving complete remission (CR) before ASCT is a significant, independent variable for Overall Survival and Time to Progression. *Aims.* Following this assertion, in a preliminary and feasibility study, we tried to obtain the best response as soon as possible with a combinated and sequential therapy with VAPLD and Bortezomib. In fact using VAPLD or Bortezomib based regimen alone we obtained an Overall Response Rate (CR/VGPR) <50% ; instead in our opinion their sequential use could permit a better tumor mass reduction and the exploitation of synergic role of Bortezomib in front of chemotherapy. *Methods.* From June 06 to September 09 we enrolled 13 patients with untreated MM and 1 pt with relapsed plasmocytoma (previously treated); median age was 53 years (34 - 65), M/F was 3/11; the M-protein type was IgG in 6 pts, IgA in 3 patients, while 4 pts presented a Micromolecular Myeloma (pt with plasmocytoma did not present M-protein at the relapse time); ISS stage was I in 9, II in 3 and III in 2 pts respectively. Patients underwent to VAPLD regimen (Vincristine 1,4 mg/m^2, Pegylated Liposomal Adryamicin (APL) 35 mg/m^2 on day 1 and Dexametasone 40 mg day 1-4) for 3 cycles (day 1-21); 15 days after last therapy, pts started Bortezomib regimen (1,3 mg/m^2 on day 1,4,8,11) for 4 cycles and 30 days after last dose pts received Cyclophosphamide 4 g/m2 and G-CSF for stem cell harvest. *Results.* Response has been evaluated according IMWG uniform response criteria. All patients achieved the partial remission after VAPLD scheme, while OR (CR+VGPR) was achieved in 11/14 (78.5%) patients post Bortezomib. All pts mobilized stem cells achieving target of CD3 4+ (10×10^6/kg) . Toxicity was low and mainly consisted of neutropenia (WHO grade I-II in 15 % of pts) and mild peripheral neuropathy (WHO ≥ grade II in 33% of pts). *Conclusion.* Since our experience was a preliminary and feasibility study, extended up-front therapy with sequential combination of VAPLD, Bortezomib, Cyclophosphamide is more effective in term of remission rate than shorter therapy schedules; moreover it is associated with low toxicity and results in an excellent stem cell harvest. 9 pts underwent to transplant; after ASCT 8/9 patients maintain CR/VGPR, while 1 patient is in RD (median follow-up 16 months, range 2-24 months).

1493

ARSENIC TRIOXIDE IN PATIENTS WITH REFRACTORY MULTIPLE MYELOMA

Z Sanaat, M Rezazadeh, J Vaez Gharamaleki, J Eivazi Ziaei, A Esfahani

Hematology and Oncology Research Center,Tabriz University of Medical Sciences, Tabriz, Iran

Background. Multiple myeloma is a plasma cell dyscrasia characterized by proliferation of plasma cells in bone marrow associated with the production of monoclonal immunoglobulins. In recent years, the use of, arsenic trioxide, formerly approved for treatment of acute promyelocytic leukemia has been considered for refractory myeloma treatment. *Aims.* This study was designed and carried out to evaluate the efficacy and possible side effects of ATO on patients with refractory multiple myeloma. *Methods.* This study carried out on myeloma patients whose diseases were at least refractory to two standard treatment regimens. Arsenic trioxide was administered as an intravenous infusion at a dose of 0.25 mg/kg/d for 5 d/week during the first 2 consecutive weeks of each 4-week cycle with 2 week rest. Patients who completed one 4-weak cycle were evaluated for response to treatment. *Results.* 12 patients with refractory disease to conventional treatment regimens, received arsenic trioxide. disease assessment was based the amount of serum proteins electrophoresis . of the10 patients; stable disease was observed in four patients (33%), progression disease in five patients (41.6%), complete response in one patient (3.8%) and the reemaning two patients could not be assessed for a response (because of increased liver enzymes after the first week). Some adverse events are: increase liver enzymes and serum creatinine , neutropenia, pruritus, nausea, vomiting, lower extremities edema, noninfectious diarrhea were observed. *Conclusion.* The use of arsenic trioxide is promising in treatment of refractory multiple myeloma.

1494

OSTEONECROSIS OF THE JAW IN PATIENTS WITH MULTIPLE MYELOMA TREATED WITH BISPHOSPHANATES

M Pavkovic,[1] G Petrushevska,[2] T Sotirova,[1] S Trpkovska-Terzieva,[1] O Karanfilski,[1] L Cevreska,[1] S Stankovic,[1] A Stojanovic[1]

[1]Department of Hematology, Medical Faculty, Skopje, Macedonia; [2]Institute of Pathology, Medical Faculty, Skopje, Macedonia

Background. Bisphosphonates are pyrophosphate analogues which inhibit osteoclastic activity. Long term use of bisphosphonates has been recently associated with osteonecrosis of the jaw (ONJ). ONJ is defined as three months non healing defect in a jaw, usually in mandibule. ONJ is commonly precipitated by a tooth extraction or other stomatological procedure in patients treated with long term, potent, high dose intravenous bisphosphonates for the management of multiple myeloma (MM), breast or prostate cancer. Current evidence shows that the risk of ONJ in non-cancerous patients, such as those with osteoporosis, is very low. *Aims.* The aim of this study was to evaluate the incidence of ONJ in patients with MM treated with bisphosphonates in our institution and to report the first two cases. *Methods.* We have analyzed 247 patients with MM diagnosed and treated in our institution in the period of 2002-2009. Annual incidence of myeloma in Republic of Macedonia in that period was 30±10.9 new cases per year. Median duration of bisphosphonate therapy was 24.7 months. We have been used 90 mg of pamidronate or 6 mg of ibandronate i.v. per month or standard dose of clodronate or ibondronate orally. Zolendronate is not available in our institution and we have only two patients treated with zolendronic acid in foreign hospitals. *Results.* We have diagnosed two patients with ONJ from 247 evaluated (0.8%). First case is a female patient 58 years old, diagnosed with IgG myeloma 10 years ago, treated with multiple chemotherapy regiments. First, she received 17 cycles of COMP (cyclophosphamide/vincristine/melphalan/prednisone) and than interferon with lamivudine and prednisone due to aggressive hepatitis B infection. We started with Thalidomide/Prednisone and bisphosphonates therapy in 2004. From August 2004 until October 2009 she received 18 doses of ibandronate i.v. 6mg/per dose and 24 doses of pamidronate i.v 90 mg/per dose. Due to X-Ray signs of ONJ bisphosphonates therapy was stopped in October 2009. She was treated surgically in January 2010 with pathological proof of ONJ. Now she receives only chemotherapy with Melphalan/Prednisone/Thalidomide (MPT). Second case is a male patient 55 years old, diagnosed with IgA myeloma in February 2008. Initially he was treated with four cycles of VAD (Vincristine/Doxorubicine/Dexamethasone), hematological remission was not achieved, so he continued with 4 cycles of COMP. From October 2008 he was treated with MPT. Therapy with oral ibandronate was started in February 2008 and it was stopped due to ONJ in August 2009. The diagnosis was pathologically confirmed. Now he is treated only with MPT chemotherapy. Both patients have regular check-ups for ONJ and condition is slowly improving. *Conclusion.* ONJ is an uncommon but long-lasting complication of long-term treatment with bisphosphonates. Fortunately this complication was rare in our hospital and we have diagnosed only two patients, one treated with oral ibandronate and one treated with i.v. pamidronate and ibandronate. Both patients didn't have stomatological procedure before occurrence of ONJ. Low incidence of ONJ in our institution could be explained with the rare use of zolendronate, which is the most commonly referred bisphosphonate causing ONJ and with relatively shorter duration of bisphosphonate treatment comparing with other studies. Despite the fact that ONJ is a rare complication in our department preventive measures like stomatological examination before bisphosphonates treatment and regular stomatological check-ups during bisphosphonates treatment must be considered.

1495

MULTIPLE MYELOMA: 68 CASES, PORTUGUESE ONCOLOGICAL CENTER'S EXPERIENCE

S Chacim, I Ferreira, L Leite, N Domingues, A Espírito-Santo, I Oliveira, L Viterbo, M Marques, A Martins, M Mariz

Instituto Português Oncologia Porto, Porto, Portugal

Background. Multiple myeloma (MM) is a disease caused by plasma cell clonal proliferation, and it represents 10% of all hematological malignances. *Aims.* Characterization, determination of the prognostic factors, treatment response and overall survival of the patients diagnosed with MM at Instituto Português de Oncologia do Porto, Portugal. *Methods.* We gathered a series of cases, based on retrospective revision of

clinical data of patients diagnosed with multiple myeloma, at our Institution, between January 2007 and January 2009. Statistical analysis was made on xlstat2009. *Results.* 68 patients were identified (53% male, median 65 years old). Median follow up was 16,5 months. Twenty patients (29%) had international staging system (ISS) 1, 27 (40%) had ISS2 and 21 (31%) had ISS3. At diagnosis, 16 patients (23,5%) had and increased creatinine and 20 patients (29%) had lactic desidrogenase above normal. Median hematological values were: 10,9g/L hemoglobin, $5{,}76\times10^9$ WBC/L, $1{,}82\times10^9$ Lymphocyte/L, 195000 Platelets/L. Median bone marrow plasma cell count was 30%. The most prevalent immunoglobulin was IgG (37patients, 54%), followed by IgA in 18 patients (26%) and light chain in 7 patients (10%). Thirty patients (44%) were submitted to chemotherapy with ID (idarrubicin+dexamethasone), 15 (22%) with MP (melphalan+prednisone), 7 (10%) with MPT (melphalan+prednisolone+thalidomide), 4 (6%) with TD (thalidomide+dexamethasone) and 4 (6%) were enrolled on international investigational protocols. Thirty four patients (50%) had disease progression. Regarding 2nd line treatment, 21 (62%) of them used tacydex (thalidomide+cyclophosphamide+dexamethasone), 3 patients (9%) used bortezomib+dexamethasone and 3 (9%) of them were enrolled in international investigational protocols. Twenty five patients (37%) underwent autologous bone marrow transplantation. Median overall survival of these patients is statistical superior when compared with those who were not submitted to transplantation (wilcoxon P=0,006). ISS shows 3 statistical different overall survival curves. Global overall survival hasn't reached yet the median survival. Creatinine value at diagnosis shows a statistical difference in global survival (wilcoxon P=0,048). Lactic desidrogenase appears to separate two statistical different overall survival groups (wilcoxon P=0,056). Total lymphocyte count doesn't show statistical difference on overall survival (wilcoxon P=0,789). *Conclusion.* The presented case series puts in evidence the changes in adopted treatments, considering recent advances in this field. Overall survival curves are similar to those published in literature, enhancing the importance of autologous transplantation. The ISS, creatinine value at diagnosis and lactic desidrogenase are prognosis factors, in this series.

1496

COMBINATION OF BORTEZOMID, CYCLOPHOSPHAMIDE AND DEXAMETHASONE: TREATMENT OF MULTIPLE MYELOMA AND PLASMATIC CELL LEUKEMIA PATIENTS. EXPERIENCE OF ONLY ONE INSTITUTION

MD De Miguel,[1] N Golbano,[1] MI Lopez San Roman,[1] M Diaz Morfa,[1] D Morales,[1] J Arbeteta,[1] S Herrero,[2] B Pinedo[1]

[1]Hospital Universitario de Guadalajara, Guadalajara, Spain; [2]Hosptial Universitario de Guadalajara, Guadalajara, Spain

Background. Novel sequential combination therapy for induction may improve the quality of response and therefore prolong survival in newly diagnosed multiple myeloma (MM) patients. This concept should be allocated in refractory / relapse multiple myeloma patients. *Material and methods.* We present our experience with the combination of Bortezomid (1.3 mg/m^2 D1, D4, D8, D11), Cyclophosphamide (600 mg/m^2 D1, D8) and Dexamethasone (40 mg D1-2, D4-D5, D8 - D9, D11-D12) for 21-days cycles in newly and relapsed multiple myeloma and plasmatic cell leukemia patients. From February 2009 until February 2010, we treated 12 patients (7 in first line). On the front line in less than 65 years old as induction therapy prior to stem-cell transplantation, have treated 5 patients (1 plasma cell leukemia included). In first line, over 70 years, two patients with plasma cell leukemia. In the 5 patients in relapse had received at least two lines of prior chemotherapy (2-5), all had received prior Bortezomib, and 1 patient had been transplanted previously. The number of cycles (BCD) administered ranged between 1-6 (mean 2.4). 4 patients received only one cycle, 3 died of disease progression and in newly diagnosed patients stopped treatment for pneumonia (Candida plus H1N1 virus) and he admitted in intensive care unit because he did need mechanic ventilation support. *Results.* 8 patients are evaluable for response; Overall response rate was 100%, including 12.5% CR, and 87.5% partial response. 4 patients treated with RP, they patients have undergone stem-cell transplantation. Full results will be presented the congress. At the moment, 5 patients completed all six cycles. Toxicities were predictable and manageable; the most-commonly reported grade 3/4 toxicity was neuropathy (37.5%).The limiting toxicity was peripheral neuropathy, present in 3 patients, necessitating dose reduction of Bortezomid a step in 2 patients, and manage it in one week. 4 patients (50%) developed neutropenia grade 3-4, and required to use G-CSF. Infectious complications that required hospital admission in 3 patients (1 ZHV spread, bacteremia Staf., 2 pneumonias). *Conclusions.* 1) The BCD combination gets quality and fast respond. 2) hematological toxicity, is easily manageable, and the incidence of infection complications is higher in refractory / relapsed patients and with associated comorbidity. 3) In refractory / relapse patients, respond rate is obtained as first-line patients. Patients retreated with bortezomid had good results, with an increased of neuropathy.

1497

NEGATIVE ASPIRATION OF SUBCUTANEOUS FATTY TISSUE WITH NEGATIVE ORGAN INVOLVED BIOPSY DO NOT EXCLUDE A DIAGNOSIS OF PRIMARY SISTEMIC AMYLOIDOSIS

L López Corral, E Ocio San Miguel, M Mateos, R García-Sanz, A Carpio, J San Miguel, M Cabrero, J Labrador, E Pérez, J San Miguel

University Hospital of Salamanca, Salamanca, Spain

Background. Primary Sistemic Amyloidosis (AL) is the most frequent form of systemic amyloidosis and its morbilility is associated with Ig light chains deposition in vital organs. Early diagnosis and treatment is crucial. We report two consecutive patients with a final diagnosis of AL who had negative aspiration of subcutaneous fatty tissue (ASFT) and initial negative organ-involved biopsy. *Cases reports.* Patient 1: A 56-year-old male consulted our department with nephrotic syndrome and monoclonal G- protein in the serum with a peak of 0.5 g/dL. The complementary exams are showed in Table 1. With a high suspicion of AL, an ASFT with congo red staining was performed being negative for amyloid. Subsequently, a kidney biopsy was carried out but no amyloid or Ig deposition was proved so patient was supposed to have a MGUS. Nephrotic syndrome was treated unsuccessfully with steroids and 10 months later a new kidney biopsy was repeated, showing amyloid deposition. The revaluation showed biological deterioration (Table 1). Orthostatic hypotension appeared and increased wall thickness was evidenced in the echocardiographic examination. These new findings led to a diagnosis of AL. As he had three organs involved, the transplantation was not consider, and he has been treated with Melphalan and Dexamethasone. To date, after four cycles, he has reached partial response. Patient 2: A 76-year-old male suffered from nephrotic syndrome with an Ig G paraproteinemia (0.58g/dL) and 8-months history of anasarca, the "racoon sign"in physical examination and complementary exams showed in Table 1. An ASFT and a kidney biopsy failed to demonstrate amyloid or Ig deposition. Despite these findings, a rectal biopsy was performed, showing amyloid. An echocardiographic examination showed a restrictive cardiomyopathy with ventricular septum hypertrophic. He has been treated with Melphalan and Dexamethasone without response after two cycles. *Discussion.* In both patients, despite the high clinical suspicion of AL, both ASFT and biopsy of the organ involved failed to confirm the diagnosis. First patient suffered from a wrong diagnosis and the second one could only be correctly diagnosed after a rectal biopsy. Amyloidosis diagnosis is determined through histological material from biopsy of different parenchymal organs, which have high diagnostic value, but hide risk of bleeding. ASFT is a safe, simple and fast method for detecting amyloid and its sensitivity is about 60-90%, so this technique can be used as a screening test. However, sometimes ASFT fails so biopsy from a symptom-giving organ is mandatory in cases with high clinical suspicion with negative ASFT. In these cases, although the combination of ASFT and involved organ biopsy has a very high sensitivity, if both techniques are negative, we must perform a rectal or gingival mucosa biopsy, or repeat

the organ biopsy, but never give up, because clinical suspicion, very frequently leads to the diagnosis of AL, and late diagnosis or misdiagnosis could have fatal consequences.

Table. Principal biological findings of the two cases.

BIOLOGICAL FINDINGS:	Patient 1: Diagnosis	Patient 1: evolution	Patient 2
•Creatinine (mg/dl)	0,6	0,8	1,8
•Calcium (mg/dl)	7,6	8,6	8,8
•Albumin (g(dl)	1,5	1,1	2,5
•MC (g/dl)	0,51	0,58	0,9
•Isotipe of MC	Ig G λ	Ig G λ	Ig G λ
•ProBNP (pg/ml)	362,5	4891	6807
•serum Free light chains (ratio)	0,34	0,06	0,14
•Prot urine (g/24h)	23,46	45	9,1
•BJ (g/24h)	0,46 λ	0,26 λ	0,36 λ
•BMPC (%)	3	-	13
•CPa/CP flow cytometry (%)	97	-	88
•Bone radiographies	normal	normal	Skull lesions
•Aspiration of subcutaneous fatty tissue (congo red)	negative	negative	negative
•Renal Biopsie (congo red)	negative	positive	negative
•Rectal Biopsie (congo red)	-	-	positive

1498

HYPOMETHYLATING THERAPY INDUCES CLINICAL RESPONSE IN MULTIPLE MYELOMA

L García, M Berenguer, V Cabañas, F Labbadia

Hospital Virgen de la Arrixaca, El Palmar, Murcia, Spain

Background. Azacitidine, a hypomethylating agent approved in Europe (December 2008) for the treatment of myelodysplastic syndromes (MDS), has demonstrated *in vitro* efficacy in the treatment of multiple myeloma (MM) cells. *Aims.* We present the clinical data of a patient treated with azacitidine for MDS who also showed a response for MM. *Methods.* A 56-year-old man diagnosed with stage-IIIB MM in December 2003 (baseline status at diagnosis: IgA lambda in urine 4380 mg/24 h, severe bone disease and vertebral mass with plasmacytomas, 40% bone marrow infiltration, Bence-Jones protein 500 mg/dL, Hb 9.3 g/dL, platelets 19 500/μL, WBC 9000 cel/mL, calcium 8.9 mg/100 mL, β2M 5625 U; creatinine 2.8 g) was initially treated with VAD (4 cycles), followed by hyper-CVAD (3 cycles) plus radiation therapy, melphalan-prednisone (5 cycles), dexamethasone plus melphalan (1 cycle) and dexamethasone (5 cycles, 40 mg for 4 days). He also received deferoxamine for 1 year for ferritin levels of 3000 ng/mL (starting in April 2006), and interferon-α (from May 2007 to April 2009) for hepatitis C virus (HCV) infection diagnosed in March 2007. From May to September 2009 12 RBC units were transfused for Hb levels of 7 g/dL. The diagnosis of MDS and refractory anemia with ringed sideroblasts (RARS) was confirmed in June 2009 (baseline status at diagnosis: bone marrow trilineage dysplasia, multiple cytogenetic changes, blasts 1%, plasma cells 3%, ringed sideroblasts 40%), and treatment with azacitidine was initiated at 75 mg/m^2 for 5 days in a 28-day cycle.

Table 1.

		Situación inicial (Agosto 2009): MM y SMD (ARSA)					
		Hg (g/dl)	Plaquetas (u/ul)	Neutrófilos (cel/mm^3)	B2M (unidades)	Leucocitos (cel/ml)	Ferritina (ng/ml)
		10,5	32000	800	3000		
		VIDAZA ®					
	Dosis	Hg (g/dl)	Plaquetas (u/ul)	Neutrófilos (cel/mm^3)	B2M (unidades)	Leucocitos (cel/ml)	Ferritina (ng/ml)
Tras ciclo 1	75mg/m^2/5días	8	19000	280			
Tras ciclo 2	37,5mg/m^2/5días Dosis reducida por toxicidad	11,5	108000	1260			
Tras ciclo 3		14,5	120000			6000	
Tras ciclo 4					2000		
Tras ciclo 6		14,2	82000	1940			700

Results. The patient was refractory to VAD and hyper-CVAD therapy plus radiotherapy. Subsequent treatment with melphalan-prednisone, melphalan-dexamethasone and dexamethasone (due to melphalan toxicity) achieved a good response. In November 2005 IgA lambda levels were 1090 mg/24 h. Ferritin levels decreased from 3000 ng/mL to 400 ng/mL after treatment with deferoxamine. Further to HCV-DNA negativization, treatment with interferon was continued because it proved to be beneficial for the patient's MM: IgA levels had diminished to 300 mg/dL (kappa/lambda ratio 0.19) and Bence-Jones protein decreased to 100 mg/24 h. In April 2009 interferon was discontinued due to decreased platelet counts and Hb levels. Following the diagnosis of MDS-RARS, azacitidine therapy was initiated in August 2009. In September 2009 the monoclonal band (IgA λ) was still detectable despite transfusion of 12 RBC units for low Hb (7 g/dL). The following results were obtained (Table 1). The initial dose was reduced to 50% due toxicity from cycle 2. The increased levels of hemoglobin, neutrophils and platelets indicated response of the MDS-RARS. In December 2009 (cycle 6) no monoclonal band was detected, which indicated response of the MM. *Summary conclusions.* Azacitidine elicited a complete response of MDS (RARS) in several studies, but in our patient it also improves the response of previously treated MM. To our knowledge this is the first clinical evidence of the efficacy of azacitidine in MM.

NEUTROPHILIA IN ASSOCIATION WITH MULTIPLE MYELOMA: CASE REPORT

K Quiroz, A Lemes, MT Gómez Casares, Y Ramos, G Santana, CE López Jorge, C Campo, S Jiménez, J López Brito, S Fumero, C Rodríguez, T Molero

Hospital Universitario de Gran Canaria Doctor Negrin, Las Palmas De Gran Canaria, Spain

Background. Neutrophilia might be present in certain types of solid tumors and hematological malignancies. Case report: We report the case of a 77 year-old woman who was admitted in our hospital due to a one-month evolution constitutional syndrome. As relevant, CBC showed ,71000/μl leukocytes (left shift, metamyelocytes and myelocytes in the blood smear) and 7.5 g/dl of hemoglobin. Biochemistry pathologic values were: creatinine 4.7 mg/dl, Uric acid 10.7 mg/dL, LDH 455U/L, GGT 264U/L and Vit B12>2000 pg/mL. Chest X-ray showed bilateral pleural effusion. An splenomegaly of 17cm was observed in the abdominal ultrasound and CT. The NAP was 145. With the suspected of chronic myeloproliferative syndrome, a bone marrow (BM) biopsy was performed. BM aspiration was hypercellular with granulocytic hyperplasia and 12% of pathologic plasmatic cells (100% showed an aberrant immunophenotype: CD19$^-$/CD56$^+$/CD117$^+$/CD28$^-$, monoclonal kappa). BM biopsy showed myeloid proliferation, and infiltration by kappa monoclonal plasmatic cells. There was also a moderate reticulin fibrosis. The study for BCR/ABL and JAK2V617F was negative. There were no cytogenetic abnormalities. At the same time, we got the blood and urine proteinogram. It showed a serum biclonal component (IgA-kappa of 5.39 g/L and free kappa light chains of 1.80 g/L) and a monoclonal component, in 24-hour urine, of 2.73 g/L with positive inmunofixation for free kappa light chains. The B2M was 19.5 μg/mL. As all these results directed us to a probably Multiple Myeloma (MM), we asked for a total body X-ray, that was normal. Given the association of a suspected MM with leukocytosis, we reviewed the literature related to this issue. As it seems that this association is related to G-CSF production by plasmatic cells, we quantified the mRNA of this gene in the BM. Plasmatic cells were selected by CD138 positive cell separation. The analysis by real-time PCR demonstrated an intense expression of G-CSF by pathologic plasmatic cells. The final diagnosis was a G-CSF-producing IgA-MM. The patient was treated with Bortezomib and Dexamethasone, showing a lessening in the number of leukocytes as well as in the BM infiltration by plasmatic cells. *Discussion.* G-CSF is produced by monocytes, macrophages, endothelial cells and fibroblasts but not by normal plasmatic cells. It has also been demonstrated the production of G-CSF in some solid tumors and hematological malignancies (Hodgkin's lymphoma and anaplastic large cell lymphoma). In the few case-reports describing the coexistence of Monoclonal Gammapathy (MG) and neutrophilia, it was suggested that plasmatic cells might secrete some kind of interleukin or growth factor that stimulates myeloid proliferation. When serum was analyzed, high levels of G-CSF were detected, which was consistent with a study where molecular RNA overexpression of G-CSF was observed in plasmatic cells. We report another case of RNA overexpression of G-CSF in pathological plasmatic cells, which might explain the high neutrophil and myeloid proliferation associated with a primary diagnosis of MM. As the literature describes an association between chronic neutrophilic leukemia and plasma cell dyscrasia, we considered that it might be the result of a G-CSF-producing MM, instead of a real coexistence of both diseases.

THE EVALUATION OF THE EFFICACY COMBINED TREATMENT WITH REVLIMID AND DEXAMETHASONE IN PREVIOUSLY TREATED SUBJECTS WITH MULTIPLE MYELOMA (MM) - THE OWN STUDY REPORT

B Ceglarek, K Warzocha, L Konopka

Institute of Hematology and Blood Transfusion, Warsaw, Poland

Multiple myeloma (MM) is an incurable disease that is characterized by the accumulation of clonal plasma cells in the bone marrow.The primary approach to the treatment of MM is systemic antineoplastic therapy, which increased the median survival but does not allow to achieve sustained disease stabilization. Revlimid is the analogue of the Thalidomide administered to heavily pretreated patients with relapsed or refractory multiple myeloma. The mechanism of anti -myeloma activities are : modulation of the adhesion of myeloma cells to bone marrow stromal cells, cytokine inhibition, antiangiogenesis, immune modulatory effects- induction of a Th1 T-cell response with secretion of interferon-y and interleukin-2 and direct effects on myeloma cells and / or bone marrow stromal cells. The aim our study was to compare the efficacy of oral Revlimid in combination with oral pulse high-dose Dexamethasone in refractory multiple myeloma patients (1-3 lines of therapy). *Materials and Methods.* We randomized 10 MM II-IIIoA-B Durie Salmon stage patients (4 female, 6 male), aged 33-77 who were considered to have disease progression after at least 2 cycles of anti-myeloma treatment or have relapsed with progressive disease after treatment. Patients received Revlimid at a dose 25mg daily for 21 days every 28 days and oral pulse dexamethasone at a dose of 40mg daily on Days 1-4, 9-12 and 17-20 of each 28-day cycle. All dose modifications were due to Revlimid toxicity (3/4 grade NCI). *Results.* We obtained the Plateau Phase of Hematological Response at 5/10 pts.-

Table 1.

Response RR
Number of pts. 1
Since Cycle Number 12
Median Response Time (mo) 6.5
CR -2pts since 4-8 cycle , median response time- 38.6 months
PR- 2pts since 2-4 cycle ; median response time- 5.6 months
S- 4pts ; median response time -50.4 months

Of 7 pts were discontinued because of progression disease (PD). Two patients died of acute heart failure and 4 died of PD. All patients have different side effects (diarrhea, infections, bone and abdominal pain, fever, disorders of consciousness) and the dose of Revlimid was modied at 1 patient. Median progression free survival time was 20.4 months, time of survival since diagnosis was 67 months, and time of survival since Revlimid therapy 36.9 months. *Conclusions.* - Revlimid is the effective oral medicine which induces a high proportion of complete and partial long-lasting remissions in patients with relapsed or refractory multiple myeloma. - Toxicity at patients was acceptable (grade 1-3)

BORTEZOMIB FOR THE TREATMENT OF MYELOMA IN OUR HEMATOLOGY DEPARTMENT

I Ionita, L Cheveresan, M Cheveresan, M Ionita, V Todorescu, CO Ionita, D Oros, M Iordache, H Ionita

UMF Victor Babes, Timisoara, Romania

Background. Bortezomib is a selective proteosome inhibitor used for the treatment of myeloma. Trials demonstrated useful therapeutic effect; however its use was associated with a significant early discontinuation rate due to side effects. *Aims.* The aim was to determinate how Bortezomib was being used in our department: specifically, to determine the number of treatment courses patients are able to complete; to establish clinical affectiveness in multiple myeloma patients; to determine the overall survival and tolerability. *Methods.* Retrospective analysis was done for 27 multiple myeloma patients. We analysed the number of courses, the response rate, the tolerability and the side effects. 16 patients were male, 11 were female; median age 62 (range 45-80). 69% received Bortezomib in combination with Dexamethasone and 21% received Bortezomib in combination with other chemotherapy. 58% of patients received Bortezomib as third line treatment or greater. *Results.*The median number of treatment cycles completed was 4 (range 1 to 8). The complete response rate was 10% and the partial response rate 51%. 39% of patients discontinued treatment early due to side effects: neuropathy, fatigue and gastrointestinal symptoms were the most commonly cited. The median overall survival derived by Kaplain/Meier, method was 14 months. Peripheral neuropathy was the single most frequent side effect necessitating early discontinuation. The combination of Bortezomib with corticosteroids may be associated with higher rates of autonomic neuropathy than single agent Bortezomib. *Conclusions.* Our experience is that Bortezomib is an effective treatment for patients with multiple myeloma and peripheral neuropathy can determine early discontinuation of therapy.

SPECTRAL KARYOTYPING (SKY) REVEALS A NEW SUBSET OF PATIENTS WITH MYELODISPLASTIC SYNDROME (MDS) AND CHROMOSOMAL ABNORMALITIES NOT SEEN IN G-BANDING ANALYSIS

F Oliveira,[1] M Favarin,[1] T Colognese,[1] S Leite-Cueva,[2] R Passetto Falcão,[1] B Pinto Simões[3]

[1]Faculty of Medicine of Ribeirão Preto, Ribeirão Preto, Brazil; [2]Departament of Genetics, Ribeirão Preto, Brazil; [3]Department of Internal Medicine and Center for Research on Cell-Based Therapy, Ribeirão Preto, Brazil

Background. In myelodisplastic syndrome (MDS) cytogenetic findings are essential for a correct diagnosis and classification of the disease and constitute one of the most important independent prognostic factor. The cytogenetic profile, however, often cannot be fully resolved by banding because of the presence of marker chromosomes, rings, and unidentified material attached to chromosomes. Spectral karyotyping (SKY) has proven to be a powerful tool because it allows for refinement of the interpretation of complex karyotypes in hematological malignancies. AIMS The objective of this investigation were the comparison of SKY with G-banding analysis in order to identify new chromosomal abnormalities "masked"by the limited resolution of classical cytogenetics. METHODS Bone marrow samples of 24 patients diagnosed with MDS were incubated in RPMI 1640 with 20% fetal calf serum for 72~96h at 37 C. Cells were exposed to Colcemid (0.1 μg/mL) for 20min at 37 C and harvested routinely. Metaphase chromosomes were GTGbanded by a conventional Trypsin-Giemsa technique. Karyotypes were described following the recommendations of the International System for Human Cytogenetic Nomenclature. For SKY analysis, slides were freshly prepared from chromosome suspensions stored in fixative (methanol/acetic acid 3:1) at -20 C. *Results.* In a group of 24 cases studied, the cytogenetic analysis (G-banding) showed chromosomal aberrations in 13 patients (54.2%) and normal karyotype was observed in 11 subjects (45.8%). The abnormalities observed were dup(1)(q21q32), inv(3)(q21q26), t(3;3)(q21;q26), +4, del(5)(q31), -7, del(7)(q22q36), +8, add(17)(p12), +i(17)(q10), del(20)(q11). In the group with normal cytogenetic, SKY analysis revealed "masked"chromosomal abnormalities in 6 patients, being t(7;9)(q36;q34), ins(1;6)(q21;?), t(11;12)(p15;q24.1), ins(3;5)(p21;?), t(8;16)(q23;?) and ins(6;11)(q21;?). Among 13 cases studied with previous chromosomal abnormalities by G-banding analysis, SKY identified additional abnormalities in 8 patients. Some abnormalities found include t(6;9)(q27;q22), t(12;17)(p13;p12) and t(8;11)(p12;q12). Although in the majority of the cases the frequency of the abnormal clones was less than 50%, the abnormalities identified by SKY were classified as clonal. In five cases SKY analysis would have changed patient's cytogenetic risk (WPSS from low to intermediate in 3 cases and intermediate to high risk in 2 cases). Conclusions. SKY analysis has proved to be a promising and reliable method for identification of additional and complex chromosomal abnormalities usually present in a great number of human neoplasias. To better define the prognostic contribution of these new chromosomal abnormalities identified by SKY, the analysis of a larger number of patients are necessary.

MUTATIONAL ANALYSIS OF TET2 GENE IN BCR-ABL1 NEGATIVE CHRONIC MYELOPROLIFERATIVE NEOPLASMS

B Euba, P Aranaz, MJ García-Barchino, C Hurtado, MJ Calasanz, J Novo, JL Vizmanos, M García-Delgado

University of Navarra, Pamplona, Spain

Background. It has been recently reported that acquired loss of heterozygosity at chromosome 4q24 (where *TET2* is located) is associated with myeloproliferative neoplasms (CMPN) and myelodysplastic syndromes. Moreover, recent research has also detected mutations in

TET2 in these syndromes. *Aims.* Our purpose is to analyze all the coding region of *TET2* in 11 cell lines derived from patients with different hematological malignancies (MOLT-4, RAJI, K-562, HL60, KARPAS-299, BK0006, BK0013, M07-e, UKE-1, SET-2, HEL) and in 34 patients with CMPN (10 positive and 24 negative for *JAK2V617F*). We also analyzed 20 samples from healthy Caucasians as controls. *Methods.* To perform the mutational analysis of *TET2* we used denaturing High Performance Liquid Chromatography (dHPLC) and sequenced two samples from each elution profile for every fragment. Sequence traces were analyzed using *Mutation Surveyor* and reviewed manually. Statistical analyses to determine putative associations between allele and genotype frequencies of SNPs detected and disease development were carried out with *SNPStats*, two tailed Fisher's exact test and chi-square 2×3 contingency test with two degrees of freedom with two rows. In order to check the potential effect of intronic changes (both SNPs and mutations) on mRNA splicing, we used the splicing prediction web tool *Human Splicing Finder*. *Results.* We detected eight polymorphisms already described in dbSNP, and four not previously described. All of them were found both in control samples and in patients. Furthermore, we detected seventeen mutations not previously reported in two cell lines and nine NMPC patients. Twenty percent (2 of 10) of *JAK2V617F*-positive patients showed mutations in *TET2* (both cases were PV patients), while mutations were found in 29% (7 of 24) of *JAK2V617F*-negative patients. Four of these 7 patients (57%) had more than one mutation in *TET2*. Five of the 17 mutations detected were located in *TET2* regions highly conserved in other *TET* family proteins and also across species. None of the eight polymorphisms already described in dbSNP showed different distribution between patients and controls or between *JAK2 V617F*-positive and -negative patients. *Conclusions.* As it has been previously described by other authors, our results show that *TET2* is frequently mutated in NMPC patients (26.5%). The mutations detected were heterozygous and 13 were potentially inactivating mutations: five nonsense mutations, four missense mutations and four frameshifts. *TET2* exons 4 and 11 were the most frequently affected. Among the seven *JAK2 V617F*-negative patients with *TET2* mutations, five (72%) had a low survival. Further studies are required to understand the biological consequence of these mutations. To confirm that the four sequence changes, detected in control samples and patients, are polymorphisms, we will include more control samples.

BCR/ABL EXPRESSION IS NOT A RARE EVENT IN PROGRESSION OF CHRONIC MYELOPROLIFERATIVE DISORDERS

A Misyurin,[1] E Misyurina,[2] L Kesaeva,[1] M Isakov,[1] A Krutov,[1] I Soldatova,[1] T Grigorieva,[1] K Kaysina,[2] S Markova,[2] E Samyshina,[3] T Ostapenkova,[4] E Ovanesova,[5] T Gaponova,[6] E Vorozhejkina,[6] Y Kochkareva,[7] O Zakharov,[8] I Lazarev,[9] V Ivanova[9]

[1]Research Center for Hematology, Moscow, Russian Federation; [2]Research Lab for Molecular Hematology, GeneTechnology LLC, Moscow, Russian Federation; [3]Oncology Dispensary 4, Moscow, Russian Federation; [4]Oncology Dispensary 3 , Moscow, Russian Federation; [5]Outpatient Department, Moscow, Russian Federation; [6]Outpatient Department 218, Moscow, Russian Federation; [7]Outpatient Department 117, Moscow, Russian Federation; [8]Outpatient Department 150, Moscow, Russian Federation; [9]Botkin Municipal Clinical Hospital, Moskow, Russian Federation

Background. Understanding of the molecular pathogenesis of chronic myeloproliferative disorders (CMDs) was significantly improved after discovery of Jak2V617F mutation, deletions of exon 12 of Jak2 (Jak2-ex12) and MPLW515L/K. Nevertheless, there are still questions concerning the difference of clinical representation of polycythemia vera (PV), essential thrombocythemia (ET) and idiopathic myelofibrosis (IMF) as well as the molecular mechanisms that underlie progression of this group of diseases. In 2007 Dr I Mirza had described two PV cases that being initially BCR/ABL negative finally transformed into Ph-chromosome positive CML. In some of earlier papers that were published before Jak2V617F era there were a few mentions of BCR/ABL positivity in CMDs that was found by means of RT PCR. It gives us some reason to see if BCR/ABL positivity in CMDs still makes sense at least in the cases of poor clinical course and when the signs of progression and therapy resistance are visible. *Aim.* To collect blood samples from a number of CMD pts with unfavorable course and to see if some of them may demonstrate BCR/ABL positivity. *Methods.* To perform this study we have exploited qualitative and quantitative PCR detection of BCR/ABL fusion gene expression by means of RT PCR and RQ PCR. We have analyzed gene variants responsible for p190, p210 and p230 types of BCR/ABL protein synthesis. We have also performed detection of Jak2V617F, Jak2-ex12 and MPLW515L/K using AS PCR, direct PCR fragment sequencing and restriction analysis. This research was performed from 16.09.09 till 25.12.09. After receiving informed concerns blood samples (N=151) of CMD pts with unfavorable clinical course were collected in 8 local sites of Russia and sent to our lab. *Results.* We have examined 151 pts with CMD in progression (32(21%) - PV, 34(23%) - ET, 85 (56%) -IMF), median age was 62 y (23-86y), 98 females (65%), 53 males (35%). BCR/ABL expression was found in 43 of 151 (29%) CMD pts. Most of the cases were p210, only 2 were p190 and there were no p230. Jak2V617F was in 117 pts (78%), Jak2-ex12 was in 2 (1%), MPLW515L/K were not found; in 32 (21%) pts common Jak2 and MPL mutations were not found. BCR/ABL-positive (BA^+) and BCR/ABL-negative (BA-) groups show a distinct difference in leukocyte count: (L=9,4 (2,5-280)×10^9/L *vs.* 45(2,1-32,4)×10^9/L, P=0,017), other parameters were rather similar: Tr=439 (4,26-2000)×10^9/L *vs.* 485(93-5970)×10^9/L, Hb=133(62-218)g/L *vs.* 138(72-205)g/L, Er=4,3(2,49-9,3)×10^{12}/L *vs.* 4,9(2,4-7,3)×10^{12}/L. There was no difference in age and sex distribution among BA^+ and BA^-. The other prominent difference was hepatosplenomegaly (HSM): 40% in BA^+ *vs.* 28% in BA^-, P=0,021. BCR/ABL expression level in BA+ was rather low: 0,03(0,02-0,07)% IS (ELN International Scale). *Conclusion.* We have found a frequent (29%) BCR/ABL positivity detected by RT PCR and RQ PCR in CMD pts with clinical signs of the progression. This finding recalls the former discussion about the role of BCR/ABL in CMD pathology that seized down after Jak2 mutation era had begun. We suppose here that low BCR/ABL level in CMD may be a result of RNA editing rather than t(9;22).

1505

THE JAK2 RS10974944 SNP, PART OF JAK2 46/1 HAPLOTYPE, STRONGLY PREDISPOSES TO JAK2 V617F POSITIVE MYELOPROLIFERATIVE NEOPLASMS

A Trifa,[1] A Cucuianu,[2] L Petrov,[2] L Urian,[2] D Dima,[2] M Militaru,[1] I Pop,[1] R Popp[1]

[1]Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania; [2]Ion Chiricuta Cancer Institute, Cluj-Napoca, Romania

Background. Polycythemia vera, essential thrombocythemia and primary myelofibrosis are myeloproliferative neoplasms, characterized in a majority of cases by a unique somatic point mutation, JAK2 V617F. Recently, it was shown that JAK2 V617F occurs more frequently on a specific JAK2 haplotype, named JAK2 46/1. *Aims.* To evaluate the relationship between JAK2 rs10974944 SNP, part of the JAK2 46/1 haplotype, and JAK2 V617F mutation in a representative cohort of Romanian myeloproliferative neoplasms patients. *Methods.* We genotyped 149 myeloproliferative neoplasms patients (69 had polycythemia vera, 65 had essential thrombocythemia and 15 had primary myelofibrosis) with a known JAK2 V617F mutational status and 150 controls for the JAK2 rs10974944 (C/G) SNP (single nucleotide polymorphism), in which the G allele tags the 46/1 haplotype. *Results.* We found that the rs10974944 GG/CG genotypes were significantly enriched in patients compared to controls (P<0.0001). After stratifying for the JAK2 V617F mutational status and for the mutant allele burden, we demonstrated that GG/CG genotypes were significantly more frequent in V617F positive compared to V617F negative patients (P=0.001), but not in V617F negative patients compared to controls (P=0.29). Similarly, the GG/CG genotypes were significantly enriched in V617F positive patients with a mutant allele burden >50% compared to those with a mutant allele burden <50% (P=0.0006). *Summary/Conclusions.* Our results indicate that the G allele, part of the JAK2 46/1 haplotype, contributes significantly to the occurrence of JAK2 V617F - positive myeloproliferative neoplasms. Moreover, the JAK2 46/1 haplotype seems to be associated with mutant allele burden >50% in JAK2 V617F - positive myeloproliferative neoplasms patients.

1506

BIOPHISICAL PROPERTIES OF PLATELET MEMBRANE IN PATIENTS WITH PH-NEGATIVE CHRONIC MYELOPROLIFERATIVE DISORDERS

VM Popov,[1] AM Vladareanu,[2] H Bumbea,[2] A Nicolescu,[2] M Onisai,[2] K Eugenia,[3] T Savopol,[3] M Moisescu,[3] M Iordache,[3] C Mihai[3]

[1]County Emergency Hospital Arges, Pitesti, Romania; [2]University Emergency Hospital, Bucharest, Romania; [3]University of Medicine and Pharmacy Carol Davilla, Bucharest, Romania

Background. Patients with Chronic Myeloproliferative Neoplasms (MPN) often associate altered platelet function,these patients have more frequent thrombotic or haemorrhagic events.The purpose of the study is to identify the alterations of the platelet function in patients with MPN and to correlate changes in cell membrane fluidity with the platelet aggregation results. *Material and Methods.* This prospective study included 109 MPN patients (39 ET, 27 IMF, 43 PV) during the past 3 years in the Hematology Department . Platelet function was investigated by platelet aggregation with optical method and fluorescence anisotropy measurements. A group of 24 healthy volunteers was used for comparative *Results.* Statistics was performed using ANOVA. *Results and Discussion.* Platelets from patients with Ph negative MPN presented a low response to all the stimuli when compared to controls (ADP 30.97% *vs.* 70.25%, P<0.001; Collagen 27.2% *vs.* 70.86%, P<0.001; Epinephrin 10.68% *vs.* 73.33%, P<0.001; Ristocetin 28.76% *vs.* 71.7%, P<0.001).The low response of platelet aggregation is correlated with low fluidity of platelet membrane (ADP 0.1367for normal response *vs.* 0.1329 for low or absent response,collagen 0.1392 *vs.* 0.1310,epinephrine 0.1456 *vs.* 0.1232without statistical significance), ristocetin 0.1422 *vs.* 0.097-with statistical significance, P=0.02. Considering the type of MPN, we observed a statistically significant difference only for the amplitude of aggregation curves to ADP in ET patients *vs.* IMF patients (47.67% *vs.* 34.9%, P<0.05). The duration and the amplitude of the lag phase for ADP and collagen is higher for the patients with MPN *vs.* controls (ADP -amplitude 21.4% *vs.* 4.74%, P<0.05; duration 12.69% *vs.* 10.72%, P<0.05; Collagen -amplitude 23.84% *vs.* 4.74%, P<0.05; duration 94.69% *vs.* 10.72%, P<0.05). We observed a statistically significant correlation between the alterations of the lag phase and a higher medium platelet volume and thrombocrit (P<0.05). The incidence of deaggregation was higher for ADP (80/171 *vs.* 0/24,P=0.04), followed by ristocetin (22/162 *vs.*0/24) and collagen (15/70 *vs.* 0/0). Compared to the number of normal curves, the incidence of deaggregation to collagen is lower, but without a statistical significance. Patients with deaggregation have an high anisotropy than patients without deaggregation without statistical significance. Patients with MPN JAK positive presented major thrombotic accidents (portal vein thrombosis - 4cases, Budd-Chiari syndrome - 2cases, repetitive stroke - 3 cases). In these cases we observed a higher amplitude and slope to ristocetin *vs.* controls (83.1% *vs.* 71.7%), a lower incidence of deaggregation to ADP (2cases), collagen (no case), ristocetin (no case). The results are not statistically significant (not all the patients had access to detection of JAK mutation). *Conclusions.* The platelets of patients with Ph negative MPN presents more functional defects (altered platelet receptors, rigidity of membrane, insufficiency of granule release). The expression of platelet receptors are influenced by fluidity of platelet membrane. A low fluidity is correlate with low response especially for ristocetin. Presence of altered platelets determines variations of the lag phase and the possibility of deaggregation. JAK positive MPN may be associated with a higher incidence of major thrombotic accidents which may be correlated with a higher and a more rapid aggregation of platelets to ristocetin.

The informed consent was obtained.

LEUKEMIA STEM CELLS (LSCS) INVADING LIVER IN THE MURINE MPD-LIKE MYELOID LEUKEMIA WITH LIVER LESION: MOLECULAR CHARACTERISTICS

E Bigildeev, J Drize

Hematology Research Centre, RAMS, Moscow, Russian Federation

Background. LSCs are a small subset of leukemia cells capable for maintaining the bulk of tumor cells. Using a unique murine model of transplantable myeloid leukemia which gives metastases to the liver we were able to evaluate important characteristics of LSCs. After i.v. transplantation of 106 bone marrow or liver cells from affected mice the recipients die from acute liver failure due to massive invasion and proliferation of leukemic cells in the liver. The concentration of LSCs in the liver of moribund mice is very high and equals 1 LSC per 45 cells invaiding liver. *Aim.* The aim of this study was to characterize the properties of LSCs in given disease. *Methods.* Mice were injected with 106 bone marrow cell from leukemic donors. At the terminal stage of the disease $CD45^+$ cells were sorted by means of Miltenyi Biotec® MACS® magnetic separation columns from the liver of affected and control mice. RNA was isolated using guanidine isotyocianate. After evaluation of the quality of isolated RNA first strand cDNA synthesis was made using RT2 First strand kit (SABiosciences). The expression of 168 genes of interest was assessed by means of Real Time PCR using RT2 ProfilerTM PCR Arrays (SABiosciences). *Results.* Several known oncogenes were upregulated in CD45+ cells of leukemic origin compared to the same population of normal cells. Among them Runx1 (AML1), Etv6 (TEL), Cbfb, Vav1, Myc and components of AP-1 transcription factor c-Jun and c-Fos were elevated 47, 88, 53, 72, 26, 8 and 4 times respectively. Etv6 and Cbfb genes are common translocation parnters of Runx1 in different leukemias. Elevated expression of both points the potential first hit in studied leukemia. Transcription factors that are not oncogenes but regulators of hematopoiesis were also upregulated, for example Cepb-family genes Cebpb, Cebpe and Cebpg were overexpressed 80, 20 and 12 times respectively. It was shown that Notch signaling was activated in leukemic cells as Notch1 and Notch2 were overexpressed 13 and 72 times. It was shown that apparantly NF-kB pathway was activated in leukemic cells because activators (IL1), key regulators of this pathway (Ikbkb, Nfkbia) as well as many target genes (CyclinD1, Myc, Vcam1, Icam1, Nos2, cIAP1, cIAP2) were overexpressed. Housekeeping genes - Actb, Gapdh, Hsp90ab1, Hprt1 and Gusb were elevated 224, 221, 67, 48 and 38 times respectively and so were not suitable for normalization. Such high level of expression of these genes could be explained by active metabolism and rapid proliferation of leukemic cells. Nevertheless the expression level of several genes such as Fn1, Vegfa, Wnt1, Pax5, Jag1 and others did not change in leukemic cells and therefore could be used for normalization. *Conclusion.* Several oncogenes and transcription factors are overexpressed in analysed population of cells enriched with LSCs. This diversity could be explained by the accumulation of genetic events in constantly proliferating leukemic cells as well as the heterogeneity of studied population of cells. This model can be used for further characterizing LSCs, determing mechanisms of leukemic transformation and studying of extranodal involvement of malignant cells in leukemias.

ENDOTELIAL CELLS PROTHROMBOTIC ALTERATIONS IN PATIENTS WITH MYELOPROLIFERATIVE DISORDERS AND BUDD-CHIARI SYNDROME: PRELIMINARY DATA

ML Randi, F Tezza, M Valente, E Duner, I Bertozzi, M Treleani, S Rizzo, F Fabris

University of Padua, Padova, Italy

Background. Endotelial cells (EC) are known to be involved by the malignant process in hematologic malignancies, such as chronic myelogenous leukemia and multiple myeloma. Recently, EC have been found to be interested also in patients with polycythemia vera (PV) and primary myelofibrosis (MF). Budd Chiari syndrome (BCS), due to thrombosis of the supra-hepatic veins, is a rare but dramatic complication in patients with PV or essential thrombocythemia (ET). It is more common in young females and in most of them it occurs with a mild increase in platelet count; sometimes other associated prothrombotic risk factors have been found. *Patients and methods.* In 4 patients with BCS (1 male with PV and 3 females with ET, mean age 35±3.2 years) we have performed biopsies of dorsal left foot vein to study the expression of CD31 (PECAM-1),CD34 and von Willebrand factor (VWF) on EC mem-

brane. EC were evaluated both with optical and electronic microscopy and histochemical studies were performed. *Results.* EC of our patients showed over expression of CD31 and CD34 on their membrane, as well as VWF. Electronic transmission microscopy showed in EC the presence of very high number of Weidel Palade bodies containing VWF. *Conclusions.* Vascular endothelium is known to provide a non-adhesive surface to circulating neutrophils and platelets while helping to prevent blood clotting. However, EC dysfunction might contribute to the hypercoagulable state associated with PV and ET. Recently, the presence of JAK2V617F mutation has been observed in EC of hepatic sinusoids belonging to patients with PV and BCS. We observed significant amounts of pro-thrombotic proteins in EC of peripheral veins of ET and PV patients and BCS. If these alterations are the result or the cause of the thrombotic event is not defined. The relationship between the EC involvement by the malignant process, the prothrombotic EC alterations and the development of thrombosis in ET and PV require further careful evaluation.

MUTATIONAL ANALYSIS OF THE EGF RECEPTOR GENE IN BCR-ABL1 NEGATIVE AND JAK2V617F NEGATIVE CHRONIC MYELOPROLIFERATIVE NEOPLASMS

P Aranaz, C Hurtado, C Ormazábal, I Erquiaga, MJ Calasanz, M García-Delgado, FJ Novo, JL Vizmanos

University of Navarra, Pamplona, Spain

Background. BCR-ABL1 negative chronic myeloproliferative neoplasms (CMPNs) are a heterogeneous group of clonal hematological malignancies. In last years, some genetic alterations have been described to cause these diseases, most of them activating tyrosine kinase (TK) genes. Tyrosine kinases proteins have an important role in cell growth and oncogenesis. Gain-of-function mutations in TK genes can produce a constitutive activation of several signaling pathways. *Aims.* In this study, we study the EGFR gene that codes for a tyrosine kinase receptor (RTK) involved in signaling pathways relevant in hematological cells. Mutations in this gene have been found involved in lung cancer, and it could have an important role in the pathogenesis of hematological disorders. *Methods.* We have analyzed the transmembrane and TK-coding domains of EGFR by dHPLC to detect mutations on samples from 44 BCR-ABL1 negative / V617FJAK2 negative CMPN patients and 20 control samples from healthy individuals. *Results.* Our results show that this gene is not frequently mutated in CMPNs. *Conclusion.* The EGF Receptor gene does not appear to be involved in the pathogenesis of the myeloproliferative neoplasms.

This work has been funded with the help of the Institute of Health Carlos III (FIS PI040037), Spanish Ministry of Science and Innovation (SAF 2007-62473), the PIUNA Program of the University of Navarra and the Caja Navarra Foundation through the Program "You choose, you decide"(Project 10830).

ENDOGENOUS THROMBIN POTENTIAL (ETP) IN MYELOPROLIFERATIVE DISORDERS (MPD)

E Papakonstantinou,[1] E Yfantis,[1] A Theofani,[1] E Sini,[2] A Hepetary,[2] A Maris,[2] A Filiotou,[2] F Kontopidou,[2] C Manti[1]

[1]*Thriassion Hospital, Agia Paraskevi, Greece;* [2]*Ippokration Hospital, Athens, Greece*

Background. People with MPD have an increased incidence of both arterial and venous thrombosis. Extensive coagulation studies have failed to derive a stable model of thrombosis in MPDs. In our study we associated thrombophilia in MPD patients measuring ETP parameters. *Aim.* Measurement of ETP parameters in MPD patients. *Methods.* The ETP parameters were studied in 24 patients with MPD [10 essential thrombocythaemia (ET 41.7%), 2 atypical MPDas (8.3%), 9 polycythaemia vera (PV 37.5%), 2 chronic myeloid leukaemia (CML 8.3%) and 1 mastocytosis (4.2%)]. 12 men (50%),12 women (50%) and a control group of 30 healthy subjects were recruited. We used the chromogenic method on the fully automated Behring Coagulation System (BCS) for the measurement of thrombin generation parameters. *Results.* Table. Patients with ET compared with patients with PV had decreased tlag (24 *vs.* 34.8), tmax (67.7 *vs.* 84.1) but increased Cmax (113.3 *vs.* 80) and ETP (409.1 *vs.* 312.2). The above results were statistically significant (P<0.008) except for tmax (P=0.211). ET patients had increased ETP compared to control group (409.1 *vs.* 394.7). *Conclusions.* Thrombotic tendency in MPDs, by ETP parameters, did not emerge in this study except the increase of ETP in ET compared to the control group. We must highlight the increased values of ETP in ET compared to PV. Prospective studies with larger numbers of patients are needed to assess the prognostic role of ETP values in thrombosis at MPD patients.

Table.

	Control group	MPD	P
tlag	19.3	29.3	0.0001
tmax	54.4	77.2	0.0001
Cmax	123.5	95.3	0.0001
ETP	394.7	358.1	0.033

1511

MONTHLY CYCLES OF ORAL MELPHALAN IN PATIENTS WITH PRIMARY AND SECONDARY MYELOFIBROSIS

I Carmosino,[1] R Latagliata,[1] M Breccia,[1] L Cannella,[1] F Vozella,[1] P Volpicelli,[1] M Santopietro,[1] A Spadea,[2] MC Petti,[2] G Alimena[1]

[1]*Ematologia - Università La Sapienza, Rome, Italy;* [2]*Ematologia - IFO Regina Elena, Rome, Italy*

Background. Prolonged continuous oral Melphalan treatment was successfully employed in patients with Idiopathic Myelofibrosis (IM); however, a high incidence of evolution into blastic phase (BP) was observed. *Aim.* In order to reduce the incidence of BP and other side effects, a different Melphalan schedule with intermittent monthly cycles was tested at our Institution. *Methods.* From 1/2003 to 2/2009, 24 patients (16 males and 8 females, median age 66.2 years, range 41.7-76.2) were enrolled into the study; 19/24 had primary IM while in 5 there was a previous history of Polycythemia Vera/Essential Thrombocythemia. Six patients (25%) had been pretreated with Hydroxyurea. A symptomatic splenomegaly was present in all patients, with median spleen enlargement below costal margin of 12 cm (range 7-22). Median WBC level was 11.6×10^9/L (range 3.6-63.6), with 11/24 patients having WBC $>12.0\times10^9$/L; in addition, 3 patients had PLT level $> 500\times10^9$/L, 11 patients Hb level <10 g/dL and 3 patients had transfusional requirement. Melphalan was administered orally at the dose of 8 mg/day for 5 consecutive days every month. *Results.* Twelve patients (50%) had a reduction of spleen enlargement >75%, 2 patients >50% and 1 patient >25%, with a global response rate of 15/24 patients (62.5%): the remaining 9 patients had no variation in spleen volume. Elevated WBC values reduced to normal in all but one patient, elevated PLT values reduced to normal in 2 out of 3 patients, transfusional requirement disappeared in 1 out of 3 patients. Median number of cycles to best response was 10 (range 2-30). As concerns hematological toxicity, 4 patients had Hb decrease <8 g/dL, with 3/4 requiring transient transfusional support, and 1 patient had PLT decrease to $<50\times10^9$/L. One patient resistant to treatment died from broncopneumonia and 1 patient with normal PLT values died from cerebral hemorrhage; two patients had a grade 3-4 gastro-intestinal hemorrhage. Interestingly, only 2/24 patients (8.3%) had a BP evolution after 8 and 16 months from start of Melphalan, respectively. After a median number of treatment cycles of 18 (range 2-68), 12 patients are still in therapy and 12 discontinued Melphalan due to toxicity (4), resistance (3), relapse (3) or evolution to BP (2). *Conclusions.* The intermittent cyclic schedule of oral Melphalan seems capable to maintain a good response rate with reduction of symptomatic spleen enlargement in more than 50% of patients without excessive toxicity and with a lower rate of BP evolution, as compared to continuous Melphalan administration.

1512

BILINEAGE INVOLVMENT OF THE FUSION GENE IN A PATIENT WITH FIP1L1-PDGFRA POSITIVE CHRONIC EOSINOPHILIC LEUKEMIA AND T-CELL LYMPHOBLASTIC LYMPHOMA

A Degulys,[1] R Pileckyte,[1] E Gineikiene,[1] V Valceckiene,[1] M Stoskus,[1] R Dambrauskiene,[2] U Mickys,[3] L Griskevicius[4]

[1]Vilnius University Hospital Santariskiu Clinics, Vilnius, Lithuania; [2]Departament of Hematology, Clinics of Kaunas Medical University, Kaunas, Lithuania; [3]National Centre of Pathology, Vilnius, Lithuania; [4]Vilnius University Hospital Santariskiu Clinics and Vilnius University, Vilnius, Lithuania

Background. There are successful attempts treating FIP1L1-PDGFRA positive chronic eosinophilic leukemia (CEL) with low dose imatinib mesylate. However, FIP1L1-PDGFRA fusion gene can induce both proliferation and differentiation of eosinophils, neutrophils, monocytes, lymphocytes and mast cells. A recent reports noted three cases with association of FIP1L1-PDGFRA positive CEL and T-cell lymphoblastic lymphoma (T-LBL). *Case.* We report on the case of 42 years-old man who presented with splenomegaly and lymphadenopathy. Peripheral blood count showed leucocytosis 51×10^9/L with marked eosinophilia 22×10^9/L and elevated promyelocytes and myelocites but no blasts. Bone marrow biopsy exhibited massive granulocyte hyperplasia with marked eosinophilia, iron deposits and 2nd grade reticular fibrosis. G-band karyotyping showed no abnormalities and BCR-ABL was absent in the peripheral blood. Histological examination of cervical lymph node biopsy detected T-LBL. 6 cycles of ACVBP chemotherapy was administered resulting in complete remission of T-LBL and decrease of eosinophil counts to upper normal range. However, eosinophilia progressed again to more 47×10^9/L in a couple of months after completion of chemotherapy. FIP1L1-PDGFRA transcripts by RT-PCR were identified in peripheral blood, bone marrow and the lymph nodes affected by T-LBL. The final diagnosis of FIP1L1-PDGFRA positive CEL and T-LBL was established. Blood and bone marrow counts normalized after the initiation of imatinib mesylate 100 mg/d. 2 years after the final diagnosis the patient is alive in complete clinical, hematological and molecular remission on imatinib 100 mg/d. *Conclusion.* FIP1L1-PDGFRA-positive CEL in conjunction with T-cell LBL suggests a bilineage cell involvement probably arising from an early hematopoietic progenitor. Identification of FIP1L1-PDGFRA in cases of T-LBL with concurrent eosinophilia helps to select the targeted tyrosine kinase therapy.

1513

THE ASSOCIATION OF JAK 2 V617F MUTATION AND LEUKOCYTOSIS WITH THROMBOCYTIC EVENTS IN ESSENTIAL THROMBOCYTHEMIA

E Tothova,[1] A Kafkova,[1] M Hlebaskova,[1] N Stecova,[1] A Vasilova[2]

[1]University Hospital L.Pasteur, Košice, Slovakia; [2]GenDiagnostika, Košice, Slovakia

Background. Essential thrombocythemia (ET) is a chronic myeloproliferative disorder that primarily involves the megakaryocytic lineage, and is characterized by sustained thrombocytosis in the blood and increased number of large, mature megakaryocytes in the bone marrow with the sensitivity to several different growth factors. A recently discovered mutation in the gene for Janus kinase 2 (JAK 2 V617F - exon 14 mutation) on chromosome 9p 24 offers and explanation for this hypersensivity. The JAK 2 V617F mutation is found in approximately 50% of the ET patients predominantly in the heterozygous form, while 42% of the patients have wild type. We investigated the frequency of mutations in ET patients and analyzed the relationship with their clinical features. *Material and methods.* Eighty-four ET patients were evaluated in our study. The amplification refractory mutation system was applied for the mutation survey of JAK2 V617F. DNA was extracted from whole blood samples with NucleoSpin (Macherey-Nagel) kit according to manufacture's directions. Analysis was performed using the JAK2 MutaScreen kit for detection of JAK2 V617F mutation (Ipsogen) Real-Time PCR by LightCycler 2.0 instrument. *Results.* Fifty-three (64%) patients harboring the JAK2 (V617F) mutation, including 4 homozygous and 49 heterozygous changes during follow-up, 27 (32%) patients suffered from documented thrombotic events, with 24 having JAK2 V617F mutations. Statistical analysis showed that patients with the JAK2 mutation had significantly higher hemoglobin level, leukocytes, and thrombotic events (P=0.027, P=0.01, and P=0.024), respectively. Thrombotic events were also significantly correlated with age above 60 years, previous history of thrombosis and leukocytosis. No correlations were found between long duration of thombocytosis, number of platelets and JAK2 V617F. *Conclusions.*Our findings supports the opinion that both factors, JAK2 V617F and leukocytosis should be taken into account when ET patients are evaluated for risk of thrombotic complications. Therefore, detection of the JAK2 V617F mutation can affect not only the diagnosis, but also the management of ET patients.

1514

CHRONIC EOSINOPHILIC LEUKAEMIA - NOT OTHERWISE SPECIFIED (CEL-NOS) A POOR PROGNOSED DISORDER WITH RESISTANCE TO CONVENTIONAL CHEMOTHERAPY

G Helbig,[1] M Hus,[2] J Piszcz,[3] M Rozny,[4] M Rodzaj,[4] K Zawilska,[3] L Malendowicz-Portala,[5] R Wichary,[1] D Kata,[1] S Krzemien[1]

[1]Silesian Medical University, Katowice, Poland; [2]Department of Hematooncology, Lublin, Poland; [3]Department of Haematology, Bialystok, Poland; [4]Department of Haematology and Internal Medicine, Krakow, Poland

Background. Chronic eosinophilic leukaemia (CEL) is a myeloproliferative neoplasm characterized by clonal proliferation of eosinophil precursors resulting in increased eosinophilia count in peripheral blood and marrow with subsequent organ damage. Material and *Methods.* Ten patients (7 male/ 3 female) with a median age of 64 years (range 23-77) were diagnosed as having CEL according to criteria proposed by WHO classification 2008. Patients who met the criteria for idiopathic hypereosinophilic syndromes and CEL with FIP1L1-PDGFRA transcripts were excluded. *Results.* Eight patients had increased number of blast cells in peripheral blood and/or bone marrow or the presence of cytogenetic abnormality, in the remaining 2 cases- JAK2V617F point mutation was documented. The organ involvements included splenomegaly (n=6), hepatomegaly (n=4), mitral valve regurgitation (n=1), cardiac failure (n=1), peripheral neuropathy (n=2). A median white blood cell (WBC) count was 23.9×10^9/L (range 9.3-175) with absolute eosinophil count (AEC) of 9.6×10^9/L (1.5-136) and eosinophil marrow infiltration of 37% (14-64). Serum IgE and vitamin B12 levels were 151 Iu/mL (3.8-856) and 813 pg/mL (410-3359) respectively. The cytogenetic exam was available in 8 patients and revealed normal karyotype in 5, -4 in 1, -11,-19 in 1 and -7 in 1. A median number of treatment lines was 3 (1-5). All patients were resistant to conventionally used agents such hydroxyurea, busulphan, imatinib, interferon and low dose cytarabine. One patient achieved complete remission after allogeneic stem cell transplantation. Two patients remain in partial response while on hydroxyurea with prednisone. Seven patients died from 1) progression to acute myeloid leukaemia (n=3), 2) concurrent development of lymphoblastic lymphoma (n=1), 3) cardiac complications in refractory CEL (n=3) and 4) myocardial infarction (n=1). *Conclusions.* CEL-NOS is a rare disorder with resistance to conventional chemotherapy. Allogeneic stem cell transplantation remains the only curative therapeutic option.

1515

ANAGRELIDE TREATMENT AND PROSPECTIVE CADIOVASCULAR EVALUATION IN ESSENTIAL THROMBOCYTHAEMIA PATIENTS: A PILOT STUDY OF THE REGISTRO ITALIANO TROMBOCITEMIA (RIT)

L Gugliotta,[1] A Tieghi,[2] A Imovilli,[2] K Codeluppi,[2] G Tortorella[3]

[1]Institute L.and A. Seragnoli S.Orsola Hospital, University of Bologna, Bologna, Italy; [2]Arcispedale S.Maria Nuova, Hematology Unit, Reggio Emilia, Italy; [3]Arcispedale S.Maria Nuova, Cardiology Unit, Reggio Emilia, Italy

Background. The cardiovascular (CV) adverse events are reported in the Essential Thrombocythaemia (ET) patients treated with Anagrelide as a cause of treatment withdrawal. *Objective.* To define the role of an attentive CV monitoring in the ET patients candidate to or receiving Anagrelide treatment. *Materials and methods.* Twenty-nine ET patients (PVSG or WHO criteria) potentially candidate to Anagrelide treatment were object of this observational prospective study. The planned CV evaluation included clinical aspects as family and personal history, general CV risk factors, physical examination; biological parameters as Troponin I and Pro-BNP; instrumental parameters obtained with ECG, Echocardiography, and if indicated with Holter ECG and ergometric test. This CV evaluation was planned to be done before Anagrelide treatment and then after 3-6, 9-12, and 18-24 months. *Results.* All 29 patients were judged able to be treated with Anagrelide, but only 18 of them actually started the treatment and are object of this report. The patients, 11 females and 7 males, aged 14-67 years (median 42), had at diagnosis a median PLT count of 756×10^9/L (range 456-1518). The JAK2 V617F mutation was documented in 8 cases (44 %). At the start of Anagrelide treatment all patients had previously received a cytoreductive therapy, and were receiving Aspirin 100 mg/day. The Anagrelide dose at start was 1 mg/day and during the maintenance phase had a median

value of 1.5 mg/day (range 1-3 mg). The baseline CV evaluation documented no abnormalities contraindicating the treatment with Anagrelide (NYHA Class I in 18/18 cases). A palpitation was reported in two cases, and the heart rate was >100/min in one case, being the median value 81; the ECG was normal in 18/18; the Echocardiography documented: Ejection Fraction (EF) >50% in all 18 cases with a median value 66%; a left ventricle hypertrophy in two cases; and a minor valvulopathy in six cases. Supplementary information were obtained in four patients with ergometric test and Holter ECG. The Troponin I was always normal and the Pro-BNP was elevated in one case. During the follow-up, after 3-6 and 9-12 months in 12 cases and after 18-24 months in 6 cases, the median PLT count was 461, 355, and 210×10^9/L, respectively; the median pulse rate was 80, 77, and 75/min; the median value of EF was 68%, 66% and 65% (always >50%); the ECG, Troponin I and Pro-BNP were always normal; a palpitation occurred in two cases; a palpitation associated with arterial hypertension in another case was cancelled with use of a beta-blocker; Oedema occurred in two cases. The Anagrelide withdrawal was due to the occurrence of grade III-IV oedema in one case, and to the planning of pregnancy and of a BMT procedure in other two cases. *Conclusion.* This pilot prospective study shows that an attentive CV monitoring may be very useful to safely enrol and treat ET patients with Anagrelide.

DETECTION OF MUTATIONS ASSOCIATED WITH CHRONIC MYELOPROLIFERATIVE DISORDERS USING BEAD-BASED LIQUID ASSAY

M Shivarov,[1] M Ivanova-Shivarova,[2] E Hadjiev,[2] E Naumova[2]

[1]National Hematology Hospital, Sofia, Bulgaria; [2]University Hospital Alexandrovska, Sofia, Bulgaria

Background. The JAK2 V617F mutation has recently been reported to be associated with the pathogenesis of chronic myeloproliferative disorders (CMPDs). Several techniques such as restriction fragment length polymorphism, direct sequencing analysis, pyrosequencing, real-time AS-PCR and a denaturing high-performance liquid chromatography have been developed for the detection of this kind of mutation. *Aims.* We aimed at the establishment and validation of a novel rapid, cost-effective and moderate-throughput method for JAK2 V617F mutation identification using a multiplexed bead-based suspension array platform - LuminexRxMAPTM. *Methods.* A 354 bp region of spanning exon 14 of the human JAK2 gene was amplified using biotinylated primers and genotyping was performed by direct hybridization with 2 oligonucleotide probes, specific for the wild type and mutant alleles. The probes were synthesized with 5' amino group and 20 bases spacer oligonucleotides to allow covalent binding to carboxylated microbeads (Luminex Corp). *Results.* The method was validated by testing on different proportion mixtures of artificial plasmid construct harboring either the wild type and mutant JAK2 allele and a panel of DNA samples from patients with known CMPDs, genotyped by direct DNA sequencing. The sensitivity of this novel assay was approximately 5% mutant DNA in a wild-type *Background.* No discrepancies between the novel Luninex-based method and sequencing were observed. *Conclusions.* Our novel method could be successfully implemented in the diagnostic work-up for CMPDs. Additionally, the assay allows quantification of the JAK2 mutant allele burden and therefore is applicable for assessment of minimal residual disease in patients undergoing JAK2 targeted therapy or alloHSCT. Furthermore, this system would allow the design of multiplex assays for simultaneous testing for the presence of various mutations associated with CMPDs. *Acknowledgements.* This work was supported by Grant ID_09_157 (Contract 5/16.12.2009) of the National Science Fund, Bulgaria. Research activities of *vs.* and EH are also partially supported by Grant CV_119_09 of the National Science Fund, Bulgaria.

A NEW JAK2 EXON12 DELETION IN AN ELDERLY WOMAN WITH POLYCYTHEMIA VERA

G Cevadinha Caetano, A Estevinho, M Coucelo, C Bento, M Duarte, C Menezes, L Ribeiro

Centro Hospitalar de Coimbra, EPE, Coimbra, Portugal

Background. Mutations in the JAK2 gene, mainly the JAK2V617F, are present in about 95% of the Polycythemia Vera (PV) patients. Since 2007, mutations in the exon 12 have been described in a minority of patients previously described as PV JAK2V617F negative or idiopathic erythrocytosis (IE). Apparently, patients with JAK2 exon12 mutations have higher haemoglobin levels than the other PV patients, normal leukocytes and platelets counts and isolated bone marrow erythroid hyperplasia. The prevalence seams to be higher in females and younger age patients comparing with JAK2V617F positive PV. *Aim.* To describe the clinical case of a female presenting at the age of 87 with Polycythemia Vera and a JAK2 exon12 mutation not previously described. *Methods.* Mutation studies were performed in genomic DNA extracted from peripheral blood leucocytes and bone marrow. JAK2V617F was screened by ASO-PCR. JAK2 exon 12 mutations were investigated by direct sequencing. *Clinical Case.* In November 2009 a 87 years old female was referred to our Hematology out-patient clinic to investigate an erythrocytosis accidentally discovered in pre-surgery routine analysis (uterine prolapse). Hb 20 g/dL, Ht 70%, WBC 10.4×10^9/L, Plat 353×10^9/L. Patient complains with headache, dizziness, facial plethora and exercise dyspnea for the last 2 years. She is non smoker, with controlled arterial hypertension, auricular flutter (NYHA 2) and a previous surgery for uterine prolapse (2002). She is not aware of other family member with blood disorders. Non haematological conditions causing erythrocytosis were excluded. The level of EPO was 7,6 mUI/mL (normal 3-30) and Ferritin 10,7 ng/mL (normal 9-120). Molecular studies: Screening for JAK2V617F was negative. Direct sequencing of JAK2 exon12 revealed the mutation R541-D544del in the DNA extracted from peripheral blood leukocytes and bone marrow. Cytoreductive treatment with Hydroxiurea was initiated. *Conclusions.* This new JAK2 exon12 deletion R541-D544 occurs in a highly specific cluster of activating mutations occurring between residues 537 and 543 (Butcher *et al.*). We previously described a 17 year old male with splenomegaly, splenic vein thrombosis, Hb 23,7g/dL, Hct>60%, normal leukocytes and platelets counts, with a JAK2 exon12 deletion in the same region, R541-E543delinsK. This new JAK2 exon12 R541-D544del mutation was discovered in an elderly woman whose most relevant anomaly was an isolated erythrocytosis.

This study was supported by the grant PTDC/SAU-GMG/74375/2006 from the FCT, Portugal.

MYELOID NEOPLASM WITH FIP1L1-PDGFRA REARRANGEMENT RESPONSIVE TO IMATINIB DESPITE LONG TERM EVOLUTION

MC Mateos,[1] JM Arguiñano,[1] MA Ardáiz,[1] MJ Calasanz,[2] M Lasa,[1] MA Goñi,[1] MV Aznar,[1] M Echeveste,[1] M Pérez,[1] Y Burguete,[1] AM Redondo,[1] MJ Paloma,[1] I Ezpeleta,[1] FJ Oyarzabal[1]

[1]Hospital Virgen del Camino, Pamplona, Spain; [2]Universidad de Navarra, Pamplona, Spain

Background. Myeloid and lymphoid neoplasms with eosinophilia and rearrangements of PDGFRa, PDGFRb or FGFR1 have been recognised a separate category in the 2008 WHO classification of tumours, most common being PDGFRa rearrangements. Main features recognised to date are eosinophilia, splenomegaly, cardiac involvement, thrombosis and elevated serum levels of cobalamin and tryptase. Commonly the PDGFRa rearrangement can only be detected by PCR or FISH; cytogenetic analysis is normal and additional abnormalities (trisomy 8) are likely to represent disease evolution. This disease carried a dismal prognosis before an exquisite response to imatinib was reported, so reports on long term evolution are scarce. We report a case of a 55 year old male with eosinophilia and PDGFRa rearrangement diagnosed in evolution to acute leukemia after 13 years' evolution. *Case report.* The patient was first studied in 1996 because of persistent eosinophilia above 1500 per cubic milimeter. After a steady increase in eosinophils, a bone marrow examination was performed in 2003 yielding normal counts and cytogenetic analysis; a diagnosis of idiopathic hypereosinophilic syndrome was made and the patient remained asymptomatic and therefore untreated for six more years. In 2009, the patient was admitted to hospital with persistent fever, night sweats, fatigue and anorexia. Splenomegaly was the only remarkable physical finding, confirmed by CT scan to be 20 cm in size. Blood counts showed normal hemoglobin and platelets, along with leukocytosis of 61000 per cubic milimeter. Most remarkable findings in differential count were eosinophilia of 22000 per cubic milimeter, left shift and myeloblasts accounting for 3% of leukocytes. Serum chemistry yielded a LDH of 1105 U/L,normal tryptase and cobalamin of 1610 pg/mL. Echocardiography found a normal heart structure and function. Bone marrow counts confirmed considerable eosinophilia and 11% myeloblasts; no excess mast cells were noted. Trisomy 8 was the only finding on conventional marrow cyto-

genetics, confirmed by FISH in 35% nuclei; FISH also detected FIP1L1-PDGFRa rearrangement in 90% cells. Imatinib therapy was initiated and an hematologic response reached within two weeks, preceded by mild cytopenias not requiring drug withdrawal. Trisomy 8 and FIP1L1-PDGFRa rearrangement were undetectable by FISH in peripheral blood in four weeks. From then on, blood counts are within normal limits and the drug is administered at 100 mg three times a week. Comments on this case: Natural history of eosinophilia with PDGFRa rearrangement can span several years before symptoms arise. Initial imatinib response is maintained despite long term disease evolution and clonal evolution. Trisomy 8 is considered part of the malignant clone, because of response to imatinib therapy.

1519

SYSTEMIC MASTOCYTOSIS: AN-UNDER DIAGNOSED DISEASE. A COHORT STUDY WITH 12 CASES

MD Garrido,[1] P Navarro,[1] J Tercedor,[1] A Orfao,[2] P Becerra,[1] P Jimenez,[1] F Ruiz-Cabello[1]

[1]Hospital Universitario Virgen de las Nieves, Granada, Spain; [2]Hematology Department, Hospital Clinico. Centro de Investigacion del Cancer, Salamanca, Spain

Background. mastocytosis is a neoplastic disease characterized by malignant transformation of mast cells (MC), and which symptoms are a consequence of proliferation, accumulation of the mast cells, as well as liberation of biological mediators. There are several diagnostics criteria. *Major Criteria.* Multifocal dense mast cell (MC) infiltrates (≥15 MC/infiltrate) in the bone marrow or in any other internal organ. Minor Criteria: 1) >25% spindle-shaped cells in MC-infiltrates; or >25% of all MC are atypical MC (type I and/or type II) in bone marrow smears; 2) expression of CD2 and/or CD25 on bone marrow MC3; 3) serum tryptase level >20 ng/mL; 4) c-kit point mutation at codon 816 (mostly D816V) in bone marrow or in another internal organ. The diagnosis of the Systemic Mastocytosis is established if at least 1major and 1 minor, or 3 minor criteria are fulfilled. The clinical courses of mastocytosis vary. The majority of the patients, especially those with Cutaneous Mastocytosis (CM) or with Indolent Systemic Mastocytosis (ISM), demonstrate an indolent period that could last for many years or even decades, while other patients, such as with Systemic Aggressive Mastocytosis (SAM) or Systemic Mastocytosis Associated with Hematological Malignant Disease (SM-AHMD), present with an aggressive course with frequent lethality. *Aims.* Retrospective study aimed at description and analysis of clinical data of the patients with mastocytosis of the Hematology Department. We have analyzed clinical cases between 1998 and 2009. We have revised the following results of the analysis: previous clinical symptoms, data from the blood tests, calcium metabolism, tryptase and histaminuria, hormonal assays, immunophenotype of the bone marrow samples, mutational analysis of the Asp816/Val (D816V) and cKit in neutrophils/monocytes/eosinophils. *Methods and Results.* Among the 12 studied patients, 7 were males and 5 females, with ages between 4 and 79 years. Two of them presented with CM, six with ISM, and three patients had SM-AHMD. Patient with ISM showed from 0.01% to 3% of mastocyte infiltration in bone marrow. The serum tryptase levels varied between 6.6 mcg/L and 189 mcg/ç. The D816V mutation was detected in 7 cases, while two cases were negative. In one patient we detected a different mutation not clasificable and in two of the patients the mutational analysis was not possible to do. All the patients had similar general symptoms, including head ache, itchy skin, flushing, hypotension, abdominal pain with gastrointestinal symptoms. In eight cases we observed bone pathology, including two cases with osteosclerosis. The four cases with SAM presented hipoalbuminemia, organomegaly, splenomegaly and three of them hematological alterations. All the of these patients received symptomatic treatment, including disodic chromoglycane, antihistaminics H1 and H2, and steroids. Four patients were treated with interferon with good clinical response in only one case without hematologycal alterations. *Conclusions.* we believe that the systemic mastocytosis is an under-diagnosed disease because patients are treated for years by different specialists, who partially relieve symptoms without final diagnosis and adequate treatment. We conclude that it is important to diagnose early and start early adequate treatment, especially in cases SM-AHMD, which have poor prognosis.

1520

THE IMPORTANCE OF SCORING SYSTEM DEFINING IN THE PROGNOSIS OF PATIENTS WITH PRIMARY MYELOFIBROSIS

A Vidovic,[1] J Ljubicic,[2] N Suvajdzic-Vukovic,[1] I Djunic,[1] M Perunicic-Jovanovic,[1] V Djordjevic,[1] N Colovic,[1] A Pavlovic,[1] M Colovic[1]

[1]Institute of Haematology, Clinical Center of Serbia, Belgrade, Serbia; [2]Medical Centre Studenica, Kraljevo, Serbia

Background. Primary myelofibrosis (PMF) is a clonal myeloproliferative neoplasm (MPN) characterised by a proliferation of predominantly megakaryocytes and granulocytes in the bone marrow that in fully developed disease is associated with reactive fibrosis and with extramedullary haematopoiesis. *Aim.* Define initial, clinical, haematological and pathohistological features of patients with PMF, as well as classify patients into the risk groups according to different scoring systems (Lylsk, Kelnsk, Tefferi, Meyo, IPSS, Strasser, Cervantes) and assess the prognosis importance of previously mentioned parameters and scoring systems. *Patients and methods.* 77 patients with PMF, F/M 32/45; at the average age of 59.3 yrs (29-79 yrs) were examined and treated at the Institute of Haematology in the period from November 1995 to January 2006. Primary clinical, haematological and pathohistological parameters of the disease were determined with each of the patients. The degree of hepatosplenomegaly was expressed in cm palpability below costal margin. Dying according to Gomori was used for reticular fibrosis as well as Azan according to Heidenheimu for collagen fibrosis. Cytogenetic analysis was performed applying HG-banding technique. The patients were divided into three risk groups according to the following scoring system: Lylsk, Kelnsk, Tefferi, Strasser, IPSS, Meyo and Cervantes. Statistical *Methods.* descriptive statistics, graphical displaying, and Kaplan-Meier for the surviving probability. *Results.* Average time of patient surviving was 82.8 months in the range of 9-120 months, whereby 24 patients died. Statistically important factors of shorter surviving period were: the male sex, Hb<100g/L; Platelets <100×10^9/L; prominent leucoerythroblastosis with dacryocytosis; % of myeloblasts >2%; advantage stage of disease, hepatomegaly, and presence of constitutional symptoms. Starasser, Cervantes and Kelnsky's scores didn't display any statistical importance concerning the period of surviving. Lylsk, Tefferi, Mejo and IPSS scoring system pointed out significant differences of the length of surviving period between low risk and intermediate risk groups (P<0.05), but without any importance between high risk and intermediate risk groups (P>0.05). *Conclusion.* The choice of treatment options and surviving of PMF patients are still unsatisfactory. Prognosis scoring systems have great importance in the choice of optimal treatment and the time of its initiating.

1521

FAVORABLE RESPONSE TO ALPHA-INTERFERON IN A PEDIATRIC PATIENT WITH AGNOGENIC MYELOID METAPLASIA COMBINED WITH FV LEIDEN ANOMALY

A Colita,[1] A Colita,[1] C Arion,[1] A Lupu,[1] T Puscariu,[2] C Dobrea,[1] M Closca,[3] O Ciocan,[1] C Diaconu,[4] M Chivu,[4] R Talmaci,[1] D Coriu,[1] S Avram[1]

[1]Carol Davila University of Medicine, Bucharest, Romania; [2]Fundeni Institute, Bucharest, Romania; [3]Coltea Hospital, Bucharest, Romania; [4]Stefan Nicolau Institute of Virology, Bucharest, Romania

Background. Agnogenic Myeloid Metaplasia with myelofibrosis (AMM) is a myeloproliferative disease chracterized by leukoerythroblastosis, myeloid metaplasia and variyng degrees of myelofibrosis with very low incidence in pediatric patients. Symptoms inlude malaise, weight loss and splenomegaly. AMM is clonal disease but the JAK2V617F mutation seems to be less frequent than in adults. The natural history can be variable with survival variyng from 1.5 to 5 years. The treatment is ill defined although hydroxyureea, anagrelide and alpha-Interferon have been used. *Aim.* we present a case of a 17 years old girl diagnosed in March 2009 with AMM and thrombophilia (FV Leiden anomaly) with wery good response to alpha-Interferon (alphaIFN). *Methods.* diagnosis was formulated after clinical examination, peripheral blood analysis, bone marrow biopsy, cellular colonies assays and molecular tests for BCR/ABL, JAK2 and coagulation FV Leiden mutation. *Results.* the onset consisted in weight loss, subfebrility, upper abdominal pain with nauseea and emesis. The clinical examination showed palor and large hepato-splenomegaly. Initial blood count revealed Hb= 10.5 g/dL, WBC= 6.8×10^9/L, PLT= 919×10^9/L, and blood

smear examination showed marked anisopoikylocytosis, dacryocytosis, leukoerythroblastic picture. Bone marrow aspirate was hipocellular. Bone marrow biopsy showed hiperplasia with panmyelosis, hiperplasia of atypical megakaryocytes (with nuclear hiperlobulation, disposed in perivascular and paratrabecular large areas); G/E = 3/1; diffuse mild densification of reticuline network. Molecular testing for BCR/ABL and JAK2 mutation were negative. The colony assay showed incresed numbers of GM-CFU and the presence of erythroid endogenous colonies with slowly increased level of seric erythropoietin level. The abdominal ultrasonografic examination, CT-Scan and MRI revealed marked hepato-splenomegaly, portal cavernoma and extensive thrombosis of portal, splenic, suprahepatic veins. The superior endoscopy showed the presence of esophageal grade I varices. Hemostasis evaluation showed global alteration of coagulation screening tests (prolonged PT, APTT), normal C ans S porteins, with abnormal activated protein C resistence. The PCR test for FV showed the presence of FV Leiden mutation in heterozigot form. HLA-typing identified a full-match donor among her brothers. The patient was initially treated with alpha IFN (3 MU / 3 times per week), low dose aspirin (75 mg/day) and propranolol (40 mg/day) in order to decrease the portal hipertension. The patient is followed on a monthly basis with blood counts, coagulation tests and atevery 3 month with abdominal ultrasound. After the treatment we obtained a very good response consisting in remission of hepatosplenomegaly and normalization of platelets counts after 10 weeks with maintainace of normal clinical and hematological picture at 1 year after diagnosis. *Summary.* AMM is a very rare disease in children and adolescents, with few cases reported in the literature making it difficult to establish a standardized treatment. The favorable response of this case after treatment with alpha IFN led us to postpone the indication of sibling allogeneic stem cell transplantation.

1522

PRIMARY MYELOFIBROSIS: FREQUENCY OF GENETIC ABNORMALITIES IN BRAZILIAN PATIENTS AND INCREASED FREQUENCY OF PATIENTS YOUNGER THEN 50 YRS

ML Chauffaille,[1] L Santos,[2] J Ribeiro,[2] A Carbonel,[2] N Silva,[2] M Silva[2]

[1]Fleury / Unifesp, São Paulo- SP, Brazil; [2]Unifesp, São Paulo, Brazil

Primary myelofibrosis (PMF) is a myeloproliferative neoplasia characterized by progressive marrow (BM) fibrosis, extramedullary hematopoiesis with splenomegaly, anemia and peripheral blood (PB) smear showing teardrop red cells and leukoerythroblastosis. Around 50% of cases present JAK2 V617F, while MPL W515L/K mutations are present in <9% of patients without JAK2 V617F. The aim of this study was to describe the frequency of cytogenetics aberrations (karyotype and FISH), detect JAK2 and MPL W515K/L mutations and classify a group of PMF patients in a prognostic scoring system. Twenty patients with PMF consecutively diagnosed according to WHO classification of tumors at Unifesp, São Paulo, Brazil, were selected for the study. Diagnose work up included: PB and BM cell morphology analysis, BM biopsy, karyotype, FISH, JAK2 and MPL mutations detection among others tests. Male to female ratio was 0.8:1; median age was 65 years (from 42 to 88), three patients (15%) were younger then 50 years-old; median spleen size was 7cm from LCM (from 0 to 17cm); mean Hb level was 11.2g/dL (from 6.4 to 16g/dL), anemia was present in 13 (65%) patients; mean WBC was 16132/μL (from 3680 to 84000/μL); WBC exceeded 10000 in 13 (65%) cases; only one patient presented leucopenia; mean platelet count was 660450/μL (from 2000 to 1600000 /μL); thrombocytopenia was found in three (15%) patients and thrombocytosis in 11(55%). Karyotype was successful in 14 patients, and three (22%) of them were abnormal: two cases with +8 and one +9. FISH using probes for centromere of 8, centromere of 9, del(13q) and del(20q) were performed in cases with normal karyotype or unsuccessful results but did not reveal additional abnormalities. JAK2 V617F was detected in 11 (55%) patients and MPL W515K/L was detected in one (5%) case without JAK2 V617F. According to a scoring system based on two adverse prognostic factors, namely Hb below 10g/dL and WBC below 4000/μL or greater then 30000/μL (Dupriez *et al.* 1996), 14 patients were classified as low risk and 6 as intermediate risk. According to independent cytogenetic risk categorization (Hussein *et al.*, 2010), patients with +8 had an unfavorable prognosis with 34m of survival as compared to +9 with 113m. In fact, one of the +8-patients who was classified as intermediate risk was the only death observed in this group in the 5-year-follow up period, confirming literature data. The patient with MPL W515K/L mutation was an 87yr-old female with severe anemia (6.4g/dL). As described, PMF associated with MPL mutations tends to commit more frequently older women, and leads to a more intense degree of anemia. In conclusion there was an increased frequency of PMF (15%) in younger patients (<50yrs), phenomenum also observed in CML, a disease of youth in Brazil (de Campos *et al.*, 2010). The frequency of JAK2 as well as MPL mutations was similar to international series; the frequency of chromosomal abnormalities was a bit smaller and +8 stratified unfavorable evolution.

1523

LEUKEMIC TRANSFORMATION OF PHILADELPHIA CHROMOSOME-NEGATIVE MYELOPROLIFERATIVE DISORDERS: ARE ASIAN PATIENTS DIFFERENT?

GC Wong

Singapore General Hospital, Singapore, Singapore

Background. Leukemic transformation (LT) is rare in the natural history of Philadelphia (Ph) chromosome-negative myeloproliferative disorders (MPD). Prognosis is dismal with a median survival of less than 5 months irrespective of chemotherapy regimens, type, duration and treatment of MPD. Little literature is available on Asian patients. *Aims.* To study LT of Ph chromosome-negative MPD in Asian patients and determine the disease profile in Asian population. *Methods.* Patients were recruited from the MPD Registry of Singapore General Hospital Department of Hematology, an Ethics Committee (EC)-approved computerized database capturing clinical data of patients diagnosed with Ph chromosome-negative MPD from 1980 to 2009. Patient informed consent was waived by EC. Ph chromosome-negative MPD were diagnosed based on accepted criteria in use at time of diagnosis. All LT cases fulfilled WHO criteria and were included in the study. Reviews of clinical data including MPD diagnosis, treatment modalities and duration of use in myeloproliferative phase, latency to LT, type and characteristics of leukemia, chemotherapy administered and survival after LT were examined. *Results.* Over the 29-year period, there were 22 Asian patients with LT of Ph chromosome-negative MPD. LT incidence is 3% (22/725). Four of the patients had polycythemia rubra vera (PRV), 9 essential thrombocythemia (ET), 7 myelofibrosis (MF) and 2 MPD unspecified (MPD-U). 46% were males. 95%(n=21) were Chinese and the other patient was Malay. Median age at LT diagnosis was 67.5 years. All 4 PRV patients had received hydroxyurea(HU) for a mean duration of 10.5 years before LT. Eight of 9 ET patients had received HU for mean duration of 8.8 years. One had 32P, an alkylating agent. Five of 7 MF patients received HU, for a mean duration of 1.6 years. One MPD-U patient had HU for 1 year and the other presented with acute leukemia with marrow features of MPD. Median latency to LT was 14 years for PRV, 10 years for ET and 1 year for MF. Nineteen patients had myeloid leukemia, 2 were biphenotypic leukemia and 1 patient presented with granulocytic sarcoma. Nine patients had complex cytogenetics, with abnormalities of chromosomes 5 and 7 being common. Overall prognosis of patients who developed LT was dismal. Eight patients received AML induction chemotherapy but failed to achieve durable remissions. Fourteen patients were given low-dose chemotherapy for palliation or supportive care because of advanced age or poor performance status. None of the 22 patients received transplant because of refractory disease and /or overwhelming infections. Median survival of patients was 2 months. Survival was independent of MPD type and treatment administered. *Conclusion.* LT of Ph chromosome-negative MPD is rare and uniformly fatal. HU was the primary treatment for most MPD but it is difficult to determine its leukemogenecity from this cohort. Transformation was mainly to myeloid leukemia. Common cytogenetic abnormalities involved chromosomes 5 and 7. Despite chemotherapy, survival was poor and patients succumbed to refractory disease and infections. Asian patients did not have a more favorable outcome. It remains to be investigated whether upfront stem cell transplant may be a treatment option.

1524

INTERSTITIAL PNEUMONITIS ASSOCIATED WITH ANAGRELIDE IN A PATIENT WITH ESSENTIAL THROMBOCYTHEMIA

A Pascual,[1] A Biedma,[2] J Berruga[2]

[1]Hospital San Juan De La Cruz, Ubeda, Spain; [2]Hospital San Juan de la Cruz, Ubeda, Spain

Background. Anagrelide (ANA) is a quinazoline derivative that acts selectively on megakaryocite proliferation and maturation. In cases of Essential Thrombocythemia (ET) ANA is indicated in young patients of high risk who need to initiate cyto-reductive therapy and in patients with clinical resistance or intolerance to hydroxyurea. ANA-related

adverse events are infrecuently dyspnea and pneumonia, and rarely pulmonary infiltrates. We have only found two cases of Interstitial Pneumonitis in the literature related to ANA therapy. *Case summary.* A 54-year-old woman was diagnosed with ET in May, 2002. She was offered Anagrelide to control thrombocytosis (baseline platelets > 1.500×10^9/L) after cardiological evaluation. After one month she achieved normalization of the platelet count (platelets 223×10^9/L). She needed 3 mg/día of ANA and showed a good tolerance. Two months after initiating the treatment, she was admitted to the Hospital with a progressive difficulty in breathing in case of moderate effort, with cough, costal pain, and a feverish sensation of 4 days evolution. She presented the following results from exploration: temperature 38ºC, AT 100/50, tachypnoea, bilateral fine crackles at auscultation. Blood test: leukocytes 8.1×10^9/L, Hb 10.7g/dL, platelets 129×10^9/L. The pulse oximeter reading was 90%. Blood gas: pH 7.49, pO2 55, pCO2 27. Chest-X-rays: bilateral alveolointerstitial infiltrates with bilateral pleural effusions. CT of the chest showed patchy areas of ground-glass opacifications that mainly involve the upper lung zones and small alveolar peripheral infiltrates in lower right lung zone. Echocardiogram was normal. We discard infection for Legionella and Micoplasma. Pneumonitis for hypersensitivity by ANA was suspected so the medication was suspended. There is a clinical, functional and radiological progressive improvement, it not being necessary to establish corticosteroid therapy. In ambulatory control the patient does not have dyspnea, with platelet count of 1.000×10^9/L. Pulse oximeter and Chest-X-ray are normal. The case is notified to Andalusian Pharmacovigilance Centre. According to the algorithm of causality of Karch-Lasagna modified, it qualifies as "possibly", coinciding with the category assigned by the Centre. The reaction is considered to be serious. *Conclusions.* In all the patients who take ANA it is necessary to monitor both the cardiac and the pulmonary function. Vigilance is advised in patients who develop cough or dyspnea to maintain awareness of the possibility of the development of Pneumonitis.

1525

IS ORGAN TRANSPLANTATION CONTRAINDICATED DURING POLYCYTHEMIA VERA?

J Rey,[1] V Moal,[2] E Tabouret,[1] V Ivanov,[1] D Coso,[1] M Mozziconacci,[1] R Bouabdallah[1]

[1]Paoli-Calmettes, Marseille, France; [2]AP-HM, Marseille, France

Background. Chronic myeloproliferative neoplasms are characterized by long lasting evolution complicated by vascular complications and haematological transformation (secondary myelofibrosis, acute leukaemia). Risk factors for these complications are bad understood. It is generally admitted that clonal haematological disease represent contraindication for organ transplantation. Consequences of transplantation-induced immunodepression on evolution of chronic myeloproliferative disorder are bad described, in particular on the risk of aggravation or haematological transformation. *Aims.* We report the case of a man with polycythemia vera who has benefited from a renal transplantation. *Methods.* A 39 year-old man was diagnosed with polycythemia vera. He was treated with phlebotomies and then hydroxyurea with good response. He suffered also from a renal polykystosis and developed progressively a renal insufficiency with need from dialysis. After 2 years, it was decided to perform a renal transplantation. A complete evaluation with bone marrow biopsy excluded progression to secondary myelofibrosis. Jak2 mutation was positive before transplant at 75%. This procedure allowed us to monitor evolution after renal transplantation. After renal transplantation, hyperleucocytosis was noted and necessitated to augment hydroxyurea dose. After 18 months of follow up after renal transplantation, the patient was still in good haematological response on hydroxyurea. No significant modification of Jak2 allele burden was noted. *Results.* Indication for organ transplantation in the context of clonal haematological disease is always difficult to retain, especially in chronic disorder. Literature data are scarce. Case reports suggested that immunodepression can deteriorate haematological disease with even transformation in acute leukaemia. Organ transplantation in chronic myeloproliferative disorders is more frequently observed in the context of Budd Chiari and liver transplantation. *Conclusions.* Organ transplantation is possible in the context of chronic myeloproliferative neoplasms after multidisciplinary discussion. More cases are needed to confirm the safe evolution and to obtain supplemental arguments for this procedure.

1526

SIX YEAR RESULTS OF TARGETED THERAPY FOR CHRONIC MYELOGENOUS LEUKEMIA

A Lyamkina,[1] T Pospelova,[1] I Nechunaeva[2]

[1]Novosibirsk State Medical University, Novosibirsk, Russian Federation; [2]Clinical Hospital ,[2] Novosibirsk, Russian Federation

Background. The use of tyrosine kinase inhibitors (TKI) has dramatically changed prognosis in patients with chronic myelogenous leukemia (CML). The estimated median survival associated with TKI administration exceeds 15 years. *Aims.* To evaluate six year results of chronic myelogenous leukemia treatment with tyrosine kinase inhibitors. *Methods.* For the period of 2004 and up until now the 74 CML patients have been observed at the municipal hematology center of Novosibirsk, specifically: 55 patients in the chronic phase (CP), 11 patients in the accelerated phase (AP), and 8 patients with blast crisis. Those 74 patients included 29 men (39.2%) and 45 women (60.8%), with age ranging from 16 to 78 years, and the mean value being 44.7±18.17 years. 51 patients were administered TKI within the first 12 months since the diagnosis of CML was established, of them 43 patients have been receiving treatment for over 6 months (group 1), whereas 8 patients - less than 6 months. In the group of 23 subjects treatment with TKI was initiated in 24 or more months since the diagnosis of CML was established, and those patients had been significantly pre-treated with various medications, comprising Group 2. All patients from the II group prior to Glivec administration were administered various cytostatic agents and interferons: hydroxyurea - 92,8% patients; IFN-α medications in the doses of 3-9 mln IU daily - 78,3%; cycles of low dose cytarabine - 39,1%; bisulphan -13%. Among the 74 patients 67 are administered imatinib mesylate in the doses ranging from 400 to 800 mg daily, whereas 7 patients are administered nilotinib in the dose of 800 mg daily as 2nd line treatment after imatinib resistance or intolerance. *Results.* Administration of a TKI as a single agent in group 1 was followed by a complete clinical and hematological remission (CHR) in 90.7% patients, complete cytogenetic response (CCyR) - in 72,1%, partial response (ph^+ metaphases below 35%) - in 7%, therefore, major cytogenetic responses (MCyR) was achieved in 79.1% patients. Complete molecular response (CMR) was achieved in 55.8% of the studied patients, whereas major molecular response (MMO) - in 25.6%. In group 2 complete clinical and hematological remission was achieved in 52.2% patients, CCyR - in 13%, PCyR - in 4.4%, therefore, MCyR was achieved in 17.4% of the studied patients. Survival was analyzed in patients administered TKI, as compared to patients not administered TKI (data based on the retrospective review of medical records of CML patients observed at Novosibirsk municipal hematology center for the period of 1999-2004). A statistical method of calculating the cumulative fraction of survivals (Kaplan-Meier) was used to evaluate survival, with $P<0,05$ established as the reliability criterion. No medial survival was not established in the group administered TKI, whereas the 10-year survival rate exceeded 70%. In the group administered cytostatic agents median survival 4,1 years, the 10-year survival rate was 9%, $P<0,000001$. *Conclusions.* TKI are considered an effective and safe method of treatment for CML associated with a high MCyR rate in the chronic phase and a high CHR rate in the accelerated phase, therefore considerably improving patients' survival.

1527

SHWACHMAN-DIAMOND SYNDROME: CLINICAL REPORT OF TWO CASES

A Quintero

San Joan de Deu Hospital, Barcelona, Spain

Background. Shwachman-Diamond syndrome (SDS) is a rare autosomal-recessive, multisystem disease characterized by impaired hematopoiesis and exocrine pancreatic insufficiency. Other clinical features include skeletal, hepatic, cardiac disorders and short stature. Patients with SDS have an increased risk for myelodysplasia and acute myelogenous leukemia (AML). Marrow cytogenetic clonal abnormalities, particularly involving chromosome 7 (monosomy 7, der[7], i[7q] and del(20q)) have been reported. Around 90% of SDS patients have biallellic mutations in the Shwachman-Bodian-Diamond syndrome (SBDS) gene, located on chromosome 7 and involved in ribosome biogenesis. The most common cytopenia is neutropenia, with frequent impaired mobility, migration and chemotaxis of neutrophiles. Anemia and thrombocytopenia are less frequent. The cytopenias present in the earlier years of age and the incidence of transformation to AML has been reported as 5% in children, but increases with age (approximate-

ly 25% in adults). *Aim.* to report the diagnosis and evolution of two patients diagnosed with SDS in our center. *Results.* First case report: a 10 year old boy presented with neutropenia at 3 months of age. A bone marrow aspirate was performed, showing normal cellularity without signs of dysplasia nor stop in the granulocytic maturation. The cytogenetic study was normal. In the first year of age, the boy presented transaminitis and mild hepatomegaly, with low fecal elastase levels and mild steatorrhea. An SDS was suspected and molecular analysis was performed, showing a novel mutation in SBDS gene. The relatives were studied confirming the presence of the mutation in maternal grandmother. Subsequently, annually studies of bone marrow aspirate and karyotype have been done, without abnormalities. Currently the patient has no clinical nor analytical symptoms (steatorrhea or neutropenia). Second case report: a girl of 11 years was referred to our center for the study of chronic neutropenia and chromosome 7 abnormality. She had a history of self-limited transaminitis, recurrent otitis media with hearing loss, and diabetes mellitus. The bone marrow aspirate performed showed no dysplastic features and 4% blasts. The cytogenetic study displayed 46, XX [10] / 46, XX i (7) (q10) [10].The blood analysis showed low levels of fecal elastase and steatorrhea. A SBDS gene mutation was found confirming the SDS diagnosis. In the complementary studies to discard other alterations an atrial septal defect was found, requiring surgical correction. During the follow-up of the girl, the bone marrow was found progressively hypocellular without signs of dysplasia and new alterations in the karyotype were found: 46, XX del20q [10] / 46, XX. She has no clinical complications at present. *Conclusion.* SDS should be included in the differential diagnosis of children with chronic neutropenia and / or exocrine pancreatic insufficiency. Fecal elastase level is a good non-invasive test for exocrine pancreatic insufficiency. Once the SDS is suspected, some complementary studies must be done to confirm the clinical diagnosis, including molecular analysis of SBDS gene, a bone marrow aspirate and cytogenetics. In addition, studies of bone marrow during the follow-up are mandatory to exclude the progression to myelodysplasia and AML.

1528

IMPLICATIONS OF JAK2 MUTATION (V617F) ON THE EVOLUTION AND PROGNOSIS OF CHRONIC MYELOPROLIFERATIVE DISORDERS BCR-ABL NEGATIVE

M Balea,[1] D Georgescu,[1] I Nicorescu,[2] A Ilea[3]

[1]Clinical Hospital Colentina, Bucharest, Romania; [2]Emergency Universitary Hospital, Bucharest, Romania; [3]Ritus Biotec, Codlea/Brasov, Romania

This analysis of a lot consisting of 65 subjects, 22 male sex (33.8%) and 43 female (66.2%), 37 subjects with Jak2 mutation positive (57%) and 28 subjects with Jak2 mutation negative (43%), distribution are: polycythaemia vera: 23% (15 subjects), essential thrombocythaemia: 69% (45 subjects) and idiopathic myelofibrosis: 8% (5 subjects). Clinical data were studied: splenic enlargement, the frequency of thrombotic accidents and biological data: serum LDH level, uric acid, platelet number, erythrocyte number, leukocyte number, erythropoietin, degree of marrow fibrosis and therapeutic response. Subjects Jak2-positive men are 12 and have an average age of 56.5 years (42-73 years) and the Jak2-positive women are a total of 25, with a mean age of 65.6 years (32-87 years). Subjects Jak2-negative men are 10 and have an average age of 66 years (50-90 years) and the Jak2-negative women are a total of 18, with a mean age of 59.83 years (29-87 years). We found: massive splenomegaly in 28.5% of subjects Jak2-negative and in 16.2% of Jak2-positive, moderate splenomegaly in 60.7% of subjects Jak2-negative and in 67.6% of Jak2-positive, hypercelularrity on peripheral blood for 39.2% of subjects Jak2-negative and for 45.9% of Jak2-positive; maximum values of serum LDH to 21.4 % of subjects Jak2-negative and 21.69% respectively of the Jak2-positive; moderately elevated values of serum LDH to 71.4% of subjects Jak2-negative and to 70.2% of Jak2-positive; maximum values of serum uric acid at 21.4% of subjects Jak2-negative and at 21.6% of Jak2-positive; moderately elevated values serum uric acid to 60.7% of subjects Jak2-negative and to 54% of Jak2-positive; identical marrow fibrosis. Thrombotic complications (recurrent myocardial infarction, recurrent stroke, arterial and/or deep venous thrombosis or superficial, gangrene, pulmonary thrombosis *in situ*, microvascular infarction of the spleen) had an incidence of 11% in subjects Jak2-negative female and 44% in Jak2-positive women, respectively 10% in subjects Jak2-negative male and 83% in Jak2-positive male. The average age of thrombotic accidents was 55.8 years for subjects Jak2-positive men and 71.25 years for those of Jak2-positive women. For Jak2-negative subjects the average age of thrombosis was 72.5 years for women and 52 years respectively in men. Therapeutic response was identical. Statistical analysis indicates that the only statistically significant difference (P<0.01) is the incidence of thrombotic accidents in subjects Jak2-positive *vs.* Jak2-negative. *Conclusions.* Jak2 mutation have a potential thrombophilic risk.

THROMBOEMBOLISM PREDICTIVE FACTORS IN POLYCYTHEMIA VERA AND ESSENTIAL THROMBOCYTOPENIA

MI Ionita,[1] I Ionita,[1] R Pacurar,[2] DE Nicola,[2] CO Ionita,[1] V Todorescu,[1] H Ionita[1]

[1]UMF Victor Babes, Timisoara, Romania; [2]County Clinical Hospital, Timisoara, Romania

Background. Polycythemia vera (PV) and Essential Thrombocythemia (ET) are myeloproliferative chronic disease characterized by the frequent expression of JAK2V617F mutation (90% and 60% respectively). Thromboembolism is a complication that highly impacts on overall survival. *Aims.* A retrospective study of a group of patients affected by PV and ET, classified in accordance with WHO 2008 guide-lines, has been performed. We tried to study potential correlation between thrombotic events and clinical and laboratory variables. *Methods.* We retrospectively analysed the incidence of both arterial and venous thrombosis and their relationship with clinical variables. *Results.* We considered 125 patients:74 female and 51 male. A thrombotic event occurred in 29 patients (23,2%) during the course of their disease: 10 (8%) within the PV group (7 venous and 3 arterial) and only 19 (15,2%) within the ET group (12 venous and 7 arterial). The mean and median time between diagnosis and the occurrence of the thrombotic event were 279 and 172 days respectively. The mean and median time between the star of any treatment for the mieloproliferative disorder and the occurrence of the thrombotic event were 197 and 152 days respectively. Platelets (plt), leukocytes (wbc) and hematocrit (ht) at diagnosis were not statistical different between patients who had a thrombotic event and those who did not. Moreover blood count variables were not different between the diagnosis and the time of the thrombotic event. At the event time all the 29 patients with thrombosis were treated with ASA, and 21 of them received also cytostatics. *Conclusions.* We confirmed the high incidence rate of thromboembolic complications in patients affected by PV and ET. Leucocitosis has been suggested as a risk factor for thrombosis, but in our experience none of them statistically influenced the occurrence of a thrombotic event. This can be due to the relative low number of patients analyzed. The role of leukocytes and platelet number has to be analyzed in prospective studies.

1530

TREATMENT RESPONSE AND COMPLICATIONS OF PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA

MI Ionita,[1] L Cheveresan,[1] I Ionita,[1] DE Nicola,[2] CO Ionita,[1] A Pascalau,[2] D Oros,[1] H Ionita[1]

[1]UMF Victor Babes, Timisoara, Romania; [2]County Clinical Hospital, Timisoara, Romania

Background. Essential thrombocythemia (ET) is a myeloproliferative disorder characterized by persistent thrombocytosis. The frequency of JAK2V617F mutation is estimated at approximately 50% of the patients. Thrombotic episodes and bleeding complications are the most frequent events. Secondary malignancies can also occur. Hydroxyurea, anagrelide and interferon-α are available treatments. *Aims.* To asses the treatment response and complications in patients with essential thrombocythemia in our department. *Methods.* We studied retrospectively 97 patients, 41 male and 56 female with a median age of 52 years (27-80). Thrombosis at diagnosis presented in 16/97 patients and hemorrhage in 5/97. Median platelet count was 850×10^6/L (602-2500×10^6/L). Splenomegaly was present in 35 patients and fibrosis in 42. The majority of the patients received anagrelide and 10 interferon-α, 4 received a combined therapy with HU and interferon-α while 7 patients received no therapy. *Results.* Hemoglobin level and platelet count were similar in the two groups of patients. The WBC and PLT count was not correlated with thrombosis or bleeding at diagnosis. Of the patients receiving hydroxyurea, 89% had a response, a significantly higher percentage compared to the other therapy groups (P<0,001). Response was considered when a patient didn't need a second-line therapy in a not otherwise refractory disease. Response at six months (PLT<600.000×10^6/L) was more frequently seen with HU compared with anagrelide (P<0.05). A quick response did not

reduce the incidence of thrombotic or bleeding complications. Secondary malignancies were observed in 4/97 patients (4.12%) with no correlation to HU therapy. *Conclusions.* Our study showed a significant difference between the HU group of patients and those who did not receive HU as front line therapy with regard to therapy response. A response at six months did not affect the incidence of complications.

1531

CLINICOPATHOLOGICAL DIFFERENCES BETWEEN HIV-POSITIVE AND HIV-NEGATIVE PLASMABLASTIC LYMPHOMA

J Castillo, C Milani, M Jabbour, K Perez, E Winer, D Stachurski

The Miriam Hospital, Providence, RI, USA

Background. Plasmablastic lymphoma (PBL) is a distinct subtype of diffuse large B-cell lymphoma characterized by the malignant growth of lymphocytes with plasmablastic appearance. It is most commonly encountered in individuals with HIV infection and usually has an aggressive clinical course with a poor prognosis. PBL has also been described in patients without HIV infection. *Aims.* The objective of our study was to identify potential clinicopathological differences between HIV-positive and HIV-negative PBL. *Methods.* A comprehensive search using MEDLINE was made looking for HIV-positive and HIV-negative cases of PBL since January 1997 to June 2009. Plasmablastic microlymphoma or HHV-8-associated PBL cases were excluded from our study. Clinicopathological data was gathered, whenever available, and included age, sex, HIV status, clinical stage, site of involvement, presence of B symptoms, bone marrow involvement, EBV expression, Ki-67 expression, outcome and survival in months. Cases were separated according to their HIV status and groups were compared. The T-test was used to compare the age distribution of the groups. The Chi-square test was used to compare sex, stage, oral involvement, B symptoms, bone marrow involvement, EBV expression by EBER or LMP-1 and Ki-67 expression over 80% between groups. Survival curves were obtained using Kaplan-Meier estimates and then compared using the log-rank test. *Results.* Out of 194 identified cases, 181 reported HIV status, 130 were HIV-positive (72%) and 51 were HIV-negative (28%). The mean age for HIV-positive cases was 39 years (SE 10.12) and for HIV-negative cases was 55 years (SE 19.28) (P<0.0001). In terms of sex distribution, male cases were seen in 82% of HIV-positive cases and 62% of HIV-negative cases (P=0.0017). Oral involvement was seen in 64% of HIV-positive cases and 18% of HIV-negative cases (P<0.0001). EBV expression was seen in 69% of HIV-positive cases and 41% of HIV-negative cases (P=0.0068). Ki-67 expression higher than 80% was seen in 79% of HIV-positive cases and 39% of HIV-negative cases (P=0.0055). There were no differences between stage distribution, presence of B symptoms and bone marrow involvement. In terms of survival, HIV-positive cases had a median survival of 13 months (n=66) and HIV-negative cases of 9 months (n=41) (P=0.0015).

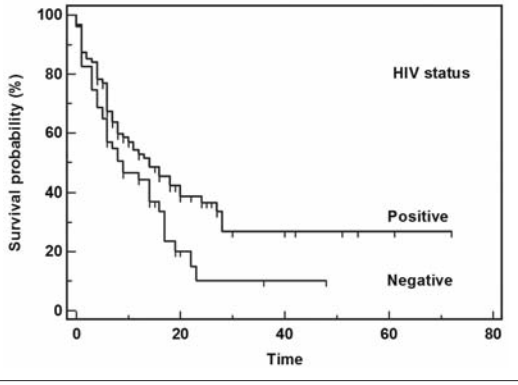

Figure. Survival for PBL according to HIV status.

Conclusions. HIV-positive and HIV-negative PBL have significant clinicopathological differences. HIV-positive PBL tend to affect younger individuals than HIV-negative PBL. It also tends to present more commonly in male patients, with oral involvement, EBV expression in the tumoral cells and higher percentages of Ki-67. Additionally, patients with HIV-positive PBL have a better prognosis than their HIV-negative counterparts. Further research is necessary to clarify these potential differences in order to improve our understanding of the physiopathology and biology of PBL.

EVALUATION OF CANCER-TESTIS ANTIGENS AS CANDIDATES FOR IMMUNOTHERAPY IN NON-HODGKIN´S LYMPHOMAS USING PROTEIN EXPRESSION AND SPONTANEOUS HUMORAL IMMUNE RESPONSE ANALYSES

R Inaoka,[1] A Jungbluth,[2] N Hanson,[2] D Frosina,[2] J Tassello,[2] S Gnjatic,[2] E Ritter,[2] F Carvalho,[1] L Etto,[1] A Alves,[1] M Franco,[1] G Colleoni[1]

[1]Federal University of Sao Paulo, Sao Paulo-SP, Brazil; [2]Ludwig Institute for Cancer Research, New York, USA

Cancer-testis antigens(CTAs) are expressed in a variety of malignant tumors and in normal adult tissues solely in testicular germ cells. Based on this tumor-associated expression pattern, these antigens are potential targets for immunotherapy. Though carcinomas have been extensively analyzed, less is known about other malignancies such as non-Hodgkin's lymphoma (NHL). *Aims.* To evaluate the potential of tumor specific antigens as candidates for immunotherapy in NHL throughout CTAs protein expression and spontaneous humoral immune response analyses. *Methods.* A tissue microarray was generated from 106 archival cases of NHL. Immunohistochemistry(IHC) was done using a panel of 9 monoclonal antibodies (to the following CTAs): MA454(MAGE-A1), M3H67(MAGE-A3), 57B(MAGE-A4), CT7-33(CT7/MAGE-C1), CT10#5(CT10/MAGE-C2), E978(NY-ESO-1), 219-510-23(LAGE-1 and NY-ESO-1) and #26(GAGE). Spontaneous humoral immune response against 9 CTAs (MAGE-A1, MAGE-A3, MAGE-A4, MAGE-A10, NY-ESO-1, CT7, CT10, LAGE-1 and GAGE-2) was tested in 97 untreated NHL patient samples, including 63 cases from the TMA cohort, using ELISA technique. *Results.* 12/106(11.3%) NHLs expressed at least 1 of 9 CTAs. DLBCL showed the highest frequency among positive cases. The 12 positive cases were: 9/56 diffuse large B-cell lymphoma(DLBCL), 1/2 anaplastic large cell lymphoma(ALCL), 1/3 lymphoplasmacytic lymphoma and 1/9 peripheral T-cell lymphoma. Among the 12 positive cases, 4 had low, 5 intermediate and 2 high IPI score (1 case was unclassified). Four of these positive cases obtained complete response and 8 partial response or progressive disease using CHOP-like regimens. The most frequently expressed CTAs were GAGE(5.7%), NY-ESO-1(4.8%), CT7(4.8%), MAGE-A1(3.8%) and MAGE-A3(3.8%). In ELISA analyses, 13(13.4%) of 97 LNH sera samples expressed at least 1 of 9 CTAs. Among the 13 positive cases, 6/50 were DLBCL, 2/4 were mantle cell lymphoma, 2/10 were FL, 2/3 were small lymphocytic B-cell lymphoma and 1/2 was ALCL. Five of these patients had low, 4 intermediate and 2 high IPI score (2 cases were unclassified). Seven cases obtained complete response and 6 had partial response or progressive disease, using CHOP-like regimens. The spontaneous humoral immune response was more frequent against NY-ESO-1(5.1%), MAGE-A4(5.1%) and MAGE-A3(4.1%). In the 63 cases with both tissue and sera available, we found 3 positive cases by IHC and 10 positive cases by ELISA; 2/4 IHC-positive cases were also positive by ELISA and 1 IHC positive case was negative by ELISA. We also tested the spontaneous humoral response against CT24(0%), CT45(5.1%), CT46(0%), CT47(7.2%), CT63(1%), CT83(0%), SSX-1(0%), SSX-2(1%), SSX-4(1%), SAGE-1(0%) and XAGE-1(0%) in order to analyze other CTAs in addition to the IHC panel. *Conclusions.* To our knowledge this is the first side by side analysis of the protein expression of CTAs and the autologous serological response in NHL patients. We found low expression (~13%) of CTAs in our series of NHL TMA and sera samples. However, other CTAs should be explored to establish the real potential of these antigens as candidates for immunotherapeutic approach in NHL. Considering that most of advanced stage low-grade lymphomas, mantle cell lymphoma and T-cell lymphomas are still incurable diseases and need the development of new therapeutic approach, these tumors should be further explored as to the presence of CTAs.

1533

ESTABLISHMENT, CHARACTERIZATION AND PHARMACOLOGIC EVALUATION OF A UNIQUE IN VITRO AND EX VIVO STUDY MODEL FOR B-CELL NODAL MARGINAL ZONE LYMPHOMA

Z Rassidakis,[1] P Tsioli,[2] K Dimas,[3] V Atsaves,[2] A Anronoglou,[2] T Vassilakopoulos,[2] P Panayiotidis,[2] E Patsouris[2]

[1]National and Kapodistrian University of Athens, Athens, Greece; [2]National snd Kapodistrian University of Athens, Athens, Greece; [3]Biomedical Research Foundation, Academy of Athens, Athens, Greece

Background. A number of cell lines derived from patients with B-cell non-Hodgkin lymphomas (B-NHL) have been established over the last decades and served as research tools for *in vitro* studies focusing on the

mechanisms of lymphomagenesis as well as testing of new therapeutic approaches for these patients. However, the established B-NHL cell lines have been derived mostly from aggressive, high proliferating B-NHL, while cell lines derived from patients with "low-grade"B-NHL types are largely lacking. *Aims.* This study aimed to develop and characterize a novel *in vitro* and *ex vivo* study model for B-cell nodal marginal zone lymphoma (NMZL). *Methods.* Primary tumor cells obtained from a lymph node biopsy specimen were put in culture, and the suspension cells were maintained under culture conditions in RPMI medium with increased concentration of FBS (20%). When the cells overcame the cell culture crisis and started to proliferate, 10X106 cells were injected subcutaneously in SCID mice, which subsequently developed xenografts. Cells from xenografts were sub-cultured and re-injected in new SCID mice and this procedure was repeated three times. The established cell line named "LGH1"and its first xenograft (xLGHp1), were characterized by immunophenotypic (flow cytometry), immunohistochemical and cytogenetic analysis. A number of drugs were tested for activity against both the LGH1 primary cells and the cells originated from the xenograft (xLGHp1) using the Sulforhodamine B, trypan blue exclusion, MTS and other assays. *Results.* Cell line was derived from a 66-year old patient presented with non-bulky left inguinal lymphadenopathy and no other symptoms or physical findings. Thoracic and abdominal CT scans as well as upper GI endoscopy were negative. A bone marrow biopsy and immunophenotype were negative. Both blood and bone marrow samples were negative for clonal immunoglobulin rearrangements by PCR. Lymph node biopsy was consistent with a NMZL with a cell proliferation index (Ki-67) of 10-15%. Conventional clinical stage was IA; PET-based stage was IIA. Immunophenotypic analysis (flow cytometry) and immunohistochemistry performed on cell blocks from cultured cells were typical for NMZL consistent with the original histologic diagnosis. LGH1 cell karyotype was normal (46, XY). Mutation analysis revealed wild-type p53 gene. Pharmacologic evaluation showed no significant differences regarding their response to the drugs between the LGH1 and xLGHp1 cells. The most active drugs in this NMZL model were found to be the two anthracyclines doxorubicin and epirubicin with growth inhibiting activities at 1μM. In addition, LGH1 cells responded significantly to nutlin 3A (10μM), a potent MDM2 inhibitor that stabilized and activates wild-type p53. Moderate biologic responses to rapamycin were observed at a concentration of 40nM. Fludarabine, one of the established drugs used for lymphoma treatment, was found to be almost inactive as it demonstrated marginal activity at the highest concentration tested (100μM). *Conclusions.* A unique *in vitro* and *ex vivo* model for NMZL was established and characterized, thus providing a research tool to perform new mechanistic studies in order to shed light on the NMZL pathogenesis. Furthermore, pharmacologic studies using LGH1 may lead to the development of novel targeted therapies for patients with NMZL.

1534

INHIBITION OF THE INTRINSIC APOPTOSIS PATHWAY IN FOLLICULAR LYMPHOMA IS CAUSED BY DYSREGULATION OF THE MITOCHONDRIA

M Wondergem,[1] L Holtman,[1] L Moesbergen,[1] L Appelman,[1] N Rekers,[1] J Oudejans,[2] J Zijlstra,[1] P Huijgens,[1] C Meijer,[1] S Cillessen[1]

[1]VU University Medical Center, Amsterdam, Netherlands; [2]Diakonessenziekenhuis, Utrecht, Netherlands

Aim. Inhibition of the apoptosis cascade is an important cause of therapy resistance in follicular lymphoma (FL). In this study we investigate possible mechanisms in the apoptosis pathway and expression levels of apoptosis related genes that may be responsible for differences in chemotherapy sensitivity between FL patients. *Methods.* Isolated lymphoma cells of 30 FL patients and 5 samples of centroblasts and centrocytes of healthy donors were investigated for their expression levels of apoptosis related genes using RT-Multiplex Ligation dependant Probe Amplification (RT-MLPA) analysis. Functional analysis of the intrinsic caspase 9 mediated pathway was performed using immunohistochemistry and FACS analysis. *Results.* All FL samples tested demonstrated inhibition of the intrinsic apoptosis pathway and resistance to etoposide. Using RT-MLPA analysis different expression patterns of apoptosis regulating genes were observed: one group characterized by extremely low pro-apoptotic gene expression, and one group with relatively low pro-apoptotic and high anti-apoptotic gene expression. Functional analysis revealed very low spontaneous caspase 9 activity and impermeability of the mitochondrial membrane in FL patient cells. Furthermore, Bcl-2 and/or Bcl-XL expression were high in the majority of the FL samples. In these cases, apoptosis could be restored using a Bcl-2/Bcl-XL antagonist. *Conclusion.* We conclude that in most FL patient samples the intrinsic caspase 9-mediated pathway is inhibited upstream by disruption of the function of the mitochondria. Apoptosis can be restored by treatment with a Bcl-2/Bcl-XL antagonist which therefore might be an alternative therapy option for FL.

P-GLYCOPROTEIN EXPRESSION IS ENHANCED IN EPSTEIN-BARR VIRUS (EBV)-INFECTED T OR NK CELLS AND MAY CAUSE DRUG RESISTANCE OF CHRONIC ACTIVE EBV INFECTION

A Arai,[1] M Takahashi,[2] K Imadome,[3] M Kurata,[2] T Koyama,[2] S Fujiwara,[3] O Miura[2]

[1]Department of Hematology, Tokyo Medical and Dental University, Tokyo, Japan; [2]Tokyo Medical and Dental University, Tokyo, Japan, Tokyo, Japan; [3]National Research Institute for Child Health and Development, Tokyo, Japan, Tokyo, Japan

Background. Epstein-Barr virus (EBV) infects B cells and occasionally T or NK cells, causing EBV-positive T/NK-cell lymphoproliferative disorders (EBV-T/NK-LPD). Chronic active EBV infection (CAEBV), a form of EBV-T/NK-LPD, is a rare disease accompanied by persistent infectious mononucleosis-like syndrome and associated with high titers of antibodies against EBV. CHOP is usually selected as first-line treatment. However, it has resulted in limited effects while prognosis remains very poor. *Aims.* To clarify the molecular mechanism of chemoresistance of CAEBV, we focused on multi-drug resistance 1 (MDR1) gene expression. This gene encodes for P-glycoprotein (P-gp), which is a well-known drug efflux pump. It was previously reported that cells of extranodal NK/T-cell lymphoma (ENKL), a form of EBV-T/NK-LPD, expressed P-gp, resulting in high resistance to CHOP. We analyzed its expression and function in cells derived from CAEBV patients. *Methods.* CAEBV was diagnosed according to the criteria suggested by Okano M. *et al*. (Am J Hematol 80:64-9, 2005). To detect and isolate EBV-infected cells, T and NK cells were separated using magnetic beads from peripheral blood mononuclear cells of CAEBV patients. DNA was extracted and EBV-DNA was quantified using a real-time quantitative PCR assay. The clonality of EBV was determined by southern blotting using a terminal repeat probe. Transcription of MDR1-RNA and expression of P-gp was examined by RT-PCR and flow cytometry (FCM), respectively. The fluorescent compound rhodamine 123 was used as a P-gp substrate to examine the function of P-gp. SNK6, derived from ENKL, and MD901, a B-cell lymphoma cell line, were used as positive and negative controls, respectively. The study was approved by the ethical committee and written informed consent was obtained from each patient. *Results.* Four CAEBV patients were diagnosed and treated with CHOP in our hospital. Patient age at the start of treatment ranged from 24 to 48. The infected cells were T cells in all the patients ($CD4^-$ or CD8-positive in 1 or 3 cases, respectively). Monoclonal expansion was confirmed in all patients. After treated with CHOP, 3 patients demonstrated no effects, and only 1, CD4-type patient, achieved 1-log reduction of EBV-DNA in peripheral blood. EBV-infected cells derived from 13 CAEBV patients (aged 8-45 years; 6 male, 7 female; 2 $CD4^-$, 4 $CD8^-$, 6 $CD56^-$, and 1 γδ-cell types) were investigated. Transcription of MDR1 was detected in all patients. P-gp expression was confirmed by FACS. The mRNA level of MDR1 was highest in CD56-positive cells and lowest in $CD4^+$ cells, which was compatible with the effect of CHOP in our patients. In addition, function of P-gp was confirmed by rhodamine 123 efflux assay in 5 patients. Efflux was completely inhibited by treatment with a P-gp inhibitor, cyclosporin A, which induced CAEBV cell death synergistically with doxorubicin. *Conclusion.* EBV-infected T or NK cells expressed P-gp, which may contribute to multi-drug resistance of CAEBV. Differences in expression level between the infected cells were observed, suggesting that a different treatment strategy should be considered for each disease type. Further studies analyzing more cases should be performed to establish the optimal treatment.

1536

DOWNREGULATION OF CD19, CD20 AND CD22 SURFACE EXPRESSION ON MANTLE CELL LYMPHOMA BY LENALIDOMIDE

E Eve,[1] J Richardson,[2] S Rule[1]

[1]Derriford Hospital, Plymouth, UK; [2]Peninsula College of Medicine & Dentistry, University of Plymouth, Plymouth, UK

Background & Aims. Lenalidomide is a second-generation immunomodulatory drug with clear activity against mantle cell lymphoma (MCL) as a single agent. Recent clinical trials have investigated combining lenalido-

mide with the anti-CD20 monoclonal antibody rituximab in an attempt to further improve efficacy in MCL. However, lenalidomide has been shown *in vitro* to downregulate CD20 surface expression on primary chronic lymphocytic leukaemia cells thereby diminishing rituximab-mediated apoptosis and antibody-dependent cellular cytotoxicity. With the increasing use of rituximab for the treatment of MCL together with the advent of new therapeutic monoclonal antibodies against alternative B cell markers such as CD19 and CD22, we evaluated the effects of lenalidomide on the surface expression of these antigens using the MCL cell line Granta 519. *Methods.* Granta 519 cells (0.5×10^6/mL) were incubated in complete culture medium with or without dimethyl sulphoxide (DMSO, vehicle control), thalidomide (1 μg/mL or 10 μg/mL) or lenalidomide (0.26 μg/mL or 10 μg/mL) for up to 72 hours. The lower concentrations of thalidomide and lenalidomide were chosen to represent therapeutic plasma levels achievable in patients. CD19, CD20 and CD22 surface expression on Granta 519 cells was quantified by flow cytometry after 24, 48 and 74 hours. Results were expressed as mean percentage change compared to control (complete culture medium alone), and Students t test was used to determine differences between the treatment arms at each timepoint. Two-tailed p values <0.05 were considered statistically significant. *Results.* Incubation for up to 72 hours with thalidomide did not result in any significant change of CD19, CD20 or CD22 surface expression on Granta 519 cells. In contrast, lenalidomide 10 μg/mL significantly downregulated CD20 surface expression at 24, 48 and 72 hours with a mean reduction of 14.0% (P=0.0371), 28.1% (P=0.0219) and 28.4% (P=0.0003) respectively. Moreover, lenalidomide 0.26 μg/mL also significantly downregulated CD20 surface expression at 72 hours with a mean reduction of 22.0% (P=0.0043). Preliminary analysis of CD19 surface expression showed a similar pattern of downregulation following treatment with lenalidomide 10 μg/mL for 48 hours (mean reduction 22.7%, P=0.0372) and lenalidomide 0.26 μg/mL for 72 hours (mean reduction 17.2%, P=0.0223). Preliminary analysis of CD22 surface expression also revealed significant downregulation with lenalidomide 10 μg/mL at 48 hours (mean reduction 30.9%, P=0.0254) as well as a trend towards downregulation with lenalidomide 0.26 μg/mL (mean reduction 19.6%, P=0.0821). Summary/*Conclusion.* Lenalidomide at a concentration achievable in plasma (0.26 μg/mL) has the ability to downregulate the B cell markers CD19, CD20 and CD22 on the MCL cell line Granta 519. This has clear implications when considering the combination of lenalidomide with monoclonal antibodies directed against these surface antigens, and would suggest that a sequential approach to administering these agents may be more efficacious than a simultaneous one. Further confirmatory work utilising primary MCL cells isolated from patients is ongoing.

1537

DIFFUSE LARGE B CELL LYMPHOMA: DIFFERENCES IN BIOLOGICAL CHARACTERIZATION OF THE NODAL VERSUS EXTRANODAL PRESENTATION BY IMMUNOHISTOCHEMISTRY

MK Kim,[1] S Bae,[2] HM Ryoo,[2] WS Lee,[3] YD Joo,[3] SA Koh,[1] HY Lee,[1] YK Bae,[1] HS Cho,[1] KH Lee,[1] MS Hyun[1]

[1]Yeungnam University College of Medicine, Daegu, South-Korea; [2]Catholic University of Daegu School of Medicine, Daegu, South-Korea; [3]Inje University, Busan Paik hospital, Busan, South-Korea

Introduction. We hypothesized that diffuse large B cell lymphoma (DLBCL) with primary extranodal origin may be immunophenotypically different from primary nodal origin. Primary extranodal lymphoma cells may originate from activated B cell rather than germinal center B cell. We evaluated the clinicopathological features of patients with diffuse large B cell lymphoma (DLBCL) according to the primary site, lymph node or different extranodal organs of the disease. *Patients and methods.* Immunohistochemistry was performed for detection of CD10, Bcl-6, Bcl-2 and MUM1 in paraffin-embedded tissue from 123 patients with DLBCL. We classified cases into germinal center B-cell like (GCB) and non-GCB groups using the immunohistochemical expression of CD10, bcl-6, or MUM1 by Hans' algorithm. Lymphomas presenting in extranodal organs with no or only minor lymph node involvement were considered primary extranodal and those lymphomas with extensive disease involving both nodal and extranodal sites were considered nodal. Statistical analysis was performed using χ^2 and Fisher's exact tests. Survival data were analyzed by the Kaplan-Meier method and compared using a log-rank test. *Results.* Thirty-eight (31%) of the 123 cases were of germinal center phenotype ($CD10^+$ or $CD10^-$, $Bcl\text{-}6^+$, and $MUM1^-$) and 85 (69%) were of non-GCB phenotype (all CD10- and either $bcl\text{-}6^-$, or $bcl\text{-}6^+$ and $MUM1^+$). Fifty-one patients (42%) presented at primary extranodal sites. The distinction according to the extranodal sites was as follows; GI tracts (29; 14 cases of stomach and 15 cases of Intestine); testis/ovary/adrenal (4); skin/soft tissue (3); thyroid/parotid (3); bone/bone marrow (2); pancreas (2); cervix (2); and prostate (1). Five patients showed multiple extranodal lymphomas. Of these, 16 (31%) was classified as GCB subtype and 35 (69%) was non-GCB subtype. 3 (20%) in the intestines were GCB subtype and 7 (50%) in the gastric DLBCL were of GCB subtype (P=0.12). 72 patients had a primary nodal DLBCL. Of these, 22 (31%) was classified as GCB subtype and 50 (69%) was non-GCB subtype. There was no difference in frequencies of GCB and non-GCB subtype between primary extranodal and primary nodal DLBCL. However, Bcl-2 expression is less frequent in primary extranodal disease (P=0.008). Among stage I or II patients, primary extranodal DLBCL showed a trend toward better overall survival than primary nodal DLBCL (P=0.09) and among stage III or IV patients, there was no survival difference between the two groups. *Conclusion.* Consistent with previous reports, the GCB subtype of DLBCL was less frequent in Asian. There was no difference in GCB and non-GCB phenotype in primary extanodal and primary nodal DLBCL in our patient population. Further studies are warranted to elucidate the molecular differences between primary extranodal and primary nodal lymphoma.

CLONAL EVOLUTION IN A CASE OF HEPATOSPLENIC T CELL LYMPHOMA

V Martinelli,[1] A Gravetti,[1] A Peluso,[2] G Giagnuolo,[3] E Madonna,[3] G Scalia,[2] V Martinelli,[3] L Del Vecchio,[2] F Pane[3]

[1]Federico II Ematologia, Napoli, Italy; [2]Ceinge, Napoli, Italy; [3]Ematologia Federico II, Napoli, Italy

γHepatosplenic T-cell lymphoma (HSTCL) is an uncommon disease. It is characterized by involvement of the spleen, liver and often bone marrow (BM). HSTCL affected Patients usually show hepatosplenomegaly and cytopenias; lymphadenopathy is minimal or absent. The disease has a progressive clinical course and poor prognosis. Here, we describe the case of a 51-years old gamma-delta HSTCL affected female.In May 2006, the Patient showed massive hepatosplenomegaly; blood counts revealed mild pancytopenia. The Patient underwent splenectomy, hepatic biopsy and BM analysis. The three parenchymas were infiltrated by a population of abnormal lymphoid cells. Cytofluorimetric analysis of BM, spleen and liver biopsy showed $CD45^+$ $CD2^+$ $CD3^+$ $CD7^+$ $CD56^+$ TcR-$\gamma\delta^+$ $CD5^-$ $CD4^-$ $CD8^-$ neoplastic cells. Molecular analysis, performed by denaturing high-performance liquid chromatography (DHPLC), showed clonal rearrangement of TcR-γ chain gene on the same samples. Sequencing analysis of both DNA strands confirmed DHPLC results, by allowing us to identify the monoclonal rearrangement Vγ10-JγP1. Therapy consisted of six CEOP-14 regimen. In December 2006 a complete remission (CR) was demonstrated by immunological, histological and molecular analysis of BM and liver biopsy. CR lasted 21 months; in February, 2008 mild pancytopenia appeared. Positron emission tomography - computed tomography (CT-PET), immunophenotipic and histological studies were negative; TcR-γ clone was not detectable. In September 2008 anaemia worsened, mild elevation of liver enzyme and abnormal serum ferritin appeared. Histological BM biopsy was positive for lymphoma infiltration, despite negative cytofluorimetric and morphological analysis. Histological and cytofluorimetric analysis of liver biopsy were both positive for T lymphoma with $CD45^+$ $CD2^+$ $CD7^+$ $CD56^+$ $CD3^-$ $CD5^-$ $CD4^-$ $CD8^-$ TcRαβ$^-$, TcRγδ$^-$ large abnormal lymphocytes. Molecular study showed the Vγ10-JγP1 and an additional Vγ11-JγP1 clonal rearrangement on bone marrow.The Patient was treated with four cycles of DHAP reaching CR (at liver level as well); in March 2009, she underwent auto-TMO. In August 2009, a second relapse occurred. On liver biopsy, histological study showed absence of neoplastic cells, but cytofluorimetric analysis was positive for large neoplastic cells. BM biopsy was positive for lymphoma infiltration. The Patient was treated with GEMOX regimen. In November 2009, sequencing analysis on bone marrow biopsy detected only the Vγ11-JγP1 clone; cytofluorimetric analysis identified a NK-like immunophenotype cell population; one cycle of Nelarabine was administered but the Patient died on December 2009. With the aim to add data in a rare disease like HSTCL we want to point of: (a) immunophenotypic changes from a T-cell ($CD45^+$ $CD2^+$ $CD3^+$ $CD7^+$ $CD56^+$ TcRγδ+ $CD5^-$ $CD4^-$ $CD8^-$, at diagnosis) to a NK-like ($CD45^+$ $CD2^+$ $CD7^+$ $CD56^+$ $CD3^-$ $CD5^-$ $CD4^-$ $CD8^-$ TcRγδ-, at second relapse) immunophenotype; (b) the evidence of two different clonal rearrangements of TcR-γ- chain gene (Vγ10-JγP1 and Vγ11-JgP1).

PROINFLAMATORY CHEMOKINE GENE EXPRESSION INFLUENCES SURVIVAL OF PATIENTS WITH NON-HODGKIN'S LYMPHOMAS

G Mazur,[1] E Jaskula,[2] I Kryczek,[2] D Dlubek,[2] A Butrym,[3] T Wrobel,[3] A Lange,[2] M Jelen,[4] K Kuliczkowski[3]

[1]Wroclaw Medical University, Wroclaw, Poland; [2]Ludwik Hirszfeld Institute of Immunology and Experi-mental Therapy, Polish Acade, Wroclaw, Poland; [3]Dept. of Haematology, Wroclaw Medical University, Wroclaw, Poland; [4]Dept of Pathomorphology, Wroclaw Medical University, Poland, Wroclaw, Poland

Background. Cell migration, surviving and proliferation creates base for all physiologic and pathologic process in human body. All those reactions are regulated by complex chemokine network, that guides lymphocytes homing, chemotaxis, adhesion and interplaying between immunologic system response cells. Chemokines also are responsible for metastatic dissemination of cancers, including Hodgkin's and non-Hodgin's lymphomas. *Aim.* The purpose of the study was to determinate chemokine gene expression (CXCL8, CXCL10, CCL2, CCL3, CCL4 and CCL5) in lymphoma lymph nodes comparing to their expression in reactive lymph nodes. We also wanted to analyze the influence of chemokines gene expression on lymphoma patient survival. *Methods.* Chemokine gene expression was evaluated in 37 lymphoma lymph nodes (16 women and 21 men, aged 18-81 years; median age 43 years) at the moment of diagnosis. In 25 samples of reactive lymph nodes (taken from 15 women and 10 men; aged 18-59; median age 32 years) expression of chemokine genes was also studied. Gene expression of chemokines CXCL8, CXCL10, CCL2, CCL3, CCL4 and CCL5 was measured by PCR method and estimated in arbitrary units (AU) from 0 to 3 AU points scale. PCR was conducted using primer pairs for CCL2 (sense TCC AGC ATG AAA GTC TCT GC, antisense TGG AAT CCT GAA CCC ACT TC, 245 bp), CCL3 (sense GTC ATC TTC CTA ACC AAG CG, antisense TGT GGC TGT TTG GCA ACA AC, 229 bp), CCL4 (sense AGG AAG CTT CCT CGC AAC TT, antisense AGT CCT GAG TAT GGA GGA GA, 244 bp), CCL5 (sense CAT TGC TAC TGC CCT CTG CG, antisense GGG TTG GCA CAC ACT GTT CG, 192 bp), CXCL8 (sense TTG GCA GCC TTC CTG ATT, antisense AAC TTC TCC ACA ACC CTC TG, 403 bp), CXLC10 (sense TGG CAT TCA AGG AGT ACC TC, antisense TGT AGG GAA GTG ATG GGA GA, 326 bp), β-actin (sense GGG TCA GAA GGA TTC CTA TG, antisense GGT CTC AAA CAT GAT CTG GG, 250 bp). Statistical analysis was performed using the CSS Statistica for Windows (version 7.0) software. Probability values <0.05 were considered statistically significant and those between 0.05 and 0.1 as indicative of a trend. *Results.* Lower expression of CXCL10 gene was found in lymphoma lymph nodes comparing to reactive lymph nodes (P=0.002). In lymphomas CCL2 (P=0.0008) and CCL3 expression in was higher than in reactive lymph nodes. Patients with high expression of CCL2 (P=0.004) and CXCL10 (P=0.002) had significantly shorter survival. *Conclusions.* CCL2 and CXCL10 expression seems to be important in non-Hodgkin's lymphomas, as it has shown to have predictive value on patients' survival.

1540

IDENTIFICATION OF T(11;14)(Q13;Q32) IN VARIOUS HEMATOPOIETIC LINEAGES OF MANTLE CELL LYMPHOMA PATIENTS. JOINT APPLICATION OF FLUORESCENCE-ACTIVATED CELL SORTING AND FLUORESCENCE IN SITU HYBRIDIZATION

V Vorobiev, E Gretsov, T Obukhova, E Domracheva, Y Lorie, V Zherebtsova, I Vorobjev

National Research Center for Hematology, Moscow, Russian Federation

Background. Mantle cell lymphoma (MCL) is a distinct incurable B-cell neoplasm with a median survival of 3 to 5 years. t(11;14)(q13;q32) is the hallmark of the disease leading to overexpression of protooncogene cyclin D1. Chemoresistance to conventional treatment and continuous disease relapses even after high dose therapy and auto stem cell transplantation define the clinical course of the disease. A possible cause of this frequent recurrences may be that t(11;14)(q13;q32) occurs in early hematopoietic precursors, capable of multilineage differentiation. *Aim.* evaluation of t(11;14)(q13;q32) in different hematopoietic lineages of MCL patients. *Methods.* Bone marrow mononuclears from 4 MCL patients were sorted by Fluorescence-Activated Cell Sorting (BD FACSVantage SE) to divide the following lineages of hematopoiesis: $CD45^+CD34^+$ (progenitor cells); $CD45^+CD5^+CD19^+$light chain Ig (mantle cell lymphoma); $CD45^+CD5^-CD19^+$ (normal B-cells); $CD45^+CD14^+$ (monocytes); $CD45^+CD3^+$ (T-cells); $CD45^-GlyA^+$ (erythrokaryocytes) and granulocytes by light scattering, without range including $CD14^+CD45^+$ cells. The purity of sorted cells was checked by flow cytometry (BD FACSCanto II) and directly correlated to the number of sorted cells - if the cells were more than 50 thousands the purity was more than 92% (usually more 97%), but if the cells were less than 20 thousands the purity was 80% (never the less). After sorting cells in the test-tube were washed from the salt solutions, fixed in methanol and glacial acetic acid mixture and layered onto slides by cytospin cytocentrifuge (Cellspin II Tharmac) in 8 minutes, 1000 rpm. Furthermore, the probes have been denatured at 75oC for 6 minutes, and hybridized with dual fusion LSI IGH-CCND1 probes (Vysis Inc.) at 37oC for 17-20 hours. Signals were visualized with Olympus microscope with triple filter cube (DAPI / FITC / TexasRed). *Results.* In sorted mantle cell lymphoma cells t(11;14)(q13;q32) was present in more than 80%, whereas in cells of all other lineages including normal B-cells t(11;14)(q13;q32) was less than 0,5%. However, direct assessment of t(11;14)(q13;q32) in $CD34^+CD45^+$ cells and in normal B-cells was difficult due to the small population of these cells and further studies are required for more definite conclusion. *Conclusions.* Out data suggests the absence of t(11;14)(q13;q32) in pluripotent stem cells, and the direction of our future research would be the search for t(11;14)(q13;q32) in early B-cell lymphoid progenitors.

1541

CD10 EXPRESSION IN LYMPH NODE STROMAL CELLS DOES NOT SIGNIFICANTLY INFLUENCE GENE EXPRESSION ANALYSIS OF CD10 POSITIVITY OR NEGATIVITY OF A TUMOR

H Votavova,[1] K Forsterova,[1] V Campr,[2] J Stritesky,[1] Z Velenska,[1] R Pytlik,[1] B Prochazka,[3] M Trneny[4]

[1]Charles University General Hospital, Prague, Czech Republic; [2]Motol University Hospital, Prague, Czech Republic; [3]National Institute of Public Health, Prague, Czech Republic; [4]Charles University in Prague, Prague, Czech Republic

Backgroung. Gene expression profiling (GEP) is a method widely used in science. For example, diffuse large B-cell lymphoma (DLBCL) was divided into three groups with the method. One of the important molecules in DLBCL subclassification is CD10 and its expression in tumour cells. Complete paraffin slides without using laser dissection are commonly used in GEP examination, however, CD10 molecule is sometimes expressed also in nonmalignant stromal cells of a lymph node. *Aims.* Our aim was to analyze whether CD10 positivity of stromal cells in CD10 negative tumours can elevate the GEP result so much that such a sample could be considered a CD10 positive tumour. *Methods.* 69 formalin-fixed, paraffin embedded (FFPE) samples of verified DLBCLs were included in the study. RNA extraction and RTqPCR analysis were performed following the protocol we previously published. Only cases with 80% and more malignant cells in the slide were included. Immunohistochemical CD10 staining using standard methods was performed on FFPE slides. The percentage of CD10 positive cells was evaluated in the malignant and stromal cell population in each sample. Cut off of 10% was used as a criterion of positivity. *Results.* Tumors were divided into four groups accordig to their tumor(T)/stromal(S) positivity and their combinations: Group1 T^-/S^-, group 2 T^-/S^+, group 3 T^+/S^- and group 4 T^+/S^+. CD10 positive and negative tumours were significantly different from each other (P<0,001), regardless of the positivity or negativity of the stroma. Groups 1 and 2 were not significantly different in CD10 gene expression (P=0,096). Groups 2 and 3 were significantly different (P=0,012) from each other. Group 2 differed significantly also from group 4 (P<0.001). Positive tumours did not show significant difference between stromal positive and negative cases (P=0,820).*Summary/Conclusions.* CD10 stromal positivity slightly elevates CD10 level measured with real-time quantitative polymerase chain reaction (RTqPCR), however, such elevation is not statistically significant and does not reach the expression level of positive tumors. There is an obvious difference in CD10 gene expression between T^-/S^+ and T^+/S^- samples and between T^-/S^+ and T^+/S^+ ones.

ANGIOGENESIS IN INDOLENT NON-HODGKIN'S LYMPHOMA (NHL)

A Guarini,[1] C Minoia,[1] A Iacobazzi,[1] A Rana,[1] A Lapietra,[1] M Giannoccaro,[1] A Ferrucci,[2] G Daniele,[1] A Vacca,[2] A Zito[1]

[1]NTL Cancer Institute Giovanni Paolo II, Bari, Italy; [2]Dept Internal Medicine and Oncology, Bari, Italy

Background. The role of angiogenesis in lymphoma is still under active investigation. Microvessel density (MVD) measures lymphoma neovas-

cularity with a wide range of results reported in the literature. Indeed, the clinical predictive value of MVD with respect to underlying lymphoma subtypes remains unclear. MVD at diagnosis is more represented in aggressive histotypes than in indolent ones. Increased vascularization is associated with both poor outcome and resistance to therapies in diffuse large B-cell lymphoma, independently from the IPI score. Few data are available in relapsed/refractory indolent NHL. Stromal cells (mostly monocytes and macrophages) and tumor microenvironment contribute to neo-angiogenesis with several authors reporting possible correlations among macrophage infiltration, neovascularity and prognosis. *Aim.* The aims of this study are the analysis of neoangiogenic pattern of indolent NHL patients (pts) and the role of stromal cells in neovascularisation at diagnosis and relapse/progression disease in order to identify a subset of pts that could benefit by integrated antiangiogenic treatment. *Patients and methods.* Nodal and bone marrow biopsies from 6 follicular (FL) and 7 small lymphocytic (SLL) NHL's pts were selected and studied at diagnosis and disease relapse/progression (9 males and 5 female; mean age at diagnosis 59.8 yrs; 13/13 stage III/IV; low/intermediate FLIPI 7/13 pts, high risk FLIPI 6/13 pts, 8 relapsed pts with median PFS 33.37 months and 5 refractory). We evaluated MVD both by immunohistochemistry (anti-CD34) and morphometric analysis (vascular hot spots, vhs/field) and the monocytic-macrophagic infiltrating cells (anti-CD68). *Results.* At diagnosis we observed an angiogenic activity in all nodal samples with an homogeneous vascular distribution in SLL and perifollicular in FL (mean of 27.50 vascular hot spots (vhs)/field; median of 20 vhs/field in nodal biopsies). Moreover, at onset patients with low/intermediate prognostic risk showed a higher vhs/field. The number of vhs/field increased in all cases at relapse/progressive disease (mean 39,6; median 44 vhs/field) with statistical significance (T-test P=0.0049; Wilcoxon signed-rank test P=0.03) (Figure 1). On the contrary, no significant angiogenic activity was reported in bone marrow neither at diagnosis nor at relapse/progression. The distribution of monocytic-macrophagic infiltrate was heterogeneous in nodal samples with a focal or diffuse pattern and with a different match with the neovessels The percentage of monocytic-macrophagic infiltrate showed a poor increment at relapse/progression and seemed to lack any correlation with clinical features. *Conclusions.* These preliminary data could justify the employment of angiogenesis analysis in the prognostic stratification of indolent NHL and hypothesize the use of anti-angiogenic drugs in patients relapsed or refractory to treatment. Larger series are warranted to confirm these data.

DIFFERENTIAL F-18 FDG UPTAKE AFTER 1 CYCLE CHEMOTHERAPY IN NK T-CELL LYMPHOMA: COMPARISON WITH DIFFUSE LARGE B CELL LYMPHOMA (DLBL)

S Kim,[1] YH Park[2]

[1]Korea University Guo Hospital, Korea University College of Medicine, Seoul, South-Korea; [2]Samsung Medical Center, Sunkyunkwan University School of Medicine, Seoul, South-Korea

We prospectively compared the F-18 FDG uptake after 1 cycle between NK T-cell and DLBL. Five patients (M: F = 5: 1, 45 +/- 8.76 year) with NK-T cell lymphoma and 14 patients (M: F = 11: 14, 55.5+/- 14.15) with DLBL were prospectively enrolled in this study from May 2005 to Feb 2007. The protocol was approved by our Institutional Review Board and all patients gave informed written consent. F-18 FDG PET/CT was performed before to chemotherapy (baseline) and then was repeated after 1 cycle chemotherapy. Semi quantitative and visual analyses were performed. We selected 1-9 regions of interest (ROIs) from each patient, for a total of 78 ROIs from all 19 patients. (1) the corrected SUV (SUV cor) was calculated by subtrating the SUV of surrounding normal tissue of tissue opposite the ROIs from the SUVmax of the ROIs, as the SUVmax alone does not correctly reflect tumor activity in regions in which the SUV is low or the background uptake is high. The decrease rate of SUV [RI (%)]= (baseline max SUVcor (SUV1) - after 1 cycle max SUVcor (SUV2)/ SUV1) × 100. (2) Visible change (%) in the extent of FDG uptake in longest dimension was calculated. (the decrease rate of metabolic extent [DI (%)] = baseline metabolic extent (cm2)(D1)-metabolic extent (cm2)((D2) /D1 X 100). A total of 52 ROIs [23 NK T (n=5), 42 DLBL (n=15),] were evaluated in 19 patients. (1) In 23 NK-T, SUV1 ranged 3.97 to 7.64 (mean 5.72; SD 1.02), SUV2 ranged 3.96 to 7.52 (mean 5.66; SD 1.01), RI ranged 0.2 to 2.71 (mean 1.12; SD 0.88) and decreased rate ranged 97 to 100 % (mean 99; SD 0.2). In 23 NK-T, D1 ranged 1.5 to 6.09 (mean 3.58; SD 1.48), D2 ranged 0.47 to 3.37 (mean 1.92; SD 0.16), and LI ranged 16.67 to 75 (mean 45.76; SD 17.23). 2) In 42 DLBL, DI ranged 2.19-10.45 (mean 5.26; SD 2.02) cm, L2 ranged 0 to 0.78 (mean 0.21, SD 0.23) cm and LI ranged 91 to 100 (mean 96, SD 3.06) %. There were significant difference of the DI between NK-T and DLBL (P<0.0001, non paired student t-test).

This study shows significant different changes in FDG uptake between the NK/T and DLBL after first cycle chemotherapy.

1544

THE ROLE OF HELICOBACTER PYLORI IN OCULAR MALT LYMPHOMA: A REVIEW OF OUR SERIES

S Suarez Ordoñez,[1] C Maceira Quintás,[2] JA Díaz Arias,[2] J Forteza Vila,[3] E Varela Ledo,[4] C Figueiredo,[4] F Carneiro,[5] JL Bello López[2]

[1]Hospital CLínico Santiago Compostela, La Coruña, Spain; [2]Hematology and Hemotherapy Department, Santiago de Compostela, Spain; [3]Pathological Anathomy, Santiago de Compostela, Spain; [4]Microbiology Department, Santiago de Compostela, Spain; [5]Pathological Anatomy Department, O Porto, Portugal

Background. The MALT lymphoma was firstly described in 1983 by Isaacson and Wright(1) in two cases with digestive system involvement and similar features to mucosa-associated lymphoid tissue. It is a well-defined nosologic entity in the new classification by the WHO(2). A close relationship between *Helicobacter pylori* infection and the development of gastric MALT lymphoma has been observed several years ago(3-6) and their response to antibiotherapy(7-8). *Aims.* Starting from a case in a patient with a gastric and conjunctival MALT non Hodgkin lymphoma that showed sensitivity to antibiotic treatment (Figure 1) we looked for some similar published cases. We found an article of a Korean research group who showed the 100% presence of *H.pylori* by PCR analysis in 15 cases of conjunctival MALT lymphoma(9). We stablished the hypothesis of a cause-effect relationship between the H.pylori infection and the conjunctival MALT lymphoma based on the observed response to antibiotherapy in our patient. We developed a retrospective study in order to determine presence of genomic material of *H.pylori* by PCR analysis in biopsies samples of gastric and orbital MALT lymphomas in our cases. *Methods.* We determine the presence of genomic material of *H.pylori* by PCR analysis in samples from seven gastric biopsies and five orbitals tissue with MALT lymphomas. DNA extraction: after the deparaffination with xylenes, we employed QIA amp DNA Mini Kit QIAGEN GmbH, D40724 Hilden. Helicobacter DNA was used as an amplification control. It was obtained from a culture by mechanical lysis in MagNALyser and extraction in MagNA Pure Compact. PCR in real time: in 20 uL of the following mixture of capilar reaction: 0,5 mM of each primer (HP-FOR, 5'-TTA TCG GTA AAG ACA CCA GAA A-3', y HP-REV, 5'-ATC ACA GCG CAT GTC TTC-3') 2.4 mM MgCl2, 2 ul FastSart DNA Master SYBRE-Gren I and 10 ul DNA from the samples and the control. *Results.*Our results were two negative test and five positive results in gastric mucosa and five negative results in the five biopsies of ocular adnexal tissue. *Summary/Conclusions.* Due to the disagreement results between our cases and published Korean series, we checked the methodology that both groups had employed trying to explain this disaccord. As a result, we found an important difference between the used primers. They chose primers from the vacA region, whereas we used primers from the ureC region.

We redirected our study by employing the same primers that Korean group but we obtained the same results as before. We think that this disagreement could be explained through the different prevalence of the *H.pylori* infection in the Asian region and genetic differences between studied populations. Because of these conditions these studies are not comparable. Would require further meta-analysis including larger samples from several geographical areas and include more clinical data to compare results and draw conclusions about the role of *Helicobacter pylori* in non gastric MALT lymphomas.

AFFECT OF CD20 STRENGTH ON B CELL LYMPHOMA PATIENTS' BACKGROUND AND PROGNOSIS

Y Suzuki,[1] T Yoshida,[1] G Wang,[1] H Kamata,[1] H Kimura,[1] T Katayama,[1] R Ishii,[1] K Miyazaki,[1] S Ohtani,[1] M Nakayama,[1] K Iwabuchi,[1] R Horie,[1] N Nakamura,[2] M Higashihara[1]

[1]*Kitasato University, Sagamihara, Japan;* [2]*Tokai University, Isehara, Japan*

Background and Aim. Anti CD20 antibody, thus Rituximab have improved the disease free survival and overall survial of several types of B cell lymphoma, which are expressed CD20 on the surface and in the cytoplasma. Expression of CD20 analized by flow cytometry varies from null, weak to strong. Affect of CD20 strength on lymphoma therapy have not well elucidated in spite of the clnical importance of this protein. *Patients, materials and methods.* 214 cases with newly diagnosed B-cell lymphoma were analyzed. All of them were biopsied, also analyzed by flow cytometry, and were newly diagnosed as B cell lymphoma from January in 2002 to April in 2009, in our institute. Informed consent was obtained. The biopsy specimens were fixed in formalin and stained with Hematoxylin-Eosin, and were also immunostained. The histological subtypes were defined according to the World Health Organization Classification Ver 3. The mean florescence intensity of CD20 and CD19 was determined by FCM, and The cytoplasmic expression of CD20 was determined by immunohistochemistry(IHC). 1) The cases were categolized as follows; Group A: CD20 negative, B: CD20/19 less than 20%, C: CD20/19 20-50% and D: CD20/19 more than 50%. And background of patients, pathological diagnosis, primary lesion, expresion of CD5, 23, IgM, T cell markers on lymphoma cells, Karyotypes, etc were analyzed. 2) Among DLBCL cases, 76 cases treated with R-chemo were selected and analyzed in point of the response to treatment and overall survival. *Results.* 1) DLBCL 128, Follicular lymphoma 58, MALT 7, CLL 4 and so on. Among DLBCL cases, 6 cases (4%) were CD20 negative and three were positive by IHC. Weak expression were obsereved in 15 cases (B: 4, C:11). Among DLBCL, expression of CD20 were significantly weaker in CD5 positve group compared with CD5 negative group(P=0.01), age of negative group tend to be high (74.28 *vs.* 64.36, P=0.06, t-test) . However; Among thsese groups, in point of gender, IPI, clinical stage, biopsy lesion, expression of Karyotype statistical significance were not obsereved. Among FL cases, there were no CD20 negative, but low expression were obsereved in two cases(3.4%). 2)76 cases of DLBCL treated with R-Chemo were analyzed with Kaplan-Meier method. In the point of overall survival, GroupA(CD20negative) were significatlly lower. Between B+C(CD20 weak) and D(CD20 normal), there were no statistical significance. Some amount of CD20 may be enough to treat B cell lymphoma patient. *Summary and Conclutions.* Weaker expression of CD20 was observed in any types of B cell lymphoma. Among DLBCL, expression of CD5 and age are highly associated with weaker CD20. In DLBCL, weakness of CD20 may be the prognostic factor of DLBCL. Further analysis will be necessary.

1546

VIRAL INFECTIOUS IN CHRONIC LYMPHOPROLIFERATIVE DISORDERS - IMMUNOPHENOTYPIC CHANGES

H Bumbea,[1] AM Vladareanu,[1] S Radesi,[1] A Vintilescu,[1] V Roman,[2] C Ciufu,[1] D Hotnog,[2] V Arama,[3] M Onisai,[1] VM Popov,[4] C Baluta,[1] O Cazaceanu,[1] I Voican,[1] D Cisleanu,[1] C Marinescu,[1] S Arama,[1] A Rafila,[3] A Streinu-Cercel,[3] A Nicolescu,[1] M Gaman,[1] A Ichim,[1] M Begu[1]

[1]*Carol DavilaUniversity of Medicine, Bucharest, Romania;* [2]*Stefan Nicolau National Institute of Virusology, Bucharest, Romania;* [3]*Matei Bals Infectious Disease Institute, Bucharest, Romania;* [4]*County Hospital, Pitesti, Romania*

Background. Chronic lymphoproliferative disorders (CLD) frequently associate coinfection with hepatitis viruses, which may possibly be involved in their pathogeny. *Aim.* Immunophenotype changes of malignant lymphocyte in B-cell CLD with viral infections. *Materials and methods.* Bone marrow aspirate, peripheral blood samples on EDTA were available for analysis from 41 patients with CLD. Immunophenotyping was performed on a four color FACS Calibur according to EGIL/WHO panel. 13 CLD patients without viral coinfections were used as controls. Identification of B or T lineage of malignant cell was followed by detailed analysis of immunophenotype and clonality assessment. For statistical analysis we used SPSS software. *Results.* Disease type: 90% B-CLD; 5% T-CLD; 5% Hodgkin disease. Viral infections incidence: 58.53% HCV, 34.41% HBV, 2.43% HBV+HDV, 2.43% coinfection HCV+HDV, 2.43% triple viral infection HBV+HCV+HDV. We studied the immunophenotypical pattern (Figure 1) in patients with CLD with viral coinfection and we observed significant differences only in CLL group with viral infection: elevated expression of CD20 (Median level 90% compared to 39% in controls - patients without viral infection), of CD79b (Median 58% *vs.* 31% in controls), and of CD23 (Median 67% *vs.* 37% in controls). CD19 (Median 95% *vs.* 92% in controls) was unchanged in CLD with viruses (v-CLD). Higher expressions in v-CLD were observed for: CD38 (Median 49% *vs.* 24% in controls); antiapoptotic proteins were increased only in v-CLL group: bcl-2 (Median 46% *vs.* 5% in controls) and cyclin D1 (Median 11% *vs.* 0.5% in controls). No change in ZAP-70 expression: Median 59.5% *vs.* 59.1% in controls.

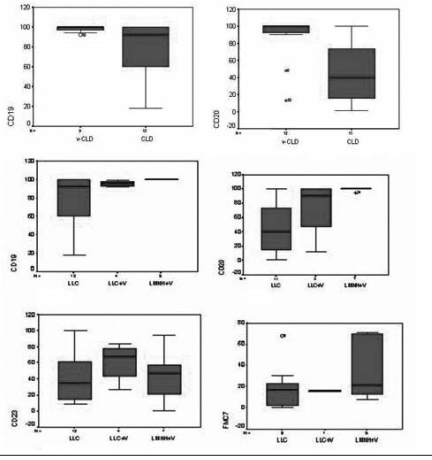

Figure 1. Boxplots representing different expression of CD20, CD79b, CD23, FMC7 in B-CLD with viral coinfection.

Conclusions. Hepatitis viruses could be involved in the pathogeny of CLD, but also as trigger for a more aggressive outcome. Higher expression of B-cell marker CD20, CD79b and CD23 suggest a lymphoma-like phenotype or a change to atypical CLL, associated with elevated expression of known prognosis markers bcl-2, cyclinD1, CD38. Unchanged expression of ZAP-70 could suggest a strong relationship with a basic unmutated IgVH status, and not with viral coinfection. Our interim data describe a significant change of immunophenotype of CLD in coinfection with hepatitis viruses, which suggest that the viral infection could produce a change to an atypical disease, with poor outcome.

F-18 FDG PET AS A PREDICTOR OF CHEMOTHERAPY SENSITIVITY IN MALIGNANT LYMPHOMA

S Kim

Korea University Guo Hospital, Korea University College of Medicine, Seoul, South-Korea

1.The usefulness of the PET scanning for malignant lymphoma was discussed for many times and verified with the contribution to the diagnosis, treatment and recurrence evaluation. However, quantitative analyses were rarely identified for this disease entity. Although majority of the malignant lymphomas are chemotherapy sensitive tumors, only about 50% of the patients have long-term survival. High chemotherapy sensitivity may reflect that lymphoma has high proliferating tumor cells. 2.To evaluate quantitative value of FDG uptake as a proliferating index and clinical significance as a response predictor, we performed this study. 3.A retrospective analysis of 42 patients admitted to our institution for F-18 FDG-PET imaging before multiagent-chemotherapy was performed. Patients with a verified diagnosis of malignant lymphoma were included in this evaluation. In all study patients, reassessment of histological specimens was performed by a hematopathologist. In addition, the proliferating activity was analyzed using the Ki-67 (MIB-1) immunohistochemical assay and was judged by the percentage of lymphoma cells showing staining with the antibody. We investigated the nodal F-18-FDG uptake (visual analysis and semiquantitative analysis; SUV and relative uptake ratio) in lymphoma patient before chemotherapy. We compared maximum nodal F-18 FDG-PET uptake-ratio with Ki-67 expression that may be prognostically or therapeutically important, as well as with the response to multiagent chemotherapy. Attenuation-corrected whole body PET images were acquired 60 minutes after injection of 370-555 MBq FDG with a dedicated PET scanner (ECAT HR$^+$ scanner, Siemens-CTI, Knoxvile, Tenn., USA). Images visually interpreted by two experienced nuclear physicians, who had achieved consensus. We analyzed the degree of FDG uptake. Visually, the degree of FDG uptake was classified from grade -1 to grade 3: -1, lower; 0, equal; 1, slightly higher; 2, moderately higher; 3, intensely higher. Maximal standard uptake value (max SUV) and uptake ratio of max SUV for lesion to the mean SUV for contralateral basal lung were calculated. At diagnosis, median age was 49 years (range, 21-70). Hodgkin's lymphomas were in 6 cases. According to the WHO classifications, the most common histologic subtype was diffuse large cell lymphoma among 36 Non-Hodgkin's lymphoma patients. According to the Ann Arbor staging system, 4 patients had stage I disease, 21 patients had stage II disease, 12 patients had stage III disease, and 5 patients had stage IV disease. All chemotherapy regimens contained doxorubicin. 4. Nodal F-18-FDG uptakes were showed linear correlation with Ki-67 expression levels (correlation coefficient r=0.667, P=0.0001, Figure). Total response rate to chemotherapy was 70.2%. The patients with higher nodal F-18 FDG uptakes (grade +2, +3) had higher response rates than with lower nodal F-18-FDG uptakes (grade –1, 0, +1) (45.2% *vs.* 25.0%, P=0.018). The nodal F-18-FDG uptakes were significantly related with the responses to doxorubicin-based multiagent chemotherapy. 5. In conclusion, nodal F-18-FDG uptakes may be able to function as a predictor of chemotherapy sensitivity. Further studies for survival will be followed.

1548

GENE EXPRESSION PROFILING OF A SMALL COHORT OF FOLLICULAR LYMPHOMA PATIENTS FROM TUSCANY AND CORRELATION BETWEEN THE EXPRESSION OF ION CHANNELS AND LYMPHOMA GRADING

M Masselli,[1] S Pillozzi,[1] O Crociani,[1] P Laise,[1] L Rigacci,[2] E Meacci,[1] A Arcangeli[1]

[1]*University of Firenze, Firenze, Italy;* [2]*Azienda Ospedaliera Universitaria, Careggi, Firenze, Italy*

Background. Non-Hodgkin's lymphomas (NHL) comprise a diverse group of diseases that are subclassified by the state of differentiation of the malignant B cells, presence of specific cytogenetic abnormalities, and characteristic morphology. Follicular lymphomas (FL) are the most common indolent NHL. Current diagnostic NHL categories do not adequately anticipate the tumor behaviour because there is considerable heterogeneity in tumors with the same diagnosis. This heterogeneity is often present in the tumor at the time of diagnosis and can be measured using microarray technique for gene expression profiling. *Aims.* The aim of this study is the characterization of the gene expression profile (GEP) of FL samples to better understand the biology of this disease and find new molecular targets that could be used in clinical therapy. *Methods.* We collected several primary lymph node tissues derived from Tuscany patients and we evaluated their GEP by whole genome microarrays. Among them, 7 FL samples were analyzed by bioinformatics tools and public databases. *Results.* We found that genes involved in clearly defined pathways were differentially expressed between lymphoma samples and normal lymph node tissue. In particular, we identified some genes of the NF-kB pathway, expressed by cells of tumor microenvironment implicated in the immune response and genes involved in the folate homeostasis. Moreover, using a specific clustering analysis focused on ion channels expression, we found an interesting evidence: the differential expression of ion channel genes reflects the molecular differences between different histological grades of the inspected samples, suggesting a correlation between such genes and FL grading. *Summary.* In this study we remarked the importance of microarray technology in understanding the molecular biology of diseases. In particular, in our samples, we identified some genes that are differentially expressed in FL patients and that are able to characterize distinct lymphoma grades, suggesting their different role in the lymphomagenesis and/or progression. This could be a starting point to evaluate new target therapy in this field.

1549

COX-2 EXPRESSION AND MICROVESSEL DENSITY IN DIFFUSE LARGE B CELL LYMPHOMA

E Ozturk,[1] F Oz Puyan,[2] E Tekgunduz,[2] M Demir[2]

[1]*Gülhane Military Academy of Medicine, Ankara, Turkey;* [2]*Trakya University, Edirne, Turkey*

COX-2 and microvessel density are important factors in many solid tumors but there are no strong data for the DLBCL. Some studies showed that COX-2 expression and MVD are corallate by the poor prognosis. The role of the COX-2 in DLBCL pathogenesis remains a questionmark. Forty-nine formalin fixed, paraffin wax embedded DLBCL tissue samples from the archives of the clinics of pathology and the clinic of hematology at the University of Trakya were included in our study. The study made with the tissue micro array (TMA) construction and the area of 0.57 mm^2 stained with the CD34 and COX-2 (Cyclooxygenase-2) histochemistry slides were reviewed at magnification of x200. Expression of COX-2 and MVD (Micro vessel Density) were counted at the 10 binocular areas. MVD which was greater than 10, defined as elevated. COX-2 scored as 0 (negative), 1 (weak), 2 (medium) and 3 (strong) according to expression of the tissue. The tissues which were negative or weak and medium or strong COX-2 expression defined as negative and positive respectively. MVD, COX-2 expression, stage, treatment, overall survive are tested with Sapiro-Wilk test, Mann-Whitney U test, Chi-square and Chi-square Fisher Exact tests. COX-2 expression was greater in women (P=0.030). COX-2 expression was negative in 41 (83.7%) and positive in 8 (16.3%) patients. MVD counted at the range of 2-87. Median MVD reviewed as 12.5 (IQR=12.1). The patients whose COX-2 expression reviewed as negative and positive, MVD increased at 25 (61.0%) and 8 (100%) patients respectively. COX-2 expression was correlated with the MVD (P=0.031). There were no correlation between COX-2 expression and treatment response (χ^2=0.633; P=0.426). Median survival was determined as 12 weeks (OR 95% CI 8.95 - 15.05). There was no correlation between overall survive and the COX-2 expression (χ^2=0.175; P=0.676). No correlation has been found between overall survive and the MVD (χ^2=0.190; P=0.663). These data show that COX-2 expression and MVD are not correlate by the overall survive and treatment outcomes at diffuse large B cell lymphomas. In conclusion COX-2 expression and MVD are not increased in DLBCL and not correlate with the prognosis. More confirmatory studies are needed.

BONE MARROW INFILTRATION IN MARGINAL ZONE B-CELL LYMPHOMAS

MD Vilarino,[1] M Perez,[2] M Sobas,[2] C Aliste,[2] J Diaz,[2] C Maceira,[2] S Suarez,[2] E Fernandez,[2] N Alonso,[2] J Forteza,[2] J Bello[2]

[1]*Hospital Clinico Universitario de Santiago, Santiago de Compostela, Spain;* [2]*Hospital Clinico Universitario de Santiago de Compostela, Santiago de Compostela, Spain*

Background. There are a various histological types of marginal zone lymphoma (MZL). Although all are thought that to have a common germinal centre origin, they present different clinical, treatment, and prognostic characteristics. *Aims.* The purpose of our study was to determine the relation between certain patterns of bone marrow infiltration and the

type of MZL. *Methods.* Here we analysed different patterns of infiltration in bone marrow biopsy from 50 MZL cases which presented bone marrow infiltration at diagnosis: 37 splenic MZL (SMZL), 7 nodal MZL (NMZL), and 6 mucosa-associated lymphoid tissue lymphoma (MALT). We differentiated 4 patterns of bone marrow infiltration (nodular, interstitial, diffuse, paratrabecular). We also took into consideration clinical and analytical parameters such as age, sex, ECOG, B2-microglobuline, number of nodal and extranodal areas, IPI, haemoglobin, leukocytes, neutrophils, lymphocytes, platelets, cariotype, and transformation to high-grade lymphoma. *Results.* We found that the most frequent pattern was nodular (48%), followed by interstitial (38%), diffuse and paratrabecular. When we compared bone marrow infiltration patterns according to MZL histological subtype we observed that in SMZL and MALT, the most frequent pattern was nodular, followed by interstitial and diffuse, while in NMZL, the most frequent pattern was interstitial (see table). However, none of the differences were statistically significant (P=0.28). An additional analysis was carried out which classified cased into only 2 groups of infiltration pattern (nodular and non-nodular). No significant correlation was found with the types of lymphoma under study (P=0.125). With respect to clinical and analytical parameters of each bone marrow infiltration pattern, the only statistically significant difference found was B2-microglobuline (P=0.046), which was higher in non-nodular patterns. *Conclusions.* 1. Our MZL cases presented a wide variety of infiltration patterns in bone marrow biopsy. 2. We could not demonstrate the existence of any infiltration pattern in bone marrow biopsy which is specifically related to MZL type, with the possible exception of the association between diffuse pattern and SZML. 3. It is possible that a nodular infiltration pattern reflects lower tumour activity, while diffuse patterns suggest high tumour activity. 4. A proper diagnosis of MZL type must take into consideration the combination of bone marrow infiltration, immunophenotype, and clinical parameters. Moreover, confirmation of MZL type should involve a biopsy from another nodal or extranodal organ whenever possible.

1551

THE USEFULNESS AND LIMITATIONS OF COMBINED FINE-NEEDLE ASPIRATION IMPEDANCEMETRY AND FLOW CYTOMETRY IN THE DIAGNOSIS AND SUBCLASSIFICATION OF NON HODGKIN'S LYMPHOMA

M Brahimi,[1] D Saidi,[2] A Arabi,[3] M Bey,[1] H Berredouane,[1] N Yafour,[1] S Osmani,[1] H Touhami,[2] MA Bekadja[1]

[1]University Hospital Of Oran [1]st November, Oran, Algeria; [2]Clinic of Haematology, University Hospital, Oran, Algeria; [3]University Hospital of Oran [1]st November, Oran, Algeria

Background. Cell morphology and immunophenotype are two primordial features in diagnosis and sub classification of non-Hodgkin`s lymphoma (NHL). The Coulter ACT Diff instrument gives an impedance size distribution histogram, which is very helpful in assessing lymphoid cells size. WBC histograms display the classification of leukocytes according to size following lysis. *Aims.* We reviewed our experience based on fine needle aspiration by combining impedancemetry and flow cytometry to determine their usefulness based on the new WHO-classification of malignant lymphoma. *Methods.* Impedance size distribution histograms and flow cytometry reports of patients who underwent both methods at the same time were examined. Both methods were classified according to the new WHO-classification of malignant lymphoma 2008. *Results.* There were total 50 cases included in this study. In seven cases FNA failed in gathering sufficient material for immunophenotyping. In ten cases there was no monoclonality B or T (5 Hodgkin's lymphomas, 3 carcinomas, and 2 lymphadenitis). 33 cases were diagnosed as NHL and were classified on impedancemetry as predominant small cells (19) and large cells (14) and on flow cytometry T NHL (4) and B NHL (29). Light chain restriction was demonstrated in 19/29 cases of B-NHL. With the help of combined impedancemetry and flow cytometry, it was possible to sub-classify 16 cases of the 33 NHL (48%) according to WHO classification. 17 cases were labelled as NHL not otherwise specified (NHL-NOS). *Conclusions.* Impedancemetry combined with flow cytometry may be helpful in accurately diagnosing and sub-classifying NHL into B or T types and small or large cell types. These methods are not sufficient to sub-classify all lymphomas according to WHO classification and the histopathology remains the main tool for the WHO classification.

1552

RADIOIMMUNOTHERAPY FOLLOWED BY BEAM CONDITIONING REGIMEN AND AUTOLOGOUS TRANSPLANTATION IS EFFECTIVE AND SAFE IN HIGH RISK RELAPSED/RESISTANT NON HODGKIN'S LYMPHOMA: A SINGLE INSTITUTION EXPERIENCE

B Botto, M Bellò, C Ciochetto, E Audisio, C Boccomini, A Chiappella, R Freilone, F Marmont, L Orsucci, R Passera, P Pregno, A Tonso, G Bisi, U Vitolo

Azienda Ospedaliera S Giovanni Battista, Torino, Italy

Background. High dose chemotherapy (HDC) followed by autologous stem cell transplantiation (ASCT) is an effective approach for the treatment of relapsed aggressive NHL. High risk patients i.e no response prior ASCT or early relapse have a dismal prognosis even with this approach with a 2-year PFS lower than 30-20%. Radiolabelled immunotherapy (RIT) with 90Yttrium Zevalin delivers targeted irradiation without TBI toxicity. Standard dose Zevalin (0.4 mCi/kg) combined with conventional conditioning regimen BEAM (Z-BEAM) was tested with promising results in the treatment of high risk relapsed/resistant aggressive NHL. *Aims.* We evaluated the efficacy as complete remission (CR) progression free survival (PFS) and overall survival (OS) of Z-BEAM followed by ASCT in a group of high risk relapsed/refractory patients treated in a single institution. The safety was considered as hematologic and extra-hematologic toxicity. Patients and methods Between October 2006 and October 2009 twenty patients were treated with Zevalin (day -14) followed by standard dose BEAM (day -7 to -1) and ASCT. Patients were considered at high risk of failure if: progression or early relapse (<1 year) after first line therapy, presence of multiple relapses or partial/no remission disease before Z-BEAM. Rituximab+ DHAP/ICE was used as induction and mobilizing treatment. *Results.* Clinical characteristics were: median age 47 years(range 27-69), eleven refractory and nine early or multiple relapse; fifteen grade III follicular/PML/DLBCL, three MCL and two indolent; five stage II and fifteen stage III-IV; nine had bulky disease and ten bone marrow involvement; ten had LDH level above normal. Eight patients received one previous therapy and twelve were resistant or relapsed after[3] 2 lines before Z-BEAM. All patients were previously treated with Rituximab. Response status before Z-BEAM was: CR 5 (25%), PR 8 (40%), SD/PD 7 (35%). At the end of treatment response status was: CR 12 (60%), PR 6 (30%) and SD/PD 2 (10%). Overall response rate was converted from 65% to 90% after Z-BEAM+ASCT. Z-BEAM was able to convert 4/7 patients with a SD/PG status in PR/CR at the end of therapy. With a median follow up of 25 months PFS and OS were 68% and 80% respectively. Two refractory pts before Z-BEAM showed a subsequent progression and four patients relapsed; four patients died for lymphoma 4,6,10,12 months after ASCT. Median $CD34^+$ cells infused was 7.26 106/kg (range 4.43-8.9). All patients engrafted with median time to platelet and neutrophils count higher than 20×10^9/L and 0.5×10^9/L of 11 and 10 days respectively. Febrile neutropenia occurred in twelve patients (60%), all resolved with empirical antibiotic therapy. No toxic deaths were recorded. Late toxicity (>100 days after ASCT) (lung Aspergillosis and cardiac failure) was recorded in only one patients heavily pre-treated with antraciclines and mediastinal radiotherapy. *Conclusions.* In this group of patients with high risk relapsed/resistant aggressive lymphoma Z-BEAM+ASCT was able to achieve a high response rate with complete engraftment and acceptable toxicity, not different from conventional BEAM. PFS appears to be improved compared to historical data. This approach needs to be tested in a larger multicenter study with longer follow up.

1553

CLINICAL IMPACT OF STAGING FOLLICULAR LYMPHOMA USING 18-FDG-PET/CT VERSUS DIAGNOSTIC CT

T El-Galaly, V. Prakash, P Jensen, I Christiansen, V Iyer, R Fisker, M Kubik, L Juhler Andersen, M Boegsted, L Juhler Andersen, A Bukh

Aalborg University Hospital, Aalborg, Denmark

Background. Follicular lymphomas (FL) are known to be 18-FDG avid. Integrated 18-FDG-PET/CT (PET/CT) could prove useful in FL due to the importance of more accurately discriminating local from disseminated disease. Reviewing the literature, there is a paucity of data comparing the clinical impact of staging FL with PET/CT *vs.* diagnostic CT. *Aims.* To evaluate the clinical impact of staging newly diagnosed or relapsed FL patients (pts) with PET/CT *vs.* diagnostic CT. *Methods.* Pts with biopsy proven FL who had been staged using PET/CT at diagnosis or relapse were included in this retrospective study. A lymph node was defined as pathological if FDG avid by qualitative visual assessment or if above the threshold size limit for CT criteria of the anatom-

ical region. Numbers of lymph nodes were counted on regional basis according to the manikin used in the FLIPI scoring index. Two experienced haematologists specializing in lymphoma treatment determined a management strategy based on diagnostic CT followed by a management strategy based on PET/CT. If radiation therapy was included, an oncologist reviewed the scans to determine if the radiation field was changed by the PET/CT compared to diagnostic CT. Changes in management strategy were defined as major (curative to palliative) or minor (changes in chemotherapy type/ number of cycles/radiation field). *Results.* Twenty-four newly diagnosed pts and four relapsed pts with FL were eligible (median age: 57). The FL's were characterized pathologically as grade I (9 pts), grade II (15 pts), grade III (two pts) and undefined (two pts). PET/CT identified 138 pathological lymph node regions whereas diagnostic CT identified 111. PET/CT detected additional pathological lymph node regions in 43 % of pts (95% CI 24-62). PET/CT identified CT unseen extra-nodal disease in three pts. PET/CT upstaged one patient (from II to III Ann Arbor) and upstaged FLIPI score in three pts. For CT stage I, PET/CT did not detect additional disease in any pts. However, in CT stage II-IV, PET/CT detected additional disease in a significant number of pts (Figure). PET/CT did not confer any major change in management strategy in any of the pts. However, in one patient, PET/CT did lead to a minor change by increasing the size of the radiation field against an extra-nodal area in a stage IV patient. *Conclusion.* PET/CT reveals more pathological lymph node regions in FL pts compared to diagnostic CT as it identifies disease in non-enlarged nodes. PET/CT is also better at detecting extra-nodal disease. However, we found no major clinical impact of performing PET/CT staging in FL patients compared to conventional staging. The role of PET/CT in FL needs to be defined in larger prospective studies.

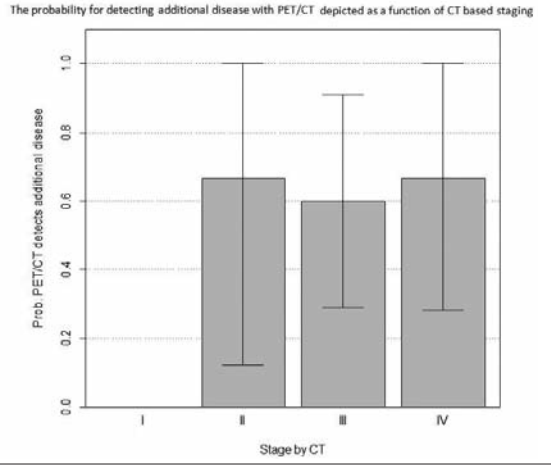

Figure.

1554

OCULAR ADNEXAL LYMPHOMA: A CLINICOPATHOLOGIC STUDY WITH NO EVIDENCE OF ASSOCIATION WITH CHLAMYDOPHILA PSITTACI IN OUR GEOGRAFICAL AREA

A Jaramillo Rodriguez, M Navarrete, MC Ruiz Marcella, J Castelvi, R Medel, J Hernandez, A Garcia, M Gironella Mesa, S Ramón y Cajal, M Tórtola, P Abrisqueta, A Lopez, F Bosch

Hospital Universitari Vall d'Hebron, Barcelona, Spain

Background. Ocular adnexal lymphomas (OAL) are a heterogeneous group of malignancies accounting for approximately 1-2% of non-Hodgkin lymphomas and 5-15% of extranodal lymphomas. OAL constitute the most frequent malignant tumor of the orbit. Analysis of somatic mutations in the V region of the Ig heavy (H) chain gene segment have suggested a role of chronic antigen stimulation. A variety of microbial pathogens that underlie chronic inflammatory processes can eventually lead to the acquisition of primary ocular adnexal MALT lymphoma (OAML) and may also play a pivotal role in both malignant transformation and subsequent clonal expansion of the lymphoma. OAML was initially associated with infection by *Chlamydophila psittaci*, although further reports did not support this association. Studies carried out using centralized molecular analyses have detected a certain geographical heterogeneity by showing discrepancies in the prevalence of *Chlamydophila psittaci* infection on OAML among countries and among different regions within the same country. *Aims of the study.* With this background, we decided to analyze the pathological and clinical characteristics in a series of 42 consecutive patients diagnosed with AOL in the same institution, to ascertain the pathogenic association with *Chlamydophila psittaci* in our area, and to detect the presence of t(11;18)(q21;q21) in OAML. *Methods.* Forty-two cases of OAL were enrolled in the study. The main clinical characteristics were recorded and analyzed. Pathological diagnosis was independently reviewed by two observers. DNA was extracted from the paraffin-embedded tissue samples and analyzed by PCR for IgH chain gene rearrangement and for *Chlamydophila psittaci* detection (n=28). In twenty-eight cases the translocations t(11;18)(q21;q21) was analyzed by fluorescence *in situ* hybridization. *Results.* Among 42 cases of AOL, 28 were diagnosed with OAML, 6 with DLBCL and 8 with other diagnosis (Table 1).

Table 1. Clinical features of patients with ocular adnexal lymphoma.

Characteristic	No. of patients OAL n=42 (%)	No. of patients OAML n=28 (%)
Age, y		
Median	71,5	70,4
Range	31-89	31-89
Sex		
No. female/no. male	21 / 21	16 / 12
Involved sites, no.		
Orbit	25 (60)	17 (61)
Lacrimal gland	7 (17)	4 (14)
Conjuntiva	5 (12)	5 (18)
Eyelip	3 (7)	1 (4)
Retroconal	2 (4)	1 (4)
Stage, no.		
I	29 (69)	22 (79)
II	3 (7)	2 (7)
III	2 (4)	
IV	8 (19)	4(14)
Histologic category, no.		
MALT	28 (67)	28 (100)
DLBCL	6 (15)	
Follicular	5 (12)	
Mantle cell	1 (2)	
Lymphoplasmacytoid	1 (2)	
Anaplasic T-cells	1 (2)	
Symptoms, no.		
Mass/swelling	26 (62)	17 (61)
Proptosis	12 (29)	8 (29)
Diplopia	3 (7)	2 (7)
Eye redness	1 (2)	1 (4)
Lateral, no.		
Left	23 (55)	14 (50)
Right	10 (24)	8 (29)
Bilateral	9 (21)	6 (21)

MALT denotes mucosa-associated lymphoid tissue
DLBCL denotes diffuse large B-cell lymhoma

The OALs were anatomically distributed as follows: orbit in 25 patients (60%), conjunctiva in 5 (12%), lacrimal gland in 7 (17%), eyelid in 3 (7%) and retroconal in 2 (5%). Bilateral involvement was observed in 9 patients (21%). Patients with OAML had a median age at diagnosis of 70 years (range, 31-89) and 57% were female. The most common presenting symptoms in OAML were mass/swelling in 17 patients (61%). No patient had B symptoms. The majority of patients with OAML (79%) presented at IE stage. IgH rearrangement was detected in 25 out of 28 cases with OAML, whereas the t(11;18)(q21;q21) was found in only 2 patients. PCR for *Chlamydophila psittaci* infection was negative in all 28 tumor specimens. After a median follow-up of 43 months, estimated 10-year overall survival was 71% (95% CI: 53%-99%) for OAL patients and 88% (95% CI: 70.5%-100%) for OAML. *Conclusion.* The great majority of patients with OAML presented as localized disease and indolent behavior. The lack of evidence of Chlamydophila psittaci infection in this series, in contrast to some prior reports, indicates that there may be geographic heterogeneity in the pathogenesis of OAML. Finally, the incidence of t(11;18)(q21;q21) was lower (7%) than previously reported in other locations (13.5%-30%).

1555

HERPESVIRIDAE VIRAL INFECTIONS FOLLOWING CHEMOTHERAPY IN PATIENTS WITH DIFFUSE LARGE B CELL LYMPHOMA UNDERGOING RITUXIMAB COMBINED CHEMOTHERAPY: INCIDENCE AND RISK FACTORS

YS Kim,[1] JS Chung,[2] YD Joo,[3] HS Lee[1]

[1]Kosin University Gospel Hospital, Pusan, South-Korea; [2]Pusan National University hospital, Pusan, South-Korea; [3]Pusan Paik Hospital Inje University, Pusan, South-Korea

Background. Herpesviridae family includes herpes simplex virus, varicella zoster virus, Epstein-Barr virus, and cytomegalovirus, etc. Herpesviridae viral infection (HVI) can lead to serious complications including dissemination, secondary infection, bacterial super infection in patients with lymphoma undergoing chemotherapy. But there was no consensus on the dose and duration of antiviral agents prophylaxis in diffuse large B cell lymphoma undergoing Rituximab combined chemotherapy. We retrospectively analyzed the incidence and the risk factors for HVI. *Methods.* A total of 128 patients who newly diagnosed and received an chemotherapy with or without prophylaxis of acyclovir at the South Korea between Jan 2004 and Feb 2010 were enrolled retrospectively in the current study. HVI was confirmed based on clinical diagnosis, serologic test or pathologic diagnosis. The characteristics of the patients were as follows: the median age was 56years (range 22-81 years) with a female-to-male ratio of 59:69. The enrolled diseases included only diffuse large B cell lymphoma undergoing Rituximab combined chemotherapy. The results were analyzed using a chi-square test and independent samples T test. For the multivariate analysis, we used logistic regression test.

Figure 1. Curves for cumulative incidence of herpesviridae viral infection in all patients with diffuse large B cell lymphoma undergoing chemotherapy.

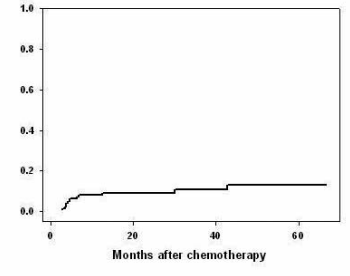

Figure 2. Curves for cumulative incidence of herpesviridae viral infection in patients with diffuse large B cell lymphoma undergoing chemotherapy. solid lines represent the more than one line, and dashed lines signify only one line of total number of chemotherapy and radiotherapy.

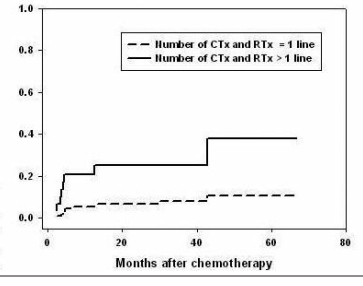

Figure.

Results. Thirteen patients (10.2%) developed HVI at a median of 9.96 months (range 2.53-42.90 months) after initial chemotherapy. In univariate analyses, risk factors for HVI were cumulative dose of steroid (P=0.018 , 6.3% in less than 4000mg *vs.* 21.9% in more than 4000mg), total number of sequential chemotherapy and radiotherapy (P=0.002, 5.1% in only one line *vs.* 27.6% in more than one line), presence of relapse (P=0.010, 27.3% in relapse *vs.* 6.6% in non-relapse). In multivariate analysis, the results confirmed only one variable as independent predictive factors for the total number of sequential chemotherapy and radiotherapy (P=0.032, hazard ratio (HR): 7.719, 95% confidence interval (CI) 1.189-50.096). There was no different mortality rate and survival rate between HVI and non-HVI group. *Conclusion.* Number of sequential chemotherapy and radiotherapy of more than one line was seemed to be high risk for HVI in patients with diffuse large B cell lymphoma undergoing Rituximab combined chemotherapy. Low-dose acyclovir prophylaxis for HVI may be needed in higher risk lymphoma patients undergoing chemotherapy.

IS 18F-FDG-PET USEFUL IN FOLLICULAR LYMPHOMA? A PRELIMINARY REPORT FROM A SINGLE CENTRE EXPERIENCE

G Mansueto,[1] R Guariglia,[2] G Pietrantuono,[2] O Villani,[2] M Martorelli,[2] A Nappi,[2] A Venetucci,[2] D Capacchione,[2] F Barbato,[2] F D'Auria,[2] V Grieco,[2] G Bianchino,[2] E Zifarone,[2] A Zonno,[2] G Storto,[2] P Musto[2]

[1]IRCCS-CROB Rionero, Rionero in Vulture, Italy; [2]IRCCS-CROB, Rionero in Vulture, Italy

Background. Follicular lymphoma (FL) is one of the most frequently occurring lymphoma entities in Europe and North America and is the most common indolent lymphoma. 18F-FDG-PET is becoming a routine measure for staging and follow-up of patients with aggressive lymphoma. By contrast, there are more limited data on its use in indolent lymphomas and, in particular, the role of this methodology in FL is still under investigation. *Aims.* We evaluated 18F-FDG-PET/CT (PET) at diagnosis and in the follow-up of patients with FL aiming to assess its possible usefulness on staging and clinical outcome. *Methods.* 18F-FDG-PET/CT (PET) was employed in all patients with FL referred to our Institution during the last three-year period. Overall, study population included 21 patients (11 males, 10 females; median age 58 years, range 42-77) with FL WHO grade I-II-III (5, 8 and 6 patients, respectively), plus 2 patients with mixed diffuse large B-cell lymphoma/FL. A total of 28 PET scans (9 before therapy and 19 for response assessment after treatment) were evaluated and compared with conventional staging. In 7 patients PET evaluation was longitudinally performed before and after therapy. Treatments were heterogeneous and given according to local policy, age and clinical conditions of patients, and research protocols applied: they included FND (Fludarabine, Mitoxantrone, Dexamethasone) with or without Rituximab, R-CHOP or R-CHOP- like regimens, R-CVP, R-FM (Rituximab, Fludarabine, Mitoxantrone). Two patients received Rituximab or Chlorambucil alone, respectively. *Results.* At diagnosis, seven cases demonstrated FDG avidity (78%), with a mean maximum standardized uptake value (SUV) of 8.2 (range 6.1-10.4). In one of the PET negative cases, disease had been completely excised. PET scan showed less diffused involvement than computed tomography (CT) in 2 of 9 patients, without, however, changing in the stage. At re-staging, twelve out of 19 evaluated patients had both CT and PET negative: all these patients maintain complete remission after a median follow-up of 38 months (range 21 to 56). By contrast, three patients who had CT negative/PET positive findings at re-staging experienced relapse/progression 12 to 23 months after completing induction therapy. Interestingly, one of these patients had achieved molecular remission after therapy, as showed by negative PCR for t (14;18) transcript. Four patients were PET and CT positive after therapy. All had progressive disease within few months and underwent alternative approaches. *Conclusions.* Though still preliminary and requiring confirmation on larger numbers of patients, our data indicate that FL is frequently FDG-avid and that persisting positive PET after treatment can contribute to identify patients with poorer prognosis.

1557

TREATING HIV-RELATED LYMPHOMA WITH CURATIVE INTENT DURING THE HAART ERA

A Re,[1] C Cattaneo,[1] S Casari,[2] S Ferrari,[1] L Baushi,[1] A Tucci,[1] G Cristini,[3] G Carosi,[4] G Rossi[1]

[1]Hematology, Spedali Civili di Brescia, Brescia, Italy; [2]Infectious Disease II, Spedali Civili di Brescia, Brescia, Italy; [3]Infectious Disease I, Spedali Civili di Brescia, Brescia, Italy; [4]Malattie Infettive II, Spedali Civili di Brescia, Brescia, Italy

Background. Before the advent of effective antiretroviral therapy many HIV positive (pos) patients (pts) with Hodgkin (HL) and non Hodgkin lymphoma (NHL) couldn't receive adequate treatment due to poor clinical conditions or early deaths. The introduction of highly active antiretroviral therapy (HAART) in 1997 has reduced HIV-related complications, making HIV-related lymphoma (HIV-Ly) more treatable. Similar results as for HIV negative (neg) pts are reported for HIV-Ly who received aggressive treatment, at least in selected series. *Aims.* To evaluate the chance of HIV pos pts with HL and NHL to receive adequate treatment, before and after the advent of HAART. *Methods.* We evaluated the proportion of pts consecutively diagnosed with HIV-Ly at our center, who received treatment with curative intent, in the pre-HAART and HAART era, in comparison with our concomitant series of HIV neg pts. Pts were excluded from treatment in case of poor performance status, major infections or severe comorbidities. Pts aged more than 65 were excluded.

Results. From 1985-1996 (pre-HAART period), we diagnosed 109 HIV-Ly, 84 systemic aggressive NHL (sNHL), 14 primary central nervous system lymphoma (PCNSL) and 11 HL and from 1997-2008 (HAART period) 102 HIV-Ly, 67 sNHL, 6 PCNSL and 29 HL. Before 1997, we could treat with curative intent 67% pts with sNHL [complete remission (CR) 56%] and 21% PCNSL. After 1997, the proportion increased to 78% for sNHL (P=0.1) (CR 57%), while only 1 pt with PCNSL received treatment. In the HAART era only 55% of pts were on HAART at sNHL diagnosis. However, the proportion of treated pts was similar between pts receiving or not HAART (76% *vs.* 80%). Only 1 pt was on HAART at PSNCL diagnosis. The long-term OS of treated pts in the HAART era was significantly better compared to the pre HAART period (52% *vs.*14%, P=0.0006). Within our series of HIV-related HL, we could treat 64% of pts in the pre-HAART (CR 43%) and 72% in the HAART era (CR 62%). After 1997, 65% of pts were on HAART at HL diagnosis; 79% of them received treatment, compared with 62% of those who started HAART at diagnosis. The long-term OS of pts treated after 1997 wasn't significantly better than before (35% *vs.* 29%). Within our consecutive HIV neg pts with lymphoma aged less than 66, we treated after 1997 96.3% sNHL, (compared to 78% of HIV pos pts, P<0.0001), and 100% of PCNSL (compared to 17%; P=0.004). Concomitantly, all (100%) HIV neg pts with HL, younger than 65, received full-dose treatment at our center. *Conclusions.* In our single center series of consecutive non selected HIV-Ly, the proportion of pts who cannot receive adequate treatment, due to poor performance status or comorbidities, remains significantly higher compared to the HIV neg population, even in the HAART era. The outcome of treated is significantly improved, at least for sNHL. Treating PCNSL in HIV pos pts remains a challenge even in the HAART era.

1558

CLINICAL IMPACT OF BULKY MASS IN THE PATIENT WITH PRIMARY EXTRANODAL DIFFUSE LARGE B CELL LYMPHOMA TREATED WITH R-CHOP THERAPY

MK Song,[1] JS Chung,[1] GW Lee,[2] SY Oh,[3] HJ Shin,[1] YM Seol,[1] GJ Cho[1]

[1]Pusan National University Hospital, Busan, South-Korea; [2]Gyeongsang National University Hospital, Jinju, South-Korea; [3]Dong-A Medical center, Busan, South-Korea

Background. Although numerous studies about primary extranodal diffuse large B cell lymphoma (DLBCL) were reported sporadically, the literature of clinical value of immunophenotype and bulky diameter in rituximab era is limited. *Aims.* We analyzed in primary extranodal DLBCL patients treated with R-CHOP (rutiximab, cyclophosphamide, doxorubicin, vincristine and prednisone) therapy to evaluate whether immunophenotype and size of bulky disease are significantly important. *Patients and methods.* A total of 96 patients with primary extranodal DLBCL were enrolled in the present study. All patients were treated with R-CHOP therapy. Radiotherapy at extranodal site was given to 10 patients by physician's discretion.

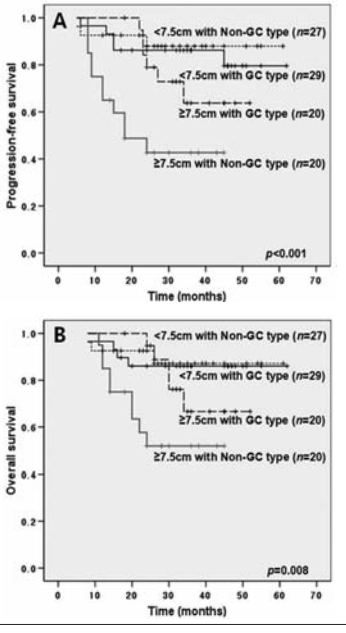

Figure.

Results. A total of 96 primary extranodal DLBCL patients were analyzed in the present study. Median follow-up duration was 36 months. Ann Arbor stage at diagnosis were IE (n=23) and IIE (n=73). Forty-four patients had an elevated LDH status at the time of diagnosis. Fifty-one patients were >60 years of age and 36 subjects had an Eastern Cooperative Oncology Group (ECOG) performance status >2. The GC type was applied to 49 of 96 cases; the other 47 were of the non-GC type-International prognostic index (IPI) was still important prognostic factor for progression-free survival (PFS) and ov! erall survival (OS) (P=0.003, P=0.027). Difference of survival between immunohistochemically germinal center (GC) type and non-GC tpye was not different (PFS, P=0.192; OS, P=0.197). In two separated groups according to extranodal maximum tumor diameter (EN-MTD) 7.5 cm as cut-off value for survival, the group of EN-MTD ≥7.5 cm had lower PFS and OS than <7.5 cm (PFS, P=0.001; OS, P=0.008). In four divided subgroups according to EN-MTD combined with immunophenotype, the subgroup of non-GC type with EN-MTD ≥7.5 cm had lower PFS and OS compared with other subgroups (PFS, P<0.001; OS, P=0.008). Multivariate analysis revealed that non-GC with EN-MTD ≥ 7.5cm was an independent prognostic parameter (PFS, HR=5.407, 95%CI=2! .378-12.294, P<0.001; OS, HR=4.136, 95%CI=1.721-9.941, P=0.002). *Conclusion.* It appears that bulky primary extranodal DLBCL would be associated with unfavorable outcome especially in non-GC type. More intensive treatment to the patients may improve the outcome.

1559

IMMUNE RECONSTITUTION IN PATIENTS WIHT B-NON HODGKIN LYMPHOMA (B-NHL) TREATED WITH RITUXIMAB, CHEMOTHERAPY OR BOTH - A COHORT STUDY

A Afonso

Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisbon, Portugal

Background. B-NHL patients present prolonged periods of myelo and immunosuppression after (immuno)chemotherapy, leading to an increased risk of infections and possibly tumor recurrence. *Aims.* We prospectively analyzed the immune reconstitution kinetics and profile of infections in B-NHL patients treated with Rituximab (R), Rituximab+Chemotherapy (RCT) or Chemotherapy only (CT). *Methods.* Clinical and immunological characterization (complete blood counts, lymphocyte subpopulations, immunoglobulin serum levels and analysis of medical records), were done before and up to 7 months (M) after treatment. The study was approved by the local Ethics and Research Committees; all patients signed informed consent. *Results.* Thirteen patients (69% men, median age of 69, 47-86 yo), including 7 CLL, 2 MALT, 2 B-NOS, 1 Lymphoplasmocytic and 1 Follicular received CT (54%-Fludarabine/Cyclophosphamide, 38%-Chlorambucil/Prednisolone and 8%-Fludarabine/Mitoxantrone/Cyclophosphamide); 28 patients (38%-men, median age 63.5, 44-82 yo) received RCT (68%-CHOP, 28%-RCVP, 4%-RCHOP and RCNOP), including 10 Follicular, 10 DLBCL, 3 MCL, 1 MALT, 3 B-NOS and 1 Lymphoplasmocytic; 13 MALT patients (62%-men, median age 65, 43-82 yo) received R. All patients under R or RCT significantly decrease peripheral blood B-cell numbers 1 and 4M after treatment, compared to pre-treatment, P=0.009 and P=0.01, respectively. However, patients receiving R showed higher B-cell numbers 7M pos-treatment when compared to RCT patients (3.5 *vs.* 0.5 fold increase at 1 and 7M, respectively). IgM levels were most affected by treatment. RCT patients have a significant decrease of serum IgM and IgG, 1 and 4M after-treatment compared to pre-treatment (P=0.029, P=0.026, for IgM and P=0.002, P=0,036 for IgG, respectively). Patients receiving R or CT showed no significant alterations in Ig levels during follow-up. $CD3^+$T-cells were reduced by all treatments, and significantly by CT regimen at 7M pos-treatment (P=0,039). Only patients receiving CT alone (mostly with purine analogs) revealed a significant decrease of $CD4^+$ and $CD8^+$T-cells subpopulations at all time points compared to baseline values (P=0.006). $CD4^+$ naïve T-cells ($CD4^+CD45RA^+CD62L^+$) suffered a significant decrease compared to $CD8^+$ naïve T-cells ($CD8^+CD45RA^+CD27^-$) in patients treated with RCT (P=0.001): 50% *vs.* 13% from pre-treatment to 1M pos-treatment. The same regimen significantly increased $CD4^+$ memory T-cells ($CD4^+CD45RA^-CD62L^-$) at 7M pos-treatment (1 to 1.4 increments, P=0.01) and decreased of $CD8^+$ memory T-cells ($CD8^+CD45RA^-CD27^+$) immediately (1M) after therapy. These may explain the higher incidence (4 to 11 times) of infections observed in this group of patients as compared to CT and R patients. In fact, bacterial, viral and fungal infections were more frequent during RCT treatment; those diminished during follow-up, although a cluster of fungal infections was again observed at 7M. Moreover, the frequency of infections was inversely and significantly correlated with %CD4+ naïve T-cells (P<0.001). *Summary/Conclusions.* Rituximab treatment does

not seem to significantly alter the immunological parameters including Ig levels and T-cells subpopulations. Also, B-cell numbers recovered faster in Rituximab only treated patients as compared to patients undergoing other treatments. This may explain the lower incidence and severity of infections observed. Naïve $CD4^+$T-cells seem to be relevant for protection against infections during treatment and short-term follow-up time.

PROGNOSTIC SIGNIFICANCE OF LYMPHOMA ASSOCIATED MACROPHAGES (LAM), KI-67 AND HYSTOLOGICAL GRADE IN NEWLY DIAGNOSED FOLLICULAR LYMPHOMA PATIENTS

B Andjelic, M Todorovic, J Bila, M Smiljanic, M Perunicic-Jovanovic, Lj Jakovic, M Petrovic, B Mihaljevic

Clinic for Hematology, Clinical Center of Serbia, Belgrade, Serbia

Background. In spite of great progress in treatment of follicular lymphoma in past few years some patients still have bad clinical course of the disease and short survival. Many prognostic models have been suggested to identify this subgroup of patients, but they are exclusively based on clinicial and laboratory findings. The investigations of molecular hallmarks of lymphomas and their possible prognostic influence have been attractive for the past few years. *Aims.* The aim of this study was to investigate possible influence on survival of the number of CD68 positive cells (Lymphoma associated macrophages, LAM) in tumor tissue, proliferation index Ki-67 and hystological grade. *Methods.* In this retrospective study were included 50 newly diagnosed FL pts treated at the Clinic for Hematology Clinical Centre of Serbia from September 2001 until March 2006. The diagnose of FL in patients included in this study was made from lymph node biospy. The analysis was performed on specimen from paraffin embeded tissue of lymph node from diagnosis. *Results.* The patients with more than 10 intrafollicular LAM had signifficantly worse outcome than the patients who didn't have them (log-rank, P=0.018). There was no difference on survival regarding extrafollicular number of LAM. Patients with Ki-67>30% had signifficantly worse outcome compared to patients who had low Ki-67 (log-rank, P=0.002). There was no signifficant difference in survival of patients regrading to hystologic grade of follicular lymphoma, but the patient with grade 3 had tendency towards worse survival compared to patients with grade 1 and 2. In univariate analysis survival was influenced by number of intrafollicular LAM>10 (P=0.023) and Ki-67>30% (P=0.006). In multivariate Cox model, only Ki-67>30% was predictive for poor outcome (P=0.014). *Conclusion.* In our study patients with high number of intrafollicular LAM and Ki-67>30% had poor outcome, but Cox regression multivariate analysis identified only Ki-67 as independent variable. Regardless of this, we think that large multicenter study with unique hystopathological methodology is needed to estimate the influence of microenvironment, proliferation index and hystological grade on outcome and if it proves to have an influence, to be assesed for possible insertion in prognostic indices.

1561

OUTCOME AND PROGNOSTIC FACTORS IN FOLLICULAR LYMPHOMA. RESULTS WITH CHLORAMBUCIL WITH OR WITHOUT RITUXIMAB

M Angelopoulou,[1] G Pangalis,[1] P Tsirkinidis,[2] S Kokoris,[1] M Siakantaris,[1] E Dimitriadou,[1] M Dimou,[1] S Sachanas,[3] P Korkolopoulou,[1] MC Kyrtsonis,[1] P Panayiotidis,[1] P Beris,[1] T Vassilakopoulos[1]

[1]University of Athens, Athens, Greece; [24]0[1] General Army Hospital, Athens, Greece; [3]Athens Medical Center, Athens, Greece

Background. Follicular Lymphoma (FL) is the most common low grade lymphoma. Due to its long natural history, prolonged follow-up is needed to evaluate the impact of different prognostic parameters. *Aims.* To analyze prognostic factors in a series of 118 FL patients diagnosed, treated and followed in a single Hematology Unit between 2000 and 2009 and to compare outcome between patients treated with or without Rituximab (R). *Methods.* 118 consecutive patients were retrospectively reviewed. The following parameters were examined by univariate analysis as possible prognostic factors: age, gender, performance status (PS), FLIPI score, clinical stage (CS), B symptoms, LDH, hemoglobin (Hb), absolute lymphocyte counts (ALC) and bulky disease. *Results.* 75% had grade 1 or 2 histology, 64% were males with a median age of 57.5 years (range 25-85). The distribution of CS was as follows: 30%, 12%, 15% and 44% for CS I, II, III and IV, respectively, while 12% had B symptoms and 91% a PS 0-1. Hb was <12g/dL in 18% and LDH was elevated in 13%. ALC were $<1.5\times10^9$/L and $<1\times10^9$/L in 13% and 39% of patients respectively. Bulky disease was evident in 25%, while 37% and 17% had 1 and ≥2 extranodal sites. Bone marrow involvement was evident in 42%. FLIPI score was 0-1 in 47%, 2-3 in 40% and 4-5 in 13%. The most frequent treatments were chlorambucil in 23 patients, R-chlorambucil in 40, R-CHOP in 25 and radiotherapy in 18. At a median follow-up of 47 months (7-114) the 5-year progression free survival (PFS) and overall survival (OS) were 59% and 89% respectively and did not differ among grades 1-2 and 3. However there was a trend for a plateau in the survival curve for grade 3 cases. The only significant prognostic factor for PFS was bulky disease (5-year PFS: 71% *vs.* 22%, P<0.001). FLIPI, PS, CS, ALC and bulky disease proved to be significant factors for OS. Patients with FLIPI score 0-1, 2-3 and 4-5 had a 5-year OS of 100%, 86% and 43% respectively (P<0.05). Patients with PS 2-4 had an inferior 5-year OS compared to PS 0-1 (80% *vs.* 91%, P=0.045). Limited CS (I-II) had a superior OS compared to advanced (III-IV) FL patients (100% *vs.* 85%, P=0.05). Low ALC were poor prognostic factors for OS at both cut-off levels (5-year OS: 91% for ALC$\geq1.5\times10^9$/L and $\geq1\times10^9$/L *vs.* 87% and 75% for ALC$<1.5\times10^9$/L and $<1\times10^9$/L respectively, P=0.045 and P=0.025). Patients with bulky disease had an inferior OS (70% *vs.* 98%, P=0.018).The impact of Rituximab was evident in the prolongation of PFS: Patients treated with R-chlorambucil had a superior 5-year PFS (78%) compared to those treated with chlorambucil only (40%, P<0.02). However OS did not differ between the two groups, most likely due to subsequent R-containing chemotherapy. *Conclusions.* In this retrospective analysis the FLIPI score, PS, CS, ALC and bulky disease proved significant prognostic factors, whereas histologic grade did not have any impact on OS. Moreover, the addition of RItuximab to chlorambucil prolonged PFS significantly compared to chlorambucil monotherapy.

1562

CONTINUATIVE IMMUNO-CHEMOTHERAPY FOLLOWED BY HIGH-DOSE AND AUTOLOGOUS CELL TRANSPLANTATION IN UNTREATED MANTLE CELL LYMPHOMA PATIENTS. EXPERIENCE AT THE EUROPEAN INSTITUTE OF ONCOLOGY IN MILAN

S Bassi, A Alietti, C Corsini, L Roveda, P Bertazzoni, F Gigli, J Quarna, S Sammassimo, A Vanazzi, R Pastano, A Agazzi, L Calabrese, G Pruneri, G Martinelli

European Institute of Oncology, Milan, Italy

Background. High-dose chemotherapy followed by autologous stem cells transplantation (ASCT) is considered a reasonable option in patients with mantle cell lymphoma (MCL) responding to anthracycline-based chemotherapy regimens. MCL cells express CD20 in their surface, providing a target for immunotherapy with Rituximab and even if the full impact of adding the anti-CD20 monoclonal antibody to the treatment of MCL remains unclear, it may be important. *Aims.* We analysed our experience with the use of Rituximab as *in vivo* purging in association chemotherapy followed by ASCT as front-line treatment in naïve MCL patients followed at our Institution from 2000. *Methods.* From May 2000 to August 2008 27 newly diagnosed patients with histological proven MCL were treated in our Institution. We considered 20 males and 7 female with MCL, with median age of 55 years old (range 39-66) and in advanced disease (stage III-IV 25/27). Twelve patients presented extranodal disease and 9 of them gastrointestinal involvement. Induction treatment included anthracycline-containing chemotherapy (ACOD) in combination with monoclonal antibody, followed by two cycles of DHAP-modified regimen (ESHAP) with Rituximab. Responding patients received a conditioning regimen (high-dose Melphalan plus anthracycline) in association with Rituximab at day -7 and followed by autologous stem cells reinfusion. All patients underwent restaging before and just after ASCT procedure. *Results.* Before transplantation 26/27 patients presented a clinical response, 19 were in complete response and 7 in partial. Three patients did not underwent ASCT, one because serious infection in course of induction CHT, another because of patients refuse and the last because of progressive disease. After ASCT 23/24 patients achieved a complete response. The median time to recovery neutrophils ($>0.5\times10^3$) was 11 days (range 5-20) and that of platelets ($>20\times10^3$) was 15 days (range 9-48). During aplasia, 22 patients developed fever, mainly (17/22) of unknown origin. No toxic death was observed. With a median follow up of 40 months (range 4-97 months) 17 patients are still alive and 12 of them in complete remission. *Summary/Conclusions.* According to other published experience, our experience seems to confirm that high-dose chemotherapy fol-

lowed by ASCT is a valid option as up-front treatment in MCL patients and the addition of Rituximab may play an important role in improving results of chemotherapy used alone, probably because of its *in vivo* purging and synergic effect.

1563

TREATMENT OF PRIMARY MEDIASTINAL B CELL LYMPHOMA (PMBCL) WITH RITUXIMAB-CHOP PLUS RADIOTHERAPY: A MULTICENTRIC EXPERIENCE

S Falorio,[1] F Fioritoni,[1] G Fioritoni,[1] F Ferrara,[2] B Bocali,[2] N Di Renzo,[3] E Pennese,[3] F Angrilli[1]

[1]Civic Hospital, Pescara, Italy; [2]Division of Hematology and Stem Cell Transplantation Unit, Cardarelli Hospital, Naples, Italy; [3]Unit of Hematology, Vito Fazzi Hospital, Lecce, Italy

Background. Rituximab-CHOP (R-CHOP) immunochemotherapy is the current standard treatment of diffuse large B-cell lymphoma, but its impact on PMBCL is being evaluated. *Aims.* To retrospectively evaluate clinical characteristics and outcome of patients with PMBCL treated with R-CHOP plus radiotherapy (RT) in three Italian institutions. *Methods.* Between 3/2003 and 5/2009, 31 untreated patients with PMBCL have been admitted in our institutions. Disease evaluation was performed with whole-body computed tomography at diagnosis, after 3-4 courses of chemotherapy and at the completion of immunochemotherapy. Finally, all patients received PET/CT after treatment conclusion. The planned treatment consisted of 6-8 courses of R-CHOP21 or R-CHOP14 plus involved field (IF) RT (25-44 Gy). According to our treatment strategy, patients who obtained at least a partial remission (PR) at first restaging completed planned therapy, while patients who failed to achieve complete remission (CR) or had progressive disease (PD) started high dose chemotherapy (HDC) followed by autologous stem cell transplantation (ASCT). Retrospectively, we evaluated the response rate, overall survival (OS) and freedom from treatment failure (FFTF). *Results.* Seven patients were male and 24 female, with a median age of 35 years (15-81). Stage I-II was present in 25 patients (81%) and stage III-IV in 6 (19%). Nineteen patients (61%) had B symptoms; aaIPI was 0-1 in 23 cases (74%) and 2-3 in 8 cases (26%). Bulky disease, defined as a mass of 10 cm or more in greatest dimension, was reported in 24 cases (77%).Twenty-nine patients completed R-CHOP program and 28 of them received IFRT. RT was omitted in an 81 year old patient with non-bulky IA clinical stage, who gained CR after ICHT. After R-CHOP with or without RT, 26 patients (84%) achieved CR, 2 patients (10%) PR and one (6%) progressed. The last 3 patients and 2 patients who were unresponsive during immunochemotherapy received salvage treatment with HDC and ASCT. Four of them achieved CR and one died of PD. Among the 30 patients who obtained CR following first-line or salvage treatment, none relapsed so far. After a median follow-up of 31 months, OS and FFTF were 96% and 84%, respectively. *Discussion.* The best therapy for PMBCL is unknown. In retrospective analyses, but not in prospective randomized studies, third generation chemotherapy regimens, namely MACOP-B or VACOP-B, plus RT achieved better results in comparison with conventional CHOP. We think that R-CHOP plus IFRT is feasible, safe and effective in inducing durable CR in a high proportion of patients with PMBCL. Moreover, HDC and ASCT seems an efficacious salvage treatment for patients with refractory PMBCL and this approach should be applied immediately at the first signs of unresponsive disease.

1564

CENTRAL NERVOUS SYSTEM INVOLVEMENT IN PRIMARY MEDIASTINAL LARGE B-CELL LYMPHOMA: A SINGLE INSTITUTION EXPERIENCE

M Kichigina, G Tumyan, A Kovrigina, A Chekan, O Trofimova, D Bykov, N Tupitsin, D Osmanov

N.N. Blokhin Russian Cancer Research Center RAMS, Moscow, Russian Federation

Introduction. Primary mediastinal (thymic) large B-cell lymphoma (PMLBCL) is recognized as subtype of aggressive non-Hodgkin lymphoma with unique clinical and immunopathologic characteristics and relatively favorable outcome. PMLBCL has a high propensity for involving distant extranodal sites including central nervous system (CNS). The aim of our study was to evaluate the frequency and pattern of CNS involvement in PMLCL. *Methods.* Beetween 2004 and 2009, 86 previously untreated patients (pts) with PMLBCL were diagnosed and treated at our center. The median age was 30 years (range 15-63) and 49\86 (56%) were females. Stage II/IIE (63%) resulting from direct extension of the mediastinal mass has 54 pts (63%). Patients often presented with B symptoms (75%), bulky mediastinal masses (73%), extranodal involvement (80%) and increased LDH (84%). All patients received a regimen containing doxorubicin (CHOP+R, MACOP-B+R) with or without RT as initial therapy. *Results.* Five patients (5,8%) developed brain parenchymal involvement, 3 pts during or very shortly (2 months) after completion of treatment, 2 pts at relapse. Increased LDG, B symptoms and extranodal disease occurred at presentation in all pts, 3 pts had distant sites involvement (kidneys, adrenals, ovaries, pancreas, stomach). According to the age-adjusted International Prognostic Index score (aaIPI) 4 pts had aaIPI=2-3. As initial treatment, two pts received R-CHOP, 1- CHOP, 2 - R-MACOP-B. Four pts died of CNS disease, one patient now is alive after MCP regimen (HD MTX on days 1, 15, 30, CCNU on day 1, procarbazine on days 1-10). *Conclusions.* These data demonstrate that all patients PMBCL with CNS involvement initially belonged to the high-risk group. CNS relapse occurs early (median time to relapse 2 months) and is associated with a very poor prognosis. The propensity to involve the CNS parenchyma raises the concern that intrathecal prophylaxis may not be effective, moreover 2 pts had systemic therapy incorporating middle-dose MTX (400 mg/m^2). Our data suggests that CNS imaging should be considered in patients PMBCL with extranodal disease and addition of high-dose MTX (>1g\m^2) to the primary therapy may reduce CNS recurrence.

1565

PROGNOSTICAL SIGNIFICANCE OF KI-67 EXPRESSION AND IPI SCORE IN PATIENTS WITH PRIMARY MEDIASTINAL LARGE B-CELL LYMPHOMA: A SINGLE CENTRE RETROSPECTIVE ANALYSIS

L Lekovic, J Bila, M Todorovic, B Andelic, A Sretenovic, M Smiljanic, B Mihaljevic

Institute of Hematology, Clinical Center of Serbia, Belgrade, Serbia

Background. Primary mediastinal large B-cell lymphoma (PMBCL) is a relatively rare subtype of diffuse large B-cell lymphoma with distinctive clinical, immunophenotypic and genotypic features. In the absence of randomized trials, the prognostic factors and the optimal treatment of the patients with PMBCL remain a matter of debate. *Aim.* The aim of our study was to make a retrospective analysis of clinical features, prognostic factors, treatment approaches and outcome in patients with PMBCL. *Patients and methods.* Our study included 42 PMBCL pts who were treated in our institution between June 1999 and November 2009. Five patients were treated with chemotherapy (CT) including MACOP-B, EPOCH or CHOP and 37 pts with immunochemotherapy (ICT) (Rituximab+CT). Two patients had surgical resection of lungs followed with ICT. Twenty-eight patients (67%) received mediastinal involved-field radiotherapy (RT) at a median dose of 36Gy. All samples of lymph-node biopsies were analyzed for the immunohistochemical expression of Ki-67. The median follow up was 59 months. *Results.* The median age was 32±12,09 (range 19-73); 29/13 (69%) were females; 32 pts (76%) were younger than 40 yrs; 2 pts had stage I, 30 stage II, 7 stage III, 3 stage IV; 33 pts (78%) presented as a bulky disease; EN presentation had 8 pts (19%); Ki-67 expression ≥80% had 31 pts (74%); LDH was increased in 33 pts (78%), B2M in 23 (55%), and 19 (45%) had a superior vena cava syndrome. According to the IPI score, 22 pts had an IPI=0-1 and 20 an IPI=2-3-4. The response rate was CR/CRu= 31 pts (74%), PR=9 (21%) and NR=2 (5%). Twelve patients (27%) with PR achieved a CR after RT. Relapse of disease was found in 13 pts (31%) while 2 pts had two relapses. The 4-year OS and PFS were 61% and 52% respectively. The overall survival was significantly higher in female pts (log rank P=0,036), in pts with ECOG performance status <2 (log rank P=0,001) and in pts who received ICT (Tarone-Ware P=0,048). The patients in advanced CS (log rank P=0,04) had significantly shorter PFS. Analyzing the expression of KI-67 (<80% *vs.* ≥80%) and IPI score (<2 *vs.* ≥2), we found that these factors had the greatest prediction of disease progression. The patients with high Ki-67 expression had shorter PFS and frequent relapse of disease even in patients treated with ICT. *Conclusions.* Although the number of patients in the study was limited, data showed that the Ki-67 expression and IPI score have prognostic value in PMBCL patients. Futher more, the study showed that immunochemotherapy truely improves the survival and consolidation radiotherapy improves the quality of response in PMBCL patients.

1566

MALT VERSUS NON-MALT GASTROINTESTINAL (GIT) LYMPHOMAS-PROGNOSTIC PARAMETERS AND SURVIVAL

B Mihaljevic,[1] V Vujicic,[2] D Antic,[1] M Perunicic Jovanovic[1]

[1]Clinical Center Serbia, Belgrade, Serbia; [2]Clinical Center Podgorica, Podgorica, Montenegro

Background. Most frequent lymphomas located in the digestive tract are low grade B cell lymphomas arising from mucosa associated lymphoid tissue (MALT) and diffuse large B cell lymphomas (DLBCL). The most common site of involvement is the stomach followed by the small intestine and the colorectum. *Aim.* This study compared patients with extranodal lymphomas based on pathohistological finding (MALT *vs.* non-MALT) as well as regarding gastric and non-gastric localization, and also determining the significance of clinical-laboratory parameters related to therapeutic response and length of survival. *Methods.* A total of 82 patients with extranodal non-Hodgkin's lymphomas of the gastrointestinal tract were evaluated over a period 1998./2008. We analyzed demographic features, clinico-bilogical parameters, outcome to therapy and survival. *Results.* Regarding the localisation of the disease, the stomach was most frequently affected (55 patients, 67.1%) followed by small and large intestines (27 patients, 32.9% patients). As for the pathohistological findings, MALT lymphoma accounted for 55%, DLBCL 37%, while other subtypes accounted for 8% patients. Patients with MALT lymphoma had Helicobacter pylori infection significantly more than patients with other type of lymphomas (P<0.001). Statistically significant difference in patients' distribution was not found with respect to IPI index, bone marrow infiltration, anemia, hypoalbuminemia, or histological subtype and localization. Fifty one patients received chemotherapy, while others received immunochemotherapy. Complete remission achived 53 patients. Five years overall survival was 60%. There were no differences in outcome of patients regarding to pathohistological type, affected gastrointestinal tract organ and type of therapy. Statistically significant differences according to survival probability was obtained based on sex (survival was longer in woman), according to CS regarding to Ann Arbor and Lugano classifications (the patients with lower CS live significantly longer); according to IPI index (the survival is significantly longer in patients with low IPI score 0,1, and 2), as well as patients free of bone marrow infiltration whose survival is also significantly longer. In univariate analysis Ann Arbor stage IV (P=0.001), Lugano stage IV (P=0,002), bone marrow infiltration (P=0.002), IPI score more than 2 (P=0.001) and elevated LDH level (P=0.055) were significantly associated with poor survival. But, in multivariate analysis only Ann Arbor stage IV (P=0.023) retained their prognostic significance. *Conclusion.* Our results did not confirm differences between pathohistological type, affected gastrointestinal tract organ and type of therapy regarding to survival. Also, the parameters of disease extension at presentation (CS, IPI, marrow infiltration) are the most important prognostic factor in our group of GIT lymphoma.

1567

THE ROLE OF FDG-PET SCAN IN PATIENTS WITH INDOLENT NON HODGKIN LYMPHOMA (NHL)

T Perrone,[1] F Gaudio,[2] P Curci,[2] A Giordano,[2] C De Risi,[2] A Spina,[2] S Scardino,[2] A Niccoli Asabella,[3] I Montemurro,[3] G Rubini,[3] A Liso,[4] G Specchia[2]

[1]Bari University, Bari, Italy; [2]Hematology, Bari University, Bari, Italy; [3]Nuclear Medicine, Bari, Italy; [4]Haematology, Foggia University, Foggia, Italy

Background. Positron emission tomography (PET) imaging using 18-fluoro-2-deoxyglucose (FDG) is routinely used in the management of Lymphomas. Although several studies have demonstrated PET sensitivity and specificity in high grade non-Hodgkin lymphoma (NHL) and in Hodgkin lymphoma, the intensity of FDG uptake is generally low in indolent lymphomas and few data are available regarding PET accuracy in low grade NHL . Several studies have concluded that PET appears useful for the staging of Follicular lymphoma (FL) but has a limited usefulness in the other indolent lymphoma subtypes. Aim of our study was to investigate the potential impact of PET in the management of patients with indolent lymphomas. *Methods.* We performed a retrospective single institution study on a population of 48 patients (pts) with indolent NHL, observed from September 2005 to January 2009, who underwent PET for evaluation of treatment response; 18 (37%) of them had also undergone PET at the time of the initial diagnosis. Median age was 56ys (37-86), 32 (66%) had stage IV, 15 (31%) LDH and 23 (48%) high β2μ globulin levels. Histology was: follicular lymphoma (FL) in 31 pts (65%), Marginal zone lymphoma (MZL) in 12 (26%), small lymphocytic lymphoma (SLL) in 3 (6%), Lymphoplasmocytic lymphoma in 2 (3%). All pts underwent CT scan, Bone Marrow biopsy, and physical examinations. In 16 (92%) pts PET was positive; 13 (75%) of them had FL. In 15 (85%) pts there was agreement between CT scan and PET. In 3, PET was positive and CT negative. Chemo-immunotherapy was administered in all pts, RCHOP like in 37 (77%), RFND 11 (23%). We performed a correlation between positive PET at diagnosis and the achievement of Complete Remission (CR). *Results.* Response to treatment was evaluated with CT scan, PET and clinical examinations. Thirty-four (70%) pts achieved CR, 14 (30%) Partial Remission (PR). In 27 pts (57%) there was agreement between CT scan and PET. In 16 (34%) pts PET was negative and CT positive. All these pts received more treatment and subsequently achieved CR. As to the correlation between PET at diagnosis and the achievement of CR: 14 (85%) pts with positive PET did not obtain CR. After a median follow up of 21 months (7- 57), comparing the two groups with negative and positive PET, respectively, at the end of treatment, Progression Free Survival (PFS) of pts with a negative PET was significantly better (P= 0.015). *Conclusions.* In our study, in agreement with literature, we observed that PET has a good sensitivity in FL; PET positivity at the initial staging is correlated with a worse response rate, and PFS at 2 years for pts with a negative PET at the end of treatment is significantly better than with a positive PET. Further studies need to be designed to investigate the role of PET in indolent lymphomas, the optimal timing for PET, and to establish a possible predictive value of PET for response to treatment and PFS.

1568

NT-PROBNP IS AN INDEPENDENT BIOMARKER OF MAJOR CHEMOTHERAPY-RELATED TOXICITY AND CLINICAL OUTCOME IN NON-HODGKIN LYMPHOMA

A Salar,[1] E Gimeno,[2] J Comin,[3] A Alvarez-Larrán,[2] M Gomez,[3] B Sanchez-Gonzalez,[2] E Domingo-Domenech,[4] F Garcia-Pallerols,[2] C Pedro,[2] E Abella,[2] S Saumell,[2] C Besses[2]

[1]Hospital del Mar, Barcelona, Spain; [2]Hematology, Hospital del Mar, Barecelona, Spain; [3]Cardiology, Hospital del Mar, Barcelona, Barecelona, Spain; [4]Hematology, ICO/Hospital de Bellvitge, Barecelona, Spain

Introduction. NT-ProBNP provides diagnostic and prognostic information in many heart syndromes but its role in lymphoma patients has yet not been established. The aim of the study was to investigate the association between NT-ProBNP levels and the risk of major chemotherapy-related toxicity and death. *Patients and methods.* We studied 104 consecutive patients with non-Hodgkin lymphoma treated with chemotherapy. High-resolution echocardiography and serum NT-ProBNP concentration were determined prior to chemotherapy. Major toxicity events after first-line chemotherapy and death from any cause were the primary end points of the study. An independent series of patients served as validation set. *Results.* With a median follow up of 13 months, 26 patients had a major toxic event related to first-line chemotherapy and 18 had died at last follow-up. The NT-ProBNP threshold with the best predictive accuracy for major chemotherapy-related toxicity and death was 900 pg/mL. In a multivariate Cox regression model, the hazard ratio (HR) for major chemotherapy-related toxicity and death for patients with NT-proBNP levels of >900 pg/mL were 7.3 (95% CI, 3.2-16.4; P<0.001) and 11.1 (95% CI, 3.8-32.9; P<0.001), respectively. NT-ProBNP added prognostic information independently of other well-established risk factors, including the International Prognostic Index. This marker also proved to be a predictor of death in the validation set (HR 4.4 [95% CI, 1.6-12.2] P=0.02). *Conclusion.* NT-ProBNP is a marker of major toxicity after first-line chemotherapy and death from any cause in non-Hodgkin lymphoma patients. It provides new additional prognostic information surpassing the one given by conventional lymphoma risk factors.

1569

CLINICAL FEATURES OF THE PATIENTS WITH LYMPHOPROLIFERATIVE DISORDERS AND ASSOCIATED AUTOIMMUNE RHEUMATIC DISEASES: SINGLE CENTER STUDY

D Suvajdzic,[1] M Djurdjevic,[2] R Colovic,[1] M Petrovic,[1] V Elezovic,[1] S Tomin,[1] D Gotic,[1] A Jankovic,[1] R Todorovic,[1] D Vidovic,[1] D Bila,[1] T Djunic,[1] M Perunicic,[1] S Mihaljevic[1]

[1]Clinical Center Serbia, Belgrade, Serbia; [2]Clinical Center Kragujevac, Hematology Department, Kragujevac, Serbia

Background. It has been suggested that patients affected by autoimmune rheumatic diseases (ARD) particularly rheumatoid arthritis (RA),

systemic lupus erythematosus (SLE) and Sjögren's syndrome (SS) are more prone to developing lymphoproliferative diseases (LPD). *Aims.* To analyze clinical features of LPD occurring in patients with ARD. *Methods.* 40 patients with LPD (35 non-Hodgkin lymphoma, 3 Hodgkin lymphoma and 2 myeloma) in the setting of ARD (11 RA, 15 SLE, 12 SS, 1 sclerodermia, 1 dermatomyositis) managed in the Clinic of Hematology during the period 1994-2006 were retrospectively analyzed. For the LPD cases ascertained descriptive statistics and Cox regression were calculated. *Results.* The median age of LPD patients at diagnosis was 55 years (range 33-76). There were 31 female and 9 male. In 37/40 patients ARD preceded LPD. The median interval between the onset of ARD and LPD development was 91 months (range 21-212). This interval was significantly longer in RA (113 months, range 25 - 212) than in SLE (75 months, range 21-132) and SS patients (65 months, range 29-154). In only 3 patients LPD (2 follicular NHL, 1 small lymphocytic NHL) preceded ARD (SLE 2, SS 1) with median interval time from LPD to ARD development of 39 months (range 9-72). The most frequent LPD type was NHL (35/40). The primary site of NHL was nodal in 18 and extranodal in 17 cases. The clinical stages (CS) distribution of NHL patients was as follows: CS I 5, CS II 3, CS III 13 and CS IV 14. Constitutional symptoms and bulky disease were registered in 26/35 and 3/35 cases, respectively. 32/35 NHL cases were of B-cell type (RA 8, SLE 13, SS 11) while 3 cases were of T-cell type (SLE 2, RA1). The NHL histological distribution was as follows: diffuse large B-cell lymphoma (12/35), follicular (7/35), small lymphocytic (5/35), marginal zone (5/35), Burkett NHL (2/35), anaplastic large T-cell (2/35), lymphoplasmacytic lymphoma 1/35, peripheral T-cell lymphoma (1/35). The LPD patients were treated as follows: chemotherapy alone in 22/40 (CHOP 13, COP 1, FC 2, VAD 2, ABVD 2, Chlorambucil 2), rituximab plus CHOP in 9/40 cases, chemotherapy (ABVD 1, COP 4) followed by radiotherapy in 5/40 and radiotherapy alone in 4/40 patients. The evaluation of the first line therapy showed: complete response in 16/35, unconfirmed complete response in 2/35, partial response in 8/35, stable disease in 7/14 and disease progression in 7/14 patients. NSAID, corticosteroids, cyclophosphamide, azathioprine, methotrexate and hydroxychloroquine were used for treatment of ARD before LPD development. There was no correlation between LPD histological subtype and type of antirheumatic therapy. 31 patients had died until the end of the study with a median survival of 39 months (range 3-78) after LPD diagnosis. *Summary.* Our findings are in line with mostly other reports showing more aggressive course of LPD in the setting of ARD represented in advanced clinical stages, constitutional symptoms, extranodal manifestation and aggressive histological subtype. without significant correlation between used antirheumatic drugs and LPD histological subtype.

1570

RITUXIMAB MAINTENANCE AFTER FIRST LINE IMMUNOCHEMOTHERAPY ACHIEVES EXCELLENT HIGH DISEASE CONTROL IN BOTH *DE NOVO* FOLLICULAR AND MANTLE CELL LYMPHOMAS

A Angona,[1] S Saumell,[2] B Sánchez-González,[2] C Pedro,[3] E Gimeno,[3] M García,[2] A Alvarez-Larrán,[3] E Abella,[2] J Tena,[2] A Ferrer,[3] C Jiménez,[2] C Besses,[3] A Salar[2]

[1]Hospital del Mar, Barcelona, Spain; [2]Hematología clínica, Hospital del Mar, Barcelona, Spain; [3]Hematología Clínica, Hospital del Mar, Barcelona, Spain

Background. Rituximab (R) maintenance has demonstrated survival improvement compared with observation in patients with relapsed or refractory follicular lymphoma (FL). The efficacy and safety of RM in patients with advanced follicular lymphoma after first line immunochemotherapy is still unknown. The aim of this study was to retrospectively evaluate our experience with rituximab maintenance (RM) in *de novo* follicular (FL) and mantle cell lymphoma (MCL). *Patients and methods.* patients with *de novo* FL or MCL achieving complete remission (CR) or partial remission (PR) after first line immunochemotherapy were eligible. Three types of RM were used during study period: RM1) 375 mg/m^2/week × 4 consecutive weeks every 6 months during 2 years, RM2) R 375 mg/m^2 every 3 months during 2 years or RM3) R 375 mg/m^2 every 2 months during 2 years. Progression free survival was calculated from the day of the first R infusion and overall survival from the day of first treatment. *Results.* Forty-four patients were included: 39 (89%) FL and 5 (11%) MCL. The median age was 69 years (range 27-85) with 46% being male. Status at diagnosis: Stage I in 5%, II in 9%, III in 16% and IV in 71%; B-symptoms in 32%; IPI 0-1 in 21%, 2-3 in 58% and 4-5 in 21%. Immunochemotherapy regimens prior to RM: without anthracyclines 30%, with anthracyclines 61% and with purine analogs 9%. Status previous starting RM: CR in 35 (80%) and PR in 9 (20%). Types of RM: RM1 in 41%, RM2 in 52% and RM3 in 7%. Eight pts did not finish RM: 5 progressive disease, 1 infection, 1 delayed prolonged neutropenia and 1 exitus. Eleven pts are still receiving RM. During RM, 4 pts have progressed among CR group and 3 pts among PR group. Three out of 7 pts in the PR group have improved to CR during RM. PFS was 80% at 2 years and 74% at 4 years. PFS was significantly better for those pts receiving anthracyclin-containing immunochemotherapy prior RM compared with those who did not (91% *vs.* 61% at 2 years, P=0.025). OS was 97% at 2 years and 94% at 4 years. Toxicity was generally low, mainly minor respiratory infections. RM was prematurely withdrawn by adverse events in 2 pts (5% of the whole series): 1 pt due to recurrent infections (64 years old) and 1 pt due to delayed severe neutropenia (69 years old). Hipogammaglobulinemia was present in 42 % of cases before RM and in 39% in the last RM received. *Conclusions.* Rituximab maintenance after first-line immunochemotherapy is very active strategy for both *de novo* follicular and mantle cell lymphomas. Interestingly, anthracyclin-containing chemotherapy prior to RM has a reduced progression rate. Although, minor adverse events are seen, mainly respiratory infections, RM in first line is feasible for the majority of patients.

1571

HIGH FREQUENCY OF PRIMARY THYROID TUMORS (PTC) OCCURRING IN A GROUP OF 428 CONSECUTIVE LYMPHOMA PATIENTS OBSERVED IN A 5 YEARS PERIOD IN A SINGLE HAEMATOLOGICAL UNIT

G Antolino, MC Cox, R Baldini, A Bartolazzi, C Tatarelli, V Naso, B Veggia, B Monarca, MA Aloe Spiriti, S Sciacchitano

AO Sant'Andrea, 2nd School of Medicine, Sapienza University of Rome, Rome, Italy

Background. The emergence of secondary neoplasia after treatment of a primary cancer is a more and more frequent event. The probability of a secondary cancer is due to the toxic effect of therapies and to genetic predisposition. Nonetheless epidemiological studies have highlighted that, despite previous therapies, several gene mutations and/or polymorphism are involved in the individual predisposition to multiple primary tumors. *Aims.* Evaluating the incidence of primary solid tumors in patients affected by lymphoma. *Methods.* The incidence of other primary cancers, was investigated in a series of 428 patients diagnosed with lymphoma between January 2003 and January 2010. Primary cancers were considered 1) cancer diagnosed at the same time of lymphoma in patients who had not previously received chemotherapy and/or radiotherapy 2) solid cancers that were not synchronous with the diagnosis of lymphoma but diagnosed in patients who were not treated with chemotherapy and/or radiotherapy, with the exception of those patients who received radiotherapy outside the field of tumor occurrence. Patients suffering from Sjogren syndrome were excluded from the analysis. *Results.* 21 patients (4.9%) out of 428 consecutive lymphoma patients, had a diagnoses of a primary solid tumour and overall 25 cancers were diagnosed. The relative frequency (RR) of the different tumours was the following: thyroid 32% (8 cases), renal 16% (4 cases), melanoma 12% (3 cases), breast 15% (2 cases), lung 8% (2 cases), uterus 15% (2 cases), liver 4% (1 case), colon 4% (1 case), myxofibrosarcoma 4% (1 case), tongue 4% (1 case). *Conclusions.* The RR of PTC (32%) in our group of lymphoma patients appears to be unexpectedly high compared to the RR of PTC in the Italian Register of Tumours (1.6%), suggesting possible common mechanism or similar pathogenetic pathways. This association deserves further studies to be elucidated.

1572

REVISED INTERNATIONAL PROGNOSTIC INDEX (R-IPI): A NEW PROGNOSTIC MODEL FOR DIFFUSE LARGE B-CELL LYMPHOMA PATIENTS

E Gimeno,[1] T Gimenez,[1] F Garcia-Pallerols,[2] A Alvarez-Larrán,[2] B Sánchez-González,[2] C Pedro,[2] E Abella,[2] S Saumell,[2] A Angona,[1] M García,[1] C Besses,[2] A Salar[2]

[1]Hospital del Mar, Barcelona, Spain; [2]Hematology, Hospital del Mar, Barcelona, Spain

Background. In the last decade, anti-CD20 monoclonal antibodies have modified treatment strategies for diffuse large B-cell lymphoma (DLBCL), leading to a marked improvement in patients outcome. The International Prognostic Index (IPI) is the prognostic score most commonly used to predict overall survival (OS) and progression free survival (PFS) in patients with DLBCL. However, it was designed before the addition of Rituximab (R) to the standard chemotherapy regimens. Recently, a new modified IPI score (R-IPI) has been described for Rituximab-treated patients. *Aim.* To compare the standard IPI and R-IPI model scores

in patients with DLBCL treated with R-containing regimens. *Methods.* A retrospective analysis of 100 patients (median age [range] 62 years [19-89]) diagnosed with CD20 positive DLBCL was performed in Hospital del Mar, Barcelona. First line treatment consisted of R monotherapy (n= 4), R-CHOP (n= 59), R-CMyOP (n= 20), R-EPOCH (n= 8) and R-another chemotherapy schedules (n=9). *Results.* Distribution of patients by standard IPI and R-IPI, and OS and PFS at 48 months according to the IPI and R-IPI were as follows (Table 1). Median follow up was 35 (range 1-87) months. OS and PFS of the whole cohort were 70% and 67.5% at 4 years, respectively. Median OS and PFS were 61 months (CI 95%, 53-69%) and 62 months (CI 95%, 54--70), respectively. *Conclusions.* 1. Standard IPI score and R-IPI model can identify different risk groups of patients with statistically significant different OS and PFS. 2. R-IPI model is slightly better for stratifying low risk DLBCL patients in the Rituximab® era.

Table 1.

IPI Risk Groups	patient n	OS (%)	PFS (%)	R-IPI Risk Groups	patient n	OS (%)	PFS (%)
Low 0-1	42	87	85	Low 0	14	100	91
Low-Intermediate 2	16	71	80	Intermediate 1-2	44	78	75

TREATMENT OF SPLENIC MARGINAL ZONE LYMPHOMA

H Julhakyan, A Grjimolovskiy, S Karagulyan, A Magomedova, A Kremenetskaya, S Kravchenko, T Obukhova, I Kaplanskaya, R Samoylova, A Vorobjev

Hematology Research Center of Russian Academy of Medical Science, Moscow, Russian Federation

Splenic marginal zone lymphoma (SMZL) is well known lymphoma. *Aim.* Our goal is to characterized SMZL and shows the most effective method of treatment. *Material and methods.* 86 patients (33 males, 53 females) with average age 59,6 years were included in the study. The diagnosis based on a typical histological picture and immunophenotype. We gathered demographic and clinical data, blood counts at presentation, spleen and liver sizes, lymphadenopathy, the presence of monoclonal component, anti-HCV, anti-HBsAg antibodies, lesions of bone marrow, cytogenetic findings, treatment, type of response and duration. Follow up was from 3 months to 7 years. Splenomegaly and bone marrow involvement was diagnosed in all cases, hepatomegaly in 60,5% cases, visceral lymphadenopathy, high level of LDH and B-symptoms in half of cases, combination with AIHA in 6 cases, positive serology for viral hepatitis in 13 patients. In 5 cases we are identified aberrant phenotype with $CD5^+$ expression. In half of patients we revealed cytogenetic abnormalities (trisomy 3, 12, 18, deletion 7, t(14;19)(q32;q13)). Depending on the initial treatment strategy, all patients were divided into groups: I group - untreated patients, II group - patients who have chemotherapy held as first-line therapy, III group - patients who performed a splenectomy, IV group - patients who performed a splenectomy and subsequent chemotherapy. *Results.* In II group after an average of 6 months had a progression and progression-free survival (PFS) was 0%. In the III group, PFS (in terms of monitoring up to 7 years) was 70% (P=0.01). Overall survival III group was about 95% (for a period of observation up to 7 years). *Conclusion.* SMZL is a heterogeneous, due to the clinical course (secretion of paraprotein, the combination with AIHA), different cytogenetic abnormalities, aberrant expression of CD5. Splenectomy is the first-line therapy in patients with SMZL, which confirmed the data PFS, which amounted to the deadline of 7 years was 70% (P=0,01).

1574

PRIMARY NODAL DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL), STAGE I-II. CLINICOBIOLOGICAL FEATURES AND PROGNOSTIC FACTORS: EXPERIENCE IN A SINGLE INSTITUTION

S Mercadal,[1] N Garcia Muñoz,[1] E González-Barca,[1] E Domingo-Domenech,[1] F Climent,[2] AC Oliveira,[1] J Sarra,[1] V Clapes,[1] V Romagosa,[2] A Fernandez de Sevilla[1]

[1]Ico L'Hospitalet, Barcelona, Spain; [2]H. Bellvitge, Barcelona, Spain

Background. DLBCL is an aggressive and potentially curable lymphoma. It presents itself as a localized disease in 30% of all cases and as primary nodal in 50-60% of these. *Aims.* To analyze the main clinicobiological characteristics, response to therapy, outcome and prognostic factors. *Methods.* Ninety four patients (42/52 M/F; median age, 60.5 years) with a novo primary nodal DLBCL, Ann-Arbor I-II stage were diagnosed in our centre during a 17-year period and recorded in a data base. *Results.* Twenty-eight patients (30%) were stage I and 66 (70%) stage II. The distribution according to IPI were as follows: low risk, 44 (47%); low-intermediate risk, 37 (39.4%) and high-intermediate risk, 13 (13.6 %). The main clinicobiological features are in the Table. The treatment consists of: fifty one patients were treated with CHOP-like chemotherapy, forty two with CHOP-like plus rituximab chemotherapy and radiotherapy (1). Complementary radiotherapy (C-RT) was administered in 61%. C-RT was associated with a significant overall survival (OS) and event free survival (EFS) at 5 years (77% *vs.* 58%; P=0.015 and 76% *vs.* 52%; P=0.019 for patients who received C-RT respect the ones that didn´t receive C-RT). Response rates were as follows: 82% complete response (CR), 9.5% partial response and 8.5% failure. The overall survival (OS) at 5 years was 70% (CI 95%: 60-80%). CR and OS were slightly higher in regimens containing rituximab than without rituximab (83% *vs.* 80%, respectively; P=0.31, y 73% *vs.* 68%, respectively; P=0.43). The median follow-up was 4.2 years. 16 of 77 patients in CR eventually progressed, with a event free survival at 5 years 66% (CI 95%: 56-76%). Thirty-two patients died (progression, 28; sepsis, 2; acute ischemic stroke, 1 and gastric adenocarcinoma, 1). The IPI at diagnosis and β2-microglobulin were the main prognostic factors (OS at 5 years: 84%, 60% and 47% for patients with low, low-intermediate and high-intermediate risk, respectively; P=0,001; OS at 5 years: 80% and 58% for patients with high and low β2-microglobulin, respectively; P=0,014). *Summary.* localized nodal DLBCL have a particular clinicobiological features. C-RT seems to be associated with better OS and EFS. IPI and β2-microglobulin are the main prognostic factors. The exact rule of treatment with rituximab need to be investigated.

Table.

	DLBCL (N=81)

DRAMATIC RESPONSE TO LENALIDOMIDE OF A REFRACTORY CUTANEOUS DIFFUSE LARGE B-CELL LYMPHOMA,LEG-TYPE

O Fitoussi,[1] B Beylot-Barry,[2] S Cosculluela,[1] M Parrens,[2] JP Merlio[2]

[1]Polyclinique Bordeaux Nord Aquitaine, Bordeaux, France; [2]Hôpital Haut-Lévêque, Pessac, France

Background. Primary cutaneous diffuse large B-cell lymphoma, leg-type (PCLBCL-LT) is a distinct entity which mostly occurs in the elderly and which has a predilection for the legs. It is characterized by confluent sheets of large cells, with a round morphology and a strong expression of BCL2, Foxp3 and IRF4, without IRF4 rearrangement. As opposed to other primary cutaneous B-cell lymphoma, PCLCCL-LT

has a poor prognosis with a five-year survival rate around 50%. Moreover, while initial responses are usually obtained with a combination of chemotherapy and rituximab, skin but also extra-cutaneous relapses occur in 50% of patients. We report herein a dramatic response to lenalidomide in a PCLBCL-LT refractory to various treatment protocols. *Case.* A 75 year old woman presented with a dark purple nodule on the left leg in September 2005. Skin biopsy showed dense proliferation of centroblasts with a CD20, BCL2, BCL6, MUM1 positive staining and high proliferative index as all the cells expressed Mib1. A B-cell clone was detected by PCR. PET scan detected multiple foci on the same leg and a spread to the inguinal lymph node (SUV >4). An initial complete response was obtained by May 2006 after 6 cycles of R-CHOP associated with radiotherapy. From November 2007, skin recurrences were treated successively with radiotherapy, ibritumab tiuxetan and then six cycles of Mini-CHVP + rituximab, followed by rituximab maintenance every two months. In April 2009, a fourth skin recurrence, associated with neurogenic pain along the path of the sciatic nerve, led to a regimen of Holoxan-VP 16. This treatment was ineffective with progression of tumors on the same leg (Figure 1A). Skin biopsy showed a similar histology and phenotype profile. FISH analysis did not detect IRF4 gene rearrangement and a B-cell clone identical to the initial one was found by PCR. Finally, in September 2009, the patient was prescribed single-agent lenalidomide (10 mg/day), administered in cycles of three weeks separated by one-week wash-out periods. Within one month, all lesions had regressed (Figure 1B) and the neurogenic pain had disappeared. Six months later, the patient was maintained on lenalidomide (20 mg/day) with no recurrence and no clinical or biological adverse reactions. *Conclusion.* The encouraging rapid complete response observed in this patient suggests that lenalidomide may be safe and effective in relapsed or refractory aggressive lymphoma such as PCLBCL-LT. To our knowledge, this is the first time that such a case has been reported. Carefully designed studies are needed to determine the place of lenalidomide in PCLBCL-LT management as well as its biological effects possibly through a down regulation of the IRF4 and NF-KB pathway that has been demonstrated to be involved in PCLBCL-T.

Figure. Left leg in September 2009 (1A) and after one month of lenalidomide treatment (1B).

1576

RITUXIMAB PLUS CVP (CYCLOPHOSPHAMIDE, VINCRISTINE, AND PREDNISOLONE) COMBINATION CHEMOTHERAPY IN ADVANCED STAGE MARGINAL ZONE B-CELL LYMPHOMA AS A FIRST-LINE THERAPY

HJ Kang,[1] BY Ryoo,[1] CW Suh,[2] WS Kim,[3] SJ Kim,[3] JS Kim,[4] JJ Lee,[5] DH Yang,[5] SR Lee,[6] GW Lee,[7] HJ Kim,[8] HY Kim,[8] SY Oh,[9] HC Kim,[10] HS Eom,[11] J Chung,[12] J Park[13]

Background and Aims. Although successful results were reported with local treatment or several antibiotics for localized marginal zone B-cell lymphoma (MZBCL), it presents as a disseminated disease in one-third of the cases at diagnosis and relapses involving distant sites after local therapy have been reported. We performed multi-center, phase II trial to investigate the efficacy and safety of rituximab plus CVP (R-CVP) combination chemotherapy in patients with previously untreated stage III/IV MZBCL. Preliminary results of this trial previously reported at the 14th EHA (abstr 980), in here, we report updated results. *Methods.* Patients received rituximab 375mg/m^2 on day1 of each cycle. CVP consisted of cyclophosphamide 750 mg/m^2 and vincristine 1.4 mg/m^2 (maximum 2.0 mg), given intravenously on day 1, and oral prednisolone 100 mg on days 1-5. The treatment was repeated every 3 weeks and continued for 6 or 8 cycles until disease progression, withdrawal due to toxicity, or withdrawal of consent. *Results.* Between March 2006 and July 2008, a total of 42 patients were enrolled with informed consent at this trial from 13 institutes in Korea. Among these patients, 2 patients were dropped out after 1 and 2 cycles of chemotherapy without evaluation. The median age of the evaluated 40 (24 males, 16 females) patients is 56 (range, 29-77) years. Thirty three patients (82.5%) had extranodal sites involvement, 19 (47.5%) of who had 2 or more sites involved. The IPI score were 1 in 10 (25%), 2 in 17 (43%), 3 in 11 (27%), and 4 in 2 (5%) patients. The patients received a total of 287 cycles of R-CVP chemotherapy (range 3 - 8 [median 8] cycles/person). There were 24 CR (60%), 11 PR (27.5%), 4 SD (10%), and 1 PD (2.5%), making response rate 87.5% (95% confidence interval, 77.1 - 97.9%). There were 30/287 cycles (10.5%) and 5/287 cycles (1.7%) of grade 3/4 neutropenia and febrile neutropenia, respectively. Non-hematologic toxicities were mild and tolerable. There were 19 cycles (6.6%) of delayed chemotherapy (median 1 week) mainly because of neutropenia (10 cycles) and non-hematologic toxicities (6 cycles). Dose reduction was needed in 9 patients (23 cycles) for cyclophosphamide and in 1 patient (4 cycles) for vincristine. There was toxicity-related hospitalization in 9 patients (22.5%) during treatment. But, there was no treatment-related death. After a median follow-up of 30.7 months (range, 11.1-43.8 months), the estimated three-year progression-free survival and overall survival were 59.5% and 95.0%, respectively. *Conclusions.* R-CVP regimen seems rather effective and tolerable in the treatment of advanced stage MZBCL. Longer follow-up period for these patients and other comparative studies are warranted to verify the results of this trial.

1577

PROPOSAL OF NEW DISEASE EXTENT GROUPS IN PATIENTS WITH PRIMARY EXTRANODAL DIFFUSE LARGE B CELL LYMPHOMA

EK Kim, K Kim, DH Yoon, S Kim, J Huh, DH Lee, CW Suh

Asan Medical Center, Seoul, South-Korea

Background. The incidence of primary extranodal non-Hodgkin's lymphoma (NHL) is increasing worldwide. The primary extranodal NHL is very heterogeneous disease and there is a variety of opinions about the uniform application of the traditional Ann Arbor staging system to primary extranodal NHL. *Aims.*We explored modification of disease extent groups for patients with primary extranodal diffuse large B cell lymphoma (DLBCL). *Methods.* We retrospectively evaluated 249 patients with primary extranodal DLBCL who diagnosed between July 1993 and July 2007. We applied various disease extent grouping systems and compared to Ann Arbor staging system. *Results.* The median age was 55 years (range, 15-84). The gender distribution was 49.0% (122/249) men and 51.0% women (127/249). The stomach was the most common primary extranodal site (30.1%, 75/249). Ann Arbor staging system could not discriminate appropriately the survival among stage 1 through 4. Disease extent groups in figure showed the best discrimination. According to modified disease extent groups, especially group 4 showed significantly worse outcome compared to other groups (P<0.05). *Summary/Conclusions.* Ann-Arbor system cannot be easily applied to primary extranodal DLBCL. Modified disease extent grouping system of current study could be useful for patients with primary extranodal DLBCL.

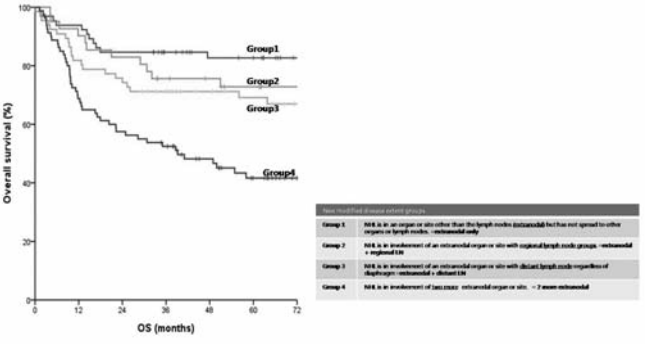

Figure. Modified disease extent groups.

EXPRESSION OF C-FLIP IN NODAL DIFFUSE LARGE B CELL LYMPHOMA (DLBCL): AN IMMUNOHISTOCHEMICAL STUDY

O Markovic,[1] D Marisavljevic,[2] B Filipovic,[1] V Cemerikic,[3] M Todorovic,[4] M Perunicic,[4] B Mihaljevic[4]

[1]KBC Bezanijska kosa, Belgrade, Serbia; [2]KBC Bezanijska Kosa, Belgrade, Serbia; [3]Histolab, Belgrade, Serbia; [4]Institute of Hematology, KCS, Belgrade, Serbia

Background. C-FLIP is one of the important antiapoptotic proteins that have been shown to be overexpressed in various tumor cells. It was shown that downregulation of c-flip results in sensiting resistent lymphoma cells, but data about his clinical and prognostic significance in patients with DLBCL are not consistent. The aim of this study was to evaluate the incidence and prognostic significance of c-FLIP expression in patients with nodal DLBCL, as well as the relationship of their expression with selected clinical data, histological features and proliferative activity of lymphoma cells. *Methods.* We studied 54 patients with primary nodal DLBCL. Immunohistochemistry was performed on formalin/fixed, paraffin/embedded tissue section of lymph nodes with monoclonal antibody against c-FLIP. Expression of c-FLIP was analyzed using standard immunohistochemical method on routinely processed paraffin-embedded lymph node specimens. Cut off value of 40% was used for discriminate c-FLIP positive and c-FLIP negative sections. The patients were treated with CHOP or R-CHOP chemotherapy regimen. *Results.* The group consisted 30 of men and 24 women with median age of 54,98 years. Advanced stage (III/IV) was observed in 37 (68.52%) cases, and distribution according to the IPI was as follows: low risk 16 (29.62%) patients, low intermediate risk 21 (38.88%), high/intermediate risk 11 (20,37%) and high risk 6 (11.11%) patients. Overall response rate was achieved in 42 patients (64.45%). A complete response (CR) was achieved in 31 patients (73.8%). C-FLIP expression was detected as diffuse cytoplasmatic staining in 23 (42.59%). There was no significant correlation between c-FLIP expression and age, gender, clinical stage, IPI, hemoglobin concentration, platelet count and histological type. No association was observed between the expression of c-FLIP and proliferative activity index (measured with Ki-67 immunoreactivity), subtype (GCB/ABC) and response to therapy. No significant difference was observed regarding overall survival between c-FLIP positive and c-FLIP negative patients (P=0.410). *Conclusion.* Our results have shown that c-FLIP has not the prognostic significance in patients with nodal DLBCL. However, larger studies are mandatory to confirm these observations.

1579

MULTIPLE MUCOSA-ASSOCIATED LYMPHOID TISSUES (MALT)-ORGAN INVOLVED MARGINAL ZONE B-CELL LYMPHOMA: CONSORTIUM FOR IMPROVING SURVIVAL OF LYMPHOMA (CISL) STUDY

SY Oh,[1] WS Kim,[2] JS Kim,[3] SJ Kim,[2] DH Lee,[4] JH Won,[5] IG Hwang,[6] MK Kim,[7] SI Lee,[8] JG Kim,[9] DH Yang,[10] HJ Kang,[11] CW Choi,[12] J Park,[13] HJ Kim,[14] JH Kwon,[14] HS Lee,[15] GW Lee,[16] HS Hyeon Seok,[17] CW Suh[4]

Background. According to previous review, multiple mucosa-associated lymphoid tissues (MALT)-organ involved marginal zone B-cell lymphomas (MZLs) are present in 10%~30% of patients. But, specific relationship among involved organs, clinical features, and prognosis were not clearly identified. *Aims.* In this study we conducted retrospective analyses of multiple MALT organs involved MZLS (MM-MZLs) to identify their clinical features, treatment, and prognosis. *Methods.* For analysis, between Jun. 1987 and Jun. 2009, a total of 55 patients with histologic diagnosis of MM-MZL from 17 different institutions in Korea were included. MM-MZL was defined that MZL involved more than 2 different MALT organs. Multiple involvements within one MALT organ (ex- multiple lung nodules, multiple stomach lesions) were excluded. *Results.* The male/female ratio of the 55 patients was 41 to 14. The median age of our subjects was 59 years (range: 30-82 years). MM-MZL without lymph node (LN) or was only 9 patients (36.2%). BM involved observed 17 patients (30.9%). The most common site of involvement was gastrointestinal (GI) tract (25 patients-45.5%) followed by lung (40%), waldeyer's ring (WR) (27.3%), and ocular area (25.5%). Ocular MZLs were commonly accompanied with WR- or lung-MZLs. GI- MZLs were WR or GI-MZLs. Lung MZLs were frequently observed with ocular and GI-MZLs. WR-MZLs were ocular or GI-MZLs (Figure). 53 patients had treated -2 watchful wait. 48 patients had received chemotherapy based treatment. Out of them, CR or PR was achieved in 38 patients (79.2%, 95% CI, 67-91%). Median time to progression (TTP) was 2.3 years (95% CI, 1.4-3.2 years). Cause-specific overall survival (OS) was not reached median value. 5 year OS rate was 84.9%. There were no differences between MM-MZL alone and LN or BM involved MM-MZL in median TTP (5.7 years *vs.* 2.0 years, P=0.271) *Conclusion.* MM-MZLs tend to be an indolent disease - characterized by prolonged survival with frequent relapses. The majority of them was controlled well with chemotherapy based treatment, and could achieve prolonged survival. GI, lung, WR, and ocular area were commonly presented with other MALT site MZL and it seems to be existing organ relationship within MM-MZLs.

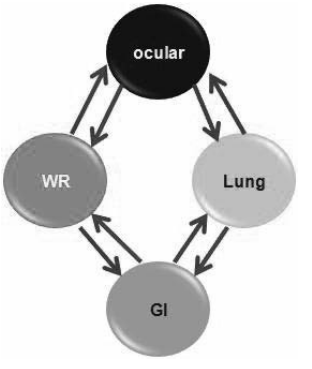

Figure. Organ relation.

MODIFIED HYPERCVAD AS AN EFFECTIVE TREATMENT FOR PLASMABLASTIC LYMPHOMA

V Singh, M Rowlands

North Manchester General Hospital, Manchester, UK

Background. Plasmablastic lymphoma (PBL) a distinct subtype of NHL, is classified as an individual entity by the WHO based upon morphological, immunological and clinical features.[1] It typically occurs in the setting of HIV infection, with a predilection for the oral cavity. It consists of lymphocytes of immunoblastic morphology, absent or weak expression of CD45 & CD20, but expression of plasma cell related antigens like CD138. Ki-67 index is generally >90% and about 60% of cases are said to be EBV-related. Since its first description in 1997 by Delecluse[2] there have been more than 100 cases reported. Over time, the disease's clinical spectrum has expanded, with a number of case reports in HIV-negative and extra-oral sites as well. Inspite of this, there still is no standard treatment and it is continues to be associated with poor prognosis with a high relapse rate. *Aims.* We describe 4 patients with PBL successfully treated with a modified HyperCVAD at a single centre. *Methods.* HIV status was known in 2 of the 4 patients and both were already on HAART. In the other 2 patients, HIV was diagnosed after tissue biopsy had confirmed the nature of the lymphoma. Patient characteristics are summarised in Table 1. Disease staging included CT scan of thorax, abdomen and pelvis and bone marrow biopsy. Following completion of treatment response was confirmed by CT scan, supplemented by a PET scan. All 4 patients were treated with the 3 cycles of modified HyperCVAD alternating with methotrexate/cytarabine (Table 2). The 4th patient also had localized radiotherapy at the end of the chemotherapy. Intrathecal chemotherapy was administered with prophylaxis intent as there was no evidence of CSF infiltration. All patients were also on concomi-

tant HAART and prophylaxis with fluconazole, acyclovir and dapsone. There were no major complications throughout the treatment course. *Results.* All the 4 patients achieved CR and continue to be in remission shortest being 10 months and the longest 4 years. *Discussion.* Castillo3 presented a comprehensive summary of 112 published cases, concluding CHOP failed to show an association with survival. This is not surprising, as this is an aggressive lymphoma with high proliferation index. A good response to HAART was usually associated with better prognosis. Unlike CHOP, CODOX-M/IVAC, a chemotherapy regime most commonly used with aggressive lymphomas has been used with more success.[3,4] However it is an inpatient regime, more toxic than HyperC-VAD and treatment related deaths have been reported.4 CD20 negativity means that Rituximab does not have any role in its management. Modified Hyper CVAD regime we used with slight alterations from the original regime described for acute lymphoblastic lymphoma. Cyclophosphamide was given 12 hours apart for the 1st 2 doses, and then as a single daily dose, thus achieving outpatient treatment. Day 11 to 14 dose of dexamethasone as originally described was omitted. *Conclusion.* These 4 cases show HyperCVAD to be an effective alternative to CODOX-M/IVAC option for this rare lymphoma, with good safety profile. *(Note Table 1, 2 & references not included).*

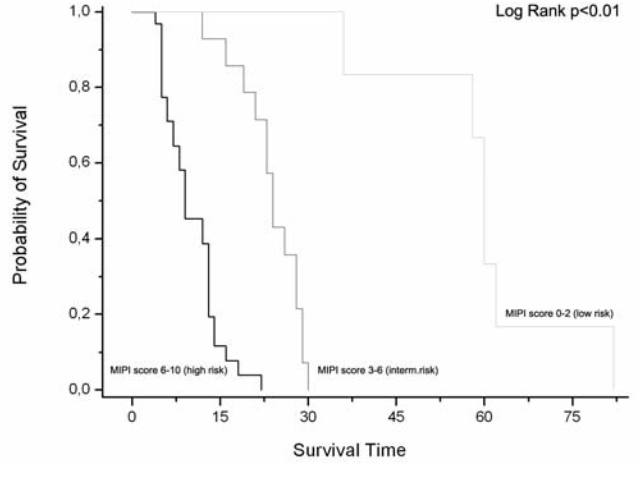

Figure. Abdominal mass in patient 3.

INTERNATIONAL PROGNOSTIC INDEX (IPI) VS. MANTLE-IPI (MIPI) RELATION IN THE PATIENTS WITH ADVANCED STAGE MANTLE CELL LYMPHOMA (MCL): THE CORRELATION BETWEEN LABORATORY DATA AND CLINICAL OUTCOME

M Todorovic,[1] B Andjelic,[2] V Palibrk,[2] B Balint,[3] N Kraguljac Kurtovic,[2] B Mihaljevic[2]

, Belgrade, Serbia; [2]Clinic for Hematology, Belgrade, Serbia; [3]Institute for Medica Research, Belgrade, Serbia

Background. Mantle cell lymphoma (MCL) is a hematologic malignancy with affected B-cell lineage on the basis of specific molecular genetics involving cyclin D1 gene over-expression and resulting pathological alteration. Extranodal involvement and low-level answer to therapy are typical for MCL patients. Most of them have advanced stage of disease. *Aims.* to evaluate international prognostic index (IPI) *vs.* mantle-IPI (MIPI) in correlation with immunophenotype and clinical characteristics in advanced stage MCL patients and their influence on overall survival (OS). *Methods.* Mantle-international prognostic index (MIPI) was scoring by each patient according to standard recomendations including: age, leukocyte count, LDH value and ECOG performance status. In low risk group are patients with MIPI 0-3, intermediate risk 4 and 5 and high 6-10. Bone marrow (BM) and/or peripheral blood (PB) derived cell flow cytometric analyses for following antigens (Ag) were performed: HLA-DR, CD19, CD20, CD22, CD23, CD25, CD10, SmIg, kappa, lambda, CD79b, CD38, FMC7, CD3, CD2, and CD5. Cut-off for Ag expression was accepted positivity > 30%. Pathohistology and immunohistochemical testings were performed in BM an lymph node biopsies. The used monoclonal antibody specifies were: CD5, CD20, CD23, CD10, CD79b, and cyclin D1. The influence between immunophenotype and clinical parameters was estimated by Spearman's correlation. The survival curves were estimated using the Kaplan-Meier method. The log rank test evaluated association between overall survival (OS) and clinical characteristics, IPI and MIPI. The use of the Cox proportional hazards model determinated that independent prognostic factors influenced OS. *Results.* A total of 54 patients diagnosed between 1996 and 2009 were evaluated. There was 17 patients in IV CS, while 37 patients had leukemic phase at presentation. Among patients, 46 were treated with CHOP, 2 with FND, and 6 with Hyper-CVAD as initial treatment option. Typical immunophenotype was presented in all cases: $CD5^+$, $CD23^-$, Cyclin $D1^+$. Pathohystological type of BM infiltration was diffuse (63% of patients) and in remainder nodular. Hematological parameters showed median Hb 113g/L, Plt 121×10^9/Ll, WBC 29×10^9/L. Extranodal involvement (22%) included pleural effusions, bowel, sinus and palpebral infiltration. Among patients, 9 of them achieved complete and 23 partial remission. Median OS was 23 months, and there were no significant OS-differences between CS IV and leukemic phase patients. Survival analyses showed that negative prognostic influence had high IPI (P<0.001), MIPI (P<0.001), presence of extranodal localization (P<0.01), and diffuse type of BM involvement (P<0.01). The level of IPI correlated more with the age of patient with high statistic significance (P<0.001). Regarding the immunophenotype of malignant cells, higher expression of CD5 and CD22 correlated with high MIPI value and short survival, with low statistic significance (P<0.05). Using Cox regression according to OS, MIPI had independent prognostic value (P<0.001). *Conclusion.* In the advanced MCL, higher MIPI, IPI, diffuse BM infiltration, extranodal disease localization had negative influence on survival. In contrary to IPI, MIPI value reflects much more biological characteristics of disease.

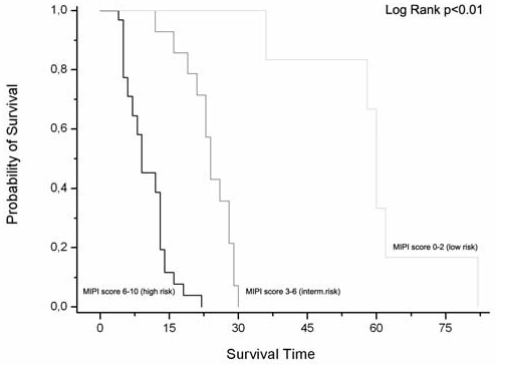

Figure. Survival according to different MIPI values.

1582

ADDITION OF RITUXIMAB TO HIGH-DOSE METHOTREXATE-BASED CHEMOTHERAPY IMPROVES OUTCOMES IN ADULT BURKITT LYMPHOMA PATIENTS

D Dujmovic, I Aurer, I Radman, R Serventi-Seiwerth, R Stern-Padovan, S Dotlic, K Dubravcic, F Santek, B Labar

UHC Zagreb, Zagreb, Croatia

Background. Burkitt lymphoma (BL) is a very aggressive B-cell lymphoid neoplasm. Results of treatment have been substantially improved by the introduction of high-dose methotrexate-based chemotherapy with overall survival rates in adult patients with disseminated disease ranging from 40-60%. BL tumor cells express CD20, but there is a dearth of data on the effect of anti-CD20 therapy in this disease. *Aims.* To analyze the influence of the addition of rituximab to a standard chemotherapy regimen in adult patients with sporadic BL. *Methods.* This is a retrospective study performed by chart-review of all adult patients with sporadic BL treated at our center with the modified B-NHL 86 regimen adopted from the German Multicenter Study Group for the Treatment of Adult ALL (GMALL) consisting of high-dose methotrexate, ifosfamide, vincristine, cytarabine, cyclophosphamide, doxorubicine and etoposide with central nervous system prophylaxis. Six cycles of treatment were planned. Since 2006 all newly diagnosed patients also received rituximab, 375 mg/m^2 per cycle. Patients in PR after the end of treatment received involved-field radiotherapy. We identified 19 patients, 15 men and 4 women, 16-61 years old (median 35) with BL stage II-IV. Eight were treated without and 11 with rituximab. *Results.* Toxicity of the treatment was substantial. Three patients, 1 in the rituximab and 2 in the chemotherapy-only group, died early after diagnosis due to multiple organ failure. All surviving patients had

episodes of grade III or IV febrile neutropenia, 1 in the rituximab and 1 in the chemotherapy-only group died. Of the remaining 5 patients in the chemotherapy-only group, 2 relapsed during treatment and died shortly thereafter. The remaining 3 patients all achieved CR. None of the patients in the rituximab-treated group was refractory to treatment or relapsed. At the end of treatment 6 had CR and 3 PR. The difference in response to treatment is statistically significant (38% *vs.* 82 %, P= 0.048, Pearson chi-square test). None of the patients in remission after the end of treatment relapsed. With a median follow-up of 47 months, progression-free and overall survival in the chemotherapy-only group is 38% and in the rituximab-treated group 82% (P=0.060, log-rank test) (Figure 1). *Conclusions.* The addition of rituximab to a high-dose methotrexate-based chemotherapy regimen improves response rates, progression-free and overall survival of adult patients with disseminated sporadic BL. The toxicity of this type of treatment is substantial; mortality is most frequently caused by metabolic complications at the beginning of the treatment.

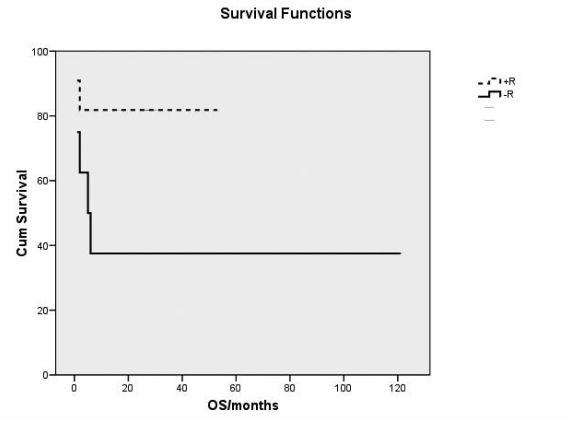

Figure 1.

1583

PROGNOSTIC VALUE OF FDG-PET BEFORE AUTOLOGOUS TRANSPLANTATION IN RELAPSING/REFRACTORY HODGKIN'S LYMPHOMA: A SINGLE CENTRE EXPERIENCE

A Giordano,[1] F Gaudio,[1] T Perrone,[1] C De Risi,[1] A Spina,[1] F Laddaga,[1] S Scardino,[1] N Merenda,[2] G Rubini,[2] V Liso,[1] G Specchia[1]

[1]*Hematology, Bari, Italy;* [2]*Nuclear Medicine, Bari, Italy*

Background. FDG-PET (PET) has assumed a relevant role in the management of patients with Hodgkin's Lymphoma (HL) in recent years. PET performed after two courses of ABVD chemotherapy is presently considered the most relevant available prognostic factor and correlates with survival. Recent data show a high prognostic value of pre-transplant PET in patients with recurrent or refractory HL. *Aim.* to evaluate the role of PET in predicting outcome before high dose chemotherapy and autologous stem cell transplantation (ASCT) in resistant or relapsed HL. *Methods.* We retrospectively evaluated 20 patients (pts) (8M, 12F, median age 39 years, range 16-52) treated with 3 courses of IGEV followed by peripheral blood stem cell collection and BEAM conditioned ASCT, from April 2005 to February 2008. At the time of enrolment, B symptoms were present in 8 pts (40%), bulky disease in 2 pts (10%), extranodal involvement in 4 pts (20%) and the International Prognostic Score was >2 in 6 pts (30%). After first line chemotherapy, 11 pts were resistant and 9 pts were in first relapse. PET was performed at relapse/progression and after the third cycle of IGEV, before ASCT. Univariate analysis was performed to assess the correlation of progression free survival (PFS) with the pre-transplant PET result, presence of bulky disease, extranodal disease and chemoresistance/chemosensitivity to pre-transplant therapy evaluated by CT scan. *Results.* The pre-transplant PET evaluation was positive in 14 pts (70%) and negative in 6 (30%). Among pts with a positive pre-transplant PET evaluation, 8 (57%) progressed after a median follow-up of 13 months, 5 pts (35%) died of lymphoma-related death, 5 pts (35%) relapsed and 1 pt (7 %) is in continuous complete remission at 9 months. Among the 6 pts with a negative pre-transplant-PET evaluation, 5 pts (83%) are in continuous complete remission after a median follow-up of 14 months and 1 pt (16%) relapsed after a follow-up of 20 months. After a median follow-up of 15 months, among the parameters analyzed only pre-transplantation PET significantly influenced the PFS (P=0,01). *Conclusion.* This retrospective study shows that the pre-transplant PET result is significantly correlated to outcome after ASCT in patients with recurrent or refractory HL. Multicentric studies in larger patients cohorts are warranted to confirm these preliminary data.

1584

A UNIQUE PATTERN OF EXTRANODAL INVOLVEMENT IN KOREAN ADULT SPORADIC BURKITT LYMPHOMA

SJ Jang,[1] S Kim,[2] J Huh,[3] DH Lee,[2] CW Suh[2]

[1]*Department of Internal Medicine, Asan Medical Center, Seoul, South-Korea;* [2]*Department of Oncology, Asan Medical Center, Seoul, South-Korea;* [3]*Department of Pathology, Asan Medical Center, Seoul, South-Korea*

Background. Extranodal involvement is very common in patients with Burkitt lymphoma (BL). The pattern of extranodal involvement might have regional diversity with prognostic implications. We evaluated the pattern of extranodal involvement and their impact on clinical outcomes in Korean adult patients with BL. *Methods.* Total 64 patient data of Burkitt lymphoma was available between 1996 - 2009 in Asan Medical Center Non-Hodgkin's Lymphoma registry (n=1,725). We performed retrospective analysis of patient data and characterized the distribution of extranodal involvement sites of BL. *Results.* Median age was 48, ranging from 16 to 81, and male: female ratio was 1.28:1. Only seven patients (10.9%) had B symptoms. Median LDH level was 455.5 U/L and 45 patients (70.3%) had elevated LDH level (>250 U/L). Thirteen patients (20.3%) were with ECOG (Eastern cooperative oncology group) performance status ≥2. Ann Arbor stage IV was predominant (40 patients, 62.6%). Most of the patients had extranodal involvements of BL (57/64, 89.0%). Thirty-seven patients (57.8%) had low or low-intermediate risk and 27 patients (42.2%) had high-intermediate or high international prognostic index (IPI). Thirty-four patients (53.1%) had two or more extranodal involvement sites. Stomach (26.6%) was the most common extranodal involvement site. Small and large intestine (25%), bone marrow (23.4%), genitourinary tract (21.9%), and bone (18.8%) were also common extranodal involvement sites. Stomach, genitourinary tract and bone are unique extranodal sites relatively more frequently involved compared to previous reports. Involvement of central nervous system, which was common in western reports, was in 2 patients (3.1%). Patients with involvement of small and or large intestine showed better complete response rate than those who were not involved (100% *vs.* 62.1%, P=0.037). Two-year overall survival was significantly lower in patients with bone marrow involvement (33.3% *vs.* 73.3%, P=0.027), central nervous system involvement (0.0% *vs.* 67.6%, P=0.025). Patients with two or more extranodal involvements showed worse overall survival rate (47.6% *vs.* 83.3%, P=0.041). *Conclusions.* Stomach, genitourinary tract, and bone were uniquely more frequent extranodal involvement sites in Korean adult patients with BL compared to previous reports. Central nervous system involvement was not common. Bone marrow and central nervous system involvements were associated with poor survival.

1585

HIV-ASSOCIATED NON-HODGKIN'S LYMPHOMA: A SINGLE CENTRE RETROSPECTIVE STUDY

L Lekovic,[1] J Jevtovic,[2] A Antic,[1] I Đunic,[1] J Ranin,[2] D Salemovic,[2] D Tomin,[1] B Mihaljevic[1]

[1]*Institute of Hematology, Clinical Center of Serbia, Belgrade, Serbia;* [2]*HIV/AIDS Department, Hospital for Infectious Disease, Clinical Center Serbia, Belgrade, Serbia*

Background. The increased risk for B-cell non-Hodgkin's lymphoma (NHL) development in patients with human immunodeficiency virus infection (HIV) is confirmed in many studies published so far. But, in the absence of randomized trials, the prognostic factors and the optimal treatment of the patients with HIV-associated NHL remain a matter of debate. *Aim.* The aim of our study was to analyze clinical features, prognostic factors, optimal treatment and outcome in patients with HIV-associated NHL. *Patients and methods.* Our study included 34 pts with HIV- associated NHL treated at the Clinical Center of Serbia during the period September 1996 to January 2010. The median patient age was 49±12,7 (range 32-83); 23/11 (68%) were males; 16 pts (47%) had a previous AIDS diagnosis; 32 pts (94%) had an aggressive type of lymphoma (DLBCL, Burkitt); EN presentation had 23 pts (68%). Accord-

ing to the IPI score, 5/20 pts had an IPI=0-2 and 15/20 had an IPI=2-4. Chemotherapy (ldmBACOD, CHOP, EPOCH) received 26 pts (76%), while 19 (56%) were treated with combination chemotherapy (CT) and highly active antiretroviral therapy (HAART). Number of $CD4^+$ cells was quantified by flow cytometry. Analyses included the comparison of aforementioned parameters in two subgroups: survivors and those who died. The median follow up was 26±32 (range 1-120) months. *Results.* The median IPI score for survivors was 1,4±1,1 while pts who died had IPI score 2,8± 0,9. Patients with IPI score <2 had a significantly better survival than pts with IPI score ≥2 (log rank P=0,018). Six pts (18%) achieved complete or partial remission with median survival 60±24 months while 28 (82%) were non-responders with significantly shorter median survival 19±29 months (log rank P<0,01). The median survival of pts treated with combination CT+HAART was 60 months while in a subgroup treated with CT alone was less than 12 months (log rank P<0,01). The median CD4+ cell count among survivors was higher but without significance for survival (246±91/μL *vs.* 131±36/μL P=0,058). *Conclusions.* The present data showed that the most reliable prognostic factor for the overall survival in patients with HIV-associated NHL is an IPI score and a type of applied therapy (HAART and CT). Studies with larger numbers of patients and randomized trials are needed in order to confirm our data.

CLINICOPATHOLOGIC CHARACTERISTICS OF A CASE SERIES OF PRIMARY SOFT TISSUE DIFFUSE LARGE B-CELL LYMPHOMA (ST-DLBCL). COMPARISON OF OUTCOME BETWEEN ST AND NONE ST-DLBCL

F Pasquet, P Faurie, C Ferlay, O Derbel, P Meeus, C Chassagne-Clement, MP Sunyach, C Sebban, P Biron, I Ray-Coquard, JY Blay, H Ghesquieres

Centre Leon Berard, Lyon, France

Background. Extra nodal involvement is common in Diffuse Large B-Cell lymphoma (DLBCL). Primary soft tissue DLBCL (ST-DLBCL) is a rare clinical presentation that can mimic sarcoma. Only few studies have described the characteristics of soft tissue non-Hodgkin lymphoma (ST-NHL) and none have focused on DLBCL. *Aim.* This retrospective study analyzed the clinicobiological features at diagnosis, response to therapy of ST-DLBCL and compared their outcomes with none ST-DLBCL. *Methods.* All patients with primary ST-NHL diagnosed between January 1981 and December 2007 and followed up in our institution were selected. We identified one Burkitt lymphoma, one ALK-negative anaplastic large cell lymphoma, one secondary transformation of a known Waldenstrom lymphoma and eleven DLBCL. Among these 11 DLBCL, one was HIV positive. We focused our study on ten immunocompetent patients with ST-DLBCL. *Results.* Median age was 71 years (range, 40-86). The male to female ratio was 1.5. All patients presented with a palpable mass which was the cause of the initial consultation. Sarcoma was the presumed initial diagnosis in half of the patients. The soft tissue involved was: the posterior chest wall (n=1), the pectoralis major muscle (n=1), the biceps (n=1), the crow's foot (n=1), the gluteus maximus (n=1), the transverse abdominis (n=1), the thigh (rectus femoris n=1, posterior chamber n=1), the gastrocnemius muscles (n=1) and pelvic soft tissues (n=1). Two patients had a performance status ≥ 2 and none had B symptoms. Ann Arbor staging was as followed: stage IV =5, stage IIE =3, stage IE =2. All had elevated LDH level. Three patients had associated nodal involvement whereas 5 had other extra nodal localisations (bone marrow n=3, pleura n=1, meningeal involvement n=1 and underlying bone involvement n=2). Four patients had low-intermediate IPI risk, whereas others patients had high-intermediate (n=3) and high (n=3) IPI risk. Nine patients received anthracyclin-based chemotherapy (RCHOP n=4; CHOP n=3; RMCOPA n=1, RACVBP followed by high-dose chemotherapy with autologous stem cell transplantation n=1). One patient underwent surgery alone. Seven patients had a complete response, one had a partial response and one had primary refractory disease. One patient died after 2 courses of sepsis. Three patients relapsed, all with soft tissue localisations. At the end of follow-up, 6 patients had persistent complete response, one had progressive disease and 2 had died of disease progression. With a median follow-up of 60 months, the 5-year overall survival (OS) and event-free survival (EFS) were 70% (CI95% [40-89]) and 40% (CI95% [17-69]), respectively. Comparison of outcome of ST-DLBCL and 400 none ST-DLBCL treated in our institution between 1996 and 2008 showed that OS and EFS were similar: 5-year OS and EFS were 67% and 62%, respectively for none ST-DLBCL (P=0.94 for OS, P=0.10 for EFS). *Conclusions.* Primary soft tissue involvement is a rare presentation of DLBCL and can be mistaken for sarcoma. Such clinical presentation should require core needle biopsy to allow appropriate diagnosis and therapeutic management. The IPI score and LDH levels of ST-DLBCL are frequently high, but outcome does not seem to differ from none ST-DLBCL.

NO DIFFERENCE OF SURVIVAL BETWEEN LOCALIZED AND DISSEMINATED DISEASE IN PATIENTS WITH STAGE II DIFFUSE LARGE B-CELL LYMPHOMA

C Yoo, J Jo, Y Ahn, SJ Park, SK Yoon, J Huh, S Kim, DH Lee, SW Kim, J Lee, CW Suh

Asan Medical Center, Seoul, South-Korea

Background Treatment approach of patients with stage II diffuse large B-cell lymphoma (DLBCL) is usually different according to tumor extent. Therefore, Stage II DLBCL has been categorized into localized disease (LD; 2 adjacent lymph-node regions involved or organ involvement with involvement of regional lymph-nodes), and disseminated disease (DD; extensive involvement over LD). *Aims.* This study was intended to assess prognostic factors and compare survival outcome between LD and DD in patients stage II DLBCL. *Methods.* We searched lymphoma database of Asan Medical Center, Seoul, Korea, and found 91 patients with stage II DLBCL who diagnosed between January 2000 and October 2007. We performed retrospective analysis of progression-free survival (PFS) and overall survival (OS) according to the clinical factors, such as age, sex, tumor extent, lactate dehydrogenase, performance status, tumor location (i.e., supradiaphragm *vs.* infradiaphragm), primary extranodal disease, treatment method, and chemotherapy regimen. *Results.* Median age (range) was 53 (18-83) year-old, and 56 (61.5%) patients were male. Sixty-two (68.1%) patients received chemotherapy and 29 (31.9%) patients received combined chemotherapy and radiotherapy. In terms of tumor extent, 59 (64.8%) patients were LD and 32 (35.2%) were DD. CHOP was administered in 39 (42.9%) patients and R-CHOP was in 52 (57.1%). Median cycle (range) of chemotherapy was 4 (1-8). With 55 months of median follow-up, 5 year-rates of PFS and OS were 71% and 75%, respectively. There was no difference of survival outcome (P=0.46 in PFS, P=0.30 in OS) between LD and DD. The results were consistent if LD and DD were compared in patients with each treatment modality (chemotherapy or combined chemotherapy and radiotherapy) and chemotherapy regimen (CHOP or R-CHOP). Young age (≤60 years) was related to better survival outcomes (P=0.02 in PFS, P=0.02 in OS), however other clinical factors were not associated with survival. *Summary/Conclusions.* In patients with stage II DLBCL, survival outcomes were not different whether tumor is localized or disseminated. Although old age was associated with poor survival outcomes, any other clinical factors fail to show prognostic information. To provide personalized care for stage II DLBCL, further studies are warranted to investigate new prognostic or predictive factors.

1589

CLINICAL FEATURES AND RESPONSE TO CHEMOTHERAPY OF CHRONIC ACTIVE EPSTEIN-BARR VIRUS INFECTION IN ADULTHOOD: A RETROSPECTIVE ANALYSIS

A Arai,[1] Y Watanabe,[2] K Imadome,[3] M Takahashi,[2] S Fujiwara,[3] O Miura[2]

[1]Department of Hematology, Tokyo Medical and Dental University, Tokyo, Japan; [2]Tokyo Medical and Dental University, Tokyo, Japan, Tokyo, Japan; [3]National Research Institute for Child Health and Development, Tokyo, Japan, Tokyo, Japan

Background. Chronic active Epstein-Barr virus (EBV) infection (CAEBV) is a rare disease accompanied by persistent infectious mononucleosis-like syndrome associated with high titers of antibodies. In these patients, T or NK cells are EBV-infected and proliferate clonally. Because most of these patients are children, severe CAEBV with clonally proliferating T cells was named EBV-positive T-cell lymphoproliferative disorders (EBV-TLPD) of childhood according to the WHO classification revised in 2008. However, adult-onset CAEBV has been reported. In addition, EBV can also infect NK cells, causing clonal expansion resulting in CAEBV. Placement of adult-onset or NK cell-infected CAEBV in the WHO classification, and its recommended treatment has neither been discussed nor reviewed. *Aim.* The aim was to clarify the clinical features and response to chemotherapy for adult CAEBV. *Methods.* We reviewed patients who were treated in our hospital according to the strategy originally arranged

for children consisting of cyclosporin A and prednisolone (CP) followed by CHOP and the Capizzi regimen (Int J Hematol, 82:437, 2005). Diagnosis was made according to the criteria suggested by Okano *et al*. (Am J Hematol, 80:64,2005). To detect EBV-infected cells, T and NK cells were separated using magnetic beads from peripheral blood mononuclear cells of CAEBV patients. EBV-DNA was quantified using a real-time quantitative PCR assay. The clonality of EBV was examined by southern blotting using a terminal repeat probe. Written informed consent was obtained from each patient. *Results.* We diagnosed and treated 4 adult CAEBV patients aged 24-48 years at the start of treatment. Infected cells in all patients were T cells. Monoclonal expansion was confirmed in all patients. Three patients were adult-onset, and duration from the onset of disease to treatment initiation was 4-18 months. The onset of disease in the youngest patient was at 7 years of age, while the treatment began at 24 years of age. CP followed by CHOP was given to all. Three patients demonstrated no effects, and only 1, CD4-type patient, achieved 1-log reduction of EBV-DNA in peripheral blood. Grade 4 neutropenia was developed in all patients. The Capizzi regimen was administered to 3 patients. Shortly after starting the regimen, grade 4 non-hematological events occurred in all patients, which led to the discontinuation of cytarabine. Next we reviewed 36 adult-onset CAEBV, adding 33 reported patients searched and selected from PubMed to the present 3 patients, in order to clarify clinical features. T cells were most commonly infected (32/36), whereas infection of T and NK cell types were equally common in child-onset CAEV. Monoclonality was confirmed in 18 patients. Clinical course in 33 patients was documented, and 15 (45.5%) died within 12 months. The average duration from treatment initiation to death was 22.6 days for NK cell-infected type and 8.6 months for T cell-infected type, whereas child-onset CAEV could be observed for 12 to 336 months. *Conclusion.* Adult-onset CAEBV might be aggressive and chemoresistant and has different clinical features from that of child cases. Cases should be accumulated to clarify clinical features and to establish optimal treatment.

1590

RESULTS OF R-CODOX-M/IVAC IN BURKITT-LIKE NHL AND AGGRESSIVE CELL-B NHL

MD De Miguel, M Diaz Morfa, MI Lopez San Roman, N Golbano, D Morales, J Arbeteta, B Pinedo

Hospital Universitario de Guadalajara, Guadalajara, Spain

Background. Poor prognosis diffuse large B-cell lymphoma (DLBCL) represents 50% of all DLBCL with overall cure rates ranging from 50-60% with dose-dense immunochemotherapy regimens such as R-CHOP. CODOX-M/ IVAC, this regimen is very intensive and was introduced by Magrath and colleagues at the National Cancer Institute, USA to treat Burkitt's lymphoma. Early results in this rare condition for both children and adults were very promising and the regimen has been adopted by many centers for the treatment of the most aggressive, poor risk high grade non-Hodgkin's lymphomas. The search for new treatment strategies in order to improve the survival rate, it should be continue. Therefore, we compared the results of patients treated with R-CHOP and those patients that had received therapy with CODOX-M/ IVAC regimen. *Material and methods.* We reported our experience employing CODOX-M/IVAC-R regimen for patients with poor prognosis diffuse large B-cell lymphoma (DLBCL), burkitt-like NHL and grade 3 follicular NHL. Thirty-nine patients, aged 13-91-years (median 60.3), with an age-adjusted International Prognostic Index (IPI) of 0 or 5, were enrolled since 2003. Group A: It included at 25 patients treated with R-CHOP, aged 20-91 (median 66.16), aaIIPI >3 was presented in 16% patients. Number of cycles administered ranged between 1-8 (median 5.2), 32% (8 patients) had an III-IV stage and aaIPI of 2-4. Overall response was 87.5%, 8 patients with poor prognosis (75%) achieved a complete remission (CR), one patient (12-5%) achieved a partial remission, and one patient (12.5%) died during induction because of bacteriemia. One patient died within 6-months due to infection. None patient had progressed at moment. Grade 3-4 neutropenia developed in 52% of cycles and neutropenic fever in 14% of cycles (51% of patients). Group B: It included at 14 patients treated with R-CODOX-M/IVAC, 13 patients treated in first line, and one patient treated after he had progressed with 2 cycles of R-EPOCH. Patients were aged 13-73 (median 48.78). Number of cycles administered ranged between 1-5 (median 3.7), 27.1% (8 patients) had an III-IV stage and aaIPI of 0-5 (median 2.4), 67% patients had an IPI>3. Overall, 12 patients (85.7%) achieved a complete remission (CR), and two patients (14.3%) died during induction because of bacteriemia. Two patients have relapsed at nine months since diagnosis. One of them patients relapsed and died within 9-months due to infection. Grade 4 neutropenia developed in 100% of cycles and neutropenic fever in 100% of cycles. *Conclusions.* 1) Overall response is similar in both groups (87.5%), with a higher CR rate in the group of patients treated with R-CODOX-M (87.5 *vs.* 75%). 2) The toxicity profile is poorer in the group of patients treated with R-CODOX-M, with a mortality rate greater at induction (first cycle) 14.5 *vs.* 12.3%). We should remember that this group was younger (48.8 *vs.* 60.3) and they had received loss number of cycles (3.7 *vs.* 5.2).

FRONTLINE ANTIVIRAL THERAPY IN A SERIES OF HCV-RELATED LOW GRADE NON-HODGKIN LYMPHOMA

A Ferrario,[1] A Aghemo,[2] M Goldaniga,[3] F Rossi,[3] E De Gasperi,[2] A Fracanzani,[4] B Olivero,[3] L Cro,[3] S Fargion,[4] G Lambertenghi Deliliers,[3] L Baldini[3]

[1]UO Ematologia, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Unive, Milano, Italy; [2]UO Gastroenterologia ,[1] Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlini, Milano, Italy; [3]UO Ematologia ,[1] Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Uni, Milano, Italy; [4]UO Medicina Interna IB, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlini, Milano, Italy

Background. The association between HCV infection and type II crioglobulinemia or B-cell non-Hodgkin lymphoma (NHL) suggested its role in clonal B cell proliferation. The regression of NHL after antiviral treatment could be an indirect evidence of this pathogenetic hypothesis. *Aim.* We have treated 5 patients, affected by low grade B-cell NHL (LG-NHL), with different clinical presentations, with antiviral therapy alone with pegylated interferon (PegIFN) and ribavirin (Rbv) in order to evaluate the hematological response in respect of viral response. *Methods.* From 2005 to 2009, 5 patients, affected by LG- NHL at diagnosis have been treated by only antiviral therapy with PegIFN and Rbv (PegIFNα2a 180 mcg weekly, Rbv 800-1000 mg daily) for 6 months (4 pts) or 12 months (1 pt). M/F ratio was 4/1; the mean age was 57.2 years (range 51-73). HCV infection was diagnosed by means of HCV-RNA poliymerase chain reaction (3 cases with genotype 2 and 2 with 1b), before in 4 pts and concomitant in 1 patient, at lymphoma diagnosis. Only one patient has already received other combinations of antiviral therapy in the past. The study included 2 marginal zone lymphoma (MZL), 2 not otherwise specified LG-NHL and 1 lymphplasmacytic lymphoma/ Waldenstrom macroglobulinemia (LPL). The two marginal zone lymphomas showed bone marrow involvement, one with abdominal nodes, bilateral orbital mass and sub cutaneous lesions, the other with splenomegaly, thoracic and abdominal nodes and peripheral B cell clone. The two LG-NHL showed in one case only multiple liver lesions, in the other the patient presented with splenomegaly, a modest bone marrow involvement and a peripheral B cell clone (CD5, CD10 and CD43 negative). The case of LPL presented with splenomegaly, bone marrow involvement and carried a serum monoclonal component IgMk. No patients presented nor B symptom neither bulky disease. *Results.* All five patients completed the planned treatment course. Sustained virologic response (SVR) was achieved in four patients. Hematologic re-staging at the end of antiviral therapy, demonstrated that, among the four patients that gained a SVR, 3 had a CR and one had a PR. The patient that obtained only a reduction of viremia was in hematologic PR. The treatment was well tolerated; only one patients presented a hematologic toxicity grade I WHO, and needed erithropoietine support. After a mean follow up of 14.6 months from the end of therapy (range 1-27), three patients are still in CR and maintain SVR, two patients are in PR; interestingly one patient in SVR, presents a progressive reduction of monoclonal component and splenomegaly. *Conclusion.* Although the limited number of patients involved, the study demonstrates that antiviral therapy could be considered as frontline therapeutic option in a subset of HCV-related LG-NHL, confirming the important role of HCV chronic stimulation in lymphomagenesis. The relationship between SVR and hematologic response is impressive and, in 1 patient, the quality of PR improved during the follow-up.

1592

USEFULNESS OF POSITRON EMISSION TOMOGRAPHY/COMPUTER TOMOGRAPHY (PET/CT) IN PATIENTS WITH BURKITT OR BURKITT-LIKE LYMPHOMA/LEUKEMIA. PRELIMINARY DATA FROM A SINGLE INSTITUTION

E Morello, C Pagani, F Antoniazzi, L Baushi, F Bertagna, C Cattaneo, E Borlenghi, R Giubbini, G Rossi

Azienda Spedali Civili di Brescia, Brescia, Italy

Background. Positron emission tomograph /Computer Tomography is a non invasive imaging tool increasingly used in the management of lymphoma. In the setting of Burkitts' Lymphoma/Leukemia (BL) a study supporting the usefulness of PET/CT at diagnosis has been recently reported (Zeng 2009). No data on the usefulness of PET/CT during or after treatment are available. The GMALL B-ALL/NHL 2002 treatment protocol is reported as one of the most effective treatments of BL with a high cure rate. However a proportion of patients still relapses or fails treatment. *Aims.* To analyze the role of PET/CT integrated into the GMALL B-ALL/NHL 2002 protocol in order to optimize management of BL or diffuse large B cell lymphoma (DLBLC) with high proliferation index. *Patients and methods.* From August 2004 to June 2009 29 patients with acute mature B Burkitts' Leukemia (7), Burkitts' Lymphoma (16) and DLBCL (6) were treated at our institution according to the GMALL B-ALL/NHL 2002 protocol. PET-CT was performed in 15 patients (4 with mature B-ALL, 8 with BL and 3 with DLBCL). PET/CT imaging was available at diagnosis in 12/15 patients, during treatment in 6 patients, and in 11 patients at the end of treatment, since 4 patients (with positive PET/CT at diagnosis) died of infection during the first or second block of treatment and could therefore not been evaluated. *Results.* In 8 patients (3 BL, 3 mature B-ALL, 2 DLBCL) PET/CT was strongly positive at diagnosis and proved negative at the end of treatment; all these patients are in continuous complete remission (CCR) with a median follow up of 407 days. Six patients underwent PET/CT scan during treatment: 3 were proved negative, 2 doubtful (negative after subsequent treatment) and one positive. In one patient positive after 2 blocks, PET/CT scan demonstrated progression of disease at the end of treatment and the patient died one month later. In two patients undergoing PET/CT only at the end of therapy, no metabolic uptake of 18F-FDG was detected and the patients are currently in CCR. Therefore PET/CT scan performed at the end of protocol had a 100% accuracy in predicting one year disease free survival. *Conclusions.* Despite the low number of patients of this retrospective study, negative PET at the end of treatment according to GMALL B-ALL/NHL 2002 protocol is associated with sustained CCR and probably cure, given the long duration of follow-up. On the other hand in patients with a positive scan further treatment should be considered mandatory. The enrollment of more patients - currently ongoing - is needed to confirm this data and the role of PET/CT after 2 blocks in order to modulate the intensity of treatment is under investigation.

1593

UTILITY OF 18F-FDG-PET IN MARGINAL ZONE LYMPHOMA

C Pegenaute,[1] R García-Muñoz,[2] E Panizo,[1] S Varea,[1] JA Páramo,[1] JJ Rifón,[1] MJ García Velloso,[1] CM Panizo[1]

[1]Clínica Universidad de Navarra, Pamplona, Spain; [2]Hospital San Pedro, Logroño, Spain

Background. WHO classification distinguished three different MZL types derived from the marginal zone of B-cell follicles: splenic marginal zone lymphoma, MALT lymphoma and nodal marginal zone lymphoma. According to recent reports imaging with 18F-FDG-PET has a limited role in the diagnostic workup of patients with MZL as involvement is less reliable at detecting marginal zone lymphoma, particularly in the case of extranodal MZL. *Materials and methods.* We retrospective studied 21 patients with MZL who had undergone 18F-FDG-PET at the time of diagnosis. Whole-body 18F-FDG-PET scans were performed on a PET scanner 60 min after intravenous injection of 428.23MBq of 18F-FDG. *Results.* The group included 21 patients, with an age range of 40-79 years (average, 62 years), 52% woman. Histological reassessment of biopsy specimens confirmed the diagnosis of MALT MZL in 12 patients, while a diagnosis of splenic MZL was verified in 7 patients. Two patients presented with peripheral blood disease. Common sites of MALT lymphoma were the oral cavity (2), lung (1), orbit (1), lachrymal gland (1), cavum (3), and small bowel (1). Forty-three percent of the patients had localized disease (stages I and II), and 57% had bone marrow involvement at presentation. Nineteen percent presented various abnormalities in the karyotype. B symptoms were present in only four patients (19%). Most patients were categorized as low or low-intermediate risk group by international prognostic index (IPI). Two patients associated hepatitis C virus infection. 18F-FDG PET detected disease in 52% of patients, with a medium SUVmáx of 4,48 (1,42-10). Five patients with splenic MZL (71%) showed a positive 18F-FDG-PET at diagnosis, with a medium SUVmáx uptake in the spleen of 3,26. We did not find statistically significant differences comparing the results of 18F-FDG-PET between splenic MZL and MALT lymphoma. 18F-FDG-PET detected 29 disease sites (average 1.4 disease sites per patient, range 0-6), 15 of these lesions were lymph node regions and 8 were extranodal lesions. 18F-FDG-PET detected bone marrow disease in only 2 of 13 patients with bone marrow involvement (15%). Fifty percent of the patients achieved complete remission (CR) after the initial therapy, that includes Rituximab and fludarabine in most of them. The median follow-up was 1 year (range 0-3). *Conclusions.* These data suggest that 18F-FDG-PET is a useful tool for initial staging in patients with MZL. Its sensitivity depends on disease location and stage at initial diagnosis. The high number of patients in whom PET did not detect bone marrow involvement suggest that PET is complementary to bone marrow aspiration and trepination in this group of patients.

1594

UPFRONT TREATMENT OF MANTLE CELL LYMPHOMA BY SEQUENTIAL HIGH DOSE IMMUNOCHEMOTHERAPY SUPPORTED BY *IN VIVO*-PURGED STEM CELL DOUBLE AUTOLOGOUS TRANSPLANTATION: A SINGLE INSTITUTION EXPERIENCE

G Saporiti,[1] F Onida,[1] A Ferrario,[1] D Vincenti,[1] C Basilico,[2] P Usardi,[2] F Rossi,[1] E Tagliaferri,[2] M Goldaniga,[2] C Annaloro,[2] L Baldini,[1] G Lambertenghi Deliliers[1]

[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico - University of Milan, Milan, Italy; [2]Fondazione IRCCS Ca[1] Granda Ospedale Maggiore Policlinico, Milan, Italy

Background. Mantle Cell Lymphoma (MCL) is characterized by a good response rate to conventional anthracycline-based regimens but long-lasting remissions are sporadic. *Aims.* we retrospectively analyzed the outcome of 15 MCL patients upfront treated with sequential high dose immunochemotherapy followed by double autologous stem cell transplant (ASCT). Patients and *Methods.* from 2000 to 2009, 15 MCL patients, eligible for ASCT, have been consecutively treated as follow: a) standard dose phase: APO: doxorubicin, 75 mg/sqm i.v., day 1; prednisone, 60 mg/sqm orally, day 1 to 5 and day 9 to 12; vincristine, 1.4 mg/sqm i.v., day 1 and 8; DHAP: cisplatin 70 mg/sqm, day 1; cytarabin 1500 mg/sqm i.v., days 2-3; dexametasone 40 mg i.v., days 1 to 3; b) rituximab high dose sequence: high dose cyclophosphamide (CTX 5 g/sqm) and high dose cytarabine (Ara-C 2 g/sqm every 12 for 6 consecutive days) followed by leukapheresis; c) high dose melphalan (180 mg/sqm) and high dose mitoxantrone plus melphalan (60 mg/sqm and 180 mg/sqm, respectively) followed by PSC infusion. Rituximab (375 mg/sqm) was infused twice after CTX, cytarabine and double autologous transplantation (modified from Gianni *et al.*, Blood, 102, 749, 2003). All patients (8 female and 7 male) had a histological diagnosis of MCL according to WHO classification criteria; molecular rearrangement of bcl-1 locus was detected by PCR in the bone marrow of 7 patients. The median age at diagnosis was 57 years (range 37-68); 13 patients were in stage IV and 2 in stage III; 2 patients had bulky disease at presentation. Four patients were in overt leukemic phase and 2 had extranodal localization. According to MIPI score, 10 patients were classified as low risk (67%), 3 as intermediate risk (2%) and 2 as high risk (1%). Double transplant was performed in all but 2 patients (one for refusal and one because second procedure is currently ongoing). *Results.* The standard dose phase, which included a median number of 4 cycles (range 3-5), was generally well tolerated, with only one patient experiencing tumor lysis syndrome. After induction, clinical CR was achieved in four patients. PBSC were successfully collected after both CTX/rituximab ($1.8\text{-}9.7\times10^6$/Kg) and Ara-C/rituximab (7.1- 40.0×10^6/Kg) cycles. At the end of these phases, 5 patients were in CR while 10 were in PR. Following transplants, median times to ANC >500/μL were 11 days (range 10-14) in both the procedures, whereas median times to platelet recovery (>50000/μL) were 18 days (range 10-172) after the first transplant and 23 days (range 11-298) after the second one. Most frequent complications were FUO and grade III-IV mucositis, especially following the second transplant. After a median follow-up of 28 months (range 13-105), 11 patients (73%) were alive, whereas 4 died from disease progression. With regard to disease status, 11 patients were in CR and 4 patients were in PR. Both overall and disease free survival at 7-years were 70%, respectively. *Conclusions.* Our results confirmed that in MCL the use of sequential high dose immunochemotherapy followed by double autologous transplantation associates to high remission rates with long-term survival.

1595

HIGH GRADE B-NHL IN FRAIL PATIENTS: MANAGEMENT AND RESULTS OF A SINGLE INSTITUTION

MR Specchia, A Maggi, F Casulli, P Mazza

Hospital S.G. Moscati, Taranto, Italy

The fate of those patients with high grade NHL, who do not enter in specific protocols because the very old age and the presence of comorbidities, is generally not known or not extensively dealt with. In fact a proportion of patients with NHL of about 20% are so called frail because the age or clinical problems out of the lymphoma. We present our experience on 68 patients with B-HGNHL defined frail and observed over 4 years, since 2002 to 2006. The median age was 68y (61-81) with a prevalence of males (31/27). Symptoms B were present in 35(53%) and advanced stage (III-IV) was recognized in 50(73%); histology was DLCBL in 63(94%) and MCL in 5. PS was >2 in 62(93%). Comorbidities were inclusive of heart problems (52%), diabetes (28%), renal failure (12%), liver elevation of enzymes or liver failure (18%); 65 pts (96%) had almost 2 comorbidities. The therapy was patient related by avoiding Antracyclines in case of myocardial problems, avoiding glucocorticoids in unregulated diabetes and avoiding intensive or great associations in those with renal or liver falure. Schemes included VNCOP-B (16 pts), CHOP (7pts), CHOP/R (9pts), CHOP-like with liposomal Doxorubicin and Rituximab (5 pts), CVP/R (13 pts), Vincristine and Cyclophosphamide low dose (18 pts). 70% of pts reduced or discontinued the therapy and 30% stopped definitely the treatment. Supportive care consisted of transfusion or growth factors as needed. The overall response rate inclusive of CR and good PR was 30% in those patients who completed the therapy not inclusive of the Antracyclin, with rituximab or not, and 55% in those inclusive of Antracyclin, either liposomal or not, and Rituximab; other patients treated by alternative schemes had mild or transient responses. Side effects diabetes disregulation (98%), infections (13%), heart falure (15%), renal falure (20%). Deaths due to therapy were 2 in those treated by Antracyclin. The fate of patients who obtained remission is to maintain CR in 60% of those who did Rituximab and Antracyclin and 20% of those who did not. The cause of death was the progression of lymphoma in 80% of those who did not obtained remission and comorbidity related in 20% of the same patients. The relapsed patients had mostly a progression of disease. We conclude that the therapy of frail patients with HG-BNHL should include Antracyclin (liposomal?) and Rituximab in order to obtain more and durable remissions, although the risk of related deaths is increased with this approach.

1596

CLINICAL CHARACTERISTICS AND THERAPY RESPONSE OF PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA (PCNSL) PATIENTS TREATED WITH DE ANGELIS REGIMEN: A SINGLE INSTITUTION EXPERIENCE

A. Sretenovic, B. Andjelic, S. Jankovic, M. Sretenovic, N. Colovic, R. Nedeljkov- Jancic, I. Elezovic, M. Petrovic, B.Mihaljevic

Institute of Hematology, Clinical Centre of Serbia, Belgrade, Serbia

Background. PCNSL is a rare tumor, defined as a non-Hodgkins lymphoma that is confined to the craniospinal axis without systemic involvement. PCNSL accounts for 1% to 2% of all lymphomas and less than 5% of all primary CNS tumors. The outlook has improved but remains generally poor. *Aim.* To compare clinical characteristics in pts with PCNSL and their response to De Angelis regimen (MTX 1 g/m^2 IV d1, d8; 6 doses of intrathecal MTX 12 mg; Dexamethasone 16 mg IV d1-d15, radiotherapy (RT)- 40 Gy to the whole brain + 14 Gy boost to the tumor; after RT: Cytarabin 3 g/m^2 IV d1, d2, d22, d23). *Methods.* 17 pts with PCNSL diagnosed and treated at the Institute of Hematology, Clinical Centre of Serbia, in the period of 1994-2009, were analyzed. The diagnosis was based on histological and immunohistochemical analysis of tumor biopsy. Tumor histology was diffuse large B- cell lymphoma in all our pts. *Results.* We analyzed 17 pts, 12 males and 5 females, median age was 53 (range 27-66 yrs). All of our pts were immunocompetent, there was no evidence of HIV infection. Most pts had symptoms suggestive of an intracranial mass lesion (headaches, personality changes) and less common seizures. Response to De Angelis regimen: 3 pts CR, 6 pts PR, 8 pts (3 pts were older than 60 yrs, 4 pts had ECOG performance status 3 and greater and elevated serum LDH) didn't respond to the therapy and died within 6 months after the diagnosis was established. In responders group 6 pts are alive, 1 pt died in first relapse 4 months after completing De Angelis regimen, 2 pts in first relapse (after 17 months and 27 months respectively) were treated with salvage chemotherapy, achieved secondary remission lasting 38 and 7 months, and both died within 17 months after second relapse. *Conclusion.* PCNSL pts have generally poor outcome and the optimum chemotherapy and radiotherapy strategy has yet to be established.

1597

IMMUNOCHEMOTHERAPY VERSUS CHEMOTHERAPY IN 90 NEWLY DIAGNOSED PATIENTS WITH FOLLICULAR LYMPHOMA: A SINGLE INSTITUTION STUDY

B Andjelic, M Todorovic, J Bila, M Smiljanic, M Perunicic-Jovanovic, Lj Jakovic, A Sretenovic, V Palibrk, B Mihaljevic

Clinic for Hematology, Clinical Center of Serbia, Belgrade, Serbia

Background. Follicular lymphoma (FL) is the most common type of low grade Non Hodgkin Lymphoma. In past few years the great improvement in treatment of follicular lymphoma patients was achieved by introducing immunochemotherapy as the standard first line therapy. All widely accepted prognostic indices such as Follicular Lymphoma International Prognostic Index (FLIPI), Italian Lymphoma Intergroup (ILI) and, for immunochemotherapy treated patients recently established FLIPI 2, identify different risk groups of patients, but great heterogenity in the outcome within these groups still persists. *Aims.* The aim of this study was to compare the outcome of FL patients treated with immunochemotherapy and chemotherapy. The second aim was to identify high risk patients regardless to received frontline therapy. *Methods.* In this retrospective study were included 90 newly diagnosed FL patients treated in the Clinic for Hematology Clinical Centre of Serbia from April 2000 until March 2006. 60 patients were treated with chemotherapy and 30 with immunochemotherapy. Initial FLIPI, ECOG performance status (ECOG PS), ESR and the presence of Bulky tumor (tu mass >7 cm) were determined in all patients. *Results.* Patients treated with immunochemotherapy had signifficantly longer event free survival (EFS) compared to patients treated with chemotherapy (log rank, P=0.028) and there was no difference in overal survival (log rank, P=0.075), but there is a trend toward better survival in patients treated with immunochemotherapy. 52 patients had high risk according to FLIPI, 25 intermediate and 13 low risk. All the patients with low and intermediate risk had high tumor burden according to GELF 94 criteria, predominantly B symptoms and high tumor burden. Bulky disease was present in 29 patients (in 18 treated with chemotherapy and 11 treated with immunochmeotherapy), ESR>30 mm/1h had 48 pts (32 treated with chemotherapy and 16 treated with immunochmeotherapy) and ECOG PS>2 had 26 patients (18 treated with chemotherapy and 8 treated with immunochemotherapy). FLIPI and Bulky disease didn't have prognostic impact on survival in both groups, but there was a trend of worse survival in FLIPI high risk patients regardless to treatment and better survival in FLIPI high risk patients and patients with Bulky disease treated with immunochemotherapy. The patients treated with chemotherapy with ESR>30 mm/1h had signifficantly worse outcome than the patients who didn't (log rank, P=0.002), but this was not recorded in group of patients treated with immunochemotherapy (log rank, P=0.957). The patients treated with immunochemotherapy with ECOG PS>2 had signifficantly worse outcome (log rank, P=0.02), but it was not the case in group of patients treated with chemotherapy (log rank, P=0.497). In patients with ECOG PS>2 there was no difference in outcome regardless to initial treatment, chemotherapy *vs.* immunochemotherapy (log rank, P=0.461). *Conclusions.* Immunochemotherapy improved outcome in patients with newly diagnosed follicular lymphoma and it is overcoming the influence on outcome of ESR recorded in patients treated with chemotherapy. Still, there is a subgroup of patients (ECOG PS>2) that doesn't have a benefit from immunochemotherapy and furhter investigations are needed to define appropriate therapeutic approach to these patients.

1598

NON-HODGKIN LYMPHOMA WITH SOFT TISSUE LESION

D Bykov,[1] I Subortseva,[1] A Chekan,[1] P Zeynalova,[1] N Tupitsin,[1] G Tumyan,[1] T Kondratieva,[1] A Kovrigina,[1] I Poddubnaya,[1] A Semenova,[1] R Chakyi,[1] D Osmanov[2]

[1]*N. N. Blokhin Russin Cancer Research Center, Moscow, Russian Federation;* [2]*N.N. Blokhin Russin Cancer Research Center, Moscow, Russian Federation*

Introduction. Soft tissue involvement accounts for 5,2% of all non-Hodgkin lymphoma (NHL). The aim of our study was to describe the clinicopathologic characteristics of patients with soft tissue lesion. *Methods.* In N.N. Blokhin Russian Cancer Research Center of the Russian Academy of Medical Science from 1983 to 2007 years 582 patients (pts)

with NHL were observed; 73 (12%) of them had a lesion of soft tissue, diagnosed at various time of a clinical course. The median age was 52 years (range 16-81). Only in 9\73 (12%) cases the lesion of soft tissue had been diagnosed at the first reference of the patient. *Results.* B-cell phenotype of a tumor had 70 from 73 patients, only 3 patients (4 %) had peripheral T-cell lymphoma, not specified. The frequency of various variants of B-lymphomas with soft tissue lesion is presented in Table. According to the International Prognostic Index (IPI) 89% of patients at the primary diagnostics of lymphoma had made a group of the high-intermediate/high risk, 87% of patients had the advanced stage of disease. The majority of patients had more than 1 extranodal site. B-symptoms had 31(44%). Median time from primary diagnostics to soft tissue involvement was 6 month. At 66 from 70 patients soft tissue involvement was a part of relapse/progression and only 4 patients had isolated soft tissue lesion. All patients received treatment according to the morphological variant of NHL, therefore treatment was quite heterogeneous. The median progression-free survival was 5 month, median overall survival - 23 month. *Conclusions.* Last time soft tissue involvement in patients with extranodal lymphomas in connection with growth of disease draws special attention of researchers. Involving of soft tissue in tumoral process is more often diagnosed at later time of development of disease and can be associated with high IPI score (3-5). The majority of NHL with soft tissue lesion had the B-cell origin and concern one of the variants of large cell lymphomas. The treatment strategy in patients with soft tissue lesion because of the listed above reasons need to be corrected.

Table. Distribution of pts according to B-NHL variants.

Variant of B-NHL	Abs.	%%
1. Diffuse large B-cell lymphoma	41	59%
2. Primary Mediastinal (Thymic) Large B Cell Lymphoma	4	6%
3. Burkitt lymphoma	9	13%
4. Follicular lymphoma		
Grade I-II	11	15%
Grade III	2	3%
5. Mantle cell lymphoma	3	4%
TOTAL	70	100%

1599

PRIMARY B AND T CELL NON HODGKIN'S LYMPHOMA (NHL) OF THE GASTROINTESTINAL (GI) TRACT: COMPARATIVE OUTCOMES FOLLOWING ANTHRACYCLINE BASED CHEMOTHERAPY

K Cadoo, M Lowery, J McCaffrey, D Carney

The Mater Misericordiae University Hospital, Dublin ,[7] Ireland

Background. Anthracycline based chemotherapy is the treatment of choice for aggressive primary lymphomas of the GI tract. We report outcomes of 61 patients with primary GI NHL treated over 18 years. *Aim.* To establish the outcome of GI lymphomas, at our institution, according histological subtype. *Methods.* Cases were identified from the histology database and records reviewed. *Results.* There were 34 (56%) males and 27 (44%) females. The median age at diagnosis was 60 (15-83). 43 (70%) were diffuse large B cell lymphoma (DLBCL), 10 (16%) were T-cell and 8 (14%) were mucosa-associated lymphoid tissue tumor (MALT). The 8 patients with MALT were treated with single agent chemotherapy; 7 (88%) are alive at median follow up of 8.5 years (2-16). Of the aggressive lymphomas (53 DLBCL and T cell), all patients with T cell lymphoma had small bowel as primary site and histological evidence of coeliac associated enteropathy, even in the absence of known coeliac disease. Primary sites of DLBCL were stomach in 30 patients (70%), small bowel in 8 (19%) and colon in 5 (11%). 34 patients underwent surgery at diagnosis due to acute presentation with perforation, obstruction or bleeding, or to obtain histology. Following confirmed diagnosis, 51 patients received anthracycline-based chemotherapy (CHOP/ CHOP-R/ M-BACOD). 2 patients with T-cell lymphoma presented with perforation, had surgery only and died of rapid disease progression. Of the 53 patients with aggressive NHL, 33 (62%) remain alive and disease free at median follow up of 7 years (1-18). 31 (72%) with DLBCL are alive and disease free, 4 deaths in this group were not related to cancer or treatment. 2 (20%) of the T-cell lymphomas are alive and disease free, all deaths in this group were from progressive disease. *Conclusion.* Patients with aggressive primary B cell GI NHL have >70% survival following anthracycline based chemotherapy. However, in contrast, coeliac enteropathy associated T cell lymphomas present with rapidly progressive disease and have a poor prognosis. Novel therapeutic approaches are required to improve outcome in this group.

1600

CIRCULATING CYTOKINE LEVELS IN PATIENTS WITH NON-HODGKIN LYMPHOMA AND OTHER LYMPHOPROLIFERATIVE DISORDERS

N Domnikova,[1] E Petrusenko,[1] O Reshetnikov,[2] N Varaksin[3]

[1]Research Institute of Regional Pathology and Pathomorphology, Novosibirsk, Russian Federation; [2]Research Institute of Therapy, Novosibirsk, Russian Federation; [3]Vector-Best, Novosibirsk, Russian Federation

Background. Is it known about important part of different cytokines in pathogenesis and course of lymphoproliferative diseases. But the going data are not absolute and entire. *Aims.* The aim of the present study was an evaluation of circulating cytokine levels in patients with Non-Hodgkin lymphoma and other lymphoproliferative disorders. *Methods.* The study included 20 patients with Non-Hodgkin lymphoma (NHL), 10 patients with Hodgkin lymphoma (HL), and 10 patients with multiple myeloma (MM) (18 males, 22 females, mean age is 55,43±2,41). Serum concentrations of cytokines (IL-1β, IL-2, IL-4, IL-6, IL-8, IL-10, TNF-α, IFN-α, IFN-γ, IL-1RA, and antibodies to IFN-α) were studied with enzyme-linked immunoassay (Vector-Best, Novosibirsk, Russia). Written informed consent was obtained from each patient. *Results.* Increasing levels of pro-inflammatory cytokines IL-6, IL-8, IFN-γ were found. The mean level of cytokines did not differ between NHL, HL and MM groups with the exception of IL-10 which concentration was the highest in NHL and the lowest in MM (37.7±8.5 pg/mL and 6.1±5.4 pg/mL, respectively, P=0.013). A significant correlation between the concentration of pro-inflammatory cytokines: IFN-γ and IL-6 (r=0.51, P=0.001), IFN-γ and IL-8 (r=0.39; P=0.014), IL-6 and IL-8 (r = 0.37; P=0.019), as well as between the level of anti-inflammatory cytokine IL-10 and the levels of pro-inflammatory cytokines IL-8 (r=0.39, P=0.015), IL-6 (r=0.46, P=0.003), and IFN-γ (r=0.65, P<0.001) were revealed. Therefore, there is an interdependent increasing concentrations of cytokines IL-6, IL-8, IFN-γ, and the resulting increase in the level of anti-inflammatory cytokine IL-10. Symptoms of tumor activity were not associated with normal levels of IL-10 and IL-6 (P=0.016). Correlation was found between the level of IL-6 and the level of C-reactive protein (r=0.85, P<0.001), and between the increase in IFN-γ and abnormal weight loss (r=0.34, P=0.039). Hemoglobin level <80 g/l was correlated with increased IL-8 level (r=0.38, P=0.017). Infiltration of bone marrow with tumor cells in NHL was associated with increased concentration of IFN-γ (P=0.036) and IL-10 (P=0.026). *Summary.* In conclusion, among the cytokine panel studied, increased levels of pro-inflammatory cytokines IL-6, IL-8, IFN-γ and anti-inflammatory cytokine IL-10 were observed. This increase was associated with clinical and laboratory symptoms that characterize the aggressive course of disease. Additionally, anemia was associated with increased production of IL-8.

1601

HIGH INCIDENCE OF HEPATITIS B OR C VIRUS INFECTION IN LYMPHOMAS

G Gaman, A Gaman

University of Medicine and Pharmacy, Craiova, Romania

Introduction. Several reports for different countries have shown that patients with lymphoma have a higher prevalence of HCV or HBV infections. The infection rates were different even in virus endemic areas as Balkan countries, including Romania. However, an association between the virus infection and lymphoma should be evaluated and discussed with the background of virus prevalence in the comunity. This study showed the prevalence of HBV or HCV infection status in lymphoma at patients in the Oltenia county of Romania. *Methods and results.* the study was conduted in Oltenia county (Romania). This study included 321 newly diagnosed patients with lymphomas admitted in the Clinic of Hematology from Craiova and 298 non-lymphomas control patients enrolled from January 2001 to December 2009. We evaluated the prevalence of HBV or HCV infections in both groups of patients and compared the clinical-pathological characteristics HBV or HCV positve and its negative lymphoma cases (17 of 321, 11,1%) than control group (2,6%, P<0,001).The higher prevalence was observed in both sexes and especially diffuse large B-cell lymphoma; compared with the HBV negative lymphoma group, the positive group displayed more liver or spleen involvement (P=0,001). The rate of HCV infection was higher

than those in the control group in HCV infected cases, more liver involvement was indicated (P<0,003). *Conclusions.* the present study, so far the largest trial of incidence of HBV or HCV infections at lymphoma patients demonstrated that patients with lymphoma in Romania had higher prevalence of HBV or HCV infection. This appears to be a possible role of HBV or HCV infection in the induction of malignant transformations, resulting in the development of lymphoma.

1602

POORER PROGNOSIS OF INTERMEDIATE BL/DLBCL COMPARED TO BURKITT LYMPHOMA IN RITUXIMAB ERA: A RETROSPECTIVE ANALYSIS WITH CLINICAL AND PATHOLOGICAL FEATURES

H Nagai, Y Suzuki, S Moritani, N Imoto, R Kihara, E Aoki, C Kato, T Yokozawa, H Ohashi, M Hamaguchi, S Ichihara, T Hotta

National Hospital Organization Nagoya Medical Center, Nagoya, Japan

Background and aims. The distinction of Burkitt lymphoma (BL) and diffuse large B-cell lymphoma (DLBCL) is critical for the therapeutic strategy. But there are some population with features of both BL and DLBCL. Such cases are now categorized into intermediate BL/DLBCL in 4th edition of WHO classification. Intermediate BL/DLBCL often has aggressive clinical courses, but at the present time optimal therapy was not established to this entity. To evaluate the clinical outcomes of intermediate BL/DLBCL in rituximab era, we conducted a retrospective cohort study of intermediate BL/DLBCL, BL, and DLBCL. *Methods.* All DLBCL and BL newly diagnosed and treated at our hospital after Dec 2003 (rituximab era in Japan) were serially registerd. Distinction of BL and intermediate BL/DLBCL was mainly based on morphological features, including immunohistochemistry (bcl2 expression and MIB1 index). Genetic information was not available for all patients. Overall survival (OS) was assessed using the Kaplan-Meier method, and the groups (BL and intermediate BL/DLBCL) were compared using the log-rank test. *Results.* Eleven BL and 10 intermediate BL/DLBCLs were included in this study. All patients diagnosed as BL received high intensity regimen (i.e. CODOX-M/IVAC, HyprCVAD/MA) without rituximab except for one case. Five out of 10 intermediate BL/DLBCL patients were treated by R-CHOP based regimen, and others were treated by high intensity regimen mostly in combination with rituximab. Median age and the IPI risk group between these disease entities were not statistically different. The 3 years OS rate was 79.6% in BL and 32.8% in intermediate BL/DLBCL. The favorable clinical outcome was shown in BL rather than intermediate BL/DLBCL, nevertheless the difference was not statistically significant (P=0.126). *Conclusions.* Intermediate BL/DLBCL showed poorer prognosis than Burkitt lymphoma, and the benefit of the high intensity therapy in combination with rituximab remains to be elucidated.

1603

SIX-YEAR EXPERIENCE IN THE TREATMENT OF PRIMARY AGGRESSIVE GASTRIC LYMPHOMAS WITH MODIFIED NHL-BFM-90 PROTOCOL

E Zvonkov

Hematology scientific center Russian Academy of Science, Moscow, Russian Federation

Background. CHOP chemotherapy can induce complete responses (CR) in up to 80% of patients with Primary Aggressive Gastric Lymphomas (PAGL) but the presence of adverse prognostic factors (APF) (bulky disease; stage>IE; B-symptoms; elevated LDH; undetected diagnosis of primary gastric Burkitt's lymphoma) decrease the efficacy of this therapy. Optimal therapy of these lymphomas is controversial. *Aim.* efficacy and safety assessment of the modified chemotherapy protocol NHL-BFM-90 (mNHL-BFM-90) in the treatment PAGL with APF. *Methods.* Twenty seven patients PAGL with APF underwent mNHL-BFM-90 between Oct 2003 and Dec 2009. The type of lymphoma was classified according to the WHO classification system. NHL-BFM-90 program (2 courses A and 2 courses B) was modified for primary gastric diffuse large B-cell lymphoma (PGDLBL) in the following way: Doxorubicin (50 mg/m^2) was added on the third day of course A. NHL-BFM-90 program (2 courses A and 2 courses C) was modified for primary gastric Burkitt's lymphoma (PGBL) in the following way: Doxorubicin (50 mg/m^2) was added on the third day of course A. Methotrexate (1 g/m^2 i/v) was added on the first day of course C. *Results.* There were 16 women and 11 men. The mean age at presentation was 45 years (14-73 years), 7 patients were older than 60. All patients had one or more APF. Diagnosis of PGDLBL was proved in 21 and PGBL in 6 cases, accordingly. Translocation t(8;14) was assessed for diagnosis of PGBL. None of the patients received surgical treatment before chemotherapy and consolidating radiotherapy. Only 4 patients were treated by mNHL-BFM-90 with addition of rituximab. Hematologic toxity of grade 3 and 4 was observed in all patients. Severe reversible complication became the reason for subsequent switch to CHOP therapy after 2 courses in 6 cases. All patients achieved complete remissions.The mean follow-up is 33 months (range 2-78). No relapses have been registered so far. *Conclusion.* mNHL-BFM-90 protocol is highly effective in both PGDLBL with AFP and PGBL.

1604

PROGNOSTIC SIGNIFICANCE OF APOPTOSIS-RELATED PROTEINS IN DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) PATIENTS (PTS) TREATED WITH CHOP-BASED CHEMOTHERAPY

SH Jeong, HW Lee, MS Ahn, JH Choi, JH Han, JS Park

Ajou University School of Medicine, Suwon, South-Korea

Background. Chemotherapy-induced apoptosis is one of the most important mechanisms of treatment in DLBCL. *Aims.* We evaluated the prognostic significance of apoptosis-related proteins in DLBCL pts treated with cylophosphamide/doxorubicin/vincristine/prednisone (CHOP) chemotheraoy with or without rituximab (R). *Methods.* Pretreatment tumor biopsy specimens from 30 pts (stage I: 4, II: 14, III: 9, IV: 3 pts) with DLBCL were analyzed for Bcl-2, Bcl-6, Bax and P53 proteins expression by immunohistochemistry. Fifteen pts were treated with CHOP regimen, while 15 pts with R-CHOP. *Results.* Within median follow-up duration of 67 months (28-166months) in survivors, 5-years overall survival (OS) of all pts was 65%. In univariate analysis, high expression of Bcl-2 and Bcl-6 was associated with poor OS in all pts (P=0.032 and 0.019). In R-CHOP group, high expression of Bcl-6 was associated with poor outcome (P=0.007), while high expression of Bcl-2, Bax and P53 was not correlated with pts outcome (P=0.086, P=0.055, and P=0.753). In addition, all apoptosis-related proteins did not show any prognostic significance in CHOP group. In multivariate analysis for all pts, high expression of Bcl-6 was the only significant independent predictor of poor OS (P=0.028). *Conclusions.* High expression of Bcl-6 may be useful for prediction of poor outcome in pts with DLBCL treated with R-CHOP.

1605

EVALUATION OF SAFETY, TOLERABILITY AND ACTIVITY: A REGISTRY FOR TEMSIROLIMUS-TREATED PATIENTS WITH MANTLE-CELL LYMPHOMA (MCL) IN THE USUAL HEALTH CARE SETTING

H Pelz,[1] G Hess,[2] M Dreyling,[3] M Kosch[1]

[1]*Wyeth Pharmaceuticals, a company of the Pfizer group, Muenster, Germany;* [2]*Johannes Gutenberg-University, Mainz, Germany;* [3]*Ludwig Maximilian-University, Munic, Germany*

Background. Temsirolimus (TEMS), an i.v. mTOR inhibitor, was approved for the treatment of patients with relapsed and refractory MCL in Aug 2009. A pivotal study had demonstrated significantly increased progression free survival with TEMS in relapsed and refractory MCL compared to investigator´s choice mono-chemotherapy (4.8 mo *vs.* 1.9 mo). *Aims.* To better identify the safety profile and efficacy of TEMS during clinical routine, continuous collection of data on pharmacovigilance in the post-approval period e.g. in a non-interventional trial (NIT) is essential. *Methods.* To prospectively evaluate TEMS in the usual health care setting a registry for TEMS-treated patients with advanced renal cell carcinoma (aRCC) has already been initiated in Germany in Jan 2008 (NCT00700258). With regulatory and ethic committee's notification this NIT was amended and extended to include patients with MCL. Primary objective is the evaluation of TEMS´s safety profile. Secondary objectives include efficacy of TEMS as well as the profile, comorbidity and characteristics of patients and sequence of systemic therapies in MCL. Inclusion criteria: histologically confirmed diagnosis of MCL that will be treated with TEMS, written informed consent by the patient prior to data collection. *Results.* 297 pts with aRCC have been included from February 2008 to January 2010. Since the amendment to open the NIT for patients with MCL in November 2009, patients with MCL were also included. The data collection period will last for approx. 5 years. Up to the end of January 2010 88 centers have been initiated and are currently recruiting patients. *Conclusions.* To better understand the safety, tolerability and efficacy of TEMS in the treatment of MCL - a rare tumor entity - in the real-life clinical setting Wyeth started a registry to further evaluate TEMS in the usual health care setting. First results of the MCL-part of this NIT will be presented in June 2010.

1606

AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT) IN POOR-PROGNOSIS DIFFUSE LARGE-B CELL LYMPHOMA (DLBCL)

E Pérez-Ceballos, ML Amigo, JJ Sanchez-Blanco, C Castilla, I Heras, F De Arriba, JB Nieto, V Vicente

Hospital Morales Mesguer, Murcia, Spain

Background. High-dose therapy and ASCT is considered to be an option of treatment to overcome cellular resistance and eradicate minimal disease in patients with non-Hodgkin's lymphoma *Aims.* The purpose of this study was to evaluate the impact on outcome of ASCT in patients with poor prognosis DLBCL. *Methods.* We have retrospectively analyzed 43 patients with DLBCL who underwent high-dose therapy and ASCT between January 1993 and March 2009 in our institution. Information was gathered from clinical records. *Results.* There were 22 (51%) males and 21 (49%) females with a median age of 45 years (range, 14-71 years). At diagnosis, 35 patients (81%) were in stage III-IV, 22 (51%) suffered B-symptoms, bulky disease was present in 20 (46%) and extranodal disease in 25 (58%). LDH value was available in 41 cases and was elevated in 88%. The International Prognosis Index (IPI) was evaluated in 41 and in 22 (54%) was ≥3. Median number of prior chemotherapy regimens was 2 (range, 1-3), and 4 (9%) had received prior radiation as part of induction or as salvage therapy. The median time from diagnosis to ASCT was 8 months (range, 5-36 months). Nineteen (44%) underwent transplantation in first complete remission (CR), 14 of then had received only one prior regimen and underwent ASCT as consolidation (IPI ≥3). Nineteen (44%) were in partial remission at ASCT, and 5 (12%) in second or subsequent remission. Conditioning regimens were carmustine, etoposide, cytarabine, and melphalan (BEAM) in 41 patients, total body irradiation/high-dose cyclophosphamide in 1 patient and bususfan/cyclophosphamide/thiotepa in another. All patients received peripheral blood stem cells. Fifteen patients with bulky disease at diagnosis received involved field irradiation as consolidation after ASCT. The early procedure-related mortality rate was 2,3% (one of 43 patients) and cardiac toxicity has been observed in one patient. At 3 months, the CR rate was 84%, two cases had relapsed and 5 were in progression. At a median follow-up 30 months (range, 1-158 months), the 5-year Kaplan-Meier estimates of probability of overall survival and event free survival are 64% and 62% respectively. Patients who underwent ASCT in first CR as early consolidation because of IPI ≥3 (n=14) had an actuarial 5-year survival rate of 75% compared with 55% for those with resistant/relapsed disease (P=0,04). Twenty-nine patients remain in CR maintained without continued therapy. The 13 cases with relapsed or resistant disease after transplant have received salvage chemotherapy but 12 of them have died. No second malignancies have been detected. *Conclusions.* ASCT is an effective regimen in poor risk DLBCL with low toxicity. Results of ASCT as consolidation in patients with IPI ≥3 in first CR are encouraging but prospective randomized trials are needed.

1607

LONG-TERM SURVIVAL OF MANTLE CELL LYMPHOMA - A SINGLE INSTITUTION EXPERIENCE IN TAIWAN

TD Tan, MC Wu, LW Chiou

Koo Foundation Sun Yat-Sen Cancer Center, Taipei, Taiwan

Background. Mantle cell lymphoma is a well-defined subtype of B-cell non-Hodgkin lymphoma which is approximately 6% of lymphoid neoplasm. The median survival is 3 to 4 years as literatures reported. Typically in older adults patients with male predominance and patients usually presented with stage IV disease. The response to chemotherapy usually resulted in tumor regression but unmaintained remissions are short. *Methods.* Between March 2003 and August 2009, we treated 38 mantle cell lymphoma patients with various protocols in 17 years. Diagnosis of mantle cell lymphoma is according to the histopathology and flow cytometry with positive for CD20, CD5, and negative for CD23 or cyclin D1(+). Initial treatment regimen includes regular intensity chemotherapy (eg. CHOP, COP, chlorambucil and prednisolone, with or without rituximab) for 32 patients and intensive chemotherapy (eg. HyperCVAD/MA or high dose Ara-C containing chemotherapy) for 6 patients. *Results.* In these 38 patients, the median age on initial presentation is 60.8 years with range between 26 and 77 years of age with male predominance (M/F 29/9). Most patients (76.3%) presented with stage IV disease (29/38). There were 4 patients underwent reduced intensity allogeneic peripheral blood stem cell transplantation as the salvage treatment. The 8-year disease free survival was 15.9% and overall survival rate was 28.4%. All the 6 patients underwent intensive HyperCVAD/MA chemotherapy are alive in 5 years but 63.5% got disease relapse in 4 years. Three of them underwent salvage RIC allotransplant and in disease free. *Conclusions.* Mantle cell lymphoma is easy to remission after chemotherapy but easy to relapse soon as well. The long-term follow up survival curve does not see the plateau which indicated difficult to cure whatever regular or more intensive chemotherapy as the initial treatment. For relapsed patients, we could see the promising finding of durable survival in these patients (66.7% in 5 years) but need more longer follow up and more patients *Results.* We plan to perform clinical trial of RIC allotransplant as the frontline treatment for CR1 patients.

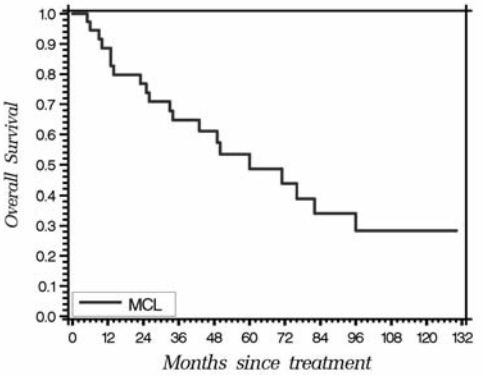

Figure. 8-year survival of Mantle cell lymphoma patients.

1608

TREATMENT OF SPLENIC MARGINAL ZONE NON HODGKIN LYMPHOMA(SMZL)

V Violaki,[1] G Tsirakis,[1] A Kolovou,[1] M Fameli,[2] A Papanikolaou,[2] L Marinos,[2] T Papadaki,[2] F Markidou[1]

[1]General Hospital of Chania, Chania, Greece; [2]Evangelismos Hospital, Athens, Greece

The Splenic marginal zone lymphoma (SMZL) is a B-cell low grade neoplasm which has been recognized as separate entity with dinstictive clinical, immunophenotypic and histological features. *Aim.* To define the clinical characteristics and the therapeutic outcomes in SMZL. *Patients and methods.* Fifteen patients with SMZL were studied in our department. Diagnosis required splenic involvement, with or without bone marrow infiltration and the absence of excessive lymphadenopathy or evidence of extranodal (MALT) lymphoma. Patients' characteristics are presented in Table 1. Immunophenotypic features: Follicular or difuse infiltration with splenic sinuses involvement, extended from splenic marginal zone to red pulp, from small or medium sized centrocyte like or monocytoid B-cells, characterized by the immunophenotypic features of $CD20^+$, $CD79a^+$, $CD45^+$, IgM^+, $CD5^-$, $CD10^-$,$CD23^-$,Cyclin $D1^-$, and Bcl 6^-. Treatment included watch and wait, splenectomy, chemotherapy, and Rituximab as monotherapy in dose 375 mgr/m^2 weekly, for 4 weeks as induction therapy, and then one dose every 2 months for 4 doses totally as maintenance therapy. Six patients (40%) were treated with Rituximab monotherapy, five patients (33%) with splenectomy(four of them due to progressive disease received plus Rituximab monotherapy), three patients (20%) were treated with CVP like regimen or R-CHOP/with Caelyx because of extensive disease, and one patient (7%) was under observation ,watch and wait. *Results.* Overall response rate was 86%. Eight patients (53%) achieved complete response (CR) and three patients (20%) partial response (PR). In addition two patients are still on therapy, while a third patient had refractory disease to the CVP like regimen and presented allergic reactions after Rituximab administration. Median follow-up time for the entire serie was 36m(7-276). Only one patient who was under observation died during the follow-up period from other cause. *Summary/Conclusions.* The SMZL is characterized from moderate clinical course and long survival. The treatment is based mainly in splenectomy, while enough other therapeutic options have been applied. There are important evidence that Rituximab monotherapy may substitute splenectomy as first line treatment. This approach is particularly appealing in older patients, with other comorbidities and in cases of coexisting autoimmune events. The high response rate, the long duration of remission, the simple way of administration and the little adverse effects constitute

important advantages in favor of immunotherapy. The role of chemotherapy is discussing. The combination (immuno. and chemotherapy) appears effective but has not been compared to immunotherapy monotherapy. Splenectomy can be used in case of refractory disease to the Rituximab.

BIODISTRIBUTION AND RADIATION DOSIMETRY OF 90Y-IBRITUMOMAB-TIUXETAN USING 89ZR-IBRITUMOMAB-TIUXETAN AND IMMUNO- PET IN PATIENTS WITH B-CELL NHL

O Visser,[1] N Rizvi,[2] M Wondergem,[3] A van Lingen,[2] G van Dongen,[2] O Hoekstra,[2] J Zijlstra,[3] P Huijgens,[3] M Lubberink[2]

[1]VU University Medical Center, Department of Hematology, Amsterdam, Netherlands; [2]VU University Medical Center Department of Nuclear Medicine and PET research, Amsterdam, Netherlands; [3]VU University Medical Center Department of Hematology, Amsterdam, Netherlands

Background. 89Zr-ibritumomab-tiuxetan-PET can be used to monitor biodistribution of 90Y-ibritumomab-tiuxetan (Zevalin®) as shown in mice. The aim of this study was to assess biodistribution and radiation dosimetry of Zevalin in humans using PET to evaluate whether co-injection of a therapeutic dose of Zevalin influences the biodistribution of 89Zr-ibritumomab-tiuxetan. If not, such combined administration may facilitate the prediction of the actual dose delivered to organs and tumor. *Methods.* Six patients with B cell NHL relapsing after anti-CD20 containing immuno-chemotherapy and scheduled for autologous stem cell transplantation underwent PET scans at 1, 72 and 144 h after injection of 50 MBq 89Zr-ibritumomab-tiuxetan and again after co-injection of 14.8 MBq/kg Zevalin. Volumes of interest (VOIs) were drawn over liver, kidneys, lungs, spleen and tumours. Zevalin organ absorbed doses were calculated using a special computer program (Olinda). Red marrow dosimetry was based on blood samples, taken at different time points. Tumor absorbed doses were calculated using an exponential fit. Agreement between uptake prior to and during therapy was assessed using intraclass correlation coefficients (ICC). *Results.* Highest 90Y absorbed dose was seen in the liver (4.4±2.5 mGy/MBq), followed by spleen, kidneys and lungs. No liver function abnormalities have been observed. There is significant uptake in lymphoma tissue, despite extensive pre-treatment with anti-CD20 (Figure 1).

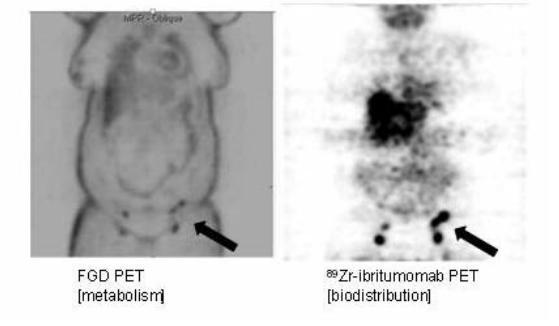

Figure 1.

Red marrow dose was 0.7±0.1 mGy/MBq. Effective dose was 0.7±0.2 mSv/MBq. Tumor doses ranged from 9 to 29 mGy/MBq. Pre-therapy and therapy uptake in source organs showed a high agreement (ICC = 0.97, mean difference 5±15%). Agreement between predicted 90Y effective doses was high as well (ICC = 0.91). No significant difference between pre-therapy and therapy tumor doses was found, but their correlation was lower (ICC 0.75, mean difference 5±33%). *Conclusion.* Biodistribution of 89Zr-ibritumomab-tiuxetan is not influenced by simultaneous therapy with Zevalin. Absorbed doses to kidney and spleen were significantly higher and lower, respectively, than those previously estimated using 111In-ibritumomab-tiuxetan. Combined administration of immunotracer and immunotherapy is feasible and facilitates actual biodistribution and dosimetry-calculations.

1610

PERIPHERICAL T CELL LYMPHOMA: DIAGNOSIS, TREATMENT AND SURVIVALL (PORTUGUESE ONCOLOGICAL CENTER'S EXPERIENCE)

S Chacim, L Leite, I Ferreira, D Marques, A Araújo, N Domingues, A Espírito-Santo, I Oliveira, L Viterbo, M Marques, A Oliveira, R Henrique, A Martins, M Mariz

Instituto Português Oncologia Porto, Porto, Portugal

Background. Peripherical T cell non-Hodgkin Lymphoma (PTCL-NOS) is uncommon and has adverse clinical prognosis. They represent 23% of the T cell lymphomas treated at our Institution. *Aims.* Characterization, determination of the prognostic factors, treatment response and overall survival of the patients diagnosed with PTCL-NOS at Instituto Português de Oncologia do Porto, Portugal. *Methods.* We gathered a series of cases, based on retrospective revision of clinical data of patients diagnosed with PTCL-NOS, at our Institution, between January 1998 and July 2009. Statistical analysis was made on xlstat2009. *Results.* 25 patients were diagnosed (64%male, median 56 year old). Seventeen patients (68%) presented B symptoms, 10 (40%) were at III/IV Ann Arbor stage, 8 (32%) had IPI≥3. Fourteen patients (56%) presented extranodular involvement, 4 (16%) had bone marrow involvement, 9 (36%) patients had cutaneous involvement, 2 (8%) had CNS involvement, 2 (8%) had enterical involvement, 2 (8%) had pulmonary involvement and 1 (4%) patient had spleen involvement. Three patients had leukemic presentation. Median follow up was 30 months. Initial treatment was CHOP in 20 cases (80%), followed by radiotherapy in 6 cases (24%). There were 10 (42%) complete responses (CR), 10 (42%) progressions and 4 (16%) partial responses (PR). Most patients (6/10) that had progression had no adicional chemotherapy treatement, and had supportive treatment. In respect of the other patients that had progression, 2 of them received chemotherapy with alentuzumab+ ICE, one was treated with H-CVAD and another received ESHAP, as second line treatment. Only one had CR with alentuzumab+ICE and went consolidation with autologous bone marrow transplantation. All other patients died with disease (9/10). Two patients with PR are with active inaugural treatment (CHOP), while the two remaining patients with PR obtained CR with second line treatment (ESHAP and CHOP, respectively). Six patients (24%) initially with CR had relapse disease, 4 of them were treated with ESHAP and one with Alentuzumab+ICE. There were 5 (83%) CR, one of these patients underwent autologous bone marrow transplantation. There was also a progression, treated with alentuzumab+fludarabine, with CR. There were 11 deaths (44%) related with disease events, and 14 are still in follow up. Median overall survival is 71 months (stand. dv. 0,67months). Median overall survival, according IPI stage, is 55 months to IPI≤2, 6,5 months to IPI≥3, which is statistically different (wilcoxon 0,014).

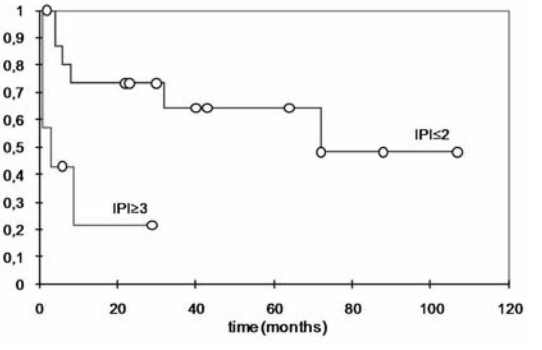

Figure. Overall survival PTCL.

Conclusion. PTCL-NOS is a disease with poor chemotherapy response, when compared with B cell Lymphomas. In 10 chemo-resistant patients to first line treatment, only one achieved CR. After CR in first line treatment, every relapse achieved CR, after 2nd or 3rd line treatment. IPI stratification could identify patients with worst prognosis. Intensified chemotherapy should be offered to these patients (alentuzumab or bone marrow transplantation).

1611

SECONDARY OSTEOPOROSIS AND SKELETAL RELATED EVENT (SRE) IN NON-HODGKIN'S LYMPHOMA TREATED WITH HIGH DOSE GLUCOCORTICOIDS

YS Kim,[1] YD Joo,[2] CS Kim[3]

[1]Kosin University Gospel Hospital, Pusan, South-Korea; [2]Pusan Paik Hospital Inje University, Pusan, South-Korea; [3]Inha University Hospital, Incheon, South-Korea

Objectives. Treatment with glucocorticoids is associated with bone loss is an increased risk of fracture. This study was performed to determine risk of osteoporosis and skeletal related event associated with high dose steroid among non-Hodgkin's lymphoma (NHL) patients. *Methods.* Data were from retrospective medical database. From March 2004 to March 2008, newly diagnosed Non Hodgkin's lymphoma patients treated with high dose glucocorticoids containing chemotherapy were examined bone mineral densitometry (BMD) studies before and end of chemotherapy courses. Skeletal related event were evaluated during all course of treatment. *Results.* The prevalence of Skeletal related event defined as BMD -2.5 or less and 0.5 decline after treatment and development fracture is about 70%. Clinically meaningful and statistically significant factor associated with skeletal related event were age older than 60yrs, baseline decline of BMD, 0.5 or more loss of femur and spine BMD after treatment. In multivariable analysis, the age older than 60yrs and 0.5 or more loss of spine BMD are statistically significant risk factor. *Conclusion.* Risk of osteoporosis and Skeletal related event is relatively high in NHL treated with high dose glucocorticoids containing chemotherapy. Preventive support and comprehensive evaluation for osteoporosis is warranted especially in elderly and patients who have history of previous bone loss.

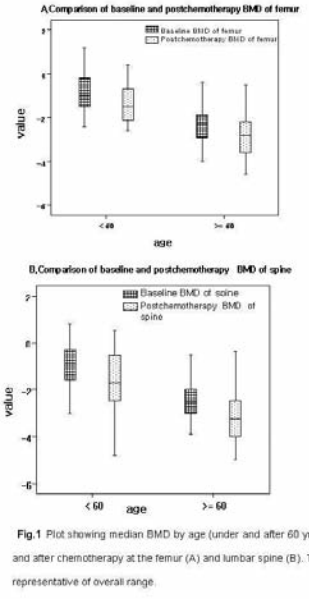

Fig.1 Plot showing median BMD by age (under and after 60 yrs) before and after chemotherapy at the femur (A) and lumbar spine (B). The bar is representative of overall range.

RADIOTHERAPY FOR THE INICIAL TREATMENT OF PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA

MP Silveira, C Afonso, P Santos, A Reichter, A Gomes, F Lima

Hospital S Francisco Xavier, CHLO, Lisboa, Portugal

Background. Primary Central Nervous System Lymphoma (PCNSL) is a rare disease that accounts for less than 1 % of all non Hodgkin Lymphoma and about 3 % of primary CNS tumors. Until 1990 PCNSL was treated with radiotherapy (RT) alone. However, disease recurrence was high despite good initial responses. Chemotherapy based on high dose methotrexate (MTX) has been shown to improve survival compared to RT alone. However the optimal approach is still unclear. The role of RT in initial treatment regimen is not defined and the combined therapy can be associated with long term neurotoxicity (NT). Since 2006, trying to minimize NT we are treating patients without RT if they are more than 50 years old. Our aim was to compare progression free survival in patients treated with or without RT in initial treatment schedule. *Patients and Methods.* Twenty six immunocompetent patients with PSNCL were considered for high dose MTX in our institution between 1998 and 2009. After excluding systemic disease, diagnosis was done by biopsy of the lesion in all but one patient (cerebrospinal fluid (CSF) positive). Until 2006 we used high dose MTX according to Memorial Sloan-Kettering Cancer Center (MSKCC) 1990 protocol (Table 1). After that we started treating patients according to the 2002 MSKCC protocol (Table 2). *Results.* Twenty six patients initiated the protocol. Only 17 have completed the treatment (9 patients before 2006 and 8 patients after 2006) because infectious complications (n=5) and disease progression (n=3). Mean age was 61 years (range 35 to 84 years). All but one achieved complete remission (CR) at the end of the treatment. In the first group (before 2006) we lost 1 patient to follow up. The remaining 7 patients are in CR at 30 months follow up and 4 of them are still in CR after 60 months follow up. In the second group (after 2006) five patients had more than 50 years at diagnosis so RT was deferred. Four of them relapsed (18, 19, 22 and 32 months after diagnosis). Only one is in CR (44 months). Two patients with less than 50 years old were treated after 2006 (CR at 22 and 30 months follow up). None of the patients treated after 2006 had positive CSF. *Conclusions.* In the group of patients who did not receive RT in the initial treatment, progression free survival is shortened. We also point out that none of this patient received intrathecal MTX. Because patients that relapse end up including RT in their treatment the impact of deferring RT in NT was not assessed. We are reconsidering the role of RT in the initial treatment of PCNSL patients.

Table 1. MSKCC 1990.

MTX (1 g/m^2) (2 cycles)
Intrathecal MTX (6 cycles)

CENTRAL NERVOUS SYSTEM RECURRENCE IN AGGRESSIVE B-CELL LYMPHOMA: A SINGLE INSTITUTION EXPERIENCE

A Chekan, M Kichigina, G Tumyan, A Kovrigina, N Tupitsin, O Trofimova, D Bykov, I Poddubnaya, D Osmanov

Russian Cancer Research Center named after N.N.Blokhin RAMS, Moscow, Russian Federation

Introduction. Central nervous system involvement is uncommon (nearly 5%), but serious and usually fatal complication of aggressive lym-

phoma. This single centre retrosprctive study investigated the clinicopathologic characteristic and outcome of patients with relapse in the central nervous system. *Methods.* We identified 15 patients (8 female and 7 male) with secondary central nervous system lymphoma (SCNSL), treated at our center from 2004 to 2009. The median age was 47 years (range 21-67); 5 patients had initial diagnosis mediastinal large B-cell lymphoma (PMLBCL) and 10 patients (pts) - diffuse large B-cell lymphoma (DLBCL). In addition to 5 pts with PMLBCL, 8 pts DLBCL presented with a extranodal disease (testis, breast, stomach, tonsil, bone). According to the age-adjusted International Prognostic Index score (aaIPI), 11 pts had IPI=2-3. Patients were previously treated with CHOP or MACOP-B regimen, 8 pts received Rituximab (375 mg\m^2 - N 4-6). *Results.* CNS relapse usually was defined as brain parenchymal involvement, only 1 pts has leptomeningial disease. The median time from diagnosis to CNS relapse was 6 months (range 1 to 40 months), 6 pts had SCNSL during or very shortly (1-3 months) after completion of chemotherapy. CNS was the only site of progression/relapse in 7 pts. Treatment of patients with CNS disease was quite heterogeneous, but usually systemic therapy incorporating HD-MTX (>1g/m^2), 7 pts received MCP (HD MTX on days 1, 15, 30, CCNU on day 1, procarbazine on days 1-10). The median progression-free survival was 7 months, overall survival - 31 months, 1 pts is 20 months on complete remission after MCP. *Conclusions.* Our data suggests that CNS relapse of aggressive lymphoma occurs early (median time to relapse 6 months). SCNSL was associated with extranodal involvement and increased aaIPI score. The combination of HD-MTX with CCNU and procarbazine is feasible and effective, however, given the small number of patients, the power of this analysis is limited.

1614

HIGH PREVALENCE OF HEPATITIS C (HCV) INFECTION AND FAVORABLE PROGNOSIS IN PRIMARY HEPATIC LYMPHOMA (PHL)

A De Renzo,[1] M Persico,[2] R Cuccurullo,[1] F Perna,[1] M Masarone,[2] S Luponio,[1] G Cerciello,[1] F Grimaldi,[1] I De Sio,[3] G Ciancia,[4] P Zeppa,[5] F Pane[1]

[1]University Federico II, Naples, Italy; [2]Hepatology,II University, Naples, Italy; [3]Department of Internal Medicine and Gastroenterlogy, II University, Naples, Italy; [4]Department of Pathology, University Federico II, Naples, Italy; [5]Department of Pathology,University Federico II, Naples, Italy

Background. Primary Hepatic non-Hodgkin's lymphoma (PHL) is a rare disease, representing 0,4% of extranodal non-Hodgkin's lymphomas. To date, less than 150 cases have been published. We report nine patients with PHL diagnosed in 1995 and 2009 at our center, with a study of the viral status and the result of cytotoxic treatment. *Results.* Nine patients with PHL were identified. The disease occurred in middle-aged men (median age: 58 years). The main presenting complaint was right upper quadrant abdominal pain (4/9 patients). Tumour markers (α-fetoprotein and CEA) were normal in six patients tested. Liver scans demonstrated either a solitary nodule or multiple lesions. Pathologic examination revealed diffuse large B cell lymphoma in 6 patients, two case of centrocytic lymphoma and one case of T cell lymphoma. Six patients were HCV-positive. Seven patients received chemotherapy (6CHOP,1 R-CHOP), one received chemotherapy (R-FN), while a patient with a single focal lesion received surgical treatment. The complete remission rate was 100% (9/9); one patient, who had HCV-related cirrhosis, died of hepato-renal syndrome in complete remission from lymphoma, and another patient died of acute myeloid leukemia. *Conclusions.* The outcome of patients with PHL who are treated with combination chemotherapy seems excellent. The frequent association of PHL with HCV infection suggests a possible role of this virus in lymphomagenesis. HCV- infection does not appear to influence the outcome of therapy.

1615

COMPLETE REMISSION INDUCED BY FOTEMUSTINE AS SALVAGE TREATMENT IN RELAPSED PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA: A CASE REPORT

E Pennese, MR De Paolis, P Forese, C Vergine, N Di Renzo

Haematology Division, Lecce, Italy

Background. Despite recent therapeutic advances, primary central nervous system lymphoma (PCNSL) shows the worst prognosis among all Non-Hodgkin lymphomas (NHL), with a 5-years survival rate ranging from 4-40%. Front-line therapy for patients with PCNSL is a combined chemo-radiation regimen, and more recently high-dose chemotherapy with autologous stem-cell support (ASCT) as consolidation therapy. This therapeutic approach has improved Complete Response (CR) rate and median survival, but the prognosis of PCNSL remains poor with high rate of fatal relapse. There is no effective salvage therapy for patients who fail or relapse after front-line treatment. Fotemustine is a third generation nitrosourea, with elevated lipophilic properties, which contributes to facilitate its passage through the blood-brain barrier and into malignant cells; the drug has been approved in the treatment of malignant metastatic melanoma and primary brain tumors. Recently the drug has been used in a novel fotemustine-based high dose conditioning regimen in lymphoma patients. We report here the case of a patient with relapsing PCNSL after front-line and consolidation therapy, who received fotemustine as salvage therapy. A 33-year-old patient was admitted to the hospital because of signs of intracranial hypertension. Computerized tomography scan (CT) and magnetic resonance (MR) revealed a cerebral mass localized in the median deep region of the brain. Immunoistochemical analysis of the tissue (stereotactic biopsy) diagnosed a diffuse B large cell PCNSL. Front line therapy consisted of two courses of high dose Methotrexate and three courses of L-VAMP (Vincristine, Cytosine Arabinoside, Dexamethasone) combined with inthratecal lyposomal cytarabine and whole brain radiation therapy at the total dose of 40 Gy followed by a boost of 10 Gy. At the end of front-line program CR was documented by negative cerebral positron emission tomography (PET). After three months a consolidation treatment with autologous stem cell support has been carried out. Conditioning regimen consisted of FEAM (Fotemustine 150 mg/m^2 on days -8 and -7; Etoposide 200 mg/m^2 on days -6, -5, -4 and -3; Cytarabine 400 mg/m^2 on days -6, -5, -4 and -3; Melphalan 140 mg/m^2 on day -2). After a follow-up of 16 months, a progressive hearing loss and ataxia appeared; CT scan and MR showed a cerebellar relapse. Fotemustine was administered every 15 days at the dose of 100 mg/m^2, as salvage therapy. Patient achieved a second CR after eight courses of fotemustine. Fotemustine was well tolerated with a main haematological toxicity consisting of grade II thrombocytophenia. No extra-hematological toxicities were recorded. After a follow up of six months patient is still in CR confirmed also by PET. *Conclusion.* At our knowledge this represent the first report of CR achieved with fotemustine as single agent in patients with PCNSL relapsing after high-dose therapy and stem-cell support. Is noteworthy that CR in this patient has been achieved despite previous exposure to fotemustine, suggesting that drug does not induce resistance. However more patients have to be treated before to define the exact role of this agent in the treatment of relapsing PSNCL.

1616

INFILTRATION OF ORBIT IN ADVANCED STAGE NON-HODGKIN LYMPHOMAS

W Spychalowicz,[1] J Wojnar,[1] A Spychalowicz[2]

[1]Clinic Hospital Medical Silesian University, Katowice, Poland; [2]I Clinic of Internal and Agricultural Medicine CM UJ, Krakow, Poland

Involvement of extralympatic tissues and organs is of significance in course and managment of non-Hodgkin lymphoma. Our goal was to determine in a retrospective analysis the frequency of orbital involvement in advanced non-Hodgkin lymphomas and the influence of such affection on the short- and long-term efficacy of a treatment used. During 2004-2008 period 411 patients with advanced stage (CS III-IV) non-Hodgkin lymphoma were hospitalized in Internal Medicine and Chemotherapy Clinic. During initial diagnostics 17 of those patients (4.1%) were recognized with exophthalmus: 11 with uni- and 6 with bilateral.A lymphomatic infiltration of orbital cavity tissues was present in 12 patients with exophthalmus. The group with orbital infiltration consisted of 8 females and 4 males aged 48 to 79 years (mean - 67,4 years). DLBCL histological subtype occurred in 6 patients, SLL in 3, MALT in 2, and FL in 1 patient. After verification by biopsy an exophthalmus was found not to be caused by lymphomatic infiltration in 5 patients. Instead it was associated with superior caval vein syndrome in 2 patients and with hyperthyroidism in another 2. The underlying pathomechanism could have been not revealed in one remaining patient. Except for histological and ophthalmological examination, methods used for exophthalmus evaluation included ultrasonography of the orbit, CT/NMR, and since year 2006 also PET (in indolent lymphoma group avidity occurred in 2 out of 4 patients who had undergone the scan before the treatment). Because of advanced stage of the disease patients had been qualified to undergo chemotherapy: DLBCL according to R-CHOP scheme - 6-8 cycles, SLL according to COP or R-

CVP schemes - 6 cycles, MALT according to COP scheme - 4-6 cycles, FL according to R-CVP scheme - 8 cycles. Regarding orbital cavity pathologies, total postchemoterapeutic regression was achieved in 10 out of 12 patients, who therefore received no further treatment in that area. As chemotherapy failed to affect orbital lymphomatic infiltration in 2 remaining patients they were qualified for radiotherapy. Treatment *Results.* DLBCL = 3×CR + 2×PR + 1×PD->death; SLL = 1×CR + 2×PR; MALT = 1×CR + 1×PR; FL = 1×CR. Follow up lasted for 18-55 months (median 34 months). Relapse took place in 1 patient with MALT subtype after 27 months, whereas progression took place in 1 patient with DLBCL after 12 months, and one patient with SLL subtype after 21 months. No recurrence of orbital cavity infiltration was observed in patients who undergone successful chemotherapy (10 of 12) including those with relapse or progression of lymphoma itself. *Conclusions.* Infiltration of orbital cavity in advanced stage non-Hodgkin lymphomas does not deteriorate the prognosis. Standard chemotherapy is effective form of treatment ensuring remission of orbital infiltration in vast majority (10/12=83%) of cases. Current observation (median of 34 months) indicates this effect to be stable also in patients who experienced either progression or recurrence of lymphoma itself.

1617

SEVERE CASE OF HEPATITIS C INFECTION AT A FOLLICULAR NON-HODGKIN LYMPHOMA PATIENT UNDER RITUXIMAB MAINTENANCE THERAPY

I Benedek,[1] E Bendek Lazar,[1] J Kopeczi,[1] A Tunyogi,[1] D Georgescu,[2] Z Opris,[3] E Kakucs,[1] M Istrati,[1] A Kurtus[1]

[1]Clinical Hematology and BMT Unit, Targu-Mures, Romania; [2]Emergency County Hospital Gastroenterology, Targu-Mures, Romania; [3]Emergency County Hospital Imagistical Department, Targu-Mures, Romania

Background. We present this case due to the possibility of contacting a serious viral infection or activating a previous one of patients undergoing monoclonal antibody treatment for non-hodgkin lymphomas. *Aims.* The aim of presenting this case is to draw the attention of physicians to a very serious viral complication in lymphoma patients treated with rituximab maintenance. *Methods.* The methods of investigation were: paraclinical, hematologycal (biochemistry, tumor marker measured by ELISA, cantitative PCR) imagistical (abdominal ultrasound and CT-scan). *Results.* We present the case of a 39 years old patient with B cell follicular lymphoma diagnosed in 2007 with abdominal and retroperitoneal localization. Initially the histological confirmation being done from abdominal adenopathies. She underwent 8 courses of R-CHOP with very good evolution. Her treatment was continued with rituximab maintenance. 1 $^1/_2$ years after starting maintenance therapy she developed fatigue and a slightly elevated bilirubin levels (total bilirubin 2.05 mg/dL). Initially we considered relapse of the lymphoma but the CT-scan didn't confirmed the presence of adenopathies in the abdomen and retroperitoneum. Because of the presence of an ovarian chist we suspected ovarian carcinoma, the level of CA-125 being very high 1282 U/L. The gynecological exam and biopsy didn't confirmed this. The paraclinical examination confirmed a hepatic cytolysis with elevated transaminase: sGOT 154 U/L, sGTP 229U/L, GGT 116 U/L and the level of alkalic phosphatase being 105 U/L. The HBs antigen was absent and the tests were negative for HCV antibodies. The total bilirubin was 2.59 mg/dL. The gastroenterologist still suspected the relapse of lymphoma but we decided not to continue the monoclonal antibody treatment and to observe the patient for a possible viral infection. In 3 weeks the patient was addmited to our clinic in a very bad clinical condition with extreme fatigue, jaundice, generalizated oedema and a big quantity of ascites. The paraclinical examination showed the following: sGOT 393 U/L, sGPT 681 U/L, GGT 779 U/L and highly elevated levels of total bilirubin 24 mg/dL, level of total proteins 2.1 g/L. The repeated viral tests confirmed the presence of virus C and the viral replication by repeated PCR showed very high levels of HCV ARN: 215.291.400 UL/mL, the sensibility of the method being ≥15UL/mL). The treatment she received was interferon alpha 3×3.000.000 Ui/week, human albumin, acid ursodeoxycholic. In 3 weeks the evolution become slightly favorable with lowering level of bilirubin (BiT 7.67 mg/dL, BiD 7.45 mg/dL) and the slow disappearance of the ascites from the abdominal cavity. *Conclusions.* We consider this a case of severe hepatitis C viral infection at a patient with compromised immunity due to prior chemotherapy and monoclonal antibody therapy. We think it is necessary to follow very closely the patients with monoclonal antibody therapy for viral infection and also to take into consideration the possibility of false pozitive tumor marker levels in the case of concomitent viral infections.

1618

INDEX FOR SERUM GLOBULIN COMPENSATION IN DIFFUSE LARGE B CELL NON HODGIN LYMPHOMA

A Duletic Nacinovic, D Petranovic, D Grohovac, T Zekic, T Valkovic, I Host, K Lucin, I Seili, R Dobrila Dintinjana, N Jonjic

Clinical Hospital Center, Rijeka, Croatia

Background. Low level of serum albumin have been used as prognostic factor for many malignant and other chronic diseases. Usually the decrease may be partly compensated by globular proteins but in some patients the failure of globulins to compensate may reflect advanced disease. *Aim.* We examined the prognostic value of globulin compensation index in patients with diffuse large B-cell non Hodgkin lymphoma (DLBCL). *Methods.* In Clinical Hospital Center of Rijeka, Croatia, 108 patients with DLBCL were analysed according the globulin compensation index (GCI) and other clinical and laboratory parameters. The GCI was determined using mathematical formula as described previously (F S Al-Joudy, Singapore Med J 2005;46(12):710). According to literature patients were classified into three categories: 1.negative GCI and negative compensation; 2.GCI of 0 to less than 1.0 with partial compensation and 3. GCI equal or greater than 1.0 with full compensation. *Results.* Negative GCI in patients with DLBCL showed a significant association with stage III/IV, > or =2 extranodal involvements and risk of high international prognostic index (P<0.05). The complete response (CR) rate (85.9%) in the full compensation (elevated GCI) was higher than in the negative or partial compensation (21.5%). The time to progression and overall survival were shorter in the group with negative GCI (P<0.05). *Summary/Conclusions.* GCI might be useful marker to indicate the extent of lymphoma involvement and prognosis in DLBCL patients.

1619

CHOP CHEMOTHERAPY FOLLOWED BY 90YT IBRITUMOMAB TIUXETAN (ZEVALIN) IN PATIENTS WITH UNTREATED DIFFUSE LARGE B CELL LYMPHOMA

S Issaragrisil

Siriraj Hospital, Bangkok, Thailand

Background. Radioimmunotherapy represents a significant advance over unlabeled immunotherapy for the treatment of patients with B-cell non-Hodgkin's lymphoma. The response rates tend to be higher with patients who treated wtih fewer prior therapies. *Objective.* To investigate efficacy and safety of a treatment approach combining introduction chemotherapy with cyclophosphamide, doxorubicin, vincristine and prednisolone (CHOP) followed by a course of 90Yt ibritumomab tiuxetan in patients with untreated diffuse large B cell lymphoma (DLBCL) stage II, III, or IV. *Methods.* This is a prospective, single-arm, open-label phase II trial. Thirteen patients with untreated DLBCL stage II-IV received an introduction of 6 cycles of CHOP chemotherapy followed 4-6 weeks later by 90Yt ibritumomab tiuxetan. Efficacy and tolerability were evaluated. *Results.* 13 patients were enrolled; 8 were men and 5 women. The age ranged from 19.8 to 71.4 years. Six were in stage II, 6 stage III and 1 stage IV. After 8 weeks of treatment, 12 patients were in complete response, whereas 1 patient had relapse of the disease. With a median follow up time of 13.9 months (range = 2.6, 24.6), the 2-year progression free survival was 76.9% (10/13) and 2-year overall survival was 92.3% (12/13). No patients were discontinued from the study due to drug intolerability. *Conclusion.* The study regimen has demonstrated good efficacy and tolerability in patients with DLBCL.

1620

IMPROVED SURVIVAL IN PATIENTS WITH HIV-ASSOCIATED BURKITT LYMPHOMA TREATED WITH INTENSIVE CHEMOTHERAPY AND HAART

A Rodrigo,[1] K Hicks,[2] C Cheung,[3] W Song,[4] A Ezzat,[1] S Leger,[1] R Taggart,[3] C Boro,[2] S Montaner,[5] X Harris,[5] A Leitch[1]

[1]St. Paul's Hospital, Vancouver, Canada; [2]St. Michael's Hospital, Toronto, Canada; [3]Sunnybrook Hospital, Toronto, Canada; [4]Leukemia/BMT Program of British Columbia, Vancouver, Canada; [5]BC Center for Excellence in HIV/AIDS (CFE), Vancouver, Canada

Background. The incidence of Burkitt Lymphoma (BL) is increased in HIV/AIDS at 200-1000 fold the HIV-negative population. Standard chemotherapy yields a median overall survival (OS) of only 6 months. Intensive chemotherapy such as the Magrath regimen (CODOX-M/IVAC +/- rituximab) yields long term OS in non-HIV BL of >85%. Prior to availability of HAART, outcomes for HIV+ pts with lymphoma

were poor because of opportunistic infections, sepsis and progressive lymphoma on chemotherapy. In the HAART era, survival may be equivalent to HIV-negative pts with standard chemotherapy. Rituximab is routinely added to the CODOX-M/IVAC regimen in non-HIV pts with BL. *Aims.* To determine the safety and efficacy of intensive chemotherapy with CODOX-M/IVAC +/- R in HIV+ pts with BL. *Methods.* We reviewed all pts with HIV-associated BL receiving the Magrath regimen to identify the frequency of toxicity, BL response to chemotherapy and survival. *Results.* 12 pts were identified. Median age at BL diagnosis (dx) was 45 (range 32-56) years and all 12 pts were male. BL stage was: I, n=2; II, n=1; III, n=3; IV, n=6; limited stage/low risk, n=1; advanced stage/high risk, n=11. ECOG performance status (n=8) was: 0-1, n=4; >2, n=4. HIV risk factor (n=10): sexual, n=9; injection drug use, n=1; a prior AIDS-defining illness (n=11) was present in 1. Median CD4 count and HIV viral load at BL dx were 380 cells/mL and <40 copies/mL (undetectable; n=11). Coinfections were: hepatitis B (n=10), n=2; hepatitis C (n=11), n=1. 11 pts received HAART with chemotherapy. Number of Magrath cycles (of 4 planned) were: 4, n=4; 3, n=1; and 1-2, n=6 (2 pts are on treatment). 8 pts received rituximab with chemotherapy; all 12 received CNS prophylaxis; and 11 received G-CSF. Prophylaxis was: PCP, n=12; HSV/VZV, n=6; fungal, n=2. Complications were: bacterial infection, 10 episodes in 5 pts; febrile neutropenia, n=4; late neutropenia, n=4; peripheral neuropathy, n=2; increased liver function tests, n=1 (in a hepatitis C+ pt); skin reaction, n=1; hallucinations, n=1, oral thrush, n=1. Grade 3-4 hematological toxicity occurred in all pts but dose reduction or delay was required in only 2. All pts with late neutropenia recovered counts fully with brief G-CSF support. At a median follow-up of 9.6 (1.4-47) months, 10 pts (83%) are alive. Of 8 pts who received HAART and rituximab with chemotherapy, all 8 are alive and in remission. There were 2 deaths, both from progressive BL, both in pts not receiving rituximab, 1 in a pt with CNS involvement at dx (CD4 140 cells/mL at BL dx, did not receive HAART); neither death was from treatment-related toxicity. *Conclusions.* Patients with HIV-associated BL have acceptable tolerance of the Magrath regimen. All 8 patients who received rituximab with chemotherapy are alive and in remission. There were no deaths in pts receiving rituximab and HAART with chemotherapy. The survival of HIV+ pts with Burkitt Lymphoma without CNS involvement receiving intensive chemotherapy appears superior to that achieved with standard chemotherapy and is similar to non-HIV-associated BL, provided HIV control is optimized.

1621

HELICOBACTER PYLORI AND PRIMARY GASTRIC MALT LYMPHOMA

I Rotaru,[1] G Gaman,[1] T Ciurea[2]

[1]Hematology Clinic Craiova, Craiova, Romania; [2]Medicine University, Craiova, Romania

Background. Helicobacter pylori has been claimed to be an important etiological factor which raises the risk of mucosa-associated tissue lymphoid (MALT) lymphoma. However, some studies on gastric MALT lymphoma revealed a low rate of H. pylori infection suggesting that not all gastric lymphomas are related to H. pylori infection. *Aim.* was to verify the H. pylori infection frequency in a series of patients with primary gastric MALT lymphomas and to examine the relationship between H. pylori and the pathological features of those lymphomas. *Methods and results.* 14 cases of gastric lymphoma were analysed: 9 cases (64,28%) were low-grade MALT lymphomas and 5 cases (35,71%) were high-grade MALT lymphomas. Helicobacter pylori was found in 12 of 14 (85,71%) cases. Helicobacter pylori infection was significantly correlated with the grade and depth of invasion of MALT lymphoma since over 64% of superficial low-grade MALT lymphomas were positive for H. pylori compared with 35,71% of advanced high-grade MALT lymphomas. *Conclusion.* We confirmed the relationship between H. pylori infection and a subset of gastric MALT lymphoma. Our results also showed that not all low- and high-grade gastric MALT lymphomas are H. pylori-dependent. This suggests that H. pylori infection may play a promoter role in the development of MALT lymphoma. Because the groups were small in size, statistical significance was not achieved.

1622

AUTOLOGOUS STEM CELL TRANSPLANTATION IN ADULT PATIENTS WITH RELAPSED OR PRIMARY REFRACTORY PERIPHERAL T-CELL LYMPHOMA

H Shimizu,[1] Y Hshimoto,[2] A Yokohama,[2] T Saitoh,[2] H Handa,[2] H Irisawa,[3] T Jinbo,[1] K Murayama,[3] M Matsumoto,[4] M Sawamura,[4] N Tsukamoto,[2] H Murakami[2]

[1]Fujioka Jeneral Hospital, Fujioka Gunma, Japan; [2]Gunma University Graduate School of Medicine, Maebashi Gunma, Japan; [3]Devision of Hematology, Gunma Prefectural Cancer Center, Gunma, Japan; [4]Devision of Hematology, Nishigunma National Hospital, Gunma, Japan

Background. Autologous stem cell transplantation (ASCT) is established as salvage therapy for chemosensitive relapsed or primary refractory aggressive lymphoma such as diffuse large B-cell lymphoma (DLBCL). But it is not clear whether ASCT improve the prognosis in the subset of patients with peripheral T-cell lymphoma (PTCL). *Aims.* The aim of this study was to evaluate the efficacy of ASCT in adult patients with chemosensitive relapsed or primary refractory PTCL. *Methods.* Between January 1996 and December 2008, 14 consecutive patients (median age 47.5 (22-62), male/female; 10/4) with chemosensitive relapsed or primary refractory PTCL who underwent ASCT were included. Patients with anaplastic lymphoma kinase (ALK) expressing anaplastic large cell lymphoma (ALCL) were excluded. The results of 14 patients with PTCL were compared with those of 32 consecutive patients (median age 55.5 (23-67), male/female; 24/8) with chemosensitive relapsed or primary refractory DLBCL who underwent ASCT during the same period. The χ^2-test was used for the binary variable comparison. The Mann-Whitney U test was used for the continuous variable comparison. Overall survival (OS) and event free survival (EFS) were estimated by the Kaplan-Meier method, and compared using the log-rank test. The Cox proportional hazards regression model was used for the multivariate analysis of prognostic factors. P<0.05 was considered to indicate a statistical significance. *Results.* Histological PTCL subtype included PTCL not otherwise specified (n=4), ALK-negative ALCL (n=6), angioimmunoblastic T-cell lymphoma (n=3), and subcutaneous panniculitis-like T-cell Lymphoma (n=1). No significant differences in age, sex, international prognostic index (IPI) at diagnosis, and conditioning regimen contained total-body irradiation or not were demonstrated in both groups. The proportion of patients in CR and PR at the time of ASCT was not significantly difference in both groups. The 5-year PFS rates for patients with PTCL and DLBCL were 29% and 37% respectively (P=0.62). The 5-year OS rates for patients with PTCL and DLBCL were 32% and 48% respectively (P=0.75). In patients with PTCL the 5-year PFS rates for patients in CR and PR at the time of ASCT were 67% and 18% respectively (P=0.11), and the 5-year OS rates were 100% and 18% respectively (P=0.04). Disease progression occurred in 82% of patients in PR at the time of ASCT within 1-year. Multivariate analysis of both OS and PFS in patients with PTCL showed an independent prognostic significance of only a CR status at the time of ASCT. *Conclusions.* The prognosis after ASCT in patients with chemosensitive relapsed or primary refractory PTCL and DLBCL were similar. Based on this result patients with relapsed or primary refractory PTCL should be treated with salvage therapy with the intent of ASCT for patients with chemosensitive disease. However, the prognosis in patients who did not achieve CR at the time of ASCT was dismal. To improve the outcome of these patients allogenic stem cell transplantation should be investigated.

1623

CNS INVOLVEMENT IN A CASE OF HUMAN T LYMPHOTROPIC VIRUS TYPE 1 (HTLV-1) ASSOCIATED LEUKEMIA/LYMPHOMA

N Valizadeh

Urmia University of Medical Sciences, Urmia, Iran

Background. Central nervous system involvement in adult T-cell leukemia/lymphoma is rare and has been demonstrated with with mass lesions on imaging. We want to present a 20 -year-old woman,known case of lymphoblastic lymphoma in complete remissin who admitted with seizure and comatose state and further evaluation revealed HTLV-1 antibodies in her serum and CSF.Serial brain imaging revealed CNS involvement. We started Dexamethasone, Zidovudine, interferon and Systemic chemotherapy including High dose of Methotrexate and then rain radiation and saw good clinical response. *Case Report.* A 20 y/o married female a case of lymphoblastic lymphoma admitted in ICU

with loss of consciousness and seizure. She was history of Non - Hodgkin lymphoma (lymphoblastic-type) one year ago and received chemotherapy in another center. At presentation time she had cervical lymphadenopathy, splenomegaly and bone marrow involvement. After 8 cycle of chemotherapy (CHOP)regimen she had achieved complete remission. Her family complained history of ataxia, diplopia and vertigo since 2 week PTA and 3 times seizure in the day of admission. Physical examination showed comatose state, nystagmus,bilateral extensor plantar reflexes.Laboratory findings are included hypercalcemia,normal CBC diff, BUN, Cr, Na, K, Liver function test.Brain CT scan with contrast was normal and cerebrospinal fluid(CSF) analysis revealed acellular CSF with clear appearance, 47 mg/dL glucose and 28 mg/dL protein. HTLV -I antibody(ELISA) was positive in blood and CSF. Brain CT was repeated after one week and revealed a 3x3cm mass in the left sided deep white matter near basal ganglia.Initially we started Dexamethasone, Pamidronate and Intratechal chemotherapy and antiviral therapy including Interferon 3,000,000 unit 3 times a week & Zidovudine 300 mg q12 h then we administered systemic chemotherapy included high dose methotrexate (3.5 gr MTX) with leucovorine rescuse. After several days her level of consciousness was rised slowly and she was be able to move her left sided upper and lower extremities. After ten day brain radiotherapy was done for her which leads to significant increase in level of consciousness ,and she was be able to open her eyes and obey the orders and speech but right sided hemiparesis was persisted. *Result.* In this case of lymphoblastic lymphoma who was admitted with seizure and comatose state,despite initially normal reported brain CT scan with contrast and acellular CSF we found HTLV-1 antibodies in Blood and CSF. We repeated brain CTscan after one week that showed a 3×3 Cm mass lesion in left sided deep white matter near basal ganglia. We started antiviral therapy with Interferon and Zidovudine and saw a good clinical response after administration of high dose of MTX with leucovorine rescues followed by brain radiotherapy. *Conclusion.* We recommend searching for HTLV-1 Ab in any case of T-cell lymphoblastic lymphoma and neurologic finding although in presence of acellular CSF with norma glucose and protein. We also recommend serial Brain imaging in the presence of positive neurologic findings in patient with adult T-cell leukemia lymphoma. Combination of antiviral therapy with systemic chemotherapy included high-dose MTX with leucovorine rescues and brain irradiation are recommended in patients with adul T-cell leukemia/lymphoma and CNS involvement which presents of mass lesion in brain imaging.

1624

COAGULATION DISORDERS IN ELDERLY PATIENTS WITH NON HODGKIN'S LYMPHOMA

A De Renzo,[1] R Cuccurullo,[1] E Cimino,[2] A Coppola,[3] A Cerbone,[4] A Tufano,[4] A Ruocco,[5] S Luponio,[1] G Di Minno,[4] F Pane[1]

[1]University Federico II, Naples, Italy; [2]Regional reference Centre for Coagulation Disorders,Dep. of Clinical and Experi, Naples, Italy; [3]Regional reference Centre for Coagulation Disorders,Dep. of Clinical and Experim, Naples, Italy; [4]Regional Reference Centre for coagulation disorders,dep. of Clinical and Experim, Naples, Italy; [5]DBBM University Federico II, Naples, Italy

Acquired hemophilia is a rare coagulation disorder characterized by autoantibodies against circulating coagulation factor, frequently against factor VIII. Patients often have not history of bleeding disorder and present spontaneous hemorrhage, an isolated prolonged aPTT and PT and antibodies against coagulation factors. It has an incidence of 0,2-1 cases/million/year. This condition may be associated in 50% of cases with autoimmune disease, solid tumor, lymphoproliferative disorders and pregnancy. We describe our experience with two patients with indolent non-Hodgkin's lymphoma who showed isolated prolonged aPTT and PT. *Case one.* A 72-year-old man referred to our Institution because of recurrent epistaxis and abnormalities of coagulation tests PT INR 2.5, a PTT ratio 2.73. No previous personal or family history of bleeding disorders, or recent surgery and new drug intake, were reported. Spleen enlargement, with a large focal lesion, and pancytopenia (Leukocytes 2800/μL; Haemoglobin 9 g/dL; Platelets 82,000/μL)were observed. Laboratory test showed a reduction of Factor VIII activity, Factor II activity, Factor V activity, Factor VII activity, Factor IX activity, Factor activity X and Factor activity XI (FVIII:C 16%; FII: 44%; FV:8%; FVII: 11%; FIX: 10%; FX:30%; FXI:27%) and appearance of antibodies against many coagulation factors. The bone marrow showed a lymphoid infiltrate. Fluorodeoxyglucose F-18 positron emission tomography whole-body scan revealed abnormally high uptake in the spleen and in a slightly enlargement supraclavear lymphonode. Fine needle aspiration biopsy at this site, covered by 60 μg/Kg recombinant Factor VIIa (NovoSeven) injections, enabled the diagnosis of non-Hodgkin's lymphoma ($CD5^-$, $CD22^+$, $lamba^+$). The patient made six administration of chemotherapy with cyclophosfamide, vincristine, epirubicin and prednisolone (CEOP) and achieved complete remission. We observed that the end of treatment, coagulation parameters and factor activity returned normally. *Case two.* A 62 year-old female came to our observation for lymphoadenopathy, hepatoplenomegaly, anemia and lymphocitosis. The patient didn't present any personal or family bleeding disorders and didn't take drugs. Laboratory tests showed abnormalities of coagulation: PT INR 3.26, aPTT ratio 4.92. They also showed a reduction of factor VIII activity, Factor II activity, Factor VII activity, Factor IX activity, Factor activity X and Factor activity XI (FVIII:C: 2.3%; FII: 32%; FVII: 47%; FIX: 1%; FX:43%; FXI:1%) and appearance of antibodies against many coagulation factors. Fluorodeoxyglucose F-18 positron emission tomography whole-body scan revealed increased uptake at axillary and inguinal lymphonodes and at spleen. The bone marrow showed a lymphoid infiltrate and enabled the diagnosis of non-Hodgkin's lymphoma ($CD5^-$, $CD22^+$, $lamba^+$). The patient made two administration of chemotherapy with Rituximab, fludarabine. After second administration of chemotherapy, was observed a slow normalization of PT and aPTT. In both cases there was a correction of the PT and aPTT after the first cycle chemotherapy. In these patients the onset of an acquired coagulation disorder can be used as diagnostic and prognostic marker of derangement of the immunologic network due to an underlying, apparently indolent, lymphoproliferative disease.

1625

SINUS HISTIOCYTOSIS WITH MASSIVE LYMPHADENOPATHY ASSOCIATED TO DIFFUSE LARGE B CELL LYMPHOMA

M Lasa, MC Mateos, JM Arguiñano, MV Aznar, M Echeveste, MA Ardáiz, MA Goñi, MJ Paloma, AM Redondo, M Perez, I Ezpeleta, F Garcia-Bragado

Hospital Virgen del Camino, Pamplona, Spain

Background. Sinus Histiocytosis with Massive Lymphadenopathy (SHML) is a rare benign disorder characterized by painless lymphadenopathy. Cervical lymph nodes are most frecuently involved. Tipically, the lymph nodes are expanded because of a proliferation of histiocytes that sometimes show emperipolesis of lymphocytes. Extension below diaphragm is unusual, as is association with other lymphoproliferative disorders. We report a case of SHML associated to Diffuse Large B Cell Lymphoma. *Case report.* A 72 year old woman was studied because of elevated transaminases. Physical examination revealed an enlargement of a right inguinal lymph node. There were no skin eruptions. Mild anemia, elevated Beta-2-microglobulin and LDH were found. CT-Scan revealed enlargement of lateroaortic and inguinal lymph nodes in addition to multiple nodules on lungs and spleen. A PET confirmed lungs and spleen involvement, as well as axial bones infiltration. Right inguinal node biopsy led to diagnosis of SHML. After 4 months' Prednisone therapy a new CT-Scan was performed. It revealed mediastinic and axilar lymph nodes enlargement and an increase of size and number of lung and spleen nodules. A bone marrow biopsy showed no alterations. Clinical worsening prompted a treatment change to Clorambucil and Prednisone cycles, soon abandoned due to side effects. Two months later, the patient was admitted to our Hospital because of abdominal pain, weigth loss and fatigue. A new CT-Scan revealed progression of previous tumours as well as a new pelvic mass infiltrating bladder, rectum and iliac bone. Biopsy of this mass showed SHML and Diffuse Large B Cell Lymphoma. Of note, both hystologic patterns were present in the same biopsy specimen. Repeated bone marrow biopsy, found infiltration by Lymphoma. Final diagnosis was extended SHML and stage IV-B Diffuse Large B Cell Lymphoma. The patient started treatment with Cyclophosphamide, Doxorrubicine, Vincristine, Prednisone and Rituximab (R-CHOP). She is still receiving treatment. *Comments on this case.* SHML seldom extends below diaphragm; and rarely progresses to cause symptoms. A few cases of association of SHML and Diffuse Large Cell Lymphoma have been reported to date.

1626

DIFFUSE LARGE B - CELL LYMPHOMA IN THE COURSE OF COMMON VARIABLE IMMUNODEFICIENCY SUCCESFULY TREATED WITH IMMUNOCHEMOTHERAPY: A CASE REPORT

M Todorovic,[1] S Andrejevic,[2] B Andjelic,[3] V Palibrk,[3] N Kraguljac Kurtovic,[3] B Mihaljevic[3]

, Belgrade, Serbia; [2]Clinic for Immunology and Alergology, Belgrade, Serbia; [3]Clinic for Hematology, Belgrade, Serbia

Background. Common variable immunodeficiency (CVID) is the primary hypogammaglobulinemia of unknown aetiopathogenesis. The common denominator is a dysregulation of immune responses affecting T and B cells with both central and peripheral tolerance mechanisms being disturbed. It is characterized by low levels of IgG/IgA antibodies, recurrent respiratory tract infections, granuloma formation, and the predisposition to malignancies. Lymphoma is one of the most severe complications of CVID. *Aim.* We report a patient with diffuse large B cell lymphoma (DLBCL) developed 3 years after the setting of CVID diagnosis sucesfully treated with immunochemotherapy. *A case report.* A 55-year old female patient was admitted on Institute of hematology with a high fever, bilateral cervical lymphadenopathy, splenomegaly, and fingernail thickening due to fungal infection. In the past history of this patient CVID associated with lung and lymph node granulomatosis was diagnosed and substitutive intravenous immunoglobulin (IVIg) therapy was inititate at a dose of 0.5 g/kg monthly. Laboratory test results showed mild normocytic anemia, 109 g/L, WBC 10×10^9/L; with granulocytosis, 8.1×10^9/L, lymphopenia, 1.1×10^9/L; PLT 283×10^9/L. Analysis of biohumoral parameters showed increase in sedimentation rate 36 mm/h and fibrinogen 5.1 g/l. She had severe hypogammaglobulinemia, IgG was 2.55g/L (N: 6.78-12.60), with mild decrease in IgA (0.26g/L, N: 0.82-2.62). Flow cytometry analysis of peripheral blood lymphocytes revealed a significant decrease in $CD4^+CD45RA^+$T cell count and increase in $CD4^+CD45RO^+$ T cell count. The T cell population ($CD3^+$) was 90% among T lymphocytes, with apparent excess in T suppressor cell subset ($CD3^+CD8^+$) - 30% and decrease in NK T cell subset - 1.5%. The relation between T helper and T suppressor was 0.75 which is diminished comparing to normal. Population of B - lymphocytes was minor and polyclonal, and the relation between lymphocytes expressing kappa and lambda light chain was within the reference value (1.75, N: 1.10-1.80). Virusological markers for HIV, HBV, HCV and EBV infection were negative. Immunohistochemical analysis of lymph node sections revealed a diffuse large B cell lymphoma ($CD20^+$, $CD79\alpha^+$, $CD3^-$, $CD5^-$, $bcl2^-$, MUM1-/+, Ki 67 40%). Disease was staged as IIB S^+ CS. Immunochemotherapy R-CHOP-21 was initiated along with monthly IVIg therapy. After VI cy patient achieived complete remission of lymphoma with continuing substitution of hypogammaglobulinemia. *Conclusion.* Relative risk of malignant lymphoma development in patients with CVID resembles the same risk in patients with HIV/AIDS patients. The specific phenotypic T cell changes in CVID patients correspond to those in viral infection and correlate with the B cell immaturity. That enhances importance of good viral infection prevention in CVID patients. The resulting immune dysregulation may lead to self-reactivity with developing malignancy. Combined immunochemotherapy in this condition induced lymphoma remission without any negative influence on immune deficienty.

1627

'SEVERE AUTO-IMUNE THROMBOCYTOPENIA AND THYROIDITIS AS PRESENTATION OF NON-HODGKIN B-CELL LYMPHOMA - A CASE STUDY'

A Azevedo,[1] A Reis,[2] A Gomes,[3] J Pereira,[2] A Reichert,[3] C Afonso,[3] C Silva,[3] S Matos,[3] P Santos,[3] M Pedro,[3] M Hodorogea,[3] F Lima,[3] E Junior[1]

[1]Hospital Sao Fransisco Xavier, Chlo, Lisbon, Portugal; [2]Hospital São Fransisco Xavier, Chlo, Lisbon, Portugal; [3]Hospital São Francisco Xavier, Chlo, Lisbon, Portugal

Background. B cell neoplasms are clonal tumours of immature and mature B cells, which comprise over 90% of lymphoid neoplasms worldwide. Mature B-cell neoplasias are often associated with immune processes, which are also, either immunodeficiency or autoimmune diseases, major known risk factors for the development of these neoplasias. Frequently, morphology and immunophenotype are sufficient for the diagnosis of lymphoid neoplasms. However, no one antigenic marker is specific for any neoplasm, and a combination of morphologic features and a panel of antigenic markers are necessary for correct diagnosis. *Aims.* Present a case study of a patient with auto-immune thyroiditis and severe auto-immune thrombocytopenia preceding Non-Hodgkin B-Cell Lymphoma (NHBCL). *Methods.* The patient was clinically evaluated and submitted to some diagnostic tests: full blood count, biochemical tests, viral serology, anti-platelets, anti-thyroid and anti-cardiolipin antibodies, ANCA's, ENA's, abdominal ultrasound and computorized tomography, bone marrow aspiration, immunophenotyping (flow citometry), kariotype, FISH technique, spleen histology. The patient was treated with corticotherapy, immunoglobulin and R-CVP (one cycle), followed by cyclosporin and R-CHOP (six cycles), and later on did splenectomy. *Results.* Personal antecedents: thyroid node in 2006, medicated with levothyroxin for six months and asthma. Clinical features: haemorrhagic discrasia of oral mucosa, splenomegaly, no lymphadenopathy. Laboratory findings: platelets severe and persistently decreased (1 to $5,7\times10^9$/L), unresponsive to therapy until splenectomy. No anaemia, white blood cells including lymphocytes counts normal, with heterogeneous morphology, without villous lymphocytes. Biochemical tests: elevation of IgG, slightly decreased IgM, elevated free T3 and T4 and decreased TSH after first cycle of R-CHOP, normalized post-therapy. Proteinogram normal. Viral serology: negative, except for EBV IgG. Anti-platelets antibodies: positive, that soon responded to corticotherapy. Anti-thyroid antibodies: anti-tiroglobulin antibodies negative, with TRAB positive, becoming negative with corticotherapy and immunosupression. Anti-cardiolipin antibodies: IgM slightly increased. ANCA's and ENA's: negative. Abdominal computorized tomography: hepatosplenomegaly without adenomegaly. Bone marrow (BM) aspirate: 50% infiltration of small lymphoid cells, some with less dense chromatin and irregular nucleous contour. BM immunophenotyping (IF): 9% of lymphoid cells CD5, CD10, CD103 negative, CD23, FMC7, CD79b, CD20, CD25 positive and lambda weak. Peripheral blood IF: 18% of lymphoid cells, with same phenotype. Genetics: 46, XY(20). Fish technique: negative for t(14:18) and t(11;14). After two cycles of chemotherapy BM aspirate and biopsy showed no infiltration of lymphoid cells and megacariocytes numbers and morphology of immune thrombocytopenia. Spleen histology: no infiltration. *Summary/Conclusions.* This is an interesting example of an autoimmune process (thyroiditis and thrombocytopenia) that preceded the lymphoma diagnosis, supporting some published studies. The patient presented a very good response to chemotherapy and all the immune factors were rapidly controlled with corticotherapy and immunosupression. However, despite antiplatelets antibodies being already negative, the patient maintained a severe thrombocytopenia, probably due to hypersplenism. Platelets counts normalized, only after splenectomy. Curiously, spleen histology (after therapy) did not revealed infiltration by lymphoid cells. Conjugated with the fact that there was no adenomegaly, the results of morphology, immunophenotyping, and cytogenetics, it was not possible to classify with certainty the sub-type of this splenic lymphoma (splenic marginal zone lymphoma/splenic diffuse red pulp small B-cell lymphoma).

1628

PRIMARY DUODENAL FOLLICULAR LYMPHOMA: REPORT OF TWO CASES

S Falorio, F Angrilli

Civic Hospital, Pescara, Italy

Background. Gastrointestinal (GI) tract is the most frequent site of extranodal non-Hodgkin lymphoma (ENHL), and the stomach is predominantly involved. Instead, the duodenum is rarely affected by ENHL. High-grade lymphomas are the most common histological subtype affecting the GI tract excluding the stomach, where MALT lymphoma represents nearly half of all cases. Although nodal follicular lymphoma (FL) is the most common subtype of indolent lymphoma, extranodal FL represents only the 7% of GI lymphomas. Consequently, primary FL of the duodenum is rare and few cases are reported in the literature. The gold standard treatment of this disease is unknown. *Aims.* To retrospectively evaluate the outcome of two patients (pts) affected by primary duodenal FL treated with combination of rituximab and CVP polichemotherapy (R-CVP). *Methods.* Two pts, women aged 47 and 68 years, were admitted to our hospital with a diagnosis of duodenal NHL. In both cases histological reevaluation of biopsy specimens found a lymphoid infiltrate of the duodenal mucosa composed of predominantly CD20, CD10 and Bcl2 positive small-cleaved cells, consistent with FL. Total body CT scan and bone marrow (BM) biopsy showed no abnormalities. Both pts presented Bcl2-IgH rearrangement in BM. The stage of disease was evaluated as IE A according to Ann Arbor staging system and the FLIPI score as 0. Both pts received 4 courses of R-CVP. *Results.* After treatment completion, the pts received esoph-

agogastroduodenoscopy and BM biopsy. There was no detectable lymphoma in the duodenal biopsy specimens and no detectable Bcl2 rearrangement in BM. Both pts are alive and lymphoma-free so far, after 23 and 36 months respectively. *Conclusions.* Different treatment strategies such as radiotherapy (RT), chemotherapy (CHT) and rituximab, alone or in combination have been tried in early stage FL. Rituximab combined with CHT could improve overall survival for pts with advanced FL. Rituximab with or without CHT is also effective in primary duodenal FL. We believe that rituximab combined with CHT could be a very good option to achieve clinical and molecular response. We submitted our pts to only four courses of R-CVP because of their low tumor burden. Considering that median time to retreatment is longer than 30 months in advanced FL treated with R-CVP, we are unable to evaluate long-term significance of molecular response in our pts today because of short follow up. Nevertheless, we think that this result is very promising because pts who achieve a molecular response have a longer failure free survival than those who do not.

THE FIRST EXPERIENCE IN THE TREATMENT OF DIFFUSE LARGE B-CELL LYMPHOMA WITH BONE MARROW (DLBCLWBM) INVOLVEMENT BY MODIFIED PROGRAM NHL-BFM-90 AND SEQUENTIAL HIGH-DOSE CHEMOTHERAPY WITH AUTO-SCT (MNHL-BFM-90$^+$ SHD$^+$ASCT)

N Gabeeva, A Magomedova, E Zvonkov, S Kravchenko, A Kremenetskaya, D Marin, E Gilyazitdinova, T Fomina, A Vorobyev

Hematology Scientific Centre Russian Academy of Medical Science, Moscow, Russian Federation

Background. DLBCLwBM has poor prognosis. In standard therapy (CHOP, R-CHOP) the risk of relapse is high. The 3-year OS is 38% on CHOP regimen. *Aim.* to evaluate efficacy and safety of the mNHL-BFM-90+SHD+ASCT for DLBCLwBM. *Methods.* five pts (all men, 23-47 years, middle 37) with DLBCLwBM were treated between Feb 2007 and Dec 2009. The patterns of bone marrow lymphoid infiltration were diffuse large-cell in 3 cases and nodular mixed-cell in 2 cases. Three pts had generalised lymphadenopathy, one-dorsal vertebra lesion, one- isolated tumor in caecum. In all cases bone marrow lymphoid infiltrates were evaluated by morphology, immunohistochemistry and molecular analyses (PCR). The NHL-BFM-90 program (block A and block C) was modified in the following way: doxorubicin 50mg\m^2 was added on the third day of block A, methotrexate 1g\m^2 i\v was added on the first day of block C. All pts received mNHL-BFM as first line therapy from 4 to 6 blocks continued by SHD. Following high-dose cyclophosphamide 3 pts achieved the target number of CD34$^+$ cells, 1 after high-dose etoposide. Four pts as conditioning regimen have received BEAM with ASCT. One failed stem-cell mobilization and was excluded. *Results.* All patients achieved complete remission at the beginning of SHD. One had relapse in 5 months after BEAM. He received salvage chemotherapy. All pts are alive. The mean follow-up is 23 month (range 15-30). Hematologic toxicity of grade 3 and 4 was observed, the severe infectious complications were not registered. *Conclusions.* mNHL-BFM-90$^+$ SHD$^+$ASCT is well tolerated and effective in pts with DLBCLwBM. Further study and longer follow-up are necessary.

1630

COEXISTING PLASMOCYTOSIS OF THE SKIN AND LOW GRADE B LYMPHOMA: REVIEW OF LITERATURE AND CASE REPORT

G Giglio,[1] A Antuzzi,[2] M Musacchio,[2] C Carrozza,[2] D De Filippo,[3] R Reccia,[4] A Antrilli[5]

[1]Hematology Unit A. Cardarelli Hospital - ASREM, Campobasso, Italy; [2]Hematology Unit - A. Cardarelli Hospital - ASREM, Campobasso, Italy; [3]Phatology Unit - A. Cardarelli Hospital - ASREM, Campobasso, Italy; [4]Nuclear Medicine Unit - A. Cardarelli Hospital - ASREM, Campobasso, Italy; [5]Dermatology Unit - A. Cardarelli Hospital - ASREM, Campobasso, Italy

Introduction. The plasmocytosis of the skin and systems (PCS) is rare not neoplastic reactive lymphoplasmocytic disorder that affecting mainly the far est, particularly the Japanese. Initially it was known as plasmocytosis skin, today is also called systemic for extracutaneous involvement. Clinically, its distinctive feature is polymorphous lesions (macules, papules, plaques, nodules) of various color of the skin. There may be superficial lymphadenopathy with interfollicular infiltrates of polyclonal plasma cells, anemia, hepato-splenomegaly and pulmonary, renal, retroperitoneal and breast involvement. *Case report.* A 62 years old men was observed by us for confluent bright red lesions, raised of his face appeared for several months. He had only a moderate itching. There was no superficial lymphadenopathy, anemia, weight loss or fever. CT scan and PET scan showed only one lymph node at the chest. Two biopsy specimens were taken from the cheek and the nose and histological examination revealed a normal epidermis, but dense interstitial and perivascular infiltrated of mature plasma cells (CD138$^+$) in the dermis; no clonal restriction for immunoglobulin light chains to immunohistochemical staining. Polymerase chain reaction revealed no evidence of a clonal gene rearrangement of immunoglobulin heavy chains. Serological tests for Borrelia burgdorferi and syphilis were negative. The blood tests pointed high lymphocytes cell count and erythrocyte sedimentation and a double monoclonal gammopathy IgM k with elevated urinary free kappa light chains. No Bence-Jones protein was detected. A bone marrow biopsy specimen revealed a moderately increased number of mature plasma cells, and slight lymphocytic B infiltration compatible with lymphocitic non Hodgkin's Lymphoma. Flow-cytometric analysis of the bone marrow aspirate showed pathological elements lymphoid B, CD 19$^+$, CD20$^+$, CD22$^+$, light chain restriction of type k compatible with chronic B disorder. No therapy was performed and the patient is only in "watch and wait". *Discussion.* First description of PCS in literature was in 1976 by Yashiro and are about one hundred the cases described in literature; it prefers the adult males. The histology showed a infiltrating pupils perished in the superficial and deep dermis consisting of mature plasma cells. The lymphoplasmocitic infiltration can remember a primary cutaneous B-cell lymphoma. Immunohistochemistry demonstrates the infiltrators with polyclonal light chain expression of kappa and lambda. At the bone marrow plasma cell population is usually normal. In most cases, the PCS has a benign course. The diagnosis of PCS is mainly based on exclusion and polyclonal plasma cell infiltration of the skin. The etiology is unknown and often is associated with POEMS syndrome and Castleman's disease. The IL6, elevated in the serum of this patients, has a role. Treatments consist in topical and or systemic corticosteroides, topical tacrolimus or pimecrolimus, PUVA therapy, cyclophosphamide, rituximab or local radiation. We must follow the disease for many years for possible malignant transformation. *Conclusion.* the case described is characteristic because it combines the presence of a plasmocytosis which is a skin condition that potentially evolve into malignant disease with a low-grade B lymphoma with minimal expression at the bone marrow and peripheral blood without clinical expression.

1630a

EFFICACY AND SAFETY OF ORAL BEXAROTENE IN THE TREATMENT OF PRIMARY CUTANEOUS T-CELL LYMPHOMAS

P Lugtenburg, M Kruip, F Ibrahim, H de Vijlder, E de Haas

Erasmus MC, Rotterdam, Netherlands

Background. Cutaneous T-cell lymphoma (CTCL) is a heterogeneous group of lymphoproliferative disorders, characterized by the infiltration of the epidermis by mature and activated malignant T-lymphocytes. Bexarotene, a highly selective retinoid X receptor (RXR) retinoid, is approved for the treatment of all stages of CTCL in patients refractory to at least one systemic therapy. CTCL is a rare disease and data on the use of bexarotene are limited. *Aims.* To summarize the clinical experience with oral bexarotene for patients with CTCL, with the aim of assessing efficacy and safety in the setting of a large Dutch university hospital. *Methods.* All patients commenced on bexarotene were identified from patient records at the departments of Hematology and Dermatology at Erasmus MC Rotterdam, the Netherlands. Diagnosis was obtained using skin histology, immunohistochemistry and T-cell receptor gene analysis. Patients were staged according to the WHO-EORTC classification. All patients were discussed in the Dutch National Workgroup for CTCL at time of diagnosis. Patients started with bexarotene 150 mg/m^2 daily titrating up to 300 mg/m^2 if tolerated. All patients received lipid lowering agents and thyroxin substitution before bexarotene start. *Results.* We studied 10 patients. Six had Mycosis Fungoides (MF), one a folliculotropic MF, one Sezary syndrome, one subcutaneous panniculitis-like T-cell lymphoma, and one unspecified primary cutaneous peripheral T-cell lymphoma. Five patients had early stage disease, the other five had advanced stage disease. Patient age at starting treatment ranged from 20 to 88 years with a mean age of 59 years. All patients received extensive local and/or UV therapy and/or systemic therapies (multichemotherapy, cyclosporine and prednisone) in the past before starting with bexarotene. During bexarotene therapy seven out of ten patients used additional systemic (prednisone n=1) or UV therapy (n=2), or local radiotherapy (n=1) and/or local steroids (n=6). Three patients used bexarotene monotherapy. Overall nine out of ten (9/10) patients responded during bexarotene therapy. One patient had a sustained complete response and eight patients had a

partial response. One patient had stable disease. The time needed for the first response to occur since bexarotene use varied from 0.2 months to 15 months, with a mean of 2.3 months. The duration of response varied from 2 months to more than 24 months. Out of the nine responders, three patients progressed while on therapy. These patients all had advanced stage CTCL. One patient died because of cardiopulmonary disease not related to bexarotene. Most frequently observed adverse side-effects experienced by our cohort were central hypothyroidism (n=6), hyperlipidemia (n=3) and hypertriglyceridemia (n=7). These side effects could be managed with thyroid replacement and lipid-lowering therapy. Other side effects were pruritis (n=1), hair loss (n=2), high liver enzymes (n=3) and leucopenia (n=1). *Conclusions.* Our data demonstrate that bexarotene produces durable responses in most CTCL patients, especially in those with early stage disease. Side effects of bexarotene are manageable and reversible.

1631

FREQUENCY AND IMPACT OF CHRONIC GRAFT VERSUS HOST DISEASE (CGVHD) IN OUTCOME OF 822 PATIENTS WHO UNDERWENT ALLOGENEIC BONE MARROW TRANSPLANTATION IN TEN YEARS PERIOD

R Ahmed Nacer, D Ait Ouali, M Benakli, F Mehdid, N Rahmoune, R Belhadj, M Baazizi, F Harieche, F Zerhouni, RM Hamladji

Pierre and Marie Curie Center, Algiers, Algeria

Introduction. cGVHD is a common complication occurring after allogeneic hematopoietic stem cell transplant (HSCT) and is the leading cause of non-relapse mortality and morbidity affecting long term survivors. In this presentation we studies incidence and impact of cGVHD in outcome (survival and quality of life) for 822 pts underwent allogeneic HSCT. *Material and method.* From March 1998 to December 2007 (141 months period) 822 pts, with hematologic malignancies (HM): 622 and non-malignant disorders (NMD): 200, underwent allogeneic HSCT (from HLA-identical sibling donors: 816; pheno identical: 6). For study of frequency and impact of cGVHD on survival only 616 pts are appraisable (HM: 495, NHD: 121) (excluded 206 pts: early death < day 100 or early relapse); median age 27 years (4,5 to 59); sex ratio (M/F) 1,23; two conditioning regimens with chemotherapy alone was used: Myeloablative: 426 and non myéloablative: 190; GVHD prophylaxis associated cyclosporin and methotrexate or cyclosporin and mycophenolate mofetil for non myeloablative regimen; Peripheral blood stem cell (PBSC) were used to 585 pts and bone marrow transplant (BMT) to 31 pts ; acute GVHD occurred in 122 pts with 69 grade II-IV and median follow-up 66 months (4-134). cGVHD occurred in 344 pts (55,8%) with median of follow-up 61 months (4-133). To evaluate quality of life (QoL) based on one simple question to pts: do you feel well in live after graft when handicap is absent; all handicap are considered as bad QoL. Only pts who survive above one year are enrolled: 518 pts (HM: 404, NMD: 114) with median age 22 years (4,5 to 59); sex ratio (M/F) 1,44; Myeloablative conditioning regimen : 362 and non myéloablative: 156; GVHD prophylaxis as above; PBSC were used to 500 pts and BMT to 18 pts; cGVHD occurred in 311 pts and no cGVHD in 207 pts; median of follow-up 62 months (13-133). At December 2009 maximal follow up is 141 months and minimal 24 months. *Results.* cGVHD occurred in 344 pts (55,8%): 299 HM (60,4 % of HM) and 45 NMD (37,2% of NMD); with 218 extensive (35,3%) and 126 limited (20,5%). Using a new NIH classification: 293 classic cGVHD (47,6%) and 51 Overlap (8,3%). The Overall Survival (OS) for all pts is 70% at 11 years; OS is 70,4% and 67,6% in pts with and no cGVHD group respectively with limit signification (P=0,04). A good QoL is found in 357 pts (68,9%) with significant difference (P=18-8) between 165 pts cGVHD group (53%) and 192 no cGVHD group (92,7%); A bad QoL is found in 161 pts (31,1 %) (146 pts cGVHD group (46,9%) and 15 no cGVHD group (7,2%; P=10-8). *Conclusion.* The total incidence of cGVHD in our cohort is similar to literature with less Overlap form and incidence of cGVHD is superior in HM than NMD. OS seems similar in the two groups (with or no cGVHD), but in another hand, cGVHD have an impact in QoL as shown that pts without cGVHD had better QoL.

1632

IN VITRO PLURIPOTENT PROPERTIES AND CHARACTERIZATION OF UMBILICAL CORD BLOOD MESENCHYMAL STEM CELLS

S Ayhan, Z Genç, A Okcu, G Duruksu, A Aksoy, E Karaöz

Kocaeli University, Kocaeli, Turkey

Background. In recent years, multi-potential mesenchymal stem cells (MSCs) have become an attractive therapeutic tool because of their unique characteristics, such as their ability to be easily isolated and cultured and their high expansive potential *ex vivo*. Umbilical cord blood (UCB) is well known to be a rich source of hematopoietic stem cells with practical and ethical advantages, but the presence of mesenchymal stem cells (MSCs) in UCB has been disputed and it remains to be validated. *Aims.* Because of their availability property the idea that UCB-MSCs can be an alternative source against bone marrow mesenchymal stem cell well accepted by scientists. In our study we use cord blood (n=5) derived mesenchymal stem cells to identify their proliferation, immunphenotypic, immunogenetic and differentiation properties in a comparison with bone marrow mesenchymal stem cells (BM-MSC). *Methods.* Cells were isolated by ficoll-gradient procedure. Immunophenotyping of UCB-MSCs was performed at P3 with antibodies against human antigens CD13, CD44, CD90, CD146 ve CD166, CD3, CD8, CD11b, CD14, CD15, CD19, CD33, CD34, CD45, CD117 by flow cytometry. For immunhistochemistry cells were stained with CD44, CD105, CD146, alfa-smooth muscle actin, beta tubulin, vimentin, fibronectin, nestin, type I and II collagen, c-Fos, myosinIIa, desmin, osteopontine, osteonectine, osteocalsin, CD23, CD31, CD34, CD45, CD71, VWF, PCNA and pluripotent markers such as nanog and OCT4. _mmunhistochemistry datas were confirmed with gene expressions by RT-PCR. Telomerase activity of UCB-MSC and BM-MSCs were performed and for compare proliferation capacity of both cells MTT assay was used. In addition cells at P3 induced osteogenic, adipogenic, myogenic and neurogenic differentiation with appropriate culture conditions. *Results.* UCB-MSCs displayed important embryonic stem (ES) cell characteristics including OCT-4 Rex-1, FoxD, Sox-2, Nanog, SSEA-4. UCB-MSCs also expressed mesenchymal stem cell antigens including CD13, CD44, CD90, CD146 ve CD166, but were negative for CD3, CD8, CD11b, CD14, CD15, CD19, CD33, CD34, CD45, CD117 ve HLA-DR. All of these protein levels were confirmed with gene expressions by RT-PCR. However, telomerase enzyme activity of UCB-MSCs was higher than BM-MSCs. *Conclusions.* Our results demonstrate that, because of UCB-MSCs high telomerase enzyme activity, high potential for expansion and differentiation properties can make them an important resource in regenerative medicine. We considered that , this study will shed light as an important research for future studies of UCB-MSC.

1633

DIAGNOSTIC VALUE OF CYTOKINE NETWORKS DURING POST-TRANSPLANT COMPLICATIONS

M Döring, P Lang, R Handgretinger, I Müller

University Children´s Hospital Tübingen, Tübingen, Germany

Backround and Objectives. Complications such as bacterial, fungal and viral infections, veno-occlusive disease, graft-versus-host disease, rejection and relapse are compromise survival following allogeneic and autologous stem cell transplantation (SCT). Although the analysis of a single cytokine is not predictive for any of these problems, concurrent assessment of several serological inflammatory markers may reveal patterns that can be used in clinical situations. Therefore, we measured IL-1β, sIL-2, IL-6, IL-8, IL-10, TNF-α, procalcitonin (PCT) and Ferritin in pediatric patients undergoing stem cell transplantation. *Design and methods.* Maximum values of IL-1β, sIL-2, IL-6, IL-8, IL-10, TNF-α, procalcitonin and ferritin were prospectively analyzed during clinical events post-transplant (range 15 - 245 days) in a cohort of 81 pediatric patients (median age of 7 years) with hematologic malignancies, and non-malignant diseases undergoing allogeneic (in total 74 patients) and autologous (7 patients) hematopoietic SCT. *Results.* PCT, ferritin, IL-6 and IL-1β were strongly correlated with the severity of systemic reaction during infection. An increase of IL-8 was observed in the early phase of sepsis. Upon rejection there was a clear increase of IL-6, TNF-α, PCT and ferritin. An increase of IL-6, PCT and ferritin strongly correlated with the occurrence of veno-occlusive disease, while an increase in ferritin and TNF-α accompanied acute liver GvHD. IL-10 showed a significant increase in acute intestinal GvHD. Interpretation and *Conclusions.* The diagnostic values of IL-1β, sIL-2, IL-6, IL-8, IL-10, TNF-α, PCT, and ferritin may be useful in studies which compare the severity of post-transplant complications. Key factors in this regard are the increase of IL-10 in the acute intestinal GvHD, the increase of TNF-α and ferritin in acute liver GvHD, and the rejection after hematopoietic SCT. Although some patterns could be identified, analysis of more cytokines will be needed to increase the predictive value of these patterns.

1634

TRANSPLANTATION IN CHILDREN WITH LEUKEMIA WHO LACK HLA-MATCHED RELATED DONORS: CHOICE BETWEEN SEROLOGICALLY MISMATCHED UMBILICAL CORD BLOOD OR ALLELE-MATCHED OR -MISMATCHED UNRELATED DONORS?

H Kook, HJ Baek, HJ Kim, DK Han, SJ Park, HJ Kim, TJ Hwang

Chonnam National University Hwasun Hospital, Hwasun, South-Korea

Backgroud: The choice of the best donor for hematopoietic stem cell transplantation (HSCT) is often difficult for pediatric patients lacking HLA-matched related donors (MRDs). *Aims.* The aim of this study was to compare the clinical outcomes of allele-matched (M)-unrelated donor (UD) or -mismatched (MM)-UD transplantation and those of unrelated umbilical cord blood (UCB) transplantation in children with leukemia. *Methods.* We retrospectively evaluated 34 children with leukemias transplanted from UDs at Chonnam National University Hospital between Jan., 1996 and July, 2009. And the results were compared with those from 35 MRD transplants. All UCBs were typed for HLA-A, -B, and -DR at antigen levels. UDs were matched based on allele typing of HLA-A, -B, -C and -DRB1. Allele-MM UDs were accepted for transplantation only when they were 6/6 matched at antigen levels (HLA-A, -B, and DRB1). *Results.* The numbers of transplants were as follows: Allele-M-UD, 10; MM-UD, 13; UCB, 11. In MM-UD group, one allele locus was mismatched in 7, two loci in 5, and three in 1. Most UCBs (n=9) were one antigen mismatched. UCB units were chosen primarily based on cell dose. Median day to absolute neutrophil count (ANC) ≥ 0.5×10^9/L was 15 in MRD, 16 in M-UD, 18 in MM-UD, and 21 in UCB group (P=.01). Median day to platelet ≥20×10^9/L was 19, 23, 30 and 45, respectively (P=.003). Acute graft-versus-host disease (GvHD) of grade II-IV was found in 11.4%, 30.0%, 15.4%, and 36.4%, respectively (P=.124). The incidence of chronic GvHD was 20.3%, 27.1%, 37.7%, and 28.6%, respectively (P=.403). The 5-year Kaplan-Meier overall survival (OS) rate was 77.1% for MRD, 53.8% for M-UD, 71.8% for MM-UD, and 45.5% for UCB (P=.050). MRD group showed higher OS and LFS rate than UCB group (P=.013, P=.017, respectively). However, the OS rate of M- and MM-UD together (65.7%) was not different from that of MRD group (77.1%, P=.270), or from that of UCB (45.5%, P=.153). The cumulative incidence of relapse at 5 years was 18.6%, 25.0%, 10.0%, and 0%, respectively (P=.530). The cumulative incidence of 100-day transplant-related mortality (TRM) was 2.9%, 22.2%, 7.7%, and 36.4%, respectively (P=.011). *Conclusion.* The outcome of HSCT in children using alternative donors has improved significantly in recent years, now approaching to that from MRDs. MM-UD transplants showed at least comparable survival to M-UD transplants, if serologically 6/6 matched. The benefit of low relapse rate in UCB group was offset by a high TRM in early post-transplant period, probably secondary to a slower engraftment. UD transplant, even mismatched, should be pursued in patients who lack MRD. Improvement in the selection of UCB units and supportive measures should result in a better outcome in UCB transplantation. These results justified the simultaneous search of unrelated BM donors and unrelated UCB units when a child with acute leukemia is in need of an alternative transplants. The decision should be based on the number of HLA disparities, the urgency of the transplant, and cell contents of the graft.

1635

A BENEFICIAL ANTI-VIRAL IMMUNE RESPONSE RESTRICTED BY ALLO-HLA

M Lamboo, E Anastasopoulou, H Jolink, F Falkenburg, M Heemskerk

LUMC, Leiden, Netherlands

Background. Recognition of an antigen in the context of allo-HLA molecules is not always harmful. Tumor associated self antigens (TAAs) recognized in the context of allo-HLA can be targeted for therapeutic purposes. Several research groups have investigated whether they could generate high avidity T cells against TAAs presented in allo-HLA molecules by stimulating T cells with HLA mismatched stimulator cells loaded with TAAs, thereby circumventing self tolerance. We recently showed that high avidity PRAME specific T cells which are allo-HLA restricted, could develop *in vivo* exerting high reactivity against multiple tumors with very limited recognition of normal tissues *in vitro*. We wondered whether beneficial T cell responses against viral antigens recognized in the context of allo-HLA could also develop *in vivo* after HLA mismatched SCT. *Aim of the study.* We investigated whether anti-viral immune responses restricted by allo-HLA can develop *in vivo* after HLA mismatched SCT. *Methods.* PBMCs of patients collected at different time points after HLA mismatched SCT were stimulated with EBV-LCLs loaded with CMV pp65 or IE-1 overlapping peptides for 4 hours after which intracellular IFN-γ was measured in CD4 and CD8 T cells. The EBV-LCLs were derived from patient, donor, or HLA typed individuals expressing one of the shared or non-shared HLA alleles of patient and donor. In addition, tetramer stainings were performed. *Results.* In a patient (HLA A*0220 A*2402 B*0801 B*1401) transplanted with a haploidentical donor (HLA A*0220 A*0101 B*0801 B*1401) we observed shortly after SCT at the time of CMV reactivation, CMV specific immune responses restricted by the shared HLA-B8 molecule as well as CMV responses restricted by donor non-shared HLA-A1. The immune response restricted to the shared HLA-B8 increased in time, and was present still 3 years after SCT. In contrast, the HLA-A1 restricted immune response decreased in time, and was undetectable 1 year after SCT. Interestingly, at the time of reactivation a CMV-IE1 immune response restricted by patient non-shared HLA-A24 was observed. The virus specific T cells were of donor origin. The HLA-A24 restricted response increased over time and persisted for several years after SCT. In addition, both the HLA-A24 as well as HLA-B8 restricted response correlated with viral load. T cells were clonally expanded and demonstrated IE1 peptide specific HLA-A24 restricted IFN-γ production, whereas A24 restricted EBV-LCLs without CMV-IE1 peptide were not recognized, indicating that this response was solely IE1 peptide specific. *Conclusion.* In a haplo-identical transplanted patient an immune response was found against a CMV-peptide presented in allo-HLA which substantially contributed to the immune response leading to the clearance of CMV viral reactivations next to an immune response via a shared HLA-molecule. These results demonstrate that beneficial anti-viral immune responses restricted by allo-HLA molecules can develop *in vivo* after HLA mismatched SCT.

1636

THE IL-12B 3'UTR (-1188 A/C) POLYMORPHISM IS ASSOCIATED WITH SURVIVAL OUTCOME OF HEMATOPOIETIC STEM CELL TRANSPLANTS

S Nadarajan, R Subramaniam, GG Gan

University Malaya, Kuala Lumpur, Malaysia

Introductio: Interleukin-12 (IL-12) is a pro-inflammatory cytokine which mediates a myriad number of roles , among which includes the differentiation of naïve $CD4^+$ T-cells to Th1 lymphocytes and the stimulation of Interferon-γ (IFN) production from T and natural killer (NK) cells. IL-12 is a 75 kDa heterodimer, composed of p35 and p40 subunits. Several polymorphisms have been identified at the IL-12 p40 gene (IL12B), of which the IL12B 3'UTR (-1188A/C) polymorphism has been reported to influence IL-12 and IL-10 production. We sought to identify if this polymorphism had an impact on the outcome of allogeneic hematopoietic stem cell transplantation (HSCT), in view of its potential role in mediating cell mediated and innate immunity. *Materials and Methods.* Thirty-one patients undergoing HSCT for various hematological conditions were recruited. Pre-transplant peripheral blood samples were obtained and subjected to genotyping for the cytokine IL12B 3'UTR (-1188A/C) polymorphism, among others, by PCR-SSP using the Cytokine Genotyping Kit (Invitrogen, WI, USA). HSCT survival outcomes were compared for the different genotypes by Kaplan-Meier analysis and multivariate Cox regression. *Results.* Gene frequencies of the biallelic IL12B 3'UTR (-1188A/C) polymorphism in the study population was not significantly different from the expected Hardy Weinberg proportions with 8/31 (26%) subjects AA homozygous, 15/31 (48%) AC heterozygous and 8/31(26%) CC homozygous. IL12B 3'UTR polymorphism was significantly associated (P=.030) with overall survival (OS) following HSCT. Subjects who were AA homozygous had a median survival of 282 days (95% CI: 0 - 610 days) in comparison to 1,155 days (95% CI: 591 - 1,711 days) for AC and CC subjects combined. Analysis for other factors which may have contributed to poor post-HSCT OS revealed that disease status with patients transplanted while in blast crisis of chronic myeloid leukemia or after first or second relapse of acute myeloid leukemia had significantly (P=.032) reduced OS. IL12B 3'UTR polymorphism however remained significant for OS after adjustment for disease status using a multivariate Cox proportional hazards model. *Conclusions.* Our study demonstrates that the IL12B 3'UTR (-1188A/C) polymorphism may play a role in the survival outcome of patients undergoing HSCT. Individuals AA homozygous at this position have been shown to have reduced IL-12 secretion from stimulated peripheral blood mononuclear cells. This may have relevance in our cohort of patients who were AA homozygous, as the cause of death in all of them were attributed to either infection or disease relapse but not graft *vs.* host disease. Attenuation of IL-12 response in AA homozygote patients may contribute to suboptimal graft *vs.*

leukemic response leading to disease relapse, as well as lowered cell mediated immunity leading to risk of viral infections.

1637

WHERE HAVE ALL THE ABSTRACTS GONE? PUBLICATION BIAS IN BLOOD AND MARROW TRANSPLANTATION

C Paulson, M Saeed, D Szwajcer, M Seftel

University of Manitoba, Winnipeg, Canada

Background. Only a small proportion of abstracts lead to full publication, leading to publication bias. Clinical and "positive"studies are more likely to be published than other abstracts. This issue has not been examined in the hematology or blood and marrow transplantation (BMT) literature. *Aims.* We intend to review the rate of publication of abstracts presented at the Canadian Blood and Marrow Transplant Group (CBMTG) Annual Meetings, and determine factors associated with publication. We hypothesized that as BMT centres in Canada are based at large, academic centres, the proportion of abstracts leading to publication will be high. *Methods.* All abstracts presented at the CBMTG Annual Meeting in 2002, 2004, and 2006 were reviewed and categorized by: study type; funding source; single or multi-centre; form of presentation; "positive"or "negative", using the authors' definition. To determine publication, each reference was searched on multiple databases (MEDLINE, EMBASE, Web of Science, and CINAHL) by first, second and final authors. Two authors undertook abstract categorization and searching, and disagreements were resolved by consensus. *Results.* 141 abstracts were reviewed, of which 43 were published (30.4%); this proportion is comparable to other medical specialties. 21 studies were published from 2002 (36.8%), as compared to 12 from 2004 (24.0%) and 10 from 2006 (29.4%) (P=0.35). Clinical studies (retrospective or prospective) were more likely to be published than non-clinical studies (P=0.014). Number of centres involved and positive results were not associated with publication likelihood. Funded studies were more likely to be published (P=0.009). Finally, oral presentations were more likely than posters to be published (P=0.004). *Conclusion.* Publication bias exists at the CBMTG meeting at a rate similar to that of other medical disciplines. Studies with clinical outcomes, ones that were externally funded, and those presented orally were more likely to be published. Efforts to encourage full publication of scientific abstracts should be sought.

Table 1. Study results.

Predictors of Abstract Publication	Rate of Publication	Significance
Form of Presentation		
Oral	59.1%	p = 0.004
Poster	25.2%	
Funded Study		
Funded Study	70.0%	p = 0.009
Non-Funded Study	27.5%	
Study Type

VALIDATION OF THE DNA DYE 7AAD FOR THE DETECTION OF LOSS OF VIABILITY IN STORED HAEMATOPOIETIC PROGENITOR CELLS: A COMPARISON WITH OTHER VIABILITY PROBES AND CORROBORATED BY LONG TERM CULTURE

S Phillips, K Wilson

University Hospital of Wales, Cardiff, UK

Haematopoietic Progenitor Cells (HPC) are stored at 4°C up to 72 hours or cryopreserved and their subsequent viability is central to the success of HPC transplantation. Because levels of apoptosis and necrosis in thawed HPC harvests have been reported to be high (>50%) and testing of cryopreserved products is not possible before infusion, small pilot samples were cryopreserved or stored at 4°C. The initial aim of this study was to validate the use of pilot samples by comparison with samples taken from the harvest at infusion using flow cytometry of the fluorescent probe 7 amino-actinomycin D (7AAD) which reportedly discriminates three populations: negative (viable), dim (apoptotic) and bright (necrotic), in the CD34+ve HPCs. The second aim was to show that 7AAD was as sensitive as other viability probes; - Annexin V, - 3, 3'- dihexylocarbocyanine iodide (DiOC6(3)), - AldefluorTM, - Syto16, and that there was a direct relationship between staining with 7AAD and the ability of HPC to produce cobblestone areas and granulocytes into the supernatant when co-cultured on normal bone marrow derived stromal cells for a minimum of 5 weeks (functional assay). To perform the functional assay, normal bone marrow cells were cultured for between 6 and 14 weeks after which they were passaged and re-seeded into αMEM. These cultures were taken through 4 further passages before the medium was replaced with a long term culture style medium. The stromal layers were then innocculated with either fresh or cryopreserved HPC. There was no increase in 7AAD uptake in pilot samples, P=0.22 making them an effective surrogate. Storage of HPC for 72 hours at 4°C, which is the generally accepted expiry, only showed a significant change in one of the probes measured, AldefluorTM, and it has been previously reported (by other authors) that a reduction in the proportion of AldefluorTM bright HPC can be correlated with prolonged platelet engraftment times. The functional assay showed that there was no significant difference between the production of cells into the supernatant after 5 weeks culture in unstored (fresh) and cryopreserved HPC P=0.34. The cell production from cultures of HPC stored between 24 and 72 hours at 4°C was increased, possibly as a result of loss of monocytes which may be inhibitory in this model system. Co-cultured cryopreserved samples that showed high 7AAD staining either did not survive for 5 weeks or showed minimal cobblestone and cell production. There was a decrease in the proportion of Aldefluor bright HPC in cryopreserved pilot samples by comparison with unstored HPC, P=0.08. In conclusion, AldefluorTM may be a more sensitive probe than 7AAD for loss of viability in products stored at 4°C and cryopreserved however this was not corroborated by long term culture studies. The loss of AldefluorTM bright cells may be measuring the loss of progenitors that do not contribute to cell production in this long term culture model. Assay of 7AAD uptake by HPC is a simple and cost effective method of measuring HPC viability that correlates well with the results of long term co-culture.

LONG -TERM OUTCOME AFTER BONE MARROW VERSUS PERIPHERAL BLOOD STEM CELL TRANSPLANTATION: A RETROSPECTIVE SINGLE- CENTRE ANALYSIS

D Stamatovic, L Tukic, B Balint, M Elez, O Tarabar, Z Tatomirovic, S Marjanovic

Military Medical Academy, Belgrade, Serbia

Introduction. Peripheral blood (PB) is used more frequently as a source of stem cells (SC) for allogeneic transplantation. Despite many years of experience, the effect of SC source on the clinical outcome in allogeneic transplantation, as treatment modality of hematological malignancies is not yet well established. *Aim.* We have compared results of allogeneic peripheral blood SC transplantation (PBSCT) with bone marrow transplantation (BMT) in the treatment of hematological malignancies with respect to engraftment, transfusional needs, frequency and severity of immediate (mucositis, acute Graft *vs.* Host Disease - aGvHD) and delayed (chronic GvHD - cGvHD) complications of the procedure, transplant related mortality (TRM), relapses and overall survival (OS). *Methods.* We have analyzed 158 patients (pts.), median age was 29 (range 9-57), 64 females, 94 males with different hematological diseases (AML - 39, ALL - 47, CML - 32, MDS - 10, HL - 2, MM- 3, Granulocytic sarcoma -3, SAA-22) in whom we performed allogeneic stem cell transplantation (SCT) in our center from 1989. until 2009. Pts. were divided into two groups according to the SC source: the first group with BMT-74 pts. and second group with PBSCT- 84 pts. Each patient had HLA identical sibling donor. SC from bone marrow (BM) were collected by standard procedure and from the PB by one procedure of "large volume apheresis" after the application of rHuG-CSF 5-12 μg/kgbm during 5 days. All pts. have received unmanipulated suspension of SC. Conditioning regimens were applied according to primary disease, GvHD prophylaxis were consisted of combination of Cyclosporine A and Methotrexate. *Results.* Engraftment, according to number of polymorphonuclear (PMN) and platelets (Plt) were significantly faster for 6 days (P<0.001) in the group of pts. treated with PBSCT comparing to BMT group. Needs for the transfusional support (red blood cells- RBC and Plt) were significantly higher in the BMT group (P<0.01). Those pts. had more frequently oropharingeal mucosi-

tis grade 3/4 (33.3% *vs.* 10.0%, P<0.05). There were no significant differences in the frequency of aGvHD and cGvHD between these two groups. Pts. who were undervented PBSCT had more frequently extensive cGvHD in comparison to those pts. treated with BMT (29.1% *vs.* 11.29%, P<0.05). Source of SC had no significant influence on TRM (21,62% *vs.* 23,8%, P=0,64, ns), incidence of relapses (21.6% *vs.* 29.7%, P=0.32, ns). Pts. in whom SC source was BM had significantly better OS then other group (log-rank 2.33, P<0.05). *Conclusion.* PB as a source of allogeneic hematopoietic SC gives better mononuclear cells (MNC) yield and faster engraftment with consequently decrease of immediate transplantation related complications, with positive influence on economic aspect of treatment. However, allogeneic PBSCT was associated with more frequent extensive cGvHD, while we haven't noticed influence of SC source to TRM and relapses. In our series, better OS had patients with BMT but future investigations are needed.

HUMAN T-CELL LYMPHOTROPIC VIRUS TYPE 1 (HTLV-1) PROVIRAL DNA LOADS IN THE LONG SURVIVORS WITH ADULT T-CELL LEUKEMIA/LYMPHOMA (ATLL) AFTER ALLOGENIC HEMATOPOIETIC CELL TRANSPLANTATION

S Takeuchi, A Utsunomiya

Imamura Bun-in Hospital, Kagoshima, Japan

Background. Adult T-cell leukemia/lymphoma (ATLL) is a highly aggressive hematological malignancy caused by a human T-cell lymphotropic virus type 1 (HTLV-1), and has a poor prognosis. Recently, some patients achieve long survival after allogenic hematopoietic cell transplantation (allo-HCT). However, HTLV-1 proviral DNA loads in the long survivors with ATLL after allo-HCT are not clarified. *Aims.* By analyzing HTLV-1 proviral DNA loads in the long survivors with ATLL after allo- HCT, we clarify the association between risk of ATLL relapse and HTLV-1 proviral DNA loads. *Methods.* We analyzed HTLV-1 proviral DNA loads in peripheral blood in 10 ATLL patients survived over 24 months after allo-HCT in our hospital. Of these, 9 had acute type, 1 had chronic type. Disease status at HCT were 8 remission, 2 non-remission. Eight cases had conventional stem cell transplantation (CST) and 2 cases had reduced-intensity stem cell transplantation (RIST). Six patients received stem cells from bone marrow, 4 patients received from peripheral blood. Six patients underwent HCT from HLA-identical siblings, 1 donor having anti-HTLV-1 antibodies, and 4 from unrelated HLA-identical donors. We compared proviral loads in the 9 patients with remission for long time (non-therapy over 6 years) after chemotherapy and in the172 asymptomatic HTLV-1 carriers. The HTLV-1 proviral loads in peripheral blood mononuclear cells (PBMCs) were measured by quantitative real-time PCR (RT-PCR) with primers specific for HTLV-1 pX. *Results.* The mean value of HTLV-1 proviral DNA loads were 0.09 copies/100 PBMCs in the allo-HCT patients and 6.28, 3.72 copies/100 PBMCs in the patients with remission after chemotherapy in the asymptomatic HTLV-1 carriers respectively. Proviral loads in the allo-HCT patients were significantly lower than in the patients with remission after chemotherapy (P=0.03), lower than in the asymptomatic HTLV-1 carriers (P=0.05). Proviral loads in the long suvivors with ATLL after allo- HCT rapidly decreased after HCT and extremely low loads maintained. *Summary/Conclusions.* Our results suggest that risk of ATLL relapse is lower in the long survivors after allo-HCT than in the patients with remission after chemotherapy and in the asymptomatic HTLV-1 carriers. Further studies are needed to clarify the association-between relapse and HTLV-1 proviral DNA loads.

A THEORETICAL MODEL FOR CELL DYNAMICS AFTER ALLOGENEIC STEM CELL TRANSPLANTATION IN ACUTE LEUKEMIA

M Arghirescu,[1] M Cucuianu,[2] A Serban,[1] P Precup[3]

[1]*Spitalul de Copii Louis Turcanu, Timisoara, Romania;* [2]*Institutul Oncologic Ion Chiricuta, Cluj-Napoca, Romania;* [3]*Universitatea Babes-Bolyai, Cluj-Napoca, Romania*

Background. The beneficial effect of allogeneic stem cell transplantation (allo-SCT) is two-pronged: on one hand the conditioning regimen is intended to destroy the recipient's hematopoiesis, which at the time of the transplant contains both normal and leukemic stem cells and on the other hand the donor-derived T-lymphocytes exert a long-lasting immunologic graft-versus-leukemia effect (GVL), aimed at destroying those recipient cells that have withstood the effect of the conditioning regimen. It has also been demonstrated that by reducing the conditioning regimen dose and enhancing the GVL effect by transplanting high quantities of donor derived stem cells and T-cytotoxic lymphocytes, the outcome of the transplants may be improved. *Aims.* Understanding the cell dynamics during and after transplantation is essential for devising new strategies, aimed at improving both the efficacy and safety of allo-SCT. *Methods.* We used mathematical modeling with the help of dynamic systems and we performed numerical simulations with Maple 11.

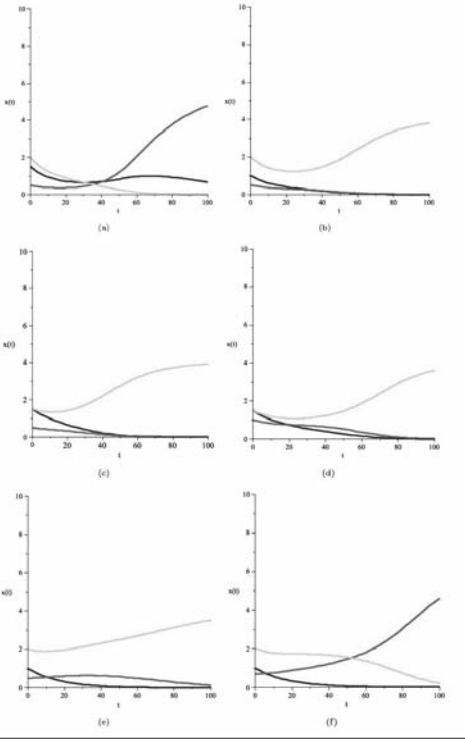

Figure.

Results. We obtained a basic mathematical model expressed by a system of ordinary differential equations tracking the time evolution of three cell lines after allo-SCT: normal host cells, leukemic host cells and donor cells. The evolution of these cell populations is one of competitive type and depends upon kinetic parameters: intrinsic growth, death and microenvironment sensitivity rates of each of the populations and parameters measuring the intensity of the cell-cell interactions between these populations. By numerical simulations we show that the evolution can ultimately lead either to the normal hematopoietic state with the donor cells eliminating the host cells, or to the leukemic state characterized by the proliferation of the leukemic line and the suppression of the other cell lines. One state or the other is reached depending on cell-cell interactions (anti-host, anti-leukemia and anti-graft effects) and initial cell concentrations at transplantation. The figure presents in (a)+(b) numerical simulations for identical anti-host, anti-leukemia and anti-graft effects and two sets of initial (at time t = 0) cell concentrations. In case

(a), in time, normal cell population (blue line) and donor cell population (green line) approach 0 while the cancer cell population (red line) becomes dominant; in case (b) host normal and cancer cell populations tend to 0 while donor cells restore the normal hematopoietic state. In (c)+(d) we assume that anti-host and anti-leukemia effects are intense while anti-graft effect is weak. Then the transplant is successful with high concentrations of host cells and relatively low concentration of donor cells. Next in (e)+(f) we assume strong anti-host effect and weak anti-leukemia and anti-graft effects. This makes the transplant result very sensitive to the initial leukemic cell concentration. *Conclusions.* Although simple, our model takes into account essential biological properties and processes such as cell growth and death, cell-environment and cell-cell interactions. It allows us to perform numerical simulations to investigate the impact of the intensiveness of cell-cell interactions and of initial cell concentrations on transplant success. The model can also be used to control the post-transplant patient evolution and provide better guidance towards the recovery of normal hematological status.

INFLUENCE OF NEONATAL SEX, WEIGHT AND STROMAL CELL-DERIVED FACTOR 1 POLYMORPHISM ON CD34+ CELL CONCENTRATION IN UMBILICAL CORD BLOOD

F Bijou, Z Ivanovic, D Fizet, B Dazey, JM Boiron, X Lafarge

Etablissement Français du Sang, Bordeaux, France

Background. Hematopoietic stem cells (HSC) transplantation over the last decade has been marked by frequent use of umbilical cord blood (UCB) as an alternative source of donor's HSC. Therefore, a main limitation to increase the use of UCB in adults' transplantation is related to UCB's low total nucleated cell (TNC) and $CD34^+$ cell dose/kg recipient body weight. *Aims.* For this reason many attempts are evaluated for selecting units best suited for transplantation in the aim of improving its efficiency in adults and reduce the cost of processing. In this study the impact of sex, weight of neonates and stromal derived factor 1α (SDF1 α) polymorphism on the yield of UCB units has been evaluated. *Materials and methods.* Cord blood was collected in Macopharma bags containing 21 ml of citrate phosphate dextrose anticoagulant, by trained midwives before the delivery of the placenta. CD34+ cell concentration in placental blood was routinely determined by flow cytometry only in units exceeding 100 g for possible banking. The number of TNC was determined by Cell-Dyn 3000. Seven hundred and fifty cord blood samples were analysed with respect to the sex of neonates and the collected volume. One hundred and eighty neonates were investigated for SDF1 polymorphism (homozygoties A/A, G/G, or heterozygoties A/G), determined by a particular tetra PCR after obtaining parental consent. *Results.* Ninety percent of UCB samples range between 14-75 $CD34^+$ cells/mm^3 (median=32) and in contrast with the TNC number, $CD34^+$ cells concentration did not respect the Gauss distribution. Our results in 750 UCB units (male N= 365 and female N= 385) showed that male neonates UCB were richer in CD34+ (P<0,001) though the female ones were richer in total nucleated cells (TNC) (P=0,01); a slight correlation between $CD34^+$ cells concentration and UCB sample weight (P<0,01) could be attributed to a higher weight in male neonates. Furthermore, using a particular tetra PCR performed in 180 neonates and considering SDF1 α polymorphism, no difference between A/A, G/G, A/G allelic combination was found. *Conclusion.* These data emphasize the lack of predictive factors influencing the $CD34^+$ and TNC concentration in UCB units before processing. Indeed, our results suggest that sex and weight of neonates influence $CD34^+$ cell content as it has been hypothesized by previous studies. Moreover, genetically determined polymorphism in SDF1α axis did not seem to be relevant and useful for the a priori selection of UCB units exhibiting a better hematopoietic potential.

ROLE OF ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION FOR PATIENTS WITH RELAPSED/REFRACTORY ACUTE MYELOID LEUKEMIA

DY Kim, JH Lee, JH Lee, SN Lim, SD Kim, Y Choi, KH Lee, JY Kim, YS Lee, YA Kang, M Seol, M Jeon, YJ Lee, KH Lee

Asan Medical Center, University of Ulsan College of Medicine, Seoul, South-Korea

Background. Patients with AML can rarely get long-term survival with chemotherapy alone when they are in primary-refractory status or fail to achieve remission with reinduction (RI) after relapse. *Aims.* It remains unknown whether allogeneic hematopoietic cell transplantation (alloHCT) can induce a durable remission for patients with detectable disease at the time of alloHCT. *Methods.* Patients who received alloHCT in their relapsed status after the 1st remission (CR1) or in refractory status between 1996 and 2009 at the Asan Medical Center were analyzed. Those who relapsed were categorized into 3 groups; relapsed and obtained remission with RI (REL-S), relapsed and did not receive RI (REL-U), relapsed and did not obtained remission with RI(REL-R). Those who were primarily refractory were categorized as a separate group (REF). *Results.* Median age of fifty patients (male: female = 30: 20) was 35.5 (range, 17-63) years. Number of patients in each group was 25(REL-S), 12(REL-U), 4(REL-R) and 9(REF). Among 41 patients except those in 'REF', median time between CR1 and relapse ranged from 5.5 for 'REL-U' to 15.3 months for 'REL-S'. Type of conditioning and immunosuppressant were not different significantly among 4 groups. Engraftment was achieved in 96% of patients and BM examination was performed on a median day 35 (range, 15-197) from the cell infusion. Outcomes in each group were listed at Table 1. When patients in 'REL-S' were analyzed in combination with those in 'REL-R', the overall survival (OS) of 29 patients was similar to that in 'REL-U' (21.8 *vs.* 20.7 months, P=0.562). Among those in 'REL-U', age (<40 *vs.* ≥40 years) and BM blast percentage (<12.5 *vs.* ≥12.5%) were associated with OS in univariate analysis. *Conclusion.* Although most of patients in 'REL-U' failed to achieve a durable remission, OS could be improved and selected patients could obtain a long-term survival. The role of alloHCT needs to be investigated further for those in 'REL-R'.

Table 1.

	Total (n=50)	REL-S (n=25)	REL-U (n=12)	REL-R(n=4)	REF(n=9)
Complete remission	40(80%)	23(92%)	10(83%)	0	7(78%)
Duration of response (months)	-	15.4(2.5-164.0)	2.6(0.7-101.9)	-	6.3(1.1-21.6)
Event rate among CR	25(63%)	13(57%)	9(90%)	-	3(43%)
Death without relapse	3(8%)	3(13%)	0		0
Relapse	20(50%)	9(39%)	8(80%)		3(43%)
Performance of DLI	2(5%)	1(4%)	1(10%)		0
Status of disease at last f/u					
No evidence of disease	28(56%)	19(76%)	3(25%)	1(25%)	5(56%)
Persistent disease	20(40%)	5(20%)	9(75%)	3(75%)	3(33%)
Event-free survival (months)	8.9(1.5-77.7)	17.4(4.6-77.7)	5.2(1.5-9.1)	6.0(3.7-8.2)	4.7(1.8-26.4)
Overall survival (months)	17.4(1.8-165)	48.0(4.6-165)	20.7(2.9-103)	6.6(6.0-11.1)	17.4(1.8-26.4)

1645

TACROLIMUS/SIROLIMUS AS A GVHD PROPHYLAXIS AFTER HIGH RISK ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION: COMPARISON WITH CONVENTIONAL REGIMENS

SK Park,[1] SH Kim,[1] HJ Kim,[1] CK Kim,[1] JH Won,[1] DS Hong,[1] HS Park,[1] S Lee,[2] JY Kwak,[3] JA Kim,[4] JH Moon,[5] SK Sohn[5]

[1]Soon Chunhyang University Hospital, Bucheon, South-Korea; [2]Catholic University Hospital of Korea, Seoul, South-Korea; [3]Chonbuk National University Hospital, Jeonju, South-Korea; [4]St. Vincent Hospital, Suwon, South-Korea; [5]Kyungpook National University Hospital, Daegu, South-Korea

Background. Graft-versus-host disease (GVHD) remains a major cause of morbidity and mortality after allogeneic hematopoietic stem cell transplantation (HSCT). Transplantation from donors other than HLA-matched siblings is limited by a substantial risk of severe GVHD using conventional cyclosporine (CsA) or tacrolimus based prophylaxis. The combination of sirolimus, an inhibitor of the mammalian target of rapamycin (mTOR) and tacrolimus has resulted in a low incidence of acute GVHD and reduced transplant-related toxicity in several studies. However, in a recent study, administration of sirolimus was discontinued earlier than planned due to its toxicity. Other studies showed sirolimus was associated with an increase risk of some serious complication, such as thrombotic microangiopathy and veno-occlusive disease. *Aims.* We sought to confirm the efficacy and safety of sirolimus in combination with tacrolimus for GVHD prophylaxis compared to conventional regimens (CsA/MTX or tacrolimus/MTX) in mismatched related or unrelated donor transplantation. *Methods.* 48 patients received filgrastim-mobilized peripheral blood stem cells after conditioning regimen consisting of busulfan and fludarabine±antithymoglobulin. And patients were treated with 3 different regimens for GVHD prophylaxis: CsA/MTX (n=17), Tacrolimus/MTX (Tac/MTX; n=18), and Tacrolimus/Sirolimus (Tac/Sir; n=13). *Results.* All patients engrafted, with a median time to neutrophil engraftment of 12 days. The incidence of grade II-IV acute GVHD in Tac/Sir group was lower than other groups (15.4% for Tac/Sir group *vs.* 42% for CsA/MTX group, and 50% for Tac/MTX group; P=0.44). Significant factor associated with increase the risk of grade II-IV acute GVHD were conditioning regimen includ-

ing anti-thymocyte globulin and unrelated donor compared to mismatched sibling donor. The day-100 non-relapse mortality (NRM) was similar in the each group (7.7% for Tac/Sir group, 5.5% for Tac/MTX group, and 11.8% for CsA/MTX group). Veno-occlusive disease of liver was developed in one case with CsA/MTX, and two cases with Tac/MTX. However, there was no patient who experienced thrombotic microangiopathy. Although the incidence of CMV or EBV reactivation in Tac/Sir group was higher than other group (61.5% *vs.* 41.8% for CsA/MTX group, and 38.9% for Tac/MTX group), there was no case with opportunistic viral disease which led to death. Most of cases with viral reactivation developed within the day-100 after HSCT. To evaluate the influence of GVHD prophylaxis regimens on immune reconstitution, $CD4^+$ cells seemed to be lower on days 100 after HSCT in Tac/Sir group without statistical significance. *Conclusions.* The combination of tacrolimus and sirolimus is well tolerated and may be helpful in deceasing the risk of acute GVHD and NRM in case of high risk allogeneic HSCT. However, this combination must be used with caution because of its toxicity and we need a differentiated strategy according to the risk of acute GVHD.

1646

DASATINIB AS SALVAGE THERAPY FOR IMATINIB-REFRACTORY SCLEROTIC CHRONIC GRAFT-VERSUS-HOST DISEASE

I Sánchez-Ortega,[1] O Servitje,[2] R Penín,[3] T Peralta,[1] B Patiño,[1] R Duarte[1]

[1]Institut Català d'Oncologia, Hospital Duran i Reynals, Barcelona, Spain; [2]Department of Dermatology, Hospital Universitari de Bellvitge, Barcelona, Spain; [3]Department of Pathology, Hospital Universitari de Bellvitge, Barcelona, Spain

Background. Sclerotic chronic graft-versus-host disease (ScGvHD) is an immune mediated disease resembling systemic sclerosis with limited and disappointing treatment options. Upregulation of platelet derived growth factor-receptor (PDGF-R) intracellular signalling pathway has been proposed as a key mechanism which leads to the pathologic lesions observed in these fibrotic diseases. Imatinib mesylate (IM) inhibits PDGF-R kinase activity, and has been proposed as a novel therapeutic alternative for ScGVHD. Several case reports and two small series have shown that up to 50-79% of ScGVHD patients can improve following IM treatment. Conversely, one third to half of these patients failed to respond or was intolerant to IM. Dasatinib is a second-generation PDGF-R kinase inhibitor with a greater inhibitory potency and proven clinical efficacy in the treatment of CML patients refractory or intolerant to IM. *Aims.* We hypothesized that dasatinib may be an effective therapeutic alternative for patients with ScGVHD who are intolerant or refractory to IM. *Patients and methods.* We describe here a small series of three patients with extensive ScGvHD who failed IM treatment and went on to receive salvage therapy with dasatinib. Patient #1: female, 58 years, AML, related reduced-intensity conditioning alloSCT. Patient #2: male, 28 years, AML, related myeloablative alloSCT. Patient #3: female, 27 years, AML, matched unrelated myeloablative alloSCT. Histological features of ScGVHD were documented in all three cases (e.g. pandermal collagenosis, panniculitis, loss of rete ridges, dermal apendages and hair follicles). Prior to dasatinib, all patients had failed treatment with systemic corticosteroids, cyclosporine A and mofetil mycophenolate, in addition to IM (#1 and #2 IM-intolerant after eight and three months, respectively, #3 IM-refractory with progressive ScGVHD despite five months on IM). *Results.* Dasatinib was prescribed on compassionate use basis at a starting dose of 50mg daily, was well tolerated, and the dose escalated up to 100mg daily in all cases within 8 weeks from the start. Patients #1 and #2 have achieved partial responses and objectivable clinical recovery (improvement in Karnofsky Performance Status, skin score and thickness, range of motion, reduction in the body surface area involved by non-moveable sclerosis and resolution of skin ulcers) at three months, which continue at seven and five months most recent follow-up, respectively. Patient #1, who also suffered severe lung involvement, showed measurable improvement in pulmonary function tests and at 2-minute walk distance test. Furthermore, dasatinib treatment induced stable disease at three months in patient #3, who had progressed while on treatment with IM (non-moveable sclerosis involving >30% of body surface area, joint contracture predominantly in left lower extremity and Karnofsky Performance Status score 2). During dasatinib treatment, none of the patients presented worsening of any sclerotic area. In addition, the dose of corticosteroids could be reduced >75% to <0.1 mg/kg of oral prednisone in all cases. *Conclusions.* Our small series suggests that Dasatinib, a potent second-generation PDGF-R kinase inhibitor, may be an effective and well tolerated therapeutic alternative for patients with ScGVHD who are intolerant or refractory to IM. The evaluation of its role in this clinical setting needs further investigation.

1647

NOD2/CARD15 VARIANTS ARE NOT A RISK FACTOR FOR CLINICAL OUTCOME AFTER NON-MYELOABLATIVE ALLOGENEIC STEM CELL TRANSPLANTATION

H van der Straaten,[1] M Paquay,[1] M Tilanus,[2] N van Geloven,[3] L Verdonck,[4] C Huisman[5]

[1]UMCU, Utrecht, Netherlands; [2]UMCU, Utrecht, currently Academic Hospital Maastricht, Maastricht, Netherlands; [3]Academic Medical Center, Amsterdam, Netherlands; [4]UMCU, Utrecht, currently Isala Clinics, Zwolle, Netherlands; [5]UMCU, Utrecht, currently Academic Medical Center, Amsterdam, Netherlands

Background. Single nucleotide polymorphisms (SNPs) in the innate immunity receptor NOD2/CARD15 have been demonstrated to modulate the outcome of allogeneic hematopoietic stem cell transplantation (SCT). The effect of NOD2/CARD15 polymorphism seems to be associated with type of donor (sibling or matched unrelated donor) as well as type of conditioning regimen. *Methods.* We reviewed NOD2/CARD15 SNPs in all donor/recipient pairs of 192 consecutive patients who received non-myeloablative allogeneic SCT at our institution between 2002 and 2006. All patients were treated with fludarabine 30 mg/m^2/day for 3 days followed by 200 cGy total body irradiation (TBI) (n=154) or TBI alone (n=38) and received grafts from HLA-matched related (n=132) or unrelated (n=61) donors. *Results.* NOD2/CARD15 polymorphisms were observed in 36 of 192 (19%) patients and in 35 of 192 (18%) donors. The incidences of acute and chronic graft-versus-host disease (GVHD) were 39% and 49% respectively in patients with NOD2/CARD15 variants *vs.* 51% and 61% in patients with wild type. The relapse rate at three years was 38% in patients with variants and 36% in patients with wild type. The incidence of transplant-related mortality was 22% for patients with SNPs and 21% for patients with wild type. Overall survival at three years was 56% in patients with variants and 64% in patients with wild type NOD2/CARD15. There was no significant impact on clinical outcome (P>0.05, Kaplan Meier and Fine & Gray's test). Conclusion. These data indicate that mutations in the NOD2/CARD15 gene are not a risk factor for clinical outcome in non-myeloablative allogeneic SCT. Therefore, screening for NOD2/CARD15 polymorphisms in patients or donors does not have additional value in patients undergoing non-myeloablative SCT.

1648

SUCCESSFUL MOBILIZATION OF PERIPHERAL BLOOD PROGENITOR CELLS WITH PEGFILGRASTIM

K Bouabdallah,[1] F Bijou,[2] MS Dilhuydy,[1] R Bouzgarrou,[2] A Banos,[3] N Milpied[1]

[1]Service des Maladies du Sang, Pessac, France; [2]Etablissement Français du Sang Aquitaine Limousin, Bordeaux, France; [3]Service d'hématologie, CH Côte Basque, Bayonne, France

Background. Pegfilgrastim is a pegylated growth factor with an extented serum hal-life. Many studies have shown its efficacy in chemotherapy induced neutropenia. Although few, some studies suggest that a single dose of Pegfilgrastim can mobilize patients with lymphoma. *Aims.* To evaluate the efficacy and safety of Pegfilgrastim 6mg for mobilizing peripheral blood progenitor cells. To evaluate the engrafment in pts undergoing autologous stem cell transplant (ASCT). *Methods.* Between june 2006 and june 2009, 52 consecutive pts (M = 31, F = 21)with Non Hodgkin's Lymphoma (NHL) (n=42) or Hodgkin's disease (HD) (n=10) in first line or salvage treatment and planned to receive ACST received a single Pegfilgrastim 6 mg injection 24 to 48 hours after the end of chemotherapy. CD34 circulating cells were monitored from day 6 of Pegfilgrastim injection and apheresis were started as soon as the targeted CD34 cells of 10/mm^3 was reached. All atients collected and with chemosensitive disease were then planned to receive high dose chemotherapy (HDT) with BEAM or Z-BEAM (1 pt) and stem cell support followed by standard growth factors from day 5 until ANC count > 1.000/mm^3. The primary end-point of the study was to evaluate the ability to achieve a number of harvested CD34 cells/Kg ≥2×10^6. *Results.* Fifty pts (96%) have been succesfully collected. The median number of CD34 cells collected was 4×10^6/Kg (0.6-30.1) and the median number of apheresis was 2 (1-4). The median number of circulating CD34 cells

at time of first apheresis was 34/mm^3 (10-416). It is worthy of note that 86% of pts (45/52) required only 1 or 2 apheresis. Thirty nine pts (78%) underwent HDT followed by ASCT.All pts recovered from aplasia within a median of 10 days (6-24) without unexpected complications. *Conclusion.* A single injection of Pegfilgrastim 6 mg is safe and effective with 96% of pts succesfully mobilized. Only one or two apheresis are sufficient for the majority of pts (86%).

Updated results will be presented at the meeting.

EPCR GENE'S HAPLOTYPES AND ACUTE GRAFT VERSUS HOST DISEASES

A Bucalossi,[1] R Crupi,[2] F Toraldo,[1] M Tozzi,[1] F Lauria,[2] G Marotta[1]

[1]Stem Cell Transplant Unit, Siena, Italy; [2]Hematology Unit, Siena, Italy

Graft-versus-host disease (GVHD) is the major cause of morbility and mortality after allogeneic hematopoietic stem cell transplantation (HSCT). GVHD has traditionally been classified in acute and chronic according to the time of the onset. Acute GVHD (aGVHD) involves skin, liver, gastrointestinal tract, and possibly other organs and its pathophysiology may be divided into three distinct phases: a) host tissue damage, b) donor T-cells activation, and c) cytokine- and cell-mediated target tissue apoptosis and lysis. Therefore, inflammatory process is a common underlying mechanisms leading to aGVHD. Anti-inflammatory mechanism may constitute an important protection against the development of aGVHD and in this setting protein C (PC) might play a significant role for its cytoprotective effect. PC is activated on the surface of endothelial cells (EC) by the thrombin-thrombomodulin complex, when PC is bound to its receptor, the endothelial protein C receptor (EPCR). Soluble form of EPCR (sEPCR) inhibits PC activation on EC by competing with membrane-associated EPCR. Increased levels of sEPCR are observed during inflammatory process and constitutively are associated with A3 haplotype of EPCR gene. In patients with haplotype A3 of EPCR gene the elevated sEPCR levels are due to increased EPCR shedding by metalloprotease ADAM17 and to the alternative mRNA splicing in A3-carrying cells. The aim of the present study was to investigate if haplotype A3 of EPCR gene is associated with aGVHD development. We studied EPCR gene haplotypes (A1, A2, and A3) in 60 consecutive patients underwent allogeneic HSCT and evaluated their correlation with aGVHD onset. Of the 60 patients enrolled in the study, 27 (45%) developed an aGVHD (14 skin, 5 GI, 2 liver, 2 skin+liver, 2 skin+GI+liver, 1 skin+GI, and 1 GI+liver). Sixteen cases out of 60 (27%) showed A3 haplotype (both in homozygosis and heterozygosis) and in this subgroup of patients 7 out of 16 showed an aGVHD (44%). In 44 patient out of 60 with non-A3 haplotype (73% of cases), aGVHD was observed in 20 of them (45%). In the present study we didn't find any significant correlation between the A3 haplotype of EPCR gene and the incidence of aGVHD. This lack of correlation could be partially due to the reduced number of cases studied and to the presence of many heterozygosis patients for A3 haplotype. However, the evaluation of sEPCR levels in the patients studied for EPCR gene haplotypes is in progress for a more precise analysis of the results.

HAEMATOPOIETIC STEM CELL TRANSPLANT AS A FEASIBLE CONSOLIDATION POST SALVAGE THERAPY FOR FAVOURABLE CYTOGENETICS ACUTE MYELOID LEUKAEMIA IN SECOND COMPLETE REMISSION: A SINGLE CENTRE EXPERIENCE

YK GUAN,[1] TC Ong,[2] KM Chang[1]

[1]Hospital Ampang, Ampang, Malaysia; [2]HOSPITAL AMPANG, Ampang, Malaysia

Background. Acute Myeloid Leukaemia (AML) with favourable cytogenetics are usually treated with success with just chemotherapy. However, relapsed patients usually still do well after salvage therapy and post salvage haematopoietic stem cell transplantation (HSCT). Autologous HCST is a feasible option and is effective in this group of patients and is able to give long term remission. *Aims.* We wanted to examine the characteristics and overall survival of patients with AML with favourable cytogenetics who had a HSCT. *Methods.* We examine retrospectively our centre's experience in AML who underwent HSCT from the year 1999 to January 2010. Patients who were transplanted and had favourable cytogenetics results on diagnosis were included and analysed for demographics, disease details, remission status and overall survival. Acute promyelocytic leukaemia (APML) were induced and consolidated with All-trans retinoic acid (ATRA) and idarubicin. Relapsed patients were salvaged with arsenic trioxide with or without chemotherapy(high dose cytarabine). AML with t(8;21) were induced with 2 cycles of 3+7 regimen(daunorubicin with cytarabine) and consolidated with 2 to 3 cycles of high dose cytarabine with or without mitoxandrone or idarubicin. Relapsed patients were salvaged with Fludarabine+cytarabine+GCSF+Idarubicin(FLAG-Ida). Both sets of patients had peripheral blood stem cells collected with Etoposide/GCSF and had myeloablative conditioning regimen for the HSCT(busulfan and cyclophosphamide). *Results.* We had a total of 133 AML patients transplanted in our centre in the period with 14.3%(19) with favourable cytogenetics. 9.8%(13) had t(15;17) and 4.5%(6) had t(8;21). There was significant difference(P=0.04) in 4-year overall survival among those with(79%) and without(49%) favourable cytogenetics. Of the 13 patient with t(15;17), 1 had been transplanted in first complete remission(CR1) whereas 12 had HSCT in second complete remission(CR2). The only patient transplanted in CR1 had an autologous HSCT and died due to failure of engraftment. Of the remaining 12 patients transplanted in CR2, 2 had allogenic HSCT and 10 had autologous HSCT. Of the 6 patient with t(8;21), 2 had autologous HSCT in CR1, 1 had autologous HSCT in CR2, 1 had allogenic HSCT in CR1, 1 had allogenic HSCT in CR2 and 1 had allogenic HSCT in relapsed refractory disease. All patients were still alive on assessment except for the patient who had relapsed refractory disease who died 3 months post transplant due to relapse. *Conclusions.* AML with favourable cytogenetics could be salvaged with chemotherapy and transplanted in CR2 with good overall survival. Both autologous and allogenic HSCT are feasible options.

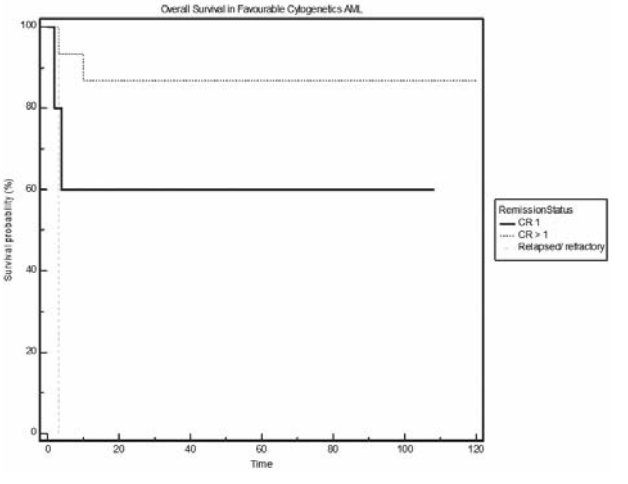

Figure. Remission status and survival in favourable AML.

MAGIC-TT: A NEW STRATEGY OF STEM CELL TRANSPLANTATION TO PROMOTE DONOR CELLS ENGRAFTMENT IN BONE MARROW AND HEMATOPOIETIC RECONSTITUTION

QL Jiang,[1] S Jiang,[1] W Chang,[2] ZS Yi,[3] XX Zheng,[2] LJ Liu,[2] YF Pan,[2] CX Yin,[3] GN Yu,[2] J Sun,[3] QF Liu,[3] FY Meng[3]

[1]Nanfang Hospital, Guangzhou, China; [2]Southern Medical University, Guangzhou, China; [3]Department of Hematology, Nanfang Hospital, Guangzhou, China

Background. It is tempting and challenging to facilitate hematopoietic stem cells (HSCs) homing to bone marrow. If it is successful, we can easily perform umbilical cord blood transplantation for adults, resulting in better engraftment with less donor cells, as well as less graft-versus-host-disease (GVHD) in allogenic transplantation. It is a big problem that few HSCs (some reported as 1.56%±0.32%) can homing back to bone marrow when infused from veins, some researchers therefore, tried to infuse HSCs from artery or directly into bone marrow. Unfortunately, improvement was limited. *Aims.* To establish a novel stem cell transplantation strategy named MagIC-TT (Magnetism-induced cell targeting transplantation) which can facilitates donor cells engraftment and hematopoietic reconstitution. *Methods.* Male FVB-GFP (H-2p) transgenic mice were used as donors, and female BALB/C (H-2d) mice as recipients. In this (H-2p→H-2d) allogenic bone marrow transplantation model, great immune barrier has to be overcome. At first, 4 groups of mice (n=10) were preconditioned with 8 Gy total body irra-

diation, and then each mouse was infused with 5×10e6 GFP+ bone marrow nucleus cells from vena caudalis or from the right femur bone, with or without MagIC-TT method (named as MagIC-TT i.v group, MagIC-TT f.b group, control i.v group and control f.b group, respectively). Routinely, mice survival, weight, GVHD manifestation and peripheral blood test were done. Also, fluorescence activated cell sorting (FACS), quantitative real-time RT-PCR, magnetic resonance imaging (MRI) and pathological examinations were used to trace the donor GFP cells. Subsequently, serially diluted donor GFP+ bone marrow nucleus cells were used in 5 more MagIC-TT i.v groups (n=10), compared with control groups, to identify the efficiency improved by MagIC-TT method. *Results.* Compared with control groups, much more donor cells were found rapidly homing to bone marrow within 24h in both MagIC-TT groups identified by pathological examinations, FACS and MRI, etc. Hematopoietic reconstitution in both MagIC-TT groups was much faster than control groups. In both MagIC-TT groups, more mice survived on +300d, with less GVHD. Even compared with dead ones, mice in MagIC-TT groups survived longer. The GFP cells distribution in organs of survival mice demonstrated no difference among different groups. The efficiency of donor cells engraftment was markedly improved by MagIC-TT method. *Summary and Conclusions.* 1. The MagIC-TT proves to be an effective and safe strategy, which facilitates donor cells engraftment in bone marrow and hematopoietic reconstitution. 2. The mechanism of this strategy is quite different from traditional transplantation, which means less donor cells but better engraftment. It will be helpful to improve the outcome of HLA mismatch allogenic transplantation, cord blood transplantation to adults, and GVHD control. 3. MagIC-TT may also be used in other cell transplantations or cell therapy.

IMPLICATIONS OF TRANSPLANTED DOSES OF VARIOUS PROGENITOR CELLS ON DEVELOPMENT OF CHRONIC GRAFT VERSUS HOST DISEASE IN ALLOGENEIC STEM CELL TRANSPLANTATION OF PEDIATRIC PATIENTS

H Kim, JW Lee, HJ Kang, KD Park, HY Shin, HS Ahn

Seoul National University College of Medicine, Seoul, South-Korea

Background. Chronic graft-versus-host-disease (cGVHD) remains the most frequent late complication after allogeneic hematopoietic stem cell transplantation (HSCT). It is known that various cellular interactions and responses are involved in the pathogenesis of cGVHD and that the more cells are infused, the incidences of GVHD become higher. However, there are only a few studies which specifically focus on infused cells by cellular composition and their influences on cGHVD, especially in pediatric patients. *Aims.* We analyzed the influences of absolute numbers and relative proportions of various immune competent progenitor cells in peripheral blood (PB) allograft on cGVHD in pediatric patients. *Methods.* We retrospectively analyzed 37 children given HLA-matched allogeneic G-CSF mobilized PB HSCTs for malignant (n=25) or nonmalignant (n=12) diseases. *Results.* The donor was an HLA-identical sibling in 8 cases and an unrelated donor in 29. Conditioning regimens were varied according to the disease status. The GVHD prophylaxis consisted of cyclosporine and prednisolone in sibling donor, tacrolimus and methotrexate in others. Chronic GVHD developed in 7 children (18.9%) with malignant disease at a median of 166 days after HSCT and three-year cGVHD probability was 20.6%. In 37 transplants, the median numbers of infused total nucleated cells (TNCs), $CD34^+$ cells were $20.7(7.9\text{-}218.4)\times10^8$/kg, $12.1(2.2\text{-}113.2)\times10^6$/kg, respectively. As a result of flow cytometric analysis of allograft, the median numbers of infused $CD3^+$, $CD4^+$, $CD8^+$, $CD19^+$, $CD16^+CD56^+$ cells were $4.1(1.9\text{-}21)\times10^8$/kg, $2.2(1.2\text{-}10.8)\times10^8$/kg, $1.7(0.6\text{-}10.8)\times10^8$/kg, $1.3(0.5\text{-}5.3)\times10^8$/kg, $0.8(0.2\text{-}5.1)\times10^8$/kg, respectively. Stepwise Cox regression analysis revealed that the $CD4^+$ to $CD3^+$ ratio was significantly correlated with the development of cGVHD (HR 1.185; 95% CI 1.042-1.348; P=0.01). The incidence of cGVHD was statistically higher in those receiving allograft with more than 0.53 in $CD4^+$ to $CD3^+$ ratio (P=0.03). And there were increasing trends in cGVHD incidence when $CD4^+$ to $CD8^+$ ratio was over 1.1 (P=0.09), when infused $CD34^+$ cells were higher than 7.43×10^6/kg (P=0.18) and when infused $CD19^+$ cells were higher than 1.3×10^8/kg (P=0.16), although not statistically correlated. Otherwise the associations of transplanted doses of TNC, $CD34^+$, $CD3^+$, $CD4^+$, $CD8^+$, $CD19^+$ and $CD16^+56^+$ cells with cGVHD were not statistically significant and there was no trends between cell dose with cGVHD. Also there was no definite correlation between cell numbers or compositions with organs involved or extents of the cGVHD. The overall survival and event free survival rates were 78.3% and 31.9%, respectively. T here were 10 events which composed of 7 relapses, 1 non-relapse-mortality, and 2 secondary malignancies without engraftment failure. *Summary/conclusions.* The incidence of cGVHD was significantly correlated with high $CD4^+$ to $CD3^+$ ratio in allogeneic G-CSF mobilized PB HSCTs of pediatric patients. This result suggests that $CD3^+$ and $CD4^+$ cell may play an important role in development of cGVHD. $CD4^+$ cells could be many lineage progenitors rather than regulatory T cells known as GVHD modulators, so further studies for additional analysis of $CD4^+$ cells and also standardization of T and B cell doses for clinical adjustment to reduce cGVHD with proper engraftment are warranted.

1653

A FATAL MICROASCUS CINEREUS (ANAMORPH SCOPULARIOPSIS) BRAIN ABSCESS IN AN ALLOGENEIC BONE MARROW TRANSPLANT RECIPIENT

B Mohty, K Bouchuiguir-Wafa, J Ambriosini, D Robert, C van Delden, J Schrenzel, J Passweg, Y Chalandon

Geneva University Hospital, Geneva, Switzerland

Background. Microascus cinereus, an ascomycetous mold in the order Microascales, family Microascaceae, is one of the most common species of the genus Microascus. It is an uncommon pathogen in humans or animals. *Aims.* We report the second case of brain abscess due to M. cinereus in a bone marrow transplant recipient and discuss the mycological findings. *Methods.* Retrospective analysis of clinical chart and microbiology *Results. Results.* A 34-year-old male allogeneic hematopoietic stem cell transplant (allo-HSCT) recipient for Hodgkin lymphoma was admitted 4 years post-transplantation with right lateral homonym hemianopsia. At the time of this complication, he was treated with tacrolimus, corticosteroids and mycophenolate mofetil for extensive chronic severe graft-versus-host disease (GVHD) he had developed after receiving DLI to treat relapsed Hodgkin lymphoma, as well as ciprofloxacine, metronidazole and voriconazole. A magnetic resonance imaging scan (MRI) of the brain revealed a 1,5- by 2-cm enhancing lesion in the posterior part of the left internal capsule. Liposomal amphotericin B was added to voriconazole, and a stereotactic brain biopsy performed that was unrevealing most likely for technical reasons. Two weeks later, he developed a complete right sensory-motor hemiplegia. A second MRI showed no change in the size of the lesion. The patient underwent a second stereotactic-guided aspiration of the abscess cavity. Direct smear of biopsy specimen prepared with Fungi-Fluor™ showed septate hyphae and oblong cells in short chains (Figure 1). Abscess material from the lesion was inoculated onto potato dextrose, sabouraud's dextrose and brain heart infusion agar with and without chloramphenicol/gentamicin. Growth was first visible on brain heart infusion agar and developed into small grayish mold colonies. Within one week of incubation at 30°C the mold was also isolated on potato dextrose and sabouraud dextrose agar (Figure 2). Microscopic examination of potato dextrose agar slide revealed conidiogenous cells cylindrical or slightly tapering, annellidic, 4 to 5.5 × 2.5 to 3 µm. arising from either single or penicillate flask (Figure 3). These features were consistent with a dematiaceous Scopulariopsis species. Ascomata spherical, black, 130 to 340 µm diameter, with a short-cylindrical ostiolar beak were seen after 2 to 3 weeks of incubation (Figure 4). Partial sequencing of the large ribosomal subunit 28S identified the mold as Microascus cinereus, in accordance with the morphological.

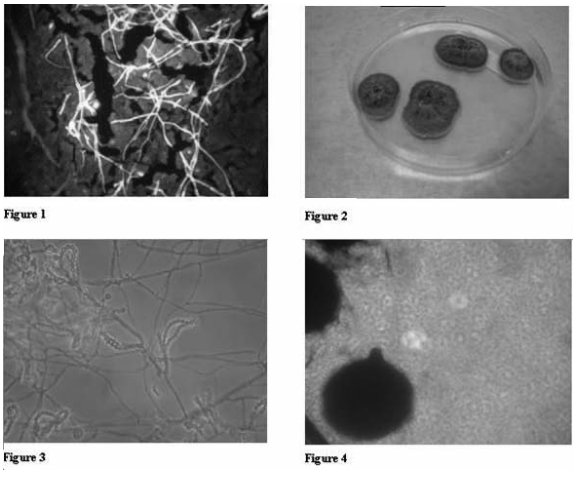

Figure. Morphological features of Microascus cinereus.

Results. Although posaconazole was added to the treatment, the patient died of progressive fungal infection within days. *Conclusions.* We describe the second case of brain abscess caused by M. cinereus after allo-HSCT, an organism that is uncommon and rarely pathogenic in humans. Predisposing factors for infection with this organism included severe immunosuppression, GVHD and exposure to broad-spectrum antibiotics. The isolation of this organism from brain abscess tissue extends the list of known neurotropic dematiaceous organisms capable of causing cerebral phaeohyphomycosis.

1654

PROTECTIVE EFFECT OF DEFIBROTIDE ON THE ENDOTHELIAL ACTIVATION INDUCED BY AUTOLOGOUS SCT ON BOTH MACROVASCULAR AND MICROVASCULAR LOCATIONS

M Palomo, M Díaz-Ricart, M Rovira, G Escolar, E Carreras

Hospital Clinic, Barcelona, Spain

There is evidence of endothelial activation and damage associated with autologous hematopoietic stem cell transplantation (SCT). Most of the complications appearing early after HCT have a microvascular location. The activation and damage of endothelial cells of both macro (HUVEC) and microvascular (HMEC-1) origin occurring early during autologous HSCT and the potential protective effect of Defibrotide (DF, at 100 μg/mL) were investigated. Sera samples were collected before conditioning (Pre), at the time of transplantation (day 0), and at days 7, 14 and 21 after SCT. Changes in the expression of endothelial cell receptors at the cell surface, presence and reactivity of extracellular adhesive proteins, and the signalling pathways involved were analyzed. The expression of ICAM-1 at the cell surface increased progressively in both HUVEC and HMEC-1. However, a more prothrombotic profile was denoted for HMEC-1, especially at the time of transplantation (day 0), which reflects the deleterious effect of the conditioning treatment on the endothelium especially at a microvascular location. Interestingly, this observation correlated with a higher increase in the expression of both tissue factor (TF) and von Willebrand factor (VWF) on the extracellular matrix. Previous exposure and continuous incubation of cells with DF prevented the signs of activation and damage induced by the autologous sera, being more effective in the HMEC-1 setting. Taken together, these observations indicate that DF has a potential protective effect on the endothelium at both macrovascular and microvascular locations.

1655

POST-TRANSPLANT CHIMERISM ANALYSES USING DNA EXTRACTED FROM ASPIRATE PARTICLE SMEARS BETTER PREDICTS DISEASE RELAPSE THAN FROM CONVENTIONAL ASPIRATE SAMPLES IN PEDIATRIC PATIENTS WITH AML

CH Park

Samsung Medical Center, Seoul, South-Korea

Background. Chimerism analyses using short tandem repeat (STR) markers has become an essential workup for post-transplant surveillance of engraftment and disease relapse. Conventionally, DNA from bone marrow aspirate drawn into EDTA bottles (Conv-BM) is used for chimerism analyses. However, it is conceivable that recipient DNA (%R) from Conv-BM might be underestimated due to potential peripheral blood dilution. In this regard, DNA from aspirate particle smears (PS-BM) would best represent the chimerism status of BM. *Aims.* This study was performed to compare chimerism status from Conv-BM with those from PS-BM in a series of pediatric AML. *Materials and methods.* The study subjects were pediatric patients with AML who experienced disease relapse after allogeneic HSCT. Chimerism status was routinely monitored by quantitative analyses of informative STR markers using the PCR-gene scan technique. DNA samples were additionally obtained from PS-BM at 2 time-points in selected cases, immediately prior to relapse (Pre-Rel) and at the time of relapse (Rel). Chimerism analyses were performed on the same set of informative STR as previously selected for Conv-BM. The %R obtained from PS-BM were compared with those from Conv-BM. *Results.* Total 7 cases of AML were selected in a consecutive manner (5 boys and 2 girls; age range 2-17 years, median 13 years). In all patients except for Patient 5, %R from Conv-BM was 0% at Pre-Rel (complete chimerism). On the other hand, chimerism analyses using DNA from PS-BM revealed mixed chimerism in all cases, with %R from 1.1% up to 8% (mean 3.7%). Also at the time of relapse, a significant difference was observed between %R from Conv-BM and from PS-BM, with Δ%R (%R[Conv-BM] - %R[PS-BM]) from -34.5% to 9.6% (mean -7.5%). *Conclusion.* Chimerism analyses using DNA obtained from particle smears better predicted disease relapse than from conventional aspirate samples in pediatric AML. Potential underestimation of disease markers due to dilution effect need to be addressed in other diagnostic workup in hematologic malignancy.

1656

IMMUNE RECONSTITUTION AT DAY +100 - AN IMPORTANT DETERMINANT OF COMPLICATIONS FOLLOWING HEMATOPOIETIC STEM CELL TRANSPLANTATION

A Tomaszewska, B Nasilowska-Adamska, A Gajewska, U Podstawka, J Kopec-Szlezak, B Marianska

Institute of Hematology and Transfusion Medicine, Warsaw, Poland

Background. The immune recovery correlates with the outcome after hematopoietic stem cell transplantation (HSCT). Different lymphocytes subsets at various time points after HSCT were evaluated. *Aim.* The aim of present study was to evaluate the impact of lymphocyte subset reconstitution on relapse rate and opportunistic infectious complications following HSCT. The group of 56 patients, female to male 25/31, with median age 40 (range 19-65), underwent allogeneic (27 pts) or autologous (29 pts) stem cell transplantation due to hematologic malignancies, were enrolled in this study. *Methods.* T lymphocyte subsets (T CD3, CD4, CD8, TCR gamma/delta, Treg and NKT) and NK cells were enumerated in fresh whole blood EDTA samples by direct 3 or 4-colour immunofluorescence analysis (FACScalibur, Becton Dickinson) at day 100 after transplant. The controls were blood samples obtained from healthy donors. *Results.* We have noticed that immune recovery after alloHSCT differs from that after autoHSCT. Counts of NKT cells were higher after autoHSCT in comparison with controls (P=0.02) and Treg (P=0.06) and NK cells (P=0.0003) were lower, whereas in alloHSCT group these subsets of lymphocytes were similar to controls. Only number of CD4 T cells were significantly lower in both groups of transplants in comparison with the control (P=0.0001). We observed the higher relapse rate in patients (n=22)with lower counts at day +100 of: CD4 T-cells (P=0.0001), Treg (P=0.0001) and NK cells (P=0.0002). CMV reactivation (n=13) was strongly correlated with low number of CD3 (P=0.0497), CD4 (P=0.0001) and Treg (P=0.0153) subset. Besides in patients with extremely low counts of CD3, CD4 and Treg measured at day +100 extrapulmonary tuberculosis (n=2) and invasive fungal infections (n=2) developed subsequently. *Conclusion.* The count of lymphocyte subsets (CD3, CD4, Treg and NK) measured at day 100 seems to be associated with the risk of opportunistic infectious complications and relapses in patients after HSCT. Due to heterogeneity and small sample size our results should be determined in a larger study.

1657

MOBILIZATION OF PERIPHERAL BLOOD STEM CELLS (PBSC) FOR AUTOLOGOUS STEM CELLTRANSPLANTATION (ASCT) IN PATIENTS WITH LYMPHOMA AND HUMAN IMMUNODEFICIENCY VIRUS (HIV) INFECTION

M Sagüés,[1] JM Sancho,[1] D Serrano,[2] P Balsalobre,[2] J Gayoso,[2] M Morgades,[1] E Conde,[3] A Iriondo,[3] A Varela,[4] L Escoda,[5] I Espigado,[6] P Fernández-Abellan,[7] JL Diez,[2] JM Ribera[1]

[1]Hospital Universitari Germans Trias i Pujol / Universitat Autónoma de Barcelona, Badalona, Spain; [2]Hospital General Gregorio Marañón, Madrid, Spain; [3]Hospital Marqués de Valdecilla, Santander, Spain; [4]Hospital Juan Canalejo, A Coruña, Spain; [5]Hospital Joan XXIII, Tarragona, Spain; [6]Hospital Virgen del Rocío, Sevilla, Spain; [7]Hospital General Universitario de Alicante, Alicante, Spain

Background and Aim. Several studies have demonstrated the feasibility of ASCT in patients with lymphoma and HIV infection. In addition to advanced age, radiotherapy, bone marrow involvement and previous myelosuppressive therapy with alkylating agents or purine analogues, HIV infection has been considered a risk factor for poor mobilization. The aim of this study was to evaluate the results of the mobilization schedules of PBSC in patients with lymphoma and HIV infection. *Methods.* Retrospective study of patients with lymphoma and HIV infection, who have received an ASCT in seven Spanish hospitals. Demographic, clinical, biological data, previous chemotherapy and outcome were collected. Mobilization schedules were classified in two groups: G-CSF and G-CSF^{+} chemotherapy (CHT). *Results.* Thirty-four patients were

included, with mean (SD)age 44 (9) yr., 31 (91%) were male, and all received highly active antiretroviral therapy (HAART). Twenty-two patients (65%) were diagnosed of non-Hodgkin lymphoma (NHL), and 12 (35%) of Hodgkin lymphoma (HL). The stage of the lymphoma was limited (I-II) in 7 patients (21%), and advanced (III-IV) in 27 (79%). Twenty-one patients (65%) presented extranodal involvement and 14 (41%) showed an International Prognosis Index (IPI)>2. The number of CHT regimens received prior to ASCT was of 1 in 5 patients (15%), 2 in 25 (73%) and 3 in 4 (12%). Disease status before ASCT was first remission (CR1) in 12 patients (35%), second or further remission (CR>1) in 11 (32%), and partial response (PR) in 11 (32%). Patients mobilized with G-CSF (n=20) were comparable with those mobilized with G-CSF+CHT (n=14) for age, type of lymphoma, type of response at ASCT and number of prior CHT regimens. Sixteen out of 20 patients (80%) mobilized successfully wit G-CSF regimen, and 11 out of 14 (78%) mobilized with G-CSF+CHT. The number of $CD34^+$ cells was higher in patients successfully mobilized with G-CSF^+CHT than in those with G-CSF (mean [SD] 8.7 [7.7] $\times 10^6$ CD34 cells/kg *vs.* 3.9 [1.3] x106 CD34 cells/kg, P=0.459). Disease status pre-ASCT was the only predictive factor for successful mobilization (20/22 patients [91%] in CR *vs.* 5/12 [42%] in PR, P=0.038). No differences were observed in mobilization between patients in CR1 and CR>1. Neither age nor type of lymphoma, stage of disease, LDH level or performance status prior to mobilization had influence on the success of mobilization. No differences were observed in neutrophil and platelet engraftment between patients mobilized with G-CSF or G-CSF^+CHT. *Conclusions.* In HIV-related lymphomas the rate of successful PBSC mobilization was similar with G-CSF or G-CSF^+CHT. The only risk factor for successful mobilization was the disease status prior to ASCT.

Supported in part by grants P-EF/08 from FIJC, RD-06/0020/1056 from RETICS and 36606/06 from FIPSE.

PROGNOSTIC INFLUENCE OF ELEVATED PRETRANSPLANT SERUM FERRITIN ON THE RESULTS AFTER ALLOGENIC HEMATOPOETIC STEM CELL TRANSPLANTATION

P Belohlavkova,[1] P Zak,[2] A Zavrelova,[2] J Radocha,[2] M Lanska,[2] J Horacek,[2] J Voglova,[2] L Jebavy,[2] J Maly[2]

[1]*Charles University, Hradec Králové, Czech Republic;* [2]*Charles University, Dpt. of Haematology, Hradec Králové, Czech Republic*

Background. Iron overload is common in patients undergoing hematopoetic stem cell transplantation. Several studies have reported that an elevated pretransplantation serum ferritin was associated with lower overall survival and increased nonrelapse mortality. Iron overload increases the risk of infection, veno-occlusive disease and might influence the risk of acute and chronic GvHD. *Patients and methods.* We evaluated 86 patients (pts) retrospectively who were known the level of serum ferritin before the beginning of the conditioning procedure. These patients underwent allogenic hematopoetic stem cell transplantation (HSCT) between December 1998 and November 2009. The group included 22 pts with acute myeloid leukemia, 6 pts with acute lymphoid leukemia, 6 pts with chronic myeloid leukemia, 13 pts with myelodysplastic syndrome, 6 pts with primary myelofibrosis, 9 pts with aplastic anemia, 22 pts with non- Hodgkin's lymphoma and 2 pts with other disease. The median age was 50 years (range, 19-66 years). There were 53 males and 35 females. Fifty seven patients (67%) received a myeloablative conditioning, whereas a reduced intensity conditioning was administered to 28 patients (33%). Most patients (97%) received peripheral blood stem cells as a graft. *Results.* The median level of serum ferritin was 820 ug/L (range, 2-10 466 ug/L). Median follow-up period after HSCT was 11 months (range, 1-144 months). The patients were divided into two groups (group with low ferritin <500 ug/L and group with high ferritin >500 ug/). At 5 years patients in the group with high ferritin had a significantly inferior overal survival than those in the low ferritin group (72% *vs.* 38%, P<0,001). Patients in the high ferritin group more likely to die of infection (in four cases was occured aspergilosis). We have shown a slight diference in relapse rate (13% *vs.* 29%). There was no statistical difference in the cumulative incidence of GvHD. The time to engraftment was shorter in the first group (median 15 days, range: 8 - 44 days) compared with the high ferritin group (median 16 days, range 10 - 30 days). *Conclusion.* Our findings indicate that patients with elevated pretransplantation serum ferritin level had inferior survival because of increased non-relapse mortality, mainly from infection. Iron overload may adversely affect the time to engraftment.

PREDICTIVE VALUE OF SCORING SYSTEM WITH AUTOANTIBODY EXPRESSIONS IN ALLOGENEIC STEM CELL RECIPIENTS

JH Moon, SJ Lee, BW Kang, YS Chae, JG Kim, KS Lee, JS Suh, SK Sohn

Kyungpook National University Hospital, Daegu, South-Korea

Background. In our previous study, patients expressing autoantibodies especially ANA showed a better survival in allogeneic stem cell recipients. *Aims.* The current study was designed to implicate the expression of autoantibodies as an prognostic marker after allogeneic stem cell transplantation (SCT). *Methods.* A total of 144 consecutive patients who underwent allogeneic SCT from November 2001 to Sep 2009 and survived at least 3 months were included in the current study. ANA and anti-dsDNA were screened at 3, 6, 12 month and yearly thereafter. *Results.* ANA was positive in 31 patients (21.5%) at median 364 days (range, 90-1141) and anti-dsDNA (>3.0 Iu/mL) in 76 (52.8%) at median 100 days (range, 46-1458). In the multivariate analysis, ANA [hazard ratio (HR) 0.315] and anti-dsDNA >3.0 Iu/mL (HR 0.328) were identified as good prognostic factors for survival and relapse. When scored as the number of autoantibody expression with ANA and anti-dsDNA; score 0 as no autoantibody expression, score 1 as one and score 2 as two, the patients for score 2 showed a 91.8% 5-yr overall survival (OS) (HR 0.075, P<0.001) and 0.4% relapse rate (HR 0.059, P<0.006), those for score 1 a 64.1% 5-yr OS (HR 0.352, P<0.001) and 26.3% relapse rate (HR 0.422, P=0.011), and those for score 0 a 35.7% 5-yr OS and 53.7% relapse rate. *Conclusion.* Patients expressing multiple autoantibodies (ANA and anti-dsDNA) showed a better survival and lower relapse rate in allogeneic stem cell transplantation settings. Scoring with autoantibody expressions could be used as a prognostic marker for long-term survival and lower relapse risk after allogeneic SCT.

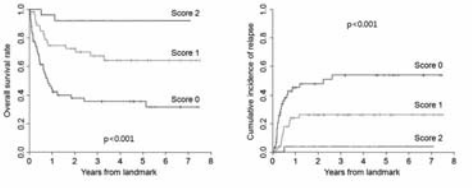

Figure. OS and relapse according to the autoantibody score.

COUNTING OF PERIPHERAL BLOOD STEM CELL: CD34 BY FLOW CYTOMETRY AND HEMATOPOIETIC PROGENITOR CELL ON SYSMEX® XE-2100 AFTER MODIFICATION OF SOFTWARE AND REAGENTS XE-HPC MASTER

M Belkaid, N Bakiri, AM Pequin, L Mermet, P Agape, T Henni, JC Saly

CHR Reunion, Saint Denis, Reunion

During the organization of collection of PBSC, a crucial problem is to determine the best time to start the harvest. Circulating hematopoietic stem cells (CHSC) evaluation is based on counting of CD34+ cells by IF. This method is expensive, complex, time consuming and induces organization difficulties as regard to bed occupancy and staff timetable. With the increasing acceptance of stem cell transplantation as a standard therapy worldwide, there has been an accompanying increase in demand for technologies that can detect and count progenitor cells. An automatic counter, the Sysmex XE 2100 is equipped with a unique Immature Myeloid Information (IMI) channel, a specially designed unit for the detection of immature myeloid cells which are resistant to lysis reagent and HPC are counted on the basis of direct current and radiofrequency in the IMI-HPC area. The HPC parameter of the IMI channel is used for screening the presence of haematopoietic progenitor (stem) cells in peripheral blood and cord blood samples. Sysmex has developed a hematology analyzer that identifies a small population of immature myeloid cells in the peripheral blood according to cell size, cell density and differential lysis resistance. Since 2004, Sysmex Company undertook software and reagents modification of this cellular counting. The goal of this study was to determine the correlation between the two methods of counting: HPC and CD34 by IF, on peripheral blood sample. We have compared also the results of HPC count on Sysmex XE-2100 and $CD34^+$ cells count before and after software and reagents

modification of HPC counting. We have analyzed HPC and CD34 counting for 95 and 67 CHSC samples before and after modified XE-HPC master. Our results showed a significant correlation between the quantification of the CD34 by IF and HPC before modification (R^2=0.89), this correlation coefficient was not more than 0.53 after the modification. The analysis of these results enabled us to propose a minimal threshold from 20 HPC/mm^3, value of lower part of which, a numeration of the CD34 was required before the modification (R^2=0.87), this is not true after software and reagents modification (R^2 =0.46). The interest of the HPC count is that it is time and cost saving, and thus can be used as a first time method before harvesting stem cells, but, regrettably, the modifications of reagent and software seem to have been out of favor with this promising methodology.

1661

STUDY ON THE IMMUNO-SUPPRESSIVE CHARACTERISTICS OF HUMAN DENTAL PULP DERIVED MESENCHYMAL STEM CELLS ON T CELLS IN-VITRO: INITIAL STUDY OUTPUTS

P Demircan Cetinalp,[1] G Gacar,[2] A Eker Sariboyaci,[2] E Karaoz[2]

[1]Center for Stem Cell and Gene Therapies Research and Practice, Dep. of Stem Cell, Izmit/Kocaeli,, Turkey; [2]Center for Stem Cell and Gene Therapies, Izmit/Kocaeli, Turkey

Recent studies demonstrated that bone marrow (BM-) derived mesenchymal stem cells (MCS) have immuno-suppressive and/or immunomodulator characteristics on T-cells and can be used for the purpose of inhibition and/or treatment of many immunodeficiencies (e.g. systemic sclerosis, systemic lupus erythematosus, rheumatoid arthritis and immune cytopenia) particularly multiple sclerosis (MS), and graft *vs.* host disease (GVHD)). In our study, we aimed to demonstrate immunosuppressive effects on in-vitro induced T-cells of human embedded molar dental pulp derived (hDP-) BM-MCS's which show similar characteristics with BM-MCS's in terms of immunophenotypic, structural, proliferation and differentiation capabilities, by the use of miscellaneous experimental instruments.

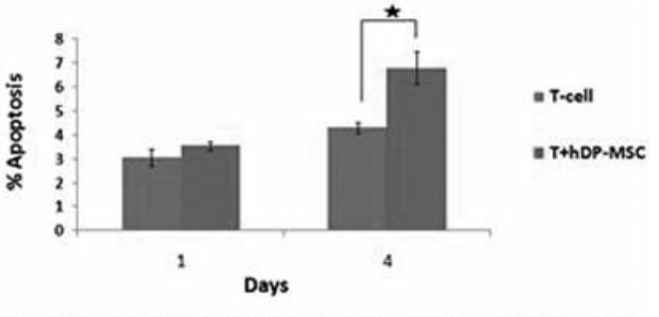

Figure 1: As a result of 4-day indirect co-culture experiments in vitro on hDP-MCS's and T-cells induced by phytohaemagglutinin, we found that hDP-MCS's produced apoptotic effect on T-cells at the 4th day (p<0,05).

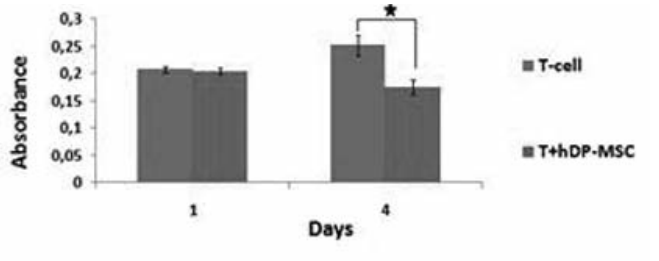

Figure 2: As a result of 4-day indirect co-culture experiments in vitro on hDP-MCS's and T-cells induced by phytohaemagglutinin, we found that hDP-MCS's produced anti-proliferative effect on T-cells at the 4th day (p<0,05).

Figure 1, 2.

For this purpose, MCS's isolated from human embedded dental pulp by enzymatic digestion method were used. For immunophenotypic characterization studies, in flow cytometry device these cells produced positive reaction for CD13, CD44, CD90, CD146 and CD166; reaction was negative for CD3, CD8, CD11b, CD14, CD15, CD19, CD33, CD34, CD45, CD117 and HLA-DR. Telomerase enzyme activity determination, proliferation capacities (by MTT), embryonic gene expressions (Oct4, Rex-1, FoxD3, Sox-2 and Nanog), differentiation studies (osteogenic, chondrogenic, adipogenic, myogenic and neurogenic) and characterization studies were completed. In the second phase, T cells were obtained from peripheral blood samples of healthy adults by the method of negative selection (with rosette-sep kit) and characterization process was completed with flow cytometry, immunohistochemical and gene expression studies. T-cells of which characterization process was completed were induced by phytohaemagglutinin (PHA). In order to study the immunosuppressive effects of MCS's, induced T-cells were taken to indirect coculture system with MCS's in passage 3. For this purpose, MCS's (4×10^5) were transplanted to the bottom of 6-well plates and 2 hour waiting period is left for their adherence. 0.4 micron diameter transwell inserts (main-section) were placed to the wells and 4×10^5 T-cell was placed in each well (at the ratio 1:1) and taken to in-vitro indirect coculture for a period of 4 days. Following each period of time, activity/proliferation capacity in T-cells on the upper side of the intermediate section was measured on spectrophotometer device via MTT method and by evaluating the apoptosis levels after Annexin V-PI staining on flow cytometry device (each experiment was repeated 3 times). After 4-day indirect coculture experiments on hDP-MCS's and induced T cells, we found that hDP-MCS's inhibit proliferation on T cells (P<0,05) and induce apoptosis (P<0,05) (Figure 1, Figure 2). Consequently, initial outputs of our study demonstrated that hDP-MCS's create immuno-suppressive effects on in-vitro induced T-cells. This study was implemented within the scope of project no 108S291 supported by Tubitak.

ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANT CAN AMELIORATE THE ADVERSE IMPACT OF FLT3-ITD MUTATION IN PATIENTS WITH ACUTE MYELOID LEUKEMIA WITH NORMAL CYTOGENETICS

Y Loh, GF How, W Hwang, YC Linn, YT Goh, CP Diong, LC Lim

Singapore General Hospital, Singapore, Singapore

Background. Acute myeloid leukemia (AML) with normal cytogenetics has historically been regarded as intermediate risk on the basis of karyotypic classification. However, data over the last few years has demonstrated that the presence of recurrent molecular mutations such as the FLT3 internal tandem duplication (FLT3-ITD) is associated with adverse outcomes with high relapse rates and reduced overall survival (OS). The ability of allogeneic transplant to improve outcomes has been demonstrated in some studies but not others. *Aims.* We undertook an analysis of the outcomes of adult patients with AML in our center to determine the impact of FLT3 ITD on outcomes. We assessed whether complete response rate (CR), relapse rate, OS and cumulative probability of relapse following chemotherapy, autologous or allogeneic transplant are affected by the presence of a FLT3-ITD mutation. We also sought to assess if an allograft would be able to ameliorate the adverse impact of the FLT3 mutation amongst our patients. *Methods.* This is a retrospective analysis of adult AML patients with normal cytogenetics treated at our centre between 2003 and 2008. In our center, all patients with AML undergo standard induction with idarubicin for 3 days and cytarabine for 7 days, followed by a similar cycle of consolidation. Patients with normal cytogenetics below age 50 years who have a sibling donor are usually offered an allogeneic transplant. Those who do not, either undergo consolidation with high dose cytarabine or an autologous hematopoietic cell transplant (HCT). Patients with poor risk features such as needing more than one cycle to achieve CR or persistent blasts are considered for an unrelated donor allograft if a suitable donor is found. The conditioning regimen was either myeloablative (busulfan 16 mg/kg and cyclophosphamide 120 mg/kg) or reduced intenstity (fludarabine 120 mg/m^2 and busulphan 8mg/kg to 16mg/kg). Choice of reduced intensity regimen was based on patient's age (above 50 years) or co-morbidities. *Results.* The median duration of follow up was 22 months (0-78 months). Fifty-three patients with median age 51 years (15-61 years) were treated. Of these, 20 underwent autologous HCT, 9 underwent sibling allograft and 6 unrelated donor HCT while the rest received chemotherapy alone. The FLT3-ITD was present in 23 patients. Comparing patients with and without FLT3 mutation, the likelihood of CR after induction was similar (74.1% *vs.* 73.1%) and the probability of OS was 20.9% *vs.* 31.9% (P=0.85). However, the probability of OS among FLT3 positive patients was significantly different based on treatment type: sibling allograft 66.7% *vs.* unrelated donor 20.8% *vs.* autologous allograft 13.8% *vs.* chemotherapy 0% (P<0.001). The cumulative probability of relapse: sibling allograft 33% *vs.* autograft 77% *vs.* unrelated donor 75% (P<0.001). *Conclusions.* The presence of FLT3-ITD confers a poor prognosis on patients with AML with normal

cytogenetics. Our data demonstrates that autologous HCT should not be performed in patients with FLT3-ITD but a sibling allograft may ameliorate the adverse impact of FLT3-ITD mutation.

TACROLIMUS AND SHORT COURSE SIROLIMUS GRAFT VERSUS HOST DISEASE PROHYLAXIS REGIMEN FOR HLA IDENTICAL SIBLING MYELOABLATIVE PERIHERAL BLOOD STEM CELL TRANSPLANTATION

P Reményi, Á Bátai, A Barta, É Torbágyi, L Lengyel, L Gopcsa, Z Csukly, A Sípos, M Réti, T Masszi

Szent László Kórház, Budapest, Hungary

Based on the GVHD prevention regimen published by the Dana Farber group we truncated the adminsitration of sirolimus at day 30 post-transplant and maintained tacrolimus until 180 days. The purpose of our study to find a good balance between toxicity and efficacy and graft *vs.* tumor effect with tacrolimus and short sirolimus GVHD profilaxis regimen. From January 2006 to December 2009 we transplanted 46 patients (23 male, 23 female) patients with acute myeloid leukemia(30), acute lymphoid leukemia (6),advannced chronic myeloid leukemia (4), and myelodysplastic syndrome (5). 22/46 patients belonged to the standard risk group and 24/46 to the high risk group. The median age of the patients was 40 (15-61) years. All patients received myeloablative conditioning regimen and unmanipulated peripheral stem cell graft from a HLA indentical sibling donor. The median follow up period is 11.9 (1.2-47) months. All patients engrafted, and reached full donor chimerism and complete remission by bone marrow histology at day 30. The cumulative incidence of acute GVHD was 34%, 13 patients had grade I-II, 2 patients grade III and all of them were steroid responsive. 18/46 patients had chronic GVHD (9 limited, 9 extensive). The toxicity was mild, 3 patients had sinusoidal obstructive syndrome (SOS), 4 patients transplant associated microangiopathy (TMA). We observed 1 CMV diesease, 1 invasive fungal infection, and 8 bacterial blood stream infection. Eleven patients died (5 relapse, 5 chr. GVHD+infection, 1 secondary malignancy). 44/46 (95%) of the patients lived at day 100, 39/46 (85%) at one year, 35/46 (76%) at two year. The probability of four year survival is 63% for the whole cohort, 87% for the standard risk group and 49% for the high risk group of patient. Our patient cohort is in line with the data published by the Dana Farber group but seems to be less toxic regarding SOS syndrome and TMA.

1664

BASELINE PLATELET COUNT AS A PREDICTOR OF AUTOLOGOUS PERIPHERAL BLOOD PROGENITOR CELL COLLECTION

A Cantalapiedra, A Dueñas, MJ Peñarrubia, R Sanchez, O Gutierrez, E Fernández-Fontecha, C Del Villar, J García-Frade

Hospital Río Hortega, Valladolid, Spain

Background. It is still a current problem how to predict the best timing to collect stem cell progenitors after chemotherapy, and if the amount collected will allow one or even two transplants. *Aims.* The primary endpoint was to evaluate the CD34 cells/Kg collected. We studied the correlation with basal platelets count, basal haemoglobin and basal WBC count, before mobilization treatment and first stem cell apheresis. *Material and methods.* Progenitor cell collection procedures were retrospectively evaluated in a period of 10 years (2000-2010) to analyze factors predictive of autologous peripheral progenitor blood cell collection. All the patients had a lymphoproliferative disease (68 lymphoma and 47 Multiple Myeloma). 90% of patients received a mobilization schema with chemotherapy and G-CSF. We studied the correlation with basal platelet count, basal haemoglobin and basal WBC count, before mobilization treatment and the first stem cell apheresis. Statistical analysis was made with the SPSS 15.0 for Windows XP program. *Results.* We analyzed a total of 115 progenitors collection procedures in 106 patients (69 male, 37 female; age: median = 56 years; range = 14-73; weight : median =72 Kg; range= 36-110). The median baseline platelet count was 220×10^9/L (range 36-686×10^9/L); the median baseline platelet count at the first apheresis was 123.5×10^9/L (range 4-151×10^9/L); the median total CD34$^+$/Kg collected was 2.8×10^6/Kg (range 0.3-20×10^6/Kg) and the median baseline CD34$^+$/mL in peripheral blood at the first apheresis was 19.890/mL (range 130-510.000); finally the median of CD34$^+$ cells/Kg in the first apheresis was 1.55×10^6/Kg (range 0.2-20×10^6/Kg). Baseline platelet count before mobilization treatment significantly correlated with total CD34$^+$/Kg cell yield and CD34$^+$/Kg cell count in the first apheresis (Spearman r = 0.321, P=0.001 and Spearman R=0.426 P<0.001 respectively). In addition an inverse correlation with the number of apheresis procedures was observed (Spearman r = - 0.277 P=0.003). A direct correlation between the basal platelet count before the first apheresis and total CD34$^+$/Kg cell count (Spearman r = 0.302 P=0.001) was found. *Conclusions.* Baseline platelet count before mobilization and harvest correlates with an adequate CD34+ progenitor cells collection number. Baseline platelet count before mobilization procedures could be used to predict a successful collection.

1665

INCIDENCE OF GRAFT-VERSUS-HOST DISEASE (GVHD) IN PATIENTS WITH ALLOGENEIC PERIPHERAL HEMATOPOIETIC STEM CELL TRANSPLANTATION AFTER A NON-MYELOABLATIVE CONDITIONING

O Cantú,[1] H Gutiérrez,[1] G Ruiz,[2] A López,[2] C Mancias,[1] S Martínez,[1] O González,[1] J Jaime,[1] D Gómez[1]

[1]University Hospital, Monterrey, Mexico; [2]Center of Hematology and Internal Medicine, Puebla, Mexico

Background. Graft-versus-host disease (GVHD) is the most common complication of allogeneic hematopoietic cell transplantation (alloHCT) and may affect the transplant outcome. Its incidence is higher when the preparative regimen used is a non-myeloablative and the stem cell's source is peripheral blood after mobilization. *Aims.* To demonstrate the 10 years incidence of GVHD in 2 Mexican transplant centers using peripheral hematopoietic stem cell transplantation (PHSCT) in related donors after non-myeloablative conditioning. *Methods.* Three hundred and four patients with hematological and non-hematological malignancies that underwent PHSCT after non-myeloablative conditioning between March 1996 and July 2008 were included. The age ranged between 1 and 71 years (median of 30.5). One hundred and eighty-four patients were men and 120 women. They received cyclosporine 4mg/kg per day and intramuscular methotrexate 5 mg/ m^2 in days +1, +3, +5 and +11 for GVHD prophylaxis. *Results.* Two hundred seventy-seven (91.1%) patients were successfully engrafted. One hundred and fifty-eight patients (52%) developed acute and/or chronic GVHD. Of this last number of patients, 104 (34.2%) developed acute GVHD, 91 (29.9%) developed chronic GVHD, and 36 (11.8%) developed both. Thirty five patients (11.5%) who developed acute GVHD were grade III or IV, and 34 (11.2%) of chronic GVHD patients presented in the extensive way. GVHD was the cause of dead in 35 patients (11.5%), even when immunosuppressive therapy (high dose steroids and rituximab) was used. Last death was 24 months ago; subsequently, alemtuzumab was included in GVHD treatment. *Summary/Conclusions.* The incidence of acute and chronic GVHD in our patients is lower than the reported in the literature, even though the source of hematopoietic stem cells was peripheral blood. The mortality rate has decreased due to the introduction of new and more aggressive immunosuppressive agents like alemtuzumab.

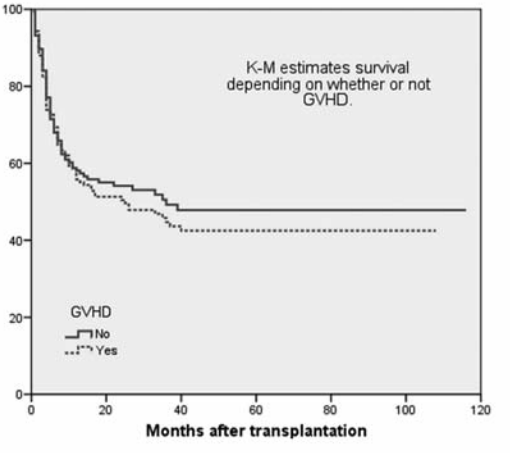

Figure.

1666

EX VIVO EXPANSION OF UCB HSCS THROUGH COCULTURE WITH OSTEOBLASTS DIFFERENTIATED FROM MESENCHYMAL STEMCELL

M Kazemi manesh,[1] N Amirizadeh,[2] A Gharebaghian,[3] M Nikoogoftar,[4] L Kazemi manesh,[5] F Mojarad[6]

[1]IBTO(iranian blood transfusion organisation)research center, Tehran, Iran; [2]Naser, Tehran, Iran; [3]Ahmad, Tehran, Iran; [4]IBTO(Iranian Blood Transfusion Organisation)Research Center, Tehran, Iran; [5]Leila, Tehran, Iran; [6]Farid, Tehran, Iran

Background. Interaction of HSCs with their specific microenviroment,niche,is critical for maintaining HSCs properties and their fate and one of the most important elements in niche are osteoblasts. *Aim. Ex vivo* expansion of UCB HSCs. *Methods.*After induce difrentiation of MSCs to osteoblasts in 3D,2D condition for ten days we seperated CD34+cells from UCB with MACS and then coculture them with osteoblasts. Result. The mean of $CD34^+$cells in 3D cndition(scaffolds and osteoblasts which diffrentiated from MSCs) was 25/7±4/3 and in 2D conditions in present of osteoblasts was 34/5±3/7 and at the present of cytocines was 64/1±5/7. The mean of Total colonise in 3D cndition(scaffolds and osteoblasts which diffrentiated from MSCs) was 63±3/6 and in 2D conditions in present of osteoblasts was 56±4/2 and at the present of cytocinse was 73±2/1. In Brdu analysis ,Brdu+ cells in 2D condition decreased about 10% and in 3D condition about 8% decreased. *Summary/Conclusions.*;We copare the invitro culture conditions which have the most quiescence without use of expensive cytocinse therfor use of HSCs coculture with osteoblasts can be replaced in use of cytocinse to expansion and maintaining of HSCs properties in selfrenewality.

1667

ALLERGIC RECONSTITUTION AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION

HS Kim,[1] SC Won,[2] CJ Lyu[2]

[1]Yonsei University College of Medicine, Seoul, South-Korea; [2]Yonsei university College of Medicine, Seoul, South-Korea

Background. In the pathogenesis of allergy, two main types of cells play a role: hematolymphatic cells (mast cells, eosinophils, T cells, B cells) and nonhematolymphatic cells (airway smooth muscle cells, epithelial cells). Hematolymphatic cells, particularly CD4 T cells, appear to play an important role. Immune deficiencies that are caused by defect of hematolyphatic cells are typically cured by allogeneic hematopoietic stem cell transplantation (HSCT). Allogeneic HSCT can also lead to transfer or cure of autoimmune diseases. *Aims.* We aimed to investigate the alteration of allergic tendency in patients undergoing HSCT and to evaluate the relation between allergic reconstitution and graft *vs.* host disease (GVHD) development. *Methods.* Eighteen patients who received HSCT between November 2008 and November 2009 were included. We checked serum total IgE and radioallergosorbent test (RAST) before and after HSCT, and investigated correlation with GVHD. *Results.* Among eighteen patients, two patients underwent autologous HSCT five patients underwent allogenic HSCT from sibling donor, and the others from unrelated donor. Among sixteen patients with allogeneic HSCT, nine patients received peripheral blood, six patients received bone marrow, and one patient received umbilical cord blood. Eleven patients changed their allergic status after HSCT. Six patients increased their total IgE or RAST score, but five patients showed decrease. *Conclusions.* Allergic reconstitution after HSCT shows a tendency towards correlation with source of hematopoietic stem cell rather than GVHD development, probably due to the fact that CD4 T cells play an important role in the pathogenesis of allergy. The most likely mechanism of allergy reconstitution is transfer of either hematopoietic stem cell precursors having a tendency to differentiate into allergy-prone hematolymphatic cell, or mature allergen-specific B or T cells from donor. To determine the likelihoods of transfer of allergy in patients undergoing allogeneic HSCT, large prospective study with inclusion of the allergic status of donor is needed.

1668

THE TREATMENT OF RESISTANT LIFE-THREATENING INFECTIONS IN PRIMARY IMMUNODEFICIENCIES TREATED WITH BONE MARROW TRANSPLANT IN RELATION TO ALLOGENEIC IMMUNE RECOVERY

A Krasowska-Kwiecien, J Gozdzik, A Wedrychowicz, S Skoczen, W Czogala, O Wiecha

Jagiellonian University Institute of Pediatrics, Cracow, Poland

Severe, persistent, non-curable, opportunistic infections are a specific challenge of allogeneic bone marrow transplantation (BMT) in primary immunodeficiencies. The aim of this study was to asses the results of BMT in patients affected by life-treatening, antimicrobial agent-resistant pathogens. In our department 7 allogeneic BMT were performed in 6 children with severe primary immunodeficiencies (4 sibling and 3 matched unrelated donor transplants) since 2007 to 2009. One child underwent BMT twice, because of the graft failure. The group consisted of 5 boys and one girl, aged 6,8 years (range 0,5 - 13). Four children were diagnosed with chronic granulomatous disease (CGD), one child with Omenn syndrome, and another with hyper-IgM syndrome. Ablative conditioning was administered in five and reduced intensity therapy in two cases. The number of transplanted $CD34^+$ cells ranged 2 -8×10^6 per kg (median 4,53×10^6). Leukocyte recovery was observed 9 to 22 days after BMT (median 18 days). Life-threatening, resistant to any antimicrobial treatment infections, present before the transplant procedure, affected four children (57% of transplants). Among them, Staphylococcus epidermidis MRSE MLS was found causing the recurrent sepsis in the child with Omenn syndrome and as the persistent soft tissue infection in the child with CGD. Therapy resistant CMV disease affected two boys: with Omenn syndrome and CGD. Aspergillus flavus caused chronic sinusitis in the girl with CGD. The boy with hiper-IgM syndrome suffered from chronic progressive cholangitis and hepatitis due to Cryptosporidium parvum. In two children with CGD the therapy resistant granulomas in liver and in soft tissue was observed. The therapeutic strategy after BMT for these infections was the application of the antimicrobial drugs together with maintenance of the high serum concentation of immunoglobulins and intensive supportive care until the time of immune recovery and self-ability to eliminate the pathogen. The blood stream MRSE infection was eliminated after leukocyte recovery in the 9th day after BMT. The soft tissue granulomas resolved three weeks after BMT, while normal values of chemiluminescence and NBT tests were found on 28th day. Resistant CMV infection in Omenn child was not detectable in the 78th day, contemporary to T-cell repertoire recovery. Aspergillus sinusitis declined in several weeks after transplant, with the normal granulocyte function score on the day 49th. Cryptosporidium parvum was absent in affected patient in the 131st day, when the immunoglobulin class switching was found sufficient. The granuloma in the liver of one boy with CGD resolved in two months, in the other boy granulomas in his liver decreased during three months after BMT. Until now five children achieved the good physical condition, without symptoms of the primary immunodeficiency. One boy is treated for chronic graft *vs.* host disease. *Conclusions.* 1. The specific feature of transplantation in children with severe primary immunodeficiences were the infections resistant to antimicrobial therapy, found before BMT (4 children, 57%). 2. Antimicrobial agents with the maintenance of high immunoglobulin concentration and proper supportive care until the time of immune recovery was the effective treatment of the severe, resistant, opportunistic infections.

1669

EFFECTS OF COMBINED APPLICATION RECOMBINANT HUMAN ERYTHROPOIETIN (RHU-EPO) AND GRANULOCYTE COLONY STIMULATING FACTOR (G-CSF) ON HAEMOPOIETIC RECOVERY AFTER HIGH DOSE CHEMOTHERAPY WITH ALLOGENIC STEM CELL TRANSPLANTATION

H Kuzmich,[1] V Zmachinski,[1] N Novoselova[2]

[1]Research Institute of Hematology, Minsk, Belarus, Republic of; [2]United Institute of Informatics Problems, Minsk, Belarus, Republic of

From 1994 to 2006 years in Belarussian Research Institute of Haematology 79 patients(42 male, 37 female) with different diagnoses(chronic myeloid leukemia-38, acute myeloid leukemia-10, acute lymphocytic leukemia-7, aplastic anemia-21, multiple myeloma-1, myelofibrosis-1, acute promyelocytic leukemia-1) have been treated by method high dose chemotherapy (HDC) with allogenic stem cell transplantation (SCT).Median age was 30,6 years (range 11-50). All patients have been

divided into 3 groups. The first group (n=33) did not receive any haemopoietic growth factors, the second group (n=34)-received granulocyte colony stimulating factor (G-CSF) (300mkg per day), the third group (n=12) was treated with combination of recombinant human erythropoietin (rHu-EPO) and granulocyte colony stimulating factor (G-CSF). Criteria of haemopoesis restoration after allogenic SCT were following: Hb>90 g/L, erythrocytes > $3,0\times10^{12}$/L leukocytes >$1,0\times10^{9}$/L, neutrofiles>$0,5\times10^{9}$/L, thrombocytes > $20,0\times10^{9}$/L. For comparison of efficiency of haematologic recovery in investigated groups used day of achievement specified above indicators of peripheral blood after allogenic SCT. *Results.* Time of Hb restoration in group of patients received rHu-EPO+G-CSF was 13,8+9,7 *vs.* 20,2+9,8 in group G-CSF (P=0,06) and 22,2+9,1 in group without CSF (P=0,01). Time of erythrocytes restoration in group rHu-EPO+G-CSF was 12,6+9,3 *vs.* 20,8+10,1 in group G-CSF (P=0,017) and 20,8+10,0 in group without CSF (P=0,016). Time of leukocytes restoration in group rHu-EPO+G-CSF was 15,2+5,4 *vs.* 19,6+6,3 in group G-CSF (P=0,03) and 18,8+5,7 in group without CSF (P=0,07). Time of neutrofiles restoration in group received rHu-EPO+G-CSF was 13,3+4,6 *vs.* 19,0+7,3 in group G-CSF (P=0,016) and 19,1+5,5 in group without CSF (P=0,002). Time of thrombocytes restoration didn't have statistical distinctions. *Conclusion.* Time of restoration of Hb, erythrocytes, leukocytes and neutrofiles in group of the patients received rHu-EPO + G-CSF, was both shorter, than in groups G-CSF and with no CSF. This result shows that combined application of rHu-EPO and G-CSF in early posttransplant period is most favorable for the acceleration of restoration of specified above peripheral blood indicators.

CMV INFECTION AND DISEASE IN PEDIATRIC HEMATOPOIETIC STEM CELL TRANSPLANTATION, EXPERIENCE OF ONE CENTRE

M Sedky,[1] Y Mekki,[2] M BenChaib,[3] N Bleyzac,[4] V Mialou,[5] F Najioullah,[2] Y Bertrand[6]

[1]Children Cancer Hospital Egypt, Cairo, Egypt; [2]Virology Department, Lyon University, Lyon, France; [3]Reproduction Department, Lyon University, Lyon, France; [4]Hopital Debrousse, Universite de Lyon, Lyon, France; [5]Pediatric Hematology Department, Hopital Debrousse, Lyon University, Lyon, France; [6]Pediatric hematology department, Hopital Debrousse, Lyon University, Lyon, France

Background. Cytomegalovirus (CMV) infection remains an important cause of morbidity and mortality in allogeneic hematopoietic stem cell transplantation (Allo-HSCT). Acyclovir prophylaxis, CMV monitoring by RT PCR and preemptive antiviral drugs declined remarkably the incidence of infection and subsequently of disease. However we are still confronted by pejorative prognostic factors that favour CMV infection, recurrence, resistance and disease. *Aims.* To evaluate retrospectively the magnitude of CMV problem and various prognostic factors in one pediatric HSCT centre. *Methods.* In the period between 9/2000 and 6/2007, 81 children having the following recipient (R) / donor (D) pair CMV serostatus: (R^-/D^+) or (R^+/D^-) or (R^+/D^+) were subjected to Allo-HSCT at Debrousse Hospital, Lyon University. All patients received herpes prophylactic acyclovir or native. CMV was monitored by RT-PCR starting from the 1st week post transplant. Ganciclovir (GNC) or Foscavir (FSC) was used mainly as preemptive and curative treatment. *Results.* Out of 81transplants, 40 patients presented CMV infection and 10 CMV disease. The median CMV onset of infection was 39 days post transplant (2 to 68). The mean DNA copies magnitude was 19986(<500-1580000). Of those 40 infected patients, 14 resolved spontaneously and 26 received preemptive antiviral: GNC n=21 (resolution n=16 and resistance n=5) and FSC n= 5 all resisting. Of those resolving CMV DNA copies, 8 patients showed recurrence. The median duration before infection negativity was 125 days (7-625). It shows that 15% of infected patients reached more than 600 days of infection. Six of the 10 diseased patients were cured and the rest died of CMV disease progression. In univariate analysis progressing DNA copies (cDNA) from <500 to positive >500 were responsible of recurrence p0.027, resistance p0.003 and disease p0.007. In multivariate analysis, CMV infection occurred, more significantly with associated (R^+/D^-) pair p0.01, high dose corticosteroids more than 2 mg/kg p0.006, Anti thymocyte globulin (ATG) p0.002 and non bone marrow stem cell source p0.02. Both (R^+/D^-) pair p0.005 and non geno-identical transplant p0.05 were responsible for increased CMV resistance. *Conclusions.* Preemptive treatment should be started at minimal CMV documentation <500 cDNA to prevent recurrence and resistance. CMV positive recipient are better transplanted from positive donor. Prolonged immune suppression should be avoided. Early positive RT PCR CMV in first week post transplant should raise the question about the real source of infection either the donor or recipient.

1671

SEVERE NEUROTOXICITY ASSOCIATED WITH DIMETHYL SULPHOXIDE FOLLOWING PERIPHERAL BLOOD STEM CELL TRANSPLANTATION

D Stamatovic, L Tukic, M Elez, B Balint, O Tarabar, Z Tatomirovic, S Marjanovic

Military Medical Academy, Belgrade, Serbia

Dimethyl sulphoxide (DMSO) is used as a cryoprotectant for long-term storage of hematopoietic stem cells (HSC) from the marrow or blood. Various complications during infusion of cryopreserved HSC have been described as nausea, vomiting, transient hypertension or hypotension and anaphylaxis. Until recently, there has been little information on the neurological toxicity of DMSO. DMSO-related neurotoxicity, including transient global amnesia, cerebral infarction, migrene, seizures, encephalopathy and even coma, has been described, mostly as anecdotic events.We are reporting 3 cases of DMSO-related severe, transient neurotoxicity out of 223 autologous peripheral blood stem cell transplantation (PBSCT) performed in our center between 2000.-2009. All patients (pts) - 2 males, 1 female, 51, 59 and 39 years old, have stage III of multiple myeloma. The first-line therapy for all pts was Dexamethasone - based regimen (VAD or D-CEP). A PBSC collection was performed with Cyclophosphamide (4g/m^2) and rhG-CSF (5 μg/kg/day) and optimal numbers of mononuclear cells (MNC- median 8×10^8/kgBW) were harvested. The cells were cryopreserved on 10% DMSO using a controlled-rate freezer and stored at -900C. The final volume cryopreserved was 450-480ml (5-6 bags). After PBSC collection pts underwent autologous PBSCT. The conditioning regimen consisted of Melphalan at a dose 200 mg/m^2. The bags were thawed in a 37o water bath and infused at a rate of 10 mL/min. On day "0" pts were premedicated with Diphenhydramine and Methylprednisolone (1 mg/kgBW). After the infusion of the last bag all pts were developed a complete loss of consciousness accompanied by incontinence, without clonic convulsions or focal neurological sings. Pulse rate and blood pressure were normal. The pts were transferred to intensive care unit (ICU) for ventilation. No laboratory abnormalities, including electrolytes, osmolarity, coagulation screen, serum glucose and enzymes, were evidenced upon repeated testing. Pts were treated with steroids and forced hydration. The urgent CT scan was unremarkable. All pts recovered consciousness in 3-5h after assistance ventilation was started. Finally, they were extubated within 24h and discharged from ICU on day +1. All pts have optimal engraftment.Because of the strict temporal relationship between the infusion and development of neurological sings and their resolution upon forced hydration, we circumstantially attribute the encephalopathy to the infusion of DMSO-contained in the PBSC suspension. The risk-factors for development of DMSO-neurotoxicity are still unclear. The preconditioning exposure to central nervous system (CNS)-penetrating agents and M protein in multiple myeloma pts might contribute to the occurrence of DMSO -associated neurological toxicity, but a large analyzes are needed.

1672

HIGH-DOSE CYCLOPHOSPHAMIDE, ETOPOSIDE AND BCNU WITH NON-CRYOPRESERVED AUTOLOGOUS HAEMATOPOIETIC STEM CELL TRANSPLANTATION FOR POOR PROGNOSIS HODGKIN'S LYMPHOMA

M Brahimi,[1] N Yafour,[1] S Osmani,[1] F Attaf,[2] H Tadj,[2] A Arabi,[2] B Enta Soltan,[2] H Berredouane,[1] B Benzineb,[2] M Bey,[1] N Bahlat,[2] MA Bekadja[1]

[1]University Hospital Of Oran 1st November, Oran, Algeria; [2]University Hospital of Oran 1st November, Oran, Algeria

Background and aim. Several high dose chemotherapy regimens have been used in autologous transplants for Hodgkin's lymphomas (HL). Most of these high-dose therapy schedules were designed to deliver cytotoxic drugs over a number of days [e.g. 6 days for BEAM, CBV or ICE], freezing of the harvest product was traditionally carried out to maintain cell viability until stem-cell reinfusion. Unfortunately cryopresevation unities are not available in many developing countries so the liquid storage of harvested stem cells, in standard blood refrigerators, is an alternative to cryopreservation. The aim of this study is to demonstrate the feasibility and safety of autotransplants with noncryopreserved peripheral blood stem cells. *Methods.* 10 patients with poor prognosis malignant Hodgkin's lymphoma were treated with high-dose cyclophosphamide (120 mg/kg), etoposide (2100 mg/m^2) and BCNU (400 mg/m^2) followed by reinfusion of autologous non-frozen PSC, which had been stored for 72 hours at 4°C. *Results.* The median time to achieve an absolute neutrophil count greater than 0.5×10^9/L was 13

days (range 11-20 days). The median time to self-sustained platelet count greater than 20×10^9/L was 20 days (range 15-30 days). Eight of the 10 patients are still alive and disease free and one patient died of severe infection. *Conclusion.* We conclude that high-dose chemotherapy with non-frozen autologous bone marrow transplantation is safe in terms of haematopoietic reconstitution and the preliminary follow-up data suggest a useful efficacy. The procedure is easy to perform without requiring costly cryopreservation.

1673

THE APPLICATION OF INTRA-ARTERIAL STEROID IN ACUTE STEROID RESISTANT GASTROINTESTINAL GRAFT VERSUS HOST DISEASE (GVHD)

S Dagdas,[1] G Özet,[1] F Ceran,[1] Ü Üre,[2] G Tokgöz,[1] M Alaguney,[2] M Kaplan,[2] M Attepe[2]

[1]Ankara Numune Education and Research Hospital, Ankara, Turkey; [2]Numune Education and Research Hospital, Ankara, Turkey

Acute graft *vs.* host disease (GVHD) is a major complication of allogeneic bone marrow transplantation and leads to death for most of the patients with resistance to steroid. Application of topical steroid regimens for resistant acute gastrointestinal GVHD allows high doses of steroid to reach the region and overcome resistence which is caused by the decrease of the number and affinity of intestinal steroid receptors. In our clinic, we gave intraarterial steroid infusion treatment of to two patients that we followed for grade 4 acute steroid resistant gastrointestinal GVHD. One of them was a 30 year-old female patient with ALL, and the other was a 34 year-old male patient with AML. Both of the patients were transplanted from full match sibling donors after a preparation regimen with Busulfan and Cyclophosphamide. 3 months after the transplantation, both of the patients developed grade 4 acut gastrointestinal GVHD. And both of them did not respond to 2 mg/kg/day iv prednisolon therapy. The female patient with ALL did not respond to the secondary treatment with ATG and infliximab either. The male with ALL did not have any secondary systemic treatment. 1 mg/kg metilprednisolon infusion to the inferior and superior mesenteric arteries was performed for both of the patients by using angiografi. No complication related to the procedure occurred. And in the following 2 days the frequency of diarrhea decreased and after 3-4 days it dissappeared completely. We believe that the use of intraarterial steroid is easy, safe and efficient for the treatment of acute iv steroid resistent gastrointestinal GVHD.

1674

IMPLICATION OF EARLY LYMPHOCYTE RECOVERY AFTER ALLOGENEIC STEM CELL TRANSPLANTATION IN CHILDREN WITH LEUKEMIA

H Kook, DK Han, SY Kim, HJ Baek, SJ Park, HJ Kim, TJ Hwang

Chonnam National University Hwasun Hospital, Hwasun, South-Korea

Background. The repopulating lymphocytes after allogeneic hematopoietic stem cell transplantation (HSCT) have an important role not only on the prevention of serious infections in the early transplantation period, but on killing the residual leukemic cells by graft-versus-leukemia effect. Previous studies have suggested that earlier lymphocyte recovery after HSCT was associated with a lower relapse and a better survival in adult patients. *Aims.* The aim of this study was to analyze the impact of lymphocyte recovery after HSCT in children with hematologic malignancies. *Methods.* We retrospectively evaluated 69 children transplanted for ALL (n=34), AML (n=26), chronic leukemia (n=7) and juvenile myelomonocytic leukemia (n=2) at the Chonnam National University Hospital. Stem cell sources were: BM (n=46), PBSC (n=10), umbilical cord blood (n = 12), and BM + PBSC (n=1). Matched sibling donor was used in 26, while unrelated donors in 43. The patients were grouped based on absolute lymphocyte count (ALC) <500/μL or ≥500/μL at D+21 and D+30 after transplant: Low at D+21 (n=28) *vs.* High at D+21 (n=41); Low at D+30 (n=19) *vs.* High at D+30 (n=49). The impact of lymphocyte recovery after HSCT on predicting the survival, relapse, transplant-related mortality (TRM), and graft *vs.* host disease (GVHD) was retrospectively analyzed. *Results.* The median age at transplant was 7.1 years (range, 0.4-18.2). Patients with High ALC at D+21 and D+30 had faster neutrophil and platelet engraftment: The median day of neutrophil engraftment (>1,000/μL) was D+16 for High at D+21 *vs.* D+21 for Low at D+21 (P=.001); and D+17 for High at D+30 *vs.* D+20 for Low at D+30 (P=.02), respectively; The median time of platelet engraftment (>20,000/μL) was D+19 for High at D+21 *vs.* D+38 for Low at D+21 (P=.04); and D+22 for High at D+30 *vs.* D+40 for Low at D+30 (P=.07), respectively. The High at D+30 group exhibited a better 5 year overall survival (71% *vs.* 53%, P=.043) and event free survival (72% *vs.* 53%, P =.065) than Low at D+30 group. The incidence of grade II-IV aGVHD and cGVHD was not different by the ALC counts. Also relapse rate was not different between ALC groups. But the Low at D+30 group was associated with a significantly increased risk of TRM (P=.019). In univariate analysis, factors associated with decreased survival were Low ALC at D+30 and high risk in ALL patients, and grade II-IV aGVHD in both ALL and AML. Grade II-IV aGVHD was the only variable with a significantly negative impact on survival by multivariate Cox regression analysis. *Conclusion.* We found that earlier lymphocyte recovery greater than 500/μL on D+30 was associated with faster neutrophil and platelet engraftment, decreased TRM, and better survival without increasing the incidence of GVHD. However, faster lymphocyte recovery was not translated into decreased relapse rate. Serial lymphocyte measurement early posttransplant would be a simple but useful method for predicting transplant outcomes. Further studies incorporating larger number of cases and longer follow-up are warranted in children.

1675

CAN SERUM LACTATE DEHYDROGENASE ENZYME LEVEL BE AN EARLY MARKER OF MYELOID ENGRAFTMENT IN RECIPIENTS OF HEMATOPOIETIC STEM CELL TRANSPLANTATION?

AE Kurekci, O Gursel, A Atay, D Altun, I Aydin, T Cayci

Gulhane Military Medical Academy, Ankara, Turkey

Background. Lactic Dehydrogenase (LDH) is an intracytoplasmic enzyme, which catalyzes the transformation of pyruvate into lactate and it is reported that serum LDH levels can increase in parallel to the maturation of myeloid progenitors in the bone marrow and the increase of neutorphils in the periferal blood. *Aims.* In the present study, the relationship between myeloid engraftment time and serum LDH enzyme levels in patients, who underwent hematopoietic stem cell transplantation (HSCT) was studied. *Methods.* The whole blood parameters and serum LDH, ALP, GGT, AST and ALT analyses of 25 patients, 24 of whom underwent allogeneic and 1 autologous HSCT were studied thrice weekly. The parameters on the onset of preparation regimen, the day, in which the product infusion was peformed, 5 days before myeloid engraftment, the day of myeloid engraftment and 5 days after engraftment were evaluated and statistically analysed. The study was approved by the local ethics committee. *Results.* Allogeneic HSCT were performed on 25 patients aging between 7 months and 15 years. The AST, ALT and GGT levels of 3 cases were high before transplantation and remained high throughout the transplantation period. The other patients did not have any illness, which could cause high levels of LDH and G-CSF was not used in any patient. No statistically significant difference was present between the LDH levels on the onset of preparation regimen and on the infusion day (median 343 IU/L *vs.* 374 IU/L, P>0,05). It was detected that the LDH levels on 5 days before myeloid engraftment started to increase with statistical significance (median 374 IU/L *vs.* 433 IU/L, P<0.001), and that this increase continued on engraftment day and 5 days after engraftment and that there were no statistically significant difference between the levels on 5 days before engraftment, the day of engraftment and 5 days after engraftment (median 433 IU/L *vs.* 456 IU/L *vs.* 471 IU/L, P>0,05). It was also detected that the results were similar in the evaluation of cases with no elevation of transaminase levels and that LDH enzyme levels were not affected by high levels of transaminases. *Discussion.* LDH is widespread present in many tissues of the body including neutrophils. It is demonstrated that serum LDH levels begin to increase with the increase of neutrophils in patients whom were applied G-CSF because of myeloid aplasia due to chemotherapy and this incerase is shown to originate from neutrophils. But there is no study, which examined the relationship between myeloid engraftment and LDH in patients, whom were applied HSCT. In the present study, it was detected that serum LDH levels begin to increase 5 days before myeloid engraftment It can be suggested that this increase in LDH levels might be related to the increase of myelopoiesis in the bone marrow. In conclusion, the sequential follow up of serum LDH levels in patients undergoing HSCT and the detection of the period of increase in enzyme levels can herald subsequent engraftment.

1676

MOBILIZATION AND HARVESTING OF PERIFERAL BLOOD STEM CELL WITH INTERMEDIATE DOSE ARA-C IN A PREVIOUS POOR MOBILIZER HAEMATOLOGIC MALIGNANCIES PATIENTS

PR Scalzulli,[1] G D'Arena,[2] M Dell'Olio,[2] L Melillo,[2] A Falcone,[2] G Sanpaolo,[2] G Fania,[3] N Dello Iacono,[3] P Marchesani,[3] A Giacobazzi,[4] A Guarini,[4] MR Valvano,[1] D Valente,[2] L Di Mauro,[3] N Cascavilla[2]

[1]IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy; [2]Haematology Unit IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy; [3]Tansfusional Service-IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy; [4]Hematology Unit IRCCS Ospedale Oncologico, Bari, Italy

Background. The inability to mobilize sufficient number of HSC are a significant clinical problem for relapsed/refractory hematologic malignancies patients eligible to receive high-dose chemotherapy and autologous stem cell transplant. Several lines of treatments, use of alchilating agents, cisplatin and fludarabine, are all factors adversely affecting PBPCs mobilitation. *Aims.* In this study we assessed the efficacy and safety of intermediate dose ARA-C given to mobilize PBSCs. *Patients and methods.* Thirty-six patients (23 M; 13 F; median age 61 yrs; range (26-70) with hematologic malignancies: 17 non-Hodgkin's lymphoma (NHL), 1 Hodgkin's Disease (HD), 15 multiple myeloma (MM) and 3 LAM, di cui 1 have failed a previous attempt between January 2007 and May 2009, were scheduled to receive intermediate dose ARA-C to mobilize PBSCs. *Methods.* Patients were primed using intermediate dose of ARA-C administered intravenously at a dose of 800 mg/m^2 every 12 h for 6 consecutive doses, + rhG-CSF 5 or 10 microgr/Kg subcutaneously. *Results.* A median of 3 chemotherapeutic regimens (range 2-7) were previously given and all patients failed prior harvesting of PBSCs. Three patients with MM were given two consecutive autotransplants with Melphalan 200 mg/mq as conditioning regimen. One patient with NHL received 4 cycles of chemotherapy, one patient underwent Bone Marrow Autotransplant and 2 cycles of Ibritumomab Tiuxetan (Zevalin®). Collection of PBSCs was successfull in 34 out of 36 patients (94%) (17 NHL, 1 HD, 13 MM and 3 LAM). Two patients with MM were no mobilizers with intermediate dose of ARA-C also (one of them received two consecutive autologous PBSC while one other showed a refractory disease at the time of mobilization). Harvesting of PBSCs was performed at a median time of 13.2 days (range 7-17 days) after ARA-C administration. The median number of subcutaneous injections of rhG-CSF was 6 (range 4-13). The median number of WBC count was 4200/mmc (range 1400-15000) at the time of collection with CD34$^+$ median number of 1.8 % (range 0.3-6.2). Among the 34 patients who mobilized, in only two cases the required number of CD34$^+$ cells were harvested after two leukapheresis. The median number of CD34 $^+$ cells collected was 7×10^6/Kg (range 2.04-27,7) with 4 as a median number of cryopreserved bags (range 2-8). All patients experienced neutropenia < 500/microL, and 13 out of 34 had febbrile neutropenia (1 to 4 days). Nineteen patients received a median of 1 packed red cell transfusions (range 1-3) and 30 patients a median of 1 apheretic platelet products (range 1-3). No patients experienced WHO grade III-IV mucositis and diarrhoea. *Results.* These data indicate that mobilization and collection of PBSC strongly depend on the type of chemotherapeutic regimen used. Our experience, showed that PBSC collection using intermediate-dose of ARA-C + rhG-CSF is safe and effective in poor mobilize patients with haematologic malignancies. Mobilization and collection of PBPCs were found independent from the number and type of previous chemotherapies. Indeed it is surprising that mobilization was also achieved in the patient with LNH who received several chemotherapies, Bone Marrow Autotransplant and two cycles of Zevalin®.

1677

ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANTATION (AHSCT) FOR MYELOFIBROSIS RESULTED IN DISAPPEARANCE OF CONSTITUTIONAL SYMPTOMS, REDUCTION OF SPLEEN SIZE AND DECLINE OF THE JAK2V617F ALLELE RATIO

A Wieczorkiewicz, G Helbig, M Markiewicz, T Kruzel, K Wozniczka, S Kyrcz-Krzemien

Silesian Medical University, Katowice, Poland

Background. Allogeneic hematopoietic stem cell transplantation (AHSCT) remains the only curative therapeutic option for primary myelofibrosis (PMF) however its wide use is limited by high rate of transplant-related mortality. We have reported the preliminary results of AHSCT preceded by reduced-intensity conditioning (RIC) for patients with PMF. *Design and methods.* Six patients (3F/3M) with a median age at transplant of 40 years (range 28-51 yrs) were transplanted between 2008 and 2010. The diagnoses were following: PMF (n=4), post-thrombocythemic myelofibrosis (n=1) and post-polycythemic myelofibrosis (n=1). A median spleen size was 18.4 cm (range16-19cm). The constitutional symptoms including cachexia, weakness, weight loss were present in all studied patients. Risk profile according the Lille score was low in 1 patient and intermediate in the remaining 5. 17% of transplanted patients had an intermediate-1 IPSS, 50% -intermediate-2 and 33%- high IPSS. The JAK2V617F mutation analysis was performed using commercially available test MutaScreen (Ipsogen). The JAK2V617 point mutation was detectable in 4 patients. A median JAK2 allele ratio was 26.5% (range 25-90%). *Results.* Before transplant from sibling (4/6) or unrelated donors (2/6), all patients received reduced-intensity conditioning consisting of fludarabine, busulfan and anti-thymocyte globulin. The source of stem cells was as follows: marrow and peripheral blood in 3 patients and only peripheral blood in 3. The median number of transplanted CD34$^+$ cells per kilogram of body weight was 6.03×10^6/L (range 3.7-10.8×10^6/L). The median time to leukocyte engraftment (absolute neutrophil count >0.5×10^9/L) was 18 days (range 15-24 days), and the median time to platelet engraftment (>20×10^9/L) was 25.5 days (range 14-31 days). Two patients eradicated JAK2V617F clone after transplant and 2 patients significantly reduced JAK2 allele levels. The enlarged spleen returned to normal size in all patients within 2 months after transplant together with constitutional symptoms disappearance. Acute graft-versus-host disease was observed in 4 patients and chronic graft-versus-host disease occurred in 3 patients. One patient died 7 months after AHSCT due to infectious complications. The median follow-up after transplant is 7.5 months (range 1-20). *Conclusions.* RIC before AHSCT resulted in high engraftment rate and low transplant-related mortality. This procedure seems to be safe and highly effective.

1678

THE ROLE OF STEM CELL TRANSPLANTATION FOR PEDIATRIC SOLID TUMORS - SINGLE CENTER EXPERIENCE

A Colita,[1] C Arion,[1] L Dumitrache,[2] A Tanase,[2] Z Varady,[2] A Dumitrescu,[2] T Puscariu,[2] C Calugaroiu,[2] C Dobrea,[1] C Ghita,[2] T Puscariu[2]

[1]Carol Davila University of Medicine, Bucharest, Romania; [2]Fundeni Institute, Bucharest, Romania

Background. Ewing's sarcoma (ES), neuroblastoma (NB) and germinal cell tumors (GCT) are rare solid tumors in children and adolescents with low survival rates in cases with advanced disease. The role, the type and the indication of high dose chemotherapy, in the complex treatment of these diseases isn't well established. *Aim.* to evaluate retrospectively the impact of high-dose chemotherapy on outcome of pediatric solid tumors patients. *Methods.* 8 patients transplanted in our center between 2003-2009 were included in this analysis: 4 with ES, 3 with NB, 1 with germinal cell tumor. The patients with ES received chemotherapy according to EWS 97 protocol followed by autologous stem cell transplantation (ASCT) with BuMel (Busulfan, melphalan) conditioning in 2 cases, MEC (melphalan, etoposide, carboplatin) conditioning in 1 case and tandem ME (melphalan, etoposide) in one case. The patients with NB received COJEC protocol followed by ASCT with MEC conditioning. All patients received radiotherapy after ASCT. The patient with germinal cell tumor (yolk sac) received 4 courses of BEP (bleomicyn, etoposide, cisplatinum) + 3 courses of ICE (ifosfamide, carbiplatin and etoposide) followed by tandem autologous transplantation with carboplatine - etoposide conditioning. *Results.* the patients with ES were 4 girls with 9, 13, 14 and 18 y diagnosed with ES metastatic disease in 3 cases and localized disease in one case. The graft was obtained after mobilization with ciclofosfamide and G-CSF and contained 3-18×10^6 CD34/Kg. The patients with NB were 2 boys and 1 girl with 4, 5 and 9 y at diagnosis. The graft was obtained after the last course of chemotherapy contained 1,3-5×10^6 CD34/kg. The patient with metastatic germinal cell tumor was a 19 y old boy. The graft obtained after a ICE course contained 7×10^6 CD34/Kg. All patients engrafted after 9-12 days without severe infectious or hemorrhagic complications. The transplant mortality rate (TMR) was 0%. We analyzed the treatment response according to the status of disease at transplantation: localized *vs.* metastatic disease. After ASCT the ES patient with localized disease remained in CR at 5y; 2 patients with ES metastatic disease obtained CR after ASCT, but one relapsed after 9 months; the other ES patient with metatstaic disease never obtained CR, but remained in stable disease 2 y after transplantation. All three NB patients obtained the CR

after ASCT, but relapsed after a median of 12 months. The patient with germinal cell tumor also obtained CR after transplnatation. *Conclusion.* ASCT is a safe procedure, with 0% TMR. The procedure is effective for patients with ES and localized disease before transplantation; in case of NB, the ASCT allows a longer overall survival, without effect on event free survival.

1679

PLERIXAFOR IS EFFECTIVE AND SAFE FOR STEM CELL MOBILIZATION IN HEAVILY PRETREATED GERM CELL TUMOR PATIENTS

S Kobold,[1] J Isernhagen,[2] K Hübel,[3] N Kilic,[2] C Bogner,[4] N Frickhofen,[5] C Bokemeyer,[2] W Fiedler[2]

[1]Ludwigs-Maximilian-University, München, Germany; [2]University medical center Hamburg Eppendorf, Department of Oncology, Hematology, Hamburg, Germany; [3]Department I of Internal Medicine, University Hospital of Cologne, Cologne, Germany; [4,3]rd Department of Medicine, Hematology and Oncology, Technical University, Munich, Germany; [5]Department of Internal Medicine III, HSK Wiesbaden, Wiesbaden, Germany

Background. Up to 10% of germ cell tumor patients require salvage high dose chemotherapy with stem cell support achieving cure rates in the range of 25-60%. Stem cell mobilization may be difficult in these patients due to multiple pretreatments with platin-containing therapies known to seriously hamper stem cell recovery. New strategies to enhance stem cell mobilization are needed for such patients. Recently, Plerixafor has been approved by the FDA and EMEA in combination with G-CSF for stem cell mobilization in patients with multiple myeloma or lymphoma. Plerixafor significantly enhanced the success of the $CD34^+$ cell harvest, even in cases in which prior mobilization attempts have failed. As the mechanism of action of Plerixafor is not disease specific, we utilized Plerixafor off-label in 6 germ cell cancer patients, refractory to G-CSF alone or in combination with chemotherapy for stem cell mobilisation. *Aims.* Assess efficacy of Plerixafor in germ cell tumor patients who were not able to adequately mobilize $CD\ 34^+$ cells for subsequent autologous stem cell transplantation. *Results.* Six germ cell tumor patients provided informed consent and were included in the compassionate use program at three different specialized centers. All patients were heavily pretreated, with a median of 3.33 prior therapies (Δ 1-6). All failed prior mobilization with G-CSF alone or in combination with chemotherapy. Five patients successfully harvested a median of 7.55×10^6 CD34 + cells/kg body weight (Δ 2.0-24.79×106) in a median of 3.6 apheresis days (Δ 2-6). Three patients underwent high dose chemotherapy with autologous stem cell support. Median time to leukocyte engraftment was 10 days (Δ 8-12) Median time to platelet engraftment was 12 days (Δ 12-13). One patient failed platelet engraftment. No Plerixafor related side effects were reported. *Conclusion.* Plerixafor is safe and effective in germ cell tumor patients who have failed prior mobilization therapy. Larger prospective studies are warranted to further assess its application.

TREATMENT OF SECONDARY PROGRESSIVE MULTIPLE SCLEROSIS WITH AUTOLOGOUS STEM CELL TRANSPLANTATION

M Elez,[1] D Stamatovic,[2] L Tukic,[1] O Tarabar,[1] B Balint,[1] D Obradovic,[1] V Skuletic,[1] S Marjanovic[1]

[1]Military Medical Academy, Belgrade, Serbia; [2]Clinic of Hematology, Belgrade, Serbia

Introduction. High dose chemotherapy followed with autologous stem cell transplantation (ASCT) has been proposed in the last few years as a potential treatment option for patients (pts) with secondary progressive multiple sclerosis (MS). *Aim.* We analyze retrospectively small cohort of pts with secondary progressive MS treated with ASCT within ESTIMS trial. *Methods.* Since 2005. five pts with secondary progressive MS, who have failed to several lines of therapies (Interferon beta, Mitoxantrone...) was treated in our center with ASCT. Median age was 31 (21-52), male/ female 4/1, baseline median disability status scale (EDSS) of 6,0 (3,5-9,0). All of them were mobilized with Cyclophosphamide 4 g/m^2 and G-CSF 10 microg/kgTT and in all cases conditioning was up to standard BEAM regimen with addition of ATG. EDSS was estimated 3, 6, 9 and 12 months after the procedure. *Results.* With the median follow up of 21 months (10-55), 1 pt (20%) remained stable without new lesions on MRI and other 4 (80%) have showed improvement according to EDSS by at least 0,5 points. Also, there were no transplant related mortality and engraftment was observed in each case of this small group of pts. *Conclusion.* This modest retrospective analysis shows benefit of autologous SCT in pts with secondary progessive multiple sclerosis. Larger number and adequate pts selection with longer follow up is necessary for more valid estimation of efficacy and safety of this therapy option.

1681

IS THERE POSSIBILITY TO IMPROVE TREATMENT OF REFRACTORY CHRONIC EXTENSIVE GAFT VERUS HOST DISEASE

M Elez,[1] D Stamatovic,[2] L Tukic,[1] O Tarabar,[1] B Balint,[1] O Tasic-Radic,[1] V Skuletic,[1] S Marjanovic,[1] M Malesevic[1]

[1]Military Medical Academy, Belgrade, Serbia; [2]Clinic of Hematology, Belgrade, Serbia

Introduction. Chronic graft *vs.* host disease (cGvHD) is main determination of long term outcome after transplantation. Similarities in the clinical features with several autoimmune diseases are due to B lymphocyte (B-Ly) disregulation (caused by Th2 cytokines produced by CD4+ donor cells) which is responsible for abnormal production of various auto antibodies. Bad response of cGvHD to different immunosuppressives and fact that chimeric monoclonal anti CD20 antibody (MOAB) induces "*in vivo* depletion" of B-Ly makes this agent interesting as attempt to control refractory cGvHD. *Objective.* Estimating efficacy and safety of MOAB in the therapy of extensive cGvHD refractory to previous treatment approaches. *Methods.* 6 patients (pts) have received MOAB after failure of standard treatment (Methylprednisolone-MPDN, Cyclosporine A- CsA, Mycophenolate mofetil- MMF, Azathioprim- AZA, PUVA[3DOTS]) Pts characteristics were 4 males/ 2 females, median age was 29 years (18-49). Concerning primary diseases 2 of them had ALL, 3 AML and 1 hypoplastic MDS. All of them have received HLA identical sibling transplant with stem cells from peripheral blood in 4 and bone marrow in 2 cases. Despite GvHD prophylaxis with CsA, Methotrexate and MPDN, 4 of them had acute GvHD grade 1-2 and all of them had extensive cGvHD with lichenoid, sclerodermic or pemphyoid skin involvement, oral mucositis and sicca syndrome. Extracutaneous manifestation included lung in 4, liver in 3 and thrombocytopenia in 3 cases. One pt had CMV infection prior to exacerbation of cGvHD. We applied MOAB in recommended regimen (375 mg/m^2 weekly for 4 weeks). *Results.* Exact responses were measured with Schirmer test, spirometry, liver function parameters and hematological findings and response was observed in 5 pts (83,3%) even after first application. It seems that best results were achieved in skin and mucosal improvement (significant reducing of sicca syndrome, improvement of skin turgor and reconstitution of lichenoid and pemphigoid changes). Lung and liver function were improved but it should be mentioned that other immunosuppressants were also given (particularly MMF and AZA). Two pts had severe infectious complication, one of them have died from sepsis after second application, and other developed abcessus pulmonalis in fourth week of treatment. *Conclusion.* Our preliminary data suggests that MOAB in treatment of extensive refractory cGvHD is encouring but needs more investigation at larger number of pts.

1682

SOCIAL BENEFIT IMPROVING ACCESS TO AUTOLOGUS TRANSPLANTATION WITH HEMATOPOIETIC STEM CELL: THE EXPERIENCE OF ONCOLOGY DEPARTMENT OF LECCO (ITALY)

P Ferrando

Hospital Manzoni, Lecco, Italy

Background. HSC harvest and storage are not widely available in all hospitals and patients are usually referred to large Hematology Department often located in large cities far from their homes with a significant distress for patients and their families although high dose chemotherapy (HDC) with HSC rescue has definite indications in hematologic malignancies. *Aims.* Considering that the hematologic malignancies range at Lecco's hospital has registered twice as much the number of cases in the last years, it appears more and more important for citizens from Lecco to undergo the HDC with HSC rescue at their local hospital without being obliged to reach hospitals too far from their homes. *Methods.* Oncology Department of Lecco in collaboration with the Haematology Unit of Niguarda Hospital in Milan started a cooperative protocol of HDC-HSC rescue intending to offer these procedures to patients living in Lecco with multiple myeloma (MM) or lymphomas (Hodgkin's, HD, or Non Hodgkin's, NHL) for whom indication for HDS-HCS rescue was agreed, underwent remission induc-

tion. HSC mobilization and peripheral $CD34^+$ monitoring was performed at Oncology Department of Lecco while harvesting and storage at Niguarda Hospital in Milan. HDC with HSC rescue was then performed either at Niguarda Hospital or at Lecco Hospital: in the latter case HSC were transported and reinfused at Lecco Hospital one day following HDC. *Results.* 50 patients (27 male and 23 female), median age 51(range 23-72 years), 23 multiple myeloma (MM), 13 high grade non-Hodgkin lymphoma and 6 non-Hodgkin's lymphoma (NHL), 7 HD in first relapse and 1 LLC entered the protocol mobilization consisted of DCEP for MM, DHAP for NHL and HD. A total of 80 leukapheresis (1-4 per patient, median 1) have been performed and a median 9,3 (4-39,3)$\times 10^6$/Kg of HSC were stored. HDC with HSC rescue has been delivered to 32 patients (8 MM double transplantation, 15 MM single transplantation and 8 NHL and 6 HD single) either at Niguarda Hospital (myeloablative, 27 procedures) or at Lecco Hospital (8 myeloablative and 10 non-myeloablative procedures). *Conclusions.* Based on our experience, HDC with HSC rescue is feasible also in an Oncology department which does not have facilities for HSC harvest and storage provided a strict cooperative protocol with a referral center is agreed. Patients from Lecco area received full HDC with HSC rescue with reduced logistic problems and limited distress for patients and their families and the resulting social benefit is remarkable to with little expenses from the Hospital services maximizing.

1683

REDUCED-INTENSITY CONDITIONING ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANTATION: AN 8-YEAR EXPERIENCE

D Diego, M Calbacho, P Herrera, J García-Laraña

Hospital Ramón y Cajal, Madrid, Spain

Background. Reduced-intensity conditioning allogeneic haematopoietic stem cell transplantation (RIC-SCT) is a potentially curative option for patients with haematologic neoplasms that can not undertake an allogeneic haematopoietic stem cell transplantation with conventional myeloablative conditioning. *Aims.* To report overall and relapse-free survival at 12 and 24 months after RIC-AlloHSCT, as well as the most prevalent complications of this procedure in a reference center. *Methods.* Retrospective study of consecutive patients treated with RIC-AlloHSCT in our center (Hospital Ramon y Cajal, Madrid), from the years 2000 to 2008. We recorded demographic, clinical and therapeutic variables. *Results.* There were 34 patients, sex ratio 1:1, average age 46,3 (range 18-65) year-old. Number of cases per diagnostics was 8 MDS/AML, 3ALL, 6 Hodgkin's lymphoma, 8 high-grade non-Hodgkin lymphoma, 3 CLL/low-grade non-Hodgkin lymphoma, 4 MM, 1 CML and 1 idiopathic myelofibrosis. Sort of donor was related 94%, unrelated 6%. Previous chemotherapy lines 3 (1-8), previous status (partial remission 41%, complete remission 50%), sort of conditioning Flu/Mel: 68%, Flu/Bul: 26%, Flu/Mel/ATG: 6% and graft-versus-host disease prophylaxis CSA 12%, CSA + MTX 88%. Most common complication was graft-versus-host disease (GVHD) (53%, grade III/IV 27%). Chronic GVHD was 47%. Infections occurred in 56% (12% invasive fungal infection, 21% cytomegalovirus reactivation and 12% both of them). Main mortality causes were infections (53%), GVHD (18%), and disease progression (18%). There was only one conditioning related decease. First year and second year overall survival was 52.5% and 40.4% respectively. Relapse-free survival after 1 year was 72.6%. 60% of deceased patients were in complete remission. *Conclusions.* RIC-SCT presents an overall and relapse-free survival that makes it an option for patients that are not candidate for conventional SCT. In our series, best results were achieved in MM, non-Hodgkin lymphoma and MDS/AML.

1684

ACUTE LEUKEMIA IN PEDIATRIC PATIENTS: THE CLINIC DATA OF A SINGLE CENTER

G. De simone, MR D'Amico, G Menna, F Petruzziello, V. Poggi, M Ripaldi

AORN Santobono-Pausilipon, Napoli, Italy

Background. Analyzes the data of 52 consecutive transplants of allogeneic bone marrow, of which 46 donor family and 6 from unrelated donor in patients with acute leukemia. *Aim and methods.* In 50 children, 52 transplant have been performed, 30 for Acute Lymphoblastic Leukemia (ALL) and 22 for Acute Myeloid Leukemia (AML). The diseases for which have been used for transplantation are as follows: for the ALL group 17 relapse, 5 LLA-T, 5 High Risk, 2 infant, 1 resistant; for the AML group 3 M1, 1 M2, 6 M3, 3 M4, 7 M5, 2 M6. For the group ALL 23 patients was male, 5 female; for the AML group were 12 males and 10 females. The mean age was 11.5 years for ALL (8 months-17 years) and 9 years for AML (23 months-15 years). The donors were 24 males and 4 females in the group ALL, while 12 males and 10 females in the AML group. Conditioning protocols were TBI-TY-EDX and TBI-VP16-EDX for the ALL group , BU-EDX -LPAM for the AML group. Immunosuppressive therapy with cyclosporine has been implemented for all patients, in 6 cases (MUD) was also used MTX and ATG. *Results.* The take was achieved, as regards the PMN to 14 days for ALL (range 11-80), 13 days for AML (range 11-28), with regard to the platelets to 22 days for ALL (range 11-112) and 25 days for AML (range 14-35). One patient with ALL has not reached the take. Mucositis was grade I-II in 21 patients (70%), grade III-IV in 5 patients (16,6%) for the ALL group; I-II in 13 patients (59%), grade III-IV in 8 patients (36%) to the AML group. The overall TRM was 11%. In 8 patients there was acute Graft *vs.* Host Disease(GVHD) III-IV grade, 5 patients (16%) for the ALL group, 3 patients (14%) to the AML group; while with regard to chronic GVHD in 6 patients occurred in limited form, in 6 patients extensively. There were no differences in the distribution in the two groups as regards the c-GVHD. The event free survival, with a median follow-up of 7 years, was 60% in the ALL, and 82% in the LMA group. The overall survival is 70%. *Conclusions.* our experience, although on a limited number of patients, confirms that the bone marrow transplant is a valid tool for the treatment of serious disease such as acute leukemia, otherwise fatal. Although burdened by a relapse and a significant GVHD the transplantion for LLA, it should however be taken into account in the patients who do not have other therapeutic possibilities. For the AML the transplant represent the only chance of healing for our patients.

1685

CXCR7 REGULATE CXCR4/SDF-1 MEDIATED HEMATOPOIETIC SUPPORTING ACTIVITY OF STROMAL CELLS BY CONTROLING EXTRACELLULAR SDF-1 CONCENTRATIONS

H Bouamar,[1] Y Zhang,[1] D Jouni,[1] M Wittner,[1] M Bensidhoum,[2] H Petit,[2] O Albagli,[1] W Vainchenker,[1] F Louache[1]

[1]Institut Gustave Roussy, Inserm U1009, Villejuif, France; [2]CNRS UMR 7052, Faculté de Médecine Lariboisière-Saint-Louis, Paris, France

Stromal cell-derived factor 1 (SDF-1)/CXCR4 axis plays a major role in regulating the interactions between hematopoietic stem and progenitor cells (HPSC) and their stromal microenvironment within the bone marrow. A second SDF-1/CXCL12 receptor, CXCR7 binds SDF-1 with high affinity but little is known about its function in hematopoiesis. In the present study, we demonstrate that the activity of CXCR7 is crucial for proper maintenance of hematopoietic activity on stromal layers. Using quantitative reverse transcription-PCR analysis, we demonstrate that CXCR7 is highly expressed in stromal cells whereas it is at the threshold of detection in hematopoietic cells suggesting that it functions primarily in the stromal microenvironment compartment. In favour of this hypothesis CXCR7 stable expression in hematopoietic cells fails to support SDF-1 induced migration and signalling, in coculture CXCR7 expressing cells could inhibit the migration of SDF-1 induced migration of control hematopoietic cells suggesting that they could titrate SDF-1. Furthermore overexpression of CXCR7 in MS-5 stromal cells leads to a reduction of SDF-1 concentration in the supernatants. Supernatants from these cells had substantially lower efficiency in promoting integrin $\alpha 4\beta 1$-mediated adhesion and migration of Mo7e cells to vascular cell adhesion molecule-1 (VCAM-1) and CS-1/fibronectin than their control GFP counterparts. Moreover, human cord blood CD34+ hematopoietic progenitor cells displayed SDF-1-dependent reduced responses in chemotaxis, transendothelial migration, and up-regulation of adhesion to VCAM-1 when supernatants from CXCR7 expressing MS-5 cells were used compared with supernatants from GFP expressing MS-5 cells. Finally, phenotypically primitive murine cells displayed reduced hematopoietic activity when cultured on CXCR7 expressing MS-5 cells. This reduced hematopoietic activity is partly reverted when recombinant SDF-1 was added to CXCR7 overexpressing MS-5 cells. Taken together, our results indicate that CXCR7 controls the bioavailability of SDF-1 and influences BM cell migration, adhesion and hematopoietic activity. Thus CXCR7 behaves as a decoy receptor regulating the SDF-1 level in BM environment.

1686

ROLE OF IFNα TARGET GENES IN THE IFNα -INDUCED ACTIVATION OF DORMANT HSCS IN VIVO

S Wurzer, M Essers, A Trumpp

German Cancer Research Center, Heidelberg, Germany

Maintenance of the blood system is dependent on dormant haematopoietic stem cells (HSCs) with long-term self-renewal capacity. Upon injury these cells are induced to proliferate in order to quickly re-establish homeostasis. The signalling molecules promoting the exit of HSCs out of the dormant stage remain largely unknown. We have recently uncovered that in response to treatment of mice with interferon-alpha (IFNα), HSCs efficiently exit G0 and enter an active cell cycle. HSCs respond to IFNα treatment by increased phosphorylation of STAT1 and PKB/Akt, expression of IFNα target genes and up-regulation of stem cell antigen-1 (Sca-1). HSCs lacking either the interferon-a/b receptor (IFNAR), STAT1 or Sca-1 are insensitive to IFNα stimulation, demonstrating that STAT1 and Sca-1 mediate IFNα induced HSC proliferation. To confirm the direct effect of IFNα on HSCs and gain more insight into the mechanism of activation we have performed micro-array analysis on sorted HSCs from IFNα treated mice. This analysis revealed the specific induction of a typical set of known IFN target genes in HSCs from IFNα treated mice, strongly supporting our data that IFNα directly activates dormant HSCs. In addition, expression of several cell cycle genes is altered in IFNα stimulated HSCs, including up-regulation of cyclinB2 and CDK7, as well as repression of Pten and Elavl1, known to stabilize p21CIP1 protein. We will present our newest data on the confirmation of the effect on these IFNα target genes and cell cycle related genes. Moreover, we are examining the role of the different IFNα target genes in the effects of IFNα on HSCs. These data will provide us with more insights into the mechanism of IFNα induced activation of dormant HSCs.

1687

IL-17 AND FGF SIGNALING INVOLVED IN MESENCHYMAL STEM CELL PROLIFERATION

D Bugarski, S Mojsilovic, V Ilic, G Jovcic, A Krstic

Institute for Medical Research, Belgrade, Serbia

Background. Mesenchymal stem cells (MSCs) are widespread in adult organisms and are involved in tissue maintenance and repair, as well as in the regulation of hematopoiesis and immune responses. MSCs have enormous potential for cellular therapies, but also can be used in preclinical models for tissue engineering, biocompatibility studies or in basic studies of cell function and tissue development. Therefore, identifying factors inducing MSCs proliferation/expansion and elucidating associated signaling pathways is of great importance for their further exploration within all these settings. *Aims.* We investigated the effects and signaling of IL-17, a Th17 cell cytokine implicated in modulation of immune and hematopoietic responses, and/or FGFb, a growth factor used in standard procedures for stromal cells isolation and expansion, on murine bone marrow MSCs (mBMMSCs) proliferation and elucidated the signaling pathways involved. *Methods.* mBMMSCs were generated from femurs of CBA mice as plastic-adherent cells and quantified by CFU-F assay. mBMMSCs between passages 2 and 5 were used; their "stemness"was confirmed by the capacity to differentiate into chondrogenic, osteogenic and adipogenic lineages; proliferation was analyzed by the MTT assay, while the signaling events were detected by immunoblotting. *Results.* The data demonstrated that stimulation with IL-17 induced dose-dependent increase, while FGFb supplementation had no significant effect, on the CFU-F colony formation. Surprisingly, the combination of IL-17 and FGFb in culture markedly reduced the average number of CFU-F colonies. Western blotting analysis showed that mBMMSCs used expressed cell surface IL-17 receptor. The results of proliferation assay demonstrated dose-dependent augmentation in cell metabolic activity after exposure of cells to either IL-17 or FGFb, being in good agreement with proliferation values previously reported for treatment of MSCs using a single growth factor; however, the proliferative effects were not additive. We next investigated MAPKs signaling pathways and revealed baseline levels of phosphorylated p38 and ERK1/2, but not JNK, activity in mBMMSCs. FGFb treatment led to increased levels of both the phosphorylated p38 and ERK1/2 MAPKs, whereas IL-17 only induced increased phosphorylation of p38 MAPK within first 15 minutes of stimulation. Interestingly, the simultaneous combination of both cytokines did not change the intensity and duration of FGFb-induced ERK1/2, but augmented the intensity and duration of both IL-17- and FGFb-induced p38 phosphorylation levels up to 60 minutes of incubation. *Conclusions.* The results of our study indicated that IL-17 and FGFb utilize distinctive signaling pathways to induce mBMMSCs proliferation. The lack of cooperative activity of these agents on both the growth of CFU-F and the proliferation of BMMSCs can also be explained through the signaling events obtained. Namely, in cases when the signaling pathways induced by different cytokines overlap with each other or merge on a common downstream effector, one can suppose that poor or even lack of synergistic cooperation between factors could be observed. The results highlight the complexity and specificity of the mutual signaling of multiple growth factors involved in BMMSCs proliferation and also reveal necessary data for achieving better control over the MSCs expansion process.

1688

SIGNIFICANT UP-REGULATION OF CXCR4 IN CD34$^+$ AND CD34$^-$ MESENCHYMAL STROMAL CELLS IN PATIENTS WITH PRIMARY MYELOFIBROSIS

A Livun,[1] T Manshouri,[2] R Kusec,[1] Y Zhang,[2] L Knez,[2] H Kantarjian,[2] S Verstovsek[2]

[1]KB Dubrava, Zagreb, Croatia; [2]MD Anderson, Houston, USA

Background. Primary myelofibrosis (PMF) is the most aggressive stem cell derived Philadelphia chromosome-negative chronic myeloproliferative neoplasia (MPN), with average survival of 5-7 years and no effective therapy. It is characterized by bone marrow (BM) fibrosis, cytopenias, leukoerythroblastosis, teardrop poikilocytosis, extramedullary hematopoiesis, splenomegaly and elevated number of CD34+ cells in peripheral blood (PB). Understanding of biological abnormalities in PMF may lead to the development of new targeted therapies. Discovery of a single point mutation in the tyrosine kinase JAK2 (JAK2V617F) in MPN has revealed an abnormality contributing to the existence to these diseases, and JAK2 inhibitors are being developed clinically. Mobilization of hematopoietic progenitors from BM to spleen and liver in PMF suggests that alternations in the cross talk between hematopoietic and mesenchymal stromal cells (MSC) may also participate in disease biology. *Aim.* To assess the expression of selected group of genes in CD34$^+$ BM cells, as well as BM-derived MSC, from patients with PMF, which may have a role in the biology of this disease. The genes examined included those involved in cell-stromal adhesion (SPARC, CXCR4), metabolism (COX-2, HIF1α), and differentiation and signaling (Pax5 and Socs3). *Materials and methods.* Mononuclear cells (MNC) from BM aspirates from 20 PMF patients and five healthy donors (used as a control) were cultured in αMEM medium containing 20% fetal bovine serum for 2 weeks. Adherent MSC, as well as nonadherent cells, were then collected and sorted using CD34 microbeads. Total RNA was isolated from sorted CD34$^+$ and CD34$^-$ cells and Q-RT-PCR was performed to measure the expression levels of SPARC, COX-2, CXCR4, FOS, Pax5 and HIF1 transcripts, with β-actin as internal control. Results were analyzed using GraphPad Prism (Kruskal-Wallis test and Dunns test). *Results.* (Table 1). There was no significant change in FOS and HIF1α expression between control and patients' MSC. COX-2 was down-regulated in CD34$^+$ patients' nonadherent cells in comparison to CD34- adherent patients' MSC, but in comparison to control cells there was no significant change.

Table 1. Significant differences in gene expressio.

	Sparc	COX-2	CXCR4	Pax5
Kruskal-Wallis	0.0006	0.0034	<0.0001	<0.0001
CTL NA CD34- (n=6) vs CTL A CD34- (n=3)	0.0170 ↑			
CTL NA CD34- (n=5) vs PA CD34+ (n=11)	0.0004 ↑			
PA CD34- (n=11) vs PNA CD34+ (n=18)		0.0004 ↑		
CTL NA CD34+ (n=5) vs PA CD34- (n=9)			0.0026 ↓	
PA CD34+ (n=9) vs PNA CD34- (n=20)			0.0007 ↑	
PA CD34- (n=9) vs PNA CD34+ (n=20)			P<0.0001 ↑	
PA CD34- (n=9) vs PNA CD34- (n=20)			P<0.0001 ↑	
PA CD34- (n=8) vs PNA CD34+ (n=10)				0.0004 ↑

Abbreviations: CTL NA-Control nonadherent, CTL A- Control adherent, PA-Patients adherent, PNA-Patients nonadherent

SPARC was down-regulated in patients' CD34$^+$ adherent MSC in comparison to CD34$^-$ control nonadherent cells. Pax5 showed statistically significant (P<0.0001) up-regulation in patients' CD34$^-$ adherent MSC *vs.* CD34$^+$ nonadherent cells. CXCR4 was significantly (P<0.0001) up-regulated in patients' CD34$^-$ and CD34$^+$ adherent cells *vs.* patients' nonadherent MSC CD34$^-$ and CD34$^+$. *Conclusion.* The expression of

selected genes differs in CD34+ and CD34- adherent MSC and nonadherent cells from patients with PMF as compared to expression in cells from healthy controls. In particular, patients' MSC have significantly higher expression of CXCR4 gene that encodes a CXC chemokine receptor specific for stromal cell-derived factor-1, suggesting its role in the mobilization of hematopoietic progenitors from BM. CXCR4 is also involved in haematopoiesis, angiogenic activity, apoptosis, T-cell differentiation and phagocyte activation. Further investigation of the CXCR4 gene regulation in both adherent MSC and nonadherent mononuclear cells in PMF is warranted.

1689

A NOTCH REPORTER LINE FOR THE IN VIVO STUDY OF HEMOGENIC ENDOTHELIUM

A McMahon, A Haase, R Thambyrajah, M Gering

University of Nottingham, Nottingham, UK

Background. The Notch pathway has been shown to play an important role in the formation of definitive haematopoietic stem cells (HSCs) in both mouse and zebrafish embryos. Signalling from the Notch pathway is activated when transmembrane notch receptors present on the surface of one cell are bound by transmembrane ligands, such as Delta and Jagged, on the surface of a neighbouring cell. This triggers endocytosis of the ligand followed by cleavage of the receptor resulting in the release of the Notch Intracellular Domain (NICD). NICD forms a complex with the transcription factor RBPJk/Suppressor of Hairless (CSL) and Mastermind to activate transcription of downstream target genes. *Aims.* We sought to establish an *in vivo* notch reporter line using the zebrafish as a model and to use this line to further define the role of notch in HSC specification. *Methods.* Previous studies have used the CSL DNA binding sequence to drive expression of GFP in a notch reporter system in mammalian cell lines. We utilised this method to establish a stable notch reporter line in the zebrafish. *Results.* We show that our reporter is specifically responsive to notch signalling and can be used to visualise notch activity in a variety of tissues in both embryos and adults. Notch activity is present in both the ventral and dorsal wall of the aorta at timepoints at which we see HSC development from hemogenic endothelium. Using this reporter line, we have also been able to establish more clearly the position of notch signalling in the hierarchy of pathways regulating hematopoietic stem cell formation in the embryo. *Summary.* Using a novel *in vivo* notch reporter line we have further elucidated the role of notch in establishing HSC identity in the embryo.

1690

COMPARATIVE ANALYSIS OF TELOMERASE ACTIVITIES OF MESENCHYMAL STEM CELLS ISOLATED FROM DIFFERENT HUMAN TISSUES

G Duruksu, A Aksoy, A Okcu, E Karaoz

University of Kocaeli, Kocaeli, Turkey

Background. Mesenchymal stem cells (MSC) are defined as non-hematopoietic multipotent adult stem cells isolated form bone marrows as well as from other tissue sources. Possessing many application opportunities in tissue regeneration, treatment of autoimmune diseases and gene therapies, MSC should have considerable proliferation capacity before hand. As the telomeric region of chromosome under goes repetitive shortening after each mitotic division, MSC to be used in clinical applications ought to have considerable telomerase activity (TA) to cover the reduction before mitotic crisis.[1] *Aims.* In this study, it was aimed the determination of TA of MSC isolated form different human tissues and their comparative analysis to reveal the relation between the TA and life span of MSC for the selection of prominent cells in experimental treatment. *Methods.* MSC were isolated from different human tissue sources; endometrium (E), adipose tissue (AT), bone marrow (BM), periodontal ligament (PDL), chondrocyte (C), umbilical cordon blood (CB), and amniotic fluid (AF). The TA was determined by Telomeric Repeat Amplification Protocol (TRAP) following the ELISA assay to quantify the activity of the enzyme isolated from MSC. *Results.* Telomerase activities of seven MSC isolated from different tissues were analyzed (Table 1). Depending on their sources, the MSC showed variable TA: in PDL MSC (Case 1), in AF MSC (Case 3) and in E MSC (Case 2). Even in the unsynchronized culture of BM MSC (in Case 2 and 3), it was demonstrated to have TA in contrast to the information in the literature.[2,3] It was remarkable that CB MSC (Case 1 and 2), which showed high proliferation rates, have TA as high as HeLa cells (immortal cell line derived from cervical cancer cells) and considerably high TA in comparison with those of embryonic stem cells in the literature.[2,4] Convincingly, those cells were different in their growth characteristics. *Conclusions.* Generally, the telomerase activity showed deviations within the MSC depending on their isolated source, the donors' age and their clinical history. In the later passages of the same cell line, the variable rate of decrement of TA was observed in relation with the senescence, which limits the life-span of MSC. Therefore, not only the level, but also the rate of change of TA is important in the selection of the MSC for the potential applications.

Table 1. Relative telomerase activity (RTA) of human MSC (%/μg total protein).

Tissue/ Case	Passage No.	RTA	St. Dev.	Tissue/ Case	Passage No.	RTA	St. Dev.

BREAST CARCINOMA CELLS MODULATE PHENOTYPE AND FUNCTION OF HUMAN BONE MARROW-DERIVED MESENCHYMAL STROMAL CELLS IN A NON-CONTACT DEPENDENT MANNER

M Wobus, T Dittrich, L Hofbauer, G Ehninger, M Bornhaeuser

University Hospital Dresden, Dresden, Germany

Introduction. Many solid tumors, including breast cancers, have a predisposition to metastasize to the bone marrow where they might negatively influence hematopoiesis. Mesenchymal stem cells (MSCs) are the progenitors for all stromal cells in the bone marrow and produce cytokines and chemokines to support hematopoietic stem cells (HSCs). In this study, we investigated in-vitro whether tumor cells are able to modulate the bone marrow microenvironment. *Methods.* Human MSCs (derived from the bone marrow of healthy volunteers and the immortalised MSC line SCP-1) were cocultured with MCF-7 breast carcinoma cells or incubated with conditioned medium of these cells. The proliferation potential was detected by BrdU staining or by MTT assay. Flow-cytometric analysis included MSC, HSC as well as tumor markers (CD34, CD44, CD45, CD73, CD90, CD105, CD146, CD166, CXCR4). The osteogenic differentiation potential was considered by ALP measurement after a two week incubation period with differentiation medium. SDF-1 mRNA levels of MSCs were quantified by real-time PCR and the levels of secreted protein were measured using an ELISA kit. *Results.* MSC/MCF-7 cocultures showed a lower MSC proliferation activity in comparison to MSC control cultures. SCP-1 proliferation was decreased to 52.5% by MCF-7 conditioned medium which suggests that the effect on proliferation is cell contact independent. Furthermore, incubation with tumor cell conditioned medium caused a decrease in the positive fraction and mean fluorescence intensity of CD105 and CD146 on MSCs. Downregulation of CD146 correlated with an inhibition of the osteogenic differentiation potential as shown by ALP levels which decreased to about 30% in the presence of MCF-7 conditioned medium. SDF-1 concentrations in coculture supernatants decreased in a time-dependent manner (on average MSCs 717 pg/mL; MSC/MCF-7 145

pg/mL). Incubation with tumor cell conditioned medium caused also a significant decrease of SDF-1 secretion. In accordance with the SDF-1 protein levels the mRNA levels were downregulated in MSCs incubated with MCF-7 conditioned medium. Interestingly, the effects could be reversed after a medium change to normal DMEM. *Conclusion.* The phenotypic and functional changes induced in MSCs during cocultures with breast carcinoma cells or conditioned medium, respectively, suggest a negative impact on the supportive function of MSC for hematopoietic stem cells. The coculture model chosen allows to mimic the competition between tumor cells and HSC for the stromal niche compartment in-vitro.

BONE MARROW-DERIVED MESENCHYMAL STEM CELLS CO-CULTURED WITH PANCREATIC ISLETS DISPLAY BETA-CELL PLASTICITY

E Karaoz,[1] S Ayhan,[2] A Okçu,[2] A Aksoy,[1] G Bayazit,[1] A Gürol,[1] G Duruksu[1]

[1]Kocaeli University, Koaceli, Turkey; [2]Kocaeli University,Center for Stem Cell and Gene Therapies Research and, Kocaeli, Turkey

Background. Numerous studies conducted to date have indicated that specific stem cells derived from adult human tissues can be reprogrammed in order to differentiate into suitable cell types. Reprogramming may be achieved by changing the microenvironment in which the cells are growing to provide signals that may activate metabolic pathways. Successful experiments were carried out *in vivo* by using the microenvironment of the target cell type. When conditions similar to *in vivo* microenvironment are provided, differentiation of stem cells into the desired cell types with full functionality can be obtained *in vitro*. One of the approaches for *in vitro* differentiation is to use cocultures with the microenvironment of the specific cells of the desired cell type, tissue / organ samples (extracts), extracellular matrix compounds or biologically absorbable materials. *Aims.* To study the direct coculturing effect of rat bone-marrow-derived-mesenchymal-stem-cells (rBM-MSCs) on the pancreatic islets (PIs) to obtain functional islet cells. *Methods.* rBM-MSCs were isolated from the rat bone marrow and cultivated under standard conditions. rBM-MSCs at the passage 3 were plated at the density of 1×10^6 cells into T75 flasks and incubated for 2 d until they reached to 50% confluence. The medium was exchanged with the same medium containing 10 mM of BrdU. After 48 h of incubation at 37 °C and 5% CO2, the BrdU-labeled MSCs were trypsinized and evaluated for viability. rBM-MSCs were directly (with cell-islet contact) cocultured with recovered PIs together with the single cell cultures of those cell cultures as control. The effect of direct cocultures of rBM-MSCs with PIs of the normal rats was investigated by using immunophenotypical and functional methods. The change in the amount of insulin secretion was evaluated as indicator for differentiation of rBM-MSCs. *Results.* At the end of the experiment (approximately 37 d of incubation), the original three-dimensional architectures of all islets were impaired and MSCs mixed with islet-derived cells. In rBM-MSCs/islets cocultures we observed positive for insulin and BrdU Islets secreted insulin into the medium but the secretion has increased in the cocultures due to additive effect of insulin secretion from differentiated rBM-MSCs. The functionality tests by ELISA confirmed that insulin secretion of cocultured MSCs with islets (14.57±0.03 ng/mL) was higher than islets (12.83±1.72 ng/mL).

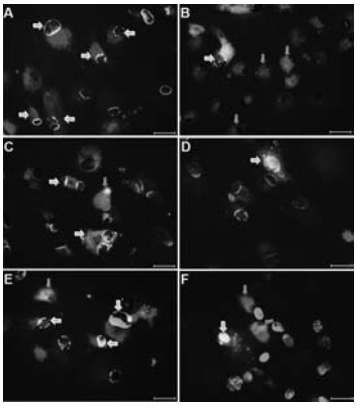

Figure. Coculture of rBM-MSCs with rPIs.

Conclusions. To our knowledge, this is first data that refined these approaches and rather than using pancreatic extracts used well-isolated pure rPIs to achieve differentiation of rBM-MSCs into IPCs. The interaction between MSCs and islets in cocultures initiated differentiation by direct cell-cell contact and by soluble paracrine factors. This approach and similar approaches used by the others will help development of refined well-defined methods for generation of functional insulin-producing cells from stem cells. The development of these methods, however, depends on molecular approaches that will describe novel signal molecules and their associated pathways.

ROLE OF LEUKOTRIENE B4 IN UPREGULATION OF TRANSENDOTHELIAL MIGRATION OF HEMATOPOIETIC PROGENITOR CELL: MODULATION OF HEMATOPOIETIC PROGENITOR CELL-ENDOTHELIAL CELL ADHESION

YC Mun, JY Ahn, S Lee, ES Yoo, JY Cho, KE Lee, EM Nam, SN Lee, CM Seong

Ewha Womans University School of Medicin, Seoul, South-Korea

Backgrounds. The mechanisms on hematopoietic progenitor cell (HPC) mobilization by hematopoietic growth factors seem to be multifactorial processes. Though the roles of protease and cell adhesion molecules (CAMs) seem to be important, the precise mechanisms on HPC mobilization are still unknown. Leukotriene B4 (LTB4) is lipid mediator derived from membrane phospholipids during the process of inflammation, and have many roles (ie; inducer of chemotaxis, the production of nitric oxide, transepithelial migration of neutrophil). The major activities of LTB4 include the recruitment and activation of leukocytes, suggesting that it has considerable functional overlap with the chemokine family of chemoattractant peptides, which are known as a HPC mobilizer recently. We previously had reported that LTB4 was able to mobilize HPC of 8.5-fold baseline within only 4 hours without significant side effects in the murine models and LTB4 receptor and reactive oxygen species were involved in the pathway of mobilization induced by LTB4 or G-CSF using C57BL/6 mice. In this study, we investigated the cellular mechanisms of HPC mobilization which was induced by LTB4. *Methods.* We studied the expression of LTB4 receptors (BLT1 and BLT2) on the surface of murine HPC, neutrophil, b.End3 cell (murine microvascular cell line), and MS5 cell (murine stromal cell line) using PCR technique. To elucidate the effects of LTB4 on the cells which compose the bone marrow environment for the HPC mobilization, we studied the influence of LTB4 on proliferation, transmigration, permeability, adhesion and expression of CAMs on HPCs and neutrophils from C57BL/6 mice, MS5 cells and b.End3 cells as well. *Results.* Proliferations and permeability of b.End3 cell and MS-5 cell were not affected by treatment of LTB4. After LTB4 treatment, transendothelial migrations of total nucleated cells (TNC) (22.2% *vs.* 9.4%), HPC (2.7% *vs.* 0%) and neutrophils (75.6% *vs.* 13.6%) from the C57BL/6 mice bone marrow were increased compared to control in transmigration assay. These effects were reversed by LTB4 receptor antagonists, LTB4APA, U75302, and LY255283. Adhesion between HPC and b.End3 cell was increased within 10 minute after LTB4 treatment in adhesion assay. Such phenomena were reversed by LTB4 receptor antagonists. However, The expressions of ICAM-1, VCAM-1, Selectin (E-, L-, P-) on the surface of b.End3 cell, murine microvascular endothelial cell and the expressions of CXCR4, LFA-1 and VLA-4 on the surface of HPC using flow cytometry were not affected by treatment of LTB4. *Conclusions.* Through our data, it is suggested that transendothelial migration of HPCs was upregulated by LTB4 via modulating the adhesion between HPC and endothelial cell. These results suggest that the mobilization of HPC in response of LTB4 may be accomplished by upregulated transendothelial migration of HPC through the modulation of HPC-endothelial cell adhesion in the bone marrow environment. Further studies are necessary to find exact intracellular and molecular mechanisms on the HPC-endothelial cell adhesion by LTB4.

OSTEOGENESIS IS IMPAIRED IN MESENCHYMAL STEM CELLS OBTAINED FROM FEMORAL HEADS OF OSTEOPOROTIC PATIENTS

S Muntion,[1] F Sanchez-Guijo,[1] J Blanco,[1] C Santamaria,[1] S Carrancio,[1] P Hernandez-Campo,[1] E Villaron,[1] O Lopez-Villar,[1] N Lopez-Holgado,[1] J Briñon,[2] J San Miguel,[1] MC Del Cañizo[1]

[1]Hospital Universitario de Salamanca, Salamanca, Spain; [2]Universidad de Salamanca, Salamanca, Spain

Background. Mesenchymal stem cells (MSC) are the stromal progenitors in bone marrow, and have the ability to differentiate into several

cell types, including osteoblasts, adipocytes and chondrocytes. MSC in osteoporotic patients have scarcely been studied. *Aims.* To isolate and assess the functional capacity and the genomic profile of MSC obtained from femoral heads of patients with osteoporotic fracture compared to the iliac crest counterpart from the same patients. *Methods.* Mononuclear cells (MNC) were obtained after mechanical fragmentations of femoral heads from 20 patients undergoing hip arthoplasty for osteoporotic fracture, together with MNC from iliac crest aspiration from the same patients during the surgical procedure. MSC were isolated following standard *in vitro* expansion in media containing DMEM and 10% fetal calf serum. After third passage, MSC from both sources were tripsinized and used for extensive characterization. This included flow cytometric evaluation of surface markers and *in vitro* multilineage differentiation, with special focus on osteogenesis, that included evaluation of mineralization with alizarin-red staining and PCR of the relevant genes. The presence of genomic changes was studied by array-CGH technology. MSC from osteoporotic fracture and from iliac crest were also compared in terms of microarray expression and confirmed by RT-PCR. *Results.* When compared to MSC from iliac crest, MSC from femoral heads of osteoporotic fractures had a lower expansion capacity. Cells from both sources had similar immunophenotypic pattern and multilineage differentiation ability. Nevertheless, bone mineralization was lower in MSC from osteoporotic femoral heads. In addition, basal expression of markers of osteogenesis such as alkaline phosphatase, osteonectin and type 1 collagen was reduced in this group. No genomic aberrations were detected in MSC from both sources by array-CGH. When gene expression profile of MSC from both sources was analyzed, cells from osteoporotic femoral heads displayed an enhanced expression of negative regulators of osteogenesis (e.g. SFRP1 and 4, PDE1A), and hyperexpression of adipogenesis-inductor genes (e.g. PPAR-gamma, AEBP1). *Summary.* Our study shows that MSC isolated from femoral heads of osteporotic fractures do not harbour genomic aberrations, although these cells have reduced expansion ability and a blockage in their osteogenetic capacity.

SEMI-SOLID DECALCIFICATION AND RESEARCH SYSTEM: A NOVEL METHOD TO STUDY FLUORESCENCE PROTEIN GENE MODIFIED STEM CELLS IN BONE

QL Jiang,[1] S Jiang,[1] Y Zhang,[2] L Li,[2] P Zhao,[2] YF Pan,[2] W Chang,[2] LJ Liu,[2] GN Yu,[2] H Wang[2]

[1]Nanfang Hospital, Guangzhou, China; [2]Southern Medical University, Guangzhou, China

Background. It is a great challenge to study the mechanism of stem cells and microenvironment in bone. Gene marking with fluorescent protein (GFP, RFP, etc.) is a powerful technique for stem cells tracing, however, not working well in bone. Why? Bone is such an organ that it is solid, compact, poor lucency and porous. Complex tissues of different characteristics interlace inside bone, such as bone cortex, cells, blood vessels, nerve, matrix and blood, etc. Traditional paraffin embedding and frozen section after decalcification are not proper ways, which may cause the heat injuries in paraffin imbedding, protein denaturation in strong acid decalcification and even the inhibition of antigen-antibody reaction. More important, when bone is decalcified, the cells and other soft tissues inside would move from their original positions without the support of bone frameworks. Glycol methacrylate (GMA) cold embedding technique seems good, but is only suitable for tiny bone. Plastic embedding for hard tissue slicing and frozen section without decalcification maybe better, however, is too expensive to be used widely. *Aim.* To establish a novel, efficient, economical decalcification and research system for the study of stem cells and microenvironment in large bone. *Methods.* Porous and osseous β-tricalcium phosphate (β-TCP) biomaterial scaffold (1×1×0.8 cm) was purchased from Bio-lu Biomaterial Company, China. GFP and RFP gene modified bone marrow mesenchymal stem cells (BMSCs-GFP, BMSCs-RFP) were inoculated in β-TCP scaffolds and cultured for several days. Then, the scaffolds were fixed with 4% paraformaldehyde phosphate and decalcified within an own-made semi-solid decalcification system. After that, 4~8μm frozen sections were made. Histochemical stain, immunohistochemical stain, fluorescence chromosomal *in situ* (FISH), electron microscope, and PCR were tested with those sections. GMA cold embedding technique was used as control. An auto-BMT murine model was also used, bone marrow cells from male FVB-GFP transgenic mice were transplanted into female FVB-RFP transgenic mice, whom was preconditioned with 8 Gy total body irradiation, 4w later, bones of recipient mice were taken out and under investigation. *Results.* During semi-solid decalcification, hard component of the β-TCP scaffold is disappeared slowly, frameworks of the scaffold were replaced gradually by semi-solid substance. After decalcification, position, form, and fluorescence of the BMSCs-GFP and BMSCs-RFP do not change, observed by fluorescence invert microscope, confocal microscopy and frozen sections. Histochemical stain, immunohistochemical stain, FISH, electron microscope and PCR work well in these frozen sections. GMA cold embedding section could also work, but only suitable for tiny bone with a diameter of 2~3 mm. The experiment of auto-BMT GFP to RFP transgenic murine model is still going on. *Conclusion.* This semisolid decalcification and research system make it possible to research thoroughly the location, growth, proliferation, differentiation, migration and interaction of GFP/RFP gene modified stem cells and also the interaction between cells and microenvironment in bone. The on-going study of the GFP to RFP transgenic mice model, especially the changes in the bone, will prove the feasibility of this novel decalcification and research system.

PURIFIED GR1+CD11B+ CELLS INDUCE NEOVASCULARIZATION IN AN ISCHEMIC HIND LIMB MOUSE MODEL

JA Kim,[1] JY Kwak,[2] SK Park,[3] OK Hong,[4] JH Jung,[1] S Lee[5]

[1]The Catholic University of Korea St. Vincent's hospital, Suwon, South-Korea; [2]Chonbuk National University Hospital, Jeonju, South-Korea; [3]Soon Chun Hyang University Hospital, Bucheon, South-Korea; [4]The Catholic University of Korea, Seoul, South-Korea; [5]The Catholic University of Korea St. Mary's hospital, Seoul, South-Korea

Introduction and Backgroud. Gr1+CD11b+ cells have been recently described as myeloid-derived suppressor cells that may be involved in tumor angiogenesis. However, there has been little investigation of the role of $Gr1^+CD11b^+$ cells in non-tumor angiogenesis. *Hypothesis.* To study the relationship of $Gr1^+CD11b^+$ cells to neovascularization in an ischemic hind-limb model of C57BL/6 mice, we tested the following hypotheses: (1) The number of tissue-resident $Gr1^+CD11b^+$ cells increases in BM and ischemic muscle after the ischemic injury; (2) prospectively isolated $Gr1^+CD11b^+$ cells can manifest characteristics of endothelial differentiation; and (3) $Gr1^+CD11b^+$ cells modulate neovascularization in ischemic hind-limbs of C57BL/6 mice upon direct injection into ischemic muscle. *Research and observations.* (1) The number of Gr1+CD11b+ cells markedly increased in the ischemic muscle at 4 days post-surgery (n=5 each; $1.08\pm0.65\times10^5$/g tissue in non-surgically treated mice *vs.* $13.43\pm7.52\times10^5$/g tissue in the ischemic muscle, $P<0.05$); then returned to basal level at day 10. (2) Cultured muscle-derived $Gr1dimCD11b^+$ cells aggregated and formed vascular structures in collagen gel culture. In two weeks of Matrigel culture muscle-derived $Gr1dimCD11b^+$ cells expressed endothelial cell makers, CD31 and VE-Cadherin. (3) Following direct injection of purified $Gr1^+CD11b^+$ cells, laser Doppler imaging revealed an increase in blood flow recovery by 14 days post-femoral artery dissection in the cell injected group compared to the control group (n=7 each, 41.14±1.28% in $Gr1^+CD11b^+$ cell injected group *vs.* 35.83±2.57% in control group). *Conclusions.* These results suggest that Gr1dimCD11b+ cells are recruited into ischemic regions after ischemia and may be directly involved in angiogenesis by their capacity to generate the vascular cells.

MODELING CHEMOTHERAPEUTIC DAMAGE TO MESENCHYMAL STEM CELLS

E May,[1] J Xu,[1] R Morse,[1] N Avent,[1] C Cox,[2] S Wexler,[2] C Donaldson[1]

[1]*University of the West of England, Bristol, UK;* [2]*Royal United Hospital, Bath, UK*

Background. Mesenchymal Stem Cells/Stromal Cells (MSC) form the bone marrow microenvironment and are essential in supporting haematopoiesis. Following stem cell transplantation (SCT), whilst haematopoietic cells are replaced, MSC remain of recipient origin. MSC have previously been shown to be damaged by chemotherapeutic treatment, which is administered prior to SCT. If damage to MSC is severe, it may be implicated in lack of engraftment following some SCT, occurring in 10% of allogeneic peripheral blood transplants, one of the leading causes of mortality in this setting. *Aim.* To elucidate this damage to MSC, a physiologically relevant in-vitro model is needed. This can be challenging as many chemotherapeutic agents are extensively metabolised by hepatic cytochrome P450 enzymes. *Methods.* Several important chemotherapy drugs are administered in an inactive prodrug form, requiring metabolism to the main cytotoxic metabolites (e.g. cyclophosphamide to phosphoramide mustard). The vast majority of agents, however, are administered in an active form e.g. vincristine (VIN) and extensively metabolised by the liver to generally less toxic metabolites. Whereas damaging effects from prodrugs can often be underestimated in-vitro if metabolism is not representative of the in-vivo situation, modelling of damage from drugs such as VIN can easily be overestimated if the agent is not detoxified as in-vivo. Previous in-vitro models of chemotherapy damage have often utilised S9 liver extract, rich in P450 enzymes. However, experiments have raised concerns over the toxicity of S9 itself, particularly over extended periods in culture (e.g. 48 hours), highlighting the need for a more physiologically relevant model. An in-vitro model utilising HepG2 (hepatocyte cell line) spheroids within a co-culture system as a source of metabolic enzymes has been developed. It has been evaluated by analysing MSC morphology, proliferative capacity and expression of adhesion molecules (e.g. CD44) and compared with effects seen in MSC from patients who have received chemotherapy in-vivo (with patient consent and LREC approval). *Results.* The new co-culture model was compared with an S9 model and following 48 hour exposure to cyclophosphamide (CY), expansion of MSC was greatly reduced in the presence of both S9 ($P<0.001$) and HepG2 spheroids ($P<0.01$). However, following 3hr treatment, subsequent expansion of MSC exposed to CY in the presence of S9 was no different to MSC exposed to CY alone, whereas expansion of those exposed in the presence of liver spheroids was significantly reduced ($P<0.05$).In addition, MSC morphology is less uniform and an altered adhesion molecule expression (e.g. CD44) can be demonstrated. When MSC were exposed to VIN alone for 48hrs, morphology was altered, MSC expansion significantly decreased long-term ($P<0.001$) and CD44 expression reduced ($P<0.01$). However, when exposed to VIN in the presence of HepG2 liver spheroids, all of these effects were minimised, with both expansion and CD44 levels less reduced ($P<0.001$ and $P<0.05$ respectively), with CD44 expression not differing significantly from untreated MSC. *Conclusions.* A physiologically relevant model to study chemotherapeutic damage utilising HepG2 spheroids has been developed and results obtained are comparable with effects seen in patients who have undergone chemotherapy treatment for haematological malignancy.

1698

OPTIMIZING THE ISOLATION OF HOMOGENOUS POPULATION OF MESENCHYMAL STEM CELL BY NEGATIVE SELECTION OF CD45, CD11B, CD146 AND TER-119 FROM MURINE BONE MARROW CELLS

A Teófilo Saturi, P Vianna Bonini Palma, C Menezes, D Tadeu Covas, J Voltarelli, K Ribeiro Malmegrim

National Institute of Science and Technology in Stem Cells and Cell Therapy, Ribeirão Preto, Brazil

Background. Mesenchymal stem cells (MSCs) can be defined as multipotent cells able to differentiate towards the mesodermal and nonmesodermal lineages. They have shown immunoregulatory and immunossupressive properties by some suggested mechanisms like release of soluble factors (IDO, TGF-β1, IL-10, HGF, PGE2 and HLA-G1) and cell-to-cell contact (PD-L1). Recent reports suggest that MSCs are distributed *in vivo* throughout the body, possibly associated with the blood vessels, interfering in the immunoregulation and peripheral immune tolerance *in vivo*. The plastic-adherent murine MSCs isolated from bone marrow (BM) are heterogeneous populations and murine MSCs cultures remain contaminated by hematopoietic cell populations, like CD11b positive cells, for many passages. *Aim.* Once we are interested in isolating a homogenous MSCs population from NOD mice for gene expression studies of type 1 diabetes by microarrays, the aim was optimizing the isolation of MSCs by magnetic separation of CD45, CD11b, CD146 and Ter-119 from primary culture from NOD mice BM. *Methods.* BM was collected from female NOD mice and cultured at 370C and 5% CO2 until the confluence. Firstly, the primary culture was trypsinized and analyzed by flow cytometry for the expression of CD45, CD11b, CD31, CD117, CD34, CD105, CD90, Sca-1 and CD140b. Then, four plates of primary culture were trypsinized and the harvested cells were incubated with magnetic beads conjugated to anti-CD45, anti-CD11b and anti-CD146 for the immunodepletion. Cell suspension was applied onto the column and the unlabeled cells were collected and analyzed by flow cytometry for the expression of CD45, CD11b, CD31, CD117, CD105, CD90, Sca-1 and CD140b, and the cell viability was analyzed by propidium iodide (PI) incorporation. *Results.* The flow cytometry analysis from primary culture cells showed the percentage of CD45 (85.12±6.17), CD11b (84.38±6.13), CD31 (2.23±1.06), CD117 (13.22±1.89), CD34 (1.96±0.10), CD105 (19.49±10.37), CD90 (9.88±2.59), Sca-1(34.81±0.22), CD140b (10.01±2.20). After the immunodepletion, the percentage of $CD45^+$, $CD11b^+$, $CD31^+$, $CD117^+$ cells was 15%, 13%, 2% and 0.2%, respectively, in the collected cells. These cells showed characteristic adherent fibroblast-like morphology and the expression of mesenchymal markers like CD105, CD90, Sca-1 and CD140b was 45%, 8%, 9% and 19%, respectively. The percentage of collected cells was about 4% in relation to the primary culture. The cell viability of the collected cells was 80%. *Conclusions.* We demonstrated that the isolation of MSCs by magnetic separation from primary culture could reduce the percentage of major contaminant cells and it might be a good strategy for enrichment of a mesenchymal stem cell population for gene expression studies by microarrays. Moreover the viability of isolated cells could make possible to keep a pure culture of mesenchymal stem cells and to make functional or other experimental assays for validation of gene expression studies.

MORPHOTYPES AND PHENOTYPES IN PRIMARY CULTURES BONE MARROW MESENCHYMAL CELL FROM HEALTHY DONORS AND MYELODYSPLASTIC PATIENTS

L Campos,[1] C Aanei,[1] F Zugun Eloae,[2] P Flandrin,[1] F Solly,[1] D Guyotat,[3] E Carasevici[2]

[1]*Hopital Nord, Saint Etienne, France;* [2]*Gr T Popa University, Iasi, Romania;* [3]*Institut Cancerologie de la Loire, Saint Priest en Jarez, France*

Background. Myelodysplastic syndromes (MDS) are clonal disorders affecting hematopoietic progenitor cells (HPC). Despite the relevance of microenvironment in developing MDS, only few studies analyze stromal cell population. *Aims.* We propose an *in vitro* model to study mesenchymal stem cell (MSC) differentiation and functionality and to identify the immunopathogenic mechanisms responsible for the initiation and maintenance of MDS. In order to evaluate MSC niche and the ability of differentiation of these cells, we analyzed 3 normal bone marrows (BM), 5 Refractory Anemias (RA) and 6 Refractory Anemia with excess of blasts (RAEB). We performed: 1. Setting of the appropriate culture conditions for the expansion of MSCs; 2. Morphological evaluation of MSC; 3. Phenotype profile of MSCs antigens and adhesion molecules. Primary MSCs cultures were useful in assessing functional capacity of MSCs compartment because they enable us to identify three different types of cells: multipotent uncommitted MSCs, "committed tripotent-bipotent precursor cells and fibrocytes, mature cells without proliferative capacity. *Results.* Compared to normal BM, in RA we detected a decreased number of committed cells and an increased number of fibrocytes. In RAEB we observed disorganization of architecture, giant amorphous deposits in cultures, a lowest number of uncommitted cells and dysplastic changes of MSCs cells, very similar to those described in the hematopoietic compartment. In addition, there were abnormalities regarding the cellular components of the hematopoietic niche, highlighting the role of other cells, like sinusoidal endothelial and adventitial reticular cells. In conclusion, this data suggests that morphological and phenotypical characterization of MSCs niche is useful in understanding the pathogenesis of MDS.

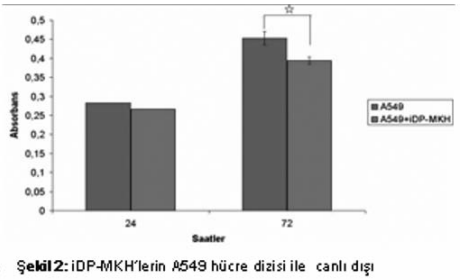
THE EXAMINATION OF CYTOTOXIC EFFECT OF DENTAL PULP DERIVED MESENCHYMAL STEM CELLS AGAINST A-549 CANCER CELLS

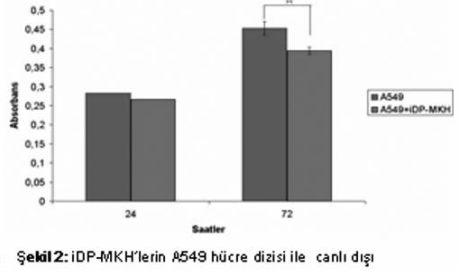
G Gacar,[1] P Demircan Cetinalp,[2] A Sariboyaci Eker,[3] S Korkmaz,[4] E Karaöz[3]

[1]Kocaeli Üniversitesi, Izmit/Kocaeli, Turkey; [2]Center for Stem Cell and Gene Therapies Research and Practice, Dep. of Stem Cell, Izmit/Kocaeli,, Turkey; [3]Center for Stem Cell and Gene Therapies, Izmit/Kocaeli, Turkey; [4]Fargem A.S., Düzce, Turkey

Stem cells are immature, unspecialized cells that are capable of perpetuating themselves as stem cellls and of undergoing differentiation into one or more specialized types of cells .There is strong experimental evience for the notion that cancer develops from cancer stem cells. Cancer stem cells are in many aspects similar to the stem cells. Cancer stem cells have the ability of self-renewal and proliferation, are resistant to drugs, and express typical markers of stem cells. The purpose of cell-based therapy, emerging as a treatment strategy for a good deal of human infections, is to restore, repair or expand the biological role of a damaged tissue or organ. The fundamental biological material used in the studies conducted for this purpose is "stem cells". Due to their immunosuppressive and/or immunomodulator characteristics, mesenchymal stem cells (MSC) today come into use for the purpose of inhibition and/or treatment of many immunodeficiencies in allogeneic transplantations, particularly GVHD (Greft *vs.* Host Disease). Recent reports suggest yet another application for mesenchymal stem cells tecnology: using such cells to immunize against cancer. It was shown that they secrete soluble factor(s) that are capable of inhibiting growth of cancer cells. As a result of the studies toward understanding the mechanism of these immunosuppressive characteristics of MSC's, it was observed that MSC's exhibit potent immunosuppressive activity when they are directly cocultured with Cancer cells, which is believed to arise from cell-cell contact. In our study aiming to research cytotoxic effects of MSC's, human cancer cells were indirectly cocultured *in vitro* with human stem cells isolated as a new cell source for regenerative medicine and immunosuppressive effects of the stem cells on the cancer cells were studied by various methods. For this purpose, MCS's isolated from human embedded dental pulp by enzymatic digestion method were used. For immunophenotypic characterization studies, in flow cytometry device these cells produced positive reaction for CD13, CD44, CD90, CD146 and CD166; reaction was negative for CD3, CD8, CD11b, CD14, CD15, CD19, CD33, CD34, CD45, CD117 and HLA-DR. Cancer-cells (A-549) were maintained in appropriate medium. MSCs in passge 3 were co-cultured with cancer-cells.



Şekil 2: iDP-MKH'lerin A549 hücre dizisi ile canlı dışı koşullarda 24 ve 72 saat süreyle 1:1 oranında indirekt ko-kültür deneyleri sonucunda 72. saatte iDP-MKH'lerin A549 hücreleri üzerinde anti-proliferatif etki gösterdiğini tespit ettik



Şekil 2: iDP-MKH'lerin A549 hücre dizisi ile canlı dışı koşullarda 24 ve 72 saat süreyle 1:1 oranında indirekt ko-kültür deneyleri sonucunda 72. saatte iDP-MKH'lerin A549 hücreleri üzerinde anti-proliferatif etki gösterdiğini tespit ettik

Figure 1, 2.

MCS's (4×10^5) were transplanted to the bottom of 6-well plates and 2 hour waiting period is left for their adherence. 0.4 micron diameter transwell inserts (main-section) were placed to the wells and 4×105. Cancer -cells were placed in each well (at the ratio 1:1) and taken to in-vitro indirect coculture for a period of 4 days. Following each period of time, activity/proliferation capacity in cancer-cells on the upper side of the intermediate section was measured on spectrophotometer device via MTT method and by evaluating the apoptosis levels after Annexin V-PI staining on flow cytometry device (each experiment was repeated 3 times). After 4-day indirect coculture experiments on hDP-MCS's and cancer cells, we found that hDP-MCS's inhibit proliferation on cancer cells ($P<0.05$) and induce apoptosis ($P<0.05$) (Figure 1, Figure 2). Consequently, initial outputs of our study demonstrated that hDP-MCS's create cytotoxic effects on cancer cells.

1701

BONE MARROW DERIVED MESENCHYMAL STEM CELLS CAN EXPRESS GENES WITH KNOWN ANTI-APOPTOTIC FUNCTION AND CO-STIMULATORY MOLECULES OF ANTIGEN PRESENTING CELLS WITHOUT STIMULATION IN VITRO

E Karaoz,[1] A Okçu,[2] O Saglam,[2] S Ayhan,[2] G Gacar,[2] G Duruksu[2]

[1]Kocaeli University, Koaceli, Turkey; [2]Kocaeli University,Center for Stem Cell and Gene Therapies Research and, Kocaeli, Turkey

Background. Therapeutic effects of mesenchymal stem cells (MSCs) occur not only by direct differentiation into injured tissue but also by production of paracrine and autocrine factors. MSCs under injured tissue environments can promote the secretion of a variety of cytokines and growth factors that have both paracrine and autocrine activities. Ex-vivo-expanded MSCs isolated from different species, including human, have been shown to suppress the activity of a broad range of immune cells, including T-cells, natural killer cells and B cells. Also, *in vitro* expanded and purified rat MSCs spontaneously secrete transforming growth factor-beta1 (TGF-β1), hepatocyte growth factor (HGF), interleukin (IL)-6, but no interferon (IFN)-γ, IL-4, IL-5 and IL-10. MSCs promote tissue repair by secreting soluble factors that modulate inflammation and angiogenesis. Studies by at least three independent groups have shown that IFN-γ-stimulated MSCs could act as antigen-presenting cells that shown activated effects of MSCs on immune responses. *Aims.* The aim of this study was to investigate the presence of molecules involved in antigen-presentation in addition to genes with known anti-apoptotic functions including mitogen-activated protein kinase-activated protein kinase 2 (MAPKAP2), tumor necrosis factor, alpha induced protein 3 (TNFAIP3) interacting protein 1 and Bcl-3 in rat bone marrow-derived-MSCs (rBM-). We also examined the cytokine and soluble factor secretion by unstimulated rBM-MSCs. *Methods.* rBM-MSCs were isolated from the rat bone marrow and cultivated under standard conditions. Following their characterization, total RNA was isolated from P3 cell cultures and reverse-transcribed into cDNA. The PCR products were analyzed by agarose gel (2%) electrophoresis.

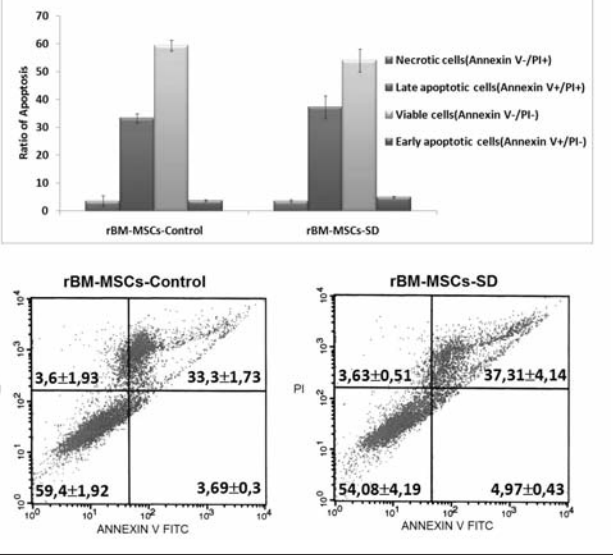


Figure. Serum-deprivation induced apoptosis in rBM-MSCs.

Secretion of rat IL-4, IL-6, IL-10, IFN-γ, TNF-α and TGF-β1 was determined in supernatants by ELISA. rBM-MSCs were seeded at 12×10^3 cells per well in a 96-well plate and then subjected to 24 to 72 hours exposure to serum free medium. Apoptotic cell percentage was detected by flow cytometry with Annexin-V-FITC Apoptosis Detection Kit. *Results.* rBM-SCs did not express CD86 while expressing CD80 which are both counterligands of CD28 with co-stimulatory activity. Interestingly, we determined that besides CD80, rBM-MSCs showed the expression of another co-stimulatory protein CD40. MAPKAP2, TNFAIP3 interacting protein 1 and Bcl-3 were expressed by rBM-MSCs. rBM-MSCs secreted, IL-4, IL-6 and TGF-β1, the secretion was independent from stimulation. But, rBM-MSCs have no IL-10, TNF-α, and IFN-γ secretion. The average percentages of Annexin V+/PI- (early apoptotic) cells were 4.97±0.43 for rBM-MSCs that were incubated serum deprivated medium, and 3.69±0.32 for rBM-MSCs that were incubated complete medium. There was no statistical significance between the two groups (P>0.05). *Conclusions.* Finally, the survivability of rBM-MSCs under serum deprivation may relate with the expression of transcripts with known anti-apoptotic functions. This may highlight the influence of protective role played by anti-apoptotic mechanisms and provide alternative approaches to the treatment of ischemic diseases. The presence of transcripts coding for antigen presenting surface proteins CD 40 and CD80 indicated that these cells were non-professional APCs. In overall, the results of this study emphasized the importance of BM-MSCs in immune system homeostasis along with their regenerative functions.

MAST CELLS AND ANGIOGENESIS IN HAEMATOLOGICAL MALIGNANCIES

D Ribatti,[1] B Nico,[1] S Molica[2]

[1]University of Bari Medical School, Bari, Italy; [2]Department of Hematology-Oncology, Catanzaro, Italy

Bone marrow angiogenesis plays an important role in the pathogenesis and progression of haematological malignancies. Growth is halted and a dormancy state is induced in the avascular phase, whereas with clonal expansion and epigenetic modifications of the microenvironment switch to an angiogenic phenotype that generates the vascular phase, and involves changes in the local balance between pro- and antiangiogenic factors secreted by by inflammatory cells and stromal cells. Tumor cells are surrounded by an infiltrate of inflammatory cells, namely lymphocytes, neutrophils, macrophages and mast cells (MCs). Increasing evidence indicates that MCs play a role in tumor growth and tumor-related angiogenesis in both solid and haematological tumors. We have extensively studied the involvement of MCs in angiogenesis in haematological malignancies, i.e. multiple myeloma, B-cell non-Hodgkin's lymphoma, B-cell chronic lymphocytic leukemia and myelodysplastic syndrome. In this context, MCs might act as a new target for the adjuvant treatment of haematological tumors through the selective inhibition of angiogenesis, tissue remodeling and tumor-promoting molecules, permitting the secretion of cytotoxic cytokines and preventing MCs-mediated immune suppression. We have demonstrated that bone marrow angiogenesis decreases significantly in patients with B-cell chronic lymphocytic leukemia who responded to fludarabine therapy, supporting the hypothesis that angiogenesis is a relevant target of therapy in chronic lymphocytic leukemia and providing insight into the role of fludarabine as a potential anti-angiogenic agent. We have further investigated bone marrow angiogenesis in B-cell chronic lymphocytic leukemia patients treated sequentially with fludarabine and low doses of alemtuzumab. Results showed that the complete response rate improved from 45% after fludarabile induction to 90% after alemtuzumab consolidation. Parallely, the extent of bone marrow angiogenesis and the number of MCs decreased continuously after either fludarabine or alemtuzumab.

ROLE OF TUMOR'S CELLS REVEAL IN BONE MARROW IN BREAST CANCER PATIENTS

S Sivkovich,[1] O Kalyuta,[2] A Lytvinenko[2]

[1]Institute of hematology and transfusiology of UAMS, Kyiv, Ukraine; [2]Medical clinic Innovation, Kyiv, Ukraine

Introduction. According to the literature revue, the tumor's cells metastasis into the bone marrow (myelocarcinosis) are diagnosed in 30-90% cases of breast cancer patients. Prognosis for these patients is much worse than for patients without mentioned complication. Thereby, besides the investigation of primary tumor's site, revealing of myelocarcinosis in breast cancer patients could be used for the prognostic estimation of course of decease, as well as in monitoring of systemic therapy *Results.* Therefore, purpose of the investigation was the revelation of atypical cells in bone marrow in breast cancer patients. *Materials and methods.* 48 patients in the age 29 - 66 years with hystomorphologically confirmed diagnosis of breast cancer were considered within our observation. Distribution according to the stage of decease was the following: 0 stage - 1 patient, I stage - 5, IIA - 11, IIB- 12, IIIA - 6, IIIB-7, IV-6. All the patients were carried out a sternal biopsy for the purpose of bone marrow samples investigation and probable revelation of atypical cells of breast cancer metastasis into the site. Pappenheim stain was used for bone marrow samples revue. *Results.* The number of myelocariocytes varied within $45\text{-}187\times10^9$/L. 20 patients (41.7%) had a normocellular bone marrow with a ratio myeloid/erithroid cells 3:1, any abnormal cells were identified in the samples. In 28 (58,3%) patients' bone marrow samples, against the background of hypocellular bone marrow, were revealed a large, round, epithelial cells with hyperbasophilic and vacuolization cytoplasm, interpreted as metastasis cells. According to the stage of breast cancer, patients with myelocarcinosis findings were distributed as follows: IIA - 2 patients, IIB - 2, IIIA - 2, IIIB - 3, IV - 3. *Conclusions.* We confirmed myelocarcinosis in 58.3% of breast cancer patients within our investigation. Therefore, bone marrow biopsy is necessary for all of them to clarify metastasis dissemination and to optimize their future treatment.

PRAME UP-REGULATES MAGE-A3, MAGE-A6, MAGE-A12, A NUMBER OF ANTI-APOPTOTIC GENES AND DOWN-REGULATES PRO-APOPTOTIC AND DIFFERENTIATION-INDUCING ANTI-ONCOGENES

A Misyurin, N Lapshyna, T Akhlynina, E Aksenova, Y Finashutina

Research Center for Hematology, Moscow, Russian Federation

Background. The preferentially expressed antigen of melanoma (PRAME) is expressed at high levels in large proportion of human malignancies including acute and chronic myeloid, chronic lymphoid leukemia, diffuse large cell lymphoma and multiple myeloma. PRAME is turned out to be an important marker for diagnosis of various malignant diseases and a relevant parameter for monitoring minimal residual disease. In many cases PRAME is a factor of unfavorable prognosis. It was shown recently that PRAME is an inhibitor of RARa protein activity. Nevertheless, distinct elucidation and description of PRAME targets is still necessary in order to reveal a full specter of its tumorigenic properties. *Aim.* Our purpose was to investigate the influence of PRAME on an expression profile of a wide range of genes exploiting a molecular cell model. *Methods.* We cloned PRAME coding sequence under a strong CMV promoter using pCEP4 (Invitrogen) vector. Cell line of human PRAME-negative fibroblasts WI38 was then transfected by PRAME-pCEP4 and pCEP4 itself to obtain both PRAME-expressing variant of WI38 and negative control. Stable PRAME expressing and non-expressing lines of WI38 were selected using hygromycin B. High level of PRAME expression in PRAME transfected line was confirmed by real-time PCR and cell staining with mAb against this protein. Gene expression profiles in these lines were compared by means of microarray analysis using vast panels of dots (25000 genes) and arrays restricted by particular collection of targets (cell cycle and apoptosis regulating genes and transcription factors). Statistical analysis was performed using the dChip software. Selected genes were submitted to real-time PCR confirmation. *Results.* We have revealed that PRAME activation up-regulates MAGE-A3, MAGE-A6, MAGE-A12, membralin (cancer-testis antigens), XIAP, SCC-S2/GG2-1/NDED/ TNFAIP8, BNIP1, RIPK1, acinus, G1P3 (anti-apoptotic genes), SP110 (RARa inhibitor), MAD2L1 (cell cycle regulation), EMP2, IRF9, STAT1 (mitogenic and transcription factors), BOP1 (increases the percentage of multipolar mitotic spindles causing genomic instability) and down-regulates PLAB (genes), PCTK1, TNFAIP2, TNRC6, RNF8 (pro-apoptotic and differentiation anti-oncogenes). *Conclusion.* Our data suggest that PRAME regulates a number of downstream genes in a tumor-enhancing manner. It makes the PRAME to be an important factor of malignisation due to the great diversity of PRAME-dependent genes and their well-known involvement into tumorgenesis.

1705

IN VIVO FUNCTION OF A NOVEL ADAPTOR PROTEIN STAP2 IN THE PROGRESS OF INFLAMMATION

N Fujita,[1] K Oritani,[1] T Yokota,[1] N Saitoh,[1] T Sudo,[1] Y Sekina,[2] T Matsuda,[2] Y Kanakura[1]

[1]Osaka University Graduate School of Medicine, Osaka, Japan; [2]Hokkaido University Graduate School of Pharmaceutical Sciences, Sapporo, Japan

Background and *Aims.* Signal-transducing adaptor protein-2 (STAP2) is composed of PH and SH2 as well as proline-rich domains, each of which acts as docking sites for several signaling molecules. Our previous *in vitro* experiments have suggested that STAP2 might be involved in multiple steps of inflammatory responses, such as the cytokine production, the mobility of macrophages, and the migration of T-lymphocytes. In the present study, we analyzed *in vivo* effects of STAP2 on inflammation using STAP2-knock out (KO) mice. *Methods.* To confirm the blood component of STAP2-KO mice, we analyzed bone marrow (BM), spleen and thymus samples with flow cytometry. As a model of inflammation, dextran sulfate sodium (DSS)-induced colitis was employed. STAP2-KO and wild-type (WT) C57/BL6 mice aged 15-20 weeks were administered 1.75% or 3.5% DSS (molecular weight 36,000-50,000) dissolved in sterilized drinking water for 7 days. Animals were weighted daily and monitored for rectal bleeding. The severity of colitis was also evaluated by the serum amyloid A (SAA) measurement with ELISA as well as the assessment of colon tissue samples with immunohistochemistry. Briefly, the middle portion of colon tissues were fixed in 4% (w/v) paraformaldehyde, embedded in paraffin, and sliced into 3-mm-thick sections, followed by the staining with hematoxylin and eosin as well as immunohistological staining. *Results.* Flow cytometry analysis of BM cells from WT and STAP2-KO mice showed similar pattern of staining for CD43 and B220 (WT: 4.1% pro-B, 14.5% pre-B, and 8.1% immature B; STAP2-KO: 3.8% pro-B, 17.0% pre-B, and 9.5% immature B). Their BM cells also contained TER119- or Mac1-positive cells similarly. When thymocytes were stained with CD4 and CD8, no difference was observed between WT and STAP2-KO mice (WT: 3.8% DN, 84.2% DP, 9.6% CD4-SP, and 2.5% CD8-SP; STAP2-KO: 4.4% DN, 82.0% DP, 11.2% CD4-SP, and 2.4% CD8-SP). In addition, similar proportion of CD3- or B220-positive cells was detected in their spleen cells. Thus, STAP2-KO mice are likely to have normal blood components, leading us to investigate *in vivo* effects of STAP2 on inflammatory responses. We observed a significant decrease in the body weight of DSS-treated WT mice compared to DSS-treated STAP2-KO mice ($P<0.01$). In addition, DSS-treated WT mice showed rectal bleeding earlier and more frequently than DSS-treated STAP2-KO mice. The shortening of colon length was more obvious in DSS-treated WT mice on day 7. In morphological examinations of colon sections on day 4, the shortening and loss of crypts as well as the infiltration of macrophages (F4/80-positive) and T-lymphocytes (CD3-positive) were demonstrated in WT mice, but not in STAP2-KO mice. The alterations of the colon tissues were observed much earlier and severer in WT mice. Finally, the increase of serum SAA was higher in DSS-treated WT mice than DSS-treated STAP2-KO mice. Thus, DSS-induced colitis becomes less prominent by knock out of STAP2 proteins. *Conclusions.* The development of lympho-hematopoietic cells is independent on the expression of STAP2. However, our experiments using a DSS-induced colitis model have indicated that STAP2 is clearly involved in the progress of inflammation *in vivo*.

MOLECULAR MECHANISMS OF RESVERATROL-INDUCED CELL DEATH IN K562 CHRONIC MYELOID LEUKEMIA CELLS

Y Baran,[1] M Kartal,[2] G Can,[3] G Saydam,[4] F Sahin[5]

[1]Izmir Institute of Technology, Faculty of Science, Dept.of Mol.Biol. & Genetics, Urla Izmir, Turkey; [2]Izmir Institute of Technology, Faculty of Science,Dept.of Mol.Biol. & Genetics, Izmir, Turkey; [3]Izmir Institute of Technology, Fac.of Science,Dept.of Mol.Biol.& Genetics, IZMIR, Turkey; [4]Ege University,Faculty of Science, Department of Hematology, Izmir, Turkey; [5]Ege University,Faculty of Science, Department of Biology, Izmir, Turkey

Background. Resveratrol is a natural product derived from various plants in order to protect them under stress conditions. Resveratrol has drawn increasingly more attention recently since it affects the processes underlying tumor initiation, promotion and progression. Although we and some other groups have shown antiproliferative and apoptotic effects of resveratrol on chronic myeloid leukemia cells, mechanisms regulated by resveratrol have not been examined in detail. *Aims.* We aimed to investigate the molecular mechanisms of resveratrol induced apoptosis in K562 chronic myeloid leukemia cells. *Methods.* Antiproliferative effects of resveratrol on K562 cells were conducted by XTT cell proliferation assay. Changes in expression patterns of 84 genes involved in apoptosis, cell cycle, senescence, adhesion, invasion, metastasis, angiogenesis, transcription factors, and signal transduction molecules were examined by PCR array in K562 cells exposed to increasing concentrations of resveratrol (10 and 50 μM) for 72 h. *Results.* There were dose-dependent decreases in cell proliferation in response to resveratrol (IC50;80 μM in K562 cells). PCR array results demonstrated that there were more than 3-fold increases in expression levels of 26 and 52 among 84 genes in response to 10 and 50 μM resveratrol, respectively, as compared to untreated controls. (Threshold> 3, $P<0.05$). On the other hand, expression levels of 2 among 84 genes were reduced more than 3 times in response to 50 μM resveratrol. There were overexpression of the genes involved in apoptosis, tumor suppression and cell cycle arrest. The most important ones being TNF, SerpinB5, TNFRSF25, FAS, GZMA, Bax, and Bad. The highest increase (7.5 and 62-fold) was observed in SerpinB5 tumor supressor gene in K562 cells exposed 10 and 50 μM resveratrol comparing to untreated control group. The highest decrease (3.4 fold) was detected in Myc transcription factor genes in response to resveratrol as compared to untreated K562 cells. *Summary/Conclusion.* By this study we explained the molecular mechanisms of resveratrol-induced cell death in chronic myeloid leukemia cells. The results demonstrated that resveratrol triggers apoptosis and inhibits proliferation through regulating cell cycle controller, apoptosis, and tumor suppressor genes in K562 cells. The results of this study strengthen the potential of resveratrol as an anticancer agent for the treatment of cancers including chronic myeloid leukemia.

UNRESPONSIVENESS OF MDS CELLS TO SDF-1 IS DUE TO PKCZETA INEFFECTIVE CXCR4 RECRUITMENT TO THE PLASMA MEMBRANE

C Bigarella, M Baratti, L Ricon, A Duarte, F Costa, S Saad

University of Campinas, Campinas, Brazil

Background. Myelodysplastic syndrome (MDS) is a clonal hematological disorder that mainly affects the elderly and is characterized by dysplasia in multiple lineages of blood cells, including myeloid, erythroid and megakaryocytic-platelet lineages. MDS is thus believed to result from the malignant transformation of plutipotent hematopoietic stem cells (HSCs). Another important characteristic of MDS is the co-existence of increased cellularity in bone marrow (BM) and cytopenias in peripheral blood. Immature BM cells of individuals with MDS may therefore be defective regarding differentiation or may undergo apoptosis before giving rise to a sufficient number of progeny. Currently the role of the bone marrow niche is being defined as crucial for the correct pluripotency maintenance or differentiation state of HSCs. The chemokine stromal-derived-factor-1 (SDF-1) and its receptor, CXCR4, are thought to develop a main role within the BM microenviroment promoting migration, retention and development of hematopoietic progenitors. Hematopoietic stem and progenitor cells of MDS patients are known to express levels of CXCR4 comparable to normal individuals however their cells do not respond to SDF-1 gradients (Matsuda *et al.,* 2004). Recently, the protein kinase C (PKC) isotype zeta increased activity due to cAMP treatment has been shown to raise CXCR4 expression in $CD34^+$ HPSC (Goichberg *et al.,* 2006). Indeed, PKCzeta act downstream SDF-1 signaling in hematopoietic progenitors through protein G-coupled that activates PI3K, which in turn activates PKCzeta and, consequently, leads towards the activation of proliferation and induction of adhesive or migrating phenotypes (Goichberg *et al.,* 2005). *Aim.* The aim of this study was to identify the poorly express PKCzeta to be the main cause of MDS cells unresponsiveness to SDF-1 gradients, despite CXCR4 being expressed at normal levels. *Methods.* flow cytometry, confocal microscopy, western blotting and transwells migration assays were performed. *Results.* P39 myelomonocytic cell line was used as a MDS model despite having been recently shown to be contaminated with HL-60 cells (Steensma, 2010) and it displayed several MDS-similar behaviors. The unresponsiveness of MDS $CD34^+$ cells to stromal cell derived factor 1 (SDF-1) (Matsuda *et al.,* 2004) was also observed in P39 cells through transwell migration assays using 200 ng/mL SDF-1. We hypothesize that this unresponsiveness to SDF-1 is possibly due to a defective recruitment of CXCR4 to the plasma membrane, as only permeabilized P39 cells exhibited positivity for CXCR4. Furthermore, confocal analysis of P39 cells using a CXCR4 specific antibody showed it to be localized on cell cytoplasm. Western blotting analy-

sis of bone marrow mononuclear cells from MDS patients as well as P39 cell lysates displayed a lack of PKCzeta expression in comparison to $CD34^+$ cells of normal blood donors. *Conclusions.* This work reveals for the first time that the inability of MDS cells to respond to SDF-1 gradients is due to the lack of PKCzeta expression and, consequently, CXCR4 internalization.

1708

PHARMACOGENOMIC VARIANTS OF CYP2C9, CYP4F2 AND VKORC1 AND ITS RELATION TO WARFARIN RESPONSE IN NATIVE OMANI PATIENTS

A Pathare,[1] S AlZadjali,[1] R Misquith,[1] D Gravell,[1] K Al Falahi,[1] H Al-Haddabi,[1] R Krishnamoorthy[2]

[1]Sultan Qaboos University, Muscat, Oman; [2]INSERM, U,[763] Paris, France

Background. The three clinically significant genetic determinants of warfarin inter individual variability are cytochrome P450 [CYP] CYP2C9, CYP4F2 and vitamin K epoxide reductase 1(VKORC1) polymorphisms. CYP2C9 & CYP4F2 polymorphisms alter the pharmacokinetics whereas; the VKORC1 polymorphisms predominantly affect the pharmacodynamic characteristics of warfarin. *Aims.* To study the CYP2C9, CYP4F2 genotypes and VCORC1 haplotypes in the native Omani patients receiving warfarin and correlate them with the dosage. *Methods.* In 214 Omani patients started on warfarin therapy, we assessed six CYP2C9 alleles (CYP2C9*1,*2 ,*3,*4,*5 &*8), two CYP4F2 alleles (CYP4F2*1 & *3) and four VKORC1 nucleotide variants linked to the VKORC1*1, *2,*3 &*4 haplotypes (g.-1639G>A,g.497 G>T,g.698C>T, g.3730G>A,). In patients with warfarin resistance [weekly dose>60 mg] we directly sequenced the PCR amplicons of all the 3 VKORC1 exons, including the intron-exon junctions for the known warfarin resistance associated nucleotide changes.(g.85G>T[p.V29L], g.106G>T[p.D36Y], g.121G>T[p.A41S], g.134T>C[p.V45A], g.172A>G[p.R58G], g.133G>A[p.V66M] and g.3487T>G[p.L128R]) Additionally, demographic and ethnic data, clinical characteristics, response to therapy (as determined by the international normalized ratio(INR)) and steady state warfarin dose requirements were also noted. *Results.* Amongst the patients studied, the mean daily warfarin dose (mg) was 1.0, 3.8, 4, 4.75 and 5.5 in the CYP2C9*3 homozygote, *8 heterozygote, *3 heterozygote,*2 heterozygote and *1 (wild type) respectively (P<0.05). The mean warfarin daily dose (mg) was 2.6, 4.5 and 5.7 in CYP4F2 *3 homozygotes, *1/*3 heterozygotes, and *1 homozygotes (wild type) respectively (P<0.02). When warfarin dose was compared between the VKORC1 A haplotype (*1)[wild type] *vs.* (*3, & *4) the mean daily warfarin dose (mg) was significantly lower at 4.0+1.7 compared to 7.3+1.9(P<0.05) in the former. Similarly, when warfarin dose was compared between the VKORC1 A haplotype (*2) *vs.* (*1) the mean daily warfarin dose (mg) was significantly lower at 2.1+1.7 compared to 4.0+1.7(P<0.05) in the later. In the warfarin resistant group,[weekly warfarin dose > 60 mg; n=8] we identified 2 patients with V66M mutation, one patient with D36Y mutation. In the warfarin sensitive group [weekly warfarin dose<15 mg; n=20] we identified 2 CYP2C9*3/*3 homozygote, 3CYP2C9*3 heterozygote and 11 VKORC1*2/*2 homozygote. We did not find any case with CYP2C9*4,*5, or *2 homozygote in this study. *Summary/Conclusions.* The study confirms that CYP2C9, CYP4F2 and VKORC1 polymorphisms played a significant role in the Omani patients treated with warfarin. Warfarin sensitivity was observed in a significant number of cases and was represented by CYP2C9*3/*3 homozygotes, CYP2C9*3 & *8 heterozygotes, and VKORC1*2/*2 homozygotes. This information is being now used as clinically relevant predictors in this population when practicing pre-prescription CYP2C9, CYP4F2 genotyping and VKORC1 haplotyping to predict at the probable warfarin dose that will be safe and effective for optimal anticoagulation.

1709

MIRNA-29C EXPRESSION IS ASSOCIATED WITH IMATINIB RESISTANCE AND MCL-1 ANTI-APOPTOIC GENE EXPRESSION IN CHRONIC MYELOID LEUKEMIA PATIENTS

A Ferreira,[1] B Pinto Simões,[1] W Silva Júnior,[1] I Tojal Silva,[1] MA Zanichelli,[2] MD Colassanti,[2] N Hamerschlak,[3] D Covas,[4] S Kashima,[1] AM Souza,[5] F Castro[5]

[1]University of São Paulo, Ribeirão Preto, Brazil; [2]Hospital Brigadeiro, São Paulo, Brazil; [3]Sociedade Beneficente Israelita e Brasileira Hospital Albert Einstein, São Paulo, Brazil; [4]Faculdade de Medicina - USP, Ribeirão Preto, Brazil; [5]Faculdade de Ciências Farmacêuticas - USP, Ribeirão Preto, Brazil

Background. Chronic myeloid leukemia (CML) is a myeloproliferative disease characterized by the presence of the Philadelphia chromosome and Bcr-Abl oncoprotein. Bcr-Abl is a tyrosine kinase (TK) with a deregulated activity which results in leukemic cells proliferation and apoptosis resistance. miRNAs are small non-protein-coding molecules which regulate gene expression at the translational level and have essential roles in cell differentiation, proliferation and apoptosis. Mcl-1 is an anti-apoptotic gene, member of Bcl-2 family, that has been reported as miR-29c target. This miRNA over-expression is also observed in chronic lymphoid leukemia (CLL) and can inhibit tumor formation in an animal model. *Aims.* 1) To verify miR-29c and mcl-1 expression in healthy subjects (controls), CML patients in different phases of the disease, in patients who achieved complete cytogenetic response (CCR) and imatinib (IM) resistant. 2) To correlate mcl-1 mRNA levels with miR-29c expression in CML patients. *Methods.* CML patients' and healthy subjects' peripheral blood mononuclear cells (PBMC) were submitted to RNA extraction by trizol method and reverse transcription was performed with specified primers RT stem loop for each miRNA. TaqMan Universal PCR master mix kit was used for miR-29c expression assay at ABIPRISM 7500 Real Time PCR. SYBRTM Green PCR master mix kit was used for mcl-1 expression assay. The miR-29c and mcl-1 expressions were given as 2-ddCt and URE, respectively. Mann-Whitney and Kruskal-Wallis (Dunns post-test) tests were used for statistical analysis. *Results.* CML patients, in chronic (median=3.24) and advanced phases (median=1.97), presented higher miR-29c expression when compared to control group (median=1.0). However, no difference in miRNA levels was observed among patients in chronic and advanced phases of disease. miR-29c expression was decreased in CML patients resistant to IM (median=1.62) when compared to patients who achieved CCR (median=11.87); (P=0.0010). *Conclusions.* miR-29c might be regulated by Bcr-Abl once its expression was higher in CML patients than in controls. mir-29c expression was associated with IM response. We speculate that miR-29c can modulate mcl-1 expression in IM resistant CML patients.

DETECTION OF C-KIT D816V IN PATIENTS WITH MASTOCYTOSIS FROM PERIPHERAL BLOOD

A Polonyfi,[1] N Mikos,[2] S Raptis,[1] E Kompoti,[2] V Kalotychou,[1] J Meletis,[1] A Aessopos,[1] G Vaiopoulos,[1] M Mantzourani[1]

[1]National and Kapodistrian University of Athens, Athens, Greece, Athens, Greece; [2]Laikon Hospital, Athens, Greece

Background. Mastocytosis is a rare disease characterized by pathological mast cell accumulation and activation in tissues such as skin, bone marrow, liver, spleen, and lymph nodes. The clinical spectrum of mastocytosis is variable and may range from a self-limited disease confined to skin in patients to progressive and life-threatening variants associated with poor prognosis. Detection of a codon 816 c-kit mutation is included as a minor diagnostic criterion in the World Health Organization's diagnostic criteria for systemic mastocytosis. Most patients with mastocytosis exhibit the D816V point mutation in the tyrosine kinase domain of the transmembrane receptor protein Kit, leading to its constitutive activation in bone marrow or lesional skin tissue. We studied blood samples from patients with mastocytosis for detection of a codon 816 c-kit mutation. *Methods.* Fifteen patients, nine with systemic mastocytosis and six with cutaneous mastocytosis participated in this study. All patients have serum tryptase level greater than 20 ng/mL. DNA was extracted from peripheral blood and PCR method and RFLPs analysis were applied for the detection of D816V mutation. The amplified region confirmed by sequencing. *Results.* Two patients from the fifteen selected for the study carried the 2447 A>T point variation (D816V) in exon 17 of the KIT gene. One patient was diagnosed for systemic mastocytosis and the other one for cutaneous mastocytosis. *Conclusion.* Detection of the D816V variation in Systemic Mastocystosis patients is important for determining treatment strategy, but as the population of malignant cells carrying this variation is often small relative to the normal cell population, standard molecular detection methods can be unsuccessful. Determining mutational status of the c-kit gene also has pharmacogenomic implications in patients considered for investigational mast cell cytoreductive therapies.

1711

CHARACTERIZATION OF THE C.(-203)A>G VARIANT IN THE GLUCOCEREBROSIDASE GENE AND ITS ASSOTIATION WITH GAUCHER DISEASE PHENOTYPE

P Alfonso,[1] S Pampín,[2] B García-Rodríguez,[3] MT Tejedor,[4] JC Rodríguez-Rey,[2] C Dominguez,[5] P Giraldo,[6] P Pocovi[7]

[1]Aragon Health Sciences Institute (I+CS)- CIBERER, Zaragoza, Spain; [2]Department of Molecular Biology. University of Cantabria, Santander, Spain; [3]Laboratory of Molecular Investigation. University of Zaragoza., Zaragoza, Spain; [5]Center of Molecular and Biochemistry Investigation. Vall D'Hebrón Universitary H, Barcelona, Spain; [6]Service of Hematology. Miguel Servet Universitary Hospital, Zaragoza, Spain; [7]Department of Biochemistry and Cellular and Molecular Biology. Uni. of Zaragoza, Zaragoza, Spain

Background. Gaucher disease (GD) is a rare autosomal recessive disorder characterized by defective function of glucocerebrosidase. The main cause of disease is due to mutations of GBA gene. High phenotypic variability has been observed among patients who carry the same genotype, therefore other factors may influence GD phenotype, including polymorphic variants. Previously we have reported the presence of the c.(-203)A>G (g.1256A>G) variant in exon 1 of GBA gene in Spanish GD patients. *Aim.* To determine its role in GD we analyzed the allelic frequency of this change in 206 unrelated Spanish GD patients and a control group (50 samples of cord blood and 100 adult healthy subjects). *Results.* Our results showed the G-allele frequency for GD group was 0.0097±0.0048 and 0.0200±0.0081 for control group, without no statistical significance (P=0.336). In GD patients, G allele was always found in association to another mutation on the same allele and patients carrying c.(-203)A>G variant compared to patients non carriers showed a more severe phenotype. Electrophoretic mobility shift assays demonstrated that the existence of different protein affinity from nuclear extract with mutated promoter with respect to wild promoter. To evaluate whether the variant influenced promoter activity, luciferase reporter plasmids containing 620 bp of the proximal promoter region were constructed. In transient transfection assays, allele G resulted in a 35 % reduction of promoter activity. *Conclusion.* The c.(-203)A>G variant could be a polymorphism and exert a significant effect on GBA promoter activity and might explain in part the phenotype of some GD patients.

CG- AND CNG-TYPES OF MDR1- GENE PROMOTER METHYLATION IN PATIENTS WITH DIFFERENT TYPES OF LEUKEMIA

D Marinitch,[1] D Tsvirko,[1] N Volkovets,[1] Y Buryanov,[2] T Shevtchuk,[2] O Dyachenko[2]

[1]Byelorussian Hematology Center, Minsk, Belarus, Republic of; [2]Branch of Institute of Bioorganic Chemistry, Russian Biology Center, Pustchino,, Pustchino, Russian Federation

The epigenetic changes (DNA-methylation), revealed in the process of leukemia progression affects expression of many genes including multidrug-resistance gene (MDR1). But the exact correlation between MDR1-gene promoter methylation and MDR1 expression remains unclear. The CG- and CNG-comparative methylation status of the 5'-promoter region of this gene in patients with acute lymphoblastic leukemia (ALL), acute myeloid leukemia (AML), chronic myeloid leukemia (CML) and myelodisplastic syndrome (MDS) patients was investigated. Totally 39 DNA samples from 28 patients (6 ALL, 14 AML, 4 CML (chronic phase) and 4 MDS (early stage of the disease) obtained from mononuclear cells of peripheral blood and bone marrow were employed in the experiment. We investigated two fragments of MDR1-promoter region with both CG- and CNG- sites presence. Methyl-sensitive PCR method was applied. CG- (HpaII) and CNG- (EcoRII) restriction enzymes were used. Two pairs of primers flanking CG- and CNG-recognition sites of MDR1 gene were constructed for this purpose. 1-st pair: 5'-TAGAGAGGTGCAACGGAAGC-3', 5'-CTCAGGCTTCCT-GTGGCAA-3', 2-nd pair: 5'-AGTCCATGGGGACCAAGTG-3'. 5'-CATCTCCACGAAGGCAGAGTT-3'. For the first time we revealed CNG-type of methylation in cases of hematology malignancies. This phenomena was detected in one ALL, one AML and all MDS and CML cases. In all these cases CG-sites was also methylated. It is interesting to note, that both above-mentioned patients with acute leukemia (ALL and AML) was in complete remission. The rest of DNA samples were CG-hypomethylated. Hypomethylation of MDR1-promoter region is often correlates with overexpression of the MDR1 gene, which is well known as a marker of poor prognosis. This coincides with clinical prognosis estimation of "hypomethylated' patiens. The exact role of both types of methylation of MDR1-promoter region and MDR1-gene expression needs further investigation.

1713

ELEVATED LEUKOTRIENE B4 PRODUCTION BY PERIPHERAL BLOOD MONONUCLEAR CELLS FROM HTLV-1 INFECTED INDIVIDUALS

B Trindade,[1] L Nicollete,[1] T Malta,[1] C Sorgi,[1] O Takayanagui,[1] D Covas,[2] S Kashima,[2] L Faccioli[1]

[1]University of São Paulo, Ribeirão Preto, Brazil; [2]Fundação Hemocentro de Ribeirão Preto, Ribeirão Preto, Brazil

Background. Leukotriene B4 is bioactive lipid derived from 5-lipoxygenase (5-LO) pathway of arachidonic acid metabolism, and act by signaling mainly through their high affinity membrane receptor BLT1. It is powerful chemoattractant and pro-inflammatory mediator in several inflammatory conditions. However, the relationship of LT and HTLV-1 infection and related diseases like HAM/TSP is still unknown. *Aim.* The aim of this study was to analyze the production of LTB4 and gene expression profile of enzymes involved in the 5-LO pathway and the high affinity receptor for LTB4 in peripheral blood mononuclear cells (PBMCs) obtained from HTLV-1 infected individuals. *Methods.* PBMCs were obtained from ten healthy donors, eleven subjects with HAM/TSP and ten asymptomatic HTLV-1 carriers (HAC), which were used in cell culture and RNA extraction using Trizol® method. The cells were incubated during 48 hours and LTB4 production was evaluated by EIA after calcium ionophore stimuli. Moreover, cDNAs from PBMCs were synthesized and a quantitative PCR (qPCR) was performed to 5-LO, FLAP and BLT1 genes to determine their relative expression. *Results.* An increased concentration of LTB4 was observed in culture supernatant from asymptomatic and symptomatic groups when compared to health group ($P<0.05$). The level of this lipid mediator was similar between infected groups. Furthermore, PBMCs from HAM/TSP patients constitutively expressed higher levels of 5-LO mRNA than asymptomatic and health donors. In contrast, equivalent amounts of RNA transcripts to FLAP enzyme and BLT1 receptor were observed in cells from both analyzed groups. *Conclusion.* Our data suggest that PBMCs from HTLV-1 infected patients have prominent ability to produce LTB4. These results may be useful for understanding the involvement of arachidonic acid metabolites in pathogenesis of HAM/TSP.

1714

PREVALENCE OF VDR GENE POLYMORPHISM AND ITS ASSOCIATION WITH BONE MINERAL DENSITY IN BETA-THALASSEMIA MAJOR CASES OF NORTH INDIA

S Agarwal, R Kumar, S Phadke, P Dabadgaon

SGPGIMS, Lucknow, India

Background. Bone disease in thalassemia is actually a low bone mass, which remains a frequent, debilitating, and poorly understood problem since very long, even in well transfused and chelated pre-pubertal and adult patients. *Objective.* This work was an attempt to delineate calcium status and bone mineral density in a group of transfusion dependent thalassemic adolescents of both sexes, and to correlate it with VDR gene polymorphisms. *Methods.* Bone mineral density (BMD) at both the lumbar spine and hips were measured in 22 adolescents between 10-28 years age of beta thalassemia major by Dual-energy X-ray absorbiometry (DEXA) scanning. The Z score of BMD at lumbar spine and hips were correlated to calcium and phosphorus levels. To find out the prevalence of Vitamin D receptor (VDR) gene polymorphism at exon 2 (Fok1) and exon 9 (Taq1) the Polymerase chain reaction- Restriction Fragment Length polymorphism (PCR-RFLP) studies have been done in 100 thalassemia major cases. Only 22 cases of thalassemia major cases where BMD studies have been performed were estimated for genotype polymorphism of Fok I and Taq I to reveal association. *Result.* Calcium deficiency was found in 31% of Thalassemia patients. However, no significant association of Z score of BMD and Calcium and Phosphorus levels were found. Z-score of BMD at the lumbar spine (-2.3, +/-1.3) was lower than that of the Z-score of the Hips (-2.1, -/+0.89), (P=0.001). Patient with Ff genotype of Fok I site have significantly lower Z- score of BMD at Hips (P=0.034) as compared to patients with FF genotype. However there is no significant change of Z- score of BMD at lumber spine in Fok1 genotype (P=0.46) was observed. We found no

significant change of Z- score of BMD at both Lumber spine and Hips in Taq1 polymorphism. The genotypes frequency for FF, Ff and ff and TT, Tt and tt was 41%, 52% and 7% and 36%, 53% and 11% respectively. On comparing the prevalence of genotypes reported in the literature for north Indians and the prevalence found in present study showed no significant difference. This confirms that frequency and distribution of the polymorphisms in India are though different from other population and ethnic groups but has significant contribution in the field of clinical epidemiological data. *Conclusion.* This is the first report from India, which shows the association of BMD and vitamin D receptor gene polymorphism in thalassemia patients.

1715

TRANSCRIPTIONAL ACTIVITY OF TRANSFORMING GROWTH FACTOR BETA1 (TGF-β1) AND ITS RECEPTORS (TβR-I, TβR-II, TβR-III) AFTER ALLOGENEIC BONE MARROW TRANSPLANTATION

P Zielinska, G Helbig, A Wieczorkiewicz, M Markiewicz, S Kyrcz-Krzemien

Medical University of Silesia, Katowice, Poland

Background. An increasing use of unrelated and mismatched donors results in a frequent incidence of graft-versus-host disease (GVHD) that continues to be a serious complication following allogeneic haematopoietic stem cell transplantation (alloHSCT). Transforming growth factor beta1 (TGF-β1) seems to be one of the factors that may play a role in the development of GVHD symptoms. *Aims.* The aim of this study was to determine whether transforming growth factor beta1 (TGF-β1), were associated with the occurrence of GVHD in patients who underwent alloHSCT for myeloid leukemias. *Methods.* We investigated the transcriptional activity of TGF-β1 and its three receptors: TβR-I, TβR-II, TβR-III by quantitive real time polymerase chain reaction (Q-PCR) using ABI PRISMTM 7700 (TaqMan). GAPDH gene was used as an endogenous control. *Results.* Fourty adult patients with myeloid leukemias were treated with alloHSCT, 15 from HLA-typical siblings and 25 from unrelated donor. Acute GVHD was observed 20 patients, and 11 patients had chronic GVHD. A prompt decrease in TGF-β1 mRNA expression was demonstrated after conditioning. In patients with acute GVHD, TGF-β1 mRNA expression remained low until day +30 after transplantation. TGF-β1 mRNA expression significantly increased on day +100 in patients who developed chronic GVHD. Multivariate analysis revealed that transcriptional activity of TGF-β1 on day +30 after HSCT is an important factor providing data on the risk of chronic GVHD. No differences were detected in transcriptional activity of TβR-I, TβR-II, TβR-III. *Conclusions.* These results show that low TGF-β1 mRNA expression seem to be associated with the development of acute GVHD and that chronic GVHD symptoms seem to correlate significantly with high TGF-β1 mRNA expression in patients who underwent bone marrow transplantation for myeloid leukemias. Further studies including higher number of patients are needed to establish the role of TGF-β1 in graft *vs.* host disease.

APPLICATION OF MULTISPECTRAL IMAGING FLOW CYTOMETRY TO CHARACTERIZE NORMAL AND ALTERED HEMATOPOYESIS IN BONE MARROW AND PERIPHERAL BLOOD

JE O'Connor,[1] P León,[2] G Herrera,[1] J Platas,[1] F Sala-de-Oyanguren,[1] MJ Cejalvo[2]

[1]*Centro de Investigacion Principe Felipe, Valencia, Spain;* [2]*Servicio de Hematología, Hospital Universitario Doctor Peset, Valencia, Spain*

Background. Clinical characterization of normal and altered hematopyesis is mostly performed by separate examination by flow cytometry and light microscopy of bone marrow and peripheral blood samples. The advantages of a system allowing simultaneous determination of immunophenotype and morphology in standard haematological samples are evident. *Aims.* To assess the usefulness of the novel approach of multispectral imaging flow cytometry (MsIFC) in the diagnosis of haematological disorders and rare diseases with haematological profile. *Methods.* Bone marrow and peripheral blood samples from patients undergoing clinical diagnosis at the Haematology Service, for leukaemia, lymphoma or rare disease (mastocytosis, Gaucher's Syndrome) were examined by morphology and processed according to the established multicolor flow cytometry protocols. Aliquots of diagnostic samples plus appropriate single-stained tubes were transferred to the Laboratory of Cytomics for MsIFC. Samples were concentrated by centrifugation and run on an Amnis ImageStream multispectral imaging flow cytometer (Amnis Co., Seattle, USA) using standard acquisition protocols. For each sample 5000 events were stored as .rif files and compensated off line. The corresponding .daf files were analyzed using the interfaced Ideas 4.0 to define fluorescence-based flow cytometric parameters and morpholgy-associated descriptors that could be easily compared to standard phenotype and morphology parameters and also to define new strategies to reveal cell suboppulations of diagnostic relevance. *Results.* Using MsIFC, we have defined in a single-run the appropriate immunophenotypic and morphologyic patterns of normal bone marrow and peripheral blood immune cell subpopulations. In a second step, we have characterized these features on several relevant lymphoproliferative and myelodisplastic syndromes, as well as in some rare diseases, including mastocytosis, hypereosinophylia and Gaucher's syndrome. Also, this approach allowed us to improve the interpretation of ambiguous data in standard immunophenotype and to image rare events. *Summary/Conclusions.* The application of MsIFC to bone marrow and peripheral blood samples prepared as for standard polychromatic flow cytometry is a technically affordable, promising approach to improve diagnosis and translational investigation in oncohaematology.

1717

DETERMINATION OF THE PATERNAL RHD ZYGOSITY BY TWO DIFFERENT METHODS REVEALED ALTERED RHESUS BOXES

V Arya, S Agarwal

SGPGIMS, Lucknow, India

Background. The RhD gene is flanked by two highly homologous DNA segments of approximately 9000 bp, the upstream and downstream Rhesus boxes. In haplotypes with an RhD deletion, the fusion of the two Rhesus boxes generates the single-hybrid Rhesus box. The discrimination of D+/D+ from D+/D- partners of D- mother with anti D is important to estimate the risk for HDN. This may be achieved by knowing the status of presence or absence of the hybrid rhesus box in the father. *Objectives.* To determine RhD zygosity in RhD positive husband by two different PCR based method. *Methods.* A total of 104 women with RhD negative blood group were recruited for study. Husband's blood group (ABO & RhD), was done in all cases serologically. Blood samples of the husband where blood group was found to be RhD positive were collected in EDTA vial. The samples were tested for the hybrid rhesus box by two different *Methods.* PCR-Restriction fragment length polymorphism (PCR-RFLP) and Sequence specific primer (PCR-SSP). The double blinded methodology was used in the detection. *Results.* Of the 104 women with RhD negative blood group, husband's blood group was found to be Rh D negative in 4 (3.8%). Of the 100 blood samples that were found Rh D positive, 26 were D hemizygous which by both methods were positive for the hybrid rhesus box. No discrepancy was observed in the *Results.* The 4 RhD negative samples were used as control to indicate positive amplification of the RHD deleted allele. *Conclusion.* The precise and rapid detection of RhD zygosity to check the hybrid rhesus boxes is established. As PCR-SSP method included internal control it may be preferable for RhD zygosity determination. Determining paternal Rh zygosity also helps in avoiding unnecessary fetal blood group determination.

1718

IMPLEMENTATION OF AN EFFICIENT WORKFLOW IN CHRONIC MYELOID LEUKEMIA MONITORING IN ROMANIA

R Talmaci,[1] D Jardan,[1] M Dragomir,[2] D Coriu[1]

[1]*University of Medicine and Pharmacy Carol Davila, Bucharest, Romania;* [2]*Fundeni Clinical Institute, Bucharest, Romania*

Background. The success of imatinib therapy for chronic myeloid leukemia (CML) has brought new challenges; these include optimizing disease monitoring, imatinib resistance and use of novel, more potent tyrosine kinase inhibitors. Thus, there is a need to establish new best practices for CML management in the post-imatinib era. In Romania imatinib therapy is in progress since 2002, but for some financial reasons the molecular diagnosis is not routinely available so far. In 2007 with research grants support we have set up in our institution a Molecular Biology Laboratory and here we report our results. *Methods.* Total RNA extracted from 2×10^7 cells has been transcribed by RT-PCR into cDNA. For diagnostic samples, the use of Multiplex PCR has been applied to detect simultaneously several kinds of BCR-ABL transcripts. For quantification of BCR-ABL transcript levels a Real-Time Quantitative - Polymerase Chain Reaction (RQ-PCR) using LightCycler® tech-

nology has been applied. Total ABL transcripts were quantified as internal control and results were expressed as the ratio BCR-ABL/ABL. The Nested PCR qualitative method has been used for MRD detection in case of RQ-PCR negative results. *Results.* A total of 535 peripheral blood samples collected from 230 patients with positive BCR-ABL transcript at diagnosis and follow-up has been procesed. Identification of transcript type by Multiplex PCR revealed b3a2 and b2a2 BCR-ABL transcripts in 67% of cases and 33% respectively. In two cases we identified a dual b3a2+b2a2 type. Quantification of BCR-ABL was performed according to the European LeukemiaNet protocol and using a CF=0.7838 for International Scale converssion. From total investigated cases, 133 patients were at first molecular investigation and 97 were in periodical investigation in our laboratory for MRD monitoring. The median of relative quantity of BCR-ABL in the blood before imatinib therapy was 50%. The number of the transcripts in imatinib-sensitive subjects decreased to 2,62% in 6 months. After 12 months of the treatment the BCR-ABL median was 0,038%. Forty patients present a resistance to imatinib with the BCR-ABL range of 12-48% during the treatment. For these patients direct sequencing of the ABL KD was performed. In seven patients we identified 8 mutation types - E450A, Q252H, E450K, E459K, L387M, M244V, F359V and E255K. The association of two mutations per genotype was identified in two patients: L387M + M244V and E450A+Q252H respectively.So this assay generated clinically useful information regarding the therapy with new BCR-ABL inhibitors in our patients. *Conclusions.* It is thought that CML is a rare hematologycal disease, but in Romania it is in increasing frequence. This study, the first in our country, indicates that transcript quantification and mutation screening in BCR-ABL kinase domain could provide practical indications able to direct therapeutic interventions for CML patients. Thus, the molecular monitoring must be an essential part in the clinical management of patients with CML treated with tyrosine kinase inhibitors.

This work was supported by the Research Grant PN II 41-087 from the Romanian Ministry of Education and Research. The authors express their gratitude to European LeukemiaNet for their permanent support.

1719

SCREENING OF AUTOIMMUNE LYMPHOPROLIFERATIVE SYNDROME (ALPS)

A Ruiz-Llobet,[1] T Toll,[1] M Camos,[1] O De La Calle-Martín,[2] M Torrebadell,[1] A Català,[1] S Rives,[1] R Berrueco,[1] N Conde,[1] R Castro,[1] AE Quintero,[1] J Estella[1]

[1]Hospital Sant Joan de Déu, Esplugues de Llobregat (Barcelona), Spain; [2]Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background. ALPS is a rare disorder caused by a defective FAS-mediated lymphocyte apoptosis that leads to chronic lymphoproliferation, autoimmune manifestations and increased risk of malignancies. The elevation of double negative T cells (DNTs; $CD3^+$, $CD4^-$, $CD8^-$, TCRα/β+) above the normal upper limit (<1% of lymphocytes) in peripheral blood has been described as a diagnostic criteria for ALPS. *Aim.* to describe the results of DNTs measurement by flow cytometry as a screening test for ALPS in a series of pediatric patients. *Methods.* Samples of patients with unexplained autoimmune cytopenias, organomegaly and/or lymphadenopathy were studied between 2005 and 2009. The measurement of peripheral blood lymphocytes, including CD3, CD4, CD8 and TCRgd subpopulations was assessed by flow cytometry in our laboratory. In those cases with elevated DNTs a blood sample was referred to a specialized laboratory to perform FAS mutation studies by molecular methods. *Results.* A total of 29 samples from pediatric patients (age 1-16 years, 58% males) were studied. The level of DNTs was <1% en 18 cases (62% of the whole series), 1-5% in 9 patients (31%) and 2 cases presented markedly elevated DNTs (8% and 14% DNTs). The latter cases were subsequently found to harbor mutations in FAS gene associated with ALPS. In contrast, no mutations were found in patients with DNTs <5%. The confirmed ALPS cases included a patient who had splenomegaly and hemolytic anemia and the second case presented with splenomegaly and bicytopenia. The first-degree relatives of such cases were subsequently studied, confirming, in both cases, the presence of FAS gene mutations in other family members. *Conclusions.* In our series, FAS mutations were found in two cases with very high level of DNTs (>5%). Screening with DNTs by flow cytometry can be routinely available in most clinical laboratories and is a useful tool when ALPS is suspected.

1720

THE UTILITY OF EXTENDED WHITE BLOOD CELL DIFFERENTIAL BY FLOW CYTOMETRY IN ROUTINE HEMATOLOGY

E Rusanova,[1] Y Zueva,[1] G Bouvier,[2] E Sukhacheva,[3] D Cherednichenko,[1] F Montero,[2] R Hebert,[4] R Simon-Lopez,[3] E Gautherot[2]

[1]Pavlov State Medical University, Saint-Petersburg, Russian Federation; [2]Beckman Coulter Immunotech, Marseille, France; [3]Beckman Coulter Eurocenter, Nyon, Switzerland; [4]Beckman Coulter Inc., Miami, FL, USA

Background. Today's white blood cells (WBC) identification and enumeration by hematology instruments is limited to only six cell types: neutrophils, lymphocytes, monocytes, eosinophils, basophils and NRBCs. Automation of the WBC manual differential is possible by flow cytometry for more accurate and automated information. *Aims.* to evaluate the efficacy of single tube flow cytometry analysis of peripheral blood (PB) for screening different pathological conditions. *Methods.* The CytoDiff™ panel is a 5-color / 6-marker reagent that provides a 9-part cytometric differential from whole blood specimens and comprises CD36-FITC, (CD2+CD294)-PE, CD19-ECD, CD16-PC5, and CD45-PC7 (Beckman Coulter, Inc. (BEC)) and specimens were lysed using VersaLyse (BEC). At least 20,000 $CD45^+$ events per sample were acquired on an FC500 Cytomics flow cytometer (BEC). For each case with elevated numbers of leukocytes or with abnormal cells, additional analyses were performed using light microscopy, full panel extended flow cytometric immunophenotyping and cytogenetics to identify lineages and the level of differentiation of the cells. PB was evaluated from 58 patients with different pathological conditions. Half the patients were females and half males, with adult median age 60. Four boys; median age 10.5, and two girls; median age 4.5 were also evaluated. The study was approved by The Pavlov State Medical University's Institutional Review Board. *Results.* Two cases had no immunological abnormalities in WBC subsets. Extended immunophenotyping determined 13 lymphocytosis cases with more than 50% of nucleated cells (53.1-94.5%) to be B-lymphocytosis, with 12 B-CLL and one PLL. One specimen with normal lymphocytes had high B-cells (45%) and extended immunophenotyping specified it as hairy cell leukemia. Six cases were identified with B-blasts, nine with myeloblasts and two with immature granulocytes. The extended analysis of these specimens identified six B-cell precursors ALL, two cases of MDS transformation to AML, two relapses of AML with maturation, one new diagnosed case of AML with maturation, one case of AML with myelomonoblastic differentiation, three cases of residual disease after AML chemotherapy, one plasmablastic leukemia and one acute promyelocytic leukemia (APL) with t(15;17). Therefore, true positive blasts were identified in 15 of 17 PB specimens using extended immunophenotyping. One case with immature granulocytes in PB was misclassified with the CytoDiff™ panel but verified as plasmablastic and in another case the Imm NE were not normal but abnormal promyelocytes corresponding to an APL t(15;17). The CytoDiff profile in the case of APL was different and may be identified. The final diagnosis was made after bone marrow extended immunophenotyping and cytogenetics. Nine cases had increased numbers of monocytes (14.2-32.0%). Three cases came from the surgery department with more than 20% of monocytes being inflammatory $CD16^+$. Two cases with multiple myeloma after chemotherapy and cytopenia recovery had 38.8% and 43.0% of monocytes being inflammatory $CD16^+$. *Conclusion.* Data demonstrate that a differential leukocyte count using Cytodiff™ allows for verification of a wide spectrum of normal and pathological cells in PB. This will provide clinicians with a diagnostic tool to rapidly determine appropriate therapies for a wide variety of blood-related diseases.

1721

FLOW CYTOMETRIC ANALYSIS IN PAROXYSMAL NOCTURNAL HEMOGLOBINURIA (H.P.N): A SCREENING OF 161 ALGERIAN PATIENTS

F Harieche, F Boukhemia, N Abdennebi, A Talbi, F Mehdid, N Rahmoune, N Aouanouk, F Zerhouni, RM Hamladji

Pierre and Marie Curie Center, Algiers, Algeria

Background. P.N.H is a consequence of non malignant clonal expansion of one or several hematopoeitic stem cells that have acquired a somatic mutation of PIG-A. The affected cells are deficient in Glycosyl PhospahtidylInositol-anchored proteins (GPI-APs). The variable clinical manifestations are: intravascular hemolytic anemia, venous and cytopenia. The disease often arises in the setting of bone marrow failure syndromes, particularly, aplastic anemia and refractory anemia-MDS. The diagnosis is definitively established by demonstrating the deficiency of

GPI-anchored proteins on blood cells, using monoclonal antibodies. *Patients and methods.* From July 2005 to December 2009, 161 patients were screened for PNH: 110 patients with aplastic anemia (50 new AA, 60 AA under immunosuppressive therapy), 24 patients with myelodysplasia, 12 patients with Coombs negative hemolytic anemia, 10 patients with thrombosis in hepatic veins, 15 Fanconi anemia. We used a 2 color analysis flow cytometry to assess expression of GPI-APs on granulocytes, erythrocytes and monocytes using monoclonal antibodies to CD55, CD59, CD16, CD66b and CD14. *Results.* Evidence of PNH was found in 14 of 110 (37%) patients with aplastic anemia: 29 of 60 (48%) AA under immunosuppressive therapy and 12 of 50 (24%) patients with new AA; 4 of 12 (33%) hemolytic anemia; 5 of 24 (21%) patients with MDS and 4 of 10 (40%) patients with hepatic thrombosis. No abnormal cells were detected in patients with Fanconi anemia. In almost all patients 50 of 54 (93%), the deficiency was partial (PNH II cells). A complete deficiency was found in only 4 patients (2 thrombosis and 2 AA). The PNH clone size ranged from 10 - 96% in AA who undergone immunosuppressive therapy, 7-41% in new AA and on average 38% of PNH granulocytes were found in MDS, 70% in hemolytic anemia and 80% in thrombosis. *Conclusion.* PNH frequently arises in association with disorders of bone marrow failure; particularly in aplastic anemia (37 %in our study). Screening for PNH in patients with AA, even in the absence of clinical evidence of hemolysis is highly recommended at diagnosis since identifying subclinical PNH (PNH-sc) appears clinically relevant. Flow cytometric analysis is the most sensitive and informative assay available for diagnosis of PNH.

1722

CYP1A1 POLYMORPHISM AND RISK OF LEUKEMIA

F Razmkhah, V Pazhakh, F Zaker, F Atashrazm

Iran University of Medical Sciences, Tehran, Iran

Background. The cytochrome P450 (CYP) enzymes constitute one of the biggest gene families which is involved in the metabolism of both endogenous and exogenous molecules. One of the members of this family, CYP1A1, plays a very important role in metabolizing carsinogens and medications. *Aim.* This case-control study aimed to detect the frequency of CYP1A1*2C polymorphism in Iranian patients with leukemia and racially matched controls. Further, it will help to determine the association of this allele's variants if any, as risk factor to develop leukemia. *Methods.* Our study group consisted of 39 patients with chronic myeloid leukemia (CML), 105 patients with acute myeloid leukemia (AML) and 95 unrelated healthy volunteers as an adult control group. Also 85 children with acute lymphoblastic leukemia (ALL) and 94 age and sex meched healthy individuals as a children control group were involved (informed consent was obtained). Genomic DNA was assayed for restriction fragment length polymorphism in the CYP1A1*2C loci by amplification followed by digestion with BsrDI. The data was analyzed statistically employing chi-square and logistic regression analysis. *Results.* The frequencies of AA genotype (wild type) were 82.05, 62.85, 84.70, 85.10 and 80% in CML, AML, ALL, children and adult control groups, respectively. The frequencies of AG genotype (heterozygote variant) were found to be 17.95, 36.20, 15.30, 14.90, 18.95% in CML, AML, ALL, children and adult control groups. The GG genotype (mutant variant) was 0.95 and 1.05% in AML and adult control groups while it was not observed in CML, ALL and children control groups. Logistic regression analyses showed a significant correlation just between the CYP1A1*2C polymorphism AG and AML patients (OR=2.4 , 95% CI=1.3-4.7, P=0.05). *Conclusion.* A higher frequency of CYP1A1*2C which was observed in AML patients as compared to adult control group, indicates an increased risk for AML in individuals carrying the heterozygote allele CYP1A1*2C. however, the results did not show any association between CYP1A1*2C genotypes and risk of ALL and CML.

1723

HLA CLASS I AND CLASS II ANTIGEN FREQUENCIES IN DIFFUSE LARGE B-CELL LYMPHOMA

M Alcoceba, L Marín, A Balanzategui, M Sarasquete, MC Chillón, C Santamaría, N Puig, R Corral, E Sebastián, MD Caballero, R García-Sanz, J San Miguel, M González

Hospital Universitario de Salamanca, Salamanca, Spain

Introduction. Diffuse large B-cell lymphoma (DLBCL) is the most frequent lymphoma within non-Hodgkin lymphoma (30-50% of all NHL). HLA system class I and II plays an important role in antitumor immune response and lymphoma cells apoptosis. There are some evidences that show a relation between HLA alleles with the incidence and evolution of certain malignant hematological diseases, including B-CLL, pre-B ALL or Multiple Myeloma, between others. Specifically, some works in NHL in certain ethnical groups founds a relationship between the presence of a determined HLA allele with a higher susceptibility to develop the disease. In the same sense, it has been described that the presence and/or absence of certain HLA alleles and/or haplotypes let to identify NHL patients (including DLBCL) with different prognosis. However, up to date there are no studies that analyze these possible associations specifically in DLBCL. *Aim.* To analyze the role of HLA specificities in DLBCL characteristics or behavior. *Patients and methods.* A total of 114 patients diagnosed of DLBCL from a non-biased population from one centre were analyzed. Additionally, a total of 1818 healthy donor individuals from the Castilla y León registry for hematopoietic stem cell-transplantation were included as control population. HLA class I (-A y -B) and II (-DRB1) typing at low-resolution level was carried out according to the standards of the EFI. Allele frequencies were estimated by direct counting. Comparisons of allele and phenotype frequencies between populations were performed with the two-sided Fisher's. P<0.05 were considered statistically significant and it was corrected (Pc) for the number of valid comparisons made (Bonferroni correction). *Results.* Significantly differences among DLBCL patients and healthy control individuals were found. Thus, DRB1*01 phenotypic frequencies were significantly higher in the patients as compared to healthy control individual (34.5% *vs.* 22.3%, P=0.0027, Pc=0.038). In addition, a trend was shown for specificities B*51 (21.9% *vs.* 15.6%, P=0.08, Pc=NS) and DRB1*03 (30.7% *vs.* 23.9%, P=0.09, Pc=NS). *Conclusions.* The present data suggest a possible specific association between HLA and DLBCL incidence. Though, the present study should be considered as preliminary, and higher number of cases is required.

CELLA-VISION DM96 HEMATOLOGIC ANALYZER EVALUATION IN PATHOLOGICAL SAMPLES

Y Ramos, A Lemes, A Martin, S De La Iglesia, J Lopez, MT Gómez-Casares, T Molero

Hospital Universitario de Gran Canaria Dr Negrín, Las Palmas de GC, Spain

Objectives. The Cella-VisionTM DM96 (CV) is an automatic system which consists of an automated blood smearing device, a digital microscope and a software. It shows cell images of peripheral blood smears by staining with May Grümwald-Giemsa. Leukocyte differential, erithrocyte morphology and platelet count are performed by the CV. The aim of this study is to evaluate CV functionality in an hematology laboratory, compared to the expert hematologists observation in pathological samples. *Methods.* 50 pathological peripheral blood samples were randomly chosen from Cell-Dyn Sapphire (CD) (Abbott). Of them, 10 showed leukocytosis, 10 monocytosis, 10 lymphocytosis, 10 thrombocytosis and 10 thrombocytopenia. The smear and stain were automatically performed by the Sysmex SP1000. They were also evaluated by CV and by optical microcopic review by an hematologist, afterwards. Differential leukocyte counts given by the CV and CD were compared with the ones given by the cytologist. The estimated platelet count by the CV was compared with the optic and impedance methods given by the Cell-Dyn Sapphire (Abbot). The statistical analysis was peformed by Bland-Altman tests. *Results.* Among the samples which showed lymphocytosis, the CD was the best method in lymphocyte counting, as the CV gave an understimation respect to the expert cytologist view of an 11.4% cells bias. It identified these cells as plasmatic cells, non identified or smudge cells. In monocytosis samples, the best counting method was the CV, as the CD method overestimated the monocyte count respect to expert cytologist with a 5.9% cells bias. These were recognized in most of the cases as blastic cells. In the leukocytosis samples the best counting method for neutrophiles was the CD because the CV method gave an understimation with respect to expert cytologist of a 14.9% cells bias. They were recognized in most of the cases as band neutrophiles. Therefore, neutrophiles count by the CV was overestimated with a 11% cells bias. Related to the thrombocytopenic samples, the optic count and the one given by the CV were the ones with less bias shown. It was higher in the impedance method, which showed an overstimation respect to the optic size (3.9×10^9/mm^3 plt) and in the one given by the CV (5×10^9/mm^3 plt). In the other hand, the thrombocytosic samples counting were overestimated, both impedance and optical methods, with respect to CV. *Conclusions.* In our previous studies, the digital cell autoanalyzer CV gives an appropiate ini-

tial accuracy to the leukocyte formula and platelet count in non-pathological peripheral blood samples. However, according to the results in this study, we believe that an expert cytologist supervision is necessary in pathological samples, specially in those which show atipycal lymphocytosis. The rest of the parameters of this study would not need to be checked by the cytologist.

1725

THE CHANGES IN HEMATOLOGIC PARAMETERS OF NEWBORNS OF HYPERTENSIVE MOTHERS

A Bolat, AE Kurekci, O Gursel, A Atay, O Ozcan

Gulhane Military Medical Academy, Ankara, Turkey

Background. Hypertension is a common disorder in pregnancy. It is the most common reason of maternal and perinatal mortality. Complications are the results of uteroplasental insufficiency. *Aims.* In this study, we investigated the changes in blood parameters including blood cell morphology in newborns of hypertensive pregnant women. *Methods.* Cord bloods of the newborns from 31 hypertensive pregnant women that followed-up at least 3 months and from 32 healthy pregnant women were examined prospectively. Demografic characteristics of mothers and newborns and 1st and 5th minute apgar scores of the newborns are recorded. Complete blood count, peripheral blood smear, reticulocyte count, vitamin B12, folate and ferritin levels and hemoglobin electrophoresis tests were studied. The study was approved by the local ethics committee. *Results.* The age of mothers, the numbers of pregnancy, gestational age, the type of birth, the situations of meconium, nuchal cord, deseleration and neonatal resuscitation, 1st and 5th minute apgar scores, neonatal mortality did not differ between study and control groups. In the study group birth ages are statistically significant lower than the control group (P=0.008). Folic acid, vitamin B12 and ferritin levels did not differ between study and control groups. In the study group, Hb F levels were statistically significant higher (P<0.001) and Hb A levels were statistically significant lower than control group (P<0.001). Both groups showed no significant differences in Hb A2 levels. In the study group, the erythrocyte counts, hemoglobin values, reticulocyte percentages and normoblast counts were statistically significant higher than the control group (P<0.05). There were no statistically significant differences in MCV, MCH and MCHC levels between groups. Leukocyte, neutrophil, lymphocyte, monocyte and eosinophil counts were statistically significant low in the study group (P<0.05). Statistically significant differences were not found in the number of basophils. Although the platelet counts were low, MPV and PDW values were high in hypertensive group. Statistically significant differences were not detected in terms of giant platelet percentages between the two groups. The number of cases with neutropenia and thrombocytopenia in the study group were statistically significant higher than the control group (P<0.001). The two groups did not statistically significant differences in terms of the number of cases with lymphopenia. In both groups, the great percentage of the cytopenic cases was premature. The dysplastic changes in neutrophils and erythrocytes in peripheral blood smears of the study group were more than the control. The number of infections in the study group was statistically significant higher than control group (P<0.05). Increased percentage of the patients with frequent infections initially had neutropenia and also showed disorders of nuclear structure, cytoplasmic granules and cytoplasmic membran abnormalities in leukocytes in peripheral blood smears. Although the blood counts were normal in controls, there were disorders of cytoplasmic granules in peripheral blood smears. *Conclusion.* Neonates of hypertensive mothers should be evaluated for the hematological changes. Complete blood count and peripheral blood smear examination should be used for the early diagnosis of possible hematological complications.

1726

FLOW CYTOMETRY (FC) IN DIAGNOSIS OF LYMPHOPROLIFERATIVE DISEASES

M Abad, S Oukid, S Taoussi

Hopital, Blida, Algeria

Background. A major application of flow cytometry is to help to better characterize lymphoproliferative diseases, providing additional informations to define and specify the monoclonality. *Aims.* Flow cytometry (FC) is one of the most powerful weapon to ensure diagnosis of lymphoproliferative disease; we apply it consistently in our laboratory in complement to cytology and histology. *Materials and methods.* We report the results of 149 patients that have chronic lymphocytosis evaluated by flow cytometry in the hematology department EHS CAC. The methods are based on clinical examination, a cytological study and immunophenotyping performed on a blood sample in 149 patients and a bone marrow sampling in 02 patients; we use a panel of monoclonal AC against lymphoid cells B, T and NK. The results are based on using the Matutes score and the percentage and intensity of positive cells. *Results.* Based on cytological criteria: 03 groups. Group 1: suspicion of CLL in 120 cases: 47 women and 73 men with an average age of 68.7 years (37- 86). The results of flow cytometry: - CLL: 92 patients with a Matutes score: 3 / 5: 03 Pts, 4 / 5: 43 pts and 5 / 5: 46 pts. - Mantle NHL: 10 pts. - Villous NHL: 07 pts. - Follicular NHL: 04cas. - NHL of marginal zone: 02 pts. - Prolymphocytic leukemia: 01. - T leukaemic NHL: 01 pts. - Undefined NHL: 03 pts. Group 2: small cell leukemia NHL: 24 Patients. 11 women, 13 men, average age = 67.18 years (41-81). The results of flow cytometry: - Mantle NHL: 10 pts. - NHL of marginal zone: 04 pts. - Follicular NHL: 04 pts. - Villous NHL: 02 pts. - Undefined NHL: 02 pts. - LLC: 02 pts with a Matutes score: 4 / 5 and 5 / 5. Group 3: suspicion of hairy cell leukemia: 05 pts: 05 men, average age = 50.6 years (36-66). Clinic: spleen: 02 pts, infectious syndrome: 02 pts and an anemic syndrome: 01 pt. Biology: pancytopenia: 02 pts, leucopenia: 01 pt and leucocytosis: 01 case. Bone marrow biopsy: 05 pts with hairy cell leukemia. The results of flow cytometry: Hairy cell leukemia: 04 pts. Normal: 01 pt. *Comments.* In our population, FC specified the nature of lymphomatous monoclonal populations in most patients. Thus immunophenotyping by flow cytometry should be a routine method for diagnosis when lymphoproliferative disease is suspected.

1727

ASSOCIATION OF WIP1 AND BCR-ABL GENES EXPRESSION IN CHRONIC MYELOID LEUKEMIA

F Razmkhah, M Safa, A Kazemi, M Razavi

Iran University of Medical Sciences, Tehran, Iran

Background. BCR-ABL fusion oncogene is an activated tyrosin kinase which activates several signaling pathways leading to chronic myeloid leukemia (CML). In addition, the wild-type p53-induced phosphatase 1(Wip1) has been shown to be amplified and overexpressed in multiple human cancer types. *Aim.* This study aimed to determine the relationship between Wip1 and BCR-ABL genes expression in patients with CML. *Methods.* 30 patients in chronic phase of CML were studied (informed consent was obtained). Total RNA was extracted from peripheral blood and cDNA was synthesized accordingly. BCR-ABL gene expression was evaluated by Taqman based Real Time PCR and Wip1 gene expression was assessed by SYBR Green based Real Time PCR. Final data were analyzed statistically. *Results.* In this study, we found a significant correlation between Wip1 and BCR-ABL genes expression in CML patients (P=0.042). *Conclusion.* Our data may suggest a BCR-ABL dependent or independent role for Wip1 in pathogenesis of CML.

1728

VALIDATION OF RAPID MUTATION SCANNING FOR NUCLEOPHOSMIN (NPM1) MUTATIONS IN ACUTE MYELOID LEUKEMIA

E Oppliger Leibundgut, N Porret, M Bienz Muggli, B Pfanner-Meyer, G Baerlocher

University Hospital Bern and University of Bern, Bern, Switzerland

Background. NPM1 mutations, the most frequent molecular alterations in acute myeloid leukemia (AML) present in up to 40% of patients with normal karyotype, are increasingly important for risk stratification and treatment decisions. Rapid mutation scanning as an alternative to sequencing is of high interest because of the potential for considerable savings in both time and costs. Currently, most reported methods for detecting NPM1 mutations are either technically challenging and/or require additional laboratory equipment. *Aims.* We describe a rapid and simple screening method based on PCR and agarose-gel detection validated on 211 patient samples. *Methods.* Bone marrow or peripheral blood leukemic cells were collected at diagnosis. For RT-PCR analysis, a primer pair was designed that covers exons 7 to 12 of the NPM1 gene. Following FAST PCR, amplicons were visualized on a 2% agarose E-gel, where a double band indicates a mutation and a single band represents the wild-type sequence. All PCR products were verified by direct sequencing. *Results.* Of 211 AML samples analyzed, 101 were NPM1 mutated and 110 were wild-type. Mutations include 93 typical 4-bp insertions (types A, B, D, D7, Gm, G0, J, Nm and IV) and 8 previously

unreported mutations. All 101 positive samples detected by the FAST PCR screening method carried a mutation, and none of the 110 negative cases were mutated, resulting in 100% sensitivity and specificity of the FAST PCR screening method. Dilution experiments resulted in a detection limit of 10% of mutation present in the sample. Of note, a previously undescribed polymorphism in exon 8 was detected in 1 mutated and 5 unmutated samples. *Conclusions.* We conclude that FAST PCR followed by agarose gel electrophoresis is a rapid (less than 2 hours), simple and highly sensitive and specific mutation-scanning technique suitable for the detection of NPM1 mutations. Moreover, this method is inexpensive and can easily be integrated in the routine molecular diagnostic work-up of established risk factors in AML using standard laboratory equipment.

1729

GLOBAL GENETIC CHARACTERIZATION OF THREE PEDIATRIC AGRESSIVE B-CELL LYMPHOMAS WITH FEATURES OF BURKITT LYMPHOMA

I Salaverria,[1] I Vater,[1] J Richter,[1] M Szczepanowski,[1] O Batic,[1] S Gesk,[1] I Oschlies,[1] A Reiter,[2] B Burkhardt,[2] M Harder,[1] W Klapper,[1] R Siebert[1]

[1]CAU Kiel, Kiel, Germany; [2]Justus-Liebig University, Giessen, Germany

Background. Burkitt Lymphoma (BL) is an aggressive B-cell lymphoma that is characterized by typical morphological, immunophenotypic and molecular features. The genetic hallmark of this disease is the t(8;14)(q24;q32) and variants resulting in the juxtaposition of the oncogene MYC next to one of the immunoglobulin (IG) loci leading to deregulation of MYC. It is a matter of debate whether MYC-negative BL do exist. Additionally, a microRNAs (mir) expression study of these cases has shown that hsa-mir-34b is down-regulated only in BL cases negative for the MYC translocation. *Aims.* The aim of this study was to perform a complete genetic characterization of three rare pediatric agressive B-cell lymphomas with features of BL but lacking a MYC-break to elucidate their genetic profile and to determine common genetic alterations that could be associated to this phenotype. *Methods.* Three pediatric patients (2 males/1 female, ages: 7, 7 and 16 years) morphologically diagnosed with BL (n=2) or atypical BL (n=1) were studied by conventional cytogenetics (R-banding), Fluorescence *in situ* Hybridization (FISH) and SNP array analyses. One of the patients was also diagnosed with Ataxia Telangiectasia. Hypothesizing a possible hypermethylation pattern of mir hsa-mir-34b in these rare cases, bisulfite pyrosequencing (BPS) assay for hsa-mir-34b was performed in the present series. *Results.* All three cases presented complexly aberrant karyotypes devoid of a t(8;14) or variant. Recurrent cytogenetic changes affected chromosomes 6, 11 and 18. Cryptic MYC translocations were excluded by FISH analyses. SNP array analyses revealed 24, 25 and 17 aberrations per case. In total, 40 chromosomal gains, 6 amplifications and 17 losses were observed. Several commonly altered regions were identified including losses of 6q14.2-q22.2 (2 cases), gains/amplifications of 11q12.2-q23.3 (2 cases), losses of 11q23.3-qter (3 cases) and gains/amplifications of 18q21.1-q22.1 (2 cases). FISH analysis with selected probes confirmed several alterations like gains of ATM and amplifications of BCL2 and MALT. No clear methylation pattern that could explain the down-regulation of mir-34b in these rare cases was observed. Interestingly, in a cytogenetic review performed on pediatric NHL based on cases available on the Mitelman database, from 29 cases diagnosed of BL/Atypical without the t(8;14) translocation or variants, 11 (37%) presented alterations involving chromosome 11. *Summary/Conclusions.* The three MYC-break negative cases diagnosed as BL/atypical BL present common regions of alteration. These regions might harbor pathogenetically relevant target genes involved in the formation of a phenotype resembling Burkitt lymphoma in this rare group of mature aggressive B-cell lymphoma. Moreover, we confirmed by BPS that methylation of hsa-mir-34b is not present in this series, suggesting that other epigenetic mechanism could be involved in the described down-regulation or that the different pattern of expression of mir-34b do not correspond to true MYC-negative BL. Finally, a review the literature describing cases that can be classified as MYC-negative BL/Atypical-BL confirmed that alterations of 11q are recurrent in these cases as observed in the present series.

1730

QUANTITATIVE ANALYSIS OF MN1 GENE EXPRESSION FOR EVALUATION OF MINIMAL RESIDUAL DISEASE IN CYTOGENETICALLY NORMAL ACUTE MYELOID LEUKEMIA PATIENTS

M Tiribelli, E Toffoletti, R Gallina, D Damiani, A Candoni, R Fanin

Division of Hematology and BMT, Udine, Italy

Background. Molecular characterization of acute myeloid leukemia (AML) is essential for management of therapy. Molecular markers are necessary for prognostic stratification and monitoring of minimal residual disease (MRD), including early detection of relapse. Unfortunately, only 30% of AML patients (pts) presents a disease-specific molecular signature. So, in the last years, efforts have been made to detect a "universal"marker for AML. WT1 gene is over-expressed in about 80% of all AML cases, and has been successfully used for MRD monitoring. More recently, the meningioma 1 (MN1) gene has been found to be over-expressed in AML with inv(16), and high MN1 levels seems to have prognostic impact in cytogenetically normal (CN) AML pts. *Aims.* To test the possible role of MN1 in AML, we first studied MN1 expression in a group of CN AML pts, evaluating the role of MN1 as marker of MDR in cases over-expressing WT1, by comparing the levels of these two genes at various stage of disease. We then analysed MN1 expression in a group of WT1-negative AML pts, to determine if MN1 could be used for MDR assessment in pts lacking specific molecular markers. *Methods.* To assess MN1 expression, we designed a quantitative PCR assay with TaqMan chemistry, using ABL as housekeeping gene. The assay has been localized on the junction between two exons of MN1. The standard curve was prepared with 5 serial dilutions of RNA from a patient with inv(16) AML; the assay efficiency resulted 0.98. To determine the relative quantification of MN1 expression, we used the 2- Ct method, based on a calibrator obtained on a control group of 12 healthy donors. Then we analysed the expression of MN1 in 23 pts with CN AML over-expressing WT1, comparing the 2 markers at different time points (diagnosis, after chemotherapy, before and after transplantation). Finally, we tested MN1 expression in 11 cases of CN AML with normal WT1 levels. *Results.* Median expression level (2- Ct) of MN1 in healthy controls was 0.37 (range: 0.15-3.44). Among the 23 pts with CN AML and high WT1 expression, the proportion of cases with MN1 level >3.44 was 39% (9 pts), with a median value of 24.72 (range: 3.48-64.74). After chemotherapy, 8/9 pts responded and presented MN1 and WT1 levels within the normal values, while one resistant patient over-expressed both MN1 (17.85) and WT1. One of the eight responding pts relapsed after transplant; both MN1 and WT1 raised, but the former increased to pathological values earlier. Among the 11 AML pts with low WT1 at diagnosis, only one case (9%) over-expressed MN1 (6.76); this patient died during induction therapy. *Conclusions.* MN1 was over-expressed in about 30% of CN AML pts, and its levels correlated well with clinical course and other molecular marker (where available), thus representing a potential candidate gene for MRD assessment. In our small cohort of AML without WT1 over-expression the proportion of cases positive for MN1 was unexpectedly low (only 9%), therefore MN1 could not be used to monitor MRD in pts without other molecular markers.

1731

MRD LEVELS IN NPM1 MUTATION POSITIVE AML CAN BE ASSESSED WITH EQUAL EFFICIENCY USING EITHER DNA OR RNA OF BONE MARROW MONONUCLEAR CELLS

V Juvonen,[1] T Lundán,[1] K Remes,[2] V Kairisto[3]

[1]Tykslab, Turku University Hospital, Turku, Finland; [2]Department of Medicine, Turku University Hospital, Turku, Finland; [3]TYKSLAB, Turku University Hospital, Turku, Finland

Nucleophosmin (NPM1) mutated acute myeloid leukaemia (AML) accounts for 30% of AML. Analysis of NPM1 mutation by real-time quantitative PCR during AML treatment has been shown to be a clinically informative means of analysing minimal residual disease (MRD). Analysis can be performed either from DNA or RNA. Analysis from DNA can be related directly to the number of residual leukemic cells, but this may not be the case for RNA. Expression of mutated NPM1 on diagnostic samples has been shown to be highly variable, as results can vary over 100 fold. It has been unclear whether such high variation remains in the MRD setting and thus how well the remaining mutated NPM1 expression actually reflects the amount of residual leukemic cells. We studied mutated NPM1 levels both from RNA and DNA in diagnosis and follow up samples (n=69) from patients with NPM1

mutation type A (n=24), type B (n=1) or type D (n=2) positive AML. Our aim was to study the correlation of NPM1 levels between the two types of sample material and thus to find out how MRD level measured from NPM1 mutated RNA correlates with the actual load of residual leukemic cells. Bone marrow mononuclear cells were used for total RNA and DNA extractions. Cells were frozen in liquid nitrogen in 107 cells aliquots and stored in -80°C until used for analyses. One microgram of RNA was reverse transcribed to cDNA using random hexamers and M-MLV reverse transcriptase. The NPM1 MutaQuant Kit (Ipsogen, Marseille, France) was used according to the manufacturer's protocol to measure normalised copy numbers (NCN) of mutated NPM1 RNA-transcripts relative to the housekeeping gene ABL transcripts. DNA based quantification of NPM1 mutation was done using in house primers and albumin gene for normalisation. DNA based results were expressed as percentage (%) of MRD relative to patients individual baseline at diagnosis. At diagnosis the median NCN for NPM1 mutated transcripts was 356 but the range was wide (16-930). Most of the follow-up samples that were MRD positive from DNA were MRD positive also from RNA (38/43, 88%). At least two RNA samples were degraded, which may have been the reason for the discrepant results. Quantitative results from the samples positive and measurable by both methods were compared by log-linear regression (R2=0,882) (see figure below). Results show that highly concordant estimates of MRD can be produced from RNA and DNA. The burden of residual malignant cells can thus be estimated even from RNA as source material. The better stability of DNA may, however, favour its use in routine clinical diagnostics.

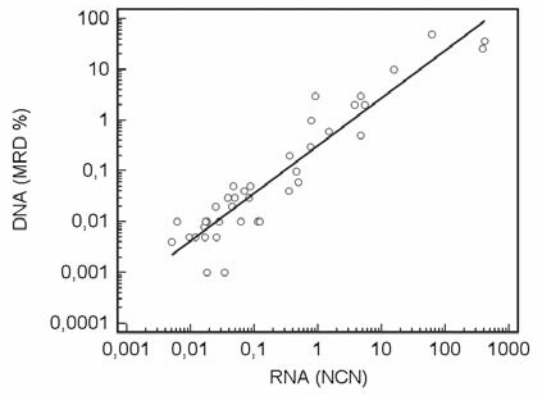

Figure. Correlation of MRD estimates from RNA and DNA.

1732

IMPROVED DETECTION OF RECURRENT CYTOGENETIC ABERRATIONS USING INTERPHASE FISH ON IMMUNOLOGICALLY IDENTIFIED OR SORTED PLASMA CELLS COMPARED TO CULTURED WHOLE BONE MARROW CELLS

N Put, H Lemmens, P Konings, I Wlodarska, Y Moreau, P Vandenberghe, L Michaux

Katholieke Universiteit Leuven, Leuven, Belgium

Background. Multiple myeloma (MM) is a clonal plasma cell (PC) disorder characterized by the early presence of recurrent numerical and structural chromosomal aberrations which can be identified by conventional cytogenetic studies. However, abnormal karyotypes are reported in only 30-40 % of newly diagnosed cases, because of low proliferation rates and limited bone marrow (BM) infiltration. The advent of interphase fluorescence *in situ* hybridization (FISH) allows for an increased detection rate of aberrations, and, in addition, for the identification of recurrent cryptic and prognostically significant changes. Current guidelines based on consensus agreement recommend to perform FISH on PCs. However, FISH is still performed on whole BM in many centres and no comparative data are available so far. *Aim.* The aim of the present study was to assess the impact of different interphase FISH procedures on the detection of chromosomal abnormalities. *Methods.* Two hundred thirty-five BM samples were collected from 225 patients with MM or related PC disorders regardless of treatment status. FISH was performed both on unselected BM cells after a 4 day cytogenetic culture (n=235) and on purified PCs, obtained from fresh BM samples by immunomagnetic selection using anti-CD138 (AutoMACS Miltenyi Biotec,Utrecht, The Netherlands; n=8 or Easy Sep, Stem Cell Technologies, Grenoble, France; n=11) or on BM smears in which PCs were identified by kappa/lambda+ immunostaining (n=216). The low number of cases (n=2), in which both immunomagnetic selection and immunostaining were applied, did not allow a comparison of PC selection techniques. The routine panel included probes for *IGH, RB1, P53* and centromere 9 or BCL6. Other analyzed loci were *CCND1(-XT), MYC, FGFR3, CCND3, TCRαδ/TRAF3* and *PBX1*. *Results.* The following patient and sample characteristics were observed: male/female ratio 122/103, median age 66,8 years (range 35,3-89,4 years) and a median percentage PCs of 32,5 % (range 1-100%). One probe was tested in 129 samples, two probes in 40 samples, three probes in 41 samples and four probes in 25 samples. LSI *IGH*, LSI 13, LSI p53, LSI *BCL6*, LSI *IGH/CCND1*, LSI *IGH/FGFR3*, LSI *MYC* and LSI *IGH/CCNDI-XT* were applied in 197, 85, 79, 41, 16, 4, 3 and 3 samples, and probes for centromere 9, *CCND3, TCRαδ/TRAF3* and PBX1 each in one sample. Of a total of 432 tests, 111 were excluded for further analysis as less than 20 plasma cells could be evaluated per probe. In the remaining 321 tests, FISH on PCs detected abnormalities in 71 % of cases, compared with 35 % of abnormal cases in FISH on cultured whole BM (P<0,0001). Moreover, FISH on PCs allowed to detect more abnormalities per case and identified higher percentages abnormal nuclei (P<0,0001). *Conclusion.* In summary, FISH has a higher detection rate of chromosomal abnormalities if plasma cells are selectively analyzed. In addition, more abnormalities per case could be detected. This study confirms FISH on PCs to be the preferred technique for routine cytogenetic investigation of MM.

1733

COMPARATIVE STUDY OF DETECTION LIMITS IN 3 DIFFERENT ASSAYS FOR MOLECULAR MONITORING IN CML: STANDARD RQ-PCR, REPLICATE RQ-PCR AND DIGITAL PCR

HG Goh,[1] D Kim,[2] SY Choi,[2] SH Kim,[2] J Lee,[2] YS Lee,[2] S Park,[2] MS Kim,[2] M Lin,[3] T Fukushima,[4] DW Kim[5]

[1]The Catholic University of Korea, Seoul, South-Korea; [2]Molecular Genetics Research Institute, The Catholic University of Korea, Seoul, South-Korea; [3]Fluidigm Corporation, CA, USA; [4]Fluidigm K.K., Tokyo, Japan; [5]Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, South-Korea

Background. Prolonged imatinib therapy leads to a progressive reduction in BCR-ABL transcript levels measured by RQ-PCR assay, and some patients achieve complete molecular response (CMR), which is defined as sustained undetectable BCR-ABL using RQ-PCR assay with a sensitivity of at least 4.5-log below the standardized baseline. As more potent novel tyrosine kinase inhibitors have become available for newly diagnosed chronic phase chronic myeloid leukemia (CML) patients, the number of patients with CMR may increase. However, due to the sensitivity limit of the current RQ-PCR technology, CMR should not be considered as cure as more than 10^6 leukemic cells can still remain in the absence of detectable BCR-ABL transcripts by RQ-PCR, and currently there is no methodology to further classify the patients in CMR. *Aims.* In this study, sensitivity limits of replicate RQ-PCR (rRQ-PCR) and digital PCR (dPCR) assays for measurement of BCR-ABL transcript level was compared to that of standard RQ-PCR assay to assess if more sensitive detection methodology can be implemented for molecular monitoring in CML. *Methods.* Cell line and patient sample dilutions ranging from 10^{-3} to 10^{-7} were used to determine sensitivity limits in standard RQ-PCR, rRQ-PCR and dPCR assays. For preparation of serial dilutions, 10-fold serial dilutions were performed by mixing RNA from K562 cell line (BCR-ABL positive) and RNA from healthy donor peripheral blood mononuclear cells (PBMC) (BCR-ABL negative), and by mixing RNA from one CML patient sample collected at the time of diagnosis (BCR-ABL positive) and RNA from healthy donor PBMC (BCR-ABL negative). *Results.* While standard RQ-PCR assay could detect down to 10^{-5} of cell line dilutions and down to 10^{-4} of patient sample dilutions, rRQ-PCR assay showed 2-log improvement in the detection sensitivity limit by detecting down to 10^{-7} and 10^{-6} of cell line dilutions and patient sample dilutions, respectively. (Table 1) In dPCR assay, no targets were detected from 10^{-6} of cell line dilutions and 10^{-5} of patient sample dilutions, and this sensitivity limit is equivalent to the sensitivity limit of standard RQ-PCR assay. Overall, in terms of detection sensitivity, both standard RQ-PCR assay and dPCR assay showed similar sensitivity limits, whereas rRQ-PCR assay improved the sensitivity by 2 logs. *Conclusions.* In this study, the concept of rRQ-PCR assay was to increase the number of replicates of each sample in RQ-PCR assay, and a 2-log improvement in the detection sensitivity implies that residual disease down to 10^4 leukemic cells can be detected. Patients in CMR who is currently categorized based on the data derived from standard RQ-PCR assay could be classified further using more sensitive methodologies

such as rRQ-PCR assay. Although significant enhancement of sensitivity was not induced in dPCR assay, some optimization procedures might be able to increase the sensitivity, and it would be an attractive alternative to labor-intensive rRQ-PCR assay. These data show the potential of highly sensitive PCR approaches for molecular monitoring, and these approaches examined here can be extended to expand our understanding of molecular profiles in CML patients and to correlate to clinical significance.

Table 1. Comparison of detection limits.

Assays	K562 cell line dilutions	CML patient sample dilutions
Standard RQ-PCR	10^{-5}	10^{-4}
Replicate RQ-PCR	10^{-7}	10^{-6}
Digital PCR	10^{-5}	10^{-4}

1734

THE TRANSLOCATION T(8;21) IN AML IS TRULY BALANCED AS SHOWN BY ARRAY CGH AT 2.5KB RESOLUTION

We have previously shown that the t(9;22) in CML is associated with genomic deletions resulting in loss of chromosome 9 and 22 sequences surrounding the translocation breakpoint on the derivative 9 or on additional partner chromosomes or on both. Such deletions were found in 15-20% of the patients studied and the presence of the deletion was associated with poor survival. Previous work has shown the presence of sub-microscopic deletions also in AML patients with t(8;21). These deletions were found in 6% of the patients with t(8;21), affected the der(8) chromosome and span up to 1.3 Mb in size. However 2 of the 6 patients had deletions of 5' sequences of the RUNX1T1 gene but did not carry the classical t(8;21) translocation detectable by FISH with commercial ETO/AML1 probes (Vysis), instead a RUNX1-RUNX1T1 fusion product was identified by RT-PCR. In an attempt to further characterise deletions associated with the t(8;21) we analysed 32 samples that had previously found cytogenetically to harbour a t(8;21) translocation. We employed array comparative genome hybridisation using a customised array. We enriched the areas 10 Mb upstream and downstream of the genes RUNX1 and RUNX1T1 on chromosomes 21q11.2 and 8q22.1 regions respectively achieving a probe density of 2.5 Kb. Further more, we covered the 9q21-9q34 segment with a higher density probes set to verify loss identified by conventional karyotyping. The rest of the probes (60K in total) were distributed evenly across the genome. We were unable to detect any recurrent genome loss within the areas flanking the RUNX1 and RUNX1T1 genes thus proving that the t(8;21)(q11;q22) is truly balanced. Instead, there were a number of unique genome deletions that spanned on average ~250bp within the 8q22 and 21q11 areas, the nature of which remains to be investigated.

1735

DETECTION OF AN ABERRANT FORM OF E13A2 BCR-ABL TRANSCRIPT CAUSING FAILURE OF MOLECULAR DIAGNOSTICS IN PATIENT WITH CHRONIC MYELOID LEUKEMIA (CML)

T Jurcek,[1] F Razga,[1] I Jeziskova,[1] D Zackova,[2] J Mayer,[1] D Dvorakova[1]

[1]University Hospital Brno and Medical Faculty, Masaryk University, Brno, Czech Republic; [2]Dept. of Internal Medicine and Hemato-Oncology, Univ. Hospital and Masaryk Univ., Brno, Czech Republic

Background. Molecular tools based on RT-PCR became a diagnostics standard for detection of BCR-ABL mRNA transcript in routine practice. A majority of CML patients harbor e13a2, e14a2 fusion transcripts, whereas e1a2 and e19a2 are significantly less frequent. Moreover, also atypical transcripts have been reported. These include breakpoints outside the cluster regions, interposed intronic sequences or genomic breakpoints within individual exons. Unfortunately, these represent an increased risk of miss-interpretation during investigation at the time of diagnosis. *Aims.* Description of an aberrant e13a2 BCR-ABL transcript type detected in patient with CML diagnosed in chronic phase and its role in the failure of standard RT-PCR *Methods.* Design and verification of pacient-specific TaqMan assay for quantitative monitoring of minimal residual disease (MRD). *Methods.* An optimized multiplex RT-PCR for the initial detection of BCR-ABL transcripts was used. In order to verify and validate the ambiguous results from multiplex RT-PCR, a more sensitive two-step nested RT-PCR was performed. The nested-PCR amplicon with unexpected size was subsequently analyzed by direct sequencing. The resulting sequence was compared with sequences of ABL and BCR gene. The segment of unknown sequence was analyzed using BLAST software. *Results.* The standard multiplex RT-PCR failed to identify a BCR-ABL transcript: (a) peripheral blood (PB) was detected as negative, (b) bone marrow (BM) revealed no amplification at all. Two-step nested RT-PCR revealed the atypical PCR products from both materials: (a) amplicon of unexpected size detected in external round and (b) no amplification detected in internal round. Subsequent sequence analysis revealed a joining of BCR gene exon 13 and ABL gene exon 2, with the 17 bp insertion of unknown origin between them. The inserted 17 bp fragment was subsequently identified as 100% homologous to the complementary sequence of ABL intron 1b (GenBank NG012034, bases 25707-25723). Moreover, the sequence analysis revealed the breakpoint within exon 13 of BCR gene at position 3247 (GenBank Y00661), where 56 bp were deleted. As a result, an aberrant BCR-ABL transcript e13a2 with insertion of a complementary sequence of ABL intron 1b, together with deletion within BCR exon 13, was detected (Figure 1). Considering the localization of different breakpoint within the exon 13 of BCR gene, for long-term follow-up, it was necessary to design patient-specific primers and TaqMan probe using Primer ExpressTM v.3 software. *Summary/Conclusions.* In this report we show how easy the standard and well established method for BCR-ABL fusion detection may fail in CML patient. Using the series of additional analyses, an atypical BCR-ABL transcript has been identified and the patient-specific RQ-RT-PCR system for MRD monitoring was subsequently designed. Additionally, we highlight an importance of the detailed investigation in case that unexpected results occur, since even highly standardized and properly used methods can occasionally fail.

The work was partially supported by grant MSMT CR, No. MSM0021622430.

CHROMOSOMAL ABERRATIONS IN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS DETECTED BY FISH OR CONVENTIONAL CYTOGENETIC WITH CPG OLIGONUCLEOTIDE STIMULATION - STRENGTHS AND DEFICIENCIES OF TWO METHODS

A Kotkowska, E Wawrzyniak, JZ Blonski, T Robak, A Korycka-Wolowiec

Medical University, Lodz, Poland

Background. Detection of chromosomal abnormalities in chronic lymphocytic leukemia (CLL) patients by conventional cytogenetic (CC) method does not give satisfactory results, mainly due to the low mitotic effectiveness of classical B-cells mitogens. Fluorescence *in situ* hybridization (FISH) is a more sensitive method and allows the detection of chromosomal aberration of prognostic value. However, it is expensive and suitable only for analysis of chromosomal regions with known specific DNA probes. *Aims.* The aim of our study was to compare the effectiveness of CC method with CpG- oligonucleotide DSP30 stimulation (CC-DSP30) with that of FISH in detection of chromosomal aberrations of prognostic value and to answer the question if this method allows the detection of other unknown chromosomal abnormalities. *Methods.* CC-DSP30 and FISH methods were tested in a group

of 62 previously untreated CLL patients (17 women and 45 men; mean age 67 years), after their written consent. Peripheral blood cells were cultured *in vitro* for 72 hours in the presence of CpG-oligonucleotide DSP30 (2μM/mL) (TIBMolBiol, Berlin, Germany). Chromosomes were identified by GTG banding according to standard protocols and classified according to ISCN 2009 nomenclature. In all patients peripheral blood smears were performed for interphase FISH using following locus-specific probes: LSI D13S319 (13q14.3)/LSI 13q34/CEP 12 Probe and LSI p53 (17p13.1)/LSI ATM (11q22.3) Probe (VYSIS, Germany). Metaphase FISH was performed for confirmation of some additional aberrations. To evaluate the agreement between these two methods in detection of the same chromosomal aberration, Fisher's exact test was performed. A P<0.05 was the level of confidence. The measure of agreement was estimated according to the strength of agreement using kappa coefficient. *Results.* Peripheral blood samples were successfully karyotyped in 56/62 (90%) patients. Abnormal karyotype was established in 41/56 (73%) patients by CC-DSP30 and in 52/62 (84%) by FISH. In 15/41 (37%) cases karyotype was complex (3 or more abnormalities). Deletion 13q14 was detected in 10/56 (18%) patients by CC-DSP30 and in 41/62 (66%) by FISH (P=0.01, P=0.18). In the karyotype of 12/26 (46%) patients with sole del(13)(q14) detected by FISH, the CC-DSP30 showed other numerical and structural aberrations. In this group of patients 4/12 (33%) exhibited complex karyotype. CC-DSP30 allowed to detect deletion 11q22 in 14/56 (25%) and trisomy 12 in 7/56 (13%) patients, whereas by FISH those aberrations were detected in 16/62 (26%) and in 10/62 (16%) cases, respectively (P<0.0001, P=0.91 and P<0.0001, P=0.80). Deletion 17p13 was detected in 2 patients by both methods, in 1 patient only by FISH and in 1 patient only by CC-DSP30. *Conclusions.* Both CC-DSP30 and FISH methods have similar effectiveness in del(11)(q22) and trisomy 12 detection. In case of del(13)(q14) the strength of agreement between the results obtained by both methods was poor, because this deletion is often cryptic and escapes detection by CC analysis. Additionally, CC-DSP30 allows to detect other chromosomal aberrations, especially in patients with sole del(13)(q14), that can change the good prognosis associated with this abnormality.

This study was supported by Grant No 2553/B/PO1/2008/34 from the Polish Ministry of Science and Higher Education, Poland.

SECONDARY 8Q24/C-MYC TRANSLOCATIONS IN B-CELL LYMPHOMAS

T Obukhova, E Baryakh, Y Lorie, S Kravchenko, E Domracheva

Russian Hematology Research Center, Moscow, Russian Federation

Background. c-MYC translocations are cytogenetic markers of Burkitt lymphoma (BL), with the t(8;14)(q24;q32) occurring in 80% and t(2;8)(p12;q24) or t(8;22)(q24;q11) in 20% of cases. However, c-MYC translocations with Ig or non-Ig partners also have been reported in rare cases of other B-cell neoplasms. Aim. To define clinical, morphologic, immunologic and cytogenetic features of B-cell lymphomas carrying secondary 8q24/c-MYC translocations. *Methods.* Between 2000 and 2009 in Russian Hematology Research Center c-MYC translocations were revealed in 91 cases of B-cell neoplasms by chromosomal banding or interphase fluorescence *in situ* hybridization (FISH). FISH was performed using an LSI c-MYC dual-color breakapart rearrangement probe and/or LSI c-MYC/IGH dual-color dual-fusion translocation probe (Vysis). An LSI BCL-2 and/or LSI BCL-6 dual-color breakapart rearrangement probes (Vysis) were used in 4 cases. Based on multidisciplinary diagnostic approach 84 cases were diagnosed as BL, and 7 cases as other B-cell lymphomas: 1 case as follicular lymphoma (FL), 3 cases as diffuse large B-cell lymphoma (DLBCL), 1 case as mantle cell lymphoma (MCL) and 2 cases as MGUS and multiply myeloma (MM)). In this study we analyze clinical and immunohistological data of the latter seven cases (Table1). *Results.* Aberrations involving 8q24/c-MYC were found in 3 DLBCL cases at diagnosis (#2-4). Patient #1 have had a 9-year history of t(14;18)-positive FL, t(8;14)(q24;q32) was identified in relapse with clinical features consistent with ALL. Case #5 was presented as CD10+ blastoid relapse after partial response of "classic"MCL 12 months after initial diagnosis and cytogenetically have been characterized as tetraploid complex karyotype with t(11;14)(q13;q32) and t(8q24)/c-MYC with undefined partner. In one MM patient (#7) c-MYC translocation was discovered in extramedullar relapse with normal bone marrow counts 2 years after diagnosis and was presented as t(8;11;14)(q24;q13;q32) in complex karyotype without 13q deletion confirmed by FISH. In patient #6 c-myc rearrangement was defined in progression/transformation of MGUS to plasmablastic leukemia (PBL) 5 years after diagnosis. Aberrations of 17/17p13 chromosome were detected in 2 cases of relapse/progression (#1 and #6) and in one primary tumor (#4). Histologic and cytologic features of four cases (DLBCL and MCL) were consistent with Burkitt-like lymphoma, plasmoblastic leukemia (PBL) in patient #6, one case as extramedullary transformed plasmocytoma (#7). In one case bone marrow histology was not evaluable (#1). Ki-67 was ~ 100% in cases #2-4 and #7, 42% in MCL patient and was not explored in cases #1 and 6. Bcl-2 was positive in cases #1-3(with t(14;18)(q32;q21)) and #5(with t(11;14)(q13;q32)). Case #4 was positive for BCL6 protein with 3q27 rearrangement. The clinical course of all patients was characterized by rapid progression, advanced stage, high LDH level and extranodal involvement. The median OS was 4 months (range <1-9 months) irrespective of treatment intensity. *Summary/Conclusions.* B-cell lymphomas with secondary c-myc rearrangements are highly aggressive chemoresistant neoplasms with some morphologic features of BL (cytoplasmic basophilia and vacuolization, "starry sky"pattern), frequent extranodal involvement, aberrant CD10 expression (case#5) and very short overall survival. Of interest, in our study secondary c-MYC translocations occurred more often with non-Ig partners.

Table 1.

Table 1. Clinical, cytogenetic features and survival of patients with secondary 8q24/c-MYC rearrangements.

Pt	Age/ Sex	Primary Diagnosis	FISH	Time of revelation	Survival (months)

A COMBINED ANALYSIS OF CYTOGENETIC AND CLINICAL PROGNOSTIC MARKERS IN GREEK PATIENTS WITH PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA (ALL)

V Georgakakos,[1] C Stavropoulou,[1] A Parcharidou,[2] K Manola,[1] N Katzilakis,[3] G Paterakis,[4] S Polychronopoulou,[2] G Pantelias,[1] E Patsouris,[5] C Sambani[1]

[1]NCSR Demokritos, Athens, Greece; [2]Aghia Sophia Children's Hospital, Athens, Greece; [3]University Hospital of Heraklion, Heraclion, Greece; [4]Athens General Hospital G. Gennimatas, Athens, Greece; [5]National and Kapodistrian University of Athens, Athens, Greece

Background. Clonal recurrent chromosome abnormalities in pediatric ALL are the hallmark of the disease and are routinely used in the pediatric setting to assist patient management in terms of diagnosis, prognosis, disease monitoring, and risk stratification. *Aims.* To correlate the cytogenetic data (karyotype and FISH) with clinical prognostic markers (age, sex, immunophenotype and white blood cell count (WBC)) in Greek patients with pediatric ALL at diagnosis. *Methods.* 85 children with ALL were included in the study, 52 males and 33 females (ratio 1.6:1), with a median age of 5 years (range 1-17). The median WBC was 10,120/μL (range 200-1×10^6/μL). 77/85 (90.5%) had B-ALL (23/58 common B-ALL, 30/58 pre B-ALL, 5/58 pro B-ALL) and 8/85 (9.5%) T-ALL. Karyotypic analyses were performed at diagnosis. FISH studies were conducted using commercial probes for the TEL/AML1 and BCR/ABL fusion genes, deletions of the INK4/9p21 locus, rearrangements of the MLL/11q23 gene and trisomies of chromosomes 4, 10, 17, 21 and X. *Results.* A successful karyotypic result was achieved in 76/85 (89.4%) cases. FISH analysis was successful in all cases studied. Combined classical and molecular cytogenetic analysis revealed clonal abnormalities in 70/85 (82.3%) cases. High hyperdiploidy (51-65 chromosomes) was detected in 24/79 (30.3%) cases. The translocation t(12;21)/TEL-AML1+ was detected in 18/85 (21.2%) and was accompanied by additional genetic changes in 13/18 (72%) cases. The secondary abnormalities in the TEL-AML1+ cases included: deletion of the non-rearranged TEL/12p13 gene (7/13, 53.8%), an extra

der(21)t(12;21) (5/13, 38.5%), an extra AML1/21q22 gene (5/13, 38.5%) and heterozygous deletion of the MLL/11q23 gene (2/13, 15.4%). More than one additional genetic changes were observed in 5/13 (38.5%) of these cases. Deletions of the INK4/9p21 locus was detected in 11/49 (22.4%) cases; 6/11 (54.5%) heterozygous and 5/11 (45.5%) homozygous. Other clonal abnormalities of prognostic value included MLL/11q23 gene rearrangements (3/84, 3.6%), translocation t(9;22)/BCR/ABL+ (2/77, 2.6%), hypodiploidy (≤44-45 chromosomes) (3/85, 3.5%), translocation t(1;19) (2/77, 2.6%) and amplification of the AML1/21q22 gene (2/85, 2.4%). High hyperdiploidy was significantly associated with age <10 years (P=0.03), B-ALL diagnosis (P=0.05) and low WBC (<50,000/μL) (P=0.03). Deletions of the INK4/9p21 locus were associated with high WBC (≥50,000/μL) (P=0.04) and homozygous deletions showed additional association with age ≥10 years (P=0.05) and T-ALL diagnosis (P=0.02). The translocation t(9;22) showed association with T-ALL diagnosis (P=0.02) and high WBC (P=0.04). The MLL/11q23 gene rearrangements were associated with age ≥10 years (P=0.007). AML1/21q22 gene amplification was associated with age ≥10 years (P=0.03). Heterozygous deletion of the MLL/11q23 gene was associated with age ≥10 years (P=0.03) detected in TEL/AML1+ cases (P=0.006). *Summary/Conclusions.* The incidence of prognostically significant chromosome abnormalities is similar to that reported in the literature. High hyperdiploidy, a cytogenetic hallmark of good prognosis, characterizes patients with favorable clinical markers. The heterozygous deletion of the MLL/11q23 is a nonrandom secondary change in TEL-AML1+ B-ALL, found in our older group of patients. Homozygous INK4/9p21 deletion was detected in patients with unfavorable clinical features (T lineage, high WBC, age ≥10 years), suggesting that this genetic abnormality may be considered as a poor prognostic marker.

1739

CYTOGENETIC PROFILE OF 451 PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA IN GREECE

M Karakosta, C Glytsou, P Diamantopoulou, A Daraki, G Pantelias, C Sambani, K Manola

NCSR Demokritos, Athens, Greece

BACKROUND: Chronic lymphocytic leukemia (CLL) is associated with recurrent cytogenetic abnormalities at diagnosis or during the course of the disease which are important prognostic indicators and may influence treatment choices. However, several chromosome abnormalities have not been completely determined yet due to the low mitotic *in vitro* activity of B-CLL cells. *Aim.* We present a conventional cytogenetic study of 451 B-CLL cases in order to define the most common chromosome abnormalities of CLL and their incidence in Greek population. *Patients and methods.* Chromosome studies were performed on unstimulated and stimulated bone marrow cells, initially with tetradecanoyl phorbol acetate (TPA) and more recently with the oligonucleotide DSP30 plus IL-2. Bone marrow samples were derived from 451 CLL patients, aged 16-88 years at diagnosis or during the course of the disease between 1998 and 2010. *Results.* Three hundred and three patients were male and 148 were female. The median age was 64.6 years. Cytogenetic analysis was successful in 421 patients (93.3%). A normal karyotype was found in 249 patients (~59%), and abnormal in 172 patients (~41%). Among the abnormal karyotypes 46 exhibited complex karyotypes (≥3 chromosome aberrations) (26.7%). and 91 karyotypes (53%) carried only one aberration. The frequencies of chromosome aberrations in abnormal karyotypes were the following: +12 in 29.1%, -Y in 15.1%, abnormal (abn) 17 in 14%, abn 14q in 11%, del(6q) in 7%, del(13q) in 7%, -X in 6.4 %, numerical abnormalities of chromosome 8 in 6.4 %, del(11q) in 4.7%, del(7q) in 4.1%, -18 in 4.1%, abn 20 in 4.1%, t(11;14) in 2.3%, traslocations of chromosome 11 other than t(11;14) in 5.2%, traslocations of chromosome 18 in 3.5% and chromosome markers in 14%. The most common abnormalities found in karyotypes as sole aberrations were +12 in 28.6%, -Y in 15.1%, add(14q) in 5.5% and del(6q), del(11q), del(13q), -X in 3.3% each. In complex karyotypes, chromosome markers were found in 43.5%, abn X in 21.7%, -17 in 19.6% and del(6q) in 17,4%. *Summary/Conclusions.* The sex ratio was 2.1M/1F, similar to that reported in the literature. Trisomy 12 was the most common abnormality. Surprisingly, -Y was the second most common abnormality, either as a disease associated aberration or as a consequence of advanced age. In addition the frequencies of add(14q) as a sole abnormality and abn X in complex karyotypes were higher compared to those in the literature. The presence of geographic heterogeneity of chromosome abnormalities could be attributed to population genetics and environmental factors or combination of two. The cytogenetic complexity of CLL emphasizes the value of conventional cytogenetics which permits an overview of all microscopically visible chromosome abnormalities.

1740

MYC AMPLIFICATION AND PRESENCE OF MICRONUCLEI IN TWO PATIENTS WITH ACUTE MYELOBLASTIC LEUKEMIA (AML)

L Puig Junyent,[1] M Montse,[1] L Ranera,[1] JC Gómez,[2] A Lemes,[3] JV Martínez,[1] Y Alvárez[1]

[1]Balagué Center, Hospitalet de Llobregat, Spain; [2]Hospital Universitario, Albacete, Spain; [3]Hospital Pino/Sabina/DrNegrín, Las Palmas, Spain

Background. Double minutes (dmin) observed in cytogenetic studies correspond with genic amplification of some genes like MYC or MLL. Whereas this amplification is very frequent in solid tumors, in hematological neoplasias as AML have an incidence under 1%. *Aims.* Description of two patients diagnosed of AML with presence of dmin corresponding to amplification of gene MYC. *Methods.* We present a patient 54 years old diagnosed in January of 2009 of AML with predominant monocitoid component (patient 1) and a patient 81 years old diagnosed in June of 2009 of AML with multilinial dysplasia (patient 2). Samples of bone marrow were harvested according to routine. G-banding and FISH with LSI IGH/MYC, CEP 8 Tri-color, Dual Fusion Translocation Probe (Vysis) were applied. *Results.* Patient 1 showed a karyotype 46,XY, 1~20dmin[35]/46,XY[5] and patient 2 a karyotype 47,XY,+4,~5-15dmin[20]. In the two cases, the study of FISH in interphase cells showed multiple signals of MYC (rank 1~20) confirming that dmin observed correspond to the amplification of this gene. Also, it was observed the presence of micronuclei with multiple signals of MYC gene. In addition, the study of FISH in metaphase did not show deletion of MYC gene in chromosome 8, not following therefore the theory of episome model in which previous a amplification is suggested the need of the deletion of the implied gene (Storlazzi *et al.*, 2006). Morphological features of blast cells did not correspond with AML-M1 with MYC amplification described in the literature. Also, we did not observed chromatin extrusion in the blast cells, although we observed presence of micronuclei in the FISH study. In the literature is suggested that survival could have relation with the percentage of micronuclei observed, and that dmin are related to aggressiveness of the disease and resistance to chemotherapy. In the present study patient 1 died during induction and patient 2 is still alive two months after relapse (4 months after diagnosis). *Conclusions.* Further studies are needed to establish a good correlation between percentage of micronuclei and aggressiveness of the disease and resistance to chemotherapy (Storlazzi *et al.*, 2006; Villa *et al.*, 2008). Also, it is necessary to determinate if absence of chromatin extrusion have a role in the disease.

1741

A CYTOGENETIC STUDY OF 403 ADULT ACUTE MYELOID LEUKEMIA PATIENTS IN GREECE

K Manola, A Daraki, C Sambani, M Kalomiraki, M Karakosta, M Apostolopoulou, G Pantelias

NCSR Demokritos, Athens, Greece

Background. Acute myeloid leukemia (AML) remains the most common form of leukemia and the most common cause of leukemia death. Diagnostic cytogenetics is considered one of the most valuable prognostic determinants in AML while current risk-group classification, is mainly based on cytogenetics and early treatment response. *Aims.* We reviewed the cytogenetic characteristics of 403 AML patients in order to investigate the frequencies of chromosome abnormalities among Greek patients with *de novo* AML and secondary AML (s-AML) which includes therapy-related AML and AML arising from a previous Myelodysplastic syndrome. *Methods.* Chromosome studies were performed on unstimulated bone marrow cells, derived from 403 AML patients, who were ≥18 years of age at the time of diagnosis. Patients were classified according to FAB classification. *Results.* Two hundred seventeen patients were male and 186 were female (M/F:1.2/1). The median age of patients was 56.5 years (range 18-95). FAB classification was available in 198 patients with 10 patients classified as M0 (5%), 14 as M1 (7.1%), 39 as M2 (19.7%), 54 as M3 (27.3%), 48 as M4 (24.3%), 25 as M5 (12.6%), and 8 as M6 (4%). Among AML patients, 341 had *de novo* AML with a median age of 55,2 years (range 18-88) and 62 patients had s-AML with a median age of 63.2 years (range 24-95). Cytogenetic analysis was performed in 341 patients with *de novo* AML and results were obtained in 314 (92.1%). Normal karyotypes were found in 104 patients (33.1%) and abnormal in 210 (66.9%) of which 59 were com-

plex (28%). The most frequent chromosome aberrations in *de novo* AML were +8 in 14.6%, t(15;17)(q22;q11-12) in 10.2%, -7/del(7q) in 7.3%, t(8;21)(q22;q22) in 5.73%, -5/del(5q) in 5.4%, -17 in 4.8%, inv(16)(p13q22) in 4.5%, +21 in 3.8%, 11q23 abnormalities in 3.5%, +11 in 2.2%, and abnormalities of chromosome 3 in 1.9%. Cytogenetic analysis was also performed in 62 patients with s-AML and was successful in 59 patients (95.2%). Normal karyotype was found in 15 patients (25.4%) and abnormal in 44 patients (74.57%) of which 16 were complex (36.4%). The most frequent chromosome aberrations were -7/del(7q) in 25.4% of patients, +8 in 25.4%, -5/del(5q) in 15.2%, abnormalities of chromosome 3 in 13.5%, -17 in 10%, +11 in 3.4%, inv(16)(p13q22) in 3.4%, +21 in 3.4%, 11q23 abnormalities in 3.3%, t(8;21)(q22;q22) in 1.7% and t(15;17)(q22;q11-12) in 1.7%. *Summary/Conclusions.* AML is slightly more common in men than women. The median age of patients with s-AML was higher than those with *de novo* AML. The main FAB subtypes showed a distribution different to that reported in the literature, with a higher incidence of M3 followed by M4 and M2. Interestingly, the most common chromosome abnormality was +8. The spectrum of chromosome abnormalities in s-AML was similar to *de novo* AML but the frequency of abnormal and complex karyotypes as well as +8 and abnormalities of chromosome 5, 7 and 3 were much more common in s-AML. The presence of geographic heterogeneity of cytogenetic abnormalities and FAB subtypes could reveal differences in constitutional or environmental factors.

1742

DETECTION AND INCIDENCE OF MUTATIONS OF KIT, FLT3 AND NPM1 IN ACUTE MYELOID LEUKEMIA

F Zaker,[1] M Mohammadzadeh,[2] M Mohammadi,[2] A Kazemi,[2] K Alimoghadam[3]

[1]Iran uiversity medical sciences, Tehran, Iran; [2]Iran university of medical sciences, Tehran, Iran; [3]Research center of blood and BMT of shariati hospital, Tehran, Iran

Background. Mutations in C-kit, FLT3 genes lead to uncontrolled proliferation of leukemic cells. Also, NPM1 is with high expression in the proliferating cells. The mutations of these genes are reported in AML cases. Several studies have shown these mutations represent a prognostic marker in AML patients. *Aims.* The purpose of this study was molecular charcacteristic of leukemia, diagnosis and frequency determination of these mutations with different subtypes of FAB in AML patients. *Methods.* Blood or Bone Marrow samples from newly diagnosed AML patients with various FAB classifications were obtained in hematologic and blood transfusion centers of Iran during 3 years (Informed consent was obtained from patients). The mutations of ITD (exon 11 and 12 and interon 11) and D835 (exon 20) of Flt3 gene in patients with acute leukaemia were studied by PCR and PCR-RFLP respectively. The resulted PCR products was electrophoresed on 8% PAGE. Exon 8 and exon 17 (D816) mutations in c-kit gene were analyzed by PCR followed by CSGE and RFLP respectively. The exon 12 of NPM1 was analysed using PCR followed by CSGE.Subsequently, PCR products of positive ITD, exon 8 of c-kit and NPM1 genes have been confirmed by sequencing techniques. *Results.* The median age of adult AML was 47 +/- 12 (range from18-75) years. There was no correlation between patients with mutation status and gender and age. A positive correlation with high presenting WBC > 20000/micl (58%) was demonstrated in flt3-ITD positive (P<0.05). In 212 adult AML, Flt3 ITD and D835 mutations occurred in 18% and 6% respectively. The highest frequency of ITD and D835 mutations (16% and 4% respectively) occurred within M3 subclasses and characterized by the t (15;17). Exon 8 mutations of c-kit were diagnosed in 1.3% of AML patients and 4.7% of patients showed D816 mutations with different findings in subtypes of AML. C-kit mutations demonstrated mostly in M2&M4 cases characterized by T8-21 and INV16 (CBF leukemia). 30% of patients with CBF leukemia showed mutation in exon 17. Mutations in exon 8 were novel and confirmed by sequencing method and documented in Gene Bank (FJ189474 and FJ177639). Out of 131 patients, 23 (17.55%) were known to have NPM1 mutation, and the presence of these mutations were confirmed using sequence technique. Concerning about higher frequency of cytogenetic abnormalities among these patients, it is not unlikely that above-stated fact has accounted for the lower frequency of NPM1 mutations in our *Results.* The highest frequency of mutations was found in subtypes of M4 (30.4%), M3 (21.7%), and M5 (13.04%). Besides, out of 23 patients with NPM1 mutation, 14 cases had mutated allele A (60.8%), 5 cases allele D (21.7%) and 4 cases allele B (17.4%). Also, 21 cases (16%) had ITD mutation which 8 cases were NPM1 positive (8/23=%35) and other 13 cases were NPM1 negative (13/108=12%). *Conclusions.* we demonstrated that the FLT3-ITD mutations are frequent molecular lesions in AML patients. The presence of ITD was associated significantly with M3 morphology with T15-17. The results of this research was in line with other reports in terms of the frequency of NPM1 gene mutations in monocytic subtypes of AML (M4, M5). High frequency of these mutations in M3 subtypes as well as allele D in all subtypes and high degree of association between occurrence of NPM1 and ITD mutations can be considered as interesting points of the *Results.*

1743

SEVERE AND PROGRESSIVE ACUTE DEMYELINATING ENCEPHALITIS AS THE MAIN PRESENTING MANIFESTATION OF FAMILIAL HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS

C De Fusco,[1] F De Gregorio,[2] V Poggi[2]

[1]Oncoematologia Pediatrica, Ospedale Pausillipon, Napoli, Italy; [2]AORN Santobono-Pausillipon, Naples, Italy

Background. Hemophagocytic lymphohistiocytosis (HLH) is a life-threatening condition of severe hyperinflammation caused by uncontrolled activated lymphocytes and histiocytes. HLH includes autosomal recessive familial forms and acquired "secondary" forms. Impaired function of natural killer (NK) cells and cytotoxic T-cells (CTL) is shared by all forms of HLH. Main clinical features are persistent fever, hepatosplenomegaly and pancytopenia. A third of patients presents variable neurological signs such as seizures, opisthotonic posture, or cranial nerve palsies. Early and severe neurological findings are frequent in patients with MUNC 13.4 gene mutations. *Aim.* We report a case of familial HLH occurred with severe and unusual neurological involvement. *Case.* A, a 3 year-old boy, was admitted to our unit since a history of prolonged and unresponsive to antibiotics fever. Physical examination and laboratory showed hepatosplenomegaly and cytopenia (Hb 9.5 g/dL, MCV 76.8 fl, N 570/ul, PLT 79000 u/L), slightly elevated inflammation indexes and LDH. Triglycerides, ferritin, transaminases, bilirubin, fibrinogen were normal. Viral and bacterial infections were excluded by serology and cultures. Normal bone marrow examination excluded leukemia: blast cell and hemophagocitosis were absent. Laboratory for autoimmunity was negative. Few days after, clinical course worsened since fast progressive neurological deficit (sensitive and motor) of lower segments with hyperreflexia, loss of sphincters control and bilateral papilledema occurred. Cerebral spinal fluid exam showed increased protein level (62 mg/dL), normal glucose level (47 mg/dL) and >900 WBC/mm^3. Brain magnetic resonance (MR) detected findings of acute diffuse demyelinating encephalomyelitis: high signal intensity on the T2-weighted images mainly involving cerebral white matter bilaterally with evidence of multiple enhancing nodules after injection of contrast material; similar findings were showed within cerebellum and pons and bulbus medullae. Lateral posterior spinal segments were also involved. Persistent generalized intractable seizures finally led to exitus. The severe neurological involvement strengthened the hypothesis of HLH. Detection of very decreased NK function confirmed HLH. Familial history of the patients was negative for consanguinity but revealed the exitus of an uncle and of a sister of A. due to a suspected cerebral neoplastic disease. Later also a niece of the patient received diagnosis of HLH overt with classical symptoms and similar neuroradiological imaging of A, even without neurologic symptoms. Since these findings, we suspected a case of familial HLH. Molecular analysis of PRF1 gene, UNC 13D gene, STX11 gene, STXBP2 gene revealed no mutation causing disease. *Conclusions.* We presented a familial HLH form characterized by early severe acute demyelinating encephalopathy caused by a genetic defect not yet discovered. HLH related neurological symptoms usually develop during disease progression. Demyelination is an unusual finding in HLH. Since early diagnosis and subsequent treatment is mandatory to improve the prognosis of HLH involving CNS, HLH has to be ruled out in patients with neurological disease of unknown origin above all in presence of fever, hepatosplenomegaly, cytopenia and NK reduced function.

RARE GROSS DELETION IN TCIRG1 GENE IN IRANIAN FAMILY WITH INFANTILE MALIGNANT OSTEOPETROSIS

A Modarresi, M Abbaszadegan, A Modaresi, F Khadivi-Zand, A Velayati

Mashhad University of Medical Sciences, Mashhad, Iran

Background. Infantile malignant osteopetrosis (OMIM: 259700) is an autosomal recessive disorder, manifests by severe osteosclerosis with-

in the first decade of life. Mutations in TCIRG1 (T-cell immune regulator 1) gene encoding osteoclast-spesific 116-kD subunit of H+-ATPase named as a3 subunit were found as the cause of infantile malignant osteopetrosis type. Recent research found that mutations in TCIRG1 gene are responsible for about 50% of patients. We found the first Iranian patient with a rare gross deletion identified in this gene. *Case presentation.* Z.A. was a 5 year old girl referred to hematology department of Dr Sheikh pediatric hospital with macrocephaly, facial dysmorphism, blindness, mental retardation and hepatosplenomegaly. Laboratory investigations revealed pancytopenia. Radiological images showed osteosclerotic changes in skull and limb. With these findings she was referred for molecular analysis of osteopetrosis disease. *Methods.* Molecular analysis was performed using RT-PCR for exon 10-19 of TCIRG1 gene followed by whole gene sequencing using an ABI 3730 capillary system automated sequencer. *Results.* The patient showed a 275bp unexpected amplified segment in PCR experiment. Sequencing of the PCR product revealed a gross deletion in exon 10-15 transcript region of TCIRG1. This deletion affected codon 389 to 518 including entire exon 11 to 13 of the gene. *Conclusion.* Various types of mutations in the TCIRG1 gene in infantile malignant osteopetrosis have been reported in different populations; however, gross deletions are reported rarely. This gross deletion of exon 11-13 in infantile malignant osteopetrosis is the first mutation reported among Iranian patients in this gene. This deletion is also the largest deletion of TCIRG1 gene reported until now.

SURVIVIN MUTATION AND WILD TYPE P53 TUMOR SUPPRESSOR GENE EXPRESSION IN EGYPTIAN PATIENTS WITH ADULT ACUTE LEUKEMIA BEFORE INDUCTION OF CHEMOTHERAPY

F Attia,[1] H Abo Elwafa,[2] M Hasen,[1] A Elbaz[1]

[1]Faculty of Medicine, Ismailia, Egypt; [2]Faculty of Medicine -Sohag University, Sohag, Egypt

Background. Survivin, a member of the inhibitors of apoptosis family of proteins, is one of the most frequently upregulated transcripts in solid tumors and hematopoietic malignancies. Wild type of p53 tumor suppressor gene is involved in regulation of survivin expression in leukemic cells. *Aim of the work.* This study aims to assess the expression of wild p53 tumor suppressor gene and survivin mutation in bone marrow samples from adult acute leukemia patients before chemotherapy. *Subjects and methods.* 20 adult patients with acute myeloid leukemia and another group composed of 20 adult patients with acute lymphoblastic leukemia diagnosed by standard immunologic, morphologic and cytochemical criteria. 20 adult patients with diagnosis of hypersplenism served as non leukemic control group. DNA and RNA extraction were done manually from bone marrow samples. Survivin mutation was assessed in DNA BM samples by using syber green method and expression of wild gene p53 was assessed in RNA samples by Taqman method using Real Time PCR. *Results.* Survivin mutation was detected in 20% of bone marrow samples from patients with acute myeloid leukemia (AML) and 5% of bone marrow samples in patients with acute lymphoblastic leukemia (ALL) with absence in the third group. This result is highly significant among the three groups (P<0.0001). Wild type p53 gene expression was present in 45% of patients with AML and 25% in patients with ALL and absent in the third group P<0.001. There is a relation between p53 wild gene expression and mutation of survivin gene in the AML group. Presences of survivin mutation and/ or expression of wild p53 gene are associated with poor prognostic variables (low white blood cells, low hemoglobin and young age) in AML group.*Conclusion.* Survivin mutation is associated with expression of p53 wild gene in bone marrow samples and more prominent in AML than ALL groups. These findings may highlight the importance for screening for these genes before induction of chemotherapy.

TRANSLOCATION (X; 10)(P10;P10) : A RARE BUT NON RANDOM CHROMOSOMAL ABNORMALITY IN ACUTE MYELOID LEUKEMIA

A Bennour, M Zaier, I Ouahchi, Y Ben Youssef, A Khelif, H Sennana, A Saad

Farhat Hached Hospital, Sousse, Tunisia

Background. Sex chromosomes are infrequently involved in chromosomal aberrations in patients with hematologic malignancies. There are very few reports describing structural abnormalities of the chromosome X in acute leukemia. In most instances, the abnormality is either duplication of the q arm or deletion and translocation involving the q13 and q24 regions. *Aim.* We report herein a rare translocation t(X;10)(p10;p10) in a patient with acute myeloid leukemia (AML). A kid with 2 months and 20 days initially presented with acute leucosis. *Methods.* Cytogenetic analyses were performed by R-banding karyotype and fluorescence *in situ* hybridization (FISH) to explore the chromosomal abnormalities and confirm the diagnosis. *Results.* Bone marrow examination showed a hypercellular marrow and confirmed the diagnosis of an acute myeloid leukemia (AML4). Cytogenetic analysis detected a t(X;10)(p10;p10) in 17/27 metaphases analyzed by R-banding karyotype. Thus was confirmed by FISH analysis with whole chromosome painting (WCP) specific for chromosomes X and 10. The patient was treated with chemotherapy and a complete morphologic and cytogenetic remission was obtained after two cycles. A review of the literature and the Mitelman Database of Chromosome Aberrations in Cancer showed three previous reports of a similar translocation t(X;10) in childhood AML. The first case was a 2-year-old girl with AML-M1 and t(X; 10)(p11;p11), the second child was a 14-year-old boy with a morphologically FAB-M1-peroxidase-positive acute leukemia and T-lymphoid markers and the third patient had therapy-related AML after exposure to etoposide, which was previously given as part of ALL therapy. Translocation (X;10)(p10;p10) has also been reported in two adult patients with acute leukemia, one with acute monocytic leukemia and the other with a myeloid relapse of a bilineage leukemia. *Summary.* To our knowledge, our case is the first report of a neonatal AML4 with t(X; 10). Although the patient had an excellent early response to a salvage AML-type therapy, the prognostic significance of the t(X;10) in this setting remains unclear. Due to the rarity of this translocation, further cytogenetic and molecular biologic studies are required to elucidate the clinical and molecular significance of this unusual karyotypic finding.

INCIDENCE OF CYTOGENETIC ABERRATIONS IN PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) IN LATVIA

I Grivina,[1] Z Kovalova,[2] S Kursite,[2] S Nikulshin[2]

[1]E.Gulbis laboratory, Riga, Latvia; [2]Riga Stradins University, Department of Paediatrics, Riga, Latvia

ALL is basically a genetic disease since most patients have genome changes causing uncontrollable proliferation and abnormal differentiation. Some genetic abnormalities in ALL patients are significant independent prognostic factors and thus provide a stratification basis for ALL. Summarizing and analysis of genetic aberrations found in children with ALL has not yet been performed in Latvia. *Objective.* A retrospective study was aimed to collect all available cytogenetic data (starting from 01.06.2006. when cytogenetics had been introduced as a routine diagnostic method for children with ALL) and to analyze their correlation with clinics and prognosis. *Materials and methods.* 38 consecutive ALL patients who had genetic analysis performed and had been treated at Oncohematology department of the Stradins University Childrens' Hospital were included. Information was collected from hospital and of E.Gulbis laboratory archives. 10% patients had T-ALL and 90% B-ALL; 63% were boys and 37% - girls; 74% were aged 1-5, 8% 6-10 and 18% were above 11; 38% of them belonged to the standard risk, 49% to medium risk and 13% to the high-risk group. At the time of the study 82% patients were alive without event, 5% were alive in relapse and 13% dead. Standard cytogenetic karyotype was obtained from 26 patients, chromosome analysis was carried out according to the standard procedure and karyotype was classified according to ISCN 2005. FISH hybridization was carried out using locus specific, centromere, telomere and full chromosomal probes according to manufacturer's instructions. FISH methods were used to determine clinically significant aberrations - hyperdiploidy, t(12;21), t(9;22), 9p21 and 11q23 rearrangements. *Results.* Genetic aberrations were found in 92% patients. High hyperdiploidy was detected in 48% patients (29% of

them without structural chromosomal changes). Statistically significant negative correlation between high hyperdiploidy and risk group was proven (73% patients with hyperdiploidy in the standard risk, 33% in the medium risk and 20% in the high risk group, P=0,02). There were no patients with proven hypodiploidy. Translocation(12;21) was found in 16% patients , pathological 9p was found in 18%, pathological 12p in10%. BCR-ABL1 and MLL-AFF1 mutations were not detected. *Conclusions.* During this research genetic aberrations were found in 92% of patients indicating an important role of genomic damage in ALL pathogenesis. High hyperdiploidy correlated with lower risk group, which corresponds to literature data on this aberration's association with favourable prognosis. Significant differences were noted between T- and B-ALL genotypes, which probably result from a difference in malignization pathogenesis. The found aberrations did not correlate with patients' sex and age. No correlation with therapy outcome was proven, although a longer follow-up would be necessary to define a prognostic relevance of the detected aberrations. The incidence of several aberrations was found to differ from literature data, requiring further study.

RAPID AND COST EFFICIENT SCREENING OF EIGHT MOST FREQUENT FUSION GENE TRANSCRIPTS IN ACUTE LEUKEMIA USING A MULTIPLEX RT-PCR APPROACH

D Jardan,[1] R Talmaci,[1] D Coriu,[2] A Colita,[1] C Arion[1]

[1]University of Medicine and Pharmacy Carol Davila, Bucharest, Romania; [2]Fundeni Clinical Institute, Bucharest, Romania

Background. Recurrent chromosomal translocations are present in a considerable proportion of the acute leukemias. Many of these translocations result in the formation of specific fusion genes. The identification of particular fusion genes is of major diagnostic and prognostic importance. *Aims.* this study was designed to validate the application of an "in house"multiplex RT-PCR for detection of the eight most frequent fusion gene transcripts in acute leukemia: E2A-PBX1, TEL-AML1, AML1-ETO, PML-RARα, MLL-AF4, CBFb-MYH11, BCR-ABL, SIL-TAL. *Methods.* a multiplex RT-PCR using primers published in the literature was compared for analitical specificity and sensitivity with a commertially available kit (HemaVision). *Results.* A total of 78 patient samples at presentation were tested: 48 patients with Acute Myeloid Leukemia (AML) and 30 patients with Acute Lymphoblastic Leukemia (ALL). The fusion genes transcripts were identified in 19 cases: TEL-AML (1), BCR-ABL (4), AML-ETO (2), PML-RARα (8), MLL-AF4 (1), CBFβ-MYH11 (2) and SIL-TAL (1). These findings allowed risk stratification for 25% of AML cases and 23% of ALL cases. *Summary.* Identification of MLL-AF9 fusion gene transcript associated with detection of MLL-PTD, FLT3-ITD, FLT3-TKD and detection of mutations in NPM1 allowed evaluation of prognostic and better disease management for the most of our AML patients. This approach use a Nested-PCR method, thus being suitable for MDR monitoring with an almost identical sensitivity as HemaVision assay. Lastly, our assay exhibited good sensitivity and specificity and allowed identification of fusion gene transcripts in 24% of acute leukemia. Compared with commercially available kits like HemaVision it is considerably cheaper and for our lot of patients identified the same fusion gene transcripts as HemaVision assay.

DOUBLE MINUTES IN ACUTE MYELOID LEUKEMIA WITH COMPLEX KARYOTYPE

L Luciano, M Cosenza, M Capone, I Pisano, A Guerriero, F Pane

University Federico II, Naples, Italy

The circular, extra chromosomal amplification of specific acentric DNA fragments (double minute,dmin), are observed in 1% of acute myeloid leukaemia(AML). Most of them consist of an amplified segment from chromosome band 8q24, always including the MYC gene. Moreover in AML with complex aberrant karyotype, a loss of one TP53 allele is frequently observed. Both abnormalities generally correlate with bad prognosis. We present here a case of AML with evidence of double minutes and a complex karyotype including del 17p. The conventional cytogenetic analysis showed the t(8;11)(q24;q11) translocation concomitant with del(17)(p13.1). On the contrary, the molecular cytogenetic analysis using painting probes for chromosome 8 and 11, showed no translocation between chromosome 8 and 11, but deletion of 8q24 and addition of extra genetic material at locus 11q11. Moreover, fluorescent *in situ* hybridization (FISH) on metaphases showed the presence of dmin derived from del 8q24, carrying amplification of c-Myc. Interphase FISH evidenced the deletion of p53 locus too. This case emphasizes the relevance of FISH to clarify cytogenetic abnormalities not otherwise evident, that may contribute to give more information especially about the prognosis. Analyzing the 28 cases (27 reported and our) of AML with extrachromosomal amplification of c-Myc described so far, a possible association between double minutes, complex karyotype, and deletion of p53 is suggested. Moreover almost half of these 28 cases with dmin showed also extra cytogenetic aberrations, including loss of chromosome 17 resulting in LOH at p53 locus. The poor prognosis of these patients could be related to a possible link between dmin, p53 and complex karyotype abnormalities and not to dmin alone as previously reported. This association could in part explain the resistance to chemotherapy and high proliferation rate of AML carrying this kind of complex karyotype.

1750

DIFFERENTIAL DIAGNOSIS OF FANCONI'S SYNDROME: ROTHMUND-THOMSON SYNDROME

R Berrueco, A Catalá, S Rives, T Toll, M Camós, M Vicente, MA González-Enseñat, E Gean, L Martorell, J Estella

Hospital Sant Joan de Deu, Esplugues de Llobregat, Spain

Introduction. Rothmund-Thomson Syndrome (RTS) is a rare autosomal recessive genodermatosis caused by DNA helicase defects. It shares many clinical characteristics with Fanconi Anemia (FA).*Clinical findings.* A girl 11-year old consulted in our Hospital for FA follow-up. She had been diagnosed in her country (Colombia). On physical exam short stature, characteristic face, pronounced poikiloderma, hyperkeratosic lesions in knees, ankles and hands were remarkable. She had bilateral hypoplastic tumbs and patella were absent, with epyfisaria dysplasia and knee instability. Blood analyse was normal except for macrocytosis. Fetal haemoglobin was normal and chromosomal instability test (spontaneous and mitogen induce) were negative twice. Abdominal and cardiac ultrasounds were normal. There were no opthalmological disorders, but she had bilateral transmission deafness. She is currently on treatment with growth hormone.Clinical finding were compatible with RTS and the genetic study confirmed it: double heterozygotic mutation (transition and deletion mutation) in RECQL4 gene. *Coments.* RTS is secondary to helicase gene defects (RECQL4) and inherited in an autosomal recessive fashion. Patients are characterized by poikiloderma (cutaneous findings appear during first 6 month of life), hair loss, short stature, skeletal defects of the limbs, cataracts and a high incidence of cutaneous and noncutaneous malignancies (osteosarcoma). Conflicting results for chromosomal instability have been reported.A RTS and other similar syndromes have to be ruled out in patients who share several clinical and analytical findings with FA, but have negative chromosomal instability test.

1751

MYELODYSPLASTIC SYNDROME, T-LARGE GRANULAR LYMPHOCYTE LEUKEMIA AND TURNER SYNDROME: AN EXTREMELY RARE ASSOCIATION

A Macedo,[1] A Monteiro,[1] P Amantegui,[1] MC Faria,[1] MJ Oliveira,[2] C Correia,[2] S Castedo,[2] ML Queiroz,[3] M Lima[3]

[1]Universidade da Beira Interior, Covilha, Portugal; [2]Genetica Medica e Diagnostico Pre Natal Prof Sergio Castedo, Porto, Portugal; [3]Hospital Geral Santo Antonio, Porto, Portugal

The incidence of Haemopoietic Malignancies associated with Turner Syndrome (TS) is extremely rare: a review of the literature identified only 23 cases with limited clinical data reported to date. Therefore, whether monosomy-X plays an important role in leukemogenesis has not been determined yet. TS is a genetic disorder characterized by partial or complete monosomy-X. Myelodysplastic Syndromes (MDS) represent a heterogeneous group of myeloid neoplasms characterized by abnormal myelopoiesis and genetic instability. T-Large Granular Lymphocyte (T-LGL) Leukemias are a well-described group of indolent neoplasms thought to derive from chronic antigen stimulation in some cases. We report a unique case of TS associated with MDS and T-LGL Leukemia: a 48-years-old Caucasian female with history of frequent respiratory infections since childhood, hepatic cholestasis, glaucoma and primary amenorrhea was admitted to the hospital for investigation of progressive neutropenia and macrocytic anemia (not nutrition-

al). The hematologic investigations revealed Hb 10.7, MCV 101, anisocytosis, reticulocytosis (2.4%), 1200 neuthophils, 5700 lymphocytes without B clonality by flow cytometry and 98% $CD2^+$ $CD3^+$ TCR alfa/beta$^+$ $CD7^+$ $CD57^+$ $CD94^+$ $CD94^+$ $CD45RA^+$. Bone marrow morphology showed dyserythropoiesis, internuclear bridging, binucleated erythroblasts, dysgranulopoiesis, no ringed sideroblasts; abnormal flow cytometric myeloid differentiation. Bone marrow trephine biopsy was compatible with MDS. Constitutional karyotype with 22 metaphases showed absence of one X chromosome in all mitosis (45,X0). In this case, the diagnosis of TS was concurrent with the diagnosis of MDS and T-LGL Leukemia because the patient omitted some anamnesis data and she missed the hospital visits since adolescent age. At the moment, the patient remains clinically stable since 5 years ago, without any treatment. The prognosis of TS patients suffering Haemopoietic Malignancies is still unknown and, perhaps, these associations may be more frequent than previously recognized. More case reporting is needed to determine the role of monosomy-X in leukemogenesis.

GENOTYPIC HETEROGENEITY OF ALPHA-THALASSEMIA IN ROMANIAN PATIENTS

R Talmaci,[1] C Tecuceanu,[2] L Dan,[2] D Coriu,[1] M Dogaru,[3] S Badelita[1]

[1]University of Medicine and Pharmacy Carol Davila, Bucharest, Romania; [2]Genetics Institute of Bucharest University, Bucharest, Romania; [3]Fundeni Clinical Institute, Bucharest, Romania

Alpha-thalassemia is a hereditary hemoglobin disorder caused by defects in the alpha-globin genes. The majority of the mutations involved in alpha-thalassemia are extended alpha globin gene deletions. The purpose of our work was to implement a molecular diagnosis approach for patients with suspicious diagnosis of alpha-thalassemia. Patients with modified levels of cell blood count (RBC, MCV, MCH), levels of HbA2 1-2.9% and excluding other causes of hypochromic anemia were tested for the most common alpha-thalassemia deletions. DNA samples extracted from peripheral blood of all 43 subjects included in the study were genotyped using the GAP-PCR molecular method. Our results showed ten patients with modifications in the alpha-globin genes, as following: three patients are carriers of the 3.7kb deletion and in four patients was identified the MED I deletion. An interesting finding was the identification of alpha triplicated status ($\alpha\alpha\alpha$=anti 3.7kb) in 3 patients. In one of these, alpha triplicated status is associated with cd 8 (-AA) β-thalassemia mutation resulting in a thalassemia intermedia phenotype. In conclusion, our study shows that Mediterranean alpha-thalassemia deletions -3.7 kb and MED I are quite frequently found in alpha-thalassemia cases from our country and it is the first report about alpha-thalassemia in Romania. This approach could be a very efficient application in prenatal diagnosis for a thalassemia prevention programme in our country.

CO-INHERITANCE OF HB KNOSSOS AND CD 39 MUTATION CAUSES A BETA-THALASSEMIA MAJOR PHENOTYPE IN A YOUNG PATIENT

R Talmaci,[1] L Dan,[2] M Crisan,[3] R Stoia,[3] M Dogaru,[3] S Badelita,[1] D Coriu[1]

[1]University of Medicine and Pharmacy Carol Davila, Bucharest, Romania; [2]Genetics Institute of Bucharest University, Bucharest, Romania; [3]Fundeni Clinical Institute, Bucharest, Romania

In the frame of beta-thalassemia mutation screening study, we investigated the first Romanian patient with thalassemia major due to compound heterozygosity for Hb Knossos and cd 39 (C-T) mutation. Hb Knossos (cd 27 [G-T]) is characterized by reduced synthesis and by interaction with beta-thalassemia, in which the double heterozygotes display typical features of thalassemia intermedia. Here we report the first case of Hb Knossos in our country. Molecular analysis of the mutations in the β-globin gene has been performed using the PCR based *Methods.* DGGE, ARMS-PCR and PCR-RFLP. Direct DNA sequencing confirmed that the propositus is compound heterozygous for Hb Knossos (cd 27 GCC-TCC) and cd 39 (C-T) mutation. Hb Knossos is a variant with a single base substitution causing amino acid replacement and alternative splicing of precursor beta-messenger RNA by activating cryptic donor sites in the exon I. CAG-TAG substitution at codon 39 in beta-globin gene changes codon 39 into a stop codon terminating translation. Hb Knossos displays a slightly decreased oxygen affinity; this factor may compensate in part for the severe anemia of the double heterozygotes. In our case co-inheritance with severe β^0 mutation causes the beta-thalassemia major phenotype and this is important for genetic counseling.

VNTR POLYMORPHISMS IN TPMT GENE PROMOTER: POTENTIAL TOOL FOR THIOPURINE-GUIDED THERAPY

M Radmilovic,[1] B Zukic,[1] M Stojiljkovic,[1] N Tosic,[1] F Pourfarzad,[2] L Dokmanovic,[3] D Janic,[3] N Colovic,[4] S Philipsen,[2] G Patrinos,[5] S Pavlovic[1]

[1]Institute of Molecular Genetics and Genetic Engineering, Belgrade, Serbia; [2]Erasmus MC, Faculty of Medicine and Health Sciences, MGC, Rotterdam, Netherlands; [3]University Children's Hospital, Belgrade, Serbia, [4]Institute of Hematology, Clinical Center Serbia, Belgrade, Serbia; [5]University of Patras, School of Health Sciences, Department of Pharmacy, Patras, Greece

Background. Thiopurine S-methyltransferase (TPMT; EC 2.1.1.67) is an enzyme that metabolizes immunosuppressive thiopurine medications, used in treatment of autoimmune diseases, cancer and in transplantation medicine. Its activity is polymorphic and a trimodal distribution has been demonstrated in Caucasians (low, intermediate and high methylator groups). It has been shown that certain TPMT gene polymorphisms affect TPMT enzyme activity. TPMT gene promoter contains a variable number of three types of GC-rich tandem repeats, A, B and C, ranging from 3 to 9 in length, arranged in a specific manner (AnBmC). *Aims.* We analyzed the TPMT promoter tandem repeat distribution of alleles and genotypes in Serbian population (73 childhood acute lymphoblastic leukemia (ALL) patients, 31 adult myeloid leukemia (AML) patients and 50 blood donors). We also investigated the influence of number and type of promoter tandem repeats on transcription of TPMT gene. *Methods.* We performed functional analysis of the TPMT gene promoter and its upstream regulatory region, analyzed the interaction of the A, B and C tandem repeats with transcription factors by electromobility shift assays (EMSA) and investigated the influence of 6-mercaptopurine (6-MP) on TPMT gene transcription. *Results.* We have detected 11 different types of VNTRs in the TPMT gene promoter in the Serbian population. Number of repeats ranged from 4 to 8. Within the TPMT promoters containing the same number of tandem repeats, different architecture of VNTRs has been determined, (AnBmC, where n ranged from 1-5 and m ranged from 1-6). We have determined 17 different TPMT VNTR genotypes in Serbian population. Our data show that the distribution patterns of VNTR alleles do not significantly differ among ALL and AML patients and normal individuals. Functional assays revealed that TPMT promoter with the highest activity was the one with VNTR*4b type (AB2C). Promoters with 5, 6 and 7 VNTR alleles all had successively lower activities. VNTR*8 activity was two times higher than activity of VNTR*7 types. We found differences in activity between the constructs containing the same number, but different type of tandem repeats. The most prominent difference was observed between VNTR*4 variants (A2BC and AB2C). Also, we demonstrated that the A repeat has a negative effect in TPMT gene transcription and that a positive regulatory element, identified immediately upstream to the VNTR region of the TPMT gene promoter, is indispensable for TPMT gene transcription. TPMT gene promoter demonstrated a specific response in cells treated with 6-MP (10 μM) in a VNTR-specific manner. EMSA indicated that the Sp1 and Sp3 transcription factors bind to the VNTR repeats. *Conclusions.* Our data indicated that both the number and type of VNTRs as well as the upstream regulatory region of the TPMT gene promoter determines the overall level of TPMT gene transcription. Our results showed that VNTR geno-

types that contribute to low-methylator TPMT phenotype, account for one third of TPMT VNTR genotypes in Serbian population. For that reason promoter tandem repeats could be considered as candidate pharmacogenetic marker. Further investigation will confirm if it could be of clinical importance for individualizing thiopurine therapy.

ACETYLSALICYLIC ACID (ASA) NON RESPONDER STATUS IN PATIENTS WITH CORONARY AND CEREBROVASCULAR DISEASE

V Knezevic

Blood Transfusion Institute Nis, Nis, Serbia

Background. Platelets play an important role in the pathogenesis of arterial thrombosis. Inhibition of platelet functions is an established intervention for the preventions of thrombosis events in patients with CAD, who were taking low dose ASA therapy as an antiplatet agent. The purpose of the present study was to determine the concept of ASA resistance on non responsiveness, analyzing the effect of low dose ASA therapy in patients wit CAD. *Methods.* Platelet function was evaluated using a plated function analyzer PFA-100 by determining the time to occlusion (close time CT) of an aperture in a membrane, coated with Coll/ADP or Coll/EPI as citrated whole blood flows under high shear stress conditions CT ranges with Coll/EPI cartridge was 68-167s (max. value>300s) and Coll/ADP 68-122s (max value>300s). Our study was conducted on74 patients, all of them had a chronical (6-60 months) low dose ASA therapy (100 mg/day). Tests were performed 24 hours after the last dose of ASA within a range of 30-120 minutes after blood collection. *Results.* From 74 CAD patients with chronic low dose ASA therapy 58 (78%) showed an adequate response of ASA (Coll/EPI > 167s) whereas 16 (22%) of these patients had confirmed poor response to ASA (Coll/EPI <167). Coll/ADP - CT was not significantly different. A dosage increase of 200 mg/day ASA for two months led to prolonged Coll/EPI - CT > 167s as well in 10 (62.5%) of poor responders. Patients without adequate response to ASA were treated with another platelet inhibitor or a combined medication. *Conclusion.* Our previous results, acquired by PFA-100, with Coll/EPI cartridges 24 hours after the last ASA intake, indicated that a lot of CAD patients seem to be non-responder to ASA therapy. Our study has showed: - importance of monitoring the efficacy of ASA therapy, - identification of the patients with a poor response platelet inhibition inducted by ASA therapy, - need to search an individually adapted ASA dosage or treatment with other platelet inhibitors.

1757

ROLE OF REAL-TIME QUANTITATIVE RT-PCR TO MEASURE MDR1 GENE OVEREXPRESSION AND ITS ROLE IN IMATINIB RESISTANCE CHRONIC MYELOID LEUKEMIA PATIENTS

R Mir,[1] S Sazawal,[1] J Jamsheed,[2] M Masroor,[3] A Saxena,[3] S Saxena[1]

[1]All Indian Institute of Medical Sciences, New Delhi, India; [2]Biochemistry Mamc, New Delhi, India; [3]Biochemistry MAMC, New Delhi, India

Background. Different mechanisms could sustain Imatinib resistance, including overexpression of MDR1, a gene already known to be responsible for multidrug resistance and poor prognosis in other hematologic malignancies. MDR1 overexpression may be considered as an important clinical mechanism in the diversity of resistance development in imatinib monotherapy in CML patients. *Aims.* - To develop sensitive detection of MDR1 gene in the peripheral blood mononuclear cells from in CML patients receiving imatinib. - To set up real-time quantitative RT-PCR technique to measure MDR1 gene overexpression and its clinical significance in the patients with chronic myeloid leukemia treated with imatinib. *Methods.* A cohort of 75 patients with chronic myeloid leukemia enrolled in AIIMS (2005-2009) were included in this study. Total RNA was isolated from the peripheral blood mononuclear cells from CML patients receiving imatinib. The RNA was quantified spectrophotometrically at 260 nm (ND-1000, Nanodrop technologies). First strand cDNA's were synthesized from 1ug total RNA .Real-time quantitative RT-PCR for MDR1 was performed with SYBR Green Supermix. The primers used for MDR1 and beta-actin were selected based on specificity and efficiency by qPCR analysis of a dilutions series of pooled cDNA at a temperature gradient for primer-annealing and subsequent melting curve analysis,agarose gel-electrophoresis and nucleotide sequence analysis. All patients were monitored for hematologic and molecular responses, time to progression, survival and toxicity. *Results.* Thirty of 75 imatinib resistant CML patients had high levels of MDR1 expression. The higher expression of MDR1 levels were also reported in higher age group ,≥40 years (60% *vs.* 40%; P<0. 05), and leukocyte counts ≤50×10^9/L (70% *vs.* 46%; P<0.01) but the lower expression of MDR1 was reported in the CML patients with p-loop mutations. The defined cut off for copy numbers of MDR1 transcripts corresponded with the degree of biological resistance in the peripheral blood mononuclear cells of relapsed CML patients. *Conclusion.* The molecular technology developed has a prognostic importance. Real-time quantitative RT-PCR technique using Sybre green proved economical, rapid and sensitive. MDR1 expression may play an important role in Imatinib resistance in CML patients. These results suggest the efficacy of this quantitative analysis of MDR1 expression by Sybre green to predict clinical drug resistance in CML patients receiving imatinib.

THE FIRST HYPERTRIGLYCERYDEMIA CASE REPORT WHILE MOBILIZATION OF AUTOLOGOUS PERIPHERAL BLOOD HEMATOPOIETIC CELL WITH FILGRASTIM

E Ozturk, K Kaptan, C Beyan

Gülhane Military Academy of Medicine, Ankara, Turkey

Autologous peripheral blood hematopoietic cell transplantation is one of the treatment alternative for Hodgkin lymphoma. While mobilization regimen of the autologous peripheral blood hematopoietic cell transplantation the group of myeloid growth factors are use. Filgrastim is the most used drug for mobilization of hematopoietic cells. Some side effects of Filgrastim are fever, splenomegaly, bone pain, central nervous system effects etc. There was no report of hypertriglyceridemia after exposure of Filgrastim. We present a severe hypertiglyceridemia case report after exposure of Filgrastim for mobilization of autologous peripheral blood hematopoietic cell. 40 year old man treated for stage IIA nodular sclerosis Hodgkin lymphoma. Patient takes Bornaprine 4 mg/d, Escitalopram 20 mg/d treatment for anxiety disorder. He had no metabolic disease on routine controls. Triglyceride level was 200 mg/dL on routine examination. After 3 years with remission he relapsed with cervical and mediastinal lymphadenopathy. After treatment with 3 courses of DHAP (Dexamethasone, cisplatin, high-dose cytarabine) chemotherapy regimen, patient reviewed as complete remission. Autologous peripheral blood hematopoietic cell transplantation treatment was considered. Before Filgrastim treatment triglyceride level was 230 mg/dL. For mobilization of autologous peripheral blood hematopoietic cell 10 μg/kg/day Filgrastim was used. While fourth day of treatment chilous blood sample was seen on routine blood sample and 1180 mg/dL hypertriglyceridemia, cholesterol 235 mg/dL was seen. The control study was done 2 days later and 650 mg/dL hypertrigliceridemia was seen. The patient received no additional or lipid lowering therapy. After 1 week exposure of the Filgrastim the triglyceride level was fall to 227 mg/dL. This is the first case that has hypertriglyceridemia after exposure of the Filgrastim. There is no data at the literature for this situation. Because of this we do not know the Filgrastim effect on the hypertriglyceridemia. But on the mechanism of the hypertrtiglyceridemia lipoprotein lipase, Apo C-II, Apo-V, Apo E or hepatic lipase deficiency has a great role. Filgrastim may have a role on the clearance or the function of these enzymes and apolypoproteins. In conclusion Filgrastim has wide range of use on mobilization of hematopoietic stem cell at healthy donors as patients. For this reason scanning of triglyceride levels must be done for patients and donors.

MYOCARDITIS INDUCED BY ALL-TRANS RETINOIC ACID (ATRA)

MV Aznar, MC Mateos, MA Ardáiz, M Echeveste, M Lasa, JM Arguiñano, MA Goñi, Y Burguete, MJ Paloma, M Redondo, I Ezpeleta, M Pérez, FJ Oyarzábal

Hospital Virgen del Camino, Pamplona, Spain

The introduction of all-trans retinoic acid (ATRA) in the therapy of acute promyelocytic leukaemia (APL) has improved the outcome of this rare hematologic malignancy. ATRA is usually well tolerated but some side effects have been described: headache, pseudotumor cerebri, nasal stuffiness, dry red skin, chapped lips, transient elevations in serum aminotransferases and bilirrubin and hypertriglyceridemia. However, the most important complications are: differentiation syndrome and hyperleukocytosis. In the literature, a few cases of myocarditis as drug toxicity are also refered. We present a case of myocarditis induced by ATRA in a patient with t(15;17) positive microgranular APL with PML-RAR alfa rearrangement and a negative cardiac history. Our patient, a 28 year old female, was treated with ATRA in combination with idarubicin and cytosine arabinoside (Ara-C) due to her high risk leukaemia (leukocytosis: 30.300/mm^3). During the first days of therapy, beyond fever the patient had volume loading, weight gain and signs of pulmonary hypertension on echocardiography. This clinic was resolved with diuretics. On second day of treatment the patient had macula hemorrhage on left eye. On day 20, the patient complained of tightness, which increased with deep breath and movements. The electrocardiogram showed ST elevations from V1 to V4. Laboratory analysis showed a minor increase of troponin (0,438 μg/L) with normal CK-MB. Echocardiography showed a pattern of myocarditis with an ejection fraction of 22%. ATRA was discontinued and she was given dexamethasone (first dose: 10 mg twice a day with decrease dose afterwards). The patient needed to be at intensive care unit during two days because she developed hypotension and oligoanuria. She was started on digitalis and dopamine therapy with a good clinic evolution although the ejection fraction was still of 11%. All serological tests for viral infections proved to be negative. The patient recovered and achieved complete remission on day 28. The echocardiographies done after that date were normal. In the following consolidations, ATRA was reintroduced, and she only had subclinic hypothyroidism in relation with ATRA. Nowadays she is receiving maintenance therapy consisting of 6-mercaptopurine and methotrexate once a week. In conlusion, we present a case of myocarditis due to ATRA who recovered completely with the use of steroids and was subsequently retreated with ATRA without recurrence of the myocarditis.

1760

USE OF HEMOGLOBIN RETICULOCYTE TO DETERMINE THE RESPONSE TO ERYTHROPOIETIN.

A Chacon Mayor, A Amian, A Fernández-Jurado, JA Quesada, JN Rodriguez

Hospital Juan Ramón Jiménez, Huelva, Spain

Objectives. Determine the average value of Hbr in patients with blood diseases that are indicated in the use of EPO to treat anemia, assessing the response to this at different times of treatment, checking if a parameter predictor of response to EPO. *Patients, materials and Methods.* Patients Hospital Juan Ramón Jiménez de Huelva diagnosed in our department of hematological malignancies who had received treatment with EPO from March 2007 until the present, excluding all those who have not made any determinations. We studied a total of 31 patients (16 women and 15 men) with a mean age of 64±14 years. For conditions were: 17 SMD, 8 MM, 1 NHL and 5 LLC. Was used EPO 30000 IU / week were solicited for compassionate when necessary. The control points of treatment were conducted in the 3rd, 6th and 12th week, defined as early responses (3rd week), middle (6th week) and global (12th week). Response was considered to increase at least 1 g / dl from baseline in hemoglobin. For the analysis of the counter was used Hbr 2100 Sysmex Roche according to manufacturer's instructions and software with the quality standards currently in force. Statistical analysis was performed with SPSS 14.0 software. The significance of differences between means was analyzed with the Mann Whitney test, dichotomous variables were compared with Chi-square. The significance level was set at p value <0.05. *Results.* Patients with EPO response to early, intermediate and overall had a higher Hbr to nonresponders. The response by increasing the level of hemoglobin in patients treated with EPO was 1.2 g/dL. Answered a total of 14 patients (43%) *vs.* 17 who did not (57%). Hbr Mean baseline study patients was 32.5 pg. (being the average healthy population in our area of 36.5 pg.). In the 3rd week of treatment with EPO, patients with a Hbr> 32.5 pg., Showed a response rate of 65% *vs.* 35% in nonresponders (P>0.05). Patients with Hbr <32.5 pg. Had 20% response *vs.* 80% of nonresponders (P=0.04). Hbr Having an average of 33 pg responders., And non-responders of 26.5 pg. At the 6th week of treatment with EPO, patients with a Hbr> 32.5 pg., I present a 70% response compared to 30% in non-responders (P=0.035). Patients with Hbr <32.5 pg. Had a 32% response compared to 68% of nonresponders (P=0.045). Hbr Having an average of 36.2 pg responders., And non-responders of 29.5 pg.At the 12th week of treatment with EPO, patients with a Hbr> 32.5 pg., Introduced a 80% response *vs.* 20% in non-responders (P=0.035). Patients with Hbr <32.5 pg. Had 30% response compared with 70% of nonresponders (P=0.045). Hbr Having an average of 37.1 pg responders. And non-responders, 31 pg. *Conclusions.* In this study we evaluated the early Hbr as a parameter which rises at the time of starting treatment with EPO, making it a simple method of prediction of response in patients with hematological malignancies with this treatment.

MICRORNA EXPRESSION PROFILING IN CUTANEOUS T CELL LYMPHOMAS. PRELIMINARY RESULTS

R Salgado,[1] R Pujol,[1] F Gallardo,[1] O Servitje,[2] PL Ortiz-Romero,[3] MP Garcia-Muret,[4] T Estrach,[5] F Climent,[2] M Salido,[1] C Barranco,[1] S Serrano,[1] F Solé,[1] B Espinet[1]

[1]IMIM-Hospital del Mar, Barcelona, Spain; [2]Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat, Spain; [3]Hospital [12] de Octubre, Madrid, Spain; [4]Hospital de Sant Pau, Barcelona, Spain; [5]Hospital Clinic-IDIBAPS, Barcelona, Spain

Background. Primary cutaneous T cell lymphomas (CTCL) represent 70% of all cutaneous lymphomas being the most frequent subtypes the mycosis fungoides/Sézary syndrome (MF/SS) and the anaplastic large T cell lymphoma CD30$^+$ (cALCL-CD30$^+$). In this entity, few high resolution genomic studies have been performed. The recent development of new technologies in genomic analysis offers the opportunity to improve the knowledge regarding microRNA (miRNA) expression profiles in human neoplasm as well as its potential role as prognostic markers. *Aims.* Our aim was to explore the miRNA expression signatures in MF tumoral stage and cALCL-CD30$^+$ using a microarray platform. *Methods.* Twenty-two patients with MF tumor stage (MFt) and 11 patients with cALCL-CD30$^+$ were included. RNA was extracted from frozen tissues containing more than 70% of tumor cells. As controls, we used a subset of 5 inflammatory diseases (ID, n=3 erythematous lupus, n=1 bullous pemphigoid and n=1 psoriasis). MicroRNA microarrays technology was performed to explore the global miRNA expression profile using the Human miRNA microarray (V2) from Agilent Technologies. For determining differentially regulated miRNAs moderated paired t-tests were applied using LIMMA. Probes with FDR adjusted p-value below 0.05 and additionally a fold change exceeding 1.2 in absolute value were selected as the relevant ones. All statistical analyses were performed with the Bioconductor project (v2.3) in the R statistical environment (v.2.8.1) For cluster analysis, probes which had a minimum coefficient of variation of 0.05 across all samples were selected and a correlation-based hierarchical clustering based was performed. *Results.* Regarding microRNA expression, a signature composed of 41 microRNAs was found to be differentially expressed in MFt compared with ID including the miR-142, miR-200b, miR-200a, miR-429 and miR-452 (adjusted-p value <0.001). Regarding cALCL-CD30$^+$, 36 microRNAs were found to be differentially expressed compared with ID including miR-155, miR-21, miR-200b, miR-200a, miR-30a and miR-429 (adjusted-p value <0.001). The unsupervised clustering did not segregate the lymphomas into two different clear groups. *Summary.* The application of microRNA expression microarray technology has allowed to define the microRNA signature of CTCLs. Surprisingly, both types of lymphomas have shown a similar miRNA expression profile while the clinical behaviour and the genomic profile of these two entities is quite different. The exhaustively analysis in terms of target gene analysis and the correlation with clinical data is a reasonable next step for the understanding of pathogenic mechanisms of these microRNA and also the definition of biological prognostic factors. *Acknowledgements.* RTICC grant No. RD07/0020/2004 from the Ministry of Science and Innovation.

NOVEL DELETION IN SLC19A2 GENE ASSOCIATED WITH TRMA IN A CONSANGUINEOUS NATIVE OMANI FAMILY

S Al Zadjali,[1] Y Wali,[2] I Beshlawi,[1] W Basheer,[1] S Pravin,[3] T Berbar,[3] S Al Kindi,[2] R Krishnamoorthy[3]

[1]Sultan Qaboos University Hospital, Muscat, Oman; [2]College of Medicine & Health Science, SQU, Muscat, Oman; [3]INSERM, U,763 Hopital Robert Debre, Paris, France

Background. Thiamine-responsive megaloblastic anemia (TRMA) syndrome, a rare autosomal recessive early-onset condition, is characterized by a diagnostic obligate triad of clinical features: progressive sensorineural hearing loss, diabetes mellitus and megaloblastic anemia. Loss-of-function mutations in SLC19A2 gene [1q23.3] encoding the high affinity/low capacity thiamine transporter (THTR-1) have been found to be causal of TRMA in affected kindreds from different populations. Pharmacological doses of thiamine improve the hematologic picture and may delay the onset of diabetes mellitus or reduce the insulin requirement but the hearing loss seems to be irreversible or may require thiamine supplementation early in fetal/neonatal life. Here, we report a novel homozygous deletion in the SLC19A2 gene in large consanguineous Omani family with six clinically recognized TRMA cases, two of which died early in infancy. *Aim.* To define the underlying molecular mechanism of apparent TRMA syndrome, in a child referred with megaloblastic anemia, diabetes mellitus and sensory neural hearing loss. *Methods.* Genomic DNA, isolated from peripheral blood of the patient and her family, was mapped using two microsatellite markers D1S1569 and TMG86 and the alleles were separated on an ABI 3100 automated DNA sequencer and genotypes were analyzed with ABI GeneMapper software 3.0.All the 6 exons of the SLC19A2 gene were PCR -amplified and cycle-sequenced utilizing the BigDye Terminator sequencing kit v3.1. To define the deletion breakpoint region, PCR reactions were carried out using primer pairs located in intron 3 and 3'-untranslated region with Expand Long Template PCR kit. A simple and rapid multiplex PCR strategy was designed for diagnostic purposes. *Results.* Haplotype analyses revealed that the proband was homozygous by descent for the two microsatellite markers, consistent with likely association of the disease phenotype with the SLC19A2 gene mutation. (Figure A) The PCR amplification of all exons of the SLC19A2 gene revealed absence of PCR product for exons 4, 5 and 6. The long range PCR identified an unusual 1.9-kb PCR- product, which were present only in the proband (homozygous) and the parents (heterozygous). Direct sequencing of this 1.9kb product defined the deletion size (5224bp) and the breakpoint region. Based on these data a simple multiplex PCR strategy was designed and used to screen for the novel deletion in the remaining members of the family especially to define the carrier status (Figure B). *Summary and conclusions.* We have identified a novel intragenic deletion of 5224bp encompassing exons 4 to 6 in the SLC19A2 gene in our proband and three other late- referred patients from a consanguineous native Omani family as causal of TRMA syndrome. The predicted THTR1 protein which results from this deletion is truncated by the c-terminal 154 amino acids with consequent absence of the seventh and eighth transmembrane helical regions. This very likely causes intracellular retention of the mutated protein with absent cell surface expression. A simple, rapid and cost-effective diagnostic strategy was established in order to simplify the mutational screening in the large extended family members.

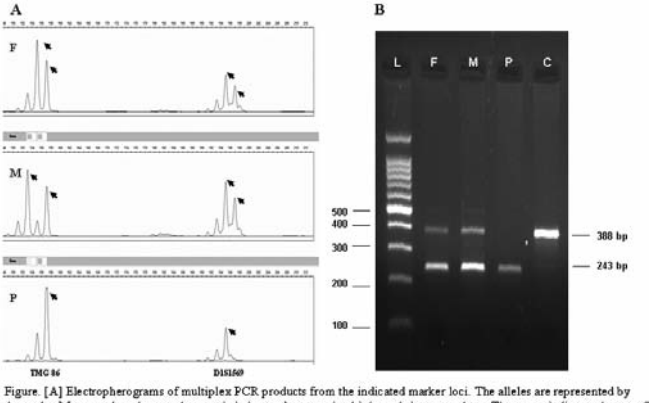

Figure. [A] Electropherograms of multiplex PCR products from the indicated marker loci. The alleles are represented by the peaks. Many markers have a characteristic 'stutter' pattern (multiple peaks), as seen here. The arrow indicates the actuall allele peak. [B] Molecular analysis of the SLC19A2 deletion. Multiplex PCR reaction was performed to amplify control (388bp) and deleted fragments (243bp).

SEROLOGY IS A SENSITIVE TOOL FOR DETERMINING RECIPIENT'S IMMUNE CELLS PERSISTENCE AFTER ABO-MISMATCHED HAEMATOPOIETIC STEM CELLS TRANSPLANTATION

P Isernia, I Sbarsi, C Badulli, EP Alessandrino, AA Colombo, M Diegoli, E Arbustini, M Martinetti, L Salvaneschi

Fondazione IRCCS Policlinico S.Matteo, Pavia, Italy

Background. ABO histo-blood groups are a system of strong immunogenic antigens on red cells involved not only in transfusion but also in transplants. Contrariwise to solid organ transplantation, haematopoietic stem cells transplantation (HSCT) is generally accepted also between pairs ABO-mismatched. The presence of post-transplant ABO chimera is one of the most important indicator for the residue of recipient's haematopoietic and immune cells. *Aims.* Immunology, immunogenetics and molecular genetics are able to provide, nowadays, wide evidences about chimerism after HSCT. The information they bring, in determining host's maintenance of immunological function, could be quite different. This prompted us to compare three techniques: serology, erythrogenomics and molecular analysis of microsatellite regions, in order to establish a hierarchy of accuracy in determining donor/recipient chimerism after HSCT. *Methods.* We analyzed three patients with haematological malignancies who underwent HSCT ABO-mismatched; data regarding the disease, recipient's and donor's blood group before transplant and the clinical outcomes are shown in the table. Patients 1 and 2 were characterized by a minor ABO incompatibility, while patient 3 had a major one. In pre- and post-HSCT samples, red blood cells phenotype was determined either with classical serological techniques and with molecular typing through PCR-SSP. All cases were tested for chimerism analysing selected polimorphic short tandem repeats (STR). *Results.* Different results were obtained dealing with the technique used. In particular, proteomic analysis showed the persistence of recipient's blood group post-HSCT, whereas ABO molecular typing underlined the presence of a full donor genotype. The determination of post-transplant chimerism throughout the study of microsatellite regions, highlighted in patient 3 the occurrence of 5% of recipient's cells and in patient 1 and 2 a full donor genotype. All patients are alive, however the first relapsed, the second one developed a cGVHD and the last is still requiring transfusional support. *Conclusions.* Even though ABO incompatibility is not considered a contraindication in HSCT, its clinical impact and management still remains a challenge for haematologists and transfusion physicians. Our observations, obtained from selected models, evidence the disparity between data obtained by classical serology and genomics. Interestingly, the former technique seems to be the most sensitive tool to detect host's residual immune cells after ABO-mismatched HSCT, while the erythrogenomic does not seem to have sufficient sensitivity to detect the presence of recipient's remaining cells if they are persistent in little amounts. The analysis of STR seems to be a good method to detect chimerism only in case of major ABO incompatibility.

Table. Blood groups and chimerism in ABO mismatched HSCT.

		Patient pre-HSCT			
	Disease	Serology	Erythrogenomics		
Patient 1	APL	A	A^2O^2		
Patient 2	MM	A	nt		
Patient 3	AML	O	O^1O^{1v}		
		Donor

THE SURVEILLANCE OF ANTI-CANCER MECHANISM OF CALCIUM/CALMODULIN-DEPENDENT PROTEIN KINASE II (CAMKII) INHIBITOR IN MULTIPLE MYELOMA CELL LINE

HG Yi,[1] TY Kim,[2] DS Lee,[2] JH Kang,[1] JH Lim,[1] MH Lee,[1] CS Kim,[1] CS Park[1]

[1]Inha Universtiy College of Medicine, Incheon, South-Korea; [2]Seoul National University College of Medicine, Seoul, South-Korea

Background. The study of novel drugs has been sparkled by the advent of new agents showing anti-cancer effect against multiple myeloma by interfering with various molecular pathways of proliferation and survival. Calcium/calmodulin-dependent protein kinase II (CaMKII) is a protein distributed mainly in central nervous system, known to get involved with long-term potentiation memory. neuronal cell development, cellular immunity and signal pathway of cardiac muscle cell. Several studies of CaMKII on cancer were reported regarding the c-FLIP expression regulation in apoptosis, replication factor C dependent cell cycle regulation, and regulation of Raf-1/Mek/Erk or Wnt/β-catenin signaling pathway. *Aims.* As there has been so far no study concerning CaMKII in multiple myeloma, this study was aimed to investigate the role of CaMKII, by using KN-93, a specific inhibitor of CaMKII. *Methods.* Cell viability test was done in multiple myeloma cell lines including RPMI8226, U266, ARH-77 and NCI-H929 after treatment with KN-93. Microarray technique with NimbleGen Human Whole Oligo 12-plex chip was done after KN-93 treatment on U266 cell line to evaluate the change of mRNA expression. The gene expression profile was analyzed in terms of the proliferation or survival signals of cancer cell. *Results.* The treatment with 10μM of KN-93 resulted in more than 50% of cell death rate in all multiple myeloma cell lines. Gene expression was variable in terms of proliferation or survival signal on analysis of the NimbleGen Human Whole Oligo 12-plex chip results. *Conclusions.* CaMKII is one of the important factors controlling proliferation and survival of cancer cell, and various cell signal transduction pathways. KN-93 has a definite anti-cancer effect on multiple myeloma cell line.

CYTOKINE GENE POLYMORPHISMS AND RESPONSE TO IMMUNOSUPPRESSIVE TREATMENT OF ACQUIRED APLASTIC ANEMIA IN KOREA

YG Lee, DY Shin, IH Kim, SS Yoon, S Park, BK Kim

Seoul National University Hospital, Seoul, South-Korea

Background. The responsiveness of acquired aplastic anemia (AA) to immunosuppressive therapy (IST) is the important clinical evidence supporting an underlying immune pathophysiology. Immune-mediated marrow failure are mediated by cytokines which induce apoptosis in hematopoietic progenitor cells. *Aims.*

To evaluate whether single nucleotide polymorphisms (SNPs) of cytokine genes are related to the risk of AA and the response to IST with antithymocyte globulin and cyclosporin. *Methods.* We tested for an association between SNPs in the gene encoding interferon-gamma (IFN-γ; rs7139169, rs2069705, rs2430561), tumor necrosis factor-alpha (TNF-α; rs1799724, rs1799964, rs1800629, rs1800630), transforming growth factor-beta (TGF-β; rs1800469, rs1800470) and FAS (rs1800682) and the risk of AA in 80 adult patients and 84 age and sex matched healthy control in Korea. We then examined the relationship between these SNPs and the response to IST in 44 patients who received IST. *Results.* The minor allele (T) of a variant in the promoter region of IFN-γ (rs7139169) was negatively associated with the risk of AA (odds ratio, 0.3; 95% CI, 0.12 to 0.75; P=0.01), whereas this allele showed no association with the response to IST (odds ratio, 0.65; 95% CI, 0.15 to 2.86; P=0.57). Other two SNPs in IFN-γ gene, four SNPs in TNF-α, two SNPs in TGF-β and one SNP in FAS showed no significant association with the risk of AA and the response to IST. *Summary/Conclusions.* Our results indicate that the minor allele (T) of a SNP in IFN-gamma (rs7139169) among 10 candidate SNPs is significantly associated with the reduced risk of AA in adults. However, all of these SNPs have no apparent impact on susceptibility to IST of AA patients.

1766

ELA2 AND HAX1 GENE MUTATIONS IN IRANIAN CONGENITAL NEUTROPENIC PATIENTS

Z Alizadeh,[1] T Salehi,[2] Z Pourpak,[2] M Fazlollahi,[2] Z Chavoshzadeh,[3] M Bemanian,[2] B Shamsian,[3] A Mahdaviani,[2] M Houshmand,[2] M Moin[2]

[1]IAARI, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran; [2]Immunology, Asthma and Allergy Research Institute, Tehran, Iran; [3]Department of Pediatrics, Mophid Children's Hospital, Shahid Beheshti Medical Un, Tehran, Iran

Severe congenital neutropenia (SCN) is a rare primary immunodeficiency. Typically, affected children are recognized in early infancy with recurrent bacterial infections, low absolute neutrophil counts (mostly less than 500/μL) and also, maturation arrest at the promyelocyte-myelocyte stage in their bone marrow. Different genes are found to be associated to SCN, including ELA2, HAX1, WAS, GFI1, G-CSFR and G6PC3. *Aim.* The aim of this study is to determine the new mutations of ELA2 and HAX1 in Iranian patients with severe congenital neutropenia referred to Immunology, Asthma and Allergy Research Institute from 2008 to 2010. *Methods.* Patients with persistent severe neutropenia, recurrent infection and maturation arrest at promyelocyte-myelocyte stage in their bone marrow entered in this study. Genomic DNA of the patients and their parents was extracted from peripheral blood sample (3 ml whole blood), and all 5 exons of ELA2 and 7 exons of HAX1 genes and their respected flanking regions were amplified by polymerase chain reaction and subjected to direct sequencing. *Results.* Sequence analyses of ELA2 and HAX1 genes in 15 patients had revealed 6 cases of homozygous HAX1 mutation in exon 2, including 5 W44X mutations and one W59X mutation. One patient was heterozygous for ELA2 mutation in exon5 (P257L), and one showed sporadic ELA2 mutation in exon3 (V98L, V101L). The other 7 patients had no mutation in ELA2 and HAX1. *Conclusions.* It can be concluded that ELA2 and HAX1 genes are more common in our patients. Despite previous reports, we found HAX1 mutation more than ELA2 mutation in the patients. Based on our results, so far, no new mutations in ELA2 and HAX1 observed in Iranian neutropenic patients included in this study. Further studies to find other responsible genes for neutropenia, are under investigation in our lab.

1767

CERAMIDES REGULATE RESVERATROL-INDUCED APOPTOSIS IN HUMAN ACUTE PROMYELOCYTIC AND CHRONIC MYELOID LEUKEMIA CELLS

Y Baran,[1] M Kartal,[2] Z Cakir,[1] G Saydam,[3] F Sahin[4]

[1]Izmir Institute of Technology, Faculty of Science, Dept.of Mol.Biol. & Genetics, Urla Izmir, Turkey; [2]Izmir Institute of Technology, Faculty of Science,Dept.of Mol.Biol. & Genetics, Izmir, Turkey; [3]Ege University,Faculty of Science, Department of Hematology, Izmir, Turkey; [4]Ege University,Faculty of Science, Department of Biology, Izmir, Turkey

Purpose. Resveratrol, an important phytoalexin in many plants, has been reported to have cytotoxic effects on several types of cancer. Ceramide is a bioactive sphingolipid that regulates many signaling pathways including cell growth and proliferation, senescence and quiescence, apoptosis, and cell cycle. Ceramides are generated by LASS gene family (LASS1-6) and they are converted to antiapoptotic molecules, glucosylceramide and sphingosine-1-phosphate by glucosylceramide synthase (GCS) and sphingosine kinase-1 (SK-1) genes, respectively. *Aims.* In this study, we examined possible cytotoxic effects of resveratrol on acute and chronic myeloid leukemia cells and determined the roles of ceramide metabolizing genes in resveratrol-induced apoptosis in addition to investigate the possibility of increasing the sensitivity of HL60, acute promyelocytic leukemia (APL) and K562, chronic myeloid leukemia (CML), cells to resveratrol by manipulating sphingolipids. *Methods.* Antiproliferative effects of resveratrol, ceramide mimetics, GCS and SK-1 inhibitors were determined by XTT cell proliferation assay. Changes in caspase-3 enzyme activity were determined by caspase-3 colorimetric assay. The mitochondrial membrane potential (MMP) was measured by JC-1 MMP detection kit. Expression levels of ceramide metabolizing genes were examined by RT-PCR. *Results.* There were synergistic cytotoxic and apoptotic effects of resveratrol in combination with ceramide analogs and inhibitors of ceramide converting agents as compared to any agent alone as determined by XTT cell proliferation and apoptotic assays in both HL60 and K562 cells. More importantly, gene expression analyses revealed that there were significant increases in the expression levels of LASS genes and decreases in expression levels of GCS and SK-1 genes in HL60 and K562 cells in response to

increasing concentrations of resveratrol in a dose-dependent manner. *Summary/Conclusion.* Our data, in total, showed for the first time that resveratrol induces apoptosis in APL and CML cells through increasing ceramide generation and decreasing conversion of apoptotic ceramide to antiapoptotic glucosylceramide and sphingosine-1-phosphate.

THE MECHANISM UNDERLYING BIOLOGICAL EFFECT OF VALPROIC ACID IN TARGETED THERAPY OF AML1/ETO POSITIVE CELLS

M Zapotocky, J Starkova, E Mejstrikova, J Trka

Charles University, 2nd School of Medicine, Prague, Czech Republic

Background. In t(8;21) acute myeloid leukaemia (AML), leukemogenesis is supposed to be promoted by interference with expression of AML1 target genes. Repressor complex associated with AML1/ETO fusion protein recruits class I histone deacetylases (HDAC). Valproic acid (VPA) was found to have an extensive effect on AML blasts, via inhibition of class I HDAC. It was shown previously that VPA treatment disrupts the AML1/ETO-HDAC1 complex from AML1 promoter thus leading to apoptosis at different cell lines. However, there is still lack of in-depth morphological and immunophenotypical proof of the hypothesized restoration of differentiation after treatment with VPA. Aim. We aimed to characterize the differentiation effect of VPA on AML1/ETO positive leukemic cells and primary patients' blasts and to determine the expression pattern of selected AML1 target and candidate genes. *Methods.* Kasumi-1 (M2 AML AML1/ETO positive) cell line, Kasumi-6 (M2 AML AML1/ETO negative) and MV4-11 (M5 AML MLL/AF4 positive) cells were treated with VPA (0,5mM and 1,0mM concentrations) and 12-0-tetra-decanoylphorbol-13-acetate (TPA; 1,62nM concentration) and examined by flow cytometry and qRT-PCR. Z-VAD-FMK (caspase inhibitor; 20 and 100uM) was used to distinguish non-specific changes of immunophenotype during apoptosis. Two AML1/ETO positive patients' bone marrow diagnostic samples and two AML1/ETO negative samples were treated with VPA and TPA to confirm *in vitro* findings. *Results.* Valproic acid induced apoptosis in AML1/ETO positive and MLL/AF4 positive cells in dose dependent manner and G1/G0 arrest in AML1-ETO negative cells. But changes of immunophenotype proving the differentiation were observed purely in AML1/ETO positive cells. Particularly VPA treatment led to decreased expression of early myeloid progenitor antigens (CD33/34/117) and increased expression of antigens typical for differentiated myeloid cells (CD11a/11b). However, differentiated cells exhibited positivity of AnnexinV (early marker of apoptosis); hence the relationship between cell death and differentiation had to be evaluated. Despite the fact that Z-VAD-FMK reduced apoptosis by 80-85%, differentiation was detected in the same extent as previously with no AnnexinV positivity. Conversely changes in immunophenotype were not detected in either of control cells. TPA, which was used to exclude incapability of cells to differentiate, induced monocytic differentiation in both, AML1/ETO positive and negative cells. As quantified by qRT-PCR, VPA treatment increased gene expression in AML1/ETO-positive cells. Concretely VPA increased expression of PU.1($P<0.001$), C/EBPalpha($P<0.001$), BPI($P<0.001$) and IGFBP7($P<0.001$). No significant changes were detected in AML1/ETO negative cells. Specific effect of VPA was confirmed in patients'samples from the time of diagnosis. All samples exhibited changes of immunophenotype after TPA treatment while VPA treatment induced similar changes only in AML1/ETO positive samples. *Conclusions.* Taken together, we provide a valid evidence of differentiation specific for AML1/ETO positive cells accompanied by the increase of the repressed gene expression. Our findings of differentiation immediately followed by apoptosis bring a new insight to the biological effect of an old drug. In view of the ever more widespread use of HDACi in treatment of haematological malignancies, it is crucial to identify subgroups of patients who will benefit most from such treatment. Our data suggests that AML1/ETO positive AML patients are just such subgroup.

GENE EXPRESSION PROFILE OF IMMUNE CITOKYNES IN PATIENTS WITH REUMATHOID ARTHRITIS UNDERGOING TREATMENT WITH IMMUNOADSORTIVE GRANULOCYTE/MACROPHAGE APHAERESIS

M Federico, E Such, B Aparicio, J Cervera, A Valencia, B Costan, M Ibañez, I Gómez, JJ Garcia, J Valero, N Carpio, ML Muñoz, J De la Rubia, D Ibañez, R Negueroles, M Sanz

University Hospital La Fe, Valencia, Spain

Introduction. Rheumatoid arthritis (RA) is a systemic disease, mainly resulting in joint inflammation, but also increasing the risk for cardiovascular diseases. Although it is of unknown origin, immune system alterations could play an important role in its pathogenesis, probably due to a misbalance between Th1 and Th2 responses. Treatments options are focused into modulate the immune response with the use of biological agents. Recently, immunoadsorptive aphaeresis for granulocyte/macrophage has been applied for the treatment of these patients on the basis that it could induce a significant immunomodulation. However, clinical evidence and biological data providing information about this strategy is scarce. *Aims.* The aims of this study were: 1. To identify a specific expression profile of cytokines that regulate immune responses in patients with RA; 2. To study changes in this expression profile during and after treatment with immuoadsortive aphaeresis. Patients and *Methods.* Between January-08 and July-08, 16 consecutive RA patients who were refractory to standard treatment and who received treatment with immunoadsortive aphaeresis were included in the study. Additionally, x healthy controls were also included to compare mRNA cytokine expression between AR patients and controls. All patients underwent five aphaeresis sessions on a two sessions per week schedule. Samples for mRNA expression were collected in all cases before treatment start, after third session and at the end of treatment. mRNA expression of IL1, IL4, IL6, IL23, IL12, IL17, IFN-γ, TNFα, TGF β and FOXP3 were analyzed by means of TaqMan® gene expression assays using GUS and GAPDH as gene controls. *Results.* There were 14 females and 2 males. The median age for patients was 57 (range 31-74) and 21 (range 23-56) for controls. At the basal time, patients with RA showed higher levels of *vs.*G ($P<0.001$), alkaline fosfatase ($P=0.010$) and PCR ($P=0.001$) than controls. Similarly, significant differences were found in the expression of several cytokines with a key role in the immune response. Patients with AR showed a higher expression of IFNγ ($P<0.001$) and IL-1 ($P=0.07$) together with a lower expression levels for IL-4 ($P=0.006$) and TGF-β ($P=0.006$) than controls. So that, the expression pattern suggests that patients with RA have a misbalance between Th1 and Th2 immune responses, with an increase on Th1 activity. This specific expression profile did not show any significant change during or after treatment with immunoadsortive aphaeresis. *Conclusion.* Our results suggest that patients with RA could be characterized by a specific expression profile for cytokines that regulates immune responses. Th1 responses could be increased with respect to Th2 responses, which is compatible with the clinical manifestations of RA. Treatment with immunoadsortive aphaeresis for granulocyte/macrophage compartment did not induce changes in this expression profile. Taken into account these findings together with the limited clinical data, further clinical trials are required before including this treatment strategy in the algorithm of RA patient's management.

AURORA-A KINASE INHIBITION ENHANCES THE CYTOSINE ARABINOSIDE-INDUCED CELL DEATH IN LEUKEMIA CELLS THROUGH APOPTOSIS AND MITOTIC CATASTROPHE

JW Cheong, YH Min, HI Jung, JI Eom, SJ Kim, H Jeung, JS Kim

Yonsei University College of Medicine, Seoul, South-Korea

Background. Aurora-A (Aur-A) is a centrosome-associated serine/threonine kinase that is overexpressed in various cancers and potentially correlated with chemoresistance, and Aurora kinase inhibition sensitized anti-tumor effects induced by chemotherapy. *Methods.* We evaluated the effect of Aur-A inhibition on the cytosine arabinoside (Ara-C)-induced cell death in the Ara-C-sensitive (Molt-3, HL60, KG1, NB4) and Ara-C-resistant (U937, K562) leukemia cell lines, respectively. *Results.* In the Ara-C-sensitive cell lines, silencing of Aur-A by small interfering RNA transfection (Aur-A siRNA) led to a significant increase in the Ara-C-induced cell death rate through induction of mitochondria-mediated, caspase-dependent apoptosis. In contrast, combined treatment of the Ara-C-resistant leukemia cells with Aur-A siRNA and Ara-C (Aur-A siRNA/Ara-C) remarkably enhanced the cell death rate via non-caspase-dependent mitotic catastrophe, which was accompanied by G2/M arrest, increase in the cells with >4N DNA content and multinucleation. Pretreatment of Ara-C-sensitive leukemia cells with a specific p38 MAPK inhibitor SB203580 abrogated the Aur-A siRNA/Ara-C-induced apoptosis, indicating the role of p38 MAPK pathway in the enhancement of apoptosis in these cells. *Summary/Conclusions.* Taken

together, Aur-A inhibition was an effective treatment for both the Ara-C-sensitive and resistant leukemia cells by increasing apoptosis and mitotic catastrophe, respectively. Further studies are necessary to evaluate whether Aur-A inhibition could be a useful therapeutic strategy for chemoresistant acute leukemia disorders.

TARGETED INTEGRATION OF TRANSGENE INTO THE AAVS1 LOCUS ON CHROMOSOME 19 USING AAV INTEGRATION MACHINERY IN HUMAN MESENCHYMAL STEM CELLS

K Ozawa, M Urabe, H Mizukami, A Kume

Jichi Medical University, Tochigi, Japan

Background. Mesenchymal stem cells (MSCs) are easily cultured from bone marrow, rapidly expanded *in vitro* and readily transduced with a variety of viral vectors, and have thus been used in early gene therapy experiments. MSCs have an ability to differentiate into various cell lineages and are attractive tools for regenerative medicine. Retroviral vectors are commonly utilized to introduce foreign genes into these cells. Although the transduced cells can express transgene for a long time, cells transduced with randomly integrating retroviral vectors may transform due to insertional mutagenesis. To date, the adeno-associated virus (AAV) has been identified that integrates its genome into a particular location in human chromosome 19 (19q13.4), known as AAVS1, through the activity of specific replicase/integrase protein, Rep, which can bind both the AAVS1 and the viral inverted terminal repeat (ITR) and mediate site-specific integration. *Aims and methods.* The AAVS1 site is a presumed hazard-free genomic location identified as the specific site. In the present study, we tested AAVS1-targeted insertion of a reporter gene in KM-102 cells (a stromal cell line established from human bone marrow cells) by transfection with a Rep plasmid and a bicistronic transgene plasmid containing a GFP gene under the control of CMV promoter and a blasticidin S resistance gene (bsr) under the transcriptional control of internal ribosomal entry site (IRES) flanked by the ITRs. *Results.* Southern blot analysis of blasticidin S resistant clones revealed that about 10% of the clones showed site-specific integration of the GFP gene into the AAVS1 site. We were also able to amplify the junction sequence between the GFP plasmid and the AAVS1 site. The AAVS1 locus overlaps with the first exon and intron of myosin binding subunit 85 (MBS85), which is involved in the assembly of actin filaments. These clones could grow well like the wild-type KM-102 cells but showed a decreased level of MBS85 mRNA. Summary/*Conclusions.* The results indicated that although the insertion of the transgene at AAVS1 affected MBS 85 expression, it did not appear to cause a phenotypic change of KM-102 cells. The use of the AAV integration machinery to insert a transgene into the AAVS1 locus will contribute to safe genetic manipulation of MSCs. This technology may also be applied to regenerative medicine using ES cells or iPS cells in the future.

5-AZACYTIDINE AND 5-AZA-2´DEOXYCYTIDINE (DECITABINE) EXERT PROFOUND PRO-APOPTOTIC EFFECTS IN NEOPLASTIC HUMAN MAST CELLS

V Winter,[1] H Herrmann,[2] E Hadzijusufovic,[1] K Blatt,[1] B Peter,[1] K Schuch,[1] S Cerny-Reiterer,[1] I Mirkina,[2] H Karlic,[2] W Pickl,[1] P Valent[1]

[1]Medical University of Vienna, Vienna, Austria; [2]Ludwig Boltzmann Cluster Oncology, Vienna, Austria

Aggressive systemic mastocytosis (ASM) and mast cell leukemia (MCL) are advanced myelogenous neoplasms with a poor prognosis. In these patients, neoplastic mast cells (MC) are resistant against most conventional drugs. Demethylating agents reportedly exert beneficial effects in some advanced myelogenous neoplasms, including myelodysplastic syndromes. We examined the effects of two demethylating agents, 5-azacytidine and 5-aza-2'deoxycytidine (decitabine) on growth and survival (apoptosis) of neoplastic MC and the human MC line HMC-1. Two HMC-1 subclones were used, HMC-1.1 lacking KIT D816V and HMC-1.2 exhibiting KIT D816V. Both demethylating agents were found to induce apoptosis in HMC-1.1 cells and HMC-1.2 cells in a dose-dependent manner (ED50: 10-20 μM). In normal cultured MC and normal bone marrow cells, no substantial effects of 5-azacytidine or decitabine on growth or viability were observed. Drug-induced apoptosis in HMC-1 cells was accompanied by cleavage and activation of Caspase 8 and Caspase 3 as well as an increased expression of proapoptotic FAS/CD95, and decreased expression of KIT/CD117. Unexpectedly, as assessed by 3H-thymidine uptake, only decitabine was found to inhibit the proliferation of HMC-1 cells at pharmacologic drug-concentrations (IC_{50}: 1-5 μM), whereas no effect was seen with 5-azacytidine (>20 μM). Moreover, only decitabine but not 5-azacytidine, was found to induce a G2/M arrest in neoplastic MC. We were also able to confirm growth-inhibitory effects of decitabine on neoplastic cells in a patient with KIT D816V+ SM associated with CMML. Together, our data show that 5-azacytidine and decitabine exert differential effects on growth and survival (apoptosis) in neoplastic MC. Whether epigenetic drugs also produce anti-neoplastic effects *in vivo* in patients with ASM and MCL remains to be determined in clinical trials.

1774

NO SYNERGISTIC EFFECTS OF LENALIDOMIDE COMBINED WITH DASATINIB REGARDING ADCC INDEPENDENT NK CELL EFFECTOR FUNCTIONS AGAINST MM CELLS IN VITRO

M Zekl, E Grella, T Stühmer, H Einsele, R Seggewiss

University of Würzburg, Internal Medicine II, Division of Hematology, Würzburg, Germany

Background. Lenalidomide, an IMiD® (immunomodulatory drug) is well established for the treatment of relapsed/refractory multiple myeloma (MM) patients. Besides its direct anti-tumor effects it has been shown to modulate natural killer (NK) cell effector functions, especially those associated with antibody dependent cellular cytotoxicity (ADCC). The multi-kinase inhibitor dasatinib inhibits oncogenic SRC family kinases, which are associated with IL-6 induced proliferation in MM. Under certain circumstances dasatinib has been described to enhance NK cell effector functions. Currently, a clinical trial applying the combination of lenalidomide, dasatinib and dexamethasone for the treatment of MM (clinicaltrials.gov Identifier NCT00560391) is ongoing. *Aims.* We examined the potential for synergistic effects of the combination of lenalidomide and dasatinib on MM cell lines, primary MM cells and key effector functions of NK cells, because NK cells are the first line of defense against MM. *Methods.* Peripheral blood mononuclear cells (PBMCs) or expanded polyclonal NK cells *ex vivo* cocultured with irradiated RPMI 8866 feeder cells (both from healthy human blood donors after written informed consent was obtained) were analyzed *in vitro*. Furthermore, direct effects of the drug combination on primary MM cells and on the MM cell lines U266 and OPM-2 were evaluated. Functional outcomes assessed in NK cells included apoptosis/necrosis induction, cytotoxicity, degranulation marker CD107a/b expression and TNFα/IFNγ production. Proliferation behavior and/or apoptosis induction were assessed in MM cell lines and primary MM cells. *Results.* Dasatinib [50nM] alone and in combination with lenalidomide [50μM] significantly increased the apoptosis/necrosis rate on day 3 and 4 in PBMCs (n=4). However, it decreased the apoptosis/necrosis rate in expanded NK cells (n=5). Cytotoxicity, CD107a/b expression and cytokine production were unaffected by 24h pre-treatment with lenalidomide [1μM - 50 μM] (PBMCs: n=3-5; expanded NK cells: n=3, only 50μM tested). 24h pre-treatment with dasatinib with or without lenalidomide significantly reduced the cytotoxicity against MM cell lines in NK cells from PBMCs (OPM-2 n=3, U266 n=5), but not in expanded NK cells (n=3 for both target cell lines). However, it significantly increased the CD107a/b expression in expanded NK cells, when stimulated with MM cell lines (OPM-2 n=3, U266 n=3). In contrast, when dasatinib with or without lenalidomide was only present in the assay, cytotoxicity was significantly inhibited (expanded NK cells, n=3 independent experiments). Cell death induction in primary MM cells in coculture with stromal cells was heterogeneous, with 4/12 samples showing an enhancement by the combination of dasatinib [1 μM] and lenalidomide [20 μM], 4/12 samples showing no improvement over the dasatinib activity alone, and the remaining samples unaffected by either the single drugs or their combination. The combination of lenalidomide [20 μM] with dasatinib [2 μM] was more effective than the single drugs alone in OPM-2 cells with or without coculture with stromal cells, but had little effect on U266 cells. *Summary/Conclusions.* According to our results the combination of dasatinib and lenalidomide does not increase the direct, ADCC independent NK-cell activity *vs.* MM *in vitro* and seems therefore not to be a promising approach for clinical immunotherapeutic application, however further evaluations are ongoing.

1775

CYTOTOXIC EFFECTS OF BENDAMUSTINE IN COMBINATION WITH ANTILEUKEMIA / LYMPHOMA AGENTS AGAINST HUMAN MALIGNANT LYMPHOID CELL LINES

Y Kano,[1] U Uesawa,[2] F Furukawa,[2] A Akutsu,[1] M Mano,[2] N Nagai,[2] O Ozawa[2]

[1]Tochigi Cancer Center, Utsunomiya, Japan; [2]Jichi Medical University, Shimotsuke, Japan

Background. Bendamustine, unique cytotoxic agent that combines alkylating and antimetabolite activities, has shown significant activity against lymphoid malignancy. Although the recent advances in the preclinical and clinical use of bendamustine has been rapid, no conclusions can be drawn from the available data regarding its mechanisms of action, the optimal dose, and schedule and the optimal drugs to combine with it. *Purpose.* To investigate the optimal drugs with bendamustine in combinations, we studied the drug interactions of bendamustine with other antileukemia/lymphoma agents in human malignant lymphoid cell lines *in vitro*. *Methods.* Human B-cell lymphoma HBL-2 cells, B-cell leukemia BALL-1 cells, and myeloma U-266 cells were used for the study. The cells were simultaneously exposed to bendamustine and the other agents for 4-7 days. Cell growth inhibition was determined using the MTT reduction assay. The cytotoxic interactions at the IC80 level were evaluated by the isobologram method (Steel and Peckham). *Results.* The IC80 levels of bendamustine were 31 μM, 23 μM, and 10 μM, respectively, in these cell lines. Bendamustine produced synergistic effects with cytarabine, gemcitabine, and 4-hydroperoxy cyclophosphamide; additive effects with doxorubicin, etoposide, F-ara-A, mitoxantrone, and vincristine; and antagonistic effects with methotrexate in all three-cell lines. Cell cycle analysis using HBL-2 cells revealed that S-phase arrest was markedly induced when bendamustine was combined with cytarabine or 4-hydroperoxy cyclophosphamide. *Conclusions.* Our findings suggest that bendamustine has favorable antitumor effects when it is administrered simultaneously with most of studied. Among them, cytarabine, gemcitabine, and 4-hydroperoxy cyclophosphamide were more cytotoxic than expected when combined with bendamustine, and so these combinations are worthy of clinical investigation, whereas methotrexate may be inappropriate for simultaneous administration with bendamustine. These data provide useful information for the establishment of clinical protocols involving bendamustine.

1776

MICROVASCULAR BLOOD FLOW ALTERATIONS IS REVERSED BY LEUKAPHERESIS IN ACUTE LEUKEMIA: A CASE STUDY

J Weigel, S Duran, P Te Boekhorst, M Van Genderen, J Bakker, C Ince

Erasmus Medical Center Rotterdam, Rotterdam, Netherlands

Background. Acute leukemia is primarily a bone marrow disorder that can be complicated by leukocytosis. Extreme leukocytosis can cause leukostasis due to sludging of circulating leukemic blasts into the microvasculature. Recently, this has been visualised by direct observation by SDF imaging.[1] Leukapheresis is used to correct hyperleukocytosis and leukostasis in the expectation of preventing microcirculatory obstruction. *Aims.* We hypothesized that this reversal of microcirculatory alterations could be observed by direct sublingual observation of the microcirculation by SDF imaging. *Methods.* In a 55 year old patient, recently diagnosed with acute myeloid leukemia (AML), was admitted to the intensive care unit with respiratory failure. Sublingual microcirculatory imaging was performed by using side stream dark field (SDF) imaging.[2] Sublingual capillary blood flow was estimated by off-line computer analysis using the semi-quantitative microvascular flow index (MFI).[3] *Results.* SDF-imaging showed a discontinuous microvascular blood flow pattern in all vessels before leukapheresis most probably caused by leukostasis (WBC count before leukapheresis 109×10^9/L; WBC count after leukapheresis 41×10^9/L). Only red blood cells can be observed by the SDF technique; the large spaces between the red blood cells suggest the occurrence of leukocytes between them. After leukapheresis the microvascular blood flow was normalized as reflected by increased MFI in all vessels. The improvement of blood flow was most obvious in the small vessels: MFI (small vessels before leukapheresis)= 0; MFI (small vessels after leukapheresis)=3. *Conclusion.* We conclude that leukapheresis is able to revert microcirculatory alterations in acute leukemia and that such effects can be directly observed by SDF imaging at the bed side.

USE OF PROPRANOLOL IS EFFECTIVE AND SAFE IN TREATING INFANTILE HAEMANGIOMAS: REPORT OF 5 CASES

M Economou, D Gidaris, V Hatzidemetriou, M Badouraki, N Gompakis, M Athanassiou-Metaxa

Hippokration General Hospital, Thessaloniki, Greece

Infantile haemangiomas (IH) are the most common vascular tumours of childhood. Usually their course is self - limiting. Albeit that, a significant minority requires treatment due to dramatic cosmetic impact or functional impairment. The efficacy of propranolol for the treatment of IH was recently serendipitously discovered. Since then, there has been a great interest in this off-label use of propranolol. We report our experience with this novel treatment in 5 children with infantile haemangiomas. The patients' age at treatment initiation was 2 months to 12 years. The haemangiomas were situated at the right forearm in 2 cases and at the right labium major, at the right cheek, uvula and right upper eyelid and at the tip of the nose in the remaining 3. Parents provided informed consent in all cases. Thorough cardiologic (clinical examination, electrocardiogram and echocardiography) and respiratory evaluation were carried out prior to initiation of treatment. Additionally, all patients had full blood count, biochemistry profile, urine dipstick for glucose, abdominal ultrasonography and ultrasonography of the IH treated. Propranolol was given every 8 hours, with an initial dose of 0.16 mg/kg/dose. The second day the dose was doubled and the third day the full dose of 0.66 mg/kg/dose was reached (total dose of 2 mg/kg/day). Parents were encouraged to feed their children frequently and anticipatory guidance was provided regarding symptoms and signs of hypoglycaemia, bradycardia and hypotension. Patients remained in hospital for 48 hours under close cardiorespiratory monitoring; fingerstick blood glucose was checked every three hours. In all cases oral propranolol led to rapid discoloration of the haemangioma, ulcer healing when present and size decrease of the lesion. No side effects were reported in any of the cases treated. Propranolol appears to be both effective and safe in the treatment of infantile haemangiomas. Large, prospective, well designed studies still need to verify these parameters as well as the best treatment regimen.

1778

EFFICACY OF RITUXIMAB FOR TREATMENT OF AUTOIMMUNE CYTOPENIAS ASSOCIATED WITH LYMPHOPROLIFERATIVE DISORDERS: THE MANITOBA EXPERIENCE

J Singh,[1] J Johnston,[1] M Geirnaert,[2] S Navaratnam,[1] P Czaykowski,[1] M Pitz,[1] K Guilbert,[2] B Lozar,[2] B Joseph,[2] V Bourrier,[2] R Kumar[1]

[1]University of Manitoba, Winnipeg, Canada; [2]CancerCare Manitoba, Winnipeg, Canada

Background. Autoimmune cytopenias (AIC) are a known complication of lymphoproliferative disorders (LPD). Treatment of AIC remains a therapeutic challenge. In recent years, the anti-CD20 monoclonal antibody rituximab has been used for the treatment of AIC refractory to or dependent on steroids or other immunosuppressants. Here we report our results of rituximab treatment for patients suffering from LPD associated AIC. *Aim.* To evaluate the efficacy of rituximab for the treatment of AIC in patients with an underlying LPD. *Methods.* All patients treated with rituximab for AIC associated with LPD in Manitoba between January 1, 2003 and December 31, 2007 were identified using the CancerCare Manitoba Pharmacy database and the Aria Information system (Varis Med Oncology Software). The charts of all these patients were reviewed retrospectively to assess response to therapy. *Results.* Rituximab was administered to 16 patients with LPD who developed AIC refractory to or dependent on steroids or other immunosuppressants. Details of the patients and outcomes are given in the table below. Of the 12 patients with autoimmune hemolytic anemia (AIHA), 10 had CLL, and 6 were Coomb's positive. All patients with immune thrombocytopenic purpura (ITP) had CLL. Rituximab was administered at a median time of 3, 13 and 4 months from the diagnosis of AIHA, ITP and AIHA + autoimmune neutropenia (AIN) respectively. A median of 4

cycles of rituximab were administered per course. All patients concomitantly received prednisone. Responses: (a) AIHA - 11 patients received a total of 15 courses of rituximab with a complete response (CR) in 80% at a median time of 2 months. Five patients achieving CR with the first course of rituximab relapsed at a median time of 17 months. Four of the five patients who relapsed received a second course of rituximab, and all four achieved a complete response. Of the 11 patients treated with rituximab, five died at a median time of 8 months post rituximab. Two of these patients died within 1 month of rituximab completion. Both these patients had advanced CLL. At last follow-up, two patients remained in remission at 3.5 and 18 months. (b) ITP - 4 patients received a total of 5 courses of rituximab with a CR in 60% and a partial response (PR) in 40% at a median time of 1 month. One patient who achieved CR with the first course of rituximab relapsed at 18 months and achieved CR with a second course of rituximab. Of the 4 patients treated with rituximab, 1 patient died at 6 months post rituximab completion. At last follow-up, 2 patients remain in remission at 25 and 26 months. (c) One patient treated for AIHA and AIN achieved CR at 2 months without relapse. This patient died at 30 months post rituximab. *Conclusion.* Rituximab therapy, regardless of regimen, appears to be safe and effective for the treatment of LPD associated AIC not responsive to conventional therapies. Patients who relapse following rituximab successfully respond to a second course of rituximab.

Table. Patient Characteristics and Response to Rituximab.

		AIHA	ITP	AIHA + AIN
Patients	Numbers	11	4	1
	Median age ritux started	70 years (range 56 -77)	69 years (range 61 - 84)	62 years
	Median lab values start of treatment*	Hgb 90g/L (range 61 - 132*)	Plts 97x10^9/L (range 18 - 147*)	Hgb 140g/L* ANC 1.9x10^9/L*
Number of courses per regimen	Total	15	5	1
	RCD	9	3	1
	R-CVP	3	–	–
	Ritux+/-steroid	3	2	–
Number of courses	One	7	3	1
	Two	4	1	–
Responses	Numbers (%)	CR: 12/15 (80%)	CR: 3/5 (60%) PR: 2/5 (40%)	CR: 1/1(100%)

RCD = Rituximab, Cyclophosphamide, Dexamethasone
R-CVP = Rituximab, Cyclophosphamide, Vincristine, Prednisone
Hgb = hemoglobin, Plts = platelets, ANC = absolute neutrophil count; Ritux = Rituximab
*high values due to ongoing steroid and/ or other immunosuppressants

INVESTIGATION OF CYTOTOXIC EFFECTS OF AU(III), PT(II) COMPLEXES OF 5-CHLORO-1,10-PHENANTHROLINE ON HL-60 (ACUTE PROMYELOCYTIC LEUKEMIA CELLS) CELL LINE

Z Canturk

Anadolu University, Eskisehir, Turkey

Backround. Au(III) complexes, the last isostructural and isoelectronic with platinum(II) complexes, are potentially attractive as anticancer agents. This, together with the recent finding that certain transitional metal complexes like Au(III) and Pt(II) complexes have been found to be potentially useful in cancer chemotherapy, created a renewed interest in the study of the interactions of metal ions with respect to the site of binding and the structure and stability of the complexes. *Aim.* The purpose of this study was to investigate the cytotoxic effect of Au(III) and Pt(II) metal complexes on human leukemic cell lines *Methods.* In this study Au(III) and Pt(II) metal complexes of 5-chloro-1,10-phenanthroline (5-Cl-phen) were synthesized and elucidated of their structure was performed by IR, 1H-NMR and MASS spectroscopic data and elemental analyses results. Then, we studied the antiproliferative effects of Au(III) and Pt(II) metal complexes of 5-chloro-1,10-phenanthroline, and cisplatin on HL-60 cell line. HL-60 was maintained in the RPMI1640 with % 10 heat-inactivated fetal calf serum, 2 mM L-glutamine, 100 Iu/mL penicillin and 100 µg/mL streptomycin, at 37 °C in a humidified incubator containing %5 CO2. The antiproliferative effects of these compounds were evaluated by 3-(4,5-dimethylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide (MTT) cell viability assay by following the 24 and 48 hours incubation of leukemic cells in 5,10,25,50,100 ul concentration of Au(III) and Pt(II) complexes and cisplatin. All experiments were repeated three times. Cytotoxic effect depending on the concentration and time was viewed also by means of light microscope. *Results.* We determined that Au(III) and Pt(II) complexes of 5-chloro-1,10-phenanthroline, and cisplatin had shown significant the time- and concentration-dependent antiproliferative effects on the HL-60 cell line. When HL-60 cells exposered to 50 and 100 µL [Au(5-Cl-phen)Cl2]Cl for 24 h, the cell viabilites decreased to 30% and 43% respectively compared to control. After 48 h 50-100 µL [Au(5-Cl-phen)Cl2]Cl concentrations significantly decreased the cell viabilty ($P<0.001$). The concentrations of 50, and 100 µL [Au(5-Cl-phen)Cl2]Cl for 48 h, the cell viability percenties were determined to 44%, 55% respectively. HL-60 cells exposered to 50 and 100 µL [Pt(5-Cl-phen)Cl2]Cl and cisplatin for 24 h, the cell viabilites decreased to 24% and 42%; 16% and 26%. The concentrations of 50, and 100 µL [Pt(5-Cl-phen)Cl2]Cl and cisplatin for 48 h, the cell viability percenties were determined to 31%, 44% and 16%, 39% respectively Especially, [Au(5-Cl-phen)Cl2]Cl observed an inhibition of cancer cell proliferation higher than [Pt(5-Cl-phen)Cl2]. *Summary/Conclusions.* In conclusion, the present study demonstrates a powerful *in vitro* antitumor action of Au(III) complexes of 5-chloro-1,10-phenanthroline ([Au(5-Cl-phen)Cl2]Cl) on HL-60 cell lines.

MITOCHONDRIA AS A MOLECULAR TARGET IN HEMATOLOGICAL NEOPLASIAS

AM Correia Barbosa Pinto Ribeiro,[1] AC Gonçalves,[2] AF Carvalho,[1] JA Carvalho,[1] V Alves,[1] T Silva,[1] AB Sarmento Ribeiro[3]

[1]Faculty of Medicine, University of Coimbra, Coimbra, Portugal; [2]Faculty of Medicine, Cimago, University of Coimbra, Coimbra, Portugal; [3]Faculty of Medicine, CIMGO, CNC, University of Coimbra, Coimbra, Portugal

Current cancer therapies seek to induce cell death, but only a limited success has been accomplished mainly due to the lack of specificity for cancer cells. Therefore, it is important to investigate treatment strategies for selective tumor cell killing in hematological malignancies.

The primary function of mitochondria is oxidative phosphorylation which supplies the majority of cellular ATP required to sustain normal and tumor cellular functions. The selective inhibition of this process may therefore provide a novel and effective strategy for cancer treatment. On the other hand, considering that mitochondria are the main site for Reactive Oxygen Species (ROS) production, it has been reported that it may have a relevant role in inducing cell death. In fact, it is widely known that mitochondria is involved in apoptotic cell death and that neoplastic cells have an higher mitochondrial potential than normal cells, which may be explored in the development of new approaches to treat cancer. Lipophilic cations possessing a delocalized positive charge (delocalized lipophilic cations or DLCs) penetrate the hydrophobic barriers of the plasma and mitochondrial membranes and accumulate in mitochondria in response to the negative inside transmembrane potentials. The higher plasma and/or mitochondrial membrane potentials of neoplastic *vs.* normal cells, in general, account for greater uptake of these compounds in neoplastic cells and may be a way to selectively target these cells since DLCs exhibit mitochondrial toxicity at high concentrations. Dequalinium (DQA) is a DLC that interferes with mitochondria and so our goal is to evaluate the therapeutic potential of DQA in haematological malignancies, namely in B-cell Chronic Lymphocytic Leukaemia (B-CLL), Acute Promyelocytic Leukaemia (APL) and Myelodysplastic Syndrome (MDS). For this purpose we used three cell lines, EHEB (B-CLL), HL-60 (APL) and F36P (MDS), to evaluate the effect of different concentrations of DQA either by single dose administration, by daily dose administration and by association with conventional anticarcinogenic agents.Cell viability and death was determined by the resazurin assay, optical microscopy and by flow cytometry. The latter was also used to evaluate the mitochondrial membrane potential, the levels of ROS (H_2O_2; $O_2^{\cdot-}$) and the antioxidant defense, Reduced Glutathione (GSH), using fluorescent probes. We found that DQA induced a decrease in cell viability inducing cell death by late apoptosis/necrosis in a time, dose and cell type dependent manner, with an IC_{50} of 2.5, 5 and 7.5 µM at 48h of exposure, respectively to HL-60, F36P and EHEB. These effects may be mediated by oxidative stress as we have observed an increase in ROS production and a decrease in GSH levels and in mitochondrial membrane potential. We also observed that if DQA is administered on a daily basis a much lower concentration is required to induce the same effect. On the other hand, the association of DQA with the conventional drug induces a synergistic effect, because lower concentration of both drugs is required to obtain the same effect. In summary, our results suggest that DQA may be used as new therapeutic approach in hematological neoplasias both in monotherapy and in association with conventional therapy.

LANGERHANS CELL HISTIOCYTOSIS IN CHILDREN - TREATMENT OF PATIENTS WITH REACTIVATION OF DISEASE

G Glamocanin,[1] A Antevska,[1] B Coneska,[1] M Martinova,[1] K Koceva,[1] P Petrusevska[2]

[1]University Children's Hospital, Skopje, Macedonia; [2]University Ss Cyril and Methodius, Institute of Pathology, Skopje, Macedonia

Background. Langerhans cell histiocytosis (LCH) is a rare disease. Despite advances in the study of LCH, the etiology and pathogenesis are poorly understood and the treatment is still not standardized. It is regarded as a clonally accumulation and proliferation of abnormal bone marrow derived Langerhans cells. *Aims.* To present the experience of University Children's Hospital in Skopje regarding to clinical features, diagnosis, treatment and follow-up of LCH in children with a reactivation of disease. *Methods and results.* During the period from January 1977 to January 2010, 55 cases with proven histology LCH (31 males and 24 females) were analyzed and treated at the Department of Hematology/Oncology. The age at diagnosis ranged from 3 to 192 months. Seven of fifty five children presented skin involvement, 8/55 presented single bone lesion, 7/55 had multiple bone lesions and 33/55 presented multisystem diseases (13 of them had organ dysfunction). Because of a very long period of analysis there were different treatment procedures: combination of Vinblastine and Prednisone, LCH-I, LCH-II and from 2003 we started to use LCH-III Protocol. Six patients were treated according to LCH-III. One patient 4 months old with multisystem disease and organ dysfunction died during the Consolidation Treatment. Three patients finished the treatment with LCH-III and they are in remission, without disease 1 month, 18 months and 7 years respectively. Two children manifested reactivation of disease. The first one was 17 years boy with multiple reactivations of multifocal bone LCH, with no involvement of risk organs. He was treated with LCH-III Protocol for the primary disease and for the first reactivation; and with Low Risk 2nd Line Treatment Initial and Consolidation Therapy for the second reactivation of disease. He received also a treatment with bisphosphonates because of very severe pain and osteoporosis produced by treatment. One year after cessation of therapy he is in Complete Remission. The second case was 6 years old girl with LCH disease with multiple reactivations. The primary disease started at the age of 7 months with vulvovaginitis recidivist, involvement of the inguinal lymph nodes, liver, skin and bones, without involvement of the lungs. She was treated with LCH-III protocol. First reactivation of the disease was manifested 9 months after the end of LCH-III Protocol involving the bones, skin, and pituitary involvement with Diabetes insipidus. She started again with LCH-III Protocol. Eight months after the end of LCH-III Protocol the child manifested soft tissue lesions of the skull with extensions of the bones. She started with Low Risk 2nd Line Initial Treatment on February 2010, with a very prompt response to the treatment. *Conclusion.* Reactivation of LCH is defined by the appearance of new sites of active disease in the same or different organs of patient in whom the signs and symptoms of the previous episode have disappeared. There is not a single strategy of treatment, and different approaches could be effective in these cases. The schedule Low Risk 2nd Line Treatment Initial and Consolidation Therapy is expected to offer good results for patients with LCH reactivation.

EVALUATION OF THE THERAPEUTIC POTENTIAL OF A RECOMBINANT TRAIL IN LEUKEMIA - A STUDY IN CELL LINES IN CULTURE

F Carvalho,[1] AS Coelho,[2] C Domingues,[2] JA Carvalho,[1] A Ribeiro,[1] S Costa,[2] AC Goncalves,[3] V Alves,[1] M Dourado,[4] AB Sarmento-Ribeiro[5]

[1]Faculty of Medicine, University of Coimbra, Coimbra, Portugal; [2]Faculty of Technology and Science, University of Coimbra, Coimbra, Portugal; [3]Faculty of Medicine, Cimago, University of Coimbra, Coimbra, Portugal; [4]Faculty of Medicine, CIMAGO, University of Coimbra, Coimbra, Portugal; [5]Faculty of Medicine, CIMAGO, CNC, University of Coimbra, Coimbra, Portugal

Recent progress has broadened us to think that deficient apoptosis is a major cause in the development and progression of cancer, namely in leukemias, and it plays a significant role in the resistance to conventional therapeutic regimes. On this way, apoptosis may be a useful target for therapeutic intervention. The tumor necrosis factor (TNF)-related apoptosis inducing ligand (TRAIL/Apo-2L) is a member of the TNF superfamily that trigger and activate 4 receptors, TRAIL-R1 and -R2, also known as death receptors, DR4 and DR5, and antagonistic receptors, TRAIL-R3 and-R4, also known as decoy receptors, DcR1 and DcR2. Several studies demonstrated that TRAIL can induces cancer cell death with low cytotoxity in normal cells, but few have been done in Leukemias. The aim of this work is to analyse the therapeutic efficacy of a recombinant TRAIL (rhAPO2L/TRAIL) in haematological cancer, namely in acute and chronic leukemias. For this purpose we use several leukemia cell lines such as: Acute Myeloid Leukemia (HL-60), Chronic Myeloid Leukemia in blast crisis (K-562), Acute Lymphocytic Leukemia T (MOLT-3) at presention, Acute Lymphocytic Leukemia T cells in remission (MOLT-4) and Chronic Lymphocytic Leukemia B (EHEB). These cell lines were treated with different concentrations of rhAPO2L/TRAIL and the viability was measure using the trypan blue method. Cell death analysis was performed by flow cytometry (Annexin V/Propidium Iodide) and Optical Microscopy. TRAIL and TRAIL-Rs were evaluated by Flow cytometry using monoclonal antibodies. Our results show that rhTRAIL induced a decrease in cell viability inducing cell death, in a time, dose and cell type dependent manner. In fact, we observe an IC_{50} in HL-60 and EHEB cells treated during 48h, respectively, with 250 ng/mL and 750 ng/mL of rhTRAIL. On the other hand, the IC50 in MOLT-3 and MOLT-4 cells were obtained earlier, after 24h of rhTRAIL incubation, and at a lower concentration (~250 ng/mL). However, after this incubation period, in ALL-T cell lines we observed a reversion on the rhTRAIL cytotoxic effect. In K562 cells, rhTRAIL wasn't able to induce a significant decrease in cell viability in monotherapy. Beside that, when we compared the effect obtained in all cell lines, we observe that acute leukemic cells (HL-60, MOLT-3 and MOLT-4) were more sensible to rhTRAIL then chronic ones (K562 and EHEB), after 24 hours treatment. However, the cytotoxic effect is maintained only in the HL-60 and in EHEB cells. These results may be correlated with the differential TRAIL receptors expression, namely the presence of the anti-apoptotic TRAIL receptors, TRAIL-R3 and TRAIL-R4, in K562 cells. On the other hand, the higher percentage of pro-apoptotic TRAIL receptors, TRAIL-R1 and TRAIL-R2, may be related with the therapeutic efficacy of rhTRAIL in the other cell lines. In conclusion, our preliminary study suggests that rhTRAIL can be use as a new therapeutic aproach in the treatment of Leukemia, namely in ALL-T, B-LLC and APL, as single agent. However, the potential use of the drug in association with conventional therapy and the schedule of drug administration must be tested.

This work is supported by CIMAGO and Amgen/Genentech.

MANUFACTURING OF BONE MARROW-DERIVED MESENCHYMAL STROMAL CELLS ACCORDING TO GMP REQUIREMENTS FOR CLINICAL TRIALS

V Foltankova, K Kolacna, E Matejkova, J Smejkalova, J Michalek

Masaryk University, Babak Research Institute, Brno, Czech Republic

Background. Mesenchymal stromal cells (MSCs) are nonhematopoietic multipotent cells residing in bone marrow with the capacity to self-renew and to differentiate into multiple lineages. They display immunomodulatory, pro-angiogenic and reparative properties that were demonstrated in both animal and human models and has generated markedly increasing interest in a wide variety of biomedical disciplines. The International Society for Cellular Therapy (ISCT) proposed minimal criteria to define human MSCs: MSCs must be plastic-adherent, have a phenotype of $CD105^+$, $CD73^+$, $CD90^+$, $CD45^-$, $CD34^-$, $CD14^-$, $HLA\text{-}DR^-$, and have the capacity to undergo *in vitro* differentiation to osteoblasts, adipocytes, and chondrocytes. *Aims.* The objective of this work was to establish optimized protocol for manufacturing of GMP-graded MSCs that are meeting the ISCT criteria, are high-quality and safe and achieve number applicable in cellular therapy of Crohn's disease, limb ischemia and graft-versus-host disease. *Methods.* Techniques for MSCs isolation from the bone marrow, seeding density, expansion, cryopreservation, transport, quality control and potency testing had to be optimized for standard laboratory and subsequently for Clean rooms. To maintain phenotypic and genotypic stability of MSCs during multiple passages, optimization of culture conditions was one of the most crucial aims of MSCs GMP production. It was necessary to establish humanized serum free cell culture system without risk of ineligible immune reaction and transmission of zoonoses. *Results.* The optimal method for MSCs isolation was density gradient centrifugation of mononuclear cells on Ficoll Paque Premium 1.073 g/mL, and separation of MSCs by plastic adherence. The best expansion potential was achieved in medium DMEM supplemented with 5% platelet lysate. MSCs were harvested by trypsin and replated in density 3×10^5 cells per cm^2. Sequential passages might affect the quality and proliferation rate

of MSCs, therefore, no more than 4 passages are advisable. In clinically produced MSCs, attention must be paid to aseptic conditions and their validation. Controls of the process qualifying the methods at the time of process validation include potency tests of the MSC immunomodulatory effect in mixed lymphocyte reactions and tests of genetic stability even in higher passages. Controls of the production as contamination control and visual control of morphology and confluence are carried out during the cell expansion; cell number and viability are monitored at every cell harvest. Release criteria take into account the effectiveness and safety of the product: cell number according to indication (10-50×10^6 cells for local and 1-5×10^6 per kg for systemic administration), ≥80% viability and immunophenotype fulfilling ISCT criteria and excluding impurities ($CD3^-$, $CD19^-$, $CD80^-$). *Conclusions.* MSCs are resident in the bone marrow in small numbers of nucleated cells (0.001 0.01%), but can be readily expanded *in vitro* to provide sufficient number of GMP grade cells for local and systemic cellular therapy. The methods used in the manufacturing protocol will be validated and the clinical protocol will be approved by Czech State Institute for Drug Control.

Supported by the Ministry of Education of the Czech Republic, NPVII-2B06058 and NPVII-2B08066.

SENESCENCE INDUCTION THERAPY FOR ADULT T-CELL LEUKEMIA

Y Maeda, A Sasakawa, C Hirase, J Mityatake

Kinki University School of Medicine, Osaka-Sayama, Japan

Background. It has been reported that retinoid (all-trans retinoic acid: ATRA or tamibaroten: Am-80) inhibits growth in HTLV-1-positive T-cell lines and fresh cells from patients with adult T-cell leukemia (ATL) *in vitro*. The retinoid therapy for ATL patients also has been evaluated in clinical status. In this study, we focused in role of cellular senescence in the treatment with retinoid. *Methods.* 1. Cellular senescence was observed by senescence-associated β-galacsidase (SA β-Gal) staining. 2. Gene expression of cyclin dependent kinase, Tax was performed by RT-PCR. 3. To determine whether or not telomere attrition was occurred, TRAP assay was performed. *Results.* 1. SA β-Gal positive cells were observed in spontaneous culture without retinoid (ATRA or Am-80) on HTLV-I (+) T-cell lines (HUT102, MT-2, MT-4, ED40515 and ATL-2) or primary cells from acute ATL patients, but not on HTLV-I (-) T cell lines (Jurkat and MOLT-4). Percent of SA β-Gal positive cells in ED40515 was lower than that of other HTLV-I (+) T-cell lines. By treatment with ATRA or Am-80, those number of SA β-Gal positive cells was increased significantly on both HTLV-I (+) T-cell lines and primary cells from acute ATL patients. However, there was no increase of SA β-Gal staining on HTLV-I (-) T-cell lines (MOLT-4 and Jurkat) even if treated with the retinoids. 2. Expression of p16INK4a was enhanced in all of HTLV-I (+) T-cell lines, but not in HTLV-I (-) T-cell lines. 4. In TRAP assay, no inhibition of telomere activity was observed in retinoid treated HTLV-I (+) T-cell lines, indicative of premature senescence. *Conclusion.* We found cellular senescence phenomenon in HTLV-I (+) T-cell lines and fresh primary cells from acute ATL patients. It has been reported that oncogene induced stress (OIS) induced cellular senescence. In this study, grade of cellular senescence on HUT102, MT-2, MT-4, and ATL-2 was greater in compared to on ED40515 that does not express Tax gene in mRNA level by nonsense mutation. By this fact, Tax gene may act as an oncogene. Furthermore, retinoid facilitated the cellular senescence. As mentioned above, chemotherapy using anti-neoplastic agents possibly decrease OIS and release cellular senescence results in rejuvenation of those cells and chemotherapy resistance.

1785

IAP INHIBITORS INDUCE APOPTOSIS IN CHILDHOOD ACUTE LEUKEMIA CELLS VIA NFκB-ACTIVATION AND TNFα-SECRETION AND OVERCOME BCL-2-MEDIATED RESISTANCE

M Fakler,[1] S Loeder,[1] K Schneider,[2] I Jeremias,[2] K-M Debatin,[1] S Fulda[1]

[1]University Children's Hospital Ulm, Ulm, Germany; [2]GSF, Munich, Germany

Despite enormous progress in the treatment of childhood acute leukemias, high risk acute lymphoblastic leukemias still do not respond well to current treatments. Because this failure is, in part, due to defects in apoptosis programs, new strategies are required that counter apoptosis resistance in order to improve the poor prognosis of high risk pediatric acute leukemia. Since "Inhibitor of Apoptosis"proteins (IAP) are expressed at high levels in acute leukemia and block apoptosis at a central point of the apoptotic machinery, they may present a suitable molecular target for therapeutic intervention. Here, we report that neutralizing IAP proteins by small molecule IAP inhibitors is a novel and effective approach to sensitize childhood acute leukemia cells for death receptor- or chemotherapy-induced apoptosis. IAP inhibitors at subtoxic concentrations, but not a structurally related control compound, synergize with TRAIL, agonistic anti-CD95 antibodies or various anti-leukemic drugs, to induce apoptosis in acute lymphoblastic leukemia cells. Further, IAP inhibitors act in concert with TRAIL, anti-CD95 antibodies or chemotherapeutic drugs to reduce clonogenic growth of ALL cells demonstrating that they also suppress long-term survival. Analysis of signaling pathways reveals that IAP inhibition triggers activation of NFκB and secretion of TNFα. IAP inhibitors increase death receptor- or chemotherapy-induced activation of caspases, loss of mitochondrial membrane potential and cytochrome c release in a caspase- and TNFα-dependent manner. Intriguingly, IAP inhibitors promote TRAIL-mediated caspase activation, mitochondrial perturbations and apoptosis regardless of high Bcl-2 expression by enhancing Bcl-2 cleavage and Bak conformational change. Thus, IAP inhibitors in combination with TRAIL even break Bcl-2-imposed resistance, a defect in the apoptotic pathway that is common in acute leukemia and associated with poor prognosis. In contrast to malignant cells, IAP inhibitors at equimolar concentrations alone or in combination with TRAIL are non-toxic to normal peripheral blood lymphocytes despite surface expression of the apoptosis-inducing TRAIL receptors, pointing to a therapeutic index. Of note, IAP inhibitors also kill primary leukemic blasts from children with ALL *ex vivo* and cooperate with TRAIL, anti-CD95 antibodies or chemotherapeutic drugs to induce apoptosis in primary leukemia cells. Most importantly, IAP inhibitors significantly reduce leukemic burden *in vivo* in a mouse model of pediatric ALL engrafted in NOD/SCID mice. Thus, IAP inhibitors present a promising novel approach for apoptosis-based therapy of childhood acute leukemia, which warrants further exploitation.

1786

G-CSF-INDUCED BONE MARROW-DERIVED STEM CELLS MOBILIZATION BEFORE SACROCOCCYGEAL PILONIDAL CYST SURGERY

M Ruella,[1] S Scuderi,[2] M Monni,[2] P Omedè,[1] C Fronticelli Baldelli,[2] C Tarella[3]

[1]University of Torino, Torino, Italy; [2]6th Division of General Surgery, AOU San Giovanni Battista, Torino, Italy; [3]Ematologia e Terapia Cellulari, ASO Mauriziano, Torino, Italy

Stem cells, in particular the easily accessible bone marrow-derived stem cells (BMSC), may favour wound healing in patients requiring surgical excision for sacro-coccygeal pilonidal cyst (SPC). The present study was undertaken to evaluate feasibility, tolerability and safety of BMSC mobilization with granulocyte-colony stimulating factor (G-CSF) administration in patients undergoing surgery for complex SPC. *Patients and methods.* Eight patients with complex pilonidal disease were included in this prospective phase I-II study. All patients were treated with G-CSF (5 μg/kg b.i.d) for three consecutive days. Standard surgical excision of the pilonidal cyst was scheduled on day 2 of mobilization. Mobilization was assessed in terms of circulating $CD34^+$ cells (flow cytometry) and myeloid CFU-GM progenitors (*in vitro* colony growth assay). Patients were monitored for adverse events and clinical outcome. *Results.* $CD34^+$ cell mobilization occurred in all patients. Expansion of circulating CFU-GM progenitors along with a marked increase in white blood cells (WBC) was present, with a median peak value of 28,435 WBC/μL on day 3 of mobilization. G-CSF was well tolerated; no adverse events occurred. All patients received the planned surgical treatment without any complications. Overall, the clinical outcome was positive in terms of symptoms, recurrence and time required for wound healing. *Conclusions.* The association of G-CSF and surgery in patients with SPC is feasible, safe and well tolerated without pre- or post-operative complications. Morevoer these preliminary clinical results compare favourably with results observed in historical controls but need to be confirmed by randomized clinical trials assessing the efficacy of G-CSF administration in patients undergoing surgery for SPC.

1787

THERAPEUTIC EFFECT EVALUATION OF MONOMERIC AND POLYMERIC FLAVONOIDS, AND PHENOLIC ACIDS IN ACUTE PROMYELOCYTIC LEUKEMIA

R Santos,[1] AC Goncalves,[2] V Alves,[1] A Figueirinha,[3] MC Lopes,[4] MT Batista,[4] AB Sarmento-Ribeiro[5]

[1]Faculty of Medicine, University of Coimbra, Coimbra, Portugal; [2]Faculty of Medicine, Cimago, University of Coimbra, Coimbra, Portugal; [3]Center of Pharmaceutical Studies, Faculty of Pharmacy, University of Coimbra, Coimbra, Portugal; [4]Center of Pharmaceutical Studies, Faculty of Pharmacy; CNC,University of Coimbra, Coimbra, Portugal; [5]Faculty of Medicine, CIMAGO, CNC, University of Coimbra, Coimbra, Portugal

The consumption of bioactive compounds is recommended for the prevention of chronic diseases, including cancer and its preventive effect is evidenced in several epidemiological studies. However, the effect of bioactive compounds present in fruit and vegetables at the cellular and molecular levels remains poorly understood. Acute promyelocytic leukemia (APL) is a subtype of acute myeloid leukemia characterized by an accumulation of abnormal promyelocytes related with the t(15;17)(q22;q12), a chromosomal translocation that contributes to cell differentiation deregulation. Several studies have clearly demonstrated that many natural bioactive compounds can interfere with multiple cell signaling pathways including proliferation, survival, differentiation and even cell death by apoptosis. These effects might be mediated by oxidative damage, cell cycle alteration, hypoxia and cell adhesion loss. Through modern scientific approaches and innovative scientific tools is possible to demonstrate the promising pharmacological activity of polyphenolic fractions obtained from medicinal plants such as Cymbopogon citratus (Cc), a native herb from India. However, there aren't any studies in hematological neoplasias, namely in APL. The aim of this work is to evaluate the potential therapeutic effect of the three different polyphenolic fractions obtained from Cc leaves, containing flavonoids, proanthocyanidins (polymeric flavonoids), and caffeic and p-coumaric acid and their derivatives in acute promyelocytic leukemia. For this purpose, a Cc leaves infusion was submitted to fractionation, monitored by TLC and HPLC, to providing those three polyphenolic fractions referred above. The HL-60 cell line, obtained from an APL patient, was cultured in absence and presence of several concentrations of the three polyphenolic fractions and of the initial infusion, for different periods of time. Cell growth and viability were evaluated by the Trypan Blue assay and the efficacy of the drugs determined by the IC50. Cell death analysis was performed by morphological studies and by flow cytometry, using annexin-V/propidium iodide incorporation. The mechanisms involved in cellular cytotoxicity were analysed by flow cytometry through the expression of proteins involved in apoptotic pathways, namely Bcl-2, Bax, Fas, Fas ligand, Caspase 3 and P53. The mitochondria function and oxidative stress evaluation were analyzed by FC, through the determination of mitochondria membrane potential, ROS production and GSH levels, respectively using the JC1, DFCFH-HA and Mercury Orange fluorescent probes. Our preliminary results show that all drugs assayed induce a decrease in HL-60 cell viability in a dose, time and fraction composition dependent manner, with an IC50 values ranging from 50 to 250 ug/mL, after 48h of incubation. Caspase 3, Fas ligand and mitochondria may be involved in apoptotic cell death induced by these compounds since we observed a significant increase in the expression of these pro-apoptotic proteins and in mitochondrial membrane depolarization. In summary, flavonoids, proanthocyanidins, caffeic and p-coumaric acid and their derivatives can be active principles for drugs development that could be used as a therapeutic approach in acute promyelocytic leukemia.

1788

THE ROLE OF EPIGENETIC MODULATORS AS A THERAPEUTIC APPROACH IN LYMPHOID LEUKEMIAS - A COMPARATIVE STUDY

JA Carvalho,[1] C Costa,[2] F Carvalho,[1] A Ribeiro,[1] AC Goncalves,[3] V Alves,[1] M Dourado,[4] AB Sarmento-Ribeiro[5]

[1]Faculty of Medicine, University of Coimbra, Coimbra, Portugal; [2]Portuguese Institute of Oncology of Lisbon, Lisbon, Portugal; [3]Faculty of Medicine, Cimago, University of Coimbra, Coimbra, Portugal; [4]Faculty of Medicine, CIMAGO, University of Coimbra, Coimbra, Portugal; [5]Faculty of Medicine, CIMAGO, CNC, University of Coimbra, Coimbra, Portugal

The hypermethylation of the 'CpG islands' and histone deacetylation have been considered key epigenetic mechanisms in the silencing of genes, namely tumour suppressor genes, and may play a crucial role in several types of cancer, as in Acute and Chronic Lymphoid Leukemias. Unlike genetic changes, which are irreversible, epigenetic changes are reversible, allowing the expression or repression of a gene that might reverse malignant phenotype. Despite hypomethylating agents are already used in the treatment of some subtypes of Myelodysplastic Syndromes, and some studies are done in acute leukemias, the role of epigenetic modulators in the treatment of lymphoid leukemias (LL), particularly in Chronic Lymphocytic Leukemia (CLL) is still unclear. With this work we intend to evaluate the potential therapeutic effect of epigenetic modulators in lymphoid leukemias, namely in a CLL cell line in culture, as single agents and in combination and to compare this efficacy with those obtained in Acute Lymphoblastic Leukemia (ALL) cell lines. For this purpose, a CLL cell line obtained from a patient 69 years old, the EHEB cells, was maintained in culture in the absence (control) and presence of the demethylating drug, Decitabine (DEC), and/or with the histone deacetylase inhibitor, Trichostatin A (TSA), in several concentrations and during variable periods of time. The density and cell viability were assessed using the Alamar Blue assays, and cell death was analysed by flow cytometry, staining the cells with Annexin V. These results are then compared with those obtained previously in our laboratory in two ALL cells lines, the MOLT-3 and MOLT-4 cells, obtained from a patient at disease presentation and at relapse, respectively. Our results show that epigenetic modulators, TSA and DEC, induce a decrease in EHEB cells proliferation and viability in a dose and time dependent manner, inducing cell death preferentially by apoptosis. However TSA was more effective in monotherapy than DEC, reaching the IC_{50} at 250 nM after 72h of incubation, while with DEC the IC_{50} was not reached, besides the higher doses used. However, a decrease about 40% in cell proliferation was observed in EHEB cells treated with the higher DEC dose (100 μM). Furthermore, when we compared the efficacy of these drugs obtained in LLC cells with those obtained previously in our lab by AB Sarmento-Ribeiro *et al*. (2008) and Costa C *et al*. (2009) in ALL cells lines, we note that, besides TSA was also more effective in monotherapy than DEC, the cytotoxic effect is achieved later in EHEB cells, for the same drug concentration. Besides that, when TSA was administered to CLL cells 4 hours before than decitabine, it was observed a slightly increase in the cytotoxic drugs effect but at lower level than that observed in ALL cell lines. This study suggests that epigenetic modulation may become a new therapeutic approach in Chronic Lymphocytic Leukemia and Acute Lymphoblastic Leukemia, including relapse. However, the schedule of drugs administration and cell type may interfere with their therapeutic efficacy.

This work was supported by GAPI and CIMAGO.

LIPOSOMAL CYTARABINE AS NEUROMENINGEAL PROPHYLAXIS IN BRAIN MALT LYMPHOMA

A Godoy, P Delgado, J García-Zueco, M Abio, R Pazo, C Sierra, D Daniel

Hospital Universitario Miguel Servet, Zaragoza, Spain

Background. Althougt a very rare entity, brain MALT lymphoma cases have been reported. *Aims.* to assess the safety, tolerability and efficacy of liposomal cytarabine as prophylaxis against lymphomatous meningeal infiltration. *Methods.* a 51 year old patient (pt), with Still's disease and bronchial asthma history, was admitted to our hospital in august 2007 by presenting partial seizures, with somatosensory discomfort in his lower right extremity (LRE) as starting symptom. Cranial MRI showed a mass in the falx cerebri, 3×2 cm, surrounded by a thin, hyperintense halo on the left side, which remained unchanged after three months. Differential diagnosis included chronic inflammatory pachymeningitis, Rosay-Dorfman disease and encapsulated abscess. It was decided to wait and see. After nine months the pt was readmitted presenting a partial seizure in his LRE. Cerebral MRI showed no changes in the dural lesion of the falx cerebri. Craniotomy was performed, with histopathologic diagnosis of NHL, primary extranodal marginal MALT with meningeal involvement, $CD20^{+}$, $CD5^{+}$, $CD43^{+}$, $bcl2^{++}$, Kappa and Lambda:$^{++}$. Postoperative imaging study in june 2008 showed hypersignal in right cerebral hemisphere, finding similar to that found previously in the contralateral side. After confirming that the extension study was negative, including cytology and flow cytometric immunophenotyping of cerebrospinal fluid, the pt received systemic chemotherapy: 5 well tolerated cycles of Rituximab (500 mg/m^2 day 1), Methotrexate (3,5 g/m^2 day 2) , Vincristine (1,4 mg/m^2 day 2) and Procarbazine (100 mg/m^2 days 1 to 7). In addition neuromeningeal prophylaxis with liposomal cytarabine (three 50 mg doses separated every four weeks) was

performed, associated with intrathecal hydrocortisone (10 mg) as prophylaxis of chemical arachnoiditis; no side effects were reported. *Results.* Reassessment MRI showed complete remission of the right mass, with significant reduction in postoperative collection on the left one. Afterwards holocraneal radiotherapy (45 Gy total dose) was administered. Currently the patient is asymptomatic and without evidence of lymphomatous disease. *Conclusions.* In our experience liposomal cytarabine may be safely used for prophylaxis of meningeal infiltration in patients with MALT lymphoma of the brain.

CLINICAL RESULTS OF BENDAMUSTINE PLUS RITUXIMAB FOR INDOLENT NHL AND CLL.EXPERIENCE OF ONLY ONE INSTITUTION

MD De Miguel, N Golbano, M Diaz Morfa, I Lopez-San Roman, D Morales, J Arbeteta, S Herrero, B Pinedo

Hospital Universitario de Guadalajara, Guadalajara, Spain

Introduction. Promising results have been reported in studies evaluating the combination of Bendamustine and Rituximab (B-R) in patients with relapsed/refractory indolent or mantle cell lymphomas. *Patients and methods.* we have analysed the role of the combination B-R in 8 patients since January 2009. They received Rituximab 375mg/m^2 (day 1) plus Bendamustine 90-100 mg/m^2 (days 1+2) every 28 days for a maximum of 6 cycles. The median patient age was 66 years (56-77 range). Most patients were in advanced stages (III-IV). Histologies were distributed: MALT NHL 12.5%, mantle cell NHL 37.5%, CLL/lymphocytic lymphoma 50%. Patients were heavily treated with a median of 3 prior regimens, including anthracycline containing chemotherapy (n=4) and purine analog chemotherapy (n=6). All patients had received previously rituximab. *Results.* Of the 8 patients, 4 are going in the treatment, they have not yet evaluated. A median number of 5 cycles was given (1-6 range). At the time of analysis February 2010, the median observation time was 6 months (1-13). Overall response rate for patients treated with B-R 100%. The CR rate was 75%. One patient progressed at 4 months. None patient died. Hematologic toxicities were observed for neutropenia grade 3+4. 15% cycles of bendamustine required patients admission in hospital. The B-R regimen was good tolerated by the patients, as evidenced by a lower rate of alopecia, number of infectious complications and estomatitis. We observed drug-associated erythematous skin reaction (rash) in one patient. There is not association between prior purine analog chemotherapy. *Conclusions.* the combination of Bendamustine +Rituximab have a excelent tolerability profile, and CR rate in heavily treated patients with relapsed/refractory indolent or mantle cell lymphomas. Further follow-up will determine whether the high RC/RCu rate corresponds to prolonged PFS. Additional updates on response will be available at the time of presentation.

EFFICACY OF RITUXIMAB FOR TREATMENT OF AUTOIMMUNE CYTOPENIAS: THE MANITOBA EXPERIENCE

J Singh,[1] M Geirnaert,[2] S Navaratnam,[1] P Czaykowski,[1] M Pitz,[1] K Guilbert,[2] B Lozar,[2] B Joseph,[2] V Bourrier,[2] R Kumar[1]

[1]*University of Manitoba, Winnipeg, Canada;* [2]*CancerCare Manitoba, Winnipeg, Canada*

Background. The treatment of autoimmune cytopenias (AIC) remains a therapeutic challenge. In recent years, the anti-CD20 monoclonal antibody rituximab has been used for the treatment of AIC refractory to or dependent on steroids or other immunosuppressants. Here we report our results of rituximab treatment for patients suffering from AIC in the absence of a lymphoproliferative disorder. *Aim.* To evaluate the efficacy of rituximab for the treatment of AIC in patients without an underlying lymphoproliferative disorder. *Methods.* All patients treated with rituximab for AIC in Manitoba between January 1, 2003 and December 31, 2007 were identified using the CancerCare Manitoba Pharmacy database and the Aria™ Information system (Varis Med Oncology Software). Patients with an underlying diagnosis of a lymphoproliferative disorder were excluded from analysis. The charts of all these patients were reviewed retrospectively to assess response to therapy. *Results.* Rituximab was administered to 5 patients with AIC refractory to or dependent on steroids or other immunosuppressants. Details of the patients and outcomes are given in the table below. Of the 3 patients with autoimmune hemolytic anemia (AIHA), all were Coomb's positive. One patient with AIHA received 4 courses of rituximab. All other patients received only one course of rituximab. All patients received 4 cycles of weekly rituximab per course except for one patient with Evans syndrome who received only 1 cycle of rituximab for immune thrombocytopenic purpura (ITP). Responses: (a) AIHA - 3 patients received a total of 6 courses of rituximab with a complete response (CR) in 67% and partial response (PR) in 33% at a median time of 2 months. One patient achieving CR with the first course of rituximab relapsed at 9 months. This patient received 3 subsequent courses of rituximab, subsequently achieving CR twice and PR once. The patient remains in remission at last follow-up 9 months post rituximab. Two of the three patients treated with rituximab died at a median time of 3 months post rituximab. Of these two, one patient died within 1 month of rituximab completion due to previously known hypotension attributed to autonomic neuropathy. (b) ITP - 2 patients received a total of 2 courses of rituximab with a complete response of 50% at a median time of 1 month. *Conclusion.* Rituximab therapy appears to be a safe and effective therapy for AIC not responsive to conventional therapies. Patients who relapse following rituximab, successfully respond to a second course of rituximab.

Table. Patient Characteristics and Response to Rituximab.

		AIHA	ITP
Patients	Numbers	3	2
	Median age when rituximab started	73 years (range 50 to 76)	26 years (ages 10 and 41)
	Median time from AIC diagnosis to rituximab initiation	16 months (range 9 to 19)	17 months (range 1 to 32)
	Median pertinent lab values at start of treatment	Hgb 88g/L (range 75 to 103)	Plts 8x10^9/L (range 3 to 12)
Number of courses	Rituximab+steroid	6	2
Responses	Numbers (%)	CR: 4/6 (67%) PR: 2/6 (33%)	CR: 1/2 (50%)
Relapses	Numbers	3	1
	Median time to relapse	8 months	30 months
Deaths	Numbers	2	0
	Median time to death	3 months	–

Hgb = hemoglobin, Plts = platelets, CR = complete response, PR = partial response

1792

EFFICACY OF INTRAPLEURAL (IP) RITUXIMAB (RMAB) IN PATIENTS (PT) WITH MALIGNANT PLEURAL EFFUSION (PE)

A Godoy, P Delgado, R Pazo, C Carlos, J García-Zueco, N Nuria, D Daniel

Hospital Universitario Miguel Servet, Zaragoza, Spain

Background. To date several agents have been used in performing pleurodesis in pleural lymphomatous infiltration, but there is little experience with the use of monoclonal antibodies. *Aims.* to evaluate the efficacy and safety of IP administration of anti-CD20 antibody. *Methods.* a 39 years old pt was diagnosed by gastric biopsy of non-Hodgkin lymphoma (NHL), diffuse large B cell with CD20$^+$ expression. Physical examination revealed multiple lymphadenopathies (submaxillary, cervical and supraclavicular), hypophonesis in both hemithorax and palpable splenomegaly. Cell blood count and blood biochemistry were normal. Lues, HIV, HBV, HCV, CMV, EBV, Toxoplasma and Rubella serologies all proved negative. A total body CT scan was performed and found submandibular, internal jugular, supraclavicular, right paratracheal, and retroperitoneal enlarged lymph nodes, bilateral PE and homogeneous splenomegaly. The pt began treatment with chemotherapy (ChT), R-CHOP-14 schedule. Because of massive PE we proceeded to endothoracic tube placement, presenting acute respiratory failure, which made it necessary tracheal intubation and ICU admission. Bilateral endothoracic tubes were placed, draining more than 1700 mL/day each. Once administered the second cycle of ChT left PE disappeared and left tube was removed; persistent right PE (draining 300 mL/day) prevented from right hemithorax extubation. After obtaining informed consent from the pt, pleurodesis with IP administration of Rmab was performed, as described: on the day 0, after premedication with chlorpheniramine maleate and corticoids, a dose of 50 mg of Rmab in 50 mL of saline (SF) was injected as a bolus in the right pleural cavity and then the tube was clamped for 6 hours (hs); on the day +1 a new dose of 150 mg of Rmab in 100 ml of SF, with subsequent clamping for another 6 hs. *Results.* treatment was well tolerated; after 72hs the right PE resolved

completely and the chest tube could be removed. *Conclusions.* IP administration of Rmab is safe and effective in controlling malignant PE in patients with NHL which express CD20+.

RIBAVIRIN MADE EASY! DEVELOPMENT OF A GUIDANCE DOCUMENT AND EDUCATIONAL DVD FOR THE PREPARATION AND ADMINISTRATION OF NEBULISED RIBAVIRIN USING THE AIOLOS DEVICE

N Lewis, L Donovan

Heath Hospital, Cardiff, UK

Ribavirin is a broad-spectrum antiviral agent, which inhibits a wide range of deoxyribonucleic acid (DNA) and ribonucleic acid (RNA) viruses by disrupting viral protein synthesis. The current licensed Virazole® (ribavirin for inhalation) is for RSV, but is widely used in other viral infections. There have been difficulties following the discontinuation of the small particle aerosol generator (SPAG) and the transition to the AIOLOS nebuliser. There have been many issues vocalised regarding concerns of nursing staff over the delivery of ribavirin by nebulisation. These encompass both the technical aspects of the equipment and the safety considerations. The main aim was to create written guidelines supported by an educational DVD to ensure the standardisation of practice in the administration of nebulised Ribavirin whilst using the Aiolos device. The secondary outcome was to ensure parity and equity of the education delivered to all staff throughout the United Kingdom and create an opportunity for them to be deemed competent in this procedure so as to deliver optimum care to patients. A multidisciplinary team (MDT), of experienced ribavirin users which included healthcare professionals from hospitals across the United Kingdom, came together to evaluate and discuss all the relevant issues and by consensus developed a guidance document. The results of which consolidate best practice, and go someway to decrease the concerns of staff by addressing the myths surrounding the usage of ribavirin. The purpose of this these documents are to act as reference material for healthcare professionals who are being trained in the preparation and administration of the drug ribavirin by nebulisation. It is also intended as a reference for those who are deemed to have been competently trained. It has been widely recognised that there has been a demand for a document such as this to provide information on the use and environmental exposure to nebulised ribavirin. The success of the guidelines can be contributed to the collaborative approach of healthcare professionals who identified a need to address the inconsistencies with the delivery of this drug so as to ensure best practice nationally for both staff and patients.

SUCCESSFUL GENERATION OF MYELOMA-SPECIFIC CYTOTOXIC T LYMPHOCYTES BY ALPHA-TYPE 1-POLARIZED DENDRITIC CELLS LOADED WITH APOPTOTIC ALLOGENEIC MYELOMA CELLS OF MATCHED SUBTYPES AGAINST AUTOLOGOUS MYELOMA CELLS

DH Yang,[1] MH Kim,[1] YK Lee,[1] CY Hong,[1] TN Nguyen Pham,[1] SY Bae,[1] JS Ahn,[1] YK Kim,[1] IJ Chung,[1] HJ Kim,[1] P Kalinski,[2] JJ Lee[1]

[1]*Chonnam National University Hwasun Hospital, Jeollanam-do, South-Korea;* [2]*University of Pittsburgh, Pittsburgh, USA*

In multiple myeloma (MM), it is not only impractical to obtain sufficient amount of autologous tumor cells as a source of tumor antigen in the clinical setting but it is also unsuitable for those with a lower tumor-burden status. In this study, we investigated the feasibility of cellular immunotherapy using autologous alpha-type 1-polarized dendritic cells (αDC1s) loaded with the UVB-irradiated allogeneic myeloma cells from other patients with the same subtypes, which could generate myeloma-specific cytotoxic T lymphocytes (CTLs) against autologous myeloma cell in patients with MM. Material and *Methods.* We generated autologous immature DCs from mononuclear cells of myeloma patients cultured with GM-CSF and IL-4 for 6 days. Their maturation was induced by adding the αDC1-polarizing cocktail composed of IL-1β, TNF-α , IFN-α, IFN-gamma and poly(I:C) and followed by loadedd with apoptotic allogeneic CD138+ myeloma cells irradiated with UVB (120 mJ/cm^2) as an tumor antigen. *Results.* αDC1s pulsed with allogeneic tumor antigen significantly increased the expression of several costimulatory molecules without the differences by those pulsed with autologous myeloma antigen. αDC1s showed high production of IL-12 during maturation and after subsequent stimulation of CD40L, but were not significantly affected by loading allogeneic myeloma antigens. Myeloma-specific CTLs against autologous CD138+ myeloma cells from MM patients were successfully induced by αDC1s loaded with allogeneic CD138+ myeloma cells in ELISPOT and JAM assay. In addition, there were no differences of CTL responses between pulsing autologous and allogeneic tumor antigen against targeting patient's myeloma cells. The specificity of the CTL response was demonstrated by the lowest level of IFN-gamma secreting cells against the NK-sensitive cell line K562. Pre-incubation of the target cells with anti-MHC class I or II monoclonal antibodies (mAbs) inhibited IFN-gamma release, indicating MHC class molecule-dependent cytotoxicity. *Conclusions.* Our data indicate that autologous DCs loaded with allogeneic CD138+ myeloma cells can generate potent myeloma-specific CTL responses against autologous myeloma cells and could be a highly-feasible and effective method for cellular immunotherapy in patients with MM.

1795

THE IMMUNOSUPPRESSIVE CAPACITY OF MESENCHYMAL STROMAL CELLS ISOLATED FROM MULTIPLE SCLEROSIS PATIENTS ON PHA-INDUCED T-CELL PROLIFERATION WAS SIGNIFICANTLY REDUCED

G Lelis Vilela Oliveira, K Ribeiro Malmegrim, A Marcos Colombini, H Brait Rino, P Vianna Bonini Palma, C Menezes, D Tadeu Covas, J Voltarelli

National Institute of Science and Technology in Stem Cells and Cell Therapy, Ribeirão Preto, Brazil

Background. Autologous bone marrow multipotent mesenchymal stromal cells (MSCs) are being currently considered as a potential cell source for therapy of autoimmune diseases (AD), due to their immunomodulatory properties. MSCs have shown ability to suppress lymphocyte proliferation *in vitro* and possess immunoregulatory functions in other immune cells. Several mechanisms have been involved in the immunosuppressive effects of MSCs, including direct cell-to-cell contact and secretion of soluble factors. These properties of MSCs suggest a potential role of these cells in the induction of tolerance in AD and also provide a rational basis for their application in the treatment of multiple sclerosis (MS). However, it is unknown whether MSCs isolated from MS patients are normal or defective. Besides, there is no data concerning antiproliferative capacity of MS patients' MSCs. *Aim.* To evaluate the antiproliferative capacity of MSCs derived from MS patients and healthy bone marrow donors on allogeneic lymphocytes isolated from healthy individuals. *Methods.* MSCs cultures were derived from bone marrow aspirates from healthy donors (N=6) and MS patients (N=6). Mononuclear cells were separated by Ficoll-Hypaque density gradient and MSCs were isolated by plastic adherence. Peripheral blood mononuclear cells (PBMCs) separated from healthy individuals were co-cultivated with patients' or healthy donors' MSCs in the presence of phytohemagglutinin (PHA) at 37°C in a 5% CO2. We tested several MSCs:PBMCs ratios (1:2, 1:5, 1:10, 1:20, 1:50 and 1:100). After 5 days of co-culture, collected PBMCs were labeled with phycoerythrin-conjugated anti-CD3 monoclonal antibodies and T-cell proliferation was assessed by CFSE dilution method and the fluorescence was analyzed by flow cytometry. This study was approved by the Clinical Hospital of Ribeirão Preto ethics committee and an informed consent was signed by patients and controls before collection.

Table.

Table: Proliferation and proliferative inhibition percentages from CD3+T-cells co-cultivated with different ratios of patients' MSCs and healthy donors' MSCs.

CD3+ T-cells	PBMCs + PHA	MSCs: PBMCs 1:2	MSCs: PBMCs 1:5	MSCs: PBMCs 1:10	MSCs: PBMCs 1:20	MSCs: PBMCs 1:50	MSCs: PBMCs 1:100
patients P%	63.6±11.7	32.4±3.4	37.2±28.3	41.3±25.9	44.8±18.9	49.3±12.9	51.6±15.9
PI%	-	47.8±10.2	44.2±40.5	37.7±34.9	31.0±22.3	22.9±12.7	19.6±16.8
controls P%	71.9 ± 5.7	14.7±6.9	26.8±10,7	36.1±10.6	49.3±10.5	63.7±9.0	69.4±6.9
PI%	-	79.7±8,7	62.8±13.6	49.6±14.3	30.7±17.2	10.7±15.3	3.2 ± 9.2

MS: Multiple sclerosis; P%: Proliferation percentage; PI%: Proliferative inhibition percentage; PBMCs: Peripheral blood mononuclear cells; PHA: Phytohemagglutinin; MSCs: Multipotent mesenchymal stromal cells. The collected cells were labeled with PE-conjugated anti-CD3 monoclonal antibodies. The results were represented by mean ± std deviation from six experiments using MS patients' MSCs and healthy donors' MSCs.

Results. We observed that both MSCs, isolated from healthy donors and MS patients efficiently inhibited PHA-induced CD3+T-cell prolifer-

ation in a dose-dependent manner, as characterized by a decrease of CFSE peak generation number. However, MS patients' MSCs inhibited T-cell proliferation at lower levels than the inhibition obtained from healthy donors' MSCs. There were significant differences in proliferation mean (P) and proliferative inhibition (PI) percentages when comparing patients' MSCs (P:32.4±3.4; PI: 47.8±10.2) and healthy donors' MSCs (P:14.7±6.9; PI: 79.7±8.7) at ratio 1:2 (Table). The antiproliferative capacity of healthy donors' MSCs was significantly higher than patients' MSCs (P=0.005). There were no significant differences in T-cell proliferation inhibition from patients' and healthy donors' MSCs in the other tested ratios (1:5, 1:10, 1:20, 1:50 and 1:100). *Conclusions.* Both MSCs, isolated from MS patients and healthy donors, were able to inhibit PHA-induced T-cell proliferation in a dose-dependent manner. However, the immunosuppressive capacity of MSCs derived from MS patients was reduced compared to MSCs from healthy donors, once we observed significant differences in proliferation and proliferative inhibition percentages at ratio 1:2. These results suggest decreased and defective antiproliferative capacity of patients' MSCs on T-cell proliferation and therefore, more studies should be conducted before considering the use of MSCs from MS patients in autologous clinical settings.

BIOLOGICAL ACTIVITY OF LONG-TERM CRYOPRESERVED PERIPHERAL BLOOD HEMATOPOIETIC STEM CELL HARVEST AND ITS ABILITY TO EXPAND CYTOKINE-INDUCED KILLER CELLS

J Ouyang,[1] L Jiang,[2] JH Chen,[1] CP Li,[1] M Zhou,[1] B Chen,[1] XY Shao[1]

[1]Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China; [2]Clinical Medical College of Southeast University, Nanjing, China

Background_Cytokine-induced killer (CIK) cells are a population of cytotoxic cells by *ex vivo* culturing peripheral blood mononuclear cells (PBMC) in the presence of different cytokines . There are no reports about if these cells are able to be inducted into cytotoxic CIK cells *ex vivo* after long-term cryopreserved. *Aims.* To observe whether cytotoxic CIK cells could be expanded from long-term cryopreserved PBSC harvest. *Methods.* Ten samples of PBSC which having been cryopreserved in liquid nitrogen for 3-6 years were used as test group and 7 fresh ones as control. CIK cells were derived from the RBC-removed PBSC harvest with cytokines: IFN-γ, CD-mAb and IL-2. On day 14, CIK cells were harvested to test viability and amplification. Proliferation ability of CIK cells was measured by calculation, phenotype of CIK cells was analyzed by flow cytometry and cytotoxicity of CIK cells against tumor cells was measured by MTT method. *Results.* CIK cells from the test group and the control group expanded 41.8 fold and 22.8 fold, respectively. The percentage of $CD8^+$ T cell increased after culture ($P<0.05$); while the purity of NKT cells ($CD3^+$ CD16 /56 +T cells) did not statistically increase. There was no significant difference between the two groups on the cytotoxicity against K562 cells. *Conclusion.* Cytotoxic CIK cells can be expanded from long-term cryopreserved PBSC harvest.

1797

PROSPECTIVE COMPARISON ON CARDIAC IRON AND LIVER IRON BY MR IN THALASSEMIA MAJOR PATIENTS TREATED WITH COMBINATION DEFERIPRON-DESFERRIOXAMINE VERSUS DEFERIPRON AND DESFERRIOXAMINE IN MONOTERAPY

A Pepe,[1] G Rossi,[2] A Meloni,[1] MC Dell'Amico,[1] M Capra,[3] V Caruso,[4] L Pitrolo,[5] M Centra,[6] P Pepe,[2] E Cracolici,[7] M Lombardi,[1] P Ricchi[8]

[1]Fondazione G.Monasterio CNR-Regione Toscana and Institute of Clinical Physiology, Pisa, Italy; [2]Institute of Clinical Physiology of CNR, Epidemiology and Biostatistics Unit, Pisa, Italy; [3]P.O. G. Di Cristina, ARNAS Civico, Palermo, Italy; [4]Centro Microcitemia, Ospedale Garibaldi, Catania, Italy; [5]UO Pediatria II, AO Villa Sofia, Palermo, Italy; [6]Servizio Trasfusionale, OORR di Foggia, Foggia, Italy; [7]Department of Radiology, University of Palermo, Palermo, Italy; [8]Unità Microcitemia, A.O.R.N. Cardarelli, Napoli, Italy

Background. Using T2* MR a randomized placebo controlled study from Sardinia demonstrated combination therapy with deferipron and desferrioxamine (DFP+DFO) significantly more effective than DFO in improving myocardial iron. One non-randomized study from Sardinia and one observational study from Greece seem to confirm for DFP+DFO therapy the most rapid clearance of cardiac iron. No data are available in literature about prospective comparisons on cardiac iron and function and liver iron in TM patients treated with DFP+DFO *vs.* DFP and DFO in monotherapy. *Aim.* The aim of this multi-centre study was to assess prospectively in a large clinical setting the efficacy of the DFP+DFO *vs.* DFP and DFO in TM patients by quantitative MR. *Methods.* Among the first 739 TM patients enrolled in the MIOT (Myocardial Iron Overload in Thalassemia) network, 253 patients performed a MR follow up study at 18±3 months according to the protocol. We evaluated prospectively the 43 patients treated with DFP+DFO *vs.* the 30 patients treated with DFP and the 66 patients treated with DFO between the 2 MR scans. Myocardial and liver iron concentrations were measured by T2* multislice multiecho technique. Biventricular function parameters were quantitatively evaluated by cine images. *Results.* The doses of the combination treatment were DFP 66±23 mg/kg/d for 6±1 d/w and DFO 41±7 mg/kg/d for 4±1 d/w, the dose of DFP was 73±16 mg/kg/d, DFO was 41±7 mg/kg/d for 5.5 d/w. Excellent/good levels of compliance were similar in the 3 groups (DFP+DFO 91% *vs.* DFP 97% *vs.* DFO 92%; P=0.76). Among the patients with no significant myocardial iron overload at baseline (global heart T2*±20 ms), there were no significant differences between groups to maintain the patients without myocardial iron overload (DFP+DFO 90% *vs.* DFP 100% *vs.* DFO 100%; P=0.053). Among the patients with myocardial iron overload at baseline (global heart T2*<20 ms), in all groups there was a significant improvement in the global heart T2* value (DFP+DFO P=0.0001, DFP P=0.001 and DFO P=0.003), in the number of segment with a normal T2* value (DFP+DFO P=0.0001, DFP P=0.031, DFO P=0.0001) and in the right global systolic function (DFP+DFO P =0.002, DFP P=0.031, DFO P=0.045). The improvement in the global heart T2* was significantly different among groups (mean difference global heart T2* DFP+DFO 6.6±6.5 ms, DFP 10.7±7.2, DFO 3.6±5.4; P=0.009). The improvement in the global heart T2* was significantly higher in the DFP+DFO *vs.* the DFO group (P=0.017), but it was not significantly different in the DFP+DFO *vs.* the DFP group (P = 0.36) (see the Figure). The changes in the global systolic bi-ventricular function were not significantly different among groups. In patients with liver iron overload at baseline (liver T2*<5.1 ms), the change in the liver T2* was not significantly different among groups (mean difference liver T2* DFP+DFO 2.9±4.7 ms, DFP 2.3±5.8, DFO 2.9±4.9; P=0.91). *Conclusions.* prospectively in a large clinical setting over 15 months in TM patients combined therapy DFP+DFO confirmed superior reduction in myocardial iron in comparison to DFO, but no significant differences were found *vs.* DFP monotherapy.

EFFECT OF DEFERASIROX ON RENAL HAEMODYNAMICS IN PATIENTS WITH BETA-THALASSAEMIA: FIRST INTERIM ANALYSIS

A Piga,[1] S Fracchia,[1] ME Lai,[2] MD Cappellini,[3] T Lawniczek,[4] V Dong,[5] A Esteban,[4] J Wang,[4] G Dai,[5] GL Forni[6]

[1]Universitá di Torino, Turin, Italy; [2]Ospedale Regionale Microcitemie, Cagliari, Italy; [3]Universitá di Milano, Policlinico Foundation IRCCS, Milan, Italy; [4]Novartis Pharma AG, Basel, Switzerland; [5]Novartis Pharmaceuticals, East Hanover, NJ, USA; [6]Ospedale Galliera, Genova, Italy

Background. Previous deferasirox studies have shown that some patients experience dose-dependent, non-progressive increases in serum creatinine (SCr), most frequently at doses of ≥30 mg/kg/day. Although the mechanism of these increases is unclear, the hypothesis is that changes are caused by a decreased glomerular filtration rate (GFR) due to a pharmacological effect of deferasirox on renal haemodynamics. *Aims.* To estimate the short-term effect of deferasirox 30 mg/kg/day on renal haemodynamics by measuring changes in the markers of renal function, in particular GFR, renal plasma flow (RPF) and filtration fraction (FF) and assessing their relationship with SCr, estimated creatinine clearance (CrCl) and serum ferritin (SF) in iron-overloaded patients with β-thalas-

saemia. *Methods.* This study enrolled deferasirox-naïve β-thalassaemia patients aged ≥18 years receiving transfusions every 2-5 weeks (iron intake ≥0.25 mg/kg/day), a transfusion history of ≥20 units of packed red blood cells, and baseline SF ≥500 ng/mL or liver iron concentration (LIC) ≥2 mg Fe/g dry weight (dw). Patients were excluded if they had baseline SCr >upper limit of normal (ULN), estimated CrCl <60 mL/min, urinary protein:creatinine ratio >0.5 mg/mg, history of nephrotic syndrome, or treatment with drugs affecting renal parameters. Patients received deferasirox 30 mg/kg/day for 8 weeks, followed by 2 weeks of washout. GFR and RPF were measured using chromium-labelled ethylenediaminetetraacetic acid (51Cr-EDTA) and 123ortho-iodohippurate (123I-OIH). All parameters were assessed at baseline, 2, 8 and 10 weeks. Descriptive statistics were provided. This planned interim analysis reports data after 50% of patients have completed the 10-week core study. *Results.* Ten patients were enrolled (mean age 34.3 years; 6:4 male:female); one discontinued due to voluntary withdrawal on day 14. Median baseline SF was 2232 ng/mL and mean LIC 9.8±6.7 mg Fe/g dw. Mean GFR (112.5±18.1 mL/min), RPF (608.6±97.9 mL/min) and FF (0.2±0.03) were normal at baseline. Mean actual deferasirox dose over 8 weeks was 29.6±1.8 mg/kg/day. After 8 weeks of treatment mean GFR decreased by 15% (90% CI -21%, -10%) and RPF by 15% (90% CI -21%, -9%) (Figure), which was paralleled by a 17% decrease in estimated CrCl. Median SF decreased by 31 ng/mL. GFR, RPF and estimated CrCl returned to near baseline after 2 weeks' washout. Mean FF showed non-significant fluctuations, while mean SCr increased slightly (22%) then returned to near baseline after 2 weeks' washout. There were no significant relationships or clear trends between absolute changes in GFR, RPF and FF, and either SCr, CrCl or SF. Trough concentrations of deferasirox showed no substantial differences from weeks 1 to 8. Investigator-assessed drug-related adverse events (AEs) included rash (n=2), upper abdominal pain (n=1) and pruritus (n=1). There were no deaths, serious AEs or discontinuations because of AEs. *Conclusions.* Deferasirox appears to produce a mild effect on renal haemodynamics, reflected by a decrease in RPF, leading to a decrease in GFR; this was reversible after drug discontinuation. Longer observation is required; this study will continue to assess the effects of deferasirox treatment on renal haemodynamics up to 2 years.

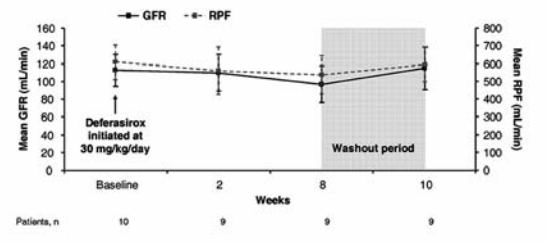

Figure. Mean (SD) GFR and RPF level in patients ith b-thalassemia.

HYPERTONIC CRYOHEMOLYSIS (CH) IS A USEFUL TEST FOR THE DIAGNOSIS OF HEREDITARY SPHEROCYTOSIS (HS): DETERMINATION OF HIGH SENSITIVITY AND SPECIFICITY VALUES WITH A SLIGHTLY MODIFIED METHOD

D Vota,[1] G Miguez,[2] G Schvartzman,[3] S Caldarola,[2] G Alfonso,[2] A Nesse,[1] H Donato[3]

[1]Facultad de Ciencias Exactas y Naturales. Universidad de Buenos Aires, Buenos Aires, Argentina; [2]Hospital Nacional A.Posadas, Buenos Aires, Argentina; [3]Consultorios de Hematologia Infantil, Buenos Aires, Argentina

Background. CH is a laboratory test developed a few years ago for diagnosing HS, based on the special susceptibility of spherocytes to cooling while suspended in hypertonic solutions. Its usefulness seems to be similar to eosin-5'-maleimide flow cytometry and osmotic fragility tests. However, its usual utilization is not widely accepted because of controversial sensitivity and specificity results reported by several authors. *Aims.* A) To determine specificity and sensitivity of CH test for the diagnosis of HS. B) To assess the usefulness of CH for study of anemias. C) To visualize morphologic changes occurring in red blood cell as CH is being performed. *Methods.* 228 normal controls and 73 anemic patients (HS 53, iron-deficiency 5, Beta thalassemia 8, hemoglobin S/Beta thalassemia 1, hereditary persistence of hemoglobin F 1, aplastic anemia 1, autoimmune hemolytic anemia 1) were studied. CH test was performed according to the method described by Streichman and Gescheidt, slightly modified. Differences with the original procedure were the use of manual shacking instead of vortex and a sucrose concentration slightly lesser than the original method (0.6 M *vs.* 0.7 M, respectively). Scanning electron microscopy (SEM) was carried out as CH was performed in one HS patient and one normal control. Between-groups comparisons were done using the student's t test. ROC analysis was used to determine specificity and sensitivity of CH. *Results.* Comparison between groups showed that HS patients had CH results significantly lower than non-spherocytic anemias and normal controls (P<0.0001) (Table). Non-spherocytic anemia showed significantly higher CH results than controls (P:0.03). Sensitivity and specificity were firstly established in a population composed by 106 normal controls and 19 HS patients; the established cut-off value was 2.8% (sensitivity 78%, specificity 96%). Thereafter, the analysis of a second cohort of 117 normal controls and 31 HS patients validated the previously established cut-off value (sensitivity 77%, specificity 95%). The use of ROC curves applied to the total number of studied cases established the following definitive values: cut-off value 2.8%, sensitivity 79.2%, specificity 95.0%, AUC 0.909. SEM allowed visualization of the lack of plasticity of spherocytes when exposed to sudden changes of temperature in a hypertonic medium. *Conclusions.* Reference values in our study are noticeably lower than those reported by other authors; however, they were established on a large number of samples, and were subsequently validated. We suggest that our modifications to the original method could explain these differences. The main advantages of CH over other HS diagnostic tests are the smaller volume of blood sample required, the shorter processing time, no requirement of specific equipment, and no need for use of simultaneous normal controls.

Table.

Group	Cryohemolysis (%)	
	Median (range)	Mean ± SD
Normal controls	1.39 (0.60 – 4.27)	1.51 ± 0.58
Hereditary Spherocytosis	8.45 (0.99 – 34.64)	9.38 ± 8.04
Non-spherocytic anemias	1.14 (0.59 – 2.23)	1.22 ± 0.45

SIGNIFICANT SENSORINEURAL HEARING LOSS IN OMANI PATIENTS WITH SICKLE CELL DISEASE

S Alkindi, H Aiokbi, A Pathare

Sultan Qaboos University, Muscat, Oman

Background. Sickle cell disease (SCD) is characterized by chronic hemolytic anemia, increased susceptibility to infections, and intermittent episodes of vascular occlusion and end-organ damage. Neurological symptoms are frequent and the potential for auditory damage is not unexpected. However, the incidence of subjective hearing impairment among sickle cell disease subjects is very low. *Aim.* To study the prevalence and pattern of hearing loss in Omani patients with SCD.

Table. Significant Hearing loss in SCD patients.

Frequencies tested	SCD patients [n=49] Mean		Control Subjects [n=31] Mean		Student t' test [SCD patients; Rt v/s Lt] p value	Student t' test [SCD patients v/s Controls] p value	
	Rt. Ear	Lt. Ear	Rt. Ear	Lt. Ear		Rt. Ear	Lt. Ear
250	18.16	16.42	13.22	12.41	0.48	0.03*	0.06
500	17.55	17.44	14.67	14.35	0.97	0.2	0.3
1000	16.12	16.44	12.91	12.41	0.92	0.16	0.39

8000	24.28	26.12	16.45	16.12	0.67	0.011*	0.07

* p <0.05; Significant

Methods. A prospective case control study of SCD patients attending the outpatient department and control subjects from age and sex matched normal volunteer blood donors were conducted after an informed consent and Medical Ethics Committee approval. Tympanometry and diagnostic audiometry were performed in all cases studied. *Results.* Forty-nine SCD patients (15 males, 30.61%) aged 16-43 years with a mean age of 29.93 years +6.8 and 31 controls (10 males, 32.25%) aged 15-39 years with a mean age of 25.03 years + 7.8 were enrolled in this study. The average hearing thresholds of SCD patients were consistently higher than controls in all frequencies tested in both right and left ears, with preponderance for the right ear and females. [Table] Of the 98 ears of SCD patients tested 11.22% had sensorineural hearing loss [SNHL]. 3 patients had bilateral SNHL; additionally 2 and 3 cases respectively had SNHL in left and right ears. All the controls had hearing thresholds within normal limits. *Summary/Conclusions.* The study reveals a significant incidence of SNHL in SCD patients although the patients were clinically asymptomatic. The hearing loss was worse in the right ear and has a female preponderance. Furthermore, the hearing loss was also more severe at the higher threshold i.e 8000. We hope that more aggressive primary and secondary prevention and adequate treatment of sickle cell crisis would reduce, if not eliminate the hearing loss found in SCD patients. Regular audiometric assessment, counseling and rehabilitation of these patients with hearing aids are recommended.

T2*MRI - AN EFFECTIVE TOOL TO INCREASE CHELATION COMPLIANCE IN THALASSEMIA MAJOR

S Daar,[1] F Al Salmi,[2] V Ableen,[2] W Jacob,[2] Z Jabeen,[2] A Pathare[2]

[1]*Sultan Qaboos University, Muscat, Oman;* [2]*Sultan Qaboos University Hospital, Muscat, Oman*

Background. Evaluation of cardiac iron load by T2* magnetic resonance imaging has become a standard tool in the management of beta thalassemia, and is used to monitor cardiac and liver iron load. *Aims.* The aim of this analysis was to see if regular monitoring by T2*MRI had any effect on chelation compliance in patients with thalassemia major. *Patients.* Inclusion criteria were a) data for cardiac T2*, liver T2* at baseline and at 3years;b) S ferritin for 3 years preceding and 3 years after instituting T2*; c) chelation with combined chelation (desferal + deferiprone) or deferiprone monotherapy (where the S ferritin was <500 ng/mL) with no marked change in prescribed chelation therapy during the 6 years of analysis (3 yrs pre- and 3years post- T2*) . T2* was repeated at intervals of 3-12 months. The patients were stratified into 3 risk groups according to cardiac T2*: 0-10ms- high risk, 10.1- 20ms - moderate risk, and >20 ms - low risk. In addition, S. ferritin for the 3 years preceding instituting T2* was compared to the 3 years post T2* availability. *Intervention.* The T2* images obtained were shown to patients (and parents where applicable) and discussed fully. Counseling regarding iron chelation was intensified if either the heart or the liver was heavily loaded. Patients with 'good 'or improving T2* results were given positive feedback. *Results.* Data was available for 60 patients from a single centre in the Sultanate of Oman. Full cohort analysis showed no significant change in cardiac iron load over the 3 year study period, (mean 22.1ms to 24.7ms). However, when analyzing the sub groups, patients in the high and moderate risk groups showed a significant improvement in cardiac T2* (P=0.006 and 0.04 respectively), with no significant change in the low risk group. Analysis of S ferritin for the whole cohort in the 3 years preceding T2* showed no significant improvement, (mean 2561ng/mL, 2655ng/mL, and 2623ng/mL, P=0.9). Although the improvement in S ferritin in the following 3 years only approached significance (P=0.06), there was a significant improvement of liver iron load as measured by T2* across the whole cohort over the 3 years post T2* implementation (P=0.03). *Conclusions.* We attribute the improvement in iron load parameters after instituting T2* to increased awareness and vigilance on the part of both physicians and patients. This was particularly important in those patients who were found to have discordance between S ferritin and cardiac iron load. Patients can clearly see improvement (or deterioration) on their own T2* images and we think that this, combined with more intensive, focused counseling has led to improved compliance.

1802

PREVALENCE OF PULMONARY HYPERTENSION IN SICKLE CELL DISEASE PATIENTS (EXPERIENCE FROM TWO CENTERS IN EASTERN SAUDI ARABIA) DO WE REALLY NEED HYDROXY UREA?

A Elshazly,[1] K Said,[2] N Abdulaty,[3] N Heida[4]

[1]*Department of Clinical Hemato Oncology, Ainshams University, Cairo, Egypt;* [2]*Cardiology Department, Ainshams University, Cairo, Egypt;* [3]*Pulmonology department, Suez Canal University, Suez, Egypt;* [4]*Clinical Pathology Department, Ainshams University, Cairo, Egypt*

Abstract. Pulmonary hypertension is one of the leading causes of morbidity and mortality in adult sickle cell disease, with a prevalence of 20% to 40%. The presentation of (SCD) in eastern province Saudi Arabia is variable in part due to the heterogeneous population and certain demographic criteria of that region. *Aim of the work.* to evaluate the prevalence of pulmonary hypertension in patients from this region and correlate our findings with the well documented characters of this patients population, comparing those on hydroxyurea treatment and those with out it. *Methods.* Doppler echocardiography was performed in 100 consecutive patients with SCD; 58 men and 42 women. Mean age was 32±6.Pulmonary hypertension was prospectively defined as a tricuspid regurgitant jet velocity of at least 2.5 m per second, and graded accordingly. The results showed that out of 100 patients, 15 had tricuspid regurgitation, with pulmonary systolic pressure ranging from36 to 60mm Hg (mean of 43.3±4.8 mmHg) which was well correlated with markers of hemolysis; including LDH, and reticulocytic count. Pressure correlation with hemoglobin F concentration revealed an inverse relationship, and higher levels correlated with lower TRJV values (P<.001). Yet lower arginase activity was well correlating with higher TRJV. Another documented point in our study was those patients who were on hydroxyurea; 45 patients, showed no significant difference as regard TRJV when compared with patients off hydroxyurea. (Mean TRJV was 2.57m/s and 2.6m/s respectively). *In summary.* patients with SCD from eastern province Saudi Arabia have special characters with pulmonary hypertension of less prevalance possibly due to higher HbF levels.

1804

MILD HEMOLYTIC ANEMIA, PROGRESSIVE NEUROMOTOR RETARDATION AND FATAL OUTCOME: A DISORDER OF GLYCOLYSIS, TRIOSE- PHOSPHATE ISOMERASE DEFICIENCY

E Zengin, N Sarper, K Kurt, B Kara

Kocaeli University, Medical Faculty, Kocaeli, Turkey

Introduction. Triose-phosphate isomerase (TPI) deficiency is a rare autosomal recessive multisystem disorder of glycolysis, characterized by decreased enzyme activity in all tissues, which is accompanied by the elevation of dihidroxyacetone phosphate (DHAP) level in erythrocytes. Homozygotes manifest congenital hemolytic anemia, increased susceptibility to infection, cardiomyopathy and progressive neuromuscular impairment and fatal outcome in early childhood. *Case report.* A 2 month-old male infant presented with jaundice and pallor. D.Coombs negative hemolytic anemia with normal osmotic fragility, G-6PD, and PK levels was diagnosed. The history revealed hyperbilirubinemia and anemia (Hb:6 g/dL) requiring phototherapy and transfusion since first post-natal day. Blood groups of mother and the infant did not confirm immune hemolytic anemia. The parents reported that their first baby also had hemolytic anemia, neuromotor retardation and at the age of 21 month he was found dead. Screening for inborn errors of metabolism was not diagnostic. There was no consanguineous marriage. During follow-up hemolytic anemia was mild and no transfusion was required. Although the baby gained excessive weight neuromotor development was retarded. There were intermittent tremor and sweating episodes. On admission at the age of 14 month, body weight was 15 kg (>97 pers.), height 83 cm (75-90 pers.) and head circumference 51 cm (>97 pers.). The patient had normal features with no jaundice or pallor. He had poor head control, could not sit and had difficulty in swallowing in the last week. Respiratory and heart rate were increased to 48/min and 152 beats/ min, respectively. Blood counts were: WBC 20600/mm^3, ANC 12400 /mm^3, PLT 345000/mm^3, MCV:111 fL and reticulocyte count was 277 000/mm^3 Peripheral blood smear showed normal erythrocyte morphology and rare basophilic stippling. T.bilirubin 4.6 mg/dL, d.bilirubin 0.6 mg/dL, ALT 33 IU/L, AST 53 IU/L, venous blood PH 7.29, PCO2 62, HCO3 29 (respiratory acidosis). Direct chest radiogram was normal. Echocardiogram showed EF 63%, small muscular ventricular septal defect, patent foramen ovale. Brain natriuretic peptide level was elevat-

ed (337 pg/mL), cardiac troponin I and creatin kinase MB levels were normal. The patient was entubated and ventilatory support was introduced. After a medline search, TPI deficiency was suspected. A highly elevated DHAP was found in patient's erythrocytes and DNA analysis showed a homozygous missense mutation in TPI gene (DNA level: c.315G>C, protein level:p.(Glu 105Asp). The patient lived for 3 months under ventilatory support and died. *Conclusion.* In infants with mild hemolytic anemia and neuromotor retardation this rare glycolytic pathway defect must be suspected. The defect causes impairment of energy metabolism and/or formation of toxic protein aggregates. Although no effective therapy is available, genetic confirmation of diagnosis gives chance for prenatal diagnosis and genetic counseling. *Acknowledgement.* Thanks to Prof.Dr.C.Jakobs and Dr.Gajja.S.Salomons from Dept. Clinical Chemistry, Metabolic Unit from VU University Medical Center in Amsterdam for erythrocyte DHAPanalysis and genetic study.

1805

DEFERASIROX EFFECTIVELY REMOVES CARDIAC IRON IN β-THALASSAEMIA PATIENTS WITH MYOCARDIAL SIDEROSIS PREVIOUSLY CHELATED WITH DEFEROXAMINE MONOTHERAPY OR DEFEROXAMINE-DEFERIPRONE THERAPY

D Pennell,[1] J Porter,[2] M Cappellini,[3] LL Chan,[4] A El-Beshlawy,[5] Y Aydinok,[6] H Ibrahim,[7] CK Li,[8] V Viprakasit,[9] M Elalfy,[10] A Kattamis,[11] G Smith,[1] D Habr,[12] B Roubert,[13] A Taher[14]

[1]Royal Brompton Hospital, London, UK; [2]University College London, London, UK; [3]Universitá di Milano, Policlinico Foundation IRCCS, Milan, Italy; [4]University Malaya Medical Centre, Kuala Lumpur, Malaysia; [5]Cairo University, Cairo, Egypt; [6]Ege University Medical Faculty, Izmir, Turkey; [7]Hospital Kuala Lumpur, Kuala Lumpur, Malaysia; [8]Prince of Wales Hospital, Chinese University of Hong Kong, Hong Kong, Hong Kong; [9]Department of Pediatrics, Siriraj Hospital, Mahidol University Bangkoknoi, Bangkok, Thailand; [10]Ain Shams University, Cairo, Egypt; [11]First Dept of Pediatrics, University of Athens, Athens, Greece; [12]Novartis Pharmaceuticals, East Hanover, NJ, USA; [13]Novartis Pharma AG, Basel, Switzerland; [14]American University of Beirut, Beirut, Lebanon

Background. In the cardiac substudy of the deferasirox EPIC trial, patients who entered the extension study received deferasirox treatment for up to 2 years. All patients enrolled in the extension study were previously chelated, either with deferoxamine (DFO) monotherapy or DFO-deferiprone (DFP) therapy. The efficacy of monotherapy deferasirox was assessed in patients previously chelated with DFO monotherapy or DFO-DFP therapy. *Aims.* To evaluate the effect of 2 years of treatment with deferasirox on cardiac iron, liver iron concentration (LIC) and serum ferritin (SF) in β-thalassaemia patients stratified by prior chelation regimens. *Methods.* Eligible patients were aged ≥10 years with myocardial T2* >5-<20 ms by cardiovascular magnetic resonance (CMR), left ventricular ejection fraction (LVEF) ≥56%, SF >2500 ng/mL, MR (R2) LIC >10 mg Fe/g dry weight (dw), and a lifetime minimum of 50 transfused blood units. All were previously chelated with DFO monotherapy or DFO-DFP therapy. Deferasirox was initiated at 30 mg/kg/day and increased to 40 mg/kg/day by the time patients had entered the extension. Dose decreases were allowed for safety reasons. *Results.* Overall, 95 patients had MRI assessments available at baseline and after 18 and/or 24 months of deferasirox treatment. Sixty-three patients (66.3%) had previously received DFO monotherapy; the mean age of these patients was 18.6±6.3 years. Thirty-two patients (33.7%) had previously received DFO-DFP therapy; mean age was 24.3±7.8 years. The mean duration of prior chelation therapy for the DFO monotherapy group was 12.0±6.3 years, and that for patients having received DFO-DFP as part of their previous chelation was 16.8±8.2 years. Average actual deferasirox dose during treatment was 34.2±5.3 and 35.2±4.0 mg/kg/day, respectively. Geometric mean myocardial T2* significantly increased by 28% in the prior DFO monotherapy group (11.8 to 15.2 ms, P<0.0001), and by 35% in the prior DFO-DFP group (10.4 to 14.0 ms, P<0.0001). In the prior DFO monotherapy group, 50/63 patients (79.4%) had an improvement in T2* of >4%; this proportion in the prior DFO-DFP group was 22/32 (68.8%). Mean LVEF increased by 1.2±4.5% (P=0.046) in the prior DFO monotherapy group; the change in the prior DFO-DFP group was not significant (-1.7±5.8%, P=0.102). In the prior DFO monotherapy group, both mean LIC and median SF were significantly reduced from baseline by 9.6±12.7 mg Fe/g dw and 2227 ng/mL, respectively (P<0.001; based on last-observation-carried-forward analysis); similar data were observed in the prior DFO-DFP group (12.4±12.5 mg Fe/g dw and 2559 ng/mL; P<0.001). *Conclusions.* Two years of deferasirox treatment led to significant improvements in cardiac T2*, LIC and SF, irrespective of whether patients had previously received DFO monotherapy or DFO-DFP therapy. This suggests that heavily iron-overloaded patients can be effectively switched to once-daily deferasirox from other chelation regimens containing DFO, which may be cumbersome to administer and therefore may lead to poor compliance and, potentially, suboptimal efficacy.

1806

IMPACT OF DIFFERENT I.V. IRON COMPOUNDS ON HEMODYNAMIC AND INFLAMMATORY RESPONSE, MARKERS OF OXIDATIVE STRESS AND IRON DEPOSITION

J Toblli, G Cao, L Oliveri, M Angerosa

Hospital Aleman, University of Buenos Aires, Ciudad De Buenos Aires, Argentina

Background. Iron deficiency anemia associated with different conditions has been effectively managed with intravenous (I.V.) iron. I.V. iron preparations may induce different physiological reactions depending on their composition and the stability of the complexes. Therefore, the effects of five I.V. iron preparations on hemodynamic and inflammatory response, oxidative stress markers and iron deposition were examined in a nonclinical rodent model. *Methods.* Ten rats per group were treated with ferric carboxymaltose, high-molecular-weight (HMW) iron dextran, low-molecular-weight (LMW) iron dextran, ferric gluconate, iron sucrose or saline solution as control. Five I.V. doses of iron (40 mg iron/kg) or saline were administered every 7 days over 4 weeks (days 0, 7, 14, 21 and 28). Blood samples were collected 24h after I.V. iron treatment (days 1, 8, 15, 22 and 29). Urine was collected for 24h at the same time period as blood sampling. Rats were sacrificed 24h after the last I.V. iron dose. Blood-free liver, heart and kidneys of each rat were removed for analysis of oxidative stress markers, microscopy and immunohistochemical evaluation. Investigators were blinded to the treatment group. *Results.* At all assessments after initial treatment, systolic blood pressure was significantly reduced in the LMW dextran group compared to all other groups, whereas proteinuria was significantly increased in the ferric gluconate group compared to all other groups (P<0.01). Compared to ferric carboxymaltose and iron sucrose, ferric gluconate was also associated with a significant reduction of creatinine clearance on days 15, 22 an 29 (P<0.01). Inflammatory cytokines TNF-α and IL-6 showed highest levels in the liver, heart and kidney of rats treated with ferric gluconate (P<0.01 *vs.* all groups). Both cytokines were also significantly higher in the iron dextran groups compared to ferric carboxymaltose, iron sucrose and saline. Blood levels of liver enzymes alanine transaminase (ALT), aspartate transaminase (AST) and alkaline phosphatase (ALP) showed the same pattern on days 1, 8 and 29; significantly highest in the ferric gluconate group and increased in both iron dextran groups compared to the other groups (P<0.01). Oxidative stress markers malondialdehyde (TBARS) and catalase were significantly increased in liver, heart and kidney homogenates of rats in the ferric gluconate group (P<0.01). CuZn-superoxide dismutase and glutathione peroxidase activity were increased and the ratio of reduced to oxidized glutathione decreased in the ferric gluconate and two dextran groups (P<0.01), whereas ferric gluconate was associated with largest deviations from control. In line with the oxidative stress markers, homogenates of organs from ferric gluconate treated rats showed significant amounts of iron (Prussian blue staining) not matched by high ferritin levels. Highest ferritin levels were measured in the ferric carboxymaltose and iron sucrose group. *Summary/Conclusions.* This study confirms that different I.V. iron preparations can result in different hemodynamic and functional response. Increased markers of inflammation and oxidative stress in vital organs of rats treated with HMW or LMW iron dextran or ferric gluconate suggest a less favorable safety profile for these compounds than for ferric carboxymaltose and iron sucrose.

The present study was supported by Vifor Pharma Ltd.

PLATELET FUNCTION ALTERATIONS AND THEIR RELATION TO P-SELECTIN (CD62P) EXPRESSION IN CHILDREN WITH IRON DEFICIENCY ANEMIA

M Buyukavci,[1] Z Yildirim,[2] M Orhan[3]

[1]Ataturk University Medical School, Erzurum, Turkey; [2]Ataturk University Medical School, Division of Pediatric Hematology-Oncology, Erzurum, Turkey; [3]Fatih University Medical Faculty, Division of Pediatric Hematology, Ankara, Turkey

Background. The CD62P antigen (P selectin) is an integral membrane protein of platelets. Upon platelet activation, the CD62P antigen is expressed on the surface of the activated platelets. It has been demon-

strated the existance of chronic platelet activation associated with the increased fraction of platelets carrying the platelet activation markers, CD62P and CD63, in thalassemic patients. At the other hand, there have been reports demonstrating that iron deficiency anemia may cause platelet aggregation dysfunction and this can be reversed by iron therapy. Those studies made us think that there may be a relationship between body iron and platelet activation markers. Increased iron load may cause to increase in expression of activation markers in thalassemic patients; however, iron deficiency may result in diminished expression of activation markers leading to platelet aggregation dysfunction in children with iron deficiency anemia. *Aims.* To investigate the alterations of platelet functions and their association with platelet activation marker (p-selectin; CD62P) expression in children with iron deficiency anemia. *Patients and methods.* Hemoglobin, erythrocyte indexes (MCV and RDW), serum levels of iron, transferrin and ferritin, platelet aggregation tests (with ADP, collagen and ristocetin), invitro bleeding time (with PFA 100), and CD62P expression were evaluated in fasting blood samples of 19 children with iron deficiency anemia and 20 children without anemia. CD62P expression was detected by flow cytometry in normal and 5μM ADP-activated platelets. *Results.* Mean values of hemoglobin, MCV, RDW, serum iron and ferritin were significantly different in patient group as expected. However, there was no difference between two groups in terms of age, gender, mean platelet counts and serum transferrin levels (Table 1). Mean closure times (either with ADP or epinefrin) were longer in patient group than control. In platelet aggregation tests, mean values of maximum aggregation times by ristocetin, ADP and collagen were also more prolonged in patient group. However, maximum aggregation rates (amplitude) by ristocetin and ADP were significantly higher in patients. These findings suggest that platelet aggregation and adhesion have been delayed in children with iron deficiency anemia. CD62P expressions were significantly higher on activated platelets of patient group although they were similar in both groups before activation by ADP (Table 1). *Conclusion.* Invitro bleeding time (closure time) and maximum aggregation time of the platelets get prolonged in children with iron deficiency anemia. However, those are not associated with CD62P expression on platelet surface. ADP activation results in more prominent increase of CD62P expression on platelets of the iron deficient cases.

Table 1. The age, gender and laboratory values of the patient and control group.

	Patient (n:19)	Control (n:20)	p
Age (year); median (min-max)	6 (1–16)	4,5 (1–15)	0,81
Gender (F/M)	19 (6/13)	20 (6/14)	0,91
	Mean±SD	Mean±SD	
Platelet ($x10^9$/L)	448 ±199	402±174	0,45

USE OF CAPILLARY BLOOD TO PERFORM THE EOSIN-5'-MALEIMIDE FLOW CYTOMETRY (EMA-FC) TEST: RESULTS ARE COMPARABLE TO VENOUS BLOOD

R Crisp,[1] L Solari,[1] D Gammela,[1] G Schvartzman,[2] G Alfonso,[1] H Donato[2]

[1]Hospital Nacional A.Posadas, Buenos Aires, Argentina; [2]Consultorios de Hematologia Infantil, Buenos Aires, Argentina

Background. Blood volume required to perform usual diagnostic laboratory tests may be hard or even not feasible to collect in neonates or infants with hemolytic anemia, due to either difficulties inherent to the sampling procedure or to the inconvenience of withdrawing large blood volumes in small babies. As a consequence, etiological diagnosis of the anemia may be delayed several weeks or months. The EMA-FC is a very useful test for the diagnosis of HS which allows getting results within 2 hours. The use of capillary blood samples to perform the test has not been reported in the literature. *Aims.* To assess the reliability of capillary blood for performing EMA-FC test. *Methods.* 31 pairs of capillary and venous blood samples belonging to 19 normal controls and 12 patients with anemia of different etiologies were simultaneously collected by venopuncture in tubes with EDTA and by digital puncture in heparinized microhematocrit tubes. EMA-FC test was simultaneously performed for both samples within 48 hours from sampling. Either the content of a microhematocrit tube or 30 μL of venous blood were washed three times with phosphate saline buffer (PSB); 5 μL of the red cell pellet were added to 5 μL of EDTA (0.5 mg/mL) and incubated 15 minutes at room temperature. Red blood cells were washed three times with PSB and suspended in 1 mL of PSB; 10000 events were acquired to determine the percentage of decrease of geometric mean fluorescence in FL-1 channel (MCF) and the increase of the coefficient of variation (CV). For the statistical analysis, the t student test for paired data and the Bland Altman graphic method were used. A p value less than 0.05 was considered significant. *Results.* No significant difference between venous and capillary blood samples was found (Table). *Conclusion.* Our results suggest that the use of capillary or venous blood makes no difference to the EMA-FC test *Results.* The use of capillary blood would allow an early etiological diagnosis in neonates and infants.

Table.

Blood sample	MCF (mean ± SD)			CV (mean ± SD)		
	Normal controls	Anemic patients	Total	Normal controls	Anemic patients	Total

1809

GROWTH AND PUBERTY STATUS IN THALASSEMIA MAJOR AT ZAGAZIG UNIVERSITY HOSPITAL - EGYPT

U El Safy, M Beshier, A El Saied

Zagazig University, Zagazig, Egypt

Introduction. Present transfusional regimen protocols for thalassemic patients have increased the life expectancy of patients with β- thalassemia major but caused a progressive iron overload that can be prevented or limited only by appropriate iron chelation. As a result of iron overload those patients develop endocrine abnormalities, cardiac failure and hepatic cirrhosis. Short stature and hypogonadism are extremely frequent in patients with thalassemia. *Aim of the work.* To evaluate the status of growth and puberty in patients with β- thalassemia major in pediatric hematology unit at Zagazig University Hospitals. *Patient and method.* One hundred patients with β- thalassemia major aged from 8-20 years old were enrolled in this study. They were classified according to regularity of iron chelation therapy into two groups (13 patients with regular chelation and 87 patients irregularly chelated). The following data were recorded in: history taking, age, sex, weight, height, serum ferritin levels and pubertal evaluation according to tanner score were done. *Results.* short stature was presented in 76% of our patients. Short stature in thalassemic patients is more apparent with increase in the age (92% of patients above 14 years old, 76% of patients aged from 10-14 years and 55% of patients younger than 10 years). There is a significant increase in height among patients with regular iron (141.1±7.4 cm) in comparison to irregular chelated patients (133.5±12.1 cm) with P value 0.025. Delayed puberty was present in 65% of patients (67.2% of males and 61.5% of females). The decrease of tanner among irregular chelated patients in comparison to regular is statistically insignificant. *Conclusion.* Compliance to iron chelation therapy is very low (13%). Growth retardation is one of common complications with significant correlation with age and ferritin level. Delayed puberty is another common complication with no correlation to ferritin levels or sex.

1810

EVALUATION OF IRON CHELATION THERAPY IN β-THALASSEMIA MAJOR PATIENTS IN EAST DELTA OF EGYPT

T Hassan,[1] M Badr,[1] M Hesham,[1] S Badawy[2]

[1]*Zagazig University, Zagazig, Egypt;* [2]*Zagazig university, Zagazig, Egypt*

Background. Beta Thalassemia is the most common chronic hemolytic anemia in Egypt. Desferrioxamine given by regular subcutaneous infusion is the standard iron chelator in these patients. However, failure of compliance is the major problem interfering with its regular use. *Aims.* We aimed to evaluate the efficacy and safety of alternating deferiprone and desferrioxamine in reducing transfusional iron overload compared to either drug alone and to assess the associations between compliance, complications and ferritin levels in thalassemic children in east delta of Egypt. *Methods.* Retrospective - Prospective cohort study was carried out on 150 transfusion dependant thalassemic children who are on irrigular desferrioxamine chelation therapy. Patients were randomized into three groups (50 patients in each group) according to iron chelation therapy regimen: Group I received deferiprone for 5 days/week alternating with desferrioxamine for 2 days/week, group II received daily deferiprone only and group III received desferrioxamine only 5 days/week. Efficacy, safety and tolerance of different chelation regimens were assessed by periodic assessment of all relevant clinical and laboratory data. *Results.* There was highly significant reduction in serum ferritin levels after chelation therapy in all studied groups. The reduction was significantly higher in group I and group III than group II especially in compliant patients. Patients of group II and group I were more compliant to chelation therapy than patients of group III. Regarding disease complications, hypogonadism and growth impairment were the commonest disease complications in our study followed by osteoprosis and osteopenia. Complications were higher in non compliant patients and those with higher serum ferritin levels. Regarding side effects of the chelators, gastrointestinal upset was the commonest complication in group II, local reactions were the commonest in group III and both complications were lower in group I. *Summary/Conclusions.* Dual chelation therapy regimen of alternating desferrioxamine and deferiprone is more effective, less toxic and well tolerated in comparison to either drug alone.

1811

THYROID DYSFUNCTION AND ANEMIA DURING INTERFERON THERAPY IN VIRUS C HEPATITIS

A Helaly,[1] N Allam,[2] G EL Azab[2]

[1]*Faculty of medicine, Alexandria, Egypt;* [2]*Monufeia university, Monufeia, Egypt*

Background. Thyroid disease is a frequent side effect of interferon (INF) - therapy for hepatitis C virus (HCV). And anemia is a major problem during therapy .Interferon and Ribavirin is the only line available now to stop this disease The aim of this work was to study the thyroid function in cases developed anemia during INF therapy. *Methods.* 371 Patients treated with combinations therapy for chronic hepatitis C between Sep. 2003 and March. 2009 were analyzed retrospectively. All patients were genotype 4 and received 48 weeks of standard doses of combined INF and Ribavirin. Anemia-related parameters were measured before and during treatment. Thyroid stimulating hormone (TSH) level was performed before initiating treatment and then every 3 months during the antiviral treatment. Thyroid dysfunction (TD) was defined as having hypothyroidism (TSH levels >4.0 mIU/L) or hyperthyroidism (TSH of <0.4 mU/L plus FT4 levels >24 and/or FT3 levels >5.5 pmol/L). *Results.* Thirty two (8.6%) patients developed TD during treatment, 27 (84%) of them were females, and the mean age was 41.03±10.2 years. Hypothyroidism (HYPO) developed in 26 cases (81.25%), 23 of them (88.5%) were females and hyperthyroidism was observed in 6 (18.75 %) patients, four of them (66.7 %) were females. In those with hypothyroidism, twenty (76.9%) patients were symptomatic and required L-thyroxin therapy. In those with hyperthyroidism (HYPER), all patients were symptomatic and required therapy. Anemia was almost universal during treatment. In HYPO Hb levels were 13.29±1.57 (10.6-16.4) , 11.11±1.62 (8.-14.3) , and 10.54±1.39 (8.50-13.6) gm/dl before, 3 months and 6 months after therapy respectively. In HYPER Hb levels were 13.73±1.66 (11.2- 16.5) , 11.62 ±0.89 (10.2-13.8) and 11.15±1.19 (9.1-13.5) gm/dl before, 3 months and 6 months after therapy respectively. *Conclusion.* thyroid dysfunction is a frequent complication during INF therapy and the occurrence of anemia is more frequent in this disorder. Hypofunction is more common than hyperfunction. Detection of the thyroid disorder is mandatory to treat anemia as a possible correctable factor to continue the interferon therapy.

1812

PLASMA LEVELS OF ADVANCED GLYCATION END-PRODUCTS ARE ASSOCIATED WITH HEMOLYSIS-RELATED ORGAN COMPLICATIONS IN SICKLE CELL PATIENTS

E Nur,[1] D Brandjes,[1] JJ Schnog,[2] HM Otten,[1] K Fijnvandraat,[3] C Schalkwijk,[4] B Biemond[3]

[1]*Slotervaart Hospital, Amsterdam, Netherlands;* [2]*Sint Elisabeth Hospital, Curacao, Netherlands Antilles;* [3]*Academic Medical Center, Amsterdam, Netherlands;* [4]*Academic Hospital Maastricht, Laboratory for Metabolism and Vascular Medicine, Maastricht, Netherlands*

Background. Oxidative stress plays an important role in the pathophysiology of sickle cell disease (SCD). Plasma levels of advanced glycation end-products (AGEs) are increased under oxidative conditions and are associated with disease severity in diabetes and inflammatory diseases. *Aims.* We questioned whether AGEs are increased in sickle cell patients and whether they are associated with SCD related complications. *Methods.* Plasma levels of the AGEs pentosidine, Nε-(carboxymethyl)lysine (CML) and Nε-(carboxy-ethyl)lysine (CEL)) were measured using single-column high performance liquid chromatography with fluorescence detection (pentosidine) and ultra performance liquid chromatography-tandem mass spectrometry (CML and CEL). *Results.* Plasma levels of pentosidine and CML were increased in HbSS/HbSβ0-thalassemia (n=60) and HbSC/HbSβ+-thalassemia (n=42) patients during steady state (P<0.01) as compared to healthy HbAA controls (n=30) without increments during painful crisis. CEL levels were comparable between all groups. Pentosidine and CML levels during the clinically asymptomatic state correlated significantly to hemolytic rate and were associated with the number of hemolysis-related organ complications (P<0.05). *Conclusions.* The increased plasma AGE levels in sickle cell patients and their association with hemolysis and hemolysis-related complications suggest that AGEs might be implicated in the pathophysiology of the hemolytic phenotype of SCD. Measurement of AGEs might be useful in predicting organ complications in SCD.

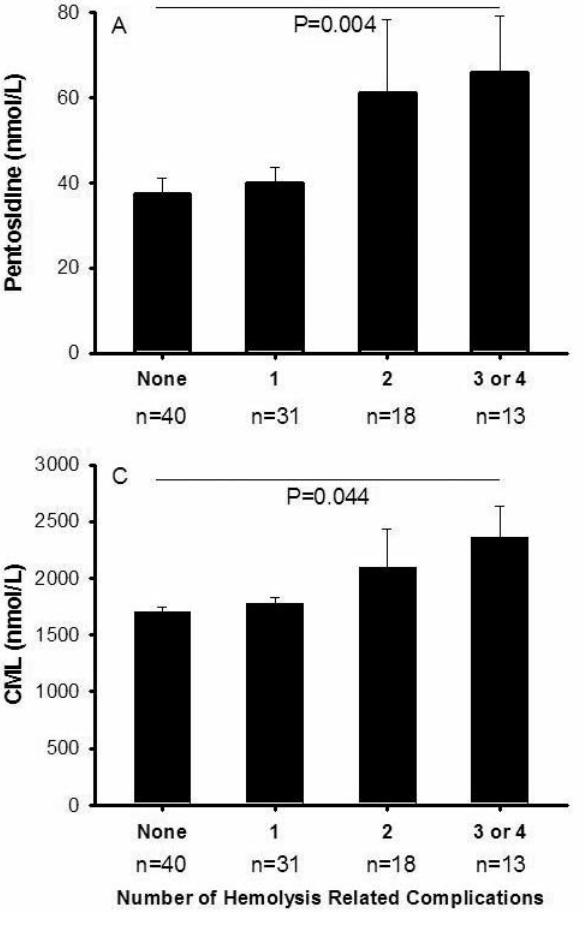

Figure. AGEs in relation to SCD related complications.

1813

EVALUATION OF GROWTH PARAMETERS AND PUBERTAL CONDITIONS IN PATIENTS WITH BETA-THALASSEMIA MAJOR

F Uysal, G Aydogan, T Akçay, A Akçay, F Akici, D Tugcu, Z Salcioglu

Istanbul Bakirkoy Maternity and Children's Research and Education Hospital, Istanbul, Turkey

Summary. Objective: multiple blood transfusions in Thalassemia Major patients causes iron overload in various tissues including endocrine glands thereby leading to multiple endocrine dysfunction. As the life expectancy of these children is increasing by transfusions and chelation therapy, endocrine complications are gaining more importance thus impairing the quality of life. The aim of this study was to determine the frequency of the growth retardation and the delayed puberty, possible causes of these complications and the effectiveness of the various chelation therapy given to the patients in our center. *Materials and methods.* Fifty-nine transfusion-dependent patients with Beta Thalassemia Major above six years of age followed up at the Istanbul Bakirkoy Maternity and Children's Research and Education Hospital were included in this study. All the information of the patients including age, gender, age of diagnosis, height, weight, parental height, target height, height velocity, puberty stage by Tanner method, treatments, volume of transfusions per month, mean ferritin levels and hemoglobin concentrations in the last two years, bone age, TSH, fT4, LH, FSH, estradiol or testosterone, cortisol, IGF, IGFBP-3 were recorded. Growth hormone and LH-RH stimulation tests were performed in selected patients. *Results.* 59 patients (33 female and 26 male), aged 13,40±4,66 (range 6,5-24 years) were studied. Mean age of diagnosis was 1,65±1,63 (0-6) years. 23 of our patients (%39) had at least one endocrinopathy. Of all patients, 16 (%27,1) had growth retardation, 8 (%13,5) had delayed puberty, 4 (%6,8) had hypothyroidism. Any of our patients did not have adrenal insufficiency. Growth hormone deficiency was determined at a rate of %15,3 in our patients. The mean ferritin level of patients was 2069±1306, the average hemoglobin level was 8.69±0.65. The mean heights of our patients were significantly less than their target heights. The patients with mean ferritin levels above 2500 ng/dL did significantly have short stature. There was a significant association between hypogonadism and short stature and also there was a significant association between the mean ferritin levels and the delayed puberty in our study. Growth retardation, height velocity, hypotiroidism and hypogonadism did not differ significantly amongst those having different chelating agents. *Conclusions.* Endocrine abnormalities should be monitored carefully and a thorough endocrine evaluation should be carried out yearly to detect endocrinopaties in every patient with thalassemia major. In conclusion, we thought that to keep the levels of ferritin down to the notable values by adequate and compatible chelation therapy will affect the growth and puberty conditions positively.

1814

CHARACTERIZATION OF A NEW HEMOGLOBIN VARIANT: HB SEVILLA BETA 81(EF5) LEU_PHE

A Villegas,[1] P Ropero,[2] MT Herrera,[3] I Dominguez,[3] FA González,[2] L Vinuesa,[2] F De la Fuente-Gonzalo,[2] J Martínez-Nieto,[2] JM Guerrero[3]

[1]Hospital Clinico San Carlos, Madrid, Spain; [2]Hematología. Hospital Clínico San Carlos, Madrid, Spain; [3]Bioquímica Clínica. Hospital Virgen del Rocío, Sevilla, Spain

The haemoglobinopathies are the more frequent monogenic alterations, nevertheless theirs detection, unless there are clinical pathology, it is very difficult, since the majority these hemoglobin variant are due to mutations which only produce changes in the surface of the molecule and that do not show clinical manifestations. In this sense, we present a new structural variant of hemoglobin which detected during a control of glycoside hemoglobin. (HbA1c). At the propositus, a 61-year-old Spanish male, with diabetes mellitus type II, an anomalous hemoglobin having had been detected during a control of HbA1c by HPLC, and on not having coincided with any known hemoglobin. The new mutation β81(EF5) Leu→Phe, has been named Hb Sevilla after the city where the proband lives. Blood samples were collected with EDTA as anticoagulant and red cell indices were determinated on an automated blood cell counter, Hb 14g/dL; MCV 97.6fL; MCH 33.1pg; PCV 41.2%; RDW 13.4% and reticolocytes 1.2%. The HbA2 (2.4%) and HbF (0%) was measured by weak cation-exchange HPLC. In the same study an Hb X, which eluted before Hb A was isolated and measured (39.6%). Reverse phase HPLC study revealed the presence of an abnormal β-globin chain (β^X, β^A y α^A). Instability test by isopropanol demonstrated normality. Oxygen binding studies (Hemox Analyzer) showed normal whole blood oxygen affinity (P50 25 mmHg). For molecular characterization, genomic DNA from leukocytes of peripheral whole was automatic extracted with a Bio-Robot EZ1 (Quiagen). Selective amplification of the β gene was performed in an Applied Biosystems 2720 Thermal Cycler by PCR. Sequencing of the b gene in both directions, in an automatic sequencing (3.77 ABI, Applied Biosystems, CA), established a substitution of CTC→TTC at codon 81. This produces the Leu→Phe change at position 81 of the β-globin chain. Hb Sevilla is the third Hb variant resulting from Leu→Phe mutation at β81(EF5). In this case, neither the function nor to the stability of the hemoglobin involve modification, because the change is owing to substitution of an animo acid apolar hydrophobic (Leu) for other of the same characteristics (Phe), in the position 5 of the EF helix (such 3D position is 2,3-DPG binding site). The other two variants with substitution in the same position, Hb La Roche-sur-Yon (→His) and Hb Baylor (→Arg) are unstable and present an affinity for the oxygen increased, being these properties more accentuated in the Hb Baylor, probably due to the fact that the Arg possesses a guanidine group with electric charge, whereas the His has a imidazol group weakly ionized. Nevertheless in three cases, the substitution of the residue Leu in this position originates structural changes in the molecule that allow its detection by electrophoretic and chromatographic methods.

1815

SICKLE CELL DISEASE: A SINGLE CENTER REVIEW OF THROMBOEMBOLIC DISEASE IN A TERTIARY HOSPITAL IN RIYADH, SAUDI ARABIA

H Algahtani, A Aleem

King Khalid University Hospital, King Saud University, Riyadh, Saudi Arabia

Background/Aim. Sickle Cell Disease (SCD) is very common in Saudi Arabia and is considered as one of the major causes of morbidity. Pulmonary disease including thromboembolic disease (TED) accounts for the large portion of the morbidity of SCD. However, unclear evidences tried to implicate SCD as a risk factor for TED, thus this study was conducted to determine the prevalence and association of TED with SCD in our institution. *Methods.* Medical records of all patients diagnosed with SCD at the hematology clinic of King Khalid University Hospital, King Saud University, Riyadh, Saudi Arabia between 1982 and 2008 were retrospectively analyzed. Demographic characteristics, co-morbidities, SCD type, laboratory and coagulation profiles, treatment, mortality and cause of death were recorded. Occurrence of adverse events including stroke, DVT and infarction were also recorded. *Results.* A total of 478 patients with mean age of 21.3±11.1 years were included in the study, 51.5% were males. Avascular necrosis was documented in 39 (8.2%) patients, bone diseases in 21 (4.4%) patients and infections (both bacterial and viral) in 103 (21.5%) patients. Splenomegaly was documented in 176 (36.8%) patients wherein splenectomy was done in 19 (4.0%) patients. Mean D-dimer level was 442.3±933.5 mg/L, mean ferritin level was 1506±2570 ng/mL, mean hemoglobin was 9.1±1.7 g/dL, mean platelet count was 421.8±190.3×10^9/L, mean white blood cell count was 12.7±5.9×10^9/ and mean LDH was 386.4±223.3 U/L. Thromboembolic disease including deep vein thrombosis (DVT), pulmonary embolism (PE) and stroke was documented in 32 (6.7%) patients. Sixteen patients had stroke, 9 had DVT and 7 had pulmonary embolism. The occurrence of thromboembolic events was significantly associated with thromboembolism (P=0.017), age (P=0.018), D-dimer level (P<0.0001), ferritin level (P<0.0001), hemoglobin level (P<0.0001), platelet level (P<0.0001) and wbc count (P<0.0001). *Conclusion.* TED among Saudi patients with SCD showed 6.7% prevalence. SCD patients may have higher risk for TED if these patients have concomitant infections, with high D-dimer level, high ferritin level, low hemoglobin and low platelet counts.

1816

FLOW CYTOMETRIC OSMOTIC FRAGILITY (FC-OF) CAN REPLACE THE TRADITIONAL OSMOTIC FRAGILITY (OF) TEST? PRELIMINARY RESULTS

R Crisp,[1] L Solari,[1] D Gammela,[1] G Schvartzman,[2] G Alfonso,[1] H Donato[2]

[1]Hospital Nacional A.Posadas, Buenos Aires, Argentina; [2]Consultorios de Hematologia Infantil, Buenos Aires, Argentina

Background. FC-OF has recently been proposed as a novel diagnostic

test for diagnosis of hereditary spherocytosis (HS). It is a simple, quantitative, and cost-effective method to determine the erythrocyte OF; its reliability seems to be similar to the traditional OF method. *Aims.* A) To assess the usefulness of FC-OF for the diagnosis of HS. B) To determine correlation between FC-OF and traditional OF *Results. Methods.* Blood samples from 19 normal controls and 15 anemic patients (HS 8, non-spherocytic anemias 7) were collected by venopuncture or digital puncture. The FC-OF test was performed according to the method described by Won and Suh, based on the observation that red cells suspended in isotonic normal saline undergo hemolysis when exposed to deionized water. The percentage of residual red cells is measured sequentially by flow cytometry in real-time before and after adding deionized water to the suspension. Traditional unincubated and incubated OF tests and FC-OF method were simultaneously performed in 10 normal controls, 5 HS patients and 3 patients with non-spherocytic anemias. Between-groups comparison was done using the Kruskal Wallis test. Correlation between the traditional OF and the FC-OF was analyzed. *Results.* HS patients had a significantly lower percentage of residual red cells than normal controls and non-spherocytic anemias (P:0.0012) (Table). Six HS samples (75%) showed results lower than the minimum value obtained in normal controls. Relationship between FC-OF and unincubated traditional OF showed an exponential fit; log of percentage of residual cells *vs.* OF showed significant correlation (r2: 0.842). *Conclusions.* FC-OF seems to be a reliable test for demonstrating increased osmotic fragility of red blood cells. Our results for normal controls and non-spherocytic anemias agree with those reported in the original description of the method; results for HS showed higher mean and wider data dispersion than those reported by Won and Suh. However, as both trials included a small number of samples, these results should be further validated through studies including large number of patients. The use of this test together with eosin-5'-maleimide flow cytometry and hypertonic cryohemolysis tests would allow diagnosing HS with capillary blood samples.

Table.

Group	% of Residual Red Cells			
	Median	Minimum	Maximum	Mean ± SD
Normal controls	63.4	23.9	94.8	58.63 ± 22.38
Hereditary Spherocytosis	8.7	4.0	81.0	19.42 ± 26.49
Non-spherocytic anemias	85.0	60.7	95.1	77.69 ± 14.04

EFFICACY AND HEMATOPOIETIC EFFECT OF DEFERASIROX IN TRANSFUSION-DEPENDENT IRON OVERLOADED CHILDREN IN KOREAN SOCIETY OF PEDIATRIC HEMATOLOGY ONCOLOGY: CICL670AKR04T

D Jeong,[1] J Lee,[1] N Chung,[1] BS Cho,[1] H Im,[2] J Seo,[2] J Park,[3] Y Lim,[4] K Ryu,[5] DG Han,[6] H Kook,[6] TJ Hwang,[6] SC Won,[7] CJ Lyu,[7] H Kang,[8] H Shin,[8] HS Ahn,[8] Y Lim,[9] Y Lee,[9] H Kim[1]

[1]College of Medicine, The Catholic University of Korea, Incheon, South-Korea; [2]Asan Medical Center, Ulsan University, Seoul, South-Korea; [3]Ajou University, Suwon, South-Korea; [4]Pusan National University, Pusan, South-Korea; [5]Ewha Womans University, Seoul, South-Korea; [6]Chonnam National University, Gwangju, South-Korea; [7]Yonsei University, Seoul, South-Korea; [8]Cancer Research Institute, Seoul National University College of Medicine, Seoul, South-Korea; [9]Hanyang University, Seoul, South-Korea

Background and objectives. Deferasirox (DFX) is a once-daily oral iron chelator for patients chronically iron overloaded by repeated red cell transfusion. This study evaluated the safety and efficacy of DFX in transfusion-dependent iron overloaded children with anemia including aplastic anemia. *Methods.* Fifty five patients were treated with once-daily DFX of 20-30 mg/kg for 52 weeks. Hematologic findings, serum ferritin (SF), amount of transfusion, and adverse events (AE) for safety were assessed every 4 weeks. *Results.* Forty three patients completed the study. Eight children withdrew due to skin rash and loss of follow up. In ITT analysis, forty patients were diagnosed with aplastic anemia and fifteen had other anemias requiring transfusion. Initial median SF was 2,553 (1003~13002) ng/mL, and time interval between primary diagnosis and enrolment was 6.2 (0.7~24.7) years. SF in aplastic anemia decreased significantly after 12 weeks of DFX administration, but showed no major change in other forms of transfusion-dependent anemia. Twenty eight patients experienced 58 cases of AE's including gastrointestinal symptoms, elevated liver enzymes, skin rash, and mild proteinuria. All AE's disappeared after interruption of DFX for about 2 weeks. In PP analysis, number of transfusions diminished significantly in all patients after DFX treatment (P=0.05), and there was a tendency for transfusion requirement to decrease in aplastic anemia patients (P=0.08), although such a trend was not observed in other anemia. *Conclusions.* DFX at daily doses of 20-30 mg/kg was well tolerated. The administration of DFX resulted in both effective iron chelation and decreased transfusion requirement in aplastic anemia patients. Dose modification should be considered in other transfusion-dependent anemia except aplastic anemia.

1818

COMBINED CHELATION THERAPY WITH DEFERASIROX AND DEFEROXAMINE IN TRANSFUSION-DEPENDENT PATIENTS WITH THALASSEMIA

V Ladis, P Delaporta, D Kyriakopoulou, A Kattamis

University of Athens, Athens, Greece

Background. Treatment of transfusional iron overload in patients with thalassemia has significantly improved with the use of deferoxamine (DFO), deferiprone (DFP) and deferasirox (DFX). These agents have been mainly used as monotherapy. Combining these drugs is a hopeful regimen, which may increase efficacy and reduce toxicity. So far, only combination of DFO and DFX has been extensively studied and it has been applied in clinical practice. *Aim.* In this report, we review the efficacy and the safety of combination treatment with DFO/DFX in patients with transfusion-dependent thalassemia. *Patients-Methods.* Thirteen patients (mean age 32.5, range 25.3-38.5 years) were treated with DFX (30-35 mg/kg/d) and DFO (35-40 mg/kg 2-5 days/week) for 12 months. The reason for initiation of combination treatment was failure to improve iron overload with previous intensification therapeutic regimen, namely DFO and deferiprone combination therapy and/or use of maximum allowed dose of oral chelating agents. Efficacy of treatment was evaluated by changes in hepatic and cardiac iron overload, as estimated by MRI (T2* sequence) and in ferritin levels. Safety parameters included transaminases, creatinine and cystatin C levels. *Results.* Mean, SD and range of the baseline evaluation showed: ferritin: 4592 ng/mL±1755 (1893-7800 ng/mL), liver iron concentration (LIC): 6.2±10 mg/g d.w. (7.1-42.5 mgFe/g d.w.), cardiac T2*: 29.2 ms (4-40ms), and left ventricular ejection fraction (LVEF): 64.4±6.2 ms (51-72.5%). Five patients had severe hepatic iron overload (LIC>15 mgFe/g d.w.) and two patients severe cardiac siderosis (T2*<10ms). After 1 year of treatment, LIC significantly improved (P=0.023) by a mean change of -3.4 mg/g d.w. (range 8.5 to -9 mgFe/g d.w.), with 9 out of the 13 patients showing any improvement of >20% from baseline LIC value. Ferritin decreased by a mean of 575±2016 ng/mL (P>0.05). There were no significant changes in cardiac T2* and LVEF. Nevertheless, improvement of LVEF to normal range was noted in the 2 patients with baseline LVEF<56%. Treatment was well tolerated and no serious adverse events were noted. Creatinine, cystatine C and transaminases levels did not change during the treatment. Compliance was variable, with many patients not receiving the recommended DFO doses. The main factors which affected efficacy, were compliance and degree of baseline hepatic iron load. *Conclusions.* This series of patients showed that combination treatment of DFO and DFX may improve iron overload without being associated with any significant toxicity. Further studies are required to verify these initial observations.

HIGH PREVALENCE OF IRON DEFICIENCY IN PATIENTS WITH VARIOUS HEMATOLOGICAL AND MALIGNANT DISEASES: A SINGLE CENTER STUDY IN 1989 SEQUENTIAL PATIENTS

H Ludwig,[1] G Endler,[1] W Hübl,[1] B Klement,[2] T Cushway[2]

[1]Wilhelminenspital, Vienna, Austria; [2]Vifor Pharma, Glattbrugg, Switzerland

Background. Iron is essential for the function of oxygen-binding molecules and plays a critical role in many metabolic pathways. Even with adequate storage iron, a restricted iron supply may result in functional iron deficiency with the potential for iron-restricted erythropoiesis and consequently anemia and impaired quality of life (QoL). This has been associated with prolonged intensive care stay, increased time in hospital and longer systemic inflammatory response syndrome, fatigue and exercise intolerance. Repletion of iron in patients with iron deficiency (ID) improves QoL and symptoms, including cognitive and exercise performance. Data on essential parameters of iron metabolism have not been reported in large number of unselected patients with cancer

as yet. *Aims.* To evaluate the prevalence of iron deficiency (ID), absolute iron deficiency (AID) and functional iron deficiency (FID) in a large cohort of patients having transferrin saturation (TSAT) and serum ferritin levels available with an additional focus on a sub-population of multiple myeloma (MM) patients. *Methods.* Data from 1989 patients (median age: 69 years, range: 8-105 years) presenting sequentially at the Center for Oncology and Hematology, Wilhelminenspital, Vienna between October 01, 2009 and January 26, 2010, have retrospectively been collected. Patients presented at different stages of their disease or even may not have had established diagnosis at the time of testing. In patients with multiple testing during this period only the first sample taken has been included. TSAT (available in all patients), serum ferritin (available in 1310 patients), serum iron, CRP, complete blood count, and other blood chemistry parameters have been determined using standard techniques. Commonly used definitions for ID (TSAT <20%), AID (TSAT <20% and serum ferritin <30 ng/mL) and for FID (TSAT <20% and serum ferritin ≥ 100 ng/mL) have been applied. *Results.* In the entire cohort of 1989 patients, iron deficiency was found in 870 (44%) and ID with anemia as defined by hemoglobin <12g/dL, in 420 (21%) patients. Cochran-Armitage trend test detected a trend for TSAT<20% across age groupings from 30-60 to >80 years (P<0.05). ID with anemia was found in 17% (103/612) of the patients 60 years of age or younger and increased significantly to 32% (118/365) in patients older than 80 years of age (P<0.0001). In the subgroup of 1310 patients with TSAT, serum ferritin and Hb available, ID was observed in 613 (47%), AID in 124 (9%), and AID with anemia in 72 (5%) of patients, respectively. FID was seen in 321 (25%) and FID with anemia in 176 (13%). For the myeloma subgroup a similar pattern was observed (Table 1). *Conclusions.* The results of this single center study show a high prevalence of ID and of FID in patients with various hematological and malignant diseases. The incidence of ID with and without anemia significantly increased with age. Inflammatory cytokines most likely account for the high ferritin values and the impaired availability of iron, diminished erythropoiesis and anemia. Whether parenteral iron supplementation will overcome the FID and improve the sequels of anemia in cancer patients should be investigated in prospective studies.

Table 1. Iron parameters and hemoglobin in patients studied.

	Sub group	TSAT<20% n (%)	TSAT<20% + Hb<12g/dL n (%)
All patients n=1989	**All, n=1989**	**870 (44%)**	**420 (21%)**
	Age <30, n=46 (2%)	26 (57%)	11 (24%)
	Age 30-60, n=566 (28%)	246 (43%)	92 (16%)
	Age 61-70, n=574 (29%)	212 (37%)	104 (18%)
	Age 71-80, n=438 (22%)	197 (45%)	95 (22%)
	Age >80, n=365 (18%)	189 (52%)	118 (32%)
TSAT and ferritin (ng/mL) available n=1310	**Any ferritin level**	**613 (47%)**	**323 (25%)**
	ferritin <30	124 (9%)	72 (5%)
	ferritin 30-100	168 (13%)	75 (6%)
	ferritin ≥100	321 (25%)	176 (13%)

TMPRSS6 GENE - TWO NEW NONSENSE MUTATIONS ASSOCIATED WITH IRIDA

MJ Palare,[1] A Ferrão,[1] L Relvas,[2] C Bento,[2] A Morais[1]

[1]Hospital Santa Maria, Lisbon, Portugal; [2]Hospital Pediatrico Coimbra, Coimbra, Portugal

TMPRSS6 gene encodes a transmembrane serine protease expressed by the liver. *Iron.* Refractory Iron Deficiency Anemia (IRIDA) has shown to be caused by mutations in the gene TMPRSS6. IRIDA is an autossomal recessive disorder characterized by iron deficiency anemia unresponsive to oral iron treatment but partially responsive to parenteral iron therapy. IRIDA patients show high levels of hepcidin, a circulating hormone produced by the liver that inhibits both iron absortion from the intestine and iron release from macrophages stores. TMPRSS6 gene down regulate hepcidin expression by the liver. *Aim.* Report two cases of IRIDA with new mutations in TMPRSS6 gene. *Methods.* Molecular studies were performed in genomic DNA extracted from peripheral blood leucocytes and mutations in HBA, HBB and TMPRSS6 gene investigated by direct sequencing. *Results.* Case 1 - A 5 year-old boy with Hb - 7.9 g/dL, VGM - 53,9 fL, ferritin - 45,5 ng/mL, normal hemoglobin electrophoresis, non-invasive screening methods to gastrointestinal tract - negative, refractory to oral iron treatment. Sequencing of the alpha and beta globin genes was normal. Sequencing of the TMPRSS6 gene with a direct and a reverse primer revealed a CD603 GGG-AGG in homozigoty. Both parents presenting normal haematological parameters, are carriers of this mutation. Case 2 - A 5 year-old girl with microcitic anemia (Hb -10,3 g/dL, VGM -70,1 fL), ferritin - 19,6 ng/mL, normal hemoglobin electrophoresis, refractory to oral iron treatment. Sequencing of the alpha and beta globin genes was normal. Sequencing of the TMPRSS6 gene with a direct and a reverse primer revealed heterozigoty for a CD521 GAC-AAT mutation. No other mutation was found in the TMPRSS6. Her mother is also a carrier of the CD521 GAC-AAT mutation and her father is normal. *Conclusion.* We report two cases of non thalassemic hypochromic microcytic anemia, caused by inherited mutations in TMPRSS6 gene. These are two new nonsense mutations in TMPRSS6 gene not described on literature yet. In the first case the mutation, CD603 GGG-AGG, was found in homozygozity, in agreement with the fact that IRIDA due to TMPRSS6 mutations is a recessive disorder. In the second case only one mutation in the TMPRSS6 was found, not enough to justify the phenotype, further studies must be done to look for an association between this mutation and other genes mutations, like DMT1.

A T2* MRI PROSPECTIVE SURVEY ON HEART AND LIVER IRON IN THALASSEMIA MAJOR PATIENTS TREATED WITH SEQUENTIAL DEFERIPRONE-DESFERRIOXAMINE VERSUS DEFERIPRON AND DESFERRIOXAMINE IN MONOTHERAPY

A Pepe,[1] G Rossi,[2] A Meloni,[1] MC Dell'Amico,[1] L Prossomariti,[3] D D'Ascola,[4] A Filosa,[5] P Pepe,[2] V Positano,[1] C Ascioti,[6] M Lombardi,[1] M Capra[7]

[1]Fondazione G.Monasterio CNR-Regione Toscana and Institute of Clinical Physiology, Pisa, Italy; [2]Institute of Clinical Physiology of CNR, Epidemiology and Biostatistics Unit, Pisa, Italy; [3]Unità Microcitemia, A.O.R.N. Cardarelli, Napoli, Italy; [4]UO Microcitemie, AO Bianchi-Melacrino-Morelli, Reggio Calabria, Italy; [5]UOC Pediatria - DH Talassemia - AORN A. Cardarelli, Napoli, Italy; [6]Struttura Complessa di Cardioradiologia-UTIC P.O. Giovanni Paolo II, Lamezia Terme (CZ), Italy; [7]P.O. G. Di Cristina, ARNAS Civico, Palermo, Italy

Background. Most deaths in thalassemia major (TM) result from cardiac complications due to iron overload. No data are available in literature about possible different changes in cardiac and liver iron in TM patients treated with sequential deferipron-deferoxamine (DFP-DFO) *vs.* deferipron (DFP) and deferoxamine (DFO) in monotherapy. Magnetic Resonance (MR) is the unique non invasive suitable technique to evaluate quantitatively this issue. *Aims.* The aim of this multi-centre study was to assess prospectively in the clinical practice the efficacy of the DFP-DFO *vs.* DFP and DFO in monotherapy in a cohort of TM patients by quantitative MR. *Methods.* Among the first 739 TM patients enrolled in the MIOT (Myocardial Iron Overload in Thalassemia) network, 253 patients performed a MR follow up study at 18±3 months according to the protocol. We evaluated prospectively the 25 patients treated with DFP-DFO *vs.* the 30 patients treated with DFP and the 66 patients treated with DFO between the 2 MR scans. Myocardial and liver iron concentrations were measured by T2* multislice multiecho technique. *Results.* The doses of the sequential treatment were DFP 70±14 mg/kg/d for 4 d/w and DFO 42±8 mg/kg/d for 3 d/w, the dose of DFP was 73±16 mg/kg/d, DFO was 41±7 mg/kg/d for 5.5 d/w. Excellent/good levels of compliance were similar in the 3 groups (DFP-DFO 96% *vs.* DFP 97% *vs.* DFO 92%; P=0.67). Among the patients with no significant myocardial iron overload at baseline (global heart T2* ≥ 20 ms), there were no significant differences between groups to maintain the patients without myocardial iron overload (DFP-DFO 95% *vs.* DFP 100% *vs.* DFO 100%; P=0.23). Among the patients with myocardial iron overload at baseline (global heart T2* <20 ms), only DFP and DFO showed a significant improvement in the global heart T2* value (P=0.001 and P=0.003, respectively) and in the number of segment with a normal T2* value (P=0.031 and P=0.0001, respectively). The improvement in the global heart T2* was significantly different among groups (mean difference global heart T2* DFP-DFO 2.2±4.1 ms, DFP

10.7±7.2, DFO 3.6±5.4; P=0.007). The improvement in the global heart T2* was significantly lower in the DFP-DFO *vs.* DFP group (P=0.014), but it was not significantly different in the DFP-DFO *vs.* the DFO group (P=0.63) (see the Figure). In patients with liver iron overload at baseline (liver T2* <5.1 ms), the change in the liver T2* was not significantly different among groups (mean difference liver T2* DFP-DFO 0.9±2.1 ms, DFP 2.3±5.8, DFO 2.9±4.9; P=0.58). *Conclusions.* prospectively in a clinical setting over 15 months we did not find significant differences on cardiac and liver iron in TM patients treated with sequential DFP-DFO *vs.* the TM patients treated with DFO. Conversely, DFP monotherapy was significantly more effective than DFP-DFO in improving myocardial siderosis.

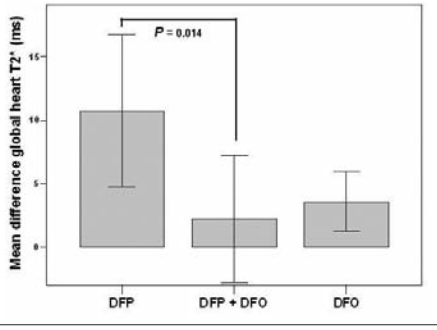

Figure.

G. Di Cristina, ARNAS Civico, Palermo, Italy; [5]UOC Pediatria - DH Talassemia - AORN A. Cardarelli, Napoli, Italy; [6]Ospedale Sant'Eugenio Papa - Centro Talassemie, Roma, Italy; [7]Catholic University of the Sacred Heart, Department of Radiology, Campobasso, Italy; [8]University of Ferrara, Department of Clinical and Experimental Medicine, Ferrara, Italy

Background. Most deaths in thalassemia major (TM) result from cardiac complications due to iron overload. No data are available in literature about possible different changes in cardiac and liver iron in TM patients treated with sequential deferipron-deferoxamine (DFP-DFO) *vs.* deferasirox (DFX). Magnetic Resonance (MR) is the unique non invasive suitable technique to evaluated quantitatively this issue. *Aims.* The aim of this multi-centre study was to assess prospectively in the clinical practice the efficacy of the DFP-DFO *vs.* DFX in a cohort of TM patients by quantitative MR. *Methods.* Among the first 739 TM patients enrolled in the MIOT (Myocardial Iron Overload in Thalassemia) network, 253 patients performed a MR follow up study at 18±3 months according to the protocol. We evaluated prospectively the 25 patients treated with DFP-DFO *vs.* the 44 patients treated with DFX between the 2 MR scans. Myocardial and liver iron concentrations were measured by T2* multislice multiecho technique. *Results.* The doses of the sequential treatment were DFP 70±14 mg/kg/d for 4 d/w and DFO 42±8 mg/kg/d for 3 d/w, the dose of DFX was 26±6 mg/kg/d. Excellent/good levels of compliance were similar in the 2 groups (DFP-DFO 96% *vs.* DFX 100%; P=0.36). At baseline the 2 groups were homogeneous for cardiac and liver iron. Among the patients with no significant myocardial iron overload at baseline (global heart T2* ≥ 20 ms), there were no significant differences between groups to maintain the patients without myocardial iron overload (DFP-DFO 95% *vs.* DFX 96%; P=1.0). Among the patients with myocardial iron overload at baseline (global heart T2* <20 ms), only in the DFX group there was a significant improvement in the global heart T2* value (11±5 ms at baseline *vs.* 16±8 at 18±3 months, P=0.0001) and in the number of segment with a normal T2* value (P=0.003). The improvement in the global heart T2* was not significantly difference in the DFP-DFO *vs.* the DFX group (mean difference global heart T2* 2.2±4.1 ms *vs.* 4.6±4.8 P=0.2). The changes in the mean serum ferritin level were not significantly different between groups. In patients with liver iron overload at baseline (liver T2* <5.1 ms), the change in the liver T2* was not significant between groups (mean difference liver T2* 0.9±2.1 ms *vs.* 2.4±5.2; P=0.3). *Conclusions.* Prospectively in the clinical setting over 15 months we did not find significant differences on cardiac and liver iron by quantitative MRI in TM patients treated with sequential DFP-DFO *vs.* the TM patients treated with DFX.

1823

EFFICACY AND SAFETY OF DEFERASIROX IN PATIENTS WITH BASELINE LIVER IRON CONCENTRATION (LIC) <7 OR =7 MG FE/G DW: RESULTS OF EPIC LIVER MAGNETIC RESONANCE IMAGING (MRI) SUBSTUDY

J Porter,[1] M Elalfy,[2] Y Aydinok,[3] LL Chan,[4] SH Lee,[5] P Sutcharitchan,[6] A Taher,[7] D Habr,[8] B Roubert,[9] A El-Beshlawy[10]

[1]University College London, London, UK; [2]Ain Shams University, Cairo, Egypt; [3]Ege University Medical Faculty, Izmir, Turkey; [4]University Malaya Medical Centre, Kuala Lumpur, Malaysia; [5]St George Hospital, Sydney, Australia; [6]Chulalongkorn University and King Chulalongkorn Memorial Hospital, Bangkok, Thailand; [7]American University of Beirut, Beirut, Lebanon; [8]Novartis Pharmaceuticals, East Hanover, NJ, USA; [9]Novartis Pharma AG, Basel, Switzerland; [10]Cairo University, Cairo, Egypt

Background. Patients enrolled in previous deferasirox studies were heavily iron-overloaded, therefore data are limited in those with low iron burden receiving ≥20 mg/kg/day. In the overall EPIC study, although deferasirox efficacy was primarily monitored using serum ferritin (SF), a substudy explored the potential role of non-invasive LIC measurement by R2-MRI. This analysis evaluates deferasirox in less *vs.* more heavily iron-overloaded patients (baseline LIC <7 *vs.* ≥7 mg Fe/g dw). *Aims.* To evaluate the efficacy and safety of deferasirox for maintaining LIC in patients with baseline LIC <7 and for reducing LIC in patients with baseline LIC ≥7. *Methods.* Patients eligible for EPIC and enrolled at selected centres involved in the MRI substudy were invited to participate; separate informed consent forms were provided. Patients were transfusion-dependent, aged ≥2 years with SF ≥1000ng/mL, or <1000 with a history of multiple transfusions (>20 transfusions or >100 mL/kg RBCs), and MRI-confirmed LIC >2. Deferasirox starting dose was 10-30 mg/kg/day depending on blood transfusion frequency; appropriate dose adjustments (range 0-40) were performed every 3 months. Efficacy was based on LIC/SF changes after 1 year; safety assessments included adverse event (AE) and laboratory parameter monitoring. *Results.* 374 patients were included, 71 and 303 with baseline LIC <7 and ≥7, respectively; baseline characteristics were generally comparable. Most patients had β-thalassaemia (81.7% and 85.5%); in each underlying anaemia >70% had baseline LIC ≥7. Most patients were previously chelated (84.5% and 92.4%), primarily with deferoxamine (70.7%) or deferoxamine-deferiprone (28.4%). During the study, mean actual deferasirox doses were 20.7±5.4 and 27.1±7.1mg/kg/day in LIC <7 and ≥7 cohorts, respectively. In line with therapeutic goals, mean LIC was maintained around baseline in LIC <7 cohort, and decreased significantly in LIC ≥7 (Figure).

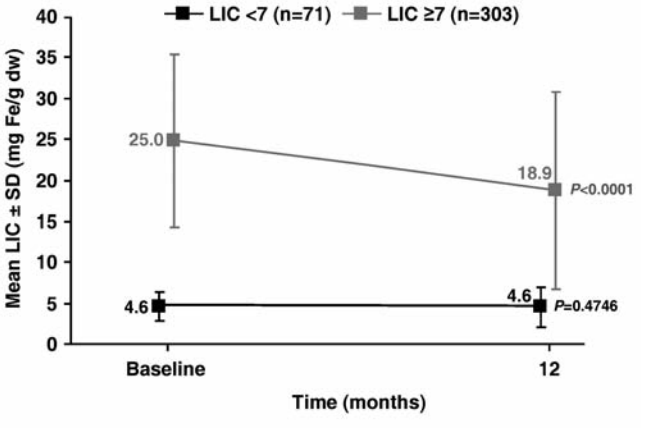

Figure. Absolute LIC during deferasirox treatment, by baseline LIC cohort.

Similar response was observed with median SF: 1479 to 1467 ng/mL in LIC <7 cohort (change -57), 4139 to 3176 ng/mL in LIC ≥7 cohort (change -830; P<0.0001). Sixty-three (88.7%) and 274 (90.4%) patients

completed 1 year. Three patients in LIC ≥7 cohort died (sepsis, n=2; pneumonia, n=1); none were considered drug-related. The most common investigator-assessed drug-related AEs were gastrointestinal, occurring more frequently in LIC <7 than ≥7 cohort (39.4% *vs.* 20.8%; P=0.001): diarrhoea (25.4% *vs.* 10.2%), abdominal pain (12.7% *vs.* 4.0%), upper abdominal pain (9.9% *vs.* 4.3%), constipation (9.9% *vs.* 3.0%). Most were mild/moderate and rarely led to dose decrease/discontinuation. Seven drug-related serious AEs were reported in LIC ≥7 cohort. Comparable proportions of patients had serum creatinine increases >33% above baseline and upper limit of normal (ULN; 7.0% *vs.* 5.3%) and alanine aminotransferase increases >10×ULN (1.4% *vs.* 0.7%). *Conclusions.* As per therapeutic objectives, a deferasirox dose of 20mg/kg/day maintained LIC/SF in patients with baseline LIC<7, whereas patients with LIC≥7 experienced significant reductions at a mean dose of 27mg/kg/day, confirming that iron balance is dose-related. Patients in LIC <7 cohort experienced more drug-related gastrointestinal AEs than LIC ≥7 cohort; neither age, underlying anaemia, nor deferasirox doses seemed to influence the differing frequencies, therefore it can be hypothesized that this may be related to lower iron burden in LIC <7 cohort.

1824

ANALYSIS OF TWO DIFFERENT SCHEMES OF IRON TREATMENT TO IMPROVE POSTOPERATIVE ANEMIA IN CARDIAC SURGERY. A RANDOMIZED, DOUBLE-DISGUISED, TRIPLE-BLIND STUDY

J Raya, P Garrido, J Raya, P Pecos, R Martínez, I Nassar, R De La Llana, M Mataró, L González-del-Castillo, I Rodriguez, P Rodríguez, P Machado

Hospital Universitario de Canarias, La Laguna, Spain

Background. Anemia and increased transfusion requirements are common postoperative problems in cardiac surgery with cardiopulmonary bypass (CS-CPB). Several strategies have been designed and, although oral administration is the conventional route, intravenous (i.v.) iron has emerged as a safe and effective alternative for perioperative anemia management. *Aims.* To evaluate the efficacy and the impact of two different schemes of iron therapy on several clinical and analytical aspects in patients undergoing CS-CPB. *Methods.* We performed a prospective double-disguised triple-blind study in 159 patients (116 men, 43 women; mean age 65) undergoing elective CS-CPB. The patients were randomised in 3 groups: Group I (n=54) treated with i.v. iron sucrose, 100 mg/24 hours x3, pre- and postoperative and oral placebo (1 pill/24 h.) during the first month after discharge; Group II (n=53) receiving oral iron ferrous sulphate (80 mg/24 h.) pre- and postoperatively and up to one month after discharge, and an i.v. placebo while hospitalized; Group III (n=52) received an oral and i.v. placebo, both pre- and postoperatively. All groups were homogenous with respect to preoperative analytical data, demographic variables, comorbid conditions, surgical procedures and operative risk. Clinical and analytical variables were collected at different moments: preoperatively, operation room, Intensive Care Unit (ICU) admission and discharge, hospital discharge and one month after surgery. Comparisons were made to investigate if there was a difference in haemoglobin and hematocrit values, blood consumption, and median ICU and hospital length of stay. *Results.* We did not find significant differences between the haemoglobin and the hematocrit values at postoperative period or at 1 month after discharge between the 3 groups, but the highest values of serum ferritin and reticulocyte count were encountered in group I (P=0,002). Patients from group I also have: 1) A shorter postoperative stay (G-I 6.1 days, G-II 8.4, G-III 7.7), although the difference is not significant (P=0.169); 2) A shorter total hospitalization time (G-I 17.6 days, G-II 22.8, G-III 21.4) (P=0.07); 3) A slightly shorter ICU stay (G-I 3.7 days, G-II 4.5, G-III 5.3); 4) A decreased requirements of amines at ICU (G-I 65% did not need amines, G-II 43%, G-III 48%) (P=0.06); 5) A lower need of red blood cell transfusions (G-I mean 1.1 units, G-II 2.1, G-III 1.6). Globally, 63% of the patients in group I did not need blood transfusions (49% in group II and 50% in the placebo group). We also observed that the greater the consumption of blood the longer the stay at the ICU (P=0.001). Patients under 75 years in group I needed less transfusions at ICU when compared with placebo group (P=0,033). *Conclusions.* Intravenous iron achieves a significant elevation in ferritin and reticulocyte count at hospital discharge and 1 month after CS-CPB, but not in hemoglobin and hematocrit values, meaning that perhaps there is no clinical improvement in terms of correction of anemia. A trend toward shorter ICU stay, shorter postoperative stay, and shorter total time of hospitalization, is observed in patients treated with i.v. iron, as well as a lower consumption of blood transfusions.

1825

CELL-FREE DNA (CFDNA) AND INEFFECTIVE ERYTHROPOIESIS IN THALASSEMIA INTERMEDIA

M Sampietro, D Tavazzi, C Cesaretti, I Nava, L Duca, M Cappellini

University of Milano, Milano, Italy

Background. Low concentrations (~ 30 ng or 5000 genome equivalents/mL) of cfDNA are found in the plasma of healthy individuals and increase in a number of conditions including cancer, chronic inflammation and trauma. The mechanisms of release of cfDNA in the blood are not well understood: DNA could originate from cells undergoing apoptosis/necrosis in tissues or from cells released in the blood and subsequently lysed. Also the tissue origin of cfDNA is unclear. It has been suggested that cfDNA, at least after bone-marrow transplantation, could be mostly hematopoietic in origin. This finding prompted us to explore whether cfDNA is increased in patients with ineffective erythropoiesis, a condition characterized by the increased proliferation and destruction of erythroid precursors, which is common in thalassemia. *Aim.* To study the behaviour of cfDNA in ineffective erythropoiesis caused by thalassemia and to assess whether cfDNA could be useful to evaluate the severity of ineffective erythropoiesis. *Methods.* We studied 51 thalassemia-intermedia patients (mean age 41 years, range 16-65), 24 of whom were splenectomized. On the basis of the genotype they were divided into three groups of increasing severity (Group 1: eterozygosis for β-thal.-ααα/αα; Group 2: genotype not included in Groups 1 and 3; Group 3: double eterozygosis or homozygosis for β+-defects). DNA was extracted with a chromatographic procedure from 200 μL of K2EDTA plasma and its concentration determined fluorometrically using the fluorescent dye PicoGreen that specifically binds to double-stranded DNA. In all patients the following parameters were also measured: hemoglobin, reticulocytes, peripheral erythroblasts, LDH, bilirubin, soluble transferrin receptor (sTfR). *Results.* In the 51 patients cfDNA ranged from 6 to 329 ng/mL with a significant difference of the distribution of values across the three groups (P=0,01). The highest mean concentration was observed in Group 3 (53+71 ng/mL) and the lowest in Group 1 (20+13 ng/mL). Comparing patients without and with splenectomy we observed a significant increase of cfDNA in splenectomized patients (22+12 *vs.* 49+63 ng/mL, P=0,001). In splenectomized patients cfDNA concentration was significantly correlated with erythroblasts (rho = 0,58 - P=0,003), LDH (rho = 0,60 - P=0,002), unconjugated bilirubin (rho = 0,52 - P=0,009). No correlation was observed between cfDNA and sTfR. *Conclusions.* Plasma cfDNA is increased in thalassemia intermedia in proportion with the severity of defects, but its concentration does not appear to correlate with the amount of ineffective erythropoiesis but only with the lysis of circulating erythroblasts which increases after splenectomy. It is likely that most erythroblasts undergoing apoptosis are engulfed by bone-marrow and spleen macrophages without releasing significant amounts of double-stranded DNA.

1826

ERYTHROCYTAPHERESIS IS NOT SUPERIOR TO WHOLE BLOOD PHLEBOTOMY IN PATIENTS WITH HEREDITARY HEMOCHROMATOSIS

T Sundic,[1] T Hervig,[2] S Berentsen[3]

[1]Department of Immunology and Transfusion Medicine, Haugesund Hospital, Haugesund, Norway; [2]Department of Immunology and Transfusion Medicine, Haukeland University Hospital, Bergen, Norway; [3]Department of Medicine, Haugesund Hospital, Haugesund, Norway

Background. Hereditary hemochromatosis (HH) may result in severe organ damage which can be prevented by therapy. Treatment with whole blood phlebotomy allows removal of excess iron and maintenance of low normal iron stores. The removed amount of iron may be increased two- or threefold for each procedure by using erythrocytapheresis, implying a reduced number of procedures and, possibly, more rapid achievement of normal iron stores and less use of time. Based on a couple of small, uncontrolled series and two small, randomized trials, some authors have concluded that apheresis is superior to phlebotomy. However, no larger, randomized study has been published. *Aim.* We wanted to study possible advantages and disadvantages of erythrocytapheresis as compared to phlebotomy in patients with HH. We report here the preliminary results. *Methods.*. In a prospective, randomized, open study performed from 2006 through 2009, patients with HH were randomized to bi-weekly apheresis or weekly whole blood phlebotomy. Prolongation of the treatment interval based on clinical assessment was allowed. Informed consent was obtained for all

patients. The minimum ferritin level required for inclusion was 300 microg/L for patients who were homozygous for the C282Y or H63D mutation, or compound heterozygous, while heterozygous individuals were eligible if ferritin was > 500 microg/L. Primary endpoints were decline of ferritin levels and transferrin saturation. Secondary endpoints were decline in hemoglobin levels, discomfort during the therapeutic procedure, and technician working time. *Results.* 67 patients were included, 9 women and 58 men, with a median transferrin saturation of 65% and median ferritin level 586 microg/L. 38 patients were homozygous for C282Y, 4 homozygous for H63D, 20 compound heterozygous and 5 heterozygous for C282Y. 33 patients were randomized to apheresis and 34 to phlebotomy. Ferritin levels < 100 microg/L were reached after a median number of 5 procedures in the apheresis group and 8 in the phlebotomy group, corresponding to 63 days in both groups. During this time, the median decline in ferritin levels was 497 microg/L (82% of baseline) in the apheresis group *vs.* 414 microg/L (74% of baseline) in the phlebotomy group; median decline in transferrin saturation, 30% (46% of baseline) *vs.* 33% (53% of baseline). Significant discomfort during or after the procedure was experienced at some time by 7 patients treated with apheresis and 6 of those treated with phlebotomy. None of these differences was statistically significant, and we observed no difference in decrease in hemoglobin levels. The mean sum of technician time consumption during the initial 63 day period was 286 minutes in the apheresis group *vs.* 238 in the phlebotomy group (P<0.001). *Conclusion.* We observed no significant differences in the rate of relative decline in ferritin levels, decline in transferring saturation, subjective discomfort or decrease in hemoglobin levels. The total technician time consumption was significantly higher in the apheresis group. In summary, we did not find any advantages of erythrocytapheresis as compared to conventional phlebotomy in the treatment of HH.

FACTORS ASSOCIATED WITH IRON ACCUMULATION IN NON-TRANSFUSION-DEPENDENT THALASSAEMIA SYNDROMES: BASELINE DATA FROM MULTICENTER INTERNATIONAL DEFERASIROX STUDY (THALASSA)

A Taher,[1] V Viprakasit,[2] J Porter,[3] A Kattamis,[4] T Lawniczek,[5] R Pereno,[5] O Schoenborn-Kellenberger,[5] MD Cappellini[6]

[1]American University of Beirut Medical Center, Beirut, Lebanon; [2]Department of Pediatrics, Siriraj Hospital, Mahidol University, Bangkoknoi, Bangkok, Thailand; [3]University College London, London, UK; [4]First Department of Pediatrics, University of Athens, Athens, Greece; [5]Novartis Pharma AG, Basel, Switzerland; [6]Universitá di Milano, Policlinico Foundation IRCCS, Milan, Italy

Background. Patients with genetically heterogeneous forms of thalassaemia, including β-thalassaemia intermedia (β-TI), HbE β-thalassaemia (HbE/β-T) and HbH disease, may not require transfusion therapy or receive only intermittent transfusions. However, recent studies have shown that iron overload still occurs due to increased gastrointestinal absorption of iron secondary to ineffective erythropoiesis, leading to the same clinical consequences as from repeated transfusions including liver, cardiac and endocrine dysfunction. Despite availability of effective iron chelation therapy (ICT), evidence suggests that monitoring and management of iron overload in non-transfusion-dependent thalassaemia (NTDT) patients is less rigorous than in thalassaemia major and other chronic anaemia patients and clinical studies are limited. A prospective, randomized, double-blind, placebo-controlled Phase II study, 'THALASSA,' evaluating the efficacy and safety of deferasirox in patients with NTDT is ongoing and will be the first large study evaluating ICT in these patients. *Aims.* To assess baseline characteristics, including iron parameters of NTDT patients from the THALASSA study. Additionally, a comparative analysis of baseline iron status and factors associated with iron accumulation in two predominating NTDT syndromes are presented. *Methods.* NTDT patients aged ≥10 years with liver iron concentration (LIC) ≥5 mg Fe/g dry weight (dw) [measured by R2 magnetic resonance imaging], and serum ferritin (SF) >300 ng/mL, are randomized 2:1/2:1 to starting doses of deferasirox 5 mg/kg/day:matching placebo/deferasirox 10 mg/kg/day:matching placebo over a planned 12-month period. Doses can be doubled after 6 months of treatment as required depending on LIC and change in LIC. Key exclusion criteria include: anticipated regular transfusions during the study (sporadic transfusions, as due to infection, permitted); any transfusion within 6 months or chelation therapy within 1 month prior to study start; HbS variants of thalassaemia; impaired renal and liver function. Primary efficacy endpoint is absolute change in LIC from baseline to 12 months. Safety assessments include adverse event and laboratory parameter monitoring. 156 patients are planned for inclusion. *Results.* As of January 2010, 92 patients have been randomized; baseline data are shown (Table). Forty-four (47.8%) patients were splenectomized; mean LIC was similar in splenectomized and non-splenectomized patients (16.8 *vs.* 15.2 mg Fe/g dw); although there were more splenectomized patients with LIC >15 mg Fe/g dw (47.7% *vs.* 39.6%). Mean SF was higher in splenectomized patients (1666 *vs.* 1032 ng/mL) and more splenectomized patients had SF >2500 ng/mL (15.9% *vs.* 2.1%). Patients with β-TI compared with HbE/β-T were older (mean 34.0 *vs.* 28.2 years), had received more blood transfusions prior to the study (median 9 *vs.* 6), and included more transfusion-naïve (20.0% *vs.* 2.8%) and splenectomized (75.0% *vs.* 33.3%) patients. Nevertheless, β-TI compared with HbE/β-T patients had lower SF (mean 1224 *vs.* 1546 ng/mL) and LIC (mean 14.6 *vs.* 17.5 mg Fe/g dw). *Conclusions.* Similar to transfusion-dependent thalassaemia patients, NTDT patients also develop iron overload shown by increased SF and LIC. The iron overload markers, SF and LIC were affected by splenectomy and underlying disease, respectively. This ongoing study will generate prospective efficacy and safety data for deferasirox in NTDT patients and may delineate pathophysiological mechanisms associated with iron overload.

Table.

Variables	Patients randomized, n=92
Disease, n (%)	
β-thalassaemia intermedia	40 (43.5)
α-thalassaemia disease	9 (9.8)
HbE/β-thalassaemia	36 (39.1)

EVALUATION OF ANTIOXIDANT SYSTEMS IN HEALTHY CHILDREN RECEIVING PROPHYLACTIC IRON THERAPY

D Hacihamdioglu, AE Kurekci, O Gursel, A Atay, N Balamtekin, O Ozcan

Gulhane Military Medical Academy, Ankara, Turkey

Background. Iron is essential to many biochemical processes such as electron transfer reactions. It is recommended for supplementation of all children of certain ages in populations with a high prevalence of anemia. It has long been suspected that free radicals may play a role in iron induced cell toxicity because of the powerful pro-oxidant action of iron *in vitro*. Iron supplementation may result in the generation of free radicals and increase oxidative damage to DNA, proteins and lipids. *Aims.* The objective of this study was to investigate potential effects of iron supplementation at 4 month of age, for 2 months, on intraerythrocytic antioxidant enzymes. *Methods.* Four-month-old healthy infants who were born term and fed exclusively breast-milk were included in the study. None of the infants received iron supplementation previously and did not have either iron deficiency or iron deficiency anemia according to complete blood count and ferritin measurement. Twenty-six infants (14 male and 12 female) chosen randomly and not given iron supplementation constituted Group 1 (control group) and twenty-seven infants (16 male and 11 female) chosen randomly and given iron supplementation in the form of ferrous sulfate at a dose of 10 mg/d constituted Group 2. Weight, length, head circumference, complete blood count, serum ferritin level and intraerythrocytic zinc, iron, copper, catalase, malondialdehyde, superoxide dismutase and glutathione peroxidase levels were measured in the infants in both groups at 4 and 6 months of age. The study was approved by the local ethics committee. *Results.* There were no statistically significant differences for RBC, Hb, MCHC, Platelet, WBC and ferritin levels between the two groups at 4 month. After iron supplementation, RBC, Hb, RDW and ferritin levels of group 2 were higher than group 1 (P<0.05). Compared with control at 6 months of age no significant differences were observed for intraerythrocyte zinc, iron, copper, catalase, malondialdehyde, superoxide dismutase and glutathione peroxidase levels. *Conclusion.* Our study showed that the use of 10 mg/d of supplemental iron during 2 months in healthy iron-replete infants did not affect antioxidant status.

1829

EVALUATION OF UPPER AND LOWER RESPIRATORY FUNCTION IN PATIENTS WITH BETA-THALASSEMIA MAJOR

E Bourli,[1] M Economou,[1] V Aivazis,[1] E Maratou,[1] V Perifanis,[1] A Christoforides,[1] I Tsatra,[1] I Stanopoulos,[2] P Argyropoulou-Pataka[2]

[1]Hippokration General Hospital, Thessaloniki, Greece; [2]Papanikolaou Hospital, Thessaloniki, Greece

Introduction. Life expectancy has greatly improved in patients with beta-thalassemia major (TM) due to regular transfusions and chelation therapy, however, complications still prevail. Hypoxia, hypercoagualability, iron overload and drug toxicity are factors attributing to multi-organ damage. Although impairment of lung function has been reported in thalassemic patients, possible involvement of the upper respiratory tract has not been evaluated. Aim. The aim of the study was to evaluate upper and as well as lower respiratory system function in patients with TM. *Patients and methods.* Fifty-two patients (25 males and 27 females), aged 9-34 years (mean age 21.3±6,2 years), were included in the study. All patients were receiving regular transfusions and chelation therapy. Patients with asthma, allergic rhinitis, pulmonary or cardiac disease and smokers were excluded from the study. Itn the study group mean pre-transfusion hemoglobin was 9,4±0,6 g/dL and mean serum feritin (as measured in the year prior of the study) was 1680.4±1404.1 ng/mL. All patients were measured for Peak Nasal Inspiratory Flow Rate (PNIFR) and Peak Inspiratory Flow Rate (PIFR) using Youlten rhinomanometer. The mucociliary clearance of the respiratory epithelium was measured using colour inert test (Edicol Orange 3% + CaHPO42H2O 97%). All patients underwent pulmonary function tests (PFTs) using an electronic spirometer. The diffusing capacity of the lungs was evaluated according to the value of the single breath carbon monoxide transfer factor (DLCO). This value was adjusted for the post-transfusional Hb (DLCO*). PNIFR, PIFR and the parameters of PFTs were measured and evaluated according to values matched for age, sex and anthropometric status. For PNIFR and PIFR a z-score was calculated. *Results.* Mean PNIFR was 175.56±33.8 l/min (z-score -1.56±1.21) and mean PIFR 258.3±43.95 l/min (z-score 0.59±1.06). Mean mucociliary clearance was 24.2±12.1min. In the study group 30/52 (57.7%) patients presented with normal PFTs, while 20/52 (38.46%) with restrictive pulmonary disease and a minority of 2/52 (3.84%) with obstructive disease. The diffusing capacity (DLCO* %) was decreased in 31/50 (62%) of the patients (mean=76.286 ±16.05). *Conclusions.* The study indicates that patients with TM do not demonstrate upper respiratory tract involvement. A restrictive type of pulmonary dysfunction and a decreased diffusing lung capacity are the predominant abnormalities, even in patients who in their majority are properly transfused and well-chelated.

1830

RETROSPECTIVE ANALYSIS OF IRON OVERLOAD IN PATIENTS WITH TRANSFUSION-DEPENDENT MYELODYSPLASTIC SYNDROME AND APLASTIC ANEMIA AND PROGNOSTIC VALUE OF IRON OVERLOAD STAGING SYSTEM

T Ito,[1] H Tsurumi,[2] Y Ozawa,[3] T Uchida,[4] A Tomita,[5] N Emi,[6] A Hanamura,[7] K Ohbayashi,[8] T Ohno,[9] A Khono,[10] E Nagura,[11] H Toyozumi,[12] H Iida,[13] T Naoe[14]

[1]Anjyo Kosei Hospital, Anjyo, Japan; [2]Gifu university, Gifu, Japan; [3]Nagoya 1st Red Cross Hospital, Nagoya, Japan; [4]Nagoya Daini Red Cross Hospital, Nagoya, Japan; [5]Nagoya University, Nagoya, Japan; [6]Fujita Hokenn University, Toyoake, Japan; [7]Gifu Prefectural Tajimi Hospital, Tajimi, Japan; [8]Toyota Memorial Hospital, Toyota, Japan; [9]Tosei General Hospital, Seto, Japan; [10]Konan Kosei Hospital, Konan, Japan; [11]Tokoname Municipal Hospital, Tokoname, Japan; [12]Toyohashi Medical Center, Toyohashi, Japan; [13]Meitetsu Hospital, Nagoya, Japan; [14]Department of Hematology/Oncology, Nagoya University Graduate School of Medicine, Nagoya, Japan

Background. Recent retrospective studies showed iron overload is one of the poor prognostic factors in the transfusion-dependent patients of myelodysplastic syndrome (MDS) and aplastic anemia (AA). And recently transfusion-dependency was included as one of the independent prognostic factors of MDS in WPSS. However, iron overload is still to be elucidated especially in the context of organ damage, prognosis and treatment. *Aims.* Iron-mediated organ damage was analyzed in transfusion-dependent patients of MDS/AA and in addition prognostic value of iron overload staging system (Takatoku M *et al.*, Eur J Haematol; 2007) was verified in MDS patients. Methods. MDS/AA patients who had received over 40 units of red blood cell (RBC) during 2007 / 1 and 2009 / 12 were recruited from the thirteen related medical institutes of our district and were analyzed retrospectively. Iron overload staging system is the indication of the level of serum ferritin(SF), that is stage 1 (SF < 1000), stage 2 (2500 < SF > 1000), stage 3 (5000 < SF > 2500) and stage 4(SF > 5000). Results. Of the 167 registered patients 146 were eligible, MDS 96 (RA 64/RARS 2 / RAEB 20 /RAEB-T 2/CMML 2/OL 6), AA 34, MF 12, PRCA 4. The median sum of the transfused RBC was 98.5 units (40-646). 57/146 (39%) patients received iron chelation therapy (ICT). Of the 132 evaluated cases of iron-mediated organ damage, 120 (90.9%) were over 1000 ng/mL of SF level and 70 / 120 (53%) showed iron-mediated organ damage including of hepatic 55 (33.7%), renal 26 (17.8%), glucose metabolism 23 (15.8%), cardiac 20 (13.7%). Cases of iron-mediated organ damage (+/-) were (75/57) and SF were 4090±3099/2244±1498 (P= 0.01). Abnormal elevation of AST / ALT were more frequent in the iron overload stage 4 than in the stage 1 (P<0.05). Total mortality was 45 (30.8%), including infection 17 (37.8%), progression of primary disease 10 (22.2%), cardiac failure 8 (17.8%), but other iron-mediated organ damage were rather rare. Comparing to the iron overload stage 1, the stage 4 of RA / RARS implied poor prognosis, which was compatible to the previous report Malcovati L *et al.*, JCO, 2005) showing iron overload as possible poor prognostic factor in low grade MDS. Conclusions. Most patients of transfusion-dependent MDS/AA showed iron overload, elevation of SF and iron-mediated organ damage. However, iron-mediated organ damage did not deteriorate OS directly. Advanced stage of iron overload correlated with iron-mediated hepatic damage and poor prognosis of low grade MDS. Active ICT was expected to improve the poor prognosis of stage 4 of heavily iron-overloaded patients of RA/RARS. On the basis of this analysis, prospective study is expected to elucidate the detailed mechanism of prognostic effect of Iron overload, and achieve established strategy of ICT.

1831

CORRELATIONS OF SERUM FERRITIN (SF) AND LIVER IRON CONCENTRATION (LIC) BEFORE AND AFTER 1 YEAR OF DEFERASIROX TREATMENT

J Porter,[1] M Elalfy,[2] Y Aydinok,[3] LL Chan,[4] SH Lee,[5] P Sutcharitchan,[6] A Taher,[7] D Habr,[8] B Roubert,[9] A El-Beshlawy[10]

[1]University College London, London, UK; [2]Ain Shams University, Cairo, Egypt; [3]Ege University Medical Faculty, Izmir, Turkey; [4]University Malaya Medical Centre, Kuala Lumpur, Malaysia; [5]St George Hospital, Sydney, Australia; [6]Chulalongkorn University and King Chulalongkorn Memorial Hospital, Bangkok, Thailand; [7]American University of Beirut, Beirut, Lebanon; [8]Novartis Pharmaceuticals, East Hanover, NJ, USA; [9]Novartis Pharma AG, Basel, Switzerland; [10]Cairo University, Cairo, Egypt

Background. LIC measurement by R2 magnetic resonance imaging (MRI) is an established, non-invasive method for assessing iron overload and monitoring chelation therapy. However, serial SF measurement remains the most common clinical approach. While SF broadly correlates with body iron and LIC, this relationship may differ depending on the severity and distribution of iron overload and on the chelator; it is therefore important to understand the relationship between these markers for a particular chelation regimen. This relationship was evaluated before and after 1-year deferasirox treatment in a subgroup of patients enrolled in EPIC. *Aims.* To evaluate the relationship between LIC and SF in transfusion-dependent patients with iron overload. *Methods.* Transfusion-dependent patients aged ≥2 years with SF≥1000 ng/mL, or <1000 with a history of multiple transfusions (>20 transfusions or >100 mL/kg red blood cells) and MRI-confirmed LIC>2 mg Fe/g dw, were enrolled in EPIC. Deferasirox starting dose was 10-30 mg/kg/day depending on blood transfusion frequency; appropriate dose adjustments (range 0-40) were performed every 3 months. LIC (in mg Fe/g dw) and SF (in ng/mL) were assessed at baseline and after 1 year; correlations were evaluated based on the Pearson correlation coefficient. *Results.* Overall, mean LIC and median SF were significantly reduced by 5 and 555, respectively, (P<0.001). For patients with baseline SF<4000, LIC correlated significantly with SF at baseline (r=0.59, P<0.0001); the relationship was weaker for those with baseline SF≥4000 (r=0.19, P=0.02). A similar relationship was noted for patients with baseline LIC<20 (r=0.46, P<0.0001) or ≥20 (r=0.21, P=0.0053). For patients with baseline LIC≥20 and SF≥4000, there was no significant baseline correlation (r=0.06, P=0.54). However, after 1 year of deferasirox the relationship was restored in all high iron burden categories (SF≥4000, r=0.48; LIC≥20, r=0.55; LIC≥20 and SF≥4000, r=0.45;

P<0.0001 for all). Overall, there was a correlation shift so that a given SF (eg 2000) reflected lower LIC after 1 year than at baseline (10 *vs.* 12 for baseline SF<4000; 24.5 *vs.* 29 for SF of 5000 in patients with baseline SF≥4000). The correlation between changes in LIC/SF was strongest at lower baseline LICs (LIC<7, r=0.70, P<0.0001; LIC<20, r=0.50, P<0.001) and baseline SF<4000 (r=0.51, P<0.0001) than at higher baseline LICs (≥20: r=0.29, P=0.0001) or SF (≥4000: r=0.37, P<0.0001). *Conclusions.* Although absolute SF values above 4000 become less reliable for predicting the absolute LIC, SF trends can still be used to monitor LIC changes with deferasirox over wide iron-overload ranges. However, the LIC/SF relationship changes after 1 year of treatment. As shown in previous studies, with SF<4000 most of it is iron-free, deriving from macrophages in a manner proportional to iron stores; at SF>4000, increasing proportions are iron-rich, deriving from damaged hepatocytes. The current results are consistent with this and explain the restoration of LIC/SF correlation after 1 year in patients with initially high SF. The proportionally greater decrease in LIC relative to SF for patients with baseline SF<4000 is consistent with previously observed preferential iron removal by deferasirox from hepatocytes *vs.* macrophages. SF changes may not fully reflect LIC decrements under these conditions.

1832

EFFICACY, PATIENT SATISFACTION AND ADHERENCE TO TREATMENT WITH DEFERASIROX DOSES OF =30 MG/KG/DAY IN PREVIOUSLY CHELATED IRON-OVERLOADED PATIENTS WITH BETA-THALASSAEMIA MAJOR

A Taher,[1] M Elalfy,[2] A El-Beshlawy,[3] D Zhou,[4] LL Chan,[5] CK Li,[6] KH Lin,[7] J Porter,[8] P Sutcharitchan,[9] D Habr,[10] H Lau,[10] B Roubert,[11] MD Cappellini[12]

[1]American University of Beirut Medical Center, Beirut, Lebanon; [2]Ain Shams University, Cairo, Egypt; [3]Cairo University, Cairo, Egypt; [4]The Second Hospital Affiliated to Sun Yat-Sen University, Guangzhou, China; [5]University Malaya Medical Center, Kuala Lumpur, Malaysia; [6]Prince of Wales Hospital, Chinese University of Hong Kong, Hong Kong, Hong Kong; [7]National Taiwan University Hospital, Taipei, Taiwan; [8]University College London, London, UK; [9]Chulalongkorn University and King Chulalongkorn Memorial Hospital, Bangkok, Thailand; [10]Novartis Pharmaceuticals, East Hanover, NJ, USA; [11]Novartis Pharma AG, Basel, Switzerland; [12]Universitá di Milano, Policlinico Foundation IRCCS, Milan, Italy

Background. Patients with β-thalassaemia major (TM) receiving regular blood transfusions frequently have serum ferritin (SF) levels >2500 ng/mL, indicative of high iron burden and potential negative clinical sequelae, despite availability of effective iron chelation therapy (ICT). The large, prospective EPIC trial of the oral iron chelator deferasirox recruited 854 patients with TM who previously received deferoxamine (DFO), deferiprone (DFP), or both. Despite a mean 10.8 years of chelation, median baseline SF was 3139 ng/mL. Previous studies have demonstrated that while deferasirox doses of 20 mg/kg/day maintain SF levels, doses ≥30 mg/kg/day are needed to significantly reduce SF in TM patients with high transfusional iron overload. *Aim.* To evaluate the efficacy of deferasirox ≥30 mg/kg/day in reducing SF in TM patients irrespective of prior ICT and to describe satisfaction with and adherence to higher doses of treatment. *Methods.* Patients with TM (≥2 years) and transfusional iron overload (SF levels ≥1000 ng/mL [or <1000 ng/mL but history of multiple transfusions] and liver iron concentration >2 mg Fe/g dry weight [measured by R2 MRI]) were enrolled. Deferasirox dose was initially based on transfusion requirements, with dose adjustments based on SF trends and safety markers. Patients that were previously chelated with DFO or DFP monotherapy, or both, and received mean actual deferasirox doses ≥30 mg/kg/day over 1 year were included in this analysis. Efficacy was assessed as change in SF at 1 year from baseline. Patients completed a Satisfaction with ICT (SICT) questionnaire to assess satisfaction and adherence. *Results.* 129 previously chelated TM patients received mean actual deferasirox doses ≥30 mg/kg/day over 1 year; 83 (mean age 19.5±8.2 years) received prior monotherapy and 46 (mean age 23.0±7.2 years) received prior DFO-DFP therapy. Mean duration of prior chelation therapy was 11.7±7.7 and 14.5±7.9 years in the prior monotherapy and DFO-DFP patients, respectively. During the study, mean transfusional iron intake was similar for both groups (monotherapy: 0.36±0.17 *vs.* DFO-DFP therapy: 0.34±0.10 mg/kg/day). In the prior monotherapy group (mean deferasirox dose 34.1±3.9 mg/kg/day), median SF decreased from 4885 ng/mL at baseline to 4282 ng/mL after 1 year (Figure a) resulting in a median decrease of 1024 ng/mL (P<0.0001; last-observation-carried-forward [LOCF]). In the prior DFO-DFP group (mean deferasirox dose 33.9±2.2 mg/kg/day), median SF decreased from 5921 to 4327 ng/mL resulting in a median decrease of 886 ng/mL (P=0.0078; LOCF). Satisfaction and adherence data were available from 26 patients. Patients reported increased satisfaction with deferasirox in SICT domains for side effects, acceptance and burden of ICT; a trend in increased satisfaction with perceived effectiveness was noted. Patients also indicated improved persistence and adherence (Figure b). Five patients (3.9%) discontinued therapy, due to cardiac failure, increased transaminases, consent withdrawal, lost to follow-up and protocol violation (all n=1). Most common investigator-assessed drug-related AEs were rash (n=14, 10.9%) and diarrhoea (n=12, 9.3%). *Conclusions.* Deferasirox doses ≥30 mg/kg/day for 1 year led to significant and clinically relevant reductions in SF in these heavily transfused TM patients, irrespective of prior ICT with monotherapy or DFO-DFP therapy. Patient-reported satisfaction and adherence to treatment also improved.

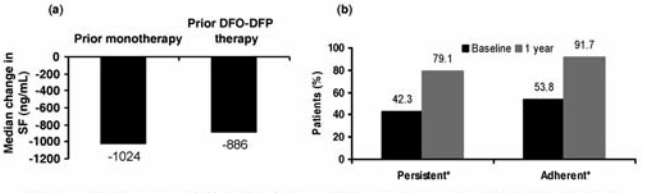

Figure. (a) Median change in SF (ng/mL) over 1 year and (b) patient-reported persistence and adherence in patients who had prior monotherapy or prior DFO-DFP therapy

1833

THE TREATMENT OF REFRACTORY FORM AUTOIMMUNE HEMOLYTIC ANEMIA BY RITUXIMAB

N Tsvetaeva,[1] F Nikulina,[1] M Gretsov,[1] A Garanga,[1] S Ghuravlev,[1] N Khoroshko[2]

[1]Hematology Recearch Crntre, Moscow, Russian Federation; [2]Hematology Recearch Centre, Moscow, Russian Federation

AIHA in 30% are resistant for traditional kind of treatment. We observed 13 patients who had resistant form of AIHA with warm autoantibody and positive direct Coombs test and 2 patients with Evans syndrome. There were 7 men and 8 women, range 19-60 y.o, had from 4 month up to 10 years of previous medical history. All patients were resistant for all kind of therapy: splenectomy for 11 patients, prednisolone, cyclophosphamide, azatioprine. The hemoglobin level during hemolyses reached 45 g/L (35-65 g/L), erythrocyte count was less $1,5\times10^{12}$, reticulocytes were in the range of 3,2% up to 34% , bilirubin level increased up to 2 - 4 times above normal. The therapy began from the high doze of methylprednisolone (500 mg, 3 days). After that Rituximab administered intravenously at a dose 375 mg/m^2, from 2 to 4 consecutive weeks. The patients received Rituximab during 2 consecutive weeks in case if B lymphocytes disappeared from the blood, at the 7 day at the beginning of the treatment. 13 patients achieved complete respond, duration 4-56 month. The first effect was seen in the period from 3 weeks - 2 month (mediana 1,5 month). 4 patients had responded in the period from 2,5 to 4 month. Controlling hemoglobin, reticulocytes, bilirubin and other parameters of hemolytic activity we could prevent the acute hemolytic crises for 7 patients, beginning the next courses of Rituximab, after 4-18 month remission. 5 patients had two courses of Rituximab, 2 patients - 4 courses. All patients had normal immunoglobulin (IgG, IgM) levels after Rituximab. Nobody had any bacterial or viral infections during or after treatment. 2 patients with viral hepatitis C and B hadn't any hepatitis activity after the treatment. *Conclusion.* The Rituximab is more effective in the treatment resistant form AIHA. The patients achieved long time remission. Between courses they didn't received any supportive therapy. Rituximab may be become alternative splenectomy for old patients.

1834

EVALUATION OF 'SILENT STROKE' IN PATIENTS WITH SICKLE CELL DISEASE BY MEASURING PLASMA LEVELS OF THE NEUROPROTEINS NSE, S100A1B-S100BB AND NT-PRO-BNP

D Afordakou,[1] F Apostolakou,[1] I Tavernarakis,[2] N Zoumbos,[2]
I Papassotiriou,[3] A Kouraklis-Symeonidis[2]

[1]Department of Clinical Biochemistry, Aghia Sophia Children's Hospital, Athens, Greece; [2]Thalassemia Unit, Hematology Division, Department of Internal Medicine, Patras, Patras, Greece; [3]Aghia Sophia Children's Hospital, Athens, Greece

Background and aims. Patients with sickle cell disease (SCD), a chronic hemolytic anemia, present with a wide variety of neurological syndromes, including ischemic and hemorrhagic stroke, transient ischemic attacks, 'soft neurological signs', seizures, headache, coma, visual loss, altered mental status, cognitive difficulties, and covert or 'silent' infarction. The S100b and neuron-specific enolase (NSE) are proteins generally considered as markers of central nervous system(CNS) injury, measured both in plasma and/or CSF (cerebrospinal fluid). S100b protein is a calcium-binding protein in the cytoplasm of CNS astroglial and Schwann cells and indicates astrocytal damage as well as dysfunction of the blood-brain barrier (BBB). Neuron-specific enolase is an enzyme localized in neuronal axons and cytoplasm and plays a crucial role in glycolysis and is regarded as a marker for neuronal cell loss. In this study, we evaluated the "silent stroke"in adult patients with SCD at steady phase, by measuring the plasma levels of s100b, NSE and the neurohormone brain-natriuretic-peptide (BNP). *Patients and methods.* Twenty-six patients with SCD, aged 40.5±13.2 y mainly with mild and moderate severity type of the disease were included in the study, while 21 apparently healthy individuals of same age served as controls. Measurements of the plasma levels of the proteins, S100 (as heterodimer S100A1B and homodimer S100BB), NSE and NT-pro-BNP were performed using fully automated electrochemiluminescence assays on the immunochemistry autoanalyzer Roche cobas e411. *Results.* The main results of the study showed that: a) NSE levels were significantly higher in patients with SCD compared to those of controls 8.3±3.6 ng/mL *vs.* 2.3±1.4 ng/mL, P<0.004; b) S100 proteins concentrations were significantly lower in patients with SCD compared to those of controls 0.05±0.02 μg/L *vs.* 0.07±0.03 μg/L, P<0.02; c) NSE levels and NT-pro-BNP correlated positively (binomial-bidirectional regression, P<0.001, while d) no correlation was found between S100 proteins concentrations and NSE and/or NT-pro-BNP levels. *Conclusions.* The increased NSE levels indicate that "silent stroke"in patients with SCD is accompanied with neuronal cell loss. There is no clear explanation for the lower than normal S100 proteins level found in patients with SCD. We postulate that it is probably due to the chronic neurological impairment of SCD patients, as decrease of their level is mentioned after acute neurological events. Moreover, it seems that in low concentration of S100 proteins act as growth factor and induce proliferation and differentiation of the neurons, while high concentrations are toxic. With regard to the results of the present study, further research is necessary to evaluate the role of S100 and NSE in patients with SCD.

1835

THYROID HYPOFUNCTION A POSSIBLE IMPORTANT ETIOLOGY OF ANEMIA DURING INTERFERON THERAPY IN VIRUS C HEPATITIS

A Helaly

Faculty of medicine, Alexandria, Egypt

The effect of interferon therapy on the development of the occurrence of anemia during virus c hepatitis therapy is always contributed to either the interferon effect on the immunomodulatory system leading to pernicious anemia. Or to the known effect of the concomitant Ribavirin leading to hemolytic anemia. Thyroid dysfunction was considered, but with a lesser important effect. The aim of this work was to study the thyroid hypofunction in cases developed anemia during the therapy and try to treat the dysfunction and detect its effect on the anemic state. In an attempt to find a solution to avoid therapy cessation as it is the only way to deal with disease. *Material and methods.* 70 anemic patients occurred during the treatment of standard doses of combined interferon and Ribavirin due to virus c hepatitis (Hb levels below 11 gm/dL). Hb and other anemic parameters, TSH and FT4 levels were measured. Those cases with TSH levels more than 4.5 mIU/L and normal or low FT4, they received levothyroxine therapy with a low dose then increasing until the daily dose of 100 microgram. Then TSH and FT4 levels were measured after 6 months. Correction of the anemic state considered if Hb is above 11gm/dL. *Results.* 70 patients (37 females and 33 males) had HB levels below 11 gm/dl were randomly selected. 37 patients had TSH levels more than 4.5 mIU/L and normal or low FT4 (53%). After levothyroxine intake and at the end of interferon therapy 29 patients out of 37 (78%) had Hb more than 11gm (P<0.05). *Conclusion.* during standard interferon therapy as the occurrence of anemia is a common finding, thyroid hypofunction is a common cause and replacement therapy is a good tool to deal with this complication and so the cessation of therapy may be avoided in most cases.

1836

THE EFFECT OF MATERNAL ANEMIA (IRON DEFICIENCY ANEMIA) ON PREGNANCY OUTCOME

A Khammaj, N Jornaz

Tripoli Central Hospital, Tripoli, Libya

Background. Iron deficiency anemia (IDA) is relatively common in the third trimester of pregnancy, but causal associations with low birth weight, premature delivery, and low Apgar score are still under study. *Objective.* The aim of the study was to assess the relationship between maternal hemoglobin (IDA) and prenatal outcome (birth weight, gestational age, and Apgar score) in a cohort of 200 pregnant women in the third trimester and to highlight the importance of antenatal care regarding maternal health and fetal outcome. *Methods.* This study was performed on a cohort of 200 selected pregnant women in their third trimester that referred to Elzahra Hospital in Eljfara area for antenatal care and delivery during November 2008 till May 2009. The data collected were based on questionnaires, clinical examination and laboratory investigations. Hematologic and iron-status measures, pregnancy outcomes, and fetal and neonatal evaluations were compared between iron deficiency anemia pregnant women (n=66) and controls (n=132). *Results.* Complete data were available for the 200 women. Anemia (hemoglobin <11 g/dL) was present in 68 (34%) pregnant women, and iron deficiency anemia (Hb <11 g/dL & ferritin ≤9 ng/mL was present in 66 (97.1%) pregnant women out of the 68 anemic women. Also the results of our study showed no association between IDA and pregnancy outcome in the third trimester of pregnancy. *Conclusion.* Maternal anemia detected during the later stages of pregnancy, especially the third trimester, often reflects the expected (and necessary) expansion of maternal plasma volume. This might explain our findings in this study which showed no significant association between maternal iron deficiency anemia in the third trimester and the health of the infant at birth in terms of premature delivery (P 0.134), low body weight (P 0.082), and low Apgar score at 1 and 5 minutes (no association).

1837

APPROPRIATE EVALUATION OF TRANSFUSIONAL CARDIAC IRON OVERLOAD BY T2* AND R2* MAGNETIC RESONANCE

J Sakuta, Y Ito, Y Kimura, J Park, K Tokuuye, K Ohyashiki

Tokyo Medical University, Tokyo, Japan

Background. Cardiac dysfunction due to transfusional iron overload is one of the most harmful complications for patients with bone marrow failure syndromes. Magnetic resonance imaging (MRI) is known to correlate to tissue iron concentration. However, it has some disadvantages including increased cost of the examination and the relatively limited availability of MRI systems. On the other hand, clinical parameters such as total red blood cell (RBC) transfusion units and serum ferritin levels are usually considered as indicators for iron chelation therapy. *Aims.* To evaluate cardiac iron overload with MRI-T2* and MRI-R2* (reciprocal values of T2*) values, and to find out whether these values corroborate some known clinical parameters based on retrospective data in blood transfusion-dependent patients. *Methods.* We examined MRI-T2*, -R2* values of myocardium and left ventricular ejection fraction (LVEF) by ultrasonography in 17 adult patients (12 men and 5 women) in our institution with blood transfusion-dependent bone marrow failure syndromes. Patients treated with anticancer drugs were excluded, since they can cause organ dysfunction. The 17 cases consisted of 6 patients with myelodysplastic syndrome, 7 with aplastic anemia and 4 with myelofibrosis. Their ages ranged from 35 to 88 (median 67 years) and none of them had previously received oral iron chelation therapy, while 9 of them had received intermittent intravenous deferoxamine. The data were analyzed to see the relationship with known parameters, such as total RBC transfusion units and serum ferritin levels. *Results.* We found a positive correlation in all patients between R2* values and serum fer-

ritin levels (r=0.83), and also the former and total RBC transfusion volume (r=0.93). The T2* values are more sensitive at the early stage of iron overload. In contrast, R2* values are more useful in the higher range. We also found that elevation of R2* values correlates with deterioration of LVEF (r=-0.72). From the formulae of R2* values, we concluded that approximately 60 Japanese RBC transfusion units or 2,000 ng/mL serum ferritin level might be the cutoff value indicating possible future cardiac dysfunction. *Summary/Conclusions.* We examined MRI-T2*, -R2* values of myocardium in 17 blood transfusion-dependent patients to find out the relationship between these values and known clinical parameters of iron overload such as serum ferritin level and total RBC transfusion units. As a result, R2* values correlated with serum ferritin levels, total RBC transfusion units and also with deterioration of LVEF. The results of our study and the formulae of R2* values which is made based on the results were compatible with the Japanese and international guidelines for iron chelation. However, there is a risk of overlooking the early stage of myocardial iron overload due to the heterogeneity of the disease. According to the fact that R2* values gradually rise as myocardial iron accumulates, it is recommended to consider the possibility of myocardial iron overload even when T2* values are in normal range and LVEF seems to be preserved.

1838

EFFICACY AND SAFETY OF DEFERASIROX (EXJADE_) IN PATIENTS WITH TRANSFUSION- DEPENDENT ANEMIAS: PRELIMINARY RESULTS FROM THE FIRST, RETROSPECTIVE, MULTICENTER BRAZILIAN STUDY

R Cancado,[1] C Chiattone,[1] J Nicolau,[2] A Fabron Jr,[3] I Angulo,[4] D Brunetta,[4] M Favarin,[4] A Pinto,[4] E Carboni,[5] L Valdez,[5] S Magalhães,[6] C Moreira,[7] R Tavares,[7] A Hallack Neto,[8] C Lobo,[9] V Pessoa,[9] C Cunha,[9] A Araujo,[10] J Peres,[10] S Cruz,[11] D Nicolau,[11] A Sousa,[12] V Pereira,[13] D Lehugeur,[14] L Daudt,[14] J Friedrisch,[14] L Silla,[14] C Costa,[6] A Araújo[6]

[1]Santa Casa Medical School, Sao Paulo, Brazil; [2]Faculdade de Medicina da Universidade Metropolitana de Santos, SP, Brazil, Santos, Brazil; [3]Faculdade de Medicina de Marília, SP, Brazil, Marilia, Brazil; [4]Hemocentro de Ribeirão Preto, SP, Brazil, Ribeirão Preto, Brazil; [5]Hospital Pequeno Príncipe, Curitiba, PR, Brazil, Curitiba, Brazil; [6]Serviço de Hematologia da Universidade Federal do Ceará, Brazil, Fortaleza, Brazil; [7]Serviço de Hematologia da Universidade Federal de Goiás, Brazil, Goias, Brazil; [8]Hemocentro Regional de Juiz de Fora, Universidade Federal de Juiz de Fora, MG, Juiz de Fora, Brazil; [9]Hemocentro do Rio de Janeiro, Brazil, Rio de Janeiro, Brazil; [10]Hemocentro de Pernambuco, Recife, Brazil; [11]11Hemomar, Supervisão de Hematologia e Hemoterapia do Maranhão, Maranhão, Brazil; [12]Hospital Infantil Nossa Sra. da Glória, Vitória, Vitoria, Brazil; [13]13Hospital Tacchini, Bento Gonçalves, RS, Bento Gonçalvez, Brazil; [14]Serviço de Hematologia e TMOssea do Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil

Background. Deferasirox is a once-daily oral iron chelator with established dose-dependent efficacy for treating transfusional iron overload. *Aims.* to evaluate the efficacy and safety of fixed starting doses of deferasirox based on transfusion history, with subsequent dose titration based on serum ferritin (SF) trends in transfusion-dependent anemia patients. *Methods.* Pts had transfusion-dependent anemia with a history of multiple transfusions (>20 transfusions) and/or SF levels ≥ 1000 ng/mL and serum creatinine level < the upper limit of normal (ULN). Deferasirox starting dose was 10-30mg/kg/day depending on transfusion requirements and subsequent dose adjustments of 5-10 mg/Kg/day (range 0-35 mg/kg/d) were done every 3 months based on changes in SF and safety parameters. Efficacy was assessed monthly by measuring change from baseline in SF levels. Safety was evaluated on a monthly basis according to the incidence and type of adverse events and measurement of laboratory parameters, including serum creatinine and liver enzyme levels. *Results.* 105 pts (40 M, 65 F; mean age 25.0±16.6 yrs) were enrolled; 46% (n=48) aged <20 yrs; 54% Afro-descendant (n=57). Underlying anemias were: sickle cell disease (n=59), β-thalassemia (n=32), myelodysplastic syndromes (n=6) and other conditions associated with anemia (n=8). Most pts (79%, n=83) had received > 40 units of red blood cell (RBC); 71.5% (n=75) were on regular RBC transfusion. Sixty-four (61%) pts started on 20 mg/kg/d and 41(39%) > 20-30 mg/kg/d, 15.2% of pts had dose increases at a median of 24 weeks after treatment initiation. Mean±SD SF levels (μg/L) did significantly reduce at 6 months and 12 months compared to baseline (BL) [from 3132.14±2237.47 to 2784.25±1969.7 at 6 months (P=0.0001) and 2327.46±1873.8 at 12 months (P=0.005)]. The proportion of patients with SF levels < 2000, 2000-3000 and > 3000 μg/L from BL to 6 and 12 months by percentage of patients changed from 36% to 47.5% and 52%; from 26% to 26.5% and 24.5%; from 38% to 26% and 23%, respectively. No patient discontinued the treatment. No death was reported by the investigators during the study. The most common drug-related (investigator-assessed) AEs were mild, transient diarrhea (n=15; 14.3%), rash (n=5; 4.7%), nausea (n=9; 8.5%) and headache (n=6; 5.7%). Seven pts (6.6%) had serum creatinine value >33% above BL on two consecutive visits, 3 (2.8%) of whom had creatinine increases above the ULN; there were no progressive increases or renal failure. Eleven (10.5%) pts had an increase in alanine aminotransferase < 5× ULN but no one experience increases ≥ 5x ULN; levels were already elevated in all of them. *Conclusions.* This first multicenter Brazilian study confirms deferasirox efficacy in achieving a reduction of iron load across a wide range of pts with transfusion-related iron overload. Deferasirox was generally well tolerated in pediatric and adult pts with a safety profile consistent with data from previous clinical trials. The availability of deferasirox as a once-daily oral iron chelator would potentially facilitate improved compliance, and thereby reduce morbidity and mortality from iron overload.

1839

IRON DISTRIBUTION BETWEEN LIVER, SPLEEN, PANCREAS, BONE MARROW, AND MYOCARDIUM IN β-THALASSEMIA MAJOR: AN R2-MRI STUDY

O Papakonstantinou,[1] N Kelekis,[1] K Foufa,[1] A Balanika,[1] E Rigatou,[2] A Kattamis,[3] S Kostaridou[3]

[1]Attikon Hospital, University of Athens, Athens, Greece; [21].Department of Paediatric Haematology Oncology, Athens, Greece; [3]Thalassemia Unit, Aghia Sophia Childrens Hospital, Athens, Greece

Background. Despite extensive research on MRI of hepatic and cardiac iron overload, there have been limited data on quantification of iron in organs other than liver and heart. *Aims.* a) to investigate the correlation between the degree of hepatic, splenic, pancreatic, vertebral bone marrow (VBM), and myocardial siderosis, as expressed by relaxation rate (R2 = 1/T2) values, b) to describe atypical MR imaging appearances of pancreas and spleen in transfusion-dependent patients with β-thalassemia major. *Methods.* From the archieves of our department, we retrieved the abdominal and cardiac MRI studies of 89 consecutive patients with β-thalassemia major (46 men and 43 women, aged 9-40 years, mean 28.2+7.5) which were performed in a 8-year period at the same 1.5 Tesla MR imager , for evaluation of liver and myocardial iron overload. The study protocol was approved by the board for retrospective studies of our institution. The MR imaging protocol included a single-slice respiratory triggered 16-echo Carr-Purcell-Meiboom-Gill (CPMG) spin echo sequence and subsequent calculation of R2 values of liver, spleen and VBM in all patients. Pancreatic R2 values were possible to determine in 58/89 patients. Additional multislice T1 axial - and T2 coronal sequences were applied. Imaging of the heart was performed in 81/89 patients, using a double oblique imaging plane while cardiac R2 was estimated at the left ventricular free wall. The same MRI protocol was applied in ten healthy controls, after informed consent. From patients' medical records, serum ferritin values closest to the MR exam (1-4 weeks) were retrieved. Statistical significance was set at P<0.05. *Results.* Hepatic R2 values were significantly increased in 85/89 patients; VBM, pancreatic, and myocardial R2 values were increased in 82/89, 36/58 and 55/81 patients, respectively. Decreased pancreatic R2 values combined with T1 hyperintensity were seen in 10 patients with severe hepatic siderosis and was attributed to fatty degeneration. Of the 44 nonsplenectomized patients, splenic R2 values were decreased in 35 and normal in nine patients; all the last ones exhibited splenomegaly. Hepatic R2 values correlated with splenic (r=0,589, P=0.001), VBM (r =0,405, p =0.002),and myocardial (r=0,357, P=0,0016). Serum ferritin levels were found to correlate with hepatic (r=0.73, P< 0.0001), bone marrow (r=0.39, P< 0.002), splenic (r=0.69, P<0.0001) R2 values and myocardial R2 (r= 0,39, P<0.01) but not with pancreatic R2 values. Pancreatic R2 values were not correlated with hepatic R2 ones or serum ferritin. *Conclusions.* Hepatic siderosis correlated with splenic, VBM and myocardial siderosis, as expressed by respective R2 values, although unpredictable patterns of iron distribution were seen. Normal splenic R2 values combined with splenomegaly were occasionally seen, that might be attributed to splenic dysfunction. Fatty degeneration of the pancreas was not uncommon; pancreatic R2 values can not be considered representative of iron deposition since the effect or iron interferes with that of fat for R2 calculations.

1840

TRANSIENT ELASTOGRAPHY (FIBROSCAN): A NEW AND SAFE TOOL FOR THE NONINVASIVE ESTIMATION OF LIVER FIBROSIS IN HEREDITARY HEMOGLOBINOPATHIES

J Schina,[1] G Mousoulis,[2] M Dimopoulou,[3] E Plata,[3] H Dimitrakopoulou,[3] E Voskaridou[3]

[1]Evangelismos General hospital, Athens, Greece; [2]Third Department of Internal Medicine, Evangelismos General Hopsital, Athens, Greece; [3]Thalassemia Center of Laiko General Hospital, Athens, Greece

Background. Hepatic iron overload and chronic hepatitis are serious complications of chronic transfusion therapy in patients with hemoglobinopathies and play an important role in the development of hepatic fibrosis and cirrhosis. Transient elastography (Fibroscan, Echosens, Paris, France) is a new, noninvasive, rapid, reproducible, bedside method allowing the assessment of liver fibrosis by measuring the liver rigidity (Liver Stiffness Measurement, LSM, kPascals). *Aims.* To evaluate liver fibrosis with Fibroscan in patients with hemoglobinopathies and correlate the LSM with demographic characteristics, ALT, ferritin, transfusion frequency and iron chelating therapy. *Methods.* We evaluated 109 adult patients with hemoglobinopathies (48M/61F, mean age 46±9,5 years). Nineteen patients (17,4%) had Thalassemia Major (TM), twenty four (22%) had Thalassemia Intermedia (TI) and sixty six had Sickle Cell Disease (60,6%). All patients were evaluated for liver fibrosis with Fibroscan. Total iron burden was monitored by measuring serum ferritin levels , ALT and indices of chronic hepatitis B or C were monitored by conventional methods. All measurements were synchronous with Fibroscan evaluation. *Results.* The median LSM was 6 kPascals with a minimum value of 3 kPascals and a maximum value of 48 kPascals, (range 4-9). The median ALT was 24 IU/L (range 16-40), median ferritin was 374 ng/mL (range 148-642). Nineteen patients (20,2%) had indications of chronic hepatitis B or C. The three subgroups of patients according to subjecting hemoglobinopathy differed significantly in age (P=0,016), ALT (P=0,032) and ferritin levels (P=0,012) but there was no statistical significant difference in LSM (P=0,482). LSM was significantly correlated with ALT levels (r=0,565, P<0,001) and the presence of chronic hepatitis (r=0,419, P<0,001) while it was not correlated with ferritin levels (r=0,63, P=0,561). *Summary/Conclusions.* Fibroscan may constitute a reliable and easy to apply noninvasive means of detecting liver fibrosis in patients with hemoglobinopathies. It seems to correlate with the presence of chronic hepatic injury, reflected by increased ALT levels and chronic infection with hepatitis viruses. The finding that ferritin levels did not correlate with LSM was expected as ferritin is not a reliable index of liver iron concentration and iron induced liver injury. The absence of differences in LSM between subgroups could be explained by the small number of patients in each subgroup.

1841

A PROSPECTIVE OBSERVATIONAL REVIEW OF FERRIC CARBOXYMALTOSE ALONE IN THE IMPROVEMENT OF ANEMIA SECONDARY TO IRON DEFICIENCY IN CANCER PATIENTS

T Steinmetz,[1] R Rohrberg,[2] S Weber-Mangal,[3] H Tesch,[4] N Marschner[5]

[1]Innere Medizin, Hämatologie und Onkologie, Köln, Germany; [2]Gemeinschaftspraxis und Tagesklinik, Hämatologie/Onkologie/Gastroenterologie, Halle, Germany; [3]Vifor Pharma Deutschland GmbH, München, Germany; [4]Onkologische Gemeinschaftspraxis, Frankfurt/Main, Germany; [5]Praxis für interdisziplinäre Hämatologie und Onkologie, Freiburg, Germany

Background. Iron is vital for all metabolic processes in the body: among others, iron-containing enzymes are essential for electron transport in the respiratory chain, transmission of nerve impulse, erythropoiesis, oxygen transport and supply to the brain and other tissues. Approximately 500 mg iron per liter of blood are required for normal hemoglobin levels. Restricted iron supply may lead to iron deficiency (ID) and, if this condition persists, to iron deficiency anemia (IDA). ID has been associated with reduced functional capacity and/or patient reported poor physical condition. These symptoms, even more manifest in the presence of anemia, may significantly decrease patient quality of life (QoL) and hence intervention is required. Within oncology, IV iron in conjunction with erythropoiesis stimulating agent (ESA) has been demonstrated to improve hemoglobin (Hb) levels. This response may originate from improved iron availability that overcomes iron restricted erythropoiesis due to increased iron demands from ESA use, as well as ID correction alone. *Aim.* Provide an initial observation of the role of intravenous (IV) iron alone in correction of anemia secondary to iron deficiency in cancer patients. *Methods.* A non-interventional observational study was initiated in December 2008 across 39 sites in Germany and is ongoing. To date, over 300 patients have consented with 163 having completed a 12-week observational period at time of analysis. Of these completed patients, 135 had no ESA use within 4 weeks of screening or during the observational period and received at least 1 dose of ferric carboxymaltose (FCM). Here we present an interim review of the aforementioned subset of patients focusing on the correction of anemia secondary to iron deficiency. *Results.* 135 patients constituting a cross section of tumors including colorectal (22%), breast (21%), and stomach (10%) cancer. The other patients (<10% per group) included more than 15 different tumor types, both hematological and solid tumors, at various stages and/or courses of treatment. On average, 1008 mg of IV iron as FCM was administered with approximately 1.0-1.5 g/dL increase in hemoglobin during the observation period (Figure 1). The total dose of iron administered ranged from 100 mg to 4,000 mg. Half of the patients received FCM as single doses of greater than 500 mg iron (with 14 having individual doses of 1,000 mg) with similar effectiveness in correcting anemia as more frequent individual lower doses. Patients that received <500 mg individual doses required approximately 6.5 administrations (average individual dose of 127 mg) whilst those with higher doses had an average of 2 administrations (average individual dose of 606 mg). Adverse events (AEs) were reported in 11 (8%) patients with 1 (0.7%) serious adverse event (SAE). The reported SAE, tachycardia, was considered by the Investigator to be unlikely related to FCM. *Summary/Conclusions.* These are the first prospective observational data of FCM in oncology and suggest a role for IV iron alone in the correction of anemia in ID patients. FCM was administered in many combinations (from multiple low doses to single high doses) with similar Hb responses.

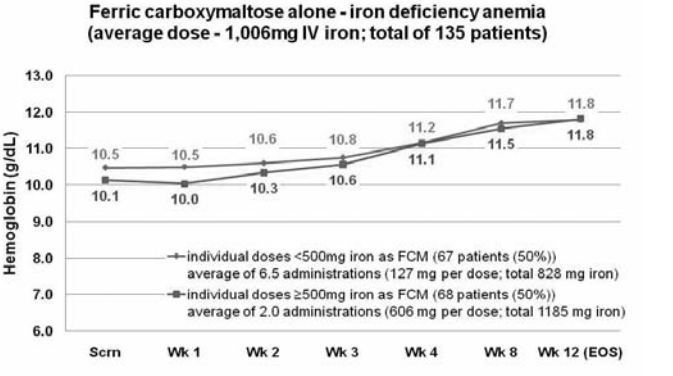

Figure 1. FCM alone in correction of iron deficiency anemia.

1842

RENAL FUNCTION IN PATIENTS WITH THALASSEMIA INTERMEDIA

A Taher,[1] K Musallam,[1] G Al-Helou,[1] MD Cappellini,[2] F Ziyadeh[1]

[1]American University of Beirut Medical Center, Beirut, Lebanon; [2]Universitá di Milano, Policlinico Foundation IRCCS, Milan, Italy

Background. Limited reports on renal function in patients with thalassemia major highlight proximal tubular damage and glomerular hyperfiltration attributed to chronic anemia, iron overload and chelation therapy. Data on renal function in patients with thalassemia intermedia (TI) is lacking. *Aims.* To evaluate levels of serum and urinary creatinine (Cr), and urinary protein in patients with TI and their correlation with several disease-related parameters. *Methods.* This was a cross-sectional study of 50 patients with TI treated at the Chronic Care Center, Beirut, Lebanon. Data on patient demographics, status of the spleen, treatment received, and disease-related complications were collected. Blood samples were obtained for assessment of steady state serum ferritin (SF), non-transferrin-bound iron (NTBI), total (Hb) and fetal (HbF) hemoglobin, nucleated red blood cells (NRBC), platelets, and serum Cr levels. Urinary samples were collected for measurement of spot protein and Cr concentrations. Direct determination of liver iron concentration (LIC) was performed using R^2 magnetic resonance imaging. None of the patients received iron chelation or fetal hemoglobin induction therapy. *Results.* Patient and disease characteristics are summarized in Table 1. None of the patients had systemic arterial hypertension. The mean±SD serum Cr, spot urinary protein, and urinary protein/Cr ratio were 0.48±0.15 mg/dL (range, 0.20-0.90 mg/dL), 269.4±291.7 mg/L (range, 59.0-1588.0 mg/l), and 325.7±282.5 mg/g (range, 93.3-1538.9

mg/g). A total of 24 (48%) patients [mean age 23.5 years, 19 males] had serum Cr levels ≤0.4 mg/dL (i.e., possible glomerular hyperfiltration), and 7 (14%) patients [mean age 27.1 years, 3 males] had a protein/Cr ratio >500 mg/g (macroproteinuria). Among study variables, age was positively and significantly correlated with serum Cr level (rs = 0.487, P<0.001), males had a significantly higher mean serum Cr level than females (0.55 *vs.* 0.43 mg/dL, P=0.002), and splenectomized patients has a significantly higher mean serum Cr level than non-splenectomized patients (0.56 *vs.* 0.46 mg/dL, P=0.031). Urinary protein/Cr ratio had a significantly positive correlation with each of the following: SF (rs = 0.202, P=0.048), NTBI (rs = 0.444, P=0.001), LIC (rs = 0.357, P=0.011), and NRBC (rs = 0.381, P=0.006); yet a significantly negative correlation with Hb level (rs = -0.252, P=0.008). *Summary/Conclusions.* Glomerular hyperfiltration and macroproteinuria are common in patients with TI who have not received iron chelation therapy. These alterations in renal function may portend future risk for progression of chronic kidney disease. Anemia, hemolysis, and iron overload play significant roles towards the development of macroproteinuria in this patient population. Large prospective trials are called for to better understand the natural history of renal function in TI patients and to assign the optimal preventive approaches before overt renal insufficiency develops.

Table 1. Patient and disease characteristics.

Parameter	Value
Mean age ± SD, years (range)	27.3 ± 12.1 (8-63)
Male/Female	22/28
Splenectomized, (%)	39 (78)
Pulmonary hypertension, n (%)	28 (56)
Thromboembolic disease, n (%)	14 (28)
Occasionally transfused, n (%)	15 (30)
Mean Hb[a] ± SD, g/dl (range)	8.3 ± 1.8 (4.9-13.1)
Mean fetal Hb ± SD, % (range)	44.1 ± 29.5 (8.7-100)
Mean platelet count ± SD, x10^9/l (range)	787.5 ± 410.3 (135.0-1733.0)
Mean NRBC count ± SD, x10^6/l (range)	376.73 ± 52.7 (0.0-1629.0)
Mean SF ± SD, ng/mL (range)	985.4 ± 669.1 (18.0-3157.5)
Mean NTBI ± SD, µmol/l (range)	2.9 ± 3.7 (-3.7-10.0)
Mean LIC ± SD, mg Fe/g dw (range)	9.6 ± 7.4 (0.6-32.6)

Hb = hemoglobin; NRBC = nucleated red blood cell; SF = serum ferritin at steady state; NTBI = non-transferrin-bound iron; LIC = liver iron concentration; dw = dry weight.

INCREASED LEVELS OF ANGIOGENIC AND INFLAMMATORY CYTOKINES IN PATIENTS WITH THALASSEMIA MAJOR AND DOUBLE HETEROZYGOUS HBS/BETA-THALASSEMIA; REDUCTION OF TNF-α POST-DEFERASIROX THERAPY

E Voskaridou,[1] D Christoulas,[2] A Papatheodorou,[3] E Plata,[1] G Marinos,[1] C Xirakia,[1] M Dimopoulou,[1] E Terpos[2]

[1]Laikon General Hospital, Athens, Greece; [2]University of Athens School of Medicine, Athens, Greece; [3251] General Air-Force Hospital, Athens, Greece

Background. Angiogenesis is a crucial process in the pathogenesis of several disorders. Endothelial damage and inflammation are implicated into the biology of sickle cell disease (SCD) and the beta-thalassemia syndromes. Deferasirox (Exjade®) is a once-daily orally administered iron chelator approved for the treatment of transfusional iron overload. *Aim.* The aim of this prospective study was to evaluate the levels of angiogenic and inflammatory cytokines in patients with thalassemia major (TM) and double heterozygocity of SCD and beta-thalassemia (HbS/beta-thal) with iron overload who received chelation therapy with deferasirox. *Patients/Methods.* Forty-five patients (16M/29F) with TM and 20 patients (7M/13F) with HbS/beta-thal were evaluated. Deferasirox was given for a period of 12 months. Serum levels of angiogenic cytokines, such as vascular endothelial growth factor (VEGF), basic fibroblast growth factor (bFGF), angiogenin (Ang), angiopoietin (Angp)-1 and -2 and of inflammatory cytokines including interleukin-6 (IL-6), tumor necrosis factor-alpha (TNF-α), IL-1α, IL-1β, IL-4, IL-10 and transforming growth factor (TGF)-β1 and β2, were measured at baseline (day 1 of deferasirox administration) and then after 12 months post-deferasirox therapy, using ELISA methodology (R&D Systems, Minneapolis, MN, USA, for angiogenic cytokines and ILs and Diaclone, Bensancon, France for TNF-α, TGF-β1 and TGF-β2). Twenty healthy blood donors of similar age and gender were also evaluated as controls. *Results.* Patients with both TM and HbS/beta-thal had increased levels of all studied angiogenic cytokines compared to controls and reduced levels of Angp-1/Angp-2 ratio (P<0.01 for all comparisons). Patients with HbS/beta-thal had increased levels of Angp-2 (P=0.002) and reduced levels of Angp-1/Angp-2 ratio (P<0.001) compared to TM patients. Both TM and HbS/beta-thal patients had also increased levels of IL-6 (P=0.008), IL-1α (P=0.01), TGF-β2 (P=0.01), IL-10 (P=0.02), IL-4 (P=0.03), and TNF-α (P=0.01) compared to controls. There were no differences between TM and HbS/beta-thal patients regarding inflammatory cytokines. In TM, VEGF strongly correlated with TGF-β1 (r=0.652, P<0.001), platelet counts (r=0.503, P=0.001) and white blood cell (WBC) counts (r=0.484, P=0.002), while Angp-2 strongly correlated with TNF-_ (r=0.536, P=0.001), WBC counts (r=0.430, P=0.008) and platelet counts (r=0.330, P=0.01). In HbS/beta-thal patients Angp-1/Angp-2 ratio strongly correlated with ALT (r=-0.611, P=0.007) and Hb (r=0.498, P=0.036). Twelve months post-deferasirox administration, there was a dramatic reduction of ferritin, SGOT and SGPT compared with baseline values in both patient groups (P<0.0001). TM patients showed a continuous increase of both VEGF (mean±SD: from 680±489 ng/mL prior to deferasirox to 801±547 ng/mL post-deferasirox; P=0.002) and bFGF (from 16.2±17.1 ng/mL prior to deferasirox to 33.1±28.8 ng/mL post-deferasirox; P=0.001) after 12 months of deferasirox therapy. Patients of HbS/beta-thal showed no alterations in terms of angiogenic cytokines that continued to be elevated compared to controls. In terms of inflammatory cytokines deferasirox produced a reduction of TNF-α in both studied groups (P<0.01 for all comparisons). *Summary/Conclusions.* Our study suggests that angiogenic and inflammatory cytokines are increased in patients with TM and HbS/beta-thal and thus they have a role in the pathogenesis of these disorders. Further studies are needed to fully elucidate the effect of deferasirox, if any, on inflammation. Deferasirox seems to have no impact on angiogenic cytokines.

COMPLICATIONS OF β – THALASSEMIA INTERMEDIA IN PATIENTS REFERRING TO HEMATOLOGY CLINIC OF ALI-ASGHAR CHILDREN HOSPITAL DURING 1996 – 2008

K Arjmandi Rafsanjani, N Mafi

Iran University of Medical Sciences, Tehran, Iran

Background. Beta thalassemia intermedia (TI) is a member of thalassemia family that has a less severe clinical phenotype compared to thalassemia major;TI patients experience many complications, including cardiopathy, pulmonary hypertension, gallstones, splenectomy, endocrinopathies, osteoporosis, etc. *Aim.* Considering the high prevalence of thalassemias in Iran we carried out this study to determine the frequency of TI complications in Iranian patients. *Methods.*Our study was a descriptive cross sectional survey; using the sampling method of "census", we enrolled all the patients with the diagnosis of TI, who had been visited in hematology clinic of Ali-Asghar children's hospital in1996-2008;164 cases were selected and the collected data from their medical records was analyzed by the SPSS software. *Results.* In 164 patients 83 were male and 81 female; mean age of the patients at last visit were 16.5±9.7 years (3-55years),mean age at diagnosis was5.4. Mean hemoglobin was 9.14±1.13,mean Hb F=59, mean serum ferritin was758 ng/mL. 40.2% of the patients were receiving transfusions, either regularly or irregularly; and the mean age at the first transfusion was 7.7±5.4 years; 45.3% and 14.5% had undergone splenectomy and cholecystectomy, respectively;61.9 % had at least one valvular abnormality,pulmonary hypertension was detected in 16%, endocrine complications were detected in 7.6 % ; hypogonadism was the most frequent(4.8),hypothyroidism in 2.1% and no diabetes mellitus; in addition, 50% of the cases were found to have either osteoporosis Z-score ≤-2.5, or osteopenia. *Conclusion.* Because some patients had very few clinical complication and others severe,a careful analysis of the clinical,hematological,genetic and molecular evaluation is necessary specially in young children.

1845

ERYTHROCYTE PHENOTYPES IN EMIRATI PEOPLE WITH α THALASSEMIA

S Denic,[1] AK Souid,[1] N Nagelkerke,[2] S Shawki[3]

[1]Faculty of Medicine and Health Sciences, Al Ain, United Arab Emirates; [2]Faculty of Medicine and Health Sciences, UAE University, Al Ain, United Arab Emirates; [3]Al Ain Hospital, Al Ain, United Arab Emirates

Background. Populations with very high frequency of α^+ thalassemia allele have three distinct red cell phenotypes: normal ($\alpha\alpha/\alpha\alpha$), silent

carriers (-α/αα) and α+ thalassemia trait (-α/-α). Although red cells of silent carriers are relatively smaller, they overlap with and are clinically indistinguishable from normal. Thus, two phenotypes are clearly recognized, normal and small red cells. In such populations, the erythroid reference intervals are widely dispersed and skewed to one side. In United Arab Emirates (UAE), one half of the population has α-gene mutations and one third has small red cells mostly due to α+ thalassemia trait. Therefore, separate standards are necessary for the people with normal and small red cells. *Aims.* To determine reference intervals for native UAE citizens with normal and small red cells. *Methods.* In UAE, the population is tribal and endogamous. Hemoglobinopathies are also very common. We studied the erythroid lineage in 1,079 participants in the premarital screening program, which uses complete blood count and hemoglobin electrophoresis to detect hemoglobinopathies. The program is mandatory and fully funded by the government. Subjects with hemoglobinopathies other than α+ thalassemia and those with iron deficiency were excluded from analysis. The frequency distribution of MCV in the remaining 896 subjects was visibly bimodal. Normix program (http://www.alumni.caltech.edu/~wolfe/normix.htm) was used to separate subjects with normal from subjects with small red cells. The small red cell phenotype by diagnostic exclusion was considered α+ thalassemia trait. Hardy-Weinberg equation was used to derive genotype frequencies from the frequency of α+ thalassemia trait, αα/αα genotype. *Results.* The normal phenotype had MCV >78.0 fl (n=715) and the α+ thalassemia trait phenotype had MCV <78.0 fl (n=181). The erythroid indices were significantly different between the two groups (Table). The prevalence of α+ thalassemia trait (0.17), silent carriers (0.48) and normal phenotype (0.35) and the frequency of α+ thalassemia allele (0.4) were all very similar to those found earlier in the same population using genotyping and other phenotyping methods. Among ten largest tribes, the prevalence of α+ thalassemia trait varied between 0 and 0.31. The reference intervals for normal phenotype closely overlapped with those for Caucasians and for normal homozygotes defined by genotyping. The intervals for α+thalassemia trait also closely overlapped with those for α+ thalassemia homozygotes defined by genotyping. *Conclusion.* In populations with very frequent α+ thalassemia mutations, two sets of reference intervals should be determined and used in clinical practice.

Table. Erythrocyte indices in subject with normal (A) and small (B) red cells.*

AUTOMATED RED CELL EXCHANGE IN PATIENTS WITH SICKLE CELL DISEASE

K Quiroz, L Guerra, J Lopea, S De La Iglesia, D Rodriguez, Y Ramos, N Navarro, C Rodriguez, S Fumero, H Luzardo, A Suarez, T Molero

Hospital de Gran Canaria Doctor Negrin, Las Palmas de G.C., Spain

The usefulness of red cell exchange (RCE) was tested in diseases such as sickle cell anemia and malaria. In adults with sickle cell disease, it has been used in the treatment of acute chest syndrome, priapism, osteonecrosis, lower limb ulcers, as well as to control painful crises and prevention of strokes. But there is little evidence of its use in patients with sickle cell disease who have more serious comorbidities such as cardiac or renal impairment. We report four cases of patients included in RCE program. *Patient 1.* 17 year-old male from Maurtania homzygous for hemoglobin S, kidney transplant secondary to membranoproliferative glomerulonephritis, with many sickle cell crises that caused acute transplanted kidney failure. For that reason we indicated RCE. He held 19 sessions (every four weeks), with an average hemoglobin S (Hb S) before the procedure of 45% and after the procedure of 23.4%. We used dialysis arteriovenours fistula as access route. *Patient 2.* 37 year-old male diagnosed with sickle cell syndrome (heterozygous Hb S and beta thalassemia minor). Mechanical aortic valve and ascending aortic prosthesis bearer; anticoagulated with acenocoumarol. He had many sickle cell crises that required long periods of admisssion to the hospital for pain management. He underwent 12 sessions of RCE. Mean Hb S before the procedure was 49% and 29% after them. *Patient 3.* 49 year-old woman heterozygous for Hb S with hemochromatosis secondary to transfusion therapy, renal failure, keratoconus and diabetes mellitus secondary to severe iron overload. Ten RCE were held with an average of 34.8% of Hb S before the procedures and 17% after them. *Patient 4.* 51 year-old portuguese female with sickle cell disease, severe pulmonary hypertension and sickle cell hemolytic crises. Six sessions were performed. The average Hb S before the procedure was 38% and 19% after that. Patients entered automated RCE program for the indications above, using the Cobe Spectra system for red cell replacement at intervals of four weeks. ACD-A and heparine were the anticoagulants chosen. The volume to be infused was estimated according to the size and weight of the patient. In the first case we used hemodialysis arteriovenous fistula as access route. In the rest of the patients femoral venous lines were used as they did not have appropiate peripheral vein access. None of them showed any complications during the procedures. *Conclusion.* Automated blood count replacement is a safe and effective procedure in patients with sickle cell disease, even in those with significant comorbidities such as renal, heart or lung disease, where it is important to keep an appropiate body volume management. In all cases low levels of Hb S less than 30% and Hb levels around 9g/dL were hold, which according to the literature prevent the development of stroke in patients with sickle cell disease. A renal graft protection was achieved in the first case. In the same way, a decreased in the quantity and intensity of pain crises was also achieved with less analgesia requirements and a better quality of life for all the patients.

CARDIAC T2* MRI ASSESSMENT IN TRANSFUSION DEPENDENT ANEMIA OF OUR PATIENTS: PRELIMINARY RESULTS

O Salcioglu,[1] A Akçay,[1] H Sen,[1] G Aydogan,[1] K Oztarhan,[1] G Karsenas,[2] O Kirdar,[2] E Uysal,[2] F Akici,[1] D Tugcu[1]

[1]Minister of Health Istanbul Bakirkoy Woman and Children Disease Education, Istanbul, Turkey; [2]Ministry of Health Istanbul Sisli Etfal Education and Research Hospital,Clinics, Istanbul, Turkey

Cardiac complications are the major cause of mortality in patients with transfusional iron deposition. Conventional tools such as serum ferritin level, ECG, echocardiography, and even magnetic resonance have been reported as unsatisfactory in defining and evaluating the risk mentioned above. Since the beginning of 2000's, myocardial T2* MRI has been widely used as a critical method for not only demonstration of iron deposition in the myocardium objectively, but also for assessment of prognosis of the patients. In current study, we aimed to evaluate the myocardial iron deposition of our patients with chronic transfusion dependent anemia by their T2* MRI results for the first time. We also overviewed other findings and treatment regimens of the patients, as well as T2* results, which studied between December 2008 and January 2010. Study group included 68 patients: 58 with thalassemia major, 3 with Fanconi aplastic anemia, 2 with thalassemia intermedia, 2 with hereditary sferositosis and 1 with pure red cell aplasia. They were consisted of 30 males (44.1%) and 38 females (55.9%), aged from 8 to 23 years old (mean 14.8±2.1). T2* results were as follow: It was lower than 10 msn in 5 patients (7.4%), between 10 and 20 msn in 33 patients (48.5%), and higher than in 20 msn in 30 patients (44.1%). In patients in whose T2* values were lower than 10 msn, between 10 and 20 msn and higher than 20 msn, mean ferritin levels were 3810±2080, 2125±950, 2451±1024 and mean LVEF were 62.8±4.6, 72.9±6.2, 74.9±4.2, respectively. The patients were treating with combination of Desferrioxamin and Deferipron (47%), Deferrioxamin only (30.9%) and Deferasirox only (17.7%) in terms of treatment options, when the time of T2* images were obtained. Here we discussed effects of T2* results on chelation treatment regimens and prognostic value in patients with iron deposition.

ROLE OF HEPCIDIN HORMONE IN EGYPTIAN PATIENTS WITH B- THALASSEMIA MAJOR

M Beshir,[1] M Hesham,[1] N Khalifa,[2] I Ahmed,[2] A Ahmed[2]

[1]Zagazig University, Zagazig, Egypt; [2]Clinical Pathology, Zagazig, Egypt

Bachground. Hepcidin, a hepatic hormone, controls plasma iron concentration and tissue distribution of iron by inhibiting intestinal iron

absorption, iron recycling by macrophages, and iron mobilization from hepatic stores. Thalassemia syndromes represent a clinical setting where hepcidin is regulated by opposing influences of ineffective erythropoiesis and elevated iron load. *Aims.* We aimed to evaluate serum erythropoietin (sEpo) and soluble serum transferrin receptors (sTfr) as indicators of erythropoietic activity and to find their relation with hepcidin concentration in patients with β thalassemia major in a trial to explain its rule in iron metabolism for those patients who have iron overload. *Methods.* This study was carried out in pediatric and clinical pathology departments of Zagazig University Hospitals in the period from March to December 2009. The study included 30 β thalassemia Major (TM) children aged between 4- 10 years with a ratio of 1.5:1(18 male and 12 female) and 10 apparently healthy children, age and sex were matched as a control group. All subjects were studied for pre-transfusion hemoglobin (Hb), reticulocytic index (RI), serum ferritin, sEpo and sTfr, and serum hepcidin level. *Results.* The mean RI, sEpo and sTfr values were significantly higher in the TM group compared to the control group. The results showed that hepcidin concentration was significantly decreased in TM than control group. There was a positive correlation between hepcidin and Hb, while there was a negative correlation between hepcidin and sEpo and sTfr values. On the other hand it did not correlate with indices of iron stores. *Summary and conclusion.* sEpo, sTfr and RI could be used as accurate and reliable indicators of successful erythroid marrow activity and these results underline the role of erythropoietic activity on low hepcidin level in thalassemic patients.

1849

XMN I POLYMORPHISM AND SEVERITY OF BETA THALASSEMIA

M Bradai

Institute of Medicine, Blida, Algeria

Background. the clinical manifestation of beta-thalassemia syndromes, are extremely diverse and accurate prediction of disease severity based on globins gene mutations alone is complicated by influence on phenotype of genetic modifiers. Among those factors XmnI polymorphism G_ polymorphism is known factor which increases fetal hemoglobin (HbF) production. *Aims.* our aim is to determinate the role of XmnI polymorphism as a factor predicting the severity of the phenotype, and his place in the therapeutic response in a cohort of Algerian patients with homozygote β-thalassemia treated with Hydroxyurea as an inductor of hemoglobin Fetal production. *Methods.* we had studied 65 patients with homozygote β-thalassemia mean age 11±5 years (ranged 3-21). Eleven was intermediate TI and 55 was major TM. we performed gene mutation and determinate Xmn I polymorphism in all patients. Disease severity was assessed based on age of first transfusion, and blood requirement (number of blood units BU per year). We defined good response to Hydroxyurea when a decrease of annual transfusion requirement greater 70% with sustained Hb level above 7g/dL by increasing of HbF level. *Results.* among thirteen mutations identified, three are common IVS1-110 G>A (41%), Codon 6(-A)(23%), Codon 39 C>T (18%), others mutations were occasional such IVS1-1G>A(4,6%) ; IVS1-5G>C ; IVS1-6G>T ; -101 C>T ; IVS2 nt848C>A ; polyA A>G (ATGAA), polyA T>C(ACAA) ; codon30G>C ; ψβ,δ,β et 3'phhf ; D-polya. Homozygosis for a mutation was observed in 33/65 patients, XmnI polymorphism was observed in 31 alleles (24% of patients) with three categories XmnI (+/+), (+/-), (-/-) Codon 6 (-A) was associated with XmnI polymorphism in 80% of cases and just 6% for others mutations. Age of the first transfusion was 31±21 months (4-70) for the category of patients with XmnI (+/+),(+/-), and 20±19 months (4-84) for patients with XmnI (-/-)(p> 0,05). The blood requirement was 10±2 BU/year in the group of XmnI (+/+), (+/-) patients, and was 14±3 BU/y in the group of XmnI (-/-) (p>0, 05). Good response to Hydroxyurea was observed in the group of XmnI (+/+), (+/-) patients (p 0,008), this response was worse in the group of XmnI (-/-) (p0, 0001) (M. Bradai and all. Decreased transfusion needs associated with hydroxyurea therapy in algerian patients with thalassemia major or intermedia, transfusion, 47, 2007). *Conclusion.* the determination of XmnI polymorphism alone seems not a determinant factor of severity of β-thalassemia. However in our experience, it's could bee used as a marker of the response to inductors agents of HbF such hydroxyurea.

1850

EVALUATION OF THE EFFICACY OF INTRAVENOUS IRON SUCROSE FOR TREATING ADULT PATIENTS WITH IRON DEFICIENCY ANEMIA

R Cancado, P Figueiredo, C Chiattone

Santa Casa Medical School, Sao Paulo, Brazil

Background. Parenteral iron preparations available in the past were associated with a risk of anaphylaxis and death, which made physicians reluctant to use them. The formulation most frequently responsible for these serious adverse events is high-molecular-weight iron dextran. The availability of four other preparations (iron sucrose, ferric gluconate, low-molecular-weight iron dextran, and, more recently, ferric carboxymaltose) with a much better safety profile, is changing the pattern of use of intravenous (IV) iron. *Aims.* The objective of this study was to evaluate the efficacy of IV iron sucrose to treat adult patients with iron deficiency anemia. *Methods.* Between January 2003 and August 2009 we studied 86 adult patients with iron deficiency anemia (IDA). The inclusion criteria were: hemoglobin (Hb) level <12.0 g/dL for women and <13.0 g/dL for men, serum ferritin <12 ng/mL and intolerance or no effect of oral iron therapy (160-200 mg/d over 2 weeks), severe anemia (Hb <7 g/dL) and pregnancy with Hb level <10 g/dL and gestational age over 16 weeks. The main laboratory tests performed were: complete blood cell count, reticulocyte count, serum iron, total iron-binding capacity and serum ferritin. The patients received a weekly dose of 200 mg of iron sucrose until Hb correction or completing the administration of the total dose of parenteral iron recommended for each patient. *Results.* The median age of the patients studied was 42.5 years (age range from 20 to 76). Sixty-nine out of 86 patients (80%) were women. The most common cause of iron deficiency anemia was abnormal uterine bleeding observed in 45.3% of female patients and partial gastrectomy in 53% of male patients. Thirty-five (40.7%) patients were included in this study due to a lack of response to oral iron therapy, 33 (38.4%) showed intolerance to oral iron, 10 (11.6%) presented with a Hb level <7.0 g/dL and 8 (9.3%) were pregnancy. The mean Hb and ferritin values were 8.54 g/dL and 7.63 ng/mL (pre-treatment) and 12.1 g/dL and 99.0 ng/mL (post-treatment) (P<0.0001), respectively. The average increase of hemoglobin were 3.29 g/dL and 4.58 gdL for women and men, respectively. Correction of anemia was obtained in 47 out of 69 female patients (68.1%) and in 12 out of 17 male patients (70.6%). Six patients received blood transfusions before starting intravenous iron treatment. None of the 86 studied patients needed red blood cell transfusions during or after completing the treatment. Only two adverse events [rash (n=1) and palpitation (n=1)] were reported by the investigators among 515 IV iron sucrose infusions. No patient discontinued the treatment. No death was reported by the investigators during the study. *Conclusions.* The use of intravenous iron sucrose is an efficacious and safe option in the treatment of adult patients with IDA who lack satisfactory response to oral iron therapy. This treatment option should be considered mainly in patients with severe anemia in order to obtain rapid increases in the hemoglobin levels and to avoid blood transfusions.

1851

ANEMIA IN ADULT PATIENTS WITH SEVERE FALCIPARUM MALARIA, OUTCOMES AND ASSOCIATED FACTORS

S Chamnanchanunt,[1] T Ouppapong,[2] W Charoenpong,[3] S Jearraksuwan,[3] R Ruangweerayut,[4] Y Wattanagoon,[3] V Desakorn[3]

[1]Tropical Medicine Institute, Bangkok, Thailand; [2]Ministry of Public Health, Nonthaburi, Thailand; [3]Faculty of Tropical Medicine, Bangkok, Thailand; [4]Mae Sot General Hospital, Tak, Thailand

Background. People in more than 100 countries (subtropical and tropical area) are suffered from falciparum malaria. Anemia is one of the most common complications in severe falciparum malaria patients. The prevalence of anemia in falciparum malaria patients varies from different area. Especially in severe anemia malaria group, the association between anemia and clinical parameters had not been discerned yet. Moreover, there is no consensus on when the most appropriate time to give pack red blood cell (PRC) transfusion is. Since the transfusion reaction may occur, physicians have to weight between the benefit of blood transfusion. Thus, the data on transfusion reaction was not available especially in severe anemia malaria patient. *Aims.* To determine the prevalence of anemia, the proportion of patients with severe anemia (using WHO criteria 2006), outcomes and associated factors of severe anemia, and the prevalence of transfusion reaction among adult patients with severe anemia falciparum malaria at Mae Sot General Hospital, Tak province, Thailand. *Methods.* A retrospective study was conducted in adult patients (age 15 years and older) with severe falciparum malaria according to WHO criteria 2006, admitted to Mae Sot General Hospital between 1st January 2004 and 30th November 2008. Case data were retrieved from hospital records. The ethice committee of Tropical Medicine Institute approved this study. *Results.* 262 patients were enrolled into the study. The majority (72.9%) were male, median age

33 years (range 15-94), and Myanmar (61.8%). The common clinical presentations were fever (99.2%), pallor (50.4%), jaundice (48.9%), Glasgow coma scale (GCS) scores ≤10 (30.7%), and hepatomegaly (20.1%). One hundred seventy six patients (68%) were given the combination of artesunate and mefloquine regimen. The prevalence of anemia and severe anemia (hemoglobin less than 5 g/dL) on admission were 70.2% and 5.3%, respectively. Two-thirds of patients without anemia on admission developed non-severe anemia during hospitalization, making the overall incidence 90.1% (236/262). Logistic regression analysis showed no factor to be independently associated with severe anemia, when compared with cases without anemia. However, the white blood cell and platelet count, and bicarbonate were independently associated with severe anemia, when compared with non-severe anemia on admission (P=0.022, 0.022 and 0.16 respectively). The following factors were independently associated with overall anemia (both severe and non-severe anemia): referred cases (P= 0.01), microcytic red cell (P<0.001), blood urea nitrogen (BUN) (P< 0.001), creatinine (P=0.021), and platelet counts (P=0.02). No patient with severe anemia malaria died. Moreover, patient with non-severe anemia malaria showed high mortality among groups (25.9%). Median number of PRC unit per each patient was 2 units (range 1-18). Patients who received PRC transfusion had longer hospital stays when compared with no PRC transfusion (P<0.001) but none of them developed an acute transfusion reaction during RPC transfusion. *Conclusions.* Overall, anemia was a common complication in severe falciparum malaria, but the rate of severe anemia was low. Factors independently associated with only anemia were BUN, creatinine, and platelet counts, microcytic red cell, and referred cases. No acute transfusion reaction was found among patients receiving PRC transfusions.

1852

CARE OF IMMIGRANT PATIENTS IN A TROPICAL MEDICINE UNIT: USEFULNESS OF SYSTEMATIC SCREENING FOR HEMOGLOBINOPATHIES

MA Molina-Arrebola, JA García-Bautista, MJ Giménez-López, R Pérez-Moyano, J Salas-Coronas, J Vázquez-Villegas, MT Cabezas-Fernández, C Avivar-Oyonarte

E.P. Hospital de Poniente, El Ejido - Almeria, Spain

Background. In 2009, more than 142,284 foreign persons live in Almeria, southern Spain, representing a 20.8% of the total population (684,426 inhabitants). The percentage of foreign residents estimated for the entire Spanish territory is around 12%. The Tropical Medicine Unit (TMU) of our hospital was founded In 2004, and it belongs to the Spanish Network of Tropical Medicine Units (REUMT), coordinated by the Carlos III Health Institute. Hemoglobinopathies, both structural and thalassemic, are frequent in black population, due, at least partly, to their protective effect against endemic malaria. *Aims.* To assess the usefulness and effectiveness of initial systematic screening for Hemoglobinopathies in all black patients seen in the TMU. *Materials and methods.* Analytical data from black immigrant patients seen for the first time in the TMU of the Poniente Hospital throughout 2008 were reviewed. Blood samples were analyzed in an ADVIA 2120 (Siemens®) hematological cell counter. As screening for the presence of structural hemoglobin variants, the high-pressure liquid chromatography (HPLC) Hi-AUTO A1c 8160 (Menarini®) system was used. For definitive characterization of abnormal hemoglobins, electrophoresis in agarose gel and acidified medium was ordered. In cases with microcytosis/hypochromia not associated to iron deficiency, HbA2 and HbF were dosified. In case they were normal, genetic analysis for α-thalassemia was carried out when suitable. *Results.* A total 335 immigrant patients coming from sub-saharan Africa were seen in the TMU during 2008; average age 28.3 years (range 15-55); 305 male (91%). The most frequent countries of origin were: Senegal (120 patients, 35,8%), Mali (60, 17,9%), Guinea-Bissau (55, 16,4%), Ghana (23, 6,9%), Mauritania (22, 6,6%) and Gambia (21, 6,3%). The average hemoglobin concentration was 14,9 g/dL (range 8,2-18,7 g/dL). Since the implementation of systematic screening, 46 cases of hemoglobinopathies have been detected. Of them, 26 (56,5%) were Hb AS (sickle cell trait), 10 (21,7%) Hb AC (heterozygous C hemoglobinopathy), 3 (6,5%) homozygous α-thalassemia, 2 heterozygous α-thalassemia, 2 Hb AS+β-talassemia minor, 1 Hb CC (homoozygous C hemoglobinopathy), 1 β-delta thalassemia and 1 Hereditary Persistence of Fetal Hemoglobin (HPFH). Sickle cell trait has been detected in patients coming from all countries, except Burkina-Fasso, Sierra Leone and Ivory Coast. Hemoglobinopathy C was detected in originals from Ghana (4 Hb AC, 1 Hb CC), Mali (4 Hb AC) and Burkina-Fasso (1 Hb AC). The higher percentage of hemoglobinopathy carriers were found in Nigeria (4/7, 57,1%), 2 homozygous alfa-thalassemias, 1 Hb AS and 1 Hb AS+β-thalassemia; Equatorial Guinea (3/7, 42,8%, carriers of Hb AS; and Ghana 7/23 (30,4%) (5 hemoglobinopathies C, 1 Hb AS and 1 HPHF). *Conclusions.* The gradual increase in the proportion of immigrant patients in our area makes it necessary to implement screening programs for hemoglobinopathies, in order to assess the real incidence, define risk groups (pregnant women, newborns) and be able to detect severe forms that would benefit from early treatment. The HPLC system is available in a large number of clinical laboratories for the measurement of HbA1c. It is a fast, simple, affordable and reliable method, and can be of great usefulness in the detection of hemoglobinopathies.

1853

PERIPHERAL QUANTITATIVE COMPUTED TOMOGRAPHY(PQCT) STUDY OF THE FUNCTIONAL MUSCLE-BONE UNIT IN FEMALE PATIENTS WITH β -THALASSEMIA MAJOR

O Papakonstantinou,[1] A Balanika,[1] C Baltas,[2] E Rigatou,[3] N Kelekis,[1] S Kostaridou[4]

[1]Attikon Hospital, University of Athens, Athens, Greece; [2]G Gennimatas General Hospital, Athens, Greece; [3]1.Department of Paediatric Haematology Oncology, Athens, Greece; [4]Thalassemia Unit, Aghia Sophia Childrens Hospital, Athens, Greece

Background. Osteoporosis, is common in adult patients with β-thalassaemia, relates to expansion of bone marrow and reduction of bone density and constitutes a major cause of bone morbididy. In most studies, osteoporosis is diagnosed on the basis of reduced bone mineral density by means of dual energy x-ray absorptiometry. Peripheral quantitative computer tomography (pQCT) was used recently to assess the changes in volumetric bone mineral density (vBMD) in various bone compartments; however the effect of osteoporosis on bone marrow cavity and muscles has yet to be explored. *Aims.* To evaluate the muscle and bone cross-sectional area, along with the cortical bone density, thickness and strength by means of pQCT in a group of female patients with β-thalassemia major and compare with an age matched control group in order to assess possible effects of muscle over bone. *Methods.* Twenty-six female patients with β -thalassemia major (age 22-41, body-mass index/BMI: 21-23) and history of fragility fracture over a 1-year period were enrolled in an open perspective study, performed in a two-year period. The control group was composed of 25 females healthy volunteers, matched for age and BMI with the patient group; all the control subjects were free from bone diseases. The study was conducted with the approval of the hospital ethics committee and informed consent was obtained from all of the human subjects. The pQCT measurements were performed at the 14%, 38% and 66% of the non-dominant tibia length. Cortical bone density (CBD), cortical thickness (CTH),marrow cavity area(MC) strain-stress index (SSI), bone cross-sectional area (BCA) and muscle cross-sectional area (MCA) were calculated. *Results.* CBD, CTH, BCA ,MCA and SSI were reduced in the β -thalassemia major females in comparison with the control subjects (P<0,001). MC of female patients were significantly higher compared with healthy female controls (P<0.01). *Conclusions.* Women with β-thalassemia major showed poor quality (low CBD, CTH) fragile bones (low CTH,BCA,SSI) with expanded marrow cavity and low adaptive response of bone to muscle force.

1854

X-LINKED SIDEROBLASTIC ANEMIA (XLSA): TWO NEW MUTATIONS IDENTIFIED IN MALES

J Pereira,[1] A Pereira,[1] M Duarte,[1] U Rebelo,[1] T Melo,[2] M Bini-Antunes,[2] J Barbot,[2] ML Ribeiro[1]

[1]Centro Hospitalar Coimbra, EPE, Coimbra, Portugal; [2]Hospital de Crianças Maria Pia, Centro Hospitalar do Porto, Porto, Portugal

Sideroblastic anemias (SA) are a heterogeneous group of disorders, congenital or acquired, associated with abnormal heme biosynthesis, characterized by: 1) microcytic hypochromic anemia, with dimorphism, 2) presence of ringed sideroblasts in the bone marrow, 3) important secondary hemosiderosis. Phenotypic expression of XLSA varies considerable in males. Most frequently, it is diagnosed during the first years of life and is associated with mutations (primarily missense) in the erythroid-specific 5-aminolevulinic acid synthase gene, ALAS2 (Xp11.21). In the less severe forms, the diagnosis may be delayed to the first two decades of life or to the middle age, when the secondary iron overload is remarkable. Females can also have severe anemia, particularly after the fourth or fifth decade of life, due to unbalanced X chromosome lionization. Depending on the ALAS2 mutation location, some patients may

respond to oral pyridoxine treatment. Severe cases are transfusion dependent. *Case 1.* A 42-year-old male was referred to elucidate a chronic microcytic hypochromic anemia: Hb 8,7 g/dL, VGM 55 fL, HGM 17 pg, RDW 30% and peripheral blood smear with dimorphism. Serum ferritin 2932 ng/mL (normal 18-370), transferrin saturation 89% and 20% of ring sideroblasts in the bone marrow. A diagnosis of XLSA was made and treatment with 150 mg/d pyridoxine raised the hemoglobin level 1,5 g/dL in 3 weeks. Molecular analysis of ALAS2 gene showed a not previously described missense mutation at codon 147 (CGC-CAC) (Glu147His) in hemizygous state. *Case 2.* An 8-year-old boy presented with microcytic hypochromic anemia: Hb 10.9 g/dL, VGM 67 fL, HGM 20 pg, RDW 17% and peripheral blood smear with anisocytosis and anysochromia but without observable dimorphism. Serum ferritin 70 ng/mL (normal 18-370), transferrin saturation 19%. His mother presented a mild normochromic and normocytic anemia (Hb 11.1 g/dL, VGM 84.8 fL, HGM 28 pg) contrasting with a high RDW (26%). Two erythrocyte populations were observable in peripheral blood smear. Histogram confirmed a marked dimorphism where 17,6% of the cells were microcytic and 22,6% hypochromic. Each one of the two populations had his own reticulocyte counterpart. Serum ferritin (451 ng/mL) was indicative of iron overload. A diagnosis of XLSA was made and after twelve months of pyridoxine treatment no increment on haemoglobin level was observed. Molecular analysis of ALAS2 gene showed a not previously described missense mutation at codon 503 (GCC-GTC), resulting in the Ala503Val amino acid change, in hemizygous state. The mother was heterozygous for the mutation. To demonstrate that these new mutations were not polymorphisms, we screened 100 DNA samples from unrelated females and not find any allele with these nucleotide substitutions. *Conclusion.* Considering that XLSA phenotype severity varies considerable in males, and can also be present in females, all patients who are suspected as having XLSA or at-risk individuals in families with XLSA should have their DNA examined for ALAS2 mutations, irrespective of their haematological findings, sex and age. Identification of the ALAS2 mutation allows an early treatment with pyridoxine and prevention of iron overload and the identification of heterozygous women in family who will benefit from genetic counselling.

1855

EVALUATION OF GENERAL EXAMINATION OF BLOOD AS PROGNOSTIC INDICATOR IN THE GENERAL POPULATION OF DEPARTMENT OF URGENT INCIDENTS

K Rousos,[1] P Patiakas,[2] C Charalampous,[3] T Mylonas[2]

[1]General hospital of Veria, Greece, Veria, Greece; [2]Microbiological Laboratory of General Hospital of kastoria, Kastoria, Greece; [3]Pathological Clinic of Psychiatric Hospital of Thessaloniki, Greece, Thessaloniki, Greece

Background-Aim. The hematological parameters of patients that arrive in the surgeries of Department of Urgent Incidents (DUI) the Hospitals - Centres of Health were correlated with the mortality inside the week. Even if there are various systems of grading the prognostic value of various laboratorial examinations, the hematological parameters do not correlated yet with particular prognostic role. *Material and Method.* 514 possessed patients (286 men and 228 women) that arrived in the DUI of our hospital and then hospitalized more than 7 days, were retrospectively studied - independent the cause of entry. The rate of mortality was 6,42% (33 individuals), while the means age of subsistent and decedent were 59,7 and 78,2 years, respectively. The values of haematological parameters were recorded and were statistically analyzed in order to find possible correlation between those values and the final result of their situation inside the week. *Results.* As you can see at the tables 1 and 2.

Tables 1 and 2.

COMPOUND HETEROZYGOSITY FOR HB C/ + β-THALASSAEMIA.A CASE PRESENTATION

S Theodoridou, M Alemayehu, S Ganta, M Tsalidou, E Katsimpourlia, P Perperidou, O Karakasidou, V Aletra, G Papaioannou

Hippokration Hospital, Thessaloniki, Greece

The Hb C is due to a replacement of the glutamic acid by lysine at point 6 of the β-chain (β,6 Glu-Lys). It is encountered mainly in the Western and South Africa, in Canada and also Italy, Sicily, Turkey and Greece. It exists at the heterozygous form, the homozygous form and the compound heterozygous form in combination with thalassaemia and other haemoglobinopathies. Combined with β-thalassaemia although rare, presents great clinical moderation. We report the case of a 22-years-old soldier of Muslim origin from Thrace, who was referred for investigation due to hypochromic, microcytic anaemia and splenomegaly. Clinical examination showed a slight increase in splenic size. The haematological data of the propositus was: Hb: 11.7 gr/dl, Hct: 38.4%, MCV: 65.4 fl, MCH: 19.9 g/dL, RBC: $5.880\times10^3/\mu L$. Ferritin levels were 67 ng/mL. Microscopic examination of a stained peripheral slide revealed intense hypochromia, severe anisocytosis, microcytosis, baseophilic stippling and target cells. No erythroblasts were found. Osmotic resistance of the red cells was elevated and sick ling test was negative. HPLC hemoglobin variants analysis showed Hb A2: 5.3%, Hb F: 1.8% and an abnormal haemoglobin 83.9% at time 4.88 minute. Electrophoresis of the haemoglobin at alkaline and acid pH showed properties of a compound heterozygote for Hb C and β-thalassaemia. Further molecular screening revealed an IVS II- 745 (β+) thalassaemic mutation. Compound heterozygosity for Hb C and β-thalassaemia is rare and was first described in an Afro-American patient. It has also been described in Italians, North Africans, Turks, Sicilians and Tunisians. The interesting feature of the haemoglobin C β-thalassaemia is the remarkable clinical heterogeneity and differences in haematological manifestations. Although reports on the molecular level are limited there are sufficient data that the variability of the clinical and haematological manifestations reflects the variability of the β-thalassaemia gene which is interacting with Hb C. In our Haemoglobinopathy Prevention Unit whish covers all over Northern Greece during the last 22 years (1986-2007) 80.401 subjects have been examined for haemoglobinopathy and thalassaemia We found 18 subjects heterozygotes for Hb C, one homozygote for Hb C and this one case presented with compound heterozygosity of β-Thalassaemia and Hb C. According to the literature we have not found such a case of a compound Hb C and IVS II- 745 (β+) thalassaemic mutation reported. Our patient seems to have mild anaemia that did not cause any symptoms and was diagnosed during the military service. Detection of thalassaemia and structural hemoglobin variants is important in clinical laboratories in countries with a high percentage of carriers, as Greece. Knowledge of the epidemiology of haemoglobinopathies provides important information for public health planning and appropriate counselling of couples.

1857

SEVERE ANEMIA IN CHILDHOOD: WHAT ABOUT THE REALITY?

G Claes,[1] P Lê,[2] P Lepage,[2] A Ferster[2]

[1]HUDERF, Brussels, Belgium; [2]Huderf, Brussels, Belgium

Background. According to the WHO, severe anemia is a public health problem and it is not often studied in the industrialized countries. The main causes affecting about 598 millions of children around the world are iron deficiency, parasitic infections, chronic diseases, nutritional deficiencies and haemoglobinopathies. The aim of our work is to review children who have a hemoglobin level less than 8 g/dL, diagnosed at the outpatient clinic or at the emergency department and to analyze their characteristics. *Material and methods.* This is a retrospective monocenter study that reviews 94 medical records of children aged 0 to 18 who were seen at the Brussels University of Children Reine Fabiola with a hemoglobin level less than 8 g/dL between January 2006 and June 2008. The data were divided into two groups: sickle cell disease (group I) *vs.* other causes of anemia (group II). They are also separated into 2 classes of age, more or less than 6 years old. *Results.* 94 children were included. Among them, 43.6 % suffer from sickle cell disease and 27.7% from e.g. iron deficiency. Furthermore, no diagnosis is observed for 5 % of the cohort and 16% of the children are lost from follow up. 35.8% of group II had a consultation with an hematologist and 64.2% were hospitalized. 42% were coming from Central Africa, mostly Sickle Cell disease patients. The average level of hemoglobin

among the patients is 6.85 g/dL (±1.1) with an average MCV of 77, 2 fL (± 16.4) and an average MCHC of 32.1 g/dL (± 3.8). *Discussion.* Every nine or ten days, a new patient with severe anemia was diagnosed. However there is a recruitment bias because the HUDERF is a pediatric reference hospital. Globally, the pediatric hematologists are taking in charge of chronic children pretty well. Unfortunately, there are failures in the practical guidance of the others when there are some elements in their medical story like prematurity. It could take time before these children achieve to the good place. Furthermore, iron deficiency is the most important cause of anemia, easily identifiable. An interesting point to underline: children older than 6 years and without sickle cell disease, were significantly smaller (≥ 2 standard deviation) than control children of their same age, suggesting an additional underlying cause. *Conclusion.* In our study, near the half is suffering from Sickle Cell disease and a third from iron deficiency. The care for anemic patients with defined underlying cause is pretty good because they are rapidly referred to hematology-oncology department. Nevertheless, for the others, the problem is obviously under recognized and under treated. That is why we recommend redefining the medical approach of children suffering from severe anemia without a clinically known etiology.

1858

HAEMOGLOBINOPATHIES SCREENING IN INMIGRANT AFRICAN POPULATION AT THEIR ARRIVAL TO CANARY ISLANDS

S De La Iglesia,[1] C Carranza,[2] JL Perez-Arellano,[2] P Ropero,[3] J Lopez,[4] M Lorenzo,[5] R Martin,[5] A Villegas,[5] T Molero[4]

[1]HUGC Doctor Negrin, Las Palmas de G.C., Spain; [2]D. Ciencias Médicas y Quirúrgicas. ULPGC., U. E. Infecciosas y M.Tropical. HUIGC., Spain; [3]S. Hematologia, H. Clinico San Carlos, Madrid, Spain; [4]S. Hematologia. HUGC Doctor Negrin, Las Palmas de G.C., Spain; [5]S. Analisis Clinicos. H.U.G.C. Doctor Negrin, Las Palmas de G.C., Spain

Structural haemoglobinopathies are one of the most important health problems all over the world. Its incidence has arised in our country in the last years due to inmigration. Canary Islands are one of the main ways of entrance to Subsaharian African and Magreb immigrants. An ordinary study of haemoglobinopathies and thalassemias is not made at their arrival. The aim of this study is to analyze the prevalence of haemoglobinopathies and talasemia in inmigrant population who go to a foster home at their arrival to Gran Canaria, with the aim to detect people with these illnesses or asymptomatic carriers. *Patients and method.* We analyze 155 samples of African individuals who have recently arrived to the island by High performance liquid chromatography (HPLC) methods using an automated D-10 HPLC system (Bio-Rad®). The obtained results were analyzed together with demographic, hematologic and biochemical data. Also molecular studies of the samples were performed. Informed consent was obtained. *Results.* 20 structural haemoglobinopathies were detected (12,9%). 19 of them were heterozygotous (12 HbS and 7 HbC) and one homozygotous (HbSS). 19 samples belonged to subsaharian people and one to a person coming from the Magreb. Most of haemoglobinopathies carriers did not show anemia (84%), nor microcytosis (58%). Genetic advice was given to these haemoglobinopathies carriers in order to minimize the occurrence of homozygotous individuals. *Conclusion.* Structural haemoglobinopathies prevalence observed in our area is ten-fold higher than the one observed in the rest of Spain and in other studies carried out among inmigrant population in our country. According to this data, it seems that screening health programs for haemoglobinopathies and thalassemias in this population should be performed at their arrival to Canary Islands.

Financing. This study has been performed, partly, thanks to FIS project PI06135.

1859

A COMPARISON OF NOVEL SERUM MARKERS FOR THE ASSESSMENT OF LIVER FIBROSIS IN PATIENTS WITH BETA THALASSEMIA MAJOR TREATED WITH DEFERASIROX

Y Aydinok,[1] C Arikan,[1] Z Karakas,[2] I Sasmaz,[3] D Canatan,[4] L Agaoglu,[2] Y Kilinc,[3] A Canatar,[5] O Ocak,[5] E Alnigenis[5]

[1]Ege University Medical School, Izmir, Turkey; [2]Istanbul University, Istanbul Medical Faculty, Istanbul, Turkey; [3]Cukurova University Medical Faculty, Adana, Turkey; [4]Suleyman Demirel University Medical Faculty, Isparta, Turkey; [5]Novartis Pharma AG, Istanbul, Turkey

Background. Iron overload enhances oxidative stress within the liver, which is associated with the development of liver fibrosis. Without effective treatment at an early stage, reversible hepatic fibrosis progresses to irreversible cirrhosis. Eighty seven beta-thalassaemia major patients were enrolled in Turkey in the ICL670A0107 study, an international one-year, phase III trial, and were randomized to deferasirox or desferrioxamine. At the completion of the core phase, those who gave consent continued into the extension protocol (ICL670A0107E) that lasted for up to 4 years. *Aim.* To evaluate the effects of up to 5 years deferasirox treatment on liver iron content and fibrosis scores, and the change in liver histology in relation with serum fibrosis markers in beta-thalassaemia patients. *Methods.* This study was run in Turkey following the completion of the ICL670A0107E extension. beta-thalassaemia major patients who completed core phase and continued with deferasirox or switched to deferasirox during 4 year extension were included after consenting for participation in this locally run study. Deferasirox dose was initially based on liver iron concentration at start of treatment; dose adjustments based on monthly serum ferritin and safety trends. Frozen serum samples and liver biopsy specimens which were collected at baseline, 1st year and end of study and stored during the ICL670A0107 core and extension protocols of those patients was used. Liver iron concentrations (LIC) and liver fibrosis scores according to Ishak system were obtained. Serum tenascin, tissue inhibitors of metalloproteinase (TIMP-1), and matrix metalloproteinase (MMP) levels were measured with commercial enzyme-linked immunoassay (ELISA) kits. The same cohort was also stratified according to liver fibrosis (F≤4 *vs.* F>4). *Results.* 66 patients who received deferasirox (n=41) since the core study and switched to deferasirox (n=25) after 1 year and completed 4 year extension study were included. LIC significantly decreased from baseline (21.2±1.6) at 1sty (14.6±1.2) and the EOS (9.4 ±1.0) (P<0.001) while fibrosis score did not differ significantly. In respect of serum fibrosis markers, there were no significant differences in mean serum levels of tenascin, collagen IV and MMP-1 between patients with mild to moderate (F≤4) and advanced liver fibrosis (F5-F6), while levels of TIMP-1 were higher in the latter group both at baseline and end of the 5th year (160.44±9.89 *vs.* 214.87±24.2 μg/L; P=0.047, 71.61±5.89 *vs.* 94.9±4.61 _g/L P=0.012). Only TIMP-1 was also significantly correlated with histological fibrosis at baseline, 1 year, and end of the 5th year (r = 0.31, P=0.048; r=0.32, P=0.02 and r=0.38, P=0.02, respectively). Further, during treatment all serum fibrosis markers decreased significantly compared to baseline irrespective of the fibrosis score. *Conclusions.* This is the first large retrospective cohort design study, to report up to 5 year data of any chelator with respect to effect on LIC, the progression of fibrosis and regulation of hepatocyte regeneration. We show here that matrix derived fibrosis marker TIMP-1 correlates with histological fibrosis and may play an important role in the regulation of hepatocyte regeneration. Serum fibrosis markers significantly decreased from baseline after long-term DFX therapy.

1860

EFFICACY OF DEFERASIROX IN PATIENTS WITH THALASSAEMIA MAJOR IS NOT AFFECTED BY A HISTORY OF HEPATITIS B OR C

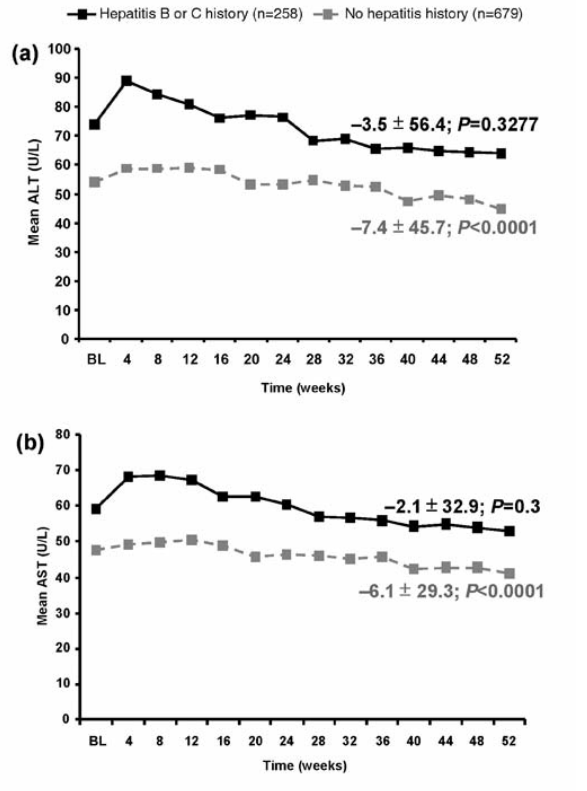
MD Cappellini,[1] M Elalfy,[2] A El-Beshlawy,[3] A Kattamis,[4] LL Chan,[5] C Li,[6] KH Lin,[7] G Quarta,[8] P Sutcharitchan,[9] A Taher,[10] D Habr,[11] B Roubert,[12] J Porter[13]

[1]Universitá di Milano, Policlinico Foundation IRCCS, Milan, Italy; [2]Ain Shams University, Cairo, Egypt; [3]Cairo University, Cairo, Egypt; [4]First Department of Pediatrics, University of Athens, Athens, Greece; [5]University Malaya Medical Centre, Kuala Lumpur, Malaysia; [6]Guang Zhou Nang Fang Hospital, Guangzhou, China; [7]National Taiwan University Hospital, Taipei, Taiwan; [8]Ospedale A. Perrino, Brindisi, Italy; [9]Chulalongkorn University and King Chulalongkorn Memorial Hospital, Bangkok, Thailand; [10]American University of Beirut, Beirut, Lebanon; [11]Novartis Pharmaceuticals, East Hanover, NJ, USA; [12]Novartis Pharma AG, Basel, Switzerland; [13]University College London, London, UK

Background. Data suggest that iron overload in thalassaemia major (TM) patients with hepatitis B or C infection increases the risk of liver fibrosis progression. As deferasirox treatment is uncommonly associated with transaminase elevations suggestive of hepatitis (0.3%), it is important to assess whether viral hepatitis status affects the safety profile of deferasirox. Data are reported from patients with a history of hepatitis B or C enrolled in the prospective, multicenter EPIC study. *Aims.* To assess the overall and liver safety of deferasirox in TM patients with/without a history of hepatitis B or C (as recorded at baseline) over 1 year. *Methods.* Transfusion-dependent TM patients aged ≥2 years with

serum ferritin (SF) levels ≥1000, or <1000 ng/mL with history of multiple transfusions (>20 transfusions or >100 mL/kg red blood cells), and MRI-confirmed LIC >2 mg Fe/g dw, were enrolled. Deferasirox starting dose was 10-30 mg/kg/day depending on blood transfusion frequency. Dose adjustments (5-10 mg/kg/day [range 0-40]) were performed every 3 months based on SF trends and safety markers. Safety was evaluated through recording adverse events (AEs) and monthly blood chemistry. *Results.* Of 937 patients with TM, 258 (27.5%) had a history of hepatitis B or C. Patients with hepatitis history were older (mean 26.5±9.9 *vs.* 15.3±9.5 years), more commonly splenectomized (50.4% *vs.* 29.9%), received more transfusions (mean 195 *vs.* 188 mL/kg) and longer duration of chelation at baseline (mean 15.9±10.5 *vs.* 8.7±7.4 years) than those without hepatitis history. Among patients with hepatitis history, 212 (82.2%) completed 1 year of treatment *vs.* 636 (93.7%) without. Most common drug-related AEs in patients with *vs.* without hepatitis history, respectively, included diarrhoea (14.7% *vs.* 6.2%; P<0.0001), abdominal pain (7.4% *vs.* 4.7%; P=0.110), nausea (5.0% *vs.* 3.5%; P=0.291) and skin rash (10.5% *vs.* 13.5%; P=0.205). Three patients (1.2%) with hepatitis history had two consecutive alanine aminotransferase (ALT) increases 10 x upper limit of normal (ULN); all had elevated baseline levels (mean 95.6 U/L). Two patients (0.3%) without hepatitis history had similar increases; one had an elevated baseline level (225 U/L). Mean ALT and aspartate aminotransferase (AST) levels decreased in both groups, significantly in patients without hepatitis history (Figure).

Figure. Mean (a) ALT and (b) AST levels in thalassemia major patients with or without a history of hepatitis B or C.



Serum creatinine was >33% above baseline and >ULN on two consecutive visits in 12 (4.7%) patients with and 25 (3.7%) without hepatitis history. Overall median SF decreased from baseline (3157 ng/mL) by 129 ng/mL after 1 year (P=0.0007) at a mean actual dose of 24.2±5.6 mg/kg/day and mean transfusional iron intake of 0.43±0.2 mg/kg/day. SF reductions were similar in patients with/without hepatitis history (-113 and -148 ng/mL, respectively). *Conclusions.* Deferasirox was well tolerated in TM patients, irrespective of hepatitis history, with no significant differences in incidence of AEs and ALT increases. Baseline liver transaminases were higher in patients with hepatitis history compared with those without, but decreased in both groups suggesting deferasirox improved liver function through iron removal. Reductions in SF were similar in both groups. Further confirmatory and long-term data are required to characterize the effects of deferasirox in patients with viral hepatitis.

1861

N-ACETYLCYSTEINE REDUCES OXIDATIVE STRESS IN SICKLE CELL PATIENTS

E Nur,[1] D Brandjes,[1] T Teerlink,[2] R Oude Elferink,[3] F Muskiet,[4] H ten Cate,[5] B Biemond,[3] A Duits,[6] JJ Schnog[7]

[1]Slotervaart Hospital, Amsterdam, Netherlands; [2]Dept. of Clinical Chemistry, VU University Medical Center, Amsterdam, Netherlands; [3]Academic Medical Center, Amsterdam, Netherlands; [4]Pathology and Laboratory Medicine, University Medical Centre Groningen, Groningen, Netherlands; [5]Laboratory of Clinical Thrombosis and Hemostasis, Academic Hospital Maastricht, Maastricht, Netherlands; [6]Immunology Laboratory,[7] Red Cross Blood Bank Foundation, Curacao, Netherlands Antilles; [7]Sint Elisabeth Hospital, Curacao, Netherlands Antilles

Background. Oxidative stress is of importance in the pathophysiology of sickle cell disease (SCD). Plasma and erythrocyte levels of the major anti-oxidant glutathione are decreased in SCD and treatment with N-acetylcysteine (NAC), the rate limiting precursor for glutathione formation, has been demonstrated to increase glutathione levels and decreased dense cell formation in sickle cell patients.

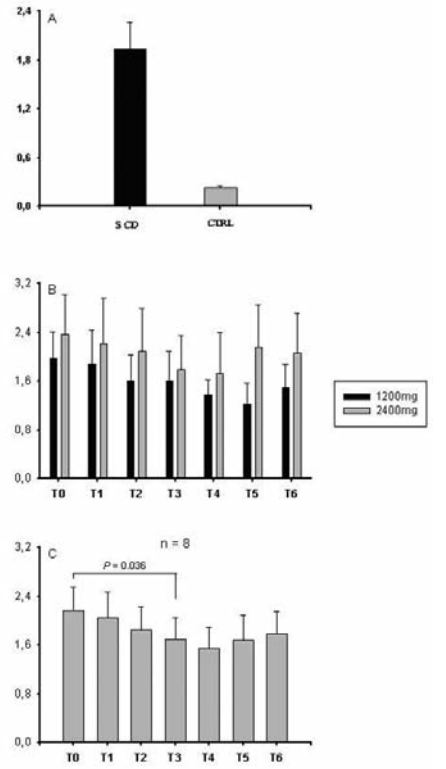


Figure. Erythrocyte phosphatidylserine (PS) expression in sickle cell patients (SCD) compared to healthy controls (CTRL) and during the study period. (A) Sickle erythrocytes (SCD) have a significantly higher outer membrane PS expression than erythrocytes of race matched healthy controls (CTRL) ($P < 0.0001$). (B) PS expression decreases in both 1200 mg (black bars, n = 4)) and 2400 mg (gray bars, n = 4) groups during NAC treatment, returning towards baseline values after cessation of NAC intake. The differences were not statistically significant. (C) Differences in PS expression shown for both NAC dose groups together, where the difference between baseline and 6 weeks (last day of NAC treatment) was statistically significant (Wilcoxon signed ranks test). Sampling performed at 2 weeks interval starting at baseline (T0). Bars indicate means ± SEM.

Figure. Erythrocyte phosphatidylserine expression.

Aims. In this open label randomized trial the effect of oral N-acetylcysteine (NAC) on oxidative stress, coagulation and endothelial activation was studied. *Methods.* Eleven consecutive patients (10 HbSS, 1 HbSβ0-thalassemia) were randomly assigned to treatment with either 1200 or 2400 mg NAC daily during 6 weeks. *Results.* Three patients were excluded due to incompliance. Whole blood glutathione levels increased and erythrocyte outer membrane phosphatidylserine exposure and plasma levels of advanced glycation end-products (AGEs) and cell-free heme decreased after 6 weeks of NAC treatment in both 1200 mg (n=4) and 2400 mg (n=4) groups. NAC treatment did not cause changes in markers of coagulation activation and endothelial activation. During the study period none of the patients experienced painful crises or other SCD or NAC related complications. *Conclusions.* Short term N-acetylcysteine treatment of sickle cell patients seems to reduce SCD related oxidative stress and hemolysis.

1862

IRON OVERLOAD IN PATIENTS WITH CHRONIC HEPATITIS C: A RANDOMIZED CONTROLLED STUDY ON EFFICACY AND TOLERABILITY OF IRON DEPLETION BEFORE ANTIVIRAL THERAPY BY PEG-IFN _2B + RIBAVIRIN

L Paesano,[1] M D'Onofrio,[1] I Gentile,[2] C Viola,[2] R Cerini,[2] F Borrelli,[2] E D'Agostino,[3] M Piazza,[2] G Borgia[2]

[1]Transfusion Medicine, S.G. Bosco Hospital, Napoli, Italy; [2]Infectious Diseases, Federico II University, Napoli, Italy; [3]Transfusion Medicine, Federico II University, Napoli, Italy

Background. About 30-39% of patients with chronic hepatitis C (CHC) is affected by iron overload. These patients have a low SVR rate to IFN or IFN + ribavirin (RBV) therapy. No study has investigated whether iron depletion before pegylated IFN or combination treatment improve SVR rate. *Aims.* We have evaluated whether blood letting affect efficacy and tolerability of PEG-IFNalpha2b + RBV in CHC patients. *Methods.* Patients with CHC and ferritin >100 ng/mL were enrolled in the study, excluding homozygotes for HFE mutations and alcohol abusers, and randomized to: 1) repeated phlebotomies up to obtaining a ferritin level <50 ng/mL followed by PEG-IFNα2b + RBV at standard dosage (active arm, AA); or 2) PEG-IFNα2b + RBV at standard dosage (control arm, CA). Primary endpoint was SVR rate; secondary endpoint was frequency of clinical and laboratoristic grade 3-4 adverse events. *Results.* 33 patients (18 naive, 29 genotype 1-4) were enrolled in the study (19 AA, 14 CA). Patients in the two arms did not differ at baseline for any parameter. AA patients underwent a median of 5 phlebotomies, which significantly reduced ferritin, transferrin saturation, ALT and hemoglobin levels, increased platelet count, and had no influence on HCV-RNA level. After a median of 31 days, patients started combination treatment. Ferritin levels increased in both arms during antiviral treatment but remained significantly lower in AA *vs.* CA at each time point. SVR was 31.6% in AA and 21.4% in CA (P=0.698) (difference of efficacy: +10.2% (95%CI -20.59 +40.89%)). Considering only the 18 naive patients, SVR was 60.0% in AA *vs.* 25% in CA (P=0.188) (difference of efficacy: +35% (95% CI: -11.19 +81.19%)). Tolerability, drug dosing reduction or withdrawal were similar in the 2 arms. *Conclusions.* Our results do not indicate that phlebotomies increase efficacy of antiviral therapy in patients with iron overload. However, the strong trend of higher SVR in naive patients undergoing phlebotomies (this subgroup analysis was defined a priori) warrants investigation in large randomized trials focused on them.

1863

FIRST CASE OF HB J-CAMAGUEY ASSOCIATED WITH ALPHA 3.7 IN SPANISH POPULATION

A Villegas,[1] L Vinuesa,[2] F De la Fuente-Gonzalo,[2] J Martínez-Nieto,[2] S Redondo,[2] P Ropero,[2] FA González[2]

[1]Hospital Clinico San Carlos, Madrid, Spain; [2]Hematología. Hospital Clínico San Carlos, Madrid, Spain

Background. Structural hemoglobinopathies are the most common monogenic disorders in the world. It have been described about 800 variants of hemoglobin (Hb). However, most of them are clinically silent because they do not produce an alteration in stability, solubility or function of Hb. Nevertheless they are easily identifiable by electrophoretic and chromatographic methods to determine a change of electric charge on the surface of the molecule. *Aims.* The purpose of this communication is the molecular characterization of Hb J-Camaguey [_141(HC3)Arg->Gly]. *Methods.* The propositus is a 70-years-old Spanish woman from Navarra which was referred to us because in a routine study an abnormal band was detected by HPLC Variant®. Hematologic data obtained by an automatic counter of red cells (Coulter GEN-S, Coulter, Hialeah, FI, USA) were in the normal range, with a slight microcytosis (MCV 75.3 fL). The Hb variant was separated by high performance liquid chromatography (HPLC-VARIANT™ BioRad Laboratories, Hercules, CA, USA) and the globin chains by reversed phase HPLC. For the molecular study was necessary a genomic DNA extraction from peripheral blood leukocytes, employing a Bio-Robot EZ1. Alpha gene deletions were studied by α-thalassemia StripAssay and point mutations were studied by automated DNA sequencing with BigDye v1.1, specific for α2 and α1 genes. *Results.* It was observed a 3.7 kb deletion in one allele; and, in the other allele, a point mutation CGT-> GGT in codon 141 of the 3rd exon of α2 gene. The amplification was performed with primers P1A (5'-162810-162829-3') and C3 (5'-163738-163757-3'), this one, specific to the 3' region of the α2 globin gene. *Conclusions.* Hb J-Camaguey [α141(HC3)Arg->Gly] was described the first time in a Cuban family with spanish ascendants and later identified in several families of Chinese origin. All of them in heterozygous state and in one case associated with a α thalassemia deletion (SEA). In these cases had not been determined which of the two α genes was located the mutations. But in our case, this mutation was localized in the α2 gene using a primer specific of the 3' UTR region of this gene. In this case the association with a 3.7 kb deletion which determines the formation of a α2/α1 fusion gene in the other allele, this makes the mutation is observed as an homozygous although it was an heterozygous, cause the other allele not amplified.

1864

HEMATOGICAL PROFILE COMPARATIVE STUDY OF PATIENTS WITH HEART FAILURE

C Charalampous,[1] S Patiakas,[2] K Rousos[2]

[1]Psychiatric hospital of Thessaloniki, Thessaloniki, Greece; [2]Microbiological laboratory of general hospital of kastoria, Kastoria, Greece

Background - Aim. To study the variance of hematocrit (Ht), white blood cells (WBC), erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), fibrinogen (Fib) and blood immunoglobulins between patients suffering from ischemic cardiomyopathy (IC) and those suffering from dilated cardiomyopathy (DC). Also to study their potential prognostic value in any case, given the fact that in the relative literature it is mentioned that anemia affects the course and evolution of the disease, in patients with congestive heart failure, while in these cases ESR is usually low. *Material - Method.* A total of 86 patients were studied (71 male and 15 female), suffering from heart failure, who presented dilation and left ventricle malfunction and ejection fraction <35%. 49 patients (39 male and 10 female) suffered from DC and 37 (32 male and 5 female) from IC. In these patients, who were under frequent observation for more than one year, the values of Ht, WBC, ESR, CRP, Fib and immunoglobulins were determined. Before this measurements took place, other possible coexisting conditions who could affect the results, such as malignancies, hematological diseases, injuries, gynecological diseases, were excluded. *Results.* Hematocrit, white blood cells and immunoglobulins presented higher values in DC, compared to IC, though there was no statistically important difference between them. CRP and Fibrinogen values were higher in IC compared to DC, though there was no statistically important difference between them. On the contrary, ESR was fairly increased (P<0.001) in the cases of IC (25.3+/-14.1), compared to DC (10.4+/-9.8). *Conclusions.* It is proven, therefore, that there is no statistically important difference between IC and DC, concerning the values of the mentioned lab parameters (who are within the normal range). ESR was an exception, fairly low values (<10) were documented in cases of DC (without a poor prognosis). The other exception was Ht, low values were documented in IC cases. In these cases the low Ht represents an unfavorable prognostic factor, which should not elude our attention.

1865

QUALITY OF LIFE OF SCHOOL AGE THALASSEMIC CHILDREN AT ZAGAZIG CITY

M Hesham, A El Dakhakhny, S El-Awady, F Mohammad

Zagazig University, Zagazig, Egypt

Background. The assessment of quality of life (QOL) in children especially in children with chronic illness such as thalassaemia is particularly important. An assessment of QOL differs from other forms of medical assessment in that it focuses on the individuals' own views of their well-being and assesses other aspects of life, giving a more holistic view of well-being. *Aims.* The present study was aimed to assess the quality of life of school-age children with thalassemia at Zagazig City. *Methods.* A descriptive study was conducted on a sample of 100 school-age thalassemic children at out-patient Hematology clinic at Zagazig University Hospitals in Sharkia Governorate, Egypt from July 2008 to April 2009. Two tools were used to collect the necessary data. The first was a structured interview questionnaire sheet about socio demographic data of children and their parents as well as medical history. The second tool was a standardized tool (the Pediatric Quality of Life Inventory TM Version 4.0). *Results.* Regarding the total QOL, results of the current study showed that less than half of the studied children (37%) had good score and 58% had fair score according to child report while, in parent report 21% of children had good score and 64% had fair score. The emotional function-

ing score was the lowest (60.2±20.1) followed by physical (63.13±17.8), school (74.95±16.5), and the highest was social functioning (84.15±12.5). There was a significant association between the total QOL of the studied thalassemic children and compliance with blood transfusion and regular iron chelation therapy in both child and parent report. We found that there was no significant association between the total QOL and gender, residence, family income and the educational level of parents while there was a negative statistically significant correlation between the total Qol and birth order. Statistics showed an agreement between both child and parent report. *Summary/Conclusions.* Thalassaemia has a negative impact on perceived physical, emotional, social and school functioning in thalassaemic patients.To improve QOL of thalassemic patients, suitable programs aimed at increasing children's adherence to the treatment regimen and providing psychosocial support are important.

1866

THE INCIDENCE OF THE SENSORINEURAL HEARING LOSS AND OCULAR TOXICITY IN β-THALASSEMIA PATIENTS RECEIVING DESFERRIOXAMINE CHELATION THERAPY

G Tüysüz,[1] G Aydogan,[1] K Eltutar,[2] Ö Yigit,[3] Ö Uzunlulu,[2] P Gör,[3] A Akçay,[1] Z Salcioglu,[1] D Tugcu,[1] F Akici,[1] H Sen[1]

[1]Bakirköy Maternity and Children Education and Research Hospital, Istanbul, Turkey; [2]Istanbul Education and Research Hospital Department of Ophtalmology, Istanbul, Turkey; [3]Istanbul Education and Research Hospital Department of ENT and Audiology, Istanbul, Turkey

β-thalassemia is an inherited disorder frequently seen in our country. Regular blood transfusion used for the treatment causes iron overload and tissue damage. To remove excess iron in patients requiring long-term transfussions, chelation therapy is used since 1960's.The first step in chelation therapy is desferrioxamine. The effectiveness of desferrioxamine to control the body iron load is proven in many of the clinical trials. The commonly seen dose limiting side effects of desferrioxamine therapy is sensorineural hearing loss and ocular toxicity. However it is shown in many clinical trials that this side effect is usually reversible, it can lead to tapering the dose and even to stop the therapy. To determine the frequency of eye and auditory complications and their relationship to drug dosage and iron stores in patients receiving desferrioxamine, we studied 52 regularly transfused patients who received desferrioxamine by subcutaneous or intravenous infusion. All enrolled patients underwent otologic and visual assessments. Although the reported incidence of sensorineural hearing loss and ocular toxicity in transfusion-dependent patients receiving desferrioxamine therapy varies from 3.8-40% we have observed no toxic effects in any of the patients. We conclude that the low doses of desferrioxamine such as mean avarage of 40 mg/kg/day given in our patients and also nightly subcutaneous infusion instead of intravenous infusion is relatively safe and limites the side effects like ocular toxicity and hearing impairment.

1867

TISSUE IRON OVERLOAD IN MULTIPLE TRANSFUSED PATIENTS WITH RARE ANEMIAS: AN MR IMAGING STUDY

O Papakonstantinou,[1] N Kelekis,[1] E Rigatou,[2] S Delikou,[2] A Balanika,[1] K Foufa,[1] S Kostaridou,[3] S Polychronopoulou[2]

[1]Attikon Hospital, University of Athens, Athens, Greece; [2]1.Department of Paediatric Haematology Oncology, Athens, Greece; [3]Thalassemia Unit, Aghia Sophia Childrens Hospital, Athens, Greece

Background. MRI has been employed for the non invasive quantification of iron overload and, most recently, for the assessment of iron distribution, in patients with beta thalassemia. However, assessment of transfusional iron overload in rare congenital anemias, other than hemoglobinopathies by means of MR imaging has yet to be described. *Aims.* We aim at a) correlating MRI measurements expressing tissue iron overload, obtained by different MR techniques, with serum ferritin (b) investigating the correlation between the degree of hepatic, splenic, pancreatic, vertebral bone marrow (VBM) siderosis, in multiple transfused patients with rare anemias. *Methods.* Signal Intensity Ratios (SIR) of liver over muscle (L/M), pancreas over muscle (P/M), spleen over muscle (S/M), vertebral bone marrow over muscle (VBM/M) on T1- TSE , T1-GRE , PD-GRE and T2*-GRE MR images, as well as R2 Relaxation rate values (R2=1/T2) of the liver, pancreas, spleen and VBM were calculated in seven multiple transfused patients with Fanconi anemia (n=3), severe aplastic anemia (n=1) , Diamond Blackfan (n=2) and CDA-II (n=1). The same MRI protocol was applied in ten healthy controls and MRI measurements of patients were compared to those of healthy controls. The study was conducted with the approval of the hospital ethics committee, and informed consent was obtained from all of the human subjects. Statistical significance was set at P<0.05. *Results.* R2 calculations, PD and T2*-GRE sequences were the most sensitive MR techniques in tissue iron overload detection : 6 patients were shown to have liver siderosis, 5 pancreatic , 4 splenic siderosis and 6 patients VBM siderosis, as implied by reduced L/M, P/M, S/M and VBM/M ratios on PD-and T2* weighted GRE images and increased respective R2 values, compared to measurements obtained by healthy controls. Despite the limited number of patients, statistically significant correlations were revealed between a) ferritin and L/M on T1-weighted TSE sequence (r=0.85, P<0.04) and PD-weighted GRE sequence (r=0.89, P<0.03) b) ferritin and P/M on T1-weighted TSE sequence (r=0.88, P<0.03) and PD- weighted GRE sequence (r=0.96, P<0.02) c) L/M and P/M on T1-weighted TSE sequence (r=0.81, P<0.03) and d) S/M and VBM/M on PD-weighted GRE sequence (r=0.94, P<0.001). MR measurements of any tissue obtained on T1-GRE and T2*-GRE weighted sequences and R2 calculations did not assign statistically significant correlations with serum ferritin. *Summary/Conclusions.* An intergraded MR imaging protocol can be employed for non invasive assessment of tissue iron overload in patients with transfusional iron overload in rare congenital anemias, other than hemoglobinopathies. Signal intensity ratios on PD-GRE weighted sequence were the most sensitive and accurate measurements for estimation of tissue iron in those patients. Statistically significant correlations between the degree of hepatic and pancreatic siderosis and between VBM and splenic siderosis were found.

1868

A STUDY OF PLATELET INDICES IN PATIENTS WITH IRON DEFICIENCY ANEMIA

G Spiroglou,[1] S Arampatzi,[1] K Chalvatzi,[1] C Kostopoulos,[2] A Kalikaki,[1] K Thisiadou,[1] C Kanonidou,[1] A Nikolaidou,[1] E Diza[1]

[1]Ahepa University Hospital, Thessaloniki, Greece; [2]Veria General Hospital, Veria, Greece

Background. Iron deficiency anemia is the most common hematological disorder in the community. Several changes concerning platelets have been found in this condition, which may connect iron metabolism to platelet indices. IPF is a novel platelet index which raises in several disease states where reticulated platelets are released in peripheral circulation, due to increased bone marrow activity. *Aims.* The aim of this study was to seek correlations among classic and novel platelet indices, as well as with parameters concerning iron metabolism, in patients with iron deficiency anemia. *Methods.* We retrospectively studied 41 patients (26 female and 15 male) with iron deficiency anemia. Platelet (PLT) count, mean platelet volume (MPV), platelet distribution width (PDW), plateletcrit (PCT), and immature platelet fraction (IPF), as well as iron levels, ferritin levels and total iron binding capacity (TIBC) were determined for these patients. Hematological parameters were assessed by SYSMEX XE2100 hematological analyzer, while biochemical parameters were assessed by MODULAR ANALYTICS P800 analyzer. Pearson's correlation coefficient was used for correlations among parameters. The significance level was defined as P<0.05. *Results.* Platelet count was statistically significantly positively correlated with TIBC (r=0,629, P=0,007). Plateletcrit was also positively correlated with TIBC (r=0,648, P=0,012). Significant correlations among platelet indices were also of some interest. Platelet count was negatively correlated with IPF (r=-0,451, P=0,003). Novel IPF index was positively correlated with MPV (r=0,749, P<0,001) and PDW (r=0,755, P<0,001). *Conclusions.* In our study, an increase in platelet number and plateletcrit was correlated with an increase in total iron binding capacity, which reflects a decrease in blood iron levels. Theoretically, this observation could be attributed to increased erythropoiesis (and erythropoietin levels). Moreover, the compensatory increase in platelet number is not followed by an increase in immature platelet forms in peripheral blood. This might reflect a less acute bone marrow response, due to the chronic nature of the disorder, with few immature large reticulated platelets released in peripheral blood.

1869

OPTIMAL RESPONSE TO ALEMTUZUMAB IN A CASE OF IDIOPATHIC OF PURE RED CELL APLASIA

C Ulibarrena,[1] J Méndez,[2] JL Sastre[2]

[1]Complexo Hospitalario de Ourense, Ourense, Spain; [2]Compleso Hospitalario de Ourense, Ourense, Spain

Pure red cell aplasia (PRCA) is an uncommon hemopathy, often related to thymoma, autoimmune diseases or lymphoproliferative disorders, whereas almost 50% remain as idiopathic. Usual therapies consist of glucocorticoids, inmmunosupressors or the adequate treatment for the primary disease whenever is known. We present the case of a patient in which the response to alemtuzumab was optimal and complete, after the failure of at least 4 different therapies. *Case.* 58 yr.-old male, firstly studied for macrocytic anemia. He stated with transfusions in 2006, when the diagnosis of PRCA was made (bone marrow exam also showed significant dysplastic features). In the initial survey, no evidence of Parvovirus, thymoma, autoimmunity or lymphoproliferative disease was ascertained; allopurinol was interrupted witout any change in the evolution. Bone marrow genetics was 46-XY. The unique anomaly was the presence of an inverted CD4/CD8 T-lymphocytes ratio, without abnormal populations (flow cytometry) and with controversial results with regard to the presence of clonality in receptor T gene (TCR). Therapies: prednisone 1 mg/kg, effective but he response was clearly dose-dependent and the patient developed significant side-effects (myopathy, osteoporosis); the addition of chlorambucil was not useful to allow the tapering of the prednisone dose, as it was not the replacement of prednisone by high-dose intermittent dexamethasone; IV immunoglobulins were also inefficacious; since [Epo] levels were <200 mUi/mL, rh-EPO started, 30,000 UI/wk, which proved to be successful (the patient's hemoglobin was around 11-12 gr/dL for more than a year with only 10 mg/48 h. of prednisone). In January-2009, he started transfusions again; a new complete workup was performed, confirming the diagnosis of PRCA; karyotype was 46-XY and no evidence of B or T-cell clonality was found. Successive therapies were regarded as failed:darbepoietin plus prednisone 1'5 mg/kg, cyclosporin (withheld due to toxicity), low-dose weekly methotrexate. In Sept.-09, he needed 2-3 blood units every 7-14 days to stay aorund 8 gr/dL of Hgb, and biochemical signs of iron overload were present, despite the early start of deferasirox. Alemtuzumab was approved by compassionate use in Nov.-09. The dose was the same as for chonic lymphocytic leukemia, and with the same prophylaxis (valacyclovir, cotrimoxazol) The reponse was evident since the second week of therapy, with an increase in [Hgb] of more than 3 gr/dL and normalization by the fourth. No complications appeared, except the expected lymphopenia and neutropenia grade 3. Once the optimal [Hgb] was reached, we began a progressive decrease of the dose, to a final 30 mg/wk). After the scheduled 12-week tretament, the reponse is considered complete. *Conclusion.* The evolution of the case shows the potential utility of alemtuzumab in idiopathic PRCA, whereas the exact dosage and the possibility of a maintenance therapy is still uncertain. This use of alemtuzumab is not included in the recommendations of the Prescribing Information document approved for the drug.

1870

MICROCYTIC ANAEMIAS IN PEDIATRICS: HOW MANY GENETICS?

F. Cecere,[1] G Pollio,[2] S Cancellario,[3] R Colella Bisogno,[3] A. Mangione,[2] A De Anseris,[2] C Perna,[2] R Albano,[2] G Menna[4]

[1]S.Giovanni di d Dio e Ruggi D'Aragona Hospital, Salerno, Italy; [2]Department of Pediatrics S.Giovanni di d Dio e Ruggi D'Aragona Hospital, Salerno, Italy; [3]Department of Transfusion Medicine,S.Giovanni di Dio e Ruggi D'aragona Hospital, Salerno, Italy; [4]Department of Onco-Haematology,Pausilipon Hospital, Naples, Italy

Background. Microcytic anaemias in pediatrics are very frequent so to be considered the most common in childhood, generally secondary to iron deficiency. Thalassemias are extimated to involve from 6 to 10 % of the Campania's (Italy) population. *Aims.* Aim of our investigation is to demonstrate that most of microcytemias are genetics (α, β ,δβ thalassemia) (thal). *Methods.* We analyzed 20 children in 2009 (14F 11M, ranged 6months-16yrs, mean age 6.5 yrs) with microcytic anaemia and/or isolated microcytemia. Once we excluded the most common causes of microcytemia and/or failure of treatment with oral iron patients underwent screening for genetics anemias , using Haemoglobin (Hb) phoresis (BIO-RAD VARIANT I KIT). When Hb phoresis shown abnormalities in the phoresis distribution, diagnostic with molecular biology to β and/or δβ thal (Bio-Rad mDx®BeTha Gene 1) was made. When no abnormal Hb came out from phoresis, we investigated by molecular biology to α thalassemias (Kit Bio-Rad mDx® Alpha Gene 2). *Results.* 10/20 evaluated children were affected by non genetic anemias, 10/20 underwent molecular biology. 3/10 had β thal trait; 2/10 δβ thal trait; 3/10i α thal trait; 2/10 no trait was shown (see table below). 1 patient had all the characteristics of a β thal trait, but no mutation was discovered, maybe because not in our panel (rare mutation?) *Summary/Conclusion.* Even if should not be considered a fully epidemiological study because of the few number of patients our investigation, using a rapid and low cost method (the median time for a complete response is about 72 hours, also considering the kit maintenance) shows an incidence of about 40% of genetic anaemias in the analysed sample of the Campania's population and it seems to be much more frequent than previously reported. The high incidence of α thal trait seems to indicate that we have to screen patient for this genetical defect, when in presence of inexplicable microcytic anaemias and /or isolated microcytemia. Further studies are obviously necessary and it should be useful to screen up ,using this kind of methodics, children of primary and secondary school of Campania to introduce a fully epidemiological investigation.

Table.

SCREENING OF HEMOGLOBINOPATHIES IN PREGNANT WOMEN IN GRAN CANARIA

K Quiroz,[1] S De La Iglesia,[1] P Ropero,[2] J Lopea,[1] N Navarro,[1] C Rodriguez,[1] S Fumero,[1] Y Ramos,[1] A Lemes,[1] A Villegas,[2] T Molero[1]

[1]Hospital de Gran Canaria Doctor Negrin, Las Palmas de G.C., Spain; [2]Hospital Clinico San Carlos, Madrid, Spain

Structural hemoglobinopathies are a group of diseases that constitute a major public health problem in the world, with an incidence that has increased in recent years in our country due to migration movements. There is a controversy about screening for this disease universally or only in high prevalence popultations. *Patients, materials and methods.* 240 consecutive peripheral blood samples in EDTA-K3 of pregnant women were analyzed in the north area of Gran Canaria. We performed high-resolution liquid chromatography (HPLC) for detection and quantification of abnormal hemoglobins. Data from hemogram and biochemistry of these patients were reviewed. Informed consent was obtained *Results.* We found 19.16% of microcytosis. One of them was a known alpha thalassemia patient and two had increased fetal hemoglobin.The prevalence of heterozygotes for hemoglobin S was 1.66%. We did not find any other structural hemoglobinopathy or any patient with sickle cell anemia. *Conclusions.* Our results show a high prevalence of heterozygotes for S hemoglobin compared to previous studies, probably related to an increment in migration movements.

1872

LEVELS OF RETICULOCYTE INDICES AND RETICULOCYTE HEMOGLOBIN CONTENT IN HETEROZYGOUS β-THALASSEMIA AND IN IRON DEFICIENCY ANEMIA

K Chalvatzi, S Spiroglou, S Arampatzi, K Thisiadou, C Kanonidou, A Nikolaidou, O Fotakeli, E Diza

Ahepa University Hospital, Thessaloniki, Greece, Thessaloniki, Greece

Background. Reticulocyte indices, IRF (Immature Reticulocyte Fraction), LFR (Low Fluorescence Reticulocytes), MFR (Medium Fluorescence Reticulocytes), HFR (High Fluorescence Reticulocytes), and mainly the index of hemoglobinisation of reticulocytes (, Reticulocyte hemoglobin content) are new parameters in blood analysis. The Ret-he, which directly reflects the recent hemoglobin synthesis in bone marrow precursors, has been suggested as a useful hematologic marker not only for early diagnosis but also for the monitoring of iron deficiency anemia. *Aim.* In this study, reticulocyte indices and Ret-he compared and evaluated in heterozygous β-thalassemia and in iron deficiency anemia. *Methods.* A retrospective study of two groups, group A: 100 patients with heterozygous β-thalassemia (57 males and 43 females), and group B: 30 patients (10 males and 20 females) with iron deficiency anemia, in which the indices IRF, LFR, MFR, HFR, Ret-he, as well as iron and ferritin were measured. The measurement of reticulocyte parameters were generated by the Sysmex XE 2100, and biochemical concentrations were determined in MODULAR ANALYTICS P 800. *Results.* Ferritin and iron concentrations were found significantly increased in group A in comparison with group B (78.29±44.7 _g/dL *vs.* 12.3±2.12 μg/dL, P<0.001, and 167.42±166.39 ng /mL *vs.* 65.59±12.18 ng/dL, P<0.001, respectively). The levels of Ret-he and HFR were significantly lower in group A compared to group B (20.73±2.84 pg *vs.* 23.8±3.63 pg, and 3.84±3.7% *vs.* 6.99±6.8%, respectively). In group A there was a positive correlation between HFR and ferritin (r = 0.317, P<0.05). The mean values of IRF, LFR and _FR showed no differences between the two groups. *Conclusions.* Ret-he and HFR could be included among red blood indices, and biochemical parameters that are used for differential diagnosis between heterozygous β-thalassemia and iron deficiency anemia.

1873

CONGENITAL NON-SPHEROCYTIC HEMOLYTIC ANEMIA DUE TO ERYTHROENZYME DEFICIENCIES IN VENEZUELAN PATIENTS

A Muller

Clinica El Avila, Caracas, Venezuela

Erithroenzyme deficiency can produce congenital chronic non spherocytic hemolytic anemia (CNHA). The object of this paper is to present the study of patients with CNHA, the biochemical characterization of their RBC enzymes, hemolysis mechanisms *in vitro* and enzymes deficiencies in different Venezuelan population to get the origen of the deficiency. *Materials and methods.* 2393 patients with CHA were studied. G-6-PD and Pyruvate kinase deficiency were studied in 450 people from different regions. Studies done: medical history, hematologies, chemistries, Hemoglobin electrophoresis, globular fragility test, G-6-PD and glycolytic enzymes determinations, G-6-PD electrophoresis, enzyme kinetic, thermo stability test, phagocytosis, intracellular Na-K- Ca, ATP and its changes with CNK The PK was studied in Basenji dogs with the deficiency and its PK was compared with the human PK enzyme. *Results.* From 2393 patients with CHA or jaundice studied, 1511 had hemoglobinopathies, 432 thalassemias, 342 enzyme deficiencies , 108 membrane defects. 271 G-6-PD deficiencies were found (145 hemicygotes,124 heterocygotes) , 42 PK, 3 hexokinase, 3 methahemoglobin reductase, 1 galactose 1 uridil transferase, 6 glutathione reductase deficiencies. Variants of G-6-PD were detected Class I: 4,9% with chronic hemolysis : G-6-PD activity : 7,5-13%, Km G-6-P: 133-200 (NV: 50-70 μM), Km NADP: 3,8-4,4(NV: 2,9 -4,4 μM), instable to the heat, G-6-PD electrophoresis mobility type A(202G-A/376A-G). Class II in 45,7% of the patients with G-6-PD activity : 0-10%, Km G-6-P: 31-200 μM, Km NADP: 2,2-4,4. Electrophoresis type B. Some of these patients had favism. Class III: 49,6% of the patients with G-6-PD activity: 11-58%, Km G-6-P: 40-73, Km NADP 1,4-2,9 μM. Electrophoresis type A and B. Na- K y Ca RBC of G-6-PD deficients were normal. 3 families with G-6-PD deficiency had Chronic Granulomatous Disease. G-6-PD deficiency was found only in Venezuelan mixed population with Caucasians and blacks people. Venezuelan indians did not have the G-6-PD neither PK deficiency. 42 PK deficients were detected (Hb :8,24+/1,24 g/dL; Hto: 28,3+/-2,9;%, retic 25,10%+/-17,21).These RBC incubated with CNK showed K and ATP decreased and Ca increased. 3 families with severe hemolysis, PK deficiency, and ulcers in legs had a biochemical mutant of PK with low KM for PEP 0,75+/- 0.5 μM (NV: 1,15+/0.1) no allosteric similar to PK of Basenji dogs. 4 families had hexokinase deficiency. A mutant Hx with severe hemolysis and ulcers in legs were characterized Conclusions the incidence of G-6-PD and glycolytic enzymes that produces hemolytic anemia and jaundice in Venezuela is presented. La deficiency of G-6-D was inherited from caucasic and black inmigrants. Three classes of G-6-PD biochemical variants, a PK and a hexokinase mutant that produces severe hemolysis and leg ulcer were detected. When PK deficient RBC were incubated with CNK loose K, ATP and increase Ca. The Ca open the K canals and water is also loose as a result the RBC suffer dehydration and probably hemolysis will occur due to phagocytosis. This could be one of the mechanisms to explain hemolysis

1874

SERUM HEPCIDIN LEVELS IN SUBTYPES OF ANEMIA WITH DISTURBED IRON METABOLISM

S Aref,[1] A Emaad,[1] R Al Ashery[2]

[1]Mansoura Faculty of Medicine, Mansoura, Egypt; [2]Pediatric Dept, Mansoura, Egypt

Hepcidin is an 25 amino acid cystine rich peptide, synthesized predominantly by hepatocytes. It was suggested that hepcidin act as a hormone regulating iron content in human body through binding to ferroprotein. The aim of this study was to assess serum hepcidin level in 3 category of patients including; iron deficiency anemia (IDA) (n= 12, age range from 3-9 years); β thalassemia major (n=15, age range from 3- 8.5 years); Hodgkin disease with B symptoms (n = 11, age range 27-48 years); and normal healthy control (n=10, age range 2.0- 8.0 years). Serum hepcidin levels was assayed by ELISA. Hepcidin serum levels was significantly elevated in β thalassemia group and HD group as compared to control (P<0.01 for both). In contrast serum hepcidin level was significantly decreased in IDA group as compared to control level (P<0.05). Serum ferritin level was inversely correlated with hepcidin level in IDA group (r=0.623, P<0.01); but significantly positively correlated in β thalassemia major group and HD group (r = 0.52, P<0.01, r=481 , P<0.05 respectively). These findings suggest that serum hepcidin level could discriminate between simple iron deficiency anemia and other anemia subtypes with disturbed iron metabolism.

1875

GAUCHER DISEASE AS A CAUSE OF ANEMIA AND THROMBOCYTOPENIA

P Kjollerstrom, A Ferreira, S Sequeira

Hospital Dona Estefânia, Lisboa, Portugal

Background. Many diseases that are not primarily hematological, as infectious, immunological, neoplastic and metabolic problems present with hematological findings, such as cytopenias, and so the hematologist is often in the first line in their diagnostic evaluation. Gaucher disease (GD) is an inherited deficiency of the enzyme glucocerebrosidase. The underlying defect leads to deposition of glucocerebroside in cells of the macrophage-monocyte system, with excessive accumulation in the bone marrow, spleen, bone and other organs. Cytopenia is an almost universal finding in untreated Gaucher disease. Anemia, thrombocytopenia and to a lesser extent leucopenia, may be observed simultaneously or independently. Other signs and symptoms include splenomegaly or hepatosplenomegaly and variable bone involvement. Malignant hematological diseases can also be associated with GD. Some patients present in childhood with virtually all the complications of GD, whereas others remain asymptomatic until later in life. Although earlier splenectomy was carried out due to functional hypersplenism and the mechanical effects of the enlarged spleen, Enzyme Replacement Therapy (ERT) with imiglucerase is currently available. *Aims.* to present the hematological features at presentation of type 1 GD and resolution after ERT. *Methods.* case report of three patients with GD initially admitted for evaluation in a Pediatric Hematology Unit. *Results.* Patient 1 presented at the age of eight with recurrent and severe bone pain. These episodes were mistaken for recurrent osteomyelitis. At the age of twelve massive splenomegaly and aggravation of anemia and thrombocytopenia were noticed and the patient underwent bone marrow examination that revealed Gaucher cells. Patient 2 was first evaluated at the age of six for fever, anemia, thrombocytopenia and hepatosplenomegaly. Multiple infectious and autoimmune investigations were carried out and proved to be negative. Due to persistent enlargement of liver and spleen and cytopenia a bone marrow aspi-

rate was performed and also showed Gaucher cells. Patient 3 was a four-year-old previously healthy boy when splenomegaly and mild thrombocytopenia were casually noticed. GD was also suspected and investigations for this disorder performed. All patients had low glucocerebrosidase activity in leucocytes and fibroblasts and increased plasma chitotriosidase and tartrate resistant acid phosphatase (TRAP). Magnetic resonance imaging of patient 3 showed bone abnormalities suggestive of Gaucher disease. ERT resulted in total regression of symptoms and hepatosplenomegaly, normalization of hematological parameters and progressive improvement of quitotriosidase and TRAP in all patients. *Summary/Conclusions.* We remember GD as a cause of anemia and thrombocytopenia associated with splenomegaly or hepatosplenomegaly. Bone involvement may be severe as in patient 1 or still asymptomatic as in patient 3. An adequate evaluation and diagnosis are the hallmark of success in the management, as ERT is available and highly effective in this otherwise progressive and debilitating disorder.

1876

MEGALOBLASTIC ANEMIA AND COBALAMIN DEFICIENCY: THE IMPORTANCE OF AN URINE SAMPLE

A Mascarenhas,[1] M Eusébio,[2] O Freitas,[1] T Almeida[1]

[1]Hospital Dona Estefânia, Lisboa, Portugal; [2]Centro Hospitalar do Barlavento Algarvio, Portimão, Portugal

Background. The Imerslund-Grasbeck Syndrome is a rare autosomal recessive disorder characterized by selective malabsorption of Vitamin B12 and asymptomatic proteinuria. The clinical manifestations appear in early childhood, usually within the first two years of life. Anemia, failure to thrive, recurrent infections and/or neurological symptoms (ie: spasticity, ataxia and cerebral atrophy) are its most common presentations. The treatment consists of Vitamin B12 administration, which usually leads to complete remission of symptoms. Proteinuria usually persists in adults but with no impact in quality of life and long-term survival, even in selected cases with altered renal function. *Aims.* to describe the importance of an urine screen in the differential diagnosis of childhood megaloblastic anemia. *Methods.* case report of a patient with pancytopenia and macrocytosis admitted for evaluation in a Pediatric Hematology Unit. *Results.* We present a previously healthy 15-month-old female child with an unremarkeable family or personal history (ie: normal growth and development and no history of recurrent infections or neurological symptoms). During an upper respiratory tract infection, icteric sclerae and progressive pallor of the skin and mucous membranes were noted. The blood test results revealed pancytopenia with macrocytosis and neutrophil hypersegmentation, accompanied by a low serum vitamin B12 level (85.7 pg/mL, normal range: 193 to 982 pg/mL). With the 12-hour proteinuria level of 38 mg/m2/h, a diagnosis of Immerslund - Grasbeck Syndrome was reached, and therapy with subcutaneous cyanocobalamin was initiated, resulting in normalization of hematologic parameters. Currently, at 7 years of age, she maintains excellent growth and development. Both parents present a mild Vitamin B12 deficit. *Conclusion.* The detection of a megaloblastic anemia in childhood should always be followed by a proteinuria screen, which enables the timely and simple treatment of a highly disabling disease.

1877

EVALUATION OF NT-PROBNP AND HOMOCYSTEINE LEVES IN PATIENTS WITH HEMOGLOBINOPATHIES

K Thisiadou, S Arampatzi, K Chalvatzi, C Kanonidou, S SpIroglou, D Michailidou, A Nikolaidou

Ahepa Hospital, Thessaloniki, Greece

Background. Despite progress in chelation therapy, heart failure is still the main cause of death in patients with hemoglobinopathies. Hyperomocysteinemia is an independent risk factor in pathogenesis of thromboembolic episodes, Early cardiovascular involvement in thallasemic patients without cardiac symptoms has not been adequately investigated.*Aim.*To assess NT-proBNP and total homocysteine (tHcy) serum levels in patients with hemoglobinopathies. *Methods.* We studied 108 patients (mean age: 39,32+19,66 years) with β-thalassemia major (β-T.M), β- thalassaemia intermedia (β-T.INT) and sickle cell anemia (SCA) divided in three groups. A control group (CG) of 40 age-matched healthy subjects was studied simultaneously and costituded a fourth group. Serum levels of NT-proBNP were determined with electrochemiluminescence immunoassay and homocysteine (tHcy) serum levels were determined using Fluorescence Polarization Immunoassay (FPIA).

Results. Our results are present in the Table 1. Serum level of NT-proBNP was significantly higher in patients with β- thalassaemia major (153,55+76,77 pg/mL *vs.* 50,12±25,06 pg/mL, P<0,01),in patients with β-thalassaemia intermedia (297,75+148,85 pg/mL *vs.* 50,12±25,06 pg/mL, P<0,05) and in patients with sickle cell anemia (151,50+75,75 pg/mL *vs.* 50,12±25,06 pg/mL, P<0,01) compared to the healthy group. It is remarkable that mean value of NT-proBNP in patients with β- thalassaemia intermedia is higher than the other groups.It is also interesting that NT-proBNP serum levels increase simultaneously with patients age.Homocysteine serum levels don't increase significantly in patients groups. No correlation was observed between NT-proBNP and homocysteine. *Conclusions.*This is one of few studies assessing NT-proBNP levels with hemoglobinopathies. The most important finding of the present study is the increase of NT-proBNP in all patients compared with normal controls. Complementary therapy with folic acid and B6 in these patients probably keep low the serum levels of homocysteine.

Table 1. Mean values (±SD) of NT -proBNP and tHcy of patients and control group (CG).

GROUP	N	NT-propBNP pg/mL	tHcy µmol/L
CG	40	50,12±25,06	7,89+3,94
β-T.M	54	153,55+76,77*	7,37+3,68
β-T.INT	24	297,75+148,85**	8,95+4,47

COMPARISON BETWEEN IRON SUCROSE AND IRON SUCROSE SIMILAR PREPARATIONS ON OXIDATIVE AND NITROSATIVE STRESS IN THE RAT CENTRAL NERVOUS SYSTEM

J Toblli, G Cao, L Oliveri

Hospital Aleman, University of Buenos Aires, Ciudad De Buenos Aires, Argentina

Background. Intravenous (IV) iron is an efficient treatment for iron deficiency. Nevertheless, iron is a highly reactive metal and may cause a variable degree of oxidative stress and tissue inflammation in central nervous system (CNS) structures. In some indications iron may be used on a chronic basis and consequently the awareness of its potential CNS toxicity is of importance. *Aims.* This study evaluates possible differences on oxidative stress, nitrosative stress and inflammatory response in brain tissue between the original iron sucrose (IS) and iron sucrose similar (ISS) preparations from different countries in normal rats.

Table 1.

Mean ± SD	G1 (n=7)	G2 (n=7)	G3 (n=7)	G4 (n=7)	G5 (n=7)
Hb (g/dL)	16.4 ± 0.4	16.1 ± 0.4	16.1 ± 0.3	16.2 ± 0.4	15.9 ± 0.3
Serum iron (µg/dL)	371.3 ± 17.7**	431.4 ± 14.1	426.4 ± 10.6	455.0 ± 21.9	317.1 ± 14.8*
TSAT (%)	68.5 ± 5.7**	85.0 ± 3.5	82.0 ± 6.4	83.1 ± 7.1	44.4 ± 4.9*
TBARS (nmol MDA/g prot.)	217.8 ± 18.8**	309.1 ± 20.6	322.7 ± 21.1	315.4 ± 25.0	191.2 ± 21.5**
GSH/GSSG ratio	6.0 ± 1.2**	3.5 ± 1.2	3.8 ± 1.3	3.9 ± 0.7	6.7 ± 1.1**
Nitrotyrosine (+cells/area)	2.1 ± 1.4**	6.7 ± 2.1	6.3 ± 1.4	6.1 ± 2.1	1.0 ± 0.7**
TNF-α (+cells/area)	3.6 ± 0.8**	10.9 ± 3.5	9.3 ± 1.4	9.0 ± 2.1	2.0 ± 0.7**
IL-6 (+cells/area)	4.2 ± 1.8**	9.8 ± 2.5	9.4 ± 2.7	10.1 ± 2.8	1.4 ± 0.6**
HSP70 (+cells/area)	5.5 ± 2.3**	11.2 ± 2.9	13.0 ± 3.5	11.5 ± 1.9	2.7 ± 1.2**
Caspase-3 (+cells/area)	0.7 ± 0.4**	4.1 ± 1.0	3.5 ± 0.9	3.8 ± 0.6	0.4 ± 0.5**
* p<0.01 vs all groups; ** p<0.01 vs G2, G3 & G4					

Methods. Five groups of Sprague Dawley rats: G1 (IS), G2 (ISS Portugal), G3 (ISS Colombia), G4 (ISS Argentina), G5 (Control saline solution) were compared. G1, G2, G3 and G4 were treated with a weekly IV dose (40 mg iron/kg bw) of the corresponding iron compound, and G5 with normal saline solution at 0, 7, 14, 21 and 28 days. Animals were killed after the last IV dose (Day 29). In brain homogenates, thiobarbituric acid reactive substances (TBARS) and GSH/GSSG ratio were evaluated.

Immunohistochemistry assessments using antibodies against nitrotyrosine, interleukin-6 (IL-6), tumour necrosis factor-α (TNF-α), heat shock protein-70 (HSP70) and caspase-3 were also performed. *Results.* At the end of the study (4 weeks), hemoglobin (Hb) did not significantly differ between groups. However, serum iron, transferrin saturation (TSAT), as well as markers of oxidative stress, nitrosative stress, inflammation and apoptosis (caspase-3) showed significant (P<0.01) differences between groups. Results at the end of the study are illustrated in Table 1. *Summary/Conclusions.* These findings demonstrate that the studied ISSs lead to substantial oxidative and nitrosative stress, increased inflammatory response and apoptosis in the normal rat brain *vs.* original iron sucrose. A possible explanation for these observations may be that labile iron is increased in ISSs due to low stability of the iron complex.

The present study was supported by Vifor Pharma Ltd.

1879

A NOVEL MUTATION OF THE ERYTHROID-SPECIFIC AMINOLEVULINATE SYNTHASE 2 GENE IN A PATIENT WITH PYRIDOXINE RESPONSIVE SIDEROBLASTIC ANEMIA AND DEFERASIROX RESPONSIVE HEMOCHROMATOSIS

H Tokgöz, Ü Çaliskan, H Yüksekkaya

Selcuk University Meram Faculty of Medicine, Konya, Turkey

Background. Sideroblastic anemias are a heterogeneous group of acquired and inherited bone marrow disorders characterized by mitochondrial iron overload in precursors of red blood cells. Ring sideroblast is the characteristic finding of all sideroblastic anemias. Pathologic iron deposition and anemia are the most common problem in patients with sideroblastic anemia. Hereditary sideroblastic anemias are caused by defects in genes present of X chromosome, otosomal genes and mitochondrial genes. *Case report.* A-14 year-old man admitted to our clinic with weakness and paleness since one month. He has hepatosplenomegaly. Blood tests and peripheral blood smear showed severe hypochromic, microcytic anemia. There is ringed sideroblasts without dysplastic hematopoiesis in bone marrow cytology. Liver tests were normal. Serum ferritin level was high. Liver biopsy showed heavy parenchymal iron deposition and grade-III fibrosis. Screening for HFE gene mutations was negative. Magnetic resonance T2 star imaging demonstrated that severe iron accumulation in liver and heart. ALAS2 gene screening showed that novel mutation in exon 7 (Gly390Gly, c.1170, C-T). Eventually, he was diagnosed as sideroblastic anemia and hemochromatosis. The patient's anemia improved with pyridoxine. Liver and hearth iron loading detected by T2 star MRI and serum ferritin level were obviously improved by deferasirox treatment. *Conclusion.* These findings suggest that the Gly390Gly in ALAS2 mutation is a novel mutation leading to sideroblastic anemia and hemochromatosis, without hereditary hemochromatosis gene mutations. This mutation can cause sideroblastic anemia that clinically pyridoxine-responsive. Deferasirox may be an effective agent for reduce hepatic and cardiac iron overload in this condition.

1880

RECORDING OF CHANGES IN HEMOGLOBIN, HEMATOCRIT, FE AND TIBC IN PATIENTS WITH MALIGNACY AT THE DURATION OF CHEMOTHERAPY

S Patiakas,[1] K Rousos,[2] F Girtovitis,[3] I Xanthakis[4]

[1]General Hospital of kastoria, Thessaloniki, Greece; [2]Heaith Center of Alexandria-general hospital of Veria, Veria, Greece; [3]General Hospital of Thessaloniki ACHEPA', Thessaloniki, Greece; [4]Pathologicai - Oncology Clinic of general Hospital Papageorgiou, Thessaloniki, Greece

Background - Aim. The changes in hematocrit, haemoglobin and iron values as well as iron-binding ability were investigated in the neoplasmatic patients during chemotherapy. *Material - Method.* 22 patients were examined (9 men and 13 women): 7 were suffered from breast cancer, 5 from lung cancer, 4 from thick intestine cancer, 3 from prostate cancer and 3 with various other type of cancers. 1st sample of blood was received before the administration of chemotherapeutic schedule. 2nd and 3rd blood sample were received 3rd and 7th day after the administration, respectively. *Results.* The percentage increase of iron values average between 1st and 2nd sample was 215%, while in another case this increase was sixfold higher. On the contrary, the higher reduction between second and third sample was 98%, while the average value reduced at 51%. The fluctuation in TIBC was lower, (changes <20%), while almost stable remained the values of hematocrit and hemoglobulin values in the various measurements. *Conclusions.* 1) The iron values and the total iron-binding ability are very high the 3rd day during chemotherapy, while the measurements return in their normal range afterwards the 7th day. 2) Reversely, the hematocrit and hemoglobulin values were not significantly influenced. 3) The simultaneous examination of bone marrow during the chemotherapy would potentially help in the explanation of our observations. Moreover, our findings should be confirmed with further studies.

1881

REDUCTION OF INVASIVE FUNGAL INFECTION (IFI) IN PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML) UNDERGOIG INDUCTION CHEMOTHERAPY WITH POSACONAZOLE FOR ANTIFUNGAL PROPHYLAXIS

E Audisio, A Busca, S D'Ardia, U Vitolo, F Marmont

Ematologia ,[2] Torino, Italy

Introduction. Patients with Acute Myeloid Leukemia (AML) undergoing chemotherapy are at high risk for bacterial and fungal infections, particularly during the induction phase. Anti bacterial and anti fungal prophylaxis with fluoroquinolones and triazoles are used to prevent infectious complications. Recently posaconazole, a "second generation"triazole, with greater potency and increased activity against yeasts and moulds, has been approved for antifungal prophylaxis in AML patients. *Patients and methods.* The infectious complications occurring during the induction chemotherapy in a series of 24 AML patients who received anti-fungal prophylaxis with posaconazole solution 200 mg tid were compared to an historical series of 81 patients, treated with prophylactic itraconazole oral solution 200 mg bid. In all patients intravenous antifungal therapy with liposomal amphotericin, voriconazole or echinocandins was initiated after no more than 5 days of fever not responding to broad-spectrum empirical antibyotic treatment. The number and type of infections were recorded, as well as the number of days with prophylactic treatment and with intravenous antifungals therapy. *Results.* Patients in the study were older than patient in the historical control cohort (median 52 *vs.* 60 years, P=.07). In the historical cohort a neutropenic fever was observed in 69/81 patients (85.2%), while in the study cohort a neutropenic fever was observed in 23/24 (95.8%).(P=.29).The incidence of Fever of Unknown Origin (FUO) was similar in the stidy group as compared to the historical group, as well the incidence of Clinically Documented Infections (CDI) and Microbiologically Documented Infections (MDI).(Tab1).An Invasive Fungal Infection (IFI) was diagnosed in 9 (13.0%) patients in the hystorical cohort (2 "possible", 3 "probable"and 4 "proven") while no fungal infection was diagnosed in the study group (Table 1).However, an intravenous antifungal therapy was administered to a comparable percentage of patients in the two cohorts: 50% (12 patients) in the study group *vs.* 55.6% (45 patients) in the hystorical group (P=.9). The median of days from the beginning of chemotherapy to the initiation of intravenous fungal therapy was also comparable in the two groups (18.6 days in the study cohort *vs.* 16.0 days in the hystorical cohort; P=.15) as well the median days of intravenous antifungal therapy (10.5 *vs.* 15.4; P=.13). The incidence of deaths during the induction phase was higher in the study group as compared to the hystorical cohort : 4 (16.7%) *vs.* 6 (7.41%) respectively (P=.24). All deaths were related to uncontrolled primary infections during the aplastic phase or breaktrough infections in patients with resistant leukemia and lack of granulocyte recovery. *Conclusions.* The prophylaxis with posaconazole was effective in reducing the incidence of IFI among pts with AML, althrough did not reduce the use of antifungal treatment.

Table 1.

	Study cohort	*(n 24)*	*Hystorical cohort*	*(n 81)*
FUO	9	(39.2%)	27	(39.2%)
CDI	7	(30.4%)	9	(13.0%)
MDI	7	(30.4%)	24	(34.8%)
IFI	0	9	(13.0%)	P=0,04

1882

HBV AND HCV PHENOMENONS IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES

T Garmaeva, S Kulikov, E Parovichnikova, N Gaidamaka, E Mihailova, V Savchenko

National Center for Hematology, Moscow, Russian Federation

Background. Viral hepatitis B and C are one of the most common cause of severe liver disfunction, including fulminant hepatitis, in patients with hematological malignancies due to reactivation or *de novo* infection. Earlier we postulated that the rate of infectious process caused by viruses hepatitis B (HBV) and hepatitis C (HCV) was extremely high in the hematology department (for HBV from 15% (39/265) to 51% (135/265) and for HCV from 7% (19/265) to 19% (51/265), 14% (37/265) pts had markers of both types of viruses) [14th Congress of EHA, 2009, abstr 0466]. Furthermore, HBV and HCV can cause prolonged bone marrow aplasia in patients receiving chemotherapy or immunosuppressive agents. *Design and methods.* We perfomed a prospective study to assess the outcomes associated with HBV and HCV infections in all patients admitted to hematology department since Feb 2004 till Jun 2006. Median follow-up was 253 days (3-1412). All unselected 265 patients were monitored prospectively by testing of HBsAg, anti-HCV, DNA-HBV, RNA-HCV, anti-HBs, anti-HBc, HBeAg, anti-HBe monthly. Total 7800 biological samples (serum, plasma, peripheral blood cells, spinal fluid, saliva, bone marrow aspirates, bone marrow, liver and spleen biopsies) were collected for HBV and HCV testing. 4000 of them were tested by PCR assays. *Results.* 205 pts (77.5%) of all monitored cases were pts with acute leukemia (AL) and aplastic anemia (AA). 125 (47.0%) were men and 140 (53.0%) were women; their median age was 38 years (15-79). Within the period of follow-up 173 pts (65.7%) were detected to have any positive marker for HBV and 69 pts (26.0%) - for HCV. 57 pts (21.5%) were infected with both HBV and HCV, that constituted 32.8% of those 174 pts infected with HBV and 81.4% of those 70 pts infected with HCV. At time of analysis 152 pts (57.4%) were alive. 113 pts (42.6%) died. 78 (69.0%) of 113 died pts were infected with HBV and HCV and two of them developed fatal fulminant hepatitis. 30 (38.5%) of those 78 pts became positive for DNA-HBV and RNA-HCV by PCR in serum, or bone marrow, or spleen, 3 to 30 days before death. This phenomenon may be explained by rapid destruction of HBV and HCV infected cells by immune attack. But it's more likely that in our cases host immune factors is collapsed and cannot control the infections. We can speculate that at the time of vital stress in order to survive all cells including those harbouring viral factors induce intracellular antiapoptotic mechanisms thus providing untolerable conditions for viral intracellular persistence and viruses leave the cell. This suggestion is supported by the fact that in some patients viral antigens were detected by immunohistochemical methods in bone marrow biopsies without serological and molecular HBV and HCV markers in serum. *Conclusions.* The present study has brightly demostrated that the patients in hematological departments have to be strictly monitored for HBV and HCV by all existed methods in all reasonable biosubstratum, particularly by PCR and immunohistochemical *Methods.* The high incidence of DNA-HBV and RNA-HCV in died patients leads us to a conclusion that these viruses are not the reasons of death but just markers of vital stress. The absence of molecular and serological markers of HBV and HCV does not mean the abcence of these infections in this cohort population.

1883

DAPTOMYCIN IN THE TREATMENT OF GRAM POSITIVE INFECTIONS IN PATIENTS WITH MALIGNANCIES ONCOHEMATOLOGICAL AND/OR NEUTROPENIC: SPANISH DATA EUCORE REGISTRY

M Salavert,[1] D Rubio,[2] M Gutierrez,[3] MT Olave,[3] FJ Garcia[2]

[1]La Fe Hospital, Valencia, Spain; [2]Miguel Servet University Hospital, Zaragoza, Spain; [3]Lozano Blesa University Hospital, Zaragoza, Spain

Background. Given the situation of multidrug resistance and therapeutic failure of traditional antibiotic therapy is necessary to have updated information on efficacy and tolerance of new antibiotics against Gram positive (GP) and Daptomycin (DPM) in the context of special guests immunocompromised, and patients with neoplasms (PN) solid or hematological, with or without neutropenia (NP). *Aims.* Evaluation of national data on efficacy and safety of Dpm in the treatment of various serious infections complicated by GP or PN from a European registry (EUCORE). *Methods.* Retrospective cohort study based on the selection and analysis of the PN included by Spanish researchers in the general database registry EUCORE (free communication experience and results of use of daptomycin in infections proven or highly suspected to be caused by GP) recorded between 2006 and September 2008 in Europe. *Results.* The Spanish contribution to record EUCORE (1127 patients) included 345 patients treated with Dpm, most treatments 'rescue' (290, 84%), a percentage of 35% in critical condition (n = 122) and having> 65 years 44% of them. The 40.32% of infections were caused by S. aureus (14.71% MRSA) and 30.83% for coagulase negative (ECN). Among them were detected 80 PN with cancer (23.19%), 21 of those admitted to the ICU. The type of cancer described in the study was hematologic cancer and solid organ cancer at the start or during the use of Dpm. 51% of them were treated with doses of 6mg/kg/d Dpm, and median days of treatment was 12 days, 14.5 days in cases of Np). GP bacteremia associated with vascular catheter (CV) (19, 24%) or not associated with CV (10, 12%) were the main types of infections in cancer patients. There were 9 infections associated with foreign bodies (11%) and 9 cases of endocarditis (11%), IcPTB 16 cases (20%). In terms of efficacy (removing 10% of evaluable patients) had successful overall therapeutic effectiveness in 77% of the NPs with cancer (83% in bacteremia, endocarditis 78%, 78% in foreign bodies). In the subgroup of PN with cancer to stay in ICU (21) the effective response rate was 81%. In the 14 PN with Np, the favorable response rate was 93% (75% in cases of bacteremia, 100% in the 6 patients with <500 neutrófilos/mm^3). No adverse effects were detected that would force the withdrawal of the DAP, although in one case there was an increase in the number of CPK than 10 times. For the total patients (n = 345) were 36 patient died (10.43%), being just one of them possibly related to the drug and recorded as sudden death. *Conclusions.* Dpm constitutes a very important antibiotic option with good efficacy and safety results in the treatment of serious infections by GP in PN, with or without NP.

NOVEL INFLUENZA A (H1N1) OUTBREAK IN HEMATOLOGIC MALIGNANCY AND HEMATOPOIETIC STEM CELL TRANSPLANTATION (HCT) PATIENTS

A Syrigou,[1] C Lalayanni,[1] M Iskas,[1] C Smias,[1] I Kioumis,[2] R Saloum,[1] D Sotiropoulos,[1] I Sakellari,[1] A Anagnostopoulos[1]

[1]Hematology Department and HCT Unit, George Papanicolaou Hospital, Thessaloniki, Greece; [2]Aristotle University Pneumonology Department, George Papanicolaou Hospital, Thessaloniki, Greece

Background - Aims. We report the clinical course and outcome of novel influenza A (H1N1) outbreak in immunocompromised patients with hematologic malignancy or HCT. All febrile ambulatory and hospitalised patients in our department were checked for H1N1 by PCR. Vaccination was performed to selected patients according to the guidelines. *Methods.* Eight patients with novel influenza (H1N1) infection were confirmed in our department between 22.12.2009 and 04.01.2010. Four patients had acute myeloid leukemia (AML). Three of the AML patients were neutropenic after induction regimens and one due to resistant disease. One patient had common variable immunodeficiency and newly diagnosed large B-cell lymphoma. Three patients had undergone HCT: one patient had extramedullary relapse of AML post HCT and developed symptoms after hematologic recovery, one suffered from severe pulmonary cGvHD 18 months post HCT, and one had CNS relapse 15 months post HCT and was vaccinated against the H1N1 virus. *Results.* Three patients had mild clinical course, presenting with fever, upper respiratory tract symptoms and normal radiological findings. Five out of eight patients had progression to severe lower respiratory tract disease. Clinical signs were fever, cough, tachypnea, rales and abnormal arterial blood gas values. Chest CT findings were nodular infiltrations, air-bronchogramm, ground-glass and tree-in-bud opacities, bronchiolitis and pleural effusions. On day 7, all five patients had severe respiratory distress and three eventually required ICU care. Three of them died. Two developed also gram negative sepsis by *Klebsiella* pneumoniae and *Burkholderia cepacia* and the other one pulmonary aspergillosis. The patient with *Klebsiella* pneumoniae suffered also from severe pulmonary cGvHD. Among the patients who survived from severe disease, two were afebrile by day 30 but unable to keep an adequate pO_2 without oxygen supply. Findings of pulmonary fibrosis were observed in their chest CTs. All patients received oseltamivir 150 mg qd. One of the AML patients had prolonged viral shedding for 22 days. His antiviral treatment was switched from oseltamivir to inhaled zanamivir. *Summary/Conclusions.* The incidence of novel influenza A (H1N1) for hospitalized patients was 5%. The progression to severe lower respiratory tract disease seems to be affected by the patient's

hematological status at the time of infection. The patient who had extramedullary AML and two out of three non-neutropenic patients didn't progress to severe lower respiratory tract disease. The only non-neutropenic patient who developed severe disease had severe refractory pulmonary cGvHD and bacterial infection. Among the five patients with complicated disease, the outcome was strongly associated with primary disease status and cofactors concerning bacterial superinfections and comorbidities. The two patients who eventually survived the severe infection were in CR after recovery from neutropenia. The three deceased patients had additional coinfections, refractory disease (two) and pulmonary cGvHD (one). Post infection pulmonary fibrosis with need of ambulatory oxygen therapy developed in the two patients who survived from severe low respiratory tract disease.

1885

COMMUNITY ACQUIRED RESPIRATORY VIRAL INFECTIONS IN HOSPITALIZED EGYPTIAN CHILDREN WITH HEMATOLOGICAL MALIGNANCY: PREVALENCE, RISK FACTORS AND CLINICAL OUTCOME

A Tantawy,[1] A Adly,[1] M Barakat,[2] M Yassin[2]

[1]Faculty of Medicine,Ain Shams University,Cairo,Egypt, Cairo, Egypt; [2]National Research Center, Cairo, Egypt

Background. Intensified chemotherapy increases susceptibility to infections. Respiratory viruses, including respiratory syncytial virus (RSV), parainfluenza virus and Influenza virus A and B are widespread in the community and easily transmitted to cancer patients. *Aim.* to assess the prevalence, risk factors and prognosis of community acquired respiratory viruses in severe lower respiratory tract infections in pediatric cancer patient. *Methods.* Ninety children with cancer admitted in the Children's Hospital, Ain Shams University from March 31st, 2007 until September 30th, 2008 suffering from severe lower respiratory tract infections (LRTIs) were included; their age ranged between 8 months-13 years (mean 6.5±2.8 years), they were 49 males and 41 females. All were subjected to history and clinical examination; investigations included complete blood picture, ESR, CRP, blood culture, plain chest x-ray, computed chest tomography. A nasopharyngeal swab was examined by multiplex PCR for influenza A and B, parainfluenza serotypes 1 and 3 and respiratory syncytial virus. *Results.* 57 patients (63.3%) had hematologic malignancy (47 ALL and 10 AML); and 33 had solid tumours (15 NHL, 3 HD, 8 neuroblastoma, 5 wilms tumour, 2 histiocytosis x). Forty one patients (45%) were in remission and 49 (54%) were in induction/consolidation phase. PCR of nasopharyngeal swabs were positive for viral infection in 34 patients (37.7%): 16 had Influenza A (17%), 3 had Influenza B (3.3%), 9 had Parainfluenza 1 (6.6%), and 5 had Parainfluenza 3 (5.5%), none had RSV . Viral infection was present in 38.5% and 36.3 % of patients with hematological and solid tumors respectively. Wheezy chest was prominent presenting feature of viral LRTI occurring in 52.9% .Bacteria were identified as single cause of LRTI in 16 cases (17.7%), viruses in 25 (27%), fungi in 4 (4.4%) and mixed in 13 cases (14%) [9 mixed viral and bacterial (6.6%), 4 mixed bacterial and fungal infections (4.4%)]. Eighty seven patients (96%) were neutropenic, 31 of them were positive for viral infection (35%). Only 7 patients with viral infection (20.5%) had abnormal CT findings (patchy infiltrates and/or lung collapse). Eight patients (8.8%) were admitted to pediatric ICU; 5 had mixed viral and bacterial infections and 3 had mixed bacterial and fungal infections. Six patients died during the study (6.6%) from infection related sequelae. Bad prognosis including ICU admission and/or death were associated with younger age (<2 years), induction/consolidation phase, signs of malnutrition, exposure to repeated invasive procedures, mixed pathogen etiology ,and presence of neutropenia. By multi-regression analysis, the most predictive factors for bad prognosis were the severity and duration of neutropenia followed by the mixed pathogen etiology. *Conclusions.* Viral etiology should be suspected with incorporation of antiviral therapy in high risk cancer patients as there are no specific signs or symptoms; moreover mixed bacterial and viral infections have the worst prognosis. Radiological findings are non specific and rapid diagnostic viral tests should be routine work up in moderate/severe respiratory tract infections in cancer patients.

1886

FLOWCYTOMETRIC IMMUNO-PHENOTYPING OF CORD BLOOD MONONUCLEAR CELLS IN SUDANESE NEWBORNS: PATTERNS OF HEALTH AND DISEASE

M Abdelsalam, E Khalil, A Musa

Institute of Endemic Diseases, Khartoum, Sudan

Objective. The general goal of this Study is determine the immunophenotypic patterns of cord blood mononuclear cells in a cohort of Sudanese newborns. And use this antigenic phenotype as surrogate markers of health and early infections. *Introduction.* Immunophenotyping of cord blood mononuclear cell is an important tool in the diagnosis and follow up of Newborn with congenital immunodeciencies, HIV infection, or other immune disorders. Infection is still an important cause of neonatal morbidity and mortality, despite the development of broad spectrum antibiotics and advanced life support machines. Serological tests and isolation of microorganisms do not give immediate results and haematological tests that are currently used can be difficult to interpret. Leucocytosis is difficult to interpret due to the wide "normal" range in the newborn (8-32.5×10^3/mL) and an increase. in neutrophil immature forms is subjective, with different morphologists giving variable *Results.* The expression of surface functional antigens on neutrophils, and their upregulation in infection is difficult to interpret due to the effects on these surface antigens by a number of variables such as anticoagulants, type of fixative used and cell separation procedures. In addition, such tests require immediate processing and are time-consuming. *Material and method.* Following institutional ethics approval from ethical committee in instuat of endemic diseases and parental consent, cord blood was collected into K3-EDTA for full blood counts, peripheral blood films examined and immunophenotyping by flow cytometry. The study population divided in to possibly infected (n=99) and non-infected (n=111) depending on the mother's account during pregnancy. *Result.* There was no different in the lymphocyte absolute count between term and preterm infants (p value= 0.2),but with statistically significant difference in absolute lymphocyte between infected and non infected neonates (p value =0.003). There were significant differences in the immunophenotypic patterns of mononuclear cells types in different newborns groups at the time of birth with respect to history of infection (P<0.005). The proportion of CD3$^+$ cells increased with gestational age and with the history infection. In addition, neonates born to mothes with a history of infection had significantly less CD4$^+$ cells and CD4$^+$/CD8$^+$ double-positive cells than neonates with no history of infection. It was also shown that the CD4$^+$/CD8$^+$ cell ratio was increased in neonates with infection. Cells that were reactive to CD4$^+$/CD45RO$^+$ and CD8$^+$/CD45RO$^+$ were more in the infected group compared to those with no history of maternal infection. A strong positive correlation in CD45RO$^+$ cells and a negative correlation with CD45RA$^+$ cells were seen with increased gestational age. In conclusion, T-cells, B-cells and mononuclear cells with CD45 RA & RO reactivity are similar in pre-term and full term babies in the absence of infection. Increased CD45RO$^+$ expression can be a valuable test for screening and monitoring early infections in the newborn. The incorporation of the CD13 (myeloid) marker and early activation markers such as CD69 and CD25 may greatly increase the chance of detection of early infections.

BACKGROUND, OBJECTIVES, AND METHODOLOGY OF MONITOR-GCSF - A PHARMACO-EPIDEMIOLOGICAL STUDY OF THE MULTI-LEVEL DETERMINANTS, PREDICTORS, AND CLINICAL OUTCOMES OF FEBRILE NEUTROPENIA PROPHYLAXIS WITH BIOSIMILAR FILGRASTIM

H Ludwig,[1] P Gascon,[2] M Aapro,[3] N Rosencher,[4] M Turner,[5] M Song,[6] K MacDonald,[7] C Lee,[8] M Muenzberg,[5] I Abraham[8]

[1]Wilhelminenspital, Wien, Austria; [2]Division of Medical Oncology, Department of Hematology-Oncology, Hospital Clínic, Barcelona, Spain; [3]Institut Multidisciplinaire d'Oncologie, Clinique de Genolier, Genolier, Switzerland; [4]Département d'Anesthésie-Réanimation, Hôpital Cochin (AP-HP), Paris Descartes, Paris, France; [5]Sandoz Biopharmaceuticals, Holzkirchen, Germany; [6]Matrix [45] and University of Pennsylvania, Philadelphia, PA, USA; [7]Matrix [4,5] Earlysville, VA, USA; [8]Matrix [45] and University of Arizona, Philadelphia, PA, USA

Background. Febrile neutropenia (FN) is a frequent and potentially life-threatening complication in cancer patients undergoing chemotherapy. FN may trigger treatment delays and thus jeopardize the effectiveness of antineoplastic treatment. FN is also associated with increased morbidity, mortality, and health care costs, and decreased quality of life. Biosimilar filgrastim (Zarzio®) has been approved by European authorities. There have been no longitudinal observational effectiveness studies on this agent. We describe the background and methodology of the pan-European MONITOR-GCSF study. *Aims.* Using an integrated framework for post-approval observational studies, MONITOR-GCSF aims to: (1) examine patient- and physician/center-related determinants of response to FN prophylaxis with biosimilar filgrastim; (2) identify patient profiles of vulnerability to poor prophylaxis outcomes; (3) model occurrence of FN breakthrough episodes; (4) identify predictors of non-response; and (5) evaluate the extent to which prophylaxis is in accordance with EORTC guidelines and approved label. *Methods.* MONITOR-GCSF study is an international, prospective, observational, pharmaco-epidemiological study of FN prophylaxis with biosimilar filgrastim in cancer patients undergoing chemotherapy (stage III or IV breast cancer; stage III or IV bladder cancer; stage III or IV non-small cell lung cancer; metastatic prostate cancer; and stage III or IV diffuse large B-cell lymphoma). As of 1 January 2010, this pan-European study has been recruiting at least 1000 patients from a minimum of 75 centers. Patients are followed over a maximum of six chemotherapy cycles. Statistical analyses procedures will consist of: descriptive and associative procedures; variance attribution methods to detect physician class effects; hierarchical linear, logistic, and Poisson modeling of clinical outcomes; Kaplan-Meier time-to-event analysis, Mantel-Cox log-rank or generalized Wilcoxon-Breslow tests, and Cox proportional hazards modeling; and clustering and related data mining techniques. *Results.* Results-reporting will include: baseline center and physician-investigator characteristics; baseline sample characteristics; interim analyses after patients enrolled in the first three months have completed 6 cycles of follow-up (approx. month 9); and 12 (approx. month 21) and 24 (approx. month 33) months later, using Pocock-adjusted levels of statistical significance; similar interim analyses on additional accrual cohorts; and end-of-study analyses. *Summary/Conclusions.* MONITOR-GCSF will provide valuable scientific and clinical information about the patient- and physician-related determinants of FN prophylaxis with biosimilar filgrastim in Europe. It will generate profiles of patients at risk for poor response to FN prophylaxis. New insights in how variability in practice patterns is associated with variability in outcomes will inform clinical practice. By comparing patterns of FN prophylaxis with biosimilar filgrastim to the EORTC guidelines, it will be possible to examine the association between guideline-compliant management of patients and clinical outcomes.

THE MOLECULAR PRESENTATION OF HUMAN PARVOVIRUS B19 INFECTION IN TRANSIENT BONE MARROW SUPPRESSED PATIENTS

B Mohammadi,[1] R Yaghobi,[2] M Dehghani[3]

[1]Azad Islamic University of Jahrom, Jahrom, Iran; [2]Shiraz Transplant Research Center, Shiraz University of Medical Sciences, Shiraz, Iran; [3]Hematology Research Center, Shiraz University of Medical Sciences, Shiraz, Iran

Background. The pathophysiologic etiology which led to transient bone marrow suppression is unknown, complicate, and multifactor. Blood born and bone marrow tropic viruses including human parvovirus B19 infection is one of the possible etiologic agents of this hematopoetic crisis. *Aim.* In this study the hematopoetic presentation of human parvovirus B19 is evaluated for determination of the possible role of this viral infection in pathogenesis of transient bone marrow suppression. *Methods.* In this investigation 27 EDTA treated blood samples where collected from patients with transient bone marrow suppression between years: 2007-2009. The genomic presentation of human parvovirus B19 was determined by an in-house qualitative Nested-PCR protocol. The relationship between B19 infection and the hematologic and biochemical demographic data of all studied patients was analyzed by SPSS version 16. *Result.* The single stranded-DNA of human parvovirus B19 was detected in 7 of 27(26%) transient bone marrow suppressed patients. Also the molecular presentation of Adenovirus was rule out from B19 infected patients. *Conclusion.* Diagnosis of high molecular incidence of human Parvovirus B19 infection in patients with transient born marrow suppression re-enounce the important role of B19 infection in transient hematopoetic crisis and related clinical outcomes.

1889

MICAFUNGIN PROPHYLAXIS IN HEMATOPOIETIC STEM CELL TRANSPLANTATION -- A SINGLE INSTITUTE EXPERIENCE

TD Tan, MC Wu, LW Chiou

Koo Foundation Sun Yat-Sen Cancer Center, Taipei, Taiwan

Backgroud. Fungal infection is one of the major complications in hematolpoietic stem cell transplantation. In randomised trials we can see the benefit of fluconazole prophylaxis as compared with placebo. Meanwhile, micafungin prophylaxis has the comparative benefitial effect or even better as compared with fluconazole. *Methods.* Between April 2007 and April 2009, 55 patients of hematologic malignancies (AML, MDS, ALL, CML, lymphoma, and myeloma) underwent allogeneic (n=33) or autologous (n=22) peripheral blood stem cell transplantation at our institute. All the transplant patients received micafungin 50mg a day as fungal prophylaxis from day +1 to +30. The preparative regimens include BUCY, TBI/CY, FluBu+/-ATG for AML, MDS, ALL, or CML; BEAM or TBI 2Gy/Flu for lymphoma; melphalan 200 for myeloma. *Results.* There were 12 events occurred which make micafungin prophylaxis shifted to empirical treatment. In these 12 events, there were 2 cases documented to be fungal infection and another 2 cases were highly suspicious fungal pneumonia. The other events ultimately proved to be CMV pneumonia (n=3), engraftment syndrome with idiopathic pneumonia (n=2), pulmonary GVHD or

bronchiolitis obliterans (n=1), recurrent Hodgkin's lymphoma (n=1), and acute lymphoblastic leukemia with liver and lung relapse (n=1). *Conclusions.* The effectiveness of micafungin prophylaxis in our 55 HSCT patients was 78.2% (43 in 55) and the breakthrough infection was 7.27% (4 in 55).

1890

MEDITERRANEAN VISCERAL LEISHMANIASIS: 20 YEARS TREATMENT EXPERIENCE

Z Trajkova-Antevska, S Glamocanin, B Coneska-Jovanova

University Childrens'Hospital, Skopje, Macedonia

Background. Mediterranean visceral Leishmaniasis is endemic disease in some arias in Macedonia. *Aims.* The aim of the study is to present 20 years experience of treatment of with single agent (Nmethyl-glucamine antimonate). *Methods.* During past 20 years (January 1990-january 2010) were diagnosed and treated 48 infants and children, 25 male, the age from 5 months to 12 years. Seven of them were infants. All 48 patients underwent standard clinical examination, biochemical investigation and bone marrow aspiration (positive finding of the parasite in 42 pts). In one patient was done hepatic biopsy and in one biopsy of lymph node. Serological method (Indirect immunofluorescent antibody test (IFAT)) was performed in 7 patients (therapy was applied in 3 pts according only to positive test). All patients were treated with Nmethyl-glucamine antimonate (60 mg/kg BW) i.m., in 14 days cycles and pause of 14 days in between. The cycles were repeated accordingly to the clinical and biochemical data before each cycle. The treatment was stopped when biochemical analyses and bone marrow aspirates were normal. *Results.* In 2 patients the treatment was stopped after first cycle, in 15 patients after 2 cycles, in 30 patients after 3 cycles and in one after 5 cycles (in circumstances of lacking of another effective drug). There were not any toxic side effects of the drug. *Conclusion.* The treatment of Mediterranean visceral Leishmaniasis with Nmethyl-glucamine antimonate in 14 days cycles and pause of 14 days in between is efficient and without toxic effects, even when the cycles are repeated several times, easy for application and not very expensive.

1891

ANALYSIS OF FALSE-POSITIVE RESULTS IN ELISA TEST FOR HIV-1 IN BLOOD DONORS WITH POSITIVE SEROLOGY OR INCONCLUSIVE

E Borges Vitor Anjos,[1] A Bezerra,[2] M Valença,[2] P Andrade,[3] S Costa[3]

[1]UNICAMP, Campinas, Brazil; [2]Hematology and Hemotherapy Foundation of Pernambuco, Recife, Brazil; [3]Department of Internal Medicine, Faculty of Medical Sciences, UNICAMP, Campinas, Brazil

Background. Disposal of blood donors by serological marker for human immunodeficiency virus type I (HIV-1 +2) gains a greater importance for the possible consequences and the clinical severity of infection and the virus becomes important target of preventive measures, including the haemovigilance. Hence the need for additional testing (confirmatory) more sensitive and specific in order to determine the HIV status of the donor. *Aims.* This study aims to determine the frequency and profile of false positive results shown by ELISA, using the Polymerase Chain Reaction (PCR) as confirmatory test. *Methods.* We analyzed 328 samples collected from donors who returned to confirm the serology was positive or indeterminate for HIV-1 at the time of donation. The period of sampling was in April 2008 to March 2009 in HEMOPE - Blood Center Recife. For confirmation of the tests were carried out reactions of nested PCR for 3 regions of the viral genome (GAG, ENV - 2 regions - and POL) from the proviral DNA, making a total of 4 reactions, nested PCR for each sample. For purposes of diagnostic criteria, it was determined that the donor will be told positive for HIV-1 to report a positive result in at least three of the four regions studied. Also included were results of indirect immunofluorescence and Western blot in the study. *Results.* Returned the following results. retest by ELISA, 52 (15.85%) were positive, 141 (42.99%) were inconclusive and 135 (41.16%) were negative. When the samples were analyzed by the reactions of 4 nested PCR for HIV-1, it was found that 282 samples (85.98%) were negative and 46 (14.02%) were positive. The results of the reactions of nested PCR were consistent with the results obtained in indirect immunofluorescence and Western blot. Of the 46 donors confirmed positive by PCR, only 3 (6.52%) were female and 43 male (93.48%). The age where the greatest number of positive individuals was 18 to 30 years (45.65%). *Conclusions.* Whereas the normal window period around 23-30 days, we can consider that these results indicate a high frequency of false-positive reactions in ELISA, and using a molecular technique can eliminate the vast majority of indeterminate results in serological defining better serostatus of the donor. PCR as a diagnostic test can make a transfusion service in reducing risk and damage to health.

1892

HEMATOLOGICAL AND INMUNOLOGICAL MANIFESTATIONS OF HIV-AIDS IN VENEZUELAN PATIENTS

S Müller,[1] A Soyano,[2] N Rojas,[3] G Salazar,[3] A Soyano,[4] J Lopez Mora[3]

[1]Institute of Hematology and Oncology, Catedra de Obstetricia, UCV, Caracas, Venezuela; [2]I.V.I.C., Caracas, Venezuela; [3]Escuela Luis Razetti (Obstetricia), UCV, Caracas, Venezuela; [4]Clinica El Avila, Caracas, Venezuela

Background. HIV virus produces immunological and hematological manifestations due to alteration host immune system, complication of secondary infections, malignancies, and as direct effect therapy on hematopoiesis. Our objective was to investigate the frequency and characteristics of 289 Venezuelan AID patients. *Patients and methods.* 322 Patients (164 male and female (nonpregnant) patients, 158 pregnant women) were diagnosed of HIV-AIDS by clinical presentation and tests ($CD4^+$ and $CD8^+$), positive serology and Western blot and hematologies. *Results.* Anemia developed in 106 (65%) patients: 10 with Hb below 10 g/dL, 30 10-12 g/dL, and 66 patients 12-14 g/dL. CD4+ were 304±243 cells/μL, with a CD4/CD8 index 0.36±0.18, viral load 22,730±8,950 RNA copies/mL. 6 required transfusions. Of the anaemic patients, 7 developed mild neutropenia (ANC: 1000-1500/μL); moderate neutropenia (ANC 500-999/μL) was observed in 4 without associated anemia; no severe cases of neutropenia were observed. 10 patients (6.1%) developed thrombocytopenia (50.000-100.000/μL); of these, 3 cases had anaemia. 158 pregnant women were HIV positive (3 first trimester, 52 second and 103 third). Immunological Studies: Third trimester CD3: 1388.94±578.71, CD4: 580.6±312.4, CD8: 840.8±370.7, CD4/CD8: 0.65±0.37; plasma viral load: 15677±35231. Second CD3: 1482.6±619.85, CD4: 427.6±299,576, CD8: 956±593.32, CD4/CD8: 1.4±0.6. Plasma Viral Load: 22061±2790.13. First trimester CD3: 1629±28.26, CD4: 841±2.8, CD8: 646±64.34. Plasma viral load: 3780±4057.4. The CD4 cell count 200-400 in 20.5% of pts, CD4 100-200 in 4.7% pts, CD4 < 100 cells count in 5,1% pts. Hematological and chemical studies third trimester: Hb 11.45±1.3 g/dL, crit: 35.3±4.1 %, WBC: 8443±3187/μL, Platelets: 217477/μL±134.7. Second trimester: Hb 11.6±1.4g/dL, crit: 34.2±3.8%, WBC: 8414±2133/ul, Platelet: 273222±91407/μL Third trimester: Hb 12.9±0.2 g/dL, crit: 39± 0%, WBC: 7600± 500/μL, Platelet: 280000± 50000/μL. The chemistries were normal except one patient with hepatic enzymes high. 152 pregnant HIV positive patients had anemia but two had Hb < 8 g/dL. WBC and Platelets were normal. 25 patients (1.74%) were positive for HIV: 18 NHL (72%) and 7 HL (34.52%). The dominant immunophenotype in the NHL was B cell. 23 patients developed anemia, 2 with Hb 8g/dL; 19 had leucopenia and 2 thrombocytopenia. 4 had Kaposi sarcoma. *Conclusions.* Our series of AIDS patients shows a frequency of anemia of 65%, in a few with mild neutropenia or thrombocytopenia. Isolated neutropenia or thrombocytopenia was uncommon. They had a low index CD4-CD8 with high viral load. 1,5 % of the pregnant women had HIV infection, the majority are in stage I, 9.8% has CD4 <200, 30.7% has anemia and severe anemia only 2 patients The WBC and Platelet count were normal . 92% lymphoma patients developed anemia, 2 with Hb <8 g/dL; 76 % had leucopenia and 2 thrombocytopenia, 4 had Kaposi sarcoma.

1893

THE USE OF DIFFERENT CYTOKINES TO PREDICT THE OUTCOME OF ONCO-HEMATOLOGIC PATIENTS WITH FEBRILE NEUTROPENIA

L Neuenschwander, B Bittencourt, AF Ribeiro, A Teixeira, M Teixeira, S Xavier, J Teixeira, V Nobre

Federal University of Minas Gerais, Belo Horizonte, Brazil

Background. Febrile neutropenia is a major complication in onco-hematologic patients. As some patients are at an high risk of contracting life-threatening infections, use of inflammatory markers, besides clinical evaluation, might improve prognostic and aim a more tailored approach. *Aims.* This study aimed to test the association of plasma levels of different inflammatory markers, named CXCL8 (IL-8), CXCL10 (IP-10), tumor necrosis factor alpha (TNFa) and its two soluble receptors, type I and type II (sTNFRI and sTNFRII), CCL2 (MCP-1),CCL3 (MIP-1α), procalcitonin (PCT) and CCL11 (eotaxin) with in-hospital mortality, fever persistency (after 3 days of antimicrobial treatment), bacteremia, and need of early adjustment (within the first 3 days) in antimicrobial treatment. *Methods.* In an observational prospective exploratory study, we evaluated the

behavior of these inflammatory markers in 37 episodes of febrile neutropenia occurring in 27 hospitalized onco-hematologic adult patients (median age: 39, 78% were man). Blood samples were obtained in three different moments of each neutropenic episode: at the first day of fever (Day 0), at Day 1 and Day 3 following the first record of fever. *Results.* Procalcitonin measured at Day 0 (cutoff value 2.27 mg / L; P=0.03), sTNFRII measured on Day 1 (cutoff value: 3,740 pg/mL; P=0.05), the delta Day 3-Day 1 of IL-8 (cutoff +320 pg/mL; P=0.05) and the delta Day 3-Day 1 of eotaxin (cutoff: 43 pg/mL; P=0.03) were significantly higher in patients who died at Day 28 of follow-up as compared to their surviving counterparts. Early adjustment on antimicrobial treatment was associated with a higher Day 3 level of IL-8 (cutoff value 217.9 pg/mL; P=0.05), sTNFRII (cutoff 3,992 pg/mL; P=0.04) and MCP-1 (cutoff 1,522 pg/mL; P=0.008), all of them measured at Day 3. No inflammatory marker was associated with bacterial blood stream infection. *Conclusions.* In this exploratory study, PCT, IL-8, sTNFRII, MCP-1 and eotaxin seem to be useful markers to assess the risk of death and the need of early adjustment on antimicrobial treatment in febrile neutropenia onco-hematologic patients. These results should be confirmed in a larger cohort of patients.

1894

USE OF INFLAMMATORY MARKERS TO PREDICT OCCURRENCE OF FEVER IN HEMATO-ONCOLOGY PATIENTS DURING NEUTROPENIA

AF Ribeiro,[1] V Nobre,[2] L Neuenschwander,[2] A Teixeira,[2] M Teixeira,[2] S Xavier,[2] F Paula,[2] J Teixeira,[2] H Bittencourt[2]

[1]Federal University of Minas Gerais, Belo Horizonte, Brazil, Belo Horizonte, Brazil; [2]Hospital das Clínicas de Belo Horizonte, Federal University of Minas Gerais, Belo Horizonte, Brazil

Background. Febrile neutropenia remains the most frequent complication in hemato-oncology patients receiving chemotherapy. Fever, however, might be a late sign of infection, with consequent delay in onset of antibiotic therapy. *Aims.* We hypothesize that change in serum level of cytokine/inflammatory markers might precede occurrence of fever in neutropenic patients, allowing an earlier onset of antibiotic therapy. Fever was defined as a single axillary temperature of ≥38°C or axillary temperature of ≥37.8°C over one hour. *Methods.* In an observational prospective single centre study, we evaluated the behavior of serum tumor necrosis factor alpha (TNF-α), soluble receptors of TNF-α (sTNFRI and sTNFRII), CCL2 (MCP-1), CCL3 (MIP-1α), CCL11 (eotaxina), CXCL8 (IL-8), CXCL10 (IP-10) and procalcitonin in 32 episodes of neutropenia occurring in hemato-oncology patients. These markers were tested in blood samples obtained in the first day of neutropenia, in the day before fever and in the day of fever were tested for these markers. Median age was 36 (18-69) yrs, and acute myeloid leukemia was the most frequent diagnosis (9 patients). Ten episodes occurred in patients who underwent hematopoietic stem cell transplantation. Eight out of the 32 episodes of neutropenia remained afebrile during the follow-up (28 days) and were considered our control group. Informed consent was obtained for all patients included in this study. *Results.* sTNFRI levels, measured a median of 11 hours (1-15 hours) before the first episode of fever, were significantly higher in febrile patients as compared to patients of control group (P=0.02). Similar results were observed for sTNFRI and CCL2 levels (P=0.04 for both markers) in the subgroup analysis of non-transplanted patients. A cut-off of 1514 pg/mL for sTNFRI was able to discriminate between neutropenic patients that presented or not fever, with sensibility of 65%, specificity of 87%, PPV of 93% and NPV of 46%. *Conclusions.* Daily measurement of sTNFRI could predict occurrence of fever in onco-hematological neutropenic patients, with low sensitivity and high specificity. CCL2 might also be useful in non-transplanted patients. A large prospective trial is needed to confirm these data.

1895

PULMONARY ASPERGILLOSIS IN ADULTS WITH ACUTE LEUKEMIA (AL) DURING INDUCTION TREATMENT: REPORT OF 32 CASES AMONG 114 AL PATIENTS

M Bellaaj

Chu Hedi Chaker, Sfax, Tunisia

Introduction. Pulmonary aspergillosis is a frequent cause of mortality in patients affected by acute leukaemia and receiving intensive therapies. The aims of our study is to present the incidence and diagnostic difficulties of pulmonary aspergillosis during induction treatment in 114 adults patients with acute leukaemia, and to evaluate management and treatment outcomes of this fungal infection in our department. Patients and methods.This is a retrospective study concerning 114 patients, 16 to 60 year old affected by acute leukaemia and admitted in the haematology department of sfax (Tunisia) for an induction course during a 5 year period (2005 - 2009). For each patient, a file has been filed, and the following data are inscribed: disease characteristics, therapeutic modalities, infections complications based on radiologic (thoracic radiography and/ or tomodensitometry) and microbiologic (aspergillary antigenemia by ELISA test+/- sputum and broncho-alveolar washing liquid when possible) examinations. Aspergillosis diagnosis is established according EORTC/MSG group criteria, with three levels of certainly: proved, probable and possible. Voriconazole was used in probable and proved aspergilosis treatment and ampho B in possible aspergilosis treatment. *Results.*We collected 39 ALL and 75 AML cases. 32 Patients (28 % of cases) presented pulmonary aspergillosis. The diagnosis was probable in 13 patients (40%), possible in 17 patients (53%) and proved (by histologic examination) in only 2 patients (6%). All patients had a suggesting clinical picture, with prolonged fever under wide spectrum antibiotics with sometimes respiratory symptoms. Radiologic examination, aspergillary antigenemia and mycological examination were positive in 90%, 46%, and 12% of cases respectively. The evolution was favorable among 42% of patients treated by Ampho B and 69% of patients treated by voriconazole. Mortality due to aspergilosis in our patients is of 38%. It was constant in our tree patients who presented this infection during rescue curse. *Conclusion.* Aspergillosis in a acute leukaemia patients under invasive chemotherapy sets diagnostic and therapeutic problems in our study as well as in the literature. Insufficiency of our explorations (precocious tomodensitometry, broncho-alveolar washing) explains uncertainly of diagnosis (half of our cases are possible), and incites us to improve our check-up procedures, which would allow more precious diagnosis and treatment.

1896

SERUM CORTISOL IN HEMATOLOGICAL PATIENTS WITH NEUTROPENIC FEVER: IS THERE ADRENAL INSUFFICIENCY?

A Juutilainen,[1] J Niemenpää,[2] S Hämäläinen,[1] T Kuittinen,[1] K Pulkki,[3] I Koivula,[1] L Niskanen,[2] E Jantunen[4]

[1]Kuopio University Hospital, Kuopio, Finland; [2]University of Eastern Finland, Kuopio, Finland; [3]Eastern Finland Laboratory Centre, University of Eastern Finland, Kuopio, Finland; [4]Kuopio University Hospital and University of Eastern Finland, Kuopio, Finland

Background. There are no data on the level of cortisol with respect to the inflammatory response in hematological patients with neutropenic fever. The aim of this study was to evaluate the association of serum cortisol with the level of C-reactive protein (CRP) and the development of severe sepsis in hematological patients with neutropenic fever. *Aims.* Altogether 69 hematological patients with 93 periods of neutropenic fever were included in this prospective study. Nineteen patients received therapy for acute myeloid leukemia and 50 patients were autologous stem cell transplantation recipients. *Methods.* Each period of neutropenic fever was classified as severe sepsis or not severe sepsis. Serum cortisol and CRP were determined at the onset of fever on day 0 and at 7-8 a.m. on days 1 to 4. *Results.* Serum cortisol level correlated positively with serum maximal CRP level during days 0 through 4 in neutropenic fever periods without severe sepsis, but no correlation was observed in fever periods with severe sepsis. Belonging to the lowest quartile range of increase of cortisol from day 0 to 1 was associated with high maximal CRP. *Summary/Conclusions.* In hematological patients with neutropenic fever but without severe sepsis the level of cortisol was associated with the severity of infection measured as maximal CRP. However, in fever periods complicated by severe sepsis the cortisol response was clearly attenuated. This discordance may reflect adrenal insufficiency in severe sepsis.

1897

CORRELATION STUDY BETWEEN THE D-DIMERS AND THE INFECTIONS, AND INVESTIGATION OF THEIR PROGNOSTIC VALUE IN THE OUTCOME OF THESE CASES

S Patiakas,[1] T Mylonas,[2] F Girtovitis,[3] I Alexidis,[2] C Charalampous[4]

[1]General Hospital of kastoria, Thessaloniki, Greece; [2]Microbiological Laboratory of General Hospital of kastoria, Kastoria, Greece; [3]General Hospital of Thessaloniki ACHEPA',, Thessaloniki, Greece; [4]Pathological Clinic of psychiatric hospital of Thessaloniki, Thessaloniki, Greece

Background-Aim. To investigate the relation of d-dimers to the infec-

tions and to estimate their prognostic value in the final outcome of the cases with increased levels. *Material-Method.* The material of the retrospective study included 108 cases of patients (62 men and 46 women), with the average age of 56,8 years. For all of these patients, the D-dimers blood level was measured, their clinical condition was studied, all the necessary laboratory tests were done, and after the registry of their final outcome, followed the statistical process x2. *Results.* It was proved that it considered 47 cases of infection, of which, 37 presented a moderate increase of d-dimers (220-1000 μg/L), 6 cases presented very high levels (>1000 μg/L), and only 4 patients had normal levels (<220μg/L). Out of the 6 patients with d-dimers level >1000 μg/L, 2 suffered from septicemia and passed away, and 4 suffered from intra-abdominal infections, of which 3 also passed away (pancreatitis, cholangitis). On the contrary, of the rest 37 with moderate increase of d-dimers, only one patient passed away, while no death was mentioned for patients with normal levels. Moreover, 3 cases of thrombo-embolic episodes (2 of them mortal) were registered with d-dimers level >1000 μg/L. *Conclusions.* It is, therefore, proved that: a)In addition to the septicaemia, the pulmonary embolism and the cancer, a clear increase of the level of d-dimers is also found in intra-abdominal infections, without nevertheless considering this parameter as an infection's diagnostic indicator. b)There is a strong correlation between the level of d-dimers and the cases of infections (91,5%), because of the activation of the exogenous coagulation system by the endotoxins, and finally, c)The major increase of the level of d-dimers represents undoubtedly an important (83,4%) aggravating prognostic factor for the outcome of patients hospitalized because of infection.

1898

STUDY OF COAGULATION DISORDERS DURING ACUTE FEBRILE INFECTIONS

C Charalampous,[1] S Patiakas[2]

[1]Psychiatric hospital of Thessaloniki, Thessaloniki, Greece; [2]Microbiological laboratory of general hospital of kastoria, Kastoria, Greece

Background-Aim. To study and document the possible disorders in the coagulation mechanism during acute febrile infections, given the fact that the inflammatory response which follows, is directly related to the activation of the coagulation mechanism. *Material - Method.* 86 patients were studied (47 male and 39 female), aged from 24 up to 78 years of age, who presented acute febrile infection, mainly of the respiratory and urinary system (24 and 17 cases correspondingly), and also of other systems (gastrointestinal, skin and soft tissue, etc). All the patients during the course of the disease (Stage A), were tested for the usual lab parameters. The coagulation mechanism was tested using automatic analyzers, with the help of tholosimetry: measurement of Prothrombin Time PT, of International Normalized Ratio INR, of activated Partial Thromboplastin Time aPTT and Fibrinogen FIB was performed. The coagulation mechanism was retested, in patients who even had one of the above mentioned parameters influenced, after the course of the disease (Stage B). The results were compared and statistically processed. *Results.* During Stage A, only 10 patients (11.6%) had no affected parameter of the coagulation mechanism. 19 patients presented INR>1.2 (22.1%), 18 presented aPTT >37 (20.9%), while FIB>400 mg was documented in 57 cases (66.3%). The corresponding measurements during Stage B showed that: 3 patients presented INR>1.2 (3.5%), 2 patients presented aPTT >37 (2.3%), while FIB>400 was documented in 8 cases (9.3%). *Conclusions.* It is proven, that in patients with acute febrile infection, the underlying inflammatory response, causes an activation of the coagulation mechanism, which results in the overwhelming majority of patients (88.4%), to present at least a parameter with disorder. On the contrary, after the passage of the disease, in the majority of patients all the coagulation parameters return to their previous normal levels.

1899

SCREENING OF FUNGEMIA USING CELL POPULATION DATA OF AUTOMATIC BLOOD CELL ANALYZER

KJ Han, JY Yang, JM Park, KG Park, YB Shim, YJ Park

Catholic University of Korea, Seoul, South-Korea

Background. Recently, fungemia(fungal sepsis) has increased dramatically due to marked increase in the pool of patients at risk. Candida species are the most common cause of fungal infection affecting immunocompromised patients and are the 3rd to 4th most common pathogen recovered from blood culture. It is associated with high morbidity and mortality and the prompt diagnosis and appropriate initiation of antifungal therapy are very important. The only available method to make diagnosis of fungemia is blood culture which needs at least 1 day of time. Fungemia often cause morphologic changes in the circulating white blood cells (WBC). Recently, Coulter DxH800 show many cell polulation data (CPD) of each WBC subpopulation. *Aims.* To find out the differences of CPD between fungemia and normal subjects and determine the usefulness of CPD as a screening marker of fungemia *Methods.* One hundred thirty four subjects without hematological disorders, 65 males and 69 females aged from 3 to 80 years old, were enrolled as normal control. Twenty seven patients with fungemia, 13 males and 14 females aged from 0 to 94 years old, were selected when routine blood culture showed growth of yeasts and their WBC count is over 1,000/μL. The isolated organisms were Candida species in 18 patients (C. albicans in 4 patients) and yeasts, not identified, in 9 patients. Routine blood culture was performed using one aerobic and one anaerobic culture bottles and automatic blood culture system (Bactec Fx, BD). Identification of the grown organisms were performed using automatic microorganism identification system (Vitek II, Biomeieux). If yeasts were not successfully identified using this system, identification was done using API 20C (Biomeieux). The EDTA-anticoagulated blood samples were analyzed using Coulter DxH800, within 8 hours after collection using DxH800, collected the CPD data of WBC subpopulation, and compared with that of normal control and the previously reported data of 117 cases of bacteremia. The study was approved by the Catholic Medical Center Institutional Review Board. *Results.* There is significant difference between fungemia and normal control in MN-V-NE, SD-V-NE, SD-C-NE, MN-MALS-NE, SD-MALS-NE, MN-LMALS-NE, SD-LMALS-NE, MN-LALS-NE, SD-LALS-NE, MN-AL2-NE, SD-AL2-NE, MN-V-LY, SD-V-LY, SD-C-LY, SD-MALS-LY, MN-UMALS-LY, SD-UMALS-LY, SD-LMALS-LY, MN-LALS-LY, SD-LALS-LY, MN-AL2-LY, SD-AL2-LY, MN-V-MO, SD-V-MO, SD-C-MO, SD-MALS-MO, SD-UMALS-MO, SD-LMALS-MO, MN-LALS-MO, SD-LALS-MO, SD-AL2-MO, MN-MALS-EO, MN-UMALS-EO, MN-LMALS-EO, MN-LALS-EO, MN-AL2-EO ($P<0.05$). Receiver operating characteristic (ROC) curves showed best sensitivity and specificity in SD-V-MO(at 23.32 sensitivity 96.3% specificity 95.5%) and lymphocyte SD parameters; sensitivity from 94 to 97%, and specificity from 92 to 96%. The MN-V-MO showed good sensitivity (at 182.5, sensitivity 88.9% specificity 97.8%). The neutrophil CPD showed sensitivity and specificity from 81% to 89%. There is significant difference between fungemia and bacteremia in MN-V-NE, SD-C-LY, SD-MALS-LY, SD-UMALS-LY, SD-LMALS-LY, SD-LALS-LY and SD-UMALS-MO ($P<0.05$). ROC curves showed best sensitivity (74.1%) and specificity (72.4%) at 12.6 of SD-LALS-LY. *Conclusion.* The CPD of neutrophils, lymphocytes and monocytes could be a very useful parameter of fungemia and could be differentiated from bacteremia also. Prediction of fungemia may be much more improved by incorporating the various significant CPD into an algorithm. It could help early detection and treatment of fungemia in patients.

FEBRILE NEUTOPENIA EPISODES IN PATIENTS WITH MULTIPLE MYELOMA AFTER AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION

A Lakhal

Centre National de Greffe de Moelle Osseuse de Tunis Tunisie, Tunis, Tunisia

Backgroud. Febrile neutropenia (FN) is a common and potentially life-threatening complication in patients with hematological malignancies. In this study, we analyse the characteristics of infectious complications occuring early after autologous hematopoietic stem cell transplantation (AHSCT). *Methods.* This is a retrospective study of FN episodes in multiple myeloma (MM) patients, who underwent AHSCT between Septembre 2003 and October 2009. Anti-infectious prophylaxis consisted of intensive hygiene measures without antibacterial chemoprophylaxis. Patients with FN received empirical antibiotic therapy with piperacilline-tazobactam and ciprofloxacine. Second-line antibiotic therapy consisted of a glycopeptide or amphotericin B. *Results.* A total of 93% of patients (93/100) developped FN after ASCT at median day +7 (range, 0-17). The median age of patients was 52 years (range, 32- 63). The median total duration of severe neutropenia was 7 days (range, 3-18). There were 67 (72%) FN of unknown origin, 10 (10.7%) FN clinically documented (5 pneumonias) and 16 (17.3%) FN microbiologically documented (8 bacteremias, 3 catheter-related blood steam infections, 2 skin infections, 1 urinary tract infection and 2 probable invasive pulmonary aspergillosis). The organisms isolated were 7 gram-negative bacteria (Pseudomonas aeroginosa (n=3), Acinetobacter baumanii (n=1),

Sphingomonas maltophilia (n=1), Proteus mirabilis (n=1) and Cryseomonas luteola (n=1)) ; 6 gram-positive bacteria (4 coagulase-negative staphylococcus, 1 Staphylococcus aureus and 1 Corynebacterium) and 1 Candida tropicalis (fungemia). Response to first-line empirical antibiotic therapy was seen in 77 (82.7%) FN patients. Median time to defervescence was 3 days (range, 1-5). Overall, 53 (56.9%) of the 93 patients needed at least a second-line antibiotic regimen based on glycopeptide and anti-fungal agents in respectively 28 (52.8%) and 12 (22.6%) cases. Response to second-line was obtained in 40 (74.4%) FN episodes. Infection- related mortality was 1% (1 case). *Conclusion.* ASCT should be considered a low-risk procedure in MM despite the slightly higher incidence of gram-negative and fungal infections observed in our study.

1901

POSITIONAL PARAMETERS IN HUMAN IMMUNODEFICIENCY VIRUS INFECTION (HIV)

E Papakonstantinou,[1] E Yfantis,[1] A Skourbouti,[1] A Lavda,[1] A Soultati,[2] P Katsaounis,[3] A Filiotou,[3] P Safioleas,[1] C Manti[1]

[1]Thriassion Hospital, Agia Paraskevi, Greece; [2]Ippokration Hospial, Athens, Greece; [3]Ippokration Hospital, Athens, Greece

Background. The Coulter LH 780 hematology analyzer (Beckman Coulter, Fullerton, CA) has the ability to measure specific parameters of lymphocyte and monocyte populations like mean and standard deviation (SD) of cell volume (MVI,SDVI), conductivity (MCI,SDCI), and light scatter (MSI, SDSI). These so-called positional parameters (PP) can detect changes in lymphocyte and monocyte populations in HIV patients. *Aims.* Changes in PP of lymphocytes and monocytes in HIV patients compared to control group. *Methods.* Lymphocytes and monocytes PP data from 21 HIV patients and from 53 age-matched healthy control subjects were prospectively analyzed. The PP was obtained by the Coulter LH 780 hematology analyzer. Comparisons between means were performed by analysis of variance. Comparison between 2 means was performed by using the Student t test. A P value less than 0, 05 were considered significant. *Results.* Table. *Conclusions.* 1)HIV infection is characterized by increased MVI and decreased MSI in both lymphocyte and monocyte populations. These results are statistically significant. 2) SDVI and SDSI also significantly increased both in lymphocytes and in monocytes compared with controls despite the fact that patients are on anti-retroviral therapy. 3)For the potential clinical utility of these findings in monitoring HIV patients we need prospective clinical trials that include untreated patients.

Table.

Mean	Control lymph.	Patient lymph.	p	Control monoc.	Patient monoc.	p
MVI	83.8	87.5	0.004	167.6	175.5	0.0001
MCI	115	114.9	0.8	122.2	122.1	0.76
MSI	75.2	68.1	0.0001	93.5	86.6	0.0001
SDVI	14.9	15.9	0.019	17.6	20.7	0.0001
SDCI	13.4	12.2	0.034	4.8	4.8	0.8

DETERMINATION OF THE SEROLOGICAL PROFILE OF CHILDREN IN GREECE WITH INFECTIOUS MONONUCLEOSIS IN THE NORTH GREECE

K Rousos,[1] P Patiakas,[2] F Girtovitis,[3] I Alexidis[4]

[1]General hospital of Veria, Greece, Veria, Greece; [2]Microbiological Laboratory of General Hospital of kastoria, Kastoria, Greece; [3]General Hospital of Thessaloniki ACHEPA', Greece, Thessaloniki, Greece; [4]Paediatric Clinic of General Hospital of Goumenissa, Goumenissa, Greece, Goumenissa, Greece

Background-Aim. To determine the serological profile of children with suspicion of Infectious Mononucleosis (IM) and to document the frequency of this infection (which in many cases is asymptomatic), as well as the epidemiological characteristics of IM. *Material-Methods.* A total of 176 children were studied, (92 boys and 84 girls), up to 17 years of age, with symptoms suspicious for Epstein-Barr virus infection. The ELISA method was used to look for specific antibodies against the capsid of the virus VCAIgG and against the nuclear antigen EBV-IgM, while taking into consideration the possible increase of the VCAIgG title between two serum samples. *Results.* Totally, 51 positive cases of children were found (29%) with active infection : 28 boys (14 <5 years of age, 12 5-10 years of age and 2 >10 years of age) and 23 girls (10 <5 years of age, 6 5-10 years of age and 7 >10 years of age). Pharyngitis was present in 47 children (92,2%), 39 had fever (76,5%) and 48 had lymphadenitis (94%). The lab tests revealed leukocytosis up to 20.000 leukocytes in 29 cases (56,9%) and leukocytosis >20.000 in 9 cases (17,6%). The most frequent complication documented was streptococcal superinfection in 13 children (25,5%) and thrombocytopenia in 8 children (15,7%). A past infection (negative EBV-IgM values and positive VCAIgG values) was documented in 24 children and teenagers (14%), while 101 children (57%), mainly of little age, were negative for infection. *Conclusions.* Therefore, it is proven that : 1)Epstein-Barr virus infection is common among children and teenagers. 2)Serum negative are mainly the children of little age and 3)There is no statistically important difference between the two sexes, while on the contrary there is a seasonal distribution of the infection, with winter and summer outbreaks.

1903

C-REACTIVE PROTEIN IS A USEFUL TOOL FOR PREDICTION OF NEUTROPENIC SEPSIS WITH OR WITHOUT FEVER

T Todd, R Tilley, D Veale, J Coppell

Royal Devon and Exeter Hospital, Exeter, UK

Background. Neutropenic infection is a serious complication of chemotherapy requiring prompt intervention. A test permitting early diagnosis could reduce diagnostic uncertainty or permit studies of early intervention. C-reactive protein (CRP) is a widely available, sensitive marker of inflammation and infection. *Aims.* To determine if CRP can predict the development and course of neutropenic infection. *Methods.* Episodes of post-chemotherapy neutropenia (neutrophil count $<0.5\times10^9$/L) lasting at least 5 days between December 2008- January 2010 were retrospectively identified from a laboratory database. Patient records were reviewed for fever, corticosteroid use, presence of disorders causing CRP elevation, antimicrobial administration, blood cultures and daily CRP *Results.* Data was collected for the following categories - Febrile Neutropenia (FN): fever >38°C but not already receiving systemic antimicrobials. Afebrile Infected Neutropenia (AIN): no fever but given systemic antimicrobials for clinically detectable infection. Uninfected Neutropenia (UN): no fever or systemic antimicrobials. Day 0 (D0) was the day of antimicrobial initiation (FN, AIN) or of maximum CRP (UN). *Results.* 50 FN, 8 AIN and 30 UN episodes were identified, 6 further episodes with incomplete CRP data were excluded. For all AIN and 48/50 FN episodes there was daily CRP rise from D-3 to D-1 with maximum CRP on D-1. UN episodes had no consistent pattern. Only 3 UN episodes had CRP>40 mg/L, one with extensive drug rash (CRP 41), one with tissue damage (60), and one otherwise well (48). One AIN and 6 FN episodes had maximum CRP<50. In two of these the patient was receiving oral corticosteroids (CRP 41 and 42). CRP>50 was therefore sensitive and specific for systemic antimicrobial requirement. However, the time from CRP >50 to antimicrobial requirement varied from 1 to 11 days. This variation was explained by inclusion of 10 FN episodes in patients with concomitant non-infective causes of CRP elevation, most commonly tissue trauma and severe drug reaction, who became febrile 7-11 days after CRP>50. In this group a CRP>50 alone, given the time to fever, probably does not equate to infection. However, a >50% CRP rise over two consecutive days was seen in all these episodes between D-1 to D-4. A 50% change alone does not discriminate well between UN and uncomplicated FN or AIN because of the small absolute value changes in some patients. Combining a minimum CRP>50 with a rise of >50% over 2 consecutive days produces a sensitivity of 86% and specificity of 100% for the subsequent development of neutropenic fever / infection within 3 days in all patients. After antimicrobial initiation, failure of CRP to fall >20% between D0 and D+3 correlated with, but did not predict, persisting fever at 48 hours and second line antimicrobial use. No CRP parameter correlated with positive blood cultures. *Conclusion.* A minimum CRP threshold of 50 mg/L combined with a minimum rate of rise of 50%

over 2 consecutive days is a highly sensitive and specific predictor of the need for systemic antimicrobials within 3 days. CRP values are not useful for predicting response to first line antimicrobials or organism isolation.

Table. Summary of CRP data.

	UN	FN	AIN	FN+AIN	FN+AIN simple	FN+AIN complex
Number of episodes	30	50	8	58	48	10

H1N1 ASSOCIATED HEMOPHAGOCYTIC SYNDROME SHOULD BE TAKEN INTO ACCOUNT

S Aytac,[1] S Aytac,[2] M Gokce,[2] S Unal,[1] O Ertekin,[2] A Kara,[2] M Ceyhan,[2] M Cetin,[2] F Gumruk,[2] M Tuncer[2]

[1]Hacettepe university, Ankara, Turkey; [2]Hacettepe University, Ankara, Turkey

We are presenting the case of a 14 year-old girl without any underlying disease who developed H1N1 associated hemophagocytic syndrome. Persistant fever without any evidence of secondary bacterial infection under antiviral treatment, hyperferritinemia and organomegaly are signs of suspected hemophagocytic lymphohistiocytosis (HLH) in H1N1 patients. To our knowledge, this is the first documented case of H1N1 complicated hemophagocytosis in a previously healthy child, and clinicians should be aware of the possibility of HLH. *Case.* A fourteen-year-old girl presented to our emergency room with complaints of fever, cough and progressive breathing difficulty for three days. She had no previously known chronic illness and her past history was unremarkable for infections and vaccinations. She was admitted to our infectious disease department with suspected H1N1 infection due to her contact with H1N1 (+) people. Upon physical examination, she was dyspneic, tachypneic and confused. Her fever was 39°C. The respiratory rate was 46/minute. Arterial pressure was 110/80 mmHg. Inspiratory crackles and wheezing were heard on auscultation. Her saturation was 56% without oxygen support. She had no organomegaly and lymphadenopathy. The initial hemogram showed: Hb: 12.8 gr/dl, WBC: $1{,}8\times10^9$/L with the 40% polymorphonucleated cells, 20% band, 20% lymphocyte and 12% monocyte, and a low platelet count (89×10^9/L). Her chest X-ray revealed diffuse, bilateral infiltration. Broad-spectrum antibiotherapy was immediately started. Because of the outbreak, a nasopharyngeal swab for H1N1 was also taken and oseltamivir was added to the treatment.She was intubated due to progressive respiratory distress, hypoxic encephalopathy and the presence of progressive respiratory acidosis on blood gases analysis at the 24th hour of admission.On the third day, H1N1 was positively diagnosed by polymerase chain reaction. During a clinical follow-up, hepatomegaly was detected on the thirteenth day. Several sets of blood, urine and stool cultures were all negative for pathogenic microorganisms. Although complete blood counts showed no cytopenia, the development of hepatomegaly and a persistant fever with spikes to 39°C made us suspect hemophagocytosis. Bone marrow aspiration was performed with a formulation of the bone marrow smears as follows: 40% normoblast, 3% promyelocyte, 16% myelocyte, 12% metamyelocyte, 5% band, 17% polymorphonuclear leukocytes, 4% lymphocyte, 3% monocyte. A bone marrow investigation also disclosed activated histiocytes with engulfment of normoblasts, erythrocytes and platelets. Serum ferritin and triglyceride levels were 1446 ng/mL and 215 mg/dL, respectively. Fibrinojen level was 513 mg/dL. Decreased NK level (CD16+56: 2%) was shown by flow-cytometer. No improvement occured in her clinical condition and hemophagocytic macrophages were shown in the aspirate from the endotracheal tube, as well as IVIG therapy. Therefore, high dose methylprednisolone (10 mg/kg/d) was started. Her body temperature normalized and serum ferritin levels decreased 2 days after steroid treatment. Cyclosporine and etoposide were added to her treatment according to HLH-2004 protocol. Infiltrations on chest X-ray apparently regressed and the pressure limits of mechanical ventilator were decreased. Our patient is still on mechanical ventilation and her treatment is ongoing. Because of the consanguineous marriage of her parents (1st cousins), hemaphagocytic lymphohistiocytosis mutation analysis is planned.

ABSOLUTE NEUTROPHIL VOLUME DISTRIBUTION WIDTH CORRELATION TO NEUTROPHIL COUNT IN ACUTE INFECTION

E Papakonstantinou, E Yfantis, K Konstantinou, A Lavda, P Giannopoulou, K Safioleas, I Grafakos, E Trikka-Graphakos, C Manti

Thriassion Hospital, Agia Paraskevi, Greece

Background. Review of peripheral blood smears can yield important diagnostic information through the identification of the morphologic changes characteristically seen in reactive neutrophils during infection. This approach, however, is labor-intensive and time-consuming because it requires manual examination. Furthermore, the results are subjective because they depend on human interpretation, and only a few hundred cells can be analyzed for any given sample. The Coulter LH 780 hematology analyzer (Beckman Coulter, Fullerton, CA) has the ability to measure specific parameters of neutrophil populations like mean and standard deviation (SD) of cell volume (MVI,SDVI), conductivity (MCI,SDCI), and light scatter (MSI, SDSI). These so-called positional parameters (PP) can detect morphologic changes in neutrophil population and can be an additional indicator for diagnosing acute infection. *Aims.* To investigate the value of the neutrophil SDVI generated by VCS technology of the Coulter LH 780 hematology analyzer, as an additional predictor of acute infection. *Methods.* Absolute neutrophils count, and SDVI data from 552 patients with positive blood cultures and from 54 age-matched healthy control subjects were prospectively analyzed. We then studied whether changes in SDVI correlated with patients absolute neutrophil counts (less or greater than 6600/μL). The PP was obtained by the Coulter LH 750 hematology analyzer. Comparisons between means were performed by analysis of variance. Comparison between 2 means was performed by using the Student t test. A P value less than 0, 05 were considered significant. *Results.* A significant increase in the SDVI was observed in the bacteremic patients compared with the controls (28, 1 *vs.* 20, 6, P<0,001). Such increase was observed even in patients with absolute neutrophil counts less than 6600/μL) (25, 7 *vs.* 20, 6, P<0,001). The more dramatic increases were seen in patients with neutrophilia (29, 1 *vs.* 20, 6, P<0,001). Table. *Summary/Conclusion.* 1) The SDVI increases in acute infection. 2) Using an SDVI cutoff of 23, as in bibliography, seems that SDVI is a good predictor of acute infection. 3) The SDVI increase correlated significantly with neutrophilia but was observed even in patients with neutrophil counts less than 6600/μL. 4) As a quantitive parameter, the SDVI has potential use as an additional indicator for diagnosing acute infection.

POSITIONAL PARAMETERS: INDICATORS OF ACUTE INFECTION

E Papakonstantinou, E Yfantis, K Konstantinou, S Chaniotaki, P Giannopoulou, I Grafakos, K Safioleas, E Trikka-Graphakos, C Manti

Thriassion Hospital, Agia Paraskevi, Greece

Background. Review of peripheral blood smears can yield important diagnostic information through the identification of the morphologic changes characteristically seen in reactive neutrophils during infection. This approach, however, is labor-intensive and time-consuming because it requires manual examination. Furthermore, the results are subjective because they depend on human interpretation, and only a few hundred cells can be analyzed for any given sample. The Coulter LH 780 hematology analyzer (Beckman Coulter, Fullerton, CA) has the ability to measure specific parameters of neutrophil populations like mean and standard deviation (SD) of cell volume (MVI,SDVI), conductivity (MCI,SDCI), and light scatter (MSI, SDSI). These so-called positional parameters (PP) can detect morphologic changes in neutrophil population and can be an additional indicator for diagnosing acute infection. *Aims.* To investigate the values of neutrophils PP generated by VCS technology of the Coulter LH 780, as additional predictors of acute infection. *Methods.* Neutrophils PP data from 552 patients with positive blood cultures and from 54 age-matched healthy control subjects were prospectively analyzed. The PP was obtained by the Coulter LH 780 hematology analyzer. Comparisons between means were performed by analysis of variance. Comparison between 2 means was performed by using the Student t test. A P value less than 0, 05 were considered significant. *Results.* 63,9% patients were male and 36,1% females. 83% positive blood cultures had 1 microorganism, 14,4% 2 and 2,6% had 3. Gram (+) microorganisms were found in 34, 8% and gram (-) microorganisms in 59,5% positive blood cultures. When we studied full blood count we found that 28, 3% had less than 6600/μL neutrophils and 71,7% more than 6600/μL neutrophils. SDVI between 1 or 3 microorganisms correlated significantly (P=0,045) but the number of 3 microorganisms in positive blood cultures was small (452 v 14). Table. *Conclusions.* 1) MVI and SDVI increase in acute infection. 2) MCI and MSI decrease in acute infection. 3) Using an SDVI cutoff of 23 and MVI cutoff of 150, as in bibliography, seems that SDVI and MVI are good predictors of acute infection. 4) As quantitive parameters, PP have potential use as additional indicators for diagnosing acute infection.

TOXOPLASMOSIS AS A CAUSE OF PANCYTOPENIA IN IMMUNOSUPPRESSED PATIENTS

P Silveira, I Esteves, R Assis, F Pires, A Alanna, M Colombini, E Velloso, P Silveira

Hospital Israelita Albert Einstein, São Paulo, Brazil

Introduction. Latent infection by Toxoplasma gondii affects millions of persons worldwide, but rarely causes significant disease in immunocompetent patients. However, in recipients of solid organ transplants it can cause significant morbidity and mortality. Reactivation of latent infection can occur during use of immunosuppressive medications, and majority of patients are asymptomatic. Development of symptomatic infection by Toxoplasma gondii is associated with a high mortality (~65% in recent series). A few reports suggest that Toxoplasma gondii can cause pancytopenia in immunocompromised patients. We describe two patients post-kidney-pancreas transplant who developed symptomatic toxoplasmosis involving the bone marrow. *Objective.* To describe two immunocompromised patients who developed pancytopenia secondary to Toxoplasma gondii infection. One of the cases was previously reported (Seguro FS *et al.,* Brit J Haematol, 2009, 147:276). *Methods and results.* Both patients were receiving tacrolimus, mycophenolate mofetil and methylprednisolone for immunosuppression after kidney-pancreas transplant. Case#1 was a 33 year-old male who developed fever, headache and tachypnea 3 months after transplantation. The patient was receiving treatment with ganciclovir for cytomegalovirus reactivation at the time. He developed pancytopenia and bone marrow biopsy revealed a hypocellular marrow with increased macrophagic activity. Afterwards, he developed microangiopathic anemia that didn´t improve with plasma exchanges and discontinuation of tacrolimus. His bone marrow was reevaluated and trophozoites suggestive of Toxoplasma gondii were identified and confirmed by immunohistochemistry. A CT scan and MRI of the brain didn´t show a mass lesion, and cerebrospinal fluid analysis was negative for Toxoplasma gondii by polymerase chain reaction. Toxoplasma gondii serology was positive for anti-toxoplasma IgM. The patient passed away before the diagnosis could be confirmed, so no specific treatment was administered. Case#2 was a 40 year-old male who was admitted 4 months post-transplant for fever of unknown origin and anemia. He had no neurologic symptoms. After 5 days the patient became pancytopenic, and a bone marrow evaluation showed Toxoplasma gondii trophozoites which were confirmed by immunohistochemistry. He received treatment with sulfadiazine-pyrimethamine but died 2 months later. *Conclusion.* Toxoplasmosis occurs due to reactivation of latent foci or from primary infection, and can cause a myriad of symptoms in immunocompromised patients, including pancytopenia. The parasite can be identified in bone marrow smears and bone marrow biopsies. Bone marrow evaluation with specific staining for Toxoplasma gondii trophozoites is indicated in immunocompromised patients post-solid organ transplant who develop pancytopenia, particularly in populations where the prevalence of infection is high.

1908

USE OF LIPID AMPHOTERICIN B (ABELCET) IN HAEMATOLOGICAL PATIENTS SUBMITTED TO ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANT: A SINGLE CENTRE EXPERIENCE

N Cascavilla, AM Carella, E Merla, G Rossi, M Greco

Hematology Casa Sollievo della Sofferenza Hospital IRCCS, San Giovanni Rotondo, Italy

Background. In haematological patients a persistent high-grade fever that does not improve when treated with antibacterials is often assumed to be due to fungal infection. The approaches to the treatment of fungal infections include several lipid formulations of Amphotericin B such as Ambisome and Abelcet and other molecules including Caspofungin and Voriconazole. *Aims.* To evaluate a single centre experience with Abelcet use in a group of haematological patients who had undergone allogeneic hematolopietic stem cell transplant (HSCT). *Methods.* This retrospective study evaluated 11 patients (7 males, 4 females), 17-54 years old (median age 31) with neoplastic haematological diseases who had recently undergone HSCT at a median time from diagnosis of 9 months. The conditioning regimen was myeloablative in 10 cases and an anti-lymphocyte treatment was associated in 3 cases. In the post-HSCT phase, during the neutropenic period (duration13-30 days, median 17), fever (BT ≥38°C) appeared in 10/11 cases after a median of 5 days (range 1-22) from HSCT. On the basis of microbiological studies and imaging (X-ray, CT, and ultrasound) the fever was associated with pneumonia in 2 cases and sepsis in 5, while it remained of undetermined origin in 3 cases. A poli-antibiotic therapy was administered in the 10 febrile patients. *Results.* Antifungal treatment with Abelcet was started at a median distance of 7 days (range 3-24) from HSCT in all 11 patients, as secondary prophylaxis in the apyretic patient (180 mg/day) and, due to the persistence of the fever in the other 10 patients, as emptive or pre-emptive treatment (300 mg/day). This Abelcet treatment had a median duration of 7 days (range 4-13 days) and, after a median time of 4 days, a creatinine increase was observed in 7/11 cases with a median duration of 6 days and with a maximum level ranging from 1.42 to 2.69 mg/dL (median 1.66). In two of these 7 cases the antifungal treatment was continued with Caspofungin. No other significant adverse events related to the Abelcet treatment were

reported. At the end of the Abelcet treatment, only 3/10 patients remained febrile and the pneumonia disappeared in one of the two cases. An acute graft *vs.* host disease grade II-III was observed in six cases and the HSCT-related mortality (within 100 days) was 27% (3/11 cases; 2/3 receiving Abelcet and then Caspofungin). *Conclusions.* Antifungal treatment with Abelcet in eleven haematological patients who had undergone allo-HSCT in a single centre, performed as secondary prophylaxis in one case and as emptive or pre-emptive treatment in the other ten cases with a median duration of seven days and with a median dose of 300 mg/day, was satisfactorily tolerated and associated with a considerable reduction of infectious complications and with an acceptable HSCT-related mortality rate.

1909

POSITIONAL PARAMETERS IN DIFFERENTIAL DIAGNOSIS OF H1N1 IN CHILDREN

E Papakonstantinou, E Yfantis, S Chaniotaki, A Lakoumenta, K Konstantinou, A Arvaniti, P Safioleas, I Grafakos, E Trikka-Graphakos, C Manti

Thriassion Hospital, Agia Paraskevi, Greece

Background. The H1N1 pandemic was a great public health problem in the last months of 2009 both for the world community and for Greece. The Coulter LH 780 hematology analyzer (Beckman Coulter, Fullerton, CA) has the ability to measure specific parameters of lymphocyte and monocyte populations like mean and standard deviation (SD) of cell volume (MVI,SDVI), conductivity (MCI,SDCI), and light scatter (MSI, SDSI). These so-called positional parameters (PP) can detect changes in lymphocyte and monocyte populations. *Aims.* The purpose of this study was to evaluate the utility of PP in differential diagnosis of H1N1 infection in children population. *Methods.* We studied 64 patients (<14 years old)) who came at emergency department with flu symptoms. Confirmation of H1N1 was by PCR. Full blood count and PP was obtained by the Coulter LH 780 hematology analyzer.Comparisons between means was performed by analysis of variance. Comparison between 2 means was performed by using the Student t test. A P value less than 0, 05 were considered significant. *Results.* Table. *Conclusions.* 1) The absolute number of lymphocytes in H1N1 positive patients is reduced significantly (P<0.0001). 2) The number of platelets in patients is reduced (P=0.073). 3) MVI (P=0.078) and MCI(P=0.023) are reduced in patients. Prospective studies with larger numbers of patients are needed to asses the possible clinical utility of PPs in H1N1.

Table.

Table	H1N1 (+)	H1N1 (-)	P
samples	34	30	
lymphocytes x $10^3/\mu l$	2.24	4.4	0.0001
MVI lymphocytes	79.76	82.43	0.078
MCI "	113.5	115.5	0.023
PLT	273.5	325.8	0.073

POSITIONAL PARAMETERS IN DIFFERENTIAL DIAGNOSIS OF H1N1

E Papakonstantinou, E Yfantis, S Chaniotaki, P Georgoutsou, K Konstantinou, A Arvaniti, K Safioleas, I Grafakos, E Trikka-Graphakos, C Manti

Thriassion Hospital, Agia Paraskevi, Greece

Background. The H1N1 pandemic was a great public health problem in the last months of 2009 both for the world community and for Greece. The Coulter LH 780 hematology analyzer (Beckman Coulter, Fullerton, CA) has the ability to measure specific parameters of lymphocyte and monocyte populations like mean and standard deviation (SD) of cell volume (MVI, SDVI), conductivity (MCI, SDCI), and light scatter (MSI, SDSI). These so-called positional parameters (PP) can detect changes in lymphocyte and monocyte populations. *Aims.* The purpose of this study was to evaluate the utility of PP in differential diagnosis of H1N1 infection. *Methods.* We studied 277 patients, aged 8 months - 83 years, who came at emergency department with flu symptoms. Confirmation of the disease was by PCR. Full blood count and PP were obtained by the Coulter LH 780 hematology analyzer. Control group were 53 samples of healthy donors. Comparisons between means were performed by analysis of variance. Comparison between 2 means was performed by using the Student t test. A P value less than 0, 05 were considered significant. *Results.* 34 positive patients were children and 92 were adults. There were a statistical significant difference in platelet number between the two groups (children $273.5\times10^3/\mu L$ *vs.* $196.6\times10^3/\times L$ adults, P<0.0001). Table. *Conclusions.* 1) The absolute number of lymphocytes in H1N1 positive patients is reduced significantly (P<0.0001). 2) The number of platelets in patients is reduced significantly (P<0.001). The length of this reduction in adult patients (a sufficient number of those verging to mild thrombocytopenia) compared to children must be noted. 3) The absolute number of monocytes in H1N1 positive patients increases significantly (P<0.0001). 4) The absolute number of lymphocytes is reduced, but monocytes MVI and lymphocytes, monocytes SDVI are increased in patients compared to controls. Prospective studies with larger numbers of patients are needed to asses the possible clinical utility of PPs in H1N1.

TOXOPLASMOSIS IN CNS: OPPORTUNISTIC INFECTION WITH DIFFICULT DIAGNOSABILITY IN A PATIENT WITH IDIOPATIC THROMBOCYTOPENIC PURPURA TREATED WITH IMMUNOSUPPRESSIVES ON A LONG-TERM BASIS

R Urbanova,[1] V Prochazka,[1] L Raida,[1] A Hlusi,[1] M Pecuchova,[1] T Papajik,[1] K Indrak,[1] D Adamova,[2] L Machala[3]

[1]*University Hospital and Medical Faculty, Palacky University Olomouc, Olomouc, Czech Republic;* [2]*Hospital de Silesia de Opava, Opava, Czech Republic;* [3]*Clinic of Infectious Diseases, Faculty Hospital Bulovka Prague, Prague, Czech Republic*

Toxoplasmosis in immunodeficient patients can have severe or even fatal progression. Laboratory diagnosis is difficult and treatment initiation must not be postponed. CNS affliction is typical, empirical treatment is used. We refer a patient case in whom the diagnosis was made on the basis of successful empiric antibiotic therapy and findings of magnetic resonance (MR). Since February 2007 a 43 years old patient with idiopatic thrombocytopenic purpura (ITP) was treated due to refractoriness of illness with substantive dose of corticoids in combination with cyklosporin A. In May 2008 a focal pulmonary diffusion process was identified on PET CT and therefore a diagnostic thoracotomy with resection of lung locus was made with histological finding of B non-Hodgkin lymphoma (B-NHL) MALT type. In August 2008 he was subfebrile and occurred cough, headaches, desorientation, visual disturbances and emesia. Neurological examination identified slight left-sided hemiparesis. The patient was meningeal when admitted into hospital. Liquor examination was negative (including PCR for Toxoplasma gondii), liquor immunophenotypization for exclusion of NHL defect was also negative. Magnetic resonance of brain identified arachnoid cyst frontally right without any signs of expansion, multiple supratentorial nidus with perifocal edema with ring enhancing imiging. Due

to toxoplasmosis suspicion a combined therapy with klindamycin 600 mg 4× per day i.v., kotrimoxazol (sulfamethoxazol and trimetoprim) i.v. in doses of sulfamethoxazol 70 mg/kg/D and pyrimetamin 50 mg/day was used. Alleviation of headaches, perplexity regression and eyesight improvement occurred within 3 days. $CD4^+$ T-lymphocytes examination from peripheral blood proved substantial lymphocyte count decrease: 0,186.109/l (referring rate: 0,44-1,8), patient is HIV 1+2 negative. Stereotactic biopsy of brain locus proved only gliosis during the therapy. After one month hospitalization the patient was released for home after-care with proven significant regression of infiltrates and perifocal edema on brain MR. Combined antitoxoplasmosis treatment was conducted for 6 weeks. Revisional lung CT in November 2008, when the patient was still asymptomatic, proved persistence of insignificant lung infiltrates and therefore transbronchial lung biopsy was indicated with histological findings of focal active inflammation of lymphocytic pneumonitis type, evaluated as postinfectious. As since June 2009 the patient observed gradual ingravescence, i.e. visual disturbances, shivering, protracted psychomotor pace, and subsequently also headaches, 1× seizure of convulsions - grand mal type, suspicion of toxoplasmosis recurrence occured. Brain CT identified three right-sided frontoparietal intraparenchym haemorrhagies with edem portion which was closed as recurrence of brain toxoplasmosis with signs of haemorrhage and therefore a combined antitoxoplasmosis therapy with pyrimetamin, klindamycin and kotrimoxazol was restarted. After 14 days significant improvement of clinical state occurred, brain MR after 4 weeks proved significant regression of findings. The invasive combined therapy continued for 8 weeks. Due to persisting immunodeficiency of $CD4^+$ T lymphocytes (0,220.10 9/L) was the risk of illness recurrence stated as high and secondary prophylaxis with pyrimetamin 25-50 mg/day in combination with klindamycin 1200 mg/day was therefore indicated. This detailed study of our patient with diagnosis of recurring CNS infection with Toxoplasma gondi was intended to demonstrate diagnostic and therapeutical issues relating to the opportunistic infection in a immunodeficient patient.

1912

BONE MARROW FAILURE , INTERSTITIAL PNEUMONIA AND COAGULOPATHY AS ONSET MANIFESTATIONS OF CHRONIC ACTIVE EPSTEIN BARR VIRUS INFECTION (CAEBV)

A Manna,[1] M Pietra,[1] L Biffignardi,[1] F Via,[2] A Carpenzano[3]

[1]Ospedale Felettino, La Spezia, Italy; [2]Laboratory Department, La Spezia, Italy; [3]Intensive Care Department, Sarzana, Italy

CAEBV is a very rare disorder in which EBV infection results in a persistent ,ongoing viral infection of one or more organ systems. CAEBV is a disease with high mortality and morbidity with life threating complications such as virus associated hemophagocytic syndrome, interstitial pneumonia, lymphoma, coronary aneurism and central system involvement. CAEBV has been defined by Straus (Straus SE, J Infect Dis 1988) usign 3 diagnostic criteria: 1) severe illness lasting 6 months or more with markedly elevated EBV serology or chronic progressive disease that began as primary EBV infection 2) histologic evidence of major organ involvement such as interstitial pneumonia 3) increased quantities of EBV in affected tissues. Many cases have been reported not fullfilling the criteria mentioned above : Kimura reported extremely high viral loads assessed by quantitative PCR in CAEBV patients, suggesting the last one as the main diagnostic criteria (Kimura Blood 2001). We report a case of CAEBV with unusual onset. A 64 yrs old female patient was admitted on August 2009 on Internal Medicine Department because of shortness of breath lasting a few days; the full blood count showed a macrocitic anemia with thrombocytopenia: Hb= 6.7g/dL , MCV= 110fl, WBC= 9300 /μL with normal differential count, Plt= 29000/μL; chest xray showed a left pleural effusion while abdominal echography revealed liver enlargement; CT lung showed diffuse ground glass opacities, pleural effusion and consolidation with multiple air bronchograms. Ten days later, because of pulmonary function tests worsening, the patient was admitted to Intensive Care with ARDS clinical picture; after CPAP withouth any improvement the patient has been intubated. Pathogens detection (Gram+ Gram- fungi and galactomannan antigen) on sample from BAL proved negative, so were negative legionella and pneumococcal urine antigens; CMV DNA and CMV Ag pp65 were negative. A week later the patient was extubated but the following day , due to EGA and Pa O2 worsening CPAP was resumed with good recovery of respiratory tests (chest x ray showed bilateral diffuse extensive nodular shadowing); a few days later a deterioration of blood parameters was observed: Hb= 8 g/dL, WBC= 700/μL (53% granulocytes; 37 % lymphocytes) Plt = 3000/μL; bone marrow aspiration showed a severe hypoplasia ; meanwhile a low fibrinogen level (< 100 mg/dL) consistent with fibrinogenolysis was detected and the patient was managed with almost daily fresh frozen plasma infusion. Paroxismal nocturnal hemoglobinuria and thrombotic thrombocytopenic purpura were ruled out respectively with peripheral blood cytofluorimetric test (CD55 and CD59 antigens regular expression) and ADAMTS 13 level evaluation ; Evans syndrome has been excluded by Coombs test negativity , antiplatelets antibodies negativity and no platelets response to steroid and high dose immunoglobulins .EBV DNA search on bone marrow resulted positive with 1000 viral copies /mL; the same test on peripheral blood showed a strong positive result with 600 viral copies/mL; standard EBV serology performed was in keeping with previous EBV infectio: IgM and EA absent, Ab antiEBV VCA 750u/mL, antiEBNA 600 u/mL. On the basis of these results the diagnosis of CAEBV was performed; a progressive slow recovery af cytopenia and fibrinogen was observed together with clinical improvement.

1913

LONG-TERM TREATMENT OF SEVERE MYASTHENIA GRAVIS BY EXTRACORPOREAL IMMUNOGLOBULIN ELIMINATION

M Blaha,[1] J Pitha,[2] V Blaha,[1] M Lanska,[1] J Maly,[1] S Filip,[1] H Langrova[1]

[1]Charles University, Medical Faculty, Hradec Králové, Czech Republic; [2]Charles University, 1st Medical Faculty, Dpt. of neurology, Praha, Czech Republic

Introduction. Myasthenia gravis (MG) is a neuromuscular disorder leading to fluctuating muscle weakness and fatigue. Rarely, long-term stabilization is not possible through the use of thymectomy or any known drug therapy. Plasmapheresis or some more specific hemapheretic methods can improve the status of patients even when the disease is resistant to standard therapy. *Methods and patients.* Presently, 1916 patients are treated at the Myasthenic Center in Prague. Only six of these patients were in severe condition despite thymectomy and drug therapy (including corticosteroids, immunosuppressive drugs and repeated doses of immunoglobulins) and could not be stabilized for a longer period of time. Therefore, these patients were included in the program of long-term therapy with extracorporeal elimination of immunoglobulins. We present our experience with extracorporeal immunoglobulin (Ig) elimination by immunoadsorption (adsorbers with human Ig antibodies). Acetylcholine receptor antibodies (AChRAs) were measured during long-term monitoring (4.7±2.9 years; range 1.1-8.0). *Results.* A total of 474 samples (232 pairs) were analyzed, and a drop in AChRA levels was observed (P=0.025). The clinical status of patients improved and stabilized. Roughly 6.8% of patients experienced clinically irrelevant side-effects. *Conclusion.* The method of Ig elimination by extracorporeal immunoadsorption (IA) is a clinical application of recent biotechnological advances. This hemapheretic method offers an effective and safe therapy for severe MG even when the disease is resistant to standard therapy.

Matteo Found, Pavia, Italy; [3]BMT Unit, Dept. of Paediatric Onco-Hematology, IRCCS Policlinico S.Matteo Found., Pavia, Italy; [4]Serological and Molecular Diagnostics, Transf.Med. Dept., IRCCS Pol.S.Matteo F., Pavia, Italy

HLA-G is a non-classical HLA class I molecule mainly expressed during pregnancy on the syncytiotrophoblast to allow maternal acceptance of the foetus. HLA-G molecule has powerful tolerogenic effects due to its immunological properties: it can inhibit the cytolysis mediated by both Natural Killer cells and antigen-specific cytotoxic T cells. In organ transplantation setting, a significant correlation has been described between heart transplant acceptance and HLA-G expression in donor's heart tissue. Not all transplanted patients expressed HLA-G, but those who produced HLA-G had a clear survival advantage and a higher protection from graft rejection. Previous studies demonstrated that a 14bp insertion/deletion polymorphism in the 3'UTR of the HLA-

G gene leads to low production of more stable subpopulation of HLA-G m-RNA. The clinical role of HLA-G 14bp polymorphism has been described in a group of adult thalassaemia patients transplanted with unrelated HLA-identical bone marrow HSC donors. Patients with the 14bp deletion/deletion genotype showed a higher risk of developing acute graft-versus-host disease (GvHD) compared to those carrying the 14bp deletion/insertion and 14bp insertion/insertion genotypes, with a relative risk increasing by three times. For this purpose, we investigated the 14bp HLA-G genotypes in 13 infant thalassaemia patients transplanted with their HLA-identical sibling Cord Blood (CB) donors (all CB units collected and cryopreserved at the Pavia CB Bank). The patient sample was composed by children comparable for age, weight, conditioning regimen, GvHD prophylaxis and CB total nucleated cell graft content infused. We performed a molecular analysis of the HLA-G genotypes of each recipient/donor couple by PCR technique. All recipients showed the same HLA-G 14bp genotype of their corresponding sibling donors. 9 patients were heterozygous (insertion/deletion), 2 were homozygous for the insertion (insertion/insertion) and 2 were homozygous for the deletion (deletion/deletion) polymorphism. None patient developed GvHD and, at present, all recipients are alive with complete neutrophils and platelets recovery within day 37 and 73 respectively. We also investigated the correlation between soluble HLA-G (sHLA-G) concentrations and HLA-G genotypes in thawed aliquots of CB plasma (stored at -190°C as the CB unit) by ELISA technique and PCR-SSP amplification respectively. No statistically significant variability was observed in CB sHLA-G levels among the 3 HLA-G genotype groups (sHLA-G average concentration 39.07 ng/mL). These results may support the hypothesis of a particular fine regulation of sHLA-G secretion during pregnancy bypassing the foetal 14pb HLA-G genotype. A quantitative sHLA-G expression screening of recipients could be a useful criterion in preventing transplant immunological adverse outcomes in unrelated adult HSC transplantation. Although preliminary for the small size of the patients sample, our findings seem to suggest that, in CB transplantation setting, the HLA-G 14bp genotype of the recipients may not influence the outcome as to rejection and GvHD, because CB may be considered an immunotolerogenic sHLA-G source per se.

1915

GRANULOCYTE TRANSFUSION THERAPY. EFFICACY TO RESOLVE THE INFECTIONS IN PATIENT WITH SEVERE NEUTROPENIA WITH IDENTIFIED GERM

I Enrico,[1] M Lopez,[2] M Prates,[1] S Yantorno,[1] J Napal,[1] L Ramirez,[1] M Firpo,[1] H Milone[1]

[1]Hospital Italiano de La Plata, La Plata, Argentina; [2]Hospital Italiano La Plata, La Plata, Argentina

Background. A Neutropenia-related infection is the main causes of morbidity and mortality in patients with hematologic malignancy. Granulocyte transfusion therapy is used to treat neutropenic patients with severe infections which do not respond to appropriate antimicrobial agents. A renewed interest in the use of the transfusion of granulocytes in this group of patients. *Aims.* To analyze the effectives of granulocyte transfusion therapy (GTT) in patients with severe neutropenia and not controlled infections with 2 or more lines of antimicrobial agent and/or adjusted to focus or germ. *Methods.* from May of 1999 until December of 2009, 210 leukapheresis was performed to 50 patients who presented a severe neutropenia (<100/mm^3) due to chemotherapy or hematopoietic stem cells transplantation (HSCT) (allogeneic 53%, autologous 21% and chemotherapy 26%). The population studied was composed for: 24 males and 26 female with an average of age of 31 years (r: 7-56). The hematological neoplasm were 27pts AML, 7pts ALL, 4pts NHL, 3pts CML, 3pts sAA, 2pts Myeloma and 4pts with solid tumors. ABO and Rh compatible healthy donor were injected subcutaneously with 5 ug/colony-stimulating factor (G-CSF) 24 and 8 hs before the Leukapheresis procedure. The product was radiated immediately before the infusion with 30 cGy. Fourth-seven (96%) presented clinical infectious focus, being the most frequently cellulitis, severe mucositis and pneumonia. The rescue microbiological was documented in 31 patients (62%): Gram-negative bacilli 16pts, Gram-positive cocci: 6 pts, and 9 pts with fungi infections. Six-teen pts, (34%) it not was found microbiological rescue. The three remaining patients did not present focus neither germ. *Results.* With an estimate of transfusions to the clinical control of the focus or recovery of neutrophil its was carried out an average of transfusion/patient of 4.2 (r: 1-15); the average of granulocyte per transfusion was of 3, 25×10^{9}L (r: 1 -7-3) Adverse reactions due to the granulocyte transfusion therapy were: one case rush, dyspnea and one case pulmonary infiltrate. Thirty-one from 50 patients analyzed (62%), responded to the GTT, with clinical improvement. According to the causal germ it was observed that the group with Gram-positive resolved the event in the 66% of the cases; 63% of the G-negative and 77% of the patients with fungal infections ,while in the group in which not germ was isolated, 36% was resolved. *Conclusions.* granulocyte transfusion is a feasible procedure for those patients who do not respond to antimicrobial therapy, with a good focus resolution index in patients with severe neutropenia, and microbiological documentation.

1916

VALIDATION OF A COMMERCIAL CRYOPRESERVATION MEDIUM: POST-THAW RECOVERY OF CD34 AND OTHER WBC

G Fritsch, V Witt, E Zipperer, E Stemberger, D Trbojevic, D Scharner, D Printz, R Geyeregger, M Artwohl

St. Anna Kinderkrebsforschung, Vienna, Austria

Background. Collection and cryopreservation of autologous stem cells is a routine therapeutic treatment in Lymphomas, multiple myelomas, neuroblastomas, nephroblastomas and other malignant diseases. We validated the commercial freezing medium CryostorTM (CS10, 10% DMSO) in comparison to our routinely used 20% DMSO and 10% human plasma derivate (Biseko^{TM}) in Ringer solution.Aims Aim of the study was to examine whether or not the recovery of viable WBC and CD34$^+$ cells was better with CS10 as compared to our conventional freezing medium.Methods Fourteen aliquots from 7 stem cell collections were 1+1 mixed with either conventional freezing medium or with protein-free CS10, frozen in a controlled rate freezer, and stored in the gas phase over liquid N2. The post-thaw recovery of viable WBC & CD34$^+$ cells was determined immediately after thawing and after 20 to 60 min, by multi-color single-platform flow cytometry. *Results.* The mean recovery (+/- SD) of WBC and CD34$^+$ cells was 67.7 (+/- 52)% and 94,3 (+/- 51)% for the conventional medium, and 72 (+/- 12)% and 99 (+/- 16)% for CS10. The T-test for 2 independent samples and different variances revealed no significant differences between both media for WBC (P=0.786) and for CD34$^+$ cells (P=0.746). As demonstrated by the F-test, however, there were highly significant differences between the variances for both WBC (P=0.00007) and CD34$^+$ cells (P=0.0004). Analyses performed 20 and 60 min after thawing revealed a dramatic cell loss (roughly 90%) in the conventional medium for all cell types, up to complete clotting in 3/10 experiments after 20 min, whereas only between 0% and 30% of cells were lost in CS10, and no clotting occurred. *Conclusions.* We conclude that CS10 has clear advantages over our conventional freezing medium, in terms of cell recovery post-thaw, particularly after 20 to 60 min storage at room temperature. Further data will have to be collected to validate the outcome of hematopoietic regeneration after reinfusion.

1917

CLINICAL USEFULNESS OF WEAK AND PARTIAL D RESEARCH IN BLOOD DONORS AND IN TRANSFUSED PATIENTS

L Paesano,[1] M D'Onofrio,[1] A Della Corte,[1] G Fratellanza,[2] S Misso,[3] G Leonardi,[1] C Nocera[1]

[1]Transfusion Medicine, S.G. Bosco Hospital, Napoli, Italy; [2]Transfusion Medicine, Federico II University, Napoli, Italy; [3]Transfusion Medicine, S.G. Moscati Hospital, Caserta, Italy

Background. The D antigen of the Rh system is a mosaic of epitopes. In Europe, about 1% of people carries Rh(D) alleles as weak or partial D. A weak D type results from a quantitative reduction of the Rh(D) antigen, whereas a partial D type indicates a qualitatively altered Rh(D) protein. Individuals, whose cells lack some epitopes of the D mosaic, may make antibody to these epitopes when exposed to a complete D antigen. Many studies have shown that there are more than 30 recognisable epitopes, but the "9 epitopes" model is clinically satisfactory. With the use of selected panels of monoclonal anti-D reagents it is possible to distinguish the red cell categories of partial-D phenotypes. On the other hand, based on serological properties different from a weak D type, a partial D type is also suspected in patients with anti-D in serum or if non-reactive to some reagents. *Aims.* In this study we have examined the reactivity patterns of red blood cells, resulted non reactive to routinely used anti-D sera, with 6 different monoclonal anti-D able to obtain an accurate characterization of Rh(D) antigen. *Methods.* We have analyzed 62 blood samples, collected between 2003 and 2009, from donors and patients typed as "suspected"weak D. In fact these samples resulted Rh-negative using monoclonal and polyclonal anti-D sera, but Rh-positive performing the weak D typing with the column

agglutination test and the Coombs' serum. For final and definitive Rh(D) typing we have used the "ID-partial RhD-typing"(Diamed, Switzerland), a card with 6 microtubes containing polyspecific anti-human globulin within the gel matrix. These sera may differentiate between categories II, IV, V, VI, VII, DFR, DBT, R0Har. Moreover, category I is obsolete and category III red cells react with all anti-D reagents but can be distinguished from normal Rh(D) positive cells by the presence of alloantibody anti-D in the serum. *Results.* Our results show 46 cases of weak D on 62 samples tested. 1 subject was genotypized as D type 3 (associated to IAT positive for anti-D), 9 patients as type V, 1 donor as type VI (associated to Ce) and 5 patients type VII (associated to Ce). *Conclusions.* Considering that the most partial D discovered in the Caucasian population are initially typed as weak D, Rh(D) typing in donors and in patients should be routinely performed using more than two anti-D reagents from different clones. Our report suggests that molecular typing of weak D, respect to serotyping, may offer a more reliable classification, probably relevant to optimize transfusion strategies. Partial DVI remains the most important category to define. Clinically, patients with partial DVI red cells should be treated in the same way as Rh(D) negative individuals both for transfusion purposes an during/after pregnancy with a Rh(D) positive fetus, to prevent the alloimmunization *vs.* the missing epitopes with possible subsequent clinical consequences.

1918

WHY IS POTENTIAL BLOOD DONORS DEFERRED FROM DONATION?

H Reikvam,[1] G Melve,[2] K Svendheim,[2] T Hervig[2]

[1]Institute of Internal Medicine, University of Bergen, Bergen, Norway; [2]Department of Immunology and Transfusion Medicine, Haukeland University Hospital, Bergen, Norway

Background. Voluntary donation is a key feature of blood banking. To ensure the safety of blood transfusions, careful donor selection is important. Although new approaches to blood safety have dramatically reduced the risks for infectious contamination of blood components, the quality and the availability of blood components depend on the willingness to donate and the reliability of the information given by the donors about their own health, including risk behavior. Donor education is an important part of this effort, and this is highlighted in the European Blood Directive. As donors who are deferred by the blood bank will be less motivated to return for donation, it is important to reduce the number of deferrals. However little is actually known about the reasons for why regular donors turn up in the blood bank for donation without fulfilling the donation requirements. *Aims.* The aim of the present study was to investigate the reasons for deferral of registered donors coming to the blood bank for donation; in order to identify areas of importance for donor education - as these deferrals potentially could be avoided by better donor comprehension.

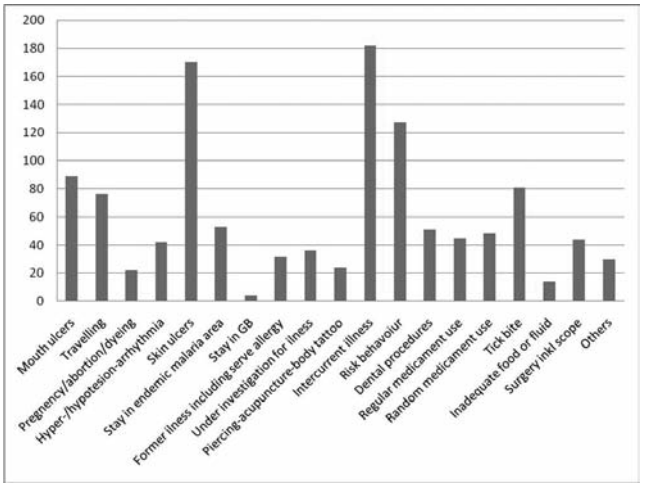

Figure 1. Reasons for deferral of 1 163 regular blood donors.

Methods. Data were collected from all blood donors who came to the Blood bank at Haukeland University Hospital, in the period between June 15, 2008 and December 15, 2009. All blood donors answered a questionnaire form about on health condition and potential risk behaviour. Results were collected and present after standard statistical models. *Results.* 1 163 of the 29 787 regular donors, who showed up for donation, were deferred (3.9%). The results demonstrate that there are multiple reasons for denying a potential donor to give blood, as summarized in Figure 1. The main reasons were intercurrent illness (n=182), skin ulcers (n=170) and risk behaviour (n=127). The underlying intercurrent illnesses were classified according to aetiology or organ system affected. The most common reasons were airway infections (n=62), gastrointestinal symptoms (n=24) and worsening of season allergy (n=10), in addition to a large group of unknown or unclassified reasons (n=58). *Summary/Conclusions.* Various measures are taken to ensure the safety of the blood supply, but donor selection and education are still the most important strategies we have to avoid potential complications to transfusion. It is important that potential donors must fill in honestly a questionnaire designed to identify specific risk factors for infectious conditions. In a community, intercurrent disease, skin ulcers and potential risk behavior are the most frequent reasons for deferral of regular donors. Strategized effort on donor education is needed, as "failure to donate"reduce donor motivation.

1919

PREVALENCE OF CYTOMEGALOVIRUS(CMV) AND EPSTEIN-BARR VIRUS(EBV) IN GREEK MULTIPLY TRANSFUSED PATIENTS WITH THALASSEMIA

E Rouka,[1] A Manafas,[2] D Adamidou,[1] A Vasdeki,[1] C Chalkias,[3] D Kyriakou[4]

[1]University hospital of Larisa, Larisa, Greece; [2]Thalassemia and haemoglobinopathy center,General hospital of Larisa, Larisa, Greece; [3]Thalassemia and Haemoglobinopathy center,General hospital of Larisa, Larisa, Greece; [4]University Hospital of Larisa, Larisa, Greece

Background. Cytomegalovirus (CMV) and Epstein-Barr virus(EBV) maintain life-long latent persistence in the majority of the adult population,including blood donors. The potential risk of CMV and EBV transmission by blood components is not well established. *Aim.* The objective of this study was to determine the prevalence of CMV and EBV among thalassemic patients and healthy blood donors of Thessaly prefecture in order to evaluate the possibility of CMV and EBV blood-born infection in Greek population. *Methods.* Fifty five(55) multiply transfused patients with thalassemia and haemoglobinopathy were included in the study (28 men, 27 women,median age: 28). The majority had received multiple blood transfusions,from 12-36 per year. Serologically, 18 of 55 patients (32,72%) were HCV^+. The control group consisted of two hundred eighteen (218) randomly selected blood donors of central Greece (183 men, 35 women,median age: 38). DNA was extracted from whole blood specimens by the automated Magtration system 12GC plus (magnetic particles technology). Presence of CMV and EBV genome copies was evaluated using single-virus quantitative real time polymerase chain reaction (qrt-pcr) assays by Nanogen Advanced Diagnostics. Amplification reactions were specific for the EBNA-1 and MIEA regions of EBV and CMV respectively. Cellular target for the beta globin gene was used to quantify cell-equivalent DNA. *Results.* CMV DNA was not detected in any patient or donor sample. In contrast 8 of 55 blood specimens among thalassemic patients (14,545%) and 42 of 218 samples among blood donors (19,26%) had detectable EBV DNA. Seropositivity for HCV co-existed in 5 of 8 EBV DNA^+ patients (62,5%). *Conclusions.* No significant difference was found in EBV DNA prevalence between the two groups (P>0.05). There are no indications for EBV transmission through transfusion in Greek population. It appears that leukoreduction of blood units provides some benefit in thalassemic patients.

1920

HEMOSURVEILLANCE OF DONORS: REPORT OF EARLY AND LATE COMPLICATIONS AFTER A BLOOD DONATION OF 450 ML

L Paesano,[1] M D'Onofrio,[1] F Varricchio,[1] A Della Corte,[1] S Misso,[2] G Fratellanza,[3] C Nocera[1]

[1]Transfusion Medicine, S.G. Bosco Hospital, Napoli, Italy; [2]Transfusion Medicine, S.G. Moscati Hospital, Caserta, Italy; [3]Transfusion Medicine, Federico II University, Napoli, Italy

Background. Hemovigilance is a set of surveillance procedure covering the complete process from blood donation to transfusion. According to European and Italian transfusion legislations, the monitoring of

reactions and/or complications following donation is an integral part of hemovigilance. In fact, the report of reactions at the phlebotomy site and of observation of complication during or after blood letting is a standard part of donation documentation. On the contrary, data about late reactions, after leaving the blood bank, are not always available. *Aims.* The aim of this study was to analyse rate and types of complications and reactions reported by donors one hour after a donation of whole blood. *Methods.* In order to obtain a correct evaluation of these post-donation events, we have invited all donors, in a period of one year, to remain under observation for 1 hour after donation in our Transfusion Centre. Collected data were statistically analysed. *Results.* We have observed 5.487 people who donated whole blood (450±10 mL) and 918 (16,7%) adverse events have been registered. The most common findings have been 411 cases (7,5%) of bruise and/or haematoma; in particular we have observed 184 cases (45%) with a reported diameter of haematoma <1 cm, 161 cases (39%) with a diameter of 1-3 cm, 45 cases (11%) of 3-5 cm and 21 cases (5%) > 5 cm. Arm nerve injuries (soreness, sensory changes, numbness, tingling) have occurred in 162 donors (2,9%). 83 donors (1,5%) have reported local irritation or/and allergic reaction in shape of the plaster. The most common systemic reactions (4,7%) have been fatigue, vasovagal symptoms and nausea and vomiting (262 cases: 187/4.099 = 4,5% of men and 75/1.388 = 5,4% of women). Three of donors had to seek medical care, one of them has been hospitalized. Periodic donors, of course, have developed fewer reactions than subjects at their first donation and women have showed fewer reactions than men. The frequency of systemic reactions has been dependent on weight of donors, with the highest frequency in the group of 50/60 Kg. *Conclusions.* In this study, the frequency of observed complications and reactions, in our opinion, is very high, but in according with available data of other Italian Transfusion Centre. Some reactions and complications are honestly predictable and avoidable, for this reason a careful management of donors need. Moreover, in order to guarantee a major safety for donors, the participation of all staff in educational and training program is also important.

1921

PLATELET TRANSFUSION AND INCIDENCE OF FEBRILE NON-HAEMOLYTIC TRANSFUSION REACTIONS (FNHTR) IN PAEDIATRIC PATIENTS: A COMPARISON BETWEEN PLASMA REDUCTION AND LEUKODEPLETION OF PLATELET CONCENTRATES

L Paesano,[1] M D'Onofrio,[1] A Della Corte,[1] S Garofalo,[1] S Misso,[2] G Fratellanza,[3] G Leonardi,[1] C Nocera[1]

[1]Transfusion Medicine, S.G. Bosco Hospital, Napoli, Italy; [2]Transfusion Medicine, S.G. Moscati Hospital, Caserta, Italy; [3]Transfusion Medicine, Federico II University, Napoli, Italy

Background. Transfusion of blood products is often necessary and beneficial for critically ill patients. Nevertheless, transfusion can lead to serious adverse effects; one of these is the febrile non-haemolytic transfusion reaction (FNHTR), that, on the basis of international data, complicates 2 to 37 percent of transfusions of random platelet concentrates (obtained from a single donor platelet-rich-plasma) in adults. On the other hand, platelet concentrates are frequently transfused in paediatric patients affected with a severe thrombocytopenia too, but the incidence of FNHTRs in these patients is not well known. *Aims.* In this study we have evaluated the incidence of FNHTRs after platelet transfusion in children. In addition, in order to identify a technical procedure able in reducing this incidence, we have also compared the results obtained from 3 different hemocomponents: 1) the "standard"platelet concentrate, obtained from a single donor platelet-rich-plasma; 2) a platelet hyper concentrate, characterized by reduction of plasma volume after storage; 3) a filtered platelet concentrate with leukodepletion before storage. *Methods.* Children from 1 until 14 years of age were eligible for this study, independently from their pathology. For the first aim of this study, we have retrospectively analyzed the platelet transfusions, using unmodified whole-blood-derived platelet concentrates, performed in a period of six months. For the second aim, in a first period of three months we have transfused platelet concentrates submitted to centrifugation and reduction of the plasma volume just before transfusion; while in a second period of three months we have used prestorage WBC-reduced hemocomponents, but the platelet concentrates were stored for a maximum of two days. Signs and symptoms characteristic of a FNHTR during, immediately after and 2 hours following transfusion were registered. *Results.* In the considering period, 115 platelet transfusions were administered to 77 children; in particular 57 "standard" platelet concentrates were transfused to 35 children enrolled in the study, 29 removed plasma hemocomponents were given to 20 little patients, while 29 leukodepleted platelets were administered to 22 subjects. A FNHTR was observed in a total of 11 cases on 115 transfusions, with an incidence of 9.6%, a value not significantly different from the one registered in adults. Analyzing the three kind of transfusions, no statistical significant differences were registered (P>0.05), in fact we have observed a FNHTR incidence of 12.3% (7 on 57 transfusions) in the first group of patients, of 6.9% (2 on 29) with removed plasma platelets and of 6.9% (2 on 29) with WBC-reduced platelets. In addition, allergic reactions occurred respectively in 8.8% (5 on 57), 3.4% (1 on 29) and 6.9% (2 on 29) of platelet transfusions. *Conclusions.* Even if no statistical evidence exists, FNHTRs may be less common among paediatric recipients of platelet transfusions than in adults. Moreover, in our study, a lower frequency of FNHTRs and allergic reactions was observed using platelet concentrates treated with post-storage plasma removal and/or pre-storage leukodepletion, but our record of cases is yet too much little to produce definitive conclusions.

1922

DOCUMENTATION OF KNOWLEDGE AND BEHAVIOR OF THE YOUTHFUL POPULATION CONCERNING HEPATITIS B AND AIDS

F Girtovitis,[1] S Patiakas,[2] A Kotelis,[2] S Chatzizisi,[3] C Charalampous[4]

[1]General Hospital of Thessaloniki ACHEPA', Greece, Thessaloniki, Greece; [2]Laboratory Biopathology of General Hospital of Kastoria, Greece, Kastoria, Greece; [3]Microbiological Laboratory of General Hospital of kastoria, Kastoria, Greece; [4]Pathological Clinic of Psychiatric Hospital of Thessaloniki, Greece, Thessaloniki, Greece

Background-Aim. To scrutinize and evaluate the knowledge of young people and to document their behavior, concerning Hepatitis B and AIDS. *Material - Method.* A total of 521 answers were studied, of young people who responded to an anonymous closed type questionnaire. 215 were high school students 15-18 years of age, 120 were Technological Educational Institution (T.E.I.) students 18-25 years of age, and 186 between the ages 25-35. Their knowledge level and behavior was scrutinized. The data process was performed with SPSS v.12.0. *Results.* The knowledge of the T.E.I. students, concerning the ways of transmission and prevention of Hepatitis B were satisfactory at 78%, while for AIDS at 97%. The group of 25-35 follows with percentages 72% and 96%, while high school students are last, presenting sufficient knowledge about Hepatitis B and AIDS in 62% and 95% correspondingly. Concerning AIDS medication, 26% of T.E.I. students have an elemental knowledge, 13% of the young adults and 10% of the high school students. 76% of T.E.I. students use a condom, 65% of the teenagers; while in young adults only 23% uses a condom (75% of them claim that they have a monogamous relationship). Moreover, 11% of the T.E.I. students and 19% of the adults claimed that they have been tested for AIDS, either after a dangerous sexual contact, or with some other opportunity (e.g. volunteer blood donor). Finally, 26% of high school students, 22% of T.E.I. students and 14 % of the adults has been vaccinated against Hepatitis B. The main source of information for this diseases, were the MEDIA in 70%, the family in 18% and the school in 12%. A total of 81% requests more information about AIDS and 93% about Hepatitis B. *Conclusions.* 1) The students knowledge is the most sufficient, followed by that of young adults, while the teenager's knowledge is lacking, a fact that can be attributed to the laxity of information campaigns in schools the last years. 2) The awareness in general concerning hepatitis is lacking compared to AIDS, a fact that needs to be dealt with. 3) Even though the knowledge of the population is satisfactory in general, a big percentage requests more information campaigns, which is rather comforting. It is pertinent, that this will be done in schools, which are lacking in knowledge, given the fact that an important percentage of students, especially of young age, demonstrate impermissible negligence concerning protection.

1923

A HTLV LOOKBACK STUDY IN KOREA

HJ Lee, SW Lee, J Oh, YH Shin

Korea Centers for Disease Control & Prevention(KCDC), Seoul, South-Korea

Background. Human T-cell lymphotrophic virus (HTLV) is known to be the significant etiologic retrovirus of adult T-cell leukemia(ATL) and HTLV-associated myelopathy(HAM). Blood transfusion is known to be the major source of HTLV infection, but few studies were done on risk of transmission -associated infection. *Aims.* The sero-conversion rate of HTLV via blood transfusion in Korea has not been identified yet. This study is aimed to identify the sero-conversion rate in recipients of blood

provided from the infected donors with HTLV in Korea. *Methods.* One hundred fifty three recipients of the blood components from 34 index donors with HTLV were recognized through an investigation. A retrospective study to investigate whether transfusion-transmitted HTLV infection occurred in the recipients were carried out by the Korean Centers for Disease Control and Prevention (KCDC) between 2008 and 2009. Among the recipients, 39 persons agreed with informed consent for this study. Laboratory tests and epidemiological studies of the participants as well as tests for all stored samples of the index donors were fulfilled. For the laboratory tests, line immune assay, western blot and PCR with HTLV were applied. *Results.* It was found out that 59 recipients were alive and 74 were deceased among the 153 recipients. One person was not transfused and no data were available for the rest 19 people. Participants of the study were 39 out of 59 who agreed with informed consent, whereas 20 recipients refused. Fifteen recipients (38.5%) by 13 index donors in total, were identified as HTLV positive status. There were no ATL and/or HAM cases developed in the positive cases. Besides, the test results of the stored samples were all positive with HTLV. *Conclusions.* A targeted lookback study to trace 153 recipients by 34 index donors with HTLV was carried out in Korea. In total, 15 recipients out of 39(38.5%) were resulted with HTLV positive status. There was no case of ATL and/or HAM cases developed in the positive cases.

1924

EXSANGUINO-TRANSFUSION AND RECONSTITUTION OF WHOLE BLOOD: AN OPERATIVE PURPOSE FOR STANDARDIZATION

L Paesano,[1] M D'Onofrio,[1] G Leonardi,[1] F Varricchio,[1] S Garofalo,[1] G Fratellanza,[2] S Misso,[3] C Nocera[1]

[1]Transfusion Medicine, S.G. Bosco Hospital, Napoli, Italy; [2]Transfusion Medicine, Federico II University, Napoli, Italy; [3]Transfusion Medicine, S.G. Moscati Hospital, Caserta, Italy

Background. Italian Scientific Societies of Transfusion Medicine (SIMTI) and Neonatology (SIN) have collaborated to the drafting of a document named "Recommendations for transfusion therapy in the neonatal period"because an observed difference between every Italian Hospital in the transfusion therapy reserved to anaemic newborns. *Aims.* In order to standardize the behavior between all Transfusion Centers in our Region, we developed a supplementary operative technical proposal for preparation of the reconstituted whole blood (RWB) and to establish its final characteristics. Our aim is to largely promote this document. *Methods.* According to Recommendations, RWB must be produced in Blood Transfusion Service through the combination of Erythrocyte Concentrate (EC) and Fresh Frozen Plasma (FFP). The used EC should be: preferably of group "0" or compatible with the newborn from an immunohematologic point of view; leukocyte-depleted (and, consequently, CMV-safe); fresh (<7 days from collection) and free of additive solutions. The used FFP should be: preferably of group "AB"or compatible with the newborn from an immunohematologic point of view; treated for viral inactivation. *Results.* Our protocol recommends the use of Erythrocyte-apheresis (from multicomponent donation) and Plasma-Safe (with industrial or home-made viral inactivation). The operating procedure involves the following steps: 1) compatibility assessment and choice of units; 2) in all cases, irradiation of EC; 3) centrifugation and hyper-concentration of EC; 4) sterile connection to a sterile transfer bag and removal of supernatant (= additive solutions); 5) determination of the weight of the remaining EC; 6) sterile connection of EC to FFP and transfer of an equivalent weight of plasma (in order to obtain a Hct of about 50%). The whole procedure must be performed by ensuring total asepsis. *Conclusions.* Multicomponent donation ensures a high efficiency leukocyte-depletion due to apheresis and successive filtration; the partial washing of EC during collection removes the contaminant plasma; at the end, hyper-concentration removes the additive (preservative and anti-coagulant) solutions. On the other hand, industrial Plasma-Safe provides a standardized amount of coagulation factors and guarantees a sterility to a larger amount of viruses and bacterial contaminants. In conclusion, standardization of the procedure and of the final product is indispensable for a correct clinical application and evaluation of therapeutic results.

1925

RISK OF ANTI-HLA ALLOIMMUNIZATION DUE TO RESIDUAL LEUKOCYTES IN PLASMA UNITS

L Paesano,[1] M D'Onofrio,[1] F Varricchio,[1] S Misso,[2] G Fratellanza,[3] C Nocera[1]

[1]Transfusion Medicine, S.G. Bosco Hospital, Napoli, Italy; [2]Transfusion Medicine, S.G. Moscati Hospital, Caserta, Italy; [3]Transfusion Medicine, Federico II University, Napoli, Italy

Background. In literature, it has been reported that viable leukocytes (WBC) are present in Fresh Frozen Plasma (FFP), even following freeze-thaw. This observation has implications for possible transfusion-related adverse effects: in fact the presence of WBC in FFC may, even if rarely, cause an anti-HLA alloimmunization and, theoretically, a transfusion-associated graft-versus-host disease (TA-GVHD); moreover leukocyte cytokines may cause febrile reactions. *Aims.* We have compared WBC levels in plasma prepared by three collection methods used at our Transfusion Medicine Units. *Methods.* Residual WBC were quantified by fluorocromatic methods (ideated by Borzini *et al.*.) in fresh (unfrozen) plasma prepared from: 71 whole blood units, 45 filtered on line blood units and 59 plasmapheresis collected by Fresenius and Haemonetics cellular separators. *Results.* Mean WBC levels in 71 plasma units produced by whole blood, with removing of buffy-coat and producing a platelet concentrate, is 47.8 cells/μL (ranged 28.6-88.5), considering the mean volume of these units = 206 mL (range 188-234), in these FFP units there are 9.8×10^6 WBC (range 5.9-18.2). Mean WBC levels in 45 plasma units produced after leukodepletion by filtration of whole blood, without producing a platelet concentrate, is 18.2 cells/μL (ranged 8.4-46.9), considering the mean volume of these units = 244 mL (range 208-256), in these FFP units there are 4.4×10^6 WBC (range 2.0-11.4). Mean WBC levels in 59 plasmapheresis is 1.6 cells/μL (ranged 0.5-5.0), considering the mean volume of these units = 388 mL (range 339-414), in these FFP units there are 0.6×10^6 WBC (range 0.2-1.9). *Conclusions.* Depending on the method of preparation, the number of whole WBC in fresh unfrozen plasma units ranged from a minimum of 0.2 to a maximum of 18.2×10^6 per component. Additional studies are needed to determine the significance of these results with respect to the risks for TA-GVHD and WBC alloimmunization.

1926

MECHANISMS AND CLINICAL IMPORTACE OF STATIN DROP AFTER EXTRACORPOREAL LDL-CHOLESTEROL ELIMINATION

M Blaha,[1] H Vlckova,[2] L Novakova,[2] D Solichova,[1] P Solich,[2] M Lanska,[1] J Maly,[1] S Filip,[1] V Blaha[1]

[1]Charles University, Medical Faculty, Hradec Králové, Czech Republic, [2]Charles University, Pharmaceutical Faculty, Hradec Králové, Czech Republic

Background. Therapeutic hemapheresis contributed to the therapy of some disorders with new possibilities. Using our statin analysis method, it was possible to uncover a significant drop in statin levels after extracorporeal LDL-cholesterol elimination (EChE) in severe familial hypercholesterolemia (FH). The purpose of this work was to identify the mechanism underlying this drop and its clinical significance as well as to propose measures to optimize a pharmacotherapeutical regimen that can prevent the loss of statins. *Methods.* Ultra-high performance liquid chromatography connected to a triple quadrupole tandem mass spectrometry (MS/MS) system was used. *Patients.* One hundred and seventy samples were analyzed (85 pairs) from a group of long-term treated patients (3-12 years of treatment) with severe familial hypercholesterolemia (FH) (12 patients) who were treated regularly by LDL-apheresis (immunoadsorption) or hemorheopheresis (cascade filtration). *Results.* After EChE, the levels of statins and their metabolites decreased (atorvastatin levels before and after LDL-apheresis were 8.83 and 3.46 nmol/L, respectively, and before and after hemorheopheresis were 37.02 and 18.94 nmol/L, respectively). A novel finding was a specific loss of statins in washing fluids (concentrations of atorvastatin in washing liquids for LDL-apheresis and hemorheopheresis were 0.28 and 3.04 nmol/L, respectively) and filters (11.07 nmol/L atorvastatin lost in filters during hemorheopheresis). To prevent a substantial loss of statin concentrations, the pharmacotherapeutical regimen should be changed to have a longer time interval between the dose of statins and EChE (15 hours). *Conclusions.* A specific loss of statins was found in adsorbent capsules and filters, especially during hemorheopheresis. The decrease in statin levels can be prevented by the suggested dosage scheme.

THERAPEUTIC ERYTHROCYTAPHERESIS (TE) IS THE FIRST LINE THERAPY OF HEREDITARY HEMOCHROMATOSIS (HH)

M D'Onofrio,[1] L Paesano,[2] F Varricchio,[2] G Leonardi,[2] D Meomartini,[3] C Nocera[2]

[1]PO San Giovanni Bosco, Napoli, Italy; [2]PO San Giovanni Bosco ASL Na[1] Centro, Napoli, Italy; [3]PO San Giovanni Bosco ASL Na,[1] Napoli, Italy

Background. Hereditary hemochromatosis (HH) is a common genetic disorder in which the iron absorption is increased, resulting in excessive iron overload in parenchymal cells with organ failure, especially with regard to the liver, pancreas, heart, joints and pituitary gland. The gene involved in the most common form of HH was called HFE and the most common mutations C282Y and H63D. The therapy is based on the removal of the excess of body iron by removing blood through phlebotomy. More recently mechanical removal of erythrocytes through therapeutic erythrocytapheresis (TE) has become a new therapeutic modality. *Aims.* In this study we have evaluated efficiency and safety of TE respect to phlebotomy to decrease iron overload in patients with hereditary hemochromatosis. *Methods.* Between 2008 and 2009, we have treated 42 patients affected by HH: 23 patients aging 31 to 78 years were treated with TE while 19 aging 43 to 73 years with phlebotomy. All patients suffered from increased aminotransferase, moreover in the TE group 4 patients suffered from heart failure and 5 patients suffered from liver cirrhosis. TE procedures were performed using Fresenius Comtec Kit PL-1. *Results.* In the considered period we have performed 64 TE: the mean value of removed erythrocytes in each procedure varied between 330 and 624 mL per individual patient. Most of the patients best tolerated an interval period of two weeks. The initial ferritin values varied between 350 to 3120 while at the end of the treatment in the TE group the serum ferritin levels varied between 22 and 88 ng/mL. The total number of treatments needed in the TE group varied between 3 and 15. The duration of treatment was between 1 and 10 months. In the phlebotomy group the serum ferritin levels varied between 36 and 76 ng/mL. The total number of treatments varied between 9 and 22 months with a total removed volume of 400-450 mL of whole blood. in the 75% of cases we have observed the normalization of liver enzymes. *Conclusions.* The results of this study indicate that TE compared to phlebotomy in the therapy of HH patients was both safe and highly efficient to remove iron excess, in fact both the number of procedures as well as the duration of the therapy was significantly reduced. An isovolemic method of therapy is therefore potentially safer than phlebotomy with its related induced hypovolemia, especially with respect to older and/or cardiovascular unstable patients. TE also preserves the valuable blood components of the patient, such as plasma proteins, platelets, clotting factors and leucocytes, potentially relevant to patients with hypoproteinemia and/or thrombocytopenia. During a TE procedure the patient receives compensation for the removed volume by saline or protein solutions, which makes this approach particularly viable for HH patients with severe cardiac disease. TE appears to be a better tolerated type of treatment applicable to a wider range of patients, in fact no adverse side-effects were observed in patients treated with TE.

1928

DEVELOPING A PREDICTIVE MODEL FOR RED BLOOD CELL TRANSFUSION REQUIREMENT FOR ACUTE LEUKEMIA PATIENTS

A Parvu,[1] A Bojan,[2] A Vasilache,[3] A Cucuianu,[2] L Urian,[2] T Torok,[2] M Zdrenghea,[2] M Patiu,[2] C Basarab,[3] D Dima,[2] L Petrov[2]

[1]Oncological Institute Cluj-Napoca, Cluj-Napoca, Romania; [2]University of Medicine and Pharmacy, Cluj-Napoca, Romania; [3]Oncological Institute, Cluj-Napoca, Romania

Background. Faced with the ongoing reduction in the number of blood donors, the clinical hematologist must often ask patient families for help in finding suitable donors. Another benefit of the predictive model is an improved communication with the blood bank, allowing the clinical hematologist to order the appropriate amount of blood units necessary for the whole duration of the aplasia. *Aims.* Creating a predictive model for red blood cell transfusion requirement in a patient with acute leukemia (mieloblastic and limphoblastic) patients in aplasia following chemotherapy. *Methods.* Study type: analytical, cohort, retrospective. We studied 246 patients with acute leukemia admitted in the Clinic of Hematology in Cluj-Napoca during 1995-2008 and treated according to international protocols (exclusion of palliative care therapy, deceased or transferred patients). 860 aplasia episodes secondary to chemotherapy were included in the study. All the patients signed the informed consent. The study has the agreement of Ethic Committee of "Iuliu Hatieganu" Medicine and Pharmacy University Cluj-Napoca, Romania. Statistical analysis was performed using a linear model (multiple regression). Independent variables used in setting out the predictive models were: age, gender, morphologic type of leukemia, bone marrow blast infiltrate, disease stage at the beginning of chemotherapy regimen (diagnosis, complete remission, partial remission, refractory disease, no response), chemotherapy regimen number, medullar erythrocyte line (normal, low, dysplastic), chemotherapy type (high-dose or standard-dose), hemoglobin levels at chemotherapy start and at the end of the aplastic period, hemorrhagic episodes during the next aplastic period, hemolytic transfusion reaction, compatibility testing type for transfused blood (classic or gel migration methods). Finding the best regression model was based on univariate analysis of all risk factors (chi-square tests). Multicollinearity was excluded when heavily correlated pairs of independent variables were found. Statistical analysis was performed using SPSS, Statistica and Excel. *Results.* The number of red blood cell units necessary to be transfused to an acute leukemia patient in an aplastic phase following chemotherapy can be estimated using the following equation: Number of blood units = 7.01-0.35 × Starting Hb + 0.77× Diagnosis - 0.91 × Partial remission - 1.01 × Complete remission + 1.21× Minor hemorrhages + 3.41 × Major hemorrhages + 1.31× Haemolysis. Number of blood units is the amount of whole blood and/or red blood cells concentrate units necessary. Independent variables Diagnosis, Partial remission and Complete remission (disease stage at chemotherapy), Minor hemorrhages and Major hemorrhages are assigned 1 if present and 0 if absent. Minor hemorrhages were represented by low quantity epistaxis, bleeding gums, purpura, etc. Major hemorrhages were represented by menorrhagia, haematemesis, melena, etc. This model has statistical significance (ANOVA test, $P<0.05$, statistically significant) therefore it can be generalized from the study group to the whole population. *Conclusions.* The variables representing the best predictors of red blood cells blood units number transfused to an acute leukemia patient in an aplastic phase following chemotherapy were: hemoglobin levels at chemotherapy start, disease stage at the beginning of chemotherapy regimen, hemorrhagic episodes during the next aplastic period and hemolytic transfusion reactions.

1929

APHERESIS ACTIVITIES IN A BELGIAN UNIVERSITY HOSPITAL

D Dierickx, S Ombelet, D Berckmans, T Bracke, M Delforge, T Devos, J Maertens, S Meers, A Janssens, H Schoemans, G Verhoef

University Hospitals Leuven, Leuven, Belgium

Background. Apheresis is a potent tool in both collecting and removing blood components. Using centrifugation-based devices both plasma and cellular components can be efficiently separated. *Aim.* We undertook a retrospective analysis of all centrifugation-based apheresis-procedures accomplished at the University Hospitals of Leuven from Januari 2006 till September 2009, aiming to obtain information about single center activity range, indications and outcome. *Methods.* Medical apheresis-records of all patients and donors subjected to therapeutic plasma exchange or cytapheresis were used for this retrospective observational study. *Results.* During this period 3877 procedures were performed, with therapeutic plasma exchange (TPE) being executed most frequently (77.4%). Neurological indications accounted for 58% of the total TPE activities, whereas 34% of the indications were hematological. Neurological indications included myasthenia gravis (37.9%), (monoclonal gammopathy-associated) polyneuropathy (17.7%), chronic inflammatory demyelinating polyneuropathy (8.1%), stiff-person syndrome (8.1%) and multiple sclerosis (7.3%). Thrombotic thrombocytopenic purpura/haemolytic uremic syndrome was the most frequent haematological indication (67.1%), followed by hyperviscosity syndromes (19.1%). Based on the AABB/ASFA guidelines for TPE, which classifies the indications into four categories ranging from standard and acceptable therapy (I) to no therapeutic benefit (IV), we calculated the proportions of indications in our center for these different categories. 142 (66.4%) indications were classified as category I/II, whereas category III/IV/NR/others included 72 indications (33.6%). Besides TPE, 22.6% of the procedures were based on cytapheresis: autologous hematopoietic progenitor cell collection (HPC-A) (33.8%), therapeutic dentritic cells (33.1%), allogeneic HCP-A (21.0%), cell depletion (9.9%), therapeutic T cells (1.7%) and extracorporal photopheresis (0.5%). Concerning HPC-A we performed an outcome analysis based on the fact whether a previous determined target (desired number of CD34+ cells/kg) had been reached. In this analysis only HPC-A procedures

between 1th January 2008 and 1 October 2009 were included. During this period 155 HPC-A procedures (90 autologous and 65 allogeneic) were performed. Target was reached in 119 (76.8%) of these collections. *Conclusion.* We report a retrospective analysis of all centrifugation-based apheresis-procedures performed in a Belgian University hospital during a 44 month period. Results of indications seems to be close to existing guidelines for less rare disorders, although the relative high number of requests for type III/IV/NR/other categories may reflect the amount of referrals of difficult-to-treat diseases to a university center, emphasizing the need for clinical trials in these disorders. Outcome analysis in HPC-A, although limited to the observation whether a target had been reached or not, seems to be comparable to similar data in the literature.

1930

A SINGLE INSTITUTION EXPERIENCE WITH NOVOSEVEN USE

J Tena, M Carrasco, M López, C Jiménez, C Besses

Hospital del Mar, Barcelona, Spain

Background. The recombinant activated factor VII (rFVIIa NovoSeven, Novonordisk, Denmark) was developed and approved for the treatment and prevention of bleeding episodes in patients with a history of congenital hemophilia, acquired hemophilia, congenital deficiency of F-VII and Glanzmann thrombasthenia. Currently, NovoSeven is being administrated as a drug for compassionate use in cases of life-threatening bleeding. *Objective.* To analyze retrospectively the indications for administration of NovoSeven in a single center. *Patients and methods.* The hospital pharmacy database was used to identify patients in which NovoSeven was administered during the period 2006-2009. A total of 22 patients (16 M/6 F; median age 54 years) were included in the analysis. rFVIIa was administered for different reasons: surgical prophylaxis in congenital FVII deficiency (n=1), acute promyelocytic leukemia with pulmonary hemorrhage (n=1), renal transplant hemorrhage (n=1), multiple trauma (n=4), upper gastrointestinal bleeding (n=4), internal bleeding (n=4), renal contusion (n=1), subdural hematoma (n=1), basal ganglia hematoma (n=1), subarachnoid hemorrhage (n=1), intraventricular hemorrhage (n=1), compartment syndrome (n=1) and ruptured abdominal aneurysm (n=1). A total of 48 doses were administered, and the average dose per patient was 2.18 units. In addition to NovoSeven, patients received on average 13.5 packed red blood cells, 5.6 units of fresh frozen plasma and 3.14 pools of platelets. *Results.* The average prothrombine time (PT) before administration of rFVIIa was 37.71% and 105.54% after NovoSeven infusion. Mean INR before administration of rFVIIa was 2.72 and subsequently 1.21. Nine out of 22 patients (41%) died, being the causes: hypovolemic shock (n=4), underlying medical conditions (n=5); one was transferred to another ICU institution and 12 (55 %) developed favorably. Two patients presented thromboembolic events following the administration of rFVIIa (thrombosis of arteriovenous fistula in a patient with chronic renal failure and cardioembolic stroke). *Conclusions.* NovoSeven was administered only in one patient according to the approved indications. More studies are needed to demonstrate the usefulness of rFVIIa in bleeding events without licensed indications. Consensus guidelines for NovoSeven use in clinical practice are needed.

1931

ENZYME REPLACEMENT THERAPY OF EGYPTIAN CHILDREN WITH GAUCHER DISEASE: SINGLE CENTER EXPERIENCE

A Khalifa,[1] A Tantawy,[1] R Shawky,[1] E Sherif,[1] S ElSayed,[1] E Fateen,[2] A Cooper[3]

[1]Faculty of Medicine,Ain Shams University,, Cairo, Egypt; [2]National Research Center, Cairo, Egypt; [3]Willink biochemical genetic Unit, Manchester children hospital,, Manchester, UK

Background. Gaucher disease (GD) is the most frequently encountered lysosomal storage disease caused by inborn defects of the membrane-bound lysosomal enzyme, acid β- glucosidase . This defective activity causes accumulation of glucocerebroside in the lysosomes of cells derived from the monocyte/ macrophage lineage. Glucocerebroside-engorged cells, termed Gaucher cells, infiltrate various organs, leading to multisystem abnormalities *Aim of study.* to present a single center experience in the diagnosis and management of Gaucher disease in Egyptian children with emphasis on phenotype-genotype relationship. *Patients and methods.* The study included 48 patients with Gaucher disease attending the Children's hospital, Ain Shams University, Cairo, Egypt, from June 1995 to December, 2006. Patients were diagnosed by low β- glucosidase enzyme activity. Enzyme replacement therapy was started in 1997 using the placenta derived aglucerase (ceredase) at low dose regimen (15 U / Kg / 2 weeks); recombinant enzyme imiglucerase (cerezyme) therapy started in March 1999 in a dose of 20-30U / Kg / month, divided into 4 equal weekly doses. In 1999 cerezyme was administered in a dose regimen of 60 U / Kg / 2 weeks. *Results.* Patients ages at presentation ranged from 37 days to 17 years with mean age of 2.54± 3.8 years. They included 10 patients with type I, 6 with type II and 26 with type III Gaucher disease. Clinical and laboratory follow up for at least 24 months revealed a significant increase in weight and height, significant reduction in the liver and spleen measurements, normalization of PT and PTT, and significant increase in haemoglobin level and platelets counts. Individual variations were observed in patients' response to ERT regarding neurological manifestations: while there was mild improvement in motor development and variable improvement of dysphagia on ERT, strabismus and ophthalmoplegia did not. Bone manifestations showed very slow improvement on ERT; but all patients demonstrated improvement in quality of life in an average period of 6 months. Plasma chitotriosidase levels showed significant decrease after ERT assay .Mutation analysis of 23 patients (14 type III, 8 type I and one type II) showed that 56.4% were homozygous L444P (11 patients type III and 2 patients type I). *Conclusions.* Since most of Egyptian children with GD have type III disease and L444P/L444P genotype, a minimum dose of 60U/kg/2 weeks should be maintained until adulthood. Higher doses started at an early age may delay the progression of neurological symptoms. Pulmonary involvement is not rare in Egyptian patients and may respond to dose increase or dose fractionation. Cardiovascular and renal symptoms should be further studied in our population.

1932

PANCYTOPENIA SECONDARY TO CHRONIC HEMOPHAGOCYTOSIS IN ASSOCIATION WITH WEBER CHRISTIAN DISEASE

M Infante,[1] F Carretero Lopez,[2] I Perez Sanchez,[3] J Menarguez Palanca,[2] J Anguita Velasco,[2] J Diez Martin[2]

[1]Hospital universitario Gregorio Marañon, Madrid, Spain; [2]Gregorio Marañon, Madrid, Spain; [3]Hospital Gregorio Marañon, Madrid, Spain

Introduction. we report a case of chronic hemophagocytosis in a patient with Weber-Christian disease. A forty-two -year-old female suffered, since her childhood, from pain and inflammation at hands, ears and cheeks skin, especially in cold weather and fever episodes that lasted 2 or 3 days. Twelve years ago pancytopenia was detected with the following blood counts: white cells $1,2\times10^9$/L, neutrophils $0,6\times10^9$/L, Hb 109 g/L, VCM 76 fL and platelets 104×10^9/L. For the last six years she has been monitored in our hospital. Hepatoesplenomegaly was always 1cm below the costal margin, lymphoid nodes were never detected at the physical examination or CT-scans. Pancytopenia didn't change and several tests showed high levels of LDH (700U/L) and consistently low levels of haptoglobin (<7) and low retyculocite counts (0.7%). Blood smear was normal. Studies for immune hemolysis, thalassemia, hemoglobinopathies, enzymopathies, HPN and red blood membrane diseases were negative. Ferritin 750 μg/L, folic acid and B12 vitamin had normal values. Three bone marrow studies carried out in different moments of the clinical evolution, only showed hystiocitic hiperplasia with outstanding hemophagocytosis of blood cells, neutrophils and platelets. Infection or lymphoma were not documented. Bone marrow cytogenetics was normal. Fanconi anemia was excluded in 2006 by chromosome breakage test. The study of peripheral blood and bone marrow markers was normal. Cytoplasmic expression of perforin was preserved. Rheumatoid factor was 39 UI/mm in 2004, increasing later to 244UI/mm, but the patient never met diagnostic cryterias for rheumatoid arthritis or LES. A skin punch was not diagnostic. Altought transaminases doubled the normal value, the liver biopsy only showed changes due to systemic disease. In January 2009 she noticed right eye exoftalm and retroocular mass biopsy showed Weber-Christian panniculitis. Alfa-1-antitripsin was normal and C1q determination was above the normal value 428 mg/L (n.v 100-255 mg/L). When she was receiving prednisone treatment for the retro-ocular panniculitis she developed fever and deep pancytopenia with neutrophils $0,1\times10^9$/L, platelets 15×10^9/mL, increased D-dimer 571 ng/mL, ferritin 2.184 μg/L, triglicerids 219mg/dL as well as EBV copy number to1350/mL. Bone marrow biopsy was similar to previous biopsies. The patient improved when prednisone was tapered and i.v. gammaglobulin was prescribed. The patient felt well, pancytopenia improved to levels of the six previous years and EBV copy number decreased to normal values. Cyclosporine treatment was added to the low dose of prednisone, but her chronic moderate pancytopenia never reverted to complete

response. Five months later, while in this treatment, she suffered colon perforation secondary to a new panniculitis episode. Prednisone and cyclosporine were stopped after 9 months of treatment, now she has started with Thalidomide. *Conclusions.* there are three remarkable points in this case: 1) It is well known the association of hemophagocytosis with rheumatoid arthritis and LES, nevertheless its association with Weber Christian disease is rare. 2) Hemophagocytic syndrome is frequently observed as an acute and serious disease, while this is a well documented case of chronic hemophagocytosis. 3) Hemophagocytic syndrome worsened when the number of EBV copies increased during prednisone treatment for retro-ocular panniculitis.

REGIONAL VARIATIONS IN GAUCHER DISEASE PRESENTATION: DATA FROM THE ICGG GAUCHER REGISTRY

H Kim,[1] A Linares,[2] N Weinreb,[3] A Cole,[4] S Vom Dahl[5]

[1]Ajou University School of Medicine, Suwon, South-Korea; [2]Universidad Nacional de Colombia, Bogota, Colombia; [3]University Research Foundation for Lysosomal Storage Disorders, Coral Springs, USA, [4]Genzyme Corporation, Cambridge, USA; [5]Franziskus-Hospital Teaching Hospital, Cologne, Germany

Background. Physicians worldwide participate in the International Collaborative Gaucher Group (ICGG) Gaucher Registry, which currently includes data on over 5,700 patients. *Aim.* To analyze data in the ICGG database by geographic region in order to identify regional disease or treatment variations. *Methods.* In 2009, the Gaucher Registry contained patient data from the following regions: North America (n=2108); Europe (n=1477); Middle East/Africa (n= 986); Latin America (n=901); and Asia-Pacific (n=238). Descriptive statistics were provided for demographic and clinical characteristics of Gaucher disease. *Results.* North America and Latin America had the highest proportion of patients with type 1 non-neuronopathic Gaucher disease (96%, 95%, respectively). Asia-Pacific, Europe, and Middle East/Africa had larger percentages (10%, 14%, 16%, respectively) of patients with type 3 neuronopathic Gaucher disease compared to other regions. Asia-Pacific, Europe, Middle East/Africa also had the highest reported frequency of the L444P/L444P genotype (20%, 9%, 11%, respectively) compared with North America and Latin America. Over 77% of patients with Gaucher disease in North America, Europe, Middle East/Africa and Latin America carried at least 1 copy of the N370S mutation. In Asia-Pacific, there were fewer patients with the N370S mutation, with 53% of patients having at least one copy of the L444P mutation. Patients in Asia-Pacific were diagnosed at a younger median age (7yr) than patients in Latin America (11yr), Europe (16yr), Middle East/Africa (10yr) and North America (18yr). *Summary/Conclusions.* Regional differences in ICGG Gaucher Registry data are indicated by the predominance of the N370S mutation, typically associated with the non-neuropathic form of Gaucher disease, in North America, Europe, Middle East/Africa and Latin America. The L444P mutation, which is typically associated with the neuronopathic form of Gaucher disease, was more common in the Asia-Pacific region.

1934

QUANTITATICATION OF MEAN NEUTROPHIL VOLUME IN ACUTE INFECTION

E Papakonstantinou, E Yfantis, K Konstantinou, A Lakoumenta, P Giannopoulou, P Safioleas, I Grafakos, E Trikka-Graphakos, C Manti

Thriassion Hospital, Agia Paraskevi, Greece

Background. Review of peripheral blood smears can yield important diagnostic information through the identification of the morphologic changes characteristically seen in reactive neutrophils during infection. This approach, however, is labor-intensive and time-consuming because it requires manual examination. Furthermore, the results are subjective because they depend on human interpretation, and only a few hundred cells can be analyzed for any given sample. The Coulter LH 780 hematology analyzer (Beckman Coulter, Fullerton, CA) has the ability to measure specific parameters of neutrophil populations like mean and standard deviation (SD) of cell volume (MVI,SDVI), conductivity (MCI,SDCI), and light scatter (MSI, SDSI). These so-called positional parameters (PP) can detect morphologic changes in neutrophil population and can be an additional indicator for diagnosing acute infection. *Aims.* To investigate the value of the neutrophil MVI generated by VCS technology of the Coulter LH 780 hematology analyzer, as an additional predictor of acute infection. *Methods.* Total white blood cell count, percentage of neutrophils, and positional parameters data from 508 patients with positive blood cultures and from 54 age-matched healthy control subjects were prospectively analyzed. We then studied whether changes in MVI correlated with the type of microorganism. Positive cultures were subdivided to gram (+) or gram (-) microorganism. The PP was obtained by the Coulter LH 750 hematology analyzer (Beckman Coulter, Fullerton, CA). Comparisons between means were performed by analysis of variance. Comparison between 2 means was performed by using the Student t test. A P value less than 0, 05 were considered significant. *Results.* Table. *Summary/Conclusion.* 1) The MVI increases in acute infection, while MSI decreases. 2) Using an MVI cutoff of 150, as in bibliography, seems that MVI is a good predictor of acute infection. 3) The MVI increase correlated significantly both with gram (+) and gram (-) microorganisms but it was greater at gram (-) microorganisms (P=0.16). 4) As a quantitive parameter, the MVI has potential use as an additional indicator for the diagnosis of acute infection.

Table.

	Control	Patients	P	Gram +	Gram -	P
Number	54	508		186	322	
MVI mean	146,17	162.71	<0.001	161.6	163.3	0.16
MCI "	145,85	140.89	<0.001	141.3	140.5	0.1
MSI "	146,06	136.57	<0.001	136.7	136.5	0.851

Background. Hot water extract of Agaricus blazei Murill (ABM) is generally known in anti-tumor and immune activities. In previous studies, we reported the increase of number of neutrophils in ABM injected mice. However, the mechanism of increase of neutrophils by ABM is not clearly understood. *Aims.* In this present study, we investigated the mechanism of increased neutrophils, functions of induced neutrophils by ABM and effective comportment of ABM. *Methods.* ABM was provided by Kyowa Wellness Co. Ltd. ABM was freeze dried and adjusted various

concentrations by PBS. ABM was fractionized from fraction number 1 (Fr.1) to 6 by gel filtration using a Shodex OHpak SB-802 HQ column and HPLC. Neutrophils were obtained from guinea pig blood. Neutrophils were isolated from blood of guinea-pig using ficoll-paque. Chemotactic activity for neutrophils was analyzed by EZ-TAXIScan. Productions of reactive oxygen species were measured by FACS using Hydroethidine and 2',7' -Dichlorofluorescin diacetate. Phagocytosis was measured by FACS using FITC labeled Latex beads. *Results.* ABM showed chemotactic activity for neutrophils. Velocities as an indicator of chemotactic activity in migrated neutrophils were 0.31±0.07 μm/sec. (mean±S.D.), 0.28 ±0.07 μm/sec. in ABM at concentration of 50, 100 mg/mL and 0.11 ±0.09μm/sec in control. There were significantly (P<0.001) difference between ABM and control. Radians as an indicator of chemotactic activity in migrated neutrophils were also significantly (P<0.001) increased by ABM at concentration of 50 and 100 mg/mL compared with control. Velocity and radian of migrated neutrophils were significantly (P<0.001) increased by Fr.2, 3 or 4 of ABM compared with control. Fr.3 of ABM showed the strongest chemotactic activity for neutrophils in the both of velocity and radian in migrated neutrophils. Effective component was Fr.3 in ABM and the effective component was substance of approximately from 50 to 200 in molecular weight. Productions of O2- or H2O2 from neutrophils were significantly (P<0.01) increased by ABM compared with control. Phagocytic activity of neutrophils was significantly (P<0.01) enhanced by ABM compared with control. *Conclusion.* Neutrophils were migrated by chemotactic activity of ABM and ABM showed potent activity for functions of neutrophils. The mechanism of increased neutrophils by ABM was due to chemotactic activity of ABM. These results suggest that increase of number and activation in neutrophils by ABM are useful to prevent infection from bacteria.

1936

GAUCHER'S DISEASE TYPE 1, ABOUT AN UNICENTRIC STUDY OF 4 PATIENTS OF LATE ONSET

S Mseddi,[1] F Kallel,[1] F Ben Rhouma,[2] I Jedidi,[3] M Ben Amar,[3] H Bellaaj,[1] M Mdhaffar,[1] N Ajmi,[1] O Kassar,[1] C Kallel,[3] T Boudawara,[3] I Beyrouti,[3] M Elloumi[1]

[1]Hedi Chaker Hospital, Sfax, Tunisia; [2]Institut Pasteur, Tunis, Tunisia; [3]Hopital Habib Bourguiba, Sfax, Tunisia

Introduction. Gaucher's disease is an uncommon inborn recessive autosomal disease due to deficient activity of the lysosomal enzyme Beta glucocerebrosidase. The not neurological form (type1) is more frequent than the neurological forms (type2 and 3), it is generally diagnosed during the 1st or 2nd decade. We report 4 cases affected by Gaucher 's disease type 1 in whom the discovery was late and made in the adulthood.

Table.

	Case 1	Case 2	Case 3	Case 4
Age (years)/sex	34/ F	35/ F	45 /M	72/ M
Symptoms in the discovery of the disease	Sense of abdominal fullness	Anaemic syndrome	Sense of abdominal fullness	Anaemic syndrome
Consanguinity	No but endogamy	5th degree	No but endogamy	Not precised
Antecedents	-	-	-	Post traumatic Splenectomy
Clinical examination	Splenomegaly 5 cm	Hepatomegaly Splenomegaly	Splenomegaly	Splenectomy
WBC 10^9/l	2980	3200	1800	5800
Hemoglobin g/dl	12.1	9.7	7.8	8.1
Platelet Giga/l	130	119	20	11
Cytology and histology of bone marrow	Gaucher's cell	Gaucher's cell	Gaucher's cell	Gaucher's cell
Other histology with Gaucher's cells	Spleen Liver		Spleen Liver	Liver
Enzymatic dosage	Not done	15 % of normal activity	Not done	Not done
Molecular biology	N370S/N370S	N370S/N370S	N370S/L444P	Not done
Treatment	Watching	Total splenectomy	Partial splenectomy	Transfusion
Evolution/Survival after diagnosis	Alive stable/1year	Alive stable/1years	-Improvement of cytopenias -Bone fracture -Parkinsonism -Still alive /8years	Died by pneumonia /6 months

Patients and Methods. The positive diagnosis of the Gaucher's disease held on the presence of Gaucher's cells by medullary cytology and /or histology (spleen, liver and/or bone marrow) and/or low rate of Béta glucocérébrosidase < 15% of normal activity without neurological disorders. *Results.* See Table joint (image). *Discussion.*The ages of our patients ranges from 34 and 71years, it is indeed a form of late-onset. In our series, the disease is paucisymptomatic: the splenomegaly and/or the signs of medullary insufficiency are the most represented. The replacement treatment is unavailable in our country, that's why we have used splenectomy to improve cytopenias. This latter would have deteriorated and precipitated the arisen of bone's complications at the patient number 3, unlike the patient number 4 the post traumatic splenectomy would have delay the diagnosis. The analysis of the mutations showed that N370S is the most frequent in our series, homozygous in two cases. This mutation allows predicting evolution towards osseous complications and Parkinsonism such is the case of the patient number 3 which is heterozygous for this mutation.

1937

BROTHER & SISTER WITH TWO OTHER CASES OF CHEDIAK HEGASHI SYNDROME WITH DIFFERENT PRESENTATIONS IN MY CHILDREN HOSPITAL - ZAGAZIG UNIVERSITY - EGYPT

S Badawy

Zagazig University Hospital, Zagazig - Egypt, Egypt

Case-1-Boy. History: Male, A.R.M, 3 ys, 1st kid, from Ismailia (Egypt),Positive consanguinity.Condition started with bloody diarrhea at 1.5 years and during next 1.5 years,he had recurrent throat infection with fever. At 3 years, the patient developed nausea,vomiting followed by jaundice&abdominal enlargement then oliguria. Then pt had severe recurrent abscesses with pain&difficulty during sitting&standing. Examination. Generalized skin darkening (mainly extremities) like-dirt, Change hair color specially forelock (black to gray&White), Two face abscesses (Nose&Cheeks), Horizontal nystagmus since birth, Hepatosplenomegaly and Massive ascitis. *Case-2-Girl(Boy's sister).* History: Female, A.R.M, 10 months, 2nd kid, from Ismailia (Egypt), Positive consanguinity. Condition started at 3 months with constipation&recurrent throat infections&fever responding to antibiotics&antipyretics. Examination. Darkening of the skin (Mainly in face) with change hair color specially forelock(black to Silver-gray&White). HLA Matching Testing: Boy: A(A29),B(B7,B62,BW6),C(CW1,CW6). Girl: A(A2,A34).B (B41,B50,BW6),C(CW2,CW6). Father: A(A29,A34),B(B41,B62,BW6),C (CW1,CW2). Mother: A(A2,A29),B(B7,B50,BW6),C(CW6). *Case-3-Girl.* History: Female, M.A.E., 2 ys, 3rd kid, from Zagazig (Egypt), Positive consanguinity. Condition started at 1 y with recurrent G.E. with bloody diarrhea&vomiting then constipation at 1.5 ys then pneumonia&effusion with abscesses in forearm&neck with history back abscess at 40 days.After that,hair color change&hepatosplenomegaly. *Case-4-Girl.* History: Female, S.O.I., 2 ys, 4th kid, Zagazig (Egypt), Positive consanguinity&older sibling with similar condition died at 10 yrs from severe recurrent infections. At 1y,recurrent throat&G.I. infections.At 1.5 ys,she had severe irritability&refusal feeding, cough, coryza&severe oral moniliasis. Examination: Albinism, red iris, horizontal nystagmus, svere oral moniliasis. Differential diagnosis: Albinism, Bacterial Mouth Infections, Cutaneous T-Cell Lymphoma, Griscelli Syndrome, Pyoderma Gangrenosum, Investigation for all four cases: CBC:cytoplasmic inclusions in lymphocytes, monocytes and neutrophils. B.M.: Hypercellular BM with vacuoles & giant granules in cytoplasm of eosinophils, eosinophilic myelocytes and lymphocytes suggesting CHS. Skin biopsy specimen:normal but may show melanin macroglobules and perhaps sparse dermal melanin. (N.B.:Almost the same findings in all four cases).

1938

CLINICAL ASPECTS AND DIAGNOSIS OF PAROXYSMAL NOCTUTNAL HEMOGLOBINURIA (PNH)

S Oukid, S Taoussi, Y Bouchakor, M Abad

Hopital, Blida, Algeria

Background. The PNH is a rare disease, acquired, chronic, is associated with clonal expansion of one or several hematopoietic stem cells carrying somatic mutations acquired PIG-A gene. Two proteins play a role in determining the CD55 DAF and CD59 MIRL. Its clinical presentation is polymorphous just be an array of hemolysis or bone marrow. Recent studies have shown that 20-25% of aplastic anemia have a PNH clone. We report 35 observations or PNH clone was searched by flow cytometry. *Aims.* Flow cytometry is a new technique used recently in

our laboratory for the positive diagnosis of PNH. *Methods.* Clinical study, biological, cytological test Dacia 03cas Ham, sucrose 01 test cases and immunophenotyping by flow cytometry carried out on a BD FACS Calibur cytometer 04 colors. This technique assesses the degree deficiency of CD 55 and CD 59 on neutrophils and red blood cells. The definitive diagnosis in practice is the detection of more than 5% of cells deficient in CD55 and CD59. *Study materials.* These 17 women and 18 men with an average age of 33 years (16-62 years). The reasons for consultation: anemia: 18 cases, bleeding: 08cas, low blood: 03 cases, pregnancies: 02 cases, bone pain: 02 cases and cough: 01 case and fortuitous: 01 cases. A bone puncture biopsy done in 26 cases: Aplastic anemia: 17 cases, hypoplasia: 07cases, normal: 02 cases, MDS: 01cas. *Results.* The deficit on the 02 proteins CD55 and CD59 in both cell populations was found in 12 cases or 34% of cases typed. This deficit was noted in 04 women and 08 men with an average age of 33 years (17-49 years). Clinics: anemia: 07 cases associated with episodes of jaundice: 02 cases and dark urine: 01 case, severe anemia in pregnancy: 01 case, bleeding: 02 cases associated with lumbar pain and signs of renal blood 01 case. BOM: Pancytopenia: 10 case and bicytopénie: 01 case. : 08 cases Aplastic anemia: 04 cases, bone marrow hypoplasia: 02 cases, ordinary: 02 cases and myelodysplasia: 01 case. The Dacia Ham test was performed in 03 cases: positive and a test Sucrose has been conducted in one case: positive. Indicative Table. *Commentary.* In our study, the CMF has been instrumental in the diagnosis of PNH. It should be performed before any bone marrow, an array of hemolysis in Coombs negative and unexplained recurrent thrombosis in search of a PNH clones because it is more sensitive and specific than traditional tests.

Table. Results.

PEDIATRIC ACUTE IDIOPATHIC THROMBOCYTOPENIC PURPURA: HOW LONG DO WE HAVE TO WAIT FOR A NEW AUTOIMMUNE MANIFESTATION?

F Cecere,[1] G Pollio,[2] P Pisano,[2] A Maio,[1] G Iannicelli,[2] N Pepe,[2] R Pacifico,[2] R Albano,[2] G Menna[3]

[1]S.Giovanni di d Dio e Ruggi D'Aragona Hospital, Salerno, Italy; [2]Department of Pediatrics S.Giovanni di d Dio e Ruggi D'Aragona Hospital, Salerno, Italy; [3]Department of Onco-Haematology,Pausilipon Hospital, Naples, Italy

Background. As well known in literature Chronic immune thrombocytopenic purpura (ITP) is often associated with other autoimmune diseases. Otherwise, often reported only as sporadic experience is the relationship between acute ITP and other autoimmune manifestations. *Aims.* The aim of our study is to evaluate the incidence of other autoimmune conditions in a cohort of paediatric patients with chronic or acute ITP. *Methods.* Since December 2007 till December 2009 we observed 16 children (8 M and 8 F) mean age 6yrs, ranged between 8 mts-15 yrs, 8 with chronic ITP and 8 with acute ITP (at least 2 yrs of follow up). All patients were periodically screened for coeliac disease (CD) determining the anti transglutaminase antibodies (TTG) and anti endomisial antibodies (EMA), and for other autoimmune conditions determining serum levels of antinuclear antibodies (ANA), anti smooth muscle antibodies (ASMA), anti mitochondrial antibodies (AMA), C3 and C4, thyroidal function, anti tireoperooxhidase antibodies (AbTPO) and anti tireoglobulin antibodies (AbTg), Direct Coombs test, and anti gastric parietal antibodies (APCA), and anti DNA antibodies. *Results.* in the group of 8 patients with chronic ITP 2/8 has shown thyroiditis, 2/8 CD, 1/8 psoriasis, 1/8 no clinical manifestations but was serologically positive for Direct Coombs Test and APCA; 2/8 had no clinical or serological manifestations of autoimmune disease. On the other hand in the group of Acute ITP 2/8 has shown positive Direct Coombs test with no clinical manifestations and/or signs of haemolysis; 1/8 was serologically positive to Anti-DNA completely asymptomatic; 5/8 serologically and clinically negative. All the 3 patients developed the autoimmune condition during the follow up, after more than 1 year from complete remission (CR). (See Table below). *Summary and conclusions.* Our study seems to confirm the high incidence of second or more autoimmune conditions in Chronic ITP. Otherwise it seems to show an high predisposal condition to autoimmunity also in CR patients with Acute ITP. It should be necessary to extend for more than the usually indicated 2 years the survey for autoimmunity in Acute ITP. Further studies, possibly multicentric, will be necessary to confirm our data and evaluations.

Table.

ACUTE ITP	CHRONIC ITP
• 2 / 8 POSITIVE COOMBS TEST •1/8 POSITIVE ANTI DNA	•2/8 THYROIDITIS •1/8 PSORYASIS •1/8 NO CLINICAL MANIFESTATION BUT POSITIVE COOMBS TEST AND APCA •2/8 NO AUTOIMMUNE MANIFESTATION

1940

DO WE KNOW AN IDEAL PATIENT WITH IMMUNE THROMBOCYTOPENIA FOR RITUXIMAB TREATMENT?

L Cervinek, J Mayer, M Doubek

FN Brno, Brno, Czech Republic

Introduction. Immune thrombocytopenia (ITP) is an autoimmune disease characterized by low count of platelets and determination to bleeding. Standard initial treatment options for ITP are corticosteroids and intravenous immunoglobulins. Adult patients with chronic disease are additionally treated with immunosupresive agents (ciclosporin, mycophenolate mofetil, azathioprin, and other). Rituximab is chimeric humanized monoclonal antibody against $CD20^+$ B lymfocytes. It is currently indicated for the treatment of malignant lymphoma, but because the rituximab targets are B lymphocytes it is also used for treatment of autoimmune diseases such as systemic lupus erytematodes and rheumatoid arthritis. In hematology, rituximab is also more often used for the treatment of autoimmune hemolytic anemia, thrombotic thrombocytopenic purpura and immune thrombocytopenia. There are many case reports published about the treatment of ITP with rituximab, however we do not know yet exactly what sort of patients is ideal to receive this therapy. *Methods.* We retrospectively analyzed data of 36 patients with diagnosis of ITP who were treated with rituximab (375 mg/m^2 weekly, four-times; standard infusion-related side-effects prophylaxis) in our center between years 2000 to 2009. In this analysis we were looking for epidemiological data such as age, sex, time from ITP diagnosis to rituximab, and number and a kind of concomitant medication. We particularly analyzed the effect of rituximab with regards to the length of duration of therapeutic response. *Results.* All our patients completed treatment. Therapeutic responses (analyzed month 2 after rituximab treatment) were as follows: complete remission (CR), n=10 (28%); partial remission (PR), n=13 (36%); and no response (NR), n=13 (36%). There was no significant difference in response rate in splenectomized and non-splenectomized patients, however a trend to better effect of rituximab was observed in patients without splenectomy. Patients with splenectomy (n=17): CR, 4 (24 %); PR, 6 (35 %); NR, 7 (41 %). Patients without splenectomy (n=19): CR, 6 (31.5%); PR, 7 (37 %); NR, 6 (31.5%). Also, there was no significant difference in response rate in patients divided according to the time from diagnosis to the rituximab administration (2 years and less *vs.* more than 2 years). In patients who reached PR or CR within 2 months after rituximab administration (n=20), the median progression-free survival was not reached. Only one of these patients patient progressed. *Summary.* Rituximab usage for adult ITP patients is one of well-tolerated 2nd line therapy options. We observed that patients with good initial response (CR, PR) tend to achieve a durable response. On the other hand, in our analysis splenectomy, a number of previous treatments, and time from diagnosis to rituximab administration were not significant predictors of favorable response. Additional studies are needed to determine an optimal timing of rituximab usage.

1941

LONG-TERM FOLLOW-UP ANALYSIS OF HELICOBACTER PYLORI ERADICATION TREATMENT FOR JAPANESE IDIOPATHIC THROMBOCYTOPENIC PURPURA PATIENTS

H Kosugi, T Kanematsu, Y Takagi, M Yuge

Ogaki Municipal Hospital, Ogaki, Japan

Background. Although many reports revealed that Helicobacter pylori (HP) eradication is effective for Japanese idiopathic/immunological thrombocytopenic purpura (ITP) patients, long-term outcome of the HP eradication treatment have been reported very little. *Aims.* We aim to clarify the effectiveness of HP eradication treatment for Japanese HP-ITP in terms of long-term outcome. *Methods.* One-hundred nine patients who showed under 100×10^9/microliter platelets at diagnosis and who could be observed for more than 6 months among 129 patients diagnosed as ITP from July 1998 to December 2007 in our hospital were analyzed. Watchful wait (w/w); 35, HP eradication; 36 (*de novo*; 22 and relapsed/refractory; 14) and other treatment (steroid hormone or splenectomy); 38 patients were included. We analyzed; (1) Complete remission ratio (CRR) and CR duration of each groups, (2) relapse rate and progression-free survival of HP eradication, and (3) clinical outcome of HP eradication in each *de novo* HP-ITP and relapsed/refractory HP-ITP. This study was performed under the guidelines for epidemiologic study established by the ministry of health, labor and welfare in Japan. *Results.* (1) CRR of HP eradication is superior to other treatment, that is 47.2%/55.2% at 2 months and 66.7%/60.5% at 6 months (P=0.0438), respectively. Mean CR duration is 1264 (range; 208-1846) days in HP eradication and 1050 (210-3337) days in other treatment. (2) No relapsed patient was observed in HP eradication and mean PFS is 1303 (208-2020) days. (3) In HP eradication treatment, CRR at 6 months is 59.1% in *de novo* HP-ITP and 78.6%% in relapsed/refractory cases (P=0.0093). *Sumarry/Conclusions.* HP eradication treatment for Japanese HP-ITP patients showed comparably high CR ratio with very high progression-free survival. We also have found out that about 10% of responders show slow response to HP eradication who could not obtain CR at 2 months but obtain CR at 6 months. It might be possible to assume that reduction of stimulation of HP antigen to immune system occur in indirect and slow manner.

TNF-α, TGF-β1, IL-10, IL-6 AND IFN-γ GENE POLYMORPHISMS IN PATIENTS WITH IDIOPATHIC THROMBOCYTOPENIC PURPURA

M Pehlivan, V Okan, T Sever, S Oguzkan Balci, M Yilmaz, T Babacan, S Pehlivan

Gaziantep University, Faculty of Medicine, Gaziantep, Turkey

Background. The polarization of Th1/Th2 towards Th1 contributes to the ethiopathogenesis of idiopathic thrombocytopenic purpura (ITP). Cytokine polymorphisms may play crucial roles in the pathogenesis of ITP. *Aims.* The purpose of this study was to investigate whether tumor necrosis factor (TNF)-α (-308), transforming growth factor beta 1 (TGF-β1) (codons 10 and 25), interleukin 10 (IL-10) (-1082, -819, and -592), IL-6 (-174) and interferon gamma (IFN-γ)(+874) polymorphisms may be responsible in part for genetic susceptibility and treatment of ITP. *Methods.* Genotyping was performed in 71 adult patients with chronic ITP and in 71 healthy individuals by PCR-SSP method. *Results.* Of these polymorphisms, frequency of the TNF-α AG genotype and IFN-λ. AA genotypes were significantly higher in ITP patients than in healthy controls (P=0.016). Frequency of the TGF-β1 (codon 10) TT genotype was significantly lower in ITP patients than in healthy controls (P=0.016). TNF-α AG genotype was significantly higher in steroid-refractory and splenectomized cases relative to steroid-responsive (complete response and remission) ones at the end of one year. When we compared the steroid responsive cases that were at the first steroid course with the 12 cases who were in remission, but in whom no complete response was achieved, we found their frequencies to be 12 (20.3%) and 6 (50%) in IFN-γ AA genotype, respectively. *Conclusions.* With these findings, TNF-α(-308) AG, TGF-β1(codon 10) TT, IFN-γ(+874) TT genotypes were detected to be the genes with tendency to ITP. It is shown that genotypes of TNF-α(-308) AG and IFN-γ(+874) AA might be important in steroid treatment for ITP in Turkish patients.

1944

RESPONSE TO SPLENECTOMY FOR ADULT PATIENTS WITH PRIMARY IMMUNE THROMBOCYTOPENIA FAILING TO FIRST- AND SECOND-LINE THERAPIES: LONG-TERM FOLLOW UP

L Tukic, D Stamatovic, O Tarabar, M Elez, Z Tatomirovic, A Ivic-Zivanovic, N Kuljic-Kapulica, B Balint, M Malesevic

Military Medical Academy, Belgrade, Serbia

Background. Primary immune thrombocytopenia (ITP), also known as idiopathic thrombocytopenic purpura, is an immune-mediated acquired disease of adults and children characterized by transient or persistent decrease of the platelet (Plt) count and, depending upon the degree of thrombocytopenia, increased risk of bleeding. The major goal for treatment of ITP is to provide a safe platelet count (e.g. one that prevents major bleeding) rather than correcting the platelet count to normal levels. For patients with ITP failing to first- and second-line treatment splenectomy is the best therapy option. *Patients and methods.* between 1991 and 2009. 15 patients (pts) (sex: 10 men; 5 women; median age 30 years) with ITP failing to first- and second-line therapy were splenectomized. The median time from diagnosis to splenectomy was 6 months (range 3 to 14). All patients were treated before surgery without results (steroids, androgens, vincristine, cyclosporine, IVIG, Rituximab). Only in 4 (40%) out of 10 patients treated before splenectomy with high-dose immunoglobulins, increased platelet count over 100×10^9/L have observed. *Results.* immediately following splenectomy in 13 patients (86.67%) increased platelets count happens. We have noticed postoperative complications in 3 patients (20%) - in 2 of them (13,3%) appearance of haemathoma in spleen loge with consecutive infection (subphrenical abscessus), while in 1 patient (6,7%) we have observed pancreatic fistula. Those particular complications have been solved successfully (fistula after 8 months). Decreasing platelet number was objected in second postoperative week in 1 patient with partial response, those one with subphrenical abscessus, with renewal appearance of hemorrhagic syndrome and we have continued with application of IVIG in combination with steroids, androgens and (following healing of abscessus) even with chemotherapy according to COP regimen (2 cycles). Six months after splenectomy, partial remission has occurred (4 years after splenectomy patient spontaneously reached complete remission). Other patient is still in the stabile partial remission after the splenectomy (Plt above 70 and below 100×10^9/L). After the long-term follow up (2 to 19 years, median time 7,6 yrs) there were neither any complication nor relapses of the ITP. *Conclusion.* This study indicates that more than 86.6% of patients with ITP failing to first- and second-line therapy could achieved long term remission with minimal risk after the splenectomy.

1945

POTENTIAL APPLICATIONS OF ROMIPLOSTIM IN THE DAILY PRACTICE

D Valcarcel, E Moreno, J Portos, D Lopez, R Martino, J Briones, MS Brunet, J Delgado, N Pujol-Moix, R Ayats, J Sierra

H. de la Santa Creu i Sant Pau, Barcelona, Spain

Background. Romiplostim is a MPL ligand recently approved as treatment for refractory immune thrombocytopenia (ITP) and currently explored in patients with low platelet counts from other causes. *Patients and methods.* We analyzed 17 consecutive patients who received Romiplostim in our center. Twelve patients were treated for refractory ITP, 4 for myelodysplastic syndrome (MDS) and 1 for severe thrombocytopenia after allogeneic stem cell transplantation (Allo-SCT). The latter 5 patients received Romiplostim on a compassionate basis. The drug was administered subcutaneously at an initial dose of 1 mcg/kg (except for two MDS patients who started with a dose of 300 mcg). The dose was increased by 1 mcg/kg weekly until achieving a platelet count above 50×10^9/L. Platelet response was defined as a platelet count of $>50\times10^9$/L and/or doubling of the pre-treatment count, in the absence of any rescue medication within the last 8 weeks. *Results.* In the 12 patients with ITP (median age 70 years, range 37-81), the median number of therapy lines before Romiplostim was 2 (1-4). Median platelet count at starting Romiplstim was 17×10^9/L (range 5-180). Ten patients achieve a complete response (83%) after a median of 2 weeks (range 1-4). The median platelet count at last follow up was 103×10^9/L (19-550). All except 2 patients continue under Romiplostim after median treatment duration of 13 weeks (range 3-34). In 1 patient the treatment was discontinued because of thrombocytosis and in another was stopped due to lack of response. Of the 4 MDS patients (median age 78 years, range 70-87), all had previously received 5-azacytidine. Median platelet

count before Romiplostim was 7×10^9/L (range 4-16), with all patients being transfusion dependent. One patient is in complete remission achieved with a dose of 6 mcg/kg and the platelet count is 84×10^9/L 24 weeks after starting treatment; another patient failed to respond and Romiplostim was discontinued after increasing the dose up to 7 ug/kg during 10 weeks. The remaining two patients are under treatment since they have only received 4 doses of the drug; of note, in one of them the platelet count has already increased from 4 to 39×10^9/L platelets and in the other from 7 to 20×10^9/L platelets with the two of them free of transfusions. The patient who received Romiplostim as therapy for persistent thrombocytopenia after Allo-SCT did not improve and the agent was discontinued after 4 weeks. Overall, there were 3 patients who showed a transient thrombocytosis. Another occasionally observed side effect was mild injection site reaction. *Conclusion.* Romiplostim has different potential indications. The use of this agent following the current recommendations appears safe and may be useful in different conditions leading to thrombocytopenia.

1946

THROMBOCYTOPENIA IN PATIENTS HOSPITALIZED IN INTENSIVE CARE UNIT (ICU)

M Abio, N Fernandez Mosteirin, A Iborra, C Sierra, M Guillén, A Godoy, N Padrón, C Salvador Osuna, M Torres, JF Lucía, D Rubio

Miguel Servet Hospital, Zaragoza, Spain

Background. Alterations of hemostasis and blood counts are common in patients admitted to ICU. Thrombocytopenia increases the morbidity and mortality being its aetiology very varied. *Aims.* 1) analyze the incidence of thrombocytopenia in patients admitted to ICU: clinical, laboratory and therapeutic factors. 2) Classification of patients undergoing cardiovascular surgery following the trend in platelet count. *Methods and patients.* A retrospective study by reviewing medical records of patients with thrombocytopenia (platelets $<125\times10^9$/L) admitted to four ICUs of our hospital during a 40 days period, classified as mild (100-50×10^9/L), moderate (50-20×10^9/L) and severe ($<20\times10^9$/L). Evaluation of patients undergoing cardiovascular surgery with cardiopulmonary bypass, classifying them according to changes in the platelet count until day 10 post surgery: type 1 pattern (biphasic evolution) and type 2 pattern (persistent decline), and their involvement with the development of Induced Thrombocytopenia Heparin (HIT) as the patterns presented by Selleng *et al.* (J Thromb Haemost 2009; 8: 27-29). *Results.* 237 patients admitted during this period, 50 showed thrombocytopenia (21%). Cumulative incidence: 19.8% in 40 days, excluding those who previously had his income. Men 56%, Women 44%, mean age 70.7 (extremes 19-88). Depending on different UCI: Coronary 9 patients, mean age 67.5, cardiovascular 25 patients, mean age 70.0; Polyvalent 11 patients, mean age: 65.8; Traumatology 6 patients, the mean age: 75.6. Reason for admission: 32% valve replacement, infection 14%, ischemic heart disease 14%, respiratory 8% hepatectomy 8%, coronary artery bypass surgery 8%, ruptured aneurysm 4%, bleeding 4%, decreased consciousness 4%, other 6 %. Mild thrombocytopenia: 94%, moderate: 0%, severe: 6%. Nadir figure rating: 90x10 9 / L. Average time duration of thrombocytopenia: 4.2 days, median: 2.5 days. Etiology surgery with cardiopulmonary bypass 42%, infectious 24%, liver pathology 14%, drug toxic-10%, blood disorder 6%, other 6%. Distribution due to drug: abciximab 8%, tirofiban 2%. Incidence bleeding: 30%, with major bleeding (10%) located in: mediastinal 2%, hematoma in back with 2% drop in hematocrit, HDA 2%, brain 2% pulmonary and 2%, the rest were minor bleeds. Thrombotic phenomenon not observed. Transfusion: CH 54%, CP 22%. Incidence of coagulopathy: 30%. Regarding the administered treatment: plasma 12%, vit K 8% FVIIr and other measures 2%, Vitamin K and plasma 2%. The attributable mortality: 10 patients (20%). Of 78 patients undergoing cardiac surgery showed thrombocytopenia 25 (32%) and all of them showed a type 2 pattern of platelet count, and in no case the etiology was HIT. *Conclusions.* 1) Surgery bypass is the most common cause of thrombocytopenia, because of our center nature, followed by infectious causes. 2) In most cases, thrombocytopenia is mild and transient, short-lived, and have not needed treatment. 3) The classification of patients according to the proposed standards could have a negative predictive value in the case of type 2 pattern, though larger series are needed for a better evaluation. 4) In the critically ill patient with multiple pathologies, thrombocytopenia is a factor with impact on morbidity and mortality.

1947

ASSOCIATION OF PLATELET PARAMETERS AND SERUM COMPLEMENT WITH COAGULASE-NEGATIVE STAPHYLOCOCCAL BACTEREMIA: A CROSS-SECTIONAL STUDY

M Dalamaga,[1] M Pantelaki,[2] K Daskalopoulou,[3] M Triantafilli,[4] K Karmaniolas,[4] G Sotiropoulos,[4] A Lekka[4]

[1]Attikon University General Hospital, Agia Paraskevi-Athens, Greece; [2]Attikon General University Hospital, Athens, Greece; [3]Elpis General Hospital, Athens, Greece; [4]NIMTS General Hospital, Athens, Greece

Background/Aims. Bacteremia and systemic inflammatory response syndrome involve inflammation, thrombopoiesis and haemostatic mechanisms. Mean platelet volume (MPV), platelet distribution width (PDW), platelet count and their correlations with serum complement levels (C3 and C4) and C-reactive protein (CRP) have not been studied in depth. The aim of this study was to explore the correlation of platelet indices with serum complement levels and CRP, and to determine their significance in the evolution of coagulase-negative staphylococcal (CNS) bacteremia. *Methods.* We have evaluated 18 incident cases of coagulase-negative staphylococcal bacteremia (10 men and 8 women, 27-80 years) and an equal number of hospital controls with minor non-infectious and non-neoplastic conditions, individually matched for age (±5 years), gender and time at diagnosis. To assess thrombopoiesis and inflammation, we have determined platelet indices and leucocyte count using Sysmex 9000 analyser. C3, C4 and CRP levels were determined using immunonephelometry. Statistical analysis of data was performed with SPSS® version 17 for Windows software. *Results.* Significantly low mean values of serum C3 complement levels ($P<0.001$) along with significantly high mean values of platelet count, MPV, PDW, platelet-to-large-cell ratio, leucocyte count and CRP were shown in patients with CNS bacteremia in comparison to their controls ($P<0.05$). Serum C4 didn't present any significant difference ($P=0.91$). There was a significant negative relationship between CRP and serum C4 in patients with bacteremia ($r=-0.49$, $P<0.03$). Adjusting for age, gender and CRP levels, the presence of CNS bacteremia is a statistically significant predictor of MPV levels ($P=0.035$). Patients with CNS bacteremia presented normal platelet indices as well as serum C3 complement levels after resolution of the infection. *Summary/Conclusions.* Platelet indices and especially MPV may provide an accessible and adjunct clinical useful index to the current laboratory parameters for estimating the degree of inflammation and the degree of bone marrow function in patients with CNS bacteremia, predicting also resolution of the infection.

1948

TIME TO SPLENECTOMY FAILURE IN PATIENT WITH REFRACTORY CHRONIC IMMUNE THROMBOCYTOPENIC PURPURA

G Gaman, A Gaman

University of Medicine and Pharmacy, Craiova, Romania

Introduction. Splenectomy has been perceived as a potentially curative treatment for chronic immune thrombocytopenic purpura (ITP). Schwartz (2003) demonstrated that the risk of relapse is between 33%-55% at patients with longterm follow-up. Splectomised patients are at risk for early and late surgical complications, infections secondary to impaired immunity, thrombotic or cardiovascular disease, pulmonar hypertension. Splenectomy requires preoperative vaccinations , general anesthesia, antibiotic prophylaxis and subsequent longterm vigilence with antibiotic treatment. *Obiective.* To decribe the time from splenectomy to splenectomy failure among patients with chronic ITP enrolled in the clinical program(prior treatment with dexamethazone -high dose). *Methods.* Date of splenectomy and prior medications for ITP were reviewed in patients enrolled in 3 clinical trials using dexamethazone highdose. Splenectomy was considered to have failed upon administration of the first treatment for ITP after surgery or than patients were not able to taper or interrupt concomitent ITP treatments in the 15 days following splenectomy. Of the 89 patients enrolled in the ITP cohorte, 32 (27%) were splenectomised and 44 were evaluable for this analysis. The analysis does not describe overall effectiveness of splenectomy as the patients were limited to splenectomy failure that required additional treatment for ITP. *Results.* 21% of patients required ITP medication within one year from the splenectomy. Five years after the splenectomy, 24% of the patients still had a response. This percentage decreased to 13% after 10 years. *Conclusions.* this retrospective analysis demonstrates that the success of splenectomy diminishes over time at patients requiring further ITP treatment, most splectomised patients who relapsed in 5 years. The treatment of chronic ITP has advanced as more

data of the safety and efficacy of new medications (Rituximab or Eltrombopag).

1949

COMPARISON OF PLATELET ACTIVITY IN PATIENTS WITH DIABETES MELLITUS AND SUBJECTS WITH PRE-DIABETES

C Kanonidou, S Arampatzi, E Kanonidou, K Thisiadou, A Kalikaki, S Spiroglou, K Chalvatzi, A Nikolaidou, E Diza

Ahepa University Hospital, Thessaloniki, Greece

Background. Large platelets are more active and hence more thrombogenic than smaller ones. Mean platelet volume (MPV) is an indicator of platelet thrombogenic function. It has been reported that patients with diabetes mellitus have significantly higher MPV values which is probably associated with increased cardiovascular morbidity. Values of fasting glucose ranging from 100 mg/dL to 125 mg/dL are considered, according to the diagnostic and classification criteria issued by the American Diabetes Association (2008), as a pre-diabetes state and a risk factor for future diabetes. The MPV in patients with impaired fasting glucose (pre-diabetes) has been lately under investigation. *Aims.* The objective of this study was to evaluate MPV in subjects with pre-diabetes compared with diabetic patients and normoglucemic control subjects, and to investigate the potential associations between MPV, fasting blood glucose (FBG) and glycated hemoglobin (HbA1c) measurements. *Methods.* A total of 122 patients from the Outpatients Department of AHEPA University Hospital were enrolled to the study. They were divided into three groups. Group 1 comprised of 50 (15 males and 35 females) diabetic patients (FBG>126 mg/dL, HbA1c>6%); group 2 of 48 (20 males and 28 females) pre-diabetic patients (FBG =100-125mg/dL, HbA1c<6%); group 3 of 24 (13 males and 11 females) normoglucemic healthy subjects. Exclusion criteria for entry into the study was the presence of co-existing thrombotic or hematological disease and the use of anticoagulant agents. MPV and platelet count were measured with hematological analyser HE-2100 SYSMEX, ROCHE, glucose levels with phasmatophotometric method with Modular P 800, ROCHE and glycated hemoglobin with high performance liquid chromatography-HPLC with the semiautomatic system VARIAN, BIORAD. Statistical analysis was made by unpaired Student's t test and correlations were tested using Pearson correlation analysis. *Results.* The laboratory parameters are reported in Table 1. MPV was significantly higher in the diabetic and the pre-diabetic groups than in the control group (P<0,001). The analysis showed that there was no significant difference between the platelet count of the three groups. MPV was positively but not significantly correlated with fasting blood glucose and HbA1c in diabetic and pre-diabetic groups. *Summary/Conclusions.* The study shows a stepwise increase in MPV, which is a marker of platelet thrombogenic function and activity, from a non-diabetic to a pre-diabetic and then further to a diabetic population. In the same samples of blood no significant change in platelet count was found. No significant correlation between MPV and glycemic control (fasting blood glucose and HbA1c) was observed. As the increase in MPV is considered an independent risk factor for myocardial infarction, patients with pre-diabetes may be at an increased risk of cardiovascular event as well as the diabetic ones.

Table 1. Platelet activity and diabetes parameters in diabetes mellitus, pre-diabetic and control group.

Laboratory parameters	Diabetic patients	Pre-diabetic subjects	Control group
Fasting blood glucose (mg/dl)	195,04 ± 67,92	116,17 ± 3,89	93,29 ± 8,14
Glycated hemoglobin (HbA1c, %)	8,08 ± 1,56	5,30 ± 0,41	4,68 ± 0,49
Platelet count (PLT, K/μL)	259,08 ± 68,23	234,39 ± 54,05	230,95 ± 69,62
Mean platelet volume (MPV, fL)	11,28 ± 0,91	11,16 ± 0,95	8,79 ± 0,79

1950

ROMIPLOSTIM FOR THE TREATMENT OF IMMUNE THROMBOCYTOPENIA ASSOCIATED TO CHRONIC LYMPHOCYTIC LEUKEMIA AND MAINTENANCE OF THE RESPONSE WITH TWICE-WEEKLY ADMINISTRATION

A Pascual,[1] A Biedma,[2] J Berruga[2]

[1]Hospital San Juan De La Cruz, Ubeda, Spain; [2]Hospital San Juan de la Cruz, Ubeda, Spain

Background. Romiplostim is an Fc-peptide fusion protein. It works intracellularly in a manner similar to that of the naturally occurring thrombopoietin (TPO) to activate the transcriptional pathways, leading to increased platelet production via stimulation of the c-Mpl receptor. Its use is approved for adult chronic immune thrombocytopenia purpura (ITP) splenectomised patients who are refractory to other treatments and as second line treatment for adult non-splenectomised patients where surgery is contraindicated. Approximately 2% of chronic lymphocytic leukemia (CLL) patients develop clinically significant ITP. The diagnosis is made on the basis of an unexplained fall in platelet count in the absence of bone marrow failure due to leukemic infiltration or hypersplenism. We use a second generation non-immunogenic TPO receptor agonist in a case of refractory ITP-CLL. *Case summary.* A 73-year-old man was diagnosed with CLL and immune thrombocytopenia associated in May, 2008. He presented extreme thrombocytopenia with moderate hemorrhagic manifestations that have needed treatment with steroids and immunoglobulin with partial response and rituximab for maintenance of the platelet response. In May 2009, he was admitted to the hospital with severe thrombocytopenia of 3×10^9/L and mucocutaneous bleeding. Treatment with corticosteroids, intravenous immunoglobulin, rituximab and vincristine was started on but thrombocytopenia showed refractoriness. The patient presented a bilateral pneumonia for Stafilococo aureus and a life-threatening digestive hemorrhage. Baseline platelet counts were 5×10^9/L so we decided to begin the treatment with Romiplostim. The initial dose of romiplostim was 3 microg / kg / week/ subcutaneus. Platelet response was observed on day 7 (58×10^9/L platelets) with a cessation of the digestive hemorrhage. Platelet counts increased with once weekly dosing. Patient was able to discontinue the concomitant medications. Durable platelet response (Platelet count ≥ 50×10^9/L during 6 or more of the last 8 weeks of treatment) was maintained with continued romiplostim twice-weekly. Romiplostim was well tolerated. Adverse events were thrombocytosis> 400×10^9/L and worsened thrombocytopenia following romiplostim discontinuation that improved with the restart of the administration. In January 2010, 31 weeks after start of treatment, the platelet counts were 139×10^9/L with Romiplostim twice-weekly without morphologic changes in the peripheral blood smear. We have proposed to the patient the accomplishment of splenectomy. *Conclusions.* Romiplostim has increased and supported the long-term platelet counts in this difficult patient with a good profile of safety. Romiplostim may provide a new therapeutic option for patients with ITP associated to CLL. Clinical trials are required to confirm its efficacy in this indication and the interval of administration.

1951

PLATELET COUNT AS PROGNOSTIC VALUE OF MORTALITY AND ORGANIC DYSFUNCTION IN PATIENTS WITH SEPSIS

A Chacon Mayor

Hospital Juan Ramón Jiménez, Huelva, Spain

To study the incidence of thrombocytopenia in patients in the emergency department with a diagnosis of severe sepsis and septic shock Correlate the value of platelet count with prognosis and mortality of these patients. Analyze the hematologic organ dysfunction related to that thrombocytopenia in the context of sepsis. *Materials and methods. Study Design.* Retrospective Cohort Sample: We analyzed all adult patients with criteria for the diagnosis of severe sepsis and septic shock in the period from November 2008 to February 2010 in the Emergency Department and Critical Care Hospital Juan Ramón Jiménez de Huelva. All these patients had to meet at the time of the study include the criteria for the diagnosis of hospital plan of management of severe sepsis and septic shock force at the Hospital. In each patient were extracted 2.5 ml of venous puncture, which was placed in tubes used as EDTA. Thrombocytopenia was defined as a platelet count less than 150000 / mm 3 during admission, at 24, 48 and 72 hours. Variables: gender, age, admission and discharge from service, patient type, time of placement in which it met the criteria of severe sepsis, platelet count, destination (high or death) and other parameters as the Score of APACHE (Acute Physiology and Chronic Health Evaluation) and SOFA score (Sequen-

tial Organ Failure Assessment). Statistical Analysis: Data were analyzed by SPSS 16.0. By t-student for independent samples and paired, χ^2, with confidence limits of 95%. *Results.* We analyzed a series of 64 patients, 34 (47%) male and 30 (53%) female, average age of patients was 64±21 years; 31 (59.6%) patients of medical management and 21 (40.4%) of surgical management.The median hospital stay for patients with severe sepsis and septic shock from 8.6±10 days. In these patients, the average platelet count was 96.000/mm 3, being the lowest count 11.000/mm 3. It is noted that mortality increases in patients with thrombocytopenia were statistically significant on admission (P=0.043) at 48 hours (P=0.032) and at 72 hours (P=0.04) at 24 hours was not found statistical significance (P=0.11). The APACHE II score of these patients was 23±7. A low platelet count has also been associated with poor prognosis and increased severity of illness reflected in the APACHE II Score was higher in those critically ill patients with thrombocytopenia than in those not suffering, results were not statistically significant probably by the small sample size. Regarding the distribution of dysfunction and its correlation with haematological dysfunction, was that in both groups the incidence of dysfunction was similar, a fact reflected in the average SOFA Score. *Conclusions.* Thus a decrease in platelet count may indicate poor outcome in critically ill, and that this simple parameter can be trusted to monitor the evolution of patients with sepsis, as several studies suggest that its correction is an important factor for a better prognosis and evolution observed in this study that patients with higher values of APACHE II at 72 hours after admission presented a decrease in platelet count.

1952

DISTURBANCES OF PLATELETS AGGREGATION IN PATIENTS WITH MULTIPLE MYELOMA

I Djunic,[1] I Elezovic,[1] D Tomin,[1] V Ilic,[2] N Suvajdzic-Vukovic,[1] J Bila,[1] D Antic,[1] A Vidovic,[1] N Milosevic-Jovcic[2]

[1]Institute of Haematology, Clinical Center of Serbia, Belgrade, Serbia; [2]Institute for Medical Research, Belgrade, Serbia

Backgraund. Some patients with multiple myeloma (MM) have haemostatic disorders at presentation, and arising mechanism is not completely explained. It is more frequently belived to be in connection with paraprotein. *Aim.* The aim of this study was proved by investigation with platelets aggregation tests, the incidence of disturbances of platelets aggregation at patients with MM, and to estimated the influence of paraprotein on platelets aggregation at healthy donors, *in vitro*. *Methods.* In this study where included 40 patients with MM. Initially investigation of platelets aggregation induced with ADP, collagen (COL), ristocetin (RIS) and epinephrine (EPI) where done. Paraprotein has been separated by Rivanol method from serum of 9 patients, who had decreased platelets aggregation on used inducers: ADP, COL, RIS and EPI, at presentation. Platelets aggregation in platelet rich plasma (PRP) was measured at 9 healthy donors before and after addition of paraprotein isolated from the patients with MM, induced by same inducers. The indentical test was repeted with addition of human immunoglobulins for intravenous used in PRP at 9 healthy donors. We measured latent time in seconds and maximal platelet aggregation in percent for all inducers. *Results.* Platelets aggregation was disturbed at one third patients. Platelets aggregation was normalized together with disappearing of paraprotein during a treatment. When patients attained remission, their platelets aggregation was normalized. Paraprotein isolated from serum of these patients inhibited platelets aggregation of healthy donors. Average of maximal levels of platelet aggregation has been significantly decreased in PRP of healthy donors after addition of paraprotein when used inducers: ADP (P=0.005), COL (P=0.007), RIS (P=0.004), and EPI (P=0.005). Average of latent time of platelet aggregation was significantly prolonged in healthy donors after addition of paraprotein with inducers: COL (P=0.018), RIS (P=0.033) and EPI (P=0.042). Average of latent time of platelet aggregation was not significantly prolonged after induction by ADP (P=0.169). In comparison, when human immunoglobulins added in PRP of healthy donors, maximal platelet aggregation and latent time were not significantly changed. *Conclusions.* These invastigations have proved that paraprotein leads to haemostatics disorder at patients with MM. Paraprotein isolated from patients with MM, who had decrease platelet aggregation at presentation, significantly decreased platelet aggregation when was added in PRP of healthy donors, *in vitro*. This is confirmed with addition of human immunoglobulins in PRP of haelthy donors, thus, platelets aggregation was not significantly changed.

1953

TREATMENT RESULTS IN PATIENTS DIAGNOSED WITH CHRONIC IMMUNE THROMBOCYTOPENIC PURPURA

CO Ionita,[1] I Ionita,[1] DE Nicola,[2] M Ionita,[1] R Pacurar,[2] H Ionita[1]

[1]UMF Victor Babes, Timisoara, Romania; [2]County Clinical Hospital, Timisoara, Romania

Background. Immune Thrombocytopenic Purpura (ITP) in adults is often a chronic disorder that requires continuous monitoring of platelet counts, bleeding events, and treatment - related side effects. Current ITP treatment options for chronic ITP include corticosteroids, intravenous immunoglobulins (IVIg), rituximab, and clinical supervision in order to prevent bleeding events by appropriate treatments. Splenectomy is reserved for those patients who do not respond or relapse after these medical therapies, or require intolerable doses to achieve safe platelet counts. *Aims.* The purpose of this study is to demonstrate that the result of treatment in patients with chronic ITP does not significantly improve under current standard of care. *Methods.* We present the initial results from a prospective, observational study in patients' previously diagnosed with chronic ITP and consecutively enrolled in this study. Data from patients' charts provided date of 1st ITP diagnosis, treatments received, and medical history. ITP treatments, dose, response, and duration of response were collected prospectively for 12 months. *Results.* The first 150 patients enroled in the study were 46% male; mean age 52 years. During the study evaluation period (at baseline or beyound) 42 patients (28%) were splenectomized and 108 (72%) received ITP - related treatments including corticosteroids (n=79), IVIg (n=25), and Anti-D Antibody (n=4). Our study indicates that the overall response was 68% with 48% CR and 20% PR. The other 32% of the patients were considered in non-remission and 20% of them presented late remission after a median evolution period of approximately 1,3 years. During the evolution, 53% of the patients have relapsed, 41% of the patients have been splenectomized, 26% of the patients which have been splenectomized presented CR and 11% of patients presented PR. The long-term follow-up in CR and PR proves a good, stabil and durable response in time for more than 7 years. The natural coure of the disease is variable. *Conclusions.*Patients with ITP chronic can have a good initial response at the steroid therapy and/or IVIg. Those that fail during this therapy can get a safe and durable response after the splenectomy. Modern treatments like monoclonal antibodies can bring a bigger benefit. Novel ITP intervention are desirable to improve both treatment satisfaction and reported effectiveness in patients with chronic ITP.

1954

EIGHT-YEAR FOLLOW-UP OF PATIENTS WITH IMMUNE THROMBOCYTOPENIC PURPURA RELATED TO H. PYLORI INFECTION

H Akiyama, T Kikuchi, T Kobayashi, T Yamashita, K Ohashi, H Sakmaki

Tokyo Metropolitan Komagome Hospital, Tokyo, Japan

Background. Thrombocytopenia related to H. pylori infection is a definitive subset of chronic immune thrombocytopenic purpura (ITP). Several systemic reviews have recently been performed and this effect had been confirmed. Meanwhile, few reports regarding the long-term effects of eradication are available. *Aims.* We present 8-year follow-up data for patients with ITP considered to be related to H. pylori infection, which was eradicated successfully. *Methods.* Patients diagnosed as having ITP at the Tokyo Metropolitan Komagome Hospital and who had been involved in a study evaluating the effects of H. pylori infection on ITP in 2001 were included. After infection was confirmed, eradication was performed and their platelet counts were followed. They were re-evaluated in 2009 for H. pylori infection and platelet count. Medical records were also examined for platelet counts in the interim. H. pylori infection was examined using 13C urea breath test (UBIT; OTSUKA Pharm. Co., Ltd, Tokyo, Japan). Eradication of H. pylori was performed using standard therapy: amoxicillin (1,000 mg, twice daily), clarithromycin (250 mg, 3 times daily) and proton-pump inhibitor (20-40 mg, twice daily) for 1 week. *Results.* In 2001, 31 patients with chronic ITP were evaluated for H. pylori infection. Nineteen of these were found to be positive and were treated for H. pylori infection. Eight years later, 13 of these 19 patients were re-evaluated for H. pylori and platelet count was followed in 17 of 19. Two patients were lost during follow-up at 5 years after treatment. At the time of eradication treatment, mean age was 59.7 years (29-74 years), 8 patients were male and median length from diagnosis was 9.3 years (0-28 years). Nine patients had received steroid treatment and splenectomy had been performed in 3. Before eradication, platelet count exceeded 100 $\times 10^9$/L in 2 patients, partly because of steroid treatment, and their platelet

counts remained below the normal range after eradication. Therefore, these patients were excluded from further discussion. Initially, 6 of 17 patients did not respond to treatment and remained no response after eight years. The platelet counts of the remaining 11 patients were initially below 50×10^9/L and 10 patients showed complete response within 6 months after treatment for H. pylori, and this was sustained for 8 years. Of these, one patient was lost during follow up after 5 years, when normal platelet count was documented. Steroid treatment was discontinued in all three patients and no relapse was observed or reported. Two of the 12 patients examined for H. pylori infection after 8 years were positive, but the timing of infection was unknown. *Conclusions.* At our institution, 11 patients who responded to treatment remained free from thrombocytopenia and no relapse has been reported during the last 8 years after treatment. Due to the difficulty of following elderly patients, the number of patients in present study is small. However, the information presented here remains valuable in establishing the long-term follow-up strategies for these patients.

1955

COMPARATIVE STUDY OF THYROID HORMONES WITH THE NUMBER, MEAN VOLUME AND DISTRIBUTION WIDTH OF PLATELETS

S Patiakas,[1] F Girtovitis,[2] K Rousos,[3] I Alexidis,[4] C Charalampous,[5] T Mylonas[4]

[1]General Hospital of kastoria, Thessaloniki, Greece; [2]General Hospital of Thessaloniki ACHEPA',, Thessaloniki, Greece; [3]Heaith Center of Alexandria-general hospital of Veria, Veria, Greece; [4]Microbiological Laboratory of General Hospital of kastoria, Kastoria, Greece; [5]Pathological Clinic of psychiatric hospital of Thessaloniki, Thessaloniki, Greece

Background-Aim. To study comparatively the possible correlation of the thyroid-stimulating hormone (TSH), thyroxine (T4) and triiodothyronine (T3) with the plain platelet parameters of a blood test (mean platelet volume (MPV), platelet distribution width (PDW) and platelet number), in cases of euthyroid patients and hyperthyroid patients. *Material-Method.* The lab test results of 75 euthyroid patients aged from 25 to 75 years (16 male and 59 female, with average age 56 years) and 46 hyperthyroid patients with similar age (12 male and 34 female, with average age 54 years) were studied. The values of the thyroid hormones were determined with the use of an automated hematogical analyzer in all the patients, followed by a statistical analysis of the data with the use of the SPSS v.10 statistical packet. *Results.* As far as T3 and T4 are concerned, there was no statistically important correlation with any of the platelet parameters, in both euthyroid and hyperthyroid patients. (In the hyperthyroid patients there clearly was a greater correlation from the euthyroid patients, but it too was not statistically important, $P>0.05$).On the contrary, as far as TSH is concerned, there was a statistically important negative correlation ($P<0.05$) with MPV and PDW in both euthyroid and hyperthyroid patients. The correlation exhibited was greater in the hyperthyroid patients (correlation coefficient r= -0.698 for MPV and r= -0.845 for PDW) and smaller, but statistically important, for the euthyroid patients (correlation coefficient r= -0.653 for MPV and r= -0.811 for PDW). More specifically, as shown in both groups, this negative correlation was stronger for PDW, compared to MPV. *Conclusions.* It is proven, therefore, that the low value of TSH is related with less in number and greater in volume activated platelets, who surely play an important role in the coagulation and endothelial disorders taking place in hyperthyroid patients.

1956

RITUXIMAB IN THE TREATMENT OF IMMUNE THROMBOCYTOPENIA: FOLLOW-UP IN SEVEN CASES

I Sampaio, MJ Palaré, A Ferrão, A Morais, A Saianda

Hospital de Santa Maria, Lisboa, Portugal

Background. Rituximab is a monoclonal antibody against the CD20 antigen whose safety and efficacy in the treatment of children with chronic immune thrombocytopenia has been demonstrated. It can be used in cases not responding to splenectomy and as an alternative to this procedure. Nevertheless, experience of its use in children with immune thrombocytopenic purpura (ITP) is limited, the largest cohort including 49 children and the longest follow up reported of 39 months. *Aims.* To report the experience of our center with the use of rituximab in children with severe chronic immune thrombocytopenia requiring repeated courses of corticosteroids and immunoglobulin. *Methods.* Retrospective study including 7 children with chronic ITP treated with rituximab in a pediatric hematology unit between December 2006 and August 2009. Data were collected from clinical records and included demographic data, treatments and blood results before rituximab therapy, response to therapy, duration of remission and adverse effects or treatment failure. *Results.* We treated 7 children now aged 4 to 18 years old. Previous ITP duration was in average 27 months (range 4 to 72 months). All children had been previously treated with steroids and immunoglobulin and one had been splenectomized. Complete response was observed in 3 children and sustained in 2 of them after 32 e 36 months follow up time. The other responding child had an initial partial response (platelet count range: 50-150.000/μL) for12 months followed by complete response for 7 months and had then a recurrence during a viral illness (influenza A). Partial response occurred in one more child and minimal or absent response was observed in 3 children. Responses occurred in all but one case after the first or second doses. Two patients were subsequently submitted to splenectomy for persistent severe ITP. Follow up time ranged from 3 to 32 months (average 22.5 months). Mild adverse effects were registered in 3 patients, consisting in pruritus, urticaria and vomiting. They all occurred during the first dose and resolved with symptomatic therapy or with reducing the infusion rate. Therapy was continued in all cases. *Summary/Conclusions.* Rituximab is a promising treatment option for children with severe treatment refractory chronic ITP. It seems to provide a sustained response in responders with minimal and tolerable toxicity. It may provide an alternative to splenectomy, especially in younger patients who have increased risk of serious infections with encapsulated organisms.

1957

ANTI-D IMMUNOGLOBULIN A COST-EFFECTIVE ALTERNATIVE FOR IMMUNE THROMBOCYTOPENIA

[1]Louis Turcanu Children Hospital, Timisoara, Romania; [2]University of Medicine and Pharmacy Victor Babes, Timisoara, Romania; [3]Louis Turcanu Childrens Hospital, Timisoara, Romania

Background. Anti-RhD immunoglobulin (anti-D) is a therapeutic alternative successfully used in the setting of both acute and chronic immune thrombocytopenia. Anti-D therapy appears to inhibit macrophage phagocytosis by a combination of both FcR blockade and inflammatory cytokine inhibition of platelet phagocytosis within the spleen. The largest body of evidence exists for the competitive inhibition of the mononuclear phagocytic system by sensitizes red blood cells. Evidence to support this as a major mechanism of the therapy includes studies which show that anti-D is ineffective in Rh-D negative patients and relatively ineffective at standard doses in patients who have had a splenectomy. *Aims.* Previous theoretical cost-minimization models have demonstrated the cost-benefit of administering Anti-D rather than IGIV for the treatment of patients with ITP. Intramuscular administration of anti-D seems to offer the same efficacy as intravenous administration but with fewer side effects. Here we report our experience with intramuscular anti-D for patients with immune thrombocytopenia (ITP). *Methods.* The clinical study comprise a group of 7 patients, aged between 2 years and 4 months and 30 years(mean 11,8 diagnosed with immune thrombocytopenia: 2 with acute and 5 with chronic evolution. There have been included only RhD positive and HIV 1-2 negative patients, requiring treatment for clinical manifestations and/or platelet count under 30×10^9.The route of administration was intramuscular for 3 consecutive days at initial dose of 50 microg/kg. The platelet daily value was followed concomitant with the level of hemoglobin, billirubin, serum urea, hemoglobinuria and parameters of coagulation. *Results.* In 6 cases of the group(85,7%), anti-D immunoglobulin showed efficacy after 7 days of the first administration with an increase in platelet count greater than 40×10^9/L (extreme values: $53\text{-}214\times10^9$/L) in condition of decrease in hemoglobin level of maximum 4 g/l only in 1 patient.The response in 4 cases was good with the correction of symptoms during 10-14 days. In two cases, after thrombocyte count restoring, splenectomy was performed, with a complete response. The maintenance therapy consisted in repeated doses of anti-D immunoglobulin weekly at doses of 10-25 microg/kg and/or in condition of trombocyte count below 30×10^9/L. Pain at the injection site was common but self-limited with no effect on activity level. Headache was reported in 3 cases, digestive complains in 5 cases, mialgia in 3 cases and local allergic rash in one case.Severe side effects were not noted. Despite of the small number of patients the results are encouraging. *Conclusions.* The use of anti-D immunoglobulin showed benefits in symptoms control of ITP in adults and children. Anti-D therapy has been shown capable of delaying splenectomy in adult patients,

but does not significantly increase in total number of patients in complete remission. The low grade toxicity and 50-60% reduction of costs in comparison to IVIG recommends the anti-D therapy. The treatment of ITP patients with Anti-D seems to provide cost-savings compared to treatment with IVIG.

1958

EFFICACY AND SAFETY OF SUCCESSFUL TREATMENT IMMUNE THROMBOCYTOPENIC PURPURA (ITP) WITH THE THROMBOPOIETIN-MIMETIC ROMIPLOSTIM

M Mantzourani, A Katsandris, F Ntziora, J Tsifis, G Vaiopoulos, J Meletis

National and Kapodistrian University of Athens, Athens, Greece

Background. Immune thrombocytopenic purpura (ITP) is a relatively common autoimmune disorder characterized by the production of antibodies against circulating platelets. Symptoms can be mild, but several patients are in high risk for bleeding and require treatment. Glucocorticoids followed by spleenectomy had been the mainstays of therapy. Recent findings suggest that immune thrombocytopenic purpura (ITP) is not only due to increased platelet destruction by to anti-platelet antibodies but there is also defect in the production of platelets by megakaryocytes. Thrombopoietin (TPO) is the normal regulator of thrombopoiesis. Romiplostim is a second-generation thrombopoietic receptor agonist that exerts its therapeutic effect by stimulating megakaryopoiesis and thrombopoiesis. *Aim.* We studied the efficacy and the safety of treatment immune thrombocytopenic purpura (ITP) with the thrombopoietin-mimetic Romiplostim. *Patients and methods.* We describe 4 patients [median age 48 years (19-62)], 3 women (2 with splenectomy) and 1 man, with chronic immune thrombocytopenic purpura refractory to other therapies, including splenectomy that is in successfully managed with romiplostim. The median time of follow up is 60 months (108-36 months). The diagnosis in our patients relies on the exclusion of alternative disorders because no specific criteria establish the diagnosis of ITP. Additional laboratory tests provide no evidence of secondary thrombocytopenia, suggesting a diagnosis of ITP according the American Society of Hematology (1). For all patients first choice of therapy is the corticosteroid. The first patient, for relapse after splenctomy received corticosteroids with satisfactory results but the treatment stopped because of psychiatric side effects. Then, she received danazol, cyclophospamide and azathioprime with poor results. At last, for 5 months she was in therapy with intravenous immune globulins with satisfactory results. Finally, two years after splenctomy, the last 40 weeks, the patient is in a weekly therapy with romiplostim 4_g/kg. The second patient for relapse after splenctomy received Romiplostim in combination to cyclosporine for 10 weeks until now. Two others patients refused splenectomy, they had serious side effects for corticosteroid and received Romiplostim 1 μg/kg for the last 8 weeks. *Results.* Initially all patients received Romiplostim 1 μg/Kg subcutaneous but everyone need dose adjustments to maintain normal or satisfactory platelet counts. All patients have managed to maintain a platelet count of above 50×10^9/L with no severe adverse-events and with no hemorrhagic events. Regarding side effects the patients had mild headache with duration of 24 hours after the Romiplostim administration that receded with paracetamol. Romiplostim changed patient's life style improving the quality of their life, although it was not able to cure the disease. *Conclusion.* The thrombopoietin-receptor agonists, with their first representative Romiplostim, give a new prospect of treatment in chronic and refractory disease. Romiplostim is very effective, has a low number of side effects, excellent tolerance and improves quality of life. Although, it doesn't offer cure of the disease, it offers hope and safety for patients with chronic immune thrombocytopenic purpura.

1959

HEMATOLOGICAL FEATURES - AND PARTICULARLY PLATELET STATUS - IN PREECLAMPSIA

M Onisai,[1] AM Vladareanu,[1] H Bumbea,[1] S Radesi,[1] A Nicolescu,[1] I Voican,[1] A Vintilescu,[1] O Cazaceanu,[1] C Baluta,[1] A Ichim,[1] M Begu,[1] D Cisleanu,[1] M Gaman,[1] C Ciufu,[1] C Marinescu,[1] AM Neagu,[1] D Vasile,[1] L Barsan,[1] V Popov,[1] M Ciorascu,[2] A Filipescu,[2] O Rotaru,[2] C Andrei,[2] R Vladareanu[2]

[1]*Emergency University Hospital Bucharest - Carol Davila University, Bucharest, Romania;* [2]*Elias University Emergency Hospital, Obstetrics-Gynecology Department, Bucharest, Romania*

Background. The hematological picture of preeclampsia varies from normal laboratory tests to severe thrombocytopenia (due to the major role of platelets in pathophysiology, platelet activation and consumption), anemia, reactive leucocytosis/leucopenia. *Aims.* To study the hematological alterations of patients with preeclampsia, with a special accent on platelet function. *Methods.* Transversal study of 30 patients with preeclampsia, *vs.* 30 controls, from University Emergency Bucharest and Elias Hospitals, Romania. We studied clinical and laboratory parameters and platelet function was assessed via flowcytometry techniques - markers of activation (CD62P: P-selectin, CD63: granulophysin), aggregation (CD41/CD61), adhesion (CD42b/CD42a, CD31 - platelet endothelial cell adhesion molecule). *Results.* 25/30 patients (83.3%) had a severe form of preeclampsia; 17/30cases (56.6%) associated intrauterine growth restriction (IUGR). Two patients (6.7%) evolved to eclampsia; HELLP syndrome complicated 6/30cases (20.0%). In one case, therapeutic abortion was performed at 22weeks of gestation. All pregnancies ended with C-section (at 35.6weeks of pregnancy in medium). From 29 newborns (medium weight 2332 grams), 13 (44.8%) were prematures, 6 (20.7%) were small for gestation age; 2 premature newborns died after 48hours (pulmonary hemorrhage), respectively 2weeks (intraventricular hemorrhage, sepsis with Klebsiella). Regarding laboratory parameters, CBC revealed: medium-severe anemia in 9/30patients - 30.0% (5 having HELLP syndrome with hemolytic microangiopathic pattern), slight leucocytosis in patients (medium WBC 11318/mmc *vs.* 10578/mmc) and lower platelet count [181800/mmc - patients *vs.* 247172/mmc - controls (P=0.01)], with a significantly higher medium platelet volume in patients - 11.3fl *vs.* 8.7fl, P<<0.0001; 12/30 (40.0%) patients presented thrombocytopenia. Biochemistry showed only increased liver enzymes in patients: medium AST 312.1U/l *vs.* 20.5U/l; ALT 126.2 *vs.* 22.0U/l; LDH was also elevated (twice the normal value). Patients presented higher platelet activation status: medium CD62P expression 74.9% in patients with preeclampsia, *vs.* 15.9% - controls (P<<0.0001); CD63: 27.7% - patients *vs.* 8.4% - controls (P<<0.0001); CD31 was also significantly higher in patients with preeclampsia: 94.1% *vs.* 68.6% (P=0.0001). For adhesion and aggregation markers, the results were different - for CD42a and CD61: results are comparable [CD42a: 95.3% - patients and 90.8% - controls (P=0.05)], [CD61: 99.2% - patients and 98.6% - controls (P=0.14)]; for CD42b and CD41, medium values were higher in patients *vs.* controls: [CD42b: 93.2% - patients and 72.5% - controls (P<0.05)], [CD41: 82.9% - patients and 68.3% - controls (P=0.02)]. We also searched for significant correlations among studied parameters; we interestingly observed: negative correlation between platelet count and activation status expressed through CD62P (r=-0.657), positive correlation of systolic BP with activation marker CD62P (r=0.846) and with aggregation marker CD41 (r=0.648), and also a positive correlation between MPV and CD31 (r=0.637). *Conclusions.* preeclampsia is a severe pregnancy complication which may pose important consequences for mother and fetus - in our study: over 50% incidence of IUGR, 45% premature newborns, 6.7% newborn deaths. Laboratory picture of preeclampsia associates thrombocytopenia (which may become severe), but with younger, regenerative platelets present (higher MPV). Platelets of preeclamptic patients are significantly more activated and express a higher level of adhesion to the endothelium; the level of activation rises with the decrease of platelet count and with the increase of blood pressure.

1960

CHANGE IN CD4/CD8 RATIO AND ABSOLUTE NEUTROPHIL COUNT AFTER INTRAVENOUS IMMUNOGLOBULIN INFUSION IN PEDIATRIC PATIENTS WITH IMMUNE THROMBOCYTOPENIC PURPURA

S Ansari, A Kazemi, E Shahabi

Iran University, Tehran, Iran

Background. high doses of Intravenous immunoglobulin (IVIG) treatment of patients with autoimmune thrombocytopenic purpura influence lymphocyte number and function. In this study we assessed effect of Intravenous immunoglobulin treatment on neutrophil and lymphocyte count, CD4 /CD8 ratio in patients with ITP. *Materials and methods.* In this study, we analyzed blood sample in 32 patient with ITP before and 1h after completion of IVIG infusion. In all patients platelet, white blood cell and differential count performed before and after IVIG infusion. The following, lymphocyte phenotypic markers CD4 and CD8 lymphocytes were also examined. Statistical analysis was carried out using paired t-test. Correlation between age and total volume IVIG infused with variables analyzed with Pearson coefficient correlation. *Results.* Cellular blood count show significant decrease in leukocyte (P<0.001), neutrophil (P<0.001) and lymphocyte count (P<0.001) 1h

after IVIG infusion, but this changes was not significant in number of platelets (P=0.377). CD4/CD8 ratio increase significantly after IVIG infusion (P<0.001). percent of CD8 lymphocytes decrease significantly 1h after IVIG administration (P=0.001). absolute count of CD4 and CD8 lymphocytes significantly decrease after IVIG treatment. (P<0.001) *Discussion.* It seem that the IVIG decrease Absolute Neutrophil Count (ANC) after treatment and can be causes of decrease in lymphocytes number. Probably change in CD4 and CD8 lymphocytes dependent to time of sample collection after IVIG infusion.

1961

STUDY OF THE CHANGES OF COAGULATION FACTORS DURING PREGNANCY

S Patiakas,[1] K Rousos,[2] T Mylonas,[3] I Alexidis[3]

[1]General Hospital of kastoria, Thessaloniki, Greece; [2]Heaith Center of Alexandria-general hospital of Veria, Veria, Greece; [3]Microbiological Laboratory of General Hospital of kastoria, Kastoria, Greece

Background-Aim. To investigate the changes of the factors related to the coagulation mechanism during pregnancy and to estimate the magnitude of hypercoagulation that they cause. As it is already known, from the 2nd trimester onwards there is an increase of both fibrinogen and antithrombin III while fibrinolysis and protein C decrease and so does the number and efficacy of platelets due to the increase of prostacyclin. *Material-Methods.* In our study 72 parturients were included who, among other lab tests, were tested from the 2nd trimester of pregnancy onwards with complete blood count as well as tests related to blood coagulation including prothrombin time (PT), partial thromboplastin time (PTT) and also fibrinogen (FIB). *Results.* PT<12 sec was found in 34 women (47.2%), PTT>40 sec in 11 women (15.3%), while FIB>4 g/l was found in 63 women (87,5%) of whom 11 (15.3%) had FIB> 6 g/l. Lastly, in regard to platelets, in 12 cases (16.7%) a platelets number lower than 140,000 was found - this was certified by microscopy examination of peripheral blood films - and in almost all cases, a decrease was recorded in following check-ups as pregnancy progressed. *Conclusions.* Consequently, it is proven that in many cases (42.7%) PT decreases during pregnancy, while in fewer cases (15.3%) an increase of PTT is recorded. Also, in the vast majority of cases (87.5%), fibrinogen is increased - and in some of them significantly increased -, while often there is a low platelets number, that continues to decrease as pregnancy progresses. Therefore, there is a great need of conducting the tests necessary to evaluate the coagulation mechanism in every pregnant woman - the earlier the better - and particularly in high risk women.

1962

STUDY OF THE CHANGES IN FIBRINOGEN AND CRP LEVELS IN ACUTE MYOCARDIAL INFARCTION AND CHRONIC LUNG OBSTRUCTION

K Rousos,[1] P Patiakas,[2] C Charalampous[3]

[1]General hospital of Veria, Greece, Veria, Greece; [2]Microbiological Laboratory of General Hospital of kastoria, Kastoria, Greece; [3]Pathological Clinic of Psychiatric Hospital of Thessaloniki, Greece, Thessaloniki, Greece

Background-Aim. To describe the changes in fibrinogen and CRP levels in patients with acute myocardial infarction(AMI) and with exacerbation of chronic lung obstruction and to evaluate the changes in these two conditions, both in comparison with the normal ranges and between the two groups of patients. *Material-Methods.* We studied 42 patients with AMI (33 men and 9 women) and 31 patients with exacerbation of chronic lung obstruction (18 men and 13 women) who were admitted in the Cardiology and Internal Medicine Department.For fibrinogen level measurement a Multifibren U reactive of DATE BEHRING Company was used while CRP levels were measured with a biochemical analyzer. For statistic evaluation of the results we used the statistic system SPSS v 13. The normal range for fibrinogen was 150-450 mg/100 ml and for CRP < 0,5 mg/dL. *Results.* a) The fibrinogen levels in patients with AMI were lower than normal range in one patient (2,4%), within normal range in three patients (7,1%) and higher than normal range in 38 patients (90,5%). Regarding to fibrinogen levels in patients with exacerbation of chronic lung obstruction we didn't find any patient with levels lower than normal range (0%), one patient within normal range (3,2%) and 30 patients higher than normal range. b) Regarding with the CRP levels in patients with AMI, we didn't find any patient with levels lower than normal range (0%), 10 were within normal range (23,8%) and 32 higher than normal range (97,6%). In patients with exacerbation of chronic lung obstruction we found no patients with lower than normal CRP levels, 3 patients within normal range (9,7%) and 28 with higher than normal range levels (90,3%). The correlation between fibrinogen and CRP was 0,21 in the AMI group and 0,5 in the chronic lung obstruction group. The average for fibrinogen was 572 in the AMI group and 632 in the chronic lung obstruction group (P=0,2).The average for CRP was 7,65 in AMI group and 8,15 in the second group (P=0,12). *Conclusions.* In the chronic lung obstruction group the fibrinogen and CRP levels were higher than normal in 96,8% and 90,3% of the patients while in the AMI group the percentages were 90,5% and 76,25. The correlation between fibrinogen and CRP was 0,5% in the chronic lung obstruction group while in the AMI group is much lower than 0,21.

1963

THE ROLE OF MULTIDRUG RESISTANCE PROTEIN(MRP-1) IN PLATELET ACTIVATION WITH ALLERGIC ASTHMA

G Kanigur,[1] C Gurel,[1] M Saitoglu,[1] S Cinar,[2] U Ozbek,[1] G Deniz,[2] B Tutluoglu[3]

[1]Department of Medical Biology,Cerrahpasa Faculty of Medicine.Istanbul Universit, Istanbul, Turkey; [2]Immunology Institute for Experimental Medicine ,Istanbul University. Department, Istanbul, Turkey; [3]Department of Internal Medical Biology,Cerrahpasa Faculty of Medicine, Istanbul, Turkey

MRP-1 may play a role in the pathology of alergic asthma. It is known that LTC4 which is the substrat of MRP-1, activates the inflamation in asthma.However ,the role of MRP-1 in platelet activation and the platelet-leucocyte association still remain unclear. There fore, we planed to investigate the gene expression level of mRP-1 in leucocyte of adult subjects with allergic asthicmatic patients (26) and explore preliminarily in correlation between mRP-1 expression level and the platelet activation. Quantitative real time PCR studies have demonstrated that MRP-1 expression levels were increased in leucocytes ofmild persistant asthmatic patient which is compared to control. We also evaluated the existence of possible association through a flow cytometry analysing the platelet-leucocyte agregates considered as an effective method to define activated platelets. We found that the CD42b fluorescent percentage, has been found significantly higher in asthmatic patients which has high level of MRP-1 expresion than the control group. We found positive correlation between MRP-1 expression levels and platelet activation with severity of asthma.

1964

VARICONZOLE HAS NO EFFECT ON PLATELET FUNCTION

K Kaptan, C Beyan, A Ifran

Gulhane School of Medicine, Ankara, Turkey

Background. Voriconazole is a recent triazole with broad-spectrum antifungal activity against clinically significant and emerging pathogens. It is widely used for life-threatening opportunistic fungal infection. Despite an extensive safety database, we could not know whether it might produce functional influence on platelet response. *Aim.* In this study, the effect of voriconazole on platelet aggregation was investigated. *Methods.* Platelet function tests were performed in 16 healthy male volunteers. Three concentrations of voriconazole solution were prepared that would result in 1, 2, 4 and 8 μg/mL voriconazole concentrations in the blood similar to that observed after clinical therapeutic oral or intravenous application. Each concentration of voriconazole solution and a control diluent without voriconazole were incubated with whole blood at 370C. After incubation for 15 min, aggregation responses were evaluated with adenosine diphosphate (ADP) (5 μM) and collagen (2 μg/mL) in platelet-rich plasma. *Results.* When compared to control, preincubation with all dilutions of voriconazole have no effect on platelet aggregation response induced by ADP and collagen in a statistically significant manner (P>0.05 for all comparisons). Voriconazole showed also no effect on platelet aggregation in a dose-dependent manner. *Conclusion.* This study with an *in vitro* model showed that voriconazole administration in clinically therapeutic doses had no effect on platelet aggregation.

1965

BLEEDING AFTER CIRCUMCISION IN EGYPTIAN PATIENTS WITH HEMOPHILIA A: A FIVE YEAR PROSPECTIVE STUDY OF TWO PEDIATRIC HEMOPHILIA CENTERS

M Elalfy,[1] N Shaheen,[2] N Elbarbary,[1] K Eltonbary[1]

[1]Ain Shams University, Cairo, Egypt; [2]Student Insurance Hospital, Cairo, Egypt

Background. Circumcision is a risky practice for hemophilia A patients especially in the developing countries, due to Lack of adequate factor supply. *Aims.* To evaluate the incidence of bleeding after circumcision in Hemophilia A patients in spite of planned management and to report the deviation from that planned treatment. *Methods.* One hundred and sixty patients with hemophilia A aged 1 to 17 years (median = 8 years) who had performed circumcision in our center between 2004 and 2009 were followed up. The hospitalization was planned to be two-three days and factor replacement therapy seven to ten days. All were inhibitor negative before circumcision; inhibitor development among them was reported / 6 months. *Results.* Hemophilia A was mild in 32(20%), moderate in 32(20%), and severe in 96(60%). Median age for circumcision in the first child with no positive family history was 2 months while in subsequent siblings was 6 Years. Positive family history was recorded in 60%. Ten percent of children developed inhibitors (4% low titer and 6% high titer) 2-12 months following circumcision and were treated with low dose immuno-tolerence. Planned therapy included 40% cryoprecipitate, 60 % factor VIII plasma derived and 25% received tranexamic acid, while 100% of those > 1 year underwent circumcision under general anesthesia. A deviation from planned post operative replacement therapy was 20% prolonged and 10 % reduced while 10% had mild bleeding and only one patient developed uncontrolled bleeding and received VIIa 90 unite/kg 2 doses and was controlled .Wound re-suturing in 5 % , the stay in hospital was prolonged > 2 weeks in 2 patients. No deaths were reported during the study period. *Summary/Conclusions.* Most of circumcised hemophilia A were treated as planned with low incidence of mild bleeding. Ten percent developed FVIII inhibitors and VIIa was used only occasionally in uncontrolled bleeding.

1966

A SENSITIVE & SPECIFIC CHROMOGENIC ASSAY FOR THE DETECTION OF 'FUNCTIONAL FVIII INHIBITORS'

K Ghosh, P Lobo, S Shetty, B Kulkarni

National Institute of Immunohaematology, Mumbai, India

Upto 25-30% of severe Haemophilia A patients and ~5% of mild or moderate Haemophilia A patients develop alloantibodies or "FVIII inhibitors"against the infused FVIII. The Bethesda assay has been the classical laboratory assay for the quantitation of inhibitory antibodies to FVIII since first published by Kasper *et al.* in 1975. Various modifications and newer methods like ELISA with increased sensitivity and specificity for the detection of inhibitors have been reported. However, in spite of the increased sensitivity achieved, the quantitation of FVIII antibodies still involves important unresolved issues such as inter-assay variability, lack of appropriate standardization of the lower limit of inhibitor detection and the definition of a negative antibody titre, as well as interference by non-neutralizing antibodies. Hence, methods to detect very low-titre FVIII inhibitors on the rise or the detection of FVIII antibodies without interference from non-neutralizing antibodies (lupus anticoagulants and other interfering antibodies) are still being explored. We report here a sensitive and specific chromogenic assay using a Coamatic Factor VIII. (Chromogenix) using a substrate S-2765 which detects only the functional FVIII inhibitors. The colour is then read photometrically at 405 nm. We tested two inhibitor positive samples and the assay was found to be sensitive upto 0.1 Bu/mL of inhibitor levels which is much lower than that detected by the conventional Bethesda assay (0.5 Bu/mL). The total time required for the detection is 2.5 hours which is much less than that of Bethesda assay. Detection of very low titer of factor VIII much earlier has specific advantages in that the therapeutic management can be modified much earlier before it can be detected by the conventional Bethesda assay. This will have also its implications as a screening technique prior to surgery as in India there is a high prevalence of patients developing inhibitors following surgery.

1967

THROMBIN GENERATION AND OTHER COAGULATION MARKERS IN PATIENTS WITH LIVER CIRRHOSIS

E Papakonstantinou,[1] E Yfantis,[1] A Theofani,[1] P Georgoutsou,[1] A Lavda,[1] I Rapti,[2] E Dimou,[2] C Manti,[1] S Hadziyannis[2]

[1]Thriassion Hospital, Agia Paraskevi, Greece; [2]Henry Dunant Hospital, Athens, Greece

Background. The role played by coagulation defects in the occurrence of bleeding in cirrhosis is still unclear. Conventional coagulation tests (PT/INR and aPTT) seem unable to predict the severity of bleeding problems in patients with cirrhosis of the liver possibly because they do not adequately reflect the balance between procoagulant and anticoagulant clotting factors. Recently a test has become available to routinely measure the endogenous thrombin generation potential (ETP) by Dade Behring (Marburg, Germany). *Aim.* The comparison of ETP values and other coagulation markers between controls and patients with liver cirrhosis. *Methods.* 56 samples, of consecutive patients with histologically confirmed liver cirrhosis, and 30 samples of controls were investigated for PT/INR, fibrinogen, d-dimers and ETP parameters. We used the chromogenic method on the fully automated Behring Coagulation System (BCS) for the measurement of thrombin generation parameters. *Results.* 6 patients had alcoholic cirrhosis, 22 HCV, 5 PBC, 7HBV, 1HBV and HDV and 13 cirrhosis of unknown origin. Table. *Summary/Conclusions.* The automated ETP test can play an important role in the evaluation of haemostatic liver function in patients with cirrhosis. A potential clinical implication of these findings is that the laboratory investigation of the coagulation function, presently performed with the PT and APTT, may be inadequate to assess the true risk of bleeding when patients with cirrhosis undergo invasive procedures such as liver biopsy and transplant surgery. Perhaps the measurement of thrombin generation might be more suitable to evaluate the hemorrhagic risk. Although plausible, this hypothesis needs to be sustained clinically by a prospective study.

ACQUIRED COAGULOPATHIES: NINE CLINICAL CASES

T Seara Sevivas,[1] T Magalhaes Maia,[2] D Patricio,[3] E Gonçalves,[3] C Silva Pinto,[3] P Martinho,[3] T Fidalgo,[3] R Salvado,[3] N Martins,[3] ML Ribeiro[3]

[1]CHC, Coimbra, Portugal; [2]CHC - Hematology department, Coimbra, Portugal; [3]CHC - Hematology Department, Coimbra, Portugal

Introduction. Acquired coagulation factor inhibitors are circulating immunoglobulins that inhibit the procoagulant factor activity. Extremely rare, result from an immune impairment, and can be associated with different antibody types: auto, allo and xenoantibodies. Autoantibodies arise spontaneously in patients without prior coagulopathy and are associated with autoimmune diseases, cancer, infections, pregnancy, drugs and bone marrow transplantation. In many cases their aetiology is unknown, and their presence is frequently associated with catastrophic bleeding. The lupus-like anticoagulants are the most prevalent. The ones that cause more severe bleeding are directed to a specific factor (F), most frequently FVIII. Laboratory diagnosis is suspected by prolonged PT and/or aPTT and low circulating levels of a particular clotting fac-

tor, in a patient without prior bleeding history, and confirmed by titration of the inhibitor. The main therapeutic purposes are controlling the bleeding events, treating the cause and suppressing the antibody. *Main goal.* To describe 9 clinical cases of acquired coagulopathy (AC) in order to illustrate the importance of an early diagnosis and aetiological identification. *Clinical cases.* 9 patients with AC diagnosed in the CHC Hematology Department: 1 with anti-prothrombin antibodies; 2 with FV inhibitors; 3 with acquired FX deficiency; 1 with acquired von Willebrand disease and 2 with acquired A Hemophilia. Patients' median age was 68 years; 3 female and 6 male. Severity of bleeding: 3 major, 5 minor and 1 asymptomatic (diagnosed during a preoperative investigation of a prolonged aPTT). Bleeding events were treated with local haemostatic measures, antifibrinolytic and bypass agents, with efficacy in all cases, except for 1 in which bleeding was controlled, but, at day 12 of admission, the patient died with a Central Nervous System haemorrhage. It was only possible to determine the AC aetiology in 5/9 patients. In 1/9 the AC appeared during an infection and was associated with an anti-prothrombin lupic anticoagulant, which disappeared spontaneously with infection resolution. Three patients had conditions that have been linked to the emergence of AC: 1 amyloidosis, 1 Waldenstrom's macroglobulinemia and 1 antiphospholipid syndrome. The inhibitors disappeared after the underlying condition treatment. In 1 patient the AC was due to an acquired FX deficiency related with valproate. There was normalization of FX plasma levels after withdraw of the drug. *Conclusion.* 8/9 patients presented with bleeding. Laboratory screening for inhibitors was positive in 5/9, and negative in the acquired FX deficiencies (3) and vWF (1). Whenever was possible to treat/eliminate the AC aetiological agent (5), the specific F plasma levels normalized. An AC should be suspected in patients without prior hemorrhagic history presenting sudden haemorrhage and prolonged PT and/or aPTT. The search for inhibitors should be done immediately as well as an exhaustive search of an aetiological factor, because the rapid diagnosis is crucial for an early correct treatment.

1969

A SEMIQUANTITAIVE ASSAY FOR DIAGNOSIS OF FACTOR XIII DEFICIENCY

K Ghosh, S Shanbhag, S Shetty, B Kulkarni

National Institute of Immunohaematology, Mumbai, India

The most widely used test in routine haemostasis laboratories for factor XIII deficiency is the clot solubility test in which the plasma is clotted either with thrombin or Calcium chloride and resistance to lysis is observed either with urea or monochloro acetic acid. Though these methods are highly specific they can detect only severe factor XIII deficiency i.e upto <2 U ML -1 leaving mild to moderate factor XIII deficient cases undiagnosed. In the present study we have compared the sensitivity of different clot solubility tests in the diagnosis of factor XIII deficiency. We used both 0.025M CaCl2 and 10u/mL thrombin for forming the clot and used 5M Urea, 1% monochloroacetic acid and 2% acetic acid for dissolving the clot and the solubility was observed after 24 hours.It was observed that the combination of 1% monochloroacetic acid plus thrombin/CaCl2 and 5M urea plus thrombin/CaCl2 is specific for factor XIII deficiency but the detection limit was upto 1 U ml-1.The best combination was found to be2% acetic acid with 10u/mL thrombin where the detection limit was upto 12.5 U ml-1. We conclude that performing a two tube method i.e 5M Urea/1% monochloroacetic acid plus CaCl2 and 2% acetic acid plus 10U.ml thrombin we should be able to differentiate between mild and severe factor XIII deficiency which otherwise is not possible by the conventional assays presently being followed in all the laboratories. Using these two sets of reagents, we can detect factor XIII level in three ranges i.e <1%, 1-12.5% and >12.5%.

1970

A STABILITY MONITORING AND EASTBLISHMENT FOR FACTOR VIII: CONCENTRATE

JS Seo,[1] NR Lee,[1] HJ Oho,[2] JS Nam,[2] SH Hong,[1] SY Kang,[2] SJ Ban[1]

[1]*National Institute of Food and Drug Safety Evaluation, Seoul, South-Korea;* [2]*Korea Food and Drug Administration, Seoul, South-Korea*

Background. In therapeutic use, the dosage of Blood coagulation factor VIII product is determined depending on the concentrate in blood, and it is essential to measure the potency accurately. Establishment of standard is required for measuring the potency. The current Korean standard for Factor VIII Concentrate, established in 2001 for measuring the potency, showed decreasing trend according to 'Establishment of Quality Management System and Evaluation Techniques of Stability Testing for National Biological Standards' in 2008. A multicenter study was carried out to evaluate the suitability of a candidate as the 2nd Korean standard and the stability. *Aims.* It is to establish 2nd Korean standard and analyze the stability trend for contribute the globalization of quality control in blood coagulation factor VIII product by establishing the standard. *Method.* Before the study, the stability trend analysis of 1st Korean standard was All participants performed 24 independent assays with an exception of one laboratory performed 35 assays for clotting and 29 assays for chromogenic. Each participant was requested to perform both two assays; the clotting assay and the chromogenic assay. Each assay result was analyzed for its accuracy, precision, linearity and specificity. *Result.* The estimated geometric mean value of potency differed from each assay; 8.9 IU/vial in clotting assay and 7.4 IU/vial in chromogenic assay. Each assay method was used to measure each potency. *Summary/Conclusion.* Based on the result, the candidate standard is accepted as the 2nd Korean National Standard for factor VIII:C concentrate. In addition, a continuous monitoring of stability studies for the 1st and 2nd Korean standard is in progress.

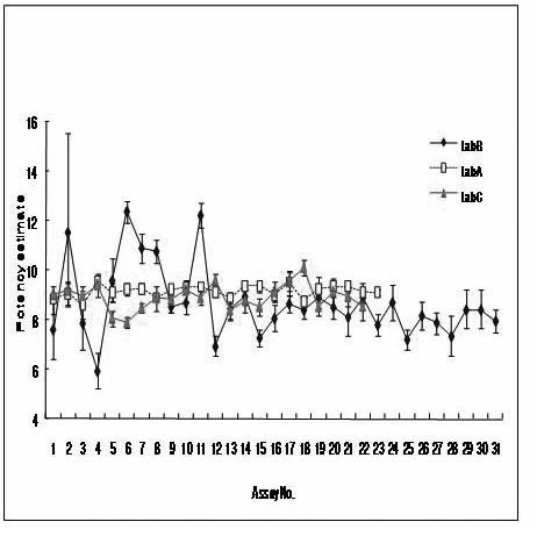

Figure 1. Distribution of potency using one-stage clotting assay.

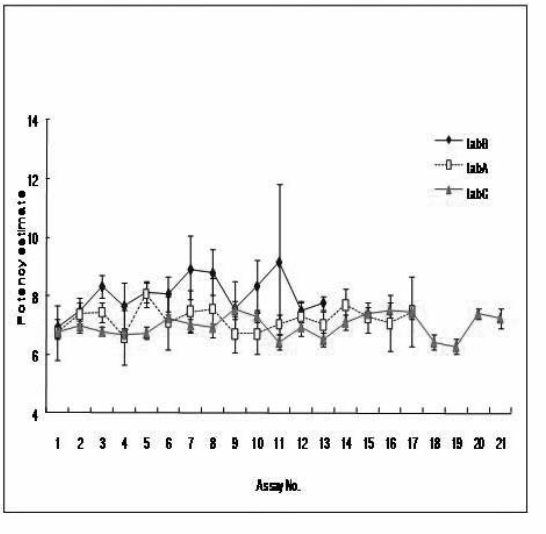

Figure 2. Distribution of potency using chromogenic assay.

SUCCESSFULL USE OF PROPHYLACTIC RECOMBINANT FACTOR VIIA IN A PATIENT WITH CONGENITAL FACTOR VII DEFICIENCY WITH INHIBITORY ANTIBODY

H Tokgöz, Ü Çaliskan

Selcuk University Meram Faculty of Medicine, Konya, Turkey

Background. Congenital factor VII (FVII) deficiency is a haematological disorder characterized by increased bleeding tendency in the affected patients. Bleeding episodes seen in these patients are treated with recombinant factor VIIa (rFVIIa). The inhibitory antibody formation could be seen in patients with severe FVII deficiency because of recurrent FVII replacement theraphies. A few publications have appeared on treatment of congenital FVII-deficient patients with inhibitory antibody until so far. *Case report.* The patient reported here is 3-month-old male patient. He was admitted to our clinic because of intracranial bleeding. FVII deficiency caused by a homozygous nonsense mutation (p.Ser112Stop (c.335C>G)) on FVII gene was detected (FVII:C %2). The patient exposed to recurrent bleeding attacks including epistaxis, intracranial, gastrointestinal, cutaneal and mucosal bleedings. rFVIIa was used succesfully during the bleeding episodes. When the patients was 1 year old, inhibitory antibody became positive (32 Bedhesda units). Althought the persistancy of inhibitory antibody to FVII, classical dose rFVIIa (20-40 mcg/kg/dose) was used effectively. Because of recurrent intracranial bleedings, the prophylactic rFVIIa (25 mcg/kg/dose, 3 dose weekly) were used. No serious bleeding episodes including intracranial bleeding were seen and the frequency of minor bleedings were appearently decreased within 12 months of prophylaxia. *Conclusion.* p.Ser112Stop (c.335C>G) mutation detected in our patient is known to cause severe FVII deficiency. Probably, the inhibitory antibody to FVII has occured because of recurrent rFVIIa replacement theraphy. However, it may be a non inhibitory antibody, because classical replacement dose of rFVIIa is effectively used for bleeding episodes. Althought the severe FVII deficiency and inhibitory antibody are present, prophylactic rFVIIa (25 mcg/kg/dose, 3 dose weekly) were used successfully. There are few data for prophylaxis in congenital FVII deficiency. The use of prophylactic rFVIIa may be effective in patient with FVII deficiency and inhibitory antibody.

1972

MOLECULAR PATHOLOGY OF HAEMOPHILIA A IN INDIAN PATIENTS

P Nair, S Shetty, K Ghosh

National Institute of Immunohaematology, Mumbai, India

Haemophilia A (HA), caused due to factor VIII deficiency, is an inherited X-linked disorder, affects in 1 in 5000 males crossing all economic, geographical and racial boundaries. The factor VIII gene is 186 Kb long having 26 exons and 25 introns. The mutations in the factor VIII gene are highly heterogeneous in nature and almost 1/3rd of the mutations can be *de novo*. Approximately 50% and 2-5% of severe haemophilia A patients are positive for the two recurrent mutations i.e intron 22 and 1 inversions respectively. We report herewith mutation analysis in 41 inversion negative HA cases (32 unrelated and 9 familial) by multiplex PCR and CSGE technique followed by sequencing to confirm the mutation. We had 10 severe (FVIII:C <1%), 14 moderate(F8 1-5%), 8 mild (F8 5-50%) cases. 12 missense, 7 deletions, 2 insertions, 1frame shift, 4 nonsense mutations, out of which 17 were recurrent mutations and 10 were novel. The novel substitution mutations were found to be deleterious using the different prediction softwares. We also encountered a double mutation (1 novel and 1 reported hot spot mutation) in a family with strong family history. A missense mutation in heterozygous state was also detected in a female bleeder (obligate carrier) with very low factor VIII levels, probably due to extreme lyonization. This study is significant as the current strategy of genetic diagnosis in HA families is to screen for intron 22 and 1 inversions and if they are negative proceed with the indirect method of gene tracking analysis using the different markers of factor VIII gene, wherein approximately 10% are found to be non-informative and there is a need for the index case and other family members. The outcome of this study would enable us to give an accurate diagnosis in all the affected families. The phenotypic, clinical and genotypic correlation will also be presented.

1973

SEVERE BLEEDING DUE TO ACQUIRED HYPOPROTHROMBINEMIA-LUPUS ANTICOAGULANT SYNDROME. CAS REPORT AND REVIEW OF LITERATURE

K Taouli

Université Abou Bekr Belkaid, Tlemcen, Algeria

Background. The presence of lupus anticoagulant is associated with an elevated risk of venous and arterial thrombosis, and recurrent miscarriages as well. The lupus anticoagulant is never accompanied by a hemorrhagic diathesis unless it is associated with a second coagulation abnormality such as thrombocytopenia or hypothrombinemia,[1] this disease can present with bleeding as a consequence of lupus anticoagulant hypothrombinemia(LAHPS). LAHPS is a rare disease. *Case report.* A 29 year-old Algerian was admitted to our departement with cerebral hemorrhagic syndrome due to a serious coagulopathy; prothrombin time(PT) INR was 1.53 and the activated partial thromboplastin time (aPTT) ratio 2.5, diluted Russell viper venom tests (dRVVT) and Staclot LA assay confirm the presence of LA, Thrombocytopenia was detected. Evaluation of the cloting factors revealed decreased levels of factors II (30%). Associated findings in this patient included positive immunologic tests for systemic lupus erythematosus, a positive IgG anti-beta(2)GPI antibodies. Therapy with prednisone was commenced and his bleeding ceased. *Discussion.* we discuss the pathogenesis, diagnosis and management of LAC-HPS in patients with SLE. Literature review revealed 3 other patients with LAHPS who developed thrombosis resulting from the treatment of factor II deficiency may promote thromboembolism.[2] *Conclusion.* the lupus anticoagulant is commonly encountered in the laboratory, but acquired hypoprothrombinemiae is extremely rare. The condition is reviewed and its treatment discussed. Attention is drawn to the difficulty in diagnosing this situation, and therapeutic options are reviewed.

ACUTE HEMORRHAGIC OEDEMA OF INFANCY: CASE REPORT

R Nofal,[1] M Badr,[1] T Hassan,[1] M Arafa,[2] M Talat[3]

[1]Zagazig University, Zagazig, Egypt; [2]Zagazig University Hospital Pediatric Department, ZAGAZIG, Egypt; [3]Zagazig university hospital pediatric department, Zagazig, Egypt

Acute hemorrhagic edema of infancy is a rare variety of cutaneous vasculitis presented in clinical triad of large bruise-like lesions, oedema and fever with mean age of affection 11 months. Pathophysiologically, it's a type of leukocytoclastic vasculitis probably mediated by immune complexes. IgA is observed in less than one third of skin biopsies of patients with AHEI. Spontaneous recovery is the rule. Possible complications are arthritis, nephritis, abdominal pain and gastrointestinal tract bleeding.

Figure. Cheeks lesions on second day of admission.

Our case is a female kid 20 months old who developed low grade fever for one day followed by purple non pruritic lesions on the cheeks and lower limbs, which became elevated, larger and tender on the following days with puffiness of the eye lids and painful mouth ulcers and bullae. There was no evidence of nephritis, arthritis nor gastrointestinal affection. She received a one week course of corticosteroids and completely resolved within two weeks with no skin scarring.

1975

CASE REPORT, CONTINUES LOW DOSES TREATMENT *VS.* ON DEMAND REGULAR DOSE TREATMENT IN CONGENITAL FVII DEFICIENCY, MORE EFFECTIVE, LESS EXPENSIVE?

Z Badiei,[1] H Farhangi[2]

[1]Mashhad university of medical sciences, Mashhad, Iran; [2]Mashhad University of Medical Sciences, Mashhad, Iran

Background & Aims. Congenital factor VII (FVII) deficiency is a consequence of a genetic polymorphism that can produce a wide spectrum of disease severity. Mildly affected patients may experience increased bleeding after surgery, trauma or mucosal bleeding, while spontaneous and life-threatening bleeding occurs in patients who are severely affected. The absence of a clear-cut and consistent correlation between bleeding symptoms and FVII clotting levels is one of the main clinical features of congenital FVII deficiency. Replacement therapy is the mainstay of treatment for patients with FVII deficiency. This has traditionally been achieved using fresh frozen plasma (FFP), prothrombin complex concentrates (PCCs), or plasma-derived FVII concentrates. Recombinant activated FVII (rFVIIa) (Novo seven 1.2 mg per 2.2 mL; Novo Nordisk, Copenhagen, Denmark) is now widely used for therapy in these patients, but therapeutic schedules, optimal dosages, and administration times still have to be precisely defined. In general the recommended dose of 15-30 μg/Kg every 4-6 h, appears to be effective in maintaining homeostasis during bleeding episodes or surgery. Unlike the hemophiliacs, prophylaxis is not a common praxis in FVII-deficient patients. However, preliminary reports suggest that prophylaxis may also be effective in scenarios such as menorrhagia with iron deficiency and in patients with recurrent haemarthrosis. *Methods & Results.* We introduce a 16 y girl (BW= 40 kg) who was investigated due to menorrhagia (it was begin from first menstrual cycle in age 11 y) and found to be a case of congenital FVII deficiency (FVII:C = 3.5%).she is Moslem and because of every day bleeding she wasn't able to pray during last 4 months and also had iron deficiency anemia. First it was recommended to use rFVIIa 30 μg/kg* q12h×2day and then 30 μg/Kg/ d×5 day in each menstrual cycle. Her daily bleedings stopped and menstrual cycles became regular but between cycles she had spotting with no response to tranexamic acid. So, she was advised to use a single dose, 30 μg/kg = 1.2 mg, rFVIIa per week. With this protocol spotting stopped completely. At this time with using only two injections of rFVIIa (1.2 mg/q 12h) in the first day of menstrual cycle and weekly injections of rFVIIa (1.2 mg/w) she experiences a normal life style without any bleeding. With using the recommended dose of 15-30 μg/kg rFVIIa every 4-6 h, she must use 4-6 vials 1.2 mg of rFVIIa per day in first days of each menstrual cycle, while she only uses 5 vial 1.2 mg per month. *Conclusions.* It seems that for some patients, continues low doses treatment may be more effective and much cost benefit than recommended doses and also with decreasing the number of injections it can increase the quality of life. *According to her body weight, for prevention of waste and using the total amount of drug in a vial, it is the least dose which she can use.

1976

HEMATURIA IN A YOUNG PATIENT WITH SEVERE HEMOPHILIA AND INHIBITOR PRESENCE RECEIVING PROPHYLACTIC TREATMENT WITH RECOMBINANT FACTOR VIIA: CASE REPORT

M Economou, E Papadopoulou, N Gompakis, M Athanassiou-Metaxa

Hippokration General Hospital, Thessaloniki, Greece

Hemophilia A is an X-linked congenital bleeding disorder resulting from a deficiency of factor VIII (FVIII). Therapy is based on the replacement of FVIII to hemostatically adequate levels for the prevention or treatment of bleedings. Patients with severe hemophilia are at risk for developing inhibitors to FVIII, the incidence of which is reported to be as high as 50% in patients with severe hemophilia. In such cases, agents that bypass the endogenous pathway of coagulation cascade are required. Most commonly used bypassing agents are recombinant factor VIIa (rFVIIa) and activated prothrombin complex concentrates, such as factor eight inhibitor bypassing activity (FEIBA®). Both agents can be used not only to control bleeding episodes but also as prophylaxis, in order to prevent or reduce joints bleeds and lower the risk of arthropathy in haemophiliac patients with inhibitors. The present case report concerns a 14-year old boy with severe hemophilia A and high titre inhibitor presence, who demonstrated two episodes of hematuria shortly after initiation of prophylactic treatment with rFVIIa (90μg kg-1 daily). During the first episode he presented with macroscopic hematuria, lumbar back pain and vomiting. Laboratory examination demonstrated the presence of urinary tract infection while kidney function tests and renal ultrasound were normal. The episode resolved with antibiotic treatment, hydration and decubitus, and rFVIIa prophylaxis was restarted. Three months later the patient developed a second episode of macroscopic hematuria. This time no apparent cause could be identified. The patient was managed successfully with hydration and decubitus; however, following the episode, rFVIIa treatment was discontinued and the patient was put on FEIBA prophylaxis (100U kg-1 three times weekly). He has been well and free of hematuria for over a year. rFVIIa has repeatedly and successfully been used in both congenital and acquired hemophilia for the management of bleeding episodes, including episodes hematuria. This is the first case of a hemophilia patient to be reported to present with haematuria while receiving intermittent doses of rFVIIa. Two cases previously described concerned adult patients receiving rFVIIa as a continuous infusion in order to treat bleeing from other sites. The authors suggested that mucosal bleeds, such as haematuria, are characterized by high fibrinolytic activity locally and may require higher peak levels of rFVIIa to generate sufficient thrombin in order to achieve and sustain hemostasis. One could, additionally, take into account the different pharmacokinetics of rFVIIa in the paediatric and adult population. Controlled studies are needed to determine the frequency of secondary mucosal bleedings in patients with hemophilia and inhibitors treated with rFVIIa and the optimal dose of rFVIIa, both in children and adults.

1977

RECOMBINANT FACTOR VIIA AND ACTIVATED PROTHROMBIN COMPLEX CONCENTRATE GIVEN AS SEQUENTIAL THERAPY TO A PATIENT WITH SEVERE HAEMOPHILIA A AND INHIBITOR DEVELOPMENT PRESENTING WITH A LIFE THREATENING HEMORRHAGE

M Economou, D Tzavella, P Dragoumi, I Tsatra, G Tsikopoulos, C Stefanidis, N Gompakis, M Athanassiou-Metaxa

Hippokration General Hospital, Thessaloniki, Greece

Patients with haemophilia A are at risk for developing inhibitors which render conventional factor replacement therapy ineffective. In such cases, bypassing the inhibitor is required to achieve haemostasis. Both activated prothrombin complex concentrates (aPCC) and recombinant factor VIIa (rVIIa) have demonstrated efficacy in treating bleeds in patients with inhibitor presence. However, clinical response may be variable between patients or between bleeding episodes and, in some cases, either therapeutic intervention may fail. Sequential use of multiple bypassing agents has been shown *in vitro* to provide a mechanism to increase efficacy but has not met with wide clinical use because of concern regarding the possibility of thrombosis. The present case report concerns a 16year old boy with severe haemophilia A, haemophilic arthropathy and inhibitor presence who was admitted to the paediatric surgery department for central venous catheter insertion in order to undergo immune tolerance induction. Despite prophylactic intravenous treatment with 90 mcg/kg of rVIIa given every 2 hours and 1g of tranexamic acid given every 8 hours, the patient developed a huge neck hematoma on the second post-operative day. Within a few hours the patient developed severe dyspnoea and had to be incubated and transferred to the intensive care unit. Due to refractory bleeding, a combined bypassing agent therapy was decided. The initial regimen consisted of 3 doses of rVIIa (90 mcg/kg) given every 2 hours followed by 1 dose of FEIBA (50 U/kg). FEIBA is the only aPCC presently on the market. Sequential therapy was administered with careful monitoring of the patient's clinical condition and frequent laboratory screening, evaluating the platelet count, fibrinogen and D-dimers to assess for thrombosis and DIC. The treatment regiment proved both effective and safe for the young patient, as the bleed was finally controlled while no systemic reaction or thrombogenicity was noted. Intensive therapy was weaned by reducing the number of rFVIIa and aPCC doses as the patient demonstrated clinical and laboratory improvement. Even a simple surgical procedure, as a central catheter insertion, can prove to be life-threatening for patients with hemophilia who have developed inhibitors. Sequential treatment with aPCC and rFVIIa can be used to

treat bleeds in patients failing monotherapy, however, with some concern. Large controlled studies are still needed to confirm efficacy and safety of this therapeutic approach, as well as to determine the best treatment regimens.

1978

THE CONTRIBUTION OF THE BALANCE OF HEMOSTASIS IN MONITORING THE PREGNANCY

Y Ouarhlent,[1] Z Kellali,[2] M Boutakakine,[2] N Grainat[2]

[1]Haematology Service, CHU BATNA ALGERIA, Faculty of Medicine BATNA, Batna, Algeria; [2]CHU of Batna, Batna, Algeria

Introduction. Pregnancy is a physiological condition which has many biological changes. The most significant are observed in the blood count and coagulation parameters disorders of hemostasis is a major cause of morbidity and maternal mortality. *Aim.* assess the impact of these disorders, etiologies and to propose a monitoring of pregnancies and support its rapid hemostasis disorders. *Materials and methods.* This is a retrospective study over a period of 5 years (2001-2006) including all patients admitted for disorders of hemostasis in peripartum reanimation medicale, CHU BATNA ,46 patients were recruited; the inclusion criteria: the parturients presented with a disorder of hemostasis during pregnancy, any woman with a disorder of haemostasis prior to pregnancy is excludedAll patients had received blood count with a platelet fibrinogen, prothrombin time (PT kaolin partial thromboplastin time (TCK)in case of pathological results, we proceeded to assay D-dimer and the degradation products of fibrinogen (PDF). *Results.* The average patient age was 22years, with a predominance of primipares74%, 80% of these pregnancies are not followed The majority of our patients who delivered vaginally. The etiologies were dominated by: *HELLP syndrome in primipares 85%. *The post partum haemorrhage among big multiparous). 15%. Overall mortality was 20%, Linked to delay care, not followed obstetrical. In our series there was a high prevalence of eclampsia occurring in young pregnant women not followed. The existence of disorders of hemostasis during eclampsia is a prognostic factor in imposing their diagnosis by a systematic review and the immediate interruption of pregnancy. *Conclusion.* The balance of hemostasis is not indicated routinely. Each patient should examined clinical ly oriented research evidence suggestive of a disorder of hemostasis. In case of suspicion of an anomalyan assessment of hemostasis will be charged (platelet count, platelet function, quick, INR, APTT, fibrinogen). We will deepen the exploration results in pathological cases. Monitoring of pregnancies and support its rapid hemostasis disorders will reduce morbidity and maternal mortality.

1979

THE PREVALENCE OF THE MOST COMMON CAUSES FOR PRIMARY THROMBOPHILIA AMONG SAUDI PATIENTS ATTENDING THE ANTICOAGULANT CLINIC

S Al Jaouni

King Abdul Aziz University Hospital, Jeddah, Saudi Arabia

Objectives. The purpose of our study was to determine whether the activated protein C resistance (APC resistance) Factor V Leiden, and Prothrombin Mutation as being the most common inherited risk factor for venous thrombosis among Saudi patients attending an anticoagulant clinic. *Methods.* The study describes the results of screening all patients attending our anticoagulant clinic with a history of proven recurrent venous thromboembolism (VTE), pulmonary embolism, the first spontaneous life threatening thrombosis or at an unusual site, and patients with unexplained repeated abortion. The test done were Antithrombin (AT), Protein C (PC), Protein S and activated Protein C resistance (APC). Molecular testing to detect the mutation of factor V Leiden (FVL) and Prothrombin G20210A and MTHFR C677T mutation. A total of 3,875 patients were referred . 580 patients have been fulfilled the criteria of the study, between October 1998 to November 2008, age (14-51 years old) and 9 patients were neonates. This study was conducted at King Abdul Aziz University Hospital, Jeddah, Kingdom of Saudi Arabia. *Results.* Summarize in the Table. *Conclusion.* Factor V Leiden is the most common cause of inherited thrombosis among Saudi patients followed by Protein S. Homozygous Protein S & C deficiencies are a serious cause of extensive thrombosis with high mortality during neonatal period, an affected neonate is a marker for a group at a high genetic risk. High prevalence MTHFR mutation among repeated abortion which need a further clinical studies.

Table. Summarize the causes of inherited thrombosis.

Table: Summarize the causes of inherited thrombosis among Saudi population in Jeddah, with DVT/PE and recurrent abortion.

Tests	Total Positive	Neonate	DVT/PE	Recurrent Abortion
Factor V leiden	117	0	100	17
Protein S	68	5	58	5
Protein C	31	4	25	2
AT	0	0	0	0
Prothrombin G20210A	5	0	5	0
MTHFR C677T	210	0	30*	180
Undiagnosed	48	0	48	0
Others	101**	0	101	0
Total	580	9	367	204

*Associated with heterozygous FVL or protein S deficiency. **associated with malignancy, SCA, renal disease, infection and intensive patients

HYPERCOAGULABILITY IN BETA-THALASSEMIA AND SICKLE CELL DISEASE

K Thisiadou, K Chalvatzi, S Arampatzi, S Spiroglou, C Kanonidou, D Lazaridou, A Nikolaidou, O Fotakeli, E Diza

Ahepa University Hospital, Thessaloniki, Greece

Background. Thalassemia and sickle cell disease (SCD) represent the most common forms of hereditary hemolytic anemia and result from a partial or complete lack of synthesis of one of the major β- or β-globin chains of hemoglobin A or from a single amino acid mutation (b6Glu fi Val) of the β-globin chain, respectively. Although they have different pathophysiologies, patients with these conditions manifest both biochemical and clinical evidence of hypercoagulability. While the frequency of various thrombotic complications may vary in β-thalassemia and homozygous SCD (sickle cell anemia-SCA), patients with both diseases manifest decreased levels of natural anticoagulant proteins, as well as increased levels of D-dimer (fibrinolysis). *Aim.* The aim of this study was to determine % activity of natural anticoagulant proteins, and plasma levels of fibrinogen and D-dimer in patients with β- thalassemia major ,β-thalassemia intermedia and sickle cell anemia. *Methods.* We evaluated in 59 patients (mean age 54.9±16.6 years, 33 with β- thalassemia major, 8 with β-thalassemia intermedia and 18 with sickle cell anemia) the % activity of protein C (PC-chromogenic method), free protein S (free PS-immunoassay), antithrombin III (AT III-chromogenic method) as well as plasma levels of fibrinogen (Fib-Clauss method) and D-dimer (D-D-turbidimetric immunoassay). A control group of 30 age-matched healthy subjects were studied simultaneously. Results were statistically analysed using Student's t test.

Table 1. Activity of PC, free-PS, AT III and plasma levels of Fib and D-D in patients with β- thalassemia major, β-thalassemia intermedia, sickle cell anemia and healthy subjects.
***(p<0,05).**

Group	N	PC %	Free-PS %	AT III %	Fibrinogen (mg/dl)	D-dimer (ng/ml)
β-thalassemia major	33	*66,84± 20,91	*66,87± 17,40	97,07± 24,98	278,18 ± 70,18	*327,35 ± 377
β-thalassemia intermedia	8	*65,87± 22,38	*60,87± 7,19	*91,75 ± 21,26	245,62 ± 46,40	*282,12± 281,59
sickle cell anemia.	18	95,22± 37,66	*74,33± 23,80	103,11± 12,81	342,94± 91,52	*653,50± 600,19

Results. The results are presented in Table 1. Between patients with β-thalassemia major, β-thalassemia intermedia and healthy control group there was significant difference in % activity of PC and free-PS (P<0,05). In patients with β-thalassemia intermedia activity of AT III was significantly lower (P<0,05) compared to the healthy group. In sickle cell anemia only free-PS % activity was significantly lower (P<0,05) compared to the healthy group. Plasma levels of D-D were significantly higher (P<0,05) in all patients while plasma levels of Fib didn't present significant difference compared to the healthy control group. *Summary/Conclusions.* 1. Patients with β-thalassemia major, β-thalassemia intermedia and sickle cell anemia present low activity of natural coagulation inhibitors such as protein C, free protein S and antithrombin III. 2. Patients with β-thalassemia major, β-thalassemia intermedia and sickle cell anemia present high plasma levels of D-dimer (D-D), evidence of increased fibrinolysis. 3. In β-thalassemia and homozygous SCD [sickle cell anaemia (SCA)], patients manifest decreased levels of natural anticoagulant proteins, as well as increased levels of D-dimer, evidence of hypercoagulability.

1981

CHANGES IN PLASMA LEVEL OF ENDOTHELIAL PROGENITOR CELLS IN PATIENTS WITH STABLE CORONARY ARTERY DISEASE WITH AND WITHOUT DIABETES MELLITUS TYPE II CORRELATE WITH DRUGS

E Bossinakou, G Bossinakos, G Roulia, A Kampoli, A Vlachopoulou, M Malliotakis, E Andronopoulou, D Tousoulis, E Bossinakou

Hippocratio Hospital, Athens, Greece

Objective. Endothelial progenitor cells (EPCs) originating from the bone marrow play a significant role in neovascularization of ischemic tissues and in re-endothelialization of injured blood vessels. The number of EPCs decreases in patients with coronary artery disease and diabetes mellitus. The aim of this study was to investigate if the administration of medication such as statins and especially rosuvastatin, and thiazolidinediones, especially pioglitazone, in patients with stable coronary artery disease with and without diabetes mellitus type II, can modify the number of endothelial progenitor cells in peripheral blood. *Method.* Eleven patients with angiographically documented coronary artery disease were recruited. Seven patients with stable coronary artery disease without diabetes mellitus and four patients with stable coronary artery disease and diabetes mellitus (defined as the need for oral antidiabetic drug treatment or insulin use). Blood for EPCs was drawn for first time on admission (baseline). In the first group of patients, was administrated rosuvastatin for a period of one month. After one month of drug's administration, blood for EPCs was drawn again. In the second group of patients, was administrated pioglitazone for one month. After one month of drug's administration blood for EPCs was drawn again. Circulating EPCs were defined by the surface markers $CD34^+$ (CD34 expressing cells) and analyzed by flow cytometry. *Results.* The endothelial progenitor cells which were enumerated by flow cytometry, were the human CD34 expressing cells. In the group of patients with stable coronary artery disease without diabetes mellitus, were observed modification of the number on the order of 0,67 ×/mL (from 2,07×/mL to 2,74 x/mL). In the group of patients with stable coronary artery disease and diabetes mellitus, were observed modification on the order of 0,89 ×/mL (from 2,1 ×/mL to 2,99 ×/mL). *Conclusion.* The results of the study demonstrate augmentation of endothelial progenitor cells after drug's administration.

1982

ROSIGLITAZONE AMELIORATES ENDOTHELIAL DYSFUNCTION AND REDUCES LDL OXIDATION POSTPRANDIALLY IN PATIENTS WITH DIABETES MELLITUS

M El -Ali, T Theodoridis, S Glytsou, S Pastromas, S Koulouris, A Karyda, A Manolis, V Christopoulou-Cokkinou

Eyangelismos General Hospital, Athens, Greece

Purpose. Postprandial lipemia is a well known atherogenic factor especially in patients with diabetes mellitus (DM). The exact mechanism, however, remains unclear. Thiazolidinediones are known antidiabetic drugs with favorable pleotropic metabolic effects. The aim of this study was to evaluate the effect of rosiglitazone, a peroxisome proliferator-activated receptor-γ (PPAR-γ) agonist, in postprandial endothelial function and LDL oxidation in this patient population. *Materials-Methods.* We randomized 50 patients (23 males) 61±9 years old, with adequately controlled type 2 diabetes (HbA1c < 7%) on sulfonylureas or metformin, without clinical signs of cardiovascular disease and with a negative stress test, in two groups. Patients in Group A (n=25) were started on rosiglitazone in addition to their standard regimen at a dose of 4 mg / day, while patients in Group B (n=25) received placebo instead. Lipid profile was acquired before and 4 hours after ingestion of an oral fat load (35 % weight/volume fat emulsion at a dose of 50 gr fat/m2 body surface). Endothelial function was estimated at the same time by ultrasound measurement of brachial artery flow mediated dilation (FMD). The same measurements were repeated after 12 weeks of treatment. Oxidized LDL (oxLDL) levels were assessed at the same time intervals with a commercialy available ELISA kit. *Results.* Triglyceride concentration was found consistently elevated and LDL cholesterol was consistently decreased postprandially in both groups at the baseline state and at the follow up (P<0.05). However, these differences were not significant between the two groups. On the other hand, the postprandial FMD drop was abolished only in Group A after 3 months of the rosiglitazone intake (P<0.05 for comparison between the 2 groups). A non significant postprandial increase of oxLDL levels was noted in both groups at the baseline. However, oxLDL was decreased significantly after the fat intake only in the rosiglitazone group in the follow up (P<0.05 for comparison between the 2 groups). *Conclusions.* Rosiglitazone seems to have a beneficial effect upon the endothelial function and the oxidation of LDL in the postprandial state in patients with DM. Our findings may further support the theory about the pleotropic antiatherogenic effects of thiazolidinediones.

1983

THE IMPACT OF THE G58A POLYMORPHISM ON FIBRINOGEN A-CHAIN GENE ON FACTORS V, X AND THROMBIN IN PATIENTS WITH ADVANCED ATHEROSCLEROSIS

Z Pallantza,[1] M Kozanitou,[2] N Papageorgiou,[2] A Vlachopoulou,[2] M Tsekoura,[2] H Kontou,[2] A Karaferi,[2] D Tousoulis,[2] E Bossinakou[2]

[1]Hippokration Hospital,Athens,Greece, Athens, Greece; [2]Hippokration Hospital, Athens, Greece

Background. The G58A polymorphism on fibrinogen a-chain gene has been associated with increased fibrinogen levels in healthy individuals, but its effect on patients with coronary artery disease (CAD) regarding to the effects on thrombosis/coagulation is still unknown. In the present study we examined the impact of this polymorphism on factor V (fV), factor X (fX) and thrombin time in patients with CAD. *Methods.* The study population consisted of 395 subjects, 246 of which angiographically documented for CAD. The G58A polymorphism was detected by polymerase chain reaction (PCR) and appropriate restriction enzymes. Factor X, f(V) and thrombin time were measured by standard coagulometry techniques. *Results.* The genotype distribution was GG: 37.8%, GA: 39.4% and AA: 22.8% for patients with CAD, while GG: 33.5%, GA: 44.3% and AA: 22.2% for controls. There was a significant difference in thrombin time (sec) for CAD patients *vs.* controls (19.7±4.8 *vs.* 18.9±2.1, P<0.05), while this difference did not persist for 455G carriers *vs.* 455AA homozygotes in CAD (19.3±2.1 *vs.* 19.5±2.4, P=NS) and controls (18.9±2.0 *vs.* 18.8±2.5). In addition, fV (%) was significantly higher in CAD patients than controls (121.7±28.4 *vs.* 108.01±23.7, P=0.0011), while no difference was observed for 58G carriers *vs.* 58AA homozygotes both in CAD patients (125.3±27.7 *vs.* 126.5±30.3, P=NS) and controls (106.2±22.7 *vs.* 119.2±30.8, P=NS). Finally, no significant difference was observed in fX (%) for CAD *vs.* controls (94.0±35.4 *vs.* 91.9±14.2, P=NS), as well as 58G carriers *vs.* 58AA homozygotes in CAD (94.6±22.1 *vs.* 96.1±21.5, P=NS) and controls respectively (92.1±13.5 *vs.* 98.2±6.7, P=NS). *Conclusions.* Our findings suggest that the G58A polymorphism on fibrinogen a-chain gene does not affect significantly coagulation markers such as factors V, X and thrombin time.

1984

THE CHANGES OF FIBRINOLYSIS IN DIABETES MELLITUS TYPE 2

J Stasko, P Kubisz, P Chudy, D Kotulicova, D Mistuna

Jessenius Faculty of Medicine, Comenius University, Martin, Slovakia

Background/Aims. The aim of the study was to investigate the relations among fibrinolysis, activation of coagulation, glycemic control, hypertension, BMI and medication in DM 2 patients with normo- and microalbuminuria. *Methods.* Forty-two normoalbuminuric (NAU), 42 microalbuminuric (MAU) DM type 2 patients and 42 blood donors as control group were enrolled. All patients agreed to participate in the study and signed a written informed consent. Thrombin-activatable fibrinolysis inhibitor (TAFI), plasminogen activator inhibitor 1 (PAI-1), tissue plasminogen activator (t-PA) and prothrombin fragments 1+2

(F1+2) were assessed by ELISA in all subjects. *Results.* TAFI was significantly increased in the MAU group, PAI-1 and F1+2 were significantly increased in both groups, but t-PA wasn't elevated in either group compared to controls. There were positive correlations in the NAU: TAFI and fibrinogen (r=0.65, P=0.02), PAI-1 and triglycerides (r=0.67, P=0.01), in the MAU: TAFI and F1+2 (r=0.48, P=0.02), TAFI and systolic blood pressure (r=0.53, P=0.01), PAI-1 and BMI (r=0.43, P<0.05). *Summary/Conclusions.* We found decreased fibrinolysis in DM type 2 presenting with increased PAI-1 in both NAU and MAU as well as the increased TAFI in MAU. ACE inhibitors, statins and oral antidiabetics (OADs) led to increased t-PA, while beta blockers had TAFI-lowering effect. OADs improve hypofibrinolytic state in DM type 2 by lowering both TAFI and PAI-1. We confirmed the hypercoagulable state in patients with DM type 2 by higher F1+2.

This work was supported by grant VEGA 1/0018/10.

CLINICAL MANIFESTATION OF ANTIPHOSPHOLIPID ANTIBODIES

V Elezovic,[1] P Miljic,[1] D Antic,[2] L Stojanovic,[3] O Markovic,[4] V Djordjevic,[5] M Kovac[6]

[1]Institute of Haematology CCS, Faculty of Medicine University of Belgrade, Belgrade, Serbia; [2]Institute of Haematology Clinical Center of Serbia, Belgrade, Serbia; [3]Clinical Hospital Center Bezanijska Kosa,, Belgrade, Serbia; [4]Clinical Hospital Center Bezanijska Kosa, Belgrade, Serbia; [5]Institute of Molecular Genetics and Genetic Engineering, Belgrade, Serbia; [6]Institute of Blood Transfusion, Belgrade, Serbia

Most of the patients with thrombosis and miscarriages have any recognizable haemostatic disorders as acquired antiphospholipid antibodies, or hereditary hypercoagulable state, or both of them. The aim of this study is to investigate incidence, localization and trigger mechanisms of thrombosis, rethrombosis, miscarriages, and management of patients with antiphospholipid antibodies. Antiphospholipid antibodies (APA) were detected in 196 patients (117 female, 97 male), with median age of 34 years at first event. Lupus anticoagulant (LA) was detected in 160 patients, anticardiolipin antibodies (ACA) in 80, beta2 glycoprotein I (b2GPI) in 28, VDRL in 12. Seventeen patients had combine LA and ACA, and 5 had LA, ACA and b2GPI. LA was negative in 11/196 (5.6%) patients. Sixty nine of 196 patients (35%) have APA associated with hereditary thrombophilias: 52 with MTHFR, 17 with APCR (FV Leiden), per 5 with prothrombin 20210 and deficience of FXII, and 14 of them (20%) have two hereditary thrombophilias. Our group consisted of highly selected patients: 115 (58%) with 245 thromboses (average 2.1), 51 women (43.6%) with 141 miscarriages (average 2.8), 53 patients (27%) with thrombocytopenia, and 26 of them without thrombosis or miscarriages, and 12 without symptoms (6%). Our patients developed first thrombosis at the median age of 39, and first miscarriage at 31 years. Patients with isolated APA (64/127) developed first thrombosis at the median age of 40 years. They had 136 thrombotic events at presentation (average 2.1) with 10.3% of arterial thrombosis (2 TIA, 6 stroke, 3 myocardial infarction, 2 infarction of spleen, 1 peripheral artery). Thirty six of 82 women had 103 miscarriages (average 2.9) with median age of 31 years at first miscarriage. Patients with APA and hereditary thrombophilias (51/69) developed first thrombosis at median age of 36 years, with 109 thrombotic events (average 2.1) and 16.5% of arterial thrombosis (3 TIA, 8 stroke, 2 myocardial infarction, 5 peripheral artery) at presentation. Fifteen of 33 women had 38 miscarriages (average 2.5) at median age of 28. Recurrent thrombosis occurred in 70/115 patients (61%) and 52.9% of them had 3 or more thrombosis when antiphospholipid syndrome (APS) was established. Most of patients developed venous thrombosis of leg (53.5%), arms (6.5%), pulmonary embolisms (18.4%), abdominal veins (2%), arterial thrombosis (13%) and others (6.6%). Thrombosis at 24 patients was associated with surgery, trauma or immobilization (11), pregnancy or delivery (5), infections (3), malignancy (2), smoke (2), and oral contraceptives (1). When diagnosis of APS was established, patients with two or more venous thromboembolisims were treated with long-term anticoagulant therapy without recurrent thrombosis. Patients with arterial thrombosis were treated with low doses of aspirin. When diagnosis of APS was established, 15 women (29.4%) with 22 miscarriages has been treated with LMWH during pregnancy, delivery and postpartum, and one with HD of IV IgG. All of them had successfully delivered 17 times. In conclusion, prophylactic long-term anticoagulant therapy is effective in patients with APS and recurrent venous thrombosis. Prophylactic anticoagulant therapy during pregnancy, delivery, and postpartum is recommended for women with APA and previously recurrence miscarriages or thrombosis.

1986

HYPERCOAGULATION SYNDROMES IN PATIENTS WITH POLYCYTHEMIA VERA (PV) AND ESSENTIAL THOMBOCYTHEMIA (ET) WITH AND WITHOUT THROMBOSIS

M Izak, O Garach-Jehoshua, J Cohen, N Rachimi-Levene, S Peller, A Kornberg

Institute of Hematology, Zrifin, Israel

Background. Increased platelet counts in ET and elevated hematocrit in PV are considered the main causes of thrombosis. However, the correlation between thrombosis and degree of thrombocytosis or hematocrit is poor. Therefore, other mechanisms should be involved in thrombus formation in both diseases. Several studies had suggested that the different heprcoagulation syndromes may contribute to thrombus formation in both diseases. *Aims.* To study the role of antithrombin III (AT), protein C (PC) and protein S (PS) deficiency, APCR, TAFI, PAI-1, tissue factor pathway inhibitor (TFPI), lupus anticoagulant (LAC), anticardiolipin (aCL) and anti β2 GPI antibodies in thrombus formation in ET and PV. *Methods.* ET (n=23) and PV (n=31) were defined according the WHO criteria. Commercial kits were used for the measurement of the factors. Lupus anticoagulant was determined by DRVVT. Normal controls (NC) (n=26) were matches for age, gender and co-morbidities. *Results.* JAK-2 mutation was found in 87% of PV and 44% of ET patients. Thrombosis was diagnosed in 14 PV patients (5 strokes, 8 MI, 1 DVT), 7 ET patients (5 strokes, 1 MI, 1 PE) and in 0 NC. The mean levels of the factors in patients with and without thrombosis in PV and ET are summarized in Table 1.

Table 1. Plasma levels of procoagulants and anticoagulants in PV and ET.

	PV (n=31) Mean ± SD		ET (n=23) Mean ± SD		Normal Controls (n=26) Mean ± SD
	Pts. with thrombosis	Pts. without thrombosis	Pts. with thrombosis	Pts. without thrombosis	
PC (%)	84.7±15.6	83.8±19.4	102.4±17.0	105.7±20.0	116±18.5
PS (%)	77.3±14.1	75.0±13.8	94.0± 7.6	85.8±17.8	105±13.0
AT III (%)	108.0±15.7	108.1±19.0	111.4±14.8	114.3±16.9	98.5±10.0
APCR	2.86±0.25	2.81±0.3	3.06±0.1	2.8±0.35	2.49±0.9
TAFI (%)	87.6± 25.6	71.6±21.0	90.3±33.4	80.0±23.8	74.3±15.1
PAI-1 (ng/ml)	14.7±7.9	12.6±6.5	26.3±18.3	12.4±9.0	11.2±8.2
TFPI (ng/ml)	12.7±5.2	9.31±2.7	12.0±5.2	11.2±5.0	6.9±2.2
LAC	1.16±0.1	1. 2±0.07	1.22±0.13	1.19±0.07	0.99±0.1
aCL (U/ml)	9.9±4.0	7. 8±3.7	12.7±11.1	7. 9±3.8	3.6±1.9
Anti β2GPI (U/ml)	16.9±13.8	6.3±5.8	4.4±1.9	4.1±1.8	3.4±1.9

The levels of PC and PS were lower in both diseases *vs.* NC but significant only in PV (95%CI 18-37, P<0.001). Patients with and without thrombosis had similar levels. AT III and APCR were significantly higher in patients *vs.* NC in both diseases but similar in cases with and without thrombosis. TAFI and PAI-1 were higher in most subgroups of patients and also in patients with thrombosis *vs.* no thrombosis. However, TAFI was significant only in PV with thrombosis *vs.* NC and PAI-1 was significant only in ET with thrombosis *vs.* ET without thrombosis and *vs.* NC (95% CI -25.6 to -2.1, P=0.02). TFPI was significantly higher in all subgroups compared to NC and also in PV with thrombosis *vs.* PV without thrombosis (95% CI -6.3 to -0.47, P<0.024). LAC and aCL were significantly higher in all subgroups *vs.* NC (95% CI -13.5 to -4.6, P<0. 001), but were not significant in patients with thrombosis compared to patients without thrombosis. Anti β2GPI was significantly higher in PV patients *vs.* NC and in PV with thrombosis *vs.* no thrombosis (95% CI -15.4 to -0.47, P=0.021). The incidence of thrombosis in patients with and without JAK-2 mutation was the same. *Conclusions.* The significantly higher levels of PAI-1 in ET and TFPI and anti β2GPI in PV, in patients with thrombosis *vs.* no thrombosis, suggest a role of those factors in thrombus formation. The low levels of PC and PS in the patients compared to NC may indicate activation of coagulation as reported previously. The high levels of AT III and APCR were unexpected. LAC and aCL were also higher in patients compared to NC. However, the non significant difference of PC, PS, AT III, APCR, LAC and aCL betweens patients with and without thrombosis suggests that the factors do not contribute to thrombosis. TAFI, which was not studied previously, was significantly higher in patients *vs.* NC but not in patients

with thrombosis *vs.* no thrombosis and therefore its role in thrombus formation is not clear. The relatively small cohort of patients in the present and previous studies merits larger studies.

1987

HIGH CONCENTRATION OF VITAMIN C REDUCES D-DIMER GENERATION DURING IN VITRO HAEMOSTATIC PROCESS

HC Kang,[1] A Macedo,[2] B Oliveira,[1] M Carvalho[1]

[1]*Universidade Federal Fluminense, Niterói, RJ, Brazil;* [2]*Instituto Nacional do Câncer, Rio de Janeiro, Brazil*

The most frequent cause of catheter malfunction is due to thrombotic occlusion requiring intervention. Because of the risks and costs associated with the removal and replacement of these devices, salvage of occluded catheters via thrombolysis is a preferred treatment option. Usually thrombolytic agents such as Streptokinasis or t-PA are used, however these drugs have risks and high costs. There are 14 years of experience using vitamin C to restore the flow of these devices in the by the nurses of Brazilian National Cancer Institute, where are a registry of 96,6% of efficiency in 65 interventions in pediatric infirmary. The aim of this study was design an *in vitro* model to analyze the action of vitamin C on blood thrombi, because we did not find any literature about the mechanism involved. The approach was investigate if vitamin C have any fibrinolytic action quantifying d-dimer. This study was approved by the ethics comitee of Universidade Federal Fluminense and carried out using blood from 10 healthy volunteers withdrawn after sign the informed consent and 13 pools of citrated plasma. The full blood study were performed incubating total blood diluted 1:1 in vitamin C solution and the control tubes diluted with saline solution before and one hour after clotting process and incubated in water bath at 37°C. At the end of incubation time we added Aprotinin to stop the action of proteases and the plasma or serum were separated and maintained at -80 C until d-dimer measurement. The treatment of citrated plasma pools were performed the same way, adding bovine thrombin 50 U NIH/mL with CaCl2 to allow the clot formation. D-dimer of twelve pools and eight total blood were tested, because two samples presented hemolysis compromising the analysis, and the results presented lower than control, statistically significance at P<0.01in non-parametric Wilcoxon test in samples diluted before and after clotting process in full blood and citrated plasma. Average values of d-dimer for full blood treate with vitamin C were: control 190,0±225,6 μg/L (8), test 71,6±34,8 μg/L (8) * and control195,3±259,0 μg/L(10), test 89,4±48,5 (10)* before and after clotting, repectivelly. The citrated plasma presented control129,7±47,0 μg/L (13), test 82,3 ±33,1 μg/L (12)* before clotting and control 107,8±37,2 μg/L (12), test 81,3±38,2 μg/L (12)* after clotting. An additional observation is that we could not isolate the clot from eight out of ten samples to weight the clot, in full blood samples treated before clot formation resulting in mean clot weight of 82,0 ±237,7mg and controls 594,0 ±216,9 mg, presenting Wilcoxon non-parametric test with P<0,01. Surprisingly, high local concentration of vitamin C reduces d-dimer generation as a result of its action in clotting process and not by increase the fibrinolytic process. This study was supported by FAPERJ.

1988

ETIOLOGY OF HYPERCOAGULABLE STATE IN WOMEN WITH RECURRENT FETAL LOSS IN TURKEY: A PRELIMINARY REPORT

C Beyan, K Kaptan, A Ifran

Gulhane Military Medical Academy, Ankara, Turkey

Background. Recurrent fetal loss (RFL) is one of the most common causes of sterility. Several studies identified thrombophilia as the principal cause of recurrent fetal loss. *Aims.* The aim of our study was to determine thrombophilia causes and their frequencies in cases admitted to our department for recurrent fetal loss and the preliminary results of our study were presented here. *Methods.* The study consists of 45 women aged 28.69±4.14 years (mean±standard deviation) (21-37 years). Patients with two or more first trimester abortion or with one or more late pregnancy loss were considered for this study. Cases with genitourinary tract abnormalities or chromosomal abnormalities were excluded from the study. These women were tested for inherited and/or acquired thrombophilia with the following tests; factor V Leiden gene polymorphism, prothrombin 20210 G → A gene polymorphism, methylene tetrahydrofolate reductase 677 C → T gene polymorphism, activated protein C resistance, antithrombin deficiency, protein C deficiency, protein S deficiency, lupus anticoagulant, anticardiolipin antibodies Ig G and Ig M, high factor VIII activity, hyperhomocysteinemia, hyperfibrinogenemia and shortened activated partial thromboplastin time. The number of fetal losses in cases was ranging between 2 and 4 (median 3). There was first trimester abortion history in all cases and 12 cases mentioned late pregnancy loss. *Results.* Our data demonstrated that 44.4% of women had one or combined thrombophilic conditions. The causes and frequencies of thrombophilia detected in our cases were shown in Table. Coclusions. As a result, our preliminary data emphasizes the role of thrombophilia in women with RFL in Turkey.

Table. The causes and frequencies of thrombophilia.

The Cause of Thrombophilia	Abnormality	Ratio (%)
Factor V Leiden gene polymorphism (n=43)	Heterozygous/Homozygous	11,6% (2,3% homozygous)
Prothrombin 20210 G →A gene polymorphism (n=43)	Heterozygous/Homozygous	2,3% (heterozygous)
Methylene tetrahydrofolate reductase 677 C →T gene polymorphism (n=20)	Homozygous	20,0%
Activated protein C resistance (n=34)	<120 second	20,6% (5,9% factor V Leiden negative)
Antithrombin deficiency (n=45)	<80%	0,0%
Protein C deficiency (n=45)	<70%	2,2%
Protein S deficiency (n=45)	<60%	2,2%
Lupus anticoagulant (n=30)	Positivity	0,0%
Anticardiolipin antibodies Ig G and Ig M (n=30)	Positivity	0,0%
High factor VIII activity (n=26)	>200%	11,5%
Hyperhomocysteinemia (n=29)	>15 μmol/l	10,3%
Hyperfibrinogenemia (n=27)	>500 mg/dl	3,7%
Shortened activated partial thromboplastin time (n=30)	<26,5 second	6,7% (3,3% normal factor VIII activity)

1989

INCIDENCE AND CLINICAL PROFILE OF APC RESISTANCE IN THE ABSCENCE OF FV LEIDEN MUTATION. A TWO YEARS EXPERIENCE

N Fernandez-Mosteirín, C Salvador Osuna, M Torres, M Guillen, M Abio, A Iborra, C Sierra, JF Lucia, D Rubio-Felix

Hospital Universitario Miguel Servet, Zaragoza, Spain

Background. APC resistance in the absence of FV Leiden is in fact very prevalent in the general population (10-15% of individuals, as determined with the aPTT-based test), and is also associated with an increased risk of venous thrombosis (deep vein thrombosis (DVT) and pulmonary embolism (PE) principally). *Aim.* To evaluate the laboratory characteristics and clinical thrombotic profile in patients tested positive for APC resistance and not carrying FV Leiden mutation. *Patients and methods.* We retrospectively reviewed the clinical files, demographic and clinical parameters, and inherited and acquired thrombophilic risk factors (protein C (PC), protein S (PS), antithrombin (AT), antiphospholipid antibodies (APA), RPCA (determined with an aPTT-based test), detection of FV Leiden and G21210A mutation) of patients tested for hypercoagulable status from January 2007 to December 2009. *Results.* 1491 patients were tested for APC resistance and 144 (0.93%) of them showed low ratio of APC resistance (<2.0). 32 patients (22.22%) (20 female / 12 male), medium age 48.5 years (range: 21-85) tested negative for FV Leiden mutation and underlying causes were investigated. Patients characteristics and laboratory results are shown in Table 1.

Table 1.

	Patients	Gender	Age	Indication to evaluate thrombophilia	Venous thrombosis	Arterial Thrombosis
FVIII↑	9	5 Female/4 Male	48 (30-85)	3 Stroke 2 DVT 2 Inherited thrombophilia 1 Optic neuropathy 1 Assisted Reproductive Technology (ART)	2	4
APA	7	5 Female/2 Male	67 (30-77)	2 PE 2 Puerperium DVT 2 Stroke 1 Stroke + DVT	5	2
Hormonal ReplacementTherapy (HRT)	4	Female	35 (32-50)	3 ART 1 Stroke	No	No
Cancer	1	Male	65			
G20210A mutation	1	Female	49	Stroke	No	1
PS↓	2	Female	35 (20-50)	1 Stroke 1 Inherited thrombophilia	No	1
FVIII↑+APA	1	Male	55	1 DVT + PE	1	No
HRT+APA	1	Female	21	1 Bilateral PE	1	No
Unknown	6	4 Female/2 Male	44 (25-67)	3 Inherited thrombophilia 1 Stroke 1 DVT 1 Miocardial infarction	1	2

Medium FVIII levels 189.5% (range: 155%-200%). 2 patients in the group of APA positive associated systemic lupus erythematous. The number of venous and arterial thrombosis was 20 in 19 patients (59.4%); 10 arterial events and 10 venous thrombosis. In our serie arterial thrombosis is slighhtly more frequent in the group of elevated levels of FVIII, and venous thrombosis more frequent in the group of APA positive patients. *Conclusions.* 1) In our serie about one-third of all cases of FV Leiden-indepedent APC resistance similar to the refered in literature. 2) Altough it is

well known that APC resistance due to other causes different from FV Leiden increases the risk of venous thrombosis, incidence of arterial and venous events in our serie is similar. 3) Overall, plasma APC resistance is a reliable indicator of clinical risk, integrating the effects of several genetic and acquired risk factors in a single measure plasma phenotype.

1990

ENDOGENOUS THROMBIN POTENTIAL (ETP) TEST AND THROMBOTIC TENDENCY MARKERS IN PATIENTS WITH LIVER CIRRHOSIS

E Papakonstantinou,[1] E Yfantis,[1] A Theofani,[1] A Skourbouti,[1] A Lavda,[1] I Rapti,[2] E Dimou,[2] C Manti,[1] S Hadziyannis[2]

[1]*Thriassion Hospital, Agia Paraskevi, Greece;* [2]*Henry Dunant Hospital, Athens, Greece*

Background. The role played by coagulation defects in the occurrence of bleeding in cirrhosis is still unclear. This is partly due to the lack of tests that truly reflect the balance of procoagulant and anticoagulant factors *in vivo*. Conventional coagulation tests (PT/INR and aPTT) seem unable to predict the severity of bleeding problems in patients with cirrhosis of the liver possibly because they do not adequately reflect the balance between procoagulant and anticoagulant clotting factors. Recently a test has become available to routinely measure the endogenous thrombin generation potential (ETP) by Dade Behring (Marburg, Germany). *Aim.* Comparison of ETP parameters and other coagulation markers - Antithrombin III, protein C, protein S, lupus anticoagulant, plasminogen, a2-antiplasmin, APCR, homocystein- between controls and patients with liver cirrhosis. *Methods.* 56 samples, of consecutive patients with histologically confirmed liver cirrhosis, and 30 samples of controls were investigated for ETP parameters and other coagulation markers - ATIII, protein C, protein S, lupus anticoagulant, plasminogen, a2-antiplasmin, APCR, homocystein-. We used the chromogenic method on the fully automated Behring Coagulation System (BCS) for the measurement of thrombin generation parameters. *Results.* 6 patients had alcoholic cirrhosis, 22 HCV, 5 PBC, 7HBV, 1HBV and HDV and 13 cirrhosis of unknown origin. Table. *Summary/Conclusions.* The reduction of procoagulant factors in patients with cirrhosis is compensated by the reduction of anticoagulant factors thus leaving the coagulation balance with minor changes. ETP might be normal in cirrhosis. For clinical validation of these findings, a prospective clinical trial is warranted where the results of ETP must be related to the occurrence of bleeding, to a much larger number of patients.

Table.

Parameters	Patients	Controls	P Value
Antithromb III	65.81 (23-102.5)	100 (79-122)	0.0001
protein C	67.3 (17-139)	105 (78-135)	0.0001
protein S	66 (22.8-89.2)	110 (66-157)	0.0001
lupus anticoagulant	1.05 (1-2)	1.1 (1-1.2)	0.28
plasminogen	85.7 (38-149.8)	107(79-132)	0.0001
a2antiplasmin	89.1 (41.2-150)	105 (82-115)	0.001
APCR	0.83 (0.64-0.96)	0.9 (0.65-1.02)	0.0001
homocystein	10.6 (1.3-26.8)	10 (7-13)	0.4
tlag	21.5 (12.5-51.1)	19.3(12.526.37)	0.16
tmax	84.4 (40.3-126.2)	54.3(45.5-62.1)	0.007
Cmax	78.1 (44.2-146.9)	123.5(113-134)	0.0001
ETP	284.4 (24.8-472,7)	394.7 (323-451)	0.0001

1991

PEDIATRIC ANTIPHOSPHOLIPID SYNDROME : EXPERIENCE OF A SINGLE BRAZILIAN CENTER

M Pereira Garanito, J David Aivazoglou Carneiro

Pediatric Hematology/Oncology Service of Instituto da Criança - HCFMUSP, São Paulo, Brazil

Background. Antiphospholipid Syndrome (APLS) and their associated clinical features have been recognized increasingly in various autoimmune and nonautoimmune diseases. A close association between APLS and recurrent arterial and/or venous thrombosis has been supported by several retrospective studies, and it seems that antiphospholipid antibodies have a direct role in the pathogenesis of the thrombophilic state of APLS. Contrasting with APLS in adults, this condition is rare in paediatric population and the relatively low prevalence and heterogeneity in children have hampered the scientific evaluation of currently available classification, diagnostic and therapeutic modalities. *Aim.* This study analyses the clinical manifestations of the paediatric patients with primary or secondary APLS treated at our service. *Materials and methods.* We reviewed the medical records of eleven patients diagnosed with primary or secondary APLS from May, 2001 to January, 2009. The patients were identified from the presence of vascular events, either venous or arterial thrombosis, anti-cardiolipin antibodies and lupus anticoagulant. *Results.* Six of eleven patients were female, with a mean age at the onset of antiphospholipid syndrome of 9.9 years. Four (36.3%) patients had an underlying autoimmune disease (Systemic Lupus Erithematosus - SLE). Venous thrombosis in the lower extremities occurred in six (54.5%), venous hepatic thrombosis in five (45.4%) and arterial thrombosis - renal, myocardial, central nervous system - in three (27.2%). The nonthrombotic clinical manifestations included hematologic manifestations in 18.1% (autoimmune hemolytic anaemia or thrombocytopenia) and skin disorders in 9.0% (skin ulcers). Inherited prothrombotic disorder - protein C deficiency - was found in one (9.0%) of 11 patients. Laboratory investigations revealed positive anticardiolipin antibodies in 90.9% of the patients and lupus anticoagulant in 63.6%. Two patients with primary APLS had serious and rare thrombotic events, namely a myocardial infarction during anticoagulation therapy and a chronic pulmonary thromboembolism, as first manifestation of the disease. All patients with thrombosis received anticoagulation therapy (low-molecular-weight heparin or vitamin K antagonists), except the patient that had myocardial infarction who received anticoagulation therapy and aspirin. *Conclusions.* APLS is a serious condition, rare in children, with high risk of recurrence and clinical manifestations of thrombosis in unusual sites. Although until now, there is not a consensus criteria for the classification and management of paediatric APLS, the diagnosis must be remembered and investigated in cases of unexplained thrombosis in childhood to the institution of early treatment and follow-up.

Table. General characteristics of patients with APLS.

Patient	Sex	Age	Events	APS	Treatment
1	F	5y3m	RVT / HVT	Primary	Anticoagulation
2	M	9y1m	HVT / IVCT DVT / MI	Primary	Anticoagulation And Antiaggregation
3	F	14y5m	AHA / SLE / DVT Ischemic stroke Skin ulcers	Secondary	Anticoagulation
4	F	14y6m	PT / SLE	Secondary	Anticoagulation
5	F	8y4m	DVT	Primary	Anticoagulation
6	F	12y2m	Thrombocytopenia RAT	Primary	Anticoagulation
7	M	14y8m	PT	Primary	Anticoagulation
8	F	12y8m	Thrombocytopenia	Primary	Antiaggregation
9	M	10y2m	SLE / DVT / IVCT	Secondary	Anticoagulation
10	M	11y9m	HVT / IVCT	Primary	Anticoagulation
11	M	13y	HVT / IVCT / DVT SLE	Secondary	Anticoagulation

RVT - renal venous thrombosis; HVT - hepatic venous thrombosis; IVCT - inferior vena cava thrombosis; DVT - deep venous thrombosis inthe lower extremities; SLE - sistemic lupus erithematosus; MI - myocardial infarction; AHA - autoimmune hemolitic anemia; PT - pulmonary thromboembolism; RAT - renal artery thrombosis

CAROTID ATHEROSCLEROSIS IN TYPE 2 DIABETES MELLITUS PATIENTS: ROLE OF CHLAMYDOPHILA PNEUMONIAE INFECTION

JC Reverter,[1] S Pellitero,[2] J Monteagudo,[1] N Alonso,[2] B Soldevila,[2] A Sanmarti,[2] J Reverter,[2] D Tassies[1]

[1]*Hospital Clinic, Barcelona, Spain;* [2]*Germans Trias i Pujol University Hospital, Badalona, Spain*

Background. Infectious agents, especially the intracellular Chlamydophila pneumoniae, have been supposed to be involved in the atherosclerotic process. *Aim.* We performed a cross-sectional, multicenter, outpatient protocol to study Chlamydophila pneumoniae DNA in leukocytes measured by a real-time PCR in patients with type 2 diabetes with different degrees of atherosclerosis evaluated by carotid ultrasound. *Methods.* One hundred thirty-five consecutive type 2 diabetic patients were studied. Clinical, metabolic (HbA1c, lipids) and inflammatory (high-ultrasensitive C-reactive protein, tumor necrosis factor-alpha, interleukin-6) variables were measured. Previous clinical

macrovascular disease was registered and B-mode ultrasound was performed. Real-time PCR protocol for Chlamydophila pneumoniae (Tib Molbiol, Berlin, Germany) in a LightCycler thermocycler (Roche, Basel, Switzerland) was performed in all patients, using adequate positive and negative internal controls. *Results.* Patients mean age was 62±7 years. Mean diabetes duration was 16±9 years. Mean HbA1c was 7.1±1.1%. In relation to carotid ultrasound results, 40.7% patients presented clinical atherosclerosis, 32.5% subclinical atherosclerosis and 26.6% no evidence of atherosclerosis. All groups were homogeneous in anthropometrical data. Biochemical determinations were similar in all groups except for cholesterol and non-HDL-cholesterol levels. Patients with clinical atherosclerosis had greater carotid intima-media thickness compared to the other two groups. No Chlamydophila pneumoniae DNA was detected in any of the type 2 diabetes patients regardless of the presence of clinical or subclinical atherosclerosis. *Conclusions.* The lack of detection of Chlamydophila pneumoniae DNA in leukocytes suggests that this bacterium does not have an active systemic role in the pathogenesis of atherosclerosis in middle-aged type 2 diabetic patients, and it is not a reliable marker for atherosclerosis in high risk patients.

1993

PREVALENCE AND CHARACTERISTICS OF PULMONARY EMBOLISM IN CANCER PATIENTS: 5-YEAR EXPERIENCE AT A TERTIARY INSTITUTION IN TAIWAN

YB Yu

Taipei Veterans General Hospital, Taipei, Taiwan

Background. Venous thromboembolism is a major problem in cancer patients and exerts a bi-directional impact. Pulmonary embolism (PE) could be fatal and contributes significantly to the morbidity and mortality of cancer patients. However, epidemiological data from Oriental societies is limited. *Aims.* We assessed the prevalence and clinical characteristics of cancer patients with pulmonary embolism at a tertiary hospital in Taiwan. *Methods.* Patients with confirmed diagnosis of PE or cancers were identified by integrated search with International Classification of Diseases codes and keyword "pulmonary embolism" from the hospitalization database in Taipei Veterans General Hospital between January 2004 and December 2008. Prevalence, clinical characteristics, and treatment outcome were recorded and analyzed using statistical analysis as appropriate. *Results.* Totally 191 patients with PE were identified and 55 (28.8%) of them had a diagnosis of active cancer. Estimated prevalence of PE in cancer patients was 2.5/1000. Among them, adenocarcinoma of lung (5.9/1000), pancreatic adenocarcinoma (10.9/1000), and ovarian cancer (9.8/1000) were the major subtypes presented with PE. Concurrent deep vein thrombosis were detected in 17 (30.9%) patients. In contrast to the patients with PE at the time of cancer diagnosis, those with PE developed during treatment were more commonly associated with advanced or refractory disease status (P=0.009 and P=0.000). 27.3% (15/55) of PE episodes in cancer patients were fatal and resulted in a 15.1-month overall survival and 7.8-month post-PE survival. *Conclusions.* Prevalence of PE in Taiwanese cancer patients is much lower than that of Western countries. Distinct features of patients developed PE at diagnosis or during treatment are worth more attention in clinical practice.

1994

LEVELS OF NATURAL COAGULATION INHIBITORS IN SICLE CELL DISEASE

S Arampatzi, K Thisiadou, S Spiroglou, K Chalvatzi, C Kanonidou, D Lazaridou, A Nikolaidou, O Fotakeli, E Diza

Ahepa University Hospital, Thessaloniki, Greece

Background. Sickle cell disease (SCD) is a common hereditary hemoglobinopathy. The clinical manifestations of SCD arise from the tendency of sickle haemoglobin, known as HbS, to polymerize at reduced oxygen tensions and deform red cells into the characteristic rigid sickle cell shape. Patients exhibit increased platelet and coagulation activation, as well as decreased levels of natural anticoagulant proteins. In addition, they are characterized by thrombotic complications. The pathogenesis of hypercoagulability is likely multifactorial, with contributions from the abnormal red blood cell (RBC) phospholipid membrane asymmetry, ischemia-reperfusion injury, and chronic hemolysis with resultant nitric oxide depletion. More studies are needed to better define the contribution of hemostatic activation to the pathophysiology. *Aim.* The aim of this study was to determine activity of natural anticoagulant proteins and plasma levels of D-dimer in patients with sickle cell disease. *Methods.* We evaluated in 58 patients, (mean age 37,5±16.6 years, 43 with homozygous and 15 with heterozygous sicle cell disease) the activity of protein C (PC- chromogenic method), free protein S (free PS- immunoassay), antithrombin III (AT III- chromogenic method) and plasma levels of D-dimer (D-D-turbidimetric immunoassay).A control group of 40 age-matched healthy subjects were studied simultaneously. Results were statistically analysed using Student's t test. *Results.* The results are presented in Table 1. PC and free-PS activity was significantly lower (P<0,05) in patients with homozygous sicle cell disease compared to healthy group. In patients with heterozygous sicle cell disease only the activity of free-PS was significantly lower (P<0,05) compared to healthy group. Plasma levels of D-D were significantly higher (P<0,05) in all patients compared to healthy group while activity of AT III didn't present significant difference. *Summary/Conclusions.* 1. Patients with sicle cell disease present low levels of activity of natural coagulation inhibitors: PC, free-PS in patients with homozygous sicle cell disease and free-PS in patients with heterozygous sicle cell disease. 2. Patients with sicle cell disease (homozygous and heterozygous) present high plasma levels of D-dimer (D-D), evidence of hypercoagulability. 3. Alterations in hemostatic system with evidence of hypercoagulability are present in sicle cell disease.

Table 1. Activity of PC, free-PS, AT III and plasma levels of D-D in patients with homozygous and heterozygous sicle cell disease and healthy subjects.

Group	N	PC (%¹)	free PS (%¹)	AT-III (%¹)	D-D (ng/ml)
Homozygous Sicle cell disease	43	*76,84±20,11	*76,83±18,30	94,05 ± 21,78	*653,50± 600
Heterozygous Sicle cell disease	15	95,22± 37,66	*74,33± 23,80	103,11± 12,81	*378,95 ± 367

A 5 YEAR PROSPECTIVE FOLLOW-UP STUDY IN ESSENTIAL CRYOFIBRINOGENEMIA PATIENTS

C Belizna,[1] C Belizna,[1] M Godin,[2] O Vitecoq,[2] M Hamidou,[3] H Lévesque[2]

[1]CHU Angers, Angers, France; [2]CHU Rouen, Rouen, France; [3]CHU Nantes, Nantes, France

Cryofibrinogenemia could be essential or secondary to some disease such as neoplasia, infection, thrombosis, collagen vascular disease. Our group have reported in a previous study the outcome of few essential cryofibrinogenemia during a short follow-up period. Therefore, we have reported that some of these cases were in fact false essential cryofibrinogenemia, and neoplasia have been revealed several months after the diagnosis of cryofibrinogenemia. *Purpose.* We have performed a prospective multicentric 5 year follow-up study for essential cryofibrinogenemia (2005-2009). *Results.* 21 cases of de essential cryofibrinogenemia have been diagnosed. Clinical manifestations were cutaneous (76%), arthralgia (32%), multinevritis 12%, thrombosis 11%, nephrotic syndrome 11%, myalgia 9%, fever 7%. The diagnosis was confirmed by three cryofibrinogenemia dosages and morpho-pathological examination (skin, kidney). 12/21 of cases (57%) initially considered such as essential cryofibrinogenemia have been revealed during a mean follow-up of 24 months that they were in fact cryofibrinogenemia secondary to lymphoma (5 T lymphoma and 3 B lymphoma). *Discussion et conclusion.* This prospective study have confirmes the previous reported data, strongly suggesting that some of the cryofibrinogenemia initially considered such as essential were in fact secondary to lymphoma that were diagnosed after several months de follow-up. Is that only an hazardous association, or some cryofibrinogenemia considered such as essential are precosious markers of indolent lymphoma? These data suggest that a regular methodical follow-up of these type of cryofibrinogenemia should be performed in order to study their potential evolution through neoplasia. However, the small number of patients (partial-

ly related to the low prevalence of this diseases, but also to some technical differences in laboratory detection) does not allow a formal conclusion.

1996

NT-PROBNP, HS-CRP, AND HOMOCYSTEINE AS INDEXES OF INFLAMMATION ON PROTHROMBOTIC STATE IN ANTICOAGULATED PATIENTS WITH ATRIAL FIBRILLATION. RELATIONSHIP TO CHADS2 STROKE RISK STRATIFICATION

A Espinoza,[1] J Román Barbero,[1] M Garcés Santos,[1] M Moreno Moreno,[1] M Barrios Suvelza,[1] I Flores Fernández,[1] A Drowsdoskj,[2] Y Pérez Ayala,[1] A Hawari Meilud,[1] C Saputelli Francisco[1]

[1]Hospital Nuestra Señora de los Reyes, Valverde, SC Tenerife, Spain; [2]Pivotal, SL, Madrid, Spain

Background. Atrial fibrillation (AF) is associated with substantial morbidity and mortality, owing to a significantly increased risk for stroke, as well as thromboembolic events. The pathogenesis of atherosclerosis involves both haemostatic and inflammatory mechanisms and there is now considerable evidence that AF is associated with an inflammatory state. Predicting which patients with atrial fibrillation will have a stroke or systemic embolic event and identifying potential risk factors for it will assist with identifying candidates who stand to gain the most from stroke prevention therapies. CHADS2 score has become the most commonly used predictive rule in clinical practice, however, the main limitation is that this risk stratification schemes were developed and are still most often applied to AF patients not yet on oral anticoagulants (OA). *Aims.* We tested the hypothesis that plasma levels of pro-B-type natriuretic peptide (NT-proBNP), a sensitive biomarker of cardiac contractile dysfunction, high sensitivity C-reactive protein (HS-CRP), homocysteine, von Willebrand factor and fibrinogen as indexes of inflammation could be related to low and high stroke risk CHADS2 stratification schema in AF patients on OA. *Methods.* We prospectively enrolled 37 AF patients recruited from subjects receiving OA from the Anticoagulation Clinic at Hospital "Nuestra Señora de los Reyes" (Canary Island, Spain) Fasting blood samples for the analysis of the biomarkers were collected from all subjects in the semi-recumbent position after 10 min rest. Blood samples were centrifuged at 3500g for 15min after clotting (15-30 min), and serum was then frozen at minus 70-80°C until the samples were analysed. Informed consent was obtained. The diagnosis of AF was identified via presentation electrocardiogram. Comparisons of clinical characteristics between low-median *vs.* high-risk AF patients was performed using the Fisher exact test for categorical data and the Wilcoxon rank sum test for continuous data. Differences between low- to high-risk groups and biomarkers were determined using the Kruskal-Wallis test. Median (with interquartile range [IQR]) levels were determined and compared. *Results.* Preliminary results of 37 AF patients, median age 75 years (range 50-91), 17 (46%) of them stratified as high-risk CHADS2 at presentation, are reported; these patients had significantly higher median NT-proBNP levels when compared with those with low-median risk (1174 *vs.* 807 pg/mL, p .0661) although AF was not independently associated with NT-proBNP after multivariable adjustment. With respect to the HS-CRP and homocysteine and CHADS2 stroke risk stratification criteria, those with high risk had the highest levels of HS-CRP (4,9 *vs.* 4,7 IU/L, p 0.04), and homocysteine 19,2 *vs.* 12,6 µmol/l, p 0.001), respectively. *Conclusion.* Among anticoagulated AF patients, HS-CRP and homocysteine were positively correlated to stroke risk factors and prognosis. NT-proBNP levels were lower in those at low to moderate-risk of stroke and not related to prognosis. The use of another approach with inflammatory biomarkers along with a CHADS2 score as risk stratification for AF patients on OA merits further study.

1997

ROLE OF ANTI-BETA2-GLYCOPROTEIN I (ABETA2GPI) ANTIBODIES IN PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME (APS). CLINICAL COURSE AND LABORATORY PROFILE

N Fernandez-Mosteirín, C Salvador Osuna, M Torres, M Guillen, M Abio, A Iborra, C Sierra, L Saez, JA Garcia-Erce, JJ Gimeno, VP Gonzalez, JF Lucia, D Rubio-Felix

Hospital Universitario Miguel Servet, Zaragoza, Spain

Background. Since 2006 the medium/high titer of ab2GpI antibodies has been included as a laboratory criteria for APS. In the last revision of the laboratory criteria in this setting at least one of the following parameters must be present: lupus anticoagulant (LA), IgG and/or IgM anticardiolipin antibodies (aCL) and IgG and/or IgM ab2GpI antibodies. Furthermore, the risk for APS related events is commonly correlated with the number of positive antiphospholipid antibodies and several studies confirm that triple positivity confers the highest risk of APS-related events. *Aim.* To evaluate the laboratory profile, clinical characteristics and clinical course of ab2GpI positive patients with clinical suspicion of APS or autoimmune disorder. *Patients and methods.* We retrospectively reviewed the clinical files, demographic and clinical parameters, and inherited and acquired thrombophilic risk factors of patients having clinical criteria of APS or related clinical manifestations according to the Sapporo criteria in our center for a period of two years. *Results.* 296 patients with clinical manifestations suggesting APS were evaluated for hiperocoagulable status. 13 patients (4,4%) (5 male (M)/ 8 female (F)) with a median age of 48 years (range: 26-78) were positive for IgG and/or IgM in the ab2GpI ELISA. Only 2 patients had a predominant IgM ab2GpI isotype. 3 patients with autoimmune disorder (2 SLE) had no clinical criteria for APS, 2 of them were LA and aCL negative, the remaining patient was triple positive and presented autoimmune thrombocytopenia and aortic valve dysfunction. The remaining 10 patients had clinical and laboratory criteria of APS. Risk stratification (more than one laboratory test positive (Category I) or single test positive (Category II)), clinical data according to laboratory criteria are sumarized in Table 1. The qualifying event at diagnosis was thrombosis in 7 patients (70%). Stroke was the most frequent thrombotic arterial event (3/7). 3 patients received long-term oral anticoagulant treatment, 3 aspirin alone and 1 patient both drugs. The thromboembolic recurrence in patients with venous or arterial thromboembolism was 1 of 7 cases presented as an stroke. Nevertheless this patient had refused oral anticoagulation voluntarly. No history of malignancy and/or inherited thrombophilia were observed. *Conclusions.* 1) In spite off the limited number of patients evalutated, category I patients, specially ion of LA and ab2GpI antibodies association seems to be related with an icreade risk of thrombosis as reported in the literature. 2) Stroke is the most frequent thromboembolic event. 3) Patients positive for more than one laboratory test and at high risk of thrombosis had primary APS as shown in other series.

Table 1.

	Category I (aβ2GpI+ LA)	Category I (Triple +)	Category II (aβ2GpI +)
Gender	3 M/1 F	3 F	1 M/2 F

IS THE DOUBLE COMPOUND HETEROZYGOSITY OF HEMOGLOBIN S/B-THALASSEMIA A RISK FACTOR FOR ABDOMINAL VENOUS THROMBOSIS?

P Koliou,[1] G Kouvelos,[2] M Mitsis,[3] M Matsagas,[4] N Kolaitis,[5] A Karamoutsios,[6] G Vartholomatos,[6] M Fatouros[3]

[1]University of Ioannina, Ioannina, Greece; [2]Vascular Surgery Unit, School of Medicine, University of Ioannina, Ioannina, Greece; [3]Department of Surgery, School of Medicine, University of Ioannina, Ioannina, Greece; [4]Vascular Surgery Unit, School Of Medicine, University of Ioannina, Ioannina, Greece; [5]Haematology Laboratory, University Hospital of Ioannina, Ioannina, Greece; [6]Haematology Laboratory, Unit of Molecular Biology, Ioannina University Hospital, Ioannina, Greece

Background. Known risk factors that predispose to abdominal vein thrombosis are divided into two main categories: congenital (protein C, and S deficiencies, ATIII deficiency, sickle cell disease) and many acquired prothrombotic states such as hematological diseases, neoplasms, abdominal infectious and inflammatory diseases, abdominal postoperative states, hepatic cirrhosis, portal hypertension, and abdominal trauma. *Aim.* To estimate the prevalence of inherited and acquired thrombophilic risk factors in patients with abdominal venous thrombosis and to compare the risk factor profiles between Budd-Chiari syn-

dromes (BCS) and splanchnic vein thrombosis (SVT) in non cirrhotic patients. *Methods.* In this retrospective study, 16 patients with abdominal venous thrombosis were evaluated. All patients with cirrhosis were not included. The patients were divided into two groups, the Budd-Chiari group (hepatic vein, inferior vena cava thrombosis) and the splanchnic venous thrombosis group (portal, splenic, superior mesenteric veins) according to venous site involved. Hereditary and acquired thrombophilic risk factors were evaluated in all patients using the Dade Behring Sysmex 1000 System for measuring protein C, S, ATIII, activated protein C resistance and coagulation factors II, V, VII, IX, X. Further, the presence of mutations for factor V-Leiden, prothrombin G20210A, and MTHFR genes was determined using the CVD Vienna Lab Strip Assay™. In 6 patients with no known risk factors determined, electrophoresis of haemoglobin using a quantitative technique was performed to evaluate the presence of HbS as a thrombosis factor. *Results.* The most common site of thrombosis determined in our patients was SVT - 9 patients, 6 had BCS, and one had mixed venous thrombosis. The acquired risk factors were significantly more common in the SVT group (SVT *vs.* BCS: 56% *vs.* 17%, P<0,05) while the hereditary risk factors had no significant differences (SVT *vs.* BCS: 11% *vs.* 33%). No risk factors were identified in 50% of patients with BCS and in 33% of patients with SVT. The patients with no risk factors identified were further tested and in 3 out of 6 haemoglobin electrophoresis was performed and it revealed double compound heterozygosity for HbS/b-thalassemia. *Conclusion.* Hereditary and acquired risk factors play an important role in the pathogenesis of abdominal venous thrombosis. Other than the known risk factors of thrombosis, sickle cell disease is a well documented factor for thrombosis at various vasculature sites. Our study rises the question of how probable could be that a double compound heterozygosity of known risk factors in the homozygous state would cause under circumstances abdominal thrombosis. After these findings further investigation has started in order to establish possible new thrombosis factors in cases where the current risk factors cannot help to establish a diagnosis especially in areas where thalassemia and sickle cell disease are prevalent.

Table 1. Sites of abdominal thrombosis and their prevalence.

	Patients w/ no risk factors	Patients w/ risk factors		Total of patients
		hereditary	acquired	
SVT	3 (33%)	1 (11%)	5 (56%)	9
BCS	3 (50%)	2 (33%)	1 (17%)	6
Mixed thrombosis	-	-	1 (100%)	1

BCS: Budd-Chiari syndromes, SVT: splachnic vein thrombosis.

1999

A NEW CASE OF DYSFIBRINOGENEMIA ASSOCIATED WITH THROMBOSIS

R Kotlín,[1] T Khaznadar,[1] J Suttnar,[1] T Riedel,[1] P Salaj,[1] J Kvasnicka,[2] J Dyr[1]

[1]Institute of Hematology and Blood Transfusion, Praha, Czech Republic; [2]General Teaching Hospital, Praha, Czech Republic

Background. Fibrinogen, a 340 kDa glycoprotein, is composed of three sets of different polypeptide chains termed Aα, Bβ, and γ. It plays a crucial role in blood coagulation and it was found to be a thrombotic risk factor. Several mutations in the fibrinogen, associated with thromboses, were reported worldwide. *Aims.* The aim of our study was to characterize a case of dysfibrinogenemia in a patient with deep vein thrombosis and pulmonary embolism, with no evidence of a common prothrombotic risk factor. *Methods.* Routine coagulation testing was performed on STA-R coagulation analyzer (Diagnostica Stago). Both, fibrin polymerization and fibrinolysis were measured by turbidimetrical method at 350 nm after addition of either human thrombin or reptilase to the patient`s plasma. Kinetics of fibrinopeptide release was measured by RP-HPLC method. Gene sequencing was performed by a Sanger method. Scanning electron microscopy (SEM) was performed on VEGA Plus TS 5135 electron microscope (Tescan s.r.o.) and the viscoelastic properties of the clot were measured using ReoRox Jr. (Medirox AB). *Results.* A 55 year-old man came to the hematological attention when deep venous thrombosis in the right calf occurred coupled with a pulmonary embolism in the right lung. The patient exhibited easy bruising after subcutaneous punctures. Coagulation testing showed decreased Clauss fibrinogen level, normal total fibrinogen level and prolonged thrombin time. No common thrombotic risk factor (the patient was negative for FV Leiden mutation as well as for prothrombin G20210A mutation) was found. The patient was former smoker and had normal weight. The patient was treated with warfarin after occurrence of thrombosis for one year. Both, thrombin and reptilase induced fibrin polymerization were significantly impaired. Kinetics of fibrinopeptide release was found to be normal. tPA-activated fibrinolysis was significantly slower and the most noticeable delay occurred during the final stages of what appeared as a diphasic lysis. DNA sequencing revealed a heterozygous point mutation in exon 5 of gene FGB causing the substitution of the Bβ Arg237Ser. SEM revealed that fibrin clot was formed by less fibrils with abrupt fibril terminations; and fibrin clot had decreased stiffness than control clot. Bβ arginine 237 was found to be high conserved in mammalian fibrinogen Bβ chain. *Conclusions.* The mutation B Arg237Ser leads to impaired fibrinolysis and abnormal clot morphology with decreased clot stiffness. It is very likely the direct cause of the thrombotic complications in this patient. *Acknowledgement.* This work was supported by a grant of The Internal Grant Agency of The Ministry of Health of the Czech Republic, number NS 9636-3/2008; by a grant of The Ministry of Health of the Czech Republic, number 2373601; and by a grant of The Academy of Sciences of the Czech Republic, number KAN200670701.

2000

THE ASSOCIATION OF FXIII VAL34LEU POLYMORPHISM WITH THE MEAN AMOUNT OF PROTEIN C AND PROTEIN S IN THROMBOTIC PATIENTS REFERRING TO IRANIAN BLOOD TRANSFUSION ORGANIZATION

S Sajadi,[1] S Sameie,[2] M Kheirandish,[3] M Tabatabaei,[2] M Jalalifar[4]

[1]Ilam university of medical sciences, Ilam, Iran; [2]IBTO research center, Tehran, Iran; [3]IBTo research center, Tehran, Iran; [4]IBTO Research Center, Tehran, Iran

Background and aims. Replacement of Val34Leu polymorphism in subunit A of coagulation factor XIII results in the replacement of Valine with Leucine in amino acid 34. As a result of this substitution, FXIII Val34Leu polymorphism acts as a factor for individual protection against thrombosis and predisposes to intracerebral hemorrhage. For the first time in Iran, the prevalence of this polymorphism in thrombotic patients was investigated and the relation between the mean amount of protein C and protein S was determined.

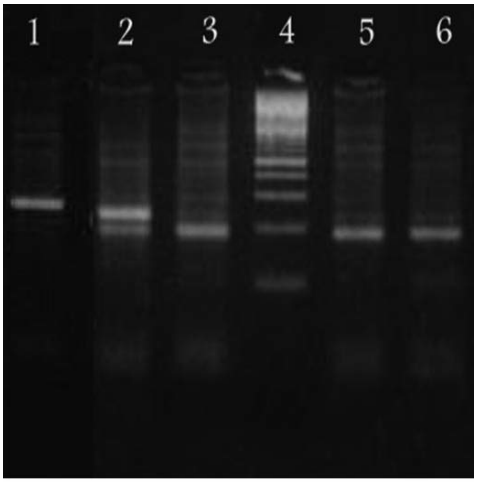

Figure.

Materials and methods. The study was performed as a retrospective case-control one. 189 referral patients with thrombotic complications were admitted to Iranian Blood Transfusion Organization (IBTO) Thrombosis and hemostasis Laboratory. The mean amount of protein C and protein S was determined in patients. Their DNA was extracted using Roche kit. Using Polymerase Chain Reaction (PCR) and RFLP methods in the presence of restriction enzyme Cfo1, genotypes of FXIII Val34Leu polymorphism were identified. The amount of protein C and protein S was determined by clotting method and STA compact instrument. Statistical analysis was performed by SPSS software version 11.5 and confidence coefficient was 95%. *Results.* The mean amount of protein C and protein S in patients who had FXIII Val34Leu polymorphism (25%) was 90.67% and 60.17%, respectively. while the mean amount of these anticoagulant proteins in patients without polymor-

phism (75%) was 113.67% and 78.98%, respectively. These results showed significant differences between the two groups (Pv=0.014). *Conclusions.* As a result significant association of this polymorphism reduced mean amount of protein C and S, it is concluded that the coexistence of FXIII Val34Leu polymorphism with these risk factors like as its coexistence with G20210A increases the risk of thrombosis. However, we recommended the larger case-control study by using of healthy individual.

2001

THROMBOPHILIA IN CONGENITAL DISORDER OF GLYCOSYLATION TYPE IA - A CASE STUDY

A Azevedo,[1] J Pereira,[2] A Gomes,[3] A Reis,[2] E Junior[1]

[1]Hospital Sao Fransisco Xavier, Chlo, Lisbon, Portugal; [2]Hospital São Fransisco Xavier, Chlo, Lisbon, Portugal; [3]Hospital São Francisco Xavier, Chlo, Lisbon, Portugal

Background. Congenital Disorders of Glycosylation (CDG) are severe, autossomal recessive, multisystemic metabolic diseases, characterized by abnormal biosynthesis of glycoproteins. The most common, CDG-Ia is related to deficient phosphomannomutase enzyme (PMM) activity, coded by PMM2 gene, situated in chromosomal segment 16p13. CDG-Ia has a broad spectrum of age related clinical findings with variation even within the same sibship. Most important clinical features involve the central nervous system, with development delay and hypotonia in combination with other findings that vary depending on the genotype, including coagulopathy, frequently during childhood, with low serum concentration of factors IX and XI, antithrombin, protein C and protein S. The potential for imbalance of the level of both pro and anticoagulant factors may lead to either bleeding or thrombosis. *Aims.* Present a case study of a 8 year old girl, with thrombophilia in the context of CDG-Ia. *Methods.* The patient was clinically evaluated and submitted to some diagnostic tests: coagulation studies including protein C, protein S, antithrombin and factors VIII, IX and XI, liver and thyroid function tests, measurement of serum albumin concentration, urinalysis, Carbohydrate-deficient Transferrin (CDT) measurement, Plasma Transferrin Isoelectric Focusing, Phosphomannomutase enzyme activity evaluation and molecular genetic testing. *Results.* Infant girl, without relevant family antecedents, observed by Neurology due to psychomotor delay. Followed since 9 months in Physiotherapy and Development Consultation due to hypotonia and motor acquisition delay. CDG-Ia diagnosis was made after CDT measurement (two determinations, 18,1% and 16,9%; reference <2,6% from total transferrin) and Plasma Transferrin Isoelectric Focusing. Phosphomannomutase enzyme activity in fibroblasts culture from skin biopsy was normal, being initially classified as CDG-X. However, molecular genetic testing of PMM2 showed a doble heterozygosity F157S/C241S, corresponding to a milder form of CDG-Ia. At 21 months physical examination revealed right eye convergent strabismus, axial and peripheric hypotonia, weak osteotendinous reflexes, sacrum-ilíac fat pads and absent inverted nipples. Coagulation studies were normal, aspartate aminotransferase (AST) and total T3 were increased, and urinalysis did not revealed proteinuria. At 7 years old, neurologic examination was almost normal, with discrete hypotonia. Actually, she presents a post-chirurgical right eye divergent strabismus and some difficulty to fine movements (ex: drawing), without overt clinical manifestation of thrombosis so far, although coagulation tests had revealed a decreased antithrombin (49%; reference 80-120%). Thyroid function normalized and other tests were similar to the previous results. She frequents a regular school, with acceptable results and discrete curricular adaptations. *Summary/Conclusions.* Deficiency of factor IX, factor XI, antithrombin, protein C and S can be associated to CDG-Ia and are indicators of a worse prognosis. Low levels of coagulation factors rarely cause clinical problems in daily activities, but must be acknowledged if an individual with CDG-Ia undergoes surgery, because of increased risk of bleeding and/or deep venous thrombosis. It should be possible to proceed to the prenatal diagnosis of these diseases and to appropriate genetic counseling. The CDG-Ia seems to be the first identified autossomal recessive disease in which the risk of recurrence in the family is greater than the expected for these situations.

2002

PULMONARY ARTERIAL HYPERTENSION IN β-THALASSEMIA MAJOR PATIENTS: SYMPTOM & QUALITY OF LIFE IMROVEMENT AFTER TREATMENT WITH BOSENTAN

K Farmaki,[1] P Kolymbianaki,[1] I Tzoumari,[1] C Pappa,[1] P Kariofillis,[2] V Voudris[2]

[1]General Hospital of Corinth, Corinth, Greece; [22]nd Cardiology Dept., Onassis Cardiac Surgery Center, Athens, Greece

Background. Cardiac failure represents the leading cause of mortality in _-thalassemia major patients (TMp). Pulmonary arterial hypertension (PAH) is implicated in cases of premature death. PAH pathophysiology is complex. *Aim.* Identify TMp at risk and investigate the efficacy of bosentan (endothelin-1 receptor antagonist). *Patients & Methods.* - We retrospectively analyzed 55 TMp (mean age 34,3±7,5y, range 10-51y). After Echo-Doppler imaging, we selected 23/55 (42%) TMp with PASP>35mmHg. 28 normal & 4 TMp with overt signs of left heart disease (LVEF<55%) were excluded. - TMp with right ventricular (RV) dysfunction were further analyzed by pulmonary function test (PFTest) and 6-minute walk test (6MWD). 1 with abnormal PFTest was excluded. The others were classified according to WHO criteria: functional class-I: 10- PASP=35-45mmHg, class-II (slight limitation of physical activity): 8- PASP=46-55mmHg, class-III (marked limitation of physical activity): 4- PASP=56-70mmHg. - Treatment with bosentan was prescribed in class II & III, for 12 months, starting from 124mg and progressing to 250mg in one month. TMp were investigated at baseline and after 12 months for: PASP, 6MWD, Brain Natriuretic Peptide (BNP), ALT, AST and Quality of Life (QOL) by SF-36 Health Survey. - Statistical analysis was performed by Stata Corp., College Station, USA. - The Hospital Ethical committee approved the study. All patients provided written informed consent. *Results.* TMp were well transfused (mean Hb before transfusion=10,8 g/dL) and well chelated by combined treatment. Mean Ferritin: 251ng/dL, LIC (Ferriscan™): 1,2 mg/g/dwt, MRI-T2*L: 28,7 msec, T2*H: 34 msec. 1. Risk factors: § 8/12 males. § 11/12 splenectomized. § Mean PTL=536±222 (8/12 acetylsalicylic acid treatment). § Hereditary thrombophilia: 2/12 homozygous MTHFR, 4/12 heterozygous PAI, 5/12 double heterozygous MTHFR+PAI, 1/12 heterozygous MTHFR. § Associated complications: 7/12 Hypothyroid, 8/12 Glucose metabolism abnormalities & Diabetes, 4/12 hep C positive. 2. Follow up after 12 months of treatment: § PASP decreased: 57,2±9,2 *vs.* 49,5±7,3mmHg (P=0.002). § 6 MWT increased: 514±80 *vs.* 609±65 (P=0.002). § BNP decreased: 35,2±18 *vs.* 29±13 (P=0.007). § No increase in ALT & AST. § Improvement of QOL: SF-36, General health (8 *vs.* 7), P=0.04; Physical function (13 *vs.* 11), P=0.006; Physical role (13 *vs.* 10,5), P=0.001; Emotional role (13 *vs.* 10), P=0.006; Social function (13 *vs.* 11), P=0.006; Bodily pain (13 *vs.* 10,5) P=0.02; Vitality (10,5 *vs.* 9), P=0.004; Mental health (10 *vs.* 8,5), P=0.02. 3. Adverse events: 1 TMp discontinued treatment because of pregnancy; she delivered a healthy baby. 2 TMp reduced bosentan dose temporarily after ALT increase (>3 and ≤5 x ULN). *Conclusion.* PAH is a progressive disease leading to right heart failure and death. This is the first study that provides evidence of treatment with bosentan. Identifying and treating TMp at risk is imperative. This data indicates that bosentan is well tolerated, improves exercise ability, decreases the rate of clinical worsening and improves QOL.

2003

FACTOR FV H1299R (HR2) IN YOUNG PATIENTS WITH THROMBOEMBOLIC DISEASE

M Malo, S Valle, I Izquierdo, E Bonafonte, C Gonzalez, M Paricio, V Dourdil, L Larraz, O Gavin, R Cornudella

Hospital Clínico Universitario Lozano Blesa, Zaragoza, Spain

Background and objectives. Is well known that FV Leiden involves a significant risk of venous thromboembolism (VTE). Recently, a complex haplotype of FV HR2 (M385T, H1299R, M1736V and D2194G) has been reported to be a possible risk factor for the develovement of VTE, althouh its implication is still questionable. The aim of this study is to evaluate the incidence of the Factor V gene mutation H1299R (HR2) in young patients with VTE in our area. *Desing and methods.* We designed a descriptive, retrospective study in our area (Sector ZARAGOZA III) The follow-up took place between 01/01/07 and 01/01/10. We selected 65 patients younger than 55 years old. They were screened for a classic thrombofilia study and an extended genetic study with the determination of FV HR2 to assess the risk factors associated to the different clinical manifestations of VTE. *Results.* The FV HR2 haplotype heterozygous has been identified in 9 patients with VTE. 5 men and 4

women. The thrombotic events found in our patients were: deep venous thrombosis (DVT) (5 patients), pulmonary embolism (PE) (1 patient), deep venous thrombosis and pulmonary embolism (DVT/PE) (4 patients) and recurrent superficial venous thrombosis (SVT) (1 patient). All patients with FV H1299R associated risk factors of VTE. 7 patients had acquired risk factors: immobilitation (3), oral contraceptive treatment (2), cancer (2). In 2 patients that developed spontaneous VTE were detected hereditary risk factors: FV R506Q mutation (1) and protein S deficiency (1). *Conclusions.* Factor V H1299R increased the risk of VTE in patients with others acquired or hereditary risk factors associated. Thus, further studies looking for no habitual genetic thrombophilic mutations are recommended.

2004

LABORATORY INVESTIGATION FOR THROMBOPHILIA IN PATIENTS <60 YEARS WITH ISCHEMIC STROKE

N Tragomalos, I Anagnosti, T Assimakopoulou, A Giotsidou, E Makri, M Stamouli, P Lianidou

KAT Hospital, Kifissia Athens, Greece

Background. Ischemic stroke is the most common type of stroke and one of the most common causes of death worldwide. Though it is considered to be a disease of the elderly, 50% of patients are <75 years and 3% are young adults. *Aims.* The aim of this study was to detect coagulation defects in patients <60 years with ischemic stroke. *Methods.* The study included 82 patients (53 men and 29 women, mean age: 50 years). Blood samples were drawn in the first 24 hours after admission in the Neurology Department of our hospital before the initiation of anticoagulant therapy. Imaging studies of the brain (CT and/or MRI) were performed in all patients. Among these patients, 50 were diagnosed with ischemic stroke, 28 with transient ischemic attack and four with transient global amnesia. The following were considered risk factors for ischemic stroke: hypertension (HT), diabetes mellitus (DM), hyperlipidemia (HL), personal and/or family history of stroke. All patients were evaluated for protein S (PS), protein C (PC), activated protein C resistance (APCR), antithrombin III (AT), lupus anticoagulant (LA), fibrinogen and D-dimers. *Results.* In this study coagulation defects were detected in 25 cases (30%). Among these patients, 11 (13%) had abnormal APCR. In three of the above 11 patients PS deficiency was observed and in four patients factor V Leiden heterozygosity was found without any coexisting risk factors (HT, DM, HL). In nine out of the 25 patients (11%) LA was present. One of these nine patients had low levels of both PC and PS. Among those 25 patients, one patient was discovered with low PS levels as the sole abnormality. No patient had AT deficiency. Fibrinogen and D-dimers were elevated in 77% and 37% of patients respectively and are considered adverse prognostic factors. Summary/*Conclusions.* a. In the sample of patients presented in this study, 30% exhibited defects of the haemostatic mechanism. b. Laboratory investigation for thrombophilia should be performed in young and middle aged patients with ischemic stroke and it could be useful in both prognosis and treatment.

2005

COAGULATION PROFILE IN PATIENTS WITH TYPE 2 DIABETES MELLITUS AND CARDIOVASCULAR DISEASE

O Badulescu, C Badescu, I Alexa, C Manuela, M Badescu

Univ.of Medicine&Pharm.Gr.T.Popa, Iasi, Romania

Background. Vascular complications are considered the first cause of death in diabetic patients. The alterations of the hemostasis in diabetes mellitus (DM), that favor a prothrombotic state, include modifications in platelet functions, in the coagulation system and fibrinolytic sistem. Individuals with DM have an increase of the levels of factor X (Stuart-Power), fibrinogen and Von Willebrand Factor, increasing the risk of cardiovascular disease. *Aims.* The determination of the thrombotic risk in patients with type 2 diabetes mellitus compared with non-diabetic patients with cardiovascular disease, and the relation between determined parameters of coagulation. *Methods.*One hundreed eighty patients divided in 3 groups (diabetic without ischemic cardiopathy-related disorders (DM), diabetic with clinical or off-clinical (EKG, Echocord) ischemic cardiopathy-related disorders (DM+IC), non-diabetic with ischemic cardiopathy-related disorders (IC)) have been includeed in study; the patients were tested by determining three factors of coagulation profile: F X, fibrinogen and Von Willebrand Factor. *Results.* The highest level of the plasmatic fibrinogen has been observed in diabetic patients (groups DM and DM+IC) and this level is in direct relation to glycemic control; in groups DM+IC (P<0,005) and DM (P<0,05) has been observed the most powerful correlations between Von Willebrand Factor *vs.* fibrinogen. *Conclusions.* DM is by itself a major atherogenesis risk factor. The risk of developing cardiovascular events is higher in DM patients than in non-diabetic patients because hyperglycemia determines endothelial dysfunction and metabolic disorders which would explain the atherosclerosis acceleration in these patients.

2006

LOW LEVELS OF HEPARIN - RELEASABLE TISSUE FACTOR PATHWAY INHIBITOR ARE ASSOCIATED WITH INCREASED RISK OF VENOUS THROMBOEMBOLISM

H Ghoneim

Egypt, Mansoura University, Faculty of Medicine, Mansoura, Egypt

Tissue factor pathway inhibitor (TFPI) is synthesized by vascular endothelial cells and is located *in vivo* in at least four pools: approximately 75% is released into the circulation after injection of heparin, 20% circulates in blood bound to lipoproteins, 2.5% circulates free and 2.5% is present in platelets. The plasma pool (lipoprotein-bound and free) has been reported to be of less importance for protection against thrombosis than the heparin releasable pool. We therefore designed this study to investigate the relation of different pools of TFPI to venous thromboembolism (VTE). We measured plasma levels of TFBI by ELISA technique before (plasma pool) and ten minutes after intravenous injection of 7500 IU of unfractionated heparin (heparin-releasable pool) in 35 patients with history of venous thromboembolism and 20 healthy individuals. The mean plasma TFPI pool value was 71.77 + 21.15 ng/mL in VTE patients compared to controls (66.01+12.81ng/mL) (P=0.1). The mean heparin releasable pool value was 260.38 + 69.46 ng/mL in VTE patients compared to controls (385.72+74.30 ng/mL) (P=0.000). At a cut off value of 40.39 ng/mL for plasma TFPI pool in controls, we found that two out of thirty five VTE patients had values below the cut off value. At a cut of value of 237.12ng/mL for heparin-releasable pool in controls, we demonstrated that 15 out of 35 VTE patients had values below the cut off value. The likelihood ratio of low plasma TFPI pool for VTE was 4.66 (P=0.119) compared to 18.6 (P=0.021) for low heparin releasable TFPI pool. *Conclusions.* the data from the present study confirms the previous reported that the plasma TFPI pool is less important for protection against venous thrmboembolism and proves the association between low heparin - releasable TFPI pool and risk of venous thromboembolism. However, a real causative role needs further elucidation.

2007

PROTEIN C LEVEL IN BETA THALASSEMIA MAJOR PATIENTS IN EAST DELTA OF EGYPT

T Hassan,[1] R Elbehedy,[2] D Youssef,[2] G Amr[2]

[1]Zagazig University, Zagazig, Egypt; [2]Zagazig university, Zagazig, Egypt

Background. Thalassemic patients have increased risk for thromboembolic complications. The question arising from this is whether thromboembolic complications are the result of deficiency of protein C or not? *Aims.* We aimed to investigate the status of protein C anticoagulant pathway in thalassemia major patients and its relation to the hypercoagulable state in these patients. *Methods.* Fifty patients with β-thalassemia major; 30 non-splenectomized and 20 splenectomized and twenty healthy children as a control group, were investigated for their serum ferritin, liver enzymes, serum albumin, fibrinogen, protein C and protein S levels, thrombin antithrombin complex (TAT) and D-dimer. *Results.* Thalassemic patients had lower levels of protein C and S and higher levels of D-dimer and TAT than control group. These findings were more obvious in splenectomized patients and those with infrequent blood transfusion. *Summary/Conclusions.* Protein C plays a major role in the hypercoagulable state in thalassemic patients. These findings raise the issue whether it would be cost-beneficial to recommend prophylactic antithrombotic therapy in high risk thalassemic patients. A wider prospective study will be necessary to delineate under which circumstances this might be implicated, and at what level of protein C deficiency to start prophylactic antithrombotic therapy.

2008

PREGNANCY COMPLICATIONS AND ANTIPHOSPHOLIPID ANTIBODIES

K Taouli, C Abiayad, S Ayad, R Benhabib

Université Abou Bekr Belkaid, Tlemcen, Algeria

Background. Women with acquired and hereditary thrombophilia are at increased risk of developing venous thromboembolism and other associated gestational vascular complications like fetal loss, preeclampsia, intrauterine growth restriction, and placental abruption during pregnancy. These complications are a major cause of maternal and fetal morbidity and mortality. The primary objective of this study was to determine if elevated antiphospholipid titers or presence of lupus anticoagulant were correlated with the presence of vascular placental complications in women who admissed in obstetric consultation of tlemcen hospital, Algeria. *Methods.* The medical records of pregnant women were retrospectively collected between january 2007 and 2010. Maternal and perinatal histories including demographic data, medications, obstetric histories, and neonatal clinical manifestations and laboratory data were analyzed. We tested anticardiolipin antibodies (acl)(igg and igm isotypes)and anti-β2 gpi by enzyme linked immuno-assay (elisa), la activity (lac) using both drvv screen /confirm and staclot la. The possibility that the relationship between elevated antiphospholipid antibody titers and the outcomes of preeclampsia/eclampsie, recurrent miscarrieges, fetal death, help syndrome may have been modified by the presence of sle was evaluated in a multipl logistic regression model by creating a composite interaction term. *Results.* 51 with pregnancy complications were included. 45 of these patients had experienced frequent spontaneous abortions (88%), and five had unexplained fetal deaths (~9%). 3 had help syndrome and eclampsie, none of them had vascular thrombosis. Specific autoimmune antibodies were detected, including anticardiolipin antibody (n=8), anti-β2 glycoprotein i (n=3), and lupus anticoagulant (n=6). Women who had elevated antiphospholipid antibody titers igg had an increased adjusted odds ratio for recurrent miscarriages (P<0.01). *Conclusion.* There are several possible mechanisms by which antiphospholipid antibodies (apl) may have adverse effects on placental functions. A strong correlation between elevated igg antiphospholipid antibodies titer status and recurrent miscarriages was also found, however, whether or not there is an association between high titers of ap antibodies and preeclampsia in the absence of aps is unclear. Further investigations are needed to better understand how apl induce obstetric complications and to better clarify the functional role of heparin in the human placenta, leading to more successful therapeutic options.

DECREASED LEVEL OF HDL-CHOLESTEROL IS A RISK FACTOR FOR THROMBOSIS IN ESSENTIAL THROMBOCYTEMIA

A Gaman,[1] C Netoiu,[2] G Gaman[1]

[1]*University of Medicine and Pharmacy Craiova, Craiova, Romania;* [2]*Filantropia City Hospital, Craiova, Romania*

Background. Thrombosis represent one of the main features of essential thrombocytemia. Prior vascular events, advanced age and higher leukocyte count have been identified as risk factors for thrombosis. *Material and method.* we evaluate the role of decreased HDL- cholesterol for thrombosis at 30 patients with essential thrombocytemia associated with dyslipidemia, diabetes mellitus, obesity, hospitalized in the Clinic of Hematology from Craiova (Romania) between 2007-2009. The biological parameters evaluated were: value of haemoglobine, leukocyte count, thrombocyte count, peripheral blood smear, bone marrow smear, bleeding time, prothrombine Quick time, coagulation time, aggregation platelets tests, value of glycemia, triglyceridemia, cholesterolemia, HDL- cholesterol, LDL- cholesterol, the usual hepatic and renal tests. *Results.* Median age was 57 years, female/male ratio = 1,4, median platelet count of diagnosis was 782×10^9/L , median leukocyte count was $10,3\times10^9$/L, median value of HDL- cholesterol was 31 mg/dL. Thrombocytemia was present in all cases and leuko- cytosis in half of patients. Dyslipidemic status was present in 14 patients , obesity in 6 patients and diabetes mellitus in 5 patients. Thrombosis were present in 10 cases: Budd- Chiari syndrome in one case, coronarian thrombosis in two cases, cerebro-vascular thrombosis in two cases, deep thrombosis of the legs in three cases and deep thrombosis of the arms in two cases. All these cases associated decreased value of HDL-cholesterol < 30 mg/dL and a higher leukocyte count; six patients associated obesity and five patients diabetes mellitus. *Conclusion.* decreased HDL- cholesterol value associated with obesity, diabetes mellitus and a higher leukocyte count represent a risk factors for thrombosis in essential thrombocytemia.

2010

EXPERIENCE IN THE STUDY OF LUPUS ANTICOAGULANT (LA) WITH STC (SILICA CLOTTING TIME) AND DRVVT (DILUTE RUSELL VIPER VENOM TEST) AS DIAGNOSTIC TOOLS.

M Infante,[1] F Carretero Lopez,[2] AM Rodriguez Huerta,[1]
C Pascual Izquierdo,[1] G Perez Rus,[1] J Diez Martin[2]

[1]*Hospital universitario Gregorio Marañon, Madrid, Spain;* [2]*Gregorio Marañon, Madrid, Spain*

The LA measures the ability of the antiphospholipid immunoglobulins to prolong (*in vitro*) phospholipid-dependent coagulation test. The amount and composition of phospholipids is a quantitative determinant in the assay, and it is important to reduce the number of platelets in the plasma. LA tests do not have a 100% sensitivity, therefore at least two different tests to study both coagulation ways are recommended. Due to the relative and poor specificity of LA tests, and the risk of false positives, it is extremely important to select the patients for the study. *Reason of the study.* to retrospectively analyze LA study in patients with the following conditions: thrombophilia study for artherious or venous thrombosis, women with pregnancy complications, prolonged APPT in asymptomatic patients, other (LES, inmune thrombocitopenia). The LA has been conducted following the 2009 guidelines for AL detection (J Thromb Haemost 2009;7:1737-40). Frozen PNP plasma was used as control. We define positive DRVVT a normalized ratio > 1,2, and a positive CTS a normalized ratio >1,4. *Materials and methods.* We reviewed 300 consecutive specimens of selected patients for the AL study in our Hematology department, processed between October 2009 and January 2010. *Results.* 42 patients resulted positive for LA at least in one of the tests (normalized ratio of dRVVT and TCS); the median age of the patients was 55 years old, and 75% of them were women. 13 patients suffered from thrombosis or pregnancy complications (3 of them had a known APS syndrome). We identified 2 groups (Table 1): group A included 13 patients with thrombotic events or pregnancy complications, with a median age of 42, and moderate or high titers of aCL and B2GPI in 8 cases. Group B included an older population (median age of 64 years), asymptomatic, with prolonged APPT and negative aCL and ABGPI. *Conclusions.* We identified a group of patients with clinical cryteria of APS (patients with thrombosis), presence of positive aCL, and/or positive B2GPI and positive AL test, that is coincident to high risk patients for thrombotic events. Furthermore positive LA is also observed in older asymptomatic patients without other aPL, that could match with a subpopulation of aPL without clinical significance. Waiting for more specific tests for LA, the SCT and Drvvt are an excellent combination for the study of LA, as the current guidelines state.

Table 1.

	GROUP A Trombosis events and pregancy complications (n=13)	GROUP B Asymptomatic with prolonged APTT (n=29)

2011

ETIOLOGIC PROFILE AND OUTCOME OF NEONATAL THROMBOPHILIA IN EAST DELTA OF EGYPT

U El Safy, T Hassan, M Beshier, M Morad, K Geraby

Zagazig University, Zagazig, Egypt

Background and objectives. Thrombophilia can be defined as a predisposition to form clots inappropriately. Thrombotic events are increasingly recognized as a significant source of mortality and morbidity. The outcome of neonatal thrombophilia depends on the site of thrombosis. The presence of prothrombotic risk factors and, in particular, of the factor V Leiden mutation, is significantly associated with poor outcome after perinatal cerebral infarction; this may to predispose to hemiplegia, cerebral palsy and seizures. *Patients and methods.* This study was carried out on 30 neonates with purpura fulminans with or without evidence of venous or arterial thrombosis, detected at the neonatal intensive care unit at Pediatric Departments of Zagazig University Hospital, in east of delta of Egypt during the period from 2000 to 2008.All the patients were screened beside routine investigations for C reactive protein, as well as blood culture. They were also screened for evidence of thrombophilia thorough level of prothrombin time, thromboplastin time, D dimer, fibrin degeneration products [FDPs] as well as level of protein c, protein s, and antithrombin and factor V Leiden levels. Follow up of the patients for one year was done to evaluate psychomotor development and the recurrence of thrombophilia with radiological and laboratory investigations. Written informed consent were taken from one of parents of studied cases. *Results.* Our results revealed that hereditary thrombophilia represented 8/30 [26.7%] of neonatal thrombophilia. Factor V Leiden mutation was detected in 4/8, protein C deficiency in 2/8, Protein S in 1/8 and one case with antithrombin III. Acquired thrombophilia was 22/30 .The most common cause was septicemia 19/22. As regard of outcome, death represented with 18 cases of acquired thrombophilia, while cases suffered from cerebral palsy diplegia and seizures. Outcome of hereditary thrombophilia revealed death occurred in 2 cases while 4 cases suffered from blindness and cerebral palsy. Other two cases suffered from deformity of skin and recurrent thrombosis and seizure. *Conclusion.* Neonatal thrombophilia is considered a cause of cerebrovascular events in children. There is a link of thrombophilia with cerebral palsy.

2012

AN OPINION SURVEY ON ANTICOAGULANTS IN A LARGE NORTH LONDON NHS TRUST IN THE UK

P Kumar, S Berney, M Wong, S Alam

Barnet General Hospital, Barnet, UK

Background. Thromboprophylaxis and therapeutic anticoagulantion for prevention and treatment of venous thromboembolism are two issues the majority of doctors registered with the General Medical Council in the United Kingdom are expected to deal with, especially in the early stages of their professional careers. Audits of compliance with NICE guidelines for VTE prevention have become a national priority, and in the UK VTE prevention will effectively be mandated through financial incentivization. Greater than 90% of NHS Trusts are expected to demonstrate compliance with the national recommendations, but at the moment less than 50% are compliant. The National Patient Safety Agency issued an alert ("Alert 18") in March 2007 to advise healthcare organizations in the UK to take steps to manage the risks associated with prescribing, among other things, of anticoagulant therapy. In the majority of NHS trusts this task (thromboprophylaxis and initiation of therapeutic anticoagulation) falls to mainly junior doctors. Competency assessments of prescribing thromboprophylaxis and anticoagulant therapy are not necessarily carried out upon commencement of new jobs, although tools are available for this. With the introduction of new anticoagulants (direct thrombin inhibitors and anti Xa inhibitors), the tools require updating. Also, although much information is available on the new drugs it is unclear if doctors outside of specialist units are aware about their indications, uses and side effects. To get a clearer understanding of prescribing habits and knowledge about the new anticoagulants, we carried out a survey among the doctors in our NHS Trust (Barnet and Chase Farm Hospitals NHS Trust) which has a catchment population of 500,000. *Aims.* 1) To gain an insight into the anticoagulant prescribing practices of doctors. 2) To assess knowledge of new anticoagulant agents. 3) To confirm if NPSA Alert 18 recommendations with regards to prescribing are being followed. *Methods.* A simple paper questionnaire was devised with 14 questions, with answer boxes to tick. Although the questionnaire was anonymous, participants were asked to indicate their specialty and rank. The questionnaire was distributed to medical colleagues across our NHS Trust by the Haematology team comprising a specialist registrar, core medical trainee (year 2) and foundation year 1 trainee. Each returned survey was entered onto a database to allow collation of results. *Results.* So far there have been 24 returned questionnaires, with 1 rejected as it was only partially completed. We are hoping for at least 80 returns in total from all the grades and specialties in the trust to get meaningful data which would allow us to implement changes in the induction of new doctors in the trust as well as update existing doctors on new developments in thromboprophylaxis and anticoagulant prescribing in order to bring the trust in line with the recommendations from the Chief Medical Officer, National Institute of Clinical Excellence and the National Patient Safety Agency.

2013

UPSHAW-SCHULMAN SYNDROME REVEALED BY A POST PARTUM COMPLICATION; ABOUT A TUNISIAN PATIENT

S Mseddi,[1] M Ghorbel,[1] A Veyradier,[2] H Rekik,[3] H Chelly,[4] M Bouaziz,[4] J Gargouri,[3] M Elloumi[1]

[1]Hedi Chaker Hospital, Sfax, Tunisia; [2]Hopital Antoine Beclere, Clamart, France; [3]Centre Régional de Transfusion Sanguine, Sfax, Tunisia; [4]Hopital Habib Bourguiba, Sfax, Tunisia

Introduction. Upshaw-Schulman syndrome is a congenital thrombotic thrombocytopenic purpura (TTP) due to mutations in the gene that encodes for ADAMTS13. It accounts for only 2-4% of all TTP cases. Many women have their first episode of TTP during pregnancy or the postpartum period. We report a case of congenital ADAMTS13 deficiency with a complex obstetric history. *Observation.* A 25-year-old woman, a previously healthy Tunisian female, issued from a non consanguineous marriage but endogamy, GI PI, was referred to our hospital at 38 weeks of gestation for gestational hypertension complicated by probable HELLP syndrome. An emergency caesarean section was performed. Afterwards, a diagnosis of TTP was made due to the combination of fever, convulsions, haemolytic anemia with presence of schizocytes (20%), peripheral thrombocytopenia and moderate renal failure. The patient was treated with repeated plasmapheresis, combined with corticosteroid therapy and oral anticoagulant with a good evolution. Further testing showed that the patient had very low (< 5% of normal) activity of ADAMTS13 and no ADAMTS13 inhibitor. The Upshaw Schulman syndrome has been retained. None of the family members (two multipareous sisters and one brother) had a history of TTP-like disorder, thrombosis, or bleeding episodes. A search for mutations in the gene for ADAMTS13 and a family inquiry are underway. Today, after a follow-up of 9 years, the patient is in sustained remission with moderate thrombocytopenia (platelet count > 100 Giga/L) and she wishes a second pregnancy! *Discussion.* TTP is difficult to diagnose, can be triggered by pregnancy, and has clinical features similar to those of other pregnancy-associated diseases such as HELLP syndrome. Therefore, the diagnosis of TTP should be considered in any patient with otherwise unexplained microangiopathic haemolytic anemia and thrombocytopenia in order to enable timely life-saving treatment. Pregnancy may precipitate TTP, presumably triggered by physiological changes. A study showed that 13% of woman diagnosed with thrombotic microangiopathy to be pregnant. According to a review of the literature, 100% of pregnant women diagnosed with congenital ADAMTS13 deficiency developed recurrent TTP in the subsequent pregnancy. What type of management plan can be constructed for today's practice for our patient, known to have congenital ADAMTS13 deficiency, who is at risk of recurrent TTP?

2014

QUALITY OF LIFE IN CHRONIC LYMPHOCYTIC LEUKEMIA AND NON-HODGKIN'S LYMPHOMA: AN ONCOLOGY CENTER STUDY OF 80 PATIENTS

G Mihaescu,[1] A Stoian,[1] R Buzas,[1] A Negru[2]

[1]Oncomed, Timisoara, Romania; [2]ONCOMED, Timisoara, Romania

Background. Although the diagnosis of chronic lymphocytic leukemia (CLL) and non-Hodgkin's lymphoma (NHL) has a profound effect an quality of life (QOL), there are only a few studies that measure the QOL in these patients or compare it with the QOL in the general population. *Methods.* We conducted an oncology center study of patients with CLL and NHL using standardized instruments with published

population norms to evaluate fatigue and quality of life. Co-morbid health conditions were assessed using the Charlson Co-morbidity Index and we used additional questions to explore how often patients thought about their disease and special worries about it. *Results.* Between July 2009 and January 2010, 80 patients with CLL and NHL responded to the study. The physical, social/family, functional and overall QOL scores were similar to published population norms. The emotional well-being scores of CLL and NHL patients were better than the scores of patients with other types of cancer, but the majority of the patients thought about their disease daily (53%). In contrast, the emotional well-being of CLL and NHL patients were lower than the scores of general population. To determine whether emotional well-being scores improved over time, we evaluated emotional QOL among patients based on time interval since diagnosis. The emotional well-being scores improved with time and treatment. Differences in QOL were observed by stage disease, being lower among patients with advanced stage disease. Overall, the mean fatigue score was higher than population norms (2.9 *vs.* 2.2) Fatigue scores of stage A (CLL) and I A or II A (NHL) were almost identical to population norms (2.3 *vs.* 2.2), scores of advanced disease-stage C and IVB patients (3.7 *vs.* 2.2) were greater than reported for general population. Factors associated with lower quality of life included age, severity of co-morbid health conditions and current treatment. *Conclusions.* CLL and NHL have a profound effect on QOL at all disease stages. The impact of both diseases on QOL appear to differ from that of other malignancies with a less marked impact on emotional QOL, compared with literature, probably because of promising new treatments. Research identifying efficacious education and psycho-oncologic support interventions for patients with both diseases, and other malignant conditions are still needed.

2015

HOW TO MEASURE COGNITION IN HEMATOLOGICAL-ONCOLOGICAL PATIENTS?

P Duska, R Dintinjana Dobrila, T Valkovic, A Duletic Nacinovic, I Host, I Roncevic Grzeta, K Ruzic, M Petkovic, I Lovasic, I Ruzic Pavlovic

Clinical Hospital Center Rijeka, Hreljin, Croatia

Background. Cognitive functions affect the quality of life of malignant disease victims. In research to date there has been a huge problem with objective measuring of cognitive abilities. Some very well-designed studies to date have not been conclusive and the authors themselves cited inadequate sensitivity of tests and equipment which were deficient in detecting minimal changes. *Aims.* The aim of research was to:1. assess to what extent malignant disease and anaemia are reflected on cognitive abilities of oncological-hemotological patients 2. define orientational norms for hematological-oncological patients, and 3. compare them with previously established norms for subjects with different educational levels and occupations using the state-of-the-art computerised equipment - a CRD instrument (Complex Reactiometer Drenovac). It is anticipated that the work will serve in designing future similar research. *Methods.* Subjects were chosen from a stratified sample of an adult patient population of both sexes who are under observation or being treated at Clinical Hospital Center, Rijeka, Croatia. A total of 400 patients divided in four commensurable groups (100 patients each) with or without malignant diseases and with or without anaemia were included in the study. The results of the psychological tests were analyzed through application of ANOVA statistical procedures. Through comparison of cognitive functions among groups, standard norms were made. *Results*. Assignment indicators in the first testing (T1) and in the repeated testing (T2) after anaemia correction, checking differences in tests among the groups as well as testing the differences between the first and second testing, demonstrated that anaemia and malignant disease are significantly connected with loss of cognitive abilities. In all assignment indicators of cognitive tests, Group 1 (with malignant disease and anemia) demonstrated the worst results in comparison with all other groups (P<0.001). After correction of anaemia, cognition improves but does not reach the result of the other groups. In Group 1 after treatment of anaemia, there was a significant restoration of cognitive functions (P=0.001) in all tests except for tests CRD21 (visual orientation) and CRD 341 (memorising). Readings for cognitive functions of all tests were compared with previously defined standards in various populations of people which allowed us to define a normative for oncological haematological patients. *Conclusions.* It was concluded that anaemia and malignant disease significantly affect cognition, where they have an additive effect. With anaemia treatment, cognitive abilities are remedied but they never reach the level of anaemia-free patients or general population. Norms for oncological-hematological patients were compared with previously established norms for subjects of different educational levels and occupations and they have been shown in tabulated form.

2016

A 15-YEAR REPORT ON NEW BIRTHS, SURVIVAL AND PRESENTING COMPLICATIONS OF PATIENTS WITH BETA-THALASSEMIA MAJOR LIVING IN NORTHERN GREECE

M Economou, A Teli, A Papagianni, V Perifanis, A Christoforides, I Tsatra, M Athanassiou-Metaxa

Hippokration General Hospital, Thessaloniki, Greece

Introduction. Life expectancy in thalassemia patients has improved over the years, reflecting dramatic changes in therapy. At the same time, national screening programs have limited the number of affected births worldwide. Aim of study: Report on new births, survival and complications in beta-thalassemia patients followed at the Thalassemia Unit of "Hippokration"General Hospital of Thessaloniki in Northern Greece. *Patients-Methods.* 163 patients participated in a retrospective study covering the last 15 years. Parameters evaluated where as follows: mean age, gender, genotype and beta gene mutation frequency, patient survival, iron overload (based on mean ferritin value of the past 5 years), disease related complications, reasons for death and number of new births. *Results.* 80 men (49%) and 83 women (51%) participated in the study. The mean age was 20.81 years (± 9.3 SD). The most frequently reported mutation was IVS1 -110 (44.4%). Survival was 86% at 30 years of age. The majority of patients (70.7%) had a mean serum ferritin level of <2.000 ng/mL. With regards to complications, a large proportion of patients presented with osteopenia or osteoporosis (80%), while a serious number presented with hypogonadism, abnormal glucose metabolism and heart failure. Thirteen deaths were reported during the 15 year period, with the major cause of death being heart disease (53.8%) and sepsis (30.7%). The number of new births during the time of study was 38, resulting mainly from absence of information (39.4%), medical mistakes concerning prenatal diagnosis or genetic counseling (36.8%) and informed choice due to religion issues. Most of the new births came as a result of interracial marriages. *Conclusions.* Survival of thalassemic patients continues to improve as a result of new therapeutic regimens but disease complications still prevail, affecting the patient's quality of life. The number of new births has decreased following the application of prenatal screening programs, however, better information of state and medical stuff is required in order to prevent new thalassemics being born.

2017

MUSCULO-SKELETAL FUNCTION ASSESMENT IN HEMOPHILIA A: A CROSS SECTIONAL STUDY IN EAST DELTA OF EGYPT

S Badawy,[1] M Badr,[2] T Hassan[2]

[1]Zagazig University Hospital, Zagazig - Egypt, Egypt; [2]Zagazig University, Zagazig, Egypt

Background. Morbidity in haemophilia A has been described predominantly in terms of musculoskeletal dysfunction and assessed by the clinical and radiological joint scores. These scores document changes in a particular joint, but do not reflect the impact of these changes on the individual in terms of his overall musculoskeletal function. The Functional Independence Score in Hemophilia (FISH) is a performance-based assessment tool used to measure the patients' musculoskeletal functional ability. *Aims.* We aimed to evaluate the musculoskeletal function in our hemophilia A patients and to assess the impact of degree of factor VIII deficiency and different replacement therapy regimens on it. *Methods.* Cross-sectional study on 120 children 80 hemophilic and 40 sex-, race-, and age-matched healthy males was conducted. Children over 5 years of age were selected. Musculoskeletal function was assesed using Functional Independence Score in Hemophilia (FISH), a performance-based instrument. FISH measures the patient's independence in performing seven activities under three categories: self-care (grooming and eating, bathing and dressing), transfers (chair and floor) and mobility (walking and step climbing). Each function is graded from 1 to 4 depending on the amount of assistance needed in performing the function. All relevant data regarding degree of factor VIII deficiency and type&frequency of replacement therapy were collected. *Results.* There were no differences in the FISH between controls and patients with mild hemophilia; however, the score was significantly higher in patients with mild hemophilia than patients with moderate or severe hemo-

philia. The most affected activities were squatting, walking, and step climbing. FISH scores were significantly higher in patients recieving regular factor VIII replacement than those recieving either irregular factor VIII replacement or fresh frozen plasma. *Summary/Conclusions.* Regular factor VIII replacement therapy is superior to fresh frozen plasma transfusion in reducing musculoskeletal dysfunction in hemophilia A patients. Also, patients with moderate and severe factor VIII deficiency are more vulnerable to have musculoskeletal dysfunction than those with mild deficiency.

2018

THE ADVANTAGES OF HOMOGENOUS ACUTE LEUKEMIA GROUPS OF PSYCHOLOGICAL SUPPORT IN CONTRAST WITH THE HETEROGENOUS GROUPS

A Parvu,[1] L Petrov[2]

[1]Oncological Institute Cluj-Napoca, Cluj-Napoca, Romania; [2]Oncological Institute, Cluj-Napoca, Romania

Background. The psychologic support group is considered the most efficient form of psychological support. The result of the group therapy is a diminuished fear at the new pacients towards the diagnosis, implicitely a raised confidence in the efficiency of therapeutical means and medical competence. It has been proven that the experience of knowing and interacting with another person suffering of a similar disease, who shares the same feelings is more valuable than an exposure made by the doctor or psychologist about a person with the same experience. *Aims.* We want to compare the efficiency and advantage of the two group types by analysing the feedback from the pacients and their relatives at the end of the group sessions, as well as the group mediators' observations. *Methods.* Since 4.5 years there have been meetings of homogenous and heterogenous support groups in the Oncological Institute, Hematology Department, Cluj-Napoca, Romania. The support groups are open. The heterogenity referrs to pacients with different age, gender, personality, cultural level, background, education, as well as to the pathology, with acces to pacients' groups regardless of their diagnosis, stage, evolution of the disease or therapy type. After two and a half years of experience in organising the groups, we decided to form homogen groups dedicated to acute leukemia. The support groups have two mediators, a psychologist and a hematologist with training of psycho-social counceling. The psychological approaches used within the support group are the informational- educational one (by which the therapeutical compliance and pacients' motivation raises and the false preconceived opinions are defeated and the pacients receive the pertinent sources of information), the cognitive- behaviourist approach (with the purpose of identification and improvment of coping, control of certain symptoms and the emotional support offered. The patients signed the informed consent and the study has the agreement of Ethic Committee of the Medicine and Pharmacy University Cluj-Napoca, Romania. *Results.* In a heterogenous group, the more participants (various in personality, disease i.e.) the more different the problems discussed and the experiences the participants share. The disadvantage of this group is represented by the fact that many times general problems are discussed, the specific disease problems being better handled in homogen groups, dedicated strictly to one pathology. The approach of a detail or a specific problem of a disease in a non-homogen group helps only one group participant, the others may feel left aside, isolated, not understood or may consider the fact that their problems are not important. Discussing in detail the specific apsects of a certain disease in the heterogenous group led to confusion, so that the pacients tried to apply the information discussed on their own disease. *Conclusion.* The acute leukemia patients consider that the more homogenous was the group, the morespecific the goals, and the more focused the intervention. The mediators of the support group consider that the heterogenous group is more difficult to facilitate. They observe that the acute leukemia patients were more active in homogenous group than in heterogenous one.

2019

EVALUATION OF ELDERLY PATIENTS HOSPITALIZED IN HEMATOLOGY DEPARTMENT

C Beyan, K Kaptan, A Ifran

Gulhane Military Medical Academy, Ankara, Turkey

Background. People aged 65 and over are accepted as elderly. People over this age limit could have various chronic diseases and some functional losses related to these disorders. The amount of people aged 65 years and older in Turkey is approximately 7% according to 2005 population census. *Aims.* The aim of our study is to investigate characteristics of elderly people hospitalized and treated in hematology department. *Methods.* This retrospective study consisted of 153 elderly patients hospitalized and treated in our clinic between 2004 and 2009. Mean age of cases was 73.13±5.45 years (mean±standard deviation) (65-88 years) and 93 of them were men. Mean duration of hospitalization was 16.69±16.89 days (mean±standard deviation) (2-86 days). *Results.* Diagnosis of patients with number of cases and hospitalization duration were shown in Table. Cases with hematological malignancy were 58.2% of all older patients and these cases were 76.2% of the cases when hospitalization duration was considered. According to both criteria (number of cases and hospitalization duration), acute myeloid leukemia was most common followed by multiple myeloma and chronic lymphocytic leukemia. One quarter of acute myeloid leukemia cases were secondary leukemia with poor prognosis. Febrile neutropenia was observed in 50.0% and antifungal treatment (except prophylaxis) was given 13.2% of cases with hematological malignancy during hospitalization. There were systemic diseases which could seriously affect standard treatment protocols in 17.0% of all elderly patients. *Conclusions.* As a result, hematological malignancies are serious and common problems observed in elderly patients with concomitant chronic diseases and related organ dysfunctions.

Table. Distribution of diagnosis in elderly patients.

Diagnosis	Distribution of Cases (%)	
	Case Number	Hospitalization Duration
Acute Myeloid Leukemia (n= 35) -secondary (n= 9)	22.9% (5.9%)	42.6% (13.1%)
Acute Lymphoid Leukemia (n= 5)	3.3%	3.3%
Chronic Myeloid Leukemia (CML) (n= 4)	2.6%	4.6%
Chronic Lymphocytic Leukemia (n= 16)	10.4%	9.0%
Hairy Cell Leukemia variant (n= 1)	0.6%	0.4%
Non-Hodgkin's Lymphoma (n= 4)	2.6%	4.3%
Multiple Myeloma (n= 22)	14.4%	11.4%
Waldenström's Macroglobulinemia (n= 2)	1.3%	0.5%
Severe Aplastic Anemia (n= 2)	1.3%	0.9%
Myelodysplastic Syndrome (n= 15)	9.8%	7.1%
Chronic Myeloproliferative Disorder (non-CML) (n= 9)	5.9%	3.5%
Myelodysplastic/Myeloproliferative Neoplasms (n= 2)	1.3%	0.7%
Nutritional Anemia (n= 16)	10.4%	3.4%
Autoimmune Hemolytic Anemia (n= 2)	1.3%	0.4%
Paroxysmal Nocturnal Hemoglobinuria (n= 1)	0.6%	0.7%
Agranulocytosis (n= 2)	1.3%	0.5%
Chronic Idiopathic Thrombocytopenic Purpura (n= 7)	4.6%	4.6%
Hemophilia A (n= 1)	0.6%	0.4%
Deep Vein Thrombosis (n= 1)	0.6%	0.2%
Adverse Effects of Drugs (Cytopenia, bleeding etc.) (n= 6)	3.9%	1.3%

2020

HYPERHOMOCYSTEINEMIA AND ESSENTIAL THROMBOCYTOSIS WITH NOURISHING DEFICIENCY

C Malem

Claudio Malem and Partners, General Alvear, Argentina

Introduction. 154 patients between the ages of 6 and 12 years old were studied: 100 of them were boys and 54 girls, residents in urban areas and belonging to middle/upper strata of society; 85% of the cases presented moderate to severe anemia and severe thrombocytosis accompanied with microcitic elements with plasmatic homocystein highly superior to normal values. An *in situ* inspection was carried out. Every chid´s house, life conditions corresponding to the family circle: parents, brothers an sisters and everybody living in the house, their personal hygiene, their clothing and everyday´s share of food of the family group was observed. As a first step it was decided to radically change the nourishing diet as the former one consisted of carbohydrates during the seven days of the week, changing it for the ingestion of nutriments of protein origin, vegetables and diary products and the use of suitable doses of acenocoumarol. *Materials and methods.* During the first 60 days they were helped with ferrous fumarat and folic acid to raise the hemoglobin level whose value was between 8 at 9 g/dL for boys and 7 at 7,5 g/dL for girls and a minimum dose of acenocoumarol (adjusted to INR) to prevent thrombotic effects. At the next blood control, all the hematologycal values were encouragingly changing, that's why it was decided to suspend the ferrous fumarat and folic acid and acenocoumarol, this allowing the new diet to perform the corresponding supply, and to control the babies and pubescent's weight here after. *Results.* After 90 days, when the corresponding blood control was done the patients had got normal analytical values: between 11 and 11,5 g/dL for boys and 11 g/dL for girls acompanied with normocitic elements and value of count of thrombocytes between 220 and 400×10^9 and the homocystein value disminished remarkably, minor values to those stimates as refer-

ence value. *Conclusion.* All these boys and girls, by means of a diet and the period in which they received ferrous fumarat and folic acid recovered their health and vitality. Basically, it was achieved to disminish the plasmatic homocystein values to normal and manageable values to prevent future thrombotic events.

2021

IFOSFAMIDE-INDUCED SEVERE RENAL TUBULAR DAMAGE IN A CHILD WITH TWO CONSECUTIVE CANCER

Z Karakas,[1] I Yildiz,[1] M Bilge,[2] A Unuvar,[1] S Anak,[1] L Agaoglu,[1] O Devecioglu[1]

[1]Istanbul University, School of Medicine, Istanbul, Turkey; [2]Istanbul University, Pediatric Nephrology, Istanbul, Turkey

Ifosfamide is widely used in the treatment of pediatric solid tumors. Its main adverse effects are various forms of renal tubular damage, but permanent tubulopathy which requires supplementation therapy is a rare situation and became a severe problem when a second tumor which requires chemotherapy occurs. *Case.* Aim was to evaluate ifosfamide-induced nephrotoxicity on growth and renal function in children treated for two consecutive cancer. The mass which detected in the left mastoid cavity during the operation of perforated chronic otitis media was diagnosed as parameningeal rhabdomyosarcoma. The patient was treated with chemotherapy included ifosfamide (Etoposide, Vincristine, Actinomicine-D, ifosfamide, Adriamycin) and radiotherapy. Because he had hypophosphatemia, hyponatremia, glucosuria, proteinuria and polyuria, after ifosphamide therapy it was thought as tubulopathy.. Patient had neurogenic bladder due to tumor, osteomalasia and failure to thrive due to tubulopathy and treated with supplementation of potassium, sodium, phosphate by the department of pediatric nephrology and growth hormone was started by division of endocrinology for severe growth retartation (9 years old, height 104 cm (<3p), weight 17.4 kg (<3p)). After 8 years he admitted to our hospital with snoring and the mass was detected in nasopharynx and parietotemporal regions with cranial MRI. The pathological diagnosis was Burkitt's lymphoma. NHL-BFM 90 protocol was started. Antibiotic and antifungal treatment against infections was regulated according to renal function during the chemotherapy. The patient has been receiving supplementation therapy of tubulopathy for last 7 years and he has no problem about malignancy. However, he is followed with complains of developmental-growth retartation, osteomalasia, tubulopathy and neurogenic bladder. *Conclusion.* Chemotherapy included ifosfamide-induced severe renal tubular damage is a potentially progressive disease. Depending on the extent of tubular dysfunction, patients with ifosfamide-induced nephrotoxicity experienced significant growth impairment and osteomalasia. So, the investigation of tubular renal function should be part of a long-term follow-up in children after chemotherapy.

2022

THROMBOCITOPENIA AND HYPERHOMOCISTEINEMIA IN ALCOHOLIC PATIENTS

C Malem,[1] M Castillo,[2] R Acosta[2]

[1]Claudio Malem and Partners, General Alvear, Argentina; [2]Hospital "Enfermeros Argentinos", General Alvear, Argentina

Introduction. From December 2007 and during the following 18 months 122 patients lorry drivers working for different companies were studied. They suggested that the cause of the high number of road accidents was probably due to their habet of drinking alcohol while driving. At the start of this study it was observed: marked macrocitocis, high white blood cells count, evident thrombocytopenia, altered hepatic profile, anemia in 92% of the cases and homocysteine value highly superior to the reference value. An *in situ*s inspection was also carried out. The hygiene and housing conditions varied from one individual to another but they equaled as regards alcoholic drinks intake and diet, mainly based on carbohydrates which ranked from 5 to seven days a week. As a first step, it was decide to radically change the diet by using protein nutrients, vegetables and diary products and eliminating the dialy alcohol consumption and also fixing psychotherapy sessions. *Materials and methods.* During 90 days they were helped with folic acid to raise the hemoglobin level which was between 9 at 10 g/dL, the right dose of prednisone to avoid hepatic disorders and minimum dose of acenocoumarol to prevent thrombosis events (adjusted at INR). At the next blood control it was clear sighted that slowly and gradually all the blood values, including the hepatic profile, were encourangingly changing. That's why it was decided to follow with acenocuomarol and suspend the folic acid and prednisone, allowing the new diet to perform the corresponding supply. *Results.* After 180 days, at the corresponding hematological control, the patients achieved normal analytical values: the hemoglobin values were between 12 and 14.5 g/dL, accompanied with normocitic elements, normal white cells count, plasmatic homocysteine values within reference values and thrombocytes count placed between 220 and 400×10. *Conclusion.* After the following that allowed this study the patient's hematological levels were regained. Not only were the individuals removed from their dependence on alcoholic drinks but they also recovered a healthy life with optimal abilities and capabilities for the work they do. Besides, road accidents were also reduced to a minimun of 1%.

2023

THE OPINION OF THE PATIENTS FROM SOUTHERN TRANSYLVANIA REGARDING THE ETHICAL ASPECTS OF THE MEDICAL STAFF CONDUIT TOWARDS THE PATIENTS WITH ACUTE LEUKEMIA

RG Mihaila,[1] L Nistor,[2] M Sintamareanu,[2] E Rezi,[2] RG Mihaila,[3] D Ciuta[1]

[1]Lucian Blaga University of Sibiu, Sibiu, Romania; [2]Emergency County Clinical Hospital, Sibiu, Romania; [3]Public Health Direction, Sibiu, Romania

Background. Together with Romania's attending to the European Union, there was also a need to adapt our internal legislation and conduit which governs the relation medical staff - patient to the European settlements. This fact involves profound changes regarding the collaboration which was established in the last half of the century between the two parts. *Aim.* We have proposed ourselves to study in what degree this new ethical conduit applied to the patients with acute leukemia by the medical staff is liked by the patients. *Methods.* We have realized a transversal study on a group of 300 consecutive hospitalized patients from the medical departments of the Emergency County Clinical Hospital from Sibiu, who have agreed to answer at a questionnaire with 14 questions regarding the attitude which the medical staff should have in communicating the diagnosis, prognosis and treatment of the patients with acute leukemia. We have analyzed the rates of the answers, their significations and we have drawn useful conclusions for medical practice. *Results.* The medium age of the studied group was 58.26±16.82 years. The gender repartition was: 53.33% women and 46.67% men. Even though many patients with acute leukemia have reduced chances of survival, even on a short time, only 66.67% of the questioned patients considered that the diagnosis should be communicated. 98.67% of the subjects consider that the doctor is the one who should inform the patient about the cause of his illness and not the nurse or the students. 96.67% consider that the family should also be informed about the patient's diagnosis. Regarding the family members who should be informed, 54.67% of the questioned subjects consider that the wife should be informed, 25.33% consider that the sons and daughters should be informed and 20% appreciate that the parents should be informed. 61.33% believe that the patient's colleagues should be aware of the diagnosis. In the situation in which the patient would not will to know the diagnosis, 73.33% of the questioned subjects, wouldn't communicate it, and 22.67% of them would still communicate the diagnosis (4% do not know). Even though the prognosis is reserved, 80.67% of the subjects agree to be recommended to start chemotherapy or radiotherapy. The opinion regarding the naturist treatment is divided: 46.67% recommend it, 38% do not recommend it and 15.33% do not know if this method is indicated. In contrast, 60% recommend the chemotherapy too to the patients who are under naturist treatment. Regarding the associated psychotherapy, 74% of the questioned subjects, consider that this will be benefic, 10.67% do not recommend it and 15.33% are undecided. The majority (97.33%) believe that the family and colleagues should donate blood so that the patients can receive transfusions with priority. 94% from the responders consider that the sanitary education regarding the prophylaxis of exposure at factors with leukemic risk would be indicated in schools; 83.33% of them consider that a natural ecological diet, with low animal fats and normal number of calories could have a protective role against leukemia-genesis, and 87.33% believe that the daily stress could be involved in the appearance of leukemia. *Conclusions.* Although not all the questioned patients accept the communication of the diagnosis at the patients with acute leukemia, the majority agree with the conventional treatment, with the blood donation and with the application of educative measures regarding prophylaxis, diet and life style.

2024

IS SOCIOPOLITICALLY-CONFLICTIVE ISRAELI REALITY AN OBSTACLE IN THE CLINICAL TRIAL PATIENT RECRUITMENT PROCESS?

R Nitzan-Inbar, L Akria, A Braester, C Giloni

Western Galilee Hospital, Nahariya, Israel

Background. Clinical trails are vital for development of pharmaceuticals. Although patient recruitment is a fundamental step in clinical research, this process has been a relatively weak area of interest for investigators. Patient recruitment problems are the most important reason for the failure of clinical trials. Other countries have found that ethnic minorities are underrepresented in clinical trials. Israeli society is known to be steeped in sociopolitical conflict, where the minority population often rejects 'establishment' endeavors. *Aims.* We examined the possible reluctance of the research staff to propose inclusion in clinical trials to the non-Jewish (i.e. minority sector) patient, and the possible reluctance of the non-Jewish patient to participate in clinical trials. We questioned whether the lack of trust in biomedical research is more accentuated in non-Jewish patients than in Jewish patients, and whether sociopolitical reasons (i.e. anti-establishment) play a part in their decision. *Methods.* We analyzed the data registered in our data-system: the number of Jewish and non-Jewish patients to whom a clinical trial (double blind) was proposed, the percentage of acceptance and refusal in both groups and the recruitment process. *Results.* The trial enrollment rate in the Jewish population (45%) was inferior to that of the non-Jewish population (62%). *Conclusion.* Israel's minority populations were well-represented in clinical trials. Good communication skills and heightened cultural sensitivity may overcome sociopolitical obstacles in clinical trials recruitment.

2025

IS THERE A TRUE INCREASE OF NEOPLASTIC HAEMATOLOGICAL DISORDERS IN EUROPE?

P Giraldo,[1] R De Angelis,[2] C Tereanu,[3] R Capocaccia,[2] M Maynadié,[4] R Marcos-Gragera,[5] A Giacomin,[6] S Ferretti,[7] C Martos,[8] P Giraldo,[9] M Sant[3]

[1]Miguel Servet University Hospital, Zaragoza, Spain; [2]Instituto Superiore di Sanità, Rome, Italy; [3]Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy; [4]Côte D'Or Cancer Registry of Haematological Malignancies, Dijon, France; [5]Girona Cancer Registry, Girona, Italy; [6]Biella Cancer Registry, Biella, Italy; [7]Ferrara Cancer Registry, Ferrara, Italy; [8]Instituto Aragones de Ciencias de la Salud, Zaragoza, Spain; [9]Instituto Aragonés de Ciencias de la Salud (I+CS), Zaragoza, Spain

Background. Evaluating the burden of Haematological malignancies (HM) in Europe from population-based cancer registries (CR) data was a task of the HAEMACARE project. *Aims.* Evaluating prevalence of HM according to standard categories and relevant morphological subgroups based on ICDO-3 in Europe. *Methods.* Data from the EUROCARE Project database involving more than 90 CRs with period of diagnosis up to 2002 and follow up to 2003. Prevalence proportions and total number of cases at 1/1/2003 by disease duration (2,5,10, years) computed with the counting method. *Results.* Among all HM the highest prevalence is found for Non Hodgkin Lymphomas (NHL). At 5 years from diagnosis it is 63 per 100,000, ranging from 38 in Eastern to 83 in Southern European countries. Prevalence for Hodgkin's Lymphoma (HL) at 5 yrs was around 10 per 100,000 in all areas. Prevalence for Myeloid malignancies (MM) is considerably lower than NHL (20 per 100,000 overall) with higher prevalence in UK-Ireland and lower in Central Europe. Discussion and *Conclusions.* Prevalence is a cumulative indicator reflecting levels and trends of incidence, survival and population ageing. Relevant advancements have been achieved in diagnosis and treatment of HM, population-based estimates of their burden help to identify specific health needs and related costs.

This work has been partially sponsored by HAEMACARE project.

2026

THE EVALUATION OF SOCIODEMOGRAPHIC PROPERTIES OF PATIENTS WITH HEMATOLOGIC MALIGNANCY

S Degirmenci,[1] U Ergene,[2] D Ozbalci[3]

[1]Akkus Goverment Hospital, Ordu, Turkey; [2]Celal Bayar University School of Medicine Department of Hematology, Manisa, Turkey; [3]Celal Bayar University School of Medicine, Hematology Department, Manisa, Turkey

Background. The relationship between health and socioeconomic status is clearly described in many studies. In our country, there is no sufficient data on relationship between socioeconomic status, smoking, alcohol use, exposure to chemical substances and etiology of hematologic malignancies. Therefore, we aimed to evaluate effect of socioeconomic status on hematologic malignancies. *Material and method.* We retrospectively evaluate 135 patients who were diagnosed as a haematological malignancy between November 2004 and September 2008 in Haematology Department of Celal Bayar University School of Medicine. We then collected the demographic (gender, age, marital status, education, living space) and socioeconomic variables (job, social security status, economic indicators) and smoking, alcohol, narcotic drug usage and exposure to chemical substances of the patients. A written informed consent was obtained from all patients. SPSS 11.0 program were used for evaluating the data and Pearson Ki-square test and Student's t test were used for statistical study. *Results.* Of the patients, 59 (43%) were women and 76 (56%) were men. The ratios of living in city and rural area were 63.7% and 36.3% respectively. When compared to the population of Manisa, there was no statistical difference between them (P>0.05). With respect to education status, the ratio of patients holding a secondary school or lesser degree and patients holding an upper degree were 87.4% and 12.6% respectively, and these figures were found to be lower than the average of Turkey (secondary school and lower 83 %, upper than secondary school 17%). When hematologic malignancies were evaluated individually, educational status of patients having ALL were significantly higher compared to the other eleven diseases (P=0.01). When employment of the cases was evaluated, it was found that 89.8% of women and 52.7% of men were unemployed. The overall poverty ratio was 31.9%, with 23.2% in those living in city and 46.9% in rural places. It was observed that poverty declines in cities and also in parallel to higher education status. The poverty ratio of our cases (31.9%) being higher than the poverty ratio of Turkey (18.5%), indicated that frequency of hematologic malignancy may increase by an increase in poverty ratio. In our study, smoking was significantly higher in chronic lymphoproliferative disorders (CLPD) group than others (acute leukaemia, chronic myeloproliferative disease, myelodisplastic syndrome, lymphoma). Moreover, it was found that the ratio of smoking in CLPD patients (53.2%) was much above the average of Turkey (31.9%). This finding connotes the idea that smoking may be related to CLPD. When exposure to chemical substances was evaluated in our patients, the ratio of patients exposed to chemical substances was significantly higher in CLPD group compared to the other groups (P=0.019). *Discussion and conclusion.* Our findings suggest that poverty is strongly related to haematological malignancy and smoking and exposure to chemical substances have connection with CLPD. More prospective studies are needed in this field to evaluate the relationship between socioeconomic status and demography.

THE EUROPEAN WORKING TIME DIRECTIVE -A BENEFIT OR BURDEN TO HAEMATOLOGY NURSING STAFF?

E Harness,[1] O Barnes[2]

[1]University hospital of wales, Cardiff, UK; [2]University Hospital of Wales, Cardiff, UK

Background. The European Working Time Directive was enacted into UK law in 1998 - seeking to protect the health and welfare of workers it gave some employers time to absorb the changes. In the N.H.S. for example Doctors hours compleid by August 2009. Nurses on our Haematology ward in University Hospital of Wales, Cardiff carried on working time practice which could be seen as at odds with the directive's recommendations - change had to evolve. How we breached regulation:- In working 2×7.5 hour day shifts (early and late) and 1×10 hour night shift staff often had only 9.75 hours break between shifts. The weekly break of 24 hour duration within 7 day period could be reduced to 2×12 hour shorter breaks. Rest breaks of at least 20 minutes (away from 'work station') became controversial. Was it paid or unpaid?

Employers tried to enforce 'unpaid' breaks which lengthened the working day, and were resisted by staff. How we modified:- Our nursing workforce called for 12.5 hour shifts. This was piloted and evaluated over 3 month period. *Aims.* To demonstrate by examination of the pilot period and anecdotally beyond that the positive / negative impact of the new nursing shift system. *Methods.* We used questionaire to staff which had some 'structured' questions and room for comments and incidental observations - from this we hoped to gain subjective data. For objective data we examined recorded sick leave prior to the period of change and compared it with the pilot period. *Results.* Staff identified less stress and paperwork to meed middle of day handover deadlines - more time for patient care. Doctors felt less of day devoted to chasing up afternoon staff, noticed that ward felt more calm and subdued. Relatives remarked that staff levels seemed improved and they appreciated speaking to nurses who were actually on doctors' a.m. rounds. Managerial finding - the same number of staff on the new rota covered more shifts at no extra cost. Rota'd to 36 hours per week not 37.5 means that every four weeks there is an extra 6 hourly shift to rota. This can be used for patient care but is flexible and often used for study days for ongoing education and updating. Also 6 hours allocated to formal study day is sufficient (the old 7.5 hours wasted more clinical time than necessary). *Summary.* In summary the law eminating from Europe in 1998 - though it has taken time to filter through has helped catalize a new shift pattern for our haematology ward nurses which has been evaluated very positively. Since the pilot, numbers on sick leave have remained lower than with the previous shift pattern which also supports the intention of the European Working Time Directive of 1998 as very much a benefit.

OPTIMISATION OF HAEMATOPOIETIC PROGENITOR CELL COLLECTION BY THE INTRODUCTION OF A STANDARD REFERRAL FORM AND FORMALISATION OF THE START OF CHEMOTHERAPY AND G-CSF MOBILISATION

S Phillips, N Lewis, S Thompson

University Hospital of Wales, Cardiff, UK

The University Hospital in Cardiff performs haematopoietic progenitor cell collections for autologous and sibling donors referred from all over Wales. For many of the patients attending for haematopoietic progenitor cell apheresis (HPC-A), the collection centre had either received no referral documentation or the information on the referral was incomplete. The information that was absent ranged from priming regimen and the quality of venous access to medication likely to be of significance to the procedure, for example anticoagulation therapy. This made the logistics of efficiently utilising the two Cobe Spectra Apheresis Machines available difficult, as on many occasions collections were delayed, cancelled or not scheduled for the correct day. Even allowing for the variable response to priming therapy seen across the spectrum of patients attending, it was felt that a more formal approach to priming might improve efficiency. It was also apparent that priming regimes and G-CSF doses were dependent on the individual prescriber or local hospital policy and there was some disparity between hospitals. When G-CSF alone was used for priming, there appeared to be more priming failures or patients requiring 2-3 collections before a satisfactory harvest was obtained. However, it was unknown whether this was related to patient factors or to the logistics of ensuring collection on the optimal day. An audit was therefore undertaken, the main objectives of which were to; - Standardise and improve the referral process between the district general hospitals and the collection centre. - Standardise priming regimes and start day of G-CSF. It was envisaged that the audit would improve efficiency and contribute to JACIE compliance. Collaboration with the referring hospitals resulted in the production of a standard referral form which included clinical information and history of treatment relevant to HPC-A collection. The audit period was 18 months, of which one year was retrospective, and included all patients who underwent HPC-A collection or for whom HPC-A collection was attempted during this time. The audit period coincided with a trial of the mobilisation therapy Plerixafor on compassionate grounds. The use of Plerixafor was noted in the audit information. The preliminary findings have shown that; - The referral form was being used successfully so that the machine time could be allocated more effectively. - The regimes and G-CSF start date were standardised. - The use of Plerixafor appears to have facilitated the collection process. Ongoing analysis will determine whether patient's disease, treatment, previous transplant or chemotherapy affected the collection process in any way.
